**Introduction:** Strong respiratory effort is recognized as a potential "second hit" in acute lung injury (ALI), introducing the concept of "patient self-inflicted lung injury" (P-SILI). We have previously reported that continuous positive airway pressure (CPAP) attenuates lung and diaphragm injury in P-SILI model.
**Objectives:** We aimed to investigate the effects of CPAP on respiratory distress symptoms, regional lung strain, and diaphragmatic contraction kinetics, in a preclinical ALI model.
**Methods:** Lung injury was induced in Sprague Dawley rats by surfactant depletion (saline lavage), followed by 3 h of unsupported or supported spontaneous breathing (Unassisted- and CPAP-groups). Respiratory distress symptoms, gas exchange, diaphragmatic ultrasound, micro-CT scans, and morphometric analysis of lungs and diaphragms were assessed.
**Results:** Compared with Unassisted-group, CPAP-group had: (1) Lower respiratory rate, nasal flaring, sternocleidomastoid and abdominal muscles use, minute ventilation (VE) and higher SpO2 at the end of the study (all $p < 0.05$). (2) A trend towards less volumetric strain progression in basal regions of the lungs. (3) A trend towards longer expiratory time and lower diaphragm contraction velocity. (4) Higher morphometric lung aeration ($p < 0.05$). (5) Higher morphometric diaphragm muscle area, and lower interstitial area ($p < 0.05$).
**Conclusions:** Unassisted spontaneous breathing induced lung and diaphragm structural damage, consistent with P-SILI and load-induced diaphragm injury models. CPAP reduced lung and diaphragmatic injury and improved respiratory distress symptoms and oxygenation. The reduction in respiratory distress symptoms and VE, the decrease in strain progression in juxta-diaphragmatic regions, and better diaphragm contraction kinetics, suggest that CPAP effectively reduced the respiratory drive.

**Introduction:** Heat stroke (HS) is a life-threatening disease comprising central nervous system dysfunction, disseminated intravascular coagulation, systemic inflammatory responses, and multiple organ dysfunction syndromes (MODS). Acute kidney disease (AKI) is one of the most serious complications of HS, which significantly increases the mortality and hospitalization expenses of inpatients with HS. The incidence rate of heat stroke induced acute kidney injury (HS-AKI) is as high as 36–43.9% and the mortality rate of severe AKI requiring dialysis is as high as 50–80%. Furthermore, recent studies have shown that HS-AKI can increase the risk of chronic kidney disease. Despite decades of research, the exact pathogenesis of HS-AKI remains unknown. Consequently, there are no specific and effective drugs to treat HS-AKI in clinical practice, and only symptomatic treatment is available.
**Objectives:** To investigate whether hypoxia inducible factor prolyl hydroxylase inhibitor (HIF-PHI) can enhance thermal endurance and reduce acute kidney injury induced by heat stroke(HS) in mice.
**Methods:** First, C57BL/6J mice were placed in a climate chamber at 39 ± 0.5 ℃ and a relative humidity of 60% ± 5% to induce HS model. HIF-PHI was dissolved and then diluted to a concentration of 1 mg/ml. All mice were continuously intraperitoneal injected with 0.01 ml/g body weight saline or HIF-PHI for 5 days before heat exposure. The human kidney cells (HK2) were placed in a culture incubator with an environmental temperature at 43 ℃ and 5% $CO_2$ concentration for 2 h to induce HS cell model. HK2 cells were pretreated with or without HIF-PHI (30 mM). Thereafter, thermotolerance, renal function, pathological changes, mitochondrial damage, inflammation, and apoptosis were evaluated in vitro and in vivo. Finally, mitophagy inhibitors Mdivi-1, 3-MA and Baf-A1 were applied to regulated mitophagy. BNIP3 small interfering RNA transfected HK-2 cells to silence BNIP3. The underlying mechanisms of HIF-PHI were further verified through western-blot, immunofluorescence staining and apoptosis assays.
**Results:** Our results showed that HIF-PHI pretreatment significantly improved renal function, enhanced thermotolerance, and increased the survival rate of mice in the context of HS. Moreover, HIF-PHI could alleviate HS-induced mitochondrial damage, inflammation, and apoptosis in renal tubular epithelial cells (RTECs) by enhancing mitophagy in vitro and in vivo. By contrast, mitophagy inhibitors Mdivi-1, 3-MA, and Baf-A1 reversed the renoprotective effects of HIF-PHI. Mechanistically, HIF-PHI protected RTECs from inflammation and apoptosis by enhancing Bcl-2 adenovirus E18 19-kDa–interacting protein 3 (BNIP3)-mediated mitophagy, while genetic ablation of BNIP3 attenuated HIF-PHI-induced mitophagy and abolished HIF-PHI-mediated renal protection.
**Conclusions:** HIF-PHI protects renal function by upregulating BNIP3 mediated mitophagy to improve HS-induced inflammation and apoptosis of RTECs, suggesting HIF-PHI as a promising therapeutic agent to treat HS-AKI.

**Introduction:** The host response in sepsis is highly heterogeneous and incompletely understood. This hampers the identification of high-risk patients eligible for targeted immunomodulatory therapy. We aimed to resolve this heterogeneity by deriving endotypes based on the expression levels of key genes that reflect the magnitude of the host response during experimental human endotoxemia, a standardized controlled model of systemic inflammation induced by bacterial lipopolysaccharide (LPS). Next, we applied these endotypes to cohorts of patients with sepsis.
**Methods:** LPS (1 ng/kg) was administered intravenously to 110 healthy volunteers (54 female, 56 male, age 23 [21–25] years). Blood was serially sampled to determine plasma cytokine kinetics. Furthermore, circulating CD14+/CD16− monocytes were isolated at two time points: before ($T=0$) and 4 h after ($T=4$) LPS administration, and RNA sequencing was performed. The area under the in vivo plasma cytokine concentration–time curve (AUC) of nine pro- and anti-inflammatory cytokines served as an integral measure of the magnitude of the inflammatory response. To identify the most discriminatory genes, these AUC values were integrated with the RNAseq profiles at $T=4$ in a sparse partial least squares-discriminant analysis (sPLS-DA). Subsequently, using these genes, stable transcriptomic inflammatory endotypes were identified by performing consensus clustering using the partition around medoids (PAM) algorithm on 1 minus Spearman correlation distances. To assess the clinical relevance of the identified endotypes, we applied them to a cohort of 65 patients with CAP and to a cohort of 522 patients with sepsis of mixed origin enrolled in the MARS study [1, 2].
**Results:** Three inflammatory endotypes, defined by 46 genes, were identified in the endotoxemia cohort: LPShypo, LPSinter, and LPShyper. Each endotype had a distinct transcriptomic and cytokine response pattern, with the LPShyper endotype displaying the most pronounced inflammatory response (Fig. 1A). When these endotypes were applied in the CAP cohort, patients with the LPShyper endotype at hospital admission also displayed significantly higher plasma cytokine concentrations compared with the other endotypes (Fig. 1B). Applying the identified LPS endotypes to patients of the MARS cohort at ICU admission also revealed significant associations with outcome: patients with the LPShyper endotype had the worst prognosis, with a 28-day mortality rate of 42%, vs. 24% and 19% for LPSinter and LPShypo, respectively ($p<0.001$, Fig. 1C). Hazard ratios [95% CI] for 28-day mortality were 2.04 [1.36–3.1], $p<0.001$ for LPShyper vs. LPSinter and 0.76 [0.49–1.2], $p=0.201$ for LPShypo vs. LPSinter (Fig. 1C). The higher mortality rate for the LPShyper endotype was primarily due to deaths in the acute phase, as 20 out 88 patients (23%) died within 4 days, compared with 22 out of 265 (8%) and 6 out of 169 (4%) for the LPSinter and LPShypo endotypes, respectively ($X2$ (2, $N=522$) = 26.0, $p<0.001$).

**Conclusions:** Our study highlights the remarkable variability in the host response, even within a highly homogeneous experimental endotoxemia cohort in healthy volunteers. Endotypes based on the expression levels of key genes associated with (hyper)inflammation were identified, potentially providing insight into the underlying mechanism of immune dysregulation. Importantly, applying these endotypes to patient cohorts also identified patients with a heightened inflammatory state who are at increased risk for adverse outcomes, especially in the acute phase of sepsis. This subgroup of patients might benefit from early initiation of immunosuppressive treatment. As such, our results hold promise in facilitating a precision medicine approach to improve the outcomes of these vulnerable patients.

**Introduction:** Diaphragm inactivity is an important mechanism of iatrogenic injury from mechanical ventilation [1–4]. The feasibility of using phrenic nerve stimulation (PNS) to prevent diaphragm inactivity during the first week of mechanical ventilation has not been investigated [5, 6]. Additionally, it is unknown whether preventing diaphragm inactivity can prevent diaphragm atrophy and improve diaphragm function in humans.

**Objectives:** To establish the safety and feasibility of continuous on-demand PNS to maintain diaphragm activity during the first week of mechanical ventilation and to assess associated changes in diaphragm structure and function.

**Methods:** STIMULUS was a phase 1 clinical trial performed at Toronto General Hospital between February and October 2023. Patients were eligible for enrolment if they required mechanical ventilation for acute hypoxemic respiratory failure (AHRF) or after pulmonary thromboendarterectomy (PTE) or lung transplantation (LuTx). Transvenous PNS delivered via a specially equipped central venous catheter (Lungpacer Medical) was titrated to achieve a diaphragm electrical activity level (Edi) consistent with an expiratory occlusion pressure (Pocc) between − 5 and − 10 cm $H_2O$. Stimulation was delivered "on demand" in synchrony with controlled ventilator breaths and inhibited when the patient triggered the ventilator. On-demand PNS was maintained for up to seven days or until a spontaneous breathing trial (SBT) was passed. Diaphragm thickness was measured at baseline and daily, and diaphragm function was assessed by measuring maximal diaphragm thickening fraction at the first SBT. These measurements were compared to values for historical control patients matched for diagnosis, age, P/F ratio, and baseline diaphragm thickness.

**Results:** Twenty patients were enrolled and 19 (8 AHRF, 8 PTE, 3 LuTx) underwent study procedures. Catheter placement and initial diaphragm activation were successfully achieved in 19 (100%) patients. Diaphragm activity was maintained on target during stimulation for at least 50% of hours on the first day of intervention in 18 (95%) patients (primary feasibility endpoint) and in 88% of hours over the seven-day study period (Fig. 1). Atrial ectopy at initiation of stimulation occurred in four patients; this was readily resolved by modifying catheter position or electrode selection. Two serious adverse events (SAEs) were related or possibly related to study procedures (venous or esophageal catheter placement); there were no serious adverse events related to stimulation. In comparison to matched historical controls, diaphragm thickness tended to increase over time and maximal diaphragm thickening fraction was increased (Fig. 2, $p < 0.0001$ for comparisons).

**Conclusions:** Continuous on-demand PNS to prevent diaphragm inactivity during mechanical ventilation is feasible and well-tolerated. This strategy may prevent diaphragm atrophy and dysfunction.

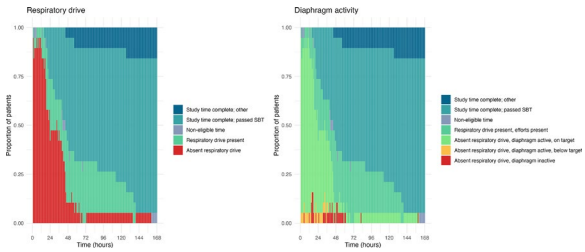

**Fig. 1 (abstract 000379)** Respiratory drive (left) and diaphragm activity (right) in the presence of continuous on-demand phrenic nerve stimulation over seven days of mechanical ventilation in 19 patients with acute respiratory failure. SBT = spontaneous breathing trial

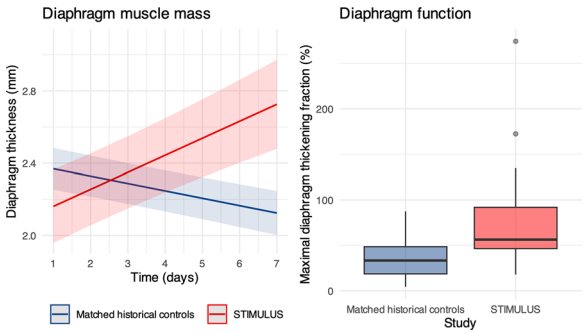

**Fig. 2 (abstract 000379)** Diaphragm structure and function in STIMULUS compared to historical controls matched for similar age, diagnosis, P/F ratio, and baseline diaphragm thickness. Left: Change in end-expiratory right hemi-diaphragm thickness over time compared to matched historical controls. The rate of change was significantly different between groups ($p < 0.0001$). Right: maximal diaphragm thickening fraction at the time of the first spontaneous breathing trial compared to matched historical controls ($p < 0.001$ for difference between groups)

**Introduction:** Accurately predicting readiness for extubation is of key importance in the care of critically ill patients. Diastolic dysfunction has been previously suggested as a risk factor for extubation failure and refers to impaired relaxation of the heart during the filling phase [1, 2]. Diastolic function can be qualified by echocardiographic parameters such as the ratio between mitral valve E-wave and A-wave (*E/A* ratio) and estimation of left ventricular filling pressures (E/e' ratio). These measures are highly influenced by preload status. Tissue Doppler e' velocity (the rate of myocardial relaxation during early diastolic filling) is considered as a more intrinsic measure of left ventricular compliance. Nevertheless, also in conditions of increased preload, the e' velocity may increase as a compensatory response to accommodate the additional volume.3 Preload status is related to fluid balance and NT-proBNP, which are also known predictors of extubation failure.
**Objectives:** To investigate the association between diastolic function parameters, fluid balance, NT-proBNP and extubation failure in patients weaning from mechanical ventilation.
**Methods:** In this prospective cohort study, adult patients who were mechanically ventilated for more than 48 h, in whom transthoracic echocardiographic measurement of diastolic function parameters could be performed, and passed a first spontaneous breathing trial (SBT) were included. Echocardiography was performed at the start and end of SBT. The primary endpoint was extubation failure (i.e., need for reintubation within 7 days). Baseline and delta values were compared between patients with and without the primary endpoint using the independent samples *T*-test or Mann–Whitney *U* test. Diastolic function parameters (*e'* and *E/e'*) were related to fluid balance in the 24 h before extubation and NT-proBNP using Pearson's correlation.
**Results:** A total of 45 patients were included (age 69 [IQR 58–75] years, 53% male, BMI 27 ± 5 kg/m$^2$, duration of mechanical ventilation 4.9 [IQR 3.0–8.7] days, SOFA score 9.0 ± 2.8). Patients with extubation success ($n = 33$) had a more negative mean fluid balance in the 24 h before extubation as compared to patients with extubation failure ($n = 12$) (Table 1). None of the investigated parameters of diastolic function and neither NT-proBNP measured at start of SBT were predictive of extubation failure in this cohort. Neither the delta of any of the diastolic function parameters during SBT was predictive of extubation failure (data not shown). We did observe a significant correlation between diastolic function parameters (e' and E/e'), fluid balance, and NT-proBNP (Fig. 1). In a multivariable logistic regression model including age, SOFA score, E/e' and fluid balance, fluid balance was the only significant predictor of extubation failure: OR 2.56 (95% CI 1.05–6.24), $p = 0.039$.

**Table 1 (abstract 000527)**

| | Extubation failure (n = 12) | Extubation succes (n = 33) | P-value |
|---|---|---|---|
| Fluid balance 24 h, L | 0.2 ± 0.6 | − 0.7 ± 1.4 | 0,007 |
| E, cm/s | 76 ± 21 | 74 ± 15 | 0,692 |
| A, cm/s | 7.5 ± 23 | 68 ± 17 | 0,348 |
| *E/A* | 1.0 [0.9–1.3] | 1.1 [0.8–1.3] | 0,596 |
| *e'* sept, cm/s | 8.1 ± 1.5 | 8.0 ± 2.8 | 0,833 |
| *e'* lat, cm/s | 10.2 ± 1.5 | 11.0 ± 3.1 | 0,229 |
| *e'* average, cm/s | 9.1 ± 1.2 | 9.4 ± 2.5 | 0,667 |
| *E/e'* average | 7,9 [6,1–10,5] | 7.5 [6.4–9.4] | 0,859 |
| NT-proBNP, pmol/L | 370 [84–1481] | 285 [73–685] | 0,755 |

**Conclusions:** In our study we could not reproduce the previously reported predictive value of diastolic dysfunction and NT-proBNP for extubation failure. Parameters of diastolic function (*e'* and *E/e'*) were significantly related to fluid balance and NT-proBNP. A negative fluid balance is likely to be the driving force of extubation success, and its pathophysiological substrate may be reflected by diastolic function parameters and NT-proBNP. Fluid-independent parameters of diastolic function are required to determine the role of intrinsic ventricular stiffness in the pathophysiology of extubation failure.

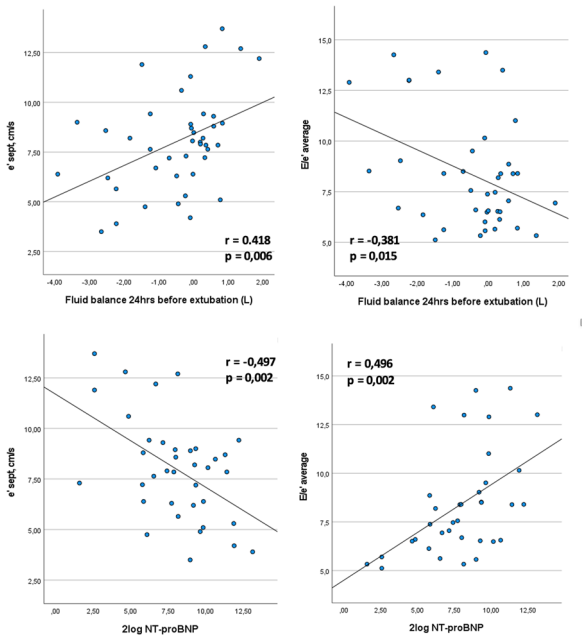

**Fig. (abstract 000527)** Pearson's correlation coefficients (*r*) of diastolic function parameters, fluid balance and NT-proBNP (*n* = 45)

## Alternative RNA splicing mechanism is involved in the pathophysiology of sepsis

M. Cao, T. Liu, W. Su, Y. Zhao[1], E. R. Jenkins, S. Abrams, G. Wang, C. H. Toh, J. Xie

**Introduction:** Sepsis, a life-threatening condition resulting from a dysregulated immune response to infection [1], is widely acknowledged for its significance in healthcare. Alternative splicing (AS) is a critical process that contributes to the diversity of gene expression and protein isoforms [2]. However, the impact of AS on sepsis development remains largely unexplored.
**Objectives:** This study aims to illuminate the role of AS in sepsis progression and investigate its therapeutic implications.
**Methods:** Phosphoproteomic analyses were conducted using various components of E. coli to replicate sepsis and systemic inflammatory response syndrome (SIRS) models. Mice were intraperitoneally injected with PBS, E. coli lysate, E. coli DNA, LPS, or DNA + LPS. After t = 2 h, mice were euthanized using carbon dioxide asphyxiation, and then spleens were dissected for mass spectrometry and protein expression analysis. Transcriptomic analysis was then performed to identify AS events in septic patients and a cecal ligation and puncture (CLP)-induced sepsis mouse model. The related datasets for this study include sepsis and healthy controls from the Gene Expression Omnibus (GEO) database, specifically the GSE185263 dataset comprising 348 sepsis patients and 44 healthy controls. RNA sequencing (RNA-seq) analysis of mouse blood was performed 6 h after CLP. We performed RNA-seq analysis to analyze the occurrence of AS events and transcript variants during sepsis. RNA-seq reads were aligned using STAR, and AS events were identified and quantified using rMATS due to its ability to handle replicated RNA samples, analyze various AS patterns, and utilize RNA-Seq reads mapped to exons and splice junctions. Differential AS genes were identified, and AS events related to prognosis were screened and analyzed. Survival time of septic mice was observed by targeting the RNA splicing pathway, and the number of immune cells and the proportion of immune cells in mice were detected by flow cytometry.
**Results:** Differentially phosphorylated proteins were found to be significantly enriched in RNA-splicing and spliceosome signaling pathways in multiple sepsis animal models compared to the control group. RNA sequencing analysis revealed AS events associated with immune response and RNA splicing in both healthy and septic patients. In the healthy vs. sepsis patient cohort, 1735 AS events in 873 genes were detected, including 48 A3SSs in 45 genes, 21 A5SSs in 21 genes, 1488 MXEs in 781 genes, 153 SEs in 129 genes, and 25 RIs in 24 genes. We next used the logistic regression model to analyze the correlation between the AS events included in the model construction and sepsis prognosis and to screen for independent risk factors. The effects of variables in the logistic regression model were described by ratio (OR) and 95% confidence interval. We further investigated the AS events in the CLP mouse model by analyzing the RNA-seq data. We detected 1362 altered AS events in CLP mouse model, and, these results also indicate that a gene may have several types of mRNA splicing events, and one gene may exhibit up to five or even six to seven AS types, while SE is the dominant type because more than 1/2 of the AS type

is an SE event. The significant DAS genes were mostly enriched in RNA splicing and spliceosome. Treatment with splicing modulator in CLP mice improved survival rates and triggered immune responses compared with CLP.
**Conclusions:** This study underscores the importance of AS signaling in sepsis pathogenesis. It provides a comprehensive analysis of sepsis multi-omics and reveals the potential of splicing modulation in sepsis from various perspectives. Intervention with splicing modulators in the CLP-induced sepsis model showed potential for attenuating sepsis severity and improving outcomes. The analysis of AS events in sepsis in this study enhances our understanding of the molecular mechanisms underlying sepsis occurrence and development, offering new directions for discovering molecular therapeutic targets for sepsis.

### Clinical predictors of VILI risk: a comparison between Driving Pressure and Mechanical Power Ratio

M. Galizia[1], B. Donati[1], S. Giovanazzi[1], D. Nocera[1], V. Ghidoni[1], G. Catozzi[1], R. D'albo[1], S. Gattarello[1], M. Busana[1], F. Collino[2], F. Romitti[1], O. Mörer[1], L. Gattinoni[1]

**Introduction:** Mechanical ventilation may cause Ventilator-Induced-Lung-Injury (VILI) during ARDS. Therefore, it is important to identify possible indicators of VILI risk. In this experimental study, we compared the effectiveness of Driving Pressure (DP) and Mechanical Power Ratio (MPR) in predicting lung damage.
**Methods:** The study population consists of 125 pigs enrolled in previous experiments on VILI. Animals were ventilated with MPR (the ratio of mechanical power to the expected one), ranging from 0.86 to 26.7, and DP, from 3 to 22 $cmH_2O$. According to the literature, two different thresholds (DP = 14 cmH2O and MPR = 4.46) were used to identify 4 groups: Group 1, DP and MPR, below the threshold; Group 2, DP above and MPR below threshold; Group 3, DP below and MPR above threshold; Group 4, DP and MPR, above the threshold. End-experiment lungs' weight was used as a marker of VILI.
**Results:** In Panel A, we represent DP as a function of MPR with the identification of the two thresholds and the four groups. In Panel B, we show the lungs' weight measured in the four groups. As shown, the lungs' weight was significantly higher in the two groups having MPR above compared to the two groups with MPR below the threshold ($p < 0.001$), regardless of DP value. Of note, we did not find any significant difference in the lungs' weight when we compared the groups having the same MPR but different DP (i.e., Group 1 vs 2 and Group 3 vs 4).
**Conclusions:** The study suggests that MPR is a more effective indicator of VILI risk than DP. This is because MPR incorporates all the factors that contribute to VILI, such as tidal volume, DP, respiratory rate, flow, and PEEP. Relying solely on DP ignores the potential impact of the other VILI contributors.

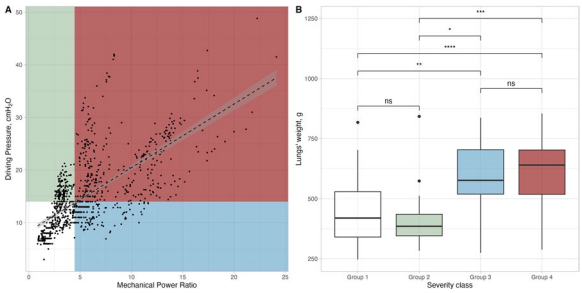

**Fig. (abstract 001309)** Comparison between Driving Pressure and Mechanical Power Ratio as a predictor of VILI. Panel A represents DP as a function of MPR with the identification of the two thresholds (see text for details; $p < 0.001$, $R2 = 0.40$). Panel B represents the comparison between the lungs' weight in the four groups as consequence of VILI (*$p = 0.015$, **$p = 0.004$, ***$p < 0.001$, ****$p < 0.001$)

**Topic:** Acute respiratory failure and mechanical ventilation

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 001327

**Introduction:** Out-of-hospital cardiac arrest survival rates have markedly risen in the last decades, while neurological outcome only improved marginally. Despite research on more than twenty neuroprotective strategies involving comatose post-cardiac arrest patients [1], none have demonstrated unequivocal evidence of efficacy [2]. Treatment with acyl-ghrelin improved functional and histological brain recovery in experimental in vitro and in vivo models of cardiac arrest [3, 4] and was safe in a wide variety of human study populations [5].
**Objectives:** To determine safety and potential efficacy of intravenous acyl-ghrelin to improve neurological outcome in comatose patients after cardiac arrest.
**Methods:** A phase 2, multicenter, double-blind, placebo-controlled trial (GRECO trial) was conducted between January 18, 2019, and October 17, 2022 in three ICUs in the Netherlands.
Inclusion criteria were adult patients (aged ≥ 18 years) after cardiac arrest in a coma. Expected death within 48 h or unfeasibility of treatment initiation within 12 h were exclusion criteria. Patients were randomized to receive 600 µg intravenous acyl-ghrelin (intervention group) or placebo (control group) within 12 h after cardiac arrest, continued for seven days, twice daily, additional to standard care. Primary outcome was the score on the cerebral performance categories (CPC) at six months. Safety outcomes included any serious adverse events. Secondary outcomes: mortality and neuron-specific enolase (NSE) levels on days one and three.

**Results:** We enrolled 160 patients with a median age of 68 years, 75% male. 81 were assigned to the intervention and 79 to the control group. The common odds ratio for any CPC shift towards a better outcome in the intervention group was 1.78; 95% CI 0.98–3.22; $p = 0.06$ [Fig. 1]. This was consistent over all CPC categories. NSE levels on day one after cardiac arrest were significantly lower in the intervention group (34 vs 56 µg/L; $p = 0.04$), on day three 28 vs 52 µg/L ($p = 0.08$). Serious adverse events were comparable in incidence and type between the groups. Mortality was 38% in the intervention vs. 50% in the control group, absolute risk reduction 12.5%, $p = 0.11$.
**Conclusions:** In comatose patients after cardiac arrest, intravenous treatment with acyl-ghrelin was safe and potentially effective to improve neurological outcome. Phase 3 trials are needed for conclusive evidence.

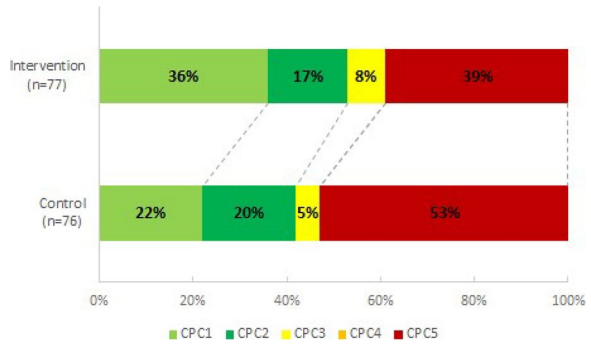

**Fig. 1 (abstract 001327)** Cerebral Performance Category scores at six months ("complete case analysis", intention-to-treat population)
The unadjusted common odds ratio for any shift towards a better outcome in the intervention group was 1.78 (95% CI 0.98–3.22; $p = 0.06$). Scores on the Cerebral Performance Category scale range from 1 to 5, with 1 indicating no or mild neurologic disability, 2 moderate disability, 3 severe disability, 4 coma, and 5 death.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 001494

**Introduction:** The optimal range of arterial oxygen levels (PaO2) in mechanically ventilated neuro-intensive care unit (neuro-ICU) patients is yet to be determined. Bayesian analysis offers novel insights into the relationship between arterial oxygen level and outcome via (1) probabilistic evaluation of current thresholds (2) incorporation of prior distributions.
**Objectives:** The primary aim was to determine the association between first 24 h ICU $PaO_2$ (worst A-a gradient) and ICU mortality in day one mechanically ventilated patients with acute ischemic stroke (AIS), intracerebral haemorrhage (ICH), and non-traumatic subarachnoid haemorrhage (SAH). Secondary outcomes were ICU length of stay (LOS) and duration of mechanical ventilation (MV days).
**Methods:** Patients admitted to Australian and New Zealand ICUs from 2016 to 2023 with primary diagnosis of AIS, ICH and SAH were extracted ($N = 83,158$). Patients mechanically ventilated from day one of ICU admission were analysed ($N = 13,635$). The 'brms' package in R for Bayesian hierarchical regression modelling was used to determine the relationship between arterial oxygen tension ($PaO_2$) and outcome. Models were adjusted for ANZROD score [1], with posterior distributions estimated through Hamiltonian Monte Carlo (HMC). Bayesian inference analysis used minimally informative, sceptical and enthusiastic prior distributions. Odds ratios (ORs) were calculated with the ESICM range ($PaO_2 = 80–120$ mmHg) as the reference group.
**Results:** 13,635 patients (AIS = 2615, ICH = 6381, SAH = 4639) were analysed (mean GCS on admission, $8 \pm 4$; mean P:F Ratio, $303.6 \pm 139.8$). APACHE III scores (mean) were similar between stroke groups: $69.7 \pm 27$; ICH, $72.7 \pm 26$; and SAH, $63.2 \pm 27$. Mild hyperoxia was more prevalent than normoxia and $PaO_2$ levels > 299 mmHg occurred in < 10% of patients across stroke subtypes. Overall, average $FiO_2$ and $PaO_2$ decreased from 2016 to 2023. Bayesian regression revealed that the optimal $PaO_2$ (lowest probability of ICU mortality) was 167.5 mmHg (95% CI for mortality: 39.8%-44.7%), 163.9 mmHg (95% CI = 23.6–28.3%) and 173.2 mmHg (95% CI = 29.4–35.2%) for ICH, SAH and AIS, respectively. Adjustment for ANZROD score had minimal effect on optimal $PaO_2$. Bayesian inference showed that, compared to patients within the ESICM range (80–120 mmHg), those with severe hyperoxia ($PaO_2 > 299$ mmHg) had increased likelihood of ICU mortality (ICH: OR = 1.5, 95% CI = 1.3–1.8, likelihood OR > 1 = 100%; SAH: OR = 1.5 95% CI = 1.2–1.9, likelihood OR > 1 = 99%; AIS: OR = 1.2, 95% CI = 0.8–1.7, likelihood OR > 1 = 81%, Fig. 1). This remained true with a sceptical prior distribution (mean = 1, SD = 0.2; likelihood OR > 1 was > 80% across subtypes). No significant association was found between $PaO_2$ and the MV days or ICU LOS.
**Conclusions:** Our findings indicate that early exposure to severe hyperoxia, particularly in ICH or SAH patients, is associated with increased ICU mortality. Moderate hyperoxia however, may confer advantage. Further adjusted analyses are needed to assist decision making in lieu of randomised controlled trials.

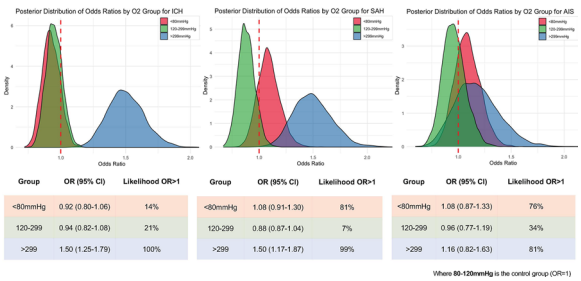

**Fig. (abstract 001494)** Posterior (predicted) distributions of Odds Ratios for ICU Mortality by caterogical oxygen exposed group (normoxia/reference group = 80–120 mmHg (ESICM recommended

range), hypoxia < 80 mmHg, severe hyperoxia > 299 mmHg). Plots show data for ICH, SAH and AIS patients from left-to-right

### Learning Curve for Intubation with a Hyper-angulated Video Laryngoscope: A Sub Analysis of a large alternating intervention trial

M. Schmidt[1], S. Ott[1], LM. Müller-Wirtz[1], A. Turan[1], K. Ruetzler[1]
[1]Department of Outcomes Research, Cleveland Clinic, Cleveland, United States of America
**Correspondence:** M. Schmidt
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 001679

**Introduction:** Traditional direct laryngoscopy (DL) has been the cornerstone of airway management for decades. The introduction of video laryngoscopy (VL) has offered advantages in visualization and intubation success. However, the optimal approach and the comparative effectiveness between these techniques remain a matter of debate. Recent trials have shown the superiority of VL compared to DL regarding the first-attempt success rate. However, while VL with hyper-angulated blades improves visualization of laryngeal anatomy, handling and insertion of the endotracheal tube might be challenging, especially for inexperienced users. Thus, our study evaluated the learning curve associated with first-attempt success rate using hyper-angulated VL.
**Methods:** This was an a-priori planned sub-analysis of the recently published clinical trial "Video Laryngoscopy vs Direct Laryngoscopy for Endotracheal Intubation in the Operating Room: A Cluster Randomized Clinical Trial" by Ruetzler et al. [1]. We utilized the cumulative sum method for plotting learning curves. The chart was created by plotting the cumulative sum values over time for each individual alongside the fixed horizontal decision limits. Crossing the upper decision limit indicates that the clinician's failure rate is significantly higher than the acceptable failure rate. Similarly, crossing the lower decision limit indicates that the clinician's failure rate is significantly lower than the acceptable failure rate. If the line remains between the two decision limits, no inference can be made. The acceptable and unacceptable failure rates for this study were set at 15% and 30%, respectively.
**Results:** We plotted learning curves for 4312 intubations across 223 unique providers (anesthesiologists, $n = 25$; CRNAs, $n = 35$; SRNAs, $n = 36$; fellows, $n = 46$; residents, $n = 81$). The median number of procedures per provider was 15. The overall first attempt failure rate was low (72 out of 4213 procedures), and the failure rates were comparable across provider groups. Sixty percent of the providers crossed the acceptance boundary, while the other 40% did not cross any of the boundaries. No provider crossed the unacceptable failure rate boundary. On average, it took 12 procedures to cross the acceptable failure rate boundary.
**Conclusions:** On average, it took health care providers 12 procedures to achieve acceptable failure rates for first-attempt intubation success rates using hyper-angulated VL.

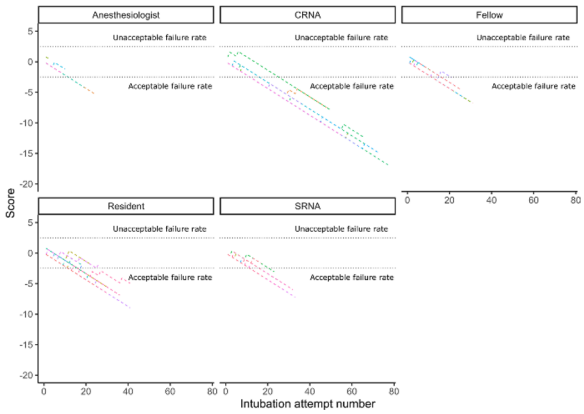

**Fig. 1 (abstract 001679)** Learning curves by health care provider group. Each differently colored line represents the learning curve of an individual provider. Individual trajectories may be obscured due to overplotting, but certain trends can be observed. No provider crossed the unacceptable failure rate boundary. Sixty percent of the providers crossed the acceptable failure rate boundary while for the rest no decision could be made. It took an average of 12 procedures to cross the acceptable failure rate boundary

### The clinical efficacy and suitable implementation of two extracorporeal blood purification therapies: AN69-oXiris versus PMX-HP

H. S. Kim[1], E. Y. Kim[1]
[1]Division of Trauma and Surgical Critical Care, Department of Surgery, Seoul St. Mary's Hospital, College of Medicine, The Catholic University, Seoul, Republic of Korea
**Correspondence:** H.S. Kim
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000006

**Introduction:** In septic shock patients, pathogens and excessive endotoxins continuously overstimulate the host's immune system with a cytokine storm that can lead to multi-organ failure and even mortality. Various types of extracorporeal blood purification treatments have recently been introduced to remove excessive endotoxins and cytokines. Herein, we compared the clinical efficacy of two blood purification methods, PMX-HP and AN69-oXiris, and discussed their detailed indications according to disease severity.

**Methods:** From December 2016 to April 2023, patients who underwent emergent surgery due to septic shock secondary to peritonitis and subsequently received blood purification treatment with AN69-oXiris or PMX-HP were enrolled. The protocol by which the patients were treated is summarized in the attached figure. Propensity score (PS)-matching was conducted to adjust for baseline characteristics between the two groups, and the changes in clinical parameters and outcomes were compared. Clinical outcomes were assessed in subgroups of patients who underwent PMX-HP treatment divided according to SOFA scores into low (0–7), intermediate (8–13), and high (> 13) disease severity groups.
**Results:** Forty patients received blood purification therapy with either PMX-HP or AN69-oXiris during the study period. After 1:2 PS matching, six patients in the AN69-oXiris group and 12 patients in the PMX-HP group were finally analyzed. Vasoactive-inotropic scores (VISs) decreased in both groups after 48 h of treatment compared to the baseline values, but the change in VISs was more pronounced in the PMX-HP group {− 57.6 [interquartile range (IQR) = − 166.4–(− 10)] vs. − 22.9 [IQR = − 64–0], respectively, $p = 0.041$}. Decreases in cardiovascular SOFA scores were significantly pronounced in the PMX-HP group [− 1.5 (IQR = − 4–0) vs. 0 (IQR = − 1–1), respectively, $p = 0.035$]. The 7-day mortality rate was significantly lower than the predicted mortality rate in a subgroup analysis of patients treated with PMX-HP in both the low disease severity group and the intermediate disease severity group.
**Conclusions:** PMX-HP and AN69-oXiris are potential therapeutic options for patients with refractory septic shock with intra-abdominal origins, especially after the surgical elimination of the infectious source. Further large-scale, prospective, randomized controlled trials that take into account patient characteristics, such as disease severity or cost burden, are needed to provide detailed guidance for blood purification treatment.

### Corticosteroids in Cardiogenic Shock: A Retrospective Analysis of the MIMIC-IV Database

G. Haddad[1], D. Maslove[2], L. Mbuagbaw[3], E. Belley-Côté[1], B. Rochwerg[4]
[1]Department of Medicine, McMaster University, Hamilton, Canada; [2]Department of Critical Care, Kingston General Hospital, Kingston, Canada; [3]Department of Medicine/Department of Health Research Methods, Evidence and Impact, McMaster University, Hamilton, Canada; [4]Division of Critical Care Medicine, Department of Medicine, McMaster University, Hamilton, Canada
**Correspondence:** G. Haddad
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000007

**Introduction:** Despite advances in the management of cardiogenic shock (CS), 1-year mortality remains high at approximately 50% [1–2]. While corticosteroid administration in septic shock has been shown to result in faster shock reversal and lower short-term mortality [3–5], the role of corticosteroids in the management of CS remains uncertain.
**Objectives:** We aimed to estimate the impact of corticosteroids on 90-day (90d) mortality (primary outcome) among patients admitted to an intensive care unit (ICU) with CS. We also planned to explore the association of corticosteroid use with hospital length-of-stay, ventilator-free days (VFDs), vasopressor-free days, ventilator-associated pneumonia, central-line associated bloodstream infections, and hyperglycemia.
**Methods:** In this retrospective observational study, we used the Medical Information Mart for Intensive Care-IV (MIMIC-IV) database which includes ICU admissions at the Beth Israel Deaconess Medical Center from 2008 until 2019 [6]. We included all adult patients (≥ 18 years old) diagnosed with CS by International Classification of Diseases (ICD-9/10) codes, excluding repeated admissions, patients with documented adrenal insufficiency, those receiving baseline corticosteroids, or requiring extracorporeal life support. We considered exposure based on receiving any systemic corticosteroids from 6 h before to 24 h post-ICU admission. We calculated Cox proportional hazards using multivariate analysis adjusting for age, sex, baseline Sequential Organ Failure Assessment (SOFA) scores, Charlson comorbidity index (CCI), body mass index, maximum lactate within the first 24 h, vasopressor use within the first 48 h, and invasive mechanical ventilation within the first 48 h.
**Results:** We included 2000 patients admitted to ICU with cardiogenic shock, 143 (7.2%) of whom received systemic corticosteroids. The median age was 73.0 (interquartile range 19), the mean CCI was 6.42 (standard deviation [SD] = 2.72), and mean SOFA score on ICU admission was 7.93 (SD = 3.84). Corticosteroid-treated patients were younger (67.72 vs. 71.15 years, $p = 0.006$), had higher baseline SOFA scores (9.45 vs. 7.80, $p < 0.001$), and more often required vasopressors (78% vs. 63%, $p < 0.001$) and invasive mechanical ventilation (73% vs. 45%, $p < 0.001$) within 48 h of admission. Corticosteroid use was associated with increased mortality in the multivariate analysis (hazard ratio [HR] 1.39, 95% confidence interval [CI] 1.05–1.85, Fig. 1). Corticosteroid use was also associated with lower VFDs (2.8 days less, 95% CI 0.35–5.26) but was not associated with differences in other secondary outcomes.
**Conclusions:** Use of corticosteroids is associated with increased 90d mortality and a reduction in VFDs in patients admitted to ICU with CS. These findings suggesting potential harm of corticosteroids in CS require confirmation in well-designed randomized clinical trials.

### Reducing In-Hospital and 60-Day Mortality in Critically Ill Pa-tients After Surgery with Strict Nutritional Supplementation: A Prospective, Single-Labeled, Randomized Controlled Trial

Y. H. Yoon[1], H. S. Kim[2], K. M. Im[1], E. Y. Kim[2]
[1]Department of Surgery, Seoul St. Mary's Hospital, College of Medicine, The Catholic University, Seoul, Republic of Korea; [2]Division of Trauma and Surgical Critical Care, Department of Surgery, Seoul St. Mary's Hospital, College of Medicine, The Catholic University, Seoul, Republic of Korea
**Correspondence:** H.S. Kim
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000008

**Introduction:** Malnutrition in critically ill patients is a global concern, especially those who undergo abdominal surgery, as it is associated to higher infectious complications, prolonged hospital stays, and increased morbidity. Despite the importance of proper nutrition, guidelines remain broad, and practical implementation is often inadequate. We aimed to assess the effects of strict nutritional provision and investigate the appropriate target for nutrition support.

**Methods:** A prospective, randomized controlled trial was conducted in critically ill patients admitted to intensive care units following abdominal surgery. The schematic diagram of study enrollment is shown in the attached Figure. The intervention group received targeted protein and calorie, with consultation from a nutritional support team upon admission.

**Results:** In total, 181 patients in the intervention and 144 in the control group were analyzed. The intervention group demonstrated improved nutrition provision and subsequently better clinical outcomes, including reduced 60-day mortality (4.4 versus 15.3, $p = 0.001$), postoperative complication (24.9 versus 47.2, $p < 0.001$), and in-hospital mortality (5 versus 17.4, $p < 0.001$). High modified Nutrition Risk in Critically Ill scores [odds ratio (OR) = 2.658, 95% CI = 1.498–4.716] were associated with increased 60-day mortality, while active nutritional intervention (OR = 0.312, 95% CI = 0.111–0.873) was associated to lower mortality rates.

**Conclusions:** Our study highlights the importance of nutritional management for surgical patients, especially those at high nutritional risk. The intervention group, targeted with specific nutritional goals, showed better clinical outcomes of postoperative complications and mortality. High mNUTRIC scores were associated with higher mortality, whereas the active nutritional intervention was linked to lower mortality. These findings emphasize the need for early and individualized nutritional support to improve patient outcomes.

**Introduction:** Although fluid administration is a prevalent therapeutic intervention in critical care, fluid overload is related to increased morbidity and mortality. Despite the availability of data referencing fluid administration timings, significant knowledge gaps exist regarding the optimal timing for fluid reduction or withdrawal. The capillary leak index (CLI), calculated as serum C-reactive protein divided by serum albumin, and the vascular leak index (VLI), calculated using a formula that considers the change in hematocrit levels at two different timepoints during fluid administration, and the net volume of the administered fluid has physiological implications. This suggests its usefulness as an indicator for the diuretic phase and fluid overload. Despite these physiological possibilities, the lacking evidence regarding its clinical efficacy presents a significant challenge.
**Objectives:** We aimed to investigate the potential correlations of the CLI at day 3 (day 3 CLI) and the VLI with the fluid balance, in mechanically ventilated patients with infectious diseases admitted to the intensive care unit (ICU).
**Methods:** We conducted a single-center retrospective study on consecutive adult patients admitted to the ICU of a tertiary hospital in Japan from October 2018 to December 2022. The inclusion criteria were patients with infectious diseases who were intubated within the first 24 h of admission and had an ICU stay > 5 days. The exclusion criteria were patients who underwent renal replacement therapy and those who received blood transfusions. The primary outcomes were the correlations of the day 3 CLI and the VLI with the fluid balance from day 2 to day 4 after admission, analyzed using Pearson's correlation coefficient. In-hospital mortality was assessed as the secondary outcome using binary logistic regression.
**Results:** This study included 250 patients (median age, 71.0 (61.0–78.0) years; 167 (66.8%) men). APACHE II scores, day 3 CLI, and VLI were 22.0 (19.0–28.0), 50.04 (14.39–96.98), and − 1.21 (− 4.37–0.81), respectively. A Moderate correlation was observed between day 3 CLI and fluid balance from day 2 to day 4 ($r = 0.41$, $p < 0.001$). And a very weak correlation, which is not statistically significant between VLI and fluid balance ($r = 0.03$, $p = 0.59$). Additionally, multivariate analysis revealed no statistically significant association of CLI and VLI with mortality (odds ratio = 1.00, 95% CI: 0.997 to 1.002; $p = 0.30$ and odds ratio = 1.00, 95% CI: 0.997 to 1.003; $p = 0.80$).
**Conclusions:** There was a moderate correlation between day 3 CLI and fluid balance from day 2 to day 4 in mechanically ventilated patients with infectious diseases admitted to the ICU. Considering the present findings, the CLI has the potential to be a useful indicator to estimate the risk of fluid retention and to determine the diuretic phase.

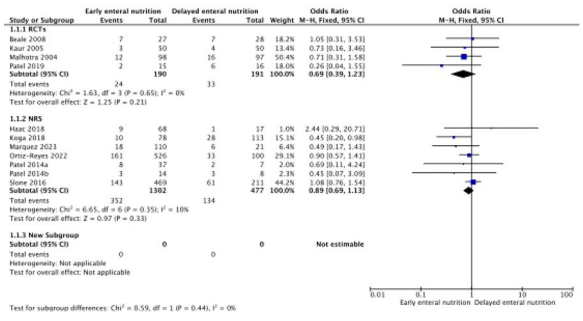
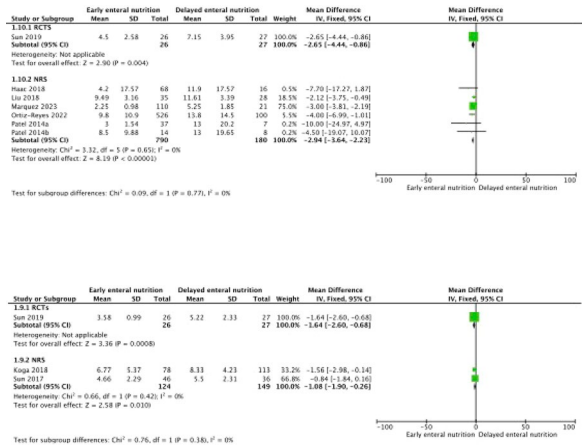
**Introduction:** Medical nutrition therapy provides the opportunity to compensate for muscle wasting and immune response activation during stress and trauma.
**Objectives:** The objective of this systematic review is to assess the safety and effectiveness of early enteral nutrition (EEN) in adults with sepsis or septic shock.
**Methods:** MEDLINE, Embase, CENTRAL, CINAHL, ClinicalTrials.gov, and ICTRP were searched from inception until July 2023. Conference proceedings, reference lists of included studies, and expert content were queried to identify additional publications. Two review authors completed study selection, data extraction, and risk of bias assessment; disagreements were resolved through discussion. Inclusion criteria were randomized controlled trials (RCTs) and non-randomized studies (NRS) comparing the administration of EEN with no or delayed enteral nutrition (DEE) in adult populations with sepsis or septic shock.
**Results:** Five RCTs ($n = 442$ participants) and ten NRS ($n = 3724$ participants) were included. Low-certainty evidence from RCTs and NRS suggests that patients receiving EEN could require fewer days of mechanical ventilation (MD − 2.65; 95% CI, − 4.44–0.86; and MD − 2.94; 95% CI, − 3.64–− 2.23, respectively), and may show lower SOFA scores during follow-up (MD − 1.64 points; 95% CI, − 2.60–− 0.68; and MD -− 1.08 points; 95% CI, − 1.90–0.26, respectively), albeit with an increased frequency of diarrhea episodes (OR 2.23, 95% CI 1.115–4.34). Even though the patients with EEN show a lower in-hospital mortality rate both in RCTs (OR 0.69; 95% CI, 0.39–1.23) and NRS (OR 0.89; 95% CI, 0.69–1.13), this difference does not achieve statistical significance. There were no apparent differences for other outcomes.
**Conclusions:** Low-quality evidence suggests that EEN may be a safe and effective intervention for the management of critically ill patients with sepsis or septic shock.





**Topic:** Metabolism, endocrinology, liver failure and nutrition

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000017

**Introduction:** The International COSMOS Registry tracks utilization patterns and clinical outcomes with real world use of the CytoSorb® (CS) hemoadsorption device in critical care settings.
**Methods:** Since July 2022, the International COSMOS Registry has been prospectively enrolling consecutive critically ill patients, including children, who undergo CS treatment as part of their standard care. Data was systematically gathered at multiple intervals, including 24 h before CS start, during CS treatment and 24 h post-CS treatment, upon intensive care unit (ICU) and hospital discharge, and final follow-up on day 90. Continuous variables were subjected to analysis via T-tests if the normal distribution assumption was met or Wilcoxon rank sum tests if not met, with findings presented as either mean ± standard deviation or median [interquartile range]. A $p$-value < 0.05 was used as the threshold for statistical significance.
**Results:** A total of 150 patients (33% female, age 59 ± 17 years) from 16 sites in Germany, Italy and Spain were included in this analysis. Indications for CS (multiple indications may apply for certain patients) included septic shock (57.6%), cardiogenic shock (12.9%), rhabdomyolysis (10.6%), acute/acute-on-chronic liver failure (10.6%), acute respiratory distress syndrome (6.8%), and others (9.1%). Median number of CS adsorbers used per patient was 2 [1, 3]. The platform used for integration of CS was renal replacement therapy (82.8%), standalone hemoperfusion (9.8%) and extracorporeal membrane oxygenation (7.4%).
Baseline median APACHE II score was 23 [17, 29] and median SOFA score was 12 [9, 15] with a median ICU-stay of 20 [11, 33] days. Compared to baseline, significantly lower plasma levels of lactate ($p$ < 0.0001) and creatinine ($p$ < 0.0001) were observed after CS, whereas albumin did not change ($p$ = 0.574). In the septic shock cohort, median lactate decreased from 3.3 [1.8, 6.7] to 1.6 [1.2, 2.9] mmol/L ($p$ < 0.0001). In patients with rhabdomyolysis (data from $n$ = 9), median myoglobin also significantly decreased after CS from 18,976 [1934, 34275] to 835 [623, 5925] µg/L ($p$ = 0.027). In the liver failure group, the decrease in bilirubin after CS from 7.28 [4.2, 15.5] to 6.11 [4.7, 8.6] mg/dL did not reach statistical significance (data from $n$ = 12, $p$ = 0.110). Median platelet count dropped significantly in the septic shock and liver failure cohorts whereas showed no significant change in the rhabdomyolysis cohort ($p$ = 0.722). Median fluid balance decreased from + 1386 [220, 3168] mL in the 24 h period before CS treatment to + 275 [− 768, 1846] mL in the 24 h post CS treatment ($p$ < 0.0001). Median norepinephrine dosage was reduced significantly from 0.31 [0.19, 0.55] to 0.20 [0.10, 0.36] µg/kg/min ($p$ < 0.0001) (see Fig. 1). Also, oxygenation significantly improved over course of treatment, with a median PaO2/FiO2 ratio increase from 132 [68, 208] to 189 [115, 260] mmHg ($p$ < 0.0001).
ICU-mortality rate was 35.0% in the overall cohort and 37.5% in the septic shock cohort and therefore lower than expected according to SOFA score.
**Conclusions:** The International COSMOS Registry provides real-world data showcasing a diverse range of indications and platforms for integrating the CS device. Compared to baseline, CytoSorb® treatment in addition to standard therapy was associated with significant reductions in lactate, creatinine, myoglobin, and the requirement for norepinephrine, leading also to significant improvements in fluid balance and arterial oxygenation. Observed mortality in the septic shock cohort compared favorably to risk score-based predicted values.
Trial registration: NCT05146336 on December 6, 2021.

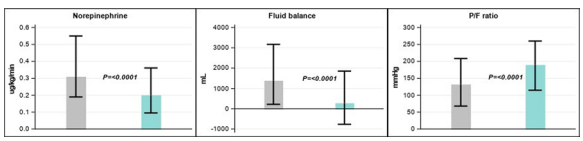

**Fig. 1 (abstract 000017)** Changes in norepinephrine, fluid balance and P/F ratio in 24 h periods before (grey) versus after CytoSorb® treatment (blue), data are presented as median and interquartile range

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000018

**Introduction:** Excessive sedation has been associated with adverse outcomes in critically ill patients. A previous study of mechanically ventilated patients in the emergency department (ED) revealed a high frequency of deep sedation in the ED which continued throughout the first 48 h of intensive care unit (ICU) admission.
**Objectives:** This study aimed to compare sedation management during and after intubation in the ED versus the ICU.
**Methods:** This was a single-center retrospective cohort study of adults intubated in the ED or in the ICU and received mechanical ventilation between Jan 2018 and Feb 2022. We collected data from the electronic medical record. The primary outcome was duration from intubation to first documentation of light sedation, defined as Sedation Agitation Scale score (SAS) of 3–4.
**Results:** The study included 264 patients (median age 63 yr, 58% male), with 95 (36%) intubated in the ED and 169 (64%) in the ICU (Table 1). Rapid sequence induction was significantly more frequent in the ED compared to the ICU (82.1% vs. 30.2%, $p<0.001$). Higher doses of sedatives and neuromuscular blocking agents were used for intubation in the ED, while no significant difference in opioid dosage was found. Regarding anesthetic agents used for intubation, ketamine was the most commonly used drug in the ED and was used more frequently than in the ICU (61% vs 40%, $p=0.001$). Propofol was the predominant sedative used in the ICU, with a higher prevalence compared to the ED (50% vs 33%, $p=0.01$). After intubation, opioids were less commonly used (25.3% vs. 68.6%, $p<0.001$), while ketamine and benzodiazepines were more frequently used (16.8% vs 4.7%, $p=0.001$; and 33.7% vs. 8.3%, $p<0.001$, respectively) in the ED compared to the ICU (Table 2). Within 24 h after intubation, 68% (65/95) ED patients and 82% (138/169) patients intubated in ICU achieved light sedation, with median durations of 13.5 h and 10.5 h. Patient location in the ED at intubation was associated with decreased probability of achieving light sedation at 24 h (adjusted odds ratio 0.64, $p=0.04$) (Fig. 1). Furthermore, deep sedation (SAS 1 or 2) was more frequently observed in the ED group at all time points, especially at 12 and 48 h (60.2% vs. 46.3%, $p=0.03$; and 26.5% vs. 13.0%, $p=0.02$, respectively) (Fig. 2).

**Table 1 (abstract 000018)** Baseline patient characteristics

| Variables | ED (*N* = 95) | ICU (*N* = 169) | *P* value |
|---|---|---|---|
| Age (year), mean (SD) | 56 (21) | 63 (15) | 0.004 |
| Male sex, *n* (%) | 55 (58) | 98 (58) | 0.99 |
| BMI (kg/m$^2$), median (IQR) | 26 (21–28) | 26 (23–31) | 0.30 |
| APACHE II, median (IQR) | 22 (17–27) | 22 (17–27) | 0.80 |
| baseline GCS <, = 8, *n* (%) | 61 (68) | 36 (25) | < 0.001 |
| Reason for intubation, *n* (%) | 8 (8) | 11 (7) | 0.56 |
| Airway obstruction | 25 (26) | 107 (63) | < 0.001 |
| Respiratory failure | 4 (4) | 4 (2) | 0.40 |
| Cardiogenic shock | 46 (48) | 22 (13) | < 0.001 |
| Neurological dysfunction | 3 (3) | 24 (14) | 0.004 |
| Sepsis | | | |

**Table 2 (abstract 000018)** Anesthetic agents used for peri-intubation in the ED versus ICU

| Drug types | ED (*N* = 95) | ICU (*N* = 169) | *P* value | ED (*N* = 95) | ICU (*N* = 169) | *P* value |
|---|---|---|---|---|---|---|
| Intubation period | During | | | After | | |
| Opioids | 9 (9.5) | 115(68) | < 0.001 | 24 (25.3) | 116 (68.6) | < 0.001 |
| Ketamine | 58 (61.1) | 68 (40.2) | 0.001 | 16 (16.8) | 8 (4.7) | 0.001 |
| Propofol | 31 (32.6) | 85 (50.3) | 0.01 | 48 (50.5) | 110 (65.1) | 0.02 |
| BZD | 6 (6.3) | 66 (39.1) | < 0.001 | 32 (33.7) | 14 (8.3) | < 0.001 |
| Rocuronium | 44 (46.3) | 64 (37.9) | 0.18 | – | – | – |

Data are shown as N (%) or median (IQR), BZD = benzodiazepine.

**Conclusions:** Critically ill patients intubated in the ED are at risk of deeper sedation and a longer time to achieve light sedation compared to patients intubated in the ICU.

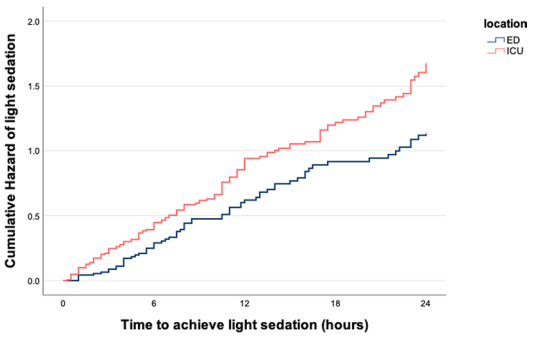

**Fig. 1 (abstract 000018)** Cumulative hazard of the time to achieve light sedation at 24 h, by patients' location of intubation

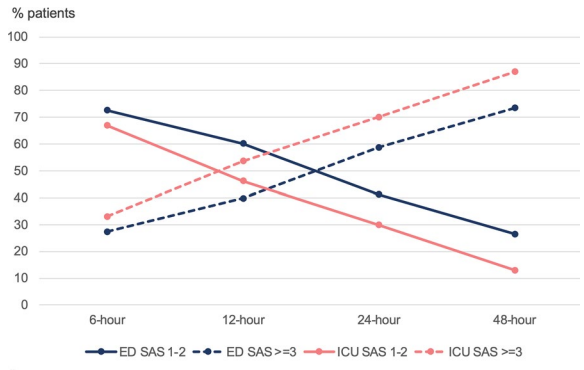

**Fig. 2 (abstract 000018)** Sedation Agitation Scale at each time point in ED and ICU patients

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000019

**Introduction:** The rate of failed extubation among patients undergoing mechanical ventilation (MV) weaning process ranges from 10 to 20%. In certain studies, this rate can reach up to 25% [1–3].
Among patients experiencing failed extubation, mortality rates range from 25 to 50%, excluding reintubations due to upper airway obstruction, as these cases do not significantly impact mortality [4, 5]. French Society of Anesthesia and Resuscitation guide for intubation and extubation in the ICU confirms the need for a chest physiotherapist in critically ill patients, with pre- and post-extubation action, to reduce the duration of weaning and extubation failure (Grade 2+), strong recommendation [6].
Despite these recommendations, many ICUs in Spain do not currently have critical care physiotherapists available to assist with patient weaning and extubation [7].
**Objectives:** The objective of this study is to evaluate the rate of reintubation at 24, 48, 72, and > 72 h post-extubation among patients who receive immediate post-extubation chest physiotherapy compared to those who do not.
**Methods:** This is a prospective observational multicenter study aimed at comparing the reintubation rates among different Spanish hospitals that perform post-extubation respiratory physiotherapy and those that do not. Approved by the ethics committee with number *PR(ATR)164/202*.
All patients aged 18 and above admitted to the intensive care unit who undergo extubation within one year will be included. Exclusion criteria include intubation for less than 48 h, contraindication for chest physiotherapy, pregnancy, life support limitation, need for intubation due to neurological or cardiothoracic surgery causes.
Post-extubation respiratory physiotherapy is defined as that which is applied within the first 2 h following the procedure.
**Results.** A total of 367 patients were included in this study (60% were male) with the main age of 59 ± 12 years old. Table 1 displays the characteristics of the included patients.
Of all patients that where extubated 72% ($N = 267$) did not required reintubation, 18.8% ($N = 69$) required reintubation during the first 24 h, 3.5% ($N = 13$) required reintubation at 24–48 h, 2.2% ($N = 8$) required reintubation at 72 h and 2.7% ($n = 10$) required reintubation after 72 h.
There were statistically significant differences related to de rate of reintubation when the physiotherapist followed up the patient during the next 2 h after extubation. A 35.5% ($N = 62$) of all patients required to be reintubated when there was no follow up, but only a 19.6% ($N = 38$) required reintubation when there was a follow up, being this difference statistically significant ($p < 0.05$) (Table 2).
**Conclusions:** Respiratory physiotherapy applied within the first 2 h following extubation could potentially benefit in reducing reintubation rates in an ICU.

Randomized, multicentre future studies could be optimal to replicate such data.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000022

**Introduction:** Acute postoperative hypertension (APH) is a common complication during the anesthesia recovery period that can lead to adverse outcomes, including cardiovascular and cerebrovascular accidents especially the patients who underwent hypertension.
Pain relief by block of parietal nociceptive afferent nerves using continuous wound infiltration with local anaesthetics and intravascular(IV) PCA may be both beneficial in multimodal postoperative pain management and stable vital sign.
In the postoperative care unit (PACU), vital sign checked out both continuous wound infusion of ropivacaine and IV PCA after open hepatectomy was analysed in a prospective, randomized, double-blinded, placebo-controlled trial.
**Methods:** Eighty-two patients who have underlying hypertension were randomized to two groups to R and S. The group R used 0.5% ropivacaine (ON-Q group) using an elastomeric pump which delivered 4 ml $h^{-1}$ over 48 h through two multiholed Soaker® catheters placed between the transverse and the internal oblique muscles and the s.c. space. The group S used IV PCA (fentanyl 1000 mcg mix to N/S total 100 ml, delivered 1 ml $h^{-1}$ over 48h). Rescue medication was injected in the condition of hypertensive crisis (nicardipine 1 mg, brevibloc 10 mg, fentanyl 50 mcg). Vital signs (BP, heart rate), total dosage of rescue medication and visual analogue scale (VAS) were recorded. APH was defined as an increase in systolic BP by more than 20% or an increase in diastolic BP to above 110 mmHg. Hypertensive crisis was defined as a systolic BP $\geq$ 180 mmHg or a diastolic BP $\geq$ 110 mmHg, with or without acute target organ involvement.
**Results:** Under the conditions of the study, S was more vulnarable for APH than R ($R = 20$, $S = 31$ $p < 0.05$). In both group who have hypertensive crisis($R = 5$, $S = 7$), the total number of rescue medication required to achieve therapeutic BP response was significantly less in the group R (mean count was $R = 1$, $S = 4$). VAS score was similar in both group in the PACU (mean VAS 3–4).
**Conclusions:** Continuous surgical wound infusion with ropivacaine lower the risk of APH. This would be make more positive surgical outcome in the patients underwent hypertension or risk of hypertensive symptoms.

### Intensive Care Unit Handover A standardized approach for improved documentation

M. Moubarak[1]
[1]Intensive Care, Lewisham And Greenwich Nhs Trust, London, United Kingdom
**Correspondence:** M. Moubarak
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000025

**Introduction:** Proper documentation of medical handovers in the Intensive Care Unit (ICU) is crucial for transmitting accurate patient information between healthcare providers. It prevents the omission of critical information, ensures accurate recording of new diagnoses in discharge summaries, and facilitates proper follow-up after discharge. Failure to document handovers and new diagnoses can lead to adverse events and medical errors. Accurate documentation also increases awareness among the medical team, reducing misunderstandings and errors [1].
It is essential for directing support and intervention strategies, improving patient outcomes. Additionally, accurate documentation is important for coding, defining case mix, and predicting the risk of death in the Intensive Care National Audit and Research Centre dataset (ICNaRC), which monitors and improves ICU performance in the UK [2].
**Objectives:** The objectives of this study were to assess the adequacy and precision of medical handover processes in the ICU, verify accurate documentation of new diagnoses made during ICU admission, ensure correct reflection of diagnoses in patients' discharge summaries, review existing documentation practices in the ICU, and identify deficiencies. Additionally, the study aimed to provide recommendations for enhancing patient care based on findings.
**Methods:** In this study, a retrospective analysis was undertaken across two cycles to assess modifications, involving a cohort of 20 intensive care unit (ICU) patients in each cycle. The age range of patients was 33–73 years in the first cycle and 28–80 years in the second cycle. The sample comprised 60% males and 40% females, encompassing diverse initial admission diagnoses. The presence of new ICU conditions was determined based on information extracted from radiology reports, laboratory results, specialty ward rounds, echo reports, and other ICU notes. Additionally, the documentation of these conditions in handover sheets and discharge summaries was also examined. The study identified specific examples of new diagnoses encountered during the analysis with the aim to provide reliable information for making recommendations to improve patient care.
**Results:** In the initial analysis, 65% of patients exhibited new ICU conditions, yet only 7.7% of these were documented in handover sheets, leaving a substantial 92.3% undocumented until discharge. In the second cycle, involving 55% of patients with new ICU diagnoses, a notable improvement occurred, with 90.9% meticulously documented in the handover sheets' diagnosis section. Regarding discharge summaries, only 38.5% of new diagnoses were initially recorded, with 61.5% left undocumented. Following recommended changes in the second cycle, a significant enhancement was observed, with 90.9% of new ICU diagnoses meticulously documented in discharge summaries' new diagnoses section—a substantial improvement from the 38.5% recorded before the introduction of new standardized forms. Fig. 1
**Conclusions:** The team conducting the analysis identified modifiable causes contributing to poor handover documentation in the first cycle and implemented targeted improvement interventions. The first improvement entailed the adoption of a standardized handover form, endorsed by the department's quality improvement team. The second enhancement involved the implementation of a standardized discharge summary for ICU patients, designed to comprehensively outline all admission and newly diagnosed conditions, including their respective stages.
This study underscores the critical importance of effective medical handover documentation in the Intensive Care Unit, emphasizing its role in ensuring the accurate transmission of patient information among healthcare providers. Proper documentation not only mitigates the risk of omitting vital information but also serves as a cornerstone in bolstering patient safety, minimizing errors, and ultimately improving overall outcomes.

**Introduction:** Mannitol, an osmotic diuretic, has been shown to induce alkalemia. The primary aim of this study was to evaluate the short-term effects of a bolus of Mannitol in mechanically ventilated critically ill patients on plasmatic and urinary electrolytes and acid–base equilibrium to the Stewart's approach.
**Methods:** Prospective study enrolling mechanically ventilated critically ill patients. While maintaining ventilatory setting constant (tidal volume on PBW = 8 mL/kg, PEEP 6), 1 g/kg PBW of Mannitol bolus was infused in 5 min. Before (baseline), immediately after the infusion and every 60 min till 180 min, we measured plasmatic electrolytes and acid–base balance-related variables, as well as respiratory mechanics and gas exchange variables, renal function indexes and fluid balance. Urinary electrolytes and acid–base balance-related variables were measured continuously using the Kidney Instant monitoriNG system (K.I.NG) and collected every 30 min. Apparent plasmatic and urinary strong ion difference (SID) were calculated.
**Results:** Preliminary data on 15 patients are reported. The average amount of Mannitol infused was 63 g. In Fig. 1, the effects of Mannitol on arterial and urinary pH, electrolytes and SID are reported. As shown, the infusion of Mannitol did not significantly change urinary composition in terms of pH and urinary [Na+] and [Cl–], while it significantly reduced both [K+] and [$NH_4^+$], resulting in a net reduction of urinary SID occurring in the first 30 min but lasting for 3 h. This behavior of urinary composition paralleled a shift of plasmatic acid–base balance

towards alkalosis, caused by a rapid increase in plasmatic SID, mainly driven by a concentration effect, related to a Mannitol-related increase in urinary output.
**Conclusions:** Urinary SID assessment by continuous urinary monitoring provided new insight on Mannitol mechanism of action with respect to Stewart's approach.

**Correspondence:** J. Sereeyotin
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000028

**Introduction:** Patients transferred from the intensive care unit (ICU) to a ward are often unprepared for the transition, as are their family members. They may lack sufficient knowledge about what will happen to them during and after transition. The use of patient/family centered written summaries supplemental to verbal information may be useful to improve knowledge and reduce transfer anxiety.

**Objectives:** We aimed to identify essential elements to include in an ICU-specific patient-oriented discharge summary tool (PODS-ICU).
**Methods:** We conducted a mixed methods study at Mount Sinai Hospital from May 2021 to December 2022. Participants were ICU patients who were transitioning to a hospital ward, and clinicians. We used a validated questionnaire to measure the relocation stress of patients; and standardized questions to qualitatively explore patients' needs during the transition, as well as perspectives of clinician stakeholders. Inductive thematic analysis was used for the qualitative analysis.
**Results:** 22 participants were recruited, including 10 patients and 12 clinician stakeholders (3 ICU physicians, 3 non-ICU physicians, 3 ICU nurses and 3 outreach team nurses). Data collected from the survey and interview were summarized into four overarching themes: experiences and transfer anxiety, information needs, support needs, and recommendations to improve the transition. 90%-100% of patients had positive experiences during the transition, whereas negative experiences were reported by 10–30% (Table 1). Patients expressed the need for more information for themselves and for their family members, including an explanation of the reason for ICU admission, a summary of the ICU course, and the reason for transfer. From all participants' perspectives, we identified the following essential elements for the PODS-ICU: the reason for transition, a summary of the ICU course, a clinical update, destination ward details, medication reconciliation, a future care plan, and the planned follow-up by the ICU outreach team (Fig. 1). The presence of family and earlier notification of an upcoming transfer were identified as support needs for patients to help them prepare mentally and reduce transfer anxiety. Moreover, using positive communication with patients and family members when providing transfer details and using the brief standardized transfer tools were recommended to improve transition care.

**Table 1 (abstract 000028)** Patient Relocation Stress Syndrome Scale (RSSS)—Short Form

| Item | Agree | Disagree | NA |
|---|---|---|---|
| I feel better able to cope and look after myself in a general ward | 50% | 20% | 30% |
| | 100% | 0 | 0 |
| I feel comfortable with the general ward environment | 90% | 0 | 10% |
| | 100% | 0 | 0 |
| I feel happy to be out of ICU and on the next stage of my recovery | 20% | 50% | 30% |
| | 30% | 70% | 0 |
| I think ward nurses know my physical condition/treatment plans well | 10% | 90% | 0 |
| | 30% | 10% | 60% |
| I feel abandoned and vulnerable following transfer to a general ward | 80% | 20% | 0 |
| | 80% | 10% | 10% |
| I don't feel ward nurses pay attention to me | 60% | 10% | 30% |
| I feel ward nurses ignore my concerns and needs | | | |
| I think my family is anxious about my condition following transfer to a general ward | | | |
| I felt well informed about my transfer from the ICU to the ward | | | |
| I think my family's role in my personal care and hygiene would be quite important in a ward | | | |
| My family and my opinions were taken into account in the decision to transfer from ICU to a ward | | | |

**Conclusions:** We identified informational gaps in patient and family knowledge at the time of ICU transfer, which informed essential elements for the PODS-ICU. The PODS-ICU may reduce transfer anxiety and improve care during the transition.

## Urinary Dickkopf-3 as a Predictor for Postoperative Acute Kidney Injury in the Intensive Care Unit

S. Yao[1]
[1]Intensive Care Unit, Peking University People's Hospital, Beijing, China
**Correspondence:** S. Yao
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000036

**Introduction:** As a life-threatening complication in patients undergoing surgery, acute kidney injury (AKI) is strongly associated with a worse prognosis. Urinary dickkopf-related protein 3 (DKK3) has been identified as a biomarker for predicting postoperative AKI in patients undergoing cardiac surgery. As a life-threatening complication in patients undergoing surgery, acute kidney injury (AKI) is strongly associated with a worse prognosis. Urinary dickkopf-related protein 3 (DKK3) has been identified as a biomarker for predicting postoperative AKI in patients undergoing cardiac surgery.
**Objectives:** To investigate the predictive value of urinary DKK3 on postoperative AKI and develop a clinical model based on the predictor for predicting the development of AKI within seven days for patients undergoing noncardiac surgery.
**Methods:** All patients who were admitted to the Intensive Care Unit (ICU) after noncardiac surgery from March 2023 to June 2023 were included in this study. The patients' baseline data on demographic characteristics, lifestyle risk factors, medical history, clinical features, and laboratory tests before surgery were collected at the time of admission. Besides, the blood samples for cystatin C and routine laboratory tests and the urine samples for DKK3 tests were simultaneously collected at the time of admission to the ICU. In addition, the independent predictors of postoperative AKI were identified by univariate, multivariate, and LASSO analyses. Moreover, a nomogram for predicting postoperative AKI was developed based on these independent predictors. Finally, the nomogram was evaluated through calibration and decision curve analyses.
**Results:** A total of 166 patients with a median age of 67 years old were included in this study, including 94 (56.63%) males. Among these patients, 47 patients (28.3%) developed postoperative AKI. Additionally, 7 independent risk factors, including preoperative serum creatinine, preoperative eGFR, preoperative serum albumin, preoperative serum potassium ion, cystatin C, uDKK3/uCr, and SOFA score, were selected by univariate and multivariate regression analyses. Eventually, 4 independent risk factors (including preoperative eGFR, cystatin C, uDKK3/uCr, and SOFA score) identified in this study by LASSO analyses were used to establish the nomogram. The area under the receiver operating characteristic (ROC) curve (AUC) for the prediction model was 0.868. The calibration curve and decision curve analysis results demonstrated that the nomogram had good prediction performance.
**Conclusions:** Urinary DKK3/creatinine was independently associated with postoperative AKI for patients in the ICU after noncardiac surgery. The nomogram constructed based on uDKK3/uCr, preoperative eGFR, cystatin C, and SOFA score showed a higher accuracy in predicting postoperative AKI.

**Introduction:** Critically ill patients, including those with acute brain injuries (BI) are frequently hospitalised in an intensive care unit (ICU). As with other critical states, an adequate stress response is essential for survival. In this regard, corticosteroid treatment has been extensively investigated in these patients. The actions of glucocorticoids are mediated by a ubiquitous intracellular receptor protein, the glucocorticoid receptor (GCR). However, data on GCR-α expression and its signalling in acute BI injury are lacking.
**Objectives:** We designed a prospective observational study aiming at investigating the expression of *GCR-α* and *GILZ* in the polymorphonuclear leukocytes (PMNs) of ICU patients with BI and to compare their expression to normal controls. We also aimed at exploring possible correlations of *GCR-α* and *GILZ* expression with BI biomarkers and with cytokines implicated in the GC response during critical illness.
**Methods:** Forty-two critically ill patients with acute BI were included. These patients suffered from traumatic BI ($N=20$), aneurysmal subarachnoid hemorrhage ($N=12$), intracerebral hemorrhage ($N=7$), or acute ischemic stroke ($N=3$). All patients were steroid-free. Twenty-four age and sex-matched healthy controls were used for comparison. Expression of *GCR-α* and the glucocorticoid-inducible leucine zipper (*GILZ*), serum cortisol, interleukins (IL) 6, 8, and 10, and the BI biomarkers GFAP and total Tau were measured on ICU admission (within 48 h) and 5–7 days from admission.
**Results:** Compared to healthy controls, in the critically ill patients with BI, *GCR-α* mRNA expression was significantly downregulated on admission, and after 5–7 days in the ICU (2.3-fold, $p<0.05$ and 2.6-fold, $p<0.01$, respectively). Even though GCR-*α* was downregulated, its downstream gene, *GILZ*, was expressed at the same levels as in normal controls on admission and was significantly upregulated 5–7 days following admission (twofold, $p<0.001$). TNF-*α* levels were undetectable at both time-points. *GCR-α* expression levels inversely correlated with IL-6 and IL-10. The levels of cortisol and the BI biomarkers did not differ between the 2 time-points.
**Conclusions:** The low-grade inflammatory response seen in our BI critically ill patients does not seem to result in glucocorticoid resistance. Our critically ill patients with BI seem to possess a sensitive GCR, leading to increased *GILZ* expression. The induction of GILZ by aldosterone via the mineralocorticoid receptor cannot be excluded.

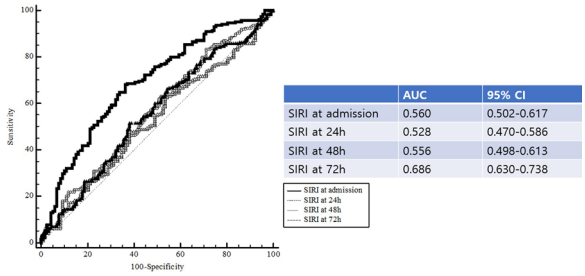
### Association between systemic inflammation response index and poor neurologic outcomes in out-of hospital cardiac arrest patients

T. Shin[1]
[1]Emergency medicine, Seoul St Mary's Hospital, Seoul, Republic of Korea
**Correspondence:** T. Shin
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000039

**Introduction:** Post-cardiac arrest syndrome (PCAS), a systemic inflammatory syndrome following CA, occurs during the reperfusion period after the ROSC. It shares several pathophysiological mechanisms with sepsis, and causes hypoxic brain injury. However, inflammatory markers to the outcome has not yet been fully investigated. An inflammation-related marker, the systemic inflammation response index (SIRI), which was developed in 2016 that can reflect the cancer-related inflammatory response, is calculated as neutrophils × monocytes/lymphocytes.
**Methods:** In this retrospective, observational singlecenter study, we tested the hypothesis that SIRI is associated with the neurological outcomes of OHCA patients treated with TTM. Venous blood sample were routinely collected at admission and at 24 h, 48 h and 72 h after the ROSC. The primary outcome was poor neurologic outcome (CPC3-5) at 6 months after CA.
**Results:** A total of 317 of 516 patients (61.4%) treated with TTM were included in the analysis. 127 of 317 patients (40.0%) had good neurologic outcome, and 190 of 317 patients (60.0%) had poor neurologic outcome. SIRI at 72 h were higher in poor neurologic outcome group, while SIRI at admission, 24 h and 48 h had no significant difference.
**Conclusions:** SIRI at 72 h after the ROSC were associated with poor neurological outcomes at 6 months after CA in patients treated with TTM.



| | AUC | 95% CI |
|---|---|---|
| SIRI at admission | 0.560 | 0.502-0.617 |
| SIRI at 24h | 0.528 | 0.470-0.586 |
| SIRI at 48h | 0.556 | 0.498-0.613 |
| SIRI at 72h | 0.686 | 0.630-0.738 |

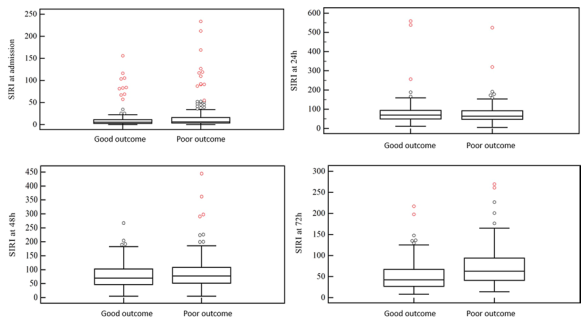


**Table (abstract 000039)** Odds ratio for poor neurologic outcomes at 6 months after ROSC

| | Poor neurologic outcomes at 6 months | | | |
|---|---|---|---|---|
| | SIRI at admission | SIRI at 24h | SIRI at 48h | SIRI at 72h |
| Multivariate | 1.006 | 0.999 | 1.004 | 1.010 |
| | (0.994-1.018) | (0.994-1.004) | (0.997-1.010) | (1.001-1.019) |
| SIRI≥50 | 1.898 | 1.110 | 1.453 | 2.635 |
| | (0.600-6.099) | (0.552-2.232) | (0.707-2.988) | (1.361-5.103) |

Adjusted by Age, Witnessed arrest, Bystander CPR, Initial shockable rhythm, Cardiac cause of arrest, Time from collapse to ROSC, Hypertension, Diabetic mellitus, hs-CRP at admission

**Introduction:** Intensive care unit (ICU) acquired weakness (ICUAW) is a clinically detected condition characterized by diffuse, symmetric weakness involving the limbs and respiratory muscles. Not all patients who are weaned in ICU off ventilator have diaphragm weakness. They may have poor muscle power or MRC score. In this study, we plan to find a correlation between diaphragmatic excursion measured using ultrasound with MRC sum score, which has not been done in earlier studies. We hypothesize that diaphragm weakness is not there in many patients in ICU, leading to their weaning from the ventilator. However, they may have muscle weakness requiring long-term physiotherapy and rehabilitation. Identifying the patient with muscle weakness with diaphragm sparing is important to fastrack weaning in this group of patients.
**Objectives**: **Primary**: To assess the correlation between MRC sum score and diaphragmatic excursion measured using USG.
**Secondary:** To assess the sensitivity and specificity of Diaphragmatic excursion measured using USG in predicting the presence of ICUAW.
**Methods:** Patients admitted in the ICU and ventilated for more than 48 h were included in the study. Demographic data, including name, age, diagnosis, and APACHE II score at the time of admission,were collected.The patients were assessed after 48 h of mechanical ventilation-when they were at spontaneous breathing trial and off sedation for at least 30 min.

We calculated the MRC-sum score by summing all the obtained strength values of the upper limbs and lower limbs.
Thirty minutes after the MRC sum score was calculated patient was put in the supine position. The patient was disconnected from the ventilator for a brief period during which. Using Vivid™ iq from GE Healthcare USG machine low-frequency curvilinear transducer (1–5 MHz) using two-dimensional M-mode imaging ultrasonography 22 was done. The right side of the diaphragm was examined from the anterior subcostal view by positioning the probe below the right costal margin between the midclavicular and anterior axillary lines. The ultrasonic beam from the probe was aimed cranially at the posterior portion of the diaphragm to get maximum excursion. The diaphragmatic excursion was measured in three successive tidal volume breaths and vital capacity breaths. The mean of these readings was calculated and used for analysis. Other data, like the use of corticosteroids, NMB, and vasoactive drugs (noradrenaline, vasopressin, adrenaline) were noted.
**Results:** On comparing the relationship between the MRC sum score and DE normal breathing, we found a moderate correlation with a Spearman coefficient of 0.39 ($p = 0.006$) but a weak correlation between the MRC sum score and DE deep breathing with a Spearman correlation coefficient of 0.27 which is not statistically significant. Among patients who had ICUAW, the patients who were not extubated had a mean DE of 9mm during normal breathing and 17.6 mm during deep breathing was significantly less when compared to a mean of 11.1 mm during normal breathing and 19.7mm during deep breathing in patients who were extubated.
**Conclusions:** Our study concludes that diaphragmatic measurement OF USG can be used as a simple screening tool for predicting ICUAW in a busy ICU. Among patients who had ICUAW, those who were not extubated had a mean DE of 9mm during normal breathing and 17.6 mm during deep breathing compared to a mean of 11.1 mm during normal breathing and 19.7 mm during deep breathing.

### Why women don't reach leadership in Critical Care Medicine

S. Siddiqui[1]
[1]Anesthesia, Critical Care and Pain Medicine, Beth Israel Deaconess Medical Center, Brookline Avenue, Boston, MA, USA, Boston, United States of America
**Correspondence:** S. Siddiqui
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000042

**Introduction:** Evidence suggests potential gender disparities amongst critical care practitioners, including critical care clinical and administrative leaders. Despite guidelines published by the Association of American Medical Colleges (AAMC) in 2009 encouraging medical schools and academic institutions to focus on improve gender equality in academia and to increase the representation of women in senior academic and leadership positions, the literature supports significant and ongoing gender disparities in academic medicine, particularly in leadership positions.
**Objectives.** We completed a systematic review to summarize evidence surrounding clinical practice and leadership opportunities forwomen in critical care. Our PICOTS question was "Why women are not equally represented in Critical Care Medicine leadership roles and other similar fields worldwide, and what organizational policies and practices impede this progression?".
**Methods. Data Sources:** A systematic literature review was undertaken using four databases: Cochrane Library, Embase, PubMed, and the Web of Science.
**Study Selection:** The types of articles included were: consensus statements, opinions, and editorials.
**Data Extraction:** The database searches generated 724 records. 49 studies met inclusion criteria for data extraction. The included studies were published between 2011 and 2023 and represent seven countries, with 38 studies originating in the United States. Eight studies were commentaries, and the rest were qualitative, observational studies. The following 5 domains were found after grouping the studies according to the thematic content analysis of the results: pipeline issues, lack of opportunities, lack of self-efficacy, lack of mentorship, and sustaining women in leadership.
Data Synthesis: Covidence platform and CASP methodology.
**Results:** The papers were tabulated and the content was analyzed qualitatively using coding, iterative analysis and separation into themes. The CASP tool was used to assess the risk of bias in all studies. The following 5 domains were found after grouping the studies according to the thematic content analysis of the results:

1. Pipeline issues in having women who are ready for leadership (family issues, qualifications, motivation, confidence).
2. Lack of opportunities offered (disparities and bias).
3. Lack of self-efficacy (belief that one can be a leader).
4. Lack of mentorship (in having women leaders).
5. Sustaining women in leadership through fair support (fair treatment, harassment, unequal pay).

**Conclusions:** While the satisfaction rates of women in critical care medicine are high 55 challenges remain for women in leadership. By creating a culture of support, we can sustain them in those roles.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000043

**Introduction:** Intravenous fluid administration is a common medical practice in hospitals. However, the knowledge of health practitioners vary and may impact patient outcomes. Despite global awareness of fluid management issues, Indonesia remains unexplored.
**Objectives:** The aim of this survey is to explore the correlation between doctors' professional status and their intravenous fluid therapy knowledge in Indonesian hospitals, hypothesizing that there is a significant difference.
**Methods:** Anesthesiologist and Resident in Training from Indonesia were asked to respond to an online survey about their opinions on fluid choices. Of the 65 multiple-choices in the survey, 25 addressed knowledge of fluid management and stewardship. For statistical analysis, data are represented as median with minimum and maximum values. The Mann Whitney U test and Chi-Square were used to study the difference in the different groups according to training status.
**Results:** 364 surveys were received, with respondents originating from 27 provinces throughout Indonesia, covering all of the country's major islands. The years of experience ranged from 0 to 57 with a mean of 10.57. The median cumulative score on the knowledge questions was 40 out of 100 with the lowest score 12 and highest score 72.
There are significant difference in the median cumulative score between resident in training 36 (12–64) and qualified anesthesiologist 44 (16–72) with P-Value 0.000. 263 (72.3%) respondents state that ringer's lactate is the most prescribed infusion in their workplace. The poor survey scores indicate that the respondents' knowledge about fluid management and stewardship still lacking, with fluid volume status assessment being the area most in need of improvement.
**Conclusions:** This survey assessed the knowledge of fluid stewardship and management across Indonesian anesthesiologist. Given that the median score was less than 50, it can be improved by proposing fluid stewardship education and training before establishing a comprehensive fluid stewardship program in Indonesia.

**Table 1 (abstract 000043)** Comparison of respndents' median scores with training status

| Variable | | Research Domain | | | | | |
|---|---|---|---|---|---|---|---|
| | | 1: Basic knowledge of electrolytes (Min-Max) | 2: Administration of IV fluids (Min-Max) | 3: Knowledge of the composition of IV fluids (Min-Max) | 4: Fluid resuscitation (Min-Max) | 5: Assessment of fluid volume status (Min-Max) | Cumulative Score (Min-Max) |
| Respondents | n=364 | 25 (0-100) | 37.5 (0-87.5) | 60 (0-100) | 40 (0-100) | 0 (0-66) | 40 (12-72) |
| **Status** | | | | | | | |
| Resident in Training | 162 (44.5%) | 25 (0-100) | 37.5 (0-87.5) | 40 (0-100) | 40 (0-100) | 0 (0-66) | 36 (12-64) |
| Qualified Anesthesiologist | 202 (55.5%) | 37.5 (0-100) | 37.5 (12.5-87.5) | 60 (0-100) | 40 (20-100) | 33 (0-66) | 44 (16-72) |
| P-value | | 0.139 | 0.053 | 0.000 | 0.074 | 0.288 | 0.000 |

### Framework for studying racial *bias* in end of life care

S. Siddiqui[1]
[1]Anesthesia, Critical Care and Pain Medicine, Beth Israel Deaconess Medical Center, Brookline Avenue, Boston, MA, USA, Boston, United States of America
**Correspondence:** S. Siddiqui
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000044

**Introduction:** Despite improved end-of-life (EOL) care in the ICU there remain significant differences in the care dispensed to Black and Hispanic patients. There is a lack of trust in clinicians which may be due to a perception of implicit bias. Implicit, or unconscious racial bias may influence how physicians communicate with patients about their end-of-life care preferences, and thus result in less patient and family compliance with treatment recommendations on the quality of end-of-life care. This can be due to the implicit bias in how ICU clinicians deliver care or communication at EOL resulting in disparate care.
**Objectives:** There is a critical need to address this knowledge gap and incorporate the voices of Black and Hispanic patients and their families in end-of-life care decision making. The proposed research objective is to provide key insights about the presence of implicit bias among ICU clinicians, as well as views of Black and Hispanic patients regarding clinician trustworthiness and perception of bias, and how this may affect their EOL decisions and rejection of clinical advice.
**Methods:** Aim 1: To assess the presence of implicit bias among ICU clinicians. We hypothesize that there exist among ICU clinicians race implicit biases that may result in differential treatment of Black and Hispanic patients. We will conduct a self-administered survey of 376 ICU doctors and nurses using the Race Implicit Association Test better understand how clinical decisions may be aligned with consciously and unconsciously held beliefs on race and ethnicity of patients. We will evaluate these survey results to examine any association of bias with participant demographics and clinical practice features.
Aim 2: To assess Black and Hispanic patient and family EOL experiences and their perception of trustworthiness of clinicians. We hypothesize that Black and Hispanic patients do not consider their clinicians providing EOL care in the ICU trustworthy and reject clinical advice in EOL decision making. We will survey and interview 50 Black and Hispanic patients and their families. Using a validated, trust survey, modified for an ICU setting, we will (Aim 2.1) evaluate the level of trust present in the healthcare system and the organization, as well as the ICU team and clinicians who helped them reach the goals of care at the EOL. We will look for associations with participant demographics, education, and socio-economic status. We will also (Aim 2.2) conduct in-depth interviews with these participants to understand their experiences and perceptions of racial bias and assess whether these perceptions impact their goals of care decisions.
Aim 3: To develop recommendations. We hypothesize that getting feedback from culturally and experientially aligned individuals can help in reaching a balanced view on the factors causing perception of clinician untrustworthiness and resulting disparities in EOL care decisions. Using clinician and patient feedback from the above aims, we will form an Advisory Committee that will include past patients,

families, physicians, social workers, ethicists and spiritual care leaders, to develop (Aim 3.1) recommendations for gaining greater insight into the diverse views of Black and Hispanic patients who receive EOL care in the ICU, and (Aim 3.2) develop a future patient experience toolkit designed to help clinicians, to achieve racially unbiased, goal concordant care in the ICU.
**Results:** We will use an innovative combination of analytical and interpretive techniques from mixed methods strategies. This research will provide key insights about the views of Black and Hispanic patients and clinicians caring for them regarding EOL care. Better understanding personal characteristics, attitudes, experiences and structural influences will suggest potential future interventional targets. Knowledge generated will be used to educate clinicians on constructive ways to listen and respond to the needs of diverse patients.
**Conclusions:** This proposal spans sociocultural and health care system domains of influence and their intersection with key interpersonal and individual levels of influence.

**Topic:** Ethics and end of life care

**Introduction:** Obtaining a properly fitting non-invasive ventilation (NIV) mask to treat acute respiratory failure is a major challenge, especially in young children and patients with craniofacial abnormalities [1, 2] Personalization of NIV masks holds promise to improve pediatric NIV efficiency [3].
**Objectives:** This study aimed to test the air leak and skin pressure performance of personalized oronasal face masks using 3D-printed soft materials.
**Methods:** Personalized masks of three different biocompatible materials (silicone and photopolymer resin) were developed and tested on three head models of young children with abnormal facial features during bench simulation of pediatric NIV. The setup is shown in Fig. 1. Air leak percentages and facial skin pressures were measured and compared for each mask.
**Results:** Personalized NIV masks could be successfully produced in under 12 h in a semi-automated 3D production process. During NIV simulation, overall air leak performance and applied skin pressures were acceptable, with leak percentages under 30% and average skin pressure values mostly remaining under normal capillary pressure. There was a small advantage of the masks produced with soft photopolymer resin material.
**Conclusions:** This first, proof-of-concept bench study simulating NIV in children with abnormal facial features, showed that it is possible to obtain biocompatible, personalized oronasal masks with acceptable air leak and skin pressure performance using a relatively short, and semi-automated production process. Further research into the clinical value and possibilities for application of personalized NIV masks in critically ill children is needed.

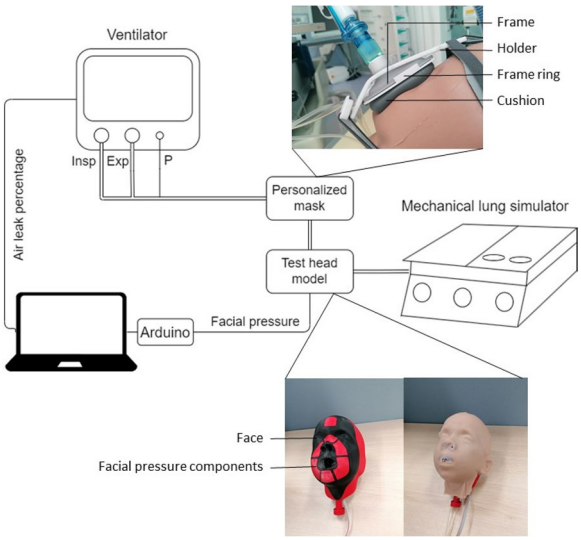

**Fig. 1 (abstract 000049)** A schematic overview of the bench test setup for pediatric non-invasive ventilation simulation with details on the test head model (A) and the personalized mask (B). The personalized mask consist of a frame, frame ring, holder and a personalized cushion. The mask is placed on the accompanying test head model, which contains facial pressure components that follow the outline of the ventilation mask. The pressure sensors underneath the components are connected to the laptop through a microcontroller (Arduino). The test head model has a 3 mm silicon layer to create an airtight connection to the mechanical lung simulator. The mask is connected to the ventilator, which directly provides information on the inspiration (insp) and expiration (exp) volumes, flows and pressures (P) to the laptop for data collection

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000051

**Introduction:** Early rehabilitation in critically ill patients increases physical function whilst reducing delirium and duration of mechanical ventilation (MV) [1, 2]. Variance in cardiorespiratory responses during rehabilitation on intensive care (ICU) exists, highlighting the challenge of targeting optimal intensity of rehabilitation [3]. Safety of rehabilitation interventions has been established [4], however, little evidence exists to support clinicians in determining target rehabilitation intensity to induce physiological adaptations, particularly in patients requiring prolonged MV. We aimed to investigate the safety and cardiorespiratory response to exercise for patients requiring > 7 days of MV.
**Methods:** Prospective, observational data was collected from patients in a large, UK, multi-specialty ICU. Eligible patients required > 7 days MV, clinical suitability to participate in rehabilitation and primary admission was not neurological or traumatic injury. Opportunistic sampling of a singular rehabilitation session for 20 patients was collected over 4-months. Rehabilitation outcomes were recorded using the Manchester Mobility Scale (MMS), with sessions aimed at achieving the highest level of mobility. Physiological data ($SpO_2$, HR, MAP, RR and MV) was collected with standard ICU monitoring pre(baseline), during (2-min intervals) and post rehabilitation (10 min after). Medians and percentage change for physiological variables at each time point were calculated to visualise responses.
**Results:** Exercise response was consistent across all variables, increasing with exercise and returning towards baseline 10 min post, except $SpO_2$ which showed little change (Graph 1–5). This trend was consistent in all forms of exercise, sitting on edge of bed, hoisting out (MMS 2 + 3, $n = 16$), standing practice and step transferring (MMS 4 + 5, $n = 4$). Average percentage change for all variables pre to post rehabilitation was < 10%. RR and MV showed greatest change during exercise (19.2% and 18.32%) (Table 1) compared with other variables, no adverse outcomes were reported during rehabilitation.

| | Spo2 | Heart rate (HR) | Mean arterial Pressure (MAP) | Respiratory Rate (RR) | Minute Ventilation (MV) |
|---|---|---|---|---|---|
| Median % change pre-during ($n = 20$) | 0 (− 1.46–0.13) | 6.39 (0.77–9.58) | 6.25 (0.00–19.62) | **19.20 (10.22–27.63)** | **18.32 (6.87–39.21)** |
| Median % change pre-during (MMS 2–3) ($n = 16$) | − 0.25 (− 1.46–0.13) | 4.81 (0.00–9.25) | 6.25 (− 0.56–19.62) | **17.48 (5.61–27.63)** | **18.32 (8.41–35.92)** |
| Median % change pre-during (MMS 4–5) ($n = 4$) | 0.00 (− 1.50–3.31) | 8.37 (6.88–13.39) | 5.95 (4.00–10.47) | **26.14 (21.63–28.27)** | **25.21 (15.32–35.11)** |
| Median % change Pre-Post ($n = 20$) | 0.00 (− 2.52–1.03) | 2.27 (− 3.34–6.37) | 2.07 (− 5.66–9.02) | 1.72 (− 10.76–24.35) | 9.16 (− 2.99–28.80) |

**Conclusions:** This small prospective audit supports that rehabilitation is safe in critically ill adults who require prolonged MV, with no adverse events reported and all physiological parameters within 10% of baseline 10 min post rehabilitation. Significant changes in MV and RR were observed during rehabilitation, indicating a greater sensitivity in exercise response. Further research investigating whether percentage change in MV and RR could be used to target rehabilitation dosage and intensity to improve outcomes is warranted.

### Ciprofol versus propofol for long-term sedation in mechanically ventilated patients with *sepsis*: a pilot randomized controlled trial

W. J. Gu[1], H. Y. Yin[1]
[1]Department of Intensive Care Unit, Jinan University First Affiliated Hospital, Guangzhou, China
**Correspondence:** H. Y. Yin
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000053

**Introduction:** Sedatives are commonly used to facilitate mechanical ventilation in patients with sepsis. Ciprofol, a novel intravenous anesthetic structurally similar to propofol [1], exhibits superior binding activity to the gamma-aminobutyric acid-A receptor, positioning it as a promising sedative candidate [2]. It has been used for the induction and maintenance of general anesthesia and short-term sedation for critically ill patients [3–5], but the role of ciprofol in long-term sedation for mechanically ventilated patients with sepsis has not been well established. This pilot randomized clinical trial aimed to compare the efficacy and safety of ciprofol and propofol for long-term sedation in mechanically ventilated patients with sepsis.
**Methods:** The trial was prospectively registered at Chinese Clinical Trial Registry (number: ChiCTR2200066835). Mechanically ventilated adults with sepsis who anticipated to require long-term sedation (≥ 24 h) were randomly assigned to receive either intravenous ciprofol

or propofol in a 1:1 ratio. The primary outcomes were the percentage of time within the target sedation range and successful sedation (the percentage of time within the target sedation range ≥ 70% without rescue sedation). Secondary outcomes included weaning time, ICU and in-hospital mortality, length of ICU and hospital stay, hypotension, and bradycardia.

**Results:** Between February 14, 2023 and July 1, 2023, 60 patients were randomized, and 4 of them were excluded because of withdrawing treatment. 28 were assigned to the ciprofol group and 28 to the propofol group. The median age of enrolled patients was 69.0 years and 64.3% were male. The main infection source was pulmonary (73.2%), and most patients (78.6%) had septic shock with receiving at least one type of vasopressor (91.1%). The mean baseline APACHE II and SOFA scores were 29.5 (7.8) and 10.9 (3.7), respectively. Patient characteristics were similar between the two groups. As shown in Fig. 1, ciprofol group had significantly higher percentage of time within the target sedation range (median [IQR], 72.2% [14.3–92.7%] vs 22.6% [0.0–45.4%], $P = 0.004$) and successful sedation rate (53.6% [15/28] vs 14.3% [4/28], $P = 0.005$). No significant differences were observed in weaning time, ICU mortality, in-hospital mortality, length of ICU stay, and length of hospital stay between the two groups. Hypotension occurred in 4 (14.3%) patients of ciprofol group and 6 (21.4%) patients of propofol group. No patient occurred bradycardia.

**Conclusions:** Ciprofol is an effective and safe agent for long-term sedation in mechanically ventilated patients with sepsis.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000054

**Introduction:** The organ donation program in Brazil is one of the largest in the world and is based on donors diagnosed with brain death and obtaining family consent. Nonetheless, there is still a significant demand for donors. Understanding the main challenges affecting the successful organ donation process is important to guide strategies and improve population access to this resource.

**Objectives:** The objective was to analyze brain death notifications from a public tertiary hospital in Brazil to identify the proportion of effective donations and the main reasons why they did not occur.

**Methods:** A cross-sectional retrospective study was conducted to evaluate all notifications of brain death that occurred in a public tertiary hospital in São Paulo, Brazil, in the years 2021 and 2022, to identify outcomes such as effective donation, organs donated, reasons for non-donation, and reasons for family refusal.

Data were collected from the service's Organ Procurement Organization records and electronic medical record review.

**Results:** In both years, there were 194 notifications of brain death: 103 in 2021 and 91 in 2022. All patients were evaluated as potential organ donors in accordance with Brazil's legislation. The main reason for not proceeding with donation was clinical contraindication (30.4%). In 10 patients (5.1%), cardiac arrest occurred before completing the brain death protocol. Family refusal occurred in 44 cases (22.6%), with the primary reason for non-consent being the time required for the donation process (39%). Lack of knowledge about the patient's desire to be a donor or previous indications of not being a donor were other reasons mentioned by family members or legal representatives for rejecting the process.

Only 77 patients (39.6%) were effective donors. The most frequently transplanted solid organs were kidneys (53 donors), followed by liver (27 donors), pancreas (12 donors), and heart (8 donors). In 7 potential donors, organs were refused by transplant teams after evaluation (Fig. 1).

**Conclusions:** To increase the number of transplants in Brazil, there are several opportunities for action. Firstly, improving clinical care in intensive care units (which is heterogeneous in our country) can lead to a reduction in the number of medical contraindications to transplants, mostly due to infectious conditions. Furthermore, optimizing the brain death diagnosis process is imperative; greater availability of human and technical resources can shorten the time for completing the brain death diagnosis protocol, reducing the number of family refusals and increasing the quality of organs offered for donation.

Additionally, public and social education policies on the topic can also contribute to increasing the number of donations and reducing transplant waiting lists.

## Effect of Hyperbaric Oxygen Therapy on *Sepsis* Induced Neuroinflammation in a Rat Cecal Slurry Model

H. Kim[1], Y. Heewon[1], M. Young-Gi[1], H. Jung[1]
[1]Emergency Medicine, Ajou University Hospital, Suwon-si, Republic of Korea
**Correspondence:** H. Kim
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000055

**Introduction:** Sepsis-associated encephalopathy (SAE), resulted from severe disturbance in the central nervous system caused by a systemic inflammatory response to sepsis, is a one of frequent and serious complications of sepsis. SAE is a major risk factor which deteriorating the prognosis of sepsis in aspect of mortality and length of hospital stay and survived SAE patients are likely to have prolonged or permanent neuro-psychological sequelae. Two vital mechanisms in the pathogenesis of SAE have been considered as follows: (1) neuro-inflammation mainly executed by microglia, (2) cerebral ischemia/hypo-perfusion caused by cerebral microcirculatory abnormalities. Although the effects of hyperbaric oxygen therapy (HBOT) in sepsis remain unclear, this study aimed to investigate effects of HBOT on neuroinflammation in a rat peritonitis model.
**Methods:** Cecal slurry peritonitis was induced in male rats, which were then randomly allocated into the HBOT and control groups. In HBOT group, two times of 90 min HBOT sessions (2.6 atmospheres absolute 100% oxygen) were performed with an interval of 24 h immediately after cecal slurry modeling. Brains of two group are harvested for mRNA isolation and RT-PCR analysis for gene expression of 4 cytokines, which are TNF-α, IL-1β, IL-6, IL-10, after two session of HBOT.
**Results:** We analysis of gene expression of three pro-inflammatory cytokines, which are TNF-α, IL-1β, IL-6, and one anti-inflammatory cytokine, which is IL-10, from the brain tissue. HBOT decreased the expression level of gene of pro-inflammatory cytokines (TNF-α, IL-1β, IL-6) significantly in peritonitis induced rats. However, the expression level of anti-inflammatory cytokine (IL-10) was not affected significantly after HBOT.
**Conclusions:** HBOT could be a promising therapeutic candidate for SAE considering the favorable effects of HBOT, which is the modulation in neuroinflammation. And treatment of SAE using HBOT may lead to increase of the survival rate and reduction of the cognitive and psychological sequelae in sepsis patients.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000058

**Introduction:** Spontaneous breathing trial (SBT) is the recommended method to determine the readiness to wean in patients who received mechanical ventilation for at least 24 h. Low pressure augmentation using pressure support (PS) ventilation is preferred as the initital SBT method rather than T-tube or continous positive airway pressure. High-flow oxygen therapy (HFT) via nasal cannual is recommended to use in several conditions. Current HFT system can be applied with tracheostomy or endotracheal tube via a specific connector and it may be an alternativeg method for SBT. However, the data regarding HFT during SBT is scant. We hypothesized that HFT will not be inferior to low PS during SBT.
**Objectives:** To compare the rate of SBT success, extubation within 48 h of SBT success, reintubation within 48 h after extubation, and hospital mortality between HFT and low PS.
**Methods:** Two centers, open-label, non-inferiority, randomized controlled trial was conducted by blocks of four randomization (Thai Clinical Trial Registration—TCTR20190703002). Adult mechanically ventilated patients > 24 h who were ready to wean were randomly assigned to HFT (Airvo-2, Fisher & Paykel) with a flow rate of 50 L/min, temperature of 37 °C, and inspired oxygen fraction ($FiO_2$) of 0.4 or low PS (PS 8 $cmH_2O$ without positive end-expiratory pressure and $FiO_2$ 0.4) for 30 min. Patients with unstable hemodynamics, significant abnormal acid–base, pregnant woman, or tracheostomized patients were excluded. The primary outcome was the rate of SBT success. The secondary outcomes included the rate of extubation within 48 h after SBT success, reintubation rate within 48 h after extubation, and hospital mortality between the two groups.
**Results:** 162 patients were enrolled (81 patients in HFT group and 81 patients in low PS group). Median age [interquartile range] was 70 [61–81] years and 56.2% of them were male. APACHE II and SOFA scores at enrollment were 12 [9–15] and 4 [2–6], respectively. No significant differences in baseline characteristics between the two groups were found except more patients with COPD in HFT group than low PS group (12.3% *vs.* 3.7%, respectively; $P = 0.04$). Pneumonia was the most common diagnosis on admission (45.7%) and acute hypoxemic respiratory failure was the most common indication of mechanical ventilation (65.4%). The rate of SBT success was 77 patients (95.1%) in HFT group and 77 patients (95.1%) in low PS group (OR = 1.00; 95% confidence interval [CI], 0.24–4.14; $P = 1.000$). Extubation within 48 h after SBT success was performed in 68 patients (84.0%) in HFT group and 62 patients (76.5%) in low PS group (OR = 1.60; 95% CI, 0.73–3.51; $P = 0.324$). Reintubation within 48 h after extubation was performed in 6 patients (9.0%) in HFT group and 11 (17.7%) in low PS group (OR = 0.46; 95% CI, 0.16–1.32); $P = 0.193$). Hospital mortality was significantly lower in HFT group compared to low PS group (11.1% *vs.* 24.7%; OR = 0.38; 95% CI, 0.16–0.90; $P = 0.039$). No significant differences in physiologic variables at end of SBT was observed between the two groups.
**Conclusions:** Among patients who were ready to wean, SBT performed with HFT was not inferior to low PS. No different in the rate of extubation within 48 h and reintubation within 48 h after extubation between the two Methods: However, mechanically ventilated patients who received SBT with HFT had significant lower hospital mortality compared to low PS.

**Correspondence:** A. Suphathamwit
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000059

**Introduction:** Urosepsis is a life-threatening condition resulting from urogenital tract infections (1) and causes high mortality ranged from 20 to 40% (2). Patients undergoing surgical procedure for urinary tract calculi removal are at an increased risk for urosepsis (2). However, a reliable predictive scoring system to assess urosepsis risk in this population is lacking.
**Objectives:** This study aimed to assess the diagnostic accuracy of various clinical scoring systems including Systemic Inflammatory Response Syndrome (SIRS), Quick Sequential Organ Failure

Assessment (qSOFA), and Modified Early Warning Score (MEWS) as well as a newly developed scoring model for predicting urosepsis development in patients undergoing procedure for urinary tract calculi removal.
**Methods:** This retrospective study was conducted at a tertiary-care university hospital between January 2019 and December 2021. Individuals aged 18 years or older who underwent urinary tractstone removal procedure were enrolled. Development of post-procedural urosepsis within 7 consecutive days was followed. Urosepsis was defined as an urinary tract infection with a SIRS score of $\geq 2$. Multivariate logistic regression analysis was employed to identify variables associated with urosepsis development and was subsequently used to developed a new predicative model. SIRS, qSOFA, MEWS and the new predictive model were evaluated for diagnostic accuracy using area under the receiver-operating characteristic curve (AUROC).
**Results:** Preliminary analysis included 406 patients, 36 (8.9%) of them developed urosepsis.
Independent risk factors for post-procedure urosepsis included positive leukocyte urinalysis, bacterial growth from urine culture, the presence of struvite or infection stone, and moderate to severe hydronephrosis. The AUROC for diagnosis of urosepsis of SIRS $\geq 3$, qSOFA $\geq 1$, MEWS $\geq 3$ and the new predictive model $\geq 4$ were 0.79 (95% CI 0.69–0.90), 0.77 (95% CI 0.66–0.87), 0.96 (95% CI 0.90–1.00), and 0.84 (95% CI 0.77–0.90), respectively.
**Conclusions:** Although, the newly developed predictive model showed good diagnostic accuracy, it had lower discriminating power compared to MEWS. Giving that the two scoring models retrieve different clinical variables, combining these two may yield higher diagnostic accuracy. Subsequently, it should help identifying patients at risk for urosepsis and perioperative management can be promptly provided to improve outcomes in patients undergoing procedure for urinary tract calculi removal.

## Peripheral Venous Oxygen Saturation as a Predictor of Early In-hospital Mortality in Emergency Department

J. Kang[1], S. Lee[1], H. Shin[2], D. Lim[3]
[1]Emergency Medicine, Jeju National University Hospital, Cheju, Republic of Korea; [2]Emergency Medicine, Gyeongsang National University Hospital, Jinju, Republic of Korea; [3]Emergency Medicine, Seoul Medical Center, Jungnang-gu, Republic of Korea

*Intensive Care Medicine Experimental* 2024, **12(suppl 1):** 000069

**Introduction:** Multiple physiological and biological parameters to evaluate the status of shock have been developed. Peripheral venous blood gas analysis is less invasive than gas analysis using arterial blood or central venous blood, but it is not commonly used as a reliable indicator of shock.
**Objectives:** We aim to investigate the correlation between initial peripheral venous blood $O_2$ saturation in emergency department and 24-h in-hospital mortality to evaluate its prognostic utility.
**Methods:** This was a retrospective observational study conducted in an academic teaching hospital with about 30,000 emergency department patients visits annually. Adult patients aged 18 years or older who visited the emergency department and underwent blood gas analysis from January 2015 to December 2019 was enrolled. Univariate and multivariate logistic regression analyses were performed to investigate the correlation with 24-h in-hospital mortality and the demographic, physiological, and biochemical variables performed for the demographic, physiological, and biochemical variables. Youden Index was used to select a cut-off $SpvO_2$ value.
**Results:** Out of a total of 69,827 patients, 20,967 were finally enrolled in this study, and 119 (0.58%) died in hospital within 24 h. Peripheral venous oxygen saturation, age, albumin, c-reactive protein, hemoglobin, bicarbonate, National Early Warning Score, and troponin I were significant independent variables in multivariate logistic regression analysis for 24-h in-hospital mortality (Table 1). For peripheral venous oxygen saturation, the odds ratio was 0.9735 ($p < 0.001$; 95% CI, 0.9622–0.9849). According to the Youden index, the peripheral venous oxygen saturation cutoff was 20.8%, which had a sensitivity of 31.9% and specificity of 91.9%. This negative correlation was unaffected by severity (low [$\leq 4$] or high [$> 4$] NEWS score) or early oxygen supplementation in emergency department.

**Table 1 (abstract 000069)** Results of multivariate logistic regression of 24 h mortality

| Variable | Odd ratio | 95% CI | *p*-value | VIF |
|---|---|---|---|---|
| Age | 1.0429 | 1.0253 to 1.0609 | < 0.0001 | 1.164 |
| Albumin | 0.3426 | 0.2387 to 0.4917 | < 0.0001 | 2.037 |
| Creatinine | 0.9896 | 0.8506 to 1.1514 | 0.8925 | 1.194 |
| CRP | 0.9969 | 0.9935 to 1.0003 | 0.0746 | 1.215 |
| Glucose | 1.0008 | 0.9991 to 1.0025 | 0.3645 | 1.067 |
| Hb | 1.2801 | 1.1584 to 1.4145 | < 0.0001 | 1.849 |
| Bicarbonate | 0.8374 | 0.8023 to 0.8740 | < 0.0001 | 1.412 |
| SpvO2 | 0.9735 | 0.9622 to 0.9849 | < 0.0001 | 1.177 |
| Potassium | 1.0467 | 0.8210 to 1.3343 | 0.7129 | 1.204 |
| NEWS | 1.3579 | 1.2671 to 1.4552 | < 0.0001 | 1.196 |
| INR | 1.1557 | 0.9344 to 1.4294 | 0.1822 | 1.143 |
| Total bilirubin | 1.0407 | 0.9825 to 1.1023 | 0.1739 | 1.111 |
| troponin I | 1.1525 | 1.0698 to 1.2416 | 0.0002 | 1.011 |

Abbreviations: VIF, Variance inflation factor, CRP, C-reactive protein, Hb, Hemoglobin, $SpvO_2$, Peripheral venous oxygen saturation, NEWS, National Early Warning Score

**Conclusions:** Initial peripheral venous oxygen saturation in emergency department was negatively correlated with 24-h in-hospital mortality and showed high specificity with cut-off value of 20.8%. In conjunction with other parameters with high sensitivity for initial mortality, such as lactate or NEWS, it can be implemented as a useful triage tool in the emergency department.

### Ten-Year Single-Centre Experience in Managing Traumatic Subclavian and Axillary Artery Injuries

S. H. Kim[1], N. H. Lee[1]
[1]Department of Trauma and Surgical Critical Care, Pusan National University Hospital, Busan, Republic of Korea
**Correspondence:** N.H. Lee
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000070

**Introduction:** Trauma-induced injuries to the subclavian and axillary arteries are rare. Treatment options include open repair and endovascular interventions, and selecting the appropriate modality requires careful consideration. We aimed to evaluate the management of traumatic subclavian and axillary artery injuries in a single trauma center and thereby suggest protocols for appropriate therapeutic approaches.
**Methods:** This single-center retrospective study analyzed the medical records of 12 patients who sustained injuries to the subclavian and axillary arteries between January 2013 and January 2023. Injury grading was categorized as follows: grade A, minimal injury (intima only); grade B, vessel laceration < 25%; grade C, laceration 25–50%; grade D, laceration > 50%; grade E, pseudoaneurysm; grade F, vessel transection; and grade G, occlusion. Patient outcomes, including in-hospital mortality, limb salvage and length of stay (LOS) in the hospital and intensive care unit (ICU), were identified.
**Results:** The mean age of the patients was 52.5 ± 16.4 years, and 67% were males. The mean Injury Severity Score (ISS) was 22 ± 4. In-hospital mortality was 17% (n = 2). Among the patients who underwent open repair, one required additional surgery for revascularization, but none of the patients required amputation. The median LOS in the hospital was 48 days (interquartile range [IQR], 22–71 days), and the ICU LOS was 4 days (IQR, 2–22 days). When categorized into the open repair, endovascular repair, and observation groups, a significant difference was observed in injury grade but not in the ISS, LOS, or ICU LOS.
**Conclusions:** In our center, open repair was more prevalent for higher injury grades. In addition, pseudoaneurysm can be effectively treated through endovascular technique.
In the absence of evidence of limb ischemia, non-operative treatment can be applied in low-grade injuries with arterial laceration less than 50%. Even high-grade arterial injuries can achieve high limb salvage rates with appropriate use of various treatment modalities.

**Table (abstract 000070)** Clinical characteristics and management outcomes of traumatic subclavian and axillary artery injuries

| | Overall (n=12) | Open repair (n=7) | Endovascular repair (n=3) | Observation (n=2) | P-value |
|---|---|---|---|---|---|
| Mean age, y | 52.5±16.4 | 46.6±18.0 | 65.7±10.8 | 53.5±3.5 | 0.258 |
| Sex, n (%) | | | | | 0.852 |

### A Temporal Deep Learning Algorithm for Predicting Extubation Failures in Critical Care Patients

J. Shen[1], Z. Huiying[1], T. Buzhou[2], A. Youzhong[1]
[1]Department of Critical Care Medicine, Peking University People's Hospital, Beijing, China; [2]Department of Computer Science, Harbin Institute of Technology, Shen Zhen Shi, China
**Correspondence:** J. Shen
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000071

**Introduction:** Failure of extubation was related to poor outcomes in critical care patients. Building predictive models will facilitate risk evaluation before extubation. However, the majority of current models were derived from static clinical data [1, 2], which did not incorporate the temporal nature of patients' status. For limited studies that used temporal data, the data was sampled with a low density of time resolution [3, 4]. Therefore, a comprehensive and dynamic algorithm that combines both the static character and temporal status with an intensive time resolution of IMV-supported patients is necessary for developing a prediction model that is more reflective of clinical reality.
**Objectives:** To build and validate a deep learning-based prediction model of extubation failure in critical care patients supported by IMV.

**Methods:** Data from MIMIC-III (Medical Information Mart for Intensive Care-III) was used for training the TrAcE (**T**emporal Deep Lea**r**ning **A**lgorithm for Predi**c**ting **E**xtubation Failures) model. This study included patients between 18 to 89 years old, received IMV for more than 6 h and did not using tracheostomy or non-invasive ventilation within 1 h after extubation. We applied a novel deep learning algorithm that processed both static and temporal data to reflect the dynamic nature of IMV-supported patients (Fig. 1). The temporal features were collected with an intensive resolution of 1 h. The model was internally validated in a 20% hold-out dataset from the training data and externally validated in the PKUPH (Peking University People's Hospital) dataset. The performance of the model was evaluated with area under the receiver operating characteristic curve (AUROC) in comparison to other machine learning and time series deep learning models. We used the Captum [5] algorithm to interpret the TrAcE model and describe the dynamic feature contributions to the prediction result.
**Results:** A total of 30,438 valid extubation records were obtained from MIMIC-III database, of which 11,668 (38.33%) were extubation failures. The TrAcE model had better performance than other classic models (Fig. 2) in both the hold-out validation dataset (AUROC 0.823 [0.808–0.837]) and PKUPH dataset (with 5174 extubation failures in 14,232 valid IMV patients [36.35%], AUROC 0.859 [0.837–0.881]). Captum interpretation of the model revealed that the contribution to the results of extubations varied between different time points for AaDO2, Temperature, Ventilation time, Sodium and Glucose levels (Fig. 3).
**Conclusions:** We developed and validated a deep learning model (TrAcE) which combines both the static and temporal data of critical care patients to predict the risk of extubation failure. The model improved prediction performance with a time resolution of 1 h and provided a dynamic interpretation of features in the model, which made real time decision making in extubation viable.

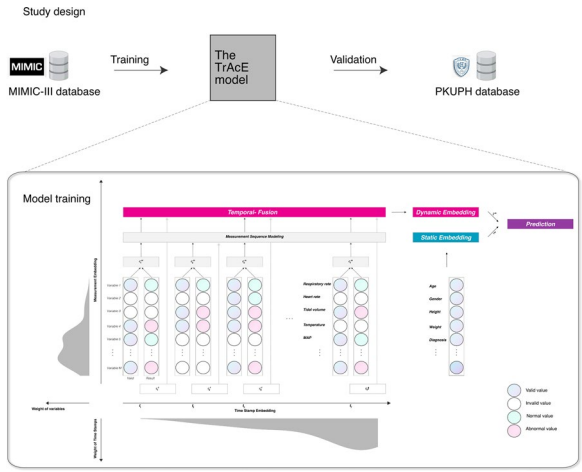

**Fig. 1 (abstract 000071)** The study design and model training process. As illustrated in the figure, the TrAcE model was trained with data from MIMIC-III dataset and externally validated with data from Peking University People's Hospital (PKUPH). The model collected both static and temporal data to better reflect the dynamic nature of IMV-supported patients. Abbreviation: MAP, Mean Arterial Pressure. MIMIC: Medical Information Mart for Intensive Care

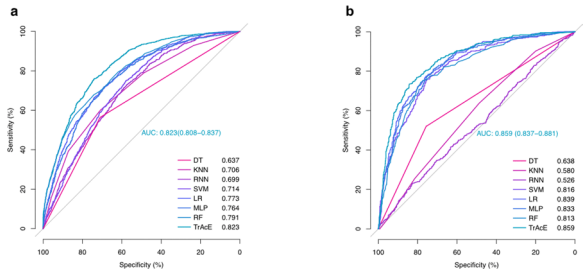

**Fig. 2 (abstract 000071)** Performance of TrAcE model in the internal (a) and external (b) validation dataset. Abbreviation: AUC, Area Under the Curve. DT, Decision Tree. KNN, K-Nearest Neighbors. LR, Logistic Regression. MLP, Multiplayer Perception. RNN, Recurrent Neural Network. SVM, Support Vector Machine

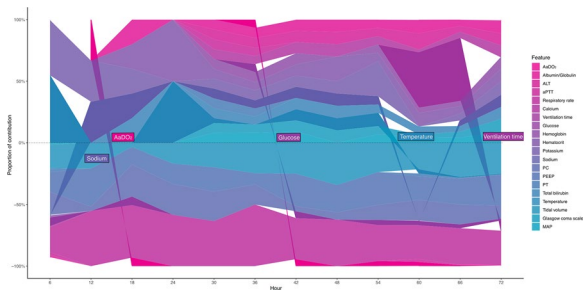

**Fig. 3 (abstract 000071)** Proportion of contributions of the top 20 features at different time point. Both positive and negative proportion of contributions were illustrated. Noted that AaDO2, Temperature, Ventilation time, Sodium and Glucose levels had both positive and negative contributions at different time. Abbreviation: AaDO2. Alveolar-arterial Oxygen Gradient. ***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000072

**Introduction:** High concentrations of oxygen can cause pulmonary complications, including direct pulmonary toxicity and absorptive atelectasis. However, there are insufficient research on how it affects clinical outcomes in elderly patients, such as hypoxia due to atelectasis, decreased lung function, pneumonia, and intensive care unit admission. Therefore, this trial aims to compare whether different oxygen concentrations administered during general anesthesia in elderly patients affect the postoperative respiratory outcomes.
**Methods:** 79 patients age 65–90 yr scheduled for general anesthesia due to lower extremity surgery were randomly assigned to group H and group L. Group L was administered with 40% fraction of inspired oxygen. Whereas, group H sustained $FiO_2$ 100% during induction and extubation, and kept $FiO_2$ 50%. Chest sonogram was done before anesthesia and at PACU in both groups. Arterial blood gas exam was conducted at the beginning of surgery, PACU and the next day. Continuous variables were analyzed with student's t-test and Mann–Whitney *U*-test. Sonographic data was examined with repeated measures analysis of variance (ANOVA) and t-test.
**Results:** There is no statistical significantly difference between the two groups in demographic data, surgical management nor anesthetic medication. The ratio of arterial oxygen partial pressure to fractional inspired oxygen (P/F ratio) was higher in group L (*p*-value 0.036). Also, patients in group L received less oxygen supplementation at the following day of operation. 80.5% of group L and 57.9% of group H did not require oxygen supply. Pre-operative chest sonographic score were 4.5 ± 4.1 in group L and 3.7 ± 4.1 in group H and post-operative score were 4.7 ± 3.9 in group L and 6.8 ± 5.6 in group H. The difference of sonographic score was less in group L.
**Conclusions:** Maintaining high oxygen concentration during anesthesia cause more atelectasis and oxygen demand than low oxygen concentration.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000081

**Introduction:** Suspicion of viable bacteria in the bloodstream in Emergency Department (ED) patients leads to important diagnostic and therapeutic clinical decisions. Blood culture collection is commonly accompanied by antibiotic administration and an admission decision pending the laboratory result, which may take up to 3 days. Monocyte Distribution Width (MDW) is a pathogen-agnostic marker of immune response and dysregulation, reported as part of a Complete Blood Count (CBC) with differential. MDW is derived from the distribution of peripheral blood monocyte volumes and aids in the identification of severe infections and sepsis in adult Emergency Department (ED) patients.

**Objectives:** To date, most MDW studies focus on the general ED population in a single region. The purpose of this analysis is to explore the relationship between MDW values and blood culture results in a multinational cohort of suspected infection patients.

**Methods:** Two data sources were included in the analysis: raw data from a multicenter, blinded, prospective cohort study conducted by Hausfater et al. [1] in two European EDs (Pitié-Salpêtrière APHP-Sorbonne Université hospital in Paris, France, and the Hospital Universitari Germans Trias i Pujol in Badalona, Spain) and interim data from a single-site observational study in the United States (Henry Ford Hospital, Detroit, Michigan, United States). All patients included in the analysis were aged 18 and older, presented to the ED, and received orders for both a CBC with differential and blood cultures. We evaluated MDW performance for the European and US studies independently and combined.

**Results:** There were 34 positive and 221 negative blood cultures across the European sites and 1408 positive and 6444 negative blood cultures in the US site. The incidence was 11.4 and 17.9, respectively. Performance for MDW relative to blood culture status in ED patients is shown in Table 1.

**Table 1 (abstract 000081)** Performance of MDW relative to blood culture status in ED patients

| | Hausfater et al. [1] | Henry Ford Hospital | Combined |
|---|---|---|---|
| MDW < 20 Blood Culture Negative | 33 | 2334 | 2367 |
| MDW < 20 Blood Culture Positive | 1 | 244 | 245 |
| MDW ≥ 20 Blood Culture Negative | 193 | 4110 | 4303 |
| MDW ≥ 20 Blood Culture Negative | 28 | 1164 | 1192 |
| Bacteremia Incidence | 0.114 | 0.179 | 0.177 |
| Sensitivity | 0.966 | 0.827 | 0.830 |
| Specificity | 0.146 | 0.362 | 0.355 |
| Positive Predictive Value | 0.127 | 0.221 | 0.217 |
| Negative Predictive Value | 0.971 | 0.905 | 0.906 |

**Conclusions:** This interim analysis suggests that MDW may be a useful adjunct to aid in bacteremia assessments in ED patients. The observed sensitivity related to MDW is consistent with the known relationship between positive blood culture and sepsis and is generalizable between different populations. Since MDW results are likely available well before blood culture results, this biomarker could support risk stratification among suspected infection patients. MDW values below 20 have a high predicative value for negative blood cultures. Further analysis incorporating additional clinical information will provide guidance for interpreting MDW values in combination blood culture results.

**Introduction:** Evaluating the prognosis of patients with COVID-19 who may be at risk of mortality by analysing inflammatory mediators provides valuable insights for treatment decisions.
**Objectives:** This study aimed to investigate the serum IL-6 levels and their rate of change in predicting the mortality of critically ill patients with COVID-19 in Vietnam.
**Methods:** We performed a retrospective observational study of critically ill COVID-19 adult patients presenting at an intensive care centre in Vietnam from July 30 to October 15, 2021. We calculated the areas under the ROC curve (AUROCs) to determine how well the admission serum IL-6 levels and their rate of change on 3rd-day of admission could predict hospital mortality. The rate of change in serum IL-6 on the 3rd day after admission = 100% × ((serum IL-6 on the 3rd day) − (admission serum IL-6))/(admission serum IL-6). We also utilized ROC curve analysis to find the best cut-off value for each level or rate. Finally, we utilized logistic regression to identify factors associated with hospital mortality.
**Results:** Of 90 patients, 41.1% were men, the median age was 60.5 years (Q1-Q3: 52.0–71.0), and 76.7% of patients died in the hospital. Elevated serum IL-6 levels were observed upon admission (99.76 pg/mL; SD: 174.33) and on the 3rd day after admission (258.64 pg/mL; SD: 452.15), along with a significant rate of change in serum IL-6 during that period (839.5%; SD: 2753.2). While admission serum IL-6 level (AUROC: 0.610 [95% CI: 0.459–0.761]; cut-off value ≥ 15.8 pg/mL) and rate of change in serum IL-6 on the 3rd day of admission (AUROC: 0.586 [95% CI: 0.420–0.751]; cut-off value ≥ − 58.7%) demonstrated poor discriminatory ability in predicting hospital mortality, the 3rd day serum IL-6 rate of change from admission ≥ -58.7% (adjusted OR: 12.812; 95% CI: 2.104–78.005) emerged as an independent predictor of hospital mortality.
**Conclusions:** This study focused on a highly selected cohort of critically ill COVID-19 patients with a high serum IL-6 level and mortality rate. Despite the poor discriminatory value of admission serum IL-6 levels, the rate of change in serum IL-6 proved valuable in predicting mortality. To identify critically ill COVID-19 patients with the highest risk for mortality, monitoring the serial serum IL-6 measurements and observing the rate of change in serum IL-6 levels over time are needed.

### Plasma Calprotectin as a Marker of Infection in the Emergency Department—a prospective observational study

T. Zimmermann[1], T. A. C. Snow[1], N. Arulkumaran[2], A. Al-Hindawi[3], M. Singer[4], D. Brealey[5]
[1]Bloomsbury Institute of Intensive Care Medicine, University College London, London, United Kingdom; [2]Intensive Care Department, University College London Hospital, London, United Kingdom; [3]Intensive Care Unit, Chelsea and Westminster Hospital, London, United Kingdom; [4]University College London, Bloomsbury Institute of Intensive Care Medicine, London, United Kingdom; [5]Critical Care, UCL Hospitals NHS Foundation Trust, London, United Kingdom
**Correspondence:** T. Zimmermann
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000084

**Introduction:** Reliably discriminating infection and sepsis from sterile inflammation is a recognised clinical challenge. Particularly in patients with cancer, after surgery or trauma, in whom a strong inflammatory reaction is often present, high levels of uncertainty promote prescription of unnecessary courses of antibiotics and increase the risk of antimicrobial resistance and adverse drug effects. Plasma levels of calprotectin, a novel infection biomarker with direct release from the cytoplasm of activated immune cells, could aid physicians in their decision making.
**Objectives:** To assess the diagnostic performance of calprotectin in an adjudicated diagnosis of infection and comparison to an established biomarker, C-reactive protein (CRP).
**Methods:** Prospective observational single-centre study recruiting patients with suspected infection in the emergency department. Diagnostic adjudication (no infection, low probability of infection, high probability of infection, confirmed infection) was performed by experienced physicians after reviewing patient files but blinded to calprotectin and other biomarker measurements. For regression modelling, non-linear associations between biomarkers and the outcome were modelled with restricted cubic splines.
**Results:** 245 patients, median age 55 years (IQR 32–70), 48% female, were recruited and eligible for analysis. Of these, 71 (29%) suffered from active cancer and 56 (23%) were receiving immunosuppressant therapies. 190 (78%) were started on antibiotics while only 15 (6%) blood cultures were eventually positive. The median calprotectin concentration in the overall cohort was 2.5 (IQR 1.6–4.7) mg/l. Ordinal regression analysis revealed a non-linear and mostly non-significant association of calprotectin with an adjudicated diagnosis of infection, while CRP showed a near-linear, significant association (Fig. 1). A sensitivity analysis excluding patients with cancer or immunosuppression showed similar Results: Comparing calprotectin levels across different sites of infection showed no significant differences (all $p > 0.05$). 181 (74%) patients had an adjudicated diagnosis of high probability of infection or confirmed infection. For a binary outcome (no infection and low probability of infection vs high probability of infection and confirmed infection), the area under the receiver operating characteristic curve was 0.57 (95%-CI 0.50–0.65) for calprotectin and 0.70 (95%-CI 0.63–0.76) for CRP.
**Conclusions:** In this study, calprotectin showed limited performance in identifying patients with an adjudicated diagnosis of infection. Calprotectin did not perform better than the established biomarker, CRP. Importantly, results were similar in the main cohort and excluding patients with cancer or immunosuppression.

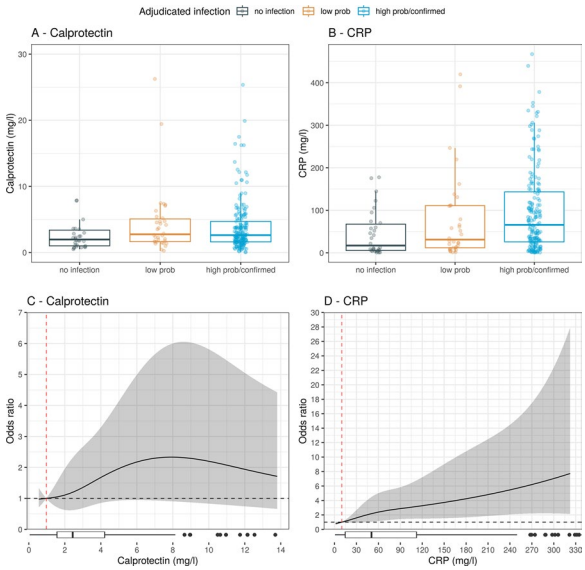

**Fig. (abstract 000084)** Boxplots showing levels of calprotectin (A) and CRP (B) across the different categories of the adjudicated diagnosis. Dose–response plots visualise flexible associations between calprotectin (C) and CRP (D) as predictors and an adjudicated diagnosis of infection as outcome in ordinal regression models. ***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000086

**Introduction:** Sepsis and septic shock represent major challenges in terms of patient mortality. Despite numerous studies involving various drugs and interventions, effective results have not been demonstrated. Recently, the role of thiamine in critically ill patients has gained attention. In this study, we aimed to assess the impact of supplemental thiamine on clinical outcomes in patients with septic shock.
**Methods:** This retrospective before-after study included patients with: (1) an age ≥ 18 years with documented or suspected infection; (2) Sequential Organ Failure Assessment score ≥ 2; (3) serum lactate levels > 18 mg/dL and hypotension, 4) mean arterial pressure < 65 mmHg maintained after volume expansion of ≥ 30 ml/kg in the first two h of treatment followed by noradrenaline vasopressor dependence (with or without vasopressin) during the first six h of treatment; (5) intensive care unit (ICU) admission during two periods: May 1 to September 30, 2022 (control group) and November 1, 2022, to March 31, 2023 (intervention group). Only the intervention group received supplemental thiamine (200 mg in 50 ml 5% dextrose twice daily) for seven days or until ICU discharge. The primary outcome was lactate clearance. The secondary outcomes were 28-day mortality, ventilation-free and vasopressor-free days within 28 days, and incidence of renal replacement therapy (RRT) within 2 d of septic shock diagnosis.
**Results:** Sixty-two patients were included: 29 in the control group and 33 in the intervention group. There was no significant statistical difference in lactate clearance (control group 13 [44.8%] vs. 16 [48.4%] in the intervention group [$p = 0.80$]). There was no difference in secondary outcomes Nine patients (27.2%) in the intervention group were administered RRT compared to three (10.3%) in the control group ($p = 0.09$). However, after adjusting for independent covariates, multivariate analysis showed that age ($p = 0.017$), lactate clearance ($p = 0.044$), and vasopressor-free days ($p = 0.043$) were associated with a lower 28-day mortality.
**Conclusions:** In this retrospective before-after study involving patients with septic shock, intravenous thiamine did not improve lactate clearance and other important outcomes. However, in the multivariate analysis, after adjusting for independent covariates, younger age, a higher number of vasopressor-free days, and better lactate clearance was associated with a lower 28-day mortality rate.

### Discovery and validation of PCED1B as a novel biomarker for naive CD4 + T cell in *sepsis*

W. shang[1], J. Liu[2], D. Chen[2]
[1]Department of Critical Care Medicine, Ruijin Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, China; [2]Department of Critical Care Medicine, Shanghai Jiaotong University, School of Medicine, Ruijin Hospital North, Shanghai, China

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000087

**Introduction:** Immune dysfunction significantly contributes to morbidity and mortality in sepsis, making the modulation of host immune responses a critical focus in clinical management. This study was undertaken to identify specific biomarkers on naive CD4 + T cells that could serve as indicators of sepsis pathogenesis and potentially inform targeted immunomodulatory interventions.
**Methods:** Publicly available single-cell RNA sequencing (scRNA-seq) and bulk RNA-seq datasets were analyzed for screening out naive CD4 + T cell-specific genes. Based on these hub genes, Mendelian randomization (MR) analysis followed by MR-Bayesian model averaging (MR-BMA) algorithm was implemented to explore the causal relationship between them and sepsis. Besides, single cell-type expression analysis, quantitative real-time PCR (qRT-PCR), cell–cell communication detection, and metabonomics evaluation were further conducted to unveil the underlying mechanism of potential therapeutic targets.
**Results:** scRNA-seq illustrated the significant exhaustion of naive CD4 + T cells in sepsis, and 33 hub genes were then identified. Both MR and MR-BMA analyses validated the elevated naive CD4 + T cell %CD4 + T cells were related to sepsis occurrence(odds ratio [OR] = 0.90, 95% confidence interval [CI], 0.83–0.97, $P = 0.0069$) and sepsis 28-day mortality(OR = 0.75, 95% CI, 0.64–0.88, $P = 0.0003$). Notably, among 33 hub genes, PCED1B was considered to have a strong causal association with 28-day mortality in sepsis patients (OR = 0.64, 95%CI, 0.51–0.81, $P = 0.0002$) which has been further validated by bulk RNA-seq analysis. Additionally, animal experiment showed a correlation between the level of PCED1B and the sepsis severity. Notably, PCED1B mediated the impact of naive CD4 + T cell %CD4 + T cell on sepsis-related death. Mechanistic

investigations revealed that PCED1B + CD4 + T cells may interact with monocytes/dendritic cells (DCs) via the MIF-(CD74 + CD44) axis, and concurrently engage with B cells/plasmablasts through the MIF-(CD74 + CXCR4) axis, thereby regulating multiple metabolic alterations in sepsis.
**Conclusions:** The interplay of PCED1B and naive CD4 + T cells revealed by this study will be helpful in sepsis therapy targeting immunity.

### Intermittent versus Continuous Renal Replacement Therapy for Sepsis-Associated Acute Kidney Injury: An Analysis Using Japanese ICU Database

H. Okano[1], H. Okamoto[1], R. Sakurai[2], T. Yamazaki[2]
[1]Department of Critical Care Medicine, St. Luke's International Hospital, Chuo City, Japan; [2]Department of Social Medical Sciences, Graduate School of Medicine, International University of Health and Welfare,, Minato City, Japan
**Correspondence:** H. Okano
*Intensive Care Medicine Experimental* 2024, **12(suppl 1):** 000088

**Introduction:** Sepsis-associated acute kidney injury (S-AKI), a common and severe complication in critically ill patients, is associated with increased mortality. Continuous renal replacement therapy (CRRT) and intermittent renal replacement therapy (IRRT) are two main modalities for the management of S-AKI. However, the optimal choice of RRT modality in S-AKI remains uncertain, with limited evidence to guide clinical decision-making.
**Methods:** We conducted a retrospective cohort study using data from the Japanese Intensive care PAtient Database (JIPAD), a multicenter, prospective registry of critically ill patients admitted to intensive care units (ICUs) in Japan. Adult patients (aged ≥ 18 years) with sepsis or septic shock who received RRT during their ICU stay were included. Patients on maintenance dialysis, post-cardiac arrest, or readmitted to the ICU were excluded. The primary outcome was in-hospital mortality. We compared patients who received CRRT only with those who received IRRT only. To account for potential confounding by indication, we performed 1:1 propensity score matching. We also conducted a pre-specified subgroup analysis based on the severity of sepsis (sepsis or septic shock).
**Results:** Among 250,672 patients registered from April 2015 to December 2021, 1,627 met the inclusion criteria and were analyzed. After propensity score matching ($n = 234$), in-hospital mortality did not significantly different between the CRRT and the IRRT groups (29.9% vs 41.9%; risk difference, − 11.97%; 95% CI, − 24.3 to 0.3; $P = 0.056$). In the subgroup analysis among patients with septic shock ($n = 180$), CRRT was associated with lower in-hospital mortality compared to IRRT (29.3% vs 50.6%; $P = 0.04$).
**Conclusions:** In this large retrospective cohort study using a JIPAD, CRRT was associated with lower in-hospital mortality compared to IRRT in patients with S-AKI due to septic shock. Our findings suggest that the choice of RRT modality may impact patient outcomes in S-AKI, and should be carefully considered in clinical practice.

**Introduction:** Over the past decade, there has been widespread and increasing interest in assessing frailty in the intensive care unit (ICU). Frailty has many operational definitions, but broadly represents a state of decreased physiologic reserve that heightens vulnerability to acute stressors. We aimed to assess the usefulness of frailty scale as prognostic tool to predict outcomes of patients in ICU.
**Methods:** Observational study conducted in the intensive care units of critical care medicine department, Alexandria University. All patients above 65 years with no learning disability admitted to general ICU were included in the study in the period from January 2021 to September 2021. The CFS was assessed prior to the acute event and admission to the ICU by data received from patients if possible or from caregivers or the medical and nursing hospital notes. APACHE II score was calculated for every patient included in the study on admission to ICU as a routine. Comparison of CFS and APACHE II score in prediction

of ICU mortality and ICU length of stay were performed. Long ICU stay was defined as ICU stay more than 7 days.
**Results:** A total of 111 patients were included in the study with variable reason of ICU admission mostly septic shock and cerebrovascular stroke. CFS significantly predicted mortality in this patient's cohort with (AUC of 0.854, $p$ value of $<0.001$) but was lower compared to APACHE II score which showed higher accuracy with (AUC of 0.955 and $p$ value of $<0.001$) CFS predicted long ICU stay more than 7 days with significant accuracy (AUC of 0.818 and P value of 0.04) while APACHE score was non-significant in prediction of long ICU stay (AUC of 0.674 and P value of 0.261).
**Conclusions:** Clinical frailty scale assessment can be a useful tool to predict prolonged ICU stay and ICU mortality with high accuracy in elderly patients aged more than 65 years.

**Introduction.** High-flow nasal cannula (HFNC) use in patients with hypoxemic respiratory failure is increasing. HFNC use reduces the rate of endotracheal intubation in patients with acute respiratory failure compared with conventional oxygen therapy [1–3]. However, failure of HFNC may cause delayed intubation and increased mortality [4]. Therefore, predicting HFNC failure and determining the appropriate timing of endotracheal intubation are important strategies for HFNC treatment.
**Methods:** This study was conducted in critical care medicine department (isolation intensive care units), Alexandria Main University Hospital during the period from January to December 2021 after approval of local ethical committee and informed consents were taken from patients or next of kin. Patients were admitted only to this unit if they had confirmed severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) in severe or critical situation as per local guidelines. Patients were included only if HFNC was applied early (<48 h) after admission. With exclusion of pregnant females or age less than 18. The following data were collected: age, sex, APACHE (acute physiology and chronic health evaluation) II score. The decision to initiate HFNC or mechanical ventilation was made by the treating clinical team. According to the Surviving Sepsis Campaign: guidelines on the management of critically ill adults with COVID-19 [9], HFNC is encouraged to use in acute hypoxemic respiratory failure despite conventional oxygen therapy.
**Results:** All 107 patients on HFNC within 48 h ended with 3 fates, 60 patients improved and weaned to less oxygen therapy to discharge (56.1%), 23 patients were invasively ventilated (21.5%) while 24 patients needed non-invasive ventilation (22.4%). Invasively ventilated patients group showed significant high APACHE II score (mean value 31.7 ± 4.2), high inflammatory markers of CRP (mean value 92.7 ± 40.7) and Interleukin 6 (mean value of 73.3 ± 30.0) which all were significantly higher than other 2 groups. ROX index measured at all intervals (1–2–6–12–24–36–48 h) were all significantly higher in patients group improved to discharge with $p$ value of 0.001 while no significant difference was found between ROX index values of invasive or non-invasive MV groups.
**Conclusions:** We concluded that ROX index can differentiate significantly between HFNC successful and failed groups at multiple intervals as early as 1 h from application and it can predict HFNC failure with remarkable accuracy.

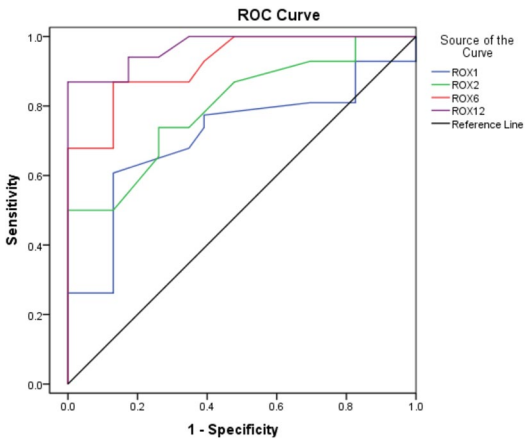

**Fig. 3 (abstract 000091)** Sensitivity, specificity and accuracy of ROX index at 1st, 2nd, 6th and 12th hours to predict mortality

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000095

**Introduction:** Although it has been suggested that hyperchloremic acidosis induced by 0.9% sodium chloride solution (saline) can adversely affect the kidney, whether chloride-restrictive fluid strategies can reduce the incidence of acute kidney injury after off-pump coronary artery bypass surgery remains unclear.
**Methods:** A total of 360 adults undergoing coronary artery bypass surgery were randomly assigned to receive balanced solution-based chloride-restrictive intravenous fluid (balanced group) or saline-based chloride-liberal intravenous fluid (saline group). The primary outcome was acute kidney injury within 7 postoperative days, as defined by the 2012 Kidney Disease: Improving Global Outcomes Clinical Practice Guideline.
**Results:** The incidence of acute kidney injury was 4.4% (8/180) in the balanced group and 7.3% (13/178) in the saline group. The difference was not statistically significant (risk difference, − 2.86%, 95% confidence interval [CI], − 7.72% to 2.01%; risk ratio, 0.61, 95% CI, 0.26 to 1.43, $P = 0.35$). Compared to the balanced group, the saline group had higher levels of intraoperative serum chloride and lower base excess, which resulted in lower pH.
**Conclusions:** In patients undergoing off-pump bypass surgery with normal estimated glomerular filtration rate, the intraoperative balanced solution-based chloride-restrictive intravenous fluid administration strategy did not reduce the rate of postoperative acute kidney injury compared to the saline-based chloride-liberal intravenous fluid administration strategy.

**Nationwide Cohort Study on the Long-Term Risks of Radiation Therapy in Pediatric Patients with Brain Tumors**

C. C. Chao[1]; L. Feng-Chin[1]
[1]Emergency Department, Taipei Medical University Hospital, Taipei, Taiwan
**Correspondence:** C.C. Chao
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000096

**Introduction:** No existing study has comprehensively assessed radiation therapy (RT)-related side effects, encompassing long-term endocrinopathies, late-delayed complications, and late cerebrovascular complications in pediatric patients with brain tumors.
**Objectives:** The objective of our study is to investigate the correlation between radiation therapy and these specific side effects in pediatric patients with brain tumors on a nationwide scale.
**Methods:** We retrieved data on pediatric patients with brain tumors from the National Health Insurance Research Database (NHIRD) of Taiwan. The radiation therapy (RT) cohort comprised 815 patients, randomly matched for age, gender, and index year with non-RT patients. Utilizing multivariate Cox proportional hazards regression, we calculated adjusted hazard ratios (aHR) to assess the likelihood of developing late side effects in the RT cohort in comparison to non-RT controls.
**Results:** In patients receiving radiation therapy (RT), the incidence of late side effects was significantly higher when pioglitazone was administered compared to non-RT patients ($p < 0.05$). The multivariate Cox regression analysis unveiled a 1.173-fold increase in the incidence of late side effects in the RT group (adjusted hazard ratio [aHR] = 1.173, 95% CI 1.063–1.430, $p < 0.05$) compared to the non-RT group, with an observed interaction between age and RT-related late side effects.
Furthermore, patients undergoing RT exhibited a 1.172-fold (95% CI 1.020–1.398) and 1.796-fold (95% CI 1.250–2.578) higher risk of developing long-term endocrinopathies and late-delayed complications, respectively, than their non-RT counterparts (all $p < 0.05$). However, the risk of late cerebrovascular complications did not show a significant difference between the two groups ($p > 0.05$).
Specifically for long-term endocrinopathies, RT patients had a 1.602-fold (95% CI 1.010–3.718) and 1.120-fold (95% CI 1.005–1.548) higher risk for gonadotropin deficiency and hypothalamic-pituitary dysfunction, respectively, compared to non-RT patients (all $p < 0.05$). In terms of late-delayed complications, RT patients had a 3.208-fold (95% CI 1.953–5.297) higher risk of post-RT necrosis of the brain stem than non-RT patients ($p < 0.05$).
**Conclusions:** Pediatric patients diagnosed with brain tumors faced an elevated risk of late side effects, especially when diagnosed at a younger age. Key among the radiation therapy (RT)-related late side effects were gonadotropin deficiency, hypothalamic-pituitary dysfunction, and brainstem necrosis. Importantly, the incidence of these deficits demonstrated a time-dependent increase, underscoring the necessity for long-term surveillance in this patient population.

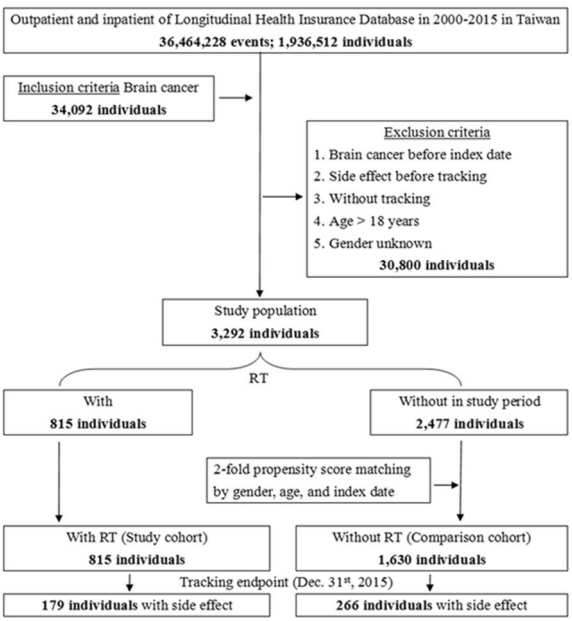

**Fig. 1 (abstract 000095)** The flowchart for selection of study population

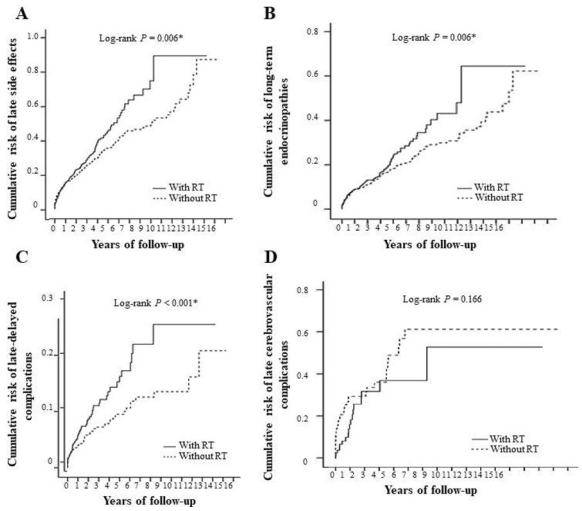

**Fig. (abstract 000095)** Kaplan–Meier plot for cumulative incidence of side effects in patients with (solid line) and without RT (dashed line). (A) Overall side effects. (B) Long-term endocrinopathies. (C) Late-delayed complications. (D) Late cerebrovascular complications. *$p < 0.05$

**Table (abstract 000095)** Multivariate Cox-regression analysis of RT associated with side effect subgroup

| | RT vs. Non-RT | |

**Correspondence:** R. Vithal
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000099

**Introduction:** This study aims to investigate brain injury biomarkers neurofilament light (NFL), tau, neuron-specific enolase (NSE), calcium-binding protein S100B (S100B) and glial fibrillary acidic protein (GFAP) in blood during general anaesthesia and abdominal surgery in patients without suspected cerebral injury.
**Methods:** This prospective observational study was conducted at the Sahlgrenska University Hospital, Gothenburg, Sweden, between September and November 2021. Patients scheduled to undergo mixed abdominal surgery under general anaesthesia were eligible for inclusion. All patients had standard monitoring of vital parameters and near-infrared spectroscopy (NIRS) monitoring cerebral perfusion. Mean arterial blood pressures were kept within 20 mmHg compared to preoperative values but never under 60 mmHg.
Blood samples were obtained preoperatively as well as 2 and 24 h postoperatively. All samples were analysed at the Clinical Neurochemistry Laboratory of the Institute of Neuroscience and Physiology, Sahlgrenska Academy, University of Gothenburg, Mölndal Campus, Sweden.
**Results:** There were 23 patients (11 females [48%] and 12 males [52%]) included in the study. NFL, tau, NSE and S100B increased significantly when 2- and 24-h concentrations were compared with preoperative values, while GFAP did not. The continuous mean arterial blood pressure was 83.5 mmHg, with a 62.2–90.4 mmHg range. The mean NIRS was 77.5% (range 62.2–90.4). No patient had a drop in NIRS of 12% or more. Postoperative symptoms of confusion or neurological deficits were not observed in any patient within 24 h from the start of anaesthesia.
**Conclusions:** General anaesthesia and abdominal surgery in patients with well-maintained cerebral perfusion and no signs of postoperative cerebral injury caused increased brain injury biomarkers NFL, tau, NSE and S100B in blood. There was no increase in levels of GFAP in the blood. These data suggest that only GFAP is unaffected by general anaesthesia and surgery. More extensive studies on this subject are warranted.

### Effect of targeted temperature management after successful endovascular reperfusion therapy in patients with acute basilar artery occlusion

H. J. Kim[1]
[1]Neurology, Jeju National University Hospital, Cheju, Republic of Korea
**Correspondence:** H.J. Kim
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000101

**Introduction:** Even undergoing endovascular reperfusion therapy (ERT), patients with acute basilar artery occlusion (BAO) still have a high morbidity and mortality rate. Targeted temperature management (TTM) improved clinical outcomes in experimental animal ischemic stroke models. TTM appears to be a promising candidate treatment for acute BAO.
**Objectives:** We investigated the clinical effects of TTM after successful endovascular reperfusion therapy in patients with acute basilar artery occlusion.
**Methods:** A retrospective analysis was performed in a prospective registry at a single comprehensive stroke center. We enrolled patients with acute ischemic stroke in the acute BAO an initial National Institutes of Health Stroke Scale $\geq$ 10) who had successfully revascularization achieved. Patients with BAO underwent a mild TTM (35–6 °C) protocol, which included mechanical ventilation and 24–48-h hypothermia. Patients with BAO who did not perform TTM were treated according to the medical management protocol. Mental status, neurologic deterioration, cerebral edema, hemorrhagic transformation, good clinical outcome (GCO, 3-month modified Rankin Scale, $\leq$ 3), mortality, and safety were compared among the group.
**Results:** Of the 35 patients who met the study inclusion criteria, 9 patients were assigned to the TTM group and 22 to the non-TTM group. Intravenous thrombolysis was used in 1 (11.1%) of the patients in the TTM group and in 9 (36.0%) of those in the non-TTM group. Good functional status at 90 days occurred in 0 patients in the TTM group and in 12 (48.0%) in the non-TTM group. Symptomatic intracranial hemorrhage occurred in 2 patients (22.2%) in the TTM group and in 3 (12.0%) in the non-TTM group. Although mortality was not statistically different among the group, morbidity was significantly higher in the TTM group.
**Conclusions:** Although a small number of patients were evaluated, in patients with acute BAO who received successful revascularization by ERT, TTM may increase neurological deterioration and reperfusion injury and lead to worsened clinical outcomes.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000102

**Introduction:** To achieve seizure control in traumatic brain injury and post-operative Brain tumor surgery reduces mortality in the neurosurgical intensive care unit. However, Primary treatment drug therapy does not result in effective seizure control in approximately 30 percent of patients. AMPA receptor (perampanel therapy, PER) was a known novel target for focal-onset seizures, with or without focal to bilateral tonic–clonic seizures, and generalized tonic–clonic seizures. This study collected efficacy and factors associated with the seizure-free rate of perampanel as an add-on or monotherapy.
**Objectives:** To collect efficacy and factors associated with the seizure-free rate of perampanel as an add-on or monotherapy in the neurosurgical intensive care unit.
**Methods:** This study is a single-center prospective interventional study. Data from all 76 patients who received PER as an add-on or monotherapy between January 2017 and December 2023. The observation period was 6 months. The observation endpoint is the drug response and retention rate at 6 months. Multivariate and linear regression analyses were performed by an array of clinical variables in relation to seizure-free rate at 6 months of follow-up and compare the differences in efficacy, retention rates, and factors associated with seizure-free, respectively.

**Results:** Clinical data were obtained for 76 patients with epilepsy and drug resistance epilepsy (DRE) (mean duration of treatment: 12.5 months). At 6 months, multivariate analysis showed significant differences in whether traumatic brain injury etiology (OR = 1.49, 95%CI: 0.072–0.734, $p = 0.030$), low-grade glioma etiology (OR = 0.55, 95%CI: 0.267–0.947, $p = 0.042$), the baseline seizure frequency less than 4 times per day (OR = 0.62, 95%CI: 0.096–0.625, $p = 0.045$), the number of previously failed anti-seizure medication less than 3 (OR = 0.43; 95%CI: 0.115–0.938, $p = 0.025$) and whether onset of PER therapy ≤ 48 h (OR = 1.31, 95%CI: 0.086–0.801, $p = 0.020$). This indicates that the factors enhancing a response to PER therapy are higher with a traumatic brain injury, low-grade glioma, baseline seizure frequency of less than 4 times per day, the number of previously failed anti-seizure medications less than 3 as well as onset of PER therapy ≤ 48 h. Therefore, a baseline frequency of less than 4 times per day and less than three previous anti-seizure treatments to control symptoms were independent factors affected PER add-on therapy for patients with DRE. Multivariate COX model showed that patients with DRE in combination with the central nervous system infection had a risk of a lower retention rate (OR = 11.832, 95% CI: 2.687–61.412, $P < 0.001$) than patients with DRE, according to other etiologies. Patients with Glioblastoma multiforme (OR = 0.062, 95% CI: 0.006–0.561, P = 0.006), and patients who have multiple types of seizures (OR = 35.251, 95% CI: 5.543–3.201, $P = 0.002$). After multivariate analysis, we found that age, Onset of PER therapy (hr), traumatic brain injury, low-grade glioma, seizure frequency at baseline, and number of previously failed medications were significantly associated with seizure-free. Age ≤ 55 year (AUC = 0.961, $p$-value < 0.001 accuracy 91.2%) was significantly cut off value that associated with seizure-free PER therapy.

**Conclusions:** Age, onset of PER therapy (hr), traumatic brain injury, low-grade glioma, seizure frequency at baseline and number of previously failed medications were significantly associated with seizure free in DRE patients with perampanel as an add-on or monotherapy in a neurosurgical intensive care unit. This provides a basis for assessing the expected patient selection and efficacy for patients with DRE.

**Introduction:** Net ultrafiltration (UFNET) during continuous renal replacement therapy (CRRT) may help control fluid balance in ICU patients, but is usually set to 0 mL/h in patients with vasopressors. Although only 50% of hemodynamic instability events associated with CRRT (HIRRT) are related to preload dependence, UFNET is also usually discontinued when these events occur (1).
**Objectives:** To evaluate the effectiveness of a UFNET strategy guided by functional hemodynamic monitoring to control the fluid balance in patients undergoing CRRT, compared to the standard of care (i.e. UFNET 0 mL/h).
**Methods:** This was a multi-center, randomized, controlled, open-label trial in 4 ICUs in France. Eligible patients were adults receiving with acute circulatory failure and receiving vasopressors, severe acute kidney injury treated with CRRT since less than 24 h and equipped with a calibrated continuous cardiac output monitoring device. Patients were randomized (ratio 1:1) to receive during 72 h a UFNET $\geq$ 100 mL/h, adjusted using a functional hemodynamic protocol (intervention), or a UFNET $\leq$ 25 mL/h (control) without the application of the hemodynamic protocol. The hemodynamic protocol was applied in the intervention arm every 4 h to decrease or stop UFNET in case of a pejorative hemodynamic profile (orange or red profiles, Fig. 1), based on the evaluations of cardiac output, central venous pressure, arterial lactate and preload depdence status. The study primary outcome was the cumulative fluid balance at H72 (corresponding to the difference in fluid inputs and outputs [including diuresis] recorded over that period) and was analyzed in the modified intention-to-treat population (mITT, i.e. all enrolled patients alive at H72 and in whom hemodynamic monitoring and CRRT were continuously provided). Secondary outcomes were analyzed in the intention-to-treat population (ITT) and included: hourly net ultrafiltration rate, hourly fluid balance, number of HIRRT episodes (hypotension, tachycardia, decrease in cardiac output or mottles). Continuous variables were reported using median [interquartile range]. Registration: ClinicalTrials.gov NCT04801784.
**Results:** Between June 2021 and April 2023, 55 patients (age 69 [62–74], 35% female) were enrolled; 25 received the intervention and 30 the control strategy. At inclusion, 48 patients (87%) had sepsis, the norepinephrine dose was 0.45 [0.21–1.05] µg/kg/min, and the SOFA score 13 [11–15]. In the mITT population (21 intervention, 24 control), the fluid balance at H72 was − 2650 [− 4574–− 309] mL in the intervention arm, and 1841 [821–5327] mL in the control arm (difference: 4942 [95% confidence interval: 2736 to 6902]) mL, $P < 0.01$). In the ITT population, the hourly net ultrafiltration rate and the hourly fluid balance were respectively and significantly higher and lower in the intervention arm, compared to controls (100 [50–140] ml/h vs. 20 [0–20] ml/h, $P < 0.01$ and − 27 [− 59–29] mL/h vs. 26 [8–69] mL/h, $P = 0.01$). The cumulative number of HIRRT episodes per patient at H72 was not statistically different between the control and intervention arms (1 [0–3] vs. 2 [1–4], $P = 0.23$). Hemodynamics, oxygenation and SOFA scores did not statistically differ between study arms at H72. Day-90 mortality

was 18/30 (60%) in controls and 17/25 (68%) in the intervention arm ($P = 0.99$).

**Conclusions:** In patients receiving vasopressors and CRRT, a fluid balance control strategy by UFNET guided by a functional hemodynamic protocol allowed a significant decrease in fluid balance, compared to the standard of care, with no increase in HIRRT incidence.

**Introduction:** Mechanical ventilation is an essential intervention in the intensive care unit (ICU). Closed-loop ventilation modes, like INTELLiVENT®-Adaptive Support Ventilation (ASV), offer important advantages by automatically adapting ventilator settings based on real-time monitoring. Previous studies demonstrated its safety and improved lung protectiveness in various patient groups [1], however knowledge gaps remain regarding clinicians' workload and acceptance.

**Objectives:** To compare workload related to alarms and interventions at the ventilator with INTELLiVENT-ASV versus conventional ventilation in patients receiving postoperative ventilation after cardiac surgery. We also determined the acceptance of the closed-loop mode by ICU caregivers.

**Methods:** We conducted preplanned analysis of POSITiVE [2], a randomized clinical trial comparing INTELLiVENT-ASV with conventional ventilation in patients after cardiac surgery. The primary outcome was a combination of the number of alarms, and the number of manual interventions at the ventilator. Manual interventions included those related to changing ventilation and alarm settings. The primary outcome was calculated over the first three hours of ventilation or until extubation. Caregivers' acceptance was determined using a questionnaire based on the Technology Acceptance Model 2 [3], and a user acceptance score ranging from 1 to 10.

**Results:** POSITiVE included 210 patients (104 automated and 106 conventional). The automated mode generated a comparable number of alarms at a similar frequency as the conventional group (2.00 [1.33–3.57] vs 2.24 [1.33–4.01] alarms per hour; $P = 0.65$), less ventilation control interventions per hour (0.33 [0.33–1.00] vs 1.00 [0.33–2.00]; $P < 0.001$), but significantly more alarm management interventions per hour (12.50 [9.13–24.00] vs 2.11 [1.33–3.65]; $P < 0.001$), compared to the conventional group. Respectively, 99 ($\geq 1$ for 95% of patients) and 103 ($\geq 1$ for 97% of patients) surveys were completed for the automated and conventional group. Perceived ease of use did not differ between the two modes. The automated mode scored higher in perceived usefulness (2.61 [2.25–2.84] vs 2.11 [1.82–2.35]; $P < 0.001$) and had higher user acceptance (7.98 [7.75–8.20] vs 7.01 [6.67–7.35]; $P < 0.001$) compared to the conventional group.

**Conclusions:** Automated ventilation for post-cardiac surgical patients reduces the number of interventions related to ventilation management and shows higher clinicians' acceptance, indicating its potential to optimize patient care and reduce bedside nurses' workload. However, while alarm frequencies were similar, interventions related to alarm management increased.

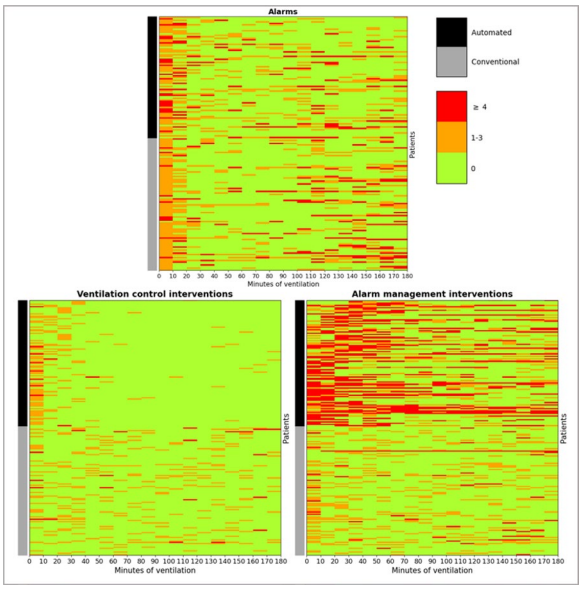

**Fig. 1 (abstract 000109)** Heatmap of the number of alarms (upper), ventilation control interventions (lower left) and alarm management interventions (lower right) occurring in the first 3 h or until extubation in intervals of 10 min. On the y-axis each patient is visualized and on

the x-axis the ventilation time. Patients following a black box represent the automated group and patients following a gray box represent the conventional group. Green represents zero alarms/interventions during that period, orange 1–3 alarms/interventions and red 4 or more alarms/interventions

**Introduction:** Emergency abdominal surgery has high rates of mortality and morbidity. Patients undergoing emergency abdominal surgery show a septic condition in about 40% at the time of surgery, and elderly patients have particularly poorly controlled comorbidities. Therefore, this patient group has a high potential to improve postoperative morbidity, mortality, and postoperative clinical outcomes through perioperative management, aggressive resuscitation, and anesthesia management. However, the incidence and risk factors of postoperative acute kidney injury (AKI) have rarely been reported. We aimed to investigate the incidence and prognosis of AKI and find potentially modifiable risk factors of AKI in these high-risk patients.
**Methods:** We retrospectively reviewed consecutive patients who underwent emergency open abdominal surgery at a single tertiary care university hospital during between 2010 to 2022 ($n=474$). Baseline characteristics, surgery and anesthesia-related parameters were included in our binary logistic regression analysis. Smooth transformation of linear associations of our covariates with AKI was evaluated using restricted cubic splines.
**Results:** The overall incidence of AKI was 20.3% ($n=96$). Postoperative AKI was significantly associated with clinical outcomes including admission to ICU, length of hospital and ICU stay, and in-hospital mortality.
Multivariable logistic regression analysis for postoperative AKI revealed that age, body-mass index and ASA classification class 3 or 4 were significant predictors. Furthermore, intraoperative vasopressin continuous infusion (odds ratio 4.06, 95% confidence interval [CI] 1.19–13.9), preoperative platelet count (odds ratio 0.72, 95% CI 0.57–0.90, $p=0.003$) and maximal serum lactate level during surgery (and odds ratio 1.14, 95% CI 1.04–1.26, $p=0.006$) were identified as potentially modifiable risk factors.
Cubic spline function curves of multivariable-adjusted relationships showed that the risk of AKI increases as the maximal serum lactate level or the level at the end of surgery increases. Also, the risk of AKI decreased as the preoperative platelet count are higher.
**Conclusions:** Our study showed that AKI after emergency abdominal surgery is significantly associated with postoperative clinical outcomes including the admission to ICU, length of hospital or ICU stay, and in-hospital mortality. We also demonstrated that preoperative platelet count, intraoperative maximal lactate level, and vasopressin infusion are potentially modifiable risk factors of postoperative AKI in patients undergoing emergency open abdominal surgery.

### Association of Heart Failure Categorized by Ejection Fraction with In-Hospital and Cardiovascular Mortality among Patients with Acute Decompensated Heart Failure

L. Yaneza[1], E. Punzalan[2], C. Cordero[2], E. Reyes[2], M. Alejandria[2], A. Bernan[2]

**Introduction:** Echocardiography derived ejection fraction (EF) is a powerful prognosticator for heart failure (HF). Acute heart failure (AHF) may either be new onset or acute decompensated heart failure (ADHF). Studies were limited on the association of heart failure categorized by EF with mortality among AHF patients particularly ADHF. Majority of studies would either do combined binary classification or use different EF range values. Further, most studies would either enrolled both de novo and acute decompensated heart failure or combined chronic and acute heart failure in the analysis. Hence, there are scarcity in knowledge and inconsistencies with data results regarding the association of heart failure categorized by ejection fraction in acute heart failure particularly in acute decompensated state.
**Objectives:***Primary Objectives:*
1. To describe the demographic, clinical characteristics, and outcome of patients with acute decompensated heart failure.
2. To determine association of heart failure (HF) categorized by ejection fraction with in hospital and cardiovascular mortality among patients with acute decompensated heart failure

**Methods:** This was a retrospective cohort study of patients enrolled in the national Philippine Heart Association HF registry admitted due to AHF from January 2015-December 2018. Patients with de novo HF were excluded. Binary logistic regression analysis was done.
**Results:** From a total of 1123 patients with AHF, 460 patients (41%) were diagnosed with ADHF. The mean EF of 412 patients was 42.44% (SD 15.44%). Heart failure reduced EF (HFrEF) was the most common classification (50%), followed by heart failure preserved EF (HFpEF 31%), and heart failure mildly reduced EF (HFmrEF 18%). The mean age was 56 years. More than 50% were males. The most common chief complain was dyspnea followed by chest pain. Majority of patients (53%) were in New York Heart Association classification III. The most common etiology of heart failure was coronary artery disease followed closely by hypertensive heart disease. Majority has no identifiable precipitating factors for decompensation. In-hospital mortality occurred in 11 patients (2.72%) with cardiovascular mortality as the major cause of death.

On adjusted analysis (Table 1), the odds of dying for HFrEF and HFmrEF was 7x (OR adj = 6.7; 95% CI 0.65–64.35) and 3x (OR adj = 3.29 95% CI 0.15–70.60) respectively compared to the odds of dying in HFpEF. However, this result was not statistically significant. The clinical variable that showed statistically significant association with mortality was COPD (adjusted OR 10.82, 95% CI 1.43–81.89). Heart rate also conferred a higher odds to mortality, for every beat/min increase of heart rate, the odds increase by 5% at 95% CI of 1.01–1.09.
**Conclusions:** This study showed that acute decompensated heart failure occurred in 41% among acute heart failure patients.HFrEF was the most common classification of HF occurring at 50%, followed by HFpEF (31%), and lastly by HFmrEF at 18%**.** The mean age was 56 years and more than 50% were males. The mean EF was 42.44%. The most common presenting symptom was dyspnea followed by chest pain. Coronary artery disease (CAD) and hypertensive heart disease (HHD) were the common etiologies for heart failure. Hypertension was the most common risk factor followed closely by diabetes. Infection and acute coronary syndrome were only second and third respectively in the precipitating factors for acute decompensation. The precipitating factor for acute decompensated heart failure could not be identified in majority of patients. In-hospital mortality occurred in 2.72% with cardiovascular mortality as the major cause of death. Although there was a trend for higher odds of dying for HFrEF and HFmrEF as compared to HFpEF, the study did not show statistical significance. This might be due to small number of events but this may suggest that EF alone should not be used as sole criterion for evaluation of AHF but should importantly consider other significant risk factors.

### Lower versus higher oxygenation target in intensive care unit patients with chronic obstructive pulmonary disease and acute hypoxaemic respiratory failure

M. Brun Nielsen[1], T. Lass Klitgaard[1], U. Møller Weinreich[2], F. Mølgaard Nielsen[1], A. Perner[3], O. Lilleholt Schjørring[1], B. Steen Rasmussen[1]

**Correspondence:** T. Lass Klitgaard
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000113

**Introduction:** Oxygen supplementation is essential in treating patients with chronic obstructive pulmonary disease (COPD) and acute hypoxaemia. While higher oxygenation targets have been discouraged in patients with COPD due to the risk of $CO_2$ retention, the optimal oxygenation target for these patients has yet to be determined in the intensive care unit (ICU).
**Objectives:** To investigate the benefits and harms of a lower partial pressure of arterial oxygen ($PaO_2$) oxygenation target of 8 kPa versus a higher $PaO_2$ oxygenation target of 12 kPa in ICU patients with COPD and acute hypoxaemic respiratory failure.
**Methods:** This is an analysis of a pre-planned subgroup in the HOT-ICU trial [1], being patients with COPD. In the HOT-ICU trial, ICU patients with acute severe hypoxaemic respiratory failure were randomised 1:1 to a lower ($PaO_2$ of 8 kPa) versus a higher ($PaO_2$ of 12 kPa) oxygenation target during ICU admission, for a duration of up to 90 days including readmissions. The randomisation was stratified for the presence or absence of COPD. The primary outcome was 90-day all-cause mortality; secondary outcomes at 90 days were the number of patients with one or more serious adverse events in the ICU (new episodes of shock, intestinal ischaemia, cerebral ischaemia, or myocardial infarction), days alive and free of life support (mechanical ventilation, vasopressors/inotropes, or renal replacement therapy), and days alive out of hospital.
**Results:** The HOT-ICU trial enrolled 2928 patients, of whom 563 had COPD: 277 patients were allocated to the lower-oxygenation group, and 286 patients to the higher-oxygenation group. The median $PaO_2$ was 9.1 kPa (interquartile range [IQR] 8.7 to 9.9) in the lower-oxygenation group compared with 12.1 kPa (IQR 11.2 to 12.9) in the higher-oxygenation group. Data for partial pressure of arterial carbon dioxide ($PaCO_2$) and pH were available for 497 patients (88%), and showed no between-group differences in time-weighted averages during ICU stay; median $PaCO_2$ 6.0 kPa (IQR 5.2 to 7.2) and pH 7.40 (IQR 7.36 to 7.43) in the lower-oxygenation group, compared with $PaCO_2$ 6.2 kPa (IQR 5.4 to 7.3) and pH 7.39 (IQR 7.34 to 7.42) in the higher-oxygenation group. Arterial blood gas data for the first 30 days are presented in Fig. 1. At 90 days 122 of 277 patients (44%) in the lower-oxygenation group versus 132 of 285 patients (46%) in the higher-oxygenation group had died (adjusted relative risk 0.98; 95% CI 0.82 to 1.17; $P = 0.67$). We found no statistically significant differences in any secondary outcomes.
**Conclusions:** In ICU patients with COPD and acute severe hypoxaemic respiratory, targeting a $PaO_2$ of 8 kPa did not reduce 90-day all-cause mortality compared with targeting a $PaO_2$ of 12 kPa. There were no between-group differences in $PaCO_2$, pH levels, or any secondary outcomes. These findings may not be transferred to COPD patients with hypercapnic respiratory.

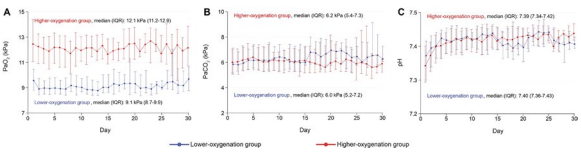

**Fig. 1 (abstract 000113)** Oxygenation and arterial blood gas data until 30 days post-randomisation. $PaO_2$ = partial pressure of arterial oxygen. $PaCO_2$ = partial pressure of arterial carbon dioxide. COPD = chronic obstructive pulmonary disease. Group medians with interquartile ranges (IQR) are calculated for the 90-day intervention period. Panel A: Oxygenation data for the 563 COPD patients in the HOT-ICU trial. Values are medians of daily patient-means with IQRs. Daily patient-means were calculated from the lowest and highest PaO2 in pre-specified 12-h intervals. Panels B-C: Arterial blood gas data for the 497 Danish COPD in the HOT-ICU trial. Values are daily medians of patients' time-weighted averages with IQRs

## Anaemia's Impact and Management Post-Aneurysmal Subarachnoid Haemorrhage

D. P. Martins Fernandes[1], E. Marques Mendes[2], E. Pereira[1], C. Dias[3], J. Artur Paiva[3], E. Monteiro[3]
[1]Intensive Care Medicine, Centro hospitalar Universitário do São João, Porto, Portugal; [2]Intensive Care Medicine, Unidade Local de Saude do Alto Minho, Viana do Castelo, Portugal; [3]Intensive Care Medicine, Centro Hospitalar Universitário do São João. ***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000114

**Introduction:** Cerebral vasospasm (CVS) and delayed cerebral ischemia (DCI) remain major morbidity and mortality factors following aneurysmal subarachnoid haemorrhage (aSAH) [1]. Anaemia is prevalent in aSAH patients and linked to worse outcomes. Nevertheless, optimal haemoglobin (Hb) and packed red blood cell transfusion (pRBCT) strategy remain unknown [2].
**Objectives:** Examine the association between anaemia and pRBCT with CVS, DCI and functional outcome after aSAH.
**Methods:** Single-centre retrospective study including all adult patients with aSAH admitted to a tertiary´s hospital Neurocritical Care Unit (NCCU) from 2018 to 2022. Primary Outcome was CVS and functional outcome assessed with the Glasgow Outcome Scale (GOS). Secondary Outcomes were NCCU and hospital length of stay. Anaemia was considered if Hb dropped below 10 g/dL, from admission and throughout the DCI risk period. CVS was diagnosed with TCD or cerebral angiography.
**Results:** A total of 221 patients were included, none of which had anaemia on admission. Baseline characteristics, treatment strategy and outcomes are shown in Table 1. Considering those who developed anaemia (n = 114, 52%), 74% were female with a mean age of 60 years, 59% had hypertension and 28% smoking history. In this subgroup, 42% had a severe aSAH (Hunt-Hess of IV/V), with the most frequent location being the anterior communicating and middle cerebral arteries; 55% were managed surgically and 45% with endovascular treatment. Patients with anaemia were more likely to present with worse neurological grade and to have their aneurysm secured by clipping ($p < 0.001$). Only 33% of patients were transfused, more likely to happen with an Hb of less than 8 g/dL (53% vs 14%) and no pRBCT were used for an Hb threshold above 10 g/dL. On univariate analysis, anaemia was associated with CVS (OR 3.17, 95% CI, 1.826–5.52, $p < 0.001$), DCI (OR 2.95, 95% CI 1.61–5.42, $p < 0.001$) and worse functional outcome, both at 6 months (OR 2.3, 95% CI 1.15–3.90, $p\ 0.014$) and one year after discharge (Or 2.34 95% CI 1.07–5.12, $p = 0.031$). Transfusion failed to alter the link between anaemia and CVS or DCI (OR 3.05, 95% CI 1.45–6.42, $p = 0.002$) and failed to improve patient outcome (OR 4.05, 95% CI 1.89–8.53, $p < 0.01$). Time to event analysis (Fig. 1), showed a statistically significant association between anaemia and CVS (Log Rank < 0.001). There was no statistically significant difference between patients with severe (Hb ≤ 8 g/dL) and moderate (8 < Hb ≤ 10 g/dL) anaemia. Anaemia was associated with prolonged NCCU and hospital stay ($p < 0.001$), longer for patients with severe anaemia versus those with moderate anaemia ($p = 0.017$ and $< 0.001$, respectively).
**Conclusions:** Anaemia is prevalent among aSAH patients and an Hb decline below 10 g/dL was strongly associated with CVS, DCI, poor functional outcome, and extended hospital and NCCU stay. Transfusion strategy for a medium Hb of 7.7–7.8 g/dL did not improve study endpoints. Our findings encourage further evaluations on the value of a higher threshold transfusion strategy in aSAH patients.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000115

**Introduction:** Presepsin is a specific and valuable biomarker of the predictive value in sepsis and community-acquired pneumonia.
**Objectives:** This study analyzed which the high plasma presepsin level (HPL) was associated with vasopressors, mechanical ventilation or death in patient with pneumonia or not.
**Methods:** This retrospective single-center study analyzed patients admitted through the emergency room at Konyang University Hospital from April to December. A total of 252 patients were enrolled, of which 78 (30.9%) were pneumonia. Excepting 1 patient without presepsin level, total 77 patients were analyzed. We used HPL as the cuf-off in this study based on a previous study in which the presepsin level was 720 pg/mL when the PSI score was above 130.
**Results:** Among all patients, 21 (27.3%) patients received vasopressors and 19 (24.6%) patients received mechanical ventilation, and death were 23 (29.9%) during hospital stay. There was no difference in the median value of presepsin levels between patients who received vasopressors and patients who did not (570.5 pg/mL (IQR 346.6–749.5 pg/mL) vs 707.0 pg/mL (IQR 414.5–1373.0 pg/mL), p = 0.352). Patients with HPL tended to receive more vasopressors within 72 h of hospitalization compared to patients with low levels, but there was no statistical difference (38.5% vs 21.5%, $p = 0.097$). There was no difference in the application of mechanical ventilation (26.9% vs 23.5%, $p = 0.475$) and death between two groups (34.6% vs 27.5%, $p = 0.346$).
**Conclusions:** Plasma level of presepsin did not predict mechanical ventilation treatment or death. There was a tendency for a high number of patients to receive vasopressor during HPL.

**Topic:** Infections and prevention

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000116

**Introduction:** When initiating ciCRRT both calcium (Ca) and magnesium (Mg) balance undergo dynamic changes before reaching steady state. In a CVVHDF model, Zakharchenko et al. demonstrated that, sampling twice within 1 h in steady state, postfilter $Mg^{2+}$ is significantly related to the postfilter $Ca^{2+}$ and that loss of Mg was not covered by magnesium concentration in ordinary dialysis/substitution fluid.
**Objectives:** To compare Ca and Mg loss in steady state over a longer period in a broader range of citrate doses but with similar clearances.
**Methods:** In this study targeting high vs. low postfilter ionized calcium by titrating citrate concentrations, calcium and magnesium loss in effluent were compared once steady state had been reached in CVVH (12, 18 and 24 h after initiation). Clearance was targeted at 30 ml/kg/h in all patients. Appropriate statistical analyses were performed, accounting for repeated measurements and normality of values.
**Results:** A total of 35 patients were included: mean age 65.4 (SD 14.8), 69% were male, APACHE II 30.0 (5.4) on admission. Mean clearance dose was 26.3 ml/kg/h (SD 1.0). Mean circuit citrate concentration was 4.2 (0.9) mmol/L of blood (minimum 3.0, maximum 5.5). In 103 measurements (34 at 12 h, 35 at 18 h, 34 at 24 h) a lower Mg loss (1.7 (0.4) mmol/h) than Ca loss (5.1 (0.9) mmol/h) from circuits ($p < 0.001$) was demonstrated. Mg and Ca loss via effluent correlated significantly ($r = 0.622$, $p < 0.001$). Calcium loss was weakly correlated to circuit citrate concentrations ($r = 0.187$, $p = 0.045$). This correlation was not present for magnesium loss.
**Conclusions:** We found a strong correlation between total magnesium and total calcium loss in effluent in ciCVVH (Fig. 1), similar to Zakharchenko's findings for postfilter $Mg^{2+}$ and $Ca^{2+}$ values. However, correlation between circuit citrate concentrations was either weak (in case of calcium effluent loss) or absent (in case of magnesium effluent loss). Calcium and magnesium balance are the product of effluent loss and replacement fluids containing them. Generally, protocols for correction of calcium loss in citrate circuits CRRT are well developed and usually incorporated in commercialized apparatus. However, protocols for magnesium correction seem to be lacking, possibly because in clinical practice total Mg is measured and $Mg^{2+}$ values are generally not available bedside.
In an elegant study, de Jonge et al. used daily measurement of total calcium measured in an effluent sample, together with other beside parameters, to develop a simple mathematical equation to calculate calcium-excretion in the ultrafiltrate during ciCVVH with citrate anticoagulation. The equation included total blood calcium concentrations, total effluent (l/24 h) and blood flow (ml/h). Addition of citrate concentrations did not improve the fit of the model. Our findings suggest that a similar study for magnesium loss in effluent would likely demonstrate similar findings.

**Introduction:** Uncontrolled inflammatory and immune responses frequently contribute to both acute and chronic renal injuries [1]. NETosis occurs when neutrophils decondense their nuclear chromatin and DNA, ultimately ejecting it in a web-like form into the extracellular space. Histones H3 and H4 are major components of nucleosomes which are the major building blocks of neutrophil extracellular traps. NETosis serves as a swift and efficient immunological reaction to mitigate and contain infections. Both basic and clinical research underscore the significance of innate immune cells like neutrophils in the onset and advancement of renal ailments [2].
**Objectives:** We evaluated levels of circulating H3.1 nucleosomes, a surrogate of NETosis, to examine if there was an association between the development of acute kidney injury (AKI) and its severity in patients with confirmed sepsis and septic shock.
**Methods:** This study was a secondary analysis of patients recruited for the SISPCT-trial (which investigated the effect of Sodium Selenite administration and procalcitonin-guided therapy on the mortality of patients with sepsis or septic shock) [3]. A cohort of 881 sepsis patients, including those with either new-onset acute kidney injury (AKI) or no AKI, was examined. AKI severity was categorized based on the maximum elevation of serum creatinine (Scr) levels observed within 7 days of enrolment. Patients with preexisting impaired renal function who did not progress to AKI were evaluated to provide a comparator. H3.1 nucleosome levels were analysed at admission and serially in frozen citrate plasma samples.
**Results:** 881 patients were eligible for inclusion in the study. 67(7.6%) patients developed stage 1 AKI, 28 developed stage 2 AKI (3.2%) and 219 (24.8%) patients progressed to stage 3 AKI. 189 (86%) with stage 3 AKI required RRT. Nu.Q® H3.1 levels were significantly higher in those who developed severe AKI when compared to patients who did not develop AKI. (1151 ng/ml [509–3797] vs 484 ng/ml [216–1127]); ($p < 0.001$). In patients who remained in RRT demonstrated a significant reduction in Nu.Q® H3.1 levels over 7 days compared to patients with AKI 3 who did not require RRT, (1335 pg/ml [604–4165] to 898 pg/ml [447–1778]; ($p < 0.001$) compared to patients with AKI 3 and without RRT (741 pg/ml [242–1362] to 625 pg/ml [399–1166]; $p = 0.924$).
Baseline values of H3.1 levels also differ in patients without evolving AKI but preexisting renal impairment. The more pronounced the reduction in GFR at baseline, the higher the levels of H3.1 at baseline ($p < 0.001$). H3.1 levels at baseline could predict severe AKI ($p < 0.001$). However, in terms of prediction of AKI they are not superior (AUC 0.695) to serum creatinine (AUC 0.755) or the glomerular filtration rate (AUC 0.754).
**Conclusions:** NETosis represent a significant element in the pathogenesis of septic AKI and may serve as an indicator for the immune status in individuals with pre-existing renal conditions. Subsequent investigations are imperative to elucidate the involvement of NETosis in both AKI and chronic kidney disease, facilitating the assessment of potential therapeutic strategies aimed at modulating these mechanisms.

**Introduction:** Posaconazole has a broad antibacterial spectrum and is mainly used for the prevention of systemic fungal infections in children or adults at high risk of invasive fungal disease (IFD), There are three dosage forms of posaconazole, namely oral suspension, enteric coated tablets, and injection. Due to various factors such as gender, weight, race, concomitant use, and drug interactions, the in vivo pharmacokinetic pharmacodynamics (PKPD) of posaconazole, especially its suspension, results in significant variability in blood drug concentrations between individuals. Studies have shown that about 30% of patients receiving posaconazole fail to reach the target of trough concentration > 0.7 mg $L^{-1}$ during the prevention of IFD, and inadequate blood concentration of posaconazole is an independent predictor of breakthrough invasive fungal infections. The prevention of Candida and Aspergillus by Posaconazole is time-dependent, and AUC/MIC can be the optimal PKPD target for Posaconazole antifungal therapy. This article presents a PK/PD study on the prevention of invasive fungal infections in children and adults using two dosage forms of posaconazole, in order to establish a new personalized anti-infection treatment model for critically ill patients with posaconazole.
**Objectives:** To evaluate the predictive ability of the Posaconazole population pharmacokinetic software (Bayesian forecasting process) in Chinese adult and children patients,and to valadate its clinical application effect.
**Methods:** A total of 382 hospitalized adults who were treated with posaconazole in our hospital were selected, including 294 patients who took enteric coated tablets (initial dose of 300 mg q12h, maintenance dose of 300 mg qd) and 88 patients who took suspension (200 mg tid). The concentrations of posaconazole from those patients was collected to develop pharmacokinetic parameters using the posaconazole population pharmacokinetics (PPK) model of NextDose-Posaconazole, and the individualized dose protocols and the predicted concentration–time curves were calculated using the patient information such as age, body weight, et al., according to Bayesian evaluation. The clinical efficacy of the protocols were verified through clinical cases.
**Results:** The average trough concentrations from the adult patients were ($1.61 \pm 0.87$) and ($0.31 \pm 0.20$) μg $mL^{-1}$ for enteric coated tablets and suspension, respectively, from the children patients were ($1.58 \pm 0.86$) and ($0.36 \pm 0.26$) μg $mL^{-1}$ for enteric coated tablets and suspension. The apparent volume of distribution (Vd) predicted by Bayesian forecasting process was ($94.59 \pm 3.24$) and ($94.73 \pm 3.62$) L, respectively; and the clearance rate (CL) was ($3.85 \pm 1.27$) and ($12.90 \pm 2.32$) L $h^{-1}$, respectively using Cavg, ss (1.25 μg·$mL^{-1}$) as the PKPD target in the adult patients; respectively, the apparent volume of distribution (Vd) predicted by Bayesian forecasting process was ($45.22 \pm 15.80$) and ($25.78 \pm 11.47$) L, respectively; and the clearance rate (CL) was ($2.76 \pm 1.10$) and ($6.70 \pm 1.50$) L $h^{-1}$ from the children patients.The trough concentration compliance rate required to reach the standard with Cavg, ss (1.25 μg·$mL^{-1}$) was 99.25% and 16.67%,

respectively. After the dosing regimens were adjusted for patients whose trough concentration does not meet the standard target, the compliance rate increased from 16.67% to 71.43%. The dose regimens predicted by Bayes were applied to patients, and the clinical case validation showed that the efficacy was satisfactory, with no adverse reactions observed.

**Conclusions:** The clinical application of NextDose-Posaconazole based on Bayesian forecasting had positive predictive ability for the individualized dosing regimen of posaconazole in Chinese patients and could help assist clinical individualized application of posaconazole.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000119

**Introduction:** The use of panels based on multiple polymerase chain reaction (PCR) in respiratory samples is widely spreading in intensive care units (ICU). More often, these tests are performed on high-quality samples collected through an invasive high-risk procedure, such as bronchoalveolar lavage (BAL) fluid sampling during fibrobronchoscopy, a technique that critical patients sometimes cannot tolerate.
**Objectives:** Primary objective: To compare sensitivity (S) and negative predictive value (NPV) of BAL, endotracheal aspirate (ETA) and sputum samples.
**Methods:** Retrospective study of a prospective database of 498 lower respiratory samples from critically ill patients with suspected respiratory infection. The BIOFIRE®FILMARRAY® Pneumonia Panel Plus (FA-PP) and conventional culture techniques (CT) (gold standard), were performed on respiratory samples. Six paired analyses (3 sensitivity and 3 NPV), with Bonferroni's correction for multiple comparisons were performed.
**Results:** No statistically significant differences were detected for S ($p = 0.2$) and NPV ($p = 0.73$) between BAL and ETA samples (Table). ETA samples showed significantly higher S ($p < 0.001$) and NPV ($p = 0.002$) than sputum (Table). The S of BAL samples was significantly higher in BAL fluid than in sputum samples, ($p < 0.001$), but showed comparable NPV ($p = 0.01$) after applying Bonferroni's correction.

| | Total (nº) | S (%) | NPV (%) |
|---|---|---|---|
| BAL | 66 | 100 | 100 |
| ETA | 369 | 96,1 | 98,6 |
| Sputum | 14 | 66,7 | 83,3 |

*Concordance table between FA-PP and CT, according to type of sample

**Conclusions:** These results suggest that ETA, being less invasive, provides comparable results to BAL, making it a reasonable choice for molecular testing, particularly in situations where the invasive nature of bronchoalveolar lavage may pose challenges for critically ill patients.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000120

**Introduction:** The International Burn Society (ISBI) recommends early initiation of enteral nutrition in severely burned patients (1). However, it is worth noting that aggressive nutritional support carries potential risks. For example, critically burn patients may suffer from acute colonic pseudo-obstruction (ACPO) due to intestinal peristalsis. In addition, gastrointestinal mucosal edema caused by severe burns may lead to malabsorption of nutrients. The consensus of clinical experts is that gastrointestinal and metabolic problems can result from excessive or inappropriate nutritional support.
**Objectives:** To explore the main factors influencing physicians' decision to initiate adaptive feeding in the early phase of burn management, to promote the early implementation of enteral nutrition that is beneficial for critically ill patients.
**Methods:** A retrospective study analyzed medical data of adult extensive burn patients between January 2009 and December 2020. Patients enrolled in the present study were admitted to the burn department within 24 h after the accident and with a burned area of more than 30% TBSA. Data were divided into two groups: the adaptive feeding group and the fasting group. The total burned area, a full-thickness burned area, burn type, inhalation injury, the start time of adaptive feeding, and the start time of enteral nutrition are the main observation. Outcome measures were 28-day mortality and hospital mortality.

**Results:** In the univariate analysis, there were significant differences in the burn type, TBSA, full-thickness burned area, and inhalation injury for the start time of adaptive feeding (all $P < 0.05$). For linear regression, the results of this analysis revealed that full-thickness burned area and inhalation injury were the main influencing factors for the start time of adaptive feeding in severely burned patients ($P < 0.05$). There was no significant difference in overall mortality, 28-day mortality, length of hospital stay, and the occurrence of gastrointestinal nutrition intolerance between the two groups; however, the start time of enteral nutrition was significantly earlier in the adaptive feeding group ($P < 0.01$). The results of propensity score matching (PSM) showed that although the survival rate was not significantly improved by adaptive feeding, the start time of enteral nutrition in the group of patients receiving adaptive feeding within 24 h of burn injury was significantly earlier than that of the fasting group.
**Conclusions:** This study found that the main influencing factors for physicians to decide between complete fasting or adaptive feeding are the burn area, the size of the full-thickness burned area, and inhalation injury. This study found that early initiation of adaptive feeding as an intervention measure is beneficial for early initiation of enteral nutrition. Because infection and wound coverage are the two major unresolved problems affecting the prognosis of patients with severe burns, the mortality rate of severe patients has not decreased significantly for decades. This explains that initial nutritional therapy with adaptive feeding does not reduce mortality. In conclusion, adaptive feeding in severely burned patients improves nutritional therapy in severely burned patients by shortening the time from injury to initiation of enteral nutrition.

**Introduction:** In haemato-oncological setting, different atypical bacteria & fungus can cause infection due to varied level of immunosuppression caused by cancer & its therapies. Identifying atypical bugs from non-sterile clinical samples may complicate clinical decision making, specially in critically ill patients with organ failure. Non–tuberculous mycobacteria are mostly coloniser & does not require treatment except in rare case scenario. Besides, their treatment protocol involves multiple drugs over long period of time. There are different case series & case reports mentioning 'outbreak' & 'pseudo-outbreak' caused by non-tubercular mycobacteria due to breach in infection control protocols. We identified 9 cases of non- tuberculous mycobacteria from 48 bronchoscopy samples over a span of 3 months.
**Objectives:** Aim of this vertical audit was to identify gaps in infection control protocols while handling fiberoptic bronchoscope in Intensive Care Unit (ICU).
**Methods:** A structure & process audit was planned in ICU in view of a 'microbiological outbreak', starting from bronchoscope log (date of utilisation with patient details), technician involved in the cleaning, cleaning steps (physical cleaning of the scope with RO water, preparation of the disinfectant solution & its usage, review of quality of the disinfectants with dipstick and regular audit of the steps), quality of the water used and training of the technicians and housekeeping staff involved in the cleaning along with review of the current bronchoscope cleaning protocol.
**Results:** All the bronchoscopy related documents during the stipulated time period were reviewed. 48 bronchoscopy specimens were sent for microbiological tests and 9 samples grew non-tuberculous mycobacteria—Mycobacterium simiae (6 cases) and Mycobacterium lentiflavum (3 cases). The disinfectant preparation was suboptimal as the date of preparation and disposal were not documented properly. The rinse water was found to be contaminated with Pseudomonas sp.; but none of the aforementioned patients developed Pseudomonas infection. Discrepancy between disinfectant solution & its quality checking system (dipstick) was observed as both were of different companies/brands with doubtful compatibility. Appropriate size bronchoscope brush for cleaning of the working channels was not available. Based on audit report, flexible bronchoscope disinfection protocol was modified and implemented in critical care unit (Table 1). Adequate hands-on training was done for ICU technicians. Follow up audit for 3 months did not show any positive report. None of the patient had received treatment for atypical mycobacterial infection.
**Conclusions:** Contamination through the semi-invasive airway equipments can be challenging with significant potential clinical impact. Strict vigilance is needed in terms of implementation of disinfection protocols. Proper outbreak evaluation is needed to identify the breach in protocol followed by training.

**Table 1 (abstract 000121)** Cleaning protocol for disposable fiberoptic bronchoscope

| Sl No | Components | Steps |
|---|---|---|
| 1 | Physical cleaning of bronchoscope after procedure | Remove of all the visible contamination and blood clots and emerge in clean (RO) water; flush thoroughly all the lumens of the scope |
| 2 | Enzymatic cleaning solution & brush | Flush all the lumen with "jet flush" with enzymatic cleaning solution to remove all kinds of organic materials. It is followed by thorough cleaning of all the lumen with reusable brush<br>Wipe and make it dry |
| 3 | Glutaraldehyde solution<br>Alternate option - 0.23% peroxyacetic (peracetic) acid | Bronchoscope to be immersed in 2.45% glutaraldehyde solution for 30 minutes<br>Supervised preparation of glutaraldehyde solution with regular quality check of the solution (e.g., Cidex test) at regular time interval – maximum life span of the solution 14 days (date & time of preparation to be marked)<br>Through cleaning with RO water – outside and of all lumens |
| 4 | ETO sterilisation | Send for ETO sterilisation<br>Keep in dedicated bronchoscope cupboard |
| 5 | Documentation | Maintain detail registry of the patients and with no of usage of the scope |
| 6 | Policy | Written policy should be present regarding Cleaning and usage of disposable fiberoptic bronchoscope (with document control)<br>Regular training and teaching of stakeholders<br>Regular audit of protocol compliance |

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000123

**Introduction:** Tracheostomy is performed in approximately 10%-15% of patients who are admitted to Intensive Care Units (ICU). Both surgical and percutaneous techniques are widely used, with a trend toward fewer complications and costs in percutaneous techniques. There are emergent and elective indications for tracheostomy, including facilitation of weaning from mechanical ventilation (MV), improving patient safety and comfort, and reducing overall costs of care. Despite several studies on the benefits of early versus late tracheostomy, the optimal timing is not well established, with some authors indicating that tracheostomy should be performed after 21 of intubation.
**Objectives:** All the tracheostomies in our Centre were performed using a surgical technique, after a referral to Ears Nose and Throat (ENT) Surgery, with the need to schedule an operating theatre. Our primary endpoint was to evaluate the number of days needed for weaning from MV after tracheostomy. The secondary endpoints included the evaluation of the timing the tracheostomy was performed, days for ICU discharge after the procedure and mortality.
**Methods:** We conducted a retrospective analysis of adult patients who underwent elective tracheostomy for facilitation of wean from MV during their admission to our ICU between January 2012 and December 2022. Data were collected from the local database and were analyzed using IBM SPSS software.
**Results:** Among 2736 patients admitted to ICU, 46 surgical tracheostomies were performed (2%). The average age was 68 years old, 54% of the patients were males and 46% were females. The average SAPS II was 58.2 (SD 16) with a predicted mortality of 64%. The referral for ENT Surgery was made on average after 18 days of intubation (SD 11.7) with tracheostomy performed after 22 days of intubation (SD 13.7). On average, patients were free of MV after 2.39 days of the tracheostomy (SD 2) and discharged from the ICU after 5 days of the procedure (SD 2.9). There was a strong correlation between the number of days of intubation before tracheostomy and the total days of MV (Pearson's $R$ 0.98, $p$-value < 0.01, CI 99%) and between the number of days of intubation before tracheostomy and the total ICU stay (Pearson's $R$ 0.93, $p$-value < 0.01, CI 99%). The number of days of intubation doesn't seem to be correlated with the number of days needed for MV weaning after tracheostomy (Pearson's $R$ 0.1) and with the number of days needed for ICU discharge after tracheostomy (Pearson's $R$ 0.2). The observed mortality at day 30 was 33%. 63% of the patients were fit for Hospital discharge. Early tracheostomy (before day 21) wasn't associated with increased mortality.
**Conclusions:** We observed that tracheostomy led to a fast liberation of MV, allowing ICU discharge with a high Hospital discharge rate, independently of the previous number of days of intubation, without an increase in mortality. The data showed a delay between the referral to ENT Surgery and the procedure, with an increase in the number of MV days, ICU stay, and risks and costs associated with prolonged MV. According to the data obtained, we performed a change in our local tracheostomy protocol, starting to perform a percutaneous technique.

### Appropriateness of respiratory physiotherapy positioning for acute lobar collapse

L. Hansell[1], M. Milross[1]; G. Ntoumenopoulos[2]
[1]Sydney School of Health Sciences, Faculty of Medicine and Health, The University of Sydney, Camperdown, Australia; [2]Department of Intensive Care, St Vincent's Hospital Sydney, Darlinghurst, Australia

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000126

**Introduction:** The primary role of a physiotherapist in mechanically ventilated patients with acute lobar atelectasis (ALA) is to optimize lung recruitment. This is achieved through the delivery of a range of treatment modalities, aimed at recruiting collapsed lung regions [1–3]. Positioning is an important part of a physiotherapist's respiratory treatment repertoire, as it works to increase lung volumes, improve V/Q matching and promote secretion clearance to achieve lung re-recruitment. Typically, the affected or more affected lung is positioned uppermost to achieve re-recruitment [4–7]. Physiotherapists rely on traditional assessment tools like lung auscultation and interpretation of chest radiographs to inform treatment selection. These tools lack diagnostic accuracy [8–11]. which could limit the ability of a physiotherapist to select appropriate treatments, including selecting the correct position to target lung regions affected by ALA. Lung ultrasound

(LUS) is an emerging technology for use by physiotherapists in the intensive care setting. It has high diagnostic accuracy 8–11 and can be used as a monitoring tool to detect lung aeration change [11]. The addition of LUS to physiotherapy respiratory clinical assessment could more accurately locate treatable ALA and aid in the selection of more appropriate respiratory physiotherapy positioning treatments for patients in the ICU setting [12,13].
**Objectives:** (1) To determine the number of clinical physiotherapist treatment positions found to be in agreement with LUS identified aeration loss; (2) To determine the diagnostic accuracy of CXR and lung auscultation against lung ultrasound as the reference standard, for the identification of location of aeration loss in mechanically ventilated patients with ALA.
**Methods:** This prospective cohort study was conducted in a tertiary teaching hospital in Sydney. Mechanically ventilated adult patients in intensive care (ICU) with ALA were included. Clinical physiotherapists selected standard care respiratory treatment positions based on clinical assessment, which included lung auscultation, interpretation of chest radiograph and physiological measures. Treatment positions selected were recorded. LUS was performed before and following treatment delivery using a standardized scanning protocol, with the location of lobar pathology detected on LUS also recorded. The clinical physiotherapist was blinded to LUS Results: Positioning as selected by the clinical physiotherapist was compared against the location of pathology from LUS Results: Respiratory physiotherapy treatment position selection was considered appropriate if the position chosen by the clinical physiotherapist targeted the affected lung with pathology as identified on LUS.
**Results:** 43 participants were included in this study. A majority of patients had bilateral lung aeration loss (88.4%). Only 3 of the 38 patients with bilateral lung pathology were treated in the appropriate alternate side-lying position. None of the 3 patients with a unilateral right lung pathology were positioned appropriately. One of the two patients with unilateral left lung pathology was positioned appropriately. Overall, 4 out of 43 patients (9.3%) were positioned appropriately when clinical physiotherapist position selection was compared against LUS Results: The rate of true positives for CXR and auscultation were highest in the lower lobes. Lung auscultation had higher sensitivities, positive predictive values and likelihood ratios (16.7–97.4%, 7.1–90.5%, 0.47–1.44) than CXR (0–59.5%, 0–95.7%, 0–2.59) in a majority of lobes when detecting lobe location of aeration loss when compared against LUS. CXR had higher specificities and negative predictive values (16.7–100%, 6.3–88.4%) than lung auscultation (0–64.9%, 0–88.9%) in a majority of lobes when detecting lobe location of aeration loss when compared against LUS.
**Conclusions:** Physiotherapists did not deliver appropriate positioning in mechanically ventilated patients with ALA in a majority of cases. The diagnostic accuracy of lung auscultation and CXR in detection of the location of aeration loss associated with ALA is low when compared with LUS. Correctly locating lung aeration loss is essential in ensuring appropriate respiratory physiotherapy positioning treatment selection. Given the low discriminatory ability of lung auscultation and CXR in locating aeration loss, physiotherapists should be considering additional assessment tools like LUS to increase their diagnostic ability.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000129

**Introduction:** Evaluating the prognosis of COVID-19 patients who may be at risk of mortality using the simple chest X-ray (CXR) severity scoring systems provides valuable insights for treatment decisions.
**Objectives:** This study aimed to assess how well the simplified Radiographic Assessment of Lung Edema (RALE) score could predict the death of critically ill COVID-19 patients in Vietnam.
**Methods:** We performed a retrospective observational study of critically ill COVID-19 adult patients presenting at an intensive care centre in Vietnam from July 30 to October 15, 2021. We calculated the areas under the receiver operator characteristic (ROC) curve (AUROC) to determine how well the simplified RALE score could predict hospital mortality. In a frontal CXR, the simplified RALE score assigns a score to each lung, ranging from 0 to 4. The overall severity score is the sum of points from both lungs, with a maximum possible score of 8. We also utilized ROC curve analysis to find the best cut-off value for this score. Finally, we utilized logistic regression to identify the association of simplified RALE score with hospital mortality.
**Results:** Of 105 patients, 40.0% were men, the median age was 61.0 years (Q1–Q3: 52.0–71.0), and 79.0% of patients died in the hospital. Most patients exhibited bilateral lung opacities on their admission CXRs (99.0%; 100/102), with the highest occurrence of opacity distribution spanning three (18.3%; 19/104) to four quadrants of the lungs (74.0%; 77/104) and a high median simplified RALE score of 8.0 (Q1–Q3: 6.0–8.0). The simplified RALE score (AUROC: 0.747 [95% CI: 0.617–0.877]; cut-off value $\geq$ 5.5; sensitivity: 93.9%; specificity: 45.5%;

PAUROC < 0.001) demonstrated a good discriminatory ability in predicting hospital mortality. After adjusting for confounding factors such as age, gender, Charlson Comorbidity Index, serum interleukin-6 level upon admission, and admission severity scoring systems, the simplified RALE score of ≥ 5.5 (adjusted OR: 18.437; 95% CI: 3.215–105.741; $p = 0.001$) was independently associated with an increased risk of hospital mortality.
**Conclusions:** This study focused on a highly selected cohort of critically ill COVID-19 patients with a high simplified RALE score and a high mortality rate. Beyond its good discriminatory ability in predicting hospital mortality, the simplified RALE score also emerged as an independent predictor of hospital mortality. For pinpointing those most at risk of progressing and dying among critically ill COVID-19 patients, the simplified RALE score can be utilized effectively.

### Effectiveness of carbon dioxide per-conditioning before recanalization in hyperacute ischemic stroke rat model

J. W. Jung[1], E. Y. Chung[2], Y. D. Kim[2], J. H. Heo[2], H. S. Nam[2]

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000134

**Introduction:** Recent research has increasingly focused on the clinical use and neuroprotective effects of mild hypercapnia; however, its efficacy in ischemic stroke remains unclear.
**Objectives:** We aimed to investigate whether carbon dioxide ($CO_2$) per-conditioning reduced oxidative stress, blood–brain barrier breakdown, and neurologic deficit in a rat model of middle cerebral artery occlusion (MCAO).
**Methods:** Rat models received intermittent inhalation of mixed gas (20% CO2, 20% O2, 60% N2) or room air during the MCAO period. After the surgery, arterial blood gas analysis and behavior test were conducted, and animals were euthanized for calculating infarct size, western blot analysis, and immunohistochemistry.
**Results:** Our results showed that CO2 per-conditioning reduced infarct size and neurological deficit. The number of 8-hydroxy-2-deoxyguanosine (8-OHdG) positive cell and matrix metalloproteinase 9 (MMP-9)/platelet derived growth factor receptor beta (PDGFR double positive cell expressions were significantly decreased after CO2 per-conditioning. The expression of tight junction protein and PDGFR were significantly elevated after CO2 per-conditioning.
**Conclusions:** This study underscores that $CO_2$ per-conditioning not only protects the ischemic penumbra from ischemia–reperfusion injury, thereby diminishing neurologic deficits, but also maintains the integrity of the blood–brain barrier and neurovascular unit, alongside mitigating oxidative stress in a hyperacute stroke rat model. $CO_2$ per-conditioning in the acute ischemic stroke appears to hold significant potential and warrants additional investigation for its clinical application.

**Introduction:** Living donor liver transplantation (LDLT) has become a viable alternative to deceased-donor transplantation (DDLT). Enhanced recovery after surgery (ERAS) protocols that include early extubation contribute to the short-term benefits, but the impact of immediate extubation in the operating room (OR) on long-term outcomes in LDLT patients remains unexplored.
**Objectives:** This study aimed to investigate whether immediate extubation in the OR is associated with long-term overall survival (OS) in patients undergoing LDLT.
**Methods:** This retrospective cohort study included 205 LDLT patients. Patients were categorized based on extubation location: operating room (OREX) or intensive care unit (NOREX). Primary outcomes focused on overall survival (OS), with secondary outcomes encompassing length of ICU and hospital stays, and various postoperative outcomes.

**Results:** Among 277 patients, 72 were excluded, and finally 205 were included in the present study (Fig. 1). 98 (47.8%) patients were extubated in the OR after LDLT. Logistic regression analysis revealed that extubation in the OR significantly reduced the incidence of 30-day composite complications (OR: 0.32, 95% CI: 0.17–0.61, $P<0.001$) Also, postoperative hospital stay, ICU stay, and duration of mechanical ventilation in the ICU were significantly shorter in the OREX group. Extubation in the OR was not an independent factor associated with OS on univariate analysis (HR: 0.50, 95% CI: 0.24–1.05, $P=0.066$). In the multivariate analyses, preoperative platelet (HR: 1.01, 95% CI: 1.00–1.01, $P=0.012$), preoperative creatinine (HR: 2.15, 95% CI: 1.12–4.13, $P=0.021$), and duration of surgery (HR: 1.20, 95% CI: 1.010–1.43, $P=0.037$) were associated with worse OS (Fig. 2). The Kaplan–Meier curve showed that the 5-year OS rates were higher in patients of OREX group than those of NOREX group [OREX: 91.3% (95% CI: 85.7–97.3), NOREX: 81.0% (95% CI: 73.6–89.1)] (Fig. 3).

**Conclusions:** In LDLT surgery, immediate extubation in the OR reduced 30-day composite complications, and shortened ICU and hospital stays, although this beneficial effect did not improve overall survival compared with extubation in the ICU.

## Comparison of core temperature using tracheal thermometer and pulmonary artery catheter in adult patients undergoing coronary artery bypass graft surgery

J. U. Yoon[1], J. P. Yoon[1], H. J. Kim[1], A. Yi[1], D. E. Lee[1], S. W. Shin[1]

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000138

**Introduction:** Core temperature is an important parameter for patients under anesthesia. The monitoring of esophageal and pulmonary artery blood temperature can be used for core temperature measurement in general anesthesia. However, these methods are challenging during cardiac surgeries involving transesophageal echocardiography (TEE) and cardiopulmonary bypass (CPB). An endotracheal

tube with a thermometer on the cuff allows for the measurement of tracheal temperature, which can be a suitable alternative to core temperature measurement.

**Objectives:** The aim of this study is to assess the clinical reliability and accuracy of the thermometer in the endotracheal tube in comparison to the core temperature measured using a pulmonary artery catheter.

**Methods:** Eleven patients who underwent coronary artery bypass graft (CABG) surgery were enrolled. The patients were intubated using an endotracheal tube equipped with a thermometer on the cuff, and a pulmonary artery catheter was also inserted. Temperature measurements of both the trachea and pulmonary artery blood were recorded at five-minute intervals for one hour before starting the cardiopulmonary bypass. The agreement between the two temperature measurement methods was investigated using the Bland–Altman method, and the correlation was evaluated using the concordance correlation coefficient (CCC).

**Results:** A total of 11 patients, with a total of 143 pairs of data included for analysis. The agreement between the tracheal and pulmonary artery temperature measurements using the ETT thermometer and PAC, was found to be significant. The mean difference between the tracheal and pulmonary artery temperatures was − 0.10 ℃. The 95% limit of agreement (LoA) calculated as ± 1.96 standard deviations (SD) ranged from − 0.34 ℃ to 0.14 ℃. The 95% confidence interval (CI) for the lower and upper LoA was − 0.38 ℃ to − 0.31 ℃ and 0.11 ℃ to 0.18 ℃, respectively (Table 1). These values indicate the range within which most temperature differences between the two methods fell. Additionally, the maximum allowed difference (Δ) was set at 0.5 ℃. Since the majority of temperature differences fell within the LoA and were well below the maximum allowed difference, it suggests a good agreement between the two measurement methods (Fig. 2). Furthermore, the concordance correlation coefficient (CCC) was 0.95, it means a substantial strength of agreement (Fig. 3).

**Table 1 (abstract 000138)** The differences between tracheal and pulmonary artery temperatures

| | **TT vs. TP** |
|---|---|
| Mean differences, ℃ (95% confidence interval) | − 0.10 (− 0.12 to − 0.08) |
| Lower limit of agreement, ℃ (95% confidence interval) | − 0.34 (− 0.38 to − 0.31) |
| Upper limit of agreement, ℃ (95% confidence interval) | 0.14 (0.11 to 0.18) |
| Concordance correlation coefficient (CCC) | 0.95 |

**Conclusions:** The agreement between the tracheal and pulmonary artery temperature measurements using the endotracheal tube thermometer and pulmonary artery catheter was found to be clinically reliable and accurate. This indicates that the tracheal temperature measurement can effectively represent the core temperature of the patients. The use of an endotracheal tube equipped with a thermometer on the cuff can be a good alternative and standalone method for measuring core temperature.

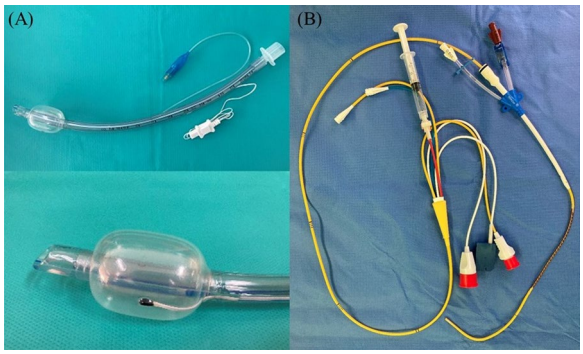

**Fig. 1 (abstract 000138)** (A) Endotracheal tube equipped with a thermometer on the cuff. (B) Pulmonary artery catheter with a 9 French central catheter

**Fig. 2 (abstract 000138)** Bland–Altman plot. The maximum allowed difference (Δ) was set at 0.5 ?. Since the majority of temperature differences fell within the LoA and were well below the maximum allowed difference, it suggests a good agreement between the two measurement Methods: *TT*, tracheal temperature; *TP*, pulmonary artery temperature; SD, standard deviation

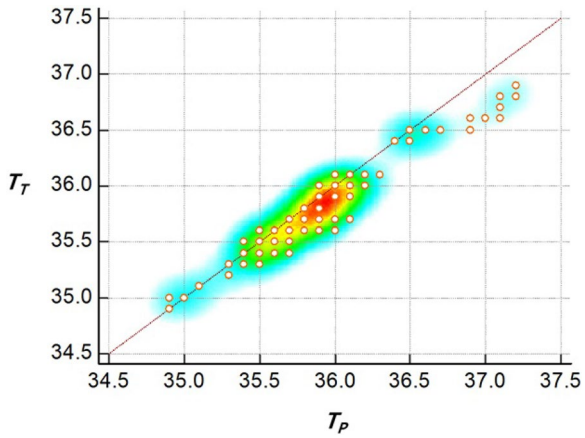

**Fig. 3 (abstract 000138)** Scatter diagram for concordance correlation coefficient. The concordance correlation coefficient (CCC) was 0.95, it means a substantial strength of agreement. *TT*, tracheal temperature; *TP*, pulmonary artery temperature; Red colors, high incidence levels; Blue colors, low incidence levels

### Effect of propofol on the osteogenic differentiation of human dental pulp stem cells under inflammatory conditions

J. U. Yoon[1], H. J. Kim[1], D. E. Lee[1], A. Yi[1], S. W. Shin[1], J. P. Yoon[1]

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000139

**Introduction:** Human dental pulp stem cells (hDPSCs) has recently been in the spotlight as an attractive tool for bone tissue regeneration. While bone marrow-derived MSC collection was invasive, hDPSC collection has the advantage of being easy and minimally invasive because it can be collected from discarded premolars or third molars. Propofol is an intravenous anesthetic commonly used in dental sedation and it has anti-inflammatory property. However, there have been no studies on propofol in pulp inflammation.
**Objectives:** The purpose of this study was to investigate the effect of propofol on the osteogenic differentiation of hDPSCs induced by lipopolysaccharide (LPS) and tumor necrosis factor-alpha (TNF-α) in vitro.
**Methods:** The concentration of propofol (10, 50, and 100 μM) was treated at cultured cells. For osteogenic differentiation, hDPSCs were cultured with osteogenic differentiation medium (ODM, 10 mM β-glycerophosphate, 0.1 mM ascorbic acid, and dexamethasone 100 nM) for 4, 7, 14, and 21 days. The cytotoxicity and proliferation of propofol on hDPSCs were measured using the MTT assay. Alkaline phosphatase (ALP) staining, Alizarin Red S (ARS) staining, RT-PCR, and Western blot were performed to investigate the effects of propofol on the osteogenic differentiation and mitogen-activated protein kinases (MAPK) pathway of hDPSCs inflamed with LPS and TNF-α. Data were obtained from at least three independent experiments performed in triplicate. To analyze statistical significance, student's t-test was used and $P < 0.05$ was considered significant.
**Results:** LPS and TNF-α significantly decreased the mRNA expressions of ALP, Runx2, OPN, BMP2, and DMP1 compared to ODM group at 7 and 14 days. And these downregulation of mRNA expressions were inhibited significantly by propofol (100 uM) at 7 and 14 days. The protein expression levels of ALP, Runx2, OPN, BMP2, and DMP1 were significantly decreased by LPS and TNF-α compared to the levels in the ODM group at 14 days. 100 uM propofol significantly increased the protein expression of osteogenic-related genes compared to LPS and TNF-α group in hDPSCs at 14 days. LPS and TNF-α treatment significantly decreased the ALP staining compared to ODM group at 4 and 7 days and all concentrations of propofol (10, 50, and 100 uM) significantly increased ALP staining compared to LPS and TNF-α group at 4 and 7 days. 100 uM propofol on LPS and TNF-α-treated hDPSCs significantly decreased the relative protein level of p-ERK/ERK and p-JNK/JNK compared to LPS and TNF-α group. Whereas relative protein level of p-p38/p38 was significantly increased by LPS and TNF-α compared to ODM group and this increase was strengthened by propofol (Fig. 1).
**Conclusions:** Propofol promotes osteogenic differentiation in inflammation induced hDPSCs through enhanced p38 MAPK activation, It suggests that propofol can enhance bone regeneration.

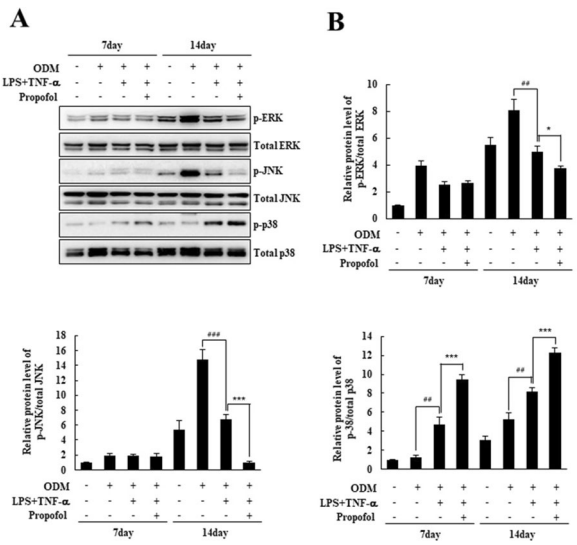

**Fig. 1 (abstract 000139)** 100 uM propofol on LPS and TNF-α-treated hDPSCs significantly decreased the relative protein level of p-ERK/ERK and p-JNK/JNK compared to LPS and TNF-α group. Whereas relative protein level of p-p38/p38 was significantly increased by LPS and TNF-α compared to ODM group and this increase was strengthened by propofol

### Diagnostic ussefulness of the multiplex PCR panel in critical patients with bacteremia

M. Rodríguez-Gómez[1], M. Calle-Romero[1], S. Domingo-Marín[1], S. De Miguel-Marín[1], F. González-Romo[2], C. González-Corralejo[2], P. Montaña-Díaz[1], V. Yordanov Zlatkov[1], F. Martínez-Sagasti[1]

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000140

**Introduction:** Early appropriate antimicrobial treatment impacts the prognosis of patients with primary or secondary bacteremia. There is ample experience in the use of rapid diagnostic tests like the multiplex PCR in respiratory infections, which shows good concordance with conventional culture. The use of these rapid techniques in bloodstream infection might improve the treatment.
**Objectives:** Primary objective: To analyze the concordance in blood cultures between the BioFire® BCIR2 Panel and conventional blood culture (CBC).
Secondary objectives: To determine the prevalence of pathogens isolated in CBC not detected by the BCIR2 panel and recording the difference in the timing of both results.
**Methods:** Retrospective study of a prospective database of blood samples from patients admitted to intensive care unit with suspected bacteremia. Upon automated detection of growth in blood cultures, multiplex PCR and CBC (gold standard) were simultaneously performed. Sensitivity (Sen), specificity (Spe), positive (PPV) and negative predictive values (NPV) of rapid techniques were calculated. Pathogens isolated in culture not detected by BCIR2 are described, and the difference in the timing of the final results of both test are analyzed.
**Results:** A total of 28 blood cultures were investigated. The median age was 67 (1st IQR 57–3rd IQR 73), 57.1% males, and secondary bacteriemias in 71.4%. We obtained 100% S, E, NPV, and PPV for the rapid test in all cases. However, in three instances, the culture provided additional information. In two cases, microorganisms not included in the panel, grew in CBC: *Fusobacterium necrophorum* and *Clostridium jeddahitimonense*, and in one case, the microorganism detected by BCIR2 had ampC, a resistance mechanism not included in the panel. The median time to obtain definitive results from CBC was 5 days (1.3), while BCIR2 requires 1 h to analyze the sample.
**Conclusions:** This study reveals excellent concordance between the BioFire® BCIR2 Panel and CBC in blood cultures of critically ill patients with bloodstream infection, yielding accurate results in 1 h. Although the rapid test showed 100% sen and spe, there were cases where the culture provided additional information about microorganisms or resistance mechanisms not included in the panel. This underscores the importance of considering results comprehensively and the complementarity usefulness between diagnostic techniques.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000142

**Introduction:** Early microbiological diagnosis improves outcomes in bacteremia for timely and effective treatment, particularly in critically ill patients. Multiple PCR panel allows early targeted antibiotics prescription. Timely diagnostics also promote antimicrobial stewardship by preventing unnecessary broad-spectrum treatments.
**Objectives:** Primary Objective: To describe prescription behavior in response to the results of the BioFire® BCIR2 Panel in blood cultures.
Secondary Objective: To determine the incidence of multi-drug resistant bacteria in blood cultures.
**Methods:** Retrospective study of a prospective database of blood samples from patients admitted to intensive care with suspected bacteremia. Upon automated detection of growth in blood cultures, a multiplex PCR (BCIR2) was applied. Rapid test results were provided to attending intensivists and modifications of antibiotic therapy were documented. These were categorized as "escalation", "de-escalation", or "no modification" for cases already on antibiotic therapy, and "initiation" versus "no initiation" for those not on antibiotics before the rapid test was performed.
**Results:** 28 blood cultures were available for analysis. In the 23 cases receiving antibiotic therapy, 6 (26.1%) were de-escalated, 8 (34.8%) were escalated, and in 9 (39.1%) no modification was performed. In 5 cases not receiving antibiotics, directed therapy was started in 4 (80%) and not prescribed in one instance (labelled as catheter infection rather than bacteremia).
In total, antibiotic therapy was modified in 64.3% of the cases. Antibiotic therapy was changed as a result of the information provided by the rapid test in 71.4% of cases, in 21.4% of cases to cover for other concomitant infections, and in 7.1% to cover for microorganisms or resistance genes not included in the panel. Risk factors for multidrug resistant bacteria (MRB) were present in 71.4% of the sampled patients, but only in 21.4% MRB were documented by BCIR2. The resistance mechanism was VIM-type carbapenemase in all cases.
**Conclusions:** The implementation of a multiplex PCR in blood cultures provides information supporting timely targeted therapy in critically ill patients with bacteremia and avoids inappropriate treatment. It is essential to remember that not all potential pathogens or resistance mechanisms causing bacteremia are included by the panel.

### Early Urinary Output as a Prognostic Marker in Cardiogenic Shock: Highlighting the Importance of the Golden Hours

S. Markart[1], G. Klemm[1], A. Hermann[2], T. Staudinger[2], G. Heinz[1], R. Zilberszac[1]

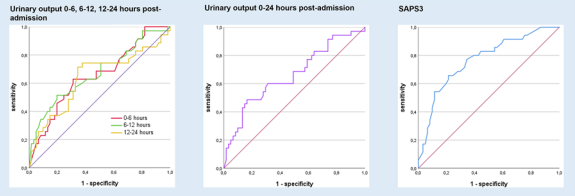
**Correspondence:** S. Markart
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000143

**Introduction:** Mortality remains high in Cardiogenic shock (CS). Besides early revascularization, other interventional strategies have not demonstrated convincing survival benefits and a relevant number of cases is not caused by acute myocardial infarction (AMI). Identifying patients who can benefit from certain therapies remains challenging and therapeutic decisions must be based on reliable prognostic markers that are readily available early on. Many of the mortality-related predictive parameters or their combinations only partially meet these requirements. In contrast to quantifying acidotic conditions due to hypoperfusion, fluid balance has been analyzed sparsely.
**Objectives:** Prognostic value of routinely taken urinary output (UO) within the first 24 h post-admission for in-hospital mortality in CS regardless of etiology.
**Methods:** Retrospective registry data were analyzed, containing data from admissions between 01/2017 and 12/2019 of two tertiary care Intensive Care Units (ICU). Among 847 patients, 96 met the criteria for CS and had UO documented completely within the first 24 h. Exclusion criteria included age under 18, pregnancy, and attempted suicide. Mean UO (ml per hour) for time periods 0–6, 6–12, and 12–24 h after admission were analyzed using univariate logistic regression models, Areas Under the Receiver Operating Characteristics Curve (AUROC) calculated and compared using the DeLong test.
**Results:** 71.9% of patients were male. Median age was 68 years in the deceased group and 63 years in the survivors. In-hospital mortality was 36.5%. CS was AMI-related in 45.8%. Median Simplified Acute Physiology Score 3 (SAPS3) was 81 points in the deceased group and 66 points among survivors. 35.4% underwent extracorporeal membrane oxygenation therapy during their stay. UO at 0–6 h, 6–12 h, and 12–24 h post-admission and the SAPS3 score were significant predictors of mortality in univariate logistic regression. AUROCs for UO parameters were similar across the first 24 h, as was the mean UO of 0–24 h, and lower compared to SAPS3. In exploratory multivariate models with SAPS3 and each UO parameter alone, only the average UO 6–12 h post-admission remained significant.
**Conclusions:** UO demonstrates notable potential for predicting in-hospital mortality in CS patients, particularly in the critical initial 6 to 12 h following admission. This finding underscores the importance of early hours after the onset of shock for determining and potentially improving patient outcomes. Although the SAPS3 score provides a more thorough evaluation, its application in acute settings is challenged by its complexity and the interpretational variability associated with some of its components. Accordingly, our study suggests that reevaluating straightforward, early and readily available predictors like UO is warranted.



AUROCs regarding in-hospital mortality for tested urinary outputs (ml/hour), total urinary output over 24 h post-admission (ml/hour) and SAPS3, reference line for area under the curve (AUC) 0.5; exact AUCs with 95% confidence intervals (CI) stated below:

— UO 0-6h AUC 0.65 (95% CI 0.54–0.77);
— UO 6-12h AUC 0.67 (95% CI 0.56–0.79);
— UO 12-24h AUC 0.64 (95% CI 0.52–0.76);
— UO 0-24h AUC 0.66 (95% CI 0.54–0.78);
— - SAPS3 AUC 0.77 (95% CI 0.67–0.87)

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000147

**Introduction:** Sepsis and septic shock is a leading cause of mortality in the intensive care unit. Promising new therapies continue to be investigated for the management of septic shock. Specific adsorption therapies use membranes with the ability to retain and/or elim#inate molecules directly involved in the pathogenesis of sepsis. They are membranes aimed at removing endotoxin, molecular patterns, and cytokines, or both. Membranes that mainly eliminating the endotoxin, cytokinesor the bacteria themselves.We tried to evaluate a novel Adsorban through a retrospective evaluation of patient's data in our centre. We used it as an adjuvant therapy in our patients with septic shock due to varied causes.
**Objectives:** The aim of this study was to evaluate the efficacy of therapeutic Adsorban in the management of patients with septic shock. In this study, we aimed to present the effect of Adsorbent therapy, which is still being discussed in the treatment of septic shock, on renal recovery and mortality with our results.
**Methods:** We retrospectively analysed data of **S**eptic shock between 2022 to 2023 had received Adsorban as adjuvant therapy along with standard of care. Patients included in the study were diagnosed according to The Third International Consensus Definitions for Sepsis and Septic Shock (Sepsis-3).In this retrospective study, patients diagnosed with septic shock and receiving CRRT treatment were divided into two groups: septic shock-oxiris and septic shock-adsorbent. A rapid decrease in PCT, WBC and CRP was achieved in both groups. Additionally, the need for NE decreased in both groups and patients. Demographic data, procalcitonin, CRP and leukocyte levels before and after therapeutic cytokine removal and duration of Adsorban application were recorded.
**Results:** 500 patients were screened in the last year. The data of 12 patients who received Adsorbent Treatment from 2500 patients were accessed.After the adsorbent treatment, the fever of the patients

decreased and the need for antipyretic decreased. White blood cell and PCT values were found to be low in all patients who received adsorbent treatment. Decreases in the hourly vasopressor drug needed by the patients were detected, but it was not statistically significant. After CRRT, an increase in urine output was observed at the end of an average of 12 h, and creatinine values decreased after hours.
**Conclusions:** Although blood purification is a controversial issue in septic shock patients, its use in patients is becoming increasingly common. There are no guidelines for the use of different membranes such as adsorbent or oxiris with CRRT. However, removing cytokines and bacterial products from the blood will definitely have positive effects. However, when these treatments are started late in patients, their effect on survival does not seem to be positive. In our study, we found that the need for NE decreased along with the decrease in PCT, CRP and WBC in adsorbent and oxiris.

**Introduction:** Whilst the ideal protein provision to ICU patient remains uncertain, the European Society for Clinical Nutrition and Metabolism (ESPEN) guidelines recommend 1.3 g/kg/day to be delivered progressively to ICU patients [1]. For obese patients (Body Mass Index, BMI > 30); the recommended protein provision is 2 g/kg/day ideal body weight (IBW) [1]. Hartl et al. [2] divides protein provision into low (< 0.8 g/kg per day), medium (0.8–1.2 g/kg/day), and high (> 1.2 g/kg/day) [2]. More evidence for ideal protein provision in ICU is needed as current evidence stems from small observational studies. The effect of higher protein dosing in critically ill patients with high nutritional risk (EFFORT protein) randomised controlled trial (RCT) [3] compared standard protein doses to higher protein doses (1.2 g/kg/day vs > 2.2 g/kg/day or more). The EFFORT RCT did not demonstrate statistical difference in the primary outcome which was incidence of time to discharge alive.
**Objectives:** The aim of this project was to establish the protein provision in PN prescribed to ICU patients in UHS.
**Methods:** The project was registered as a service evaluation (SEV/0667) with need for full ethics approval waived. Data was retrieved from the pharmacy preparation suite details of patients who were fed by the parenteral route and were deemed to be meeting their full calorific requirement. Patients were categorised by their BMI / protein requirements.
For patients with a BMI ≤ 30, patients were categorised into low/medium and high protein provision as per Hartl et al. [2], with the expectation that they would be provided ≥ 1.2–1.3g/kg/day (which is the recommendation from the ESPEN guidelines on critical care nutrition [1]).
For patients with a BMI > 30, their IBW was calculated, to determine if they received ≥ 2 g/kg/day protein of their IBW.
**Results:** Data on protein provision was retrospectively collected from 50 patients. Of the 50 patients reviewed, 34 had a BMI of ≤ 30. The results reported that of these 34 patients:

- 6 (17%) met the provision of more than 1.2 g/kg protein per day.
- 27 (80% of the 34) received protein amounts in the "medium" category i.e., between 0.8–1.2 g/kg/day
- 1 patient (3% of the 34) was in the low protein provision category (less than 0.8 g/kg/day).

None of the patients who had a BMI > 30 met the recommendation from the ESPEN guidelines to provide 2g/kg/day IBW.
ESPEN guidelines recommend that for critically ill patients, protein is delivered at 1.3 g/kg/day progressively; out of the 34 patients with a BMI ≤ 30, 2 (6%) were provided with ≥ 1.3g/kg/protein per day.
**Conclusions:** This retrospective observational review established that patients receiving PN at UHS did not typically meet the recommendation from ESPEN to provide ≥ 1.3 g/kg protein per day; less than 1 in 5 patients were provided the recommended protein advised by international nutrition guidelines and unfortunately no patients with a BMI > 30 met their protein required. Further work should focus on enhancing protein provision for ICU patients at UHS, especially in patients with a BMI > 30.

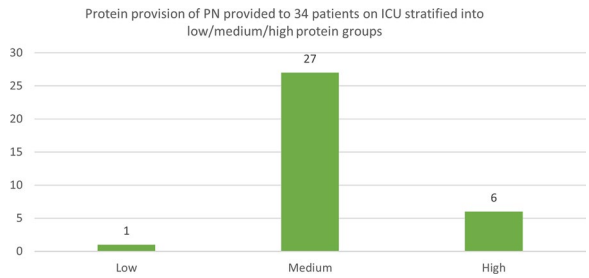

**Fig. 1 (abstract 000138)** Proportion of 34 patients (out of the 50 reviewed, that had a BMI of less than 30), and provision of protein through PN. Defined as per Hartl et al. as low (less than 0.8g/kg protein per day), medium (0.8–1.2g/kg protein per day), and high (> 1.2g/kg protein per day) protein provision

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000149

**Introduction:** LMA ProSealTM has been in use for a long time and has stood the test of time. LMA ProtectorTM promises high oropharyngeal leak pressures and gastric access like LMA ProSeal. It is a composite of various supraglottic devices; it has a preformed curved shaft like LMA FastrackTM, LMA SupremeTM and LMA AuraGainTM, it is a single use device like LMA SupremeTM and LMA UniqueTM. Besides, LMA ProtectorTM has two unique features: a dual gastric port and an in-built intracuff pressure monitor.
We found sparse literature with LMA protector and there are only a few research papers comparing LMA Protector with its similar cousin LMA ProSeal and their results are contrary with respect to oropharyngeal leak pressures.
**Objectives:** We undertook this study with the primary objective to determine and compare the oropharyngeal leak pressures (OLP) of LMA ProsealTM and LMA ProtectorTM and secondary objective of determining the insertion characteristics of the two devices and postoperative symptoms of sore throat in patients undergoing surgical procedures under general anesthesia.
**Methods:** 80 American Society of Anesthesiologists (ASA) I–II patients weighing more than 30 kg undergoing elective surgery under general anaesthesia were recruited. Patients were randomized in the LMA Protector or LMA Proseal group. After induction of anaesthesia, OLP was measured in both the groups. The insertion characteristics and postoperative sore throat with both SGDs were also recorded and compared.
**Results:** OLP was significantly higher in LMA Protector group compared to LMA ProSeal group ($34.8 \pm 3.5$ cm$H_2O$ vs $31.7 \pm 4.5$ cm$H_2O$ $p = 0.001$).
LMA insertion time was significantly longer with LMA Protector ($25.7 \pm 5.2$ s vs $23.4 \pm 5.3$ s $p = 0.047$). Ease of LMA insertion was comparable. Gastric tube insertion was grade 1 in majority of patients. Incidence and severity of postoperative sore throat at 2 and 24 h was similar in both the groups.
**Conclusions:** In comparison to LMA ProSealTM, LMA ProtectorTM achieved a better oropharyngel seal by achieving a higher oropharyngeal leak pressures. Insertion characters of both the devices were similar.

**Fig. (abstract 000149)** Difference in size of LMA Protector and LMA Proseal size 3

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000150

**Introduction:** Around 80% of patients successfully resuscitated remain comatose after return of spontaneous circulation (ROSC). Accurate Neurological prognostication in comatose cardiac arrest patients is important to identify those with the potential of having poor outcome. International guidelines [1, 2] have supported a multi-modal approach to neuroprognostication. Based on the current guidelines, local guidelines were developed in our institution to provide care post-resuscitation and a pathway for prognostication.
**Objectives:** As part of a quality improvement project, this audit was designed to measure adherence to local guidelines on the care and prognostication in comatose cardiac arrest patients and to identify focus points for improvement.
**Methods:** Approval was sought within the department to audit adult (> 18 years old) comatose patients after CA presenting to our institution and admitted to ICU from April 2022 till March 2023. We identified several aspects of care that wanted to audit, therefore data collected focused on: demographics, location of CA (in-hospital (IHCA) or out-of-hospital (OOHCA)); ICU management focused on: temperature control to avoid fever (< 37.5) for 72 h [3], normocapnia, presence of myoclonus < 72 h, regular monitoring of corneal reflexes and pupillary reflexes, time from admission to first Echo, ICU LOS and neurological outcome on discharge from ICU/hospital, withdrawal of life sustaining therapies (WLST). Based on local guidance to aid neuroprognostication, we looked if the following tests were performed: SSEP, 2 EEG and timings, NSE and CT head, MRI.
**Results:** A total of 186 patients (59.7% Males, median age 61 years) were included, 67% ($n = 114$) were OOHCA. Of these, 83% ($n = 155$) had temperature control (< 37.5C) and 53% ($n = 99$) had normocapnia maintained. Regular pupillary reflexes were measured in 100% of patients, whereas corneal reflexes were monitored in 0%. One EEG was performed in 35.5% ($n = 66$) of patients, and 20% ($n = 37$) had both EEG, only 13% had an SSEP within 24h. NSE was requested in 16 patients (9%), with a turnover mean time from request to results of 13 days, including an outlier value of 240 days since request. 85% patients had CT Head scans and 15% had MRI head scans. 16% patients had developed Status Myoclonus within 72 h.
**Conclusions:** As part of an ongoing quality improvement project, these results have identified areas of focus on both bedside care and education within our institution. With regards care, despite very good and good adherence to temperature control and normocapnia, there's a lack of regular nursing documentation of corneal reflex examination. In terms of tests to aid prognostication, we identified that both NSE (9%) and SSEP (13%) are underutilised despite being part of our local policy and international guidelines. Next steps would include streamlining current adjunct tests and nursing documentation before auditing practice.

### Cost effectiveness of ECCO2R in a UK healthcare setting

D. Roberts[1], O. Ethgen[2], V. Sanjay[3]
[1]Medical Science, Baxter Healthcare, Stockport, United Kingdom; [2]Economics, Serfan Innovation (Strategic Economic Research & F, Namur, Belgium; [3]Health Economics, Baxter Healthcare, Oxford, United Kingdom
**Correspondence:** D. Roberts
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000151

**Introduction:** This study extends on the original research by Ethgen et al. (2) on the cost-effectiveness of ultra-protective lung ventilation (ULPV) strategies with extracorporeal carbon dioxide removal (ECCO2R) by applying cost analysis from a UK National Health Service (NHS) perspective. This economic evaluation complements existing clinical studies and value in facilitating ultra-lung protective ventilation (2).
**Objectives:** The study utilised a decision-analytic model adapted for the UK NHS healthcare setting that tracks expected health states when ECCO2R with ULPV versus mechanical ventilation (MV) in patients with moderate ARDS in the ICU was used.
**Methods:** Health outcomes were based on ventilation settings, duration of ventilation, length of stay, in the Intensive Care Unit (ICU) and hospital, and complications associated with ECCO2R (Table 1).
**Results:** Base case analysis (Table 1) demonstrated ECCO2R-enabled ULPV is cost-effective compared to conventional MV by £1,133. Lifetime cost per Quality Annual Life Year (QALY) was £15,023 in the ECCO2R ULPV group, versus the £20,000 NICE QALY threshold. The analysis found this intervention aimed at enhancing ULPV adherence

in ICU's would result in an additional 0.629 quality-adjusted life years (QALYs) per patient, with an incremental cost-effectiveness ratio (ICER) of £4,100 (− 7664–£14,670) per QALY gained. Comparatively, the study found 3.086 QALYs for ULPV care and 2.457 QALYs for non-LPV care (Table 1).

Table 1 Base case analysis.

While few studies assess cost-effectiveness of MV versus ULPV with ECCO2R (2, 3), this study used numerous parameters informed by the LUNG SAFE study as the primary source (1). This international study provided data on 2377 ARDS patients, including baseline characteristics, MV settings, length of stay, and survival outcomes.

Limitations of the LUNG SAFE study to define the MV comparator in the analysis was plateau pressures were not monitored in 60% of ventilated ARDS patients, and a significant proportion of plateau pressure reached above 30 cm H2O. Influencing a possible overestimation of benefits associated with ECCO2R.

Despite these limitations, this study (1) still demonstrated the potential economic advantages of ULPV strategies with ECCO2R technology in managing ARDS patients within the UK NHS healthcare setting (Table 1).

**Conclusions:** In conclusion, this study presents data that shows how ULPV ventilation with ECCO2R can benefit survival, provide fewer days in the ICU and hospital, and lower costs in a UK NHS. Further research is needed to explore the long-term cost-effectiveness of ECCO2R and other ULPV strategies in the management of ARDS.

## Evaluating professional burnout amongst healthcare professionals in Intensive Care Unit during COVID-19 Pandemic—A Single Centre Review.

B. Ng[1], M. L. Lim[1], SJ. Lee[1], Y. L. Lee[1]
[1]Anaesthesiology and Surgical Intensive Care Unit, Singapore General Hospital, Singapore, Singapore
**Correspondence:** B. Ng
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000152

**Introduction:** Burn-out is a syndrome conceptualized from chronic workplace stress that has not been successfully managed. Studies have shown consistently that 30%–50% of clinicians are estimated

to have burnout symptoms, with a dose–response relationship with poorer patient safety outcomes. To add to professional burnout, pandemics further impose an immense psychological burden on health care staff due to a mix of workplace stressors and personal fears. For HCW in intensive care units (ICU), an even higher rate of burnout (33–70%) has been observed. Hence, we sought to evaluate professional burnout HCWs experienced during COVID pandemic and investigate the risk factors to guide future analysis and interventions.

**Objectives:** Our primary objective was to evaluate professional burnout with secondary outcomes measuring positive associations contributing such as stress, anxiety, depression and various demographic factors.

**Methods:** The study used a convenience sampling method to conduct a single-center, cross-sectional survey in Sengkang General Hospital (SKH) ICU in December 2021. A standardized questionnaire was administered to doctors, nurses and allied healthcare professionals (AHP). The survey consisted of four parts, demographic and background questions followed by 3 validated psychometric instruments: Maslach Burnout Inventory—Human Services Survey (MBI-HSS) for burnout, Cohen Perceived Stress Scale (CPSS) for stress and Patient Health Questionnaire Screening (PHQ-4) for depression and anxiety.

MBI-HSS is graded on a 7-point Likert scale. The 22 questions are divided into 3 domains, emotional exhaustion EE (9 questions), depersonalization DP (5 questions) and personal accomplishment PA (8 questions). We define Professional Burnout as either a high EE score with a high DP score; or a high EE score with a low PA score.

CPSS consists of 10 questions graded on a 5-point Likert scale and we define a summated score of $\geq 20$ as a high perceived level of stress.

The PHQ-4 is a four itemed questionnaire answered on a 4-point Likert scale, by combining the two-item measure (PHQ-2) and two-item measure for anxiety (GAD-2). Total score $\geq 3$ for first 2 questions suggests anxiety. Total score $\geq 3$ for last 2 questions suggests depression. We employed standard descriptive statistics to summarize the response to survey questions. Comparison of variables with professional burnout, stress, anxiety and depression was performed with Chi Square Test for categorical variables and Logistic Regression for continuous variables.

**Results:** Our total number of respondents is 76 healthcare workers, with 64.5% being nurses (49/76), 19.7% (15/76) doctors, and 15.8% (12/76) allied healthcare professionals. A total of 74.2% (49/66) nurses responded, 68.1% (15/22) of doctors, and 100% (12/12) allied healthcare professionals responded to our survey.

Overall burnout rate in our study population was 56.6% with allied healthcare professionals at the highest risk of developing burnout (66.7%, 8/12), compared to nurses (55.1%, 27/49) and doctors 53.3% (8/15),]. However, these differences were not statistically significant, with $p$ value of 0.739. Next, the overall stress rate in our study population was 86.6%, with physicians reporting the highest stress scores of 93.3%, followed by allied health professionals at 91.7% and nurses at 83.7% ($p = 0.541$).

We did not observe a strong positive correlation between burnout and stress, indicating that there is no strong definite association between high stress out levels with burnout ($p = 0.652$). However, there was a positive association of higher stress levels with the type of housing ($p = 0.036$), with condominiums owners reporting highest stress scores and those living in landed properties reporting lowest stress scores. We also observed that 82.9% of HCW are at risk of anxiety and depression with nurses having the greatest risk of anxiety ($p = 0.014$). There was also a positive association of burnout with anxiety and depression ($p < 0.01$). Predictors for burnout showed no significant association with demographic factors.

**Conclusions:** By raising awareness of the psychological impact that COVID has on HCWs in ICU, we hope that this highlights the need for dedicated psychosocial support.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000154

**Introduction:** Patient care is at the forefront of important guidelines set out by various health boards and Intensive Care health professionals. Documentation in the hospitals is a vital part of this and remains a problem within healthcare despite continuous efforts of improvement (1).

**Objectives:** Our project aim was to monitor documentation within the ICU department at Ysbyty Glan Clwyd Hospital over 5 months and compare data to the standards set by the ward itself and the health board recommendations. The most important objective for us was to see what is missing and what implications this has, to improve the quality of patient care within the ICU.

Specifically, we looked at ICU ward-specific documentation including Short Clinical Assessments (SCA) and the Intensive Care National Audit and Research Centre (ICNARC) sheets, as well as missing information boxes on the daily review. The SCA and ICNARC are crucial information documents to identify at-risk patients and to improve specific care plans (2). Additionally, there are similar implications to fill out the boxes of the daily review.

When looking at the health board requirements, we looked at the This Is Me document as well as missing bleeps and legibility. The This Is Me document allows for the staff to understand the patient's needs, fears

and concerns. Furthermore, the missing bleeps and legibility are crucial parts to get right in documentation to ensure patient safety and continuity of care.

**Methods:** As part of our student-selected component in the third year of our medical degree, we visited the ICU on alternating Fridays for 5 months. We used an online form to document our findings as we looked through clerking sheets, admission documents, and daily reviews. The study was checking for missing information as well as the legibility of what had been written. We produced a total of 100 responses which left us with a reliable set of data to look at.

**Results:** ICU Ward Specific Documentation:

The most prominent finding during the audit was missing or incomplete documents including the SCA and the ICNARC sheet. The SCA was missing or incomplete 89.3% of the time, and the ICNARC missing or incomplete for 42.9% of entries. Additionally, the daily review sheets had a large amount of missing documentation in almost all of those audited. 76% of note-taking we looked at had blank information boxes or incomplete information. Most commonly, this was the patient rehabilitation section with only 28% of documents being filled out, and a blood sample requirement section being filled only 8% of the time out of the 100 audits.

BCU Health Board Specific Documentation:

The This Is Me documentation at the very start of the patient note folder was incomplete 90% of the time out of the 100 audits, and the bleep number of the documenting clinician was recorded once 45% of the time, or not at all 55% of the time when comparing 4 consecutive documentation entries. Alongside this, document legibility was poor with only 45% of entries made being legible enough to read. This finding excluded nursing notes as they were found to be 100% legible.

**Conclusions:** In conclusion, documentation remains to be a challenge in the hospital setting. It is appreciated that ICU documentation is extremely vast and with the evergrowing time constraints within the NHS (3), documentation is found to be lacking in sufficiency. In a look to the future, we aim to implement awareness of these findings and have already raised them in the ICU Clinical Governance meeting. We implemented posters and posed ideas of handover reminders, patient loved ones collaboration on this is me documentation, and using blood sheets as a time-efficient tool, in a hope to improve documentation and thus patient care for the future of medicine.

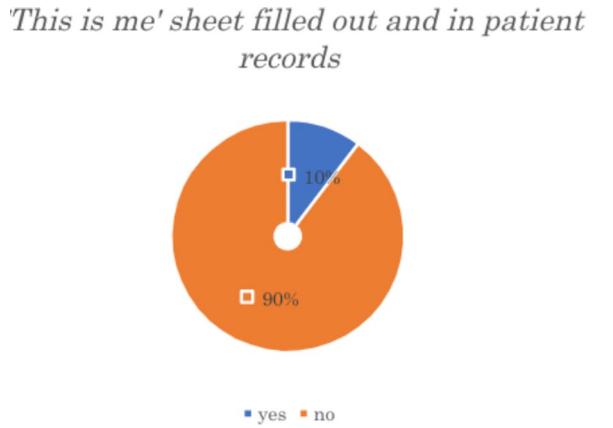

**Fig. (abstract 000154)** Diagram showing the percentage of This Is Me sheets filled out in documentation

**Fig. (abstract 000154)** Diagram showing in blue the level of missing information regarding the "tomorrow's bloods" section (92%) of the daily review sheet, in comparison to the red, where 8% had been completed

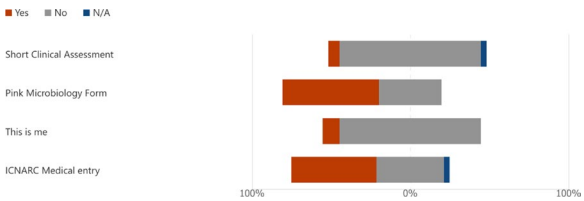

**Fig. (abstract 000154)** Diagrams showing missing information on admission, including the SCA at 89.3% missing, and the ICNARC entry missing 42.9% of the time as shown by grey colour

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000155

**Introduction:** The nutritional support provided to children in the pediatric intensive care unit (PICU) is affected by disease severity, baseline nutritional status, and invasive therapeutic interventions. In the first week of admission, achieving 60% enteral adequacy of calories and protein is associated with a survival benefit. We hypothesize that malnourished children are likely to achieve > 60% calorie and protein adequacy before compared to children with a normal nutritional status at baseline during their first week of admission to the PICU.

**Objectives:** To evaluate nutrition support adequacy in malnourished children during their first week of admission to the PICU.

**Methods:** Retrospective cohort study of children admitted (index) to Texas Children's Hospital PICU between Jan 2016 to Dec 2017. Inclusion criteria included mechanical ventilation (MV) > 48 h, PICU length of stay (LOS) > 7 days, and > 2 yrs. of age. Nutritional status was evaluated by CDC growth charts (Weight for Age [WFA] z-scores, underweight defined as WFA $z$-score < − 2). Nutrition support included enteral and parenteral nutrition, and propofol if on TPN, adequacy defined as (intake/prescription × 100). All calculations used dietitians' prescriptions and actual body weight. Optimal adequacy was defined as ≥ 60%. Comparison by Mann–Whitney.

**Results.**

Out of 4199 patient admissions, 164 children (45% female) met inclusion criteria. Anthropometric evaluation on admission was WFA z-score of -0.45 ± 2.20 [SD], with 80% normal nutritional status and 20% underweight. Patient characteristics are included in Table 1. Malnourished children vs nourished children on day 7 had a median caloric intake (kcal/kg/day) of 37 (31–52, IQR) vs 24 (14–40); $p = 0.0022$ and a protein intake (g/kg/day) of 1.63 (1.08–2.27) vs 1.20 (0.63–2.10); $p = 0.0393$. Total calorie adequacy (%) in malnourished vs nourished

children for days 1, 3, 5, and 7 were: 0 (0–0) vs 0 (0–0), $p=0.86$; 35 (0–69) vs 17 (0–55), $p=0.39$; 66 (4–101) vs 64 (27–99), $p=0.56$; and 95 (63–114) vs 71 (34–102), $p=0.0170$; respectively. Total protein adequacy (%) in malnourished vs nourished children for days 1, 3, 5, and 7 were: 0 (0–0) vs 0 (0–0), $p=0.90$; 37 (0–99) vs 15 (0–67), $p=0.27$; 76 (22–106) vs 74 (25–132), $p=0.53$; and 109 (72–152) vs 80 (42–140), $p=0.0393$; respectively. For both groups, calorie and protein adequacy of $\geq$ 60% was reached on day 5.

**Table 1 (abstract 000155)** Patient characteristics

| | All | Nourished at baseline ($n=131$) | Malnourished at baseline ($n=33$) | *P* value |
|---|---|---|---|---|
| Age (years) | 11.7 (8–15) | 11.4 (8–15) | 14.6 (9–18)* | *0.0119* |
| Weight (kg) | 37 (23–55) | 38 (25–61) | 31 (17–42)* | *0.0006* |
| MV (days) | 9.3 (6.5–16) | 9.4 (6.6–16) | 8.8 (6.4–18) | *0.7866* |
| PICU LOS (days) | 12 (9–20) | 12 (9–20) | 12 (10–22) | *0.7320* |
| Hospital LOS (days) | 30 (19–53) | 32 (19–52) | 27 (20–55) | *0.4766* |
| PIM2 ROM (%) | 3.7 (3–6) | 3.8 (3–9) | 3.4 (1–4)* | *0.0403* |
| Chronic condition n (%) | 109 (66.4) | 80 (61.1) | 29 (87.9)* | *0.0035* |
| Mortality, n (%) | 20 (12.2) | 19 (14.5) | 1 (3.03) | *0.0804* |

Values are median (IQR 25th–75th). MV: mechanical ventilation; LOS: length of stay; PIM 2 ROM: Pediatric Index of Mortality, Risk of mortality. * Comparison analysis by Mann–Whitney

**Conclusions:** In this cohort of critically ill children, 1 out of 5 were malnourished. Optimal nutrition delivery was reached on day 5 and malnourished children reached higher intakes and adequacies compared to nourished children on day 7. Earlier interventions should be enacted to ensure prompt nutrition support to underweight critically ill children.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000157

**Introduction:** Attending emergency situations outside the critical care unit is common part of ICU workload. Emergency "grab" bags are therefore commonplace. Properly stocked emergency equipment is an essential requirement to ensure vital resuscitation equipment is available for these difficult situations. It is our local policy for our emergency bags to be checked and quality assured daily. A recent audit demonstrated that compliance with Emergency Bag checks was 24%. This aspect of ICU housekeeping has been audited frequently with similar Results: To embed sustainable change, rather than audit, we applied quality improvement methodology to ensure we continually assess and reflect upon our performance.
**Objectives:** To improve compliance in Intensive Care with daily Emergency Bag by applying quality improvement methodology.
**Methods:** Following repeated short audit projects demonstrating poor compliance, a quality improvement team was formed. Following a focus group meeting a number of change ideas were implemented:

- New resuscitation bags with streamlined content
- Simplified checking system utilising Microsoft Forms QR code to allow rapid electronic checking
- Continuous compliance measurement allowing monthly reporting
- Regular education and discussion within our MDT meetings
- Pre-allocated person to improve ownership of checks

**Results:** Outcomes are recorded as percentage compliance with daily checks over a set time. Compliance for the period prior to these interventions was 24%. Compliance has improved to 61% on recent re-audit for the period of February, March and April 2024, demonstrating these changes have significantly improved compliance.
**Conclusions:** Compliance has improved but ongoing work is essential to ensure patient safety and comply with local policy. This is an ongoing area of quality improvement, data is continually collected allowing fora dynamic approach to PDSA cycles. The implementation of change is challenging and compliance is affected by factors including workload and lack of familiarity of contents. It is essential that the importance of checks is reinforced to all staff and new staff are educated on the importance of these checks.

## Smart Alarms in Intensive Care and Perioperative Medicine: A Rapid Scoping Review

M. Prendke[1], A. Chaoui[1], P. Heeren[1], L. Mosch[1], F. Balzer[1], A. S. Poncette[1], A. R. Flint[1]
[1]Institute of Medical Informatics, Charité-Universitätsmedizin Berlin, Berlin, Germany
**Correspondence:** M. Prendke
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000158

**Introduction:** As demand for intensive care increases and complexity of patient comorbidities increases [1], the reliance on sophisticated monitoring equipment intensifies. These devices are essential for the continuous surveillance of vital signs, yet their effectiveness

is deflected by a high incidence of false alarms, contributing to alarm fatigue among healthcare workers amid sensory overload [2]. There is a need for smarter alarm systems that sift through available data streams, alerting only for true physiological deterioration requiring intervention. The propagation of smart alarms promises a paradigm shift away from threshold-based alarms towards a new way of caregivers' alarm response and prioritization [3]. However, a unified concept or clear definition is currently lacking.

**Objectives:** We aim to explore the concept of smart alarms in perioperative and intensive care monitoring in the literature by investigating their current theoretical definitions and practical implementations.

**Methods:** Rapid scoping review of the literature through Pubmed search on 03/04/2024 (search string: "Smart alarm*" OR "smart alert*" OR "intelligent alert*" OR "intelligent alarm*", year $\geq$ 2000 for up-to-date concepts) [4]. Screening for inclusion criteria: smart alarm implementation or theoretical definition in perioperative and intensive care vital sign patient monitoring. Reviews, non-perioperative normal ward and outpatient settings were excluded. We extracted study type, used terms, smart alarm definition and implementation, scope and transferability. Subsequently, we distilled the common key characteristics of smart alarms, culminating in a coherent narrative synthesis of the concept of smart alarms the literature.

**Results:** Out of 76 papers found, 19 met inclusion criteria (Fig. 1). Most used term is "smart alarm". Papers mainly fall into two categories: Proof-of-concept with implementation and commentary with definition. Only two publications present both a smart alarm implementation and definition. Notably, there is no consistent definition of a smart alarm across published research. However, recurring features characterizing smart alarms include (Table 1):

1. Integration of multiple data sources (e.g., vital sign monitors, patient characteristics)
2. Based on artificial intelligence (AI) or machine learning (ML) (often models making acutely clinically significant, real-time predictions declared as smart alarms)
4. More context-sensitive than threshold-based alarms (e.g. consecutive, sustained or prioritized alarms)
5. Provision of reasoning for alarm generation or treatment suggestion

**Conclusions:** Literature encompasses limited explorations of specific application scopes and differing definitions but lacks a concise concept of smart alarms. There is consent about their potential to improve patient safety by raising situational awareness and mitigating alarm fatigue. However, further research is needed for a more precise definition and wider implementation of smart alarms, especially clinical, context-sensitive implementations combining a wider range of data modalities.

**Table 1 (abstract 000158)** Results Table with study types, used terms as synonym of smart alarm, scope of smart alarm definition or transferability of alarm implementation if applicable, included key characteristics of smart alarm of included publications. (Characteristics*: 1: Integration of multiple data sources, 2: ML/AI-based, 3: Context-sensitive/prioritization, 4: Indicate cause/suggest treatment)

**Correspondence:** B. Ferro

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000159

**Introduction:** Septic cardiomyopathy determines a deterioration of systolic and diastolic function involving both ventricles and atria. Left atrial strain measured by speckle tracking echocardiography is a technique that allows clinicians to early recognize alterations of atrial deformation that could impact on the complex hemodynamic manifestation and treatment of severe sepsis or septic shock (1). In particular, the introduction of dynamic indexes of fluid responsiveness has changed the management of fluid and vasoactive administration during the different phases of septic shock.

**Objectives:** The goal of this prospective study (LASS) was to analyze the incidence of atrial dysfunction in patients with severe sepsis

or septic shock at ICU admission and to evaluate the effect of fluid administration on Peak Atrial Longitudinal Strain (PALS) (2).

**Methods:** Patients with diagnosis of severe sepsis or septic shock following Surviving Sepsis Campaign Guidelines have been included (3), excluding age < 18 years old, anamnesis of valve, arrhythmic or cardiac disease. A sample aged matched non-septic cohort of patients was used as control. Peak longitudinal atrial strain (PALS) was measured in apical four chamber window at the end of reservoir phase of atrial filling and expressed as percentage (Fig. 1). A PALS less than 38% was considered as altered (2). Fluid expansion was obtained administering 250 ml of crystalloids in 15 min. Hemodynamic parameters including mean arterial pressure (MAP), Stroke Volume (SV), Heart rate (HR) and vasoactive dosage were assessed. Patients were considered responders if a variation of SV > 10% was measured after fluid expansion. Non-parametric statistical analysis was used to compare values of PALS between septic patients and non-septic patients. A ROC curve was built to assess the efficacy of PALS to predict fluid responsiveness.

**Results:** 44 septic patients with a median age of 60 (52 to 80) admitted to Spedali Riuniti ICU (Livorno) were included. The source of infection was abdomen 50%, urinary tract 30%, blood 10%, other 10%. At admission median PALS was 30% (22 to 40 iR) in septic patients and 35% (22 to 66 IR) in control group. This difference was not statistically significant (p = 0.5). 47% of septic patients had PALS < 30% at admission (Fig. 1A). After fluid expansion 30 septic patients were responders (increase of SV from 66 ml 55–85 to 86 ml62-105 IR) $p < 0.01$ and 10 were not responders (SV 71 ml 53 to 90 to 75 ml 66 to 90) $p = 0.2$. Mean arterial pressure increased in both responders and non-responders (MAP from 55 to 70 mmHg median values in responders and mean arterial pressure from 58 to 65 mmHg in non responders). Reduction of heart rate (from 110 bpm IR 120–90 bpm to 100 bpm IR 90–105 bpm) and norepinephrine dosage (from 0.3 mcg/kg/min IR 0.5 to 0.1 to 0.2 mcg/kg/min IR 0.07 to 0.3 mcg/kg/min $P = 0.04$) after fluid expansion. No significant variation of PALS was observed in fluid responders and non-responders when all septic patients were included in the analysis (from 22 IR 16–48 to 25 IR 16–56% in non-responders $p = 0.3$ and 34% IR 25 to 40% to 30% IR 24 to 40% p = 0.2 in responders) (Fig. 1B). Patients with PALS < 38% at admission showed a significant increase of its value after volume expansion (from 22% IR 19–25% to 27% IR 25–31%) $p = 0.04$, (Fig. 1D) (Fig. 2), but without the ability to discriminate fluid responsiveness (ROC AUC = 0.5) (Fig. 3). Septic patients with PALS > 38% at admission didn't show a significant variation of atrial strain after fluid bolus (from 40% IR 37–31% to 37–56% $p = 0.6$ (Fig. 1C).

**Conclusions:** PALS is reduced in more than 50% of septic patients admitted to ICU basing on the accepted normal values. Otherwise in our analysis there was no difference comparing septic patients and aged-matched cohort of non-septic patients, suggesting the possibility of high prevalence of atrial dysfunction in ICU. Interestingly PALS values didn't predict fluid responsiveness. Volume expansion had the ability to improve atrial function if PALS was altered at admission (PALS < 30%), but without correlation with the initial state of fluid responsiveness. In conclusion PALS could be an interesting guide for a multimodal resuscitation of diastolic function in sepsis to be expanded in future studies.

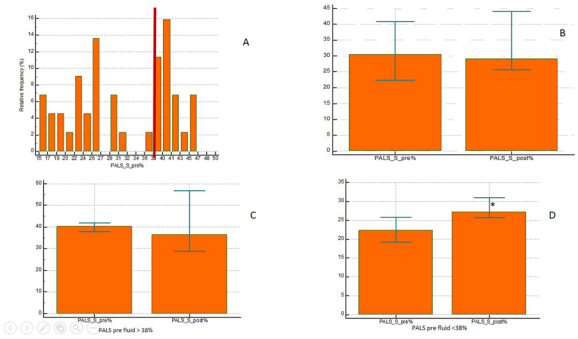

**Fig. 2 (abstract 000159)** Distribution of PALS in septic patients at ICU admission. Red line identifies lower normal limit. B No effect on PALS determined by volume expansion on global cohort of septic patient. C No effect on PALS after fluid bolus in septic patients with atrial strain > 38% at admission. D Significant increase of PALS after fluid bolus in septic patients with atrial strain < 38% at admission

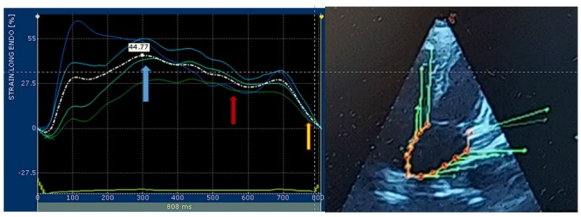

**Fig. 1 (abstract 000159)** Normal Left Atrial Strain curve assessed by speckle tracking analysis. Atrial strain is composed of reservoir phase (PALS) during systole (blue arrow), conduit phase (red arrow) followed by atrial contraction (yellow arrow) during diastole

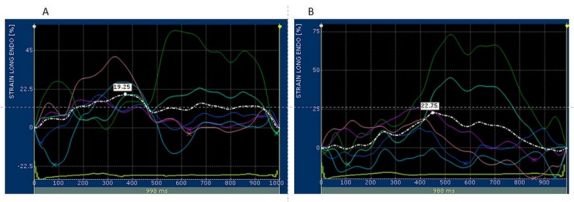

**Fig. 3 (abstract 000159)** Example of amelioration of atrial strain curve in a septic patient with altered PALS at admission (A) after volume expansion (B)

*Intensive Care Medicine Experimental* 2024, **12(suppl 1):** 000161

**Introduction:** People who survive COVID-19 critical illness may have reduced quality of life due to physical, cognitive and psychosocial impairments [1, 2]. Some UK hospitals deliver outpatient post-intensive care rehabilitation programmes to support people recovering from critical illness [3]. It is essential to identify components and outcomes important to patients who attend these programmes and their caregivers [4, 5].
**Objectives:** To identify important components and prioritise outcomes for patients attending outpatient post-intensive care physical rehabilitation programme and their caregivers.
**Methods:** People who had survived COVID-19 critical illness ($n=6$) and their caregivers ($n=2$), following participation in a 6-week outpatient post-intensive care physical rehabilitation programme. Age range 49–70 years and length of stay in intensive care range 7–52 days. In-person nominal group technique was completed following the five stages; introduction, silent idea generation, round robin, clarifications and scoring. Participants voted privately on the priority of their 6 'top' outcomes (6 being scored as the most important and 1 being the least important to them). A focus group discussion identified key components.
**Results:** Twelve important outcomes were identified and ranked (see Table 1). Additionally, four key components which outpatient post-intensive care rehabilitation programmes should provide were identified; psychological support, investigating ongoing symptoms and impairments, timely follow up and having a safe place to exercise.

**Table 1 (abstract 000161)** Important outcomes for COVID-19 critical illness survivors and caregivers, ranked from Nominal Group Technique vote

| Outcomes ranked from vote | Number of participants who voted per outcome | Sum of scores per outcome (maximum score = 48) |
|---|---|---|
| 1. Improved stamina/fatigue | 6 | 27 |
| 2. Mental health | 6 | 24 |
| 3. Reassurance | 6 | 23 |
| 4. Understanding what happened to their body | 6 | 21 |
| 5. Improved breathing | 5 | 21 |
| 6. Improved fitness | 4 | 17 |
| 7. Independence in activities of daily living | 5 | 16 |
| 8. Coming to terms/acceptance | 3 | 10 |
| 9. Sense of achievement | 3 | 3 |
| 10. Caregivers confidence in communication | 2 | 2 |
| 11. Fear of COVID-19 | 1 | 2 |
| 12. Confidence | 1 | 1 |

**Conclusions:** The range of outcomes highlights the complex nature of COVID-19 critical illness and the need for post-intensive care rehabilitation to address more than just physiological needs.
Due to the timing of our study, all our participants had COVID-19 critical illness. Participants admitted to intensive care with a wider range of critical illnesses may have identified and prioritised different key components and outcomes.
Rehabilitation features important to survivors and caregivers should inform the design of rehabilitation services. In addition to previously recommended core outcome sets, this study highlighted the need to measure reassurance, self-efficacy to exercise, sense of achievement and the survivor's understanding of 'what happened to their body' while in intensive care.

### Prediction of Mortality Using the Sequential Organ Failure Assessment Score in Critically ill COVID-19 Patients

M. A. Asghar[1]
[1]Karachi, Pakistan
**Correspondence:** M.A. Asghar
*Intensive Care Medicine Experimental* 2024, **12(suppl 1):** 000164

**Introduction:** The global health burden due to the COVID-19 pandemic urged physicians to look for accurate and predictable methods for triaging patients. Many scoring tools, such as APACHE II, SOFA, MPM, and SOFA, are present, yet there is a lack of an accurate and validated scoring system for predicting mortality in COVID-19 patients.
**Objectives:** To determine the accuracy and reliability of the SOFA score in predicting the risk of mortality in ICU-admitted COVID-19 patients.

**Methods:** Total 62 patients with a positive RT-PCR for COVID-19, admitted into the intensive care unit (ICU), were included in this descriptive cross-sectional study conducted in the COVID ICU of Aga Khan University Hospital, Karachi. Written informed consent was obtained after explaining the risks and benefits of the study to the patient/next of kin. SOFA score at the time of admission and 48 h after admission was calculated. The outcome variable, i.e., mortality, was assessed in association with the SOFA score.
**Results:** The study had a predominantly male population, 54.8% ($n=34$). Most of the patients, 69.4% ($n=43$), had severe COVID-19. The SOFA score > 7 at admission and 48 h after admission were observed in 46.8% ($n=29$) patients. Of the total 62 COVID-19 patients, the majority were found to have severe nature of the disease, i.e., 69.4% ($n=43$), followed by moderate/mild cases 30.6% ($n=19$). Depending on the requirement of the patient, 74.2% ($n=46$) were invasively ventilated while 77.4% ($n=48$) were on non-invasive ventilation. Overall the mortality rate of the present study was 43.5% ($n=27$). Scores both at admission and 48 h after admission for the survivors had a significant difference with the non survivors.
**Conclusions:** The SOFA score on admission and 48 h after had a significant positive association with the severity of COVID infection and its risk of mortality.

## Cardiac Surgery as a Means of Reversing Frailty—The CURE-Frailty Trial

V. A. Rudas[1], A. Lassnigg[1], A. Fischer[1], S. Ryz[1], J. Tichy[1], R. Ristl[2], M. Bernardi[1]

**Correspondence:** V.A. Rudas
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000167

**Introduction:** Assessment of frailty is continuously gaining importance in the care of surgical patients. Frailty is associated with a diminished physiological reserve, making patients more vulnerable to external stressors. As a result, frailty is associated with unfavorable postoperative outcomes, including mortality, perioperative adverse events and hospital length of stay. Consequently, cardiac surgery in frail patients is always a high-risk undertaking. Alleviation of symptoms of cardiovascular disease, however, might cause a simultaneous reduction of frailty, due to significant clinical overlap between frailty and heart failure. Reducing frailty potentially leads to an improved functional status and increased quality of life, important patient-centered outcomes which are often overlooked. The possibility to treat and reverse frailty has been previously discussed, but the number of studies examining frailty postoperatively is limited. Therefore, cardiac surgery as potential treatment of frailty deserves to be investigated.
**Objectives:** The aim of this study was to examine the reversibility of frailty through cardiac surgery.
**Methods:** We analyzed 76 patients undergoing elective open or interventional cardiac surgery in this prospective observational single center study. Frailty was measured using the Clinical Frailty Scale (CFS), while subjective health was assessed with the Short Form 12 Patient Questionnaire (SF-12). Follow-up was conducted at hospital discharge, as well as 6 and 12 months postoperatively. The primary endpoint of this study was a change in CFS between baseline and final follow-up. Secondary endpoints included change in subjective health, as well as surgical outcome parameters, such as mortality and length of stay.
**Results:** At baseline, 44 patients (57.9%) were classified as frail, using a cutoff at CFS $\geq 4$. Median CFS at baseline was 4, decreasing to CFS 3 six and twelve months postoperatively ($P=0.006$) (Fig. 1). At the final follow-up, 21 patients (27.6%) presented as frail, 39 patients (51.3%) as non-frail and 16 patients (21.1%) were either deceased or had been lost to follow-up (Fig. 2). General health and physical activity also improved significantly ($P<0.001$). Mortality was higher in the frail group, although not significantly (3.12% vs. 15.9%, $P=0.076$).
**Conclusions:** Frailty and cardiovascular disease are strongly related. Cardiac surgery has the potential to reduce disease symptoms and reverse frailty as a result. Still, frail patients face higher risks in the perioperative setting, making frailty assessment necessary to identify their needs and plan their care accordingly. Furthermore, the importance of postoperative quality of life as an essential patient-centered outcome must be emphasized.

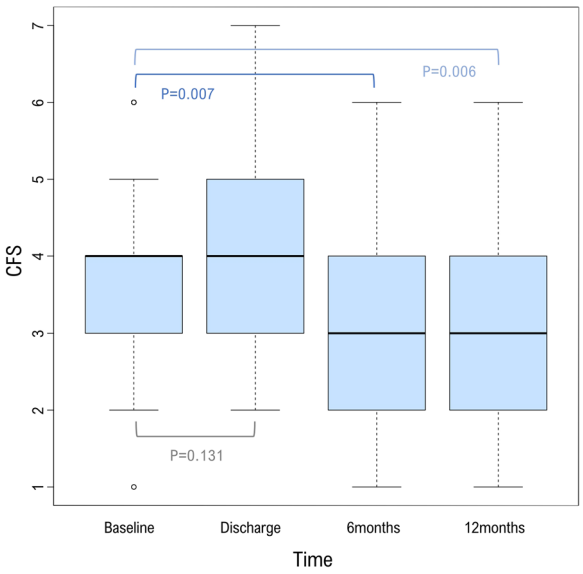

**Fig. 1 (abstract 000167)** Boxplot showing frailty distribution at each time point. P-values were calculated using Wilcoxon rank sum test

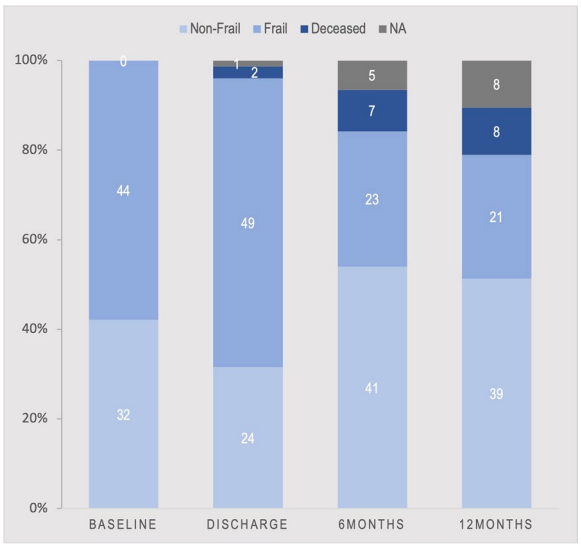

**Fig. 2 (abstract 000167)** Frailty status according to CFS at baseline, hospital discharge, 6 months and 12 months after surgery

### Description of respiratory complications after cytoreductive surgery and intraperitoneal hyperthermic chemotherapy. A decade of learning

D. R. Beltran[1], M. C. Pintado Delgado[1], A. B. Oñoro Morales[1], V. Rubio[1], M. Jimenez[1], D. Molina[1], M. Trascasa Muñoz[1], A. Robles[1], B. Llorente Ruiz[1], E. Nevado Losada[1]

**Correspondence:** D.R. Beltran
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000168

**Introduction:** Cytoreductive surgery (CRS) and hyperthermic intraperitoneal chemotherapy (HIPEC) are therapeutic options for peritoneal carcinomatosis in patients with digestive, ovarian, and primary peritoneal cancer. Although effective, these treatments carry significant risks, including considerable morbidity and mortality. However, the incidence, predisposing factors, and management of respiratory complications that may arise after CRS and HIPEC have not yet been clearly established (1, 2).
**Objectives:** To describe the respiratory complications associated with hyperthermic intraperitoneal chemotherapy (HIPEC) in patients admitted to the ICU in the last decade.
**Methods: Design:** Prospective observational study in a Spanish ICU of patients admitted after cytoreduction and HIPEC from January 2013 to December 2023.
**Variables to study:** Demographic data, APACHE, comorbidities, type of cancer, index of peritoneal carcinomatosis, need for blood products, fluid balance, days of stay, need for mechanical ventilation and mortality were collected. We define respiratory complications as the presentation of nosocomial pneumonia, ARDS, atelectasis, acute respiratory failure, and pleural effusion.
**Analysis:** Quantitative variables are described with mean and standard deviation or with median and interquartile range using the U-Mann–Whitney test for analysis. For categorical variables, percentages were calculated and compared using Fisher's exact test. In all cases, values of $p < 0.05$ were considered statistically significant.
**Results:** A total of 123 patients were accepted in the ICU during the chosen period. Of the total 61% were men, with an average age of 59.5 ± 10.5 years. The average APACHE score was ± 8.5 (6.0–12.0), and the Charlson index was 6. Of the sample, 15.4% (19) had gynecological-origin cancer, while 84.6% (104) had digestive-origin cancer.
Out of the total, 66 patients experienced respiratory complications: 3% (2) had pneumonia, 18% (12) had atelectasis, 83.3% (55) experienced acute respiratory failure and 36.36% (24) had pleural effusion.
As we can see in Table 1, there were no differences observed in the type of cancer, the rate of peritoneal carcinomatosis, postoperative fluid balance, the requirement for blood products, the need for vasopressors, or the need for intubation upon admission. Similarly, there were no differences in hospital and ICU stay or in the need for mechanical ventilation.
Mortality in the ICU within 30 days was remarkably low (0.8%) and was not associated with respiratory complications.
**Conclusions:** Patients undergoing cytoreduction and HIPEC often experience some type of respiratory complications. However, in our sample, no correlation was observed with an increased need for mechanical ventilation, longer hospital stays, or an increase in mortality.

**Table 1 (abstract 000168)**

| | Patients (123) | Respiratory complications | | p |
|---|---|---|---|---|
| | | YES (66) | NO (57) | |
| Sex (Male) | 61 (49.6%) | 31 (47.0%) | 30 (52.6%) | 0.531 |
| Age | 59.5±10.5 | 59.4±10.3 | 59.4±10.9 | 0.971 |
| APACHE II | 8.5 (6.0 - 12.0) | 9.0 (7.0 – 12.0) | 8.0 (5.0 – 11.0) | 0.028 |
| Charlson index | 6.0 (6.0 - 6.0) | 6.0 (6.0 - 6.0) | 6.0 (6.0 - 6.0) | 0.221 |
| Background | | | | |
| Mellitus diabetes | 17 (13.8%) | 10 (15.2%) | 7 (12.3%) | 0.645 |
| Arterial hypertension | 52 (42.3%) | 29 (43.9%) | 23 (40.4%) | 0.688 |
| Dyslipidemia | 47 (38.2%) | 28 (42.4%) | 19 (33.3%) | 0.301 |
| Obesity | 9 (7.3%) | 6 (9.1%) | 3 (5.3%) | 0.502 |
| Respiratory disease | 10 (8.1%) | 6 (9.1%) | 4 (7.0%) | 0.751 |

### Incidence and duration of hypotension following coronary artery bypass surgery and its association with acute kidney injury

E. Bryant[1], A. Johnson[1]
[1]Cardiothoracic Critical Care Unit, John Radcliffe Hospital, Oxford, United Kingdom
**Correspondence:** E. Bryant
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000170

**Introduction:** Acute kidney injury (AKI) is a common complication after cardiac surgery. It has a reported incidence of 22% (1) and is associated with increased morbidity and mortality (2). It has been shown to prolong duration of intensive care admission and hospital stay (3) and has a negative impact on healthcare resources. Reducing incidence of AKI has the potential to improve patient and health care system outcomes. A number of risk factors for AKI post cardiac surgery have been demonstrated (3,4). Hypotension is a potentially modifiable risk factor, however most research has focused on intra-operative hypotension.
**Objectives:** This study aimed to quantify the amount of hypotension in the first 24 h after cardiac surgery by evaluating the number & duration of hypotensive episodes in adult patients following on-pump coronary artery bypass and determine any correlation between the amount of hypotension and post-operative acute kidney injury.
**Methods:** The study was approved by the institutional R and D department as a service evaluation not requiring ethics committee approval. 20 patients were included and received usual standard of care following on-pump coronary artery bypass grafting. The patients were monitored using FlowtracTM (Edwards Lifesciences, Irvine, CA, USA) from ICU admission for up to 24 h. Hypotension was defined as > 1 min with mean arterial pressure (MAP) < 65 mmHg. The time-weighted average (TWA) of hypotension was calculated using Acumen Analytics software (Edwards Lifesciences, Irvine, CA, USA) and is defined as (depth of hypotension below MAP 65 x time)/monitoring duration. Baseline and post-operative measurements of serum creatinine (SCr) were recorded as per usual care. AKI was defined used KDIGO criteria. Patients with end stage renal failure requiring dialysis and those undergoing off-pump bypass surgery were excluded.
**Results:** 16 men and 4 women were included with an average age of 66. The frequency distributions of TWA hypotension and SCr were heavily skewed and not easily transformed to normality, therefore non-parametric tests were used to compare distributions. 18 patients had > 1 hypotensive event, median time in hypotension was 140 min (IQR 44–306). The TWA of hypotension was 0.63 mmHg (0.19–1.61) (median (IQR)). There was not a clear relationship between SCr and TWA hypotension ($r = 0.56$, $p < 0.05$), however there was a more convincing association between TWA hypotension and presence and severity of AKI (Fig. 1).
**Conclusions:** This evaluation was limited by sample size but demonstrated a significant amount of postoperative hypotension and an association between the amount of hypotension and presence and severity of AKI. The results suggest that there is scope to modify this risk factor and reduce the impact of AKI in this population, along with associated resource burdens.

## Impact of delays in sample processing on plasma markers of inflammation, chemotaxis, coagulation, and cell death

V. Gyorffy[1], D. Dwivedi[2], P. Liaw[3], A. Fox-Robichaud[2], J. L. Y. Tsang[4], A. Binnie[5]

**Correspondence:** V. Gyorffy
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000171

**Introduction:** Traditional biosampling studies in hospitals involve the collection of patient biological samples at the bedside followed by local processing and storage (ie. centrifugation, aliquotting, freezing). However, community hospitals in Canada, which care for the majority of patients, often lack infrastructure for local processing of research specimens. A potential solution is a "simplified" biosampling approach whereby blood samples are collected and shipped immediately to a central site, prior to processing. However, the impact of delayed processing on sample stability is unknown.
**Objectives:** To determine whether delays in blood sample processing affect the stability of cytokines (IL-6, TNF, IL-10, IFN-γ), chemokines (IL-8, IP-10, MCP-1, MCP-4, MIP-1α, MIP-1β), cell-free DNA (cfDNA) (released by dying cells), and blood coagulation factors.
**Methods:** Venous blood was collected into two types of anticoagulant tubes (citrate and EDTA) and left at 23 °C room temperature (RT) or 4 °C for progressive intervals (up to 72 h) before processing. Plasma cytokines and chemokines were quantified using single or multiplex immunoassays. Blood clotting process was measured using a thrombin generation assay. cfDNA (released by dying cells) was measured using Picogreen DNA Quantification.
**Results:** Blood samples were collected from 7 healthy volunteers and 9 intensive care unit (ICU) patients. ICU admission diagnoses included sepsis, trauma, intracranial hemorrhage, gastrointestinal bleed, and hyperkalemia. After delayed processing, no significant changes were identified in plasma levels of cytokines, chemokines, or cfDNA; or in blood coagulation process irrespective of whether the samples were stored at RT or 4 °C.
**Conclusions:** Delayed processing (up to 72 h) at either RT or 4 °C did not significantly affect the stability of cytokines, chemokines, cfDNA, or blood coagulation factors in plasma samples from healthy volunteers and ICU patients. Thus, a "simplified" approach to biosampling is a feasible solution for conducting biosampling research at sites lacking local biosample processing capacity.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000172

**Introduction:** The aim of this study is to assess whether a strategy combining spontaneous breathing trial (SBT) with both pressure support (PS) and positive end-expiratory pressure (PEEP) and extended use of post-extubation non-invasive ventilation (NIV) (extensively-assisted weaning) would shorten the time until successful extubation as compared with SBT with T-piece (TP) and post-extubation NIV performed in selected patients as advocated by guidelines (standard weaning), in difficult-to-wean patients from mechanical ventilation.
**Methods:** The study is a single-center prospective open label, randomized controlled superiority trial with two parallel groups and balanced randomization with a 1:1 ratio. Eligible patients were intubated patients mechanically ventilated for more than 24 h who failed their first SBT using TP. In the extensively-assisted weaning group, SBT was performed with PS (7 $cmH_2O$) and PEEP (5 cmH2O). In case of SBT success, an additional SBT with TP was performed. Failure of this SBT-TP was an additional criterion for post-extubation NIV in this group in addition to other recommended criteria. In the standard weaning group, SBT was performed with TP, and NIV was performed according to international guidelines. The primary outcome criterion was the time between inclusion and successful extubation evaluated with a Cox model with adjustment on randomization strata.
**Results:** From May 2019 to March 2023, 98 patients were included and randomized in the study (49 in each group). Four patients were excluded from the intention-to-treat population (2 in both groups); therefore, 47 patients were analyzed in each group. The extensively-assisted weaning group had a higher median age (68 [58–73] vs. 62 [55–71] yrs.) and similar sex ratio (62% male vs. 57%). Time until successful extubation was not significantly different between extensively-assisted and standard weaning groups (median, 172 [50–436] vs. 95 [47–232] hours, Cox hazard ratio for successful extubation, 0.88 [95% confidence interval: 0.55–1.42] using the standard weaning group as a reference; $p = 0.60$, Fig. 1). All secondary outcomes were not significantly different between groups.
**Conclusions:** An extensively-assisted weaning strategy did not lead to a shorter time to successful extubation than a standard weaning strategy.

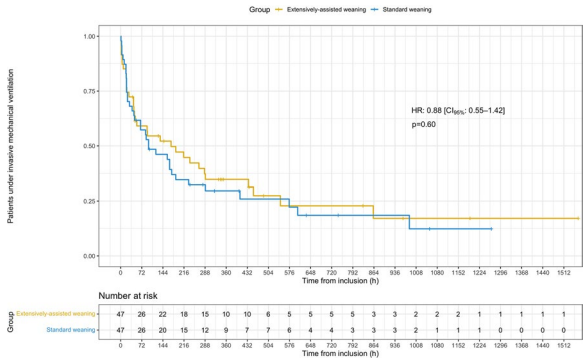

**Fig. 1 (abstract 000172)** Kaplan–Meier curve depicting the time to successful extubation. HR denotes hazard ratio and CI 95%, 95% confidence interval

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000174

**Introduction:** Ventriculo-arterial coupling (VAC) is determined by a formula involving ratio of arterial elastance/ventricular end-systolic elastance (Ea/Ees). Changes in Ea or Ees are connected to changes in ventricular end-systolic pressure-stroke volume (Pes-SV) interaction (1). Therefore, examining Pes-SV interaction can help us understand how VAC changes with treatments, like giving a fluid bolus.
**Objectives:** This study aimed to elucidate the alignment between nine pre-defined patterns of Pes-SV interaction and the observed response to fluid bolus concerning Pes-SV interaction in patients diagnosed with sepsis or septic shock.
**Methods:** We conducted a proof-of-concept study by utilizing data from three prior prospective studies. We documented alterations in arterial pressure and cardiac output (CO) before and after the administration of a fluid bolus, subsequently deriving values for Pes and stroke volume (SV). The primary outcome measured the percentage of patients exhibiting Pes-SV interaction responses to the fluid bolus that corresponded to the predefined nine patterns of Pes-SV interaction.
**Results:** Total 164 septic shock patients underwent fluid bolus were included. The responses to fluid bolus, with respect to Pes and SV, were categorized into nine predefined interaction patterns (Fig. 1). Table 1 displays the proportions of patients in each category from three data sources. Majority of patients (49.40%) manifested elevation both Pes and SV. Notably, in Fig. 2, subgroup of patients identified as worsening VAC, the highest proportion (47.50%) was found in the data source that included patients experiencing atrial fibrillation (AF). Within this worsening VAC subgroup, Ea was significantly increased (34.67%), contrasting with patients classified as improved VAC subgroup, where a negative change in Ea (− 5.74%), as illustrated in Fig. 3. Moreover, a noteworthy association was established between the three types of changes in VAC (stable, improved, or worsening) and fluid responsiveness ($\chi^2 = 27.81$, $P < 0.001$) as well as presence of AF ($\chi^2 = 21.79$, $P < 0.001$), shown in Fig. 4.

**Conclusions:** This study provides evidence for the existence of the nine proposed Pes-SV interaction patterns, potentially reflecting changes in VAC after fluid bolus in patients with septic shock. Our findings suggest that these patterns might offer valuable insights into qualitative VAC assessment.

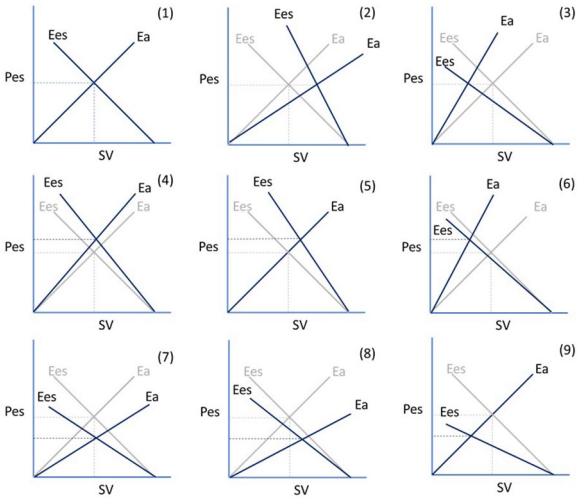

**Fig. 1 (abstract 000174)** Shows nine patterns of treatment response regarding the interaction between Pes and SV. The Ea and Ees are illustrated in slope of linear relationship between the Pes and SV. The light grey lines represent hypothetical baseline values. The dark blue lines represent the possibility of slope would be changed according to the interaction between the Pes and SV. The pattern number 1, 2, and 3 illustrate patterns with stable Pes with various change of SV. The pattern number 4, 5, and 6 illustrate patterns with increased Pes with various change of SV. The pattern number 7, 8, and 9 illustrate patterns with decreased Pes with various change of SV. Changes in patterns 1, 4, and 7 are defined as stable VAC. In patterns 2, 5, and 8, they are defined as improved VAC. Finally, in patterns 3, 6, and 9, they are defined as worsening VAC, respectively

**Table 1 (abstract 000174)** Illustrates the proportion of patients falling into the predefined nine patterns of Pes-SV interaction in response to a fluid bolus

| Patterns of Pes-SV interaction | All patients N = 164 | 1st data source N = 28 | 2nd data source N = 59 | 3rd data source N= 77 |
|---|---|---|---|---|
| no changing of Pes and SV n (%) | 1(0.60%) | 0 | 1(1.70) | 0 |
| constant of Pes, increase SV n (%) | 0 | 0 | 0 | 0 |
| constant of Pes, decrease SV n (%) | 0 | 0 | 0 | 0 |
| increase of Pes, constant SV n (%) | 6(3.70) | 0 | 3(5.10) | 3(3.90) |
| increase of Pes, increase SV n (%) | 81(49.40) | 22(78.60) | 9(15.30) | 50(64.90) |
| increase of Pes, decrease SV n (%) | 16 (9.80) | 1(3.60) | 11(18.60) | 4(5.20) |
| decrease of Pes, constant SV n (%) | 10 (6.10) | 0 | 6(10.20) | 4(5.20) |
| decrease of Pes, increase SV n (%) | 28 (17.10) | 4(14.30) | 13(22.00) | 11(14.30) |
| decrease of Pes, decrease SV n (%) | 22 (13.40) | 1(3.60) | 16(27.10) | 5(6.50) |

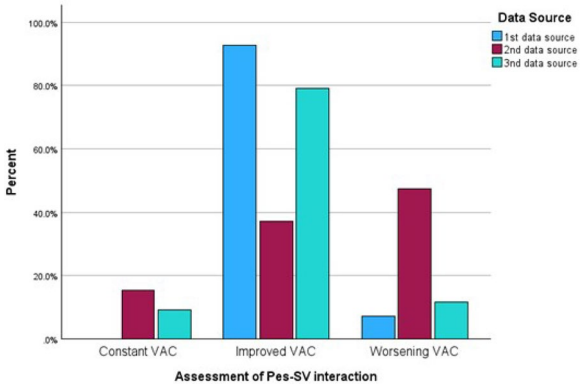

**Fig. 2 (abstract 000174)** Illustrates the proportion of patients classified into three groups characterized by the proposed VAC

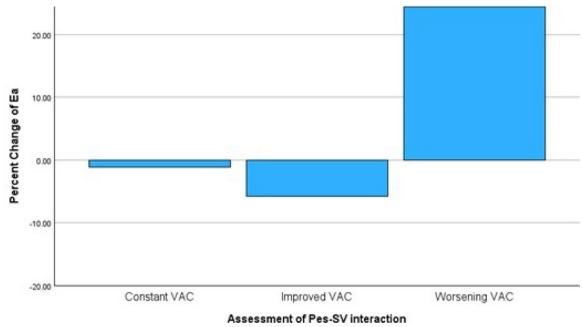

**Fig. 3 (abstract 000174)** Presents the percentage change of arterial elastance (Ea) in different patterns of the proposed VAC, characterized by Pes-SV interaction

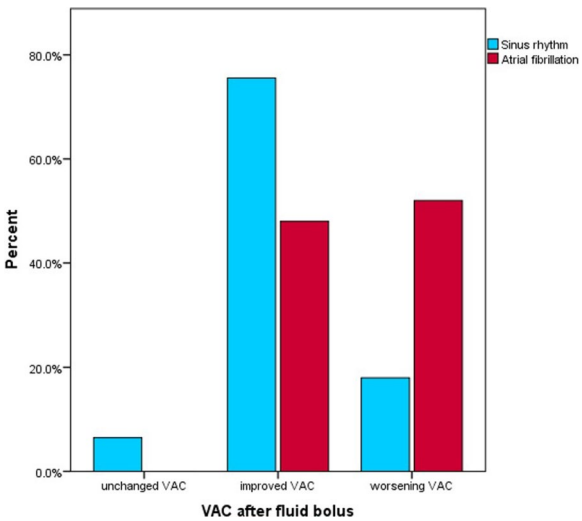

**Fig. 4 (abstract 000174)** Displays the varying proportions of patients with atrial fibrillation (AF) and sinus rhythm across each category, classified according to the proposed characteristics of volume-assisted closure (VAC) in response to a fluid bolus

### Enhanced Survival and Restored Liver Function in *Sepsis* through Selective Inhibition of Protein Kinase C alpha

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000175

**Introduction:** In 2019, bacterial pathogens accounted for 7.7 million fatalities worldwide, with sepsis contributing to 56.2% of associated deaths. The pivotal role of immune dysregulation, recently highlighted by Shankar-Hari and colleagues, and the systemic immunemodulatory properties of the liver's microenvironment underlay the clinical observation that hepatocyte dysfunction significantly exacerbates mortality rates, underscoring its importance in sepsis pathophysiology.
**Objectives:** Hepatic dysfunction, characterized by excretory liver failure and metabolic aberrations, is a common complication in sepsis, significantly amplifying mortality rates by compromising immune defenses. While experimental evidence suggests that restoring excretory liver functions can enhance immune response and sepsis survival, the mechanistic insights remain elusive.
**Methods:** Utilizing a murine peritoneal contamination and infection (PCI) model, we delved into the role of conventional Protein Kinase C alpha (PKC-α) in sepsis. We employed PKC-α knockout and Midostaurin, a clinically approved PKC inhibitor, to evaluate the kinase's impact on sepsis outcomes. Micromorphological liver stability was assessed through ultrastructural evaluations of canaliculi and microvilli. Additionally, the metabolization and elimination of deuterated chenodeoxycholic acid (CDCA-d4) were monitored to discern liver excretory function. Finally, we analyzed blood samples from AML patients, some of whom were treated with Midostaurin, to assess liver function using a sensitive technique called LC–MS.
**Results:** Both PKC-α knockout and selective inhibition significantly enhanced sepsis survival rates, with 60% of PKC-α knockout mice surviving 14 days post-infection and 47% of the inhibitor-treated mice compared to controls. Notably, both strategies preserved liver micromorphology, evidenced by intact canaliculi ultrastructures and microvilli counts. Furthermore, reduced plasma CDCA-d4 levels in both intervention groups postulated PKC-α modulation reinstated excretory liver functionality. Host immune response evaluations revealed that PKC-α knockout attenuates inflammation, evidenced by diminished cytokine levels and suppressed T cell activation, whereas PKC inhibition had no immune modulatory effects. In patients with AML experiencing a chemotherapy-induced liver acute phase response, Midostaurin-treatment significantly decreased bile acid levels by the end of the chemotherapy. These observations were corroborated by in vitro studies using a Hepatocyte model with polarized human HepaRG cells, where Midostaurin attenuated inflammation-induced canalicular remodeling.
**Conclusions:** PKC-α is a pivotal regulator of excretory liver function during sepsis. Targeting PKC-α emerges as a promising therapeutic avenue, potentially restoring liver functionality without compromising the immune response, thus potentially enhancing survival in sepsis. This translational insight underscores the therapeutic potential of PKC-α modulation in managing hepatic complications in sepsis.

### Not a quite place: understanding noise level in a newborn intensive care unit (nicu) and the stability of newborn's vital parameters

S. Rossi[1], A. Salvatore[1], G. Ottonello[1], R. Da Rin Della Mora[1], S. Parodi[2], S. Serveli[1], S. Scelsi[1]

**Correspondence:** S. Rossi
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000178

**Introduction:** Adaptation to extrauterine life is challenging for preterm. Environmental stimuli, like noises, could lead to adverse health outcomes, causing vital parameters instability and neurodevelopment impairment.
American Academy of Pediatrics recommends a maximum environmental noise $\leq 45$ decibels (dB) in NICU. However, simply trying to reduce the environmental noise in a NICU may not be the optimal approach to the problem, considering that the principal studies available in the literature show no effectiveness in maintaining noise levels low over the years and considering that some noises like monitor alarm needs to be listened by healthcare personnel.
The study presented is the first part of a larger Randomized Controlled Trial (RCT—currently ongoing) that aims to protect newborns admitted to the NICU from excessive environmental noises.
**Objectives:** The primary study objective was to describe environmental noises in a NICU and the number of patients' tachycardia, tachypnoea, and desaturation events that could be related to excessive environmental noises.
The secondary objective is to calculate the sample size for the RCT study.
**Methods:** Observational study. Environmental noises were recorded with sound level meters. Registration was performed during the morning, afternoon, and night shifts of the working day, both inside the incubator and at the patient's bedside. The vital parameters of the patient enrolled were recorded with a video camera to allow further data analysis. The data were analysed with descriptive statistics, and the confounding variables (e.g., ventilatory support, gestational age, drugs administered, timing of patient hygiene, feeding, or procedures) were controlled. The sample size calculation will be conducted following the method proposed by Cundill and Alexander.
**Results:** The average environmental noise level was always $> 45$. The minimum level of environmental noises was never $\leq 45$ dB. Six patients were enrolled, and 22 registrations were performed (1 to 4 h long). Data cleaned from confounding variables show the following vital parameter alterations (therefore maybe related to excessive environmental noises): five patients showed tachycardia episodes, with an average of 15,69 episodes for recording (min. three max. 168); three patients showed tachypnoea episodes, averaging 34,67 (min. seven max. 180); five patients showed desaturation episodes, averaging 16,4 (min. one max. 145). The analysis to evaluate the sample size necessary to reach a power of 90% shows a range from 18 to 128 patients necessary (if we consider tachycardia or tachypnoea as primary outcomes to

evaluate). Therefore, more data is needed to calculate the sample size correctly.
**Conclusions:** Study shows how the environmental noise level in the NICU is always over the safety level recommended. Patients enrolled have shown an instability of the vital parameters. The relationship between the two observed variables must be investigated through further studies.

### Critical Care Nurses' Workload: Association between Nurses' Subjective and Objective Workload: A Prospective Observational Longitudinal Cohort Study

S. Fischbacher[1], T. E. Matthias[2], M. Simon[3], D. Suzanne[4], M. M. Jeitziner[5]
[1]ICU, Stadtspital Waid, Zürich, Switzerland; [2]Intensive Care, Inselspital, Bern, Switzerland; [3]Nursing & Midwifery Research Unit, University Hospital Bern (Inselspital), Bern, Switzerland; [4]Institute of Nursing Science, < span Basel, Switzerland; [5]Department of Intensive Care Medicine, University Hospital Bern, Bern, Switzerland
**Correspondence:** S. Fischbacher
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000179

**Introduction:** A high workload for critical care nurses (CCNs) is associated with increased adverse events like patient mortality, nosocomial infections, pressure ulcers and medication errors as well as lower patient safety and satisfaction (Rae et al., 2021; Ross et al., 2023; Chang et al., 2019). Understanding the factors that influence subjective workload as well as the association between subjective and objective workload could lead to new insights to reduce CCNs' workload.
**Objectives:** (1) To describe CCNs' subjective and objective workload per shift in a university-affiliated interdisciplinary adult intensive care unit in Switzerland and (2) to explore the association between objective and subjective workload.
**Methods:** This is a prospective longitudinal cohort study using online questionnaires and routine data between November 2022 and January 2023. CCNs completed the adapted Questionnaire on the Experience and Evaluation of Work 2.0 (QEEW2.0) to assess the subjective workload at baseline and after every shift for four weeks (van Veldhoven et al., 2015). The objective workload was assessed with the Therapeutic Intervention Scoring System-28 (TISS-28), Nine Equivalents of Nursing Manpower Use Score (NEMS), Swiss Society for Intensive Care Medicine (SGI)-patients' categories and nurse-to-patient ratio (NPR) (Kommission Patientenklassifizierung (KPK-CCP), 2006; Miranda et al., 1997; Reis Miranda et al., 1996). Data was analysed using multilevel mixed models.
**Results:** 60 CCNs with a total of 765 shifts were analysed. The CCNs' mean age was 33.5 years (SD = 7.4) and 95% ($n = 57$) were female. They cared for 956 patients during their shifts. The CCNs experienced a subjective high mental load (66 ± 26), moderate pace and amount of work (30 ± 25) and physical load (33 ± 25), and low emotional-moral load (26 ± 22) (0 = never loaded, 100 = always loaded). The baseline subjective workload values were higher than the day-to-day values. For example, the CCNs perceived the emotional-moral load on average 49 (SD = 11) at baseline and 26 (SD = 22) after their shifts (0 = never loaded, 100 = always loaded). The mean objective shift load using the TISS-28 was 43 ± 16 points (equivalent to 456 min of work), the NEMS 36 ± 14 points, the SGI-category 1.1 ± 0.5 nurses needed per patient and the NPR 1.2 ± 0.4. We found positive associations between all objective workload variables to day-to-day subjective pace and amount of work, physical and mental load, but none to emotional-moral load and subjective performance. Effects from only objective workload were highest for pace and amount of work and mental load. Mental load is highest explained by objective workload including human factors. Effects from only human factors, showed the lowest effect on pace and amount of work.
**Conclusions:** Measured objective workload is associated with only certain subjective workload domains. To promote and retain CCNs in the profession, nursing management should give a high priority to understanding subjective workload and strategies for reducing it.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000180

**Introduction:** Delirium is a multi-causal condition that is frequently encountered in intensive care units (ICU) following cardiac surgery and is associated with high mortality rates, significant morbidity, prolonged hospital length of stay, elevated inpatient costs, and functional and cognitive decline up to a year post-surgery. Due to the burden that this condition places on patients and the healthcare system, there is an urgent need to undertake further studies to explore the multifactorial causes of delirium and better understand its pathophysiology.
**Objectives:** The primary aims were to: (1) Ascertain the current incidence of ICU delirium post-cardiac surgery; (2) Explore the mean patient ICU and hospital length of stay (LOS) in patients who experienced delirium; (3) Investigate critical care and hospital mortality rates in those patients with ICU delirium. Our secondary aims included identifying predisposing and contributing factors to ICU delirium post-cardiac surgery such as patient demographic data, pre- and intra-operative factors and daily ICU blood test results.
**Methods:** Between October 2023 and March 2024, a large dataset was collected retrospectively from patients' medical records for the period spanning September 2021 to September 2023. Daily measurements were obtained for blood tests and delirium (using the Confusion Assessment Method-ICU tool). Data were assigned to two different cohorts (delirium and non-delirium) to further investigate group differences. The project was locally registered as a service evaluation. Data were analysed using the Mann–Whitney test for continuous variables and Pearson's Chi-Square test or Fischer's Exact test for categorical variables using SPSS v29.
**Results:** Data were retrieved for a total of 899 patients. The mean age of patients was 63.08 (SD ± 10.71), most were men (77%) and commonly underwent cardiac bypass graft surgery (55%). From the results obtained, one in six patients developed ICU delirium after cardiac surgery ($n = 151$). Delirium was more prevalent in older patients, with a mean age of 66.74 (SD ± 9.88) compared to 62.79 (SD ± 10.46) in the non-delirium cohort, whilst no significant differences were observed between gender and the presence of delirium ($p = 0.487$). Intra-operative factors, including increased cardiopulmonary bypass and cross-clamp time, respectively 110 min (83.68–143.0) and 71.72 min (54.07–103.27), were found to be statistically associated with delirium ($p < 0.001$). The type of procedure performed was also found to be significant across the groups ($p < 0.001$), specifically when comparing single-valve procedures to complex operations involving two or more procedures in one. Patients who experienced ICU delirium had a substantially longer ICU LOS of 10.46 (SD ± 12.0) compared to patients without delirium (3.34, SD ± 1.80) ($p < 0.001$), which subsequently impacted their hospital LOS. Similarly, the hospital mortality outcome also demonstrated an association with delirium (delirium 3.97% vs non-delirium 1.34%, $p = 0.038$). Inflammatory blood markers, including C-reactive protein and white blood cells, were not statistically associated with the presence of ICU delirium. Raised renal blood test markers, such as creatinine and blood urea nitrogen, were shown to be significantly elevated in patients with ICU delirium ($p < 0.001$). ICU delirium post-cardiac surgery was also associated with higher levels of some electrolytes including sodium, calcium and phosphate ($p < 0.001$).
**Conclusions:** Delirium occurring in ICU post-cardiac surgery is associated with older age, complex and prolonged procedures, and patients exhibiting elevated renal and electrolyte blood markers. Delirium is significantly associated with prolonged patient LOS, leading to poorer patient health outcomes, including increased mortality. These factors should be taken into consideration to aid clinical decision-making regarding the prevention and management of delirium in post-cardiac surgery patients.

**Introduction:** Acute Respiratory Distress Syndrome (ARDS) is characterized primarily by lung injury resulting from systemic or local inflammation. Severe COVID-19 associated ARDS (CARDS) presents with high mortality rates and treatment complexities, often with limited efficacy from current therapies. Currently, there is a gap in research comparing the single-cell landscape of bronchoalveolar lavage fluid (BALF) among ARDS patients with varying prognoses.
**Objectives:** This study aimed to compare the BALF single-cell landscapes of severe CARDS and non-CARDS patients to investigate the dynamic changes in BALF single-cell profiles during different stages of severe CARDS.
**Methods:** This prospective study included 4 CARDS patients and 4 non-CARDS patients. BALF were collected on admission day (t1) and at a time point where the absolute difference in Murray Lung Injury Score (Δ MS, |Murray score (t2)—Murray score (t1)| ) was ≥ 1 point (t2). Exacerbation was defined as Δ MS ($t2 - t1 \geq 1$ point, and remission as Δ MS ($t2 - t1 \leq -1$ point. Patients received anesthesia and analgesic treatment before obtaining BALF, which underwent immediate single-cell RNA sequencing (scRNA-seq) analysis.
**Results:** All patients received mechanical ventilation therapy, with baseline lymphocyte counts uniformly low. Single-cell sequencing revealed neutrophils as predominant in BALF of all ARDS patients, followed by macrophages, T cells, and epithelial cells. Comparing neutrophil subtypes in BALF between exacerbation and remission groups of CARDS patients, a significant increase in IL-1β + neutrophils was observed in exacerbation group BALF compared to baseline, indicating an association between high-inflammatory neutrophils and poor prognosis in CARDS patients. Differential gene expression analysis showed significant upregulation of IL-1β, IF16, ISG15, GBP1, IL1RAP, and IL1R2 in IL-1β + neutrophils. Scmetabolism and Compass analysis suggested inhibited glucose metabolism and elevated fatty acid oxidation levels in IL-1β + neutrophils. Enhanced activity of fatty acyl-CoA desaturase and ACSL1 in IL-1β + neutrophils suggested neutrophil lipid metabolism reprogramming as a major cause of their high inflammatory levels. By associating ligands in the microenvironment with differentially expressed genes (DEGs) in IL-1β + neutrophils, IL-6

from IFIT + CXCL10 + M1 macrophages was found to induce a pro-inflammatory phenotype in IL-1β + neutrophils. OLINK validation revealed a significant increase in BALF supernatant and plasma IL-6 in the exacerbation group compared to the remission group after treatment, suggesting macrophages exacerbate the pro-inflammatory phenotype in neutrophils.

**Conclusions:** This study demonstrates neutrophil predominance in severe ARDS BALF, with IL-1β + neutrophils being a major indicator of poor CARDS prognosis. Neutrophil lipid metabolism reprogramming drives their high inflammation, while IFIT + CXCL10 + M1 macrophages exacerbate inflammation in IL-1β + neutrophils by releasing iL-6, suggesting potential therapeutic targets for CARDS.

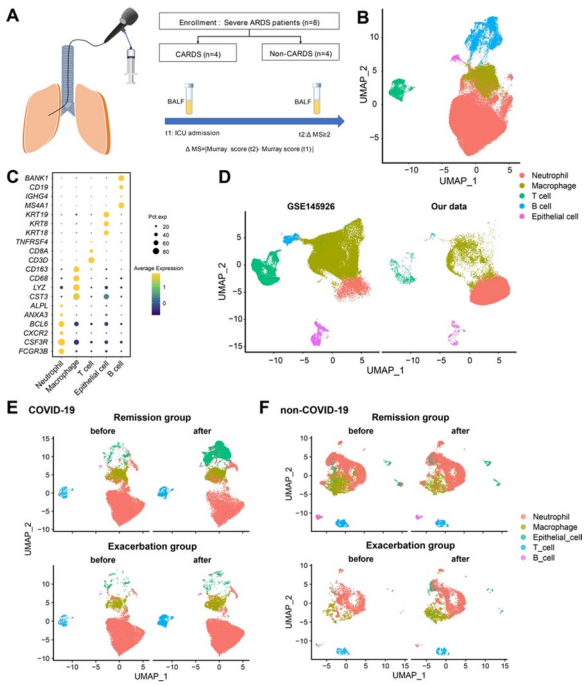

**Fig. 1 (abstract 000182)** Comparison of BALF single-cell profiles in severe ARDS patients with different prognoses. (A) Patient inclusion and specimen collection process diagram. (B) UMAP of single cells in BALF of all patients included. (C) ?Dot plot visualizing averaged expression of canonical markers across neutrophils, macrophages, T cells, B cells, and epithelial cells. (D) Comparison of BRAF single-cell profiles between our CARDS patients before treatment and GSE145926. (E) Comparison of single-cell profiles (before and after treatment) between the lung-injury exacerbation group and remission group in CARDS patients. (F) Comparison of single-cell profiles (before and after treatment) between lung-injury exacerbation group and remission group in non-CARDS patients

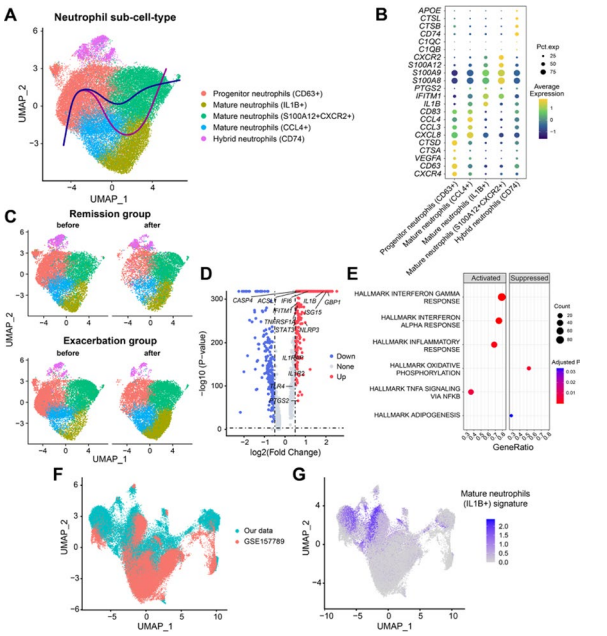

**Fig. 2 (abstract 000182)** Analysis of neutrophil subtypes in BALF patients with CARDS. **(A)** UMAP of BALF neutrophils in CARDS patients. **(B)** Dot plot visualizing averaged expression of canonical markers across BALF patients. **(C)** Comparison of single-cell neutrophil profiles (before and after treatment) between lung-injury exacerbation group and remission group in CARDS patients. **(D)** Volcano plot showing differentially expressed genes (DEGs) in IL-1B + neutrophils. **(E)** GSEA results showing the upregulation and downregulation gene sets of IL-1B + neutrophils. **(F)** UMAP of the combination of neutrophils in our data and in single-cell data of Sinha et al. (GSE157789) after removing the batch effect. **(G)** The expression profiles of IL1B + neutrophil signature in the combined data

Next, we compared the expression of IL1B signaling pathway related genes in BALF between CARDS and non-CARDS patients. The expression of *IL1B*, *IL1R1*, and *IL1RAP* genes in BALF of CARDS patients was significantly increased compared to non-CARDS patients (Fig. 3). Also, in non-CARDS patients, the proportions of IL1B + neutrophils in both the remission group and exacerbation group are fairly low, and there was no significant change before and after treatment (Fig. 3B). Considering the changes in cell type proportions of non-CARDS patients with

different prognoses in Fig. 3F, we further believe that the association between IL1B + neutrophils and prognosis is mainly a phenomenon unique to CARDS.

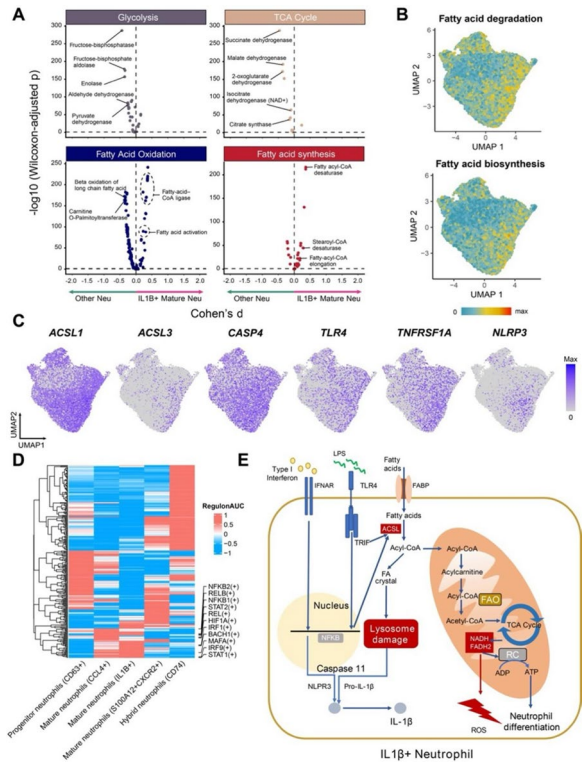

**Fig. 3 (abstract 000182)** Metabolic and regulatory network analysis on IL1B + neutrophils. **(A)** Compass-score differential activity test results comparing IL-1B + neutrophils and other types of neutrophils. **(B)** Quantifying metabolism activity at the single-cell resolution using the "scMetabolism" package. **(C)** Expression of ACSL1, ACSL3, CASP4, TLR4, TNFRSF1A, and NLRP3 in IL-1B + neutrophils. **(D)** Heatmap of regulon activity across five neutrophil groups, showing the active transcription factors of IL-1B + neutrophils. **(E)** Schematic diagram of the mechanism in IL1B + neutrophils for receiving extracellular signals, undergoing genetic regulatory changes, releasing IL-1β, and metabolic state changing

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000183

**Introduction:** Capillary leakage caused by endothelial injury is the pathological basis of sepsis. Fluid resuscitation, as the primary treatment for sepsis, can improve cellular metabolic disorders, but the mechanism is unclear. The aim of this study was to expound the metabolic changes in fluid resuscitation of sepsis and further find ways to alleviate endothelial injure in sepsis.
**Methods:** General characteristics of patients and circulation indicators were collected. Inflammatory indicators were detected using ELISA. Differential metabolites from fluid resuscitation were detected by non-targeted GC–MS and enriched in relevant metabolic pathways through KEGG. The expression of key enzymes in the tryptophan pathway during different stages of fluid resuscitation was detected by qPCR and WB. Differential metabolites and clinical indicators was detected through correlation analysis. The effects of the metabolites on endothelial cells were confirmed using in vitro and in vivo experiments. In vitro experiments, the effect of kynurenic acid (KYNA) on proliferation of HUVEC through CCK8 assay and cell migration by scratch test. The effect of KYNA on the expression of junction protein was detected by WB. Cecum ligation and puncture (CLP) was constructed. In vivo experiments, the effect of KYNA on vascular leakage was conducted using H&E and evans blue staining. The receptor of KYNA was screened by transcriptome sequencing. The expression of KYNA receptor GPR (G-protein coupled receptor) 35 was detected by WB and immunofluorescence. The shRNA vector of GPR35 was constructed to detect the downstream target genes by transcriptome sequencing. The molecular binding relationship between GPR35 and aldehyde dehydrogenase (ALDH) 1L2 was clarified through molecular docking. The effect of KYNA on endothelial cell was confirmed by ATP content. Cellular metabolic status was detected through seahorse experiments.
**Results:** It was found that tryptophan metabolism pathway was enriched in patients with sepsis who have good clinical outcomes through fluid resuscitation, and there is a transition from kynurenine (KYN) to KYNA. A significant negative correlation was observed between KYNA and IL-1β. KYNA was negatively correlated with the content of lactic acid, the results indicated that KYNA plays an anti-inflammatory role and could improve microcirculation in fluid resuscitation. It was found that the abundance of KAT undergoes dynamic changes at different stages of liquid resuscitation. In the second stage of fluid resuscitation, the level of KAT protein is significantly upregulated. There is a decrease in KAT abundance in the third stage, and a drastic decrease in KAT abundance in the fourth stage; Interestingly, the abundance trend of KYNA at different stages is completely consistent with KAT, indicating that KAT should be activated to mediate the involvement of KYNA in fluid resuscitation in sepsis. High level of expression of both KYNA and IL-1β indicates the optimization period. The stable period is defined by a high level of KYNA but a low level of IL-1β. In vivo and in vitro experiments confirmed that KYNA had anti-inflammatory effects on lipopolysaccharide (LPS)-treated HUVECs and reduced IL-1β and TNF-α in septic mice caused CLP. H&E staining indicated that KYNA could reduce the infiltration of inflammatory cells in the lung, alveolar collapse, and pulmonary vascular congestion in CLP-induced sepsis. Evans blue staining showed that KYNA could alleviate fluid leakage from lung tissue. The expression of GPR35 was increased by KYNA stimulated. Transcriptome sequencing showed that inhibiting GPR35 significantly reduced the expression of mitochondrial ALDH1L2. GPR35 and ALDH1L2 can be tightly bound through molecular docking experiments. ATP content was increased which stimulated by KYNA. After the treatment with KYNA, the overall activation level of mitochondrial aerobic phosphorylation in endothelial cells was significantly enhanced, indicating that KYNA regulates mitochondrial homeostasis in endothelial cells.
**Conclusions:** The conversion of KYN to KYNA was confirmed in fluid resuscitation. The potential application of KYNA was explored in improving capillary leakage in sepsis, providing new ideas for elucidating the mechanism of fluid resuscitation in treating capillary leakage in sepsis and optimizing the treatment of sepsis.

**Introduction:** Patients requiring emergency colorectal cancer surgery are at high risk of postoperative complications and mortality. However, data on the characteristics and outcomes of these patients admitted to the intensive care unit (ICU) are limited.
**Objectives:** This study aimed to investigate the factors associated with ICU admission and mortality in patients undergoing emergency colorectal cancer surgery.
**Methods:** We retrospectively analyzed 95 patients who underwent emergency colorectal cancer surgery at our institution between January 1, 2021, and December 31, 2023. Patients were divided into two groups based on ICU admission. Demographics, cancer characteristics, surgical details, and outcomes were compared between the groups. Univariate and multivariate analyses were performed to identify factors associated with ICU admission and mortality.
**Results:** Of the 95 patients, 37 (38.9%) required ICU admission. Patients in the ICU group had significantly longer operation time (median 170 vs. 135 min, $p=0.003$), higher intraoperative blood loss (median 190 vs. 60 ml, $p=0.003$), and a higher proportion of bowel perforation as the indication for surgery (27/37 [73.0%] vs. 29/58 [50.0%], $p=0.027$) compared to the non-ICU group. Postoperative mortality was significantly higher in the ICU group (9/37 [24.3%] vs. 1/58 [1.7%], $p<0.001$). Age, sex, cancer location (colon vs. rectum), stage, and histologic grade did not differ significantly between the groups. In multivariate analysis, operation time $\geq$ 180 min (odds ratio [OR] 3.24, 95% confidence interval [CI] 1.18–8.92, $p=0.023$) and blood loss $\geq$ 200 ml (OR 4.71, 95% CI 1.54–14.37, $p=0.007$) were independent predictors of ICU admission.
**Conclusions:** In patients undergoing emergency colorectal cancer surgery, longer operation time and higher intraoperative blood loss were associated with a higher risk of ICU admission. These findings suggest that early recognition and management of high-risk patients may improve outcomes in this critically ill population. Prospective multicenter studies are needed to validate these results and develop risk stratification models for patients requiring emergency colorectal cancer surgery.

### Thermal evaluation of fluid administration in a rat model of kidney ischemia

G. karduz[1]; U. Aksu[1]
[1]Biology, İstanbul Üniversitesi Fen Fakültesi Biyoloji Bölümü, Fatih, Turkey
**Correspondence:** G. karduz
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000189

**Introduction:** Renal ischemic reperfusion (IR) injury is one of the major sources of renal cell injury and can lead to renal failure associated with acute kidney injury (AKI). Acute normovolemic hemodilution (ANH) is a blood conservation technique shown to reduce transfusion and bleeding associated with surgery. Despite numerous advantages of hemodilution, little is known about the effect of ANH on renal failure associated with ischemia.
**Objectives:** In our study, we aimed to evaluate the relationship between fluid administration and I/R injury through thermal imaging.
**Methods:** Anesthetized Wistar albino rats ($n=7$) were divided into 7 groups: Sham-operated control (C), aortic occlusion (30 min) (ISC), 90 min reperfusion following aortic occlusion (30 min) (I/R), ANH induced by normal saline (NS) (HEM-1), ANH induced by a balanced crystalloid solution (HEM-2), ANH induced by NS following I/R (HEM-1 + ISC), and ANH induced by a balanced solution following I/R (HEM-2 + ISC). Hemodilution was targeted at a hematocrit level of 25%. Besides systemic hemodynamic parameters, serum creatinine and urea levels as indicators of renal dysfunction were measured. Also, renal tissue thermal characteristics were determined by thermal imaging.
**Results:** The target hematocrit levels were successfully achieved, resulting in a significant decrease in the hemodilution groups. When the fluid volumes and hemodilution periods were compared in the hemodilution groups, no significant difference was found to be among the HEM-1, HEM-2, HEM-1 + ISC, and HEM-2 + ISC groups. Mean arterial pressure (MAP) showed significant differences compared to respective baseline levels in all intervention groups (I/R, $p<0.01$; HEM-1, $p<0.01$; HEM-1 + ISC, $p<0.001$; HEM-2, $p<0.05$ and

HEM-2 + ISC, $p < 0.01$). However, the urea/creatinine ratios in the I/R, HEM-1, HEM-1 + ISC and HEM-2 + ISC groups were higher compared to their respective baselines ($p < 0.05$). In addition, mean temperatures showed significant decreases compared to respective baseline temperatures in the I/R, HEM-1, HEM-1 + ISC, and HEM-2 + ISC groups.

**Conclusions:** Regardless of fluid type and presence of ischemic period, fluid administration affects macrohemodynamics. Ischemic damage cannot be prevented by fluid administration. Moreover, thermal imaging can be a monitoring tool for kidney function during surgical scenarios.

**Keywords:** renal ischemia/reperfusion, thermal imaging, hemodilution.

**Introduction:** In persistent and unresolving ARDS, impaired lung healing and excessive fibroproliferation contributes to pathogenesis. Structural changes of lung tissue can impair gas-exchange and reduce pulmonary compliance. Fibroblast activation and production of ECM (extracellular matrix) components and their subsequent crosslinking play an essential role in regulating pulmonary function (1). Excessive crosslinking of ECM fibres could lead to a stiffer matrix and less airspace. Lysyl hydroxylase and lysyl oxidase (LOX) family enzymes play a role in crosslinking of collagen (2–3). Pyridinoline is collagen crosslink that makes collagen less susceptible to degradation—thus impacting the reversibility of fibrosis.
**Objectives:** We aimed to assess the abundance and crosslinking status of collagen in unresolved ARDS and compare it to controls and to idiopathic pulmonary fibrosis, an irreversible condition characterized by excessive collagen crosslinking.
**Methods:** Explanted lungs from transplanted patients with COVID-19 ARDS, post-mortem sections from non-COVID-19 ARDS, and explants from transplanted IPF patients were used. As controls, macroscopically normal regions of lung resections from patients with lung cancer were used. Experiments were approved by the Ethics Committee of the University Medical Center Groningen. Lung tissue was analysed using a hydroxyproline-based biochemical assay for for total collagen and UPLC for analysis of pyridinoline. Tissue sections were stained for LOX, LOXL1, and LOXL2 and analyzed in ImageJ. The area and intensity were defined by level of gray scale of positive pixels, divided by the total area. Airspace area was calculated in FIJI ImageJ by subtracting the tissue area from the total area of the sample. Parametric (T-test, Pearson) and non-parametric tests (Mann–Whitney *U*, Spearman Rank) were performed by IBM SPSS statistics 28. For total collagen, pyridinoline/collagen ratio, and airspace area, 20 non-COVID-19 ARDS, 12 COVID-19 ARDS, 10 IPF, and 11 control explant samples were included. For LOX, LOXl1 and LOXl2 area and intensity, 12 COVID-19 ARDS, 10 IPF, and 9 control samples were used.
**Results:** Total collagen levels were higher in non-COVID-19 ARDS (Fig. 1A, $P=0.022$) but not COVID-19 ARDS ($p=0.14$) compared to controls, while levels in IPF were significantly higher than all other groups. However, the number of collagen crosslinks per collagen molecule was not different between non-COVID-19 ARDS, COVID-19 ARDS and controls, but an increased number was seen in IPF (Fig. 1B).
The percentage airspace area was lower in COVID-19 ARDS and IPF samples compared to the control group (Fig. 1C, $P=0.032$ and $P=0.015$ respectively), but there were no differences between these patient groups ($p=0.664$). LOX-stained area and intensity were lower in COVID-19 ARDS and IPF, compared to controls (Fig. 1D, G, both $P<0.001$), with no differences between COVID-19 ARDS and IPF. LOXL1 stained area was lower in COVID-19 ARDS compared to controls (Fig. 1E, $P=0.017$), with no dissimilarities between COVID-19 and IPF.
LOXL2 area and intensity was significantly higher in COVID-19 ARDS compared to IPF (Figure IF & J, $P=0.015$ and $P=0.025$, respectively), while the LOX2L intensity was also higher compared to controls ($P=0.009$).
Airspace area inversely correlated with total collagen (Table 1, $R=-0.517$, $P=0.012$), and correlated with LOX and LOXL1 area ($R=0.693$, $P<0.001$ and $R=0.469$, $P=0.028$, respectively, Table 1). Pyridinoline/collagen ratio was inversely correlated with LOXL2 area ($R=0.427$, $P=0.026$), while LOX area correlated with LOXL1 and LOXL2 area ($R=0.529$, $P<0.001$ and $R=0.353$ and $P=0.030$, respectively).
**Conclusions:** While total collagen content is higher in unresolved ARDS compared to controls and lower in IPF, collagen and pyridinoline crosslinking is less abundant in unresolved ARDS compared to IPF samples. Since the LOX and LOXL1 crosslinking system seems to be less present in unresolved ARDS and IPF patients compared to healthy controls and LOXL2 shows the opposite, the latter couldThese findings suggest that unresolved ARDS, is not characterized by excessive collagen crosslinking, and might thus be reversible (compared to IPF).

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000191

**Introduction:** Acute Respiratory Distress Syndrome (ARDS) mortality remains high globally [1]. The current standard relies on supportive management up to Extracorporeal Membrane Oxygenation (ECMO) but lacks a definitive solution [2]. Recently, hydrogen gas has drawn fresh interest as it beneficially acts on multiple biological pathways in ARDS development [3]. A recent clinical trial demonstrated that hydrogen gas inhalation for mild-moderate ARDS via face mask improved the disease severity and respiratory symptoms [4]. However, the nebulised method poses great challenges for severe ARDS patients requiring ECMO, as the extensively collapsed alveoli hinder its application.

**Objectives:** This study aims to determine whether the administration of hydrogen gas (2%) via ECMO sweep gas can efficiently reduce severity in an ovine model of severe ARDS supported by ECMO, compared with conventional strategy using mechanical ventilation and ECMO alone.

**Methods:** This is a randomised controlled pre-clinical study over 48 h (from T0 to T48) with two groups: the hydrogen-treatment group ($n=8$) and the control group ($n=8$). Severe ARDS was induced by a validated 'double hit' oleic acid/lipopolysaccharide injury [5]. While adjusting positive end-expiratory pressure (PEEP) and tidal volume (TV) aiming the protective ventilation, T0 was when the international ECMO criteria6: $PaO_2/FIO_2 < 100$ mmHg, $PaCO_2 > 60$ mmHg, or uncontrolled hemodynamic instability due to respiratory acidosis, was met. ECMO was initiated at T1 by following the current standard guidelines for ECMO and mechanical ventilation [7, 8]. The primary outcome was respiratory mechanics (compliance and dead space ventilation). Fluid balance and the amount of vasopressor required to maintain hemodynamic were also measured.

**Results:** There was no difference in the baseline characteristics. The severity of ARDS triggering ECMO initiation was comparable (Fig. 1). The survival rate in both groups was the same (87.5%). ECMO flow was comparable and arterial oxygen (PaO2) maintained the same level for the entire period. With the same respiratory targets (i.e., plateau pressure < 24 cmH2O, driving pressure < 14 $cmH_2O$, and TV < 4 kg/ml), ventilatory settings (respiratory rate 10 times/min and PEEP 10 cmH2O), and mechanical power (J/min), static compliance after T42, and dead space after T18 non-statistically improved in the hydrogen-treatment group (Fig. 2). Following the same hemodynamic protocol for fluid resuscitation and vasopressor use and the consistent circulatory targets (i.e., heart rate < 120 beats/min and mean arterial pressure > 65 mmHg), total fluid balance and vasopressor requirement significantly decreased in the hydrogen-treatment group (Fig. 3).

**Conclusions:** Hydrogen gas delivered via ECMO sweep gas improved the respiratory mechanics. The hydrogen-treatment group required less fluid and vasopressor support, suggesting a potential anti-inflammatory effect of hydrogen that warrants further investigation.

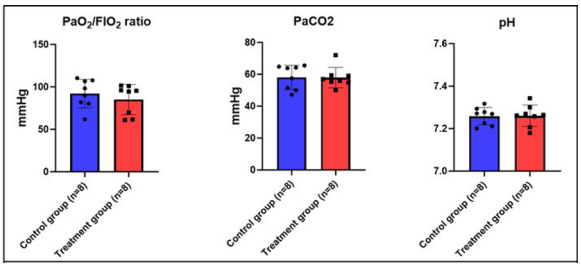

**Fig. 1 (abstract 000191)** Developed ARDS Severity before ECMO initiation. FIO2: fraction of inspired oxygen, PaCO2: partial pressure of carbon dioxide, PaO2: partial pressure of oxygen. The values of the PaO2/FIO2 ratio, PaCO2, and pH in arterial blood gas when the ECMO introduction was decided

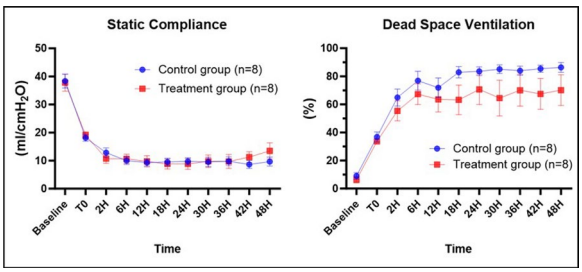

**Fig. 2 (abstract 000191)** Respiratory Severity. Statistic compliance after T42 and dead space ventilation after T18 were non-statistically better in the hydrogen-treatment group. ECMO was initiated at T1

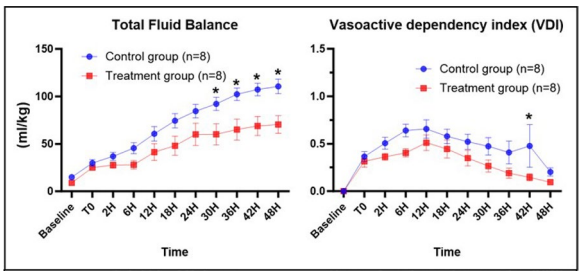

**Fig. 3 (abstract 000191)** Total Fluid Balance and Vasopressor Use. The hydrogen-treatment group had better haemodynamic stability and lower requirements for fluid resuscitation and vasopressor support. The vasopressor dependency index is the index value between the amount of vasopressor required and mean arterial pressure (MAP) at the time and is calculated as follows: ((norepinephrine dose × 100) + (vasopressin × 100) + (epinephrine × 100))/mean arterial pressure. ECMO was initiated at T1. * < 0.05

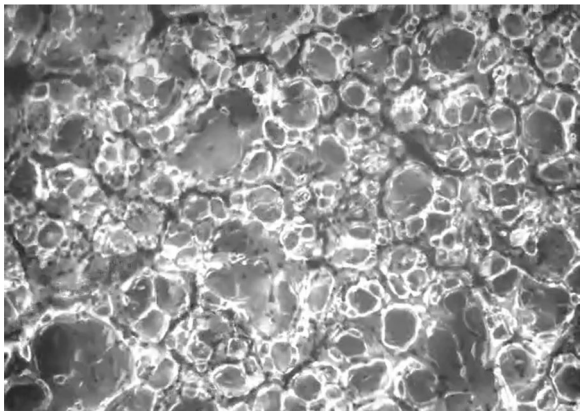
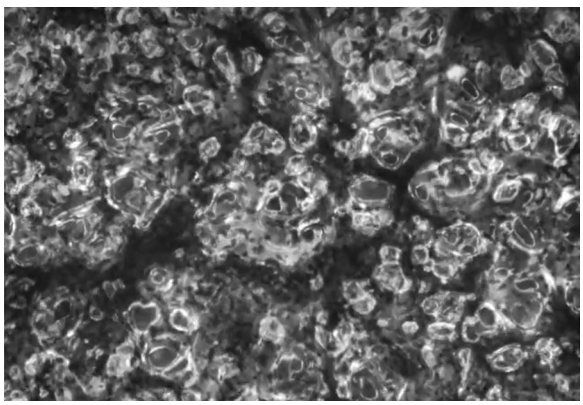
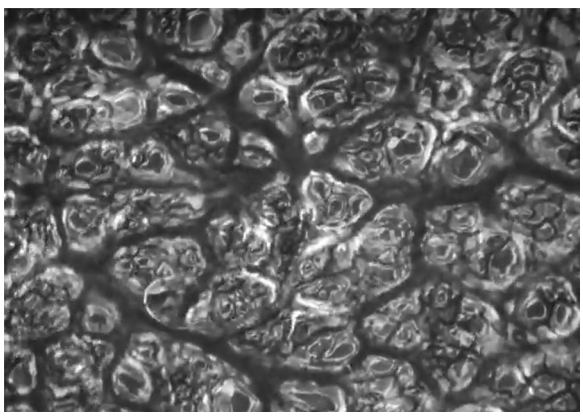
**Introduction:** This study aimed to identify the cyclical "on–off" flow of pulmonary microcirculation during inspiration and expiration by sidestream dark field imaging (SDF) technology in vivo and investigate the effects of volume status and driving pressure on cyclical "on–off" flow of microcirculation.
**Methods:** 24 ARDS-modeled rabbits were randomly divided into high-driving pressure group (HDP group) and low-driving pressure group (LDP group). Lung microcirculation measurements were performed using SDF microscope at two time points (T1 CVP 2–4 mmHg, T2 CVP 8–10 mmHg). From T1 to T2, 10 ml/kg saline was infused to increase CVP. The cyclical "on–off" pulmonary microcirculation was quantitatively assessed by the change of microcirculation between expiration and inspiration.
**Results:** Proportion of perfused vessels (PPV), microvascular flow index (MFI), Perfused vessel density (PVD),Total vessel density (TVD) at expiration were significantly higher than inspiration in HDP group. The HDP group has a higher ΔPPV and ΔPVD. After fluid loading, ΔPPV and ΔMFI decreased. TNF-α, IL-6, Ang-2 and vWF levels in the HDP group were higher. HDP group also has higher lung wet weight/body weight ratio, lung wet-to-dry weight ratio and more severe damage of pulmonary capillaries than the LDP group.
**Conclusions:** The difference in alveolar perfused microcirculation between inspiration and expiration defined as cyclical "on–off flow" can be detected. High driving pressure can enhance the cyclical "on–off" flow and fluid loading can relieve it. High driving pressure has the potential to cause injury to pulmonary capillaries due to the phenomenon of "on–off" flow, thereby exacerbating ARDS.



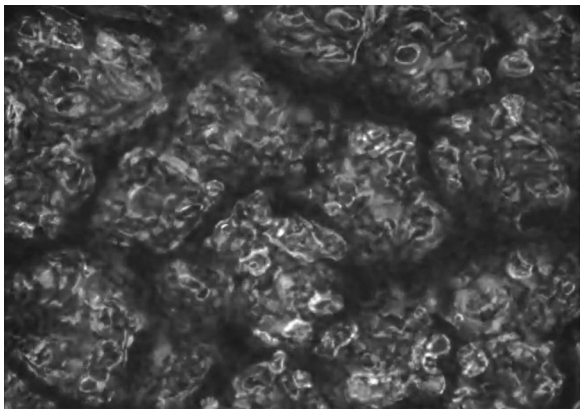
**Supplementary Video 1 (abstract 000192)** HDP at T1 during inspiration



**Supplementary Video 2 (abstract 000192)** HDP at T1 during expiration



**Supplementary Video 3 (abstract 000192)** LDP at T2 during inspiration



**Supplementary Video 4 (abstract 000192)** LDP at T2 during expiration

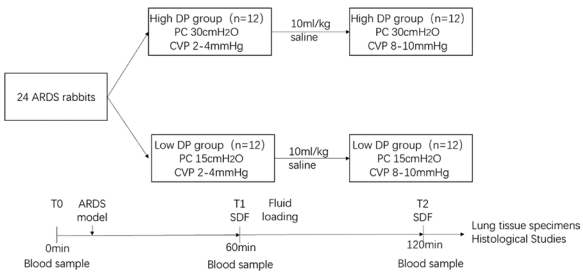


**Fig. 1 (abstract 000192)** Experimental Design
Twenty-four rabbits with acute respiratory distress syndrome (ARDS) were enrolled and stratified into two groups based on their received driving pressure (DP): a high DP group and a low DP group. Ventilation was performed using a pressure control model, with rabbits subjected to driving pressures of 30 $cmH_2O$ and 15 $cmH_2O$ for 60 min. Following the initial ventilation period, a 10 mL/kg saline solution was administered via intravenous injection, leading to an elevation in central venous pressure from 2–4 mmHg to 8–10 mmHg. Subsequently, rabbits underwent an additional 60 min of ventilation. In the end of the experiment, rabbits were sacrificed, and lung tissue specimens were collected for further analysis. Blood samples were obtained at three key time points: before the induction of ARDS, before fluid loading, and after 120 min of ventilation.
ARDS, acute respiratory distress syndrome; DP, driving pressure; PC, pressure control; CVP, central venous pressure.

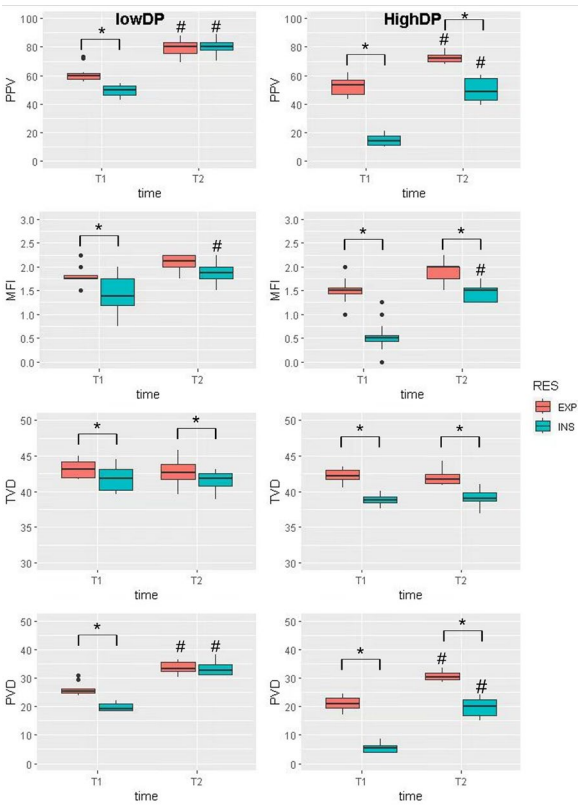

**Fig. 2 (abstract 000192)** SDF parameters in Two Ventilation Groups
SDF parameters, including PPV, MFI, TVD, and PVD, were assessed in two distinct groups. At the T1 time point, when both high and low driving pressure groups experienced low CVP, all indexes showed a significant increase during expiration compared to inspiration. After fluid loading at the T2 time point, ΔPPV, ΔMFI and ΔPVD (expiration–inspiration) narrowed both in the HDP and LDP group.
PPV, proportion of perfused vessel; MFI, microvascular flow index; TVD, total vessel density; PVD, perfused vessel density. * indicates a statistically significant difference between inspiration and expiration. # indicates a statistically significant difference between T1 and T2.

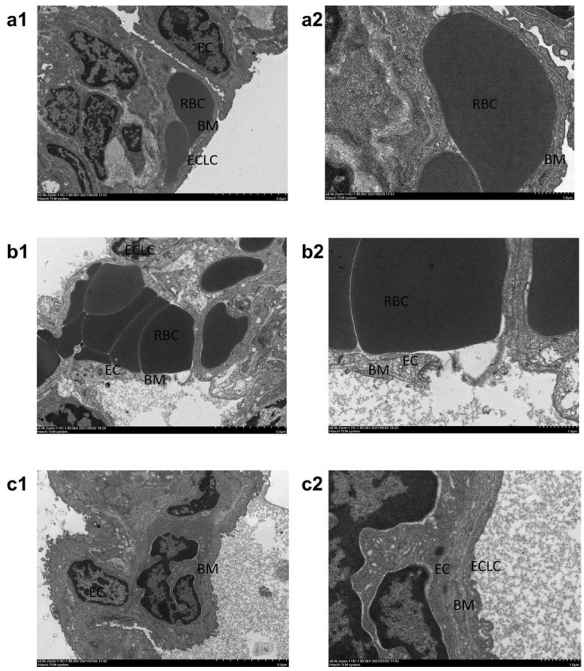

**Fig. 5 (abstract 000192)** Electron microscopy results
Among them, Fig. 5a1 shows a normal rabbit lung electron microscopy photo, the scale is 5.0um, the lung capillary structure is normal, endothelial cells (EC), capillary basement membrane (BM), lung epithelial cells (ECLC) morphological structure is basically normal and complete, red blood cells (RBC) can be seen in the capillary lumen, Fig. 5a2 is a magnified view of Fig. 5a1, the scale is 1.0 μm. Fig. 5b1 shows the pulmonary electron microscopy photo of the ARDS rabbit in the high-driving pressure group, the scale bar is 5.0um, red blood cells accumulate in the lumen of pulmonary capillaries, endothelial cells and lung epithelial cells are swollen, the capillary basement membrane structure is blurred, and some segments are broken, Fig. 5b2 is a magnified view of Fig. 5b1, the scale bar is 1.0um. Fig. 5c1 shows the pulmonary electron microscopy photo of the ARDS rabbit in the low-driving pressure group, the scale bar is 5.0um, some of the endothelial cell are swollen, but most of the structure of the capillary basement membrane is complete, Fig. 5c2 is a magnified view of Fig. 5c1, the scale bar is 1.0 μm.

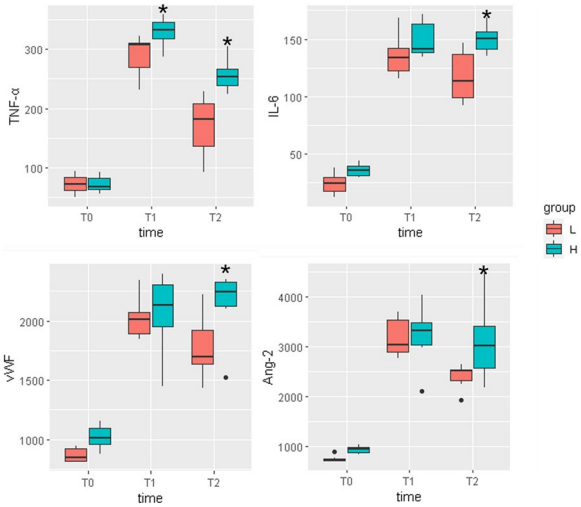

**Fig. 3 (abstract 000192)** Cytokine Profiling in Response to Ventilation Strategies
The cytokine levels in two distinct groups were assessed at three critical time points during the experiment. Blood samples were collected at T0, before the induction of ARDS; T1, following 60 min of ventilation with low CVP; and T2, after an additional 60 min of ventilation with high CVP. The cytokines analyzed included TNF-α, IL-6, Ang-2, and vWF, with a focus on elucidating differences between the two groups. At the T1 time point, it was observed that the high DP group exhibited a significant elevation in TNF-α levels compared to the low DP group. However, no significant differences were noted in the other cytokines at this juncture. At the T2 time point, the high DP group displayed higher levels of TNF-α, IL-6, Ang-2 and vWF in comparison to the low DP group.
TNF-α, tumor necrosis factor-α; IL-6, interleukin-6; Ang-2, angiopoietin-2; vWF, von Willebrand Factor.
* indicates a statistically significant difference between LDP group and HDP group.

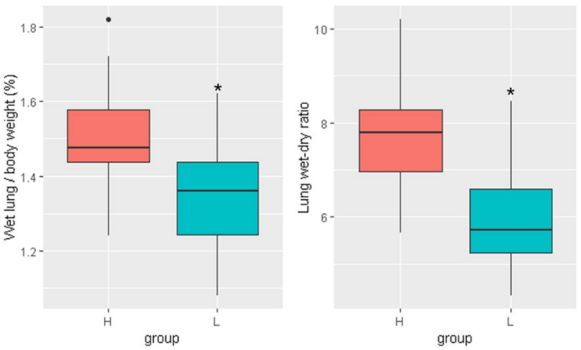

**Fig. 4 (abstract 000192)** Pulmonary Edema Comparison
Rabbits subjected to low DP group exhibited a significantly lower proportion of wet lung/body weight and lung wet-dry ratio compared to those exposed to high DP.
* indicates a statistically significant difference between the LDP group and the HDP group.

**Introduction:** Coronavirus disease (COVID-19) can cause pneumonia and hypoxaemic respiratory failure necessitating oxygen therapy and admission to the intensive care unit (ICU). While targeted oxygenation in critically ill adults has been explored in several randomised clinical trials, only few COVID-19 patients have been included [1]. Concerns are growing about long-term sequelae in COVID-19, including its impact on health-related quality of life (HRQoL) [2]. The recent Handling Oxygenation Targets in COVID-19 (HOT-COVID) trial investigated the benefits and harms of a lower vs. a higher oxygenation target in adult ICU patients with COVID-19 and acute hypoxaemic respiratory failure [3]. In this trial, we found more days alive without life support in the lower-oxygenation group at 90 days, with secondary outcomes at this timepoint also supporting the lower oxygenation target, albeit not reaching statistical significance [3]. The present study report the pre-planned one-year mortality and HRQoL of the HOT-COVID trial [4].
**Objectives:** To assess effects of a lower vs. a higher oxygenation target in adult ICU patients with COVID-19 and acute hypoxaemic respiratory

failure on one-year all-cause mortality and HRQoL. We hypothesised that the lower oxygenation target would improve both long-term survival and HRQoL compared to the higher target.

**Methods:** The HOT-COVID trial was a multicentre, randomised trial which planned to allocate 780 patients 1:1 to an arterial partial pressure of oxygen ($PaO_2$) target of 8 kPa vs. 12 kPa throughout their ICU stay for up to 90 days, including readmissions [3,4]. HRQoL was assessed using EuroQol 5 dimensions 5 levels (EQ-5D-5L) questionnaire and EQ visual analogue scale (EQ-VAS) [5]. Both outcomes were assessed at one-year follow-up in the intention-to-treat population; we assigned the worst possible score to deceased patients and applied multiple imputation for missing values in the EQ-VAS analysis. Secondary analyses of HRQoL were performed in survivors only.

**Results:** The trial was terminated early due to slow enrolment. We obtained one-year vital status for 691/726 (95.2%) and HRQoL for 642/726 (88.4%) patients. At one year, mortality was 33.6% (117/348) in the lower-oxygenation group and 39.1% (134/343) in the higher-oxygenation group (adjusted risk ratio: 0.85; 98.6% confidence interval (CI); 0.66 to 1.09 points; $p = 0.11$). Kaplan–Meier survival curves are shown in Fig. 1. Median EQ-VAS scores were 50 (interquartile range (IQR) 0–80) in the lower-oxygenation group and 40 (IQR 0–75) in the higher-oxygenation group (adjusted mean difference: 4.8; 98.6% CI − 2.2–11.9; $p = 0.09$) (Fig. 1). Similarly, we found no statistically significant differences in the analysis of survivors only.

**Conclusions:** In adult ICU patients with COVID-19 and acute hypoxaemic respiratory failure, a lower vs. a higher oxygenation target did not statistically significantly increase one-year survival or HRQoL, but the results indicate a potential overall benefit with the lower oxygenation target.

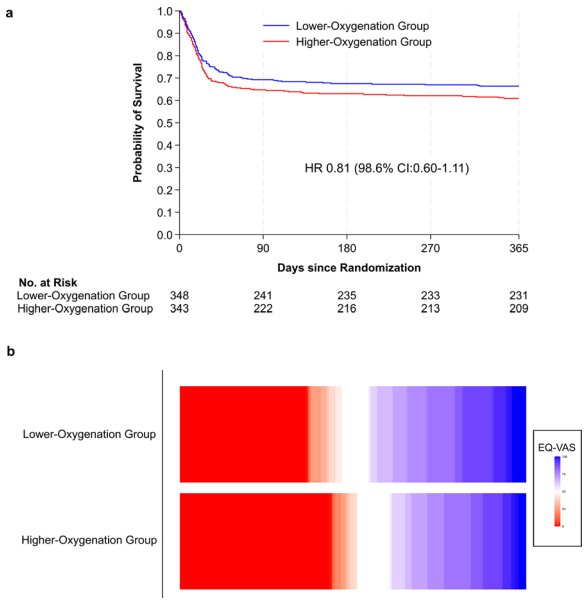

**Fig. 1 (abstract 000193)** Kaplan–Meier estimates of survival and heatmap of Euro-QoL Visual Analogue Scale data. a) Shown are the Kaplan–Meier plots of survival administratively censored at 365 days. Hazards ratio (HR) from Cox proportional hazards model adjusted for trial site. b) Shown is the distribution of EuroQol Visual Analogue Scale (EQ-VAS) data as horizontally stacked proportions in the two intervention groups; non-survivors were assigned a score of zero. Scores range from 0 to 100 and are represented by a colour scale ranging from red (worse outcomes) and blue (better outcomes) as illustrated in the legend. The horizontal axis represents the cumulated proportions of patients scoring at or below the corresponding value depicted in the legend

**Introduction:** Fonsecaea monophora is a kind of melanized fungi thatbelongs to Chaetothyriales and occurs mostly in tropicalregions, causing skin abscesses and infection. Fonsecaeamonophora is rarely found in central nervous system (CNS) infections. Cerebral phaeohyphomycosis is a CNS infectioncaused by dematiaceous fungi, and most cases of cerebralphaeohyphomycosis present as a brain abscess. Early identificationof cerebral phaeohyphomycosis is crucial; withoutprompt diagnosis, antifungal therapy is often delayed, whichleads to a high death rate. We report a case of cerebralphaeohyphomycosis caused by F. monophora in China. The patient improved with surgical intervention and voriconazole monotherapy.

**Objectives:** Fonsecaea monophora is a species of Fonsecaea that belongs to Chaetothyriales. It is usually isolated fromtropical and subtropical regions, causing reactive inflammation, skin abscesses, and pain. Cerebral infection caused by F. monophora is rare but often fatal. Diagnosing this disease at an early stage is difficult, and appropriate antifungal therapy isoften delayed as a result.

**Methods:** We report the case of a 53-year-old woman with type 2 diabetes who presented with a headache2months ago and progressive right-sided weakness of 1 month's duration. Magnetic resonance imaging revealed a spaceoccupyinglesion in the left frontal lobe and corpus callosum.

**Results:** The cystic mass was removed by surgical intervention, and theidentification of the sample based on sequencing of the internal transcribed spaced region in BLAST-N search showed thatthe sequences producing most significant alignments were F. monophora or similar (query cover 99%, *E* value 0.0, per ident 99.84).

**Conclusions:** Patient was treated with a 3-month course of twice daily voriconazole, leading to complete recovery. Consent to publish was obtained from the patient.

## Improving patient care transitions from the Intensive Care Unit to the ward by learning from everyday practice. A multicenter qualitative study on Work-As-Done from the perspective of nurses, patients and relatives

G. Hesselink[1], B. Westerhof[2], M. Moviat[3], M. Zegers[1]
[1]Intensive Care, Radboud University Medical Center, Nijmegen, Netherlands; [2]Intensive Care, Rijnstate Hospital, Arnhem, Netherlands; [3]Intensive Care, Jeroen Bosch Ziekenhuis, 's-Hertogenbosch, Netherlands
**Correspondence:** G. Hesselink
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000195

**Introduction:** The transition from the Intensive Care Unit (ICU) to the ward is an important episode in the patient's healthcare trajectory. Patients and relatives often find this transition difficult, because of the changes in care intensity and the shift of focus from stabilization and recovery to rehabilitation. While numerous procedures have been developed to optimize the transitional care process, little is known about how clinicians deal with the varying circumstances in daily practice and how their actions impact the quality of these transitions (i.e., Safety II).
**Objectives:** To gain better understanding of the everyday practices ('Work-As-Done') that hinder and facilitate patient care transitions from the ICU to the ward.
**Methods:** Multiple qualitative case studies in the ICU and various wards of three Dutch hospitals. Adult patients planned to be transferred were purposively sampled on a variety of characteristics along with their relative (if present), and the ICU and ward nurses who were involved in the transition process. Data were collected by using multiple sources (i.e., observations, semi-structured interviews and a qualitative survey) and then systematically analyzed using the thematic analysis approach until saturation was reached.
**Results:** Twenty-six cases were studied. For each case, the actual transfer was observed. Sixteen patients, five relatives and 36 nurses were interviewed. Two patients completed the survey. Fifteen themes emerged from the data, showing that the quality of transitions is influenced by the extent to which nurses anticipate to patient-specific needs (e.g., providing timely and adequate information, orientation, mental support and aftercare) and to the needs of the counterpart to continue care (e.g., by preparing handovers) besides following standard procedures. Data also shows that procedures sometimes interfere with what works best in practice (e.g., communication via a liaison service instead of direct communication between ICU and ward nurses).
**Conclusions:** Subtle, non-technical nursing skills play an important role in comforting patients and in the coordination of care when patients are transferred from the ICU to the ward. These Work-As-Done findings and their underlying narratives, that are often overlooked when focusing on quality improvement, can be used as material to

reflect on daily practice, and in turn, may stimulate ICU and ward staff in crafting interventions for optimizing the transition process.

## Major surgery induces CD8 T cell immunometabolic paralysis through stress-induced mitochondrial hyperfusion

S. Hirschberger[1], K. Lu[2], J. Büch[2], T. Barth[3], B. Wegener[4], S. Peterß[2], R. Tomasi[1], S. Kreth[1], M. Hübner[1]

**Correspondence:** M. Hübner
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000196

**Introduction:** Major surgery induces a profound immunological dysregulation frequently resulting in post-surgical immunosuppression. This pathological response particularly impairs the function of cytotoxic CD8+T cells (CTLs), which are important for effective clearance of pathogens, putting patients at risk of severe and life-threatening postoperative complications. For instance, almost 10% of patients undergoing elective major surgery develop postoperative nosocomial infections, leading to an increased mortality and additional healthcare costs of 20,000–40,000 US$ per incident [1, 2].
**Objectives:** Previously, we demonstrated that cardiopulmonary surgery leads to the transient generation of myeloid-derived suppressor cells (MDSCs) that induce massive immunoparalysis of human CTL [3], the exact mechanisms of which are currently unknown. Thus, we aimed at examining MDSC-specific immunosuppressive mechanisms and the underlying pathophysiology of postoperative CTL immunoparalysis more in detail.
**Methods:** Blood was obtained at the beginning (T1), the end (T2) of surgery and on the first postoperative day (T3) (Ethics approval: 17-241, LMU Munich). MDSC and CTL were isolated via magnetic cell separation. Cytotoxicity was assessed by Electric Cell-Substrate Impedance Sensing (ECIS). Espression profiles were determined using Next-Generation Sequencing (NGS) and proteomics. Patient serum was analysed by proteomics and metabolomics. Analysis of Reactive Oxygen Species (ROS), mitochondrial membrane potential (ΔΨm), metabolism and structure of CTL was performed using CellROX, JC1, and Seahorse.
**Results:** First, we could show that MDSC-mediated immunosuppression is a general phenomenon after major surgery and is not restricted to cardiopulmonary surgery: We detected newly emerging, acutely occurring MDSC not only after cardiac but also after other types of major surgery. CTL after major surgery (T2-CTL) displayed impaired cytotoxicity (Fig. A, − 14%±3.2%, $p=0.0074$), and IFNγ secretion was almost abrogated (− 91.1±6.5%, $p=0.0039$) compared to preoperatively isolated CTLs of the same patient (T1). As a potential cause NGS and proteomics of MDSC as well as serum proteomics and -metabolomics revealed a strong potential of ROS-production in MDSC and consecutive secretion (Fig. B-D). Mitochondria are especially prone to oxidative stress and mitochondrial fitness is directly linked to cytotoxic effector functions of CTLs. We thus next assessed CTL ROS levels and mitochondrial function in more detail: T2-CTL were shown to take up the produced ROS (Fig. E (left), +21.7%±9%, $p=0.0443$), decreasing antioxidative Glutathione in CTL (Fig. E right). T2 CTL exhibited a declined mitochondrial membrane potential (ΔΨm, Fig. F (left) − 17.4±5.8%, $p=0.0391$) accompanied by impaired mitochondrial oxidative respiration (Fig. F (right), − 58.7±35.7%, $p=0.0312$), and mitochondrial hyperfusion (Fig. G and H, mitochondria/cell: − 31.1±10.2%, $p=0.0069$; mitochondrial length: +620 nm, ±60 nm, $p<0.0001$). In contrast, fission-dependent mitochondrial translocation to the immunological synapse was severely restricted (Fig. I, − 51.6%±5.1%, $p<0.0001$). Importantly, reduction of excessive levels of mitochondrial ROS by Mitotempo, a mitochondria-specific ROS scavenger, improved mitochondrial respiration (Fig. H, +24,4±10.1%, $p=0.0312$), enhanced translocation of mitochondria to the immunological synapse (Fig. I, left +55.9±10%, $p=0.0002$) and improved cytotoxicity of CTLs as measured by ECIS (Fig. I, middle and right, +8.2±6%, $p=0.0256$.)
**Conclusions:** Major surgery induces systemic oxidative stress caused -at least in part- by newly emerging MDSC. This mechanism is responsible for damaging CTL mitochondria, leading to impaired mitochondrial integrity, collapse of the mitochondrial membrane potential and reduced mitochondrial respiration. To compensate for this severe mitochondrial dysfunction and to maintain basal metabolic functionality, mitochondria undergo hyperfusion at the expense of reduced translocation to the immunological synapse. This eventually deteriorates cytotoxic function of CTLs. Importantly, mitigation of excessive mitochondrial ROS partially abrogates mitochondrial damage and improves CTL cytotoxicity. Modulation of postoperative T-cell immunometabolism by reconstitution of mitochondrial fitness might represent a novel therapeutic approach to counteract postoperative immunoparalysis in the future.

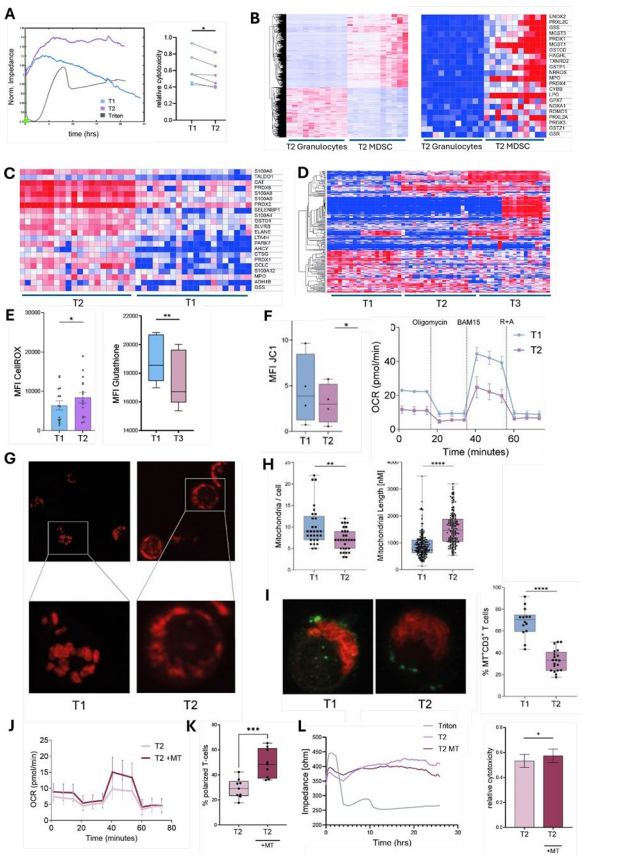

**Fig. (abstract 000196)** A–D: CD8+T cell (CTL) effector and mitochondrial function before (T1) and directly after (T2) major surgery. A) Cell lysis capacity of CTLs as measured by ECIS ($n=5$). ***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000197

**Introduction:** In patients with severe acute respiratory distress syndrome (ARDS), extracorporeal membrane oxygenation (ECMO) may improve survival [1]. During high flow veno-venous (V-V) ECMO therapy, decarboxylation becomes completely and oxygenation largely independent of ventilation and lung function. This allows intensivists to reduce the intensity of mechanical ventilation while ensuring adequate gas exchange. Therefore, improved gas exchange and reduced intensity of ventilation are likely the paths through which ECMO therapy exerts beneficial effects. However, it remains unknown to what extent improved gas exchange *versus* reduced intensity of mechanical ventilation may contribute to improved survival of patients treated with ECMO. Arterial partial pressures of oxygen ($paO_2$) and carbon dioxide ($paCO_2$) as well as arterial pH are important targets to prevent hypoxia and acidosis in patients with ARDS, while driving pressure ($DP = Pplat - PEEP$) [2] is a key driver of ventilator-induced lung injury (VILI). We hypothesized that decreased intensity of ventilation (reduced driving pressure) as well as improved gas exchange (increased $paO_2$ and pH, and reduced $paCO_2$) after ECMO initiation are associated with improved hospital survival.

**Methods:** Adult patients undergoing V–V ECMO therapy between 2019 and 2023 at Charité Universitätsmedizin Berlin, Berlin, Germany, with available ventilator data were eligible for this retrospective cohort study. Median driving pressure, $paO_2$, and $paCO_2$ during the 12 h before and after ECMO initiation were used to calculate changes during ECMO initiation. Parameters collected during a grace period of $\pm 2$ h around the time of ECMO initiation were excluded from these calculations to account for potential inaccuracies in the manual charting of ECMO initiation times. Multivariable logistic regression, adjusting for a broad range of confounding variables, was used to assess the association of changes in the aforementioned factors and hospital mortality. This study was approved by Charité's Ethics Committee (*EA2/139/20*).

**Results:** 237 patients with complete data for driving pressure and confounding variables were included. At baseline, the median driving pressure was 16cmH2O (13 to 19; interquartile range [IQR]), with a median reduction of – 4 $cmH_2O$ (− 7 to − 1; IQR) after ECMO initiation. Hospital mortality in the overall cohort was 51.9% ($n=123$). In adjusted analysis, higher baseline driving pressure was associated with increased risk of hospital mortality (adjusted odds ratio [aOR] 1.26 per 1 $cmH_2O$ increase, 95% confidence interval [CI] 1.09 to 1.47, $p=0.002$) and decreases in driving pressure after ECMO initiation were independently associated with decreased risk of hospital mortality (aOR 0.90 per 1 $cmH_2O$ decrease, 95%CI 0.81 to 0.99, $p=0.040$; adjusted risk difference [aRD] − 2.2% per 1 $cmH_2O$ decrease, 95%CI − 4.1% to − 0.2%; Fig. 1). Among patients with available arterial blood gas data before and after ECMO initiation ($n=126$), increases in $paO_2$ were associated with decreased hospital mortality (aOR 0.87 per 10 mmHg increase, 95%CI 0.77–0.98, $p=0.021$; aRD − 2.2% per 10mmHg increase, 95%CI − 4.0% to − 0.5%). Changes in paCO2 and pH were not associated with hospital mortality ($p=0.51$ and $p=0.10$, respectively).

**Conclusions:** Reducing driving pressure after ECMO initiation is associated with improved hospital survival of ARDS patients. Improvements in arterial levels of oxygen were further associated with better hospital survival. In our data, changes in arterial levels of carbon dioxide and pH were not associated with hospital survival.

These findings support the hypothesis that a substantial proportion of the beneficial effects of ECMO therapy in ARDS is explained by reduced intensity of mechanical ventilation. Further studies are needed to disentangle the paths through which ECMO exhibits beneficial effects and to identify patients most likely to benefit from this invasive intervention.

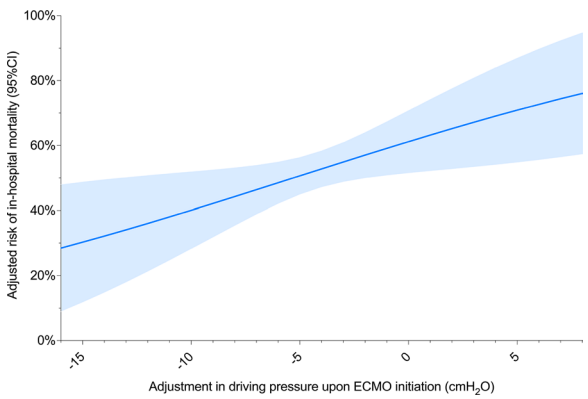

**Fig. 1 (abstract 000197)** Adjusted risk of hospital mortality by adjustments in driving pressure

Presented is the adjusted absolute risk of hospital mortality with 95% confidence intervals (95%CI) by adjustment in driving pressure upon ECMO initiation as obtained from the primary model. The range presented reflects adjustments from the 1st to the 99th percentile in the overall cohort. Hospital mortality in the overall cohort was 51.9%.

Abbreviations: 95 CI, 95 confidence interval.

### CPAx as a predictor of hospital discharge destination in patients admitted to ICU requiring prolonged mechanical ventilation

A. Harriman[1], J. Hodson[2], J. Weblin[1]
[1]Therapy Services, Queen Elizabeth Hospital Birmingham, Birmingham, United Kingdom; [2]Department of Critical Care, Queen Elizabeth Hospital Birmingham, Birmingham, United Kingdom
**Correspondence:** A. Harriman
*Intensive Care Medicine Experimental* 2024, **12(suppl 1):** 000199

**Introduction:** Critical illness is associated with muscle weakness and physical dysfunction that often persists beyond (ICU) (1), necessitating the requirement for rehabilitation post hospital discharge. Early discharge planning can reduce hospital length of stay (LOS) and readmissions, however, the predictive quality of physical assessments on discharge destination performed in ICU is uncertain (2). We aimed to evaluate the predictive accuracy of the Chelsea Critical Care Physical Assessment tool (CPAx) on discharge destination in patients admitted to ICU requiring prolonged mechanical ventilation (MV).
**Methods:** Data for patients admitted to a large, UK, ICU between September 2022–2023 was collected. Patients requiring ≥ 5 days MV without severe neurological or traumatic injury were included. Patient demographics and hospital outcomes were collected retrospectively via electronic patient records. CPAx at first rehabilitation session, defined as MMS ≥ 2 (sitting on edge of the bed), and ICU discharge was collected. Discharge destination was reported as; home; home with rehabilitation (Community or outpatient); and inpatient rehabilitation.
**Results:** 71 patients were included with a median age of 60 (IQR; 44–69), APACHE II score of 17.6 (SD ± 5.6) and Charloson Comorbidity Index of 3 (IQR; 2–5). Sedation days was 10 (IQR; 7–14) and MV days was 21 (IQR;10–32) with 51 (72%) requiring tracheostomies. Time to mobilisation was 12 days (IQR; 9–17) with a median ICU and hospital LOS of 25 (IQR; 17–40) and 40 (IQR; 26–54) days. 33 (46%) were discharged home without rehabilitation, 20 (28%) home with rehabilitation, 6 (8%) required inpatient rehabilitation one patient was transferred to another hospital and 11 (16%) died.
**Discharge destination**: First mobilisation CPAx decreased progressively across the subgroups of patients discharged home with no rehabilitation (16, IQR: 12–25); home with rehabilitation (11; 8–14); and inpatient rehabilitation (9; 8–12) ($p < 0.001$). ICU discharge CPAx mirrored this, with 'no rehabilitation' scoring 40 (IQR; 34–43), home rehabilitation 35 (IQR; 30–39) and inpatient rehabilitation 21 (IQR; 17–28) ($p < 0.001$).

| | Cohort (*N* = 71) | Hospital Discharge Destination | | | | *p*-Value |
|---|---|---|---|---|---|---|
| | | Home No Rehab (*N* = 33) | Home With Rehab (*N* = 20) | Inpatient Rehab (*N* = 6) | Died in Hospital (*N* = 11) | |
| Physical Assessments at First Mobilisation | | | | | | |
| CPAx | 13 (10–18) | 16 (12–25) | 11 (8–14) | 9 (8–12) | 11 (10–14) | **< 0.001** |
| Physical Assessments at ICU Discharge | | | | | | |
| CPAx | 35 (30–41) | 40 (34–43) | 35 (30–39) | 21 (17–28) | 34 (29–37) | **0.001** |

Hospital discharge destinations were further dichotomised into home with no rehabilitation vs. ongoing rehabilitation/death. CPAx score was significantly predictive of discharge destination at first rehabilitation (AUROC of 0.80) and at ICU discharge (AUROC of 0.75). At first mobilisation, an optimal CPAx threshold of 13 was found with 71% of patients with CPAx > 13 was discharged home without rehabilitation compared to 28% of those with CPAx ≤ 13, yielding accuracy of 67% sensitivity and 76% specificity. At ICU discharge, the optimal thresholds were CPAx > 37 yielding a similar accuracy.
**Conclusions:** In patients requiring prolonged MV, CPAx score at first mobilisation and ICU discharge is a good predictor of discharge destination. Early, and accurate identification of discharge destination may reduce hospital LOS, streamline rehabilitation processes, and improve communication within the pathway. Further research comparing the predictive accuracy of the CPAx to other physical assessments is warranted.

### Evaluating Post-Cardiac Arrest Imaging Protocols at Buckinghamshire Hospitals Trust ICU: A Comprehensive Audit from 2021 to 2023

P. Minnis[1], J. Winchester[1], T. Ali[2]
[1]Department of Intensive Care Medicine, Stoke Mandeville Hospital, High Wycombe, United Kingdom; [2]Stoke Mandeville Hospital, Buckinghamshire Healthcare NHS Trust, Stoke Mandeville, United Kingdom
**Correspondence:** P. Minnis
*Intensive Care Medicine Experimental* 2024, **12(suppl 1):** 000202

**Introduction:** The European Resuscitation Council advocates for CT brain and CT pulmonary angiography (CTPA) post-cardiac arrest to ascertain causality, focusing on pulmonary embolism or intracranial haemorrhage (1). This audit revisits and evaluates the implementation and outcomes of recommended imaging protocols within Buckinghamshire Healthcare NHS Trust's ICU following a preliminary audit in 2020, aiming to enhance post-arrest care pathways (2).
**Objectives:** To assess the adoption and impact of updated post-cardiac arrest imaging pathways in clinical practice, focusing on the diagnostic yield of CT scans in determining the cause of cardiac arrest.

**Methods:** A retrospective review of 104 patients admitted to ICU after in-hospital or out-of-hospital CPR from January 2021 to December 2023 was conducted. Data on CT scan administration, timings, and results were collected from patient records, discharge summaries, post-mortems, and death certificates.
**Results:** The audit of 104 post-cardiac arrest patients admitted from 2021 to 2023 revealed an increasing trend in admissions, with a significant uptick noted each year. Among the patients, 46% of those who underwent in-hospital CPR survived, compared to 34% for out-of-hospital CPR. While 64 patients presented with unclear causes of arrest, 40 had identifiable causes. CT imaging was performed in 97% of cases within 24 h. Despite a reduction in CT head scans from 86% in 2021 to 56% in 2023, the utilisation of CTPA remained stable, underscoring its importance in clinical assessment. Intracerebral haemorrhage ($n=4$) and ischemic stroke ($n=3$) were notable findings from CT head scans, while pneumonia and pulmonary embolism each accounted for 7 cases identified via CTPA. The data highlights the critical role of timely and targeted post-cardiac arrest imaging in enhancing patient outcomes.
**Conclusions:** The audit indicates a substantial diagnostic yield from CT imaging in post-CPR patients, underscoring the importance of adhering to updated imaging protocols. Despite a decrease in CT head scans, the consistent use of CTPA highlights its value in detecting potentially reversible causes of cardiac arrest. The findings advocate for ongoing protocol compliance to enhance patient outcomes post-arrest.

### An explainable machine-learning model for predicting persistent sepsis associated acute kidney injury: development, validation, and comparison with CCL14

W. Jiang[1]
[1]Department of Critical Care Medicine, The Northern Jiangsu People's Hosp., Yang Zhou Shi, China
**Correspondence:** W. Jiang
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000204

**Introduction:** Persistent sepsis-associated acute kidney injury (SA-AKI) portends worse clinical outcomes and remains a therapeutic challenge for clinicians. Early identification and prediction of persistent SA-AKI is crucial. The aim of this study was to develop and validate an interpretable machine learning (ML) model that predicts persistent SA-AKI.
**Methods:** Four retrospective cohorts and one prospective cohort were used for model derivation and validation. The derivation cohort utilized the MIMIC-IV database, randomly split into 80% for model construction and 20% for internal validation. External validation is conducted using subsets of the MIMIC-III dataset, the e-ICU dataset, and retrospective cohorts from the ICU of a Northern Jiangsu people`s hospital. Prospective data from the same ICU were used for validation and compared with urinary CCL14 biomarker measurements. AKI was defined based on serum creatinine and urine output, using the kidney disease: Improving Global Outcomes (KDIGO) criteria. Routine clinical data within the first 24 h of ICU admission were collected, and eight ML algorithms were utilized to construct the prediction model. Multiple evaluation metrics, including the area under the receiver operating characteristic curve (AUC), were employed to compare predictive performance. Feature importance was ranked using SHAP, and the final model was explained accordingly.
**Results:** Among eight ML models, the Gradient Boosting Machine (GBM) model demonstrated superior discriminative ability. Following feature importance ranking, a final interpretable GBM model comprising nine features was established. The final model accurately predicted the occurrence of persistent SA-AKI in both internal (AUC = 0.872) and external validation cohorts (MIMIC-III subset: AUC = 0.889, e-ICU dataset: AUC = 0.930, North Jiangsu people`s Hospital retrospective cohort: AUC = 0.942). In the prospective cohort, the GBM model outperformed urinary CCL14 in predicting persistent SA-AKI (GBM AUC = 0.850 vs. CCL14 AUC = 0.821). Additionally, the model has been

transformed into an online clinical tool to facilitate its application in clinical settings.
**Conclusions:** Our interpretable GBM model successfully and accurately predicts the occurrence of persistent SA-AKI, alleviating concerns regarding the "black box" nature of ML techniques through non-direct interpretation.

### The impact of temperature on gut microbiota in selective cerebral perfusion in neonatal arch surgery

Y. Wang[1], C. H. Huang[1], H. W. Chou[2], Y. S. Chen[2], S. C. Huang[2]

**Introduction:** The optimal temperature for selective cerebral perfusion (SCP) during neonatal aortic arch surgery remains undetermined. The primary objective of SCP is to supply oxygenated blood to the brain while temporarily interrupting blood flow to other areas of the body during aortic arch surgery. Nevertheless, the efficacy of lower temperatures during SCP in enhancing organ protection during ischemia remains unknown.
**Objectives:** The gut microbiota undergoes developmental changes from birth and experiences significant maturation within the initial 24 months of life [1]. The impact of ischemia during aortoplasty beyond coarctation site on the integrity of the gut microbiome is poorly understood. Here, we aim to investigate the influence of temperature variation during SCP in neonatal aortic arch surgery and its subsequent impact on the gut microbiota.
**Methods:** We conducted a prospective cohort study to examine the gut microbiota composition in neonates diagnosed with aortic coarctation undergoing aortoplasty utilizing cardiopulmonary bypass (CPB) and SCP techniques. Patients were stratified into two groups based on SCP core temperature: mild hypothermia (30 °C) and moderate hypothermia (25 °C). Three patients who had cardiac surgery under CPB were recruited as control group. Demographic and clinical data were collected alongside stool specimens, which were subsequently analyzed using 16S rDNA and metagenomic sequencing technologies to characterize the fecal microbiome.
**Results:** We compared ten patients under mild hypothermia with four under moderate hypothermia. No mortality or neonatal enterocolitis occurred in our cohort. Although SCP duration was similar between groups, the moderate hypothermia group experienced longer operation, CPB, and cross-clamp durations. Feeding initiation time was consistent, but the mild hypothermia group reported higher gastrointestinal symptoms (4/10) compared to moderate hypothermia (1/3) and control (1/3). Alpha and beta diversity analysis showed similar microbiota composition within the SCP group, distinct from controls. In post-operative infections, mild hypothermia patients showed Staphylococcus species colonization at the CVC site in 9 cases, along with other infections. Moderate hypothermia patients exhibited similar colonization in fewer cases. Controls had only one patient with CVC site colonization.
**Conclusions:** Differences were observed in the gut microbiota composition of neonates who underwent SCP compared to those who solely underwent CPB. Both the mild and moderate hypothermia groups displayed increased bacterial colonization than control group. However, a larger sample size is required to sufficiently discern these differences.

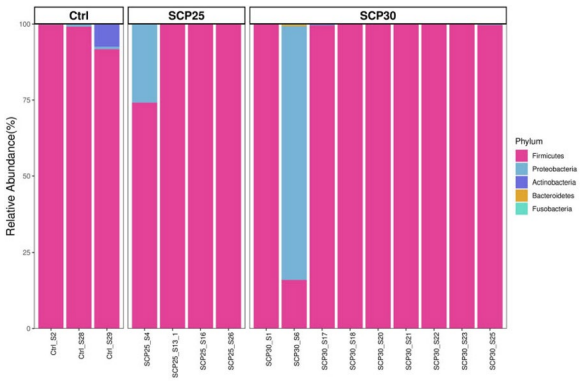

**Fig. (abstract 000205)** Gut microbiota in control group, moderate and mild hypothermia group

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000207

**Introduction:** Energy produced during mechanical ventilation has been established as a contributor to mortality in acute respiratory distress syndrome (ARDS) patients, elucidated through ventilator-induced lung injury (VILI). However, the potential association between strain energy, an engineering-based concept, and the risk of VILI remains unexplored.
**Objectives:** This study aims to investigate the correlation between strain energy and alveolar overdistension and the relationship between strain energy and single-breath mechanical power (MP) calculated by a simplified formula in patients with ARDS.
**Methods:** Ten sedated and paralyzed ARDS patients underwent decremental positive end-expiratory pressure titration by pressure-controlled ventilation, with simultaneous monitoring of esophageal pressure and electrical impedance tomography (EIT). Strain energy and single-breath MP were calculated using the following formulas from ventilator parameters.

— $\text{Strain energy} = 0.098 \times 1/2 \times (\text{Lung stress})2/12$ (joules).

Where the lung stress was determined as the following; Lung stress = plateau pressure × [1-(E_cw/E_rs)].

— Single breath MP (MPsb) = 0.098 × tidal volume × (PEEP + driving pressure) (Joules).

While EIT provided data on alveolar overdistension percentage (%OD) from EIT using the formula proposed by Costa et al.

**Results:** Enrolled ARDS patients had a mean age of 58.6 ± 22.5 years and $PaO_2/FiO_2$ of 148.3 ± 34.3. Strain energy and single-breath MP measured 1.9 ± 0.7 and 1.2 ± 0.5 J, respectively (Table 1).

In the evaluation of 10 patients, the strain energy demonstrated an elevation corresponding to changes in PEEP levels during the titration process. Across 70 events, a moderate correlation was identified between strain energy and the %OD, denoted by a correlation coefficient of 0.41 and a *p*-value < 0.001. Conversely, there was no discernible pattern in the MPsb observed throughout the PEEP titration. Consequently, no correlation was established between MPsb and %OD, with an r value of 0.10 and a *p*-value of 0.40.

No correlation was identified between strain energy and MPsb ($r = 0.01$, *p*-value 0.93). Furthermore, the values obtained from both parameters differed, as illustrated in Bland-Alman plot (Fig. 1).

According to the ROC analysis, the area under the curve for strain energy and MPsb in assessing potential alveolar overdistension was 0.735 (95% CI 0.617 to 0.853) and 0.569 (95% CI 0.433 to 0.706), respectively.

**Conclusions:** Strain energy demonstrates a stronger correlation with alveolar overdistension. This novel concept presents opportunities for further research aimed at preventing VILI.

**Table 1 (abstract 000207)** Respiratory mechanics during decremental PEEP titration

| Respiratory Mechanics | Overall population (N=10) |
|---|---|
| Optimal PEEP ($cmH_2O$) based on, mean (SD) | |
| RS compliance | 10.4 (3.0) |
| Zero Ptp at end-expiration | 15.1 (2.9) |
| EIT | 11.2 (2.1) |
| Strain Energy (joules), mean (SD) | 1.9 (0.7) |
| Single-Breath MP (joules), mean (SD) | 1.2 (0.5) |

Definition of abbreviations: n = number; SD = standard deviation; PEEP = positive end-expiratory pressure; RS = respiratory system; Ptp = transpulmonary pressure; EIT = electrical impedance tomography; MP = mechanical power

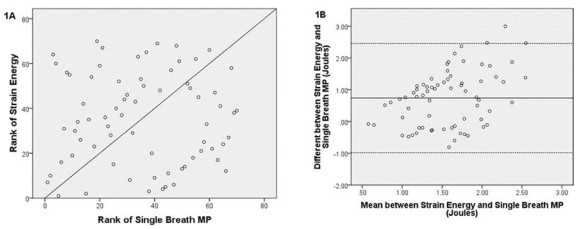

**Fig. 1 (abstract 000207)** A A linear relationship between strain energy and single-breath mechanical power without correlation ($r = 0.01$, *p*-value = 0.93); **1B** mean different values = 0.74 and standard deviation (SD) = 0.88. The limits are − 0.98 to 2.46 (mean 1.96 SD). As the mean of two measurements increases, the difference between the two measurements increases as well

### Inhibition of xanthine dehydrogenase protects against heatstroke-related acute kidney injury

C. Wenting[1], S. Yongwei[2], L. wang[3], Y. Xuesen[4], D. Huanzi[1]
[1]Department of Rheumatology and Clinical Immunology, Daping Hospital, Army Military Medical University, Chongqing, China; [2]Department of Rheumatology and Clinical Immunology, 1, chongqing, China; [3]Department of Rheumatology and Clinical Immunology,, Daping Hospital, Army Military Medical University, Chongqing, China; [4]Key Laboratory of Extreme Environmental Medicine, Ministry of Education of China, Army Military Medical University, Chongqing, China

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000210

**Introduction:** The military often faces extreme weather in combat, in which high temperature can easily lead to heatstroke and threaten the health of soldiers. Heatstroke-related acute kidney injury (HS-AKI) is a core visceral injury caused by heat stroke. Preventing and treating HS-AKI is important to maintain the health of army troops and improve the combat effectiveness of army forces. However, the underlying molecular mechanism of HS-AKI remain unclear and without effective mechanism-mediated treatment strategies.

**Objectives:** To investigate whether inhibition of xanthine dehydrogenase can protects against heatstroke-related acute kidney injury.

**Methods:** C57 male mice were divided into three groups: control group, HS group and febuxostat (Feb, an Xdh-specific inhibitor, 10 mg/kg/day) group. After establishing HS model, gene ontology (GO) was performed to investigated the enriched GO terms and differentially expressed protein. Western blots and RT-qPCR measured protein level and RNA level of differentially expressed protein in vivo and in vitro. Core body temperature was measured by rectal temperature of mice. Survival rate was calculated as percent survival versus time. Serum creatinine and urea were measured by colorimetric detection assay kit. Human kidney proximal tubule epithelial (HK-2) cells were treated with small interfering RNA against differentially expressed protein. Then, inflammation level was detected by western blots. Reactive oxygen species (ROS) Assay Kit measured ROS level.

**Results:** The GO enrichment analysis found that the differentially expressed proteins between the control group and HS group were mainly enriched in biological processes such as stress, inflammation and uric acid metabolic pathway. Xanthine dehydrogenase (Xdh), the key enzyme for uric acid metabolic pathway, protein level was greater in HS group than in control group. In vitro and in vivo validation confirmed that HS caused a significant increase in RNA and protein levels of Xdh. Compared with HS mice, core body temperature rise rate decreased in febuxostat group. Febuxostat ameliorated renal function impairment induced by HS. HS increased oxidative stress (ROS) and inflammation (TNFα, IL-6, IL-β) levels in HK2 cells. Small interfering RNA against xanthine dehydrogenase (siXdh) ameliorated oxidative stress and inflammation leaded by HS in HK2 cells.

**Conclusions:** Xdh promotes oxidative stress and inflammation in HS-AKI. Down-regulation of Xdh may be a promising target for preventing HS-AKI.

**Introduction:** Veno-arterial-venous extracorporeal membrane oxygenation (VAV-ECMO) improves global oxygen delivery (DO2) while avoiding Harlequin syndrome in patients with cardiopulmonary failure. However, multiple considerations, including cardiac function, pulmonary oxygenation, and venovenous (VV) ECMO recirculation, complicate the optimal flow diversion between VA- and VV-ECMO flows at a fixed total ECMO flow. It is well known that the systemic and pulmonary circulation can be modelled as an electric circuit using a 5-element resistance–capacitance network with four cardiac chambers represented by time-varying elastance. In the model, the addition of a bypass circuit corresponding to the anatomical inlet/outlet sites allows us to simulate VA- or VV-ECMO circulation.
**Objectives:** The aim of this study was to investigate the impact of VAV-ECMO flow diversion with fixed total ECMO flow on haemodynamics and regional oxygen saturation in patients with cardiopulmonary failure by using a VAV-ECMO simulator.
**Methods:** As shown in Fig. 2, VA-ECMO dominant management in VAV-ECMO support significantly increased global DO2 compared with VV-ECMO dominant management (VV-ECMO alone: 123 mL/min vs. VA-ECMO alone: 469 mL/min) in extremely severe cardiopulmonary failure. In severe low pulmonary oxygenation (DL: 0.014 mL/min/mmHg) with preserved LV function, a high VA-ECMO ratio significantly reduced LV SO2 (VV-ECMO alone: 89% vs. VA-ECMO alone: 67%) indicating Harlequin syndrome. In severe LV dysfunction, a high VA-ECMO ratio increased LAP (VV-ECMO alone: 22 mmHg vs. VA-ECMO alone: 26 mmHg). Figure 3 illustrates an example of flow diversion guidance to achieve global DO2 $\geq$ 400 mL/min and LV $SO_2 \geq 80\%$. As shown in the left panel of Fig. 3, lower LV function and pulmonary oxygenation required a higher VA-ECMO ratio to maintain global DO2. However, in extremely low oxygenation with preserved LV function (the right panel of Fig. 3), a high VA-ECMO ratio induced the Harlequin syndrome (blue area).
**Results:** As shown in Fig. 2, VA-ECMO dominant management in VAV-ECMO support significantly increased global DO2 compared with VV-ECMO dominant management (VV-ECMO alone: 123 mL/min vs. VA-ECMO alone: 469 mL/min) in extremely severe cardiopulmonary failure. In severe low pulmonary oxygenation (DL: 0.014 mL/min/mmHg) with preserved LV function, a high VA-ECMO ratio significantly reduced LV SO2 (VV-ECMO alone: 89% vs. VA-ECMO alone: 67%) indicating Harlequin syndrome. In severe LV dysfunction, a high VA-ECMO ratio increased LAP (VV-ECMO alone: 22 mmHg vs. VA-ECMO alone: 26 mmHg). Figure 3 illustrates an example of flow diversion guidance to achieve global DO2 $\geq$ 400 mL/min and LV SO2 $\geq$ 80%. As shown in the left panel of Fig. 3, lower LV function and pulmonary oxygenation required a higher VA-ECMO ratio to maintain global DO2. However, in extremely low oxygenation with preserved LV function (the right panel of Fig. 3), a high VA-ECMO ratio induced the Harlequin syndrome (blue area).
**Conclusions:** Severely compromised pulmonary oxygenation requires the delicate flow adjustment of VA- and VV-ECMO flow balance considering LV function. Our developed VAV-ECMO Simulator can visualise the impact of VAV-ECMO flow diversion on haemodynamics and local oxygen saturation, and provide optimisation of ECMO flow in clinically challenging cases.

**Correspondence:** L. J. Engelhardt
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000213

**Introduction:** Circadian rhythms can be disrupted in critically ill patients due to their severe illness and the artificial ICU environment (1). In the skeletal muscle, circadian disruption by Bmal1 knock out resulted in muscle atrophy and insulin resistance in mice (2). Critical Illness Myopathy is likely associated with muscle atrophy, weakness and insulin resistance, as shown by our research group (3–5). It is unclear if circadian disruption is associated with the development of Critical Illness Myopathy.
**Objectives:** To identify differences in circadian temperature rhythms in critically ill patients without Critical Illness Myopathy ("no-CIM") and with Critical Illness Myopathy ("CIM") in comparison to an immobilized healthy cohort.
**Methods:** This post-hoc analysis integrates unique data from an in-depth characterized Critical Illness Myopathy cohort from two prospectively conducted trials, consisting of ICU patients ≥ 18 years of age, SOFA Score ≥ 9, mechanical ventilation. Group categorization to "no-CIM" ($n = 30$) and "CIM" ($n = 32$) was performed by electrophysiological testing. Ethics vote: Charité EA2/061/06, and EA 2/041/10 (3–5). Healthy immobilized subjects from a bed rest study served as controls (6).
In this data-driven approach we compared circadian rhythms between the groups non-invasively, based on the digital biomarker temperature. Data analysis included: Cosinor analysis of high-frequency temperature data to identify amplitude, time of nadir and mesor using a 24-h period (7). Rhythm classification to *loss* (amplitude loss), *change* (phase shift) and *same* with use of the COMPARERHYTHMS library (8). Spearman correlation between temperature amplitude, time of nadir, mesor and myocyte cross-sectional area of Type I, IIa, and IIb fibers from *M.vastus lateralis* biopsies. Individual period estimation by Lomb-Scargle periodogram analysis.
**Results:** The temperature rhythm by cosinor analysis on ICU days 5 and 10, and the day before discharge is visualized in Fig. 1A, for healthy controls in Fig. 1B. Most critically ill patients in both the "no-CIM" and in the "CIM" groups showed either a temperature amplitude loss, phase shift or both, compared to immobilized healthy controls on all days studied. In the "no-CIM" group, the temperature amplitude was lower on the day before ICU discharge compared to the "CIM" group, mean difference [95% CI] 0.21 °C [0.09, 0.34], $p < 0.01$ (Fig. 2). Temperature amplitude was negatively correlated with myocyte cross-sectional area of Type I, IIa, and IIb fibers on the day before ICU discharge (Spearman correlation, Fig. 3A and 3B). Individual period analysis by Lomb-Scargle periodogram revealed a tendency for longer periods than 24 h in critically ill patients compared to healthy controls (Fig. 4).

**Conclusions:** Most critically ill patients without and with Critical Illness Myopathy presented with severely disrupted circadian temperature rhythms compared to immobilized healthy controls. Initially, temperature phase shifts were predominant in both ICU groups. On the day before ICU discharge, patients who did not develop Critical Illness Myopathy were more likely to have reduced temperature amplitudes, while more Critical Illness Myopathy patients remained their amplitude and their shifted temperature rhythms. Consistently, a higher temperature amplitude was associated with a lower myocyte cross-sectional area in muscle fibers. Reducing the amplitude of a phase shifted circadian rhythm may be an adaptive mechanism and protective regarding the development of Critical Illness Myopathy. Future studies are required to address this topic. The analysis of the clock network in the skeletal muscle itself during critical illness may provide further insights.
This analysis is limited by the sample size and the difficulty to control for confounders in the clinical data.

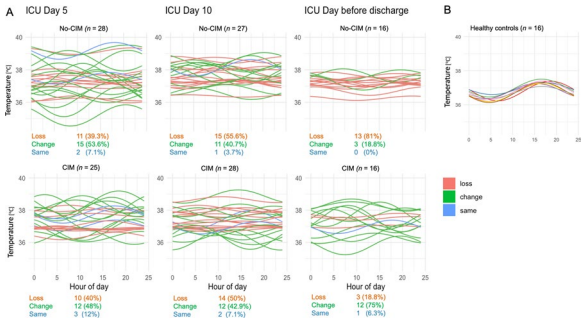

**Fig. 1 (abstract 000213)** **A** Cosinor analysis of temperature and rhythm classification to groups of "no-CIM" and "CIM" patients, ICU day 5, ICU day 10 and the day before ICU discharge. Each line represents one individual per day. Colors indicate the rhythm classification by COMPARERHYTHMS (8), orange = loss (temperature amplitude lower than in healthy controls), green = change (temperature phase shifted compared to healthy controls), blue = same. Amplitude threshold for the loss category based on the amplitude of the healthy cohort, patients below the minimum amplitude were primarily classified to the loss category and not considered for the change category. Fisher exact test for rhythm classification distribution "no-CIM" vs. "CIM", ICU day 5 $p = 0.78$, ICU day 10 $p = 1.0$, day before ICU discharge $p < 0.01$. **B** Cosinor analysis of temperature in immobilized healthy controls, raw data see (6)

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000214

**Introduction:** Severe fever with thrombocytopenia syndrome (SFTS) is an emerging tick-borne infectious disease first discovered in China in 2009 [1]. The disease is endemic in several Asian countries [2, 3]. In cases of severe condition, no effective drug or intervention has been shown to reduce mortality. In general, systemic glucocorticoid therapy serves as an adjunct treatment in patients with severe SFTS in clinical settings [4, 5]. However, no studies have specifically addressed the use of glucocorticoids in critically ill patients with SFTS in the intensive care unit (ICU).
**Objectives:** This study aimed to evaluate the potential benefits and risks of corticosteroid therapy in this patient group.
**Methods:** This retrospective observational study was conducted in the ICU of Yantai Qishan Hospital between July 2019 and April 2023. The participants were divided into glucocorticoid (GC) and non-glucocorticoid (non-GC) groups and propensity score matching (PSM) was employed to ensure comparability between the two groups. We used Cox proportional hazard models to examine the mortality risk associated with GC use, Kaplan–Meier survival analyses to assess overall survival, stratified Cox proportional hazard models for subgroup analyses, and likelihood ratio tests to examine the interactions between subgroups.
**Results:** The study of 218 SFTS patients found a median age of 71 years, 49.1% were male. 61.9% required mechanical ventilation, 58.3% received GC treatment, and the 28-day mortality rate was 61.5%. The post propensity score matching (PSM) analysis showed that glucocorticoid treatment improved 28-day mortality rates (Fig. 1), particularly when the Glasgow coma scale (GCS) was below 13 (GCS: 9–12, hazard ratio [HR]: 0.39, 95% confidence interval [CI]: 0.17–0.88, $p=0.024$; GCS: 3–8, HR: 0.09, 95% CI: 0.02–0.35, $p=0.001$), lactate levels exceeded 2 mmol/L (HR: 0.35, 95% CI: 0.15–0.83, $p=0.017$), and norepinephrine was used (HR: 0.26, 95% CI: 0.13–0.49, $p<0.001$). Combining antiviral (HR: 0.41, 95% CI: 0.22–0.78, $p=0.006$) or immunoglobulin therapy (HR: 0.22, 95% CI: 0.1–0.51, $p<0.001$) with GC treatment significantly decreased 28-day mortality rates, in comparison with GC monotherapy (Fig. 2).

**Conclusions:** Patients with severe SFTS in the ICU have a high 28-day mortality rate; however, using GC can reduce it, especially in those with a low GCS score, high lactate levels, and norepinephrine intake and those receiving combined antiviral or immunoglobulin therapy.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000216

**Introduction:** In the initial phase of acute respiratory distress syndrome (ARDS), activated lung cells initiate an inflammatory process leading to alveolar flooding [1]. While the role of bloodstream-related biotrauma in ARDS is well recognized, the contribution of inflammatory biofluids displaced to unaffected regions through the airways has not been fully investigated [2]. Our group has developed an innovative model that entirely isolates circulation (in vivo isolated lung perfusion—IVLP) and ventilation (independent lung ventilation—ILV) of one lung.
**Objectives:** This study aims to utilize the IVLP + ILV platform to elucidate the complex interplay of biofluid-induced lung injury (BILI) vs bloodstream-related biotrauma in ARDS.
**Methods:** Six initial experiments were conducted to refine study techniques and achieve complete left lung isolation for up to 2 h. The additional experiment, described herein, extends IVLP + ILV up to 24 h. In a 57 kg female pig, a left-sided dual-lumen endotracheal tube was inserted for ILV. Lung protective ventilation was applied in both lungs (Table 1). Endovascular coiling was performed to occlude left bronchial circulation. Subsequently, via left thoracotomy, cannulation of the left pulmonary artery, left superior and inferior pulmonary veins was conducted, followed by isolation of the left lung from systemic circulation using vascular clamps (Fig. 1). IVLP was commenced with a recirculating blood-only extracorporeal circuit at a flow rate

of 550 mL/min. Carbon dioxide and nitrogen were connected to the oxygenator to maintain PaO2/PaCO2 of the left pulmonary artery within 40–45 mmHg. Pressures in the right pulmonary artery and left atrium, as well as pressures downstream the cannulas in the left pulmonary artery and left pulmonary vein (Fig. 1), were monitored. Activated clotting time (ACT) in the left pulmonary circulation was maintained > 200 s.

**Results:** The animal successfully survived 24 h. Respiratory mechanics and function of both the right and left lung remained stable throughout the experiment (Table 1). Similarly, pressures in the pulmonary arteries and veins of the two lungs did not significantly vary over the study duration. The complete isolation of the left lung circulation was confirmed by anticoagulant administration assay (heparin bolus administered in the circuit, and ACT measured in the isolated vs systemic circulation after 30 min—Fig. 2A), oxygenation test (FiO2 sequentially increased from 0.3 to 1 only in the right/left lung, and PaO2 measured in the circuit vs systemic circulation after 30 min—Fig. 2B), and computed tomography angiography conducted at the end of the study (Fig. 3).

**Conclusions:** To the best of our knowledge, this is the first model in which IVLP + ILV are achieved for 24 h. While further experiments are warranted to validate reproducibility, this platform offers an innovative approach to differentiate bloodstream vs airways propagation pathways in ARDS. Future goals involve inducing injury in the isolated lung, followed by controlled dissemination of inflammation.

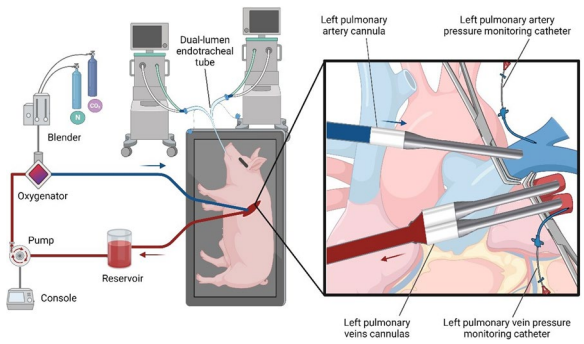

**Fig. 1 (abstract 000216)** Schematic representation of the study setting and in vivo isolated lung perfusion + independent lung ventilation system

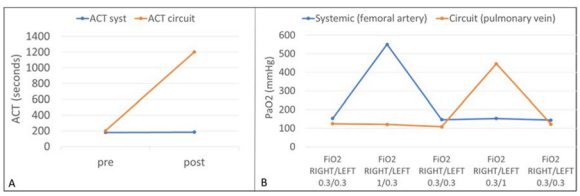

**Fig. 2 (abstract 000216)** Proof of complete isolation of the left lung circulation. Panel A—Anticoagulation Test: Activated clotting time (ACT) was measured in both systemic and extracorporeal circulation before and 30 min after administering a bolus of 2000 IU heparin in the isolated left lung circulation. Panel B—Oxygenation Test: $PaO_2$ was measured in both the systemic and extracorporeal circulation at varying FiO2 levels of the ventilator connected to the right/left lung. 30 min after increasing FiO2 solely in the right (non-isolated) lung, PaO2 increased to > 550mmHg systemically, while remaining unchanged in the circuit. Conversely, 30 min after increasing FiO2 solely in the left (isolated) lung, PaO2 increased to 445mmHg in the circuit but remained unchanged in the systemic circulation

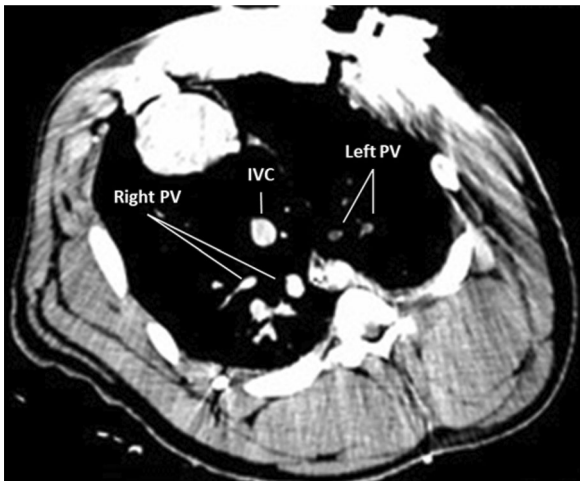

**Fig. 3 (abstract 000216)** Computed tomography angiography. At the conclusion of the experiment, contrast media was injected through the central venous line into the external jugular vein (systemic circulation). The image shows the contrast media in the vessels of the right lung (systemic circulation) after injection, while no contrast can be visualised in the vessels of the left lung (isolated circulation). IVC: inferior vena cava. PV: pulmonary veins

**Table 1 (abstract 000216)** Ventilatory settings, respiratory mechanics, gas exchange and vascular pressures of the right and left lung throughout the 24-h study

| | RIGHT LUNG | | | LEFT LUNG | | |
|---|---|---|---|---|---|---|
| Ventilatory mode | Pressure Regulated Volume controlled | | | Pressure Controlled | | |
| Tidal volume (mL) | 6.5mL/kg | | | 2.5mL/kg | | |
| PEEP ($cmH_2O$) | 8 | | | 5 | | |
| Respiratory rate per minute | 25 | | | 7 | | |
| FiO2 | 0.3 | | | 0.3 | | |
| **Timepoint** | **T0** | **T12** | **T24** | **T0** | **T12** | **T24** |
| Driving pressure ($cmH_2O$) | 11.0 | 11.0 | 12.2 | 9.8 | 13.1 | 11.2 |
| Compliance ($mL/cmH_2O$) | 35.6 | 33.7 | 29.7 | 17.8 | 13.6 | 12.7 |
| $PaO_2/FiO_2$ | 457 | 463 | 490 | 428.6 | 431.4 | 380 |
| Dead space (%) | 10.0 | 14.2 | 7.3 | 38.3 | 24.9 | 28.5 |
| Mean pulmonary artery pressure (mmHg) | 23 | 28 | 23 | 25 | 33 | 25 |
| Pulmonary vein pressure (mmHg) | 5 | 13 | 13 | 13 | 19 | 20 |

### Using Task Oriented QC Story Tool to Reduce Port-A-Related Bloodstream Infections

S. H. Wang[1]; B. A. Su[2]; J. W. Liou[2]
[1]Hematology and Oncology, Chi Mei Medical Center, Yongkang District, Taiwan; [2]Infection, Chi Mei Medical Center, Yongkang District, Taiwan

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000217

**Introduction:** Cancer patients frequently rely on a Port-A during their cancer treatment. However, Port-A-related bloodstream infections can lead to sepsis, posing a life-threatening risk. We aim to enhance the quality of care for cancer patients and reduce the density of port-A-related bloodstream infections through cooperative interdepartmental teamwork.
**Objectives:** The density of Port-A-related bloodstream infections in our ward was 1.01‰ in 2020, which increased to 2.19‰ in 2021. This rise in Port-A infections also resulted in a higher mortality rate, and cooperative interdepartmental teamwork to take action. Referring to the TCPI (Taiwan Clinical Performance Indicator) index, we established a standard of 1.75‰ for Port-A-related bloodstream infections.

**Methods:** We utilize a task-oriented Quality Control (QC) story tool that includes the following components: 1. Clear definition of topics: We focus on five aspects, including the material of the Port-A, aseptic operation techniques, nursing care for Port-A needles, the procedure of Port-A needle insertion, and post-use handling of the Port-A. We select safe and efficient procedures for Port-A needle insertion, excellent flushing methods, Port-A needle retention time, and Port-A sealing methods as the four control items. 2. Determination of key breakthrough points: We establish standard Port-A needle insertion procedures, universally adopt direct flushing methods, mandate timely replacement of Port-A needles upon expiration, and use high-concentration antibiotics for sealing during hospitalization as the four key improvement points. 3. Strategy formulation: We select four major strategies, including joint development of AI programs with the information department, holding meetings at the nursing station to announce direct flushing methods, promoting timely replacement of Port-A needles through Line group communication, and implementing checks on the Port-A needle insertion procedure.
**Results:** The density of Port-A-related bloodstream infections decreased from 2.19‰ to 1.35‰ after strategy formulation, achieving a target rate of 190.9% and showing a progress rate of 38.35%. Key achievements include 1. Revision of standard procedures. 2. Reduction in the mortality rate of Port-A bloodstream infections from 17.2% to 16.8%.
**Conclusions:** The mortality rate of Port-A-related bloodstream infections decreased by only 0.4%. The primary limitation lies in the patients' poor condition and weakened immune systems. Furthermore, doctors' immediate use of effective antibiotics and timely removal of the Port-A also play a crucial role in reducing mortality rates. These factors contribute to the continued high rates of mortality, which remain uncontrollable.

### Multitask learning to predict successful weaning in critically ill ventilated patients: a retrospective analysis of the MIMIC-IV database

W. C. Chao[1]
[1]Department of Critical Care Medicine, Taichung Veterans General Hospital, Xitun District, Taiwan
**Correspondence:** W.C. Chao
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000219

**Introduction:** Weaning is an essential issue in critical care. This study explores the efficacy of multitask learning models in predicting successful weaning in critically ill ventilated patients using the Medical Information Mart for Intensive Care (MIMIC) IV database.
**Methods:** We employed a multitask learning framework with a shared bottom network to facilitate common knowledge extraction across all tasks. We explored distinct task combinations of multitask learning. We not only used Shapley additive explanations (SHAP) plot partial

dependence plot (PDP) for model explainability but also conducted error analysis. Area under receiver operating characteristic curve (AUROC), calibration plot and decision curve analysis were used to determine the performance of the model.
**Results:** We found that 78.5% of 7758 critically ill patients were successfully weaned. Multitask learning combined with spontaneous breath trial achieved a higher performance to predict successful weaning compared with multitask learning combined with shock and mortality (area under receiver operating characteristic curve, AUROC, $0.820 \pm 0.002$ vs $0.817 \pm 0.001$, $p < 0.001$). We employed not only calibration curve and decision curve analysis to examine the performance of the model but also the SHAP and PDP plots to interpret the model. The error analysis identified a relatively high error rate among those with low disease severities, including low mean airway pressure and high enteral feeding.
**Conclusions:** We demonstrated that multitask learning increased predictive accuracy for successful weaning through combining weaning relevant tasks. The model explainability and error analysis should enhance trust in AI models.

### Improved prognosis in sepsis patients: exploring the mediating role of platelet count increase in heparin treatment—a retrospective cohort analysis

G. wang[1], J. Shen[1], H. Zhao[1], Y. An[1]
[1]Department of Critical Care Medicine, Peking University People's Hospital, Xi Cheng Qu, China
**Correspondence:** G. wang
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000220

**Introduction:** Despite advancements in therapy, sepsis still exhibits high morbidity and mortality rates, and existing therapeutic options are constrained [1]. The role of heparin in sepsis therapy has been debated considerably [2–4]. The controversy regarding heparin's role as an anticoagulant for sepsis may arise from variations in sepsis definitions, study design, drug use timing and dose, maintenance duration, complication, and patient severity.
**Objectives:** This study aimed to determine the best timing and dosage of heparin for sepsis patients, identify those who would benefit most, and find lab indicators to measure heparin's effectiveness.
**Methods:** This retrospective cohort study used the MIMIC-IV dataset to analyze sepsis patients based on sepsis 3.0 criteria. Patients were divided into heparin and non-heparin groups, and PSM was used to evaluate heparin's effectiveness. After that, the heparin group was divided into subgroups based on timing or dose for separate comparisons. To optimize the analysis of heparin treatment, the optimal heparin group was identified based on meeting the criteria for both early initiation and dose of heparin. In contrast, the non-optimal heparin group consisted of individuals who used heparin but did not meet these established criteria. The effectiveness of optimal heparin administration was determined, and a subgroup analysis was conducted to identify patients benefiting from heparin therapy. This analysis was performed using Cox proportional hazards models. Furthermore, causal mediation analysis (CMA) was performed to determine factors mediating the improvement in sepsis prognosis after heparin therapy.
**Results:** In total, 4149 participants were included: 2192 and 1957 in the heparin and non-heparin groups, respectively. After PSM, the effects of heparin therapy on 28-day mortality were better than those of non-heparin treatment (Fig. 1). Figure 2 illustrated the correlations between various heparin treatment regimens and sepsis outcomes. The optimal heparin group was more effective than others, except in cases where patients exhibited low white-blood-cell counts, alkalosis, and reduced platelet counts. Additionally, platelet count mediation analysis showed a mediation proportion of 14% (Fig. 3).
**Conclusions:** Early and sufficient heparin administration can significantly improve the prognosis of sepsis. Platelet count increase may be a potential indicator of heparin therapy effectiveness for sepsis. The findings of this study may help develop strategies for improving sepsis treatment.

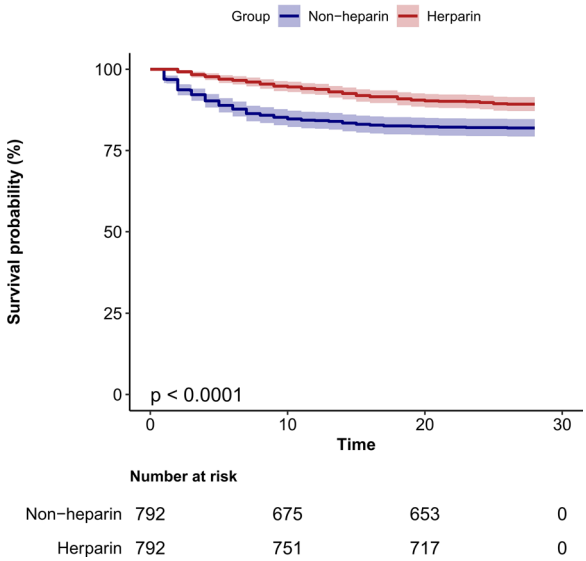

**Fig. 1 (abstract 000220)** Kaplan–Meier survival curves for patients with sepsis between the heparin and non-heparin groups

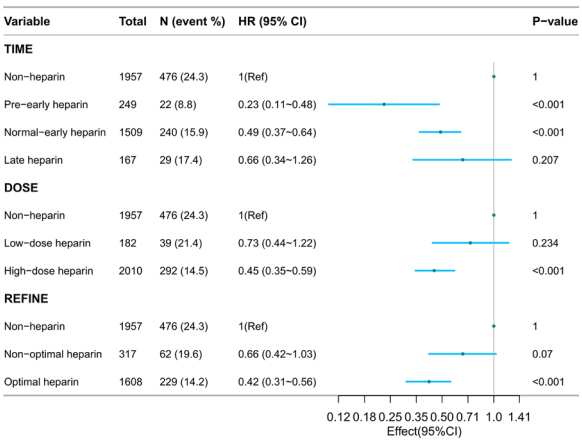

**Fig. 2 (abstract 000220)** Forest plot of 28-day mortality in different initiation times and doses of heparin-treatment groups
Cox proportional hazard model adjusted for different variables. The variables included sex, age, BMI, ethnicity, SOFA score, Elixhauser comorbidity score, hypertension, diabetes, CHD, CKD, COPD, and cancer. BMI, body mass index; CHD, Chronic heart disease; CKD, chronic kidney disease; COPD, chronic obstructive pulmonary disease; HR, Hazard ratio; 95% CI, 95% confidence interval; SOFA, sequential organ failure assessment.

### Setting up a Neuro Outreach Service in a Tertiary hospital in Singapore: A pilot study

Y. wong[1], L. Qingna[2]
[1]anaesthesia, Tan Tock Seng Hospital, Singapore, Singapore; [2]Intensive Care, Tan Tock Seng Hospital, Singapore, Singapore
**Correspondence:** Y. wong
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000221

**Introduction:** Tan Tock Seng Hospital is a tertiary 1000 bed hospital in Singapore, that focuses and specialises in neurocritical services. Due to a high volume of patients from electives, and emergency services needing neuro-related ICU and HDU beds, there was a ICU nurse-led initiatve to see if we could discharge patients in a timely manner without compromising care and safety, with the set up of a Neuro Outreach Service.
**Objectives:** The Neuro Outreach service was first proposed to mitigate the risk of neuro patients deteriorating in the General ward (GW). With a high attrition rate of nurses post COVID, the general ward nurses in non-neuro specialised GWs also have a large proportion of new nurses who are not well versed with managing specific neuro conditions, such as spinal cord injured patients, patients with an in-situ external ventricular drain (EVD), and performiing frequent tracheal toilet for tracheotomised patients following a neurologcal insult.
The objective was to provide a review for such patients within s 24 h window post discharge from ICU. The Neuro Outreach Service would review every patient that was discharged in the preceding 24 h and provide essentail training and assessment of the patient, such as Glasgow Coma Scale assessment, and EVD challenge. If there was any care gaps or practise malalignment that was identified at the bedside, this was highlighted in a non-putatitive way, and provided an opportunity to educate the general ward nurses to specific neurological assessments. The outreach team also provided just-in-time training on the care of such patients in the GW, with emphasis on some key areas, such as potential major complications such as pseudoaneursymal formation from a haematoma, or how to clinically detect cerebral vasospasm from Transcranial Doppler (TCD) Results: A survey of the GW nurses showed that itincreased their confidence and competency in caring for neuro-specific patients.
**Methods:** The Neuro Outreach Service consisted of 8 neuro trained ICU nurses. The would get a list of all patients transferred out of the ICU and HD from the electonic records, and this would allow for timely assessment and review in the GW within 24 h. All reviews and assessments were recorded. Each review consisted of a 30 min consultation with the nurse in charge at the GW bedside. Assessment of the patient was done together, and an opportunity to clarify any doubts was available. Neuro-specific tasks were carried out together e.g. challenging an EVD, and recreating suction to a redivac drain. Bedside GCS was also done together, especially in spinal cord injured patient, to ensure that a drop in power was not missed due to a haematoma formation, or extension of spinal cord injury. Results from 1 May 2022 to 29 Feb 2024 was collected for all patients that the Neuro Outreach Team reviewed in a non-neuro specialised GW.
**Results:** The neuro outreach team reviewed 100 patients from the period 1 May 2022 to 29 feb 2024 in non-neuro specialised GW beds. The outreach team provided just-in-time training on care for neuro = specific conditions. Inaccurate GCS scoring was the key practise gap identified and education was provided to approximately 80 nurses. In addition, a case of breakthrough diabetes insipidus was identified during the review. This resulted in a timely management of a medical condition, and negated the need for readmission to HD/ICU and provided an opportunity for bedside teaching of the biochemical and electrolyte issues encountered. This initiative has empowered ICU nurses to broaden their scope of expertise beyond the ICU, and given confidence to GW nurses to manage neuro-specific patients more confidently. The survey of GW nurses also confirmed that the majority (85%) found the neuro outreach service useful and beneficial for themselves and for their management of the patients under their care.
**Conclusions:** The Neuro Outreach Service is a an effective way to ensure the continuity of care of neuro-specific patients in non-neuro GWs.

### Prediction of brain damage after out-of-hospital cardiac arrest: a new model

L. Blanco[1], E. Renes Carreño[1], J. L. PerezVela[1], J. Ginestal[1], C. Galiano[1], H. Dominguez Aguado[1], L. J. Terceros Almanza[1], M. Corres Peiretti[1], M. C. Martín Delgado[1]
[1]Intensive care, University Hospital 12 de Octubre, Madrid, Spain
**Correspondence:** L. Blanco
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000222

**Introduction:** Neurological prognosis in cardiac arrest (CA) is complex and multifactorial but crucial for decision-making and conveying information to the family. This justifies the search for a model to guide us regarding the most likely evolution of each patient.
**Objectives:** To describe a simple and easy-to-use prognostic model in the initial evaluation of neurological damage after out-of-hospital CA.

**Methods:** 195 patients after out-of-hospital CA of cardiac etiology between 2012 and 2023, excluding patients in whom a neurological assessment prior to death could not be performed. Variables present upon hospital admission were included. A multivariable binomial logistic regression was performed after univariable analysis, and the predictive capacity of the model was assessed using the ROC curve. A nomogram (Fig. 1) was constructed for the application of the predictive model. Results are presented as Odds Ratios (OR) and 95% confidence intervals (95% CI). R Studio version 2023.12.1 was used for statistical analysis.

**Results:** Overall hospital mortality was 35.9%, (0.9% vs 84.1%). The Table shows the results of univariable and multivariable analysis. The variables incorporated into the final model were age, time to return of spontaneous circulation (ROSC), CPR delay exceeding 5 min, and the use of AED (p-value < 0.05). The model has an area under the curve of 0.85 (95% CI 0.79–0.91), sensitivity of 65.9%, specificity of 84.1%, positive predictive value (PPV) of 75%, and negative predictive value (NPV) of 77%.

### Low rates of failed extubations vs. a high rate of failure to extubate: staff perceptions

D. Alrashed[1]; A. Phillip[1]; R. Plant[1]
[1]Department of Anaesthesia and Intensive Care, Cork University Hospital, Cork, Ireland
**Correspondence:** D. Alrashed
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000225

**Introduction:** Usual rates of failed extubations in ICUs internationally is 10–20% [1] (failed extubations are defined by re-intubations within 48 h of extubation [2]). We are in a tertiary referral centre with mixed ICUs that include trauma and neurosurgery. We retrospectively collected all intubated patients' electronic charts over 19 months and found a failed extubation rate of only 4%.

**Objectives:** To determine the factors leading to low rates of failed extubation in order to develop appropriate interventions for quality improvement.

**Methods:** We retrospectively looked at data from January 2022 to August 2023 in both mixed ICUs and excluded the cardiothoracic ICU. We analysed the patients that were re-intubated and excluded those that were accidentally extubated, those re-intubated after more than 48 h, and those who needed intubation for a procedure under general anaesthesia. We surveyed our nursing and medical colleagues to assess attitudes and perceptions on failed extubation.

**Results:** Of 676 intubated patients during that period, 26 met inclusion criteria. The most common reason for re-intubation was respiratory failure (46%), followed by severe agitation (23%), coma (12%), post-extubation stridor (11%), aspiration of vomit (4%), and cardiac arrest (4%). The survey revealed that there is awareness we may be too cautious with our decisions, however the majority thought our rates were higher than they actually are. There is a perception that a failed extubation may reflect negatively on them as decision maker.

**Conclusions:** There is no set practice for weaning ventilation and most patients underwent very slow weaning prior to extubation. There are other factors that may have contributed to longer mechanical ventilation including the use of benzodiazepines for sedating neurosurgical patients and the pursuit of the 'perfect' extubation parameters, a rare occurrence in any ICU. Suggestions for improvement include a culture shift and empowering nursing and medical staff for more aggressive weaning plans and updating our protocol to include SBTs, SATs, and cuff leak tests.

**Introduction:** Veno-venous extracorporeal membrane oxygenation (VV-ECMO) is an established supportive therapy for acute respiratory distress syndrome (ARDS) [1,2], however it is associated with blood loss and the need for allogeneic packed red blood cell (PRBC) transfusion, particularly during decannulation [3, 4]. Blood cell salvage (BCS) can reduce the need for blood transfusion, yet it is not consistently used in UK ECMO centres or internationally.
**Objectives:** Our primary outcome was the total number of PRBC units transfused within the two calendar days following ECMO decannulation. Secondary outcomes included (1) changes in pre-specified haematological (i.e., Hb, platelets), inflammatory (i.e., C-reactive protein (CRP), white cell count (WCC)), and coagulation (activated partial thromboplastin time (APTT), international normalised ratio (INR), fibrinogen) laboratory measurements before and after decannulation; and (2) transfusion of other blood products in the same time interval.
**Methods:** We conducted an emulated trial of patients receiving VV-ECMO over 7.5 years (January 2015 to August 2022) in two high volume ECMO centres, comparing BCS to non-blood cell salvage (n-BCS) during decannulation. We estimated the average treatment effect of BCS on Hb and blood product transfusion within two calendar days of decannulation.
**Results:** We included 841 patients who underwent VV-ECMO decannulation. The mean number of packed red blood cells (PRBC) transfused with BCS was 0.23 (95%CI: 0.20, 0.27) units compared to 0.47 (95%CI: 0.42, 0.53) units with n-BCS; an average treatment effect for BCS of − 0.24 (95%CI: − 0.34, − 0.15) units. BCS reduced the risk of receiving any PRBC transfusion following decannulation by -11.3% (95%CI: − 17.6%, − 5.5%). BCS also resulted in a mean Hb increase of 1.4 (95%CI: 0.8, 2.0) g/L contrasting with a mean Hb decrease of 4.1 (95%CI: 3.6, 4.8) g/L with n-BCS. We found no effect of decannulation, or BCS compared to n-BCS on platelet levels. Fibrinogen levels overall decreased by clinically insignificant amount following decannulation (− 0.3; 95%CI: − 0.1, − 0.5 g/L) but no effect of BCS usage was observed. There was a small difference in mean white cell counts (WCC) (14.0; 95%CI: 13.2, 14.8 × 109/L versus 16.4; 95%CI: 15.8, 17.1 × 109/L) between treatment groups before decannulation, but no effects of decannulation or BCS use were observed. There was a decrease in CRP levels by 8.4 (95%CI: 5.0, 11.8) mg/L following decannulation, irrespective of BCS usage.

**Table 1 (abstract 000228)** PRBCs transfused with estimated population averaged mean PRBC counts

| | Non- Blood Cell Salvage (n = 446) | Blood Cell Salvage (n = 395) |
|---|---|---|
| Any PRBC Transfusion | 141 (32%) | 82 (21%) |
| PRBC Units transfused: | | |
| 0 | 305 (68%) | 313 (79%) |
| 1 | 89 (20%) | 70 (18%) |
| 2 | 41 (9.2%) | 12 (3.0%) |
| 3 | 4 (0.9%) | 0 (0%) |
| 4 | 6 (1.3%) | 0 (0%) |
| 5 | 1 (0.2%) | 0 (0%) |
| ITT mean count | 0.47 (95%CI: 0.42, 0.53) | 0.23 (95%CI: 0.2, 0.27) |
| PP mean count | 0.47 (95%CI: 0.42, 0.53) | 0.21 (95%CI: 0.18, 0.25) |

*n* (%); (95%CI)—95% Confidence Interval; ITT—Intention To Treat; PP—Per Protocol; PRBC—Packed Red Blood Cells

**Conclusions:** These findings suggest BCS should be considered particularly for specific patient populations or in scenarios where the availability of PRBC is scarce. Future research is required to refine our understanding of the cost-effectiveness of BCS.

### Assessment of microcirculatory dysfunction by optical coherence tomography angiography in septic shock—a preliminary report

A. Alexandre[1]; P. Povoa[2]
[1]Intensive Care Medicine Department, Hospital da Luz Lisboa, Lisboa, Portugal; [2]Polyvalent intensive care unit, São Francisco Xavier Hospital, CHLO, Lisbon, Portugal

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000229

**Introduction:** Sepsis is a life-threatening organ dysfunction caused by a dysregulated host response to infection [1]. Microcirculatory dysfunction is common in septic shock (SS), and has prognostic implications associated with increased organ failure and mortality [2–4]. *Optical coherence tomography angiography* (OCTA) is a relatively novel imaging technique that enables investigation of retinal microcirculation in a non-invasive and reproducible manner, providing high-resolution images within seconds [5]. The interpretation of OCTA findings can be fully automated [6]. Additionally, the retinal microcirculation may serve as a surrogate for changes in more critical vascular beds, such as the brain, compared to the sublingual region. We aim to

demonstrate the feasibility of OCTA in improving the assessment of microcirculatory dysfunction during SS.
**Objectives:** To characterize alterations in retinal microcirculation in SS.
**Methods:** We are conducting an ongoing prospective cross-sectional case–control study at the Intensive Care Department of Hospital da Luz Lisboa. Adult patients (≥ 18 years-old) with SS (defined according to Sepsis-3 criteria1 plus a SOFA score5 with ≥ 3 points in the cardiovascular system, despite adequate volume resuscitation) are being enrolled. Patients with pre-existing retinal pathology are excluded. Healthy voluntary controls are recruited from hospital staff and matched by age (± 5 years) and gender. An OCTA of both eyes is performed within 24 h of SS diagnosis. OCTA microcirculatory metrics are compared between groups using paired Wilcoxon signed-rank test.
**Results:** To date, we have enrolled 8 patients and 8 controls, representing 27% of intended sample size. Fifty percent of participants were females. The median age of patients was 46 years (Interquartile Range [IQR]: 34–55) and 44 years (IQR: 35–55) for controls. The most promising variables thus far are the foveal avascular zone (FAZ) area and FAZ perimeter of both eyes. Median values of these variables were lower in SS patients compared to controls (Table 1).

**Table 1 (abstract 000229)** Foveolar avascular zone differences between septic shock patients and controls

| | Right eye | | | Left eye | | |
|---|---|---|---|---|---|---|
| | **Patients** | **Controls** | ***p*-value** | **Patients** | **Controls** | ***p*-value** |
| FAZ area (mm2) | 0.20 | 0.30 | 0.01 | 0.17 | 0.31 | 0.02 |
| FAZ perimeter (mm) | 1.80 | 2.36 | 0.01 | 1.75 | 2.27 | 0.04 |

**Conclusions:** Our findings support the hypothesis that retinal microcirculatory changes occur during SS and demonstrate that OCTA is a feasible bedside tool for their assessment. OCTA shows potential in overcoming the limitations associated with the hand-held vital microscopes currently used for microcirculatory assessment. Future steps will involve longitudinally profiling these microcirculatory changes during the course of SS.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000230

**Introduction:** Analgosedation is crucial for alleviating pain and agitation in the intensive care unit (ICU) [1], while adverse effects including respiratory depression [2] limit its clinical use. Consequently, there is a significant interest in measuring the respiratory effects of these drugs, especially for new agents. Cipepofol, a novel 2,6-disubstituted phenol derivative and a structural analog of propofol, is a highly selective gamma-aminobutyric acid A receptor potentiator [3], with a non-inferior sedation profile to propofol for ICU sedation [4]. However, as a new sedative drug, further research is required, particularly detailed studies on its adverse effects, especially its respiratory effects used for ICU sedation.
**Objectives:** The present study aimed to investigate the effects of cipepofol on breathing patterns, respiratory drive, and inspiratory effort in mechanically ventilated patients.
**Methods:** The study was designed as a single-center, one-arm, physiological trial. We included intubated patients receiving invasive mechanical ventilation in partial pressure support mode. When the patients' baseline sedation level had reached a Richmond Agitation Sedation Scale (RASS) score ≥ − 2, cipepofol was initiated at 0.3 mg/kg/h and increased by 0.1 mg/kg/h every 30 min until the maximal dose of 0.8 mg/kg/h. The infusion of cipepofol would be discontinued if the RASS score was ≤ − 4, or respiratory rare < 8 breaths/min [5], or pulse oxygen saturation (SpO2) < 90% [6] before reaching the maximal dose. The reason for discontinuation and the final infusion rate for each patient were recorded. At baseline and 30 ± 5 min after each increase in the infusion rate, respiratory variables including RR, tidal volume (VT), minute ventilation (Vmin)), airway occlusion pressure after 100 ms (P0.1) [7], pressure muscle index (PMI) [8], and expiratory occlusion pressure (Pocc) [9] were recorded. The primary outcome was the change from baseline in respiratory variables to 30 min after the initiation of cipepofol at 0.3 mg/kg/h. The secondary outcomes were the changes in respiratory variables, cardiovascular variables (systolic blood pressure, diastolic blood pressure, mean arterial pressure, heart rate, SpO2, end-tidal carbon dioxide), and RASS score at different infusion rates of cipepofol.
**Results:** The infusion rate at 0.3 mg/kg/h of cipepofol was completed in all 20 patients, and all patients achieved the RASS score − 2 to + 1. For the main respiratory variables (Table 1), common features were: a significant reduction in VT ($P = 0.002$), while the change in RR ($P = 0.465$) and Vmin ($P = 0.154$) were not significant. The reductions in P0.1 ($P = 0.020$), PMI ($P = 0.019$) and Pocc ($P = 0.007$) were significant. The number of patients decreased as the cipepofol infusion rate increased, and the leading cause for discontinuation was oversedation (RASS ≤ − 4). A linear mixed-effects model was used to analyze the effect of different doses of cipepofol (Fig. 1). With the increase in cipepofol dose, there was a significant decrease in RASS score ($P < 0.001$), the increase in RR ($P < 0.001$) and decrease in VT ($P = 0.002$) was significant, while Vmin ($P = 0.430$) did not change significantly.

**Table 1 (abstract 000230)** The differences in respiratory variables from baseline to 30 min after cipepofol was infused at a rate of 0.3 mg/kg/h

| Variable | At baseline | 30 min after infusion of cipepofol | *P* value |
|---|---|---|---|
| RR, mean ± SD | 16.2 ± 3.4 | 16.7 ± 2.7 | 0.465 |
| VT, median [IQR] | 451.6 [393.5–565.9] | 390.9 [356.6–511.0] | 0.002 |
| Vmin, mean ± SD | 7.5 ± 1.9 | 7.2 ± 1.8 | 0.154 |
| P0.1, (median [IQR]) | 1.7 [1.0–3.1] | 1.4 [1.0–2.7] | 0.020 |
| PMI, (median [IQR]) | 2.1 [1.7–4.3] | 2.1 [1.3–2.7] | 0.019 |
| Pocc, (median [IQR]) | 9.4 [6.4–12.9] | 7.2 [6.1–10.6] | 0.007 |

RR, respiratory rate; SD, standard deviation; VT tidal volume; IQR, interquartile range; Vmin minute ventilation; P0.1, airway occlusion pressure after 100 ms; PMI, pressure muscle index; Pocc, expiratory occlusion pressure

**Conclusions:** Cipepofol demonstrates the capability to achieve a satisfactory sedation level of RASS -2 to + 1 in mechanically ventilated adult patients. The primary effects of cipepofol on respiratory patterns, respiratory drive, and inspiratory effort include a decrease in VT, P0.1, PMI, and Pocc, while the changes in RR and Vmin were insignificant.

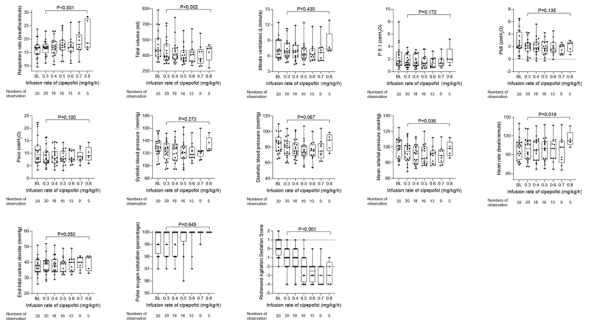

**Fig. 1 (abstract 000230)** Respiratory variables, cardiovascular variables and RASS score during cipepofol infusion at different rates. Overlaid Box-and-whisker and scatter plot. Boxes represent the median with an interquartile range; Whiskers extend the minimum and maximum values; Circles indicate individual observations; BL baseline. P0.1 airway occlusion pressure after 100 ms; PMI pressure muscle index; Pocc the expiratory occlusion pressure

### Risk Factors for Postoperative Hyperbilirubinemia in Living Donors Undergoing Living Donor Liver Transplantation

Y. Kim[1], K. W. Lee[2], Y. Choi[2], N. J. Yi[2], K. S. Suh[2]

[1]Surgery, Konyang University, Daejeon, Republic of Korea; [2]Surgery, Seoul National University Hospital, Seoul, Republic of Korea

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000234

**Introduction:** Postoperative liver failure is a critical concern for donors undergoing living donor liver transplantation. Previous research has established a significant association between elevated peak total bilirubin (TB) levels after hepatic resection and postoperative liver failure. In this study, our objective was to indirectly identify risk factors associated with postoperative hyperbilirubinemia in living donors.

**Methods:** We retrospectively reviewed data from 1075 living donors who underwent liver transplantation at Seoul National University Hospital from January 4, 2013, to April 29, 2023. After excluding 14 cases with missing data and 58 cases with left hemihepatectomy, we analyzed a total of 1003 cases. Univariate and multivariate analyses were conducted to identify statistically significant differences between groups with high and low peak TB levels postoperatively. Hyperbilirubinemia was defined as peak TB > 7 mg/dL post-operatively.

**Results:** The rate of complications higher than Grade III was 3%. Sixty-one donors (6.08%) showed hyperbiliruminemia. However, there was no case of liver failure and no difference in complication rate between hyperbilirubinemia and non-hyperbilirubinemia groups. The male donors [Hazard Ratio(HR) 8.89 (2.72–29.05)], smaller remnant volumes [HR 1.14 (1.05–1.25)], preoperative TB [HR 14.54 (6.08–34.78)] were identified as the risk factors of hyperbilirubinemia. To establish a possible threshold indicating higher peak TB values after surgery, subgroup analysis was performed for preoperative TB and remnant volume. Statistically significant associations were found for preoperative TB levels of 1.6 or higher, indicating an increased risk of higher peak TB values postoperatively. Also, in terms of remnant volume, statistically significant higher peak TB levels were observed when the remnant volume was below 32.7%.

**Conclusions:** Although no cases of postoperative liver failure were observed in the analyzed donor population, maintaining awareness of the potential for such complications remains essential. Efforts to mitigate risks by excluding preoperative risk factors are crucial.

**Introduction:** Exposure to a intense heat stress environment can lead to impaired renal function and even induce acute kidney injury (AKI), while heat acclimation(HA) can improves heat endurance, and prevents the kidney against ischemic injury induced by intense heat stress. However, the mechanism underlying of the nephroprotective effect of HA remains unclear.Ferroptosis is a programmed cell death form characterized by excessive accumulation of lipid peroxide and iron, which is involved in the development and development of multiple AKI.However, the role of ferroptosis in the HS-AKI mechanism remains elusive.Furthermore, it has been reported that mitophagy can exert protective effects on AKI through clearance of damaged mitochondria, inhibition of apoptosis, alleviation of oxidative stress and the inflammatory response.Several studies have suggested that mitophagy may influence the development of AKI through regulating intracellular iron metabolism, but it has not been reported in heat stress-induced AKI.
**Objectives:** To investigate whether heat acclimation alleviates ferroptosis to prevent heat stress-induced acute kidney injury by enhancing mitophagy.
**Methods:** 6–8-week-old C57BL / 6 mice were divided into control group (CON), heat acclimation group (HA), heat stroke group (HS), heat stroke + heat acclimation group (HS + HA), and heat stroke + heat acclimation + 3-MA group (HS + HA + 3-MA).Among them, the mice in the HS group were kept at room temperature for 30 days and then subjected to high-temperature and high-humidity environmental stress with a temperature of 39 ± 0.5 °C and a humidity of 60 ± 0.5% to establish the HS model.The mice in the HS + HA group were kept in an environment with a temperature of 34 ± 0.5 °C and a humidity of 50 ± 0.5% for 30 days to establish the HA model, followed by exposure to high-temperature and high-humidity environmental stress.Mice in the HS + HA + 3-MA group were subjected to high heat and humidity environmental stress after consecutive intraperitoneal injection

of the mitophagy inhibitor 3-MA (20 mg/kg/day) for the last 7 days of the constructed HA model.When the HS model was successfully established, the proteomic assay was applied and differential protein expression was analyzed using GO enrichment. Subsequently, the levels of thermal endurance, renal function, pathological changes, inflammation, oxidative stress, apoptosis, mitophagy and ferroptosis were assessed in each group of mice.
**Results:** The GO enrichment analysis found that the differentially expressed proteins between the CON and HS groups were mainly enriched in biological processes such as stress, inflammation and ferroptosis pathways.Transferrin is a key protein in the ferroptosis pathway, and its protein expression level was significantly higher in the HS group than in the CON group. In vivo experiments confirmed that heat acclimation significantly improved renal function, enhanced thermal endurance, and improved the survival rate of mice under HS conditions. Moreover, heat acclimation significantly enhanced mitophagy and alleviated HS-induced ferroptosis, inflammation, apoptosis and oxidative stress. In contrast, the mitophagy inhibitor 3-MA inhibited ferroptosis and reversed the renoprotective effect of the heat acclimation.
**Conclusions:** Heat acclimation may prevent heat stress-induced acute kidney injury by alleviating ferroptosis through enhanced mitophagy.

**Topic:** Acute Kidney Injury and haemofiltration

**Introduction:** Proton pump inhibitors (PPIs) have been shown to reduce clinically important upper gastrointestinal (UGI) bleeding around 40% among critically ill patients. However, there have been no clinical trials investigating the use of ilaprazole, a newer generation benzimidazole PPIs, specifically in critically ill patients with stress ulcers.
**Objectives:** To evaluate the non-inferiority of Ilaprazole to esomeprazole in preventing clinically significant UGI bleeding in critically ill patients.
**Methods:** In this Randomized, Double-Blind, non-inferiority Phase 3 trial, patients with high risk for stress ulcer bleeding and requiring invasive mechanical ventilation at 70 clinical centres in China were enrolled. Eligible patients were randomly assigned in a 1:1 ratio to receive either ilaprazole for injection (10 mg once daily, first dose doubled) or esomeprazole for injection (40 mg twice daily). The primary endpoint was absence of clinically significant UGI bleeding, in the Per-Protocol Set (PPS) with a non-inferiority margin of 5%. The trial is registered with ClinicalTrials.gov, NCT05841394 and is completed.
**Results:** From July 16, 2021, to April 28, 2022, 441 patients (mean age, 59.00 years old; 150 [34.01%] female) were enrolled: 220 patients were allocated to receive ilaprazole treatment, while 221 patients were allocated to esomeprazole treatment. The primary endpoint occurred in 189 (96.92%) patients in the ilaprazole arm and 189 (96.92%) patients in the esomeprazole arm (Absolute Risk Difference: 0, 95% CI: − 3.85 to 3.85, $p = 1.000$). Secondary outcomes demonstrated comparable incidences of clinically insignificant upper gastrointestinal (UGI) bleeding, any gastrointestinal bleeding, as well as similar 28-day mortality, ICU mortality, and pneumonitis between the two treatment arms. The incidence of study-drug-related adverse events was observed in 17 (7.7%) patients in the ilaprazole arm and 22 (10.0%) patients in the esomeprazole arm, respectively ($p = 0.526$). The ilaprazole arm had a significantly lower incidence of hepatobiliary disorders (0.9%) compared to the esomeprazole arm (5%) ($p = 0.012$).
**Conclusions:** Among critically ill patients with high-risk of stress ulcer, Ilaprazole demonstrated non-inferiority to esomeprazole in the prevention of upper gastrointestinal (UGI) bleeding, exhibited a comparable incidence of overall adverse events, and showed a lower occurrence of hepatobiliary disorders.

### Discussing expected long-term outcomes in the ICU: effect on experiences and outcomes of patients, family, and clinicians; a multicenter randomized clinical trial

L. Porter[1], K. Simons[1], J. G. Van Der Hoeven[2], M. van den Boogaard[2], M. Zegers[2]
[1]Intensive Care, Jeroen Bosch Hospital, s'Hertogenbosch, Netherlands; [2]Intensive care, Radboud University Medical Center, Nijmegen, Netherlands

*Intensive Care Medicine Experimental* 2024, **12(suppl 1):** 000239

**Introduction:** ICU survivors and their families are often unaware of the physical, mental and cognitive symptoms that can persist for months, or even years, after ICU discharge, consequently underestimating the long-term impact of critical illness. Unfortunately, these unrealistic expectations can result in a reduced quality of life (QoL), as QoL depends partly on the degree to which expectations are met. Moreover, many health care facilities aspire to increase patient and family participation in decision making. However, without adequate information on expected patient-relevant outcomes, such as long-term QoL, there is little room for patient involvement. Therefore, we developed an intervention to support conversations about expected long-term QoL during family meetings, based on a prediction model, and supported by a web-based application visualizing the personalized predictions and a comprehensive information leaflet about recovery after critical illness.
**Objectives:** To evaluate the effectiveness of the developed intervention on patient and family reported experiences and outcomes, and on experiences of ICU clinicians.
**Methods:** We conducted a randomized clinical trial in the ICUs of two Dutch hospitals. Patients $\geq$ 16 years old, admitted for at least 24 h to the ICU between March 2021 and September 2023, were included after providing informed consent, and randomly assigned to receive either the intervention or usual care. The intervention consisted of a family meeting in which physicians discussed the expected long-term outcomes with patients and/or their family, based on the predicted change in QoL one year after ICU admission using a previously validated prediction model, supplemented with extensive information on recovery after critical illness. Primary outcome was patients' and family members' experience with the shared decision-making process during a family meeting, measured with the 3-item CollaboRATE questionnaire (range 0–27). Secondary outcomes were ICU professionals' experiences with the shared decision-making process (determined using the 35-item Ethical Decision-Making Climate Questionnaire [EDMCQ] and the Collaboration and Satisfaction about Care Decisions [CSACD] questionnaire), symptoms of anxiety and depression (assessed with the Hospital Anxiety and Depression Scale [HADS]) among patients and family members 3 months and 1 year post-ICU, and patients' QoL (measured with the EuroQol five-dimensional [EQ-5D-5L] questionnaire) 3 months and 1 year post-ICU.
**Results:** In total, 160 patients were included (mean age 60 years [SD 15]; 97 men [61%]). 13 patients (8.1%) died before assessment of the primary outcome, resulting in an intervention group of 73 patients and a usual care group of 74 patients. No significant differences were seen in patients' and family members' experiences of the shared decision-making process during a family meeting, with a median CollaboRATE score of 24 (IQR 23–27) in the intervention arm, compared to 25 (IQR 23–27) in usual care ($p = 0.6$). Moreover, the outcomes of patients and family at 3 months did not significantly differ between the intervention and usual care group (Table 1). Regarding the ICU professionals' experiences, an improvement in CSACD score was observed after the intervention period (median 40 [IQR 34–45] vs median 37 [IQR 32–43], $p = 0.01$), while no significant change in the ethical decision-making climate was found.
**Conclusions:** This multicenter randomized clinical trial, evaluating the incorporation of personalized predictions of long-term QoL in family meetings, showed no difference between patients' and family members' experiences, and outcomes of patients and family 3 months post-ICU. However, after the intervention period, ICU clinicians reported better collaboration about care decisions. The 1 year outcomes of patients and family, will be available in September 2024 and presented at the conference.

**Table 1 (abstract 000239)** Patients' and family members' experiences and 3 months post-ICU outcomes

| | *Intervention (n = 73)* | *Usual care (n = 74)* | *p-value* |
|---|---|---|---|
| CollaboRATE score (range 0 – 27), *median (IQR)* | 24 (23 – 27) | 25 (23 – 27) | 0.6 |
| Patients' change in QoL (EQ-5D-5L), *mean (SD)* | -0.13 (0.30) | -0.06 (0.31) | 0.3 |
| Patients' change in anxiety (HADS-A), *mean (SD)* | -0.8 (4.4) | 0.8 (4.2) | 0.2 |
| Patients' change in depression (HADS-D), *mean (SD)* | 0.6 (4.9) | 0.5 (4.1) | >0.9 |
| Family members' change in anxiety (HADS-A), *mean (SD)* | 0.9 (5.7) | 1.8 (4.4) | 0.4 |
| Family members' change in depression (HADS-D), *mean (SD)* | 0.7 (4.6) | 2.1 (4.2) | 0.2 |

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000241

**Introduction:** Higher mortality rates have been observed among patients admitted to the hospital during the weekends and weeknights in several, but not all, studies. These observations were attributed to suboptimal hospital staffing and resource allocation during weekends and after-hours. Rapid Response Teams are activated for patients experiencing deterioration in the ward, yet the impact of the timing of activations on patient outcomes remains unclear.
**Objectives:** We aimed to investigate the association between the timing of rapid response team activation and patient outcomes.
**Methods:** We conducted a retrospective cross-sectional study of patients in the ward who had activation of the Critical Care Response Team (CCRT) of King Abdulaziz Medical City, Riyadh from January 1 to December 31, 2019. We compared the characteristics and outcomes of patients who had CRRT activation on weekends (Friday and Saturday) vs. weekdays (Sunday to Thursday) and during afterhours (1600 to 0759) vs. daytime (0800-1559).
**Results:** During the study period, there were 836 CCRT activations with 212 (25.4%) occurring during the weekend. There were no significant differences in the demographics, baseline comorbidities, admission category (medcial, surgical and trauma), and reasons for CCRT activation (Systolic BP < 90 mmHg: 34/212 [16.0%] vs. 120/624 [19.2%], $p = 0.30$; heart rate > 130/min: 44/212 [20.8%] vs. 162/624 [26.0%], $p = 0.13$; respiratory rate > 30/min: 55/212 [25.9%] vs. 175/624 [28.0%], $p = 0.55$; drop in Glasgow Coma Scale score by ≥ 2: 58/212 [27.4%] vs. 140/624 [22.4%], $p = 0.15$). Sepsis was more suspected in the weekend activations (112/212 [52.8%] vs. 276/624 [44.3%], $p = 0.03$). The rate of ICU admission was 77/212 [36.3%] vs. 185/624 [29.6%], $p = 0.07$), with no significant differences in intubation and vasopressor therapy. Patients with CCRT activations on the weekend had higher hospital mortality (69/212 [32.5%] vs. 148/624 [23.7%], $p = 0.01$). No significant differences were observed between CCRT activations during afterhours and daytime with respect to demographics, reasons for CCRT activation, ICU admission, ICU interventions and hospital mortality (110/447 [24.6%] vs. 80/338 [23.7%], $p = 0.76$). However, patients with CCRT activation during weekend afterhours had higher mortality compared with weekday afterhours (42/116 [36.2%] vs. 68/331 [20.5%], $p = 0.001$).
**Conclusions:** Patients who had CCRT activation during the weekend had higher hospital mortality, despite no major differences in clinical characteristics. This possible "weekend effect" needs further assessment, which may include collecting additional data and evaluating the hospital's operational dynamics and staffing during weekends.

### LA Reservoir Strain as a Predictor for LV Filling Pressure: Evidence from LV Catheterization

M. Kim[1], J. W. Roh[1], I. H. Jung[1], D. K. Cho[1]
[1]Cardiology, Yongin Severance Hospital, Yonsei University College of Medicine, Yongin-si, Republic of Korea.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000242

**Introduction:** Understanding of left atrial (LA) strain as a factor in predicting left ventricular (LV) filling pressure remains limited. This study aimed to predict LV filling pressure non-invasively through assessment of LA strain with existing parameters.
**Objectives:** We prospectively collected data, including pre-atrial contraction (pre-A) and LV end-systolic pressure (LVEDP) measurements, from patients who underwent coronary artery angiography and LV catheterization. Transthoracic echocardiography was conducted to assess LA strain within 24 h of LV catheterization. Patients with supraventricular tachycardia, atrial fibrillation, or acute coronary syndrome were excluded. Biomarkers, including NT-proBNP, functional, and morphological echocardiographic parameters were also collected.
**Methods:** We prospectively collected data, including pre-atrial contraction (pre-A) and LV end-systolic pressure (LVEDP) measurements, from patients who underwent coronary artery angiography and LV catheterization. Transthoracic echocardiography was conducted to assess LA strain within 24 h of LV catheterization. Patients with supraventricular tachycardia, atrial fibrillation, or acute coronary syndrome were excluded. Biomarkers, including NT-proBNP, functional, and morphological echocardiographic parameters were also collected.
**Results:** From June 2021 to September 2022, 365 participants ($61.7 \pm 11.5$ years, 25.5% female) were enrolled. The mean LA reservoir strain (LASr) was $28.7 \pm 7.4$. In c-statistics, the cutoff for LASr predicting an LVEDP of > 16 mmHg was 0.54 (0.50–0.57) at 18%, and 0.62 (0.57–0.67) at 24%. For predicting a pre-A pressure of > 12 mmHg, the c-statistics at LASr cutoffs of 18 and 24% were 0.58 (0.52–0.64) and 0.70 (0.63–0.77), respectively ($p$ for difference < 0.001). Logistic regression analysis revealed that, after covariate adjustment, the predictive power of LASr for elevated LV filling pressure was not significant at a cutoff of 18% but was an independent predictor at 24% (adjusted odds ratio [OR] 3.22 [95% confidence interval {CI} 1.77–5.88] for LVEDP ≥ 16 mmHg; adjusted OR 3.11 [95% CI 1.86–5.20] for LV pre-A ≥ 12 mmHg). As a continuous variable, LASr predicted LV pre-A pressure (c-statistics 0.79 [0.71–0.86]) better than LVEDP (c-statistics 0.71 [0.66–0.77]) in models including traditional parameters.
**Conclusions:** The LASr is an independent predictor of LV filling pressure when used with established factors.

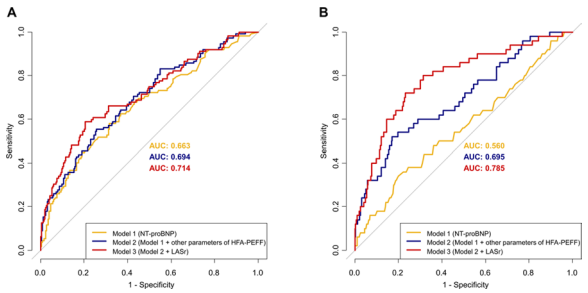

**Fig. (abstract 000242)** C-statistics of several models to predict elevated LV filling pressure of (A) LVEDP ≥ 16mmHg and (B) LV pre-A pressure ≥ 12mmHg

### Mechanical left ventricular unloading in cardiogenic shock treated with venoarterial extracorporeal membrane oxygenation: a systematic review and meta-analysis

Y. Kotani[1], P. Nardelli[2], T. Yamamoto[1], T. Koroki[1], T. Yaguchi[1], Y. Nakamura[1], M. Tonai[1], T. Karumai[1], G. Landoni[2], Y. Hayashi[1]

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000243

**Introduction:** Mechanical left ventricular unloading can prevent increased left ventricular afterload induced by venoarterial extracorporeal membrane oxygenation (VA-ECMO), thereby potentially improving clinical outcomes. A previous meta-analysis of observational studies found an association between the use of mechanical left ventricular unloading and improved survival among patients with cardiogenic shock undergoing VA-ECMO treatment. However, this result can be biased due to inherent limitations of observational studies. The recent publications of randomized controlled trials (RCTs) and propensity score-matched studies allowed for an updated meta-analysis by overcoming challenges of the previous study.
**Objectives:** This systematic review and meta-analysis focusing on RCTs and propensity score-matched studies aimed to evaluate if mechanical left ventricular unloading could reduce mortality in patients with cardiogenic shock undergoing VA-ECMO.
**Methods:** This study was registered on PROSPERO International prospective register of systematic review on January 15, 2024 (CRD42024498665). We searched MEDLINE, Embase, and the Cochrane Library for RCTs and propensity score-matched studies published from inception until December 20, 2023. The primary outcome was mortality at the longest follow-up, and the secondary outcomes included successful weaning from VA-ECMO, major bleeding, hemolysis, stroke, renal replacement therapy, limb ischemia, and bridge to heart transplantation or durable ventricular assist device. We used a *Mantel–Haenszel* random effects meta-analysis and reported the pooled results with a risk ratio (RR) and 95% confidence interval (CI).
**Results:** We identified two RCTs and eleven propensity-matched studies totaling 9858 patients. Mechanical left ventricular unloading was significantly associated with reduced mortality at the longest follow-up (RR, 0.89; 95% CI, 0.84 to 0.94; $P=0.0001$; moderate certainty of evidence). Among secondary outcomes, successful VA-ECMO weaning was more frequent with mechanical LV unloading (RR, 1.15; 95% CI, 1.02 to 1.29; $P=0.02$; low certainty of evidence), while major bleeding (RR, 1.27; 95% CI, 1.02 to 1.59; $P=0.03$; low certainty of evidence) and hemolysis (RR, 1.49; 95% CI, 1.10 to 2.02; $P=0.01$; moderate certainty of evidence) were increased. Other secondary outcomes were not significantly different.
**Conclusions:** Among adult patients with cardiogenic shock treated with VA-ECMO, mechanical left ventricular unloading was significantly associated with reduced mortality.

### Hallucinations in the Critically Ill; Prevalence and Association with Disturbed Behaviour

M. Young[1], N. Holmes[1], T. Niccol[1], S. Amjad[1], M. Gaca[1], R. Bellomo[2], A. Serpa Neto[3]

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000244

**Introduction:** Hallucinations in the critically ill are difficult to study and their prevalence and association with disturbed behaviour is unknown. These difficulties are, in part, a consequence of the challenges of reporting an intermittent and unpredictable phenomenon combined with the absence of standardised contemporaneous reporting tools. However, we hypothesised that bedside care givers would record observations regarding the presence of hallucinations and disturbed behaviour in the bedside clinical progress notes of critically ill patients. We further hypothesised that Natural Language Processing (NLP) could be used to scan these notes for words describing hallucinations and disturbed behaviour thereby enabling the identification of patients who experienced such phenomena during their intensive care stay.
**Objectives:** To evaluate the prevalence of hallucinations and the association with disturbed behaviour in critically ill patients.
**Methods:** We obtained electronic progress notes, demographics, medications, and outcomes of a cohort of critically ill patients. Using a previously validated methodology, we applied NLP to search bedside clinical progress notes for key words indicating a patient may have experienced hallucinations and / or disturbed behaviour.
**Results:** We studied 7525 patients. We found 625 (8.31%) were screened positive by NLP as having experienced hallucinations and 6900 (91.69%) were found not to have experienced hallucinations. Patients screened positive for hallucinations were younger (61.4 years vs 64 years, $p<0.001$), had higher APACHE III scores (55.0 vs 47.0, $p<0.001$), were significantly more likely to be diagnosed with renal failure (7.6% vs 2.5%, $p<0.001$) and were more likely to be diagnosed with cirrhosis (13.4% vs 6.9%, $p<0.001$). Further, we found that of patients screened positive for hallucinations, 623 (99.7%) were also screened positive for NLP diagnosed behavioural disturbance (NLP-Dx-BD) and possible delirium. However, of patients screened negative for hallucinations only 3274 (47.4%) were screened positive NLP-Dx-BD. Finally, in a sub-group analysis, we found that 25% of patients screened positive for hallucinations also received antipsychotic medication. Contrastingly, only 6.2% of patients screened negative for hallucinations received antipsychotics.
**Conclusions:** Hallucinations in critically ill patients are common. Further, critically ill patients who are screened positive for hallucinations are also likely to be screened positive for NLP-Dx-BD and, thus, likely delirium. These findings suggest that hallucinations may be a manifestation of a similar neurocognitive disfunction as delirium.

**Correspondence:** G. Hesselink
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000246

**Introduction:** Quality indicators are used in intensive care units (ICUs) as standards to measure, compare and improve quality of care. However, the number of quality indicators for which ICU clinicians need to record data increases and for many indicators there are concerns about their added value. This frustrates clinicians, and may divert time from providing and improving actual patient care.
**Objectives:** To determine whether working with only a core set of quality indicators in the ICU reduces registration time and administrative burden of ICU clinicians, and if this is associated with more joy in work without impacting the quality of ICU care.
**Methods:** Between May 2021 and June 2023, ICU clinicians of seven hospitals in the Netherlands were instructed to only register information on a consensus-based core set of quality indicators. Throughout this period, they were also empowered to resolve quality issues proactively. An implementation plan was developed and several

implementation tools were used to facilitate this process. Data on registration time, administrative burden and joy in work were collected at three time points with validated questionnaires. Longitudinal data on quality of care, expressed in standardized mortality rates (SMR) and ICU readmission rates, were gathered from the Dutch National Intensive Care (NICE) registry. Longitudinal effects and differences in outcomes between ICUs and between nurses and physicians were statistically tested.
**Results:** A total of 390 (60%), 291 (47%) and 236 (40%) questionnaires were returned at T0 (i.e., before the intervention was implemented), T1 (1-year follow-up) and T2 (2-year follow-up). At T2 the overall median registration time per day was halved by 30 min ($p < 0.01$) and median scores were lower for both physicians and nurses ($p < 0.01$). The decrease in registration time is longitudinally associated with respondents being a physician or a nurse ($p = 0.02$) and with the ICU where respondents work ($p < 0.01$). Respondents also experienced fewer unnecessary and unreasonable registration tasks at T1 ($p < 0.01$) and at T2 ($p < 0.01$). Both decreases are longitudinally associated with the ICU where respondents work ($p < 0.01$). No statistically significant changes over time were found in joy in work, SMR and ICU readmission.
**Conclusions:** Implementing a core set of quality indicators reduces registration time and the administrative burden without harming patient care. The valuable time saved as a result of this intervention can be invested in bedside patient care and in aspects that enhance joy in work in the ICU (e.g., teambuilding, professional development and breaks to socialize and recuperate from work).

### Predictors of Postoperative Oliguria in Patients Going Through Major Abdominal Surgery: A Single Center Prospective Observational Study

S. Nihlén[1]; E. Semenas[1]; M. Lipcsey[2]; M. Hultström[3]; R. Frithiof[3]; R. Kawati[1]; J. Andresen[4]; B. Jensen[5]

**Correspondence:** S. Nihlén
*Intensive Care Medicine Experimental* 2024, **12(suppl 1):** 000247

**Introduction:** Postoperative oliguria is common in patients going through major abdominal surgery. Among clinicians, oliguria is often considered a sign of hypovolemia and a risk factor for acute kidney injury (AKI), and therefore often rapidly treated with an increase in fluid administration. Alternatively, postoperative oliguria is attributed to post-surgical anti diuretic hormone (ADH) release and left untreated.
**Objectives:** The aim of our study was to investigate the predictors of urine output postoperatively, focusing on ADH levels, fluid administration, hemodynamics and patient factors.
**Methods:** In this single center prospective observational study adult patients planned for major abdominal surgery were followed with regard to the occurrence of oliguria during the first 12 h of their stay in the post-anesthesia unit (PACU). Samples were collected pre- and postoperatively for ADH and serum osmolality and blood pressure and fluid administration rates were registered.
**Results:** 54 patients were included in the study. Preoperative ADH levels were low but increased markedly postoperatively (1.5 (1.2–2.2) to 17.9 (12.0–29) pg/mL, $p < 0.001$) and correlated to serum osmolality (rho = 0.45). ADH adjusted for osmolality was not a predictor of postoperative oliguria, but higher ADH levels and increased fluid administration were associated with normalization of urine output after an oliguric episode. Oliguria was only seen in patients with hypotension relative to their blood pressure prior to anesthesia or those with mean arterial pressure (MAP) < 65 mmHg. Preoperative renal function and increased postoperative fluid administration were associated with oliguria.
**Conclusions:** ADH levels postoperatively did not predict postoperative urine output or oliguria in patients going through major abdominal surgery.

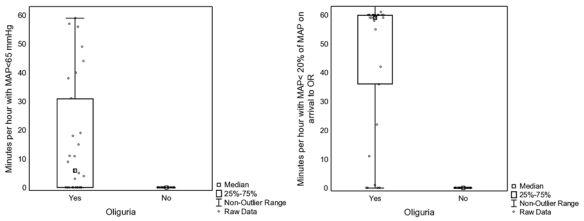

**Fig. (abstract 000247)** Minutes per hour with MAP < 65mmHg and MAP < 20% of MAP on arrival to operating room (OR) in patients with and without oliguria during the first 12 h in the in the post-anesthesia unit (PACU)

### Does the use of focused echocardiography affect the management impact of pulmonary embolism in the intensive care setting?

K. Strong[1]
[1]Bristol Medical School, University of Bristol, Bristol, United Kingdom
**Correspondence:** K. Strong
*Intensive Care Medicine Experimental* 2024, **12(suppl 1):** 000248

**Introduction:** The use of echocardiography in the intensive care setting is becoming a more utilised imaging modality. It provides information to guide therapeutic interventions and prognosticate pulmonary embolism (PE) allowing consideration of specialist referral for cardiac/surgical intervention [1].
**Objectives:** This literature review analyses primary research and explores the impact echocardiography has when assessing and treating the critically unwell patient. It aims to explore the PICO question 'Does the use of focused echocardiography affect the management impact of pulmonary embolism in the intensive care setting?'.
**Methods:** Systemic searches of the electronic database PubMed were conducted in July 2022, where articles were manually screened by the author according to the selection criteria. Main reasons for exclusion were the extensive use of transoesophageal echocardiography or the use of echocardiography in cardiology which were not included as part of this review. Assessment of the included studies were stratified against a critical appraisal checklist. From a total of 47 identified articles, 15 were included. All the studies included data that was statistically significant for the parameters (PE and haemodynamic instability). However, it must be noted that the follow up duration on some studies was limited and there were some confounding factors that might have altered the results included.
**Results:** The use of echocardiography in the haemodynamically stable patient cannot directly exclude the diagnosis of PE alone, it is used however to risk stratify PE patients to moderate or high risk groups depending on the presence or absence of right ventricular dysfunction [2]. In patients with a high clinical suspicion of PE, studies have shown a consistently high specificity (approx. 90%) and low sensitivity (56–70%) for echocardiography making it a useful rule-in test [3]. In high-risk patients with massive PE, echocardiography is widely embraced and confirms aetiology of haemodynamic compromise

however in low-risk patients echocardiography rarely yields findings and does not change prognostication. 4 New pathways have now been developed to synchronise management of acute PE utilising the advantages of echocardiography.
**Conclusions:** With the current evidence, the use of echocardiography can be favoured (when used alongside other modalities) in the diagnosis and management of PE in the intensive care environment. However, further high-quality randomised control trials with a longer follow up time are needed to make this suggestion more substantial. It is highlighted that the focused echocardiogram performed in the intensive care setting does not replace a comprehensive exam and its use is primarily around point of care ultrasound to identify life threatening PE. There is no doubt that with little complication rate the use of echocardiography to aid diagnosis and management in the intensive care setting is a rapidly evolving field and using it alongside other imaging modalities in the assessment of a patient is likely to lead to a gold-standard approach.

**Correspondence:** F. Zand
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000249

**Introduction:** Traumatic Brain Injury (TBI) is one of the most common causes of hospitalization and disability in young and middle-aged people. Modafinil is a new central nervous system stimulant with low side effects, which is recently used off-label to increase the level of consciousness in TBI patients. In this triple-blind randomized clinical trial, our aim is to compare oral modafinil with placebo in increasing the rate of recovery of consciousness in patients with moderate to severe TBI hospitalized in the intensive care units (ICUs).
**Methods:** All patients admitted to the ICUs of Shahid Rajaei level one trauma center, Shiraz, Iran between April 2021, and April 2023, who met the inclusion criteria were included in the study. A total of 97 patients aged 18 to 70 with moderate or severe TBI, who had not received intravenous sedatives continuously within 24 h prior to screening, and whose Glasgow Coma Motor score was 4 or 5 and did not increase during this period, were included and randomized in either the modafinil (M) or placebo (P) group. Patients in the M group received 200 mg of modafinil daily for 7 days, and patients in the P group received placebo for 7 days. Their motor GCS and total GCS scores were recorded three times a day. Other data such as the length of stay in the ICU and hospital, the need for mechanical ventilation, the time to remove the tracheal tube, and the need for tracheostomy insertion were recorded.
**Results:** There was no significant difference between M and P groups in the duration from starting the intervention until 2 points increase in GCS (4 vs. 3 days—*P*-value = 0.251) or 1 point increase in motor GCS (3.5 vs. 3 days—*P*-value = 0.310) Also, there was no significant difference between the two groups in the mean value of total GCS (*P*-value = 0.533) and motor GCS (*P*-value = 0.167). The only significant difference between the groups was in the percentage of patients with an increase in total GCS by 2 points (54% in M group vs. 32% in P group—P-value = 0.042) and an increase in motor GCS by 1 point (56% in M group vs. 34% in P group—P-value = 0.042); these percentages were significantly higher in M group. In other outcomes, including the length of stay in the ICU (17 vs. 18 days—*P*-value = 0.896) and hospital (24 vs. 28 days—*P*-value = 0.136), mechanical ventilation days (11 vs. 11 days—*P*-value = 0.915), and the need for tracheostomy (26 vs 24 patients—*P*-value = 0.568), there was no significant difference between M and P groups.
**Conclusions:** Oral modafinil seems to be beneficial for more rapid increase in level of consciousnesses in selected patients with severe TBI in the acute phase in ICU. Further randomized and multicenter clinical trials with larger sample size are needed.

### A retrospective analysis and comparison of Neuron-Specific Enolase (NSE) and MIRACLE2 scores in predicting outcome following out-of-hospital cardiac arrests

S. Harding[1], S. Shah[1], D. King[1]
[1]Critical Care, Southend University Hospital, Mid and South Essex NHS Foundation Trust, Southend-on-Sea, United Kingdom
**Correspondence:** S. Harding.
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000250

**Introduction:** Predicting poor outcomes following cardiac arrests is a complex task, with multiple models existing to help achieve this. Neuron-specific enolase (NSE) is a blood serum enzyme released in response to hypoxic neurological injury [1], with Resuscitation Council UK guidelines stating a NSE > 60 µg/L (mcg/L) at 48–72 h post-cardiac arrest being an indicator of poor outcome [2]. The purpose of this study was to compare the NSE biomarker with the MIRACLE2 score, a tool used to predict poor outcomes following out-of-hospital cardiac arrests [3].
**Methods:** A retrospective study was conducted at Southend hospital in the United Kingdom, where all NSE serum samples were collected over a 2-year period. Patient identifiers for each NSE test were then used to retrospectively analyse each clinical scenario, looking specifically at those involved in out-of-hospital cardiac arrests. Exclusion criteria included in-hospital cardiac arrests, duplicate entries, and

cases of inappropriate NSE testing, such as when cardiac arrest did not occur. Within each case identified, patient notes were scrutinised to manually calculate their MIRACLE2 score. Comparison was then made between the NSE and MIRACLE2 score for each patient, along with their ultimate outcome being survival or death following their out-of-hospital cardiac arrest.

**Results:** Between January 2022 and February 2024 a total of 37 NSE blood tests were analysed. Following exclusion criteria, 23 were valid for inclusion in this study. A value of greater than 16.3 (mcg/L) was deemed as being abnormally high. 19 patients were then identified as having abnormally high NSE values. In patients who did not survive, their NSE values ranged from 11.3 to 800 (mcg/L), with a mean of 190.3 (mcg/L) and median of 128.8 (mcg/L). The corresponding MIRACLE2 score for patients with abnormally high NSE values was on average 5, representing a > 80% predicted chance of poor neurological outcome at 6 months based on their MIRACLE2 score alone. Subsequent analysis then revealed that indeed 87% of those identified did not survive to discharge and had poor outcomes.

In those who survived an out-of-hospital cardiac arrest, their average MIRACLE2 score was 3, with the lowest NSE being 3.4 and the highest value being 54 (mcg/L), with a mean of 25.7 (mcg/L) and a median of 21.7 (mcg/L). Comparison between those who survived and those who died can be seen in Fig. 1. Showing overlap between the two groups suggests that relying on a single NSE value by itself does not always aid in predicting survivability.

Pearson's correlation was then applied to both the surviving and non-surviving groups, revealing a coefficient *r* value of 0.30 in the survivor dataset and a *r* value of 0.36 in the non-survivor dataset, suggesting weak-to-moderate correlation between the NSE biomarker and MIRACLE2 score.

**Conclusions:** Predicting poor outcomes following out-of-hospital cardiac arrests is a complex task. This study has shown there exists a relationship between NSE values and the corresponding MIRACLE2 score when used together to aid in prognostication of out-of-hospital cardiac arrests. Due to the small sample size, additional study in a larger population group is warranted to explore this relationship further.

**Introduction:** Muscle wasting occurs rapidly following initiation of mechanical ventilation (MV), and prolonged MV instigates a higher degree of muscle atrophy (1). This phenomenon leads to prolonged ICU stay, higher mortality and prolonged physical dysfunction following hospital discharge (2). Early and enhanced rehabilitation has been shown to counteract muscle wasting, reduce LOS and improve outcomes (3). We aimed to assess the physical and functional outcomes in WIND group 3b i.e. tracheostomy requirement for prolonged respiratory weaning, under the care of a CCPRT.

**Methods:** WIND 3b patients admitted to a large, UK ICU, without significant neurological or traumatic injury, between November 2021–2023 under the CCPRT were included. The CCPRT provide weekday enhanced rehabilitation to NICE CG83 guidelines. Patient demographics and hospital outcomes were collected retrospectively via electronic patient records. Physical function at ICU and hospital discharge was assessed using the Manchester Mobility Scale (MMS). Occurrence of ICU acquired weakness (ICU-AW) was assessed using the Medical Research Council Sum-Score (MRC-SS) at first rehabilitation session & ICU discharge.

**Results:** 157 patients were included with mean age of 57.6 ± 14.8 years and APACHE II of 16 (IQR: 7–31) on admission. 23 (15%) died in the ICU and 14 (9%) on the ward. Duration of MV was 29 days (IQR: 19–38) with an ICU LOS of 34 days (IQR: 24–46). 100% of patients had ICU-AW at first rehabilitation session (MRC < 48). 64/117 (55%) patients demonstrated ICU-AW at ICU discharge, of which 38 was significant (MRC-SS < 48) and 26 severe (MRC-SS < 36). 88% ($n = 115$) of patients were able to stand or better (MMS ≥ 4) and 57% ($n = 75$) able to mobilise (MMS ≥ 6) at ICU discharge. Hospital LOS was 50 days (IQR 38–74) with 89% ($n = 100$) of patients being able to mobilise (MMS ≥ 6) at hospital discharge. 81% ($n = 92$) of patients were discharged to their home environment.

| Outcomes | *N* | |
|---|---|---|
| Time from admission to tracheostomy | 117 | 11 (8–15.75) |
| Time from admission to mobilisation (MMS ≥ 2) | 117 | 12 (9–17) |
| MRC at ICU Discharge | 117 | 46 (36–50) |
| *No ICU-AW* | | 53 (45%) |
| *Significant ICU-AW* | | 38 (32%) |
| *Severe ICU-AW* | | 26 (22%) |
| MMS at ICU Discharge | 131 | |
| *3* | | 16 (12%) |
| *4* | | 31 (24%) |
| *5* | | 9 (7%) |
| *6* | | 39 (30%) |

| Outcomes | N | |
|---|---|---|
| *7* | | 36 (27%) |
| MMS at Hospital Discharge | 113 | |
| *3* | | 5 (4%) |
| *4* | | 6 (5%) |
| *5* | | 2 (2%) |
| *6* | | 26 (23%) |
| *7* | | 74 (66%) |
| Discharge Destination | 113 | |
| *Home (No Rehabilitation)* | | 51 (45%) |
| *Home (With Rehabilitation)* | | 41 (36%) |
| *Inpatient Rehabilitation* | | 21 (19%) |

**Conclusions:** ICU-AW was highly prevelant in WIND 3b patients at ICU discharge, despite enhanced rehabilitation. However, a specialised CCPRT achieved resolution of ICU-AW in 45% of WIND 3b patients and a high level of physical function at ICU/hospital discharge, with 81% of patients discharged to their home environment. With ever increasing survivorship, further research looking at the long-term functional outcomes in this cohort is essential.

### Can early tracheostomy cuff deflation with voice restoration reduce psychological morbidity in patients requiring prolonged mechanical ventilation? An observational study

A. Harriman[1], B. Tunnicliffe[2], J. Hodson[2], C. Snelson[2], J. Weblin[1]
[1]Therapy Services, Queen Elizabeth Hospital Birmingham, Birmingham, United Kingdom; [2]Department of Critical Care, Queen Elizabeth Hospital Birmingham, Birmingham, United Kingdom

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000252

**Introduction:** Tracheostomy placement is often required in critically ill patients who require prolonged mechanical ventilation (MV) (1) and is associated with increased Intensive Care Unit (ICU) length of stay (LOS), mortality (2) and psychological morbidity (3). Timing of tracheostomy placement and tracheostomy practice i.e. cuff deflation and voice restoration, varies between centres and regions (4). We aimed to evaluate the effect of the timing of tracheostomy cuff deflation and voice restoration on psychological morbidity in patients requiring prolonged MV.

**Methods:** Patients admitted to a large, UK ICU between November 2021–2023, requiring MV > 5 days and a tracheostomy for ventilator weaning were included. Those with significant neurological injury were excluded. Patient demographics and outcomes were collected retrospectively via electronic patient records. Patients were categorised into Early (0–5 days), intermediary (6–10 days) and delayed (> 10 days) tracheostomy cuff deflation. The incidence of psychological morbidity was collected at ICU discharge using the Hospital Anxiety & Depression Score (HADS) & Intensive Care Psychological Assessment Tool (IPAT).

**Results:** 157 patients were included. 23 (15%) died in ICU and 14 (9%) on the ward. 58 (37%) had 'early' cuff deflation, 54 (34%) 'intermediary' and 45 (29%) 'delayed'. No significant difference in patient demographics, sedation days, time to tracheostomy insertion and incidence of delirium was observed between groups. Delayed cuff deflation was associated with significantly higher levels of anxiety (HADS-A, $p = 0.040$) and psychological distress (IPAT, $p = 0.046$) at ICU discharge, with a higher prevalence of moderate and severe anxiety in the delayed cuff deflation group (47% vs 31% vs 12%). A trend towards a higher prevalence of moderate and severe depression was also observed in the delayed cuff deflation group (41% vs 28% vs 20%; p.056).

| Tracheostomy to cuff deflation | N | Whole Cohort | 0–5 Days 'early' | 6–10 Days 'intermediary' | > 10 Days 'delayed' | |
|---|---|---|---|---|---|---|
| *Psychological outcomes* | | | | | | |
| HADS-A at ICU Discharge | 89 | 8 (4–11) | 7 (3–9) | 8 (6–12) | 8 (4–14) | **0.040** |
| *Normal (0 – 7)* | | 42 (47%) | 20 (56%) | 15 (42%) | 7 (41%) | |
| *Mild Anxiety (8–10)* | | 24 (27%) | 12 (33%) | 10 (28%) | 2 (12%) | |
| *Moderate Anxiety (11–15)* | | 17 (19%) | 2 (6%) | 10 (28%) | 5 (29%) | |
| *Severe Anxiety (16–21)* | | 6 (7%) | 2 (6%) | 1 (3%) | 3 (18%) | |
| HADS-D at ICU Discharge | 89 | 8 (4–12) | 6 (3–10) | 8 (5–12) | 10 (4–15) | 0.056 |
| *Normal (0–7)* | | 43 (48%) | 21 (58%) | 15 (42%) | 7 (41%) | |
| *Mild Depression (8–10)* | | 22 (25%) | 8 (22%) | 11 (31%) | 3 (18%) | |
| *Moderate Depression (11–15)* | | 15 (17%) | 5 (14%) | 5 (14%) | 5 (29%) | |
| *Severe Depression (16–21)* | | 9 (10%) | 2 (6%) | 5 (14%) | 2 (12%) | |
| IPAT at ICU Discharge | 89 | 8 (6–12) | 8 (4–11) | 9 (7–12) | 12 (6–15) | **0.046** |
| *Psychological Distress ≥ 7* | | 60 (67%) | 21 (58%) | 27 (75%) | 12 (71%) | |

**Conclusions:** Presence of psychological morbidity within patients requiring prolonged MV and a tracheostomy is high. Our observational data suggests that earlier tracheostomy cuff deflation and voice restoration, may be protective against severe psychological morbidity.

Future trials of early tracheostomy cuff deflation to assess its efficacy in preventing psychological distress is warranted, as well as possible benefits on weaning outcomes and delirium management.

### Service evaluation of tracheostomy practice and management in patients requiring prolonged mechanical ventilation within a large, UK mixed speciality Intensive Care Unit

A. Harriman[1], B. Tunnicliffe[2], J. Hodson[2], C. Snelson[2], J. Weblin[1]
[1]Therapy services, Queen Elizabeth Hospital Birmingham, Birmingham, United Kingdom; [2]Department of Critical Care, Queen Elizabeth Hospital Birmingham, Birmingham, United Kingdom
**Correspondence:** A. Harriman
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000253

**Introduction:** Tracheostomy insertion is commonly performed to help liberate patients from mechanical ventilation (MV) in the ICU (1). TracMan investigated early (< 4 days of admission) vs late (≥ day 10) tracheostomy insertion finding no additional benefit on mortality or weaning outcomes (2). Percutaneous tracheostomies were more frequent than surgical (89.2% vs 10.8%) and the utilisation of sedative medication > 24 h after insertion was high in both the early (approx. 40%) and late (approx. 30%) groups. Regional differences remain in tracheostomy practice (3). In our service, tracheostomy insertion is dictated by clinical decision, and is not protocolised. To investigate our practice, we evaluated tracheostomy management for patients requiring prolonged MV.
**Methods:** We included consecutive patients who were admitted to a large mixed speciality ICU within the UK between November 2021–2023 who required a tracheostomy and > 5 days of MV. Patients where the tracheostomy was not solely required for ventilation weaning e.g. those with significant neurological injury, were excluded. Patient demographics, ventilation and hospital outcomes were retrospectively collected via electronic patient records.
**Results:** 157 patients were included. Mortality within the ICU was 15% ($n = 23$). Age at admission was 57.6 ± 14.8 years with 67% being male. Median duration of MV was 29 days (IQR: 19–38) with ICU length of stay 34 days (IQR: 24–46). Their median Charlson Comorbidity Index at admission was 3 (IQR: 2–5) and APACHE II score 16 (IQR: 7–31). Percutaneous tracheostomy insertion was performed in 118 (75%) patients with 39 (25%) being surgical. The median time to tracheostomy from admission was 11 days (IQR; 8–15.75). Sedation was stopped < 1 day (IQR; 0–2) after tracheostomy and 74% had sedation terminally ceased within 24 h. 77% ($n = 121$) of patients were on a spontaneous mode of ventilation within 24 h of insertion. Patients were liberated from MV on average, 14 days (IQR; 8–25) post insertion and it took 21 days (IQR; 11–31) to achieve successful decannulation.

| Tracheostomy outcomes | *N* | |
|---|---|---|
| Tracheostomy Type | 157 | |
| *Percutaneous* | | 118 (75%) |
| *Surgical* | | 39 (25%) |
| Time to tracheostomy insertion (days) | 157 | 11 (8–15.75) |
| Died in ICU | 157 | 23 (15%) |
| Duration of MV (Days) | 152 | 29 (19–38) |
| ICU Length of Stay (Days) | 132 | 34 (24–46) |
| Sedation Stopped | 157 | 155 (99%) |
| *Days from Tracheostomy* | 155 | 0 (0–2) |
| *Pre-Tracheostomy* | | 23 (15%) |
| *Same Day as Tracheostomy* | | 61 (39%) |
| *Next Day* | | 31 (20%) |
| *> 1 Day* | | 40 (26%) |
| Reached 24 Hours of TM | 144 | 139 (97%) |
| *Days from Tracheostomy* | 139 | 14 (8–25) |
| Decannulated | 157 | 128 (82%) |
| *Days from Tracheostomy* | 128 | 21 (11–31) |

**Conclusions:** Our service evaluation showed a higher incidence of surgical tracheostomies than preceding literature. Time to tracheostomy was consistent with previous studies and current evidence-based practice. We were able to achieve sedation cessation and spontaneous breathing in a higher proportion of patients < 24 h after tracheostomy than previous studies which may lead to earlier engagement in rehabilitation. This, combined with a low mortality rate, may indicate appropriate patient selection and procedure timing within our ICU. Further local evaluation of the high incidence of surgical tracheostomies may be beneficial.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000254

**Introduction:** Daily sedation interruption (DSI) has been considered as the state-of-the-art of care in intensive care unit (ICU) based mainly on the studies with before-after design, conducted in well-staffed ICU settings. The goal of this study was to design and implement a protocol for daily withdrawal of sedatives and to investigate its effect on major patient-centered outcomes in an ICU in a big teaching hospital, south of Iran.
**Methods:** In this non-randomized clinical trial, two mixed medical-surgical ICU's with similar bed numbers and nurses staffing and managed by the same intensivist-driven medical team were selected. A protocol for DSI was designed and approved after a comprehensive literature review. During a 6-month period, all adult patients who were under mechanical ventilation more than 24 h in these two ICU's who did not meet exclusion criteria were recruited. In the intervention ICU, the nursing staff were trained and encouraged to use DSI protocol on a daily basis. Protocol commitment was supervised by the investigation team, strictly. No intervention was conducted in the control ICU, where sedation regimens were according to daily physicians "as needed" orders and the nurses' decision. Two ICU's were compared for significant patient-centered outcomes during the study period.
**Results:** Sixty-three patients in P-ICU and fifty-three patients in C-ICU were eligible for recruitment during the study period with similar demographic characteristics and medical diagnoses. Mean Glasgow Coma Scale Score and mean Richmond Agitation Sedation Score of patients were significantly higher in P-ICU ($P=0.001$ and $p=0.036$, respectively). There was no significant difference between the ICU's regarding ICU and hospital length of stay and hospital mortality, however, median for ventilator free days (4 vs. 3 days, $p=0.027$) was higher and ICU mortality (19 vs. 36 percent, $p=0.043$) was lower significantly in P-ICU. Moreover, re-intubation rate (6.3 vs 20.8 percent, $p=0.021$) and readmission to ICU rate (zero vs. 7.5 percent, $p=0.041$) were significantly lower in P-ICU patients during the study period. There was no significant difference between these ICU's regarding total midazolam equivalent dosage for sedation, accidental removal of connections, intra vascular accesses and tubes or fall from bed.
**Conclusions:** Despite some limitations, this study well underscores that the implementation of the DSI protocol is a safe and useful method to improve significant ICU outcomes in mechanically ventilated patients admitted to ICU's in a variety of care model settings.

**Reference(s)**
Some of the data were recruited from Iran Intensive Care Unit Registry (IICUR). This is a Persian ICU-based registry which is launched in 2018 at Nemazee hospital affiliated with Shiraz University of Medical sciences. This registry was developed based on the COMET (CORE Outcome Measurement and Evaluation Tool) program, following the approval of the Australian and New Zealand Intensive Care Society. IICUR was approved by Ethics Committee of Shiraz University of Medical Sciences in 2018 (IR.SUMS.REC.1397.559) and recognized by Iran Ministry of Health as the first and single registry of adult ICU in Iran

**Topic:** Sedation, analgesia and delirium

## What can we learn from the morbidity and mortality process? Introducing an electronic system to capture M&M cases in the intensive care unit to promote organisational memory

F. Lanaghan[1], R. Hart[1]
[1]Critical Care, Queen Elizabeth University Hospital, Glasgow, United Kingdom
**Correspondence:** F. Lanaghan
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000255

**Introduction:** The morbidity and mortality process (M&M) is an essential component of clinical governance. A well conducted M&M will allow multi-disciplinary team (MDT) learning, identification of risk and potential system failures, and allow targeted QI interventions. We describe our experience in a large critical care unit in a tertiary hospital, of using an electronic real-time submission tool (M&M Datix) to capture, triage and publicise M&M cases. Each case report was submitted contemporaneously by a clinician involved in the case, and following discussion at departmental M&M meetings, feedback notes collated and distributed.
**Objectives:** To quantify the number and categories of cases captured via our electronic M&M submission portal.
- Describe common themes of cases that trigger an M&M review.
**Methods:** M&M Datix was used to generate "meeting outcome" notes for all M&M cases between 2017 and 2023. We reviewed all meeting outcome notes and assigned learning categories to each case. We describe an overview of the number of cases submitted via M&M Datix and quantify the common categories which lead to M&M submission.
**Results:** Since 2017 there have been 98 submissions in total via M&M Datix, with 79 cases included in analysis and broadly categorised as:
- 28 mortality cases.
- 17 morbidity cases.
- 34 educational cases.
All these cases have been discussed at a monthly departmental team-based quality review meeting. Each analysed case was allocated to a minimum of one learning category.

**Table 1 (abstract 000255)** Key themes identified during analysis of M&M Datix submissions

| Common learning categories: | Number of cases: |
|---|---|
| Team working | 58 |
| Communication | 50 |
| Education | 42 |
| Death | 28 |
| Diagnostic uncertainty | 19 |
| Others | 69 |

The positive contribution of MDT communication and planning for complex cases was emphasised commonly. Central venous catheters, although commonly used, were featured in several M&M cases including contrast extravasation, malposition, and perceived delayed insertion. The need for simulation drills for predictable critical incidents was a common recommendation.
**Conclusions:** M&M Datix has allowed the generation of post-meeting learning notes and clinical governance newsletters to bolster organisational memory. We encourage all new staff to read these to ensure they are orientated to potential risk. Furthermore, we have ensured that both our QI strategy and our MDT educational programme targets areas of learning from our M&M process. It is not surprising that team-working and communication feature heavily in critical incident analysis. It is fundamental that these important non-clinical attributes feature in all healthcare professional training and education.

### Volatile sedation in intensive care units: a systematic review and *meta*-analysis

T. Yamamoto[1], Y. Kotani[1], K. Akutagawa[1], M. Tomimatsu[1], T. Nagayama[1], M. Tonai[1], T. Karumai[1], Y. Hayashi[1]
[1]Department of intensive care, Kameda Medical Center, Kamogawa, Japan

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000257

**Introduction:** The use of volatile anesthetic agents has increased in the intensive care unit (ICU) during mechanical ventilation. Compared to intravenous sedation, volatile sedation may have several advantages including suppression of lung injury and inflammatory responses, thereby potentially improving clinical outcomes in critically ill patients. Previous meta-analyses showed a shorter duration to liberation from mechanical ventilation with the use of volatile sedation. The recent publications of large-scale randomized controlled trials (RCTs) and propensity score-matched studies justified updating a comprehensive evaluation on the efficacy and safety of volatile sedation in this setting.
**Objectives:** We aimed to test the hypothesis that volatile sedation, compared to intravenous sedation, would improve clinically relevant outcomes among critically ill adult patients undergoing mechanical ventilation.
**Methods:** This study was registered in the PROSPERO International prospective register of systematic reviews (CRD42023458064) on September 10, 2023. We searched MEDLINE, Embase, and Cochrane Library until October 2, 2023 for RCTs and propensity score-matched studies comparing volatile anesthetics with intravenous agents in critically ill adults receiving invasive mechanical ventilation in the ICU. The primary outcome was the time from termination of sedative administration to extubation. The secondary outcomes included delirium, in-hospital mortality, length of stay in the ICU and hospital, and acute kidney injury. We assessed these outcomes with a random-effects Mantel–Haenszel model.
**Results:** We included eighteen RCTs and three propensity score-matched studies, totaling 2054 patients. Volatile sedation was significantly associated with a shorter time to extubation than intravenous sedation (mean difference, − 87 min; 95% confidence interval (CI), − 125 to −49; $p < 0.001$; $I^2 = 91\%$). Among the secondary outcomes, delirium was less frequent (37/405 [9.1%] vs. 62/406 [15.3%]; risk ratio, 0.60; 95% CI, 0.41 to 0.89; $p = 0.01$; $I^2 = 0\%$) and the length of hospital stay was shorter (mean difference, − 0.92 days; 95% CI, − 1.79 to − 0.04; $p = 0.04$; $I^2 = 53\%$) in the volatile sedation group. No significant difference was detected in other outcomes.
**Conclusions:** Compared to intravenous sedation, volatile sedation was significantly associated with a reduced time to extubation, a lower incidence of delirium, and a decreased length of hospital stay among critically ill patients on mechanical ventilation.

### Activation Pattern of Dendritic Cell Necroptosis during the Acute Phase of *Sepsis* and Its Impact on Immune Function and Organ Damage

L. Wang[1], R. Yao[2], Y. Wu[3], H. Kang[1]
[1]Department of Critical Care Medicine, National Key Laboratory of Kidney Diseases, Chinese PLA General Hospital, Beijing, China; [2]Department of General Surgery, Chinese PLA General Hospital, Beijing, China; [3]Department of Critical Care Medicine, Chinese PLA General Hospital, Beijing, China
**Correspondence:** L. Wang
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000258

**Introduction:** Sepsis, a life-threatening organ dysfunction caused by a dysregulated host response to infection, remains a principal cause of mortality among critically ill patients worldwide. Studies have indicated that the early stages of sepsis can lead to a reduction in dendritic cell (DC) numbers and functional impairment. Clinical investigations have also identified a close correlation between the extent of DC depletion and fatal outcomes in patients with sepsis. Necroptosis, a form of cell death dependent on RIPK1/RIPK3 signaling, plays a pivotal role in the pathogenesis of sepsis. However, the extent and impact of DC necroptosis during sepsis have not been previously reported.

**Objectives:** To delineate the pattern of DC necroptosis during sepsis and explore its effects on the immune function and organ damage in mice with sepsis.
**Methods:** A sepsis model was established in wild-type male C57BL/6J mice using the CLP method. Splenic DCs were isolated at 0 h, 6 h, 12 h, and 24 h post-model establishment. The level of DC necroptosis was assessed through Western Blot, flow cytometry, confocal imaging, and ELISA. Additionally, a sepsis model was established in Cd11ccreMlklfl/fl mice, and immune function was evaluated 24 h post-model establishment via flow cytometry and ELISA, while serum biochemical indicators and H&E staining of vital organs (heart, liver, lungs, kidneys) were used to assess organ damage.
**Results:** In the early stages of sepsis (within 24 h), a significant necroptosis of splenic DCs was observed, correlating positively with disease progression. Sepsis induced a significant increase in the phosphorylation levels of MLKL, RIPK3, and RIPK1 in DCs, with a marked increase in the proportion of DCs undergoing necroptosis (Annexin V + 7-AAD +). The intracellular levels of p-RIPK3 and p-MLKL were significantly elevated, along with notable upregulation of necroptosis-associated factors (HMGB1, IL-1α, IL-33, LDH, and TNF-α). Knockout of the Mlkl gene in mouse DCs inhibited necroptosis, significantly increased the proportion of CD3 + T cells and CD4 + T cells in peripheral blood, decreased the proportion of Tregs, and significantly reduced the levels of pro-inflammatory (e.g., IFN-γ) and anti-inflammatory (e.g., IL-10) cytokines. Furthermore, conditional knockout of the Mlkl gene in mice resulted in a significant reduction in organ damage markers (ALT, AST, CREA, and CK) post-CLP modeling, with corresponding improvements in tissue damage in the heart, liver, lungs, and kidneys.
**Conclusions:** Sepsis induces necroptosis in splenic DCs, correlating positively with disease progression. Inhibiting DC necroptosis significantly ameliorates sepsis-related immune dysfunction and organ damage, suggesting its critical role in the pathogenesis of sepsis.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000259

**Introduction:** Sepsis is a fatal disease with high morbidity and mortality, and acute kidney injury is a common complication. Recent evidence suggests that inflammation, metabolic reprogramming and microcirculation dysfunction are the three basic mechanisms underlying the development of sepsis-associated acute kidney injury (SA-AKI)[1]. Human umbilical cord mesenchymal stem cell-derived small extracellular vesicles (hucMSC-sEVs) have the capacity for intercellular signaling communication, making them a novel therapeutic strategy for various diseases[2]. Our previous study found that hucMSC-sEVs ameliorated ischemia–reperfusion-induced AKI[3], whereas engineered red blood cell-derived extracellular vesicles significantly enhanced the ability to specifically target damaged kidneys[4]. However, the use of hucMSC-EVs in SA-KI has been rarely reported.
**Objectives:** To investigate the role and molecular mechanisms of hucMSC-sEVs in SA-AKI.
**Methods:** hucMSC-sEVs were obtained through ultracentrifugation combined with size exclusion chromatography, and characterized by transmission electron microscopy, nanoparticle tracking analysis, and western blotting. SA-AKI was induced by cecal ligation and puncture (CLP) in mice and lipopolysaccharide (LPS)-induced HK2 cell model, followed by intervention with hucMSC-sEVs. The biodistribution of hucMSC-sEVs in the SA-AKI mouse model was imaged using the IVIS spectrum imaging system. Serum creatinine, urea nitrogen and cystatin C were measured to evaluate kidney function. Histopathological changes of kidney tissues in mice were detected by H&E staining. The mRNA levels of renal injury molecules, inflammatory cytokines and key enzymes of glycolysis in kidney tissues of mice and HK-2 cells were determined by qPCR. The miRNA expression profile of hucMSC-sEVs was analyzed through small RNA sequencing.
**Results:** We found that hucMSC-sEVs exhibited significant improvements in SA-AKI both in vitro and in vivo. In vitro, hucMSC-sEVs inhibited inflammation and glycolysis in LPS-stimulated HK-2 cells. In vivo, administration of the hucMSC-sEVs improved the extent of weight loss, enhanced survival rate, reduced serum levels of creatinine, urea nitrogen, and cystatin C, ameliorated the pathological injury of kidney tissues in mice, and decreased mRNA expression levels of KIM-1, NGAL as well as IL-1β, IL-6, TNF-α, MCP-1, HK2, PKM2, LDHA, PDK1, and showing dose-dependent protective. Mechanistically, exosomal small RNA sequencing and qPCR analysis demonstrated that let-7a-5p, which is highly enriched in hucMSC-sEVs, has the ability to reduce inflammation and glycolysis by targeting TLR4/NF-κB pathway. Conversely, downregulation of let-7a-5p in hucMSCs attenuated the protective effects of hucMSC-sEVs on SA-AKI in mice.
**Conclusions:** We have unveiled a novel potential therapeutic mechanism whereby let-7a-5p in hucMSC-sEVs may ameliorate SA-AKI by modulating TLR4/NF-κB pathway to reduce inflammation and glycolysis, which may benefit patients with SA-AKI in future clinical applications.

**Introduction:** In critically ill patients with ventilator-associated pneumonia (VAP), the relationship between *Candida* species airway colonization, adverse clinical outcomes, and antifungal treatment's impact is not entirely known. We compared these variables between VAP patients with or without *Candida* isolation from the respiratory tract.

**Methods:** In this cohort study, data were retrospectively collected from three medical and surgical adult ICUs of Namazi hospital between the 1st of March 2016 and the 29th of March 2023. We assessed 426 consecutive immunocompetent patients with VAP and compared them according to the presence or absence of *Candida* spp. in their lower respiratory tract samples.

**Results:***Candida* spp. were isolated from the respiratory tract of 93 (21.8%) VAP patients. Multivariate analysis revealed that having a feeding tube (OR: 8.43, 95% CI [4.54–15.66]) and the use of proton pump inhibitors (OR: 4.04, 95% CI [1.85–8.76]) independently predicted the isolation of *Candida*. The length of mechanical ventilation and the in-hospital mortality rate were similar in both groups, while the intensive care unit (ICU) mortality rate was greater among patients with *Candida* respiratory colonization ($P \leq 0.001$). Antifungal therapy was more frequently prescribed in patients with *Candida* colonization but did not influence the outcomes. Among VAP patients with *Candida* colonization, the ICU stay in patients with antifungal therapy was longer than in those without antifungal therapy (37 vs. 26 days, $P<0.01$).

**Conclusions:** Our findings indicate that *Candida* airway colonization is associated with higher ICU mortality in patients with VAP. However, antifungal treatment did not affect mortality or clinical outcomes in VAP patients with *Candida* airway colonization.

Some of the data were recruited from Iran Intensive Care Unit Registry (IICUR). This is a Persian ICU-based registry which is launched in 2018 at Nemazee hospital affiliated with Shiraz University of Medical sciences. This registry was developed based on the COMET (CORE Outcome Measurement and Evaluation Tool) program, following the approval of the Australian and New Zealand Intensive Care Society. IICUR was approved by Ethics Committee of Shiraz University of Medical Sciences in 2018 (IR.SUMS.REC.1397.559) and recognized by Iran Ministry of Health as the first and single registry of adult ICU in Iran.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000261

**Introduction:** Sepsis is a fatal disease in which acute lung injury is the earliest and most serious complication. Excessive inflammatory response is an important mechanism in the development of sepsis-induced acute lung injury (S-ALI)[1]. Aberrant activation of the interleukin 6 (IL-6) signaling pathway plays an important role in the inflammatory cascade response in sepsis, thereby promoting SALI[2]. Our previous studies demonstrated that small extracellular vesicles derived from human umbilical cord mesenchymal stem cells (hucMSC-sEVs) have anti-inflammatory and pro-repair effects, and that engineering sEVs can also enhance their targeting to specific organs[3], [4]. However, the role of hucMSC-sEV on S-ALI and the mechanisms remain to be thoroughly explored.
**Objectives:** To investigate the protective effects and mechanisms of hucMSC-sEV against S-ALI.
**Methods:** hucMSC-sEV was obtained by differential ultracentvation combined with size exclusion chromatography and characterized. S-ALI model was established by cecal ligation and puncture (CLP) and LPS. First, the biological distribution of sEV was observed by IVIS spectroscopic imaging system and confocal microscopy, and cellular uptake was quantified by flow cytometry. ELISA was used to detect the levels of serum inflammatory factors, LD and LDH. HE staining was used to detect the pathological changes of lung tissue. Functional molecules of sEV and differentially expressed genes were analyzed by proteomics and RNA sequencing. qRT-PCR, Western blot and immunohistochemical/fluorescence were applied to assess the transcriptional and translational levels of the indicators. Inhibition assay were validated by cell transfection.
**Results:** hucMSC-sEV significantly ameliorated sepsis acute lung injury in vitro and in vivo. In vivo, the number of sEV distributed in lung increased significantly after CLP. In the sEV intervention group, mice showed less body weight loss, higher survival rate, and less pathological lung tissue damage; lower serum LD, LDH, IL-1β, IL-6, TNF-a, and IL-18 levels. In vitro, increased uptake of hucMSC-sEV by LPS-stimulated BEAS-2B cells, and the inflammatory response was suppressed. Mechanistically, RNA sequencing revealed that CLP-induced upregulated genes were mainly associated with inflammatory response, and the signal pathway was enriched in NLRs-like receptor signaling pathway, which was significantly inhibited after sEV intervention. Combined with exosomal proteomics sequencing analysis and qRT-PCR validation, it was confirmed that IL-6st was highly enriched in sEV, which could regulate the NF-κb/NLRP3/GSDMD signaling pathway by competitive binding to IL-6, thereby inhibiting pyroptosis and ameliorating lung injury. In contrast, after knocking down IL-6st in hucMSC, the protective effect of hucMSC-sEV against S-ALI was reduced.
**Conclusions:** hucMSC-sEV carries IL-6st to competitively bind IL-6, thereby inhibiting NF-κb/NLRP3/GSDMD signaling pathway-induced pyroptosis and alleviating S-ALI.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000264

**Introduction:** The intra-aortic balloon pump (IABP) was considered a device that improved outcomes in myocardial infarction complicated by cardiogenic shock. However, the IABP-SHOCK-II [1] trial found no survival benefit.
**Objectives:** We aimed to analyse the use of IABP in a critical care setting of a major tertiary cardiac centre in the UK in patients following cardiac surgery.
The primary outcome was the trend in IABP use over time. The secondary outcomes were the length of stay in Intensive Care, number of blood products used and status at ICU discharge. Tertiary outcomes included morbidity. mortality and complications suffered in this patient group.
**Methods:** We used a retrospective review of medical notes to determine the pathway of admission to Intensive Care, the date of insertion of IABP and the subsequent date of removal. Type of surgery, status at discharge, blood products used and complications suffered due to IABP and post-IABP removal were all recorded.
**Results:** Despite previous findings of SHOCK-II [2], 265 patients received IABP therapy in a major cardiothoracic centre in the UK. 69 female (26%), 196 male (74%). Average age: 66.93 years. Pathway for admission to critical care included: post-ACS: 122/265 (46%), post-cardiac surgery 106/265 (40%) and decompensated heart failure 37/265 (14%). The median length of stay was 5 days (IQR 7, Q1 3 Q3 10). The mean length of stay was 9.1 days (Range: 1–113). 54 people died during their admission in this study (20%). We found 142/265 (54%) had complications with IABP in situ and 54/265 (20%) had complications after removal. Mean number of red blood cells transfused was 1.66 (Range: 0–24) per patient. 140 patients received no blood at all. The mean units of platelets was 0.64 (Range: 0–11), with 194 receiving no platelets at all.
**Conclusions:** IABP therapy is still being used in a major cardiac centre in the UK. In light of the findings of SHOCK-II, guidelines may require change to see an impact on clinical practice. If IABP use is to continue, then research should be conducted to compare the outcomes of patients who receive IABP therapy vs those who do not.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000266

**Introduction:** The syndromic definition of Acute Respiratory Distress Syndrome (ARDS) encompasses a range of pulmonary physiological abnormalities and chest radiographic findings, alongside variations in biological pathways of injury, as evidenced by plasma protein biomarkers and gene expression profiles. Compared to residing in low-altitude regions, long-term habitation in high-altitude, hypobaric, and hypoxic environments gives rise to disparities in the pathophysiology and clinical presentations of ARDS.

**Objectives:** Analyze demographic, clinical, and paraclinical data of patients diagnosed with severe acute respiratory failure under mechanical ventilation from cities situated at 2500 m above sea level, admitted to respective intensive care units, and identify characteristic phenotypes that may facilitate a more effective therapeutic approach and improve mortality outcomes.

**Methods:** An Multicenter ambispective cohort study was carried out in patients admitted to intensive care units with a diagnosis of Acute Respiratory Distress Syndrome (ARDS) in third-level hospitals located in Colombia and Bolivia: Hospitals San José and San Jose Childrens, Cafam Clinics Of Bogotá and Hospital Agramont from El Alto city in Bolivia. Data collection spanned retrospectively from April 2022 to April 2023 and prospectively from April to June 2023, extracted from electronic medical records covering the hospitalization period. An initial descriptive analysis summarized the qualitative variables using frequencies and percentages, while the quantitative data were presented as means and interquartile ranges. Differences between survivor and deceased patients were initially explored by univariate statistical analyses. Qualitative variables were compared using chi-square tests and quantitative variables using the Student's t-tests adjusted for non-homogeneous variance when needed. These analyses were performed in IBM SPSS Statistics for Windows, Version 26.0. Armonk, NY: IBM Corp. A multivariate logistic regression of the first 10 principal components (PC) was performed to evaluate the effect of each of these PCs on the probability of decease using the model: Probability of decease ~ Intercept + PC1 + PC2 + PC3 + PC4 + PC5 + PC6 + PC7 + PC8 + PC9 + PC10. The classification cutoff was set to 0.5. PCA and logistic regression analyses were performed in GraphPad Prism version 10.0.0 for Windows, GraphPad Software, Boston, Massachusetts USA.

**Results:** 70 patients with mechanical ventilations and ARDS are included. Univariate analyses revealed differences between survivors and deceased patients in eight out of fifty-nine studied variables. Comparatively, deceased individuals showed significantly higher values of APACHE II score, CRP, total count of leucocytes, and total count and percentage of neutrophils, while the total count and percentage of lymphocytes, and the percentage of basophils were significantly lower. We were interested in surveying whether a specific combination of clinical parameters and their values which could characterize those patients who deceased from those who survived exists. Thus, we selected the variables measured as numeric continuous values (35 variables) and performed a principal component analysis (PCA). We calculated a total of 35 principal components.Thus, compared to survivors, deceased patients in our sample were characterized by elevated values of neutrophils (total count and %), leucocytes (total count), and PCR, were older, heavier, and showed decreased values of lymphocytes (total count and %), monocytes (%), basophils (%), hemoglobin, EPO, and RDW. Finally, we were interested in identifying which of the clinical variables included in PCs 2 and 4 are the best predictors of death in these patients. Logistic regression analyses revealed that basophils (%), leucocytes, lymphocytes (total count and %), neutrophils (%) and PCR significantly affect the probability of decease. However, CRP (AUC = 0.82) and % neutrophils (AUC = 0.71) are the most reliable predictors.

**Conclusions:** In ICU patients residing of High altitudes a phenotype with Inflammatory and hematological parameters demonstrated a strong association with the probability of survival or mortality.

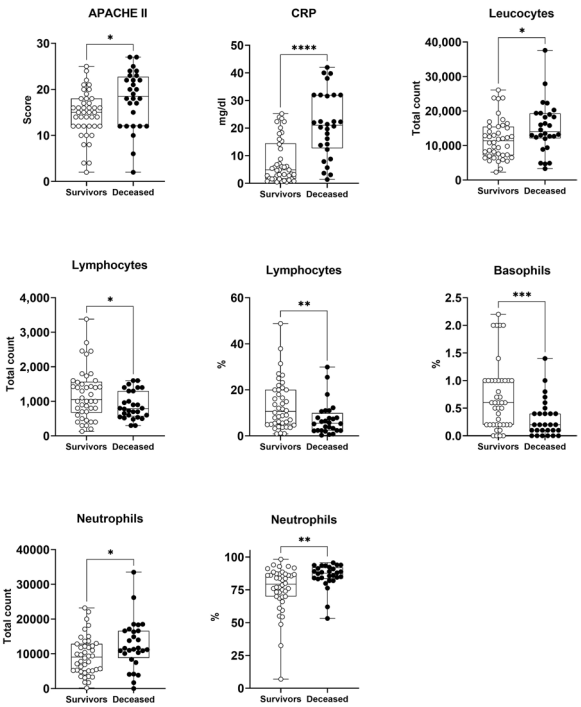

**Fig. (abstract 000266)** Survivors and deceased patients showed differences in 8 out of 59 studied variables. All these nine parameters were markers of inflammation. *$p < 0.05$; **$p < 0.01$; ***$p < 0.001$; ****$p < 0.0001$. nsurvivors = 42; ndeceased = 28

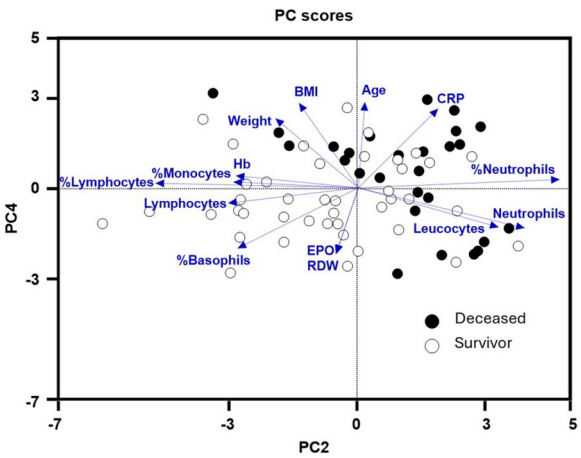

**Fig. (abstract 000266)** Deceased (black dots) and survivor (white dots) high-altitude patients with subacute respiratory failure differentiate from one another in values of hematological parameters and inflammatory markers

**Introduction:** Approximately 30% of trauma-related deaths result from traumatic brain injury (TBI) [1], in younger adults and elderly patients [2]. Management strategies may vary across age groups, potentially influencing short-term neurological outcomes [3].
**Objectives:** To investigate age-related disparities in treatment approaches and 3-month neurological outcomes among TBI patients.
**Methods:** We conducted a retrospective study of TBI patients requiring Intensive Care Unit (ICU) admission from January 1, 2015, to June 30, 2020 in a tertiary University hospital. Patient demographics, major comorbidities, ICU admission parameters, interventions, and complications were collected. A favorable neurological outcome (FO) was defined as a Glasgow Outcome Scale (GOS) score of 4–5 at 3 months. A multivariable logistic regression model was used to assess the association of age with neurological outcome.
**Results:** We enrolled 462 TBI patients, of which 290 (62.8%) had a FO. The highest prevalence of FO was found in the patients aged 35–49 (71/101, 70.3%), followed by the group aged 13–34 (60/93; 64.5%) and the group aged 50–79, 121/191 (63.4%; $p = 0.03$). Older patients (age 80 years) received significantly less invasive intracranial pressure monitoring (ICP) and less aggressive treatment for raised ICP, including osmotic therapy, decompressive craniectomy and barbiturates. Logistic regression adjusted for initial Glasgow Coma Scale (GCS), hypotension and hypoxemia on admission, pupillary reactivity on admission, glucose on admission, the presence of traumatic subarachnoid hemorrhage or epidural hematoma on CT-scan, any episode of intracranial hypertension, seizures and shock, showed that, compared to the reference group of age 17–34, the age group 35–49 had the highest (OR: 2.88; CI:1.17–7.08; *p*-value: 0.02) and the age group 80 the lowest (OR: 0.29; CI: 0.12–0.70; *p*-value: 0.006) probability of FO.
**Conclusions:** In this cohort of TBI patients, those aged 35–49 had the best neurological outcome, while patients aged 80 and older had the worst neurological outcome and received less invasive monitoring and treatment for intracranial hypertension.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000268

**Introduction:** Guillain-Barré syndrome (GBS) is the most common cause of acute flaccid paralysis worldwide.1 Data on the clinical features of GBS are limited. We aimed to describe the clinical, laboratory characteristics and outcomes of a cohort of patients with GBS in the ICU of a tertiary center.
**Methods:** This is a retrospective observational cohort study of patients admitted with GBS between January 2020 and December 2023 to the ICU of a tertiary center in Portugal. Descriptive statistics were used.
**Results:** A total of 15 patients were enrolled of which 10 (66.7%) were male and the mean age was 59,3 $3 \pm 12.9$ years. Their comorbidities were arterial hypertension (60.0%), diabetes mellitus (33.3%), dyslipidemia (53.3%), obesity (26.7%), heart failure (13.3%) and multiple sclerosis (6.7%). The most frequent trigger was respiratory infections in 26,7% followed by other viral infections in 20% and recent surgery in 13.3%. All patients presented with weakness at admission. Other clinical features are desribed in Table 1. Cerebrospinal fluid examination revealed a mean protein level of 51, $9 \pm 41.5$ g/dL and cytoalbuminological dissociation in 50%. Electrophysiologic study was performed in 14 patients from which 5 revealed a sensorimotor polyneuropathy, 3 were normal, 3 axonal demyelination, 2 Miller-Fisher and 1 acute motor sensory axonal neuropathy (AMSAN). Mean ICU length of stay was $29.9 \pm 26.4$ days with 13 (86.7%) patients requiring invasive mechanical ventilation (IMV) for a mean of $16.1 \pm 11.1$ days. Intravenous Immunoglobulin (IVIG) was used in 14 (93.3%) patients and plasma exchange in 5 (33.3%) patients, 4 (80.0%) of them after IVIG. 38.5% patients reported full recovery at 1-year follow-up. Hospital mortality was 6.7% and 1-year mortality was 13.3%.

**Table 1 (abstract 000268)** Clinical features on admission

| Clinical features at admission | N (%) |
|---|---|
| Sensory involvement | 9 (60%) |
| Bulbar symptoms | 15 (100%) |
| Ophthalmoplegia | 2 (13.3) |
| Dyspnea | 13 (86.7) |
| Ataxia | 6 (40%) |
| Areflexia | 12 (80%) |
| Autonomic dysfunction | 11 (73.3) |

**Conclusions:** The results of this review are in accordance with the literature, regarding demographic data and clinical behavior. IVIG is the preferred immunomodulatory treatment. Retreatment is controversial, however we considered it for for non-responsive patients.

### Effects of $FiO_2$ Adjustment on the Hyperoxia Biomarkers and Postoperative Complications Using Oxygen Reserve Index on One Lung Ventilation

B. Aykenar[1], A. Ayhan[2], S. Issı[3], MD. Kılıç[3], P. Zeyneloğlu[4]
[1]Anesthesiology, Gaziantep Şehir Hastanesi, Gaziantep, Turkey; [2]Anesthesilogy, Başkent University, Ankara, Turkey; [3]Thoracic Surgery, Başkent University, Ankara, Turkey; [4]Anesthesilogy and Intensive Care, Başkent University, Ankara, Turkey
**Correspondence:** B. Aykenar
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000269

**Introduction:** One-lung ventilation (OLV) is a technique used in thoracic surgeries with the aim ofenhancing the surgical field of view and preventing the transmission of unilateral pathologiesto the contralateral lung through the respiratory pathways. Ceasing ventilation of the lung onthe operated side leads to its collapse, which significantly impacts respiratory and circulatoryphysiology. Close monitoring of oxygenation and circulation is of paramount importance inthese patients. Particularly, anesthesiologists might need to administer high concentrations ofoxygen to patients due to compromised oxygenation. However, in this scenario, the harmfuleffects of hyperoxia can emerge as a result of increased oxygen exposure.In patients undergoing one-lung ventilation (OLV), alongside the use of basic pulseoximetry for oxygenation monitoring, arterial blood gas analysis is employed. While pulseoximetry serves as a satisfactory monitoring tool for detecting hypoxemia, it falls short inindicating hyperoxia. Arterial blood gas analysis, on the other hand, serves as the gold standardfor representing the oxygenation state at a specific moment, yet its feasibility for continuousmeasurement is limited. The Oxygen Reserve Index (ORi) is a noninvasive and continuous toolused to display mild hyperoxic blood oxygen values in patients. Apart from its function as anearly warning system by detecting a decrease in ORi values before hypoxemia occurs, it alsofacilitates the avoidance of hyperoxia. Its clinical utilization is present in the operating roomand intensive care unit settings.
**Objectives:** The primary objective of our study is to demonstrate whetherORi monitoring during OLV provides effective oxygenation with lower FiO2 levels; thesecondary objective is to investigate whether there are differences in biomarker levels relatedto hyperoxia in blood and tracheal aspirate, postoperative pulmonary complications, andsurgical site infections between groups with and without ORi monitoring.
**Methods:** After obtaining ethical approval from Başkent University Clinical Research EthicsCommittee and written consent from patients, a total of 60 elective thoracic surgery patientspatients undergoing one-lung ventilation (OLV) were included in the study. The patients weredivided into two groups: one group underwent ORi monitoring with FiO2 adjustments, whilethe other group had fixed FiO2 values during OLV (0.6) and dual-lung ventilation (0.5) ifhypoxemia did not occur. Blood samples were collected at anesthesia induction, postoperative 12 and 24 h. Tracheal aspirate sampling was done before extubation at the end of thesurgery. Patients were followed for pulmonary complications and surgical site infections untildischarge.
**Results:** The patients included in the study exhibited similar demographic characteristics.Comparable mechanical ventilator pressures were observed during the intraoperative period.While significant hypoxemia was not observed in either group, the intraoperative FiO2 levelswere significantly lower in the group with ORi monitoring compared to the non-monitoredgroup (0.4(0.4–0.5) vs 0.5(0.5–0.6) $p < 0.001$). However, there was no significant differencebetween the two groups in terms of IL-6, SOD, and MDA levels in both blood and trachealaspirate samples (for each biomarker $p > 0.05$). There was no statistically significant differencein the development of postoperative pulmonary complications between the two groups. Surgicalsite infection was not observed in either group.
**Conclusions:** In conclusion, ORi monitoring can be considered as an effective and safe tool inpreventing the development of hyperoxia in patients undergoing one lung ventilation. However, in clinical practice, to demonstrate its potential to reduce complications and morbidity, moreextensive and comprehensive studies are needed, particularly when high SpO2 targets are notconsidered.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000270

**Introduction:** Thrombocytopenia is the most common coagulation problem in ICU patients and is an independent predictor of death among critically ill patients. When starting antibiotic therapy in septic patient, drug-induced thrombocytopenia maybe considered as a possible game player. We aimed to compare risk factors and major outcomes associated with usual antibiotics used for coverage of gram-positive bacteria in our ICU's.
**Methods:** We conducted a retrospective study of prospectively collected data of all patients admitted to the three mixed medica-surgical ICUs between 2018 and 2023 from Iran Intensive Care Unit Registry. Every patient with equal or more than 18-year old and thrombocytopenia at least five days after start of intravenous vancomycin, linezolid or teicoplanin (V, L, and T groups, respectively) was included in the study. Any possible risk factor and major patient-centered outcomes were examined.

**Results:** From a total number of 6560 admitted patients during the study period, 678 patients received one of the target medications and 100 patients experienced thrombocytopenia. There was no significant difference between the patients who received one of the studied antibiotics, regarding demographic data except for age (younger in V group; $p < 0.001$), median duration of hospitalization before ICU admission (longer for L group; $p < 0.048$) and median platelet count at ICU admission (higher for V group; $p < 0.001$). Baseline serum creatinine was also higher and concomitant cardiovascular disease was more frequent in L group ($p < 0.001$ and $p < 0.003$, respectively). There was no significant difference between the groups regarding incidence of thrombocytopenia, ICU and hospital length of stay and ICU and hospital mortality.
**Conclusions:** Choice of antibiotic selection for definite or empirical treatment of gram-positive bacteria in septic ICU patients should be based on the clinical background and possible causative bacteria. Risk of thrombocytopenia may not be a major consideration for antibiotic selection in ICU.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000271

**Introduction:** Severe respiratory failure has high mortality and presents various treatment options, necessitating intensive care expertise for decision-making [1]. However, the effect of intensivists on treatment and outcomes in severe respiratory failure is still unknown. Severe respiratory failure has high mortality and presents various treatment options, necessitating intensive care expertise for decision-making. However, the effect of intensivists on treatment and outcomes in severe respiratory failure is still unknown.
**Objectives:** The primary goal is to compare patient outcomes at board-certified intensive care facilities to those at non-certified facilities. The secondary goal is to describe treatment differences between board-certified and non-certified intensive care facilities.
**Methods:** This retrospective cohort study, using Japan's nationwide inpatient administrative database from 2016 to 2019, enrolled patients with severe respiratory failure who underwent mechanical ventilation (MV) for over four days. The following information was collected: demographics, treatment after hospital admission, and patient outcomes. Propensity score matching compared hospital mortality as a primary outcome between patients in board-certified and non-certified intensive care facilities in Japan.
**Results:** Of 66,905 in this study (64% men; median age, 76 years), 30,588 were treated at board-certified facilities and 36,317 did not. After hospital admission, the following interventions were more common at board-certified facilities than at non-certified ones: Propofol (35% vs. 18%), dexmedetomidine (37% vs. 19%), fentanyl (50% vs. 20%), rocuronium (8.5% vs. 2.6%), vecuronium (1.9% vs. 0.6%), noradrenaline (35% vs. 19%), arginine vasopressin (8.1% vs. 2.0%), adrenaline (2.3% vs. 1.0%), dobutamine (8.7% vs. 4.8%), PDE inhibitors (1.0% vs. 0.3%), early enteral nutrition (29% vs. 14%), early rehabilitation (34% vs. 30%), RRT (15% vs. 6.7%), ECMO (1.6% vs. 0.3%), and critical care unit admission (74% vs. 30%). The following interventions were equally or less often at board-certified than at non-certified facilities: dopamine (9.0% vs. 15%), sivelestat (4.1% vs. 7.0%), high-dose corticosteroids (13% vs. 15%), and low-dose corticosteroids (18% vs. 18%). After one-to-one propensity score matching, 26,673 were included in each group. Patients in board-certified group had lower hospital mortality (31% vs. 38%, $p < 0.001$) and shorter MV duration (median 9 days vs.10 days, $p < 0.001$) compared to those in non-certified group. Sensitivity analyses for hospital mortality, using multivariable regression and inverse probability of treatment weighting, confirmed the propensity score-matched analysis results.
**Conclusions:** Patients with severe respiratory failure treated at board-certified facilities underwent more selected interventions and had lower hospital mortality compared to those at non-certified facilities. These findings highlight the need for more intensivists.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000274

**Introduction:** Family satisfaction is an important goal of care since they play a crucial role in decision-making in critically ill patients. However, the studies on family satisfaction in intensive care unit are limited in Iraq.
**Objectives:** The purpose of this study is to assess the level of family satisfaction and identify parameters correlated with family satisfaction.
**Methods:** The Iraq Medical City and Soonchunhyang University Medical Center has conducted a cross-sectional survey in two ICUs in the medical city, Iraq supported by Korea International Cooperation Agency using verified family satisfaction questionnaire. Demographic characteristics and clinical outcomes of the patient were also collected to analysis correlation patient characteristics that affect satisfaction.
**Results:** A total of 103 family members were surveyed. The mean score of family satisfaction was $80.10 \pm 13.5$ (mean $\pm$ SD; maximal score, 100). Family members reported the greatest satisfaction with "Consistency of information" ($83.17 \pm 15.85$) and "management of pain" ($83.01 \pm 16.12$). They were least satisfied with "atmosphere in the waiting room" ($64.73 \pm 33.97$). Patient death and higher severity (APACHE II $\geq 30$) were associated with lower family satisfaction ($p = 0.007$ and 0.04, respectively).
**Conclusions:** Family members were generally satisfied, but improvements are needed in some aspect. In cases of patient death and higher severity, satisfaction was lower and statistically significant. It is expected that satisfaction level will increase through the opening of the new Critical Care Specialty Hospital and strengthening the capacity of medical staffs.

**Table 2 (abstract 000274)** Demographic characteristics of family members

| | Total(n=103) |
|---|---|
| Age (mean±SD ) | 37.79 ± 12.49 |
| Sex (male, n(%)) | 64 (62.14%) |
| ICU experience (yes, n(%)) | 23 (22.33%) |
| Live with patient? (yes, n(%)) | 61 (59.22%) |
| How many time you see the patient? (n(%)) | |
| - more than weekly | 18 (17.48%) |
| - weekly | 17 (16.05%) |
| - monthly | 7 (6.80%) |
| - yearly | 1 (0.97%) |
| - less than once a year | 1 (0.97%) |
| Live near hospital? (yes, n(%)) | 79 (76.70%) |
| Relationship (n(%)) | |
| - spouse | 13 (12.62%) |
| - parents | 15 (14.56%) |
| - sibling | 38 (36.89%) |
| - offspring | 33 (32.04%) |
| - other | 4 (3.88%) |
| Education (n(%)) | |
| - under high school | 83 (80.58%) |
| - over college | 18 (17.48%) |

**Table 3 (abstract 000274)** The result of family satisfaction survey

| | Total mean±SD (or n(%)) |
|---|---|
| The courtesy, respect and compassion your family member (the patient) was given. | 81.67 ± 15.99 |
| How well the ICU staff assessed and treated your family member's pain. | 83.10 ± 16.07 |
| How well the ICU staff assessed and treated your family member's breathlessness. | 82.38 ± 16.23 |
| How well the ICU staff assessed and treated your family member's agitation | 82.28 ± 16.65 |
| How well the ICU staff showed an interest in your needs | 81.97 ± 16.51 |
| How well the ICU staff provided emotional support to you | 82.21 ± 16.95 |
| The teamwork of all the ICU staff who took care of your family member. | 82.21 ± 16.22 |
| The courtesy, respect and compassion you were given. | 81.90 ± 14.91 |
| How well the nurses cared for your family member. | 81.55 ± 16.41 |
| How often nurses communicated to you about your family member's condition. | 81.73 ± 17.15 |
| How well doctors cared for your family member. | 78.61 ± 20.71 |
| How satisfied are you with the atmosphere (mood) in the ICU waiting room? | 63.36 ± 34.48 |
| How satisfied are you with the atmosphere (mood) of the ICU? | 78.64 ± 18.98 |
| How satisfied are you with your participation in daily rounds? | 79.57 ± 17.68 |
| How satisfied are you with your participation in the care of your critically ill family member? | 80.05 ± 16.48 |
| How satisfied are you with the LEVEL or amount of health care your family member received in the ICU? | 78.64 ± 17.99 |
| How often doctors communicated to you about your family member's condition. | 80.48 ± 17.33 |
| Willingness of ICU staff to answer your questions. | 80.77 ± 17.15 |
| How well ICU staff provided you with explanations that you understood. | 79.76 ± 18.05 |
| The honesty of information provided to you about your family member's condition. | 80.24 ± 18.24 |
| How well ICU staff informed you what was happening to your family member and why things were being done. | 80.24 ± 18.24 |
| The consistency of information provided to you about your family member's condition | 83.01 ± 16.12 |
| How included or excluded did you feel in the decision making process? | 78.16 ± 15.13 |
| How supported did you feel during the decision making process? | 78.88 ± 14.33 |
| Did you feel you had control over the care of your family member? | 77.50 ± 15.28 |
| When making decisions, did you have adequate time to have your concerns addressed and questions answered? | 76.00 ± 15.86 |

**Table 4 (abstract 000274)** Characteristics of family member associated with family satisfaction

| | Satisfaction level | | p-Value |
|---|---|---|---|
| | Yes | No | |
| Death | 74.11 | 82.36 | 0.007 |
| Hospital Acquired Infection | 79.35 | 80.43 | 0.710 |
| Length of stay (Less than average) | 78.75 | 82.03 | 0.294 |
| Admitted at night | 82.1 | 78.27 | 0.318 |
| Admitted at weekend | 80.15 | 80.09 | 0.982 |

## 000276 Exhaled VOCs associated with hyoxemia after abdominal surgery

B. Wang[1], Y. An[2]
[1]Department of Critical Care Medicine, Peking University People's Hospital, Beijing, China; [2]Department of Critical Care Medicine, Peking University People's Hospital, Xi Cheng Qu, China
**Correspondence:** B. Wang
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000276

**Introduction:** One of the most common postoperative complications is pulmonary complications, among which postoperative hypoxemia the most significant impact on patients, and the mortality rate of patients with hypoxemia is more than 10 times higher than that of the control group [1]. Abdominal surgery is one of the most common

types of postoperative hypoxemia [2–6]. Therefore, how to identify patients who are prone to be complicated with hypoxemia after abdominal surgery has become the focus of attention of many physicians. And the Exhaled volatile organic compounds (VOCs) analysis, which provides us a new method to predict postoperative hypoxemia [7–9].

**Objectives:** To identify characteristic volatile organic compounds (VOCs) associated with postoperative hypoxemia in patients undergoing abdominal surgery.

**Methods:** We prospectively enrolled 76 patients with tracheal intubation who were admitted to intensive care unit (ICU) after abdominal surgery at Peking University People's Hospital from December 10, 2022 to June 30, 2023. The basic information related to the perioperative period of patients was collected, and exhaled air of patients was collected within 24 h after admission to ICU through endotracheal intubation, and thermal desorption gas chromatography mass spectrometry (TD–GC–MS) was used for analysis and detection, and VOCs components in exhaled air of patients were analyzed. To observe whether hypoxemia occurred 24 h after surgery, the patients were divided into hypoxemia group and non-hypoxemia group, and the exhaled VOCs of the two groups were compared. Lasso regression analysis was used to screen valuable VOCs variables, and then Logistics regression analysis was performed to determine VOCs related to postoperative hypoxemia.

**Results:** Among the 76 patients, 27 had hypoxemia and 49 had no hypoxemia. Lasso regression analysis was performed on VOCs in exhaled air of the patients. Three compounds that might be related to postoperative hypoxemia were screened out, and the three compounds were put into multivariate Logistic regression analysis. The results showed that the increased contents of allyl methyl sulfide (OR:1.000, $P=0.03$), benzothiazole (OR:1.000, $P=0.041$) and the decreased contents of 2,3,6-trimethyldecane (OR:1.000, $P=0.009$) in exhaled breath were associated with the occurrence of postoperative hypoxemia. The three VOCs were used to predict postoperative hypoxemia, and the AUC was 0.785 (95% CI: 0.675, 0.895).

**Conclusions:** This study shows that the increase of allyl methyl sulfide, benzothiazole and the decrease of 2,3,6-trimethyldecane in exhaled breath are associated with the occurrence of postoperative hypoxemia. These three VOCs have good predictive value for postoperative hypoxemia.

## The Experience of International Cooperation With Multimodal Telemedical Knowledge Exchange Platform During Military Conflict in Ukraine

D. Dziuba[1], A. Masoodi[1], C. Castillo Zambrano[2], L. Rovati[2], O. Gajic[2], O. Loskutov[1]

*Intensive Care Medicine Experimental* 2024, **12(suppl 1):** 000277

**Introduction:** During the war conflict, all Ukrainian doctors and medical associations are standing united to face the horrific consequences of war andergrowing anxiety in society. Recognizing the acute need for additional resources, our group developed a multimodal knowledge-sharing platform to provide trauma, critical care, and disaster medicine education and clinical support for clinicians working in Ukraine during the ongoing conflict. Using the Checklist for Early Recognition and Treatment of Acute Illness and Injury (CERTAIN) program, a multimodal trauma critical care knowledge exchange platform was created for clinicians practising in these institutions. In addition, we developed a program of weekly ICU telerounding sessions with collaborating clinicians.

**Methods:** From the early beginning of the Ukrainian conflict, a group of international trauma and critical care experts in collaboration with the Ukrainian doctors created a multimodal knowledge-sharing platform for clinicians caring for critically ill patients. The main teleeducation intervention consisted of a series of case discussions and webinars on established approaches to battlefield trauma and critical care, held by a mixed faculty of expert intensivists, surgeons, emergency physicians, and anesthesiologists from the United States, United Kingdom, and Ukraine. A secure messaging service was used to connect clinicians participating in this initiative, enabling them to ask general clinical questions and exchange educational material via a private chat group on an on-demand, asynchronous basis. In the practical part, we started educational telerounding sessions with the interprofessional faculty for Ukrainian ICU patients with implementing MAYO critical care standards in everyday practice.

**Results:** Since the program launch, 906 participants have joined the messaging group, and 16 teleeducation sessions have been delivered, with more than 5000 total views. The CERTAIN website has had about 5000 visits, mainly from Ukraine and the United States. Of the about hundred completed post-session surveys about 90% of respondents rated the course content excellent or very good, and 99% recommended it to others. Weekly, one-hour-long sessions were conducted between September 2023 and February 2024. Educational telerounding sessions using video platforms are flexible, accessible tools to bridge barriers of distance, and language and help to reinforce adherence to critical care processes. The CERTAIN standardized approach was positively received, and adopted by our Ukrainian partner hospital.

**Conclusions:** This study found that a multimodal intervention to provide education and clinical support for the care of critically ill trauma patients in response to the conflict in Ukraine was feasible, inexpensive, and associated with a high degree of clinician engagement and satisfaction. This approach can be used as a model for the development of further education and quality improvement interventions in remote and austere environments during global emergencies and disasters.

## o cardiac biomarkers the days before extubation predict extubation failure?

C. Groenland, V. Baggen[1], E. Dubois[1], L. Heunks[2], E. J. Wils[3], H. E. Endeman[1]
[1]Intensive Care, Erasmus MC, Rotterdam, Netherlands; [2]Intensive Care, Radboud University Medical Center, Nijmegen, Netherlands; [3]Intensive Care, Franciscus Gasthuis, Rotterdam, Netherlands

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000278

**Introduction:** Extubation failure is associated with higher mortality, morbidity, ICU length of stay, and healthcare costs (1,2). Accurate timing of extubation in patients with COVID-ARDS is both challenging and important, as extubation failure rate is reported to be up to 20% (3,4). Clinical and respiratory variables are generally used to predict extubation failure. Previously we observed that a single Hs-Troponin-T measurement was associated with extubation failure (5). It is unknown whether serial assessment of cardiac biomarkers in the days preceding extubation add significant prognostic information.
**Objectives:** To investigate the association between serial measurements of Hs-Troponin-T (Hs-TnT) and NT-proBNP on the days preceding extubation with extubation failure.
**Methods:** This was a single-center retrospective cohort study. From March 2020 until March 2022, 602 mechanically ventilated patients with COVID-ARDS were screened for eligibility. Patient were eligible for inclusion if they were primarily liberated from mechanical ventilation. The primary endpoint was extubation failure (i.e. reintubation within 7 days). Cardiac biomarkers (Hs-TnT and NT-proBNP) were measured daily during ICU admission.
We constructed linear mixed effect models to describe the evolution of Hs-TnT and NT-proBNP for patients with extubation success and failure. Furthermore, we constructed two logistic regression models to investigate the association between cardiac biomarkers and extubation failure. The first model was built to determine whether the area under the curve (AUC) per cardiac biomarker was associated with extubation failure. The AUC was calculated based on 4 repeating biomarker measurements before extubation. The second model was built to determine whether the change in biomarker value over the days was associated with extubation failure. To determine the change, we calculated the slope per patient per biomarker (the slope originated from the linear mixed model).
**Results:** In total 297 patients met the inclusion criteria (median age 60 years [IQR, 51–67], 70% male). Extubation failure occurred in 21.5%. Patients with extubation failure had a higher SOFA score on the day of extubation (5 [IQR, 3–7] versus 3 [IQR, 2–4], $p < 0.001$) and a longer duration of mechanical ventilation (11.5 days [IQR, 7.3–15] versus 8 days [IQR, 6–11.3], $p < 0.001$). In Fig. 1 the average evolution of log2 transformed Hs-TnT (A) and NT-proBNP (B) the days preceding extubation are depicted for patients with extubation success and failure. Log2 transformed Hs-TnT and NT-proBNP were significantly higher in patients with extubation failure ($p < 0.001$, $p = 0.004$, respectively). Both the crude log2 AUC of Hs-TnT and log2 AUC NT-proBNP were associated with extubation failure (Table 1). However, after adjustment for age, Charlson Comorbidity Index, duration of mechanical ventilation and SOFA score, the effect dissipated. The crude ORs for the slope of Hs-TnT (OR 2.42 (95%CI: 0.49–12.14)) and NT-proBNP (OR 0.88 (95% CI:0.32–2.41)) were not associated with extubation failure.

**Table 1 (abstract 000278)** Crude and adjusted Odds Ratios for extubation failure

| | Unadjusted ORs | Adjusted ORs |
|---|---|---|
| Log2 AUC Hs-TnT | 1.52 (1.23–1.90) | 1.20 (0.90–1.59) |
| Log2 AUC NT-proBNP | 1.26 (1.07–1.50) | 0.95 (0.75–1.20) |
| Age | 1.02 (1.00–1.05) | 1.02 (0.98–1.06) |
| Charlson Comorbidity Index Score | 1.14 (0.98–1.31) | 0.91 (0.70–1.15) |
| Duration of iMV before extubation (days) | 1.09 (1.03–1.15) | 1.08 (1.02–1.14) |
| SOFA score on the day of extubation | 1.42 (1.26–1.62) | 1.36 (1.18–1.57) |

**Conclusions:** Our data indicate that the log2 AUC and slope for both Hs-TnT and NT-proBNP have no additional value to predict extubation failure in patients with COVID-ARDS. This contrasts the predictive value of a single measurement of Hs-TnT on the day of extubation. To further clarify these findings, research on this topic is needed in patients without COVID-ARDS.

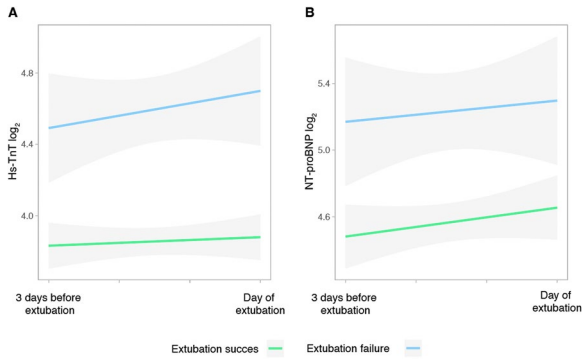

**Fig. 1 (abstract 000278)** Evolutions of log2 Hs-TnT (A) and log2 NT-proBNP (B) over the days before extubation in patients with extubation success (green) and extubation failure (blue)

### The effect of Intensive Care Unit-specific Virtual Reality on mental health and perceived quality of care of relatives of ICU patients: a randomized controlled trial

D. Drop[1]; J. H. Vlake[1]; J. Van Bommel[1]; E. J. Wils[2]; A. Schut[3]; M. Van Mol[1]; D. Gommers[1]; M. Van Genderen[1]

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000279

**Introduction:** Relatives of Intensive Care Unit (ICU) patients often experience psychological distress, contributing to the Post-Intensive Care Syndrome Family (PICS-F). This distress is frequently linked to a lack of understanding about the ICU setting and treatment modalities. Despite this, effective strategies to mitigate these psychological effects remain limited (1, 2). Given the positive reception and impact of ICU-specific Virtual Reality (ICU-VR) among survivors of critical illness, enhancing ICU aftercare perspectives, we propose that a targeted VR educational program (ICU-VR-Family) could meet informational needs and alleviate psychological stress in ICU patients' relatives (3, 4).
**Objectives:** To evaluate the acceptance of the ICU-VR-Family intervention and investigate its potential to alleviate symptoms of PICS-F, enhance quality of life, and improve perceptions of ICU care quality.
**Methods:** This multicenter, randomized controlled trial divided participants into either an intervention or control group. While all participants received standard care, those in the intervention group were also given a one-time ICU-VR-Family session during an ICU visit and received VR glasses with a link for at-home use. We collected data through questionnaires at various stages: upon enrollment, at the patient's ICU discharge, and at one, three, and six months post-discharge.
**Results:** We enrolled 189 relatives (median age 48, 95% range 23–72; 101 females, 53%) of 161 patients (median age 62, 95% range 25–80; median APACHE-IV 63, 95% range 11–123). The intervention group comprised 100 relatives of 81 patients compared to 89 relatives of 80 patients in the control group. Despite no significant differences in psychological distress or mental quality of life, the intervention was well-received: 90% would recommend ICU-VR-Family, 82% appreciated the continuous information provided, 81% preferred the VR approach over traditional brochures, and 76% reported better understanding of their relative's treatment in the ICU.
**Conclusions:** While ICU-VR-Family did not significantly affect psychological distress or quality of life, it was favorably regarded as an educational tool. It effectively conveyed information about ICU treatment, enhancing satisfaction among users. These findings advocate for incorporating ICU-VR-Family into routine practice, warranting further investigation into its optimal application.

### Use of perioperative midodrine in patients undergoing simultaneous bilateral native nephrectomy with kidney transplantation in patients with autosomal dominant polycystic kidney disease: a retrospective comparative study with historical control

J. Cisneros Correa[1], J. Gottwald,[2], A. Bentall,[3], M. Prieto,[1], M. Vogt[2], B. Vanderwielen,[2], M. Teixeira[2]
[1]Transplantation Surgery, Mayo Clinic, Rochester, United States of America; [2]Anesthesiology and Critical Care, Mayo Clinic, Rochester, United States of America; [3]Nephrology and Hypertension, Mayo Clinic, Rochester, United States of America

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000280

**Introduction:** Simultaneous bilateral native nephrectomy with kidney transplantation (BNNKT) for patients with autosomal dominant polycystic kidney disease (ADPKD) has been shown to be a safe and feasible alternative compared to a staged surgical approach under the direction of an experienced surgical team. However, hypotension after removal of the native kidneys is common and likely due to decreased renin-angiotensin levels. One recent single-center series of 51 ADPKD patients who underwent laparoscopic BNNKT noted that roughly 70% of these patients required ICU-level care post-procedure, predominantly due to hypotension and the need for ongoing vasopressor therapy. Midodrine, an oral alpha-1 adrenergic agonist prodrug, has been used off-label to treat refractory hypotension of various etiologies including in ICU patients. The use of midodrine for patients with ADPKD undergoing BNNKT has not been reported before.
**Objectives:** Assess whether administration of perioperative midodrine for patients with ADPKD undergoing BNNKT would result in a decreased need for ICU admission related to hypotension requiring vasopressor therapy post-procedure.
**Methods:** A treatment protocol of midodrine administration (20 mg PO q8 hours for 48 h) was implemented by our transplant team from March 2023 through March 2024 for ADPKD patients presenting to our institution for BNNKT. The first dose of midodrine was administered pre-operatively. Our primary outcome of interest was ICU admission rate due to ongoing vasopressor requirements for hypotension. Data from the cohort receiving midodrine was compared to retrospective historical controls for patients who underwent the same procedure without perioperative midodrine use. Patients were excluded from the analysis if they were admitted to the ICU for a reason other than treatment of hypotension with vasopressors (i.e., significant bleeding, diagnosed sepsis, monitoring).
**Results:** A total of 110 patients with ADPKD who underwent BNNKT from 2014 through March 2024 were included in the final analysis and of these, 19 received midodrine per protocol from March 2023 through March 2024. Within the midodrine treatment group, 47.4% (9/19) required ICU admission for ongoing vasopressor use compared to 61.5% (56/91) in the historical control group without midodrine use (RR 0.77, 95%CI: 0.47–1.27, $p = 0.31$, NNT:7) (Table 1).
**Conclusions:** The use of perioperative midodrine for ADPKD patients undergoing BNNKT appears to show a trend towards decreased vasopressor requirements and need for ICU admission post-procedure compared to a historical cohort who did not receive midodrine, although this was not a statistically significant difference. Including midodrine treatment as part of ongoing multidisciplinary enhanced recovery pathway for this unique patient population could be considered to further decrease the need for post-procedure ICU-level cares. Additional larger-scale studies could better inform the impact of midodrine therapy for these patients.

**Table 1 (abstract 000280)** Rate of ICU admission for Midodrine Group vs. Control Group

| | Total # Patients | ICU Admission (# patients) | No ICU Admission (# patients) | ICU Admission Rate (%) |
|---|---|---|---|---|
| Midodrine Group | 19 | 9 | 10 | **47.4** |
| Control Group | 91 | 56 | 35 | **61.5** |

### Does deep sedation have a negative prognostic effect on outcome in acute ischemic stroke patients who undergo mechanical thrombectomy?

A. M. Domínguez-Berrot[1], M. González-Vaquero[1], P. Pérez Del Pozo[1], M. E. Vallejo-Pascual[2], R. I. González-Luengo[1], J. Valdivia-Ruiz[1]
[1]Intensive Care Unit, Complejo Asistencial Universitario De León, León, Spain; [2]Economía y Estadística, University of León, León, Spain
**Correspondence:** A.M. Domínguez-Berrot
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000281

**Introduction:** Ischemic stroke is a common cause of death and/or disability; endovascular treatment using mechanical thrombectomy in eligible patients is a tool that has significantly improved prognosis. Whether to perform mechanical thrombectomy under conscious sedation or general anesthesia is still controversial; there is limited data in the literature regarding the effect of maintaining deep sedation beyond the end of the procedure, during the early hours of admission to the ICU.
**Objectives:** To evaluate whether maintaining deep sedation for a maximum of 8 h after the end of mechanical thrombectomy negatively affects the prognosis of patients admitted to the ICU for acute ischemic stroke.
**Methods:** Retrospective study. Review of medical records of all patients admitted to our ICU for endovascular treatment for ischemic stroke from 01/01/2019 to 31/12/2023. Recorded data include demographic variables, involved vascular territory, fibrinolysis (yes/no), TICI, procedure complications, sedation (yes/no), reason for sedation (routine/complication), NIHSS at admission (NIHSS-0), NIHSS at 24 h (NIHSS-24), and at ICU discharge (NIHSS-Dis). To assess patients' neurological evolution, the change in NIHSS at 24 h and at discharge (ΔNIHSS (0–24) and ΔNIHSS (0-Dis)) was calculated. The statistical analysis of quantitative variables is presented using the mean ± standard deviation (SD), or the median with percentiles 25 and 75 in situations of high dispersion and non-normality. Regarding qualitative variables, they will be expressed in absolute and relative frequencies. For comparisons between two groups of each quantitative variable, in addition to Box-Plot graphs, the Mann–Whitney test for comparing medians will be used, given the absence of normality. The software used is the IBM SPSS Statistics package, version 29.02. A $p \leq 0.05$ will be considered statistically significant.
**Results:** The study spans 5 years and includes 364 patients. Affected territories: right: 40.54%; left: 53.3%; posterior: 6.3%. TICI 3 achieved in 61%; 2c in 8%; 2b in 12.4%; 2a in 8.2%. TICI 0: 6.9%. 76.4% of patients did not receive fibrinolysis. 160 patients (46.4%) received deep sedation for < 8 h after thrombectomy. 43 patients receiving sedation due to complications are excluded from calculations. Patients are analyzed separately depending on whether they received fibrinolysis. Regarding the variable ΔNIHSS (0–24): in sedated patients, the median is 8, and the mean is 7.45 (+ 9.04); in non-sedated patients, the median is 6, mean 5.46 (+ 9.06); although data show some advantage for sedated patients, the difference does not reach statistical significance (Table 1). Regarding the variable ΔNIHSS (0-Dis), in sedated patients, the median is 11.5 and the mean is 10.81 (+ 7.5), and in non-sedated patients, the median is 12, and the mean is 11.62 (+ 7.74), with no significant differences (Table 2). No differences were found when analyzing separately patients who did/did not receive fibrinolysis (Tables 3 and 4).
**Conclusions:** Sedation for up to 8 h after mechanical thrombectomy does not negatively affect the initial evolution of patients admitted for ischemic stroke. A beneficial effect has been observed in the first 24 h, although not statistically significant.

**Introduction:** ECMO, extracorporeal membrane oxygenation, is a support therapy for respiratory and/or cardiac failure refractory to conventional measures. ECMO time and patient outcome are directly related to the infections during the use of ECMO.
**Objectives:** To present the epidemiology of nosocomial infections (NIs) associated with extracorporeal membrane oxygenation (ECMO) therapy in adult patients receiving selective digestive decontamination (SDD).
**Methods:** We retrospectively analyzed adult patients treated between January 2019 and December 2023 with extracorporeal circulatory support using exclusively percutaneous cannulation, veno-venous (VV), veno-arterial (VA) ECMO and CO2 elimination therapy (ECCOR), from more than 48 h. We use the term nosocomial infection (NI) defined by the ECDC. All patients were intubated before ECMO and received selective digestive decontamination protocol which consists of administrating enteral solution + oral paste: colistin, tobramycin, amphotericin B, and vancomycin, as well as parenteral antibiotic therapy: Ceftriaxone 2 g or Levofloxacin 500 mg every 24 h for 3 days.
**Results:** We analyzed 93 patients, of which 70 men and 23 women with a median age of 53 (45–59) years. A total of 56 patients received VV ECMO, 32 VA ECMO, and 5 ECCOR. The most common etiology was ARDS due to COVID-19 pneumonia for VV ECMO and acute myocardial infarction (AMI) for VA ECMO. The prevalence of NIs was 16%. We also present the prevalence broken down by pathologies: VAP 11.8%, UTI 2.2%, Pulmonary Aspergillosis 1%, Catheter Bacteremia 1%. The most frequent germs were P. aeruginosa, E. Coli, and S. pneumoniae (Fig. 1). As a whole, the sample has presented a mortality of 40%, and the patients diagnosed with NIs had a mortality of 30% and 34% without NIs respectively, a difference that is not statistically significant (Fig. 2). The median time on ECMO was 11 (7–18) days in the entire sample, 12 (8–34) in patients with NIs, and 11 (7–11) days in the group without NIs, a statistically non-significant difference (Fig. 3).
In recent years, ECMO-related nosocomial infections research has achieved significant growth. However, to our knowledge, there are no other publications on nosocomial infections in patients on ECMO therapy receiving DDS. The results on NIs in ECMO patients have been very heterogeneous, with prevalence between 8.8 and 64% and mortality rates between 31.5 and 75.4%.
**Conclusions:** Our results are in the lower part of the range with a prevalence of 16% and a mortality of 30% in patients with NIs and ECMO support. What is different from most other studies is that in our case there was no difference in mortality and days of ECMO with or without the presence of nosocomial infection. Results that could be influenced by DDS protocol and its ability to reduce nosocomial infections.

### A step forward to a green intensive care unit through the reduction of nebulization materials, a waste audit

N. Goedendorp[1], M. Van Mol[1], N. Hunfeld[1]
[1]Departement of intensive care, Erasmus University Medical Center, Rotterdam, Netherlands
**Correspondence:** N. Goedendorp
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000288

**Introduction:** The intensive care unit (ICU) of Erasmus MC aims to be fully circular in 2030. One of the procedures that require a lot of redundant materials is nebulisation with medication. However, we lack specific data about the current waste, including both products and medication, and possible greener alternatives.
**Objectives:** Reducing waste and medication use is an important step forward to a green ICU1. Searching for possible solutions could help the environment and reduce costs. The goals were to explore 1) the reduction of nebulisation waste and 2) the medication spillage per nebulisation moment.
**Methods:** The design of the study is a waste audit. In our ICU we use MESH nebulisation (Aerogen, United kingdom) for mechanical ventilated patients, and JET nebulisation (Teleflex Medical, USA) for all other patients. We made an inventory of al used nebulisation medication and used nebulisation products over 2023. A previous study showed that JET has a greater residue compared to MESH nebulization2.
For calculation of nebulisation medication spillage we made the assumption that every Jet nebulisation product was used only once. MESH products are used from 7 to 28 days depending on the product. The number of used JET products was used to calculate the number of MESH products needed in the same period.
**Results:** The total of nebulisation medication administrations was 31.186 in 2023 (85/day). The type of nebulised medication was mostly NaCl 0.9% (35%) and Salbutamol with Ipratropiumbromide (38%) (Fig. 1). Based on medication spillage of 0.8 ml to 2.5 ml per Jet nebulisation, this resulted in 6 L to 20 L total medication waste. For MESH nebulisation, the spillage is 0.2 ml, resulting in 1.6 L total.
Almost 8000 JET products were used, with a total waste of 651 kg. If MESH products were used, the total number of products would have been 1600 with a total waste of 145 kg. This means, a reduction of materials and medication used and reduction of waste (Fig. 2).
**Conclusions:** The waste audit identified that MESH nebulization reduces the spillage of medication. It reduces the amount of materials needed for nebulization and it reduces the amount of waste generated, compared to JET nebulization. By changing our practice to MESH nebulization products we are contributing to a greener ICU.

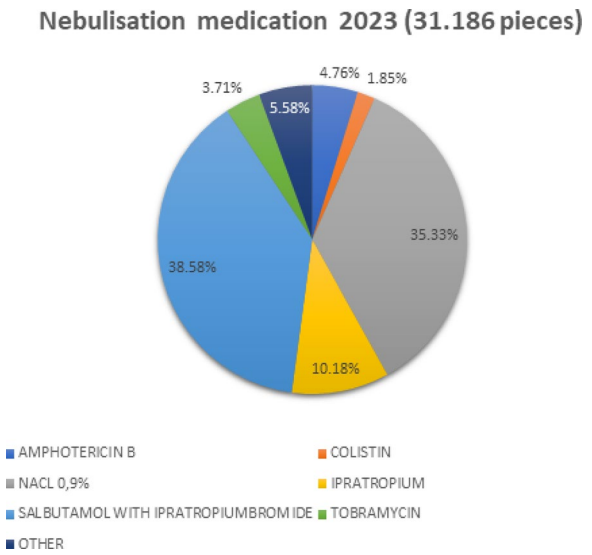

**Fig. (abstract 000288)** Most commun used nebulisation medication in our ICU

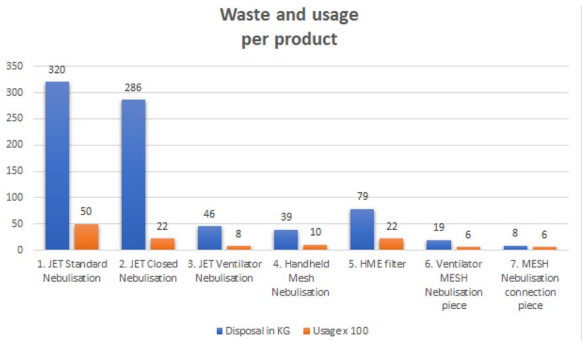

**Fig. (abstract 000288)** The blue columns show the number of waste, the orange columns sow the total products used (× 100) for the amount of waste. Column 2. Include an filter due to an closed system principle. We need to at an filter to MESH nebulisation (column 5) to create this principle. Column 4 is an calculation based on used Jet nebulisation products

### Using continuous electronic urine output monitoring for the management of acute cardio-renal syndrome in patients with acute decompensated heart failure

Y. Shacham, S. Banai, R. Anna
Cardiology, Tel Aviv Sourasky Medical Center-Ichilov, Tel Aviv-Yafo, Israel
**Correspondence:** Y. Shacham
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000289

**Introduction:** Patients admitted for acute decompensated heart failure (ADHF) are at high risk for type I cardio-renal syndrome (CRS) related to venous congestion and diuretic resistance. Positive fluid balance has been associated with adverse outcomes, including acute kidney injury (AKI) and mortality. In critically ill patients, urine output (UO) is used both to assess deterioration of renal function as well as for management of fluid balance.
**Objectives:** We investigated the possible effect of real-time UO monitoring, fluid balance, renal outcomes, and 30-day mortality of patients admitted to the cardiac intensive care unit (ICU) with ADHF.
**Methods:** We included 50 patients admitted to the cardiac ICU from July 2021 and June 2023 with ADHF. Their standard Foley catheter was connected to an electronic monitoring system (Clarity-RMS sensor kit) that continuously monitors UO in real time. Its technology is described elsewhere (1). The UO monitoring system displays UO trends on the consoles that are updated in real time. UO trends were utilized to guide an individualized approach for the pharmacologic management of each patient, based on blood pressure, hourly UO, and total fluid balance. Daily and accumulated fluid balance was registered at up to 72 h following admission. Patient outcomes included change in fluid balance, incidence of AKI, and 30-day mortality. The case series group was than compared to a historical group of 50 matched controlled patients admitted between 2019 and 2020. Patients were matched according to cause of admission, age, and glomerular filtration rate.
**Results:** In the study cohort, the median age was 71 ± 12 years, and 36 (72%) were men. In the historical cohort, the median age was 71 ± 13 years, and 36 (72%) were men.
Patients in the electronic urinary monitoring cohort demonstrated significantly more negative daily and cumulative fluid balance as compared to the historical cohort ($P < 0.001$ for all, Figure 1). Incidence of AKI and the combined endpoint of AKI and 30-day mortality was significantly lower in the electronic UO monitoring cohort (24% vs. 46%, $P = 0.0197$ and 40% vs 78%, $P < 0.0001$, respectively). These changes were more prominent in the subgroup of patients with chronic kidney disease (Figure 2).
**Conclusions:** We demonstrated that real-time monitoring of UO was associated with better prevention of fluid overload and the management of type I CRS in patients with ADHF. Further studies on larger populations are required to validate the potential utility of UO trending in the management of critically ill patients with ADHF.

### Neutrophil gelatinase-associated lipocalin (NGAL) levels for early prediction and ruling out future contrast nephropathy

Y. Shacham, S. Banai
Cardiology, Tel Aviv Sourasky Medical Center-Ichilov, Tel Aviv-Yafo, Israel
**Correspondence:** Y. Shacham
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000290

**Introduction:** The diagnosis of acute kidney injury (AKI) is of importance among patients with ST segment elevation (STEMI) undergoing primary coronary intervention (PCI). It is often delayed given the need in serial measurements of creatinine or other serum markers. Neutrophil gelatinase-associated lipocalin (NGAL) is a proven marker for AKI, although its role as an early predictor in this setting was scarcely addressed before.
**Objectives:** We aimed to investigate the diagnostic utility of sequential NGAL measurements for both prediction and ruling out of AKI among patients with ST segment elevation (STEMI) undergoing primary coronary intervention (PCI).
**Methods:** We included 133 patients with STEMI treated with PCI. Blood samples for plasma NGAL were drawn immediately before PCI (NGAL 0) and 24 h after PCI (NGAL 24). Optimal threshold for the development of AKI was determined using receiver-operating characteristic curves (ROC). Patients were also assessed for the dynamics between NGAL 0 and NGAL 24 levels.
**Results:** Mean age was 62 ± 13 years and 78% were men, and a total of 20 (15%) developed AKI. Patients with AKI demonstrated higher plasma NGAL 0 levels (164 ± 42 vs. 95 ± 30 ng/mL; $p < 0.001$) as well as NGAL 24 levels (142 ± 41 vs. 93 ± 36 ng/mL; $p < 0.001$). There were no significant changes between NGAL 0 & 24 h within the two groups (Figure 1). According to the ROC curve analysis, the optimal NGAL 0 level for AKI prediction was > 125 ng/mL (AUC 0.841, 95% CI 0.801–0.961, $p < 0.001$), with a sensitivity and specificity of 70% and 84%, respectively (Figure 2), while the negative predictive value of NGAL 0 < 125 ng/mL was 94%.
**Conclusions:** Among STEMI patients, NGAL levels before primary PCI may be utilized both for ruling out and for the prediction of AKI.

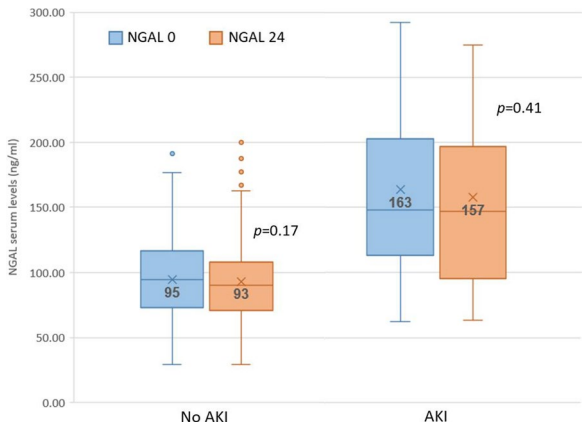

**Fig. 1 (abstract 000290)** NGAL 0 and 24 h in patients with vs. without AKI

### Enhancing ERAS compliance in a tertiary surgical centre: a multidisciplinary approach

M. Abdelrazek, T. Whittaker, T. Hughes, C. Huang, M. Gibbins
Intensive Care Unit, University Hospitals Bristol and Weston, Bristol, United Kingdom
**Correspondence:** M. Abdelrazek
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000291

**Introduction:** The Bristol Royal Infirmary is a tertiary surgical centre in Southwest England with an Adult Intensive Care Unit (ITU) catering to postoperative care. Standardized recovery pathways such as Enhanced Recovery After Surgery (ERAS) are implemented for all elective surgical patients. ERAS protocols are comprehensive perioperative care plans aimed at expediting post-surgical recovery. However, inadequate adherence and documentation poses threats to patient safety and well-being.
**Objectives:** This audit aimed to assess ERAS compliance, identify challenges, involve multidisciplinary teams, and emphasize the importance of early collaboration.
**Methods:** This was a retrospective audit of all adults admitted to general ITU after an elective upper gastrointestinal, lower gastrointestinal, maxillofacial, or thoracic procedures. Data were recorded and analysed on Microsoft excel. Two audit cycles were conducted over 4 months. This involved semi-structured interviews with nursing staff, analysis of procedural steps, and discussions with nursing and physiotherapy teams. Between the cycles, an electronic prompt was added for nursing staff to check after each encounter. Physiotherapy leads were also contacted to discuss barriers and to disseminate findings.
**Results:** Initial ERAS compliance was at 49%, with notable challenges such as declining mobility documentation over time. During the first audit cycle ($n = 40$), a trend of diminishing compliance with progressing days was observed, along with inconsistent documentation during night-time shifts and inadequate recording of drain output/input specific to ERAS. In the second audit cycle ($n = 27$), an overall improvement in compliance to 55% was noted. Notably, compliance rates for upper GI surgical cases, which typically involving extended hospital

stays, showed significant improvement. Nurses reported common themes for challenges, including paper forms, unsure of responsibility, and divergence in recovery plans.
**Conclusions:** The audit highlighted challenges in ERAS compliance, stressing the importance of collaboration. Comprehensive teamwork led to increased patient safety measures and compliance. This fostered standardized and evidence-based recoveries for patients and their families. Interviewing nurses and our modest improvement in ERAS compliance demonstrated the importance of integration of ERAS protocols in electronic systems.

CHIARA APSS-TRENTO, Trento, Italy
**Correspondence:** S. De Rosa
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000292

**Introduction:***Staphylococcusaureus* infections, particularly methicillin-resistant strains, can induce severe conditions, provoking an overwhelming immune response and contributing to systemic inflammation and organ failure. Effective antibiotic therapy and meticulous supportive care are crucial in the ICU to manage *Staphylococcusaureus*-induced septic shock. In this context, blood purification strategies target the microorganism and associated toxins, contributing to the systemic inflammatory cascade.
**Objectives:** This in-vitro study aimed to analyze the potential removal, through adsorption, by the Seraph® 100 Microbind® Affinity Blood Cartridge against *Staphylococcus aureus*. Subsequently, the study assessed whether the adsorptive capabilities of bacteria were maintained and, if so, whether the bacteria retained its bactericidal activity.
**Methods:** The study employed an in vitro model of hemoperfusion to characterize the adsorption performed by the Seraph® 100 Microbind® Affinity Blood Cartridge on a circulating bacterial load inoculated in blood for the experiment. A volume of 200 ml of blood served as a negative control (CTR-). The remaining 600 mL were enriched with a concentration of *S. aureus* bacteria equal to $1 \times 106$ and incubated for 4 h at 37 °C. At 4 h, the blood was divided into two glass bowls and stirred at 37 °C: 300 mL were circulated at a speed of 120 mL/min via a dedicated test platform (Galileo) with Seraph100, while another 300 mL was stirred and used as a positive control (CTR+) [Figure 1]. At times T0, CTR- and CTR+, and T1 and T2 (1 h and 2 h of treatment), samples were taken for injection into vials for blood cultures and placement on CNA agar.
**Results:** This study demonstrated that the S100ABC reduces the circulating bacterial load (from $1 \times 10^6$ at T0 to $0.25 \times 10^6$ at T6h) with a removal ratio of 75%, leading to the adsorption of bacteria onto the cartridge. Bacteria were found adhering to the beads contained in the cartridge.
**Conclusions:** Our preliminary data show that the Seraph® 100 Microbind® Affinity Blood Cartridge effectively reduces the circulating bacterial load. The Seraph® 100 Microbind® Affinity Blood Cartridge could be an adjunct sorbent for reducing *S.aureus* in human blood, supporting antibiotic therapy in patients with *S.aureus*-induced septic shock.

**Introduction:** In patients with septic shock, the association between the hypothermia at inclusion, the course of the body temperature during the first 24 h and the mortality remains uncertain. In this present study, we analyzed the statistical association between these three variables in a post hoc analysis of a randomized multicenter interventional trial.
**Methods:** Patients with septic shock were included within 6 h after the initiation of the norepinephrine (≥ 0.1 µg/kg/min). After inclusion, body temperature was assessed every 2 h during the first 24 h. Hypothermia was defined as a temperature < 36 °C (1). Mortality was assessed at day 90.
**Results:** We included 756 patients, of which 103 (13.6%) were with hypothermia at inclusion. After adjustment for confounding factors, as compared with patients without hypothermia at inclusion, patients with hypothermia at inclusion had a higher mortality (HR 1.88, 95% CI [1.36–2.61], *P* value < 0.001). Three groups of patients according to the evolution of the temperature were identified (Figure 1A). "Without hypothermia" (86.6%) corresponding to patients without any hypothermia; "transient hypothermia" (10%) corresponding to patients with hypothermia at inclusion and being normothermic during the first 24 h; and "persistent hypothermia" (3.4%) corresponding to patients with hypothermia at inclusion and during the first 24 h. The "persistent hypothermia" group had the highest mortality rate. Patients with transient or without hypothermia had similar mortality (Figure 1B).
**Conclusions:** In patients with septic shock, hypothermia at inclusion and persistence of hypothermia during the first 24 h were associated with higher mortality at day 90. Patients with transient hypothermia or without hypothermia during the first 24 h of the septic shock had the same mortality.

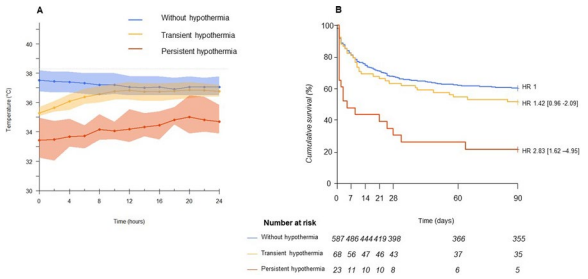

**Fig. 1 (abstract 000296)** Clusters of patients according to the evolution of the body temperature during the first 24 h of the septic shock (A) and survival according to the course of the temperature (B)
*Patients "without hypothermia" corresponded to patients without hypothermia during the first 24 h; patients with "transient hypothermia" corresponded to patients with hypothermia at inclusion but whose hypothermia had corrected within the first 24 h.*
Patients with "persistent hypothermia" corresponded to patients with hypothermia at inclusion and whose hypothermia persisted during the first 24 h.
Kaplan–Meier curves represent the survival according to the course of temperature during the first 24 h of the septic shock. Hazard ratios (HR) were calculated using a Cox model. We defined the group of patients without hypothermia as the reference. HR were adjusted on SOFA, lactate, community-acquired infection, past medical history of cancer, and the presence of mottling at inclusion.

**Introduction:** In seeking new therapeutic options for the treatment of cancer, the use of hyperthermic intraperitoneal chemotherapy (HIPEC) with associated cytoreductive surgery (CRS) has been growing. The post-operative management of these patient is reasonably difficult, and mostly occurs in the intensive care setting. One of the significant challenges is the interpretation of laboratory values and the correlation with arising complications.
**Objectives:** To evaluate the association between increased C-reactive protein (CRP) and the occurrence of complications after combined CRS and HIPEC.
**Methods:** A systematic search of databases was performed, including Embase, PubMed, and Cochrane Library. Observational studies evaluating postoperative complications and CRP kinetics in patients

undergoing CRS + HIPEC were included. For continuous variables, the results were expressed as mean difference with their 95% confidence interval (CI) and CRP values were evaluated on the first, third, and fifth post-operative days (POD).
**Results:** 238 studies were initially identified and screened by two independent evaluators. Four studies were included in the meta-analysis, with no significant difference found in the CRP value between the groups with and without complications on POD1 ($P$ value = 0.52). On POD3 and POD5, however, a statistically significant difference was identified between the groups ($P$ value = 0.04 and 0.0001, respectively).
**Conclusions:** Post-operative CRP values seemed to correlate with increased complications, especially after POD3. This laboratory test may have significant value in early detection of infectious complications; however, more studies are needed at this time to further understand the correlation.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000298

**Introduction:** The Quick Sequential Organ Failure Assessment (qSOFA), which is based on the presence of systolic BP ≤ 100 mmHg, respiratory rate ≥ 22/min, and altered mentation, has been used to predict the outcomes of patients with sepsis outside the ICU. We described patients in the ward who needed rapid response team activation and were suspected to have sepsis and evaluated the ability of qSOFA to predict hospital mortality.
**Methods:** This retrospective study was conducted in King Abdulaziz Medical City—Riyadh and included ward patients who needed activation of the critical care response team (CCRT) in 2019 and were suspected to have sepsis. We calculated qSOFA score (range: 0–3) at the time of CCRT activation for all patients. We compared hospital nonsurvivors to survivors and assessed the ability of qSOFA to predict hospital mortality using logistic regression and receiver-operating characteristic (ROC) curve analyses.
**Results:** The study included 390 patients with suspected sepsis (age: 64.4 ± 19.2 years, 41.5% females, qSOFA: 1.6 ± 0.8). 120 patients (30.8%) died in the hospital. Compared to hospital survivors, nonsurvivors were older (67.7 ± 16.4 vs. 62.9 ± 20.2 years, $p = 0.01$), and had higher prevalence of ischemic cardiac disease ($p = 0.007$), chronic obstructive pulmonary disease ($p = 0.002$) and chronic kidney disease ($p = 0.001$). Hypotension (systolic BP < 90 mmHg) ($p = 0.04$) and a drop in Glasgow Coma Scale by more than 2 points ($p = 0.001$) as reasons for CCRT activation were more common in nonsurvivors. Nonsurvivors also had higher qSOFA score (1.8 ± 0.8 vs. 1.6 ± 0.7, $p = 0.005$; 65.8% had qSOFA ≥ 2 vs. 51.9%, $p = 0.01$) and higher lactate levels (3.1 vs. 2.1 mmol/L, $p < 0.0001$). Sepsis was confirmed in 58.0% of nonsurvivors vs. 38.7% of survivors ($p < 0.0001$). Nonsurvivors required more ICU admission (54.2% vs. 28.5%, $p < 0.001$), vasopressor therapy (35.0% vs. 14.8%, $p < 0.0001$), and mechanical ventilation (30.0% vs. 11.1%, $p < 0.0001$). Multivariable logistic regression analysis showed that higher qSOFA score was associated with hospital mortality (odds ratio per unit increment: 1.60, 95% confidence interval [CI] 1.13–2.26). However, the ROC curve analysis showed that qSOFA at the time of CCRT activation alone had poor discrimination between nonsurvivors and survivors (area under the curve [AUC]: 0.58, 95% CI 0.52–0.65) and was similar to serum lactate at the time of CCRT activation (AUC: 0.55, 95% CI 0.48–0.62) (Figure 1). In patients with confirmed sepsis, qSOFA did not perform better (AUC: 0.57, 95% CI 0.48–0.66) and was similar to serum lactate (AUC 0.54, 95% CI 0.45–0.63) (Figure 1).
**Conclusions:** In ward patients who needed rapid response team for suspected sepsis, hospital mortality was high at 30.8%. A higher qSOFA score was associated with hospital mortality. However, it alone did not discriminate well between hospital nonsurvivors and survivors on ROC curve analysis.

**Introduction:** Implementing music in the intensive care unit (ICU) can help to promote a healing environment in a usually busy and stressful hospital setting. A therapeutic music program was implemented in 2019 using student and volunteer musicians at an academic medical center. The volunteer musicians played classical genre music songs for patients using a variety of instruments, including piano, cello, viola,

violin, oboe, flute, and saxophone. During the pandemic, the program was converted to live virtual with the use of two large i-Pads on wheels. The program has since resumed with both live and virtual formats. Data were collected on an ongoing basis to assess patient, clinical staff, and musicians perceptions of the therapeutic music program.
**Objectives:** The objectives of this session are to review the process of implementing and evaluating a therapeutic music program in the ICU and highlight implications for critical care clinicians.
**Methods:** Data were collected from 15 nursing staff, 6 volunteer musicians, and 50 patients using an online anonymous survey. Responses to five open-ended questions assessed participants' perceptions of the music. Quantitative data were collated and aggregated, and qualitative data were obtained, transcribed, and analyzed using NVivo, which provided the ability to quantify the qualifiable data of open-ended prose.
**Results:** Majority (66.7%) identified that therapeutic music was acceptable in the ICU. Similarly, a majority (73.3%) indicated that therapeutic music was appropriate and feasible. Seven (7) major themes were identified by the participants, including emotions evoked, preferred genre of music and instruments, life significance of music, power of music, and feedback. The majority (94%) experienced positive emotions from the music. Additionally, the majority (90%) indicated that they enjoyed the music experience and would participate in the future.
**Conclusions:** The findings suggest that therapeutic music, both in a live and virtual format, was well-received and provided tangible benefits to patients. The results have application to clinical practice and are being used to further refine and expand the program to promote a healing environment for patients, family members, and ICU staff. Additional research will explore the impact of a "dose–response" of music on the electroencephalographic (EEG) patterns, using a multisite design, with an ultimate aim of mitigating the onset or duration of ICU-related delirium.

## Real-time prediction model for short-term atrial fibrillation risk in critically ill patients using single-lead ECG

L. Lim[1], S. Jung[2], S. B. Seong[3], H. Y. Lee[4]
[1]Department of Anesthesiology and Pain Medicine, Seoul National University Hospital, Seoul, Republic of Korea; [2]Chief Technology Officer, HUINNO, Seoul, Republic of Korea; [3]AI, HUINNO, Seoul, Republic of Korea; [4]Department of Critical Care Medicine, Seoul National University Hospital, Seoul, Republic of Korea

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000302

**Introduction:** Atrial fibrillation (AF) is a common arrhythmia in critically ill patients, contributing to substantial morbidity and mortality. Nearly half of ICU patients newly develop AF in intensive care unit (ICU), with about 18% persisting upon discharge.
Existing ECG-based prediction models for AF predominantly have utilized mainly 12-lead ECGs and focused on long-term risk in outpatients, with limited external validation.
Our study aims to develop a real-time prediction model using single-lead ECG signals to assess short-term AF risk in critically ill patients.
**Methods:** Adult patients admitted to medical and surgical ICUs except for cardiothoracic ICUs in Seoul National University Hospital between January 2020 and August 2022 were included. ECG signals from Lead II, sampled at 500 Hz during ICU stays, were extracted. Our AI-based ECG classifier categorized signals into normal sinus rhythm (NSR), AF, noisy signals, or other rhythms. AF-classified signals were reviewed by three experts, defining AF rhythms lasting over 30 s with agreement from two or more experts. Patients were grouped based on AF history: AF group (history of AF + AF rhythm), new-onset AF (NOAF) group (no history of AF + AF rhythm), and Control group (no history of AF or AF rhythm).
The process of model development is shown in Figure 1. Model development involved classifying 30-s ECG segments into four types according to the changes in RR interval and the development of AF: NSR, Pre-AF, AF, and changes in RRI (Fig 1a). The evaluation of the hypothesis regarding the significant difference between the ECG segments of Pre-AF and changes in RRI is confirmed in Fig. 1b. A late fusion-based multi-modal approach utilized two independent feature extractors: f1, a 2-D ResNet50 capturing irregular RRI patterns (from recurrence plot), and f2, a convolutional recurrent neural network connected with 1-D ResNet6 and 2-layer bi-LSTM to extract morphological changes from raw ECG signals (Fig 1c). During training, the ADAM optimizer with a batch size of 32 and learning rate of 1e−4 was used, halving the learning rate every 5 epochs. Loss weighting addressed dataset imbalance, achieving convergence within 5 epochs.
The model classified ECG segments into NSR, Pre-AF, AF, and changes in RRI to predict AF development. Model performance was evaluated using AUROC and AUPRC, training on different datasets (small-scale AF, large-scale AF, NOAF, and AF + NOAF) with external validation using the Atrial Fibrillation Prediction Database (AFPDB) dataset, which was publicly open dataset.
**Results:** In the study, 672, 50, and 87 cases of patients were categorized into normal, AF, and NOAF groups, respectively. A total of 321,584 segments of NSR, 56,761 segments of changes in RR interval, 53,813 segments of Pre-AF, and 25,435 segments of AF ECGs were analyzed. Performance metrics for each model are summarized in Table 1. The model trained with the NOAF dataset exhibited strong predictive performance for NOAF, achieving an AUROC of 0.96 and AUPRC of 0.83, with predictions made 78.6 min in advance. For predicting AF, the model trained with both NOAF and AF datasets demonstrated the highest performance, achieving AUROCs of 0.97 and 0.82 for internal and AFPDB datasets, respectively. This model predicted AF development 38.9 min 21.8 min in advance for internal and AFPDB datasets, respectively.
**Conclusions:** We developed a deep-learning model to predict the risk of AF in critically ill patients. Although the performance slightly declined during external validation with an open dataset, our model still showed good performance for real-time prediction, predicting AF onset more than 20 min in advance.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000303

**Introduction:** CNS infections are severe conditions with significant associated morbidity and mortality. Timely diagnosis and initiation of antimicrobial treatment (AT) are crucial outcomes. While CSF culture is the gold standard, its sensitivity and specificity may decrease if AT has already started.
**Objectives:** To investigate the diagnostic accuracy of multiplex PCR molecular tests in CSF samples from patients with suspected CNS infection. Secondary objectives were concordance of results and identification of pathogens in the conventional culture that are not included into the panel.
**Methods:** Prospective observational study of AT decisions during the implementation phase of the FilmArray® Panel Meningitis/Encephalitis, FilmArray® Sepsis Panel (BCID) in patients admitted from May 2021 to December 2023. Simultaneous CSF samples were sent for culture, PCR-based tests, and neurotropic virus PCR test. Descriptive statistics was performed with Stata 14.2.
**Results:** Forty patients with suspected CNS infection were admitted, 26 (62.5%) were male, and mean age was 58 ± 16. 22 (55%) underwent spinal tap for CSF analysis because of suspected CNS infection, altered consciousness 11 (27.5%), seizures 6 (15%), or other reasons 1 (2.5%). FilmArray® Panel for Meningitis/Encephalitis was used in 34 (85%) of cases, while the FilmArray Sepsis (BCID) Panel was used in the remaining 6 (15%).
8 (20%) of the 40 CSF multiplex PCR panels tested positive, with 7 (87.5%) being under AT started prior to CSF sampling. Diagnostic accuracy of molecular tests is shown in Table.

| | Positive culture | Negative culture | |
|---|---|---|---|
| Positive multiplex PCR | 6 | 2 | PPV 75% |
| Negative multiplex PCR | 0 | 32 | NPV 100% |
| | Sensibility 100% | Specificity 94% | |

*Streptococcus pneumoniae* was detected in two cases, *Neisseria meningitidis* in two cases, *Herpes Simplex Virus 1* in 3 samples, and *Human Herpesvirus 6* in one sample. In three cases, culture and neurotropic virus PCR provided information not provided by the multiplex PCR tests: Epstein–Barr Virus was detected in two patients, and *Staphylococcus hominis* was isolated in one case in culture.
**Conclusions:** Molecular multiplex PCR tests of CSF samples have clinically meaningful diagnostic performance parameters and allow for swift adjustment of AT. However, as some potential pathogens are not included, multiplex PCR and conventional methods should be used in combination.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000306

**Introduction:** Severe influenza infection requiring ICU admission continues to be a challenge to the healthcare system with its high mortality. We evaluated the characteristics and outcomes of patients with influenza admitted to a tertiary-care ICU in Riyadh, Saudi Arabia.
**Methods:** This was a retrospective cohort of adult patients admitted with PCR-confirmed influenza to the ICU of King Abdulaziz Medical City-Riyadh, Saudi Arabia between January 1, 2018, and May 31, 2022. We compared the clinical characteristics, management, and outcomes of hospital nonsurvivors to survivors.
**Results:** During the 53-month study period, 675 patients were hospitalized with influenza and 151 (22.4%) were admitted to the ICU. There was no ICU admission between May 2020 and September 2021, during which SARS-CoV-2 was circulating at a high level in Riyadh, Saudi Arabia (Figure 1). Influenza A was responsible for most cases (H1N1 33.8%, H3N2 27.8%, untyped influenza A 15.2%, and Influenza B 23.2%). 34 patients (22.5%) died in the hospital. Nonsurvivors were older (69 ± 16 vs. 62 ± 20 years, $p = 0.04$), and had more prevalent ischemic heart disease (29.4% vs. 13.7%, $p = 0.03$), immunocompromised state (14.7% vs. 1.7%, $p = 0.002$), and acute kidney injury (29.4% vs. 10.3%, $p = 0.005$). Pulmonary Severity Index was slightly higher in nonsurvivors (120 ± 32 vs. 108 ± 34, $p = 0.06$). Respiratory culture was obtained in 102 patients (67.5%) with bacterial growth other than normal flora in only 24 patients (15.9%). *Pseudomonas aeruginosa* ($N = 11$, 2 were multidrug resistant) and *Staphylococcus aureus* ($N = 9$; 4 were methicillin-resistant) were the most common cultured bacteria. Bacterial growth was more common in nonsurvivors (35.3% vs. 10.3%, $p < 0.0001$). Only two patients (1.3%) had infection with Aspergillus species. Oseltamivir and antibacterial therapy were provided to almost all patients (anti-pseudomonal coverage in 64.2% and anti-MRSA coverage in 54.7% of patients). Corticosteroid therapy was used in most patients (72.2%) with no difference between nonsurvivors and survivors ($p = 0.84$). Nonsurvivors required more vasopressor therapy (85.3% vs. 55.6%, $p = 0.002$) and invasive mechanical ventilation (61.8% vs. 44.0%, $p = 0.07$). The duration of mechanical ventilation was longer in nonsurvivors (13 ± 8 vs. 7 ± 8 days, $p = 0.01$). On logistic regression analysis, age (odds ratio [OR], 1.04; 95% confidence interval [CI] 1.01–1.08), immunocompromised state (OR, 37.25; 95% CI 2.70–514.09), and vasopressor therapy (OR, 3.14; 95% CI 1.04–9.48) were independently associated with hospital mortality.
**Conclusions:** Among patients admitted to the ICU with influenza, most cases were due to Influenza A, almost one in three patients had bacterial coinfection and one in five died in the hospital. Older age, immunocompromised state, and presence of shock predicted mortality.

### The epidemiology of post-extubation respiratory supports in Japan: a retrospective cohort study using the intensive care unit registry database in Japan

T. Maezawa, M. Sakuraya
Department of Emergency and Intensive Care Medicine, JA Hiroshima General Hospital, Hatsukaichi, Japan
**Correspondence:** T. Maezawa
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000307

**Introduction:** Noninvasive ventilation (NIV) and high-flow nasal cannula (HFNC) to prevent reintubation have been used for patients with high risks of extubation failure. Considering the guideline recommendations based on accumulating evidence, the selection of the post-extubation respiratory supports may have changed [1,2]. However, a few studies investigated the epidemiology of the respiratory supports after extubation.
**Objectives:** This study aimed to address the epidemiology of post-extubation respiratory supports, and the transition of clinical outcomes in patient with those supports in Japan.
**Methods:** We performed a retrospective cohort study using the Japanese Intensive Care PAtient Database (JIPAD). From April 2018 to March 2022, we included the adult patients (> 18 years) who underwent mechanical ventilation for at least 24 h from ICU admission. Patients who underwent tracheostomy prior to ICU admission or extubation attempt, with P/F ratio greater than 300 within 24 h from ICU admission, and who had missing data for clinical outcome were excluded. We also excluded patients in the institutions that did not consecutively register cases on the JIPAD during the whole study period.
We investigated whether NIV or HFNC were used after extubation. And then, the patients were classified into four groups according to the respiratory supports after extubation: conventional oxygen therapy (COT group), NIV only (NIV group), HFNC only (HFNC group), and combination of NIV and HFNC (NIV + HFNC group). We evaluated the severity score (Acute Physiology and Chronic Health Evaluation [APACHE] score, Sequential Organ Failure Assessment [SOFA] score), the standardized mortality ratio (SMR) calculated using the APACHE III score, the duration of mechanical ventilation, and the length of ICU stay. Categorical variables were analyzed by the Cochran–Armitage trend test and continuous variables by the Jonckheere–Terpstra trend test.
**Results:** Of the 10,062 eligible patients in 38 ICUs, COT, NIV, HFNC, and combination of NIV and HFNC were performed in 7434, 554, 1581, and 493 patients, respectively. From 2018 to 2022, the proportion of patients with COT (75.0% to 72.6%, $P = 0.007$) and NIV (5.9% to 4.7%, $P = 0.020$) decreased with a significant trend. In contrast, those with HFNC increased significantly (14.2% to 18.2%, $P < 0.001$). APACHE II and SOFA score at ICU admission tended to decrease significantly in the COT and HFNC groups.

The SMR showed no increasing or decreasing trend for each group. The duration of mechanical ventilation and the length of ICU stay increased in the COT group, but did not change in the other groups.
**Conclusions:** In the 4 years since 2018, the proportion of patients undergoing HFNC after extubation has increased. Clinical outcomes in patients with HFNC after extubation did not change, despite a decreasing trend in severity scores. The threshold for HFNC use to prevent reintubation may have been lower.

*Intensive Care Medicine Experimental* 2024, **12(suppl 1):**000308

**Introduction:** Early in the pandemic, Do-Not-Resuscitate (DNR) orders were commonly used in patients with severe Coronavirus 19 disease (COVID-19) due to the high disease-fatality rate, fear of viral spread during cardiopulmonary resuscitation, and limited bed capacity. As practices of DNR orders vary by setting, we evaluated the practices of DNR orders in patients with severe COVID-19 at a tertiary-care hospital in Saudi Arabia.
**Methods:** This was a retrospective cohort study of patients with acute hypoxemic respiratory failure due to COVID-19 who were admitted to the adult intensive care units (ICUs) of King Abdulaziz Medical City in Riyadh, Saudi Arabia between March and December 2020. We compared patients who had DNR orders during ICU stay with those who had full code. We also described the clinical status on the day of DNR order implementation.
**Results:** We studied 193 patients who had acute hypoxemic respiratory failure due to COVID-19 (median age 60 years [interquartile range: 51, 69], males 73.5%, hypertension 59.6%, diabetes 65.3%). Respiratory management in the ICU included the use of high-flow nasal oxygen (70.4%), noninvasive ventilation (61.4%), invasive mechanical ventilation (52.6%), and prone positioning (44.0%). 54 patients (28.0%) had DNR orders on a median of 15 days (interquartile range: 5, 20) after ICU admission (no differences in demographics, more diabetes in patients with DNR orders but similar other comorbidities compared with the full code patients). On the day of the DNR order, 33 patients (61.1%) were on vasopressors, 5 (9.3%) on noninvasive ventilation, 49 (90.7%) on invasive mechanical ventilation (median fraction of inspired oxygen 0.70 [interquartile range: 0.54–0.90]), and 23 (46.9%) on renal replacement therapy, and the median sequential organ failure assessment score was 14.5 (Interquartile range: 13.0, 17.0). On multivariable logistic regression analysis, none of the baseline variables including age, sex, body mass index, premorbid condition, vasopressor therapy, and invasive versus noninvasive mechanical ventilation including high-flow nasal oxygen were associated with DNR orders. Of the 54 patients with DNR orders, 46 (85.2%) died in the ICU and 51 (94.4%) in the hospital.
**Conclusions:** DNR orders were commonly used in patients with severe COVID-19 during the first wave of the pandemic, mostly after 2 weeks of ICU admission. While baseline characteristics and respiratory support mode did not predict DNR orders, persistent severe organ failure during ICU stay probably did. Almost 95% of patients with DNR orders died in the hospital.

**Topic:** Ethics and end-of-life care

### The clinical utility of C-reactive protein and procalcitonin in patients with severe influenza

H. M. Al-Dorzi[1], Z. A. Alsafwani[2], E. Alsalahi[2], A. S. Aljulayfi[2], R. Alshaer[2], S. Alanazi[2], M. A. Aldossari[2], D. A. Alsahoo[2], R. Khan[1]
[1]Intensive Care Department, Ministry of National Guard—Health Affairs, KAIMRC, King Saud bin Abdulaziz University for Health Sciences (KSAU-HS), Riyadh, Saudi Arabia; [2]College of Medicine, King Saud bin Abdulaziz University for Health Sciences (KSAU-HS), Riyadh, Saudi Arabia
**Correspondence:** H.M. Al-Dorzi
*Intensive Care Medicine Experimental* 2024, **12(suppl 1):**000309

**Introduction:** Severe influenza is frequently associated with increased morbidity and mortality. This study evaluated the value of C-reactive protein (CRP) and procalcitonin (PCT) in predicting bacterial coinfection, ICU admission, and mortality in patients with severe influenza.
**Methods:** This was a retrospective study of adult patients with influenza who were admitted to a tertiary-care hospital in Riyadh, Saudi Arabia between 2018 and 2022. We compared admission levels of CRP and PCT in patients with and without bacterial coinfection (defined as growth of bacteria, including normal respiratory flora, within 48 h of admission), those who needed and did not need ICU admission, and hospital survivors, and nonsurvivors. We performed receiver-operating characteristic (ROC) curve analysis to assess the ability of admission CRP and PCT levels, change in CRP and PCT levels between admission and day 3–5, admission leukocyte count and Pneumonia Severity Index to predict bacterial coinfection, ICU admission, and hospital mortality.
**Results:** The study cohort comprised 675 patients with influenza; 42 out of the 241 patients who had respiratory culture (17.4%) had bacterial coinfection; 151 (22.4%) needed ICU admission and 50 (7.4%) died in the hospital. On admission, CRP was measured in 321 patients (median: 53 mg/L, interquartile range [IQR]: 19, 96) and PCT in 241 (median: 0.26 ng/L, IQR: 0.10, 0.86). CRP levels were similar in patients with and without bacterial coinfection ($p = 0.92$), patients who needed and did not need ICU admission ($p = 0.27$), and survivors and nonsurvivors ($p = 0.18$). PCT levels were similar in patients with and without bacterial coinfection but were higher in patients who needed ICU admission compared with those who did not (median: 0.35 ng/L, IQR: 0.20, 1.60 versus 0.23 ng/L, IQR: 0.09, 0.73; $p = 0.001$) and in nonsurvivors compared with survivors (median: 1.04 ng/L, IQR: 0.26, 3.87 versus 0.24 ng/L, IQR: 0.10, 0.73; $p < 0.0001$). The ROC curve analysis showed that CRP had poor predictive value for bacterial coinfection (area under the curve [AUC]: 0.507, 95% confidence interval [CI] 0.357, 0.658), ICU admission, and hospital mortality (Figure 1). On the other hand, PCT predictive ability was fair for bacterial coinfection (AUC: 0.630, 95% CI 0.471, 0.790), ICU admission (AUC: 0.642, 95% CI 0.565, 0.719), and good for hospital mortality (AUC: 0.735, 95% CI 0.638, 0.832) (Figure 1). However, PCT predictive ability was close to that of admission leukocyte count (AUC for mortality: 0.681, 95% CI 0.597, 0.765) and Pulmonary Severity Index (AUC for mortality: 0.698, 95% CI 0.626, 0.771). Changes in CRP and PCT over time had an uncertain ability to predict hospital mortality (Figure 1).
**Conclusions:** In our study, which was limited by a relatively small sample size, we found that PCT performed better than CRP in predicting bacterial coinfection and outcomes. However, PCT did not perform much better than admission leukocyte count and Pneumonia Severity Index in predicting hospital mortality.

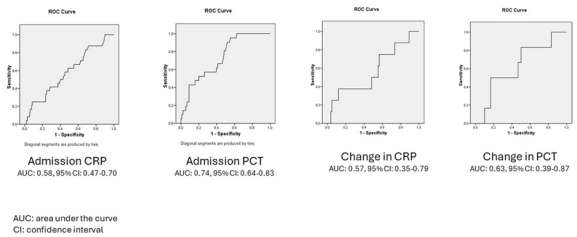

**Fig. (abstract 000309)** Receiver-operator characteristic (ROC) curve analysis for the predictive ability of C-reactive protein (CRP) and procalcitonin (PCT) for hospital mortality. Change in CRP and PCT was assessed as the difference between day 3–5 value and baseline value divided by the baseline value

**Topic:** Health services research and outcome

### Increasing illness severity of patients admitted to the intensive care unit (ICU) demonstrated by the APACHE II score over a 6-year period

S. Aziz, M. A. Cheema, J. Mitchell, S. Davey, A. Myers, T. Samuels
Intensive Care, East Surrey Hospital, Redhill, United Kingdom
**Correspondence:** S. Aziz
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000310

AQ2 **Introduction:** Severity of illness impacts resources required to treat patients and severity of illness scoring can be used to predict outcomes and mortality. Several such scoring systems have been used in intensive care, including the Acute Physiological and Chronic Health Evaluation II (APACHE II) score(1). APACHE II was first introduced in 1985 and is still used worldwide. It looks at 12 variables within 24 h of admission to produce a score out of 71, with a higher score correlating to a higher mortality risk and thus a higher degree of illness severity (2).
**Objectives:** To determine if illness severity has changed over the last six years in patients being admitted to ICU at East Surrey Hospital in the United Kingdom (UK).
**Methods:** APACHE II scores for 4540 patients admitted to ICU at East Surrey Hospital from 1/1/2018 to 30/11/2023 were analysed. Inferential statistics were performed using the Kruskal–Wallis test with a post hoc Bonferroni corrected comparison to determine specific differences between the years. The analysis was carried out using R (version 4.3.2).
**Results:** Table 1 shows the average age and median APACHE II scores for admissions to ICU by year. Overall, there was an increase in APACHE II score over the 6-year period with a median score of 14 and 18 in 2018 and 2023, respectively. Both 2022 and 2023 demonstrated significant difference when compared to preceding years (Table 2).

**Table 1 (abstract 000310)** Average age and median APACHE II scores for admissions to ICU by year

| | 2018 | 2019 | 2020 | 2021 | 2022 | 2023 |
|---|---|---|---|---|---|---|
| Age (years) | 65.1 | 64.0 | 60.6 | 61.6 | 62.2 | 62.9 |
| APACHE II score | 14 | 15 | 14 | 15 | 16 | 18 |

**Table 2 (abstract 000310)** Post hoc Bonferroni corrected comparison of years

| | 2018 | 2019 | 2020 | 2021 | 2022 |
|---|---|---|---|---|---|
| 2019 | 0.0166 | | | | |
| 2020 | 1.0000 | 0.0020 | | | |
| 2021 | 0.0978 | 1.0000 | 0.0167 | | |
| 2022 | 0.0000 | 0.0039 | 0.0000 | 0.0023 | |
| 2023 | 0.0000 | 0.0000 | 0.0000 | 0.0000 | 0.0000 |

**Conclusions:** The statistically significant increase in APACHE II score from 2018 to 2023 indicates an increase in predicted mortality and thus increased illness severity of ICU admissions at East Surrey Hospital. Since 2020, there has been an increase in APACHE II score each year, which may imply the score will continue to rise in the future. Predictably, continued increases in illness severity and mortality risk will impact the resources required to ensure adequate treatment of future ICU admissions. As this was a single-centre study, it may be beneficial to expand this study across the UK to see if other units are experiencing a similar trend in increasing illness severity.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000311

**Introduction:** In-hospital cardiac arrest (IHCA) is increasingly recognized as a distinct type of cardiac arrest (CA), and its incidence varies between countries (1). Despite the availability of immediate, high-quality cardiopulmonary resuscitation (CPR) for IHCA, mortality rates remain high (2). Due to its unique nature, cardiac arrest in cardiac catheterization laboratories requires a multifaceted approach and is often stressful (3). The specific challenges and need for high-quality CPR in cath labs are occasionally mentioned in the literature (3).
**Objectives:** This study aimed to gain insights into healthcare providers' standpoints and attitudes toward adult and paediatric cardiac arrest management in the cath lab. This was intended to be an initial step toward improving the team's performance and dynamics during such scenarios.
**Methods:** We conducted a cross-sectional study at Aswan Heart Centre from December 2023 to January 2024 through a self-administered online survey divided into 4 domains (Figure 1) with a total of 42 questions, including 3 open-ended questions. We have targeted 165 participants, including doctors and nurses, forming our rapid response team. The survey was pre-tested with a pilot study of ten participants. We reported results using descriptive statistics.

**Results:** The response rate was 58.1% (96 of 165), and the completion rate was 81.2%. 80% of the participants had ALS training in the past two years. Only 70% reported that they received feedback on their roles during CPR, and 63% reported not being involved in debriefing sessions on a regular basis. 22% mentioned the lack of clear role assignments during CPR, and 22% were unaware of the "closed-loop communication" concept. 27% reported feeling uncomfortable when giving feedback to their colleagues. The specific challenges related to the cath lab, along with proposed ideas for improvement, are summarized in Table 1.

**Table 1 (abstract 000311)** Summarized thematic analysis of responses to the open-ended survey questions

| Challenges encountered during CPR in the cath lab | | Proposed ideas for improvement of the cardiac arrest response in the cath lab | |
|---|---|---|---|
| **Challenges** | **Frequency** | **Ideas** | **Frequency** |

CPR: Cardiopulmonary Resuscitation

**Conclusions:** The cardiac catheterization lab is a distinct environment that poses multiple challenges, both technical and non-technical, during CPR. Noisy environments and crowded scenes are frequently encountered. Simulation training that imitates the Cath lab settings can prove to be useful. It is essential to develop national and international guidelines that address the specific needs for improving CPR quality in the cath lab.

### Monitoring adherence to the non-technical skills during cardiopulmonary resuscitation for victims of in-hospital cardiac arrest: the AHC-NTS Tool

E. Mosaad[1], I. Farag[2], H. Khedr[2], M. Abdelhay[2], M. El-Khatib[2], A. Eldowaik[1], M. Abdulhaleem Hamada[1]
[1]Critical care Medicine, Aswan Heart Centre (AHC), Magdi Yacoub Foundation, Aswan, Egypt; [2]Nursing Department, Aswan Heart Centre (AHC), Magdi Yacoub Foundation, Aswan, Egypt
**Correspondence:** E. Mosaad
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000312

**Introduction:** International cardiopulmonary resuscitation (CPR) guidelines have consistently emphasized the importance of non-technical skills (NTS) during resuscitation (1). These skills have been part of CPR courses, particularly simulation training (2). Assessing non-technical skills during CPR is challenging and is considered an area for research and development (3, 4).
**Objectives:** The aim of our study was to audit the adherence of CPR team members at Aswan Heart Centre to the non-technical skills advised by the Advanced Cardiovascular Life Support (ACLS) curriculum.
**Methods:** We developed the AHC-NTS Tool (Figure 1), an audit tool for evaluating adherence to non-technical skills during CPR. We identified eight fundamental NTS for recording. Non-adherence was defined as at least one event that breached any of these concepts during the resuscitation attempt. Other technical skills were also included in our tool. The CPR committee at the Aswah Heart Center approved the tool in 2021. Rapid Response Team members were trained to use and complete this form, which was implemented in 2022. Data entry was conducted through REDCap.
**Results:** We analyzed 159 adult cardiac arrest events in the period between January 2022 and December 2023. Table 1 summarizes patients' demographics and event characteristics. ROSC was achieved in 93 (60.4%) of events. Chest compression interruption for more than 5 s was reported to occur in 93 (60.4%) events. Breaching the 10-s guidelines recommendations for endotracheal intubation, if required, was reported in 38 (24.5%) events. The CPR board was only used in 75 (48.1%) events. The frequencies of non-adherence to non-technical skills are summarized in Table 2.

**Table 1 (abstract 000312)** Patient demographics and events characteristics

| **Total number of events: *n* (%)** | **159 (100%)** |
|---|---|
| Gender: male, *n* (%) | 102 (64.2%) |
| Age: median (IQR) | 61 (52–67.5) years |
| Initial rhythm: *n* (%)<br>Shockable<br>Non-shockable | 48 (30.1%)<br>108 (67.9%) |
| Duration of the resuscitation: median (IQR) | 12 (4–27) min |

**Table 2 (abstract 000312)** NTS reported and the frequencies of non-adherence

| Individual non-technical skills reported in our tool: | *n* (%) |
|---|---|
| Assignment of clear roles and responsibilities | 7 (4.4%) |
| Clear messages are maintained during the code | 2 (1.3%) |
| Knowledge sharing | 20 (12.6%) |
| Constructive interventions | 5 (3.1%) |
| Closed-loop communication | 5 (3.1%) |
| Debriefing and summarization | 29 (18.2%) |
| Acknowledging the team's limitations | 3 (1.9%) |
| Mutual respect | 1 (0.6%) |

**Conclusions:** Non-technical skills are of the utmost importance for high-quality CPR. Monitoring non-technical skills is challenging due to their subjective nature. The most common technical issue during CPR is the prolonged interruption of chest compression. On the other hand, the most common non-technical issue is the lack of regular debriefing sessions. By developing local tools and guidelines for auditing adherence, we can significantly improve the quality of CPR.

### Association between early postoperative vasoactive-inotrope score and the risk of acute kidney injury in adult patients after coronary artery bypass grafting: single-center retrospective observational study

A. Naiem, A. Elgendy, E. Mohamed, H. Hamed, M. Alfrargy, E. Mosaad
Critical Care Medicine, Aswan Heart Centre (AHC), Magdi Yacoub Foundation, Aswan, Egypt
**Correspondence:** E. Mosaad
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000313

**Introduction:** Acute kidney injury (AKI) is prevalent in patients after cardiac surgery (1). AKI is associated with increased postoperative mortality and morbidity (2). The vasoactive-inotrope score (VIS) was proposed in 2010 to expand the inotropic score (IS) to include other vasoactive medications (3, 4). VIS has shown good predictive accuracy for poor short-term outcomes after cardiac surgery, particularly in the pediatric population, based on multiple studies (2).The performance of VIS in predicting outcomes in the critically ill adult population remains an area for research.
**Objectives:** Our aim was to investigate whether a high Vasoactive-Inotrope Score (VIS) is a predictor for postoperative acute kidney injury (AKI) in adult patients after coronary artery bypass grafting (CABG).
**Methods:** We conducted a retrospective chart review study from January 2022 to December 2023. We included all adult patients who underwent CABG at our institution and whose medical charts could be retrieved. Demographic data, operative details, and post-operative AKI were recorded. VIS was calculated and reported three times: (1) at the time of ICU admission; (2) maximum VIS on the day of surgery (POD-0); and (3) maximum VIS on the first postoperative day (POD-1). AKI was identified based on the creatinine criteria of the KDIGO definition (5). Multivariate logistic regression, ROC curve, and Chi-squared statistics were used for analysis.
**Results:** We identified 140 eligible participants and were included in the analysis. 105 (75%) participants were males, and 100 (71.5%) had a BMI of 25 or more. The median (IQR) age was 56 (49–62) years. 51 (35%) patients developed AKI in different stages. When comparing patients who developed AKI and those who did not. We found a statistically significant difference between the two groups in age ($p < 0.001$), maximum POD-0 VIS ($p = 0.017$), and maximum POD-1 VIS ($p < 0.001$). Multivariate logistic regression showed that out of all variables, age (OR 1.06, 95% CI 1.01–1.1, $p = 0.007$) and maximum POD-1 VIS (OR 1.12, 95% CI 1.02–1.23, $p = 0.01$) were independent factors associated with postoperative AKI. ROC curve analysis showed that the best AUC was obtained for maximum POD-1 VIS (Figure 1).
The limitations of our study included a small sample size, the retrospective nature of the study design, and the use of creatinine criteria only for defining AKI.
**Conclusions:** Vasoactive-inotrope score in the early postoperative period can be a promising predictor for the development of AKI after cardiac surgery. In our study, advanced age and high maximum POD-1 VIS were independently associated with postoperative AKI after CABG. More large-scale studies are needed to confirm the role of VIS for critically ill patients.

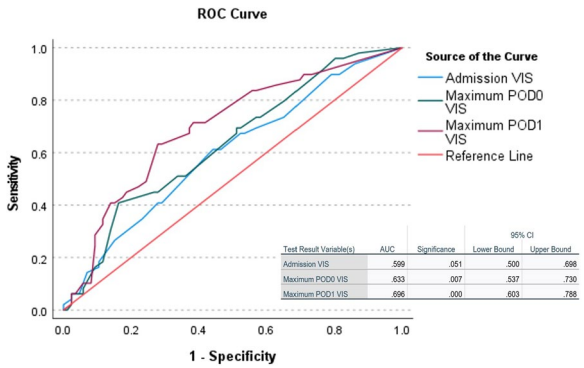

**Fig. 1 (abstract 000313)** Receiver-Operating Characteristic (ROC) comparing AUC of Vasoactive-Inotrope Score (VIS) at three different time points for predicting the risk of acute kidney injury after coronary artery bypass grafting in the study population. VIS, Vasoactive-Inotrope Score; Maximum POD0 VIS, Maximum Vasoactive-Inotrope Score on the day of surgery; Maximum POD1 VIS, Maximum Vasoactive-Inotrope Score on the first postoperative day

## A multi-dataset analysis of the associations between treatment of acute myocardial infarction (AMI) in the ICU and patient outcomes

P. Mugambi[1], S. Carreiro[2], J. Chung[3], M. Sherman[4], R. Walker[3], M. Fiterau[1]
[1]Computer Science, University of Massachusetts Amherst, Amherst, United States of America; [2]Emergency Medicine, University of Massachusetts Medical School, Worcester, United States of America; [3]Nursing, University of Massachusetts Amherst, Amherst, United States of America; [4]Emergency Medicine, Critical Care Medicine, University of Massachusetts Medical School, Worcester, United States of America
**Correspondence:** P. Mugambi

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000315

**Introduction:** Much work has shown that disparities in the treatment of AMI exist in critical care. Preliminary findings from ongoing work show that disparities manifest differently across datasets [2]. Understanding their impact on patient outcomes is important for improved care.
**Objectives:** Examine whether there is an association between treatment and patient outcomes across multiple datasets.
**Methods:** This is a retrospective analysis of three public datasets: MIMIC-III [1], collected in MA, USA 2001–2012, eICU [3], hospitalizations across USA 2014–2015, and AmsterdamUMCDb (AUMC) [4], collected in Netherlands 2003–2016. Patients with a primary diagnosis of AMI and no comorbidities were extracted. A logistic regression model was fit to examine the association between demographic variables (sex, age, race, insurance, region), disease severity markers (length of stay, N/STEMI, shock diagnosis), analgesia and AMI-related treatments (ACE-inhibitor, antiplatelet, beta-blocker, statin) and two outcomes, in-hospital mortality (IHM) and discharge location (DL), dichotomized as discharge to home (D2H), favorable, vs elsewhere. Similar to [1], eICU and MIMIC were analyzed both separately and combined into a single dataset, henceforth called Combined. AUMC did not have DL information and was only analyzed for IHM.
**Results:** There were 91, 644, and 2521 patients in AUMC, eICU, and MIMIC, respectively, who met the inclusion criteria. Being older (odds ratio = 21.2-AUMC) and experiencing shock (6.5-MIMIC, 6.3-Combined) increased the odds of IHM. Additionally, older age (0.4-MIMIC, 0.3-Combined), incidence of shock (0.2-MIMIC, 0.17-eICU, 0.22-Combined), and longer stays (0.7-eICU, 0.8-MIMIC, 0.8-Combined) decreased the odds of D2H. Having insurance was protective against IHM and unfavorable discharge. In MIMIC, traditionally undertreated groups had worse outcomes; female patients had decreased odds of D2H (0.5), while Caucasians had decreased odds of IHM (0.7). Across all datasets, AMI-related treatments decreased odds of IHM; ACE-inhibitor (0.06-AUMC, 0.2-MIMIC, OR = 0.2-Combined), aspirin (0.2-MIMIC), beta-blocker (0.1-MIMIC, 0.15-Combined), and statin (0.5-MIMIC, 0.4-Combined). Similarly, they increased the odds of D2H; beta-blocker (6.0-MIMIC, 3-Combined) and non-aspirin antiplatelets (1.7-MIMIC, 2.6-eICU, 1.8-Combined). Analgesics greatly increased the odds of IHM and decreased the odds of D2H in MIMIC; any analgesia (47.5-IHM, 0.04-DL) and multimodal (3.3-IHM).
**Conclusions:** Unlike prior findings where disparities were varied across datasets, we find that the association between treatment and patient outcomes is consistent across them. Insurance and AMI-related drugs have a protective effect against unfavorable discharge, including mortality. We hypothesize that the link between analgesia and increased odds of poor outcomes is an indicator of disease severity, i.e., sicker patients are more likely to receive analgesia and are also more likely to experience poor outcomes. For equitable care and outcomes, disparities in access to insurance and orders of AMI-related drugs should be eliminated, because they are paramount for favorable outcomes.

### Role of selective plasma exchange in critically ill patients' comparison with plasma exchange

H. Yoshida, A. Tsuruoka, T. Yamashita, K. Shigemitsu, R. Hioshi
Emergency and Critical Care Medical Center, Osaka City General Hospital, Osaka, Japan
**Correspondence:** H. Yoshida
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000316

**Introduction:** Therapeutic plasma exchange (TPE) is a potentially lifesaving but also invasive procedure with risk of adverse events. Plasma separation can be performed by centrifugation or membrane techniques. In Japan, membrane separation has been the standard method for a long time. In recent years, there have been more reports on selective plasma exchange (SePE) therapy using Evacure Plus EC-4A10® (Asahikasei Medical Co., Ltd., Japan), which has a smaller pore size of 0.03 μm than conventional membrane plasma separator of 0.3 μm (OP-05D®, Asahikasei Medical Co., Ltd., Japan). The most unique point of SePE therapy is that it can remove Immunoglobulin G (IgG) with reduced loss of fibrinogen (Fib). The sieving coefficient (SC) of Evacure plus EC4A-10® is for IgG 0.5, Fib 0, while the SC of OP-05D® is approximately 1.0, respectively.
**Objectives:** The purpose of this study was to determine the differences in removal rates and adverse events between SePE and PE in ICU patients.
**Methods:** Patients who were treated with SePE in our ICU from February 2018 to January 2024 were included in the study. We retrospectively examined the details of SePE: IgG removal rate (RR-IgG), IgM removal rate (RR-IgM), and Fib removal rate (RR-Fib) based on medical records.
**Results:** We performed 49 sessions of SePE procedures in 13 patients: five of rapidly progressive glomerulonephritis (RPGN) with alveolar hemorrhage, four of autoimmune encephalitis, one of acquired hemophilia A (AHA), one of Guillain–Barre syndrome (GBS), one of myasthenic crisis, and one of thyroid crisis.
Albumin was used as replacement fluid for all sessions in our study consisting of 8 PE sessions and 49 SePE sessions. The median values of PE and SePE per session in each category were as follows: the processed plasma volume (PV) was 1.1 and 1.4 times the circulating PV, the RR-IgG was 79.6% and 61.9%, RR-IgM was 74.7% and 0%, and the RR-Fib was 76.3% and 17.2%, respectively (Table 1).
Regarding clinical efficacy, five cases of autoimmune encephalitis, and each case of myasthenic crisis, GBS and thyroid crisis were weaned from the ventilator. Five cases of RPGN achieved disappearance of hemoptysis and improvement of respiratory condition. In one case of AHA, the inhibitor was removed, and bleeding tendency was improved. The median value of decreased blood pressure before and after session of PE and SePE were 6.3% and 3.0%, respectively. None of our sessions had bleeding event. No FFP transfusion after SePE was needed due to the Fib reduction (< 100mg/dl). However, three of eight PE sessions showed Fib reduction and the median FFP transfusion was eight units.
**Conclusions:** SePE is slightly less efficient in IgG removement but can reserve Fib better than PE. This characteristic is ideal for SePE seems to be safer modality for severe and unstable patients in ICU with bleeding tendency and it is also economically cost-saving regarding the use of FFP. SePE should be preferred only when the target immunoglobulin is IgG-class as its removal rate of IgM is 0.

**Table 1 (abstract 000316)** PV: Plasma volume, RR-IgG-Immunoglobulin G remova; rate, RR-IgM: Immunoglobulin M remova; rate, RR-Fib: Fibrinogen removal rate

| | PE (n=8) | SePE (n=49) |
|---|---|---|
| Processed PV (times) | **1.10** [1.10-1.11] | **1.40** [1.38-1.48] |
| RR-IgG (%) | **79.6** [70.2-82.9] | **61.9** [51.8-68.7] |
| RR-IgM (%) | **74.7** [73.4-78.4] | **0.0** [0.0-3.7] |
| RR-Fib (%) | **76.3** [65.5-82.2] | **17.2** [8.1-21.0] |

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000317

**Introduction:** Sepsis is characterized by a dysregulated host immune response to infection, which includes a state of significantly impaired immune function known as immunoparalysis. This weakened state increases the risk of secondary infections from ordinarily non-pathogenic organisms, thereby contributing to morbidity and mortality. Rapid and accurate immune phenotyping to assess the severity of immunoparalysis may pave the way for targeted interventions that enhance the prognosis for these critically ill patients.
**Objectives:** We hypothesized that in septic patients, subclinical immunological deficits could be precursors to immune failure. These deficits may be measurable through ex vivo whole blood stimulation assays, which assess cytokine concentrations. A correlation between these measurements and subsequent organ dysfunction may exist, indicating that such assays could serve as early indicators of evolving immune failure.
**Methods:** In a prospective observational study, adult septic patients and critically ill but non-septic controls were identified within 48 h of critical illness onset. Ninety-six adult septic and critically ill non-septic patients were enrolled. Using a rapid, ex vivo assay based on responses to lipopolysaccharide (LPS), anti-CD3/anti-CD28 antibodies, and phorbol 12-myristate 13-acetate with ionomycin (PMA), cytokine responses to immune stimulants were quantified. The Ella(TM) automated immunoassay system (Bio-Techne, Minneapolis, MN) was used for triplicate measurement of interferon (IFN)γ, tumor necrosis factor

(TNF), and interleukin (IL)-6. Cytokine concentrations were available within 90 min. The primary outcome was the relationship between early cytokine production and subsequent organ dysfunction, as measured by the Sequential Organ Failure Assessment score on day 3 of illness (SOFAd3).

**Results:** Elevated levels of TNF and IL-6 post-endotoxin challenge were inversely correlated with SOFAd3. IFNγ production per lymphocyte was inversely related to organ dysfunction at day 3 and differed between septic and non-septic patients, suggesting a role for ex vivo lymphocyte IFNγ production as a biomarker in sepsis (Fig 1). Clustering analysis revealed two distinct immune phenotypes, represented by differential responses to 18 h of LPS stimulation and 4 h of anti-CD3/anti-CD28 stimulation (Fig 2).

**Conclusions:** Our rapid immune profiling technique offers a promising tool for early prediction and management of organ dysfunction in septic patients. This information could be pivotal for early intervention and for preventing irreversible organ damage during the acute phase of critical illness.

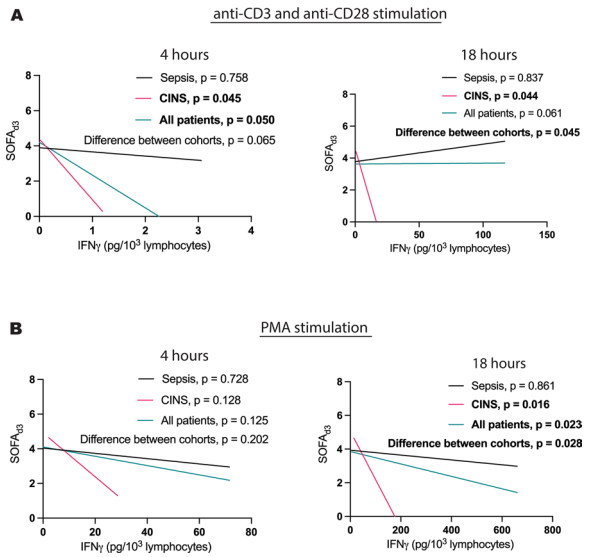

**Fig. 1 (abstract 000317)** Assessment of Ex Vivo interferon-gamma (IFNγ) production, per lymphocyte, as a predictor of subsequent organ dysfunction. Panel (A) displays interferon-gamma (IFNγ) production by $10^3$ lymphocytes following 4 and 18 h of anti-CD3/anti-CD28 stimulation. Panel (B) displays interferon-gamma (IFNγ) production by 10^3 lymphocytes following 4 and 18 h of phorbol 12-myristate 13-acetate (PMA) with ionomycin stimulation. The *p* values represent the statistical correlation between ex vivo cytokine output per cell and the SOFA score on day 3, after adjusting for confounding factors using the Acute Physiology and Chronic Health Evaluation II (APACHE II) score. 'Sepsis' refers to the relationship (slope) of the cytokine with SOFAd3 within the sepsis group, 'CINS' refers to the relationship (slope) of the cytokine with SOFAd3 within the critically ill but non-septic group, 'all patients' refers to the relationship (slope) of the cytokine with SOFAd3 with both groups combined, and 'difference between cohorts' compares 'sepsis' and 'CINS' to test for a significant difference between the slopes of the two groups

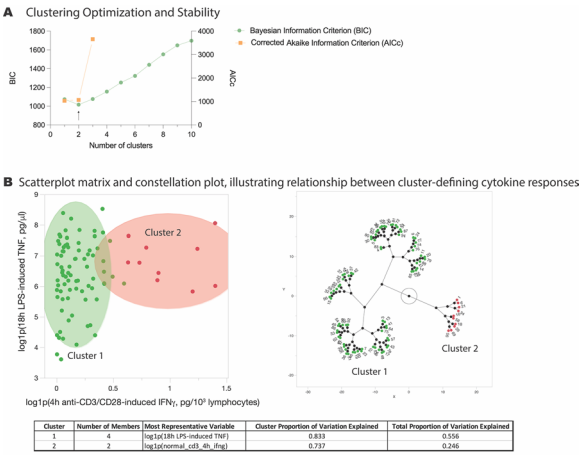

| Cluster | Number of Members | Most Representative Variable | Cluster Proportion of Variation Explained | Total Proportion of Variation Explained |
|---|---|---|---|---|
| 1 | 4 | log1p(18h LPS-induced TNF) | 0.833 | 0.556 |
| 2 | 2 | log1p(normal_cd3_4h_ifng) | 0.737 | 0.246 |

**Fig. 2 (abstract 000317)** Optimization of clustering for cytokine responses following ex vivo stimulation. (A) Gaussian Mixture Modeling (GMM) was employed to determine the optimal number of clusters, revealing cytokine responses that most characteristically defined each cluster. Arrow indicates the optimal cluster number based on Bayesian Information and Corrected Akaike Information Criteria. (B) A scatterplot matrix and constellation plot were constructed using the two cytokine responses that most accurately represented each of the two clusters identified in (A). The analysis was conducted on log-p-transformed cytokine concentrations subsequent to stimulation with LPS and anti-CD3/anti-CD28 antibodies

### Assessing seasonal trends in illness severity of patients admitted to critical care

J. Harding, S. Dawn, J. Mitchell, S. Davey, A. Myers, T. Samuels
Intensive Care Unit, East Surrey Hospital, Redhill, United Kingdom
**Correspondence:** J. Harding
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000318

**Introduction:** Seasonal variations in temperature are well known to be correlated with adverse health outcomes. UK studies have identified winter excesses in hospital admissions for asthma, falls, certain types of road accidents, atrial fibrillation, heart failure, pulmonary embolism, stroke, and critical illness (1, 2). It is often presumed that patients admitted to ICU in winter months are more unwell than those admitted in the summer; however, evidence for this is lacking. An understanding of the seasonal variations in demands on ICU services can help plan the allocation of beds and facilitate the prompt admission and management of critically unwell patients.

**Objectives:** To understand and assess if there is a seasonal trend to the illness severity of patients admitted to our critical care unit.

**Methods:** To measure illness severity, we used the Acute Physiology and Chronic Health Evaluation II Score (APACHE II) which, despite its limitations, provides a standardized and objective measure of the severity of illness in critically ill patients and continues to be used worldwide.

Between 1 January 2018 and 30 November 2023, deidentified data for 4767 patients were sampled, and of these, APACHE II scores were available for 4540 critical care patients. Given the large size of this cohort, multiple imputation was not needed to provide expected values for missing data. These data were analysed by creating a time series for monthly median APACHE II scores and additive seasonal

decomposition of the same data. All analyses were performed using R (version 4.3.2).

**Results:** Visual inspection of the time series for monthly median APACHE scores from 2018 to 2023 (Figure 1) shows irregular peaks, with a slight increasing trend towards the end, suggesting an increased acuity of patients towards the end of 2022 and start of 2023. These peaks do not occur with any regularity, suggesting that there is no seasonality to this data.

The seasonal decomposition method of examining data for seasonality involves breaking the time series into three components—the linear trend (in this case an asymptotic increasing trend), the seasonal component and random residuals (3), as seen in Figure 2. From the seasonal decomposition data, it appears that there is a seasonal component to the data; however, this only accounts for 5% of the data overall, with the trend contributing over 50%.

**Conclusions:** In our unit, we have demonstrated that there is no significant evidence to support the view that patients admitted to ICU in winter months are more unwell than those admitted in the summer, which is most likely the result of cognitive bias. We recognize that using the APACHE II score as a marker for acuity in this patient cohort may not be the best discriminator to determine seasonality. Nonetheless, our study underscores the importance of ongoing monitoring and adaptive resource allocation strategies to effectively manage critical care patient loads throughout the year.

### Comparing ICNARC physiology and APACHE II mortality prediction models in critical care patients

S. Beverley, J. Macallan, J. Mitchell, S. Davey, A. Myers, T. Samuels
Critical Care, East Surrey Hospital, Redhill, United Kingdom
**Correspondence:** S. Beverley
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000319

**Introduction:** Mortality prediction scores are a valuable tool in critical care to assist in the assessment of illness severity, guiding decision-making and shaping service delivery and design through appropriate resource allocation. Several scores have been developed with the aim of increasing the accuracy of severity of illness classification and mortality prediction.

The Acute Physiology and Chronic Health Evaluation II (APACHE II) score was introduced in 1985 and is calculated from 12 data points within the first 24 h of admission [1]. Whilst there have been further iterations, APACHE II is still widely used and is easily calculated using online tools. The Intensive Care National Audit & Research Centre (ICNARC) Physiology score was developed for use in the United Kingdom in 2007 as part of a program to analyse data from UK adult intensive care units aiming to improve care quality and patient outcomes [2]. The model used in this study is from 2018 (*h*2018 model).

Given that multiple scoring systems are in use, it is useful to understand the comparative performance of different mortality prediction models.

**Objectives:** To assess the predictive performance of the ICNARC Physiology Score and the APACHE II Score in determining mortality risk amongst critical care patients.

**Methods:** We examined deidentified data for 1383 patients admitted to critical care between 1/1/20 and 31/12/21 at a single site district general hospital in Surrey, UK.

Area under the receiver-operating characteristic curves (AUROC) provides a metric for assessing and comparing diagnostic accuracy of classification models, with a higher number indicating greater accuracy. AUROC values of 0.7–0.8 are generally regarded as "acceptable" and 0.8–0.9 "outstanding" [3]. In addition to producing receiver-operating characteristic (ROC) curves, we also compared both models using performance metrics and mean squared error (MSE) estimates.

**Results:** The AUC (Figure 1) for the ICNARC Physiology Score is 0.816, and the AUC for the APACHE II Score is 0.742. The ICNARC h2018 model generally performs better than the APACHE II model across various evaluation criteria (Table 1), including sensitivity, positive predictive value (PPV), negative predictive value (NPV), accuracy, and mean squared error (MSE).

**Conclusions:** We have demonstrated that both scoring systems show comparably good accuracy in predicting mortality outcomes. However, the ICNARC Physiology Score model does exhibit superior discriminative ability compared to the APACHE II model. In particular, the ICNARC model appears much better at discriminating true positives. Nevertheless, both models remain in use today for critical care units in the UK and this analysis suggests that the APACHE II scoring system does remain a valid scoring system despite it being nearly 40 years since its Introduction.

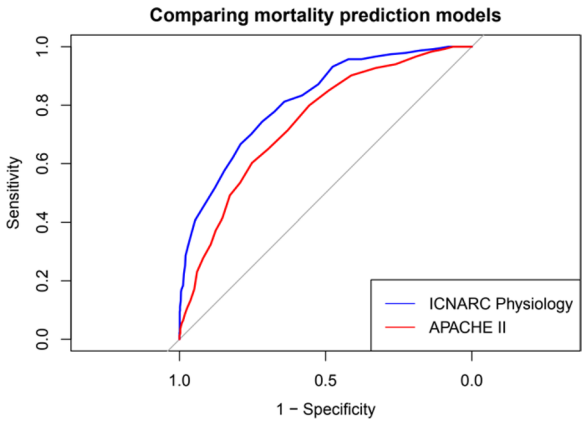

**Fig. 1 (abstract 000319)** ROC curves for ICNARC Physiology Score and APACHE II Score

**Table 1 (abstract 000319)** Performance metrics for ICNARC Physiology Score and APACHE II Score

| | Sensitivity | Specificity | PPV | NPV | Accuracy | MSE |
|---|---|---|---|---|---|---|
| ICNARC $h_{2018}$ model | 0.29 | 0.98 | 0.74 | 0.87 | 0.86 | 0.14 |
| APACHE II model | 0.09 | 0.98 | 0.49 | 0.84 | 0.83 | 0.17 |

## The disconnect between alarm priority and reality on the ICU: a retrospective analysis

A. Chaoui, M. Prendke, P. Heeren, L. Mosch, F. Balzer, A. S. Poncette, A. R. Flint
Institute of Medical Informatics, Charité–Universitätsmedizin Berlin, Berlin, Germany

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000320

**Introduction:** The high number of alarms in the ICU, most of them clinically irrelevant, leads to alarm fatigue among health care staff [1]. Ninety-five percent of nurses report feeling the burden of alarm fatigue, which has been linked with desensitization, delayed responses to alarms, and endangerment of patient safety [1–3]. According to nurses, especially the inability to discern the priority of alarms is a main obstacle to effective alarm management [2, 4, 5]. Current alarm monitors classify alarms into low (yellow) and high (red) priority alarms based on threshold excess, to inform of potentially life-threatening drops or increases of vital signs. However, it is uncertain whether this accurately assesses the priority of alarms or reflects the need for clinical interventions in response to the alarms.

**Objectives:** Assess whether the vital sign monitor alarm priorities align with the need for clinical interventions, serving as a proxy for the actual importance of the alarm.

**Methods:** Following IRB approval (Ethics vote no. EA1/127/18), alarm data were collected from monitoring devices on 15 ICUs in a tertiary care center over 23 months. Alarms were annotated as either clinically relevant or non-relevant based on whether and which clinical interventions followed them [6]. High and low blood pressure (BP), high and low heart rate (HR), and low peripheral oxygen saturation (SpO2) alarms were included as alarm types. Retrospectively, the performance of high-priority (red) alarms in predicting the alarms to be followed by an adequate clinical intervention was analyzed as compared to the baseline performance of low-priority (yellow) alarms. Specifically analyses of receiver-operating characteristic curves (ROC-Curves), precision–recall curves (PR-Curves), and confusion matrices were performed.

**Results:** In total, we analyzed 6,324,824 alarms, with 533,445 (8.4%) of these being high-priority alarms. For all alarm types analyzed, the area under the ROC-Curve (AUROC) of high-priority alarms was between 0.506 and 0.547, only slightly above the baseline of 0.5 (Figure 1). For the area under the PR-Curve (AUPRC), all alarm types beat their respective baseline, but none improved upon it by more than 10% or 1.5 percentage points (Figure 1). Sensitivity and positive predictive value (PPV) were low for all alarm types; therefore, high-priority alarms did not detect alarms needing clinical interventions at high rates and clinical interventions did not follow high-priority alarms at much higher rates (Table 1).

**Conclusions:** The currently available and implemented system in bedside vital sign monitoring devices of alarm priority offers little help in predicting situations where patients need clinical interventions. For all alarm types analyzed, the performances of high-priority alarms were too poor to be useful in clinical practice, as they were only marginally better than a random guess. Therefore, healthcare staff cannot rely on this system for prioritizing alarms or evaluating the acuity and criticality the alarm conveys. Ninety-nine percent of questioned nurses agree that alarms should inform about priority [5]. However, current systems are severely lacking in that regard.

Our findings support the need to research, develop, and implement newer and more predictive priority systems. Especially, AI-based approaches show very promising results, because they can analyze massive amounts of data to determine the priority of an alarm [7]. More intelligent patient monitoring could help to improve alarm management, reduce alarm fatigue, and improve patient safety [3, 8].

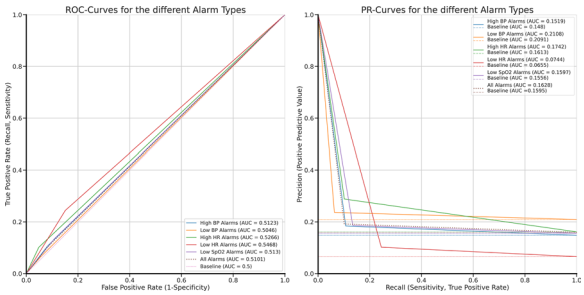

**Fig. 1 (abstract 000320)** ROC-Curves and PR-Curves for all alarm types. The two graphs show the receiver-operating characteristics curves (ROC-Curves) and the precision–recall curves (PR-Curves) for high-priority (red) alarms of all five alarm types analyzed. The two curves are drawn by analyzing the relationship of the false–positive rate and the true-positive rate (sensitivity, recall) for the ROC-Curve; and the recall (sensitivity, true positive rate) and the precision (positive predictive value) for the PR-Curve. In both graphs, the baseline of a random guess is drawn as a dotted line. The calculated area under the curves (AUC) are shown as a comparative metric in the legend

**Table 1 (abstract 000320)** Additional performance metrics for all alarm types. For high-priority (red) alarms of all alarm types, the Sensitivity (Recall, True-Positive Rate), Specificity (True-Negative Rate), Positive Predictive Value (PPV, Precision), and Negative Predictive Value (NPV) are shown. Additionally, the F1-Score was calculated, the harmonic mean between sensitivity and positive predictive value

| Alarm Type | Sensitivity (%) | Specificity (%) | PPV (%) | NPV (%) | F1-Score (%) |
|---|---|---|---|---|---|
| High BP | 10.70 | 91.76 | 18.40 | 85.53 | 13.53 |
| Low BP | 6.31 | 94.62 | 23.66 | 79.25 | 9.97 |
| High HR | 10.15 | 95.18 | 28.83 | 84.63 | 15.01 |
| Low HR | 24.45 | 84.90 | 10.19 | 94.13 | 14.38 |
| Low SpO2 | 13.42 | 89.17 | 18.60 | 84.83 | 15.59 |

Baseline rates for clinical relevance of low-priority (yellow) alarms were: High Blood Pressure (BP): 14.8%; Low Blood Pressure (BP): 20.9%; High Heart Rate (HR): 16.1%; Low Heart Rate (HR): 6.5%; Low peripheral oxygen saturation (SpO2): 15.6%.

**Introduction:** Unit-to-unit transfer of a critically ill patient infers potentially harmful practical hazards, but other factors may also be crucial to outcome. Circumstantial factors previously associated with mortality include duration of intensive care, night-time discharge, and capacity transfer (1). Distance travelled and time in transit may also constitute indirect risks and are longer for inter-hospital than intra-hospital transfer. The aim of this study was to analyse the association between these circumstantial factors and the risk of death 30 days after unit-to-unit inter-hospital transfer.
**Methods:** Transfer data from 5 years before the pandemic were retrieved from the Swedish Intensive Care Registry where unit-to-unit transfers are categorised as (1) "clinical" when due to need for specialised care, (2) "capacity transfer" when due to a lack of resources, or (3) "repatriation" when patients are returned to the ICU closest to their home. Variables included age, sex, date and time of admission, SAPS3, surgical status, primary ICU ICD-10 diagnosis, date and time of discharge, destination, transfer category, and time of death. Patients with a registered first transfer between ICUs were eligible. Subsequent or incompletely registered transfers, intra-hospital transfers, and patients lacking SAPS3 data or survival status were excluded. The association of each exposure with the risk of death, expressed as the event odds ratio, OR (95% CI), was assessed by univariable and subsequent multivariable logistic regression with premeditated adjustment for ICD-10 diagnosis and Standardised Mortality Rate (SMR).
**Results:** Among 4327 inter-hospital transfers between Jan 1, 2015 and Dec 31, 2019, 2167 were clinical, 1351 capacity transfers, and 809 repatriations. Median (Q1;Q3) age was 65 (52;73) years with 37% women. Day in the referring ICU was 1 (0;3) and 16% were night-time transfers. Kilometres travelled were 58.3 (18.8:108) with 71% of transfer distances exceeding 25 kms. SAPS3 was 60 (50;70) in the referring ICU and 60 (51:70) in the receiving ICU, both significantly higher for patients in capacity transfer. Proportions deceased after 30 days were 24% after repatriation, 21% after clinical, and 28% after capacity transfer. Using univariable logistic regression, days in the referring ICU, capacity transfer and SAPS3 in the receiving ICU were all associated with a higher risk of death at 30 days. In the multivariable logistic regression with adjustment for ICD-10 diagnosis and SMR in the receiving ICU, the OR for these predictors did not remain statistically significant.
**Conclusions:** For unit-to-unit inter-hospital intensive care transfers in Sweden, we did not find duration of intensive care before transfer, night-time transfer, transfer distance, or capacity transfer category to be statistically associated with an increased risk of death 30 days later. This suggests that inter-hospital transfer is safe to carry out at any time of day and over long distances.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000322

**Introduction:** Spinal cord injury induced by ischemia/reperfusion is a major complication of aortic repair surgery. Current treatment options for ischemia/reperfusion-induced spinal injury focus on optimizing macrohemodynamic variables 1. However, microcirculatory blood flow is essential for tissue oxygenation and organ function. Microcirculatory blood flow may be improved by fluid administration (2,3). It remains unknown whether albumin is superior to crystalloids for spinal cord microcirculatory blood flow during ischemia/reperfusion-induced spinal cord injury. We tested the hypothesis that fluid therapy with albumin compared to fluid therapy with crystalloids improves spinal cord microcirculatory blood flow in pigs with ischemia/reperfusion-induced spinal cord injury.
**Methods:** We conducted a randomized trial in 38 pigs with induced ischemia/reperfusion by supra-celiac aortic-cross-clamping. Pigs were randomized to receive either albumin or crystalloids. Spinal cord microcirculatory blood flow was measured using Laser-Doppler probes. The primary outcome was spinal cord microcirculatory blood flow 4.5 h after ischemia/reperfusion-induced spinal cord injury. Secondary outcomes included spinal cord tissue oxygenation, spinal cord function as assessed with somatosensory-evoked potentials (SEPs), and spinal cord histopathological damage including morphometric analysis of hypoxic marker (ferritin light chain). Additional outcome measures were macrohemodynamic variables.
**Results:** There were no important differences in spinal cord microcirculatory blood flow in pigs assigned to fluid therapy with albumin compared to pigs assigned to fluid therapy with crystalloids (327.2 (228.8–425.6) vs. 276.9 (178.5–375.3) arbitrary units, $p=0.476$). There were also no important differences in spinal cord tissue oxygenation (52.4 (39.4–65.5) vs. 44.0 (31.8–56.2) %, $p=0.349$) as well as somatosensory-evoked potential amplitudes (0.161 (0.082–0.241) vs. 0.167 (0.082–0.253) µV, $p=0.136$) and latencies (37.6 (32.9–42.4) vs. 40.2 (35.5–44.8) ms, $p=0.446$) of the tibial nerve between the groups. Neuropathological analysis of the spinal cord revealed no important difference between groups (2.69, [0.2–6.2] vs. 2.58 [0.3–7.2] hypoxic neurons $mm^{-2}$, $p=0.851$). In addition, morphometric analysis of ferritin light chain expression, a marker for hypoxia, did not show important differences between groups (0.50 vs. 0.48 positive pixel per region of interest (%); $p=0.863$). Macrohemodynamics including spinal cord perfusion pressure were better in pigs assigned to albumin therapy compared to crystalloid therapy.
**Conclusions:** Our model produced reliable ischemia with markedly reduced spinal cord microcirculatory blood flow, tissue oxygenation, and hypoxic changes. Fluid therapy with albumin compared to fluid therapy with crystalloids therapy did not improve spinal cord microcirculatory blood flow in pigs with ischemia/reperfusion-induced spinal cord injury.

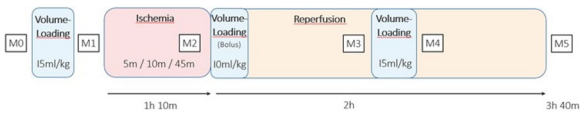

**Fig. 1 (abstract 000322)** Schematic of experimental protocol. Specimens received volume loading after baseline measurements. After another measure point ischemia was performed by supra-celiac aortic-cross-clamping with preconditioning. Measurements were taken at the end of the last clamping interval. A volume bolus was given when reperfusion was initiated. Two hours after reperfusion, another volume loading step was performed with measure points before and after. At the endpoint, 4, 5 h after the 45 m clamping interval, final measurements were taken

### Right heart function and not total ECMO blood flow or cannulation strategy determines blood recirculation in veno-venous ECMO: preliminary results of the 'ECMO Circulation trial'

N. Behnel, A. Dobbermann, K. Sascha, S. Weber-Carstens, B. Weiss, P. Pickerodt, M. Russ, V. Skrypnikov

**Introduction:** Veno-venous extracorporeal membrane oxygenation (VV-ECMO) can maintain systemic oxygenation when conservative therapy fails to support pulmonary gas exchange in patients suffering from acute respiratory distress syndrome (ARDS). A pathophysiological peculiarity of VV-ECMO is the partial recirculation of total ECMO blood flow, which is delivered through the return cannula, into the drainage cannula. This recirculation fraction (R*f*) does not contribute to systemic oxygenation and has to be subtracted from QB to determine the effective extracorporeal flow (QEFF; QEFF = QB x (1 − R*f*) (1). Total ECMO blood flow and cannula position are supposedly the main determinants for R*f* (1), but data from a pilot study suggest that right-ventricular dysfunction (RVD) may be more important (2). Thus, we tested the hypothesis whether RVD is the primary limiting factor for effective ECMO blood flow (QEFF) during VV ECMO therapy.
**Methods:** In an ongoing prospective clinical trial (ClinicalTrials.gov: NCT04754854, Charité ethics approval number: EA1/156/20), we measured R*f* in ARDS patients on VV ECMO with a saline ultrasound dilution technique (3). RVD was evaluated with transthoracic (TTE) or transesophageal echocardiography (TEE), while ECMO, and hemodynamic and ventilator parameters were recorded at the same time. The distance of the cannulae tips were measured using X-rays or CT scans.
**Results:** Data from 41 patients were included in this preliminary analysis (7 female (17%); 26 (63%) COVID-19 pneumonia, age: 53 ± 12.4 years, days on ECMO before measurements: 2.6 ± 2.4; PaO2/FIO2 before ECMO: 89.6 ± 70.7 mmHg; PaCO2 90 ± 43.2 mmHg; arterial pH 7.22 ± 0.11; number (percent) or mean ± SD). The mean QB was 3.8 ± 0.73 L/min with a mean R*f* of 9 ± 8.8% (QEFF 3.5 ± 0.72 L/min). There was not a relevant correlation between QB and R*f* (R 0.177, p = 0.29) or the distance between cannulae tips and R*f* (R 0.061, p = 0.75). QB and R*f* did not differ between cannulation types (30 femoral-jugular cannulations: QB 3.9 ± 0.76L/min, Rf 9n ± 7.8; 8 bi-femoral cannulations: QB 3.5 ± 0.61 L/min, Rf 11 ± 13.2; $p > 0.05$ for each; note 3 dual lumen cannulas: QB: 3,8, 2,9, 3,1 L/min, R*f* 1,3, 7,3, 0%). Echocardiographic signs of RVD4, especially a right-ventricular/left-ventricular diameter ratio (RVLV) ≥ 1 were observed in 12 patients (29%). R*f* correlated significantly with RV/LV (R 0.523, $p < 0.01$), especially in cases with R*f* > 0% (Fig. 1).
Of note, patients with observed RVD had a higher ICU mortality (7 dead, 58%) compared to patients without RVD (4 dead, 14%, $p < 0.01$, Chi square test).
**Conclusions:** Neither total ECMO blood flow nor cannulation strategy determined effective ECMO blood flow in our patients. Instead, right heart dysfunction was the primary limiting factor for effective ECMO blood flow. The higher ICU mortality of patients with RVD supports a rigorous monitoring of RVD and possibly R*f* during VV ECMO therapy.

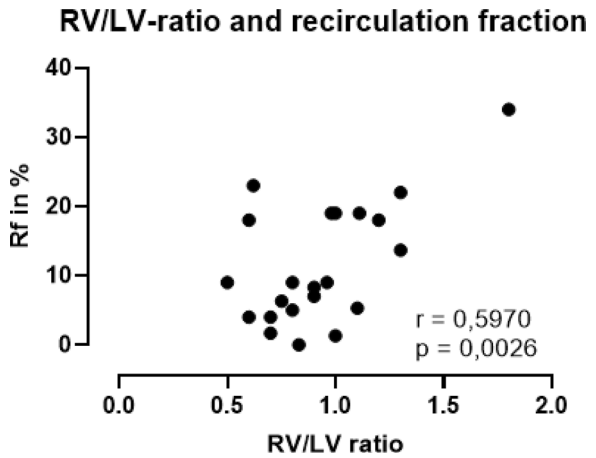

**Fig. 1 (abstract 000323)** Correlation between right-ventricular/left-ventricular diameter ratio (RV/LV) and the recirculation fraction (Rf) of total ECMO blood flow (QB) on veno-venous ECMO for patients with a Rf greater 0; *r* = Pearson correlation coefficient. QB was 3.8 ± 0.78 L/min, Rf 12 ± 8.4%, resulting effective ECMO blood flow (QEFF) 3.3 ± 0.72 L/min for the respective patients

### Correlation of optical sensor capillary refill time with near-infrared spectroscopy vascular occlusion test variables in healthy volunteers, a validation study

K. kittirukwarakorn, P. Theerawit
Medicine, Ramathibodi Hospital, Bangkok, Thailand
**Correspondence:** K. kittirukwarakorn
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):000324**

**Introduction:** Shock is a life-threatening condition with persistent microcirculatory dysfunction despite receiving standard treatment. Capillary refill time (CRT) is a simple tool for assessing peripheral perfusion, but the conventional measurement using the glass slide technique is subjective. A prototype model of an electronic optical device has been developed for CRT assessment, which detects skin color changes with an RGB sensor. This technique offers a more objective approach compared to the conventional method.
**Objectives:** This study aimed to validate the accuracy and reliability of a prototype CRT measurement model in comparison to the glass slide and NIRS with VOT techniques.
**Methods:** In this prospective observational study of 50 healthy volunteers, we compared capillary refill time (CRT) using a conventional method (glass slide compression) with a prototype device (optical RGB sensor, pressure cuff, software analysis). Bilateral measurements were taken on the index fingers. Near-infrared spectroscopy vascular occlusion test (NIRS-VOT) on the thenar eminence was employed to obtain tissue oxygen saturation (StO2) variables. Correlations between CRT methods and NIRS-VOT were analyzed.
**Results:** The prototype device demonstrated good reliability with high intra-rater reliability for repeated measurements on the same hand side ($p$ value > 0.05 for both left and right hand). Strong positive correlation was observed between left and right hand measurements (Pearson $r = 0.7924$, $p$ value < 0.001). Additionally, the device showed a strong negative correlation with StO2 recovery slope (Pearson $r = -0.5011$, $p$ value < 0.001), supporting its validity. This correlation with StO2 was significantly stronger compared to the conventional glass slide method.
**Conclusions:** This study validates a novel optical electronic device for measuring capillary refill time (CRT). The device demonstrates good reliability and offers a more accurate assessment of CRT compared to the conventional glass slide method. This aligns with our findings of a strong negative correlation between the device's CRT measurements and the StO2 recovery slope, supporting its validity. Future studies should investigate the device's performance in clinical settings, particularly in shock patients, where accurate CRT assessment is critical for patient care.

**Correspondence:** M. Young
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000326

**Introduction:** At sub-anaesthetic or low-dose levels, ketamine is a potential analgesic drug in critically ill patients. Although there is no consensus on the precise definition of a "low dose", infusion rates ranging from 0.15 to 0.5 mg/kg/h are commonly reported. Despite prior studies suggesting the possibility of an association between low-dose ketamine (LDK) and hallucinations in critically ill patients, a comprehensive study of this association has not been undertaken. In part, this is because the design of a large prospective study would be too complex due to the contemporaneous reporting requirements of hallucinatory incidents. Moreover, retrospective studies would be marred by recall bias. We hypothesised that bedside care givers would document hallucinatory incidents in the electronic clinical progress notes of critically ill patients. Further, we hypothesised that we could search these notes using natural language processing (NLP) techniques to identify patients who had experienced hallucinations during their critical care stay. In addition, we hypothesised that NLP could also be used to identify patients experiencing hyperactive or hypoactive disturbed behaviour. Finally, we hypothesised that we could use medication records of ketamine administration in these patients to study the association between LDK, hallucinations, and the phenotypes of disturbed behaviour.
**Objectives:** To study the association between LDK, hallucinations, and the phenotypes of disturbed behaviour in critically ill patients.
**Methods:** We obtained demographic data, medication records, outcomes, and electronic clinical progress notes for a cohort of critically ill patients. Using a previously validated NLP methodology, we scanned the notes for words that indicate a patient may have experienced hallucinations. We also scanned the notes for words that indicate a patient may have experienced hyperactive or hypoactive disturbed behaviour.
**Results:** We studied 7525 patients. We found that patients being treated with LDK were infused at an average rate of 0.11 (0.08–0.15) mg/kg/hour. We also found patients receiving LDK were younger (58.9 years vs 64.3, $p < 0.001$), had lower APACHE III scores (42.0 vs 48.0, $p < 0.001$), and were more likely to be admitted for surgical reasons (74.2% vs 46.5%, $p < 0.001$). Furthermore, these patients were less likely to be admitted with a diagnosis of cardiovascular disease (26.7% vs 33.7%, $p < 0.001$) and more likely to be admitted with a diagnosis of gastrointestinal disease (31.8% vs 15.7%, $p < 0.001$) disease or metastatic cancer (7.4% vs 4.1%, $p < 0.001$). Significantly, patients who received LDK were more likely to be identified by NLP as having experienced hallucinations (25.9%vs 6.6%, $p < 0.001$) and disturbed behaviour (63.5% vs 50.5%, $p < 0.001$). Finally, we found that LDK patients were more likely to be identified by NLP as having hypoactive disturbed behaviour when compared with patients not receiving LDK (51.8% vs 39.3%, $p < 0.001$).
**Conclusions:** Hallucinations are common in critically ill patients treated with LDK. Further, these patients are also likely to experience hypoactive phenotype of NLP diagnosed disturbed behaviour and, thus, likely delirium. Further investigation of these associations appears justified.

### Nationwide study on prescribing pattern of antibiotics in patients suffering from hospital-acquired infections

P. Mathur, R. Singal, S. Mitra
Medical Affairs, Mankind Pharma Limited, New Delhi, India
**Correspondence:** P. Mathur
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000327

**Introduction:** Worldwide hospital-acquired infections (HAI) pose a AQ5 significant challenge to healthcare systems, contributing to increased morbidity, mortality, and healthcare costs. Most importantly, the emergence of antibiotic-resistant bacteria within hospital settings due to extensive antibiotic use, and the risk of cross-infections among high-density patient populations, especially in intensive care units (ICUs) are of particular concern.
**Objectives:** The objective of this study was to assess the prevalence of HAI, microbial aetiology, prescribing patterns of antibiotics in patients suffering from HAI within the Indian healthcare facilities and to contribute valuable insights to the global effort to fight against antibiotic resistance.
**Methods:** A questionnaire was distributed to healthcare providers managing HAI across diverse healthcare facilities in India. Participants were recruited using stratified random sampling, ensuring representation from various settings. Data were collected through offline surveys or in-person interviews, with responses anonymized.
**Results:** As per the study data, the overall prevalence of Extended Spectrum Beta Lactamases producers was 15–20% of the total HAI infections, as stated by > 34% of the respondents. Amongst the risk factors, major contribution was from longer hospital stays (81%), followed by surgical procedures (28%). Pneumonia (51%) represented the commonest type of hospital-acquired infection followed by urinary tract infections (46%). Amongst the organisms, Klebsiella reported to be majorly responsible for HAI by around 60% of the participants followed by *E. coli* (53%) and STAPHYLOCOCCUS AUREUS by > 23% of the doctors, respectively. When asked the preferred Agent to combat HAI, Piperacillin–Tazobactam was suggested by > 78% of the healthcare practitioners, for Multi-drug Resistant infections > 64% of the participants preferred Aztreonam due to its superior efficacy. Moreover, Aztreonam is also preferred by > 31% of the respondents in patients who are allergic to beta-lactam antibiotics.
**Conclusions:** In conclusion, this survey highlights the complex nature of antibiotic prescribing in the context of HAI and emphasizes the importance of evidence-based practices, infection control measures, and antimicrobial management efforts in mitigating the impact of HAI and addressing antibiotic resistance. This study provides a baseline for the antimicrobial prescribing pattern in Indian Healthcare Setting

and results may guide in the development of prescribing guidelines, monitoring of drug resistance patterns in future.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000328

**Introduction:** Selective digestive decontamination (SDD) has been associated with a reduction in mortality and ICU-acquired infection (NI) rates. However, the effect SDD in areas where multidrug-resistant Gram-negative bacteria (MRGNB) are endemic is of great interest.
**Objectives:** To analyze the impact on MRGNB NI, antibiotic consumption, and colistin and tobramycin colonization in patients with NI in an ICU after 12 years of SDD.
**Methods:** This study was conducted in a 30-bed-medical-surgical ICU. All consecutive patients admitted to the ICU between October 1, 2011, and September 30, 2023, who were expected to require tracheal intubation > 48 h were administered SDD (SDD study group) with a 4-day course of intravenous cefotaxime plus enteral colistin, tobramycin, nystatin in an oropharyngeal paste, and digestive solution. Oropharyngeal and rectal swabs were obtained on admission and once a week. We used ENVIN NI criteria. All patients admitted to ICU with NI in ICU between October 1, 2010, and September 30, 2011 (non-SDD group) were compared with the SDD study group. A univariate and a multivariate logistic regression analysis were performed. For each of the NIs, incidences per 1000 days of exposure in each cohort and the corresponding relative risks were obtained using Poisson regression. Statistical significance was $p \leq 0.05$. Colistin- and tobramycin-resistant colonization and antibiotic consumption as defined daily doses of antibiotics (DDD) were also analyzed.
**Results:** A total of 13,383 patients were admitted to ICU. We analyzed patients who developed NI, and 856 of them received SDD. There were no statistically significant differences between the two groups in terms of admission type or demographics. SDD patients had significantly fewer Extended Spectrum Beta-lactamase (ESBL) infections $p = 0.016$, Gram Negative Multidrug Resistant Bacteria (GNB-MR) $p = 0.004$ (Table 1), and *Acinetobacter* spp. infections $p < 0.001$ (Table 2). There was also a significant reduction in the rates of ventilator-associated pneumonia (VAP), urinary tract infections, other secondary bacteremia, and multidrug-resistant bacteria infections (MR-GNB) in the SDD group versus the non-SDD group (Table 3). There was one *Clostridioides difficile* infection. Colistin-resistant colonization was 17.8% and tobramycin-resistant colonization was 24.8% of samples. There was a decrease in DDD/100 ICU stays after SDD.
**Conclusions:** After 12 years of SDD application, there was a significant reduction in ESB, GNB-MR, and *Acinetobacter* infections, as well as rates of VAP, secondary bacteremia, urinary tract infections, and MDRBI. There was a decrease in antibiotic consumption after SDD. Low rates of colonization by colistin- and tobramycin-resistant bacteria were also observed.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000329

**Introduction:** This study aims to assess the ability of clinical examination, biomarker, electrophysiology, or brain imaging and their combination to predict good neurological outcomes at 6 months after CA.
**Methods:** This was a retrospective analysis of the Korean Hypothermia Network Prospective Registry 1.0. Good outcome predictors were defined as both pupillary light reflex (PLR) and corneal reflex (CR) were presented at admission, Glasgow Coma Scale Motor score (GCS-M) > 3 at admission, neuron-specific enolase (NSE) < 17 μg/L at 24–72 h, a median nerve somatosensory-evoked potentials (SSEPs) N20/P25 amplitude > 4 μV, continuous background without discharges on electroencephalogram (EEG), and absence of anoxic injury on brain CT and DWI.
**Results:** A total of 1327 subjects were included in the final analysis. Of those, 412 subjects had a good neurological outcome at 6 months after CA. GCS-M > 3 at admission had a highest specificity of 96.7% (95% CI 95.3–97.8) and normal brain DWI had a highest sensitivity of 96.3% (95% CI 92.9–98.4). When combining two predictors, the sensitivities tended to decrease (ranged 2.7–81.1%), and the specificities tended to increase ranged 81.3–100%. Normal brain CT and DWI had the highest sensitivity of 81.1%. Through the explorative variation of the 2021 European Resuscitation Council (ERC) and the European Society of Intensive Care Medicine (ESICM) prognostication strategy algorithm, good outcome was predicted with the specificities ranged 47.5–54.6% and sensitivities ranged 84.4–88.4% in patients not predicted by the algorithm.
**Conclusions:** Clinical examination, biomarker, electrophysiology, and brain imaging could predict good outcomes at 6 months after CA. When combining two predictors, specificity was further improved. With the 2021 ERC/ESICM guidelines, good outcome prediction might reduce the number of indeterminate patients and uncertainty of prognostication.

**Introduction:** Recognition of risk factors for mortality and early intervention with appropriate administration of broad-spectrum antimicrobials in patients with nosocomial infection (NI) can significantly improve outcomes. Selective digestive decontamination (SDD) has been associated with reduced ICU mortality and acquired infection rates.
**Objectives:** To analyze the risk factors for mortality in patients with NI in an ICU after 12 years of SDD.
**Methods:** Patients with NI from October 1, 2010 to September 30, 2023 in a 30-bed polyvalent ICU were prospectively included. The SDD was applied for 12 years, from October 1, 2011 to September 30, 2023. Patients who required mechanical ventilation for more than 48 h were

given an enteral solution and a paste containing colistin, tobramycin, and nystatin every 8 h until discharge. Intravenous cefotaxime was also administered during the first 4 days. Rectal and pharyngeal exudates were collected on admission and weekly. ENVIN NI criteria were used. Categorical variables were summarized as frequencies and percentages and numerical variables as means and standard deviations or medians and interquartile ranges. Percentages were compared with the X2 test or Fisher's exact test, means with the t test and medians with the Wilcoxon test for independent data. A multidimensional logistic analysis was performed. It was considered significant if $p \leq 0.05$.

**Results:** Of the 13,383 patients admitted, 337 (34.88%) of the patients with NI died. In a univariate analysis, no statistically significant differences in ICU stay were found ($p = 0.059$). Multidrug-resistant (MR) *Pseudomonas* and MR Gram-negative bacteria (GNB) were significantly higher in patients who died (Table 1). Independent mortality risk factors were: renal replacement therapy Odds Ratio (OR): 4.460 (3.276; 6.074), neoplasm OR: 2.480 (1.512; 4.068), ventilator-associated pneumonia (VAP): 1.859 (1.342; 2.576), parenteral nutrition OR: 1.856 (1.290; 2.672), chronic obstructive pulmonary disease (COPD) OR: 1.749 (1.168; 2.617)), septic shock OR: 1.887 (1.376; 2.587), and APACHE II OR: 1.053 (1.031; 1.075) (Table 2).

**Conclusions:** In an ICU with long-term SDD application, the factors that were independently associated with mortality were: renal replacement therapy, neoplasm, VAP, parenteral nutrition, COPD, septic shock, and APACHE II. *MRs Pseudomonas* and MRs GNB also had significantly higher mortality.

## The scope of practice of the intensive care unit dietitian in personalizing nutritional care

L. de Hart, L. Buyle[1], C. Verhelst[1], E. De Waele[1]
Clinical Nutrition and Dietetics, UZ Brussel, Jette, Belgium
**Correspondence:** L. de Hart
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000332

**Introduction:** The scope of practice of the intensive care unit (ICU) dietitian (RD) has evolved over time; an increase involvement during multi-professional team (MPT) meetings, ward rounds and during critical decision-making, significantly improves the adherence of the patient to the nutrition care plan and nutritional support provided by the MPT (1, 2).

An ICU RD can improve the clinical outcome of a critically ill patient by shortening the length of stay with a trend towards lower mortality (3).

Population specific guidance is available for the ICU RD to refer to when creating a nutritional care plan, such as the ESICM, ESPEN, and ASPEN guidelines (4–6).

**Methods:** We evaluated and described the scope of practice of the ICU RD at different levels of healthcare and compared it to literature in addressing the nutritional needs of critically ill patients.

**Results:** The scope of practice of the ICU RD is summarized in Table 1.

**Table 1 (abstract 000332)**

| Level of health-care | Scope of practice |
|---|---|
| Micro | • Assessment of the patient and formulating the nutritional care plan:<br>• Evaluating current diagnoses and pre-existing conditions<br>• Anthropometry: Monitoring of weight, height, BMI, energy expenditure by indirect calorimetry, body composition<br>• Biochemistry and histology: Refeeding hypophosphatemia and -risk, electrolyte imbalance, septic markers, liver- and kidney function, protein metabolism, blood gasses<br>• Clinical signs: Assessing for micronutrient deficiencies<br>• Diet History: Identifying the appropriate route of feeding and the optimal feed, observing for gastro-intestinal intolerance, evaluating intentional and unintentional calories prescribed and received during the previous 24 h, speech therapy referral for texture modification<br>• Medication or medical treatments: Use of inotropes, vasopressors, sedatives, analgesic opioids, continues renal replacement therapy<br>• Identifying biological barriers to nutrition intake: Physiological (such as loss of appetite), psychological (such as depression), or functional (such as dysphagia)<br>• Facilitating the transition of nutritional management from ICU to the ward |
| Meso | • MDT discussion of difficult cases<br>• Identifying non-biological barriers to nutrition intake: organizational (such as missed meals due to medical procedures) and healthcare provider knowledge of the importance of nutrition<br>• Keeping up to date with scientific literature and continuing professional development through attending courses, congresses, or workshops |
| Macro | • Implementation, development or adaption of nutritional guidelines, protocols, improvement projects, and standard operating procedures<br>• Participation in scientific research and transfer of knowledge by training of dietitians and other colleagues |

**Conclusions:** The role of the modern, upskilled ICU dietitian encompasses different levels of expertise, which facilitates better nutritional care and outcomes of patients in a MPT ICU setting.

**Topic:** Metabolism, endocrinology, liver failure, and nutrition

**Introduction:** Second-level therapeutic actions to control intracranial hypertension (ICH) proposed by the European Brain Trauma Foundation include barbiturates, moderate hypothermia, and decompressive craniectomy (DC), but the results are controversial. Our aim was to evaluate factors associated with disability and mortality after ICU discharge in patients undergoing DC.
**Objectives:** To evaluate factors associated with disability and mortality, after ICU discharge, in patients with DC after 10 years.
**Methods:** Prospective study of patients admitted between January 1, 2013 and December 1, 2023 who required DC. The DC was performed for ICH refractory to medical treatment. The following were analyzed: main admission diagnosis; demographic data; neurological data (clinical examination and Glasgow Coma Score: GCS); hypotension; type of craniectomy and DC complications; Rankin scale and Glasgow Outcome Scale (GOS) at 30 and 60 days after ICU admission, at ICU discharge and 6 months after ICU discharge; preoperative serum lactate levels; hypo- and hyperglycemia; application of mannitol or hypertonic saline before and after DC; leukocytes and platelets before and after DC and other factors related to prognosis. Univariate analysis was performed for disability (Rankin > 3) and ICU mortality, 60 days after ICU admission and 6 months after ICU discharge. Statistical significance was set at $p \leq 0.05$. Data were analyzed using the R package version 4.2.1 (R Development Core Team, 2022).
**Results:** Sixty-one patients with CHD were analyzed. The majority. 26 (42.6%) were traumatic brain injury (TBI) and 9 (14.7%) patients with traumatic subarachnoid hemorrhage (SAH). There were 17 (27.8%) spontaneous SAH with DC. The most frequent complications were hydrocephalus 25 (41.7%) and need for reintervention 18 (31.6% of them). Demographic data and types of admission are shown in Table 1. Fourteen patients died upon discharge from the ICU (23.3%), 3 of them were SAH. Of the 26 (42.6%) patients with TBI and DC, 11 (42.3%) died, and 7 (26.92%) of them in the ICU. The median Rankin at ICU discharge was 5 (4–5) and the GOS was 3 (2–3). Rankin at 6 months after discharge from the ICU was 5 (3–6) and the GOS was 3 (1–4). Disability at 6 months after discharge from the ICU was significantly associated with platelet number before DC (Table 1). In the analysis of mortality after discharge from the ICU or months after discharge, we did not obtain other significantly associated risk factors (Table 2).
**Conclusions:** Mortality in patients with DC was 23.3% at ICU discharge of all patients. Patients with TBI and DC had a mortality of 26.92% at ICU discharge. The median Rankin and GOS scales reflect moderately severe disability in our DC patients at ICU discharge and 6 months later. Disability at ICU discharge was significantly associated with the number of platelets before DC.

**Introduction:** It is hypothesized that P-SILI is associated with patient effort in mechanical ventilation (Carteaux, 2021). It is, however, not easy to estimate patient effort. Direct measurement of parameters such as work of breathing (WOB) and pressure time product (PTP), requires the use of an esophageal catheter (Jubran 2005, Pham 2020), an invasive procedure that may not be suitable for all Intensive Care Unit (ICU) patients (Pham 2020). A surrogate measure for breathing effort is the P0.1, which measures the airway pressure during the first 0.1 s of inspiration during an occlusion manouver (Whitelaw 1975). The P0.1 showed an association with lung stress and diaphragm effort in the preceding hour (de Vries 2023). However, in a systematic review, Sato et al. could not define a definitive threshold differentiating between low and high effort because of study heterogeneity (Sato 2021). There still exists a lot of controversy about the exact correlation of the P0.1, patient effort, and its usefulness in estimating weaning failure or success. It would be of interest to study the correlation between the P0.1, the WOB and the PTP as measures of effort.
**Objectives:** This study aims to investigate whether there is a correlation between WOB, PTP, and P0.1 in mechanically ventilated ICU patients.
**Methods:** Data from two single-center prospective observational studies currently conducted in the Netherlands on the ICU of the LUMC (P23.068 and 2022–061) were utilized. The studies included patients who were subjected to mechanical ventilation and were breathing spontaneously with an esophageal balloon catheter in situ. We used the internal P0.1 value of the Hamilton C6 ventilator, which uses a quasi-occlusion method, together with the Pes signal from which we calculated the WOB and PTP. Three random minutes were sampled per patient and means were calculated thereof for each parameter. Statistical analysis was performed in R-studio version 4.1.3. A $p$ value < 0.05 was assumed to be significant.
**Results:** A total of 32 patients were included, resulting in 96 samples of 1 min. Mean value distribution was not normal and could not be log-normalized. Median of the mean values were as follows: P0.1, 4.2 cmH2O (IQR 1.6–6.3); WOB 4.5 J/min (IQR 2.7–7.1); PTP 73.3 cmH2O*s/min (IQR 45.1–97.7). Spearman's rank correlation coefficient was used to assess the correlation because of a non-normal distribution.
The correlations between P0.1 and WOB (Spearman $R^2 = 0.1786$, $p$-value < 0.001), and between P0.1 and PTP (Spearman $R^2 = 0.2538$, $p$ value < 0.001) were poor (Figures 1 and 2), while there was a good correlation between WOB and PTP (Spearman $R^2 = 0.8275$, $p$ value < 0.001) (Figure 3).
**Conclusions:** The observed low correlation between P0.1 and WOB/PTP suggests caution in using P0.1 as a surrogate for estimating effort in mechanically ventilated ICU patients.
The quasi-occlusion method of the Hamilton C6 used to determine P0.1 values might have influenced our results (Takane 2022).
Further research is necessary to investigate alternative measures or to refine methodologies for assessing respiratory effort in this population.

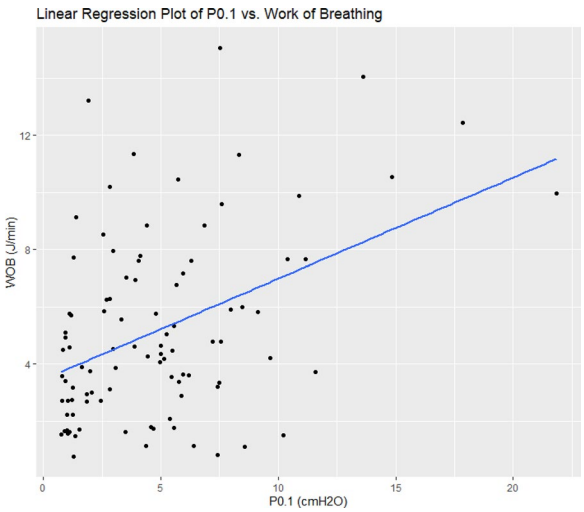

**Fig. 1 (abstract 000334)** Linear regression plot of the P0.1 (cmH2O) values compared to the work of breathing (J/min), Spearman R^2 = 0.1786, $p$ value < 0.001

**Introduction:** Mechanical ventilation does not work exactly like normal physiologic lungs, which can potentially lead to ventilator-induced lung injury (VILI). In VILI, various intracellular mediators are released and it may increase pendrin expression. Pendrin (SLC26A4) is a transmembrane anion exchanger that exchanges chloride with bicarbonate and iodide. Bronchial epithelial expression of pendrin is increased in a wide spectrum of airway inflammatory conditions. In this study, we analyzed the role of pendrin and the effectiveness of pendrin inhibitor (YS-01) in VILI.
**Methods:** We induced lung damage by applying a high tidal volume (HTV) of 30 ml/kg with a frequency of 100 breaths/min for 5 h in pendrin wild-type (WT) with or without pendrin inhibitor YS-01, as well as in pendrin-knockout (KO) 129SVEV mice in the supine or prone position. We used bronchoalveolar lavage fluid (BALF) analysis, inflammatory cytokine analysis, and a lung injury score to determine the extent of the damage. Pendrin expression was confirmed using western blotting, immunofluorescence (IF) staining, and transmission electron microscopy (TEM) with immunogold labeling Methods:
**Results:** In pendrin WT mice after HTV ventilation, the total cell count in BALF, lung injury score, and inflammatory cytokines, such as TNF-alpha, MIP-2, and IL-1 beta, were increased. However, in pendrin-KO mice, the total cell count, lung injury score, and inflammatory cytokines were decreased. In addition, those of WT mice in prone position also were decreased. When WT mice in supine position were administered YS-01, the total cell count in BALF were significantly decreased compared to those of WT mice in supine position (Figures 1, 2). Also, lung injury score and inflammatory cytokines of WT mice with YS-01 in supine position were decreased compared to those of WT mice in supine position and even in prone position (Figure 3).
**Conclusions:** We infer that pendrin plays a key role in VILI and pendrin inhibitor can improve lung injury in VILI. In addition, considering that pendrin inhibitor is superior to prone position in inflammatory cytokines level, pendrin inhibitor has the potential to act as effective treatment in VILI.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000336

**Introduction:** Approximately 20% of patients with aneurysmal subarachnoid hemorrhage (SAH) suffer delayed cerebral ischemia (DCI), which represents the main cause of death and treatable disability in these patients. Several studies have proposed markers to predict this complication. Numerous radiological risk scales have been developed, although their predictive capacity has been poorly studied and compared.

**Objectives:** To prospectively assess risk factors for DCI in patients with SAH admitted to a neurotraumatic ICU.

**Methods:** Prospectively collected data of patients admitted from October 2013 to December 2023 to a 10-bed Neurotraumatic ICU. We analyzed: main diagnosis at admission; demographics, including sex and race; neurological data (clinical examination, pupil reactivity and size, and Glasgow Coma Score: GCS; aneurysm localization and size; presence of intracranial hematoma (ICH); presence and volume of intraventricular bleeding; days to develop vasospasm; development of DCI; Fisher scale, Modified Fisher Scale (MFS), Hunt and Hess scale (HHS), Word Federation of Neurosurgeons scale (WFNS); presence of

vasospasm in Doppler or arteriography; delayed ICU admission; aneurysm treatment; complications, including infections; Glasgow Outcome Scale (GOS) at ICU discharge and 6 months after ICU discharge and several other risk factors. A univariate analysis of DCI was performed. The variables that showed significant association in univariate analysis were entered into the multivariate logistic regression analysis. To obtain a DCI prediction rule, a prediction model was obtained using the classification and regression trees (CART) procedure [1]. CART classifies data using a sequence of if–then rules. The basis of decision tree algorithms is the recursive binary partitioning of the data. First, the most discriminative variable is selected to split the data set into child nodes. The partitioning continues until some stopping criterion is reached. At each terminal node, the probability of DCI was estimated as the proportion of patients belonging to that node who developed the event. The tree was constructed according to the following algorithm: in the first stage, the tree grows until all cases are correctly classified, and in the second stage, we used the tenfold cross-validation method of successive pruning [1]. Finally, the tree that minimized the error measurement (deviance) was chosen. For this predictor, the corresponding ROC curve was obtained, and the AUC was estimated using a 95% CI. Data were analyzed using the R package, version 4.2.1 (R Development Core Team, 2022).

**Results:** A total of 278 patients with SAH were collected, of whom 64 (23, 0.02%) developed DCI. Demographic data and types of admission are shown in Table 1a and 1b. Anterior communicating artery (Aco) aneurysms were the most frequently encountered. The most frequent complications of patients with DCI were stroke 46 (71.9%) and hydrocephalus 34 (53.1%). Thirty-eight (13.7) (14. 6%) of the patients with SAH died at ICU discharge. Twelve (18.8%) of the patients with SAH and DCI died at ICU discharge. There was no statistically significant difference in mortality in patients with DCI vs. patients with SAH (Table 1a and 1b). The oriented patient was statistically independent associated with DCI in the multivariate logistic regression analysis (Table 2).The classification tree showed that: MFS $\leq 2$ had 93.5% odds of no DCI (Figure 1). The AUC was 0.671 (0. 609–0.732) (Figure 2).

**Conclusions:** Our data show that 23.02% of the patients studied had DCI. The oriented patient was statistically independent associated with DCI. The classification tree showed a high negative predictive value for DCI. Finally, mortality was not significantly higher in the patients studied than in the total patients with SAH.

**Introduction:** The Venous Excess UltraSound (VExUS) score is a promising tool to quantify venous congestion and has been validated in patients after cardiac surgery (1). There are several studies investigating its use in the Intensive Care Unit (ICU) (2, 3). However, the interrater and intrarater agreement of the VExUS score in critically ill patients is unknown.

**Objectives:** This study aims to evaluate the agreement of the VExUS score in critically ill patients.

**Methods:** This is a prospective cohort study conducted in a tertiary ICU in the Netherlands. Patients above 18 years of age and expected to be in the ICU for over 24 h were eligible. Interrater and intrarater agreements were assessed for VExUS score interpretation. Intrarater agreement was also assessed for VExUS acquisition. Raters were blinded to each other's interpretation and acquisition. Cohen's kappa coefficient and percentage agreement were used to determine agreement.

**Results:** Interrater interpretation was assessed by scoring 75 VExUS images by two independent raters and demonstrated a substantial agreement (kappa = 0.8, agreement = 86.7%). For intrarater interpretation, 75 VExUS images were scored twice and showed a good agreement (kappa = 0.9, agreement = 93.3%). For interrater acquisition, in 12 patients, images were acquired by two raters. A moderate interrater agreement was observed (kappa = 0.6, agreement = 83.3%). This moderate agreement was largely explained by the influence of the inferior vena cava measurement on the overall VExUS score.

**Conclusions:** In critically ill patients, agreement for interpretation and acquisition of the VExUS score is substantial to moderate. The vena cava measurement impacted VExUS score agreement the most, rendering the VExUS score agreement vulnerable to this influence. Nevertheless, the VExUS score appears to be reliable with a substantial agreement between and within observers.

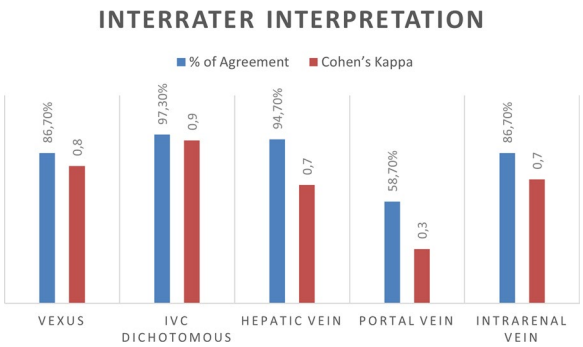

**Fig. 1 (abstract 000338)** Percentage of agreement and Cohen's Kappa of the VExUS score and individual components for interrater interpretation. IVC = inferior vena cava

**Introduction:** Seizures represent a significant complication among critically ill patients, particularly prevalent in those receiving neurocritical care. In efforts to mitigate this risk, anti-epileptic medications are commonly employed for seizure prophylaxis in various acute neurological insults, such as traumatic brain injury (TBI), epidural hematoma (EDH), subdural hematoma (SDH), subarachnoid hemorrhage (SAH), and intracerebral hemorrhage (ICH).Levetiracetam (LEV), has been increasingly used as seizure prophylaxis in several critical care conditions. However, multiple studies have shown diversity in the best LEV dosage approach for seizure prophylaxis.
**Objectives:** The objective of this study is to compare the effectiveness of a non-loading dosage strategy with an LEV loading dose strategy for seizure prophylaxis in neurocritical care patients.
**Methods:** A retrospective cohort study conducted across multiple centers, including adults (over 18 years old) who were admitted to intensive care units and received levetiracetam as prophylaxis at two tertiary hospitals in Saudi Arabia between January 1, 2018, and December 31, 2022. Eligible patients were categorized into two groups based on levetiracetam loading dose use (non-loading vs loading dose). Patients were excluded if they received levetiracetam for treatment indication. The primary endpoint was an early onset of seizure which is defined as the onset of seizure within 7 days. While a late onset of seizure during ICU stay, recurrent seizure during ICU stay, the need for additional antiepileptic medication, ICU, and hospital length of stay, 30-day mortality and in hospital mortality were secondary endpoints. The multivariable linear and logistic regression analysis were employed as applicable. The study was approved by the research ethics committee with reference number (HA-02-J-008).
**Results:** A total of 1116 patients were screened for eligibility. Among them, 208 patients were included based on the eligibility criteria. 65 patients received LEV loading dose and 143 patients did not receive loading dose. The majority of baseline characteristics were balanced except for subdural hemorrhage and TBI. Compared to the loading dose group, the non-loading dose group had a higher incidence of early seizure onset, but the difference was not statistically significant (14.2% vs. 7.7%; OR: 0.46, 95% CI 0.16, 1.41; $p = 0.18$). Furthermore, there were no significant differences in the ICU length of stay between the two groups in the univariate analysis (9 vs. 6 days; $p = 0.49$). However, after linear regression, the ICU LOS was significantly longer in the LEV loading dose group (beta coefficient: 11.22, 95% CI 1.71, 20.73; $p = 0.02$). Additionally, the 30-day and in-hospital mortality rates, recurrent seizures during the ICU stay, late onset of seizures, and the need for additional antiepileptic medication were all not statistically significant.
**Conclusions:** Levetiracetam loading dose approach for prophylaxis in neurocritical patients was not associated with a lower incidence of early or late onset of seizure during ICU stay. Further studies with larger sample sizes are needed.

**Correspondence:** C. Hui-chuan
*Intensive Care Medicine Experimental* 2024, **12(suppl 1):**000340

**Introduction:** High-flow nasal cannula (HFNC) is commonly employed in hypoxemic patients and is gradually being utilized in post-extubation patients experiencing hypoxemia after surgical procedures [1–3]. While HFNC can serve as a successful oxygen delivery device, it may also prolong patients' stay in the intensive care unit, leading to the misallocation of healthcare resources [4]. On the other hand, there is an expectation that non-invasive physiological assessments to supplant invasive evaluations, Monitoring SpO2 and HR predicts HFNC weaning success, aiding treatment plan adjustments [5]. Monitoring

physiological data changes in real time enables continuous assessment, facilitating optimal prediction for liberation from HFNC.

**Objectives:** The aim of this study is to substantiate and attempt to establish a set of vital sign changes during HFNC use, further predicting the success of liberation from high-flow cannula. This provides a reference framework for future clinical respiratory care practices.

**Methods:** Using retrospective observations, we analyzed the changes in vital signs before and after the use of High-Flow Nasal Cannula (HFNC) in patients experiencing post-surgical extubation due to hypoxemia. We aimed to predict the success of weaning from HFNC. A total of 90 patients were included in the study, and their vital signs, including respiratory rate (RR), heart rate (HR), mean blood pressure (MAP), oxygen saturation (SpO2), and respiratory rate oxygenation index (ROX), were analyzed individually. Based on these changes, predictions were made regarding the success or failure of HFNC weaning. Subsequently, in validation group, 92 patients who underwent post-surgical extubation and were administered HFNC, the observation aimed to determine whether there was concordance between the variability of vital signs before and after using HFNC and the study group.

**Results:** HFNC weaning success in study group vs. in the validation group: SpO2 exhibited a significant increase of 4.21 vs. 0.76, while RR significant decrease by 2.2 vs. 0.9. HR variability significantly decreased (7.55; 1.65), the ROX index increased by 1.13 vs. 1.01. The duration of HFNC use was 5.08 days vs. 6.47. Finally, we conducted the standard error of the forecast, and the variability of each vital sign, all within the 95% confidence interval.

**Conclusions:** The variability of SpO2, RR, HR, ROX, and HFNC days remained consistent between the validation and study groups, with the numerical changes in the validation group showing a narrower range than those in the study group. These factors serve as predictive indicators for successful HFNC weaning in cases of hypoxemic respiratory failure post-surgery. Additionally, delays in intubation may exacerbate the disease course [6], highlighting the importance of careful decision-making regarding the timing of HFNC use and discontinuation.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000341

**Introduction:** Abdominal muscles are crucial for an effective cough, which is a key factor in the success of weaning from mechanical ventilation. Cumulated abdominal muscle thickness has been correlated with expiratory pressures required to generate cough.
**Objectives:** This study aimed to evaluate by ultrasound the variations of abdominal muscle and diaphragm thickness after 7 days of mechanical ventilation. Secondary objectives were to identify factors associated with the variations of abdominal muscle thickness, to compare the variation of abdominal muscle and diaphragm thickness, and to evaluate the relation at day 7 between abdominal muscle thickness and either maximal expiratory pressure (MEP) or peak cough expiratory flow (PCEF).
**Methods:** Patients were included if intubated for less than 24 h and deemed to be on mechanical ventilation for at least 7 days. The thickness of the following muscles was measured by ultrasound, at the same location and standardized, at day 1 and 7: rectus abdominis, external oblique, internal oblique, transversus abdominis, and diaphragm. The main evaluation criteria were the cumulated thickness of the four abdominal muscles. The patients were assigned to the *decrease* group if muscle thickness decreased by more than 10% from day 1 to day 7, to the *increase* group if thickness increased by more than 10%, and to the *no change* group if the variation was less than 10% in either direction.
**Results:** 40 patients were included, and 31 of them were still on mechanical ventilation at day 7 and then kept for the analysis. The thickness of each muscle at days 1 and 7 is depicted in Table 1. Median cumulated thickness of abdominal muscles was 17.9 mm [IQR 15.5–21.8] at day 1 and 18.8 mm [IQR 14.9–21] at day 7 ($p = 0.44$). The cumulated thickness at day 7 decreased by more than 10% in 6/31 (19%), remained stable in 20/31 (65%) and increased by more than 10% in 5/31 (16%) patients. The duration of neuromuscular blockers infusion from day 1 to day 7 was significantly associated with the variation of cumulated abdominal thickness: $2.7 \pm 2.4$ days for the *decrease* group, $1.2 \pm 1.5$ in the *no change* group, and $0.2 \pm 0.4$ in the *increase* group ($p = 0.047$). Changes of cumulated abdominal muscle thickness were not correlated with changes of diaphragm thickness. For the 10 patients responsive to command at day 7 and able to perform the measures, there was no correlation between cumulated abdominal muscle thickness and either MEP or PCEF.

**Table 1 (abstract 000341)** Muscle thickness, in mm

| | Day 1 | Day 7 |
|---|---|---|
| Cumulated abdominal muscle | 17.9 [15.5–21.8] | 18.8 [14.9–21] |
| Rectus abdominis | 7.3 [6–8.2] | 7.6 [5.9–8.4] |
| External oblique | 3.6 [2.9–4.8] | 4.2 [3–5] |
| Internal oblique | 4.7 [3.4–6.2] | 4.5 [3.7–5.4] |
| Transversus abdominis | 2.4 [2–3.1] | 2.4 [2–3] |
| Diaphragm | 2.1 [1.6–2.6] | 2 [1.6–2.4] |

**Conclusions:** Abdominal muscle atrophy occurred in 19% of patients at day 7 of mechanical ventilation. The previous duration of neuromuscular blockers infusion was associated with decrease of abdominal muscle thickness.

**Topic:** Acute respiratory failure and mechanical ventilation

*Intensive Care Medicine Experimental* 2024, **12(suppl 1):**000345

**Introduction:** The Surviving Sepsis Campaign codifies the treatment of sepsis and septic shock. If the mean arterial pressure target fails to be reached with fluid resuscitation, norepinephrine (NE) is the first-line vasopressor agent and vasopressin is the second-line agent when the dose of NE is equal to or greater than 0.25–0.5 mcg/kg/min. However the optimal timing of vasopressin initiation remains unknown. Reinforcement learning (RL) is a form of machine learning that aims at identifying the optimal set of actions to take in a given environment to maximize the notion of cumulative reward.
**Objectives:** The goal of this study was to use RL to derive and validate an optimal vasopressin initiation rule to minimize mortality in adult patients treated in the ICU for septic shock.
**Methods:** To train and internally validate the algorithm, we used de-identified data from UCSF. We included patients meeting the criteria for septic shock per Sepsis 3.0 definition. The dataset was divided into training, testing, and internal validation sets (70/15/15 random splitting). To externally validate the RL algorithm, we used two publicly available databases, MIMIC-IV and eICU-CRD. Patient trajectories were discretized into hourly bins starting 1 h after shock onset and truncated either at shock recovery (cessation of vasopressors), discharge (dead or alive), or at $t = 120$ h.
Our RL algorithm considered one binary action per hour: "do not start vasopressin" or "start vasopressin" and evaluated its impact on a reward combining death/alive status, arterial lactate, mean arterial pressure, SOFA score, and NE dose. The goal was to identify the sequence of actions that maximizes the reward. To fit the RL algorithm, we employed the Fitted-Q Iteration technique. To assess the impact on ICU-mortality of accurately following the RL policy vs. not, we looked at NE doses at the time of vasopressin initiation by the clinician vs. the algorithm: Group 1 (adherent group) the clinician and the RL algorithm introduced vasopressin for the same NE dose; Group 2 (moderate discrepancy) clinicians started vasopressin for a higher NE dose (up to + 0.1 mcg/kg/min higher); Group 3 (major discrepancy) the NE dose was ≥0.1 mcg/kg/min higher at time of vasopressin initiation by the clinician compared to the algorithm. Group 4 (lower doses) the clinician administered vasopressin at a lower NE doses than the algorithm.
**Results:** 12,026 patients with septic shock were included in the analysis: UCSF (4777 patients), MIMIC-IV (4179 patients), and eICU-CRD (3070 patients). Vasopressin was initiated in 29% of the patients in the UCSF internal validation set, 35% in MIMIC-IV, and 31% in eICU. The RL algorithm recommended initiating vasopressin in 97% of the patients in the UCSF internal validation set, 92% in MIMIC-IV, and 95% in eICU. The observed dose of norepinephrine at vasopressin initiation was 0.15[0.7–0.25] mcg/kg/min in the UCSF internal validation set, 0.25[0.12–0.41] in MIMIC-IV, and 0.24[0.14–0.41] in eICU. The dose of norepinephrine at the time vasopressin initiation as recommended by the algorithm was 0.06 [0.03–0.13] mcg/kg/min in the UCSF internal validation set, 0.12[0.06–0.22] in MIMIC-IV, and 0.10 [0.05–0.22] in eICU. The most important variables driving the RL policy were the time since the shock onset, SOFA score, and norepinephrine dose.
Relative to Group 1, Group 2 was associated with an increased risk of ICU mortality [risk differences 0.10 (95%CI 0.01–0.21), 0.04 (0.01–0.08), and 0.05 (0.01–0.10) in the UCSF, MIMIC-IV, and eICU-CRD test sets, respectively]. Group 3 was associated with a significant increase in ICU mortality compared to Group 1 [RD 0.13 (0.03–0.24), 0.13 (0.10–0.17), 0.13 (0.08–0.18)]. Group 4 was also associated with an increased ICU mortality (RD 0.21 (0.03–0.40), 0.16 (0.11–0.23), 0.10 (0.02–0.18)) (Figure 1).
**Conclusions:** In patients with septic shock, a reinforcement learning-based optimal rule resulted in earlier initiation of vasopressin compared to the clinician rule. Deviation from the optimal rule was associated with increased ICU mortality.

*Intensive Care Medicine Experimental* 2024, **12(suppl 1):**000346

**Introduction:** Melatonin rhythm disturbance is common in intensive care unit (ICU) patients. It may influence contributes to an array of poor prognosis. The aim of the study was to evaluate melatonin secretion rhythm in critically ill patients and to identify factors influencing the melatonin secretion rhythm.
**Methods:** A prospective cohort study observing begin within the first day of ICU admission in surgical ICU of a tertiary teaching hospital. The study was conducted from February 2022 to December 2022. Patients who were conscious, greater than 18 years, expected ICU stay longer than 24 h, and postoperative were enroll. Light, noise, nighttime interruptions, feeding, medications, surgery, and disease information were measured. Serum melatonin was collected at 3:00, 8:00, and 16:00 on the first three days after ICU admission.
**Results:** We defined melatonin rhythmicity by calculating melatonin acrophase and amplitude. We studied 190 critically ill patients. Melatonin acrophase was delayed and abnormal in 100(52.63%) patients. Use of analgesic ($P = 0.033$), pain score ($P = 0.025$), and average nighttime interruption ($P = 0.004$) were independently related to melatonin acrophase. Melatonin amplitude was associated with age and average nighttime interruption ($P = 0.018$ and 0.048, respectively).
**Conclusions:** Age, use of analgesic, pain score, and average nighttime interruption were the risk factors contributing to the disturbance of melatonin rhythm. Clinical staff should control pain and decrease the nighttime interruption to help ICU patients maintain melatonin rhythm.

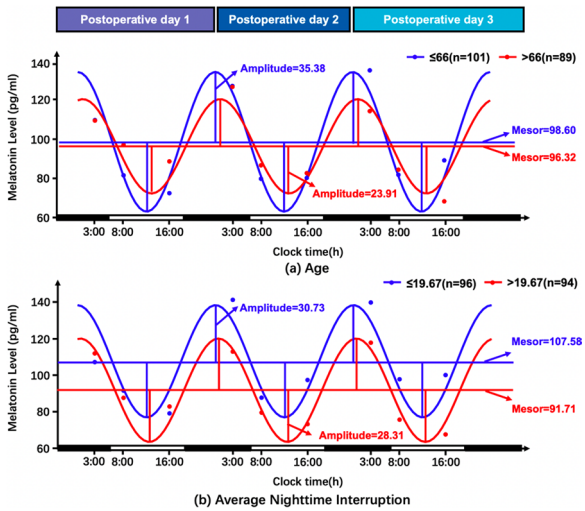

**Fig. 1 (abstract 000346)** Melatonin rhythm in different subgroups (abstract 000346) **(a)** shows the melatonin rhythm in different age group and **(b)** average nighttime interruption. The dots are the average melatonin rhythm at each time point. Data were shown as mean. As the data do not conform to the normal distribution, we divided group depend on median of patients' age and average nighttime interruption

### Clinical course and outcomes of critically ill patients with COVID-19 infection in Malaysia

A. Binti Zainudin
Anaesthesiology, Hospital Sultanah Bahiyah, Alor Setar, Alor Setar, Malaysia
**Correspondence:** A. Binti Zainudin
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000349

**Introduction:** Coronavirus disease (COVID 19) represented majority of admissions to Intensive Care Unit (ICU) during peak of its pandemic in 2020 and 2021. Management of critically ill COVID 19 patients was challenging.
**Objectives:** This study aimed to describe the clinical course and outcomes of critically ill COVID 19 patients in Malaysia.
**Methods:** Registry-based observational study describing outcomes in patients admitted to the ICU for COVID-19, using a validated test. Participants were critically ill patients admitted to ICU with a primary diagnosis of COVID-19 infection in Malaysia Registry of Intensive Care (MRIC) 2021.
**Results:** A total of 15,255 patients included. Average age was 52 years with male predominant (53.8%). More than 50% had only one or without organ failure. Respiratory failure (35.4%), neurological failure (19.8%), and cardiovascular failure (16.1%) were the top three main organ failure on ICU admission. Mean score for SOFA was 4.7 (median 3) and for SAPS II was 36.2 (median 33). Life-sustaining interventions that the patients received throughout their ICU stay include invasive mechanical ventilation (66.2%) and renal replacement therapy (13.9%). Average length of ICU was 8.9 days (median 6.6), while average hospital stay was 14.8 days (median 10.6). ICU mortality was 31.2%, hospital mortality was 38%, and standardised mortality ratio (SMR) was 1.32 (0.95–1.80). Factors associated with mortality were age (OR 1.016, 95% CI 1.006–1.025, $P=0.002$), respiratory failure (OR 1.732, 95% CI 1.292–2.321, $P<0.001$), invasive mechanical ventilation (OR 12.97, 95% CI 7.295–23.063, $P<0.001$), continuous renal replacement therapy (OR 2.495, 95% CI 1.893–3.289, $P<0.0011$), and high SAP II score (OR 1.021, 95% CI 1.010–1.032, $P<0.001$).
**Conclusions:** This study included approximately 15,255 patients demonstrated that COVID-19 infection in critically ill patients was associated with necessity for life-sustaining interventions, high mortality, and prolonged length of ICU and hospital stay.

**Topic:** Sepsis

**Correspondence:** K. Gundogan
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000350

**Introduction:** Infections are common in critically ill patients in intensive care unit (ICU) due to crush injuries and often lead to poor clinical outcomes. Molecular mechanisms of this immune depression is unknown.
**Objectives:** In this study, we aimed to investigate the contribution of damage-associated molecular patterns and alarmins to inflammation and their relationship to disease progression in patients diagnosed with crush injury due to earthquake.
**Methods:** The study included patients ($n=17$) who suffered from crush injuries and required ICU following the Kahramanmaras earthquake on 6 February 2023 and healthy controls (HC, $n=17$). Blood samples were taken on the 7th and 21th day of hospitalization. Peripheral blood mononuclear cells (PBMC) and blood plasma samples were isolated and frozen. Cytokines were quantified by multiplex ELISA to assess immune system dysfunction.
**Results:** The patients had significantly reduced interleukin (IL)-33 alarmin as well as reduced IFN-α2 in the plasma at 7th day of crush injury. IFN-γ, TNF-α, and IL-1β levels also showed a reduced trend at 21st day of crush injury. Importantly, levels of type 3 immune response-associated cytokines IL-23 and IL-17A were significantly reduced in the crush injury patients at 21st day of crush injury (Figure 1).
**Conclusions:** These result argue that the plasma levels of cytokines critical in anti-viral, anti-fungal, and -extracellular bacteria immunity are suppressed following crush injury which may help explain the poor outcome of these patients and succumbing to infections post-trauma.

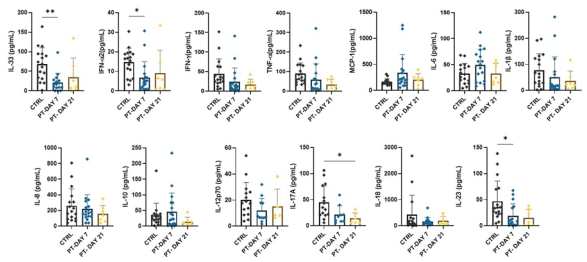

**Fig. (abstract 000350)** Cytokine levels in the peripheral blood plasma

### Machine learning can predict post-induction hypotension in a general surgical population with excellent performance

E. M. Van Dalen[1], M. P. Mulder, D. W. Donker[2], J. W. Potters[3]
[1]Biomedical Engineering, University of Twente, Enschede, The Netherlands; [2]Cardiovascular and Respiratory Physiology, University of Twente, Enschede, The Netherlands; [3]Anesthesiology, MST, Enschede, The Netherlands
**Correspondence:** M. P. Mulder
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000351

**Introduction:** Hypotension is a common event during surgery, with reported incidences varying from 5 to 99% [1], and is associated with postoperative adverse outcomes, including acute kidney injury, myocardial injury, and mortality [2]. About a third of all hypotensive events develop right after anesthetic induction, i.e., post-induction hypotension (PIH). The risk of developing PIH is largely determined by baseline patient characteristics and anesthetic management [3]. Preventing hypotension opposed to treating it prevents the physiological disturbances associated with reduced perfusion pressure. A method to predict PIH could serve as clinical decision support for altering the induction strategy, hemodynamic monitoring and/or vasopressive support. Machine learning is a technique that can make such predictions based on large amounts of data.
**Objectives:** This research aims to develop a good-performing and generalizable machine learning model to predict the occurrence of PIH, to ultimately prevent it.
**Methods:** A database consisting anonymized anesthesia records from 2004 till 2020 of the hospital Medisch Spectrum Twente, Enschede, The Netherlands was used to train the model. Only adult patients undergoing general anesthesia with sufficient valid data points were included. Features consisted of patient demographics, medication history, induction medication, and hemodynamic data before induction. PIH was defined as a drop in systolic blood pressure of at least 30% within the first 15 min after induction. The data were split into training and test set using tenfold cross-validation including hyperparameter tuning with grid search. The XGBoost algorithm, an ensemble learning technique based on decision trees, was used to classify the records.
**Results:** A total of 40,191 anesthesia records of patients undergoing general anesthesia were included in this study, of which 65.8% experienced PIH. The XGBoost model achieved an area under the receiver-operating characteristic curve of 0.83 ± 0.0; see Figure 1. For a predicted probability threshold of 0.5, the test accuracy was 77.9% ± 0.4%, sensitivity 88.1% ± 0.4%, and positive predictive value 80.2% ± 0.3%. The most important features for classification of PIH were age, administration of a muscle relaxant, and pre-operative blood pressure.
**Conclusions:** Using a large heterogeneous dataset, it is possible to train a machine learning model with excellent performance in predicting PIH. The feature importance analysis gives clinical insight in combinations of risk factors and induction strategies that are more prone to result in PIH. The model could serve as a clinical decision support system for the anesthesiologist, thereby preventing PIH in the future.

### A retrospective analysis of the microorganisms isolated in kidney transplant patients on tacrolimus with *sepsis* in the intensive care unit

J. Ng[1], A. Nicolaides[1], P. Patel[2], S. Soni[3]
[1]General Intensive Care Unit, Hammersmith Hospital, Imperial College Healthcare NHS Trust, London, United Kingdom; [2]Critical Care, Imperial College Healthcare NHS Trust, London, United Kingdom; [3]Clinical Senior Lecturer in Critical and Perioperative Care, Imperial College London, London, United Kingdom
**Correspondence:** J. Ng
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000354

**Introduction:** Sepsis remains one of the main causes of morbidity and mortality in solid organ transplant recipients [1,2]. Infections are predominantly bacterial and studies have shown that those related to Gram-negative bacilli are increasing [2]. In addition, bacteraemia with resistant organisms are more frequent in the transplant population [3]. Considering this, we aimed to investigate the epidemiology

of microorganisms isolated in this patient cohort, admitted to our ICU with sepsis.

**Methods:** We conducted a retrospective study in kidney and Gram-negative transplant patients admitted to the ICU with sepsis in 2022 and compared this to our general (i.e., non-kidney transplant) ICU patients. All transplant patients were on tacrolimus either as a single immunosuppressive agent or in combination. The inclusion criteria for sepsis were: septic shock as the reason for ICU admission, biochemical evidence of infection and microbiology-proven cases.

**Results:** 49 patients with kidney or kidney–pancreas transplants were in the ICU with sepsis in 2022, with a total of 70 independent episodes of sepsis. Of these, bacterial infections predominated, causing 66% (46/70) of all infections. Positive blood cultures were only noted in 17% (12/70) of episodes, of which 33% (4/12) were E*nterococcus* spp and 25% (3/12) isolated Enterobacteriaceae with *Klebsiella* spp, *Escherichia coli* and *Enterobacter* spp. Similarly in all ICU non-kidney transplant patients, *Enterococcus* spp and Enterobacteriaceae were predominantly seen in blood cultures at 21% (32/152) and 29% (44/152), respectively. This was followed by *Staphylococcus aureus* at 18% (28/152). In addition, 9% (14/152) of all ICU patients had candidaemia, which was not isolated in the transplant cohort. Vancomycin-resistant *Enterococcus* (VRE) was identified in 8% (1/12) of the transplant cohort in comparison to 5% of VRE and methicillin-resistant *S. aureus* in other ICU patients.

In our transplant cohort, around 50% (37/70) were positive respiratory samples and 16% (11/70) were urinary. The most common organisms causing respiratory tract infections were Enterobacteriaceae and *Pseudomonas aeruginosa* at 22% (8/37) and 14% (5/37), respectively, whilst in the urine, it was *Enterococcus* at 45% (5/11) and Enterobacteriaceae at 27% (3/11). There were 9 COVID-19 infections, of which 78% (7/9) required treatment.

In kidney transplant patients, 16% (11/70) were opportunistic infections, of which over half were due to *Pneumocystis jirovecii* and 36% from *Aspergillus fumigatus*. There was 1 case of CMV viraemia with encephalitis. All patients had discontinued *Pneumocystis* and CMV prophylaxis at the time.

**Conclusions:** Our data demonstrate that *Enterococcus* spp, Enterobacteriaceae and *Pseudomonas aeruginosa* were the most common organisms isolated in kidney and kidney–pancreas transplant patients, whilst there was also a significant incidence of opportunistic infections. These data will help guide antimicrobial management in this vulnerable patient cohort presenting to ICU with sepsis.

**Introduction:** Sepsis continues to be a huge societal problem. In 2017, sepsis accounted for nearly 20% of all global deaths [1]. In Spain, the average cost per patient with septic shock is €11,359 [2]. Sepsis is defined as a life-threatening organ dysfunction caused by a dysregulated host response to infection. Septic shock should be considered a subset of sepsis in which underlying circulatory, cellular, and metabolic abnormalities contribute to a greater risk of mortality than that posed by sepsis alone. Sepsis involves an inflammatory response to infection, commonly evaluated through biomarkers to gauge the patient's condition or for its early detection [3]; however, these methods are invasive and can take hours before offering results: recent studies show that the inflammatory response could be monitored with non-invasive methods such as Heart Rate Variability (HRV) [4,5].

**Objectives:** The primary objectives of this study were to develop an index capable of accurately assessing the inflammatory response and identifying the risk of sepsis in patients. Essential criteria for this index included non-invasiveness, rapid result generation, and predicting the severity of the inflammatory response.

**Methods:** To develop this index, data were collected from patients at Hospital Quirón Salud in Barcelona (Spain) and Clínica Interhospital in Guayaquil (Ecuador), both approved by their local ethics committee, utilizing the Coresys One monitor capable of recording two EEG channels and one ECG channel synchronously. The dataset comprised 54 patients undergoing surgeries of varying durations (ranging from 45 min to 5 h), 5 healthy volunteers, and 4 septic cases.

Subsequently, segments of the data were categorized into eight levels of inflammation using a combination of HRV analysis and insights from collaborating medical professionals. Healthy volunteers were designated a value of 1, while patients in the surgical group were assigned values ranging from 2 to 5, and those in the septic group were allocated values from 6 to 8.

Following data preprocessing and segmentation, the index was trained using an Adaptive Neuro Fuzzy Inference System (ANFIS). Inputs to the ANFIS model included heart rate, the root mean square of successive differences (RMSSD) representing time-domain HRV parameters, the ratio between low- and high-frequency components of HRV (LF/HF), and the brain activity index (BA) a consciousness index. HRV parameters were calculated every 3 min with 20-s increments from the recorded data. The resulting index, the Risk of Sepsis and Inflammation (RSI), offers real-time data of the patient's inflammatory status, facilitating prompt clinical decision-making.

The RSI index indicates that values from 0 to 25 indicate a normal state, 25 to 50 suggest a mild inflammatory response, 50 to 75 denote a strong inflammatory response and risk of sepsis, and 75 to 100 indicate a severe inflammatory response and risk of sepsis and septic shock.

**Results:** In the analysis of the trained data, the RSI index exhibited a Pk value of 0.956, accompanied by a standard error of 0.0011 and an $R^2$ Pearson correlation coefficient of 0.897.

Figure 1 illustrates the distribution of values assigned by the RSI index across the categorized inflammatory levels.

Figure 2 presents a boxplot depicting the distribution of RSI values among healthy volunteers, surgical cases, and septic cases. This visualization highlights the distinct RSI profiles across these patient groups, demonstrating the index's capacity to differentiate between different inflammatory states and patient populations.

**Conclusions:** In conclusion, the Risk of Sepsis and Inflammation (RSI) index shows promise in differentiating cases of severe inflammation and monitoring the progress of the inflammatory response. Its non-invasiveness and ability to provide rapid results in minutes make it a valuable tool for clinical decision-making.

AQ9 **Introduction:** During the acute phase of septic shock, dysfunctional hearts are prevalent with unclear preferences for energetic fuels. This cardiovascular impairment is usually supported by catecholamine infusions. Amongst alternative candidates to catecholamines, apelin agonists—apelinergics—and the apelin/APJ receptors efficiently reverse myocardial contractile dysfunction in experimental sepsis and purport to be mitotropes, energy protectors, and regulators of metabolic homeostasis.
**Objectives:** In a mice model of cecal ligation puncture, to establish the impact of apelin receptor (APJ) specific conditional knock-down (k-d) in cardiomyocytes (CMs) on heart systolic function; mitochondrial respiration, and heart & blood-related metabolomic profiles.
**Methods:** CM-specific invalidation of APJ was achieved using the tamoxifen-inducible Cre recombinase (MerCreMer) expressed under the cardiomyocyte-specific alpha-myosin heavy chain promoter (αMHC or alpha-MHC; Myh6), and double transgenic mice obtained by crossing those with APJ floxed (APJfl/fl) mice. Sepsis-Induced Myocardial Dysfunction (SIMD) was induced by Cecal Ligation and Puncture (CLP) for 18 h. Transthoracic echocardiography was performed with the Vevo 3100 echography system (FUJIFILM VisualSonics Inc.). Short-axis Fractional Shortening (FS) was used as a reference for contractile function in non-challenging conditions and Cardiac Index (CI) with long-axis calculations preferred in challenging conditions. Blood and heart tissues were then preserved for Metabolomic profiling, as well as fresh heart fibers for real-time mitochondrial respirometry (Oroboros) at the endpoint ($n = 3$–10/ group).
**Results:** APJ k-d significantly affected CI in sham female mice ($p < 0.01$). CLP decreased CI in both sexes (−35% in males & −67% in females, $p < 0.05$ and 0.01, respectively) and FS in males (−17%, $p < 0.05$). APJ k-d further amplified CI drop in both sexes ($p < 0.001$ in males, $p < 0.05$ in females) and FS in females ($p < 0.05$). Ventricular muscle fibers in septic mice lacking APJ exhibited a significant reduction in oxidative phosphorylation (OXPHOS), largely mediated by reductions in complex I-driven respiration, in males only. In contrast, the APJ k-d in females resulted in an increase in respiration, essentially mediated by an increase in complex I-driven respiration. OXPHOS reduction was associated with CI drop in males, but independent of left ventricle bioenergetics in females. In CLP heart tissues: citrate (downstream TCA metabolite & inhibitor of fatty acid oxidation) has an APJ-independent twofold increased concentration in females ($p < 0.05$), beta-OH butyrate (main ketone body) exhibited an APJ-independent sixfold elevation in males ($p < 0.01$), and alpha-OH butyrate (marker of mitochondrial dysfunction and insulin resistance) displayed a huge—15–20-fold—APJ-dependent increase in females ($p < 0.001$). In bloodstream: CLP induced a significant increase of alpha-keto-butyrate and beta-OH butyrate in males ($p < 0.01$) and a tenfold APJ-dependent and a retrieved increase of alpha- and beta-OH butyrate in females ($p < 0.001$).
**Conclusions:** CLP-induced SIMD in mice is associated with important metabolic and functional impairments in both heart and bloodstream, which are differentially translated depending on sex and (apelin receptor) APJ knock-down.

AQ10 **Introduction:** Patients with heart failure (HF) may deteriorate in hospital wards and have increased hospital mortality. We evaluated the outcomes of patients with HF who deteriorated in the ward and assessed the ability of the shock index (SI), the ratio of heart rate to systolic blood pressure (BP), to predict outcomes.
**Methods:** We retrospectively studied patients with HF in the wards of a tertiary-care hospital in Riyadh, Saudi Arabia who had activation of the Critical Care Response Team (CCRT) for clinical deterioration between 01/01/2019 and 31/12/2019. We calculated SI at the time of activation for all patients. We compared patients with preserved and reduced left-ventricular ejection fraction (EF). We performed stepwise multivariable logistic regression analysis to evaluate the risk factors for hospital mortality and receiver-operating characteristic (ROC) curve analysis to assess if SI can predict ICU admission, vasopressor therapy, and hospital mortality.
**Results:** During the study period, 276 patients with HF had CCRT activation (age 73 ± 12 years, males 56.5%, preserved EF in 67.4% [EF = 49 ± 7%] and reduced in 22.6% [EF = 27 ± 6%]). Patients with reduced EF had similar age but were more likely to be males with higher prevalence of ischemic heart disease and mitral regurgitation compared to those with preserved EF. Reasons for CCRT activation were similar (cardiovascular deterioration 38.9% vs. 33.9% and respiratory deterioration 33.3% vs. 38.2% for reduced and preserved EF groups, respectively). Patients with reduced EF had lower systolic BP (108 ± 38 vs. 121 ± 29 mmHg) but similar heart rate. SI was 0.9 ± 0.3 in patient with reduced EF compared with 0.8 ± 0.3 ($p = 0.09$) for those with preserved EF. At CCRT activation, 141 patients (51.3%) were suspected to have sepsis. 91 patients (33.0%) needed ICU admission with no difference between the reduced and preserved EF groups (32.2% vs. 33.3%, respectively; $p = 0.85$). The use of vasopressor therapy, invasive mechanical ventilation, and renal replacement therapy was similar in both EF groups. Hospital mortality was 33.0% with no difference between the reduced and preserved EF groups (36.7% vs. 31.2% respectively; $p = 0.36$). On multivariable logistic regression analysis, lower systolic BP (odds ratio [OR] 0.98, 95% confidence interval [CI] 0.97–0.99) and GCS (OR 0.86, 95% CI 0.78–0.95), interstitial lung disease (OR 18.1, 95% CI 1.74–187.85), and bacterial growth from any culture source (OR 3.40, 95% CI, 1.65–7.00), but not EF nor SI, were associated with hospital mortality. On ROC curve analysis, SI did not predict the need for ICU admission (area under the curve [AUC] 0.53, 95% CI 0.46–0.60), use of vasopressor therapy (AUC 0.6, 95% CI: 0.51–0.70), and hospital mortality (AUC 0.56, 95% CI 0.49–0.63).
**Conclusions:** Patients with HF who deteriorated in the ward requiring CCRT activation had high hospital mortality (33.0%). EF and SI did not predict outcomes.

## Improving documentation of videolaryngoscopy-assisted tracheal intubation in a tertiary centre intensive care unit in London

S. Snel[1], S. Shah[2], R. S. Chaggar[2], U. Waheed[3], S. Soni[4]
[1]Intensive Care, Hammersmith Hospital, London, United Kingdom; [2]Consultant in Anaesthesia, Northwick Park Hospital, London, United Kingdom; [3]Consultant in Intensive Care, Hammersmith Hospital, London, United Kingdom; [4]Clinical Senior Lecturer in Critical and Perioperative Care, Imperial College London, London, United Kingdom

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000359

**Introduction:** Using videolaryngoscopy (VL) to guide tracheal intubation has become increasingly common in recent years, with evidence demonstrating that it is safer than direct laryngoscopy (1). There is no standardised documentation tool to communicate tracheal intubation using VL. The Cormack and Lehane score for direct laryngoscopy is often incorrectly used for VL in the absence of an alternative tool. The 'Video Classification of Intubation' (VCI) score (2) has been developed to succinctly convey information about key elements of tracheal intubation using VL—(1) VL blade shape, (2) percentage of glottic opening to the nearest quartile during the intubation attempt, and (3) a comment about tracheal tube delivery (figure). The VCI score is reproducible in patients, which has been adopted by several anaesthetic communities. However, it is not well recognised within the critical care setting where the use of VL is becoming more prevalent.
**Objectives:** The aim of this project was to evaluate the documentation of tracheal intubation using VL in an Intensive Care Unit (ICU) of a tertiary centre in London and implement the use of the VCI score.
**Methods:** We conducted a retrospective study to assess documentation of tracheal intubation using VL over a 2-month period in 2023 in a single ICU. Anonymous data were extracted from electronic patient records. The project was registered locally as an audit.
**Results:** We collected data on 78 patients admitted to the ICU between September and October 2023. Of those patients, 19 were intubated and of those, 13 were intubated using VL. Of the 13 patients intubated using VL, the Cormack Lehane score was incorrectly used to communicate the intubation in 4 patients. For the other 9 patients, various sporadic details were documented which did not allow a clear understanding of how exactly the tracheal intubation using VL was achieved. Following this, to improve our ICU's documentation of tracheal intubation using VL, we undertook a multidisciplinary education programme about the VCI score and devised a new proforma for documenting tracheal intubations, including a specific section that required completion of the VCI score for when VL is used.
**Conclusions:** This single centre audit identified that documentation of tracheal intubation using VL does not consistently describe the process with sufficient detail to allow understanding of what equipment was used and if any difficulty was encountered. This information may prove critical in the event of an accidental extubation or subsequent deterioration and need for re-intubation. We have undertaken a teaching programme to educate airway practitioners about the importance of documenting a minimum dataset and have developed a new proforma detailing the VCI score to improve our documentation of tracheal intubation using VL.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000360

**Introduction:** Temporary cardiac pacing (TCP) is a common procedure in urgent and elective patients, providing support during interventional cardiology procedures. TCP with active fixation leads has shown better outcomes than systems without fixation, but certified devices are lacking. KronoSafe® adapts permanent pacemakers to perform TCP with active fixation leads.

**Objectives:** To demonstrate the safety and effectiveness of TCP with active fixation leads using the KronoSafe® system.

**Methods:** Multicenter clinical research of a medical device approved by the Clinical Research Ethics Committee and the Spanish Agency of Medicines and Medical Devices. Patients requiring temporary cardiac pacing for more than 48 h since January 2023 were included. An active fixation lead of 58–60 cm was implanted under echocardiographic guidance via the left or right internal jugular vein anchored to the right ventricle. Safety variables were collected: electrode impedance, R-wave detection, and stimulation threshold. Complications recorded included capture or detection failure, electrode dislocation or rupture, generator or electrode detachment, and cardiac perforation. Evolutionary variables included hours of pacing in the ICU/Cardiology Acute Care Unit and in the hospitalization ward.

**Results:** 22 patients were included from 2 centers: 8 TAVI, 7 complete AV blocks, 4 Septal Alcohol Ablations, 2 Bradycardia–Tachycardia Syndrome, and 1 Slow Atrial Fibrillation. Every 48 h, mean R-wave detections were 10.6–12.3–12.4–10.9–11.1–11.3–12.1–14.3–14.9 mV; mean impedance values were 735–600-611–614-609–602-604–606-621 Ohms, and mean thresholds were 0.6–0.5–0.5–0.5–0.4–0.6–0.6–0.5–0.4 V at 0.4 ms. One electrode dislocation due to agitation episode was recorded on day 25 without clinical repercussions. The mean duration of pacing was 7.7 days, with 73.1% of the time in the hospital ward without mobility restrictions.

**Conclusions:** 1. Temporary cardiac pacing with active fixation leads is an effective and safe therapy, allowing its use in hospitalization wards. 2. Agitation and disorientation can be risk factors for complications associated with the use of external devices. 3. The KronoSafe® system provides the necessary safety for performing this type of temporary cardiac pacing.

**Introduction:** Sepsis is an important complication in patients receiving extracorporeal membrane oxygenation (ECMO). Its early diagnosis is challenging and represents a crucial aspect for treatment optimization.
Traditional biomarkers have low diagnostic accuracy to diagnose infection on ECMO. Monocyte Distribution Width (MDW) is a novel sepsis biomarker that reflects a change in the volume of monocytes in response to infectious organisms.
**Objectives:** The objectives were to analyse the relationship between MDW, ECMO therapy, and infection; to analyse the MDW during VV-ECMO vs. VA-ECMO therapy.
**Methods:** Retrospective observational cohort study of patients under ECMO support from a single centre since 2019. Statistical analysis. Descriptive: percentages (95%CI). Quantitative: mean (SD) or median (IQR). Normality distribution was analysed using the Shapiro–Wilk test. Univariate analysis: paired *t* test.
**Results:** N = 134. Males: 76.9% (95%CI 68.8–83.7). Age: 53.2 (SD 12.5) years. VV-ECMO: 67.9% (95%CI 59.3–75.7). VA-ECMO: 32.1% (95%CI 24.3–40.7). SARS-COV-2 infection: 52.2% (95%CI 39–56.6). Respiratory infection: 72.4% (95%CI 64–80). Positive blood culture: 34.3% (95%CI 26.3–43). ECMO: 12.5 (IQR 25) days. IMV: 24.5 (IQR 37) days. ICU length of stay: 30.2 (IQR 39.3) days. Alive at ICU discharge: 53.6% (95%CI 44.9–62.6).
MDW 2 days before ECMO implementation vs. MDW at ECMO implementation: 23.8 (SD 4) vs. 26.5 (SD 5.9); ($p = 0.001$). MDW 2 days before ECMO withdrawal *vs.* MDW at ECMO withdrawal: 24.5 (SD 6.2) vs. 25.7 (SD 6.9); ($p = 0.04$). MDW 2 days before respiratory infection *vs.* MDW at respiratory infection: 24 (SD 5.6) vs. 27 (SD 9.4); ($p = 0.02$). MDW 2 days before positive blood culture *vs.* MDW at positive blood culture: 23.4 (SD 3.4) vs. 26.7 (SD 9.5); ($p = 0.02$).
MDW VV-ECMO *vs.* VA-ECMO. MDW at ECMO implementation: 27.2 vs. 27 ($p = 0.9$). MDW at ECMO withdrawal: 25.2 vs. 28.5 ($p = 0.02$). MDW at respiratory infection: 26.9–27.3 (pNS). MDW at positive blood culture: 27.7 vs. 32.7 ($p = 0.04$).
**Conclusions:** MDW increased at ECMO implementation and withdrawal, and when respiratory or blood cultures were positive. MDW tended to be higher during VA-ECMO than during VV-ECMO therapy.

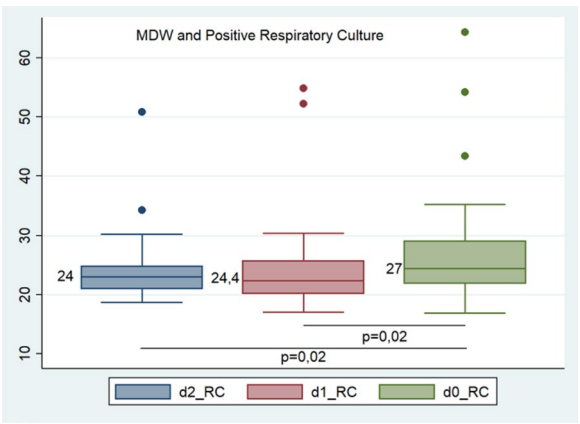

**Fig. (abstract 000361)** MDW 2 days before respiratory infection *vs.* MDW at respiratory infection: 24 (SD 5.6) vs. 27 (SD 9.4); ($p = 0.02$)

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000362

AQ12 **Introduction:** In patients with acute respiratory failure (ARF) under invasive mechanical ventilation (IMV), excessive respiratory effort may induce patient self-inflicted lung injury (P-SILI) by significantly increasing the total pressure applied to the lungs. Furthermore, vigorous diaphragmatic contractions may lead to diaphragmatic myotrauma. Observational studies have linked these effects with longer duration of IMV, increased mortality, and poor long-term outcomes in survivors (1,2).

**Objectives:** To analyze the proportion of time spent within the safe range of physiological respiratory effort variables (Pmus [5–15 cm H2O], ΔPeso [5–10 cm H2O], ΔPdi [3–12 cm H2O]) (3,4) during the first 7 days of IMV with active breathing and its correlation with patient survival.

**Methods:** Peso and Pga signals were continuously recorded during at least 7 days after the onset of spontaneous breathing in patients with ARF under IMV. Respiratory system (RS) mechanics, mechanical ventilation variables, and arterial blood gas (ABG) analyses were recorded on the first day under IMV in passive conditions. The onset of patient effort was identified using a specific software, and defined as the presence of inspiratory negative swings in the Peso signal, regardless of the applied ventilatory mode. As the number of cycles analyzed for each patient varied, the analysis of all physiological variables during respiratory effort was weighted according to each patient's representation within the total sample (number of patient's respiratory cycles analyzed/total number of patients' respiratory cycles analyzed).

**Results:** We analyzed 1.483.515 cycles from 26 patients, comprising 19 ICU survivors and 7 ICU non-survivors. No significant differences in demographics, comorbidities, or severity at admission were observed between the two groups. Regarding respiratory variables in passive conditions on day 1, plateau pressure was higher in ICU non-survivors compared to ICU survivors (31 [30–32] vs 28 [26–30], $p = 0.041$) without differences in other RS mechanics and ABG analyses. Table 1 illustrates the median values of physiological respiratory variables between the groups during the 7 days following the onset of respiratory effort. Figure 1 presents the proportion of time that each group spent in different ranges (high, safe, and low) of the respiratory effort variables during the 7 days after the onset of respiratory effort.

**Table 1 (abstract 000362)** Physiological respiratory variables during respiratory effort. Weighted analysis

| | Survivors n.19 | Non-survivors n.7 | *p* value |
|---|---|---|---|
| Vt/PBW (ml/kg) | 7.1 (5.5–7.2) | 7.2 (5.3–8.0) | 0.564 |
| RR (bpm) | 25 (23–26) | 27 (25–32) | **0.000** |
| PS (cm_H2O) | 12 (11–16) | 16 (8–17) | 0.389 |
| PEEP (cm_H2O) | 7 (6–12) | 10 (5–16) | 0.816 |
| Total cycle length (s) | 2.40 (2.30–2.72) | 2.22 (1.87–2.39) | **0.000** |
| Mech. inspiratory length(s) | 0.89 (0.70–0.99) | 0.83 (0.63–0.85) | **0.001** |
| Patient inspiratory length (s) | 0.92 (0.61–0.95) | 0.93 (0.59–1.07) | 0.518 |
| ΔPLdn (cm_H2O) | 18.9 (13.3–21.3) | 21.8 (13.8–34.6) | **0.026** |
| ExpPL (cm_H2O) | 0.2 (−0.8–3.4) | 3.4 (−0.04–5.5) | **0.010** |

**Introduction:** Hypotension after cardiac surgery is a common occurrence that can lead to various complications. Addressing hypotension effectively is crucial for improving patient outcomes. This study focuses on the impact of implementing a specific clinical pathway to manage postoperative hypotension at our Cardiovascular Intensive Care Unit (CVICU).
**Objectives:** The primary objective was to evaluate the effectiveness of the nurse-led clinical pathway in reducing the frequency, duration, and severity of intraoperative hypotension. Secondary objectives included assessing the impact on postoperative outcomes, such as acute kidney injury (AKI), ventilation hours, length of stay (LOS), readmission rates, and direct costs.
**Methods:** A retrospective analysis was conducted comparing data from 90 days before (baseline) and after (implementation) the introduction of the clinical pathway. The control group consisted of 43 patients, while the intervention group comprised 50 patients. Metrics analyzed included mean arterial pressure (MAP), cardiac index (CI), systemic vascular resistance (SVR), stroke volume (SV), pressor usage, time in target range, frequency of hypotension, duration of hypotension, severity of hypotension, and patient outcomes.
**Results:** The implementation of the nurse-led clinical pathway led to improvements in several metrics including the average time in hypotension per patient (83.5 min to 51 min), and total duration of hypotension (3549 min to 2526 min) with AUT 376 ± 386, 214 ± 232, TWA of AUT, 0.4 ± 0.43, 0.22 ± 0.25. There was a reduction in the percentage of patients experiencing hypotension after the implementation (93% to 88%) $p$ value 0.417 and pressors usage (37% to 30%) $p$ value 0.477 as well. Postoperative outcomes also improved, with reductions in AKI incidence (9% to 6%) $p$ value 0.27425, mean postoperative ventilation hours (7. to 6.3) p value 0.591, LOS (7.28 days to 6.36 days) $p$ value 0.286, 30-day readmission rates (14% to 8%) p value 0.176, and direct costs per case ($32,677.44 to $27,871.86).
**Conclusions:** The implementation of a clinical pathway for managing postoperative hypotension in the CVICU at our center has resulted in improved incidence and duration of hypotension, as well as enhanced postoperative outcomes. However, the small sample size limits our ability to demonstrate statistical significance. These findings suggest that structured clinical pathways can be an effective tool in enhancing patient care and reducing healthcare costs in the context of cardiac surgery.

**Introduction:** Chronic hyperglycemia may generate a protective cellular conditioning against damage mediated by acute stress-induced hyperglycemia [1]. This cellular conditioning mechanism would consist of the downregulation of the glucose transporter-1 (GLUT-1) and the glucose transporter-4 (GLUT-4), leading to a disturbed insulin signaling [2].
**Objectives:** This study explored the association between diabetes mellitus (DM) and stress-induced hyperglycemia with skeletal muscle expression of key genes related to glucose transport.
**Methods:** This is a prospective cohort study. Skeletal muscle biopsies were taken from the left vastus muscle of critically ill adult patients and the expression of the genes of interest, namely insulin receptor substrate 1 (*IRS1*), insulin receptor substrate 2 (*IRS2*), solute carrier family 2 member 1 (*SLC2A1*), and solute carrier family 2 member 4 (*SLC2A4*), were analyzed using qPCR. The primary analysis planned was to compare the gene expression pattern between patients with and without DM. The secondary analyses planned were the comparison of gene expression in subgroups of patients with different levels of glycemia, glycemic variability, and glycemic gap.
**Results:** A total of 50 patients were included from April 2018 to September 2018. No differences in gene expression were found between patients with or without DM (Table 1). Individuals with hyperglycemia > 200 mg/dL exhibited a downregulation of *IRS1* compared to those without (0.4 [0.1–0.8] vs. 1.1 [0.3–2.2], $p = 0.04$). Similarly, patients with a glycemic gap ≥ 80 mg/dL exhibited a downregulation of *IRS1* compared to those with a glycemic gap < 80 mg/dL (0.3 [0.1–0.7] vs. 1 [0.4–2] $p = 0.04$). .

**Table 1 (abstract 000364)** Gene expression in skeletal muscle biopsies from patients with or without diabetes mellitus. Values are expressed in n-fold changes (ΔΔCq method) and described as median and interquartile range

| Gene | Patients with DM ($n = 15$) | Patients without DM ($n = 35$) | *p* |
|---|---|---|---|
| *SLC2A1* | 0.7 (0.3–1.5) | 0.6 (0.3–1.2) | 0.87 |
| *SLC2A4* | 0.9 (0.5–2.1) | 1 (0.5–1.6) | 0.88 |
| *IRS1* | 0.6 (0.4–1.8) | 0.9 (0.3–2) | 0.72 |
| *IRS2* | 0.9 (0.8–1.1) | 1 (0.6–1.8) | 0.58 |

**Conclusions:** No significant changes were found in skeletal muscle expression of *IRS1*, *IRS2*, *SLC2A1*, and *SLC2A4* in critically ill patients with or without DM. However, *IRS1* was downregulated in patients with stress-induced hyperglycemia.

**Introduction:** About 35% of patients die after the first aneurysmal subarachnoid hemorrhage (SAH). Among those who survive, neurological damage is common, even when treatment is optimal. It is important to know the risk factors for disability and to identify those that can be prevented to reduce them.
**Objectives:** To evaluate risk factors for disability in patients with subarachnoid hemorrhage (SAH) admitted to a neurotraumatic ICU.
**Methods:** Prospectively collected data from patients admitted from October 2013 to December 2023 in a 10-bed Neurotrauma ICU. We analyzed: main diagnosis on admission; demographics, including sex and race; neurological data (clinical examination, pupil reactivity and size, and Glasgow Coma Score (GCS); aneurysm location and size; presence of intracranial hematoma (ICH); presence and volume of intraventricular hemorrhage; days to develop vasospasm; development of acute cerebral ischemia (ACI) and delayed cerebral ischemia (DCI); Fisher scale, modified Fisher scale, Hunt and Hess scale, World Federation of Neurosurgeons (WFNS) scale; presence of vasospasm on Doppler or arteriography; delayed ICU admission; treatment of the aneurysm; complications, including infections; Glasgow Outcome Scale (GOS) at ICU discharge and 6 months after ICU discharge and several other risk factors. Disability was defined as GOS ≤ 3.To identify those factors that maintained an independent association with disability, multivariate logistic regression analysis was performed. It was considered significant if $p \leq 0.05$.To determine the discriminatory ability of the Score, a receiver-operating characteristic (ROC) analysis was performed. The diagnostic ability of the Score was assessed by the area under the ROC curve, which was estimated using a 95% confidence interval. For the chosen cut-off point, sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV) were calculated.
**Results:** Among the 278 patients admitted for SAH, 99 (35,61%) had a GOS ≤ 3. DCI was not significantly different between the groups studied. Fifty-five patients died (19.8%), 38 within ICU. Decompressive craniectomy was performed in 13 (4.7%) patients with SAH, and 12 (12.1%) had a GOS ≤ 3 (Table 1a and 1b). Independent risk factors associated with disability were: mechanical ventilation (MV) > 7 days OR: 6.787 (3.113; 14.8). ACI OR: 5.141 (1.409; 18.75); Hunt and Hess score OR: 1.439 (1.108; 1.869) and Apache II on ICU admission per unit OR: 1.167 (1.094; 1.24) (Table 2).
The following score was derived from the logistic model: $0.155 \times \text{Apache II} + 1.915 \times \text{MV} > 7 \text{ days} + 1.637 \times \text{ACI} + 0.364 \times \text{Hunt}$ and Hess score.
Here, MV > 7 days = 1/0 according to MV > 7 days or not.
The area under the curve (AUC) was 0.919 IC 95% IC (0.884; 0.954) (Figure 1). Cut-off point: 0.2334; specificity: 82.2 [75.5; 87.5]; sensitivity 91.9 [84.7; 96.4]; NPV 94.7 [89.8; 97.7]; PPV: 74.6 [65.9; 82.0].

**Conclusions:** In our study, 35.61% of SAH patients had severe disability at ICU discharge In SAH patients admitted to a neurotraumatic ICU, the risk factors that were independently associated with disability were: score: MV > 7 days, ACI, Hunt and Hess score and Apache II at ICU admission per unit. A predictive score was obtained.

**Introduction:** Current antibiotic combinations do not cover all of multidrug-resistant Gram-negative bacteria or some of their resistance mechanisms, or have significant safety issues (e.g., nephrotoxicity). Cefiderocol has demonstrated potent activity against a wide range of multidrug-resistant Gram-negative bacteria in adults with limited treatment options.
**Objectives:** To analyze the efficacy and safety of the use of cefiderocol in a series of patients with severe Gram-negative bacilli (GNB) infections with limited treatment options in an ICU with selective digestive decontamination (SDD).
**Methods:** We conducted a retrospective study of patients over 18 years of age admitted to our ICU with severe Gram-negative bacilli infections from November 1, 2021 to October 31, 2023. We used DDS since October 1, 2011 in our ICU. A standard dose of cefiderocol 2 g iv/8 h as extended perfusion of 3 h was administered. Two g iv/6 h was used in case of creatinine clearance > 120 ml/h, or ECMO use with normal renal function. The dose was adjusted at 24 h according to renal function. Cefiderocol was also used in patients with *Acinetobacter baumannii*. The absence of important data or death within 48 h was exclusion criterion.
The reason of admission, severity of the patient at admission, risk factors for infection, as well as microbiological criteria, infection markers, clinical criteria at -3, 0, and 7 days after starting treatment were described. The day of microbiological and clinical negativization was evaluated. Also, antibiotic treatment 14 days before starting cefiderocol, as well as concomitant treatment with it, duration of treatment and mortality at 28 days after starting treatment with cefiderocol. Categorical variables were summarized as frequencies and numerical variables as means and standard deviation or medians and interquartile ranges (IQR).
**Results:** Twenty-one patients were treated with cefiderocol during the study period in our ICU. All used SDD. Mean age was 58.76 ± 12.9 and 61.9% (13/21) were male (see Table 1). The treated infection was ICU-acquired in 90.5% (19/21) of the patients. Three of the 21 patients had transplantation. The most frequent infection was ventilator-associated pneumonia in 11/21, 34.3%, and 6/21 of other respiratory diagnoses. In total, (17/21) 81% were of respiratory origin. Mechanical ventilation was used in 90.5% of patients (19/21). The most frequent germ was multidrug-resistant *Pseudomonas aeruginosa*. Two patients had *Acinetobacter baumannii* with clinical and microbiological cure, were alive 28 days after starting treatment and at hospital discharge. Four patients required ECMO and needed renal replacement techniques. At 7 days of treatment germ eradication was 42.85 (9/21), and clinical cure was 33.3% (7/21). Mortality at 28 days was 34.3%. Clinical cure at the end of treatment was 61.9% (13/21) with a microbiological eradication at discharge of 52.38% (11/21) (Figure 1) There were no resistant co-infections or adverse effects attributable to cefiderocol administration.
**Conclusions:** In our ICU, the use of cefiderocol in patients with severe GNB infections obtained a clinical cure at the end of treatment of 61.9%, with a microbiological eradication at discharge of 52.38%. Mortality at 28 days was 34.3%. There were no adverse effects to cefiderocol administration.

### Prolonged inhaled sedation with isoflurane: experience in a tertiary hospital

M. Vilà Rivas[1], L. Tarré Ferré[1], M. Vilà Currius[2], À. Castillo Niell[1], M. L. Palomanes Espadalé[1], C. Murcia[1]
[1]Intensive Care Unit, Hospital Universitari de Girona Doctor Josep Trueta, Girona, Spain; [2]Pharmacology Department, Hospital Universitari de Girona Doctor Josep Trueta, Girona, Spain
**Correspondence:** M. Vilà Rivas
*Intensive Care Medicine Experimental* 2024, **12(suppl 1):**000367

**Introduction:** In Intensive Care Units (ICUs), the use of inhaled sedation (IS) with isoflurane is rising due to its benefits over intravenous sedation (IVS). However, there is a gap in research on IS durations beyond 72 h despite increasing experience in managing critically ill patients.
**Objectives:** Describe patients receiving IS from ICU admission for over 72 h, assessing its effectiveness.

- Describe delirium occurrence rate and duration.
- Document identified adverse effects.

**Methods:** Prospective, observational single-center study from May 2022 to July 2023, collecting sociodemographic data, sedation levels, adverse effects, isoflurane doses, need for other sedatives, and delirium details. Additionally, evaluates awakening time to RASS 0, opioid and neuromuscular relaxant use, and SF-12 questionnaire at 6 months post-ICU discharge for quality-of-life assessment. Patients receiving IS for over 72 h are included, excluding minors, prior IVS patients, and deceased individuals. Qualitative variables presented as percentages, and quantitative variables as means ± standard deviation using R software for analysis.
**Results:** Out of 68 patients receiving IS, 20 received it continuously for more than 72 h. The mean age was 46 ± 13 years, with males making up 80% of the participants. Severity and comorbidity scores at admission were: APACHE II 26.2 ± 5.4, SAPS II 61.0 ± 10.7, SOFA 6.9 ± 3.7, and CHARLSON 1.5 ± 1.2.
Respiratory issues, including ARDS and status asthmaticus, led to 70% of admissions, often requiring deep sedation. Patients stayed in the ICU for an average of 23 ± 11 days, with mechanical ventilation needed for approximately 19 ± 11 days. IS was administered for an average of 11 ± 7 days, with mean doses of 3.7 ± 1.8 ml.
The target RASS value was achieved in all cases without requiring additional sedatives. During the weaning phase, a switch to mild IVS was made, achieving RASS 0 in 3 ± 2 days.
Delirium affected 25% of cases, lasting 3 ± 1.9 days on average. No significant adverse effects were noted, including no increased vasoactive support, QTc interval prolongation, or hepatic/renal function changes. While bilateral mydriasis is notable in our experience, none occurred in this cohort. However, one case of hyperthermia required inhaled sedation withdrawal. Opioid consumption decreased by about 50% due to inhaled sedation's potentiation effect. Likewise, neuromuscular relaxant (NMR) usage decreased due to both potentiation and train-of-four (TOF) monitoring. Quality-of-life evaluation at 6 months post-ICU discharge, especially in mental aspects (MCS12), showed higher scores than reported in literature.
**Conclusions:** Prolonged inhaled sedation is effective and safe in our population sample, with faster awakening and lower delirium rates compared to IVS. SF-12 scores at 6 months post-ICU discharge, especially in mental aspects, are higher than in similar populations. Further validation studies are needed.

**Topic:** Sedation, analgesia, and delirium

## 000368

### Inhaled sedation for periods exceeding 21 days: a descriptive study

M. Vilà Rivas[1], L. Tarré Ferré[1], M. Vilà Currius[2], À. Castillo Niell[1], M. L. Palomanes Espadalé[1], C. Murcia[1]
[1]Intensive Care Unit, Hospital Universitari de Girona Doctor Josep Trueta, Girona, Spain; [2]Pharmacology Department, Hospital Universitari de Girona Doctor Josep Trueta, Girona, Spain
**Correspondence:** M. Vilà Rivas
*Intensive Care Medicine Experimental* 2024, **12(suppl 1):**000368

**Introduction:** Inhaled sedation (IS) using isoflurane is increasingly being adopted in Intensive Care Units (ICUs).

**Compared to conventional intravenous sedation (IVS), inhaled sedation (IS) with isoflurane may offer benefits, such as reduced opioid consumption, increased number of days free from mechanical ventilation (MV), or shorter awakening periods. However, most bibliographic references to date have not examined inhaled sedation (IS) periods longer than 72 h.**
**Objectives:** To evaluate the effectiveness of IS for a period greater than 21 days.

- To analyse adverse effects associated with IS.
- To assess the awakening process and the incidence of delirium.

**Methods:** We conducted a descriptive, observational, prospective, single-centre study from May 2022 to July 2023. The study included patients who received inhaled sedation (IS) from ICU admission and for more than 21 days. We analysed sociodemographic characteristics, reasons for ICU admission, duration of mechanical ventilation (MV), administered doses of isoflurane, effectiveness of IS using the RASS objective scale and BIS system over time, as well as the awakening process. Additionally, we monitored the presence of delirium and potential related adverse effects.
**Results:** The three patients were males aged 44, 56, and 63 years, admitted to the ICU for acute respiratory failure. The reasons for admission included asthmatic status (67%) and severe chest trauma (33%). They required deep sedation and long-term neuromuscular blockade due to infectious complications. Total MV days were 31 days in two patients and 43 days in the third, with corresponding ICU stays of 35, 38, and 45 days, respectively. Inhaled sedation (IS) was initiated upon admission, successfully achieving the target RASS and BIS values in 100% of cases without the need for additional intravenous sedation (IVS). The average administered doses of isoflurane ranged from 4 to 6 ml/h. Total IS days were 23, 23, and 24 days respectively. Subsequently, weaning was performed with light sedation, achieving RASS 0 within the following 24–96 h. Hyperactive delirium, diagnosed through the CAM-ICU scale, was detected in one out of the three patients (33%). Regarding adverse effects, we did not observe increased need for vasopressor support or alterations in hepatic, renal, or QTc complex function. Although bilateral unreactive mydriasis is not uncommon in our experience, it was not detected in any of these three cases.
**Conclusions:** In our case series of patients receiving IS for more than 21 days, we observed that IS remained effective over time without the need for additional intravenous sedatives. The weaning process was conducted using light sedation, achieving a RASS score of 0 in less than 4 days. The incidence of delirium was 33%. Additionally, no adverse effects were detected during IS administration.

**Topic:** Sedation, analgesia, and delirium

## The effect of hospital-acquired infections on mortality in polytrauma patients followed in intensive care unit

M. N. Balica[1], B. D. Kosovali[1], D. K. Kocatas[1], D. K. Caliskan[1], A. I. Keskin[1], E. Toy[1], A. Altunsoy[2], B. Akan.[1]

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000369

AQ15 **Introduction:** Polytrauma is a life-threatening condition. 10% of deaths in trauma patients occur due to sepsis. Infection risks in trauma patients include damage to mechanical barriers secondary to trauma, exogenous bacterial contamination, local wound factors, and invasive diagnostic and/or therapeutic interventions. In addition, weakening of the patient's immune system; damage to the host defense, which impairs both humoral and cell-mediated responses, is another risk factor.

**Objectives:** The primary aim of this study is to determine the infectious agents in polytrauma patients followed in intensive care unit (ICU) and to find out the effect of these factors on mortality. Secondary purpose is to identify antibiotic agents that are sensitive and resistant to infectious agents and to determine other clinical and laboratory parameters that may affect mortality.

**Methods:** Adult patients aged ≥ 18 years who were followed in ICU between March 2019 and November 2023. The patients had the polytrauma criteria were included in the study. Definition of polytrauma by Pape et al. and ISS classification was used for trauma severity. Demographic characteristics of the patients, type of trauma, injured body part, body part where surgery was performed, type of culture sample, isolated microorganisms, required and duration of MV, length of stay in ICU, and mortality rates were recorded.

**Results:** Of a total of 304 polytrauma patients, the most common type of trauma was road traffic accident (61.2%), the most common injured body part was the thorax (83.6%), and the most common was extremity surgery (40.8%). According to the ISS grouping, 55.3% of the patients have an ISS score between 0 and 20. A total of 428 ICU patients' samples were examined. The most frequently reported sample type was tracheal aspirates (33%). Surviving and deceased patient groups were compared; the rate of patients with higher ISS scores was higher in the deceased group and there was statistical significance between the roups ($p = 0.000$). Abdominal surgery was performed more frequently in the deceased group and limb surgery was performed more frequently in the survived group, and these parameters were significantly different between the two groups ($p$ values 0.04; 0.000, respectively) (Table 1). All patients who died required MV. The most frequently detected microorganisms in all culture results in all patients were *Staphylococcus epidermidis* (15.1%), *Acinetobacter baumannii* (11.5%), *Pseudomonas aeruginosa* (7.6%), and *Klebsiellapneumoniae* (5.6%), respectively. When the culture results of samples taken from surviving and deceased patients were compared, there was no difference between the microorganisms isolated. In the comparison after the isolated of mycoorganisms, *Klebsiella pneumoniae* was found to be significantly higher in the group that deceased, and *Proteus mirabilis* was found to be significantly higher in the group that survived (p values; 0.007 and 0.045, respectively). In this study, mortality rate was found 17.4% (Table 2). According to the results of logistic regression analysis, age ($p = 0.008$), duration of MV ($p = 0.038$), duration of hospitalization ($p = 0.010$), APACHE II score ($p = 0.000$), ISS score ($p = 0.000$), and intracranial trauma ($p = 0.000$) had a statistically significant effect on mortality. In multilogistic regression analysis, age ($p = 0.036$), length of stay in hospital ($p = 0.010$), APACHE II score ($p = 0.038$), and ISS score ($p = 0.000$) had a statistically significant effect on mortality.

**Conclusions:** According to these results, in our opinion that ISS values will be guiding in determining the prognosis of multitrauma patients in ICU. In addition, older age, higher APACHE II score, anatomical localization of trauma, and therefore damaged organs and causative pathogens have an impact on mortality.

### A prognostic model of the probability of developing respiratory failure in the postoperative period after cardiovascular surgery

D. Fomina[1], A. Eremenko[2]
[1]Cardiac Intensive Care Unit, < span Moscow, Russia; [2]Intensive Care Unit, Russian Research Center of Surgery, Moscow, Russia
**Correspondence:** D. Fomina
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000370

**Introduction:** Respiratory failure (RF) is a frequent complication of cardiac surgery. The determination of predictors would help to identify patients of risk for early prevention of respiratory failure in the postoperative period.
**Objectives:** Creation of a prognostic scale for determining the probability of developing RF in the early postoperative period.
**Methods:** 248 patients after cardiac surgery were included (1 group—SpO2 < 92%, 2 group—SpO2 ≥ 92%). SpO2 was evaluated 8–10 h after trachealextubation on breathing atmospheric air.
**Results:** To study the influence of predictor factors on the development of RF, a one-factor logistic regression was performed. The next stage was the creation of a prognostic model, depending on statistically significant factors after the first stage, using multifactorial logistic regression. The logistic function was obtained ($p < 0.001$):
$P = 1/(1 + e{-}z)$.
$z = 0.13*\text{Xhypovent} + 0.19*\text{XBMI} + 0.45*\text{XVENT} + 2.25*\text{Xsmok} + 2.84*\text{Xproced} - 9.5$, As a result of the analysis, the values of regression coefficients, the presence of hypoventilation, BMI, duration of ventilation, smoking experience of more than 15 packs/years, and simultaneous performance of three or more procedures were obtained—factors that increase the likelihood of developing RF in the early postoperative period (sensitivity—95.2%, specificity—73.9%). Cut-off points for BMI and ventilator 27.75 kg/m$^2$ (Se = 67.7%, Sp = 65.2%, 95% CI [0.56–0.79], AUC 0.68, $p < 0.001$) and 6.3 h (Se = 66.1%, Sp = 78.3%, 95% CI [0.65–0.78], AUC 0.71, $p < 0.001$) accordingly. These factors were included in regression with optimal scaling for assigning points, points are obtained by multiplying the importance coefficient by 100 (Table 1).
The final score in the sample was calculated. To determine the threshold score, ROC analysis was performed with a graph (AUC = 0.68, 95%CI 0.57–0.78, $p = 0.004$, cut-off point 46 points). Patients with threshold scores above 46 have a high probability of RF in the postoperative period after cardiac surgery (sensitivity-64.8%, -74.8%) (Fig. 1).

**Table 1 (abstract 000370)** The result of categorical regression with optimal scaling

| Predictor | Importance | Scores |
|---|---|---|
| Hypoventilation | 0,09 | 9 |
| Body mass index | 0,19 | 19 |
| Duration of ventilation | 0,44 | 44 |
| Smoking experience of more than 15 packs/years | 0,08 | 8 |
| Simultaneous performance of three or more procedures | 0,20 | 20 |

**Conclusions:** The statistical model of RF prognosis in cardiac surgery patients was developed. Identification of patients with high probability of such a formidable complication is of great importance for early initiation of preventive and therapeutic measures.

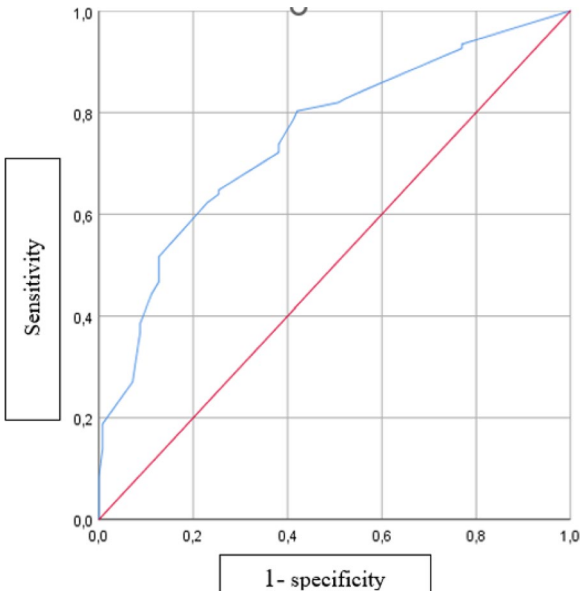

**Fig. 1 (abstract 370)** The ROC curve characterizing the dependence of the prognosis of the development of RF in the postoperative period in cardiac surgery patients

**Topic:** Acute respiratory failure and mechanical ventilation

**Introduction:** Intensive care unit (ICU) patients endure significant stress due to their critical condition and the noisy, aggressive environment. Communication difficulties contribute to feelings of frustration and stress. Despite efforts to humanize ICUs, there is a lack of real-time assessment tools for patient well-being and safety.
**Objectives:** To develop a scale assessing the feeling of well-being and safety in real time among ventilated ICU patients.
**Methods:** First, a systematic review was performed to identify study outcomes evaluating safety and well-being feeling of ICU patients. Results were used to organize focus groups, including 23 former patients and 5 relatives, and explored patients' experiences and needs

during the ICU stay, informing scale development in a co-construction framework. The scale was then developed via three-round Delphi methodology by a patient-professional expert group ($n=55$ participants). The scale was then validated through patients' interview for face validity and implementation in a multicentric cohort of 84 ICU patients. Finally, the scale was translated into English, retro-translated to French, and cross-validated.

**Results:** The systematic review initially identified 883 articles, with 136 (15%) included for analysis. Focus groups highlighted the communication challenges faced by patients and healthcare workers and the need for human support in ICUs. Scale construction emphasized simplicity and positive wording, resulting in an initial 6-item pragmatic bedside tool. Face validation showed that the constructed scale was acceptable in terms of lengths and effort required to respond and let to refining the scale changing item evaluation formats to a four-stage Likert scale. Cohort validation, comprising 305 scale administrations, indicated overall satisfaction and adequate completion rates. Psychometric analysis revealed issues with one item and residual correlation analysis suggested potential redundancy between two items, leading to the removal of two items from the scale. A simplified 4-item scale (Comfort, Safety, Information, Trust) demonstrated improved reliability and coherence, and English translation showed no issue after retro-translation.

**Conclusions:** The final scale ranges from 0 to 12 and provides a practical measure of patient well-being in ICUs and is usable in real time at the bedside.

**Introduction:** Pulmonary embolism (PE) is a significant cause of in-hospital mortality, often leading to admission to the intensive care unit (ICU) due to hemodynamic instability and/or severe hypoxemia. Worldwide data suggest an increasing incidence of PE.

**Objectives:** Worldwide data suggest an increasing incidence of PE. This study aimed to analyze changes in the incidence of PE, as well as the presentation type according to severity, treatments, independent factors associated with its diagnosis, and outcomes of patients admitted to a tertiary university hospital's ICU.

**Methods:** A retrospective study was conducted using a database including all patients admitted to the ICU between 2018 and 2023. PE was confirmed using CT angiography.

Severity stratification (high, intermediate–high, intermediate–low, low) was based on 2019 clinical guideline criteria. Right-ventricular dysfunction was diagnosed by echocardiography in the presence of right-ventricular dilation (right/left area ratio > 0.6) and/or paradoxical septal motion. Demographic and relevant clinical and physiological data were collected within the ICU stay. Follow-up time was until intensive care unit discharge. Continuous variables are presented as mean (95% confidence interval) and compared using Student's t test. Categorical variables are presented as number (percentage) and compared using the Chi-square test or Fisher's exact test. Multivariable logistic regression analysis was performed to evaluate independent factors related with PE presence, including factors associated in univariate analysis and those described in the literature.

**Results:** Over the 6-year period, 3574 patients were admitted, 41% women, with at mean age of 61.7 years (61.2–62.3) and SAPS III score of 62.6 (61.9–63.4). Of these, 118 patients were diagnosed with PE, resulting in an overall incidence of 3.3%, with significant differences observed between different years: 2018 (1.7%), 2019 (2.6%), 2020 (2.2%), 2021 (5.8%), 2022 (3.5%), and 2023 (3.8%). However, the significant increase in PE diagnoses in 2021 was mainly attributed to low and intermediate–low-risk PE, while high-risk PE showed a significant increase in 2023 (Figure 1). Compared to other patients, those diagnosed with PE were older (66 [64–69] vs. 62 [61–62]; $p=0.001$), had similar severity in terms of SAPS III (59 [56–63] vs. 63 [62–64]; $p=0.125$), similar prevalence of solid cancer history (14.4% vs. 15.7%; $p=0.113$), and a higher incidence of COVID-19 (44.1% vs. 28.1%; $p<0.001$). Regarding outcomes, patients with any degree of PE required longer ICU stays (13 [10–17] vs. 9 [9–10]; $p<0.001$) and days of mechanical ventilation (13 [10–16] vs. 9 [8–9]; $p<0.001$), with similar in-ICU mortality (32.2% vs. 25.3%; $p=0.107$).

When analyzed by PE risk subgroup (Table 1), no significant differences were found in age, sex, or cancer history. Among patients with low-risk PE, a higher percentage had COVID-19 compared to other PE groups and required more days of mechanical ventilation and ICU stay. There were no significant differences in terms of mortality. PE was the reason for admission in 87% (33 out of 38) of high-risk patients, 100% (7 out of 7) of intermediate–high-risk patients, in 1 patient out of 31 intermediate–low-risk patients, and in none of those with low-risk thromboembolism.

Regarding treatments, systemic fibrinolysis was applied in 63.2% of patients with high-risk PE, mechanical thrombectomy in 13.2%, and the remaining 23.6% did not undergo fibrinolytic treatment or thrombectomy due to poor prognosis ($n=9$). Systemic fibrinolysis was not performed in any cases of intermediate–high-risk PE, and mechanical thrombectomy was only performed in two cases.

In multivariable analysis, factors independently related to PE diagnosis in our population were age with an OR of 1.025 per year (1.011–1.040; $p=0.001$) and COVID-19 diagnosis with an OR of 1.945 (1.333–2.837; $p=0.001$).

**Conclusions:** In our cohort, there is an increasing incidence of PE, primarily driven by an increase in low-risk PE diagnosis in patients admitted in the context of COVID-19. However, in 2023, there is a significant increase in ICU admissions due to high-risk PE.

**Introduction:** Pulmonary graft-versus-host disease (GVHD) is a common late-onset non-infectious pulmonary complication post-hematopoietic stem cell transplantation (HSCT), often presenting bronchiolitis obliterans syndrome (BOS) or interstitial lung disease (ILD). Despite complexity, lung transplantation (LTx) remains a potential treatment, although rarely reported.
**Objectives:** This study aims to elucidate the clinical features and outcomes of patients who underwent LTx subsequent to HSCT, focusing on those with pulmonary GVHD.
**Methods:** A retrospective analysis was conducted on 152 consecutive LTx patients between February 2012 and December 2023. Baseline characteristics, clinical data, and short-term surgical outcomes were compared between GVHD and non-GVHD groups.
**Results:** Among 152 patients, 21 (13.8%) underwent LTx due to pulmonary GVHD after HSCT. The majority (85.7%) received bilateral sequential LTx. The GVHD group (mean age 29.7 ± 14.6 years) was significantly younger than the non-GVHD group (56.0 ± 14.7 years, $p < 0.001$). Median time from HSCT to GVHD diagnosis was 10 months (range from 2.1 month to 8.9 years) and from HSCT to LTx was 3.8 years (range from 1.3 month to 16.2 years). ECMO bridge before LTx was performed in 42.9% of GVHD patients. The GVHD group had longer ICU stays (13 days vs 10 days, $p = 0.025$), but no significant difference in 30-day mortality (9.5% vs 6.1%, $p = 0.63$), and 1-year (80.7% vs 78.1%) and 3-year survival rate (67.2% vs 65.9%, $p = 0.358$) compared to the non-GVHD group. Chronic lung allograft dysfunction occurred in 11 patients during a median 3.9-year follow-up, with one relapse of hematological malignant post-LTx.
**Conclusions:** Lung transplantation may be a valuable therapeutic option in selected patients with pulmonary GVHD post-HSCT. Further research is warranted to better understand its efficacy and long-term outcomes.

### Time-varying intensity of ventilatory efficiency and mortality in patients with acute respiratory distress syndrome

L. Jiang, H. Chen, J. Xie, L. Liu, Y. Yang
Department of Critical Care Medicine, Zhongda Hospital, School of Medicine, Southeast University, Nanjing, Jiangsu, China

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000378

**Introduction:** Acute respiratory distress syndrome (ARDS) is a life-threatening respiratory failure characterized by hypoxemia and impaired carbon dioxide (CO2) clearance, requiring support with invasive mechanical ventilation [1–2]. Maintaining adequate oxygenation and ventilation is the core purpose of mechanical ventilation [3–4]. The association between ventilatory parameters [arterial carbon dioxide pressure (PaCO2) and ventilatory ratio (VR)] and mortality for patients with ARDS remains controversial. Furthermore, it is unknown whether the association remains persistent over time.
**Objectives:** Our primary objective was to evaluate the impact of time-varying exposure to various intensities of ventilatory efficiency (as indicated by PaCO2 and VR) on the 28-day mortality in patients with ARDS and whether the strength of the effect persisted over time. We also quantified the cumulative impact of these exposure over time.
**Methods:** We performed a secondary analysis of four randomized-controlled trials (FACTT, ALTA, EDEN, and SAILS) conducted by the ARDS Network. Involved patients were all intubated and received mechanical ventilation. Patients were excluded if they received extracorporeal life support or received mechanical ventilation less than 1 day. The primary outcome was 28-day mortality. Potential confounders were identified based on the missing value, collinearity, and directed acyclic graph. We then employed the cause-specific Cox proportional hazard models and Bayesian joint models to estimate the strength of associations over time.
**Results:** Upon reviewing the data from 3027 patients, 2851 patients were finally included in our analysis. The overall 28-day mortality rate was 21.3%. After adjusting for both time-independent and time-dependent confounders, each daily increment in PaCO2 (HR 1.008, 95% CI 0.997–1.018) was not associated with mortality while daily increment in VR (HR 1.548 95% CI 1.309–1.835) was associated with increased mortality in the joint model analysis. The lack of a significant correlation between the intensity of PaCO2 and mortality remained constant throughout the entire period of ventilation. VR significantly influenced 28-day mortality, particularly in the early to middle phases

of ARDS (roughly 0–23 days of mechanical ventilation) [Figure 1]. Additionally, each additional day of exposure to potentially injurious intensity of ventilatory efficiency reflected by VR > 2 (HR 1.088 per day, 95% CI 1.034–1.147) was related to an elevated risk of death after adjustments. We also observed its cumulative impact of exposure to higher intensities of ventilatory inefficiency (HR 1.085 per area, 95% CI 1.050–1.122).

**Conclusions:** We concluded that a time- and dose-dependent exposure to harmful intensities of ventilatory efficiency measured by VR instead of PaCO2 was associated with increased mortality in ARDS. Therefore, VR needs to be closely monitored when using invasive mechanical ventilation, especially in the early and middle courses (approximately within 23 days after ventilation). Adopting ventilation strategies that limit cumulative exposure to high VR showed potential in reducing mortality among patients with ARDS.

## Epidemiology of severe acute respiratory infection in the Republic of Korea

S. Kim, S. I. Lee
Pulmonary and Critical Care Medicine, Chungnam National University Hospital, Chungam National University College of Medicine, Daejeon, Republic of Korea
**Correspondence:** S. I. Lee
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000382

**Introduction:** A nationwide prospective surveillance was conducted in the Republic of Korea from 2017 to 2022 to study severe acute respiratory tract infections across all age groups. This report analyzes the characteristics and epidemiology of 47,857 patients enrolled in the study.

**Objectives:** We conducted this study to compare the epidemiology of severe acute respiratory tract infections in Republic of Korea by patient characteristics.

**Methods:** Patients were enrolled from various institutions during 2017–2022, meeting criteria of symptom onset within 10 days of hospital admission, fever ≥ 38 °C, cough symptoms, and hospitalization.

**Results:** Among patients, 52.5% (25,132) had an identifiable pathogen, with rhinovirus (11.8%), respiratory syncytial virus (9.9%), and coronavirus-19 (9.6%) predominant (Figure). Notably, pathogen distribution varied significantly by sex, region, age, and prognostic outcome. Among them, the distribution of pathogens by age was as follows. In children younger than 7 years, rhinovirus (22.8%), respiratory syncytial virus (20.5%), and mycoplasma pneumoniae (11.3%) were most common. School-aged children (8–18 years) had a higher prevalence of Mycoplasma pneumoniae (23.1%), influenza (13.1%), and rhinovirus (12.2%). Among adults (19–64 years), coronavirus-19 (21.2%), *Streptococcus pneumoniae* (6.2%), and influenza (5.4%) were prevalent. In the elderly (≥ 65 years), coronavirus-19 (13.0%), *Streptococcuspneumoniae* (7.8%), and influenza (6.0%) were the most common pathogens.

**Conclusions:** This study provides valuable insights into the epidemiology of severe acute respiratory infections in Korea and highlights the need for targeted management strategies based on age and pathogen type. It emphasizes the importance of continuous surveillance and research to adapt to the dynamic patterns of respiratory pathogens.

### Effects of enteral nutrition timing on one-year mortality in ARDS patients receiving prone position therapy: a retrospective analysis

C. Y. Wang[1], C. H. Wang[2], C. Y. Hsu[3]
[1]Department of Critical Care Medicine, Taichung Veterans General Hospital, Taichung, Taiwan; [2]Graduate Institute of Education, National Changhua University of Education Jin De Campus, Changhua City, Taiwan; [3]Biostatistics task force, Taichung Veterans General Hospital, Taichung, Taiwan
**Correspondence:** C.Y. Wang
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000385

**Introduction:** Interventions like enteral nutrition (EN), conservative fluid management, and prone positioning are recognized for severe ARDS. While prone positioning's short-term benefits are studied, there are limited data on its long-term impact on mortality in ARDS patients. Nutritional catabolism is divided into early (Days 1–2) and late periods (Days 3–7), but it is unclear how caloric intake routes in these periods affect long-term mortality.
**Methods:** We conducted a retrospective study at a tertiary medical center, collecting data from January 2015 to March 2021. The inclusion criteria were ARDS patients who received prone position therapy in the first 7 days of ICU admission, aged 20 years or older, with exclusion criteria of ICU stays lasting less than 7 days.
**Results:** The study enrolled a total of 160 patients, with an average age of 60 years old and an APACHE II score of 30. The following factors were found to be associated with higher 1-year mortality in the multivariable Cox regression model: older age (HR: 1.02, 95% CI 1.00–1.04), shock with more than two vasopressors (HR: 2.03, 95% CI 1.09–3.79), more positive fluid balance status (HR: 1.08, 95% CI 1.02–1.14), and less caloric intake from enteral nutrition between days 3 and 7 (HR: 0.21, 95% CI 0.07–0.60). The ROC curve showed a cut value of average daily caloric intake from EN between Days 3–7 was 499 kcal/day. It was found that patients who were older than 65 years old, male gender, BMI > 18, CCI $\geq$ 3, had an APACHE II score higher than 26, experienced shock with more than two vasopressors, and NUTRIC score $\geq$ 5 were more likely to benefit from higher caloric intake.
**Conclusions:** The results of our study suggest that higher EN intake between days 3 and 7 may be associated with lower 1-year mortality in ARDS patients who received prone position therapy.

**Topic:** Metabolism, endocrinology, liver failure, and nutrition

**Introduction:** Dysregulated inflammation contributes to COVID-19 severity, with SARS-CoV-2 triggering cytokine release and potential multi-organ failure. While immunosuppressed (IS) patients are at risk due to their compromised immunity, they might experience less harmful inflammatory responses.
**Objectives:** This study aimed to compare clinical features and outcomes between IS and non-immunosuppressed patients (nIS), examine differences among IS subgroups according to etiology of the immunosuppresison, and assess tocilizumab's impact on IS patients.
**Methods:** This observational study, part of the CIBERESUCICOVID project, analyzed COVID-19 patients in 55 Spanish ICUs. Excluding those under 18 or without confirmed SARS-CoV-2 infection or known immunocompetence status, it classified patients as IS based on specific criteria like organ transplantation, HIV, active cancer, or chronic immunosuppressive medication use. The study aimed to assess mortality risk in IS patients, using propensity score matching and a multivariable model to identify predictors of in-hospital mortality, including the effect of tocilizumab treatment.
**Results:** Table 1 displays the main features of both study groups. Both in-hospital and 90-day mortality rates were higher in IS patients compared to nIS patients. Similar rates of complications were observed, with a higher incidence of renal failure and organizing pneumonia noted in IS patients. After propensity score matching, which balanced the two groups (1:1), IS patients still had a higher risk of in-hospital and 90-day mortality (Table 2). Among the different classes of IS, after propensity score matching, only transplanted patients continued to exhibit significantly higher odds of in-hospital mortality compared to nIS patients (sHR 2.28; 95% CI 1.05–4.94)( Figure 1). IS patients who received tocilizumab had lower in-hospital mortality rate compared to IS patients who did not receive it (38% vs 45%). After adjusting for confounding factors, the administration of tocilizumab was found to be an independent protective factor for in-hospital mortality (sHR 0.61; 95% CI 0.45–0.82).
**Conclusions:** IS is a significant risk factor for mortality in ICU patients. Among them, transplanted patients have the highest mortality risk. Tocilizumab could lower the in-hospital mortality risk in IS patients.

**Table 1 (abstract 000386)** Characteristics of the study population

| | Full cohort (N = 5,824) | | |
|---|---|---|---|
| | No immunosuppressed (N = 5,135) | Immunosuppressed (N = 689) | P-value |
| Age, median (Q1; Q3), years | 63 (54; 70) | 65 (55; 71) | **0.005** |

### Patients experiences after heart transplantation: systematic review of qualitative studies

M. Danielis, R. Zanotti, S. Nour El Hadi
Department of Cardiac, Thoracic, Vascular Sciences and Public Health, University of Padua, Padua, Italy

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000387

**Introduction:** After heart transplantation, patients' health is affected by a multitude of factors, many of which may be unfamiliar to the healthcare professionals. The process surrounding heart transplantation, both during and after the procedure, is highly complex, highlighting the need for studies that delve into patient experiences. Heart transplantation significantly disrupts recipients' daily activities and exposes them to various challenges that may compromise adherence to their care plan and jeopardize the success of the transplant. Given the wealth of research documenting its impact on quality of life and lifestyle adjustments, we recognized the need to synthesize these findings.
**Objectives:** To investigate the post-heart transplantation experiences of patients, this study conducted an in-depth analysis of existing qualitative research, aiming to gain a comprehensive understanding of the diverse facets of their post-transplantation journey, with a particular focus on their quality of life.

**Methods:** We conducted a systematic search across Cumulative Index to Nursing and Allied Health Literature (CINAHL), Embase (Ovid), MEDLINE (Ovid), Social Science Citation Index (Web of Science), and Scopus databases up to September 30, 2023. We included primary studies focusing on qualitative data, encompassing designs, such as phenomenology, grounded theory, ethnography, and descriptive research. Following Sandelowsky and Barroso guidelines, our analysis involved: (a)

extracting findings, (b) editing for accessibility, (c) grouping into topical domains, and (d) abstracting findings. The Critical Assessment Skills Programme checklist was used for the quality assessment of studies.
**Results:** A total of 13 studies with 176 patients were included. Figure 1 summarizes the themes and categories that emerged as affecting patients' reports of their experiences post-transplant. The 28 codes that emerged from the abstraction process were grouped into seven categories and three themes. In the theme of 'Undergoing an emotionally charged journey,' heart transplant patients described post-transplant psychological challenges, including coping with emotional optimism. Transitioning to 'Balancing personal health and social dynamics,' they navigated transformative adjustments and perceptions, managed medications and a lifelong care plan, and confronted social challenges. In the final theme, 'Fostering existential reflection,' patients explored revised life goals and navigated interpersonal dynamics.
**Conclusions:** Patients undergoing heart transplantation navigated a spectrum of emotions, faced challenges such as adjusting habits, and often embraced new opportunities for the future. Nurses and doctors should enhance the post-heart transplant experience for patients by implementing small changes, such as prioritizing effective communication, ongoing education, and fostering collaboration among multidisciplinary teams. These initiatives were essential for ensuring the delivery of high-quality care.

**Introduction:** The optimal management of sedation in critically ill patients is crucial for improving clinical outcomes. While intravenous sedation has been extensively studied, experience with inhaled sedation in critically ill patients during prolonged periods is less explored.
**Objectives:** To describe the characteristics of a cohort of patients with the use of inhaled sedation for more than 7 days.
**Methods:** Single-center retrospective study of patients admitted to the ICU of Vall d'Hebron Hospital from June 2020 to October 2023. Patients who required inhaled sedation for 7 days or more were included.
**Results:** 39 patients were included. The median age was 56 years, with 29 men (71.8%) and 11 women (28%). Comorbidities included hypertension in 23.1% ($n=9$), diabetes in 20.5% ($n=8$), and immunosuppression in 20.5% ($n=8$). Additionally, 48.7% ($n=19$) had chronic respiratory pathology, while 5.1% ($n=2$) had ischemic heart disease. Regarding lifestyle habits, 30.8% ($n=12$) were active smokers, 28.2% ($n=11$) consumed alcohol, 7.7% ($n=3$) had chronic opioid use, and 20.5% ($n=8$) had chronic benzodiazepine use. The median SOFA score at 24 h of admission was 7.
The main reason for ICU admission in 64.1% ($n=25$) of cases was respiratory causes, with other causes including sepsis 5.1% ($n=2$), neurological pathology 5.1% ($n=2$), and pancreatitis 17.9% ($n=7$).
Regarding duration, 22 patients were sedated for 7–10 days, 8 patients for 11–14 days, 4 patients for 15–20 days, and 5 patients required inhaled sedation for more than 20 days. The median duration was 8 days with a minimum of 1 day and a maximum of 38 days. Isoflurane was the most commonly used sedative.
Inhalation sedation was indicated for difficult sedation in 50.0% ($n=18$) of patients. In 2 cases, it was used due to side effects of IV sedatives. Twelve patients required its use as a bronchodilator, and in 4 cases, it was used to avoid accumulation effects of IV sedatives.
Twelve patients experienced side effects, with 10 showing pupil changes and 2 experiencing hypotension. Reported pupil changes were mainly mydriasis and anisocoria, related primarily to dose and duration of therapy. Pupil changes led to imaging tests in 6 patients, with structural pathology due to intraocular infection found in 1 case. All other events reversed after discontinuation of the sedative when the patient met sedation cessation criteria. No other adverse effects were reported.
**Conclusions:** The use of inhaled sedation for periods exceeding 7 days does not present significant adverse effects and emerges as a safe alternative. The importance of considering potential pupil alterations is emphasized.

**Introduction:** Post-cardiac arrest care advancements have improved resuscitation outcomes, but many survivors still face severe neurological deficits or death from brain injury. Accurate prognosis prediction is crucial for guiding treatment decisions, including withdrawal of life-sustaining treatment. Various methods exist, including brain computed tomography (CT), which assesses cerebral edema, a marker of poor outcome. However, subjectivity of the measurer and difficulties in selecting the measurement area in patients with severe cerebral edema limit its usefulness for prognosis in clinical practice.

**Objectives:** Herein, we propose a consistent and unbiased prognosis prediction approach using magnetic resonance imaging (MRI) to analyze anatomical regions represented by the gray and white matter, and subsequently apply it on CT to calculate the gray–white matter ratio (GWR). We compared this novel method with traditional measures to validate its ability to predict the prognosis of patients resuscitated after cardiac arrest.

**Methods:** This retrospective study was conducted at two tertiary university hospitals in South Korea between January 2018 and December 2022. Data were collected from adult cardiac arrest survivors treated with therapeutic target temperature management. Patients underwent brain CT within 2 h and brain MRI within 3 days of return of spontaneous circulation. Exclusions comprised individuals with brain parenchymal abnormalities or unsuitable CT images, along with those with pre-arrest cerebral performance category (CPC) scores of 3 or 4. Data collected encompassed demographic characteristics, pre-arrest cerebral performance category (CPC), emergency medical services (EMS) records, initial electrocardiogram (ECG) rhythms, Glasgow Coma Scale (GCS), Mean Arterial Pressure (MAP) after ROSC, target temperature during TTM, Sequential Organ Failure Assessment (SOFA) scores, and resuscitation process timing. GWR in the basal ganglia region was calculated by structuring the caudate nucleus, putamen, posterior limb of the internal capsule, and corpus callosum on MRI using MIM software and then applying it to CT using 3D slicer software to measure HU. The outcome was the neurological status at discharge. Statistical analyses included receiver-operating characteristic curve analysis and determining cut-off values to predict poor neurological outcomes.

**Results:** Overall, 51 of the 421 adult comatose cardiac arrest survivors examined met the inclusion criteria. Among these, 33 and 18 exhibited good and poor neurological outcomes, respectively. Demographic and cardiac arrest characteristics were compared between the two groups, revealing significant differences. Analyses of gray and white matter attenuation and GWR measurements highlighted significant differences between the good and poor outcome groups. MRI-based measurements generally outperformed traditional methods in predicting poor outcomes, with PU/PIC demonstrating the highest sensitivity at 100% specificity. Overall, GWRs measured by MRI-based CT showed superior predictive performance for poor neurological outcomes compared to traditional methods, with PU/PIC exhibiting the highest area under the ROC curve.

**Conclusions:** Our study introduces a novel method for measuring GWR using MRI-based brain CT, demonstrating the superior prognostic accuracy in predicting neurological outcomes in patients with post-cardiac arrest syndrome compared to traditional methods:

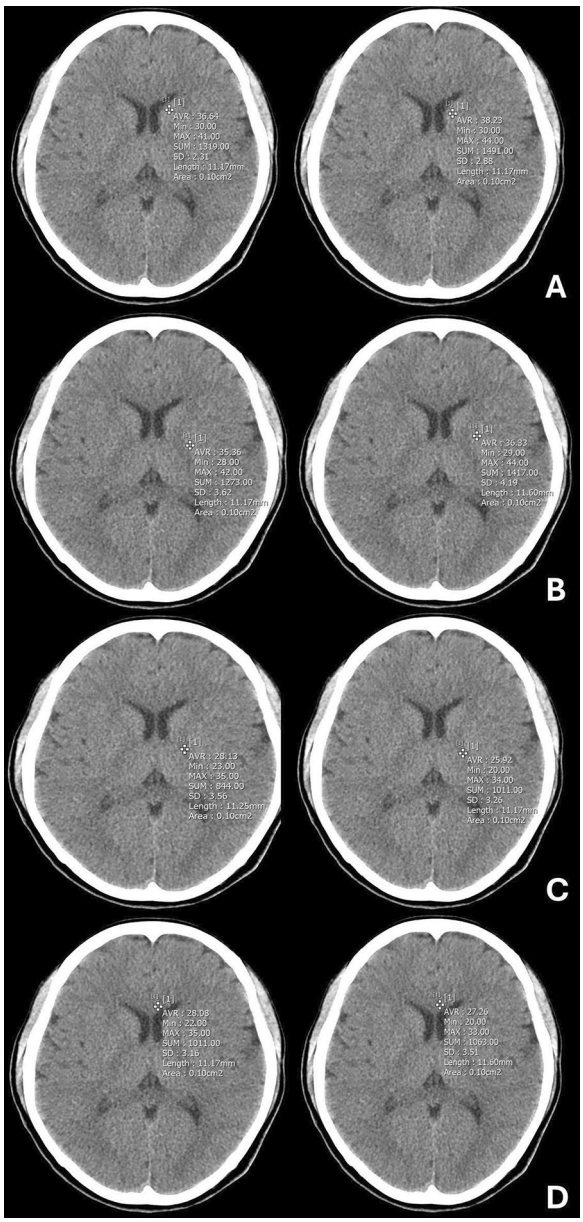

**Fig. 1 (abstract 000389)** With conventional measurement methods, differences in HU due to different measurement locations at the same anatomical site (A and B are HU measured in the caudate nucleus and

putamen, which are grey matter, and C and D are HU measured in the posterior limb of internal capsule and corpus callosum, which are white matter)

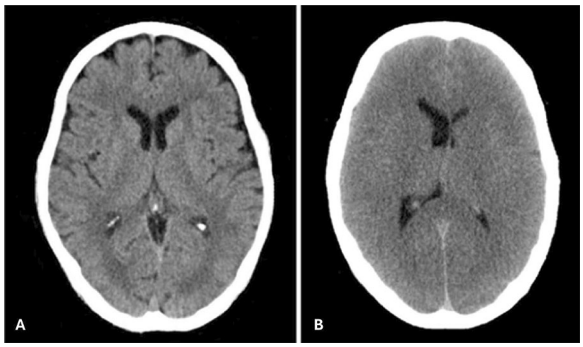

**Fig. 2 (abstract 000389)** CT of two patients, which resuscitation after cardiac arrest. It is possible in patients with clearly described anatomical structures such as A, but in patients with B with severe brain edema, subjective intervention by the measurer is inevitable, because the distinction of anatomical areas is not clear

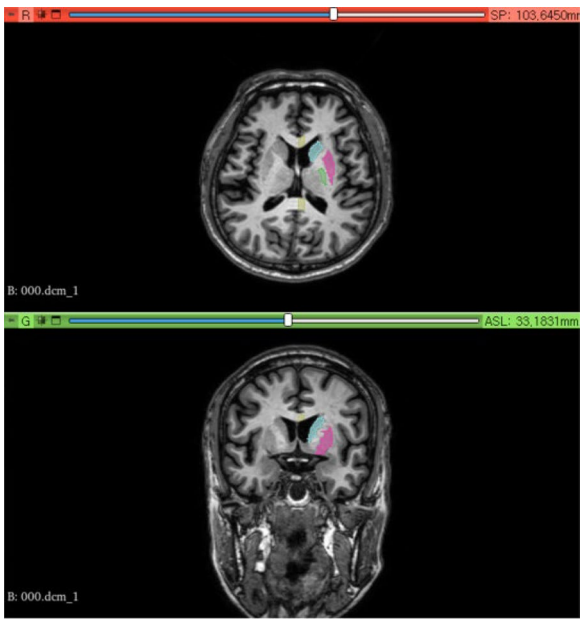

**Fig. 3 (abstract 000389)** Using 3D Slicer software (https://www.slicer.org/), patient brain MRI data were imported, and four regions of interest (ROIs) for measuring GWR-BG were delineated. These included the gray matter regions of the caudate nucleus and putamen, as well as the white matter regions of the corpus callosum and the posterior limb of the internal capsule

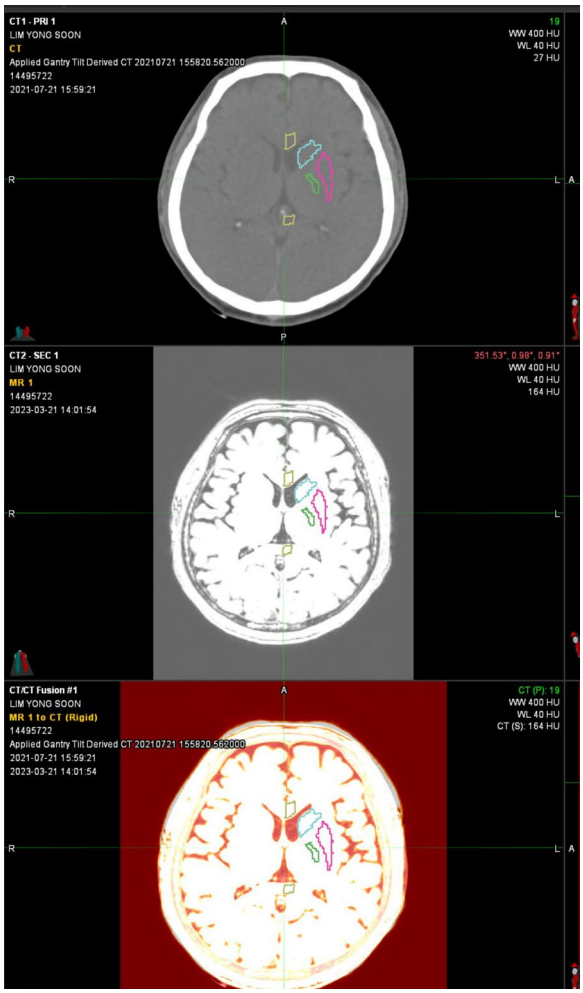

**Fig. 4 (abstract 000389)** The acquired MRI with segmentation was used to perform anatomical segmentation on CT of the same patient using the MRI-to-CT registration function of the MIM software (MIM Inc., Cleveland, OH, USA)

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000392

**Introduction:** Norepinephrine (NE) is considered a first-line vasopressor in septic shock. Nevertheless, concerns about the heterogeneity of both its formulation and use have been raised. While NE is titrated to achieve hemodynamic goals, the dose itself has been used as a proxy of severity and trigger for rescue therapies. However, considering the relationship between the drugs' clearance, plasma concentration, and body weight, scaling it to total body weight (TBW) could prove inaccurate and may lead to systematic bias in over/underweight patients. We hypothesized that TBW NE dosing would lose its mortality-predictive capacity at higher body mass index (BMI) ranges.

**Objectives:** To evaluate the predictive capacity of TBW NE dosing strategy in obese patients with septic shock.

**Methods:** We analyzed the MIMIC-IV v2.2 database, an open-access dataset of de-identified EHRs from BIDMC in Boston, Massachusetts. Patients fulfilling septic shock criteria according to Sepsis-3 consensus and with available height and weight data were included for analysis. ROC curves were constructed to assess the prognostic value of NE dose at diagnosis and maximum NE dose at 24 h for 28-day mortality, presented as AUROC [95% CI], in obese (BMI $\geq$ 30) and non-obese patients. The DeLong test was used to compare AUROC, a $p$ value < 0.05 was considered significant.

**Results:** 4123 septic shock patients (age 68 [57–78] years, BMI 27.7 [23.8–32.2]) were identified (obese: 35.6%). Charlson Comorbidity Index was 6 [4–8] and SOFA score at diagnosis was 7.8 ($\pm$2.96). 83.8% of patients were on invasive mechanical ventilation. ICU length of stay was 4.8 [2.5–9.7] days and 28-day mortality was 39.3%. Median TBW NE dose at diagnosis was 0.1 [0.05–0.2] mcg/kg/min and maximum 24 h TBW NE dose was 0.25 [0.12–0.42] mcg/kg/min.

The relationship between TBW NE dose and absolute NE dose for different BMIs of a single hypothetical 1.70m individual shows an increasing gap in absolute NE dose administered for different BMIs, especially at progressively higher doses (Fig. 1).

When comparing ROC curves of obese patients, a significant decrease in the mortality-predictive capacity of TBW diagnosis NE dose at higher doses ($\geq$ 0.3 mcg/kg/min) was observed (0.60 [0.56–0.63] and 0.50 [0.43–0.57], p = 0.021)(Fig. 2A). In contrast, this phenomenon was not observed in non-obese patients (0.56 [0.54–0.59] and 0.55 [0.50–0.60], $p$ = 0.7) (Fig. 2B). Also, at high TBW NE doses, a significant difference was observed when comparing the mortality-predictive capacity of the maximum NE dose in the first 24 h since diagnosis between obese and nonobese patients (0.56 [0.51–0.61] and 0.63 [0.60–0.66], $p$ = 0.01).

**Conclusions:** TBW NE dosing strategy loses its predictive capacity for mortality at higher doses in obese patients with septic shock, supporting the theoretical gap described in administered dose by BMI. Other dosing strategies may provide more accurate prognostic information and guide clinical decision-making in this population.

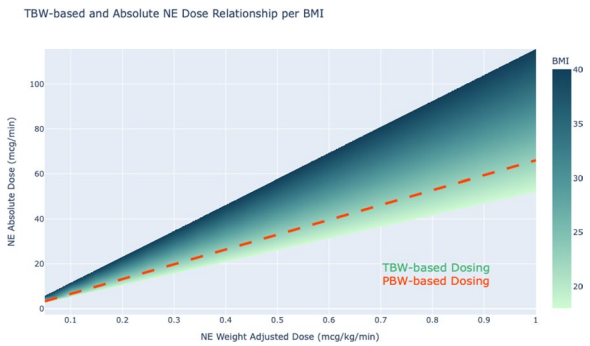

**Fig. 1 (abstract 000392)** Absolute norepinephrine dose administered at increasing total body weight-based norepinephrine dosing in a single hypothetical 1.70 m subject. The relationship was computed for different BMI values, depicting large gap in administered dose by changing the subject's weight

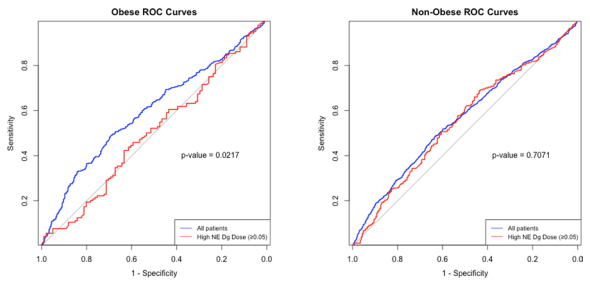

**Fig. 2A (000392)** (Left) ROC curves comparison for predictive capacity of high norepinephrine dose at diagnosis in obese patients. Figure 2B. (Right) ROC curves' comparison for predictive capacity of high norepinephrine dose at diagnosis in non-obese patients

**Introduction:** The patient's admission to an intensive care unit (ICU) can be a stressful event for their relatives (1). In this scenario, family satisfaction (FS) is defined as a quality indicator of ICU performance that measures salient aspects of relatives' experience, such as quality of patient care, communication, and decision-making (2). Despite its relevance, evidence on factors related to FS is limited with few variables being consistently reported as associated with FS (3).
**Objectives:** To explore factors associated with family satisfaction among relatives of ICU patients.
**Methods:** This is a secondary analysis of an ongoing longitudinal exploratory study exploring the incidence and related factors of post-intensive care syndrome family in a public hospital in Santiago, Chile. Relatives of ICU patients with 3–7 days of ICU stay and with respiratory support are been enrolled. Relatives provided sociodemographic data and completed 6 validated questionnaires to measure family satisfaction (FS ICU-24), anxiety/depressive symptoms (PHQ-4), vitality/fatigue (SF-36 Vt), cognitive function (MEFO test), resilience (BRCS), and perceived social support (mMOS-SSS). Spearman's correlation and Mann–Whitney *U* tests were utilized to explore potential associations and differences between constructs and FS levels. The original study was approved by the Health Sciences Ethics and Scientific Committee at Pontificia Universidad Catolica de Chile (ID: 220,318,015).
**Results:** Within the 108 relatives included in this study, clinically significant symptoms (CSS) of anxiety, depression, and fatigue accounted for 72.2%, 44.4%, and 39.8% of the sample respectively. Median perceived social support was 4.65 (IQR = 1.25) and low resilience was observed in 13.9% of family members. 11.1% of relatives were classified as at risk of mild cognitive impairment.
Bivariate analysis showed a negative association between FS and anxiety ($r = -0.227$, $p = 0.018$) and depressive symptoms ($r = -0.196$, $p = 0.042$). Conversely, a positive association between FS and vitality ($r = 0.309$, $p = 0.001$), resilience ($r = -0.306$, $p = 0.001$), and perceived social support ($r = 0.212$, $p = 0.028$). No signification association was found between FS and relatives' cognitive function or sociodemographic features ($p > 0.05$).
Then, significantly lower FS scores were observed among relatives with CSS of anxiety (*Mdn* = 76.6 v/s 84.3, $p = 0.016$), depression (*Mdn* = 73.9 v/s 81.5, $p = 0.044$), and fatigue (*Mdn* = 72.9 v/s 79.3, $p = 0.005$). Similarly, inferior FS scores but without statistical significance were observed among relatives with low resilience (*Mdn* = 73.8 v/s 80.4, $p = 0.053$) and mild cognitive impairment (73.4 v/s 78.4, $p = 0.284$).
**Conclusions:** Positive and negative psychosocial factors may influence FS levels among ICU relatives. The modifiable nature of the identified factors could assist ICU healthcare providers in their efforts to improve the quality of support and care to ICU relatives. Further studies exploring the role of relatives' psychological stressors and buffers on FS are warranted.

**Introduction:** Patients with various acute pulmonary conditions meet the diagnostic criteria for ARDS, although the conceptual model of "classic ARDS" is thought to be caused by insults, such as pneumonia, sepsis, and trauma. Guidelines published by the Society of Critical Care Medicine (SCCM) in 2024 suggest the administration of corticosteroids to adult hospitalized patients with ARDS.
**Objectives:** The aims of the present study were to investigate the proportion of patients who can be diagnosed with diffuse parenchymal lung diseases (DPLDs) by specialists in patients with acute respiratory failure who met the diagnostic criteria for ARDS prior to the emergence of COVID-19 in Japan and to investigate the associations of diagnosis with mortality and corticosteroid use.
**Methods:** This is a multicenter retrospective cohort study analyzing the electronic medical records of patients admitted to intensive care units (ICUs) across 10 hospitals in Japan between December 2017 and December 2019. We included patients who were endotracheally intubated due to acute respiratory failure and met the Berlin criteria for ARDS. We constituted an extensive database for DPLDs by extracting from the medical record as much as possible of the patient's information to be reviewed by DPLD specialists, such as basic demographics, occupation, past medical and family history, medication history, symptoms, physical findings, chest images, echocardiography, and lab results during and before hospitalization. Clinical diagnoses (initial clinical diagnosis by intensivists) and pulmonology diagnosis made based on the database by the DPLD specialists were classified into three categories, (1) Classic ARDS which was triggered by a clinical insult, (2) DPLDs other than IPF, and (3) IPF. DPLD specialists were blinded to the clinical diagnoses. The associations between diagnosis and mortality and those between corticosteroid use and mortality in each group were analyzed using the cox regression model.

**Results:** In total, 3641 patients who were on mechanical ventilation in 10 ICUs were screened, and 272 patients were included. 25.4% and 7.7% of the patients who met the diagnostic criteria of ARDS were diagnosed with DPLDs and IPF, respectively, by DPLD specialists. In addition, 13.2% of the patients clinically diagnosed with classic ARDS for whom the possibility of DPLDs was not mentioned were diagnosed with possible DPLDs by the specialists. Diagnoses of classic ARDS and IPF made by DPLD specialists were associated with increased mortality compared with DPLDs, with an unadjusted HR of 1.57 (95% CI 1.06 to 2.31, $p=0.023$) for classic ARDS and 1.71 (95% CI 1.06 to 2.75, $p=0.027$) for IPF. Corticosteroid use within 72 h after admission to the ICU was associated with higher mortality in patients with classic ARDS than in those with DPLDs (HR 5.19: 95% CI 1.69 to 15.9, $p=0.004$).
**Conclusions:** This study showed that a substantial number of patients who met the diagnostic criteria of ARDS had possible DPLDs and that individualization of patients based on diagnosis may be important in deciding whether to administer corticosteroids to patients with ARDS.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000400

**Introduction:** Postoperative hyperthermia is common and associated with neurocognitive impairment after cardiac surgery. Dexmedetomidine was reported to be associated with hyperthermia and is frequently used during and after cardiac surgery. A potential mechanism by which administration of dexmedetomidine results in hyperthermia is sparing propofol which impairs thermoregulation. We therefore performed a post hoc analysis of the DECADE trial aiming to test the hypothesis that dexmedetomidine administration increases the incidence of postoperative hyperthermia during the initial 24 h after cardiac surgery, and whether this effect is mediated by propofol dose.
**Methods:** We conducted a post hoc analysis of the DECADE trial in which patients were randomized to placebo or dexmedetomidine. Dexmedetomidine infusion was started before surgery at a rate of 0.1, was increased to 0.2 at the end of bypass, and was increased to 0.4 µg/kg/h postoperatively which was maintained until 24 h after the infusion started. DECADE tested the primary hypothesis that dexmedetomidine reduces atrial fibrillation and delirium after cardiac surgery (it did neither). For the current analysis, we primarily compared the fraction of patients having a postoperative body temperature $\geq$ 38 °C during the first 24 h after surgery in patients given dexmedetomidine or placebo using a generalized linear model for binomial distribution to estimate the relative risk (RR). Secondarily, we performed the same analysis restricted to patients with continued propofol administration within the first 24 h after surgery and with a threshold in postoperative body temperature of $\geq$ 37.5 °C, and planned to test for effect mediation by propofol dose. We adjusted for confounding in all analyses with inverse probability of treatment weighting for age, sex, race, body mass index, ASA status, and type and duration of surgery.
**Results:** We included 501 patients, 248 of whom were assigned to dexmedetomidine. After inverse propensity weighting, standardized mean differences were < 0.03 for all potential confounders. There was no significant difference in the incidence of postoperative body temperature $\geq$ 38 °C during the first 24 h after surgery (dexmedetomidine: 27%, placebo: 21%; RR: 1.2 [95%CI 0.9, 1.7], $p=0.25$). Similarly, there was no statistically significant difference in the incidence of postoperative body temperature $\geq$ 37.5 °C during postoperative propofol infusion (dexmedetomidine: 26%, placebo: 21%; RR: 1.2 [95%CI 0.8, 1.8], $p=0.32$) which precluded testing for mediation by propofol dose. Exploratory analyses for different thresholds for postoperative hyperthermia did not reveal any statistically significant difference (Table 1). A post hoc power analysis revealed that our sample size would have enabled us to detect a 52% increase in the risk for postoperative hyperthermia with a power of 80% and a type I error of 0.05.
**Conclusions:** Dexmedetomidine administration in patients having cardiac surgery did not significantly increase the incidence of postoperative hyperthermia. Our study was powered to detect increases in relative risk for postoperative hyperthermia exceeding 52%. Further studies are thus needed to exclude smaller effect sizes.

**Table 1 (abstract 000400)** Summary of the incidences of postoperative hyperthermia with different thresholds

| | Dexmedetomidine | Placebo | p-value |
|---|---|---|---|
| **During the first 24 hours after surgery (N = 501)** | | | |
| | **(N = 248)** | **(N = 253)** | |
| *Ever had postoperative core temperature ≥ 37.5 °C* | 116 (46.8) | 110 (43.5) | 0.46 [a] |
| *Ever had postoperative core temperature ≥ 38 °C* | 66 (26.6) | 52 (20.6) | 0.11 [a] |
| *Ever had postoperative core temperature ≥ 38.5 °C* | 21 (8.5) | 15 (5.9) | 0.27 [a] |
| *Ever had postoperative core temperature ≥ 39 °C* | 2 (0.81) | 3 (1.2) | 0.99 [b] |
| **During the propofol infusion period within the postoperative 24 hours (N = 320)** | | | |

### Intraoperative mechanical power is associated with impaired postoperative oxygenation: post hoc analysis of a single-center multiple crossover factorial cluster trial

L. M. Müller-Wirtz[1], C. Dussan[1], O. Kopac[2], M. Yazar[1], A. Gulluoglu[1], WM. Patterson[1], K. Mohammad[1], A. Reuter[1], S. Ott[1], L. Wang[1], M. Gama De Abreu[1], K. Ruetzler[1], A. Turan[1]

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000401

**Introduction:** Mechanical power quantifies the intensity of mechanical ventilation, considering the energy transferred from the ventilator to the respiratory system per time. Mechanical power is associated with lung edema, inflammation, postoperative pulmonary complications, and even with mortality in critically ill patients. However, data on the significance of mechanical power in surgical populations other than abdominal or thoracic surgeries remain sparse. Therefore, we conducted a post hoc analysis of our previous trial in which the effects of tidal volume and positive end expiratory pressure (PEEP) on postoperative oxygenation and pulmonary complications were investigated in patients having orthopedic surgery (1). We tested the hypothesis that the intraoperatively applied mechanical power normalized to predicted body weight (MP-PBW) is associated with impaired postoperative oxygenation in the postoperative anesthesia care unit (PACU).

**Methods:** We conducted a post hoc analysis of our recently published trial on intraoperative mechanical ventilation in patients having orthopedic surgery (1). The sequential factorial allocation of weekly clusters of patients to tidal volumes of 6 versus 10 ml/kg predicted bodyweight and a PEEP of 5 versus 8 cmH2O within the underlying trial provided a wide range of exposure to mechanical power. We calculated the MP-PBW for each patient included in the underlying trial and evaluated the association with the time-weighted average SpO2/FiO2 ratio over the first hour of PACU stay (SF-TWA) using a multivariable linear mixed model, accounting for the repeated surgeries per patient. We adjusted for the intervention treatment group in the underlying trial and demographic and intraoperative characteristics in all models.
**Results:** A total of 2,860 surgeries in 2,582 patients were included. Patients were on average 63 years (SD 14), 53% female, 83% Caucasian, had a mean BMI of 31 kg/m2 (SD: 7), and were mainly ASA III (72%). Mean MP-PBW was 0.20 J/min/kg (SD 0.06) and mean SF-TWA was 353% (SD 47). An increase in MP-PBW by 0.1 J/min/kg was associated with a reduction in SF-TWA by 11% (coefficient from multivariable linear mixed model: -11% [95%CI −14, −8], $p < 0.001$; Tab. 2). SF-TWA of patients with lower versus higher than the median MP-PBW (< 0.186 versus > 0.186 J/min/kg) were on average 8% higher (adjusted mean difference: 8%, [95%CI 4, 11], $p < 0.001$; Tab. 2).
**Conclusions:** Exposure to high intraoperative mechanical power is associated with impaired postoperative oxygenation in patients having orthopedic surgery. This supports the concept of mechanical power as a potential clinical target to optimize intraoperative ventilatory settings even in low-risk populations.

**Introduction:** Restoration of intravascular volume in the ICU after cardiac surgery improves tissue perfusion of organs previously ischemic by prolonged extracorporeal circulation (CPB) (1,2). The strategy of fluid replacement with albumin reduces endothelial damage, improves the role of coagulation, and expands the intravascular volume with a smaller amount of fluid administered, avoiding kidney damage due to overload. Achieving greater clinical benefit and lower morbidity and mortality (3,4).
**Objectives:** To assess whether 4% albumin solution in postoperative resuscitation in patients undergoing cardiac surgery shows better results compared to Ringer's lactate by reducing the incidence of postoperative complications.
**Methods:** Prospective observational cohort study, at a High Specialty Regional Hospital, level III in Northeast Mexico, during 2022–2023. Ages > 18 years were included, all with CPB > 120 min, they were observed in 2 groups: resuscitation with 4% albumin and resuscitation with lactated Ringer's during the first 48 h at 1 ml/kg/hr; the objective: perfusion, TAM > 70 mmHg, diuresis > 0.5 ml/Kg/min, lactate delta. We evaluated mortality, fluid accumulation, acute renal failure, lactate, coagulopathy, ventilation hours, and prolonged stay. We evaluated continuous variables with means ± SD, and categorical variables with proportions, using Chi(X2) and Mann–Whitney U, respectively.
**Results:** We analyzed 100 patients for 2 years, age 56.5 ± 10.8 (30–76), male 64%, hypertension 68%, DM2 58%, and dyslipidemia 33%. They were divided into 2 groups: albumin 54% vs ringer's lactate 46%. Days of ICU stay 4.48 ± 2.0 (1–14) and mortality 6% (Figure 1).

**Table (abstract 000403)**

**Outcomes**

| Variable | Albumina ($n = 54$) | Ringer ($n = 46$) | $p$ value < 0.05 |
|---|---|---|---|
| EUROSCORE | 3.80 | 3.64 | 0.434 |
| Age (years) | 55.7 | 57.4 | 0.531 |
| BMI (Kg/m$^2$) | 32.7 | 29.0 | 0.045 |
| LVEF (%) | 54 | 49 | 0.048 |
| Extracorporeal circulation time | 146 | 139 | 0.338 |
| Urine ml/h | 1.37 | 1.16 | 0.19 |
| Platelets 48 h | 253 | 209 | 0.090 |
| Days of inotropic | 1.52 | 1.54 | 0.965 |
| ICU days | 4.33 | 4.57 | 0.054 |
| Bleeding ml/48 h | 510 | 814 | 0.001 |
| Balance h 48 h/ml | 327 + | 734 + | 0.043 |
| Lactate (mmo/L) 48 h | 2.49 | 2.71 | 0.640 |
| Extubation time (h) | 8.31 | 9.7 | 0.002 |

**Conclusions:** Intravascular volume resuscitation 48 h after cardiac surgery with prolonged CPB based on 4% albumin presents balances with a tendency towards neutrality with respect to resuscitation with Ringer's lactate, as well as lower lactate levels, higher urinary volume, higher platelet count, and lower extubation time compared to intravenous use of lactated ringer's, showing similar results for days in the ICU and days of use inotrope.

### An exploration of the lived communication experience between nonverbal patients and healthcare professionals in Saudi intensive care units

H. Alodan[1], A. L. Sutt[2], R. Hill[1]; J. Cross[1]
[1]Faculty of Medicine and Health Sciences, University of East Anglia, Norwich, United Kingdom; [2]Faculty of Medicine, The University of Queensland, Saint Lucia, Australia

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000404

**Introduction:** Patients in intensive care units (ICUs) are frequently mechanically ventilated, leaving them nonverbal. This impacts their interactions with healthcare professionals (HCPs), causing frustration, anxiety, and increased burden of care. In Saudi Arabia, healthcare system is multicultural, indicating potential communication issues between HCPs and patients. However, little is known about the communication experience of nurses working with nonverbal patients in ICU, and the experiences of patients and other HCPs remain unexplored.
**Objectives:** To explore the lived communication experience between nonverbal patients and HCPs in Saudi intensive care units.
**Methods:** This qualitative study employed interpretive phenomenology. Using purposive sampling, interviews were conducted with five previously nonverbal patients and six HCPs from eight ICUs in two hospitals in Riyadh. Data were interpreted following a hermeneutic cycle and thematic analysis. Data of patients and HCPs were analysed separately but synthesised collectively to provide a comprehensive understanding of the communication dynamics between the two groups.

**Results:** Patients' experiences highlighted communication dynamics through balancing requirements and care, with two subthemes: individual experience against ICU care and elements of proper communication. HCPs' experiences showed language complexity and relevance, with three subthemes: cognition, emotions, and behaviours; individual and procedural effects; and language interference in patient-HCP communication. Findings from both groups showed that language barrier plays a vital role in enhancing or impeding effective mutual communication. Sedation was reported to delay the process of extubation and, consequently, mutual communication. Pain was regarded as the most important topic to communicate, with HCPs needing to find better ways to understand patients' pain. Communication through physical contact, lip reading, and signals was challenging due to the patients' condition and cultural and linguistic barriers. Text-based communication via mobile and communication boards was recognised as both lacking and desirable. Some HCPs reported neglecting communication, but others tried to understand their patients and learn new communication.
**Methods:** Patients indicated a need for training and learning English to understand non-Arabic-speaking HCPs. Unsuccessful communication caused negative emotions in both patients and HCPs, leading to discontinued interactions. Supportive communication from HCPs showed to improve patients' mental health and recovery, but it may be limited by a lack of tools and the language barrier.
**Conclusions:** Language barrier constitutes a central aspect that affects or is affected by other factors, including the patient's physical and psychological status, tool availability, and HCPs' attitudes. A simple communication tool customised to the ICU and the multicultural and multilingual Saudi healthcare system is suggested.

### The role of inflammation during high-dose corticosteroid therapy and its effect on mortality in COVID-19-related ARDS: a causal mediation analysis

K. Daenen[1], A. Boyd[2], H. Endeman[3]
[1]Intensive Care, Erasmus Medical Center, Rotterdam, The Netherlands; [2]Department of Infectious Diseases, Public Health Service of Amsterdam, Amsterdam, The Netherlands; [3]Intensive Care, Erasmus University Medical Center, Rotterdam, The Netherlands
**Correspondence:** K. Daenen
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000407

**Introduction:** Coronavirus disease 2019 (COVID-19) patients with acute respiratory distress syndrome (ARDS) without clinical improvement after standard of care low-dose dexamethasone [1] might benefit from treatment with high-dose corticosteroids (HDS) [2, 3]. The evaluation of the mediation effect of inflammatory biomarkers on

the association between HDS and mortality could provide valuable insights to evaluate whether a patient benefits from the treatment [4].
**Objectives:** The aim of this study is to investigate which biomarkers of inflammation mediate the effect of HDS on mortality in ICU patients with COVID-ARDS.
**Methods:** In this retrospective cohort study, patients presenting with COVID-19 caused ARSD admitted to the ICU of an academic hospital in the Netherlands, between March 2020 and June 2022 were included. HDS was defined as administration of > 6 mg of dexamethasone per day or an equivalent corticosteroid. Biomarkers evaluated were C-reactive protein (CRP), D-dimer, ferritin, leukocyte count, interleukin-6 (IL-6), lactate dehydrogenase (LDH), neutrophil-to-lymphocyte ratio (NLR) and procalcitonin (PCT). Causal mediation analysis was conducted to estimate the mediating effect of each individual biomarker on the association between HDS and all-cause in-hospital mortality. Indication bias of receiving HDS was corrected for using inverse probability of treatment weights. In addition, we performed an analysis to understand the level of inflammation over time increasing the risk of mortality, during HDS therapy.
**Results:** We included 327 patients, of whom 122 (37%) were treated with HDS and 87 (26.6%) died during hospital stay. P/F ratio, gender, SOFA-score, and date of admission were used to correct for treatment indication bias with IPTW. NLR, CRP, IL-6, and LDH were significantly mediating the effect between HDS and all-cause mortality, and the average mediation effects were 0.047 (95% CI 0.015, 0.086) for NLR, -0.030 (95% CI −0.050, −0.011) for CRP, -0.025 (95% CI −0.046, −0.009) for IL-6, and -0.013 (95% CI −0.028, −0.003) for LDH. NLR mediated 25.1% of the total effect of HDS on all-cause mortality, while decreasing CRP, IL-6, and LDH mediated 16.4%, 13.6%, and 7.2%, respectively (Figure 1). NLR exhibited an association with mortality on the majority of days after HDS. CRP demonstrated a significant association with mortality only at days 6 and 7 following HDS, while IL-6 exhibited significance only at day 7. LDH showed a significant association with mortality exclusively at day 6 after HDS (Figure 2).
**Conclusions:** Biomarkers NLR, CRP, IL-6, and LDH significantly mediated the association between HDS and all-cause mortality. The levels of inflammation posing an increased risk of mortality are most pronounced on days 6 and 7 after initiating HDS. These findings may represent an initial step towards a more personalized approach to the treatment of COVID-19-ARDS patients, but even non-COVID ARDS patients.

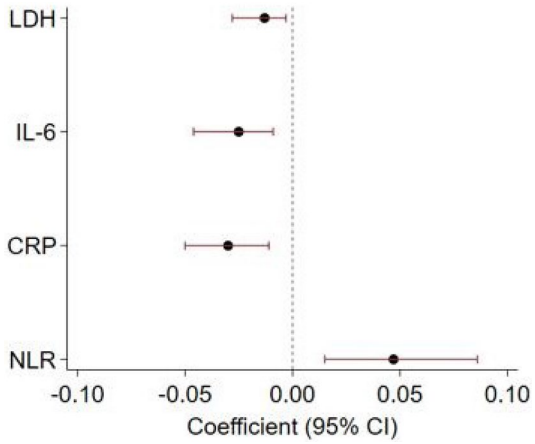

**Fig. 1 (abstract 000407)** Mediationg effect if biomarkers LDH, IL-6, CRP and NLR. In this figure, the mediation effects of biomarkers LDH, IL-6, CRP, and NLR are visualised of the association between HDS and all-cause mortality in COVID-19 ARDS patients in the ICU. Abbreviations: LDH, lactate dehydrogenase; IL-6, interleukin-6; CRP, C-reactive protein; NLR, neutrophil-to-lymphocyte ratio

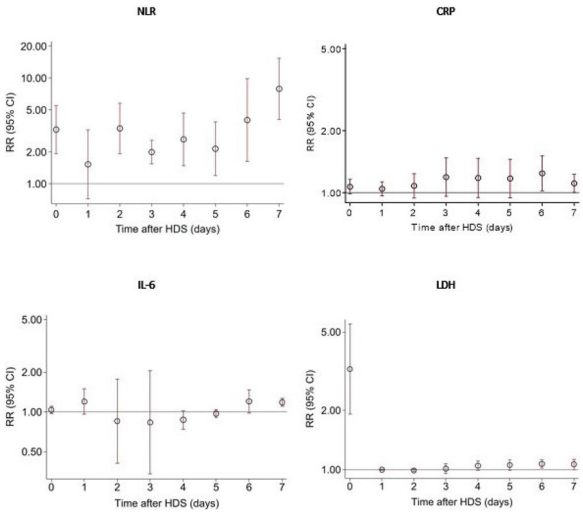

**Fig. 2 (abstract 000407)** Inflammation over time increasing the risk of mortality during high-dose corticosteroids. In this figure, the level of inflammation over time increasing the risk of mortality during HDS therapy was visualized. Abbreviations: RR, relative risk; HDS; high-dose corticosteroids; NLR, neutrophil-to-lymphocyte ratio; CRP, C-reactive protein; IL-6, interleukin-6; LDH, lactate dehydrogenase

### Use of supplemental melatonin for treating adults in intensive care with sepsis or septic shock: a systematic review and meta-analysis

M. John[1], C. McKenzie[1], M. Grocott[1], H. Galley[2], A. Cumpstey[1]
[1]NIHR Biomedical Research Centre, Perioperative and Critical Care Theme, University of Southampton School of Medicine, Southampton, United Kingdom; [2]School of Medicine, Medical Sciences and Nutrition, University of Aberdeen, Aberdeen, United Kingdom
**Correspondence:** M. John
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000408

**Introduction:** Sepsis (defined as organ dysfunction due to a dysregulated host response to infection) is a leading cause of death in the Intensive Care Unit (ICU). Despite early initiation of antimicrobials and crystalloid resuscitation, mortality remains high (> 10% for sepsis, rising to > 40% for septic shock) [1]. Effective pharmacotherapy is urgently needed. Melatonin's antioxidant, anti-inflammatory, and mitochondrial-protective properties make it a promising candidate [2, 3].

**Objectives:** Systematically review and analyse randomised and quasi-controlled trials for melatonin in sepsis and septic shock in the ICU.
**Methods:** The systematic review was registered on PROSPERO (CRD42023473436) and a search strategy devised. MEDLINE, Embase, CINAHL, and PubMed databases were searched, alongside Cochrane Register of Controlled Trials, Clinical Trials, and ISRCTN Registers from conception until 01/11/2023. The inclusion criteria were randomised or quasi-controlled trials, administering oral/enteral/intravenous supplemental melatonin in an adult ICU population (≥ 18 years), with sepsis or septic shock. Risk of bias and quality of evidence were assessed using RoB-2 (Cochrane Risk-of-bias 2) and GRADE (Grading of Recommendations, Assessment, Development and Evaluations) tools. Where appropriate, quantitative meta-analysis was performed using a random-effects model on Revman Web.
**Results:** Initial searches resulted in 306 publications. After title, abstract, and full-text screening, 5 eligible studies (total of 322 participants met all inclusion criteria. No studies were classed as 'low risk' with regards to risk-of-bias (RoB-2). Melatonin significantly reduced SOFA score from baseline (mean difference −2.22 [CI −2.63, −1.82], very low certainty, 2 studies $n=65$), and reduced all-cause mortality (odds ratio of 0.61 [CI 0.29, 1.29], very low certainty, 4 studies $n=161$) compared to placebo. Sufficient data for vasopressor-free days, ventilator-free days, and both hospital/ICU length of stay were only reported by a single study (all favoured melatonin).
**Conclusions:** Low-certainty evidence suggests melatonin (dose range 20–60 mg) appears to improve SOFA score and all-cause mortality in adults admitted to ICUs with sepsis or septic shock. Although, the findings should be interpreted with caution because of the low number of (mainly small) studies. Adequately powered clinical effectiveness trials are needed to confirm these findings.

**Introduction:** The cannulation of the internal jugular vein (VJI) is a frequent procedure in critically ill patients. As per current guidelines, real-time ultrasound navigation is employed for its execution. Our non-inferiority study compared the novel lateral in-plane short-axis approach for internal jugular vein cannulation with the conventional short-axis out-of-plane approach. The positioning of the ultrasound probe and the needle puncture direction for the novel approach are presented in Figure 1.
**Objectives:** The primary objective of the study was to prove that the first-attempt success rate in the novel approach is non-inferior to the first-attempt success rate in the conventional approach. The secondary objectives were to demonstrate that the complication rate and the functional duration of the catheter in the novel approach are not inferior to those in the conventional approach.
**Methods:** Patients eligible for VJI cannulation were randomly assigned to either the novel approach (Group A) or the conventional approach (Group B) with the use of computer algorithm. The procedure duration and the number of attempts required were documented. The functional duration of the catheter was monitored until either its extraction or malfunction. Incidences of complications were documented throughout the procedure and until catheter removal. Standard descriptive statistical methods were employed for the analysis.
**Results:** A total of 200 subjects were equally divided between the novel (Group A) and conventional (Group B) approaches for VJI cannulation. For the primary outcome, there was no significant difference in first attempt success rate (Group A: 79, Group B: 77, $p=0.434$). Secondary outcomes, including complication incidence and catheter functional time, did not differ significantly between the groups. However, the novel approach demonstrated a significantly faster procedure time (Group A: 315 s, Group B: 330 s, $p=0.016$). Notably, the novel approach was linked with significantly larger VJI diameter measured during the procedure (Group A: 18.2 mm, Group B: 12.1 mm, $p<0.001$).
**Conclusions:** The novel lateral in-plane short-axis approach for internal jugular vein (VJI) cannulation could be a potential alternative to the conventional approach.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000410

AQ19 **Introduction:** The calculation of the mean flow index (Mxa) is widely used for assessing dynamic cerebral autoregulation in different clinical populations [1]. This calculation is based on defined characteristics, including blocks, overlap periods, and epochs of the whole recordings [2].
**Objectives:** To investigate the reproducibility of different Mxa calculations, using variable blocks, overlap periods, and epochs.
**Methods:** In this pilot study, we analyzed 40 recordings previously collected from critically ill septic patients. The Mxa was computed using a classic approach (e.g., block of 10 s, overlap of 50% among blocks and epoch of 300 s, called 10–50-300) and then seven additional approaches, including overlapping blocks of 5 or 10 s, overlaps ranging from 20 to 50% and 80%, and epochs of 180 or 300 s (respectively, called 10–20-180, 10–50-180, 10–80–180, 10–20–300, 10–80–300, 5–50–180, and 5–50–300). We compared all calculated Mxa using a mixed model procedure with three within-factor analyses for repeated measurements, intraclass correlation coefficients (ICC), and Bland–Altman plots. We considered values of ICC below 0.5 as poor reliability, from 0.5 to 0.75 as moderate, those between 0.75 and 0.9 as good, and when exceeding 0.90 as excellent reliability.
**Results:** Using the classic approach, mean Mxa was 0.44 (±0.33). In the mixed model analysis, we observed no significant differences among different Mxa values. Analysis of intraclass correlation coefficients revealed excellent agreement among approaches utilizing the same epoch (180 or 300 s), with ICC values of [0.947 (0.916–0.969)] and [0.940 (0.905–0.965)], respectively. Nevertheless, when comparing approaches employing different epochs, agreement levels were lower, ranging from moderate to good. Notably, the comparison between 10–50–180 and 10–50–300 yielded an ICC of [0.782 (0.621–0.880)]. This discrepancy was further evidenced by Bland–Altman plots, which depicted wider limits of agreement between the two approaches.
**Conclusions:** No significant differences emerged among different combination of blocks, overlap, and epoch combination to calculate Mxa in septic patients. However, the impact of epoch duration should be further evaluated.

**Correspondence:** J. Rodriguez-Gomez
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000412

**Introduction:** Multidrug-resistant Gram-negative bacteria are one of the main challenges in ICUs, mainly ESBL- *Klebsiella pneumoniae* (EKP), carbapenemase-producing Enterobacterales (CPE), and *Pseudomonas aeruginosa* (PACR) and Acinetobacter spp. carbapenem-resistant (ABCR).
**Objectives:** The objectives of the study were to determine the prevalence and incidence of colonization/infection by these bacteria in ICUs in Spain, their antimicrobial sensitivity, resistome, and phylogeny.
**Methods:** This is an observational and prospective study. There were evaluated all patients admitted to the ICUs of seven large Spanish university hospitals from February 15 to March 30 of 2023. Colonization was determined in rectal and oropharyngeal exudates upon admission and the first and second week after admission. Infections caused by these bacteria were studied up to 60 days from admission. Antimicrobial susceptibility was determined by microdilution. Whole-genome sequencing (WGS) was performed by Illumina platform to analyze resistome and phylogeny (cgMLST).
**Results:** 767 patients were included during the study period. The prevalence of colonization upon admission was 2.9% (23/767) [interhospital range 0.5–10.3%]: 11 patients carried *Klebsiella pneumoniae*-ESBL (1.4%), six PARC (0.8%), five CPE (0.6%), and one ABCR (0.1%). The incidence of acquired colonization during the first and second week was 0.5 (11/1967) [interhospital range 0–1.9] and 1.3 (11/847) [interhospital range 0–4.1] per 100 patients /day, respectively, with PACR colonization being the most frequent ($n=14$). A total of 21 cases of infection by these bacteria were detected, with 14 of them being previously ($n=8$) and simultaneous ($n=6$) colonized by the same microorganism; the majority were PACR (12/21). 83 isolates (44 patients) were analyzed by WGS. Two different species were detected in sequential isolates from three colonized patients. In the rest, sequential isolates from the same patient corresponded to the same ST, being the majority identical by cgMLST. The range of allelic differences in paired comparisons in isolates from the same patient was 1–32 in *K. pneumoniae* and 1–21 in *Pseudomonas aeruginosa*. The STs and resistance mechanisms detected are shown in Table 1. Colistin, cefiderocol, and meropenem–vaborbactam were the most active antibiotics (100–97.8%) in Enterobacterales; while, in PARC, they were amikacin, colistin, cefiderocol, ceftolozane–tazobactam, ceftazidime–avibactam, and imipenem–relebactam (92–100%).
**Conclusions:** The prevalence/incidence of colonization/infection by multi-resistant Gram-negative bacteria analyzed in the participating ICUs in this study is low, but with important variations between the different hospitals. Carbapenem-resistant *Pseudomonas aeruginosa* was the most common bacteria identified. The resistance mechanisms and clones detected are mostly the same ones that circulate nationally.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000413

**Introduction:** Although hypoglycemia in the ICU is frequently secondary to insulin administration, spontaneous hypoglycemia (SH) can also occur. The primary cause of SH is insufficient hepatic gluconeogenesis [1,2,3]. The potential role of preceding liver test abnormalities as early risk factors for impending SH remains uncertain.
**Objectives:** The aim of this study was to explore the changes in routine clinical chemistry laboratory measurements before and after SH in the ICU.
**Methods:** A retrospective cohort study was conducted, including all adult patients admitted to the ICU of the UMC Groningen between 2008 and 2021. Hypoglycemia was defined as a glucose level < 3.5 mmol/L at the ICU [3] and in case of multiple hypoglycemias, the lowest glucose level was selected for further analysis. SH was defined as hypoglycemia without any insulin administration in the preceding 6 h. Data of 41 routine clinical chemistry parameters from 10 days before the SH were compared with ICU patients who sustained insulin-associated hypoglycemia (IAHG). Daily medians (IQR) were compared using the Mann–Whitney U test; a $P < 0.05$ was considered statistically significant.
**Results:** In 35,000 patients admitted to the ICU, a total of 332 patients with SH were compared with 692 patients with IAHG. In the SH group, the liver enzymes ASAT (aspartate amino transferase) and ALAT (alanine amino transferase) were significantly higher from 3 days before the hypoglycemia, compared to the IAHG group. Lactate was already significantly higher 10 days before hypoglycemia (day -10) in the SH group. Additionally, the SH group also had a significant increase in both direct and total bilirubin 9 days before the event. The coagulation tests differed significantly as early as 5 days before hypoglycemia.
The largest differences (median with IQR; all with $P < 0.001$) between the SH and the IAHG group were as follows:

Day-5: Direct bilirubin 22 (4–88) vs 4 (1–15) µmol/L.
Day-4: INR (international normalized ratio)1.8 (1.3–2.3) vs 1.2 (1.1–1.5).
Day 0: ALAT 98 (25–556) vs 38 (20–89) U/L.

ASAT 237 (49–1550) vs 47 (27–102)U/L,
lactate 5.5 (1.7–8.9) vs 1.2 (0.9–1.7) mmol/L,
total bilirubin 18 (9–41) vs 8 (5–15) µmol/L,
aPTT 50.8 (35.1–78.1) vs 35(29–46.6) s.
PT 19.2 (15.1–28.4) vs 14 (11.9–18.5) s.

**Conclusions:** Our study demonstrates that spontaneous hypoglycemia due to failing gluconeogenesis in critically ill patients is preceded by changes in liver enzymes, coagulation, and bilirubin. This may facilitate prevention of hypoglycemia with timely initiation of glucose administration.

**Introduction:** Acute respiratory distress syndrome (ARDS) is associated with high mortality, especially in low- and middle-income countries (LMICs). While many factors associated with acute illness can predict mortality, the disease prognosis for patients with ARDS in LMICs remains incompletely understood.
**Objectives:** This study aimed to investigate the mortality rate and associated factors from ARDS in Vietnam.
**Methods:** We performed a retrospective observational study that included all patients with ARDS admitted to a central hospital in Hanoi, Vietnam, between August 2015 and August 2023. We collected data on the prehospital care, characteristics, management, and outcomes of patients with ARDS and compared these data between survival and death in the hospital. We assessed factors associated with hospital mortality using logistic regression analysis.
**Results:** Of the 353 eligible patients, 68.0% were male, the median age was 55.0 years (Q1-Q3: 39.0–66.0), and 61.5% died in the hospital. Most patients were transferred from local hospitals (86.4%; 305/353). Among these patients, 80.6% (253/314) had previously received non-invasive or invasive mechanical ventilation (MV) at the referring hospital. During transportation, only 60.1% (116/201) of patients had an endotracheal tube (ET), and only 25.6% (41/160) received non-invasive or invasive MV during transport. The primary etiology of ARDS was pneumonia (98.2%, 222/226), with the predominant pathogen being influenza A(H1N1)pdm09 virus (12.8%, 29/227). On admission, the mean PaO2/FiO2 ratio was 110.04 mmHg (SD: 57.72), with the PaO2/FiO2 ratio of ≤ 100 mmHg that was most commonly observed (56.0%, 196/350), and the median Sequential Organ Failure Assessment (SOFA) score was 10.0 (Q1–Q3: 7.0–12.0). Most patients (93.4%; 211/226) received invasive MV on the first day of admission. A majority of patients (100%; 138/138) received renal replacement therapy (RRT), and 36.7% (73/199) underwent cytokine adsorption therapy during the ICU stay. Common complications included hospital-acquired pneumonia (58.9%; 208/353) and sepsis and septic shock (47.0%; 166/353). In contrast to the SOFA score of ≥ 9.50 (adjusted OR: 14.819; 95% CI 1.410–155.760; $p = 0.025$), ET during transportation (adjusted OR: 0.057; 95% CI 0.004–0.887; $p = 0.041$) was independently associated with decreased risk of hospital mortality.

**Conclusions:** In this study, we investigated a selected cohort of patients with a high mortality rate admitted to a central hospital in Hanoi, Vietnam. Most of these patients had been transferred from local hospitals, where the rates of ET and MV during transportation were low. Interestingly, ET during transportation emerged as a protective factor associated with reduced mortality risk. Enhancements in local human, medical, and sociological resources are likely to play a crucial role in mitigating the mortality of ARDS in Vietnam.

## Inspiratory effort and respiratory muscles activation during different breathing conditions in difficult to wean (DTW) patients: an explorative study

D. Poddighe, M. Van Hollebeke, B. Clerckx[1], L. Janssens[2], G. Molenberghs[3], L. Van Dyck[1], G. Hermans[1], R. Gosselink, D. Langer
[1]Department of Intensive Care Medicine, UZ Leuven, Leuven, Belgium; [2]Research and development department, Medecore, Lovenjoel, Belgium; [3]I-BioStat, Department of Public Health and Primary Care, B-3000, KU Leuven, Leuven, Belgium
**Correspondence:** D. Poddighe
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000415

**Introduction:** A recent randomized-controlled trial surprisingly indicated that DTW patients achieved similar improvements in respiratory muscle strength after both low-intensity (control group) and high-intensity (intervention group) inspiratory muscle training (IMT) [1]. This suggests that performing fast and deep inspirations against both low and high external IMT loads provided these patients with a training stimulus. However, the relationship between the external IMT load, as reflected by changes in airway pressure swings (ΔPaw), and total inspiratory effort, as assessed by esophageal pressure swings (ΔPes), remains unexplored in DTW patients. It is also unclear how ΔPes and ΔPaw are associated with activation of inspiratory muscles (EMGs).
**Objectives:** To compare ΔPes and ΔPaw and their relationship with the activation of extradiaphragmatic inspiratory muscles in DTW patients during different breathing conditions.
**Methods:** ΔPes, activation of scalene (EMGsca), sternocleidomastoid (EMGscm), and parasternal intercostal (EMGpi) muscles were recorded during 1) mechanical ventilation (MV), 2) unsupported spontaneous breathing (SB), low-load IMT (load < 10% maximal inspiratory pressure, PImax = 3cmH2O) executed with 3) slow (LLs-IMT) and 4) fast (LLf-IMT) deep inspirations, and 5) high-load IMT (load ~ 30%PImax = 11 ± 2cmH2O) executed with fast and deep inspirations (HL-IMT). ΔPaw (Paw changes from end-expiration to end-inspiration), inspiratory tidal volume (VT) and peak inspiratory flow (PIF) were recorded during conditions 2–5. Measured variables were compared across the breathing conditions with mixed model analysis. Spearman's r correlation was calculated to assess the relationship between EMGs and both ΔPes and ΔPaw [2].
**Results:** N = 5 patients (age: 68 ± 1y; 20%male; PImax:37 ± 7cmH2O; forced vital capacity: 0.66 ± 0.16L) were included. ΔPes was three-to-four times larger than ΔPaw during SB and IMT conditions (Fig. 1). ΔPaw differed significantly across conditions except between LLs- and LLf-IMT (Fig. 1). ΔPes, EMGs, VT, and PIF differed significantly across conditions except between LLf- and HL-IMT (Figs. 1–3). ΔPaw was weakly-to-moderately correlated to the EMGs, while the correlation between ΔPes and EMGs was moderate to strong (Table 1) [2].

**Table 1 (abstract 000415)** Correlations of ΔPes and ΔPaw with EMGs

| | %EMGsca,max | %EMGscm,max | %EMGpi,max |
|---|---|---|---|
| %ΔPaw,max | 0.35(0.23–0.46) | 0.55(0.45–0.64) | 0.53(0.43–0.63) |
| %ΔPes,max | 0.55(0.47–0.62) | 0.68(0.62–0.74) | 0.73(0.67–0.78) |

Values are expressed as Spearman's r correlation (95%CI). ΔPaw, ΔPes, and RMS amplitude of the EMGs were normalized to the maximum values obtained by each patient across the breathing conditions (expressed as %max)

**Conclusions:** In 5 DTW patients, the similarity of ΔPes and EMGs during LLf- and HL-IMT indicates that performing deep and fast inspirations against low or high external IMT loads provides them with a training stimulus. ΔPes was considerably larger than ΔPaw, indicating that the external IMT loads constitute only a fraction of the total inspiratory effort. ΔPes is also better related to EMGs than ΔPaw.

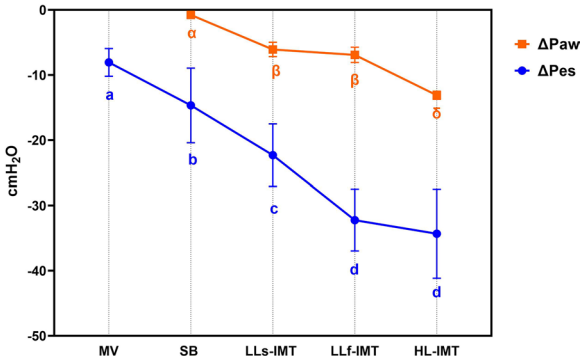

**Fig. 1 (abstract 000415)** Evolutions of airway pressure swings (ΔPaw) and esophageal pressure swings (ΔPes) across breathing conditions. For representation purposes, values are represented as means and standard deviations per condition. Statistical comparisons between conditions were conducted using mixed model analysis, a more sophisticated statistical method. Compact letter display (letters a-d and α-∂) was used for representation of comparisons of ΔPaw and ΔPes between conditions. Different assigned letters denote a significant difference between conditions (level of significance adjusted with Bonferroni correction: $p < 0.005$ for ΔPes and $p < 0.008$ for ΔPaw). Conditions sharing the same letter are not significantly different from each other. Number of breaths recorded per breathing condition: MV = 112, SB = 120, LLs-IMT = 26, LLf-IMT = 28, and HL-IMT = 45

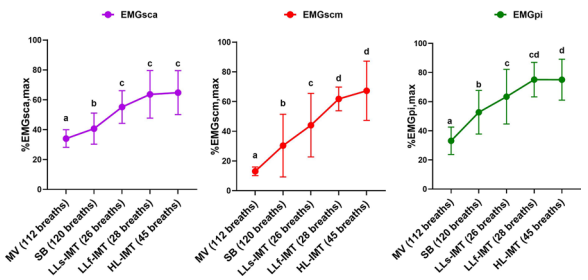

**Fig. 2 (abstract 000415)** Evolutions of activation of scalene (EMGsca), sternocleidomastoid (EMGscm), and parasternal intercostal (EMGpi) muscles across breathing conditions. EMG root-mean-square values (expressed as %EMGmax) were normalized to the highest activation value across breathing conditions. For representation purposes, values are represented as means and standard deviations per condition. Statistical comparisons between conditions were conducted using mixed model analysis, a more sophisticated statistical method. Compact letter display (letters a-d) was used for representation of comparisons of EMGs between conditions. Different assigned letters denote a significant difference between conditions (level of significance adjusted with Bonferroni correction: $p < 0.005$). Conditions

sharing the same letter are not significantly different from each other. Number of breaths recorded per breathing condition: MV = 112, SB = 120, LLs-IMT = 26, LLf-IMT = 28, and HL-IMT = 45

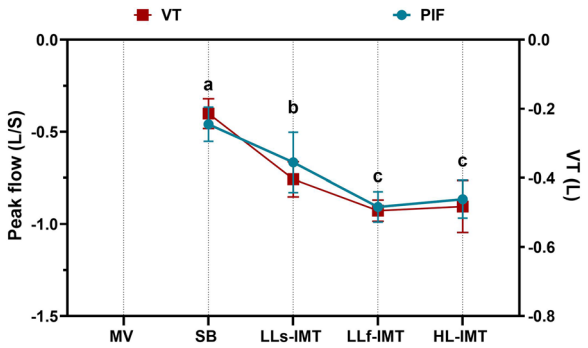

**Fig. 3 (abstract 000415)** Evolutions of inspiratory volume (VT) and peak inspiratory flow (PIF) across breathing conditions. For representation purposes, values are represented as means and standard deviations per condition. Statistical comparisons between conditions were conducted using mixed model analysis, a more sophisticated statistical method. Compact letter display (letters a–c) was used for representation of comparisons of VT and PIF between conditions. Different assigned letters denote a significant difference between conditions (level of significance adjusted with Bonferroni correction: $p < 0.008$). Conditions sharing the same letter are not significantly different from each other. Number of breaths recorded per breathing condition: MV = 112, SB = 120, LLs-IMT = 26, LLf-IMT = 28, and HL-IMT = 45

### Comparing critical care mortality prediction using general linear regression modelling (GLM) and deep learning

F. Lesser[1], M. A. Cheema[1], A. Myers[1], J. Mitchell[1], S. Davey[1], A. Papadopoulou[2], T. Samuels[1]
[1]Intensive care, East Surrey Hospital, Redhill, United Kingdom; [2]Intensive care, Royal Surrey County Hospital, Guildford, United Kingdom

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000416

**Introduction:** Prediction of mortality in critical care allows for optimization of resource allocation, early identification of high-risk patients, and aids in clinical decision-making. Regression is a traditional statistical model used to establish the relationship between predictor variables and a dependent variable and so can be used for prediction of outcomes in healthcare. Interest in using deep learning to predict mortality is rising with the hope that it can improve over traditional statistical models (Naimi, 2021; Stephens, 2023). Deep learning is a technique that uses neural networks with several layers to model complex patterns in data.
**Objectives:** To compare the effectiveness of a Deep Learning Model (DLM) and General Linear regression Model (GLM) in predicting mortality for patients being admitted to critical care.
**Methods:** Deidentified data for 1333 patients admitted to critical care at East Surrey Hospital between 1/1/20 and 30/12/23 were analysed with deep learning using a multilayer neural network and a generalised linear regression model. The variables included were age, length of stay, APACHE II and ICNARC Physiology score, maximum organ support, lowest GCS, and highest and lowest of these variables: non-central temperature, systolic BP, heart rate, serum sodium, and WBC.
The data were split into training (70%) and test (30%) datasets. All data were scaled using a min–max method. Confusion matrices were generated to predict how well deep learning predicted mortality in this group of patients, as well as to assess the accuracy of the DLM and GLM.

**Results:**

**Table 1 (abstract 000416)** Performance of the deep learning model and general regression model

| | Sensitivity | Specificity | PPV | NPV | Accuracy | MSE |
|---|---|---|---|---|---|---|
| Deep learning model | 0.55 | 0.93 | 0.47 | 0.95 | 0.89 | 0.108 |
| General regression model | 0.45 | 0.97 | 0.60 | 0.94 | 0.92 | 0.067 |

PPV: Positive Predictive Value, NPV: Negative Predictive Value, MSE: Mean Squared Error.

**Conclusions:** The comparison between a DLM and a GLM reveals interesting insights into their performance on a specific task. The DLM, despite achieving a comparatively lower accuracy of 89%, had a slightly better NPV of 95% which is a very significant parameter when it comes to mortality prediction. However, its Mean Squared Error (MSE) is higher at 0.10, indicating that its predictions have a larger average squared difference from the actual values. In comparison, the GLM boasts a higher accuracy of 92%, suggesting superior performance in correctly classifying instances. It achieves a lower MSE of 0.06, signifying closer proximity between its predictions and the true values.
In summary, while the DLM demonstrates competitive accuracy, the GLM outperforms it in terms of both accuracy and MSE. This comparison underscores the importance of evaluating models based on multiple metrics to gain a comprehensive understanding of their performance characteristics. Furthermore, it emphasises the necessity of selecting models tailored to the specific requirements and nuances of the task at hand.

**Correspondence:** E. Bogossian
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000420

**Introduction:** Metabolic dysfunction is common in acute brain injured patients and is associated with poor outcomes (1, 2). Hyperthermia and hypothermia have also been associated with poor outcome in this setting (3, 4). Few data are available on the impact of body temperature on cerebral metabolism.
**Objectives:** To assess the association between body temperature and metabolic function in acute brain injured patients.
**Methods:** This is a prospective single-center study that enrolled consecutive patients admitted to the ICU due to acute brain injury from January 2019 to January 2024 and who required invasive multimodal neuromonitoring combining invasive intracranial pressure (ICP), brain tissue oxygenation (PbtO2), and cerebral microdialysis (CMD). Metabolic crisis was defined as a lactate-to-pyruvate ratio (LPR) on CMD > 40. Hyperthermia was defined as body temperature > 37.7 °C; hypothermia as a body temperature < 35.0 °C.
**Results:** We included 51 patients resulting in 4762 measures of body temperature and 2612 measures of LPR. Twenty-seven patients (53%) had head trauma, 19 (37%) had non-traumatic subarachnoid hemorrhage and 5 (10%) had spontaneous intracerebral hemorrhage. The median age was 43 (33–56) years old and 32 (80%) patients were male. The median Glasgow outcome scale on admission was 7 (4–13). The median LPR in hyperthermia ($n = 148/586$; 25%), normothermia ($n = 271/1130$; 24%), and hypothermia episodes ($n = 51/80$; 64%) was 33 (27–39), 31 (25–39), and 43 (33–55), respectively ($p = 0.001$). In a multivariable generalized linear model including PbtO2, ICP, and cerebral perfusion pressure values, hypothermia, when compared to normothermia, was independently associated with a higher LPR (beta coefficient 9.198 (0.203–18.194), $p = 0.045$).
**Conclusions:** In this study, hypothermia was associated with a higher probability of metabolic crisis in a mixed population of acute brain injury patients.

## Multicomponent family support intervention in Swiss adult intensive care units: FICUS trial cluster baseline characteristics

R. Naef[1], M. Riguzzi[1], S. Sutter[1], L. Verweij[1], S. Oesch[2], M. M. Jeitziner[3], M. Filipovic[4]
[1]Institute for Implementation Science in Health Care, University of Zurich, Zürich, Switzerland; [2]Institute for Implementation Science in Health Care, Faculty of Medicine, University of Zurich, Zürich, Switzerland; [3]Department of Intensive Care Medicine, University Hospital Bern, Bern, Switzerland; [4]Perioperative Intensive Care Medicine, Cantonal Hospital St. Gallen, St. Gallen, Switzerland
**Correspondence:** R. Naef
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000421

**Introduction:** There is a need to develop intensive care unit (ICU) services that support families of patients experiencing critical illness to prevent acute stress and burden and to mitigate negative consequences for long-term individual and family health (Kiwankua et al., 2022; Rhoda et al., 2022; Zante et al., 2020). A Family Support Intervention (FSI) (Naef et al., 2020; 2021) was therefore developed and is currently tested for its clinical effectiveness in adult ICUs.
**Objectives:** To report cluster baseline characteristics of the FICUS cluster-randomized trial.
**Methods:** ICUs had to be able to provide highest level of patient care, run at least 8 beds, and have > 300 admission per year with a length of stay of ≥ 48 h. Intervention ICUs implemented a new family nursing role and care pathway consisting of three core components in addition to usual care: liaison and coordination, family support, and structured, interprofessional communication (Naef et al., 2022, Verweij et al., 2023). Control ICUs did not change their usual care. For each cluster, ICU characteristics were assessed at baseline via the last available Minimal Data Set as required by the Swiss Society of Intensive Care Medicine. The interprofessional core leadership teams appraised family care processes and policies, using the Self-Assessment Tool for Family-Centered Care in ICU (Hwang et al., 2017) and the Patient- and Family-Centered Care Organizational Self-Assessment Tool Institute for Healthcare Improvement, 2013). Descriptive analysis of cluster baseline characteristics was undertaken.
**Results:** A total of 30 ICUs were eligible. 16 ICUs agreed to participate and were randomly assigned 1:1 to intervention (IG) or control group (CG) using minimization. 11 were in major teaching hospitals (IG 62.5%, CG 75%). At the median, ICUs operated 12 beds (IG 11.6 vs. CG 15.4) and admitted 1037.5 patients per year (918.5 vs. 1145.5) with 21% of high-risk admissions (SAPS-2 score > 45, 21% vs. 24.1%) and a mean length of stay of 3.5 days (3.7 vs. 3.4). Most nursing staff held an ICU certification (median: 74.0%; IG 74.0%, CG 71.5%). ICUs rated the family-centeredness in the ICU with a median score of 3.0 (2.9 vs. 3.1) out of 1–4 (1 = high), and 2.1 (2.1 vs. 2.1) out of 1–5 (5 = high) for the hospital. From 06/2022 to 12/2023, 885 family members were enrolled (IG n = 412 vs. CG n = 473), with an average of 55 per cluster (52 vs. 59).
**Conclusions:** ICU characteristics were comparable across study arms. Clusters in the CG tended to be larger ICUs, treating a higher number of patients overall, and with high-risk admissions. Recruitment targets could be reached, with some heterogeneity between clusters.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000422

**Introduction:** Out-of-Hospital Cardiac Arrest (OHCA) is burdened by high mortality and the implementation of extracorporeal life support (e-CPR) has shown conflicting results (1).
**Objectives:** Test the adequacy of selection criteria for e-CPR candidacy in out-of-hospital cardiac arrest at Turin University Hospital (Italy).
**Methods:** Single-center observational study. The inclusion criteria of the e-CPR program were: refractory OCHA, age < 65, witnessed cardiac arrest, continuous CPR, no flow < 6, and low flow < 60 min, no pre-existing organ failure, EtCO2 > 10 mmHg, and shockable rhythms or PEA. The study was approved by the local ethical committee and data concerning out-of-hospital care, timing of hospital arrival, post-resuscitative care, and outcome were recorded.
**Results:** In 4 years, all 192 OCHA patients were screened and those eligible for e-CPR were evaluated for VA-ECMO cannulation. Consequently, 30 patients received e-CPR with a 30-day survival of 13.3%. No difference was found in no flow, low flow, and time to ECMO start between e-CPR survivors and non-survivors. However, survivors received better perfusion (as indicated by etCO2) and ventilation. They had higher pH and lower lactate levels at ECMO start. After 24 h the amount of support by ECMO, as measured by blood flow and gas flow, was lower in patients who ultimately survived.

**Table (abstract 000422)**

| | | Survivor | Non-survivor | *p* |
|---|---|---|---|---|
| | *n*° (%) | 4 (13,3) | 26 (86,7) | |
| No flow | | 1 (0;1) | 2 (0;5) | 0,24 |
| Low flow at hospital | | 41 (33;47) | 48 (39;60) | 0,41 |
| Time to ECMO | | 72 (58;87) | 76 (67;86) | 0,7 |
| Before ECMO start | etCO2 | 38 (38;41) | 21 (15;29) | 0,01 |
| | pH | 7,02 (7;7,04) | 6,9 (6,9;7) | 0,03 |
| | pCO2 | 51 (44;57) | 86 (67;93) | 0,06 |
| | Lactate | 10,4 (7,7;13,6) | 12,8 (10,8;17) | 0,33 |
| Start ECMO | pH | 7,37 (7,30;7,40) | 7,07 (7;7,24) | 0,047 |
| | Lactate | 4,5 (3,7;9) | 15 (11,2;17) | 0,05 |
| After 6 h ECMO | Alive | 4 (15,4) | 22 (84,6) | |
| | pH | 7,42 (7,33;7,48) | 7,32 (7,29;7,35) | 0,14 |
| | Lactate | 2,9 (2,3;4,8) | 8,1 (5,8;12) | 0,06 |
| After 24 h ECMO | Alive | 4 (25) | 12 (75) | |
| | pH | 7,36 (7,32;7,38) | 7,32 (7,23;7,40) | 0,78 |
| | Lactate | 2,3 (1,3;5,3) | 3 (2,7;5) | 0,84 |
| | Blood flow | 3,2 (3;3,5) | 4,5 (4,1;5) | 0,01 |
| | Gas flow | 1,5 (0,9;3,4) | 3 (3;4) | 0,15 |

**Conclusions:** E-CPR survivors appear to be characterized by a lower metabolic imbalance at ECMO initiation even if there is no difference in ischemia time but rather in metabolic markers such as etCO2, pH and lactate. This likely indicates that comparable low flow time could be associated with different ischemic damages, as already seen in an experimental model (*2*). Consequently, it seems of particular importance to implement the use of more sensitive markers of ischemia to select better the population to be treated with e-CPR. In the ARREST trial (*3*), rigorous patient selection made it possible to obtain a positive effect of e-CPR on survival, while the most recent INCEPTION trial (*4*) found no difference with conventional CPR. Being ECMO a highly invasive and high-cost procedure, it is undoubtedly a priority to refine the selection criteria, so that e-CPR is truly effective in improving OCHA survival.

### Impact of protein catabolism and muscle mass loss on length of hospital stay and mortality in critically ill patients

J. G. Hernandez Garcia[1], E. Pérez Cruz[2], J. C. Gasca-Aldama[3], O. A. Marché Fernández[1]

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000423

**Introduction:** Protein metabolism is the process by which the body breaks down and uses proteins to maintain effective homeostasis. In critically ill patients, protein breakdown occurs at a much faster rate than normal, caused by proteolysis, ubiquitination, bed rest, and stress. The result of this catabolic state is a substantial loss of muscle and lean body mass, which can affect ventilation time, hospital stay, and even patient mortality.
**Objectives:** To evaluate the impact of protein catabolism and loss of muscle mass on the length of hospital stay and mortality of critically ill patients in the intensive care unit (ICU).
**Methods:** We performed a prospective, descriptive, and analytical study at the adult ICU of the Hospital Juárez de México, from January 1, 2023 to January, 2024, that included critically ill patients over 18 years old who required invasive mechanical ventilation and vasopressor/inotropic agents. We excluded pregnant women, and all who did not fulfill at least 2 weeks of hospital stay. Muscle mass was analyzed through Bioelectrical Impedance Analysis (BIA) and degree of protein catabolism by quantification of nitrogen balance, serum albumin, prealbumin, and transferrin, on days 1, 5, 10, and 14 of hospital stay, and on the day of discharge. Other variables evaluated included primary diagnosis, prognostic and nutritional scales such as APACHE II, SAPS II, SOFA, and NUTRIC Score, total length of hospital stay, and/or mortality.
**Results:** 49 patients were evaluated, 29 men and 20 women with an average age 53 years. The phase angle (PA) values of 6.5° for men and 6° for women were the ones that presented the best balance between sensitivity and specificity for this study. The PA was significantly lower in patients with prolonged intubation, prone sessions, or admission for complicated surgical pathology that required more than one intervention (3.7°) than in patients with early extubation, early weaning of vasopressors, and resolution of surgical pathology without second intervention (4.81°). Significant correlations obtained between lower PA and higher degree of catabolism according to nitrogen balance ($r$: 0.411; $P < 0.00001$). The length of hospital stay in patients with a lower degree of catabolism and lower loss of muscle mass was 19.07 days (SD ± 1.9) and those with higher catabolism and loss of muscle mass were 28.77 (SD ± 7.9) ($p = 0.0001$).

**Conclusions:** Our results suggest that we now count with more feasible methods that can nicely complement the deficiencies of severity scoring systems and may be an important prognostic factor for survival in critically ill patients, as well as a predictor of length in the intensive care unit. Understanding the degree of catabolism and its impact on the muscle mass of our patients will allow us to provide appropriate and timely nutritional interventions.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000424

**Introduction:** In patients with severe ARDS, mechanical ventilation is a pillar in the treatment, being focused on low Vt and high PEEP with the objective of alveolar protection against VILI. Mechanical power and alveolar driving pressure are in close relationship with development of VILI, starting from the point where patients have a baby lung, a great emphasis on Vt, and PEEP to improve patient survival.
**Methods:** Observational study of retrospective, analytic cohort, made in the high specialty regional hospital, imss-benestar; tertiary care hospital in the northeast of Mexico. 108 patients with severe ARDS (PaO2/FIO2 < 150 mmhg) due to SARS COV 2 were included, we collect the demographic information, pre-existing diseases, clinical variables: SOFA score, alveolar distension pressure (DP) Plateau pressure, volume/minute, FIO2, Total PEEP, PaO2/FIO2, Distensibility, Pao2, Paco2, and Mechanical Power (PM). We perform categorical variables with Chi X2, continuous variables with means and standard deviation with Student T, and association measures with ODDS ratio (OR) in SPSS 24.
**Results:** 108 patients were analyzed, age 59.1 ± 13.8 (22–80), with a BMI 32 ± 6.2 (24–52), male in 66.7%, pre-existing diseases 75%, and mortality 61.9%. We found an OR 2.78 with DP > 13.4 (IC 1.9–6.25) and an OR 4.68 in MP > 17j/min (IC 2.92—7.48).

**Table (abstract 000424)**

| Variable | Survival ($n = 42$) | No survival ($n = 66$) | $p$ value < 0.05 |
|---|---|---|---|
| Age (years) | 53.4 | 62.8 | **0.001** |
| BMI (Kg/m$^2$) | 32.2 | 32.5 | 0.780 |
| APACHE II | 18 | 26 | **0.001** |
| SOFA | 7.0 | 10.3 | **0.001** |
| Days of COVID-19 at admission | 17.4 | 16.7 | 0.426 |
| Vt (l/min) | 6.2 | 5.8 | 0.625 |
| PEEP (cmH2O) | 11.2 | 11.3 | 0.778 |
| Plateau (cmH2O) | 26.3 | 29.1 | 0.024 |
| Driving P (cmH2O) | 13.4 | 17.0 | **0.004** |
| Mechanical power (j/min) | 17.1 | 20.6 | **0.000** |
| Risk factor Model including mortality | OR | IC-95% | P-value < 0.05 |
| Driving pressure > 13.4 cmH2O | 2.78 | 1.90–6.25 | **0.004** |
| SOFA | 8.77 | 3.37–22.8 | **0.001** |
| APACHE II | 14.7 | 4.93–44.1 | **0.001** |
| Mechanical power > 17 J/min | 4.68 | 2.92–7.48 | **0.001** |

**Conclusions:** A statistically significant association was found with an increase in mortality in patients with SOFA values > 8.77 points and Apache II > 14.7 at admission, as well as protective mortality values with DP < 13.4 and MP < 17. The findings of this study highlight the importance of narrow monitoring and lung protection strategies as pillar in the survival of patients with severe ARDS.

**Introduction:** Endothelial dysfunction in chronic heart failure (CHF) patients of New York Heart Association (NYHA) class II–III have been associated with reduced exercise hyperemia, impaired functional capacity, and increased incidence of hospitalization, or death [1]. The DeltaPCO2/C(a-v)O2 ratio seems a reliable marker of global anaerobic metabolism [2]. Patients suffering from CHF have microvascular abnormalities and endothelial dysfunction, so their vessels react to hyperoxia much quicker, and even light vasoconstriction will provoke essential hypoperfusion [3].
**Objectives:** The ΔPCO2 and the ΔPCO2/C(a-v)O2 in a response to hyperoxia as a predictors of postoperative complications (composite of acute myocardial infarction, need for pacemaker, intraaortic balloon pump, revision of the surgical wound for bleeding, acute kidney injury, delirium, pneumonia, mediastinitis, and stress ulcers of the gastrointestinal tract) during 60 days after surgery were assessed.
**Methods:** The study included 19 patients with CHF with reduced ejection fraction (male, 60 [54; 64] years old, BMI 26.7 [23.5; 29.8] kg/m$^2$) underwent coronary artery bypass graft with normothermic cardiopulmonary bypass (CPB). A hyperoxic test included inhaled gas mixture of 75–80% oxygen for 30 min. Test was conducted in an anesthetized, catheterized, and mechanically ventilated patients before CPB.
**Results:** The duration of the operation was median 360 [IQR 300; 480] min. The duration of CPB was 178 [113; 243] min, and the duration of myocardial ischemia was 129 [80; 153] min. The postoperative complications developed in 7 patients. Spontaneous sinus rhythm recovery in the postperfusion period was in 4 patients. The ΔPCO2 after 30 min of hyperoxia could serve as a predictor of spontaneous sinus rhythm recovery [area under curve (AUC) = 0.68 (95%CI 0.54–0.82), $p = 0.020$, cut-off more than 4.6 mmHg, sensitivity 88%, specificity 49%]. The ΔPCO2/C(a-v)O2 ratio after 10 min of hyperoxia appeared to be a predictor of postoperative complications in subgroup of patients with chronic heart failure with reduced ejection fraction [AUC = 0.83 (95%CI 0.64–1.00), $p = 0.018$, cut-off more than 0.9, sensitivity 80%, specificity 58%]. Length of stay in ICU was 2 [1; 3] days.
**Conclusions:** The ΔPCO2 after 30 min of hyperoxia could be a predictor of spontaneous sinus rhythm recovery in the post-CPB period. The ΔPCO2/C(a-v)O2 ratio after 10 min of hyperoxia can serve as a predictor of postoperative complications in patients with chronic heart failure underwent coronary artery bypass graft surgery.

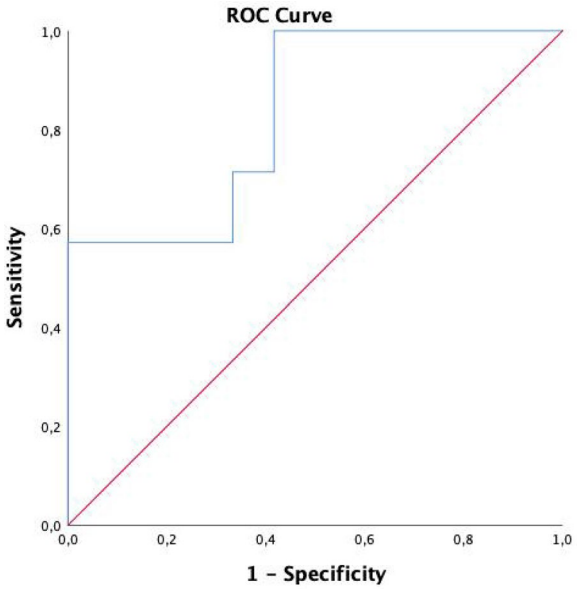

**Fig. (abstract 000425)** The ΔPCO2/C(a-v)O2 ratio after 10 min of hyperoxia appeared to be a predictor of postoperative complications in subgroup of patients with chronic heart failure with reduced ejection fraction [AUC = 0.83 (95%CI 0.64–1.00), $p = 0.018$, cut-off more than 0.9, sensitivity 80%, specificity 58%]

**Introduction:** Ultrasound (US) equipment is frequently used in ICU as a diagnostic tool and to assist procedures. Point of care echocardiography is now commonplace and National Institute of Health and Care Excellence (NICE) recommends US guidance for insertion of central venous catheters [1]. Infection control is paramount in healthcare settings and routine cleaning of equipment is essential to prevent hospital acquired infections. "I am Clean" stickers allow quick and easy communication of when an item was last cleaned. This study aimed to assess and improve cleaning practices of US equipment in ICU.
**Objectives:** 1. To establish whether US machines were being cleaned pre- and post-use, using "I am Clean" stickers. 2. To evaluate if the use of digital communications and poster interventions improved the usage of "I am Clean" stickers.
**Methods:** Our ICU has 3 echocardiography and 3 US devices. Over a 2-week pre-intervention period, the presence of "I am Clean" stickers on all US machines was reviewed and recorded once daily, and a questionnaire was distributed to ICU staff regarding their cleaning practices and frequency of sticker use. A subsequent educational intervention involved the display of posters in clinical and non-clinical areas, as well as reminder emails and teaching sessions. The post-intervention period comprised a 2-week assessment of the presence of "I am Clean" stickers on all US machines.
**Results:** We received 20 responses to the questionnaire. This highlighted that 35% of respondents used US machines daily (Figure 1). However, 57% of these staff members were unaware of the protocol for US machine disinfection. Pre-intervention, despite 55% of respondents reporting they knew about the replacement of "I am Clean" stickers (Figure 2), zero "I am Clean" stickers were displayed on US machines. 70% of respondents did not know where stickers are kept. Post-intervention, 32 stickers were used during a 2-week period.
**Conclusions:** An educational intervention regarding "I am Clean" stickers on US machines has effectively improved staff adherence to probe cleaning protocols derived from the British Medical US Society (BMUS) guidelines, evidenced by increased sticker presence post-use [2]. While visual inspection alone may not always guarantee complete reliability, this intervention facilitates easier auditing of decontamination processes and promotes staff accountability. Our results were similar to those of a multi-centred study looking at disinfection practices of US in emergency wards. Poor adherence to decontamination protocols is a widespread issue throughout clinical environments, wards, and hospitals [3].
Future study should investigate whether this intervention reduces probe contamination instances and prevents organism spread. Additionally, obtaining staff feedback on US probe decontamination protocols will guide future education initiatives. Sustaining these improvements requires ongoing monitoring and education efforts to uphold hygiene and patient safety standards.

## ROX score in pregnancies with COVID-19 respiratory failure predicts successful weaning of high-flow nasal cannula

K. Albrecht, M. Shanahan, H. Sangi-Haghpeykar, B. Burnett, M. C. Tolcher, A. Shamshirsaz
Maternal Fetal Medicine, Baylor College of Medicine, Houston, United States of America

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000429

**Introduction:** ROX score [Respiratory rate oxygenation index: SpO2 (oxygen saturation)/FiO2 (fraction of inspired oxygen)/RR (respiratory rate)] as well as ROX/HR (heart rate) Index (ROX/HR) are used in non-pregnant patients requiring high-flow nasal cannula (HFNC) for acute respiratory failure to predict the success or failure of HFNC. COVID-19 in pregnancy is associated with increased risk for mechanical ventilation. We hypothesized that ROX scores and ROX/HR index could be used in pregnant patients with COVID-19 respiratory failure to predict successful weaning of HFNC and to identify patients likely to benefit from early intubation, avoiding the adverse effects of delayed intubation.
**Methods:** Retrospective chart review of pregnant patients with COVID-19 including demographics, comorbidities, vital signs, and respiratory parameters. All pregnant patients presenting to our two hospitals at any gestational age with a positive COVID-19 test who initiated HFNC were included through 2022. Transferred patients already on HFNC or intubated were excluded. ROX and ROX/HR were calculated at four time points of HFNC: at initiation, 3, 6, and 12 h. The primary outcome was need for intubation. Statistical analyses included Chi-square, t test, Wilcoxon (for non-parametric data), and ROC curves.
**Results:** 44 patients required HFNC, of whom 11 eventually required intubation (25%). Median SpO2/FiO2 ratio, ROX score, and ROX/HR index were significantly lower at 3, 6, and 12 h of HFNC in patients who required intubation (Table 1). ROX/HR index at 6 h $< 4.16$ was associated with intubation with 91% sensitivity and 84% specificity (AUC $= 0.872$). ROX scores $> 4.88$ at 6 h and 12 h were associated with successful weaning of HNFC ($p < 0.01$).

**Conclusions:** The results of our small study of pregnant patients with COVID-19-associated respiratory failure are consistent with non-pregnant data in that ROX score and ROX/HR index may be helpful in predicting both successful weaning from HFNC and the need for intubation, especially at the 6-h HFNC time point. Validation in larger multicenter studies is needed to confirm our results:

### A dose-finding study to assess the haemodynamic and metabolic effects of the sulfide donor, ammonium tetrathiomolybdate: a putative therapy for ischaemia–reperfusion injury

K. Alotaibi, A. Dyson, M. Singer
University College London, Bloomsbury Institute of Intensive Care Medicine, London, United Kingdom

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000431

**Introduction:** Ammonium tetrathiomolybdate (ATTM) is used as an AQ21 oral copper chelator to treat Wilson's disease in humans. We recently discovered that ATTM also acts as a slow-release sulfide donor [1], reversibly inhibiting the mitochondrial electron transport chain. This leads to a reduction in both metabolic activity and reactive oxygen species production that confers therapeutic benefits in various experimental ischaemia–reperfusion injury (IRI) models [1]. To enhance its potential to translate into clinical use, an optimal dosing regimen needs to be identified.
**Objectives:** To evaluate the safety profile and haemodynamic impact of low and high ATTM dosing given to healthy rats.
**Methods:** Under isoflurane anaesthesia, instrumented Wistar rats (approx. 320-360 g) underwent carotid arterial and jugular venous cannulation, bladder catheterization, and tracheostomy. After 30–60 min stabilization, measurement was made of baseline cardiorespiratory variables (echocardiography, BP) and arterial blood gas and lactate analysis. Animals were then randomised to 4 groups: (1) control, (2) 10 mg/kg ATTM bolus, (3) 10 mg/kg ATTM bolus plus 30 mg/kg infused over 1 h, and (4) 10 mg/kg ATTM bolus plus 30 mg/kg/h infused for 3 h. At pre-specified timepoints [5 min, 60 min, and then hourly until 5 h (end-study)], repeat measurements were made as above, plus additional urine sampling at hourly intervals. Analyses were performed using 2-way RM-ANOVA and post hoc Sidak tests, and Mann–Whitney tests.
**Results:** Compared to controls, the highest dose ATTM (group 4) induced metabolic acidaemia and hyperlactataemia (all $p < 0.0001$; Fig 1, A, B, C, and D). A concurrent decrease in glucose (Fig 1E) was observed reflecting a greater reliance on glycolysis. Cardiac function and respiratory rate were comparable across the four study groups. ATTM caused a significant increase in urine output in a dose-dependent fashion ($p < 0.0001$) (Fig 1F).

**Conclusions:** The dose of 10 mg/kg plus 30 mg/kg for 1 h infusion appears to be safe and has potential to be used in IRI models. Further studies are warranted to investigate the mechanism behind the observed diuretic effect which may relate to mitochondrial inhibition of salt and water resorption via the Na + K + -ATPase.

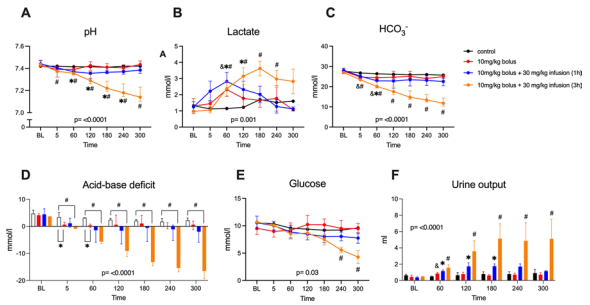

**Fig. 1 (abstract 000431)** Acid–base, glucose, and urine output changes during PK/PD study of ATTM in healthy anaesthetised rats. BL, baseline; Statistical testing by 2-way mixed effects ANOVA followed by Dunnett's test if the overall p value was significant (p-value shown is for the overall ANOVA). Data are presented as mean ± SD except pH, HCO3, and acid base deficit where data presented as median ± IQR. &S $p < 0.05$ group 2 vs control, * $p < 0.05$ group 3 vs control, # $p < 0.05$ group 4 vs control. N = 4 per group

### The role of different endotypes in acute respiratory distress syndrome

D. Orbegozo, L. Rahmania, M. Irazabal, M. Mendoza, F. Annoni, FS. Taccone, J. L. Vincent, J. Creteur
Department of Intensive Care, Erasme Hospital, Brussels, Belgium

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000432

**Introduction:** Multiple molecular and biological pathways have been implicated in the complex pathophysiology of the acute respiratory distress syndrome (ARDS) (1). Discovery of relevant endotypes will open targeted therapeutic options directed towards specific abnormal biological pathways (2).
**Objectives:** To identify different relevant biological pathways in a population of ARDS patients.
**Methods:** We included consecutive admissions to our intensive Care Department with a diagnosis of ARDS (no COVID patients) during a 5-month period. We explored 5 relevant pathways implicated in ARDS pathogenesis, within the first 24 h after diagnosis. The inflammation was assessed using interleukin-2, interleukin-6, interleukin-18 and caspase-1; the coagulation using Von Willebrand factor, platelet count, and activated partial thromboplastin time; the endothelium using soluble intercellular adhesion molecule-1, citrulline, syndecan-1, angiopoietin-2, and e-selectin; the lung interstitium using matrix metalloproteinase-1, matrix metalloproteinase-3, and tissue metallopeptidase inhibitor-1; the alveolar epithelium using Krebs von Lungen-6 antigen. For each biomarker, we calculated the best cut-off point for ICU mortality (concordance probability method), giving scores of 1 and 0 for values above and below the cut-off, respectively. Thereafter, we considered pathways as "abnormal" or "normal", if the sum of scores in each specific pathway was above or below the median value for the whole population, respectively. We sought to identify the more significant combination of different pathways correlated with the mortality, by performing an exhaustive Chi-square automatic interaction detection (CHAIDs) analysis. All statistical analysis were performed using SPSS 23.0.
**Results:** We included 96 consecutive patients with a median APACHE II score of 21 (17–27), a PaO2/FiO2 ratio of 155 (113–206), 85% were under invasive mechanical ventilation, and 67% had sepsis. At diagnosis, the five different pathways were able to identify endotypes with different ICU mortalities (Table 1). Patients with 0–1, 2–3, or 4–5 abnormal pathways had a mortality of 9%, 34%, and 71% ($p < 0.001$), respectively. The CHAIDs analysis proposed the coagulation as the most important pathway (Figure 1).

**Table 1 (abstract 000432)** ICU mortalities considering different endotypes in ARDS patients

| Pathophysiological pathway | Pathway state | ICU mortality *n* (%) | *P* |
|---|---|---|---|
| Inflammation | Abnormal | 24/50 (48) | 0.001 |
| | Normal | 8/46 (17) | |
| Coagulation | Abnormal | 22/39 (56) | 0.001 |
| | Normal | 10/57 (17) | |
| Endothelium | Abnormal | 22/46 (48) | 0.004 |
| | Normal | 10/50 (20) | |
| Lung interstitium | Abnormal | 15/32 (47) | 0.047 |
| | Normal | 17/64 (27) | |
| Alveolar epithelium | Abnormal | 19/40 (48) | 0.013 |
| | Normal | 13/56 (23) | |

**Conclusions:** The simultaneous assessment of different pathophysiological pathways can identify ARDS populations with different severities. Alterations in coagulation may identify new important ARDS endotypes.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000433

**Introduction:** Human and bovine haemoglobin (Hb) solutions have attracted considerable attention as potential blood substitutes. Beyond its primary function as an oxygen carrier, haemoglobin may also mitigate damage associated with ischaemia–reperfusion injury (IRI). We produced a recombinant human Hb from *E. coli* with mutations designed to modify its nitric oxide scavenging capability. The Hb was then homogeneously PEGylated at a unique sulfhydryl residue to increase vascular retention. We previously demonstrated safety in healthy rats.
**Objectives:** To investigate the effects of this novel recombinant haemoglobin as a therapeutic intervention in a rat model of IRI using haemorrhage-reperfusion.
**Methods:** Wistar rats (approx. 270–300 g body weight) were anaesthetized with isoflurane. Carotid arterial and jugular venous lines were then inserted, and the bladder cannulated and a tissue oxygen sensor (Oxford Optronix) inserted subcutaneously. After 30–60 min' stabilization, measurement was made of baseline cardiorespiratory variables (echocardiography, BP) and arterial blood gas and lactate analysis. Approximately 7 ml of blood (35% of circulating blood volume assuming (70 ml/kg b.w.) were then withdrawn. After a 90-min period of ischaemia, the animals were resuscitated with either 8.33 mL/kg recombinant-Hb or an equivalent volume of Hartmann's solution over 5 min, followed by ~ 14 ml Hartmann's fluid given to both groups over 15 min, and then 10 ml/kg/hr thereafter until study end. At pre-specified timepoints (60 min, study end = 240 min), repeat measurements were made as above, plus additional blood sampling for renal and liver function, markers of injury (troponin, amylase, creatine kinase), inflammatory cytokine response (IL-6, IL-10), and complement activation (C3a and C5a). Analysis was by 2-way RM-ANOVA and post hoc Sidak tests, and log-rank and Mann–Whitney tests.
**Results:** Recombinant Hb improved 4 h survival (10/17 [59%] vs 6/18 [33%] in the control group; p = 0.10). Compared to controls, the Hb-treated group normalized BP faster, increased muscle tissue PO2 and methaemoglobin, and produced an approximate fivefold increase in urine output (all $p < 0.005$) (Fig 1). In samples taken from those surviving to study end (240 min), amylase and IL-6 were significantly lower in the Hb group (both $p < 0.01$); however, C3a was significantly elevated ($p < 0.001$). Other physiological and biochemical tests were similar between groups.
**Conclusions:** In this model of haemorrhage-reperfusion, IV bolus administration of this novel recombinant Hb given at the onset of reperfusion promptly improved BP, had a marked effect on diuresis and improved 4-h survival from 33 to 59%. Further studies are warranted.

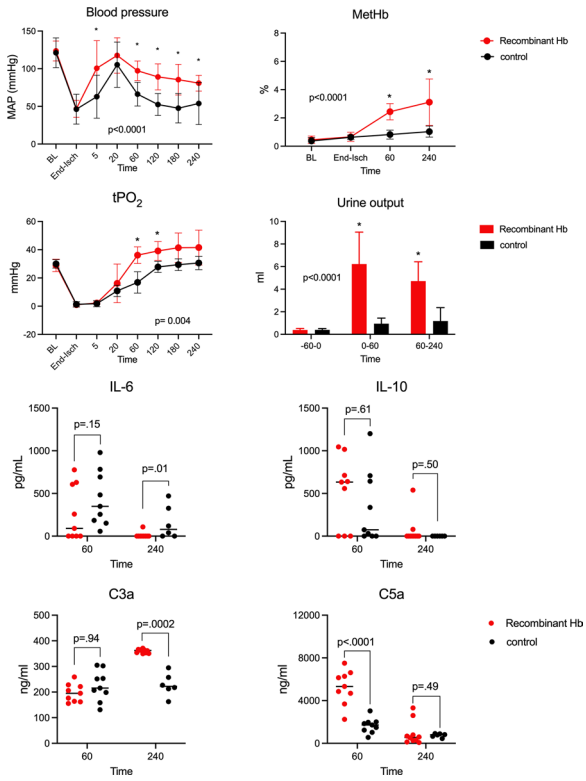

**Fig. 1 (abstract 000433)** End-Isch: end of ischaemia; MetHb: methemoglobin; Hb: haemoglobin; tPO2: tissue oxygen tension; IL: interleukin. Tests: * $p \leq 0.05$. Data are presented as median ± IQR; except for MetHb and tPO2 where data are presented as mean ± SD. RM-ANOVA, and post hoc Sidak tests, or Mann–Whitney tests

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000434

**Introduction:** Direct from ICU Sent Home (DISH) is an innovative healthcare approach that directly discharges patients from the Intensive Care Unit (ICU) to their homes upon achieving clinical stability. DISH is gaining popularity worldwide, including in Indonesia, as healthcare systems strive for improved efficiency and patient-centered care. Patient safety in critical care involves various aspects, including airway management, where tracheostomy aids in patient comfort, infection prevention, and transition to standard treatment facilities. However, implementing DISH poses challenges due to the absence of standardized success parameters and guidelines for safe discharge, prompting further investigation to establish evidence-based protocols ensuring its effectiveness and safety.

**Methods:** We conducted a retrospective analysis of medical records with ethical clearance. Eligible participants were patients who were directly sent home from the ICU with an early tracheostomy, liberation of a mechanical ventilator, and adequate family education. This study examines various factors potentially influencing the outcomes of patients discharged through the DISH program, including age, gender, initial and discharge Glasgow Coma Scale (GCS), APACHE II score, LOD score, SOFA score, length of stay, transportation method upon discharge, and caregiver involvement. The study also records the readmission and mortality rate at 3-day and 7-day intervals post-discharge. The Chi-square test was utilized for data analysis using SPSS.
**Results:** The study included 18 participants. Patient outcomes were evaluated at 3-day and 7-day intervals post-discharge from the ICU under the DISH program, with favorable outcomes defined as the absence of readmission or mortality during these periods. Statistical analysis revealed significant associations between the APACHE II score and the likelihood of readmission or mortality at 3 days (RR: 3.43, *p* value: 0.04) and 7 days (RR: 3.14, *p* value: 0.04). Similarly, a significant association was observed between the Glasgow Coma Scale (GCS) upon admission and the probability of readmission or mortality at the 7-day mark (RR: 2.00, *p* value: 0.04), highlighting varying levels of significance among different variables.
**Conclusions:** Elevated APACHE scores and diminished GCS upon admission were found to be strong predictors. The quality of caregiving and transportation methods also indicated more favorable outcomes, although without statistical significance. Further research with a larger cohort is necessary to validate these findings, emphasizing the need for caution in interpreting the results. This study highlights the complexity of factors influencing patient outcomes post-DISH discharge, offering insights for optimizing discharge protocols and enhancing patient care strategies in critical care settings.

**Table 1 (abstract 000434)** Factors influencing the outcomes of patients discharged through the DISH program

| | 3 days | | 7 days | |
|---|---|---|---|---|
| | RR (CI 95%) | P value | RR (CI 95%) | P value |

### Risk factors associated with mortality in hematological patients: 14 year experience

**Introduction:** Despite advances and new therapies, mortality of hematologic patients in the ICU remains high. Our purpose is to assess known mortality risk factors presented in HM patients admitted in ICU in a 14 year period.
**Methods:** Retrospective analysis (2009–2022) of patients with HM admitted to the ICU of a tertiary university hospital. Data were obtained through the electronic medical record. Statistical analysis: quantitative variables: medians (min–max); categorical variables: percentage (*n*). Fisher's test (continuous) and Mann–Whitney U test (categorical) were used for the analysis.
**Results:** 223 ICU admissions of patients with HM were identified. The description of the population is presented in Figure 1. Overall ICU mortality was 30% ($n=67$) with a 1 year after discharge mortality of 59% ($n=130$).
Factors statistically associated with ICU mortality were: 1) primary diagnosis of acute leukemia [40%(40) vs 22%(27) death patients; $p=0.003$]; 2) hospital length of stay prior to ICU admission [20 (0–68) vs 7 (0–393) days; $p=0.002$]; 3) requirement for vasoactive support [38% (60) vs 10% (7) death patients; $p<0.001$]; 4) presence of anuria upon ICU admission [57% (25) vs 23% (42) patients; $p<0.001$]; 5) need for renal replacement therapy [51%(34) vs 21%(32) death patients; $p<0.001$]; 6) number of organ failures (vasoactive ± intubation ± renal replacement therapy): 0–1 failures 7% (7) vs 2–3 failures 51%(60) death patients ($p<0.001$).
Mortality was not statistically associates with variables such us: sex [male 28% (39) vs female 34% (28)]; age distribution with a cut-off of 65 years [<65: 30%(52) vs >65:29% (15)]; days of ICU stay [6 days (0–127) death vs 5 (0–62) days alive patients]; or allogenic transplant (36% (35) vs non 25% (32) p:0.058).
**Conclusions:** In our study, patients with acute leukemia, longer hospital stay prior to ICU admission and multiple organ failure had a higher

mortality. There is a higher mortality rate in allogeneic bone marrow transplantation, but no statistical significance was found in this study.

### Brainstem death testing: a computational modelling investigation

M. Laviola[1], A. Beddow[1], E. Forbes[1], D. Bates[2], JG. Hardman[1]

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000437

**Introduction:** During brainstem death testing patients must be demonstrated not to make ventilatory effort if brainstem death is to be confirmed. Patients must not become hypoxaemic during the period of apnoea and must be demonstrated to have a significant increase in arterial carbon dioxide partial pressure (PaCO2).
**Objectives:** The optimal placement of an oxygen catheter and the optimal flowrate of oxygen are not currently known. Despite this, guidelines [1–4] that govern how brainstem death testing is performed specify various oxygen catheter placements and oxygen flowrates. In this study, we aimed to address this clinical problem.
**Methods:** We used a high-fidelity and highly integrated computational modelling of the cardiopulmonary system to examine the effects of the positioning of the oxygen insufflation catheter and the flow of oxygen delivered via the catheter. The modelling has been extensively validated for investigations into apnoea [5–9].
Five virtual subjects were configured whose physiological characteristics are shown in Table 1. .

**Table 1 (abstract 000437)** Model parameters and ranges used to configure the five virtual subjects

| Parameter | Range |
|---|---|
| Weight (kg) | 48–87 |
| Tidal volume (ml) | 6.3 × weight |
| Ventilatory frequency (breaths/min) | 9–11 |
| Metabolic oxygen consumption (ml/min) | [3.3–3.7] × weight |
| Functional residual capacity (litres) | 2.19–2.23 |
| Haemoglobin (g/L) | 146–165 |
| Anatomical deadspace (ml) | 2.2 × weight |
| Anatomical shunt (%) | 1–3 |

The five virtual subjects underwent pulmonary denitrogenation (pre-oxygenation) during resting, tidal breathing with an inspired oxygen fraction of 100% for 10 min. Then, apnoea commenced for 10 min and 100% of oxygen was provided at the open glottis with different five oxygen catheter placements (equally spaced between glottis [placement 1] and carina [placement 5]) and five oxygen flowrates (0.2, 0.5, 1.0, 2.0 and 5.0 L/min).
**Results:** Figure 1 shows arterial partial pressure of oxygen (PaO2) at the end of pre-oxygenation and 10 min after the commencement of the apnoea for the different oxygen flowrates and catheter placements studied. Oxygenation was achieved for all scenarios investigated.
Figure 2 shows the rate of rise of the PaCO2 calculated 1 and 10 min after the commencement of the apnoea. PaCO2 increases more rapidly in the first minute and at lower flowrates with the catheter placed at the glottis. However, CO2 clearance was minimal even at the higher flowrates and deeper placements.
**Conclusions:** This study indicates that lower oxygen flowrates still protect the subject against hypoxaemia during the brainstem death testing as all the subjects remained well-oxygenated throughout each investigation, and this could be beneficial as there is less risk of CO2 washout at lower flowrates. However, none of the flowrates and placements led to CO2 washout. Catheter placement and oxygen flowrate may have little impact on the accumulation of CO2 and O2 desaturation. This may indicate that attention should be given to pre-oxygenation to ensure the patient does not become hypoxaemic.

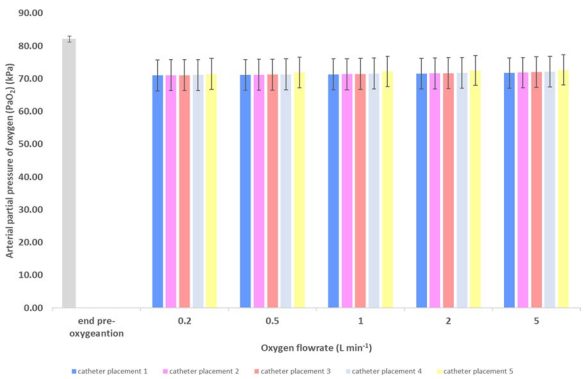

**Fig. 1 (abstract 000437)** Arterial partial pressure of oxygen (PaO2) at the end of pre-oxygenation and at 10 min after the commencement of apnoea for the various oxygen flowrate and catheter placements studied. Values are reported as mean (standard deviation) calculated over the five subjects. Catheter placement 1 corresponds to glottis and catheter placement 5 corresponds to carina. The remaining placements are equally distributed between the glottis and carina

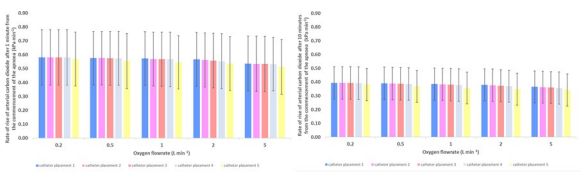

**Fig. 2 (abstract 000437)** Rate of rise of arterial partial pressure of carbon dioxide (PaCO2) calculated 1 min (left panel) and 10 min (right panel) after the commencement of the apnoea. Values are reported as mean (standard deviation) calculated over the five subjects. Catheter

placement 1 corresponds to glottis and catheter placement 5 corresponds to carina. The remaining placements are equally distributed between the glottis and carina

*Intensive Care Medicine Experimental* 2024, **12(suppl 1):**000438

**Introduction:** Multi-professional post-ICU recovery clinics address physical, psychological, and cognitive needs of ICU survivors conducting assessments and making treatment plans and onwards referrals. A few studies report clinic activity which is a surrogate for ICU survivor ongoing recovery needs.
**Objectives:** To explore number/type of outpatient referrals made and actioned and ICU recovery clinic activity comparing exclusively clinic attendees with those also enrolled on a digital recovery pathway managed by a specialised occupational therapist (OT) and commenced on hospital discharge. We hypothesised pathway patients would have (1) more outpatient referrals actioned in a shorter time; and (2) fewer referrals required at recovery clinic.
**Methods:** Retrospective cohort study of adult ICU recovery clinic attendees (Nov 2021 to June 2023). We excluded patients living outside the hospital provider catchment area as unable to ascertain actioning of referrals. We collected demographics, referral patterns, and clinic visit characteristics.
**Results:** Of 661 clinic attendees, we excluded 355 living out of catchment and 90 for other exclusions, leaving 216 participants (183 (85%) clinic only; 33 (15%) digital pathway). Mean (SD) age was 56 (15.4) years, APACHE II score 15 (5.6), with 64% male, and 72% admitted for medical reasons. Median (IQR) invasive ventilation duration was 9 (4, 22) days, ICU length of stay (LOS) 16 (8, 33) days, and hospital LOS 39 (19, 72) days. There were no statistically significant differences in baseline demographic or clinical characteristics between pathway and clinic-only patients.
At hospital discharge (baseline), mean (SD) number of outpatient referrals/patient was 4.4 (2.3) for pathway patients vs 3.7 (1.9) for clinic-only ($P=0.26$). Of 847 outpatient referrals made, most common were medical specialist clinics (respiratory, cardiac, surgical) (424, 50%), community rehabilitation (75, 9%), and home health services (73, 9%). Mean (SD) number of referrals actioned was 3.7 (2.0) for pathway patients vs 3.2 (1.7) for clinic only ($P=0.11$). Median (IQR) time to action was 32 (11, 53) days vs 37 (13, 83) for clinic only ($P=0.06$).
Mean (SD) days to clinic visit was 141 (46) for pathway patients and 162 (53) for clinic only ($P=0.03$). In recovery clinic, fewer patients required OT review (4 (12%) vs 58 (32%) $P=0.02$); review by other professionals was similar between groups. Mean (SD) number of outpatient referrals/patient made was 2.2 (1.6) for pathway vs 2.5 (2.0) for clinic-only patients ($P=0.33$) Of the 523 referrals made, most common were medical specialist clinics (136, 26%), GP (91, 17%), and community rehabilitation (51, 10%).
**Conclusions:** We found a reduction in time to actioning of referrals and number of referrals made for patients enrolled on an ICU digital recovery pathway, though this did not reach statistical significance. Fewer pathway patients required within-clinic assessment by an OT.

## Severe hypocholesterolemia in patients with septic shock is attenuated by therapeutic plasma exchange

T. Pape[1], D. A. Hofmaenner[2], B. Seeliger[1], P. D. Wendel Garcia[2], R. Lichtinghagen[3], K. Brand[3], M. Singer[4], A. Kleyman[4], C. Bode[5], S. David[2], K. Stahl[6]

**Correspondence:** T. Pape
*Intensive Care Medicine Experimental* 2024, **12(suppl 1):**000440

**Introduction:** Acquired hypocholesterolemia in patients with septic shock is associated with increased mortality. In preclinical sepsis models, survival could be improved by cholesterol substitution. However, comparable clinical therapeutic interventions have not yet been investigated.
We hypothesized that therapeutic plasma exchange (TPE), using plasma from healthy donors as substitution fluid, could attenuate hypocholesterolemia in patients with septic shock.
**Methods:** This was a retrospective clinical and biobank analysis of a non-randomized study (EXCHANGE-Pilot) and a randomized-controlled trial (EXCHANGE-1) investigating the adjunctive effect of TPE in patients with refractory (noradrenaline (NE) $\geq 0.4$ µg/kg/min $\geq 30$ min) and early (onset of shock $< 24$ h) septic shock. A single TPE was performed within 6 h of randomization and compared to a standard of care (SOC) control arm. Biomaterial was available from 34 patients in

the TPE group and 14 patients in the SOC group. Total, LDL- and HDL-cholesterol as well as triglyceride concentrations were determined enzymatically from patient plasma at time of randomization and 6 h thereafter, respectively.
**Results:** Pronounced hypocholesterolemia was observed in both the SOC and TPE groups at study inclusion (median (IQR) SOC: 1.9 (1.1–3) mmol/l vs. TPE: 1.8 (1.4–2.2) mmol/l, $p = 0.848$). While cholesterol remained unchanged in the SOC-, it increased significantly in the TPE group 6 h after randomization [SOC: 1.8 (1.3–2.4) mmol/l vs. TPE: 2.3 (2.1–2.8) mmol/l, $p = 0.006$]. The same effect of exclusive substitution in the TPE group was found for LDL ($p < 0.001$) and HDL cholesterol ($p < 0.001$). Triglyceride concentrations were not decreased at inclusion and did not differ significantly between the two groups. The relative median changes in cholesterol concentrations in both groups (SOC vs. TPE) between baseline and 6 h after randomization were -2.6 vs. + 35.7% ($p = 0.001$) for total cholesterol, -14.8 vs. + 246.7% ($p < 0.001$) for LDL- and -5.9 vs. + 175% ($p < 0.001$) for HDL-cholesterol, respectively.
**Conclusions:** Severe acquired hypocholesterolemia in patients with septic shock could be alleviated by therapeutic plasma exchange. These are the first clinical data reporting successful control of dyslipidemia in patients with septic shock. The potential of TPE will be further explored in future larger randomized trials (EXCHANGE-2).

**Topic:** Sepsis.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000442

**Introduction:** Although the obesity paradox has been continuously studied, the relationship between body composition and long-term prognosis in extracorporeal membrane oxygenation (ECMO) patients has not yet been clearly identified.
**Objectives:** In this study, we investigated factors affecting long-term survival of patients receiving ECMO treatment and determined whether they were related to body composition.
**Methods:** Among the 264 patients who received ECMO from November 2014 to June 2023, the final 212 patients participated in this study. We retrospectively reviewed patients who underwent computed tomography (CT) imaging before ECMO initiation. Sarcopenia was assessed with psoas muscle index (PMI) using an artificial intelligence-based algorithm in patients who underwent abdominal CT scan, and adiposity was assessed with body fat percentage (BFP).
**Results:** One-year mortality was not significantly different between the obese (body mass index [BMI] ≥ 25) and non-obese groups (BMI < 25). The Kaplan–Meier survival curves for 1 year mortality showed that initial BMI did not predict mortality ($\chi^2 = 0.093$, $p = 0.760$). Multivariate analyses showed that low PMI (odds ratio [OR] 2.47, 95% confidence interval [CI] 1.14–5.45, p = 0.022), bridge to transplantation (BTT) (OR 0.22, 95% CI 0.10–0.49, $p < 0.001$), use of steroid before ECMO (OR 2.49, 95% CI 1.11–5.59, $p = 0.027$), and renal replacement therapy (OR 2.16, 95% CI 1.02–4.55, $p = 0.044$), and Charlson comorbidity index (OR 1.38, 95% CI 1.13–1.68, $p = 0.001$) were associated with 1-year mortality. In a subgroup analysis of sarcopenic (low PMI) patients, hospital mortality (54.9% vs. 36.8%, $p = 0.016$) and 1-year mortality (62.2% vs. 45.3%, $p = 0.024$) were significantly higher in the high BFP group than in the low BFP group (Figure 1). However, the rate of home discharge was significantly higher in the low BFP group than in the high BFP group (35.4% vs. 55.8%, $p = 0.007$). To assess the differential impact of body fat and muscle mass on 1-year mortality in ECMO patients, four subgroups were divided according to sarcopenia and adiposity. Kaplan–Meier curves showed that sarcopenic patients with adiposity resulted in a higher risk for 1-year mortality ($\chi^2 = 10.38$, $p = 0.016$; Figure 2).
**Conclusions:** In this study, the obesity paradox was not observed in ECMO patients. Instead, sarcopenia was an important factor affecting their survival. Additionally, when sarcopenia was accompanied by adiposity, survival and functional status at hospital discharge were poor.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000443

**Introduction:** Pleural effusions are common in the intensive care unit (ICU), often requiring thoracentesis with subsequent routine fluid culturing. Despite this, pleural culture results in adult ICU patients remain poorly characterised, and as pleural infection has been associated with increased mortality in hospitalised patients, clarifying the prevalence and implications of positive pleural fluid cultures in the ICU may be crucial for patient management.
**Objectives:** This study aimed to: (1) determine the prevalence of positive pleural fluid cultures in ICU patients undergoing thoracentesis,

relating this to physicians' suspicion of pleural infection or the presence of parapneumonic effusion; (2) assess the association between pleural infection and 90-day mortality; and (3) characterise the cultured microorganisms.
**Methods:** We conducted a retrospective cohort study including all adult patients who underwent pleural fluid culturing in one of the eight ICUs in the North Denmark Region over a 10-year period, following a pre-published protocol (1). The primary outcome was a positive primary pleural fluid culture, excluding pre-specified non-pathogenic microorganisms, while the secondary outcome was 90-day all-cause mortality following primary pleural fluid sampling. Associations between pre-drainage suspicion of pleural infection and parapneumonic effusion, respectively, and the risk of a positive culture were assessed using a generalised linear model adjusted for potential confounders. The association between a positive culture and 90-day mortality was assessed similarly. Pleural fluid microbiological findings are reported descriptively.
**Results:** A total of 1251 patients were included in the study, of whom 51 patients (4.1%) exhibited a positive primary pleural fluid culture. Suspected pleural infection was associated with a higher risk of a positive culture [adjusted risk ratio (RR): 4.88, 95% confidence interval (CI) 2.70–8.83], whereas no such association was observed for parapneumonic effusions (adjusted RR: 1.41, 95% CI 0.83–2.38). A positive pleural fluid culture was associated with increased 90-day mortality (adjusted RR: 1.35, 95% CI 1.04–1.73); see Figure 1. Among the positive pleural cultures 39/51 (76.5%) exhibited monomicrobial and 12/51 (23.5%) polymicrobial growth. The most prevalent pleural microorganisms were *Candida* species (15/51, 29.4%), *Streptococcus anginosus* (9/51, 17.6%), *Staphylococcus aureus* (6/51, 11.8%), and *Escherichia coli* (6/51, 11.8%).
**Conclusions:** This 10-year retrospective cohort study revealed that 4.1% of ICU patients undergoing pleural drainage with fluid culturing exhibited positive microbiological findings. Suspected pleural infection significantly increased the likelihood of positive culture results, which was not the case for parapneumonic effusions. A positive pleural fluid culture was associated with increased 90-day mortality, underscoring its potential clinical significance in prognostication and management.

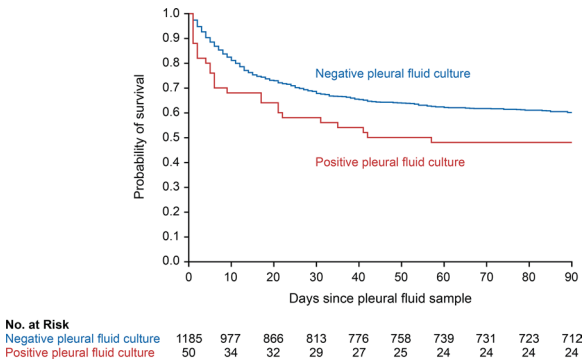

**Fig. 1 (abstract 000443)** Kaplan–Meier plots of probability of survival according to primary pleural fluid culture results, administratively censored at 90 days. A total of 15 patients with negative pleural fluid cultures and 1 patient with a positive pleural fluid culture were lost to follow-up within 90 days, and are consequently not included in the plots

**Correspondence:** F. Corradi
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000445

**Introduction:** Post-operative acute kidney injury (PO-AKI) is a prevalent complication following major abdominal surgery, with an incidence of approximately 15.5% in major laparoscopic urologic procedures. PO-AKI is linked to heightened short-term adverse outcomes and long-term morbidity and mortality. Risk factors for PO-AKI are diverse, spanning pre-operative, intra-operative, and post-operative factors. This study aims to assess the efficacy of perioperative intravenous amino acid infusion in mitigating the occurrence of PO-AKI in major laparoscopic urologic surgery.
**Objectives:** To evaluate the effectiveness of perioperative intravenous amino acid infusion in reducing the incidence of PO-AKI in major laparoscopic urologic surgery.
**Methods:** A before–after clinical study was conducted, encompassing 331 patients undergoing major urological minimally invasive surgery. Patients were allocated to receive either standard crystalloid fluid therapy or intravenous amino acid infusion perioperatively. Primary outcomes included the incidence and severity of PO-AKI, while secondary outcomes comprised intensive care unit admission, hospital length of stay, 30-day readmission, and complications. Logistic regression analysis was employed to identify predictors of reduced PO-AKI incidence.
**Results:** Out of the 331 patients included in the study, the initial 169 received perioperative crystalloid fluids, while the subsequent 162 received perioperative amino acid (AA) infusions. Post-operative acute kidney injuries (PO-AKIs) were significantly more prevalent in the crystalloid group compared to the AA group (34 vs. 17, $p=0.022$), primarily attributed to a lower incidence of KDIGO I and II in the AA group (14 vs. 30, $p=0.016$). Patients in the AA group who developed PO-AKI exhibited a higher number of risk factors compared to those who did not (2 (2–4) vs. 1 (1–2), $p=0.031$), with a cutoff of 3 risk factors identified in the ROC curve ($p=0.007$, sensitivity 47%, and specificity 83%). Furthermore, hospital length of stay was prolonged in the crystalloid group ($p<0.05$), resulting in consequent savings in hospital costs. Only intravenous amino acid infusion made a unique statistically significant contribution to the model with an OR = 0.480, CI 0.250–0.923, $p=0.028$ controlling for all other factors in the mode (see Table 1).
**Conclusions:** The study demonstrated a significant reduction in the incidence of mild-to-moderate PO-AKI in the amino acid infusion group compared to the crystalloid group, alongside a shorter hospital stay and associated cost savings. Logistic regression analysis identified intravenous amino acid infusion as a significant predictor of reduced PO-AKI incidence. These findings suggest that perioperative intravenous amino acid infusion is safe and may effectively lower the occurrence of PO-AKI, leading to shorter hospital stays and decreased costs in major urological surgeries. Further randomized trials are necessary to validate these findings and explore specific surgical interventions.

**Table (abstract 000445)** Multiple logistic regression analysis of predictors of PO-AKI

| Variables | B | OR | 95% CI | | p |
|---|---|---|---|---|---|

### Intrarenal venous flow and renal Doppler resistive index as predictors of postoperative acute kidney injury and complications in major laparoscopic urologic surgery: a prospective observational study

M. Monfroni[1], C. Brusasco[2], F. Cundari[3], G. Cucciolini[1], F. Dazzi[1], I. Corda[1], D. Filolli[1], E. Taddei[1], S. Tempini[1], L. Tessieri[1], S. De Rosa[4], F. Corradi[1]

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000446

**Introduction:** Perioperative acute kidney injury (AKI) is a severe complication associated with high morbidity and mortality rates. Despite advancements in pre- and postoperative management, the contribution of surgical techniques and perioperative care to the development of AKI remains underappreciated. Point-of-care ultrasonography (POCUS) with arterial Doppler assessment has been utilized to evaluate organ-specific blood supply. However, the role of intrarenal venous flow (IRVF) patterns in predicting postoperative AKI and complications after major laparoscopic surgery remains unexplored.
**Objectives:** The primary objective was to evaluate whether the combination of IRVF and RDRI measured at different perioperative time points could predict postoperative AKI within the first seven days. The secondary objective was to assess if IRVF and RDRI could predict the occurrence of any other postoperative complications at day 7.
**Methods:** This prospective observational study, conducted between December 2019 and April 2022, aimed to assess the utility of combining IRVF and renal Doppler resistive index (RDRI) measurements in predicting postoperative AKI and complications in patients undergoing major laparoscopic urologic surgery. Two expert operators performed ultrasonographic examinations using a Mindray TE7 ultrasound device. Demographic, clinical, and ultrasonographic data were collected, and statistical analyses were performed using SPSS and R environment.
**Results:** Patients experiencing a combination of arterial hypoperfusion and moderate-to-severe venous congestion, as indicated by POCUS, had significantly worse outcomes (hazard ratio [HR]: 2.993, 95% confidence interval [CI] 1.522–5.884 and HR: 8.124, 95% CI 3.542–18, respectively; $p < 0.001$). High intra-operative abdominal pressure was identified as the sole independent determinant of postoperative severe venous congestion (odds ratio [OR]: 1.354, 95% CI 1.017–1.804, $p = 0.038$). Moreover, the overall number of complications was found to be influenced by the balance between arterial inflow and venous outflow, ensuring peripheral perfusion adequacy. Splanchnic perfusion assessment by Doppler demonstrated high reliability, with strong inter-rater agreement (intraclass correlation coefficient [ICC]: 0.844, 95% CI 0.792–0.844).
**Conclusions:** The combination of IRVF and RDRI provides a non-invasive method for predicting postoperative AKI and complications after major laparoscopic urologic surgery. Monitoring IRVF patterns may aid in early identification of patients at risk, facilitating timely interventions to mitigate complications and improve outcomes.

### Quality improvement project on daily VTE assessments in ICU

J. Fong, C. Coronelli, A. Tahir
Intensive Care, Stoke Mandeville Hospital, Oxford, United Kingdom
**Correspondence:** J. Fong

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000448

**Introduction:** In the intensive care unit (ICU), the risk of venous thromboembolism (VTE), including deep vein thrombosis (DVT) and pulmonary embolism (PE), is significant (1,2). With PE mortality rates ranging from 8 to 13% (3), proactive management is crucial. Daily VTE assessments are essential, enabling clinicians to identify warning signs and implement preventive measures. Assessments comprise daily INR and platelet values, risk factors, and clinical markers. As a gold-standard, all patients (if appropriate) receive full prophylactic VTE treatment. Patients may deteriorate requiring treatment modification, therefore emphasising the importance of daily risk assessments.

Currently prophylaxis includes TED stockings, intermittent pneumatic compression, and prophylactic Low-Molecular Weight Heparin (LMWH).
**Objectives:** Assess whether VTE assessments are being completed and if correct VTE treatments are being administered according to this.
**Methods:** Records of 20 patients were electronically reviewed for retrospective analysis within the period of 2024. Inclusion criteria included two daily drop-down options: "mechanical VTE prophylaxis" and "Pharmacological VTE prophylaxis." Completion status was noted, with reasons sought if criteria were incomplete. Data on pharmacological treatment administration and blood results (INR, platelets) were also collected for analysis.
Post-implementation data were accessed in the same format, with dates ranging from 24/3/24 to 29/4/24.
**Results:** A total of 126 entries were assessed (20 patients). Mechanical VTE entries were not completed in 32 and pharmacological VTE in 26 with an overlap of 23 for both categories (Figure 1). Only on 3 occasions were reasons found for this in the daily reviews.
In 41 instances, Dalteparin was not administered out of which 39 had rationale documented, while 2 had none.
We informed the department of these results and provided education regarding VTE events and susceptibility on ICU to junior staff.
The re-audit showed significant improvement where 58 entries from 14 patients showed 100% completion. Of the 58 entries; 38 received prophylactic LMWH, 17 had contraindications documented, and 3 received treatment dose LMWH (Figure 2).
**Conclusions:** Prior to implementing strategies to facilitate VTE assessment completion, despite its inclusion in the daily review within the electronic system, it became apparent that clinicians were frequently overlooking this documentation. Pre-implementation data revealed a non-completion rate of 20–25%, suggesting a significant risk of patients developing preventable VTE events. Nonetheless, a multi-disciplinary approach to VTE prevention ensured appropriate prophylaxis for 98.4% of patients. With the implementation of straightforward educational interventions, we achieved 100% compliance. To sustain this improvement, we have instituted a biannual audit process to ensure ongoing adherence to the protocol.

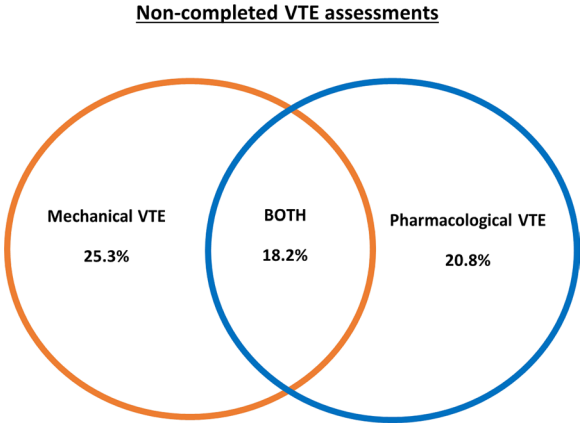

**Fig. 1 (abstract 000448)** Non-completion of daily VTE assessments. 126 entries in total

### High rate of hospital-acquired infections in an infectious diseases dedicated intensive care unit

N. Grasselli Kmet, N. Trebše
Department of Infectious Diseases, University Medical Centre Ljubljana, Ljubljana, Slovenia
**Correspondence:** N. GRASSELLI KMET
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000449

**Introduction:** Critically ill patients are exposed to invasive interventions that destroy the anatomical integrity of natural defence barriers. As a result, the frequency of hospital-acquired infections (HAI) is the highest in intensive care units (ICU), with up to 25%, varying greatly between countries. In Europe, 7.4% of patients staying in ICU presented with at least one ICU-acquired HAI in 2019.
**Objectives:** Aim of the present study was to evaluate the burden of HAI in tertiary ICU in Slovenia, specialised in treating infectious diseases.
**Methods:** We performed a prospective study, analysing the documentation on patients ($N=74$) treated in infectious diseases ICU in University Medical Centre, Ljubljana, Slovenia, between 19.2.2019 and 10.3.2020. Data were collected prospectively and statistical evaluation was performed. $P$ values $\leq 0.05$ were considered statistically significant.
**Results:** Mean age of the included patients ($\pm$SD) was $64.7 \pm 16.1$ years, 66.2% were male and average APACHE score ($\pm$SD) was $8.9 \pm 11.5$. Length of stay ($+$SD) was $21.1 \pm 27.1$ days and 82.4% patients required mechanical ventilation (MV). There were 50 HAI events recorded (Figure 1). Incidence of catheter line-associated blood stream infection (CLABSI) was 3.54/1000 catheter days and incidence of ventilator associated events/pneumonia (VAE/VAP) was 29.36/1000 MV days. Overall mortality was 12.2%. Active malignant disease ($p \leq 0.001$), chronic liver disease ($p = 0.009$), and left subclavian central vein catheterisation ($p = 0.029$) were statistically significantly associated with CLASBI, while therapeutic rest ($p = 0.007$) and initial high-flow nasal cannula (HFNC) ventilation ($p = 0.001$) were statistically significantly associated with VAE/VAP.
**Conclusions:** In our infectious diseases, ICU rate of HAI, especially VAP, was higher than the rate observed in European ICUs in the same period. Main reasons might be, that the use of antibiotics in our ICU

is higher, as we primarily treat patients with the most severe, mostly bacterial infectious diseases. We found the initial HFNC ventilation as a significant risk of VAP, which was already described previously. HFNC may help avert intubation in patients with hypoxemic respiratory failure, but further studies will be necessary to evaluate consequences of its potential failure.

### Predicting length of stay in the intensive care unit using an accelerated failure time (AFT) model

S. Dawn[1], L. Achiam[2], A. Myers[3], J. Mitchell[4], S. Davey[4], A. Papadopoulou[5], T. Samuels[6]
[1]Intensive Care Unit, East Surrey Hospital, Redhill, United Kingdom; [2]Intensive Care Medicine, East Surrey Hospital, Redhill, United Kingdom; [3]Icu, East Surrey Hospital, Redhill, United Kingdom; [4]Intensive care, East Surrey Hospital, Redhill, United Kingdom; [5]Intensive Care, Royal Surrey County Hospital, Guildford, United Kingdom; [6]Critical care, East Surrey Hospital, Redhill, United Kingdom
**Correspondence:** L. Achiam
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000450

**Introduction:** Predicting Length of Stay (LOS) in the Intensive Care Unit (ICU) is a commonly used metric which can aid individual patient management as well as to optimise wider resource utilisation, costs, and efficiency; and help clinicians efficiently deliver high quality healthcare (1,2). Most studies that have evaluated models for ICU LOS prediction use multivariate linear regression. Studies have also demonstrated that there is a nonlinear relation between ICU LOS and severity of illness. In an AFT model, the effect of these covariates acts to accelerate or decelerate the time to event of interest, i.e., shorten or extend the time to event, which in this case is the length of stay. This is a type of survival analysis that directly models the length of stay as a function of a constellation of factors (3).
**Objectives:** To investigate factors influencing the length of stay in the ICU using survival regression analysis.
**Methods:** Data were analysed retrospectively for 1451 patients within the first 24 h of admission, between 1/1/22 and 30/12/23. A total of 1203 patients had complete data, which was analysed using an accelerated failure time (AFT) model using a Weibull distribution. The model included covariates, such as sex, age, 2 organs supported, lowest systolic blood pressure, lowest heart rate, lowest and highest serum sodium levels, and lowest and highest white blood cell counts. All analyses were performed using R (version 4.3.2).
**Results:** Significant predictors of length of stay included 2 organ systems supported ($p < 0.001$) and lowest systolic blood pressure ($p = 0.040$). Age showed a trend towards significance ($p = 0.078$). Other variables, such as sex, lowest heart rate, lowest and highest serum sodium levels, and lowest and highest white blood cell counts, were not significant predictors. The Weibull distribution was used, and the model demonstrated good fit ($\chi^2 = 168.62$, $p < 0.001$).
**Conclusions:** When the maximum number of organs supported is 2, this factor emerges as a critical predictor for length of stay. Additionally, our analysis suggests that lower systolic blood pressure, indicative of hemodynamic instability and severe illness, is significantly associated with shorter critical care stays. The reason for this is unclear, but it most likely reflects the increased mortality in this cohort of patients (e.g., those presenting with septic shock). While age appears to have a marginal impact, heart rate and serum sodium levels do not show significant associations with the length of stay.
As a single-centre study, caution should be employed regarding generalisation and further work should involve analysing datasets for other patient populations. We aim to improve upon the analysis by taking into consideration some possible correlates that are not included in this model. Overall, these findings underscore the importance of timely and appropriate medical interventions, in determining the duration of hospitalization for critically ill patients.

### Setting up a national online critical care rehabilitation group: ICUsteps active

R. Devlin[1], Z. van Willigen[1], M. Peskett[2], D. McWilliams[3], C. Jones[2]
[1]Therapy Services, University Hospital Southampton, Southampton, United Kingdom; [2]ICUsteps, Peer Support Charity, London, United Kingdom; [3]Centre for Care Excellence, University Hospital Coventry & Warwickshire, Coventry, United Kingdom
**Correspondence:** R. Devlin
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000453

**Introduction:** Survivors of critical illness may suffer from a range of AQ23 physical, cognitive, and psychosocial impairments, described as Post Intensive Care Syndrome (PICS), affecting their ability to return to a satisfactory quality of life. In the United Kingdom, funding for ICU recovery services after hospital discharge is poor, resulting in patchy provision of specialist rehabilitation support for critical care survivors. A group of ICU physiotherapists worked with the UK charity ICUsteps to set up a national online critical care rehabilitation group.
**Objectives:** To set up a national online critical care rehabilitation group including weekly exercise, education, and peer support, and evaluate the impact on patient recovery.
**Methods:** The ICU physiotherapists involved worked with ICUsteps to set up a programme based on their previous experience of running online rehabilitation classes for ICU survivors of COVID-19. An online rehabilitation group for cohorts of 8 ICU patients was developed, with once weekly sessions delivered for 8 weeks. Patients were initially recruited through ICU peers around the UK. Patients were eligible

to attend who were within 2 years of ICU discharge and able to use Zoom. All patients completed baseline questionnaires (HAD, IPAT, and SF-36) and undertook the 30 s sit to stand (STS) test during their initial 1:1 online assessment. Data were also collected on challenges, enablers, and learning points over the 8 week programme.
**Results:** All patients ($n=8$) showed significant improvement in mean 30 s STS scores (8.5 vs 5.4), and a reduction in psychological distress (mean IPAT score 7.2 vs 5.4) between initial assessment and 8 week follow-up. Improvements were also seen in all dimensions of the SF36 questionnaire (see Table 1).

**Table 1 (abstract 000453)** Change in assessment between pre-group and post-group scores

| Outcome measures | Pre-score | Post-score | % Improvement |
|---|---|---|---|
| SF-36 Physical functioning | 16 | 33.2 | 108% |
| SF-36 Physical role limitations | 0.5 | 15 | 2900% |
| SF-36 Emotional role limitations | 33.32 | 40 | 20% |
| SF-36 Energy/fatigue | 15 | 40 | 167% |
| SF-36 Emotional well-being | 49.6 | 72.8 | 47% |
| SF-36 Social functioning | 30 | 57.5 | 92% |
| SF-36 Pain | 30.6 | 43.75 | 43% |
| SF-35 General health | 20 | 37.5 | 88% |

A number of challenges were identified, including obtaining referrals, clashes with research projects, and undertaking online assessments. Enablers, such as weekly motivational emails, goal setting, and group bonding, aided the group functioning. Learning points have allowed the programme to develop. Through the online group forums, it was also noted that relatives of the patients also needed help to come to term with the experiences of ICU and recovery.
**Conclusions:** All participants improved in their objective measures from baseline and feedback from the group was also universally positive. Although numbers have been small so far, the impact of the programme has provided a lot of information to build on. Additionally, the programme development may help other healthcare professionals to set up similar online groups.

### Variation of the diastolic shock index at 24 and 48 h as a factor associated with mortality in patients with distributive shock unresponsive to norepinephrine treated with arginine vasopressin

S. Foradada Ubach[1], B. Vélez Jaigua[1], M. Lladó Vilar[1], L. Cornejo Fernández[2], A. Taché Sala[1]
[1]Intensive Care Unit, Hospital Universitari de Girona Doctor Josep Trueta, Girona, Spain; [2]Girona Biomedical Research Institute (IDIBGi), Hospital Universitari de Girona Doctor Josep Trueta, Girona, Spain
**Correspondence:** S. Foradada Ubach
*Intensive Care Medicine Experimental* 2024, **12(suppl 1):**000456

**Introduction:** The use of arginine vasopressin (AVP) is recommended in septic shock when norepinephrine (NE) is between 0.25 and 0.5 ucg/kg/min and mean arterial blood pressure (MAP) $\leq$ 65 mmHg. Diastolic shock index (DSI) was defined as the ratio between heart rate and diastolic blood pressure (DBP). DSI is a reflex of circulatory system dysfunction.
**Objectives:** The aim of the study is to determine the utility of DSI for the initiation of AVP, and to assess the therapeutic response and its prognostic value for mortality.
**Methods:** Observational and prospective study in a 24-bed third-level ICU, between November 2022 and September 2023. Patients $\geq$ 18 years old with a diagnosis of distributive shock (DS) and who met criteria for AVP initiation were included. Different variables, DSI, *vasopressor inotrope score* (VIS), lactate, corticosteroid use, intra-ICU mortality, and intra-ICU stay were analyzed (Table 1). Exclusion criteria: mortality during the first 24 h from admission to the ICU. The DSI cut-off value for mortality was determined using ROC curves.
**Results:** 51 patients, 80.4% were men with a median age of 60 years. Intra-ICU mortality was 35.3%, and mean length of stay was 13 days. Higher DSI clearance was observed at 24 h and 48 h hours in survivor patients ($p=0.009$ and $p=0.004$, respectively). The cut-off point for DSI clearance at 24 h was 9.3% with a sensitivity of 94%, specificity of 62%, PPV of 82% and NPV of 84%, and AUC: 0.724 (Image 1). The cut-off point at 48 h was 22.8% with a sensitivity of 73%, a specificity of 77%, a PPV of 86% and NPV of 61%, and AUC: 0.749 (Image 2). Both at 24 h and 48 h, significant differences were observed between survivors and non-survivors patients in relation to the cut-off points found. There was no association between corticosteroids and DSI.

**Table 1 (abstract 000456)**

| % improvement DSI | 20,4 (1,8 - 35,6) | -15,6 (-45,7-24,2) | 18,7 (-9,4 - 34,2) | 0,009 | 33,3 (17,8 -46,1) | 13,5 (-0,6-22,8) | 26 (11,4-40) | 0,004 |
| LACTATE | 17 (12-29,5) | 37 (16,8-91,3) | 22 (12 - 43) | 0,048 | 14 (8,5-24,5) | 26,5 (12,3-45,5) | 15 (9-28) | 0,016 |

**Conclusions:** A 61.1% of the non-survivors patients had a worsening of more than 9.3% of the DSI at 24 h after AVP administration, and 77.8% of the non-survivors patients had a worsening of more than 22.8% at 48 h. Surviving patients had lower lactate, NE and VIS values at 24 and 48 h. We recommend the use of DSI in the first 24 and 48 h as an indicator of response to treatment and for the introduction of a rescue therapy: methylene blue, angiotensine II, ascorbic acid, and hydroxocobalamin.

**Correspondence:** A. Tsuruoka
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000458

**Introduction:** Immunoadsorption (IA) therapy for neuroimmune diseases is usually performed using a conventional plasma separator such as Plasmaflo OP® (OP-05D, Asahi Kasei Medical Co. Ltd, Japan) as the first membrane and an immunoadsorption column, Immusorba TR® (TR-350, Asahi Kasei Medical Co. Ltd, Japan) as the second membrane. The removal characteristics of IgG subclasses in IA are that IgG1 and IgG3 are adsorbed up to 2000 mL of processed plasma volume (PPV), while IgG2 is desorbed at 1500 mL of PPV and IgG4 is desorbed at 1000 mL of PPV and returned to the human body. The frequent use of this method on consecutive days causes bleeding complications due to the adsorption of fibrinogen (Fib) and coagulation factor XIII.
In this study, a female patient in her 70's admitted to the ICU with anti-acetylcholine receptor (AchR) antibody-positive myasthenia gravis crisis were treated with selective immunoadsorption (SeIA) using Evacure Plus® (EC-4A10, Asahi Kasei Medical Co. Ltd, Japan), which has a smaller pore size of 0.03 μm than conventional membrane of 0.3 μm, as the primary membrane. SeIA was performed three times and conventional IA was performed once.
**Objectives:** The purpose of this study was to investigate the removal characteristics of immunoglobulin G subclasses (IgG1, 2, 3, and 4) during SeIA and the removal rates of anti-AchR antibodies, IgG, and Fib during each therapeutic plasma exchange (TPE).
**Methods:** We examined the removal characteristics of IgG subclasses in plasma samples collected from the inlet and outlet of TR-350 (Fig 1) at 500 mL, 1000 mL, 1500 mL, and 2000 mL of PPV during the SeIA. In addition, we measured anti-AchR antibodies, IgG, and Fib before and after TPE and examined the differences in removal rates in each treatment.
**Results:** The dynamics of IgG subclasses (IgG1, 2, 3, and 4) during SeIA are shown in Fig 2. IgG1 was not detected at the outlet at 2000 mL of PPV and the concentration did not increase at the inlet. IgG2 began to be detected at the outlet at 1000 mL of PPV, but the concentration did not increase at the inlet until 2000 mL of PPV. IgG3 was not detected at the outlet at 2000 mL of PPV, and its concentration at the inlet tended to decrease. IgG4 was detected at the outlet only at 2000 mL of PPV in the second session, but the concentration did not increase at the inlet. The removal rate of anti-AchR antibody, IgG, and Fib at SeIA (average of 3 times) and IA (once) were 74.9% and 57.7%, 39.3% and 28.5%, and 36.3% and 64.4%, respectively.
**Conclusions:** The removal characteristics of IgG subclasses during SeIA were investigated, and it was found that the adsorption performances of IgG1, 2, 3, and 4 were maintained even at 2000 mL of PPV,

suggesting that the PPV could be increased to 2000 mL or more. In addition, the loss of Fib was less than that of IA, and there seemed to be lower risk of hemorrhage even if the procedure was performed frequently in a short period. In this study, we did not investigate the behavior of bradykinin, and further safety evaluations are needed.

### The efficacy and safety of galactomannan (PHGG)-enriched enteral formulas on gastrointestinal tolerance in critically ill patients

X. Pan, J. Liu, D. Chen
Department of Critical Care Medicine, Ruijin Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, China

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000459

**Introduction:** Enteral nutrition (EN) is a crucial therapeutic approach for managing critically ill patients. Early initiation of EN is linked to improved intestinal function, preservation of mucosal barrier integrity, and stabilization of microbial balance, providing significant benefits for critically ill individuals [1]. Nevertheless, compromised intestinal function in critical illness often leads to gastrointestinal (GI) intolerance, manifesting as diarrhea, bloating, emesis, and gastric retention. These clinical manifestations can result in delayed or discontinued EN administration. Galactomannan (partially hydrolyzed guar gum, PHGG) is a soluble dietary fiber known to efficaciously prevent and mitigate GI intolerance [2]. Despite this, there is a paucity of data regarding the efficacy and safety profile of PHGG-enriched EN formulas for early EN administration in Intensive Care Units (ICUs) within the Chinese healthcare setting.
**Objectives:** This study aims to evaluate the efficacy and safety of a PHGG-enriched EN formula in improving GI tolerance in critically ill patients in China.
**Methods:** This multicenter, randomized, non-inferiority trial (ChiCTR2100041789) allocated eligible patients in a 1:1 ratio to either the treatment or usual care group. The treatment group received a PHGG-enriched EN formula aimed to achieve a daily nutritional intake of 25–30 kcal/kg for 10 days, whereas the usual care group received an equivalent fiber-free EN formula for the same period. The primary outcome was the proportion of the patient who reaching the 70% of the EN target on day 7 and secondary outcomes included GI intolerance, parenteral nutrition requirement, length of ICU and hospital stay, mechanical ventilation duration, clinical scores (AGI, SOFA and APACHE-II), intra-abdominal pressure (IAP), blood glucose (BG) levels, prealbumin and nitrogen balance, 28-day mortality, and the incidence of adverse events.
**Results:** There were no significant differences in baseline characteristics among the enrolled 328 critically ill patients. The proportion of subjects achieving $\geq$ 70% of the EN goal by the 7th day did not differ between the two groups (89.66% vs 89.80%, $p = 1.00$). Notably, the treatment group exhibited lower IAP on the 5th (6.00 *vs.* 8.00, $p = 0.01$) and 10th day (5.00 vs. 8.00, $p < 0.01$) compared to the usual care group. By the 10th day, a higher proportion of patients in the treatment group demonstrated reduced GI intolerance scores compared to those receiving usual care ($p = 0.03$). On the 5th day, the treatment group reported significantly lower AGI scores than the control group

($p = 0.02$). Incidences of adverse events related to EN did not differ significantly between groups.

**Conclusions:** The PHGG-enriched EN formula did not enhance the energy achievement rate when compared to the fiber-free formula. However, it did improve GI tolerance and AGI scores in critically ill patients. In addition, the PHGG-enriched EN formula did not result in an increase in adverse events.

**Introduction:** Septic shock, not an uncommon clinical condition in critically ill patients, affects various organs including liver. Usually, acute liver injury is identified as a change in biochemical values. In recent years with advancement in ultrasonography, transient elastography (Fibroscan) is being used to detect morphological liver damage more objectively [1]. However, liver stiffness in critically ill patients with septic shock has not been studied by 2D shear-wave elastography (2D SWE) which is technically superior to the Fibroscan assessment.

**Objectives:** We aimed to study the liver stiffness in critically ill patients having septic shock with previous apparently normal liver.

**Methods:** After Institutional Ethics Committee approval and trial registration (CTRI/2023/06/053891), this prospective study screened all adult ICU patients within 1 week of septic shock onset. Those with normal liver function test (LFT) and normal liver echogenicity on ultrasonography before the onset of septic shock were considered for inclusion. Exclusion criteria were known liver disease, congestive heart failure, raised intra-abdominal pressure, and recent abdominal surgeries. All included patients underwent liver stiffness assessment by 2D SWE technique between days 2 and 7 after the onset of septic shock [Fig 1]. In included patients, further follow-up assessment was also considered among ICU survivors at 4–6 weeks after resolution of septic shock. All 2D SWE assessments were performed by an experienced radiologist as per recommendations from the World Federation for Ultrasound in Medicine and Biology guidelines published in 2018 [2]. The normal range is 2–7 kPa; highest possible value is 75 kPa.

**Results:** During the study period (Jun 2023–Mar 2024), 182 patients screened, and 26 patients met eligibility criteria. At ICU admission, included 26 patients had median age of 37.5 years (IQR 35.5–59.5) and 50% were females, Charlsons comorbidity index was 1 (IQR 0–2) and SOFA score was 9 (IQR 7–12). On the day of study inclusion, median duration of septic shock was 5 days (IQR 3–6) with median SOFA score 10 (IQR 8.25–11.75). At the time of assessment, the median vasopressor cumulative dose was 325.65 × 103 mcg (IQR 9.7–22.9 × 103 mcg) and median cumulative fluid balance was + 4.2 l (IQR 3.7–6.1), with no statistical significance correlation with the value of liver stiffness (r2 linear 0.005 and 0.012, respectively) [Fig. 2 and 3]. Liver stiffness was found elevated in all patients with a median value of 31.65 kPa (IQR 25.2–34.2). Among ICU survivors, reassessment could be done in 6 patients, in whom median values decreased significantly from 28.5 kPa (IQR 25.2–31.7) to 5.9 kPa (IQR 5.27–6.37) [Fig. 4].

**Conclusions:** Our study found out that liver stiffness, measured by 2D SWE, is significantly higher in septic shock patients. However, our study found no correlation between the degree of liver stiffness with either the cumulative dose of vasopressors or the cumulative fluid balance in these patients. However, the value of stiffness decreases in follow-up.

**Introduction:** Bloodstream infection (BSI) caused by carbapenem-resistant Gram-negative bacilli (CR-GNB) has high mortality and limited therapeutic options. Colistin is highly active against carbapenem-resistant Gram-negative bacilli (CR-GNB), with a low resistance rate.
**Objectives:** To investigate the clinical benefits of colistin-based combination therapy as compared to colistin monotherapy in treating nosocomial BSI caused by CR-GNB in intensive care units (ICU).
**Methods:** This multi-center, retrospective, cohort study enrolled ICU-admitted patients with nosocomial BSI caused by CR-GNB. Treatment outcomes were compared between patients treated with colistin monotherapy and combination therapy in the original and propensity score (PS)-matched cohorts. Differences in treatment outcomes between various sources of BSI were also compared. A subgroup analysis was performed to identify the specific population that benefitted from the combination therapy.
**Results:** We analyzed 262 patients with CR-GNB-related BSI, of whom 107 received colistin monotherapy and 155 received colistin-based combination therapy. No significant differences in mortality, clinical failure, or microbiological eradication rates were noted between monotherapy and combination therapy in the original and PS-matched cohorts. In the multivariate analysis, pneumonia-related BSI was significantly associated with day-28 mortality (aHR 1.68, 95% CI 1.13–2.49) and clinical failure (aOR 1.72, 95% CI 1.02–2.97); colistin monotherapy was not an independent factor associated with day-28 mortality and clinical failure. In the subgroup analysis, pneumonia-related BSI patients benefitted from combination therapy by reducing day-28 mortality (63.6% vs. 43.4%, $p = 0.047$), while catheter-related patients benefitted from monotherapy by reducing day-14 mortality (15.6% vs. 34.7%, $p = 0.047$).
**Conclusions:** Colistin monotherapy and combination therapy showed comparable treatment outcomes among ICU-admitted patients with nosocomial BSIs caused by CR-GNB. Subgroups of patients with pneumonia-related BSI benefitted from combination therapy by reducing day-28 mortality.

### Recovery characteristics of patients using two anesthesia techniques in major maxillofacial surgery: a randomized-controlled trial

D. Goswami[1], S. Parajuli[1], A. Roychoudhury[2], O. Bhutia[2]
[1]Anaesthesiology, Pain Medicine and Critical Care, All India Institute of Medical Sciences, New Delhi, India; [2]Oral and Maxillofacial Surgery, All India Institute of Medical Sciences, New Delhi, India.
**Correspondence:** D. Goswami
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000465

**Introduction:** General anaesthesia (GA) provided during surgical procedures is usually conducted using either inhaled anaesthetics or total intravenous anaesthesia (TIVA), but there is little evidence regarding its impact on the patient's perception of quality of recovery in the post-operative period. The Quality of Recovery-40 questionnaire (QoR-40) has been validated and used to determine the functional recovery of patients following GA in various surgeries, but its impact on patients undergoing maxillofacial surgery remains unexplored.
This study was designed with the objective to compare the difference in patient recovery using QOR-40 in patients who were anaesthetised using TIVA (propofol and dexmedetomidine) with those receiving inhalational anaesthesia (desflurane) in patients undergoing major maxillofacial surgery.
**Objectives:** Primary: To compare the QoR-40 score using two anaesthetic techniques, TIVA or inhalational anaesthesia, in patients undergoing major maxillofacial surgery on postoperative day one (POD1).
Secondary: Incidence of postoperative nausea and vomiting, postoperative analgesic requirement, blood glucose levels in the peri-operative period, extubation time, incidence of postoperative agitation, and duration of stay at post anaesthesia care unit (PACU).
**Methods:** A total of 80 patients undergoing major maxillofacial surgery were recruited prospectively. Adult patients above 18 years, belonging to ASA I-II, undergoing maxillofacial surgery for tumor or fracture with surgical duration of > 2 h were included as study subjects. Patients with cognitive/verbal communication impairment, chronic pain on analgesic medication were excluded from the study. Institutional ethical committee approval and CTRI registration *(IECPG-38/27.02.2021; CTRI/2021/03/031993)* was obtained prior to commencement of the study. Sample size was calculated from previous observations by Lee WK et al. (1).
The enrolled patients were randomized using Stata 14.0 into two groups as follows:
Group- I: desflurane in air and oxygen.
Group-T: propofol–dexmedetomidine continuous infusion.
All patients received standard anaesthesia induction with intravenous (IV) propofol, fentanyl, and atracurium followed by endotracheal intubation. Maintenance was as per the group allocation. A target plasma concentration of 4mcg/ml was maintained for propofol with target controlled infusion device and dexmedetomidine was maintained within a range of 0.2–0.75mcg/kg/hr after the initial bolus dose of 1

mcg/kg/hr over 10min. An investigator blinded to group allocation, administered the QoR-40 a day before surgery and on POD1.
Data were analysed by statistical software Stata 14.0 (Stata Corp LLC, College station, TX, USA).
**Results:** Desflurane group had significantly higher QoR-40 score (190.72 + _8.81) on POD1 compared with the TIVA group (184.1 + − 13.0) (adjusted $p = 0.045$). Among the five dimensions of QoR 40, emotional status and pain scores were better for the desflurane group. Extubation time was significantly higher in the T group ($P < 0.001$). There was no statistical difference in PONV, post-operative analgesic requirement, and blood glucose levels between the two groups. Extubation time and duration of PACU stay were significantly higher in the TIVA group ($p = 0.001$ & $p = 0.009$, respectively). Post-operative agitation was higher in the desflurane group ($p = 0.001$).
**Conclusions:** This study illustrates that the quality of recovery perceived by patients undergoing major maxillofacial surgery was better in a statistically significant way with inhalational anaesthesia as compared to TIVA. However, a mere 5-point increase in the QoR 40 may not be clinically significant.

### A comparative analysis of traumatic cardiac arrest: understanding out-of-hospital and in-hospital characteristics

S. W. Jang[1], J. S. Chung[2], J. Pil Young[2]

**Introduction:** This study aims to understand the characteristics and factors influencing post-traumatic cardiac arrest (TCA) survival rates, comparing out-of-hospital TCA (oTCA) with higher occurrence to in-hospital TCA (iTCA).
**Methods:** This is a retrospective review of 286 TCA patients transported to the regional trauma center (RTC) in Gangwon Province, Korea, between 2013 and 2019. Patients were categorized based on 72-h survival status after TCA.
**Results:** The results revealed significant protective effects for transfer from another hospital (HR 0.86 [0.76–0.97]), and longer time from accident to CPR (HR 0.95 [0.90–0.99]). Transferred patients demonstrated a significant protective effect in all patients and high injury severity score (ISS) groups, but not in the lower ISS group. Subgroup analysis indicated that patients transferred from another hospital had significantly lower HR compared to directly transported patients to RTC in oTCA (HR 0.36 [0.23–0.57]), total cardiopulmonary resuscitation (CPR) time > 30 min (HR 0.34 [0.23–0.52]), and accident-to-CPR time < 30 min (HR 0.25 [0.11–0.55]). Additionally, restricted cubic spline curve analysis revealed that shorter distances from the accident to the first hospital were associated with lower relative HRs.
**Conclusions:** Considering the extremely poor outcomes of TCA, it is important to prioritize basic resuscitation and evaluation at nearby medical institutions rather than immediate transfer to specialized trauma centers, especially when TCA occurs or is anticipated. The study's findings support the notion that early damage control resuscitation at a nearby hospital can have a significant impact on improving the survival rate of TCA patients.

### Long-term outcomes of time-dependent phenotypes of perioperative myocardial injury

M. Fält, H. Didriksson, C. Jonsson, H. A. Andersson, M. Chew
Anesthesiology and Intensive Care, Linkoping University Hospital, Linköping, Sweden
**Correspondence:** M. Fält
*Intensive Care Medicine Experimental* 2024, **12(suppl 1):**000467

**Introduction:** Myocardial injury (MI) defined as increased high-sensitivity cardiac troponin (hs-cTn) during the perioperative period is associated with increased major adverse cardiovascular events (MACE) and mortality in the short term. We evaluated how different phenotypes based on timing of MI may impact long-term MACE and mortality among patients undergoing major non-cardiac surgery (NCS).
**Methods:** Patients ≥ 50 yo undergoing elective, major NCS were included. Hs-cTnT, ECG, and symptoms were collected preoperatively and up to 3 days after surgery. Searches of patients' medical records were supplemented with national patient registries, censored 3 years after surgery. Patients were classified to (1) isolated preoperative increases (> 99th URL) in hs-cTnT, (2) normal preoperative hs-cTnT with perioperative elevation (postop-preop > 99th URL), and (3) increased preoperative hs-cTnT with perioperative elevation. Comparators were patients without hs-cTnT increases. We examined the effect of the MI phenotypes on MACE and mortality using multivariable Cox and logistic regression analyses.
**Results:** We included 1290 patients. MI phenotypes and outcomes are shown in Table **1**. MI increased the short- and long-term risk for MACE even after adjustment for age, sex, ASA class, preoperative anaemia, preoperative increased creatinine, intraoperative transfusion, duration of surgery, intraoperative hypotension, comorbidities, and RCRI (Table 2). Arrhythmias accounted for the majority of MACE (13.9%), followed by heart failure (10.0%), stroke/TIA (4.3%), angina (3.8%), myocardial infarction (2.5%), and cardiac arrest (1.2%). MI increased the risk for mortality, but no differences between the phenotypes were observed (Figure 1).

| Variable | 30 d OR (CI) | *P* | 1 y OR (CI) | *P* | 3 y OR (CI) | *P* |
|---|---|---|---|---|---|---|
| Preop normal, periop elevation | 4.5 (2.3–8.8) | < 0.001 | 4.0 (2.3–7.2) | < 0.001 | 3.5 (2.0–5.9) | < 0.001 |
| Preop increase, periop elevation | 3.4 (1.7–6.8) | < 0.001 | 3.3 (1.8–6.0) | < 0.001 | 2.3 (1.3–4.0) | 0.003 |

**Conclusions:** All MI phenotypes increased the risk for long-term MACE and mortality up to 3 years. Perioperative MI without preoperative increases in hs-TnT had the largest effect on long-term MACE. This suggests that interventions should be targeted at the prevention of perioperative MI to reduce its impact on long-term cardiovascular outcomes.

*Intensive Care Medicine Experimental* 2024, **12(suppl 1):**000469

**Introduction:** Resuscitative Endovascular Balloon Occlusion of the Aorta (REBOA) is recognized as a crucial intervention during early trauma resuscitation, providing a window of opportunity for subsequent treatment in hemodynamically unstable hemorrhagic patients. However, concerns regarding potential complications of REBOA and the absence of a standardized consensus on its indications have led to varying approaches in timing across trauma centers and among practitioners. This study seeks to compare the implementation of an early REBOA protocol in Korean trauma centers with other approaches to evaluate the effectiveness of early REBOA application.
**Methods:** This retrospective analysis includes 251 trauma patients who underwent REBOA across five Korean trauma centers between 2015 and 2021. In two institutions, an early REBOA application protocol was adopted for cases of unresponsive shock state with systolic blood pressure below 80 mmHg, and in the absence of radiologically confirmed aortic injury. The study divides these institutions into a "protocol group" and other institutions into a "no-protocol group" for comparative analysis.
**Results:** While the door-to-puncture time for the protocol group was 31.7 ± 35.1 min, comparable to the no-protocol group's time of 36.6 ± 33.5 min (p = 0.078), the puncture-to-balloon time was significantly longer in the protocol group (7.6 ± 7.3 vs 0.1 ± 0.8, $p < 0.001$). Although 24-h survival rates did not differ between the groups ($p = 0.386$), the 3-h mortality rate was significantly lower in the protocol group ($p = 0.040$). The survival benefit for the protocol group was notable in the time interval of 176–227 min, with the most pronounced effect observed within the 215–219-min interval.
**Conclusions:** The protocol group proactively inserted the REBOA catheter prior to finalizing the decision to inflate the REBOA balloon. While early REBOA application did not impact overall survival rates, it demonstrated a substantial increase in survival during the initial 3–4 h of resuscitation. This underscores REBOA's role in creating a critical time window for subsequent treatments following the initial resuscitation of severely injured patients.

### Epidemiology and Impact of *Candida auris* in the intensive care unit: insights from a tertiary hospital in Greece

A. Sakagianni[1], I. Patsis[1], C. Koufopoulou[2], M. Masouridi[3], GS. Christodoulatos[4], I. Bader[1], Z. Athanassa[1], S. Tzina[5], A. Dimoula[1], S. Michelidou[1], V. Charizopoulou[1]

*Intensive Care Medicine Experimental* 2024, **12(suppl 1):**000471

**Introduction:** Candida auris, a newly identified hospital-acquired pathogen, has shown a notable surge in both colonization and infection rates within intensive care units (ICUs). The resistant nature of *C. auris* and the significant mortality risk associated with bloodstream infections pose a significant hurdle for medical practitioners.
**Objectives:** To report epidemiological surveillance data and impact of *Candida auris* in critically ill patients admitted to the ICU of a tertiary hospital in Greece.
**Methods:** This is a single-center retrospective observational study that included all patients admitted to the ICU of a tertiary hospital in Greece, over a 33-month period (between April 2021 and January 2024), in whom *C. auris* was isolated on admission, during or after ICU stay. Cutaneous swabs from axillae and inguinal creases were screened for *C. auris* upon ICU admission and on a regular basis for epidemiological reasons. Clinical specimens (e.g., urine, blood, respiratory secretions) were also regularly screened for infection investigation

purposes. Medical records were reviewed for age, sex, source of ICU admission, previous hospitalizations and antibiotic therapy, comorbidities, candidemia, concomitant MDR infections, length of ICU, and hospital stay (LOS) and outcome. *Candida auris* was isolated in clinical and screening specimens by culture-based method on Sabouraud Chloramphenicol agar and Brilliance Candida agar (Oxoid, UK). The identification of *C. auris* was carried out by matrix-assisted laser desorption ionization–time of flight mass spectrometry (MALDI-TOF MS–AUTOF MS 1000; Autobio Diagnostics, China). Sporadically, the isothermal LAMP method (AMPLEX, Germany) was also used for the direct molecular detection of the pathogen. Categorical variables were summarized with numbers and percentages, and continuous variables with median and interquartile range.

**Results:***Candida auris* was isolated from 46 patients that were admitted to the ICU during the study period. Thirty four of them were male (74%), with a median age of 67.5 [IQR 17.5]; 20 of them (43.5%) had a diagnosis of COVID-19 infection upon hospital admission. In 37 patients (80.4%), *C. auris* was isolated from non-sterile sites. Nine patients (19.5%) developed *C. auris* bloodstream infection during their hospital stay. Among carriers, 27 (58.7%) reported hospitalization within the previous 6 months and 39 (84.8%) recent antibiotic therapy. Thirty patients (65.2%) were concomitantly colonized or infected by $\geq 1$ multidrug-resistant (MDR) Gram-negative pathogen. The median length of ICU stay was 29 days [IQR 34]. The median time of hospital stay before the first isolation of *C. auris* was 17 days [IQR 17.5], and the total length of hospital stay was 44 days [IQR 44.5]. Number of comorbidities: 31 patients (67.4%) reported more than one comorbidity and 20 (43.5%) $\geq 2$. Sites of colonization were: skin ($n=31$), urine ($n=7$), and respiratory system ($n=2$). All the patients in the cohort had a central venous catheter and received mechanical ventilation (100%). One patient underwent extracorporeal membrane oxygenation (ECMO) due to severe COVID-19 ARDS. Fifteen patients (34%) received an echinocandin and eight patients (18%) other antifungal drugs. All *C. auris* blood isolates were resistant to fluconazole (100%) and susceptible to echinocandin, while three were resistant to amphotericin B (33.3%). The overall mortality rate in the entire *C. auris* cohort was 50% (23/46), and 55% (5/9) in patients with *C. auris* bloodstream infection.

**Conclusions:** The results of our study demonstrate that critically ill patients colonized or infected by *C. auris* present a high rate of adverse outcomes, such as prolonged ICU and total hospital stay, high incidence of concurrent MDR infections, and high mortality rates. Early recognition and measures to prevent further dissemination of this highly transmissible and difficult to eradicate fungus are necessary, especially in the ICU setting.

**Introduction:** Patients admitted to hospital in low-income countries with breathlessness and hypoxaemia suffer high mortality rates [1]. In these settings, limited access to diagnostic resources impacts on patient assessment and therefore impedes prompt initiation of appropriate treatment [2,3]. In our prospective cohort study, we explore the pathology and outcomes of patients admitted to hospital with breathlessness and hypoxaemia in Malawi.

**Methods:** We enrolled adults ($\geq 18$ years) with any of: breathlessness; hypoxaemia (SpO2 < 94%); respiratory rate > 24; or those treated with oxygen therapy. Participants were consecutively recruited in two hospitals in Malawi: Queen Elizabeth Central Hospital, Blantyre and Chiradzulu District Hospital, Chiradzulu. Participants were systematically screened for common causes of breathlessness on admission using enhanced diagnostic modalities (including chest X-ray, lung ultrasound, echocardiography, microbiology, biochemistry, and spirometry), to enable determine estimates of disease pathology against gold-standard criteria. Participants were followed-up for 90 days post-admission; 1-year follow-up post-admission is currently on-going.

**Results:** We recruited 312 participants of whom 99% (310/312) completed follow-up. Mean age was 52 (standard deviation 18). In-hospital mortality rate was 23% (71/310) and day-90 mortality rate was 43% (133/310). From preliminary analyses, the most common clinical diagnoses were pneumonia (34%; 104/312), heart failure (26%; 82/312), tuberculosis (16%; 51/312) anaemia (8%; 25/312), asthma (6%; 22/312), and chronic obstructive pulmonary disease (3%; 8/312). Multiple co-existent diagnoses affected 21% (64/312) patients; the most common dual pathology was pneumonia and heart failure (6%; 18/312).

**Conclusions:** In Malawi, we have observed a high mortality among adult patients admitted to hospitals with hypoxemia and breathlessness. The in-hospital mortality rate was 23%, which nearly doubled to 43% by day 90. The restricted availability of diagnostic resources in this resource-constrained setting negatively impacts on diagnosis accuracy and subsequently affects treatment planning for these patients. Studies to develop and evaluate the impact of context-sensitive diagnostic-treatment algorithms are needed to improve outcomes for acutely breathless patients in sub-Saharan Africa.

## Checklist for analyzing educational resources on the basics of adult life support

D. Starostin
Intensive Care & Emergency medicine, Federal Research and Clinical Center of Intensive Care Medicine and Rehabilitology, Moscow, Russia
**Correspondence:** D. Starostin
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000476

**Introduction:** A lack of knowledge about cardiopulmonary resuscitation (CPR) and the fear of causing harm are the main reasons preventing people from administering CPR. Training increases the willingness of bystanders to perform resuscitation, which in turn improves the chances of survival and neurological outcomes after out-of-hospital cardiac arrest. Despite the support for CPR training in the scientific community, knowledge about CPR is not widely disseminated, especially in some regions of the world. As an alternative to traditional courses, self-learning through digital resources is proposed. However, the quality of these materials often does not meet current recommendations, which also applies to some certified courses. There is a need for a standardized system to assess the quality of educational resources on resuscitation, but a unified tool for this has not yet been developed. The study aims to create a checklist for evaluating CPR training resources for lay people.
**Objectives:** Due to the absence of a universal method for assessing the quality of training materials for lay rescuers performing basic life support (BLS) for adults, the goal of this study was to create a checklist for evaluation, developed based on international expert consensus.
**Methods:** During a two-stage research process, experts filled out questionnaires to evaluate 72 items on a preliminary drafted checklist, aimed at determining whether each item should be used to verify the compliance of Basic Life Support (BLS) educational materials for adults with resuscitation standards. The acceptance of compliance items was based on receiving a score of 7 or more points from at least 75% of experts. Experts were also given the opportunity to anonymously suggest changes or additions to the list.
**Results:** Initially, 46 participants took part in the study, of whom 42 (91.3%) passed the first round, and 40 (87.0%) passed the second. These participants represented 25 countries and had an average of 16 years of experience in the resuscitation field. Out of 72 proposed theses, 13 were rejected, 55 accepted without changes, 4 approved after modification, and 4 new items were added. The final checklist contains 63 items, distributed into categories: "safety" (1 item), "recognition" (9 items), "calling for help" (4 items), "chest compressions" (12 items), "breathing in resuscitation" (12 items), "defibrillation" (9 items), "continuing CPR" (2 items), "choking" (10 items), and "miscellaneous" (4 items).
**Conclusions:** The created checklist is a ready-to-use tool based on agreed expert opinions, designed to assess the quality of educational material used in teaching lay rescuers the basics of BLS. This tool enables the creators of educational content to ensure their materials are in line with current scientific achievements in the field of resuscitation. Moreover, it could play a role in a future global system for standardization and quality control of education in the sphere of resuscitation measures.

### Spectral edge frequency and dilation pupillary velocity in critically ill patients: a pilot study

M. Zaccarelli[1], M. Polato[2], F. S. Taccone[2]
[1]Anestesia e Reanimazione, IRCCS AOU San Martino, Genova, Italy; [2]Soins Intensif, ULB Erasme, Anderlecht, Belgium
**Correspondence:** M. Zaccarelli
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000477

**Introduction:** In a previous study, low dilation velocity (DV) measured using an automated pupillometry could effectively identify an unreactive electroencephalographic (EEG) background in critically ill patients without anoxic brain injury. However, there are no data comparing DV and other EEG-derived parameters.
**Objectives:** To assess the association of DV and the spectral edge frequency (SEF) derived from EEG in critically ill patients.
**Methods:** A prospective pilot study was conducted in the Department of Intensive Care at Erasme University Hospital in Brussels, Belgium. In critically ill patients on mechanical ventilation, and undergoing a 4-channel processed EEG monitor of sedation (SedLine, Masimo, CA, USA) according to the decision of the treating physician, pupillary assessment (NPi-300; Neuroptics, CA, USA) was performed at baseline (T1) and within 2 h from changes in sedation regimens (T2; e.g., either reduced or increased). In particular, mean value of SEF and DV values from both hemispheres or eyes were recorded at the two time-points. Changes in SEF and DV over time were calculated as = (value at T2 − value at T1)/value at T2.
**Results:** The study included 25 patients (mean age 66 years, 72% male). Median Glasgow Coma Scale on the day of recording was 5 (3–14) and 15 (60%) patients were also on continuous opioids infusion. Main reasons for ICU admission were respiratory failure ($n = 9$), heart surgery ($n = 8$), sepsis ($n = 3$), and other diseases ($n = 5$). In 18 patients, sedation regimens was increased (72%).
SEF significantly decreased (from 11.9 [7.0–14.3] to 8.5 [5.2–11.2] Hz; $p = 0.02$), while DV did not (from 0.46 [0.28–0.82] to 0.40 [0.29–0.62] mm/sec; $p = 0.36$). SEF was not correlated with DV at baseline ($r = 0.01$; $p = 0.95$), but it was after changes in sedation regimens ($r = 0.41$; $p = 0.04$). However, changes in SEF were not correlated with changes in DV after the intervention ($r = 0.15$; $p = 0.45$).
**Conclusions:** In this pilot study, dilation pupillary velocity was not correlated with baseline values or changes over time of SEF measured on simplified quantitative EEG in critically ill patients.

**Correspondence:** M. Notó Fabregas
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000478

**Introduction:** The management of Acute Respiratory Distress Syndrome (ARDS) patients requiring invasive mechanical ventilation (MV) focuses on protective MV strategies aimed to improve clinical outcomes (1,2), but can lead to a high number of patient–ventilator asynchronies (3,4). Although patient–ventilator asynchronies have been associated with negative outcomes (5–8), but some studies suggest potential positive effects in some specific scenarios (9–13). On the other hand, treatment with neuromuscular blockers (NMB) in ARDS patients with PaO2/FiO2 ratio < 150 mmHg has been associated with survival improvement (14), but this point has not been confirmed in subsequent studies (15,16). In fact, the most recent guidelines do not advocate its widespread utilization, limiting their recommendation to early ARDS with low certainty (1,2). One of the suggested beneficial mechanisms has been the reduction in patient–ventilator asynchronies, thus reducing the risk of ventilator-induced lung injury, but this has not been specifically evaluated. It is also unclear whether a total or partial blockade is necessary, merely to reduce the magnitude of the effort and reduce dyssynchronous efforts (2). Additionally, COVID-19 infection may have implications beyond respiratory and ARDS by affecting the central nervous system (CNS). The virus's potential neurotropism raises concerns regarding its effects on the respiratory center, which plays a crucial role in regulating breathing patterns and maintaining respiratory function. Then, respiratory failure observed in COVID-19 patients may be influenced not only by direct lung injury

but also by CNS involvement, which could affect the control of breathing and further complicate ventilatory management (17–19). COVID-19 ARDS patients then present unique clinical features that may influence the pattern of patient–ventilator asynchronies during MV, resulting in atypical respiratory patterns and presentation of patient–ventilator asynchronies in contrast to patients with ARDS from other causes, and which merit further study. Given the challenges posed by patient–ventilator asynchronies and the complexities of COVID-19 ARDS patients, our aim was to analyze the prevalence and characteristics of patient–ventilator asynchronies in these patients.
**Objectives:** To analyze the prevalence of patient–ventilator asynchronies in COVID-19 (ARDS) patients, its modulation by (NMBA), and their association with clinical outcomes.
**Methods:** Observational study from a prospective real-world data cohort from two hospitals. We included mechanically ventilated ARDS COVID-19 ICU patients (ClinicalTrials.gov NCT04448782). Exclusion criteria were age less than 18 years, invasive mechanical ventilation (MV) less than 48 h, and ICU admission from other centers under invasive MV. Demographic and clinical data were obtained from medical records. We analyzed the prevalence, characteristics, and clusters of the following patient–ventilator asynchronies: double triggering (DT), ineffective inspiratory efforts (IE), reverse triggering (RT), and reverse triggering with double cycling (RT-DC), which were detected using a dedicated software (Better Care S.L., Sabadell, Spain). We also explored the effect of NMBs in patient–ventilator asynchronies. The outcome measures evaluated were duration of invasive MV, length of ICU stay, and ICU mortality.
**Results:** We analyzed 82 ARDS patients. The most frequent patient–ventilator asynchronies were RT (0.72% [IQR, 0.17–3.07]) and DT (0.44% [IQR, 0.19–0.80]). The most common clusters were RT (4.6 clusters/day [IQR, 2.0–8.1]) and DT (4.6 clusters/day [IQR, 2.1–7.3]). NMB treatment was associated with lower DT (0.14% [IQR, 0.07–0.28] vs. 0.68% [IQR, 0.34–1.16]; $p < 0.001$) and lower IE (0.06% [IQR, 0.02–0.21] vs. 0.30% [IQR, 0.18–0.71]; $p = 0.001$), but not significantly difference in RT and RT-DC. The presence of DT and clusters of DT was independently associated with longer MV duration and higher ICU survival.
**Conclusions:** In ARDS COVID-19 patients, RT and DT events and clusters of DT and RT were the most frequent patient–ventilator asynchrony. The use of NMBs decreased all asynchronies but not RT and RT-DC. Patients who survived ICU exhibit higher incidence of DT. Further studies are warranted to elucidate whether clusters of DT and IE are associated with increased mortality or simply are a phenomena associated with the liberation of invasive MV.

**Topic:** Acute respiratory failure and mechanical ventilation

### Central venous catheter insertion and patient safety: an audit on current practice against updated 2023 national guidance

R. D'Abrantes, A. Tahir
Anaesthetics & Critical Care, Stoke Mandeville Hospital, Aylesbury, United Kingdom
**Correspondence:** R. D'Abrantes
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000480

**Introduction:** National Safety Standards for Invasive Procedures (NatSSIPs) aim to help organisations and healthcare teams deliver safe care in a complex and pressurised system (1). Insertion of central venous catheters (CVC) is a common procedure undertaken in Intensive Care Units (ICU). The CVC Insertion Checklist by the Intensive Care Society and the Faculty of Intensive Care Medicine was updated in November 2023 following patient safety incidents reported nationally. These incidents mainly related to the unintended arterial placement of CVCs, which can lead to significant morbidity and mortality. This new national standard states that all CVCs should be transduced prior to their use (2).
**Objectives:** Current local ICU policy states that 2 out of 3 confirmatory modalities are sufficient to confirm safe use of CVCs: transduction, paired blood gases, or ultrasound visualisation of guide wire in vein. The objectives of this audit were twofold: to check compliance to the current confirmatory modalities policy, and to compare current practice against the recently updated national standards. The key change audited being that all CVCs should be transduced prior to their use.
**Methods:** An audit was performed on patients who had a CVC inserted during their ICU stay between February and March 2024 at Buckinghamshire Healthcare NHS Trust. Checklists were reviewed to assess whether any of the 3 locally agreed safety checks were documented—transduction, paired blood gases, or venous ultrasound visualisation of guidewire.
**Results:** Forty checklists were analysed. 23 (57.5%) had 2 out of 3 safety checks recorded. 5 (12.5%) CVCs were transduced before use, 22 (55%) checklists had paired blood gases documented, and 38 (95%) indicated that ultrasound was used to visualise the guidewire in a vein.
**Conclusions:** This audit highlighted poor compliance to the locally agreed confirmatory modalities for safe use of CVCs. Additionally, results demonstrated that transduction of the line prior to use occurs infrequently. Seven out of the ten safety bulletins published by the Faculty of Intensive Care Medicine (December 2020–February 2024) reported cases of inadvertent arterial placement of central venous catheters, including cases of associated morbidity and mortality following intra-arterial infusion of vasoactive medications (3). Despite the widespread use of dynamic ultrasound scanning during CVC insertion, mechanical complications do still occur (4). A recent multicentre study in 2022 estimated the incidence of mechanical complications to be 7.7%, of which 0.4% were major complications including arterial catheterisation (5). The aim of the updated CVC guidance is to help improve the safety of this common procedure. The authors have distributed the updated guidance, findings, and conclusion of this project to the Anaesthetic and Critical Care Department, including nurses and doctors, and will re-audit soon.

**Introduction:** Our understanding of the pharmacokinetics/pharmacodynamics of antiinfectives has greatly improved over the last decades [1, 2]. Predicting the effects of renal replacement therapy (RRT) on drug levels is theoretically possible—achieving it in practice is not easily accomplished. While some antimicrobials require alternating levels, many, such as betalactam antibiotics, require sustained concentrations for efficacy [3]. Inappropriate drug exposure can lead to treatment failure or emergence of resistance. Therefore, maintaining effective antiinfective levels in critically ill patients during RRT poses an everyday challenge in intensive care medicine [4].
**Objectives:** Our primary objective is to validate the "target controlled dialysis" (TCD) concept in vitro, to offer an elegant and simple solution for reliably achieving and maintaining drug concentrations during renal replacement therapy.
**Methods:** A MultiFiltratePRO® hemodialysis circuit from Fresenius Medical Care was used. Meropenem and voriconazole were added to the dialysis solution aiming for concentrations of 30 mg/L and 1 mg/L, respectively. A 3 L simulated patient reservoir (SPR) consisting of saline and bovine serum albumin (30 g/L) was prepared, and the circuit primed. 270 mg of meropenem and 9 mg of voriconazole were then added to the SPR. The SPR was continuously dialyzed for 150 min at a "blood flow rate" of 200 mL/min, counterflow against dialysis solution containing both substances at a rate of 66.6 mL/min. Samples were collected from the dialysate outflow line and the SPR at specific intervals (Figure 1), and the antiinfective levels were quantified by high-performance liquid chromatography. Their unbound fractions were determined by an additional ultrafiltration step.
**Results:** Concentrations in the dialysis solution resulted in 37.2 mg/L and 0.9 mg/L for meropenem and voriconazole. Figures 2 and 3 depict their concentration–time curves in the SPR and the dialysate outflow line. Meropenem exhibited an unbound fraction of 100%, voriconazole of 29%.
**Conclusions:** The concentration–time curves clearly demonstrate that TCD prevents a drop in plasma concentration below the threshold set by the "target" dose in the dialysis solution. Concentrations in the dialysate outflow line decrease toward the concentration in the dialysis solution. Since only the free/unbound substance is dialyzed, levels in the simulated patient tend to stabilize at a total concentration higher than the (free) target concentration in the dialysis solution, depending on the degree of protein binding. Meropenem exhibits a very high (nearly 100%) unbound fraction, while voriconazole is significantly protein-bound. The concentrations in the dialysate outflow should closely reflect the concentration of the unbound substance in plasma. In summary, our in vitro experiments demonstrate the concept of TCD: using TCD, drug levels gradually reach and maintain the chosen target concentration during continuous renal replacement therapy, ensuring effective therapy.

**Introduction:** Rightward shifts in oxyhemoglobin dissociation curve (ODC) reflect decreased oxygen affinity to hemoglobin. In critically ill patients, decreased tissue perfusion can induce changes in tissue milieu that result in right shift. Recent studies in COVID-19 patients have shown that right shift is associated with worse clinical outcomes [1].
**Objectives:** In this study, we evaluated the association between right-shifted ODC and mortality in a large, multi-center cohort of critically ill patients. We hypothesized that right shift will be associated with increased mortality.
**Methods:** This is a retrospective, observational cohort study. The cohort was selected from a previously described blood gas and oximetry linked dataset (BOLD) containing time-aligned, paired SpO2 and SaO2 measurements and other demographic and clinical data. BOLD was developed by merging data from three publicly available, de-identified databases (MIMIC-III, MIMIC-IV, and eICU-CRD) [2][3][4]. Patients with missing data for key variables were excluded. Temporally paired PaO2 and SpO2 were used to estimate the p50 (oxygen tension when hemoglobin is 50% saturated with the oxygen) using the modified Hill equation ($p50 = PaO2\ ((1 - SpO2)/SpO2)^{2.711}$) [5]. These estimates of p50 were used to define ODC shifts as left shift ($p50 < 24$ mmHg), normal (p50 24–28 mmHg), and right shift ($p50 > 28$ mmHg). The study cohort was divided into primary dataset (eICU-CRD) and external validation dataset (MIMIC-IV). Primary dataset was further split into a training set and a test set. Multivariable logistic regression with tenfold cross-validation was used to develop the model evaluating the association between ODC shift and mortality, after adjusting for known mortality risk predictors (demographics and severity of illness indicators). Model performance was assessed in the test set and validated in the external validation set.
**Results:** A total of 23,848 patients were included in the final cohort. Mean p50 was higher in non-survivors compared to survivors ($29 \pm 13$ vs. $26 \pm 10$ mmHg, $p < 0.001$). Non-survivors also differed from survivors with respect to age ($69 \pm 15$ vs. $64 \pm 15$ years, $p < 0.001$) and severity of illness (APACHE $92 \pm 33$ vs. $63 \pm 25$, $p < 0.001$, SOFA $6.3 \pm 4.0$ vs. $4.5 \pm 3.2$ and Charlson Index $5.1 \pm 2.9$ vs. $4.0 \pm 2.7$). Multivariable logistic regression model developed showed significant association between right-shifted ODC ($p50 > 28$ mmHg) and mortality (odds ratio 1.38 with 95% confidence interval 1.20–1.58). This model performed well in the test cohort (AUC 0.773—95% CI 0.759–0.790). A model without APACHE score was developed as well from the training set and performance assessed in MIMIC-IV derived dataset (AUC 0.733—95% CI 0.708–0.757). Figure 1 shows the ODC generated from the dataset. Figure 2 shows the survival curves for the three ODC groups.
**Conclusions:** In this large cohort of critically ill patients, right shifts in ODC as assessed by p50 were associated with increased mortality independent of organ dysfunction score and illness severity.

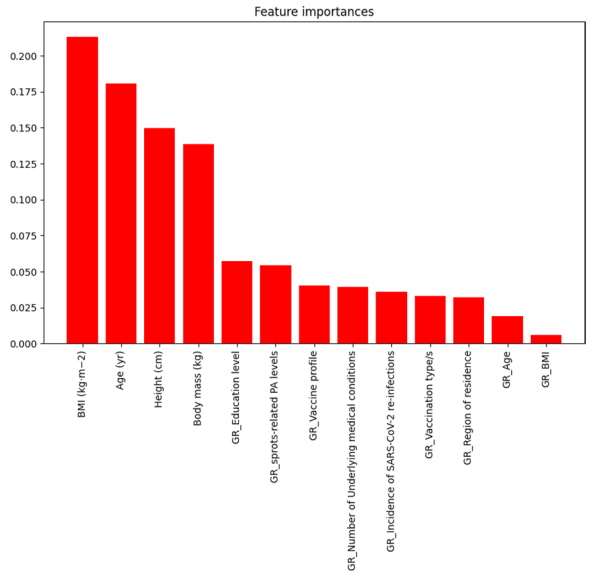
**Introduction:** The relationships between pre-SARS-CoV-2 infection sports-related physical activity (PA) levels and COVID-19 disease severity, as well as treatment outcomes remain unexplored.
**Objectives:** To investigate the unknown associations between pre-SARS-CoV-2 infection sports-related physical activity (PA) levels and COVID-19 disease severity, as well as treatment outcomes, within a Greek adult population.
**Methods:** This study utilized a comprehensive dataset derived from the Greek adult population, incorporating responses from 5829 participants. The dataset, collected via the Active-Q questionnaire, encompassed a wide range of variables, including sports-related physical activity (PA) levels prior to SARS-CoV-2 infection, and disease severity alongside post-infection treatments, demographic characteristics, medical history, vaccination status, and details regarding COVID-19 illness experiences. The primary objective was to explore the potential associations between pre-infection PA levels ("Inactive", "Low PA", "Moderate PA", "High PA"), disease severity, and post-infection treatment outcomes ("No treatment", "Home remedies", "Prescribed medication", "Hospital admission", "Intensive care unit admission").
Machine learning analysis: The analysis was conducted using the Tree-based Pipeline Optimization Tool (TPOT), an automated machine learning tool that evaluates numerous machine learning pipelines to identify the most effective model and its parameters for the given dataset. A custom TPOT configuration was utilized, focusing on the ExtraTreesClassifier due to its robustness and efficiency in handling complex datasets. The configuration specified parameters such as the number of estimators, criterion for splitting, max features, and others, aimed at optimizing the model's predictive accuracy.
A five-generation process with internal cross-validation was employed to iteratively refine and assess the performance of various pipeline configurations. Each generation's best internal cross-validation (CV) score was recorded, ensuring the selection of the most promising model based on its ability to generalize across different subsets of the dataset.
**Results:** The TPOT optimization process across five generations consistently identified the best internal CV score as approximately 0.702. This stability in CV scores across generations indicated a strong consistency in the model's predictive accuracy during the training phase.
The optimal pipeline, as determined by TPOT, featured the ExtraTreesClassifier with specific parameters: bootstrap = False, max_features = 'log2', min_samples_leaf = 1, min_samples_split = 2, and n_estimators = 100. This configuration underscores the model's reliance on ensemble methods and the effectiveness of the ExtraTreesClassifier in navigating the dataset's complexity.
Upon evaluation on the test set, the chosen model achieved a test accuracy of approximately 0.713. This performance metric signifies the model's capacity to accurately predict treatment outcomes based on pre-infection PA levels and other relevant variables, illustrating the predictive power and generalizability of the machine learning approach employed. The features that were used to predict the target variable 'TreatmentOutcome' are as follows: Age (yr), Height (cm), Body mass (kg), BMI (kg $m^{-2}$), Region of residence, Education level: Categorical variable indicating the highest level of education attained by the participants, Sports-related PA levels: Quantitative measure of physical activity levels related to sports, likely measured in metabolic equivalent minutes (MET-minutes/week) or a similar unit, Number of Underlying medical conditions, Vaccine profile (e.g., unvaccinated, partially vaccinated, fully vaccinated), Vaccination type/s: Categorical variable indicating the type of vaccine(s) received, if any, and Incidence of SARS-CoV-2 re-infections.
**Conclusions:** The results of this study demonstrate the potential of machine learning, particularly the use of ensemble methods like the ExtraTreesClassifier, in uncovering meaningful patterns within extensive datasets related to COVID-19. The consistent internal CV scores across generations highlight the robustness of the chosen model, while the test accuracy underscores its applicability in predicting COVID-19 treatment outcomes from pre-infection PA levels and other factors.

**Fig. (abstract 000484)**



Feature importances derived from the ExtraTreesClassifier model, showing the relative importance of each predictor in determining COVID-19 treatment outcomes. The highest importance is attributed to anthropometric measurements, with BMI, height, and body mass taking the lead. Error bars represent the standard deviation of the importance scores across the ensemble of decision trees.

**Introduction:** Pain assessment in critically ill patients unable to self-report is recommended to be performed with behavioral scales. However, in patients with brain damage and altered level of consciousness, experts recommend validating the existing tools to improve their applicability and pain detection capability.

**Objectives:** To validate the adaptation of the Behavioral Indicators of Pain Scale (ESCID) for patients with acquired brain injury (ESCID-DC), unable to self-report and with artificial airway.
**Methods:** Multicenter validation study conducted in 2 phases: scale development and evaluation of psychometric properties. Patient inclusion criteria were: age $\geq$ 16 years, acquired brain injury (of different etiology), unable to self-report (verbal or motor), artificial airway, and signed consent. Patients with previous pathology of injury and/or cognitive impairment, diagnosis of brain death, and conditions that prevented or limited behavioral response (spinal cord injury, severe polyneuropathy, continuous infusion of neuromuscular blocking agents, barbiturate coma, Richmond Agitation and Sedation Scale (RASS) = −5 and Glasgow Coma Scale score = 3) were excluded. The data collection procedure consisted of assessment by two independent observers, blinded to each other, of pain response with two scales: ESCID-DC and Nociception Coma Scale-Revised version-adapted for Intubated patients (NCS-R-I). Assessments were performed at 3 time points: 5 min before, during, and 15 min after the application of the procedures (painful vs. non-painful). On the day of measurement, the Glasgow Coma Score (GCS) and the RASS were evaluated. A descriptive and psychometric analysis was performed.
**Results:** 4152 pain assessments were performed in 346 patients, 70% were men with a mean age of 56 years (SD = 16.4). The most frequent etiologies of brain damage were vascular 155 (44.8%) and traumatic 144 (41.6%). The median GCS and RASS on the day of evaluation were 8.50 (RIQ = 7 to 9) and −2(RIQ = −3 to −2), respectively. In ESCID-DC, the median score was 6(RIQ = 4 to 7) during secretion aspiration, 3(RIQ = 1 to 4) for right nail pressure and 3(RIQ = 1 to 5) for left nail pressure. During the non-painful procedure, it was 0. The ESCID-DC showed a high discrimination capacity between painful versus non-painful procedures (AUC > 0.83) and is sensitive to change depending on the time of application of the scale ($p < 0.001$). High interobserver agreement (Kappa > 0.87), good internal consistency during procedures ($\alpha$-Cronbach's $\alpha \geq 0.80$), and high correlation between ESCID-DC and NCS-R-I ($r \geq 0.75$) were obtained.
**Conclusions:** The ESCID-DC is a valid and reliable tool to assess pain in patients with acquired brain injury, unable to self-report and artificial airway.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000486

**Introduction:** Patient- and family-centered care has the potential to improve care and clinical outcomes (IPFCC 2024; Secunda 2022). The Institute for Patient- and Family-Centered Care has proposed four concepts central to patient- and family-centered care; dignity and respect, information sharing, participation of patients and family in care, and collaboration (IPFCC 2024; Johnson & Abraham 2012). To fulfill the potential of patient-and family-centered care for reducing unnecessary suffering and improve short- and long-term clinical and psychological outcomes, translation of the concepts into more concrete, context-specific interventions is needed.
**Objectives:** To establish consensus between intensive care unit (ICU) experts on patient- and family-centered care statements for adult patients and relatives in the ICU.
**Methods:** We did a three-round Delphi survey with a panel of ICU health care professionals from 23 ICUs in Denmark. We used an online tool, Research Electronic Data Capture (REDCap), to create the surveys and collect all data anonymously.
In the first survey round, participants answered 20 open-ended questions, based on existing evidence (Bohart 2021; Bohart 2022). Analysis of their responses generated close-ended statements, which participants rated in second and third survey round on a five-point-Likert-scale, from very important to not important at all. Consensus was predefined as $\geq$ 75% of participants rating a statement important/very important.
**Results:** Sixty-nine clinical experts participated: 38 nurses, 24 physicians, and four occupational and physiotherapists. In total, 96%, 90% and 72% answered the first, second, and third rounds, respectively.
In round 1, participants answers resulted in > 3000 statements that were analyzed end resulted in 82 condensed statements. The statements described patient- and family-centred care interventions ranging from very concrete to more abstract interventions. In round 2 and 3, participants were asked to rate the importance of each statement. 47 statements reached consensus as important/very important.
**Conclusions:** The 47 statements rated to be important included interdisciplinary approaches to systematic information sharing and consultations with patients and family members, with the aim being to accommodate patients and family members' individual needs throughout the ICU stay. The statements will be collated in a future study, into a multicomponent patient- and family-centred care intervention and the effect on patient delirium and the psychological burden in both patients and their family members will be tested.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000488

**Introduction:** The COVID-19 pandemic has dramatically proven AQ25 the critical importance of sufficient healthcare resources (1). Given a global population increase and the aging demographic of patients admitted to ICU over the last decades, it is crucial to provide accurate predictions of the mean ICU length of stay (ICULOS) and length of mechanical ventilation (LOMV) for ICU patients within the next decades. Several studies have already aimed to address this problem using different prognostic tools (2–5). However, reliable data projecting future ICULOS and LOMV are still missing.
**Objectives:** Utilizing statistical projection models, historical data from the Australian and New Zealand Intensive Care Society (ANZICS) Adult Patient Database (ADP) from 2006 to 2019, as well as general population data of Australia and New Zealand ICULOS including ICULOS in ventilated patients (ICULOSvent) can be predicted through to the year 2040, divided by sex, age group and admission type.
**Methods:** To quantify the mean ICULOS as a function of gender, age, admission type, and calendar year, retrospective nationwide comprehensive data (from the years 2006–2019) from the ANZICS ADP of all ICU patients > 16yrs were extracted. Since data of the LOMV were only available from the year 2017 onwards, we assessed ICULOSvent as a surrogate. Data from the years 2020–2023 were excluded due to possible distortions during the COVID-19 pandemic as was data with missing characteristics of sex, age or admission type. To predict ICULOS and ICULOSvent in Australia/New Zealand for the next years until 2040, different projection models [Poisson regression, logarithmic regression, autoregressive integrated moving average modeling

(ARIMA), and exponential smoothing (ETS)] were employed. These data were set in relation to official population projections from the Australian Bureau of Statistics and Stats NZ (New Zealand) from 2020 to 2040. The prediction accuracy of each model was verified using out-of-time cross validation and the best-fitting model was chosen. The study was approved by the Ethics' committee of the University of Cologne, Germany (23–1096-retro).

**Results:** A total of 1 866 883 (72%) of 2 610 738 patient admissions from the ANZICS ADP from 2006 to 2023 could be included in our projection model. The best-validated and chosen projection model for our analysis proved to be the ARIMA and ETS model predicting a decreasing trend from 2006 onwards in the total mean ICULOS: 2.8 days (95%CI 2.7–2.8) by 2040 versus 3.4 days in 2006. The forecasted mean ICULOSvent is 4.4 days (95%CI 3.8–4.8) by 2040 compared to 4.6 days in 2006 (see figure). The decline in the mean ICULOS is foreseen in both sexes (2.6 95%CI 2.5–2.7 vs 2.9 95%CI 2.9–3.0 days in women vs men by 2040) and in all age categories. Moreover, the model prognosticates an (89%) increase of ICU-admissions of 366 141 (95%CI 338 829–393 454) in 2040 vs 193 661 admissions recorded in 2019. Regarding different admission types, the mean ICULOS is predicted to be 2.1 days (95%CI 2.1–2.2) for surgical admissions vs 3.5 days (95% CI 2.5–4.3) for non-surgical admissions in 2040.

**Conclusions:** ARIMA and ETS as statistical projection models provide essential insights into future ICULOS and ICULOSvent enabling the proactive and timely allocation of healthcare resource management. Despite a predicted general decrease in mean annual ICULOS and ICULOSvent, alongside an increase in ICU admission rates until 2040, our study reveals significant disparities among sexes, age groups, and admission types. Those differences require further in-depth investigation in the future.

### Evaluation of right-ventricular function by atrioventricular coupling as a predictor of complications in cardiac surgery patients

C. J. Gaytán García
Terapia Intensiva Cardiovascular, National Institute of Cardiology Ignacio Chavez, Ciudad de México, Mexico
**Correspondence:** C.J. Gaytán García
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000489

**Introduction:** Right-ventricular dysfunction represents an entity that worsens the prognosis of patients in any scenario; its evaluation and management is complex and requires close monitoring for adequate treatment.

In cardiac surgery patients, previous cardiac diseases have an influence on the outcome of the surgeries and a worse outcome is expected in those who present them; however, it is rare for a targeted analysis of the function of the right ventricle to be performed. To date, various tools have been used to analyze right-ventricular function, most of which are invasive strategies. With the advent of the use of echocardiography at the patient's bedside, indices such as right ventriculoarterial coupling have been designed, which, together with standard measurements such as TAPSE and S wave, guide the efficiency of ventricular function in the face of the afterload generated by the pulmonary artery, which makes it a useful tool in the analysis of right-ventricular function and its relationship with complications in cardiac surgery patients.

**Objectives:** Primary:

Demonstrate that there is a relationship between right-ventricular arterial coupling and complications in cardiac surgery.

Secondary:

Identify the right-ventricular arterial coupling cut-off point in which complications occur most frequently.

Recognize the percentage of patients who undergo surgery and have right heart failure.

To observe the characteristics of the outcomes of patients with right-ventricular dysfunction identified by ventricular–arterial coupling.

**Methods:** A cohort study is carried out in the cardiovascular therapy unit of the National Institute of Cardiology from January 1, 2020 to July 30, 2023. Patients entering cardiac surgery will be registered their pre-surgical echocardiogram and their post-surgical outcomes.

Right-ventricular arterial coupling is estimated using the TAPSE/PSAP formula, 0.36 is used as a cut-off point to define right-ventricular dysfunction. The association between the TAPSE/PSAP variable and the complications (acute kidney injury, cardiogenic shock and death) will be carried out in search of a direct relationship between both variables, and finally, using an ROC curve, the most specific and sensitive cut-off point will be sought to identify the risk of complications in cardiac surgery from ventricular–arterial coupling.

**Results:** A total of 184 patients were analyzed, of which 58% were male and the most frequent comorbidity was systemic arterial hypertension in 95 (51.6%). The surgery performed most frequently in the series of patients was aortic valve replacement 96 (52%), with an average aortic clamping time of 90 min and extracorporeal circulation time of 131 min. The most common complication was hypovolemia in 75 (40.8%). From the echocardiographic findings, we obtained an average LVEF of 56%, an average TAPSE of 21, and an average of 0.66 pre-surgical right arterial–ventricle coupling. The average hospitalization time in intensive care was 2 days and in-hospital mortality was 6%.Using TAPSE as the gold standard of right-ventricular dysfunction with a cut-off point of 17, a relationship was found between TAPSE of 17 or less and an average ventriculoarterial coupling of 0.4. In the group corresponding to TAPSE less than 17, a higher incidence of post-surgical complications such as delirium, cerebral vascular event, pneumonia, acute kidney injury, liver failure, and mesenteric ischemia was found. In a ROC curve, 0.36 was found as the most sensitive and specific cut-off point. The low TAPSE/PSAP index reports a sensitivity of 37.8% and

a specificity of 92.5, it has a positive predictive value of 56% for complications and a negative predictive value of 14%.

**Conclusions:** According this study, there is no relationship between right-ventricular arterial coupling and complications in cardiac surgery. The right-ventricular arterial coupling cut-off point of 0.36 was identified as the one with the highest sensitivity and specificity in which complications occur most frequently. 20% of patients who undergo surgery have right heart failure according to their echocardiographic findings.

### audit of diabetic ketoacidosis management patients in critical care in NHS Grampian: identifying areas for improvement in care quality and outcomes

S. Cumming[1], A. Clarkin[1], S. Philip[2]
Critical Care, Aberdeen Royal Infirmary, Aberdeen, United Kingdom; [2]Diabetes and Endocrinology, Aberdeen Royal Infirmary, Aberdeen, United Kingdom
**Correspondence:** S. Cumming
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000490

**Introduction:** Organisation and delivery of critical care have seen significant changes following the COVID-19 pandemic. This has meant that an increased number of diabetic ketoacidosis (DKA) cases are managed by the critical care team. At the same time we transitioned to electronic health systems whilst many treatment protocols, including the DKA pathway, remain paper based.
**Objectives:** Our goal was to evaluate trends, care quality, and outcomes for DKA admissions to our critical care unit against the national Joint British Diabetes Society (JBDS) guidelines (1), and analyse any demographic or disease patterns to identify areas for improvement in care quality or outcomes.
**Methods:** A retrospective baseline audit using electronic patient records from August 1, 2021 until June 21, 2023.
We audited the following standards:
1. Prescription of long-acting insulin within 24 h of admission to critical care
2. Prescription of thromboprophylaxis within 24 h of admission to critical care
3. Documentation of precipitating cause for DKA
4. Documentation of review by the local diabetes team within 24 h of admission to critical care

**Results:** We identified 110 patients admitted to critical care with DKA during the audit period. The mean age for patients in our audit was 42.9 years and 51% of patients were male. After examining Scottish Index of Multiple Deprivation quintiles our population came from more affluent postcodes compared to existing Scottish data on DKA (2), the majority of our patients were from urban postcodes.
82.6% of patients were prescribed insulin before their hospital admission and a significant majority (81.7%) of patients admitted had severe DKA as defined by the JBDS guidelines (1). 80% of the patients had a diagnosis of type 1 diabetes and 15.5% had a diagnosis of type 2 Diabetes.
The median length of stay was 2 days and 45.5% of patients were stepped down from critical care to the diabetes ward and 27% of patient went directly home. 26% of admissions were for patients who had repeat admissions with DKA in this audit period.
77.3% of patients had a long-acting insulin prescribed on admission and 99.1% of patients had thromboprophylaxis prescribed.
99% of patients had a precipitating cause documented, although 8% of there was documented as "unclear"; the most common precipitating cause was insulin non-compliance.
74.5% of patients had a diabetic review within 24 h of admission.
**Conclusions:** Over 95% of patients had thromboprophylaxis prescribed within 24 h of admission to critical care a similar proportion had documentation of a precipitating cause, although for 8% of patients, this was documented as "unclear". Areas need improvement including timely diabetic team reviews and prescription of long-acting insulin for patients.
Future initiatives will focus on integrating the paper-based DKA protocol into our electronic system, streamlining insulin, and fluid prescriptions, and facilitating diabetic team referrals. This digital integration will also enable the automation of audit cycles, a practice already shown to be effective at improving care in other regions of the UK (3).

### An ethnography on ICU rounds: a case of nurses being subjectified as "Invisible" and "Absent"

**Correspondence:** S. Parissopoulos
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000492

**Introduction:** ICU rounds are essential components of day-to-day successful patient management [1]. The participation of nurses in these rounds is crucial for ensuring continuity of care, complete information exchange, and achieving interdisciplinary clinical decisions. Effective collaboration between physicians and nurses is linked to better patient outcomes [2]. However, reduced participation of nurses in medical rounds may lead to disruption of continuity of patient care, communication breakdowns, potential errors, missed opportunities for education, reduced nurse autonomy, and poor team dynamics [3,4]. This abstract presents part of the findings of a larger doctoral study at an ICU in Greece [5].
**Objectives:** To gain a deep, contextual understanding of the social interactions, communication patterns, and cultural dynamics that shape the practices of nurses during ICU rounds.
**Methods:** Ethnography involves long-term observation and qualitative analysis, aiming to uncover the implicit norms, values, and behaviors that may not be apparent through other research Methods: The first researcher conducted a 2-year ethnographic study at a teaching ICU in Athens and 20 semi-structured interviews with ICU staff. Data were subjected to Braun and Clarke thematic analysis and were organized with Atlas.ti v8 QDA software. Categories and themes were identified via line-to-line coding [6]. The study was completed in 2021.
**Results:** By looking at nurses' and doctors' spatial and temporal practices during medical rounds, we were able to determine if the nurses at the ethnographic setting were involved—formally and informally—in the ICU team's clinical decisions. The analysis of the data revealed three main themes: (1) the ritual of the medical rounds, (2) the body practices of nurses, and (3) clinical decision-making (Figures 1 and 2). Medical rounds were conducted in a variety of formats. The medical team would confer and discuss patient care (a) in the corridor of the unit, (b) in the doctor's office, and (c) occasionally at the beside area in front of each patient. The onset and format of the round differed day by day. During the rounds, nurses seemed to be still busy with patient care (nurse-patient ratio 1:3). Nurses reported that they felt that the heavy workload of the unit did not allow them to participate in the

rounds, so they gave up trying to participate. This led to *nurse invisibility* as nurses were not attending or participating in the rounds. The participant nurses, with very few exceptions, abstained from the rounds and chose to be subjectified as *absent* rather than assume a secondary, marginal role.

**Conclusions:** In this study, the ICU rounds emerged as *points of exclusion* for nurses, as nurses seemed unable to participate in the clinical decisions of the ICU team. Considering the findings from Greece and aligning with broader literature, there is a pressing need to implement strategies that foster a culture of collaboration, communication, and shared decision-making in the ICU setting.

**Introduction:** A significant number of surgical patients require postoperative monitoring and support from intensive care units (ICUs). (1) Given the high prevalence of infection in critical care, (2) surgical wounds and drain sites can be susceptible to contamination in this setting. Therefore, regular assessment of surgical sites, as advised by the National Wound Care Strategy, (3,4) is important in allowing early detection and management of these infections to improve patient outcomes. Critical care doctors are not necessarily as familiar as surgeons with monitoring surgical sites, and thus, surgical patients may not be assessed appropriately and regularly enough during their ICU stay. The purpose of this audit was to evaluate the extent of this issue and identify potential solutions.

### Objectives:

- To assess the regularity of surgical site assessments by critical care doctors during ICU daily reviews.
- To evaluate the quality of surgical site assessments by critical care doctors during ICU daily reviews.

**Methods:** Data were collected from the Stoke Mandeville Hospital (SMH) ICU electronic patient notes via the IntelliSpace Critical Care and Anaesthesia (ICCA) platform. A search was performed on ICCA for all patients admitted to SMH ICU during October 2023. The admission documentation for each patient was reviewed and all patients that were admitted with a surgical wound ± drain were included. For each patient, the proportion of pre-ward round morning reviews with a documented surgical site assessment was calculated. The comprehensiveness of these assessments was also evaluated.

After the initial round of data collection, an infographic was designed to educate ICU junior doctors on the important aspects of a surgical site assessment (Figure 1). Additionally, modifications were made to the ICCA morning review template with the aim of prompting ICU doctors to perform a comprehensive surgical site assessment (Figure 2). A second cycle of the audit is being performed to evaluate the impact of these interventions.

**Results:** At baseline, 55% of morning reviews for patients with a surgical wound did not comment on the wound ($n = 56$). Out of the documented surgical wound assessments, less than 40% commented on whether the wound was clean and whether there was any surrounding erythema, and only 20% assessed for the presence of discharge ($n = 25$). Furthermore, 69% of morning reviews for patients with surgical drains failed to comment on the drain ($n = 39$). Only 20% of the surgical drain assessments commented on the appearance of the surgical drain fluid ($n = 12$).

**Conclusions:** In this case example, surgical wounds and drains were not being assessed daily in sufficient detail by ICU doctors. This may be partly explained by the operating surgeons assessing the surgical sites themselves and the need to minimise distress to the patient from repeated removal of dressings.

Two interventions have been made to address this issue, and the impact of these interventions will be evaluated.

## Factors related to mortality in patients with chronic kidney disease admitted to the ICU of a county hospital

A. Alonso, P. Sánchez, M. Cózar, M. Salgado, A. Ubeda
Intensive care unit, Hospital Punta de Europa, Algeciras, Spain
**Correspondence:** A. Ubeda
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000495

**Introduction:** Chronic kidney disease is an increasingly prevalent pathology in the Intensive Care Unit (ICU), with and important impact in the outcome.
**Objectives:** To analyze factors associated with mortality in patients with chronic kidney disease (CKD) admitted to the Intensive Care Unit (ICU) of the Hospital Universitario Punta de Europa.
**Methods:** Retrospective descriptive analysis on a prospective cohort performed in a 15-bed ICU from 2019 to 2023. Demographic outcomes, comorbidities, severity scores (APACHE II and SAPS II), treatment received, mechanical ventilation (MV), risk factors, ICU acquired infections, antibiotherapy, ICU and hospital length of stay (LOS), CKD stages, renal replacement therapy (RRT), and glomerular filtration rate (GFR). Statistical analysis: categorical variables (frequencies and percentages) and quantitative variables (mean and standard deviation or median and interquartile range). Comparisons: X2 test (percentages), Student's t test (means), and Mann–Whitney U test (medians). Multivariate logistic regression. Statistical significance at $p < 0.05$.
**Results:** 229 patients were included. Dead ($n = 94$) vs. survivors ($n = 135$) were compared. On admission: SAPS II (48.4 [32.8; 59] vs. 35.4 [24; 44], $p < 0.001$), APACHE II (19.3 [13; 25] vs. 13.8 [9;17], $p < 0.001$). GCS (11.5 [8; 15] vs. 13.9 [15; 15], $p < 0.001$). Type of admission ($p = 0.003$): scheduled surgery 3.2% vs. 3.7%, urgent surgery 15.9% vs. 5.9%, coronary 11.7% vs. 28.1%, non-coronary medical 68.1% vs. 62.2%. Risk factors: prior antimicrobial therapy (48 h) 48.9% vs. 22.9%, $p < 0.001$; total parenteral nutrition (TPN) 34.0% vs. 14.8%, $p < 0.001$; central venous catheter (CVC) 88.3% vs. 54.1%, $p < 0.001$; RRT 30.9% vs. 15.6, $p = 0.009$; MV 63.8% vs. 16.3%, $p < 0.001$; urinary catheter (UC) 94.6% vs. 74.8%, $p < 0.001$; tracheostomy 7.4% vs. 0%, $p = 0.002$. Comorbidities: chronic obstructive pulmonary disease (COPD) 21.3% vs. 7.4%, $p = 0.004$; cirrhosis 7.5% vs. 0%, $p = 0.002$. First ICU-acquired infection ($p = 0.004$): secondary bacteriemia 5.3% vs. 2.9%, catheter-related bloodstream infection (CRBSI) 15.9% vs. 3.7%, abdominal infection 4.3 vs. 2.2%, Catheter-associated urinary tract infections (CAUTI) 2.1% vs. 0.7%, ventilator-associated pneumonia (VAP) 2.1% vs. 0%. Days of MV (5.2 [0; 7] vs. 0.7 [0; 0], $p < 0.001$). Days of arterial catheter (3.6 [0; 5] vs. 0.8 [0; 0], $p < 0.001$). Days of UC (8.1 [1; 11] vs. 4.2 [1; 6], $p < 0.001$). Days of CVC (7.5 [1;11] vs. 3.2 [0;5], $p < 0.001$). Continuous infusion of furosemide 26.6% vs. 14.8%, $p = 0.041$. GFR at ICU discharge ($p < 0.001$): < 15 ml/min (51.0% vs. 21.5%), 15–30 ml/min (22.3% vs. 21.5%), 30–60 ml/min (13.8% vs. 36.3%), > 60 ml/min (13.8% vs. 20.7%). GFR at hospital discharge ($p < 0.001$): < 15 ml/min (51.0% vs. 20.7%), 15–30 ml/min (19.1% vs. 18.5%), 30–60 ml/min (15.9% vs. 37.7%), and > 60 ml/min (13.8% vs. 22.9%). Stage of CKD at ICU discharge ($p < 0.001$): I (8.5% vs 16.3%), II (6.3% vs. 10.4%), III (13.8% vs. 38.5%), IV (21.3% vs. 17.0%), V (50.0% vs. 17.7%). Multivariate logistic regression: Days of MV (OR 1.21 [1.09;

1.38], $p = 0.001$), stage V of CKD at hospital discharge (OR 6.19 [1.99; 21.54], $p = 0.002$), SAPS II (OR 1.05 [1.03;1.07], $p < 0.001$).
**Conclusions:** ICU mortality in patients with CKD is high. In our ICU, SAPS II on admission, the days of MV and stage 5 of CKD at ICU discharge were observed as independent risk factors of mortality.

## Quality improvement project on the usage of proton pump inhibitors and prokinetics on ICU at Buckinghamshire Healthcare NHS Trust

C. Coronelli[1], J. Fong[2], T. Ali[3]
[1]Intensive Care Unit, Buckinghamshire Healthcare NHS Trust, Oxfordshire, United Kingdom; [2]Intensive Care Unit, Buckinghamshire Healthcare NHS Trust, Oxfordshire, United States of America; [3]Stoke Mandeville Hospital, Buckinghamshire Healthcare NHS Trust, Stoke Mandeville, United Kingdom
**Correspondence:** C. Coronelli
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000496

**Introduction:** Proton pump inhibitors (PPIs) are vital in the ICU due to high risk of stress ulceration (1). However, regular review and cessation of PPIs are crucial to prevent polypharmacy and minimise side effects. Long-term PPI use (>8 weeks) is generally unnecessary except for specific conditions like Barrett's esophagus, chronic NSAID use, severe esophagitis, and documented ulcers (2). Once patients are established on enteral, discontinuing PPIs is essential.
Following trust guidelines, prokinetics should be prescribed when nasogastric (NG) aspirates exceed 500 ml to reduce aspiration risk. Prescribing prokinetics is unwarranted for aspirates below this threshold, aiming to prevent unnecessary polypharmacy and multiple antibiotic usage, as erythromycin is the preferred prokinetic.
**Objectives:** Evaluate the review of PPIs on daily ward rounds and timely cessation. Evaluate whether prokinetics are prescribed appropriately for high NG aspirates.
**Methods:** We conducted an audit to assess PPI prescription upon admission and daily review of stress ulcer prophylaxis. A daily checklist exists for stress ulcer prophylaxis review, alongside a GI section examining feeding initiation, PPI use, and cessation plans. At discharge, we checked for inappropriate PPI continuation. We also assessed for prokinetic initiation and reason.
**Results:** Twenty patients were audited in the first cycle using our electronic database. Out of 77 possible daily reviews spanning the 20 patients, PPI prophylaxis was reviewed 40 times (52%), shown in image 1. Of these 77 occasions, there were 16 (21%) encounters where the patient's PPI should have been stopped as they had been established on oral feed.
Upon discharge, 1 patient was discharged with Lansoprazole when not indicated, and a further 2 patients had no medication documented on their discharge. However, their PPI had not been stopped and they had been established on feed days prior, which indicates a high likelihood of discharge with this medication.
These results were disseminated amongst the department with recommendations, and we re-audited patients.
Out of 36 possible daily encounters, PPI was reviewed 31 times, a total of 86%, shown in image 2. The patients were all being NG fed, so appropriate PPI cessation could not be assessed.
During our research, any patients started on a prokinetic were not started due to NG aspirates, so we were unable to audit this.
**Conclusions:** The initial data demonstrated 52% compliance with daily review protocol, implying inadequate compliance requiring addressing. Furthermore, despite only 3 out of 20 patients being discharged with a PPI inappropriately, any unnecessary medication can result in unwanted side effects.
The intervention improved significantly; however, there is still dimension for improvement; further avenues for research include distributing training during inductions, weekly MDT session reminders, and discharge summary notes re-iterating the importance of medication review prior to discharge.

### Critically ill patients under thromboprophylaxis with enoxaparin: are we getting there?

N. Andrade, J. Nogueira, S. Almeida, M. Santos, C. Mendes Silva, P. Martins, J. P. Baptista
Serviço de Medicina Intensiva, Unidade Local de Saúde de Coimbra—Hospitais da Universidade, Coimbra, Portugal
**Correspondence:** N. Andrade
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000498

**Introduction:** Critically ill patients are at increased risk of venous thromboembolism during their ICU stay, reason why a prophylactic dose of enoxaparin is commonly indicated. However, the pharmacokinetics of enoxaparin in critical ill setting is unpredictable and standard prophylactic dosing can jeopardize its efficacy.
**Objectives:** Evaluation of the adequacy of thromboprophylaxis with enoxaparin (40 mg once daily) in a population of critically ill patients.
**Methods:** Prospective and observational study, including critically ill adult patients in a tertiary hospital, between October 2022 and March 2024, who received a prophylaxis dose of 40 mg/day of enoxaparin. Anti-Xa peak activity was measured at day four (D4) and day seven (D7) after starting prophylaxis. Demographic data, and clinical variables at admission and during ICU stay were collected. Patients with renal impairment (creatinine clearance < 60 mL/min) were excluded. Statistical significance was set at $p < 0.05$.
**Results:** Sixty-four patients were included: half were surgical patients, 34.4% had a medical condition, and 15.6% had trauma. Median SOFA score at admission was 8.0 [6–10], APACHE II was 18.5 [14–24] and Charlson comorbidity index was 2 [1–4]. The most frequent comorbidities were diabetes mellitus (15.6%) and heart failure (7.8%). Median 8-h urinary creatinine clearance (CLCRD4) was 120 [84–150] mL/min and 106 [91–150] mL/min, at D4 and D7, respectively. Median anti-Xa activity in D4 was 0.26 [0.19–0.32] IU/mL and 0.31 [0.26–0.38] IU/mL in D7. At D4, 73% of patients (47 of 64) showed anti-Xa activity within desired range (0.2–0.5 IU/mL). A comparison between patients with on-target and below-target anti-Xa activity at D4 was made, with no statistical differences found between groups (Table 1). In D7, 93% of evaluable patients ($n = 29$) were on target. Hemorrhagic or thrombotic events were present in two and one patient, 3.2% and 1.6%, respectively. The ICU and intra-hospital mortality was 6.3%.
**Conclusions:** Two-thirds of the patients had adequate levels of thromboprophylaxis with enoxaparin on D4. Rate of target attainment increases between D4 and D7.

**Table 1 (abstract 000498)** Comparison between patients with on-target and below-target anti-Xa activity at D4

| | Total (N=64) | Bellow-target (N=16) | On-target (N=47) | *p* value |

### Comparative analysis of GPT-3.5 and GPT-4 in accuracy and efficiency of citation screening using large language models

T. Oami[1], Y. Okada[2], T. A. Nakada[1]
[1]Department of Emergency and Critical Care Medicine, Chiba University School of Medicine, Chiba, Japan; [2]Department of Preventive Services, Kyoto University Graduate School of Medicine, Kyoto, Japan
**Correspondence:** T. Oami
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000499

**Introduction:** The development of clinical practice guidelines based on systematic reviews is an essential component for improving the quality of clinical decision-making also in the field of critical care. Large language models (LLMs) have been recognized as promising tools for citation screening in systematic reviews. However, their accuracy and efficiency between GPT-3.5 and GPT-4 have not yet been determined.
**Objectives:** To compare the accuracy and efficiency of LLMs between GPT-3.5 and GPT-4 in title/abstract literature screening.
**Methods:** We compared the efficiency and accuracy between GPT-3.5 and GPT-4 in LLM-assisted citation screening using the data from title and abstract screening process for five clinical questions (CQs) in the development of the Japanese Clinical Practice Guidelines for Management of Sepsis and Septic Shock. The LLM determined the relevance of each reference by considering criteria, such as patient characteristics, interventions, comparisons, and study designs of the selected CQs. We compared the accuracy of the LLM-assisted citation screening by measuring its sensitivity and specificity, using the final list of included studies in the conventional review as the reference standard in our primary analysis. Subsequently, we integrated these measures to estimate the pooled sensitivity and specificity for the LLM-assisted procedure. We also compared the screening times between GPT-3.5 and GPT-4 in LLM-assisted screening.
**Results:** In the conventional citation screening process, 8 of 5634 publications in CQ1 (0.14%), 4 of 3418 in CQ2 (0.12%), 4 of 1038 in CQ3 (0.39%), 17 of 4326 in CQ4 (0.39%), and 8 of 2253 in CQ5 (0.36%) were selected in the second session of full-text evaluation within each systematic review as the standard reference for the primary analysis in this study. In the primary analysis, the integrated sensitivity and specificity were 0.84 (95% confidence interval [CI], 0.69–0.93) and 0.50 (95% CI, 0.38–0.63) in GPT-3.5 and 0.89 (95% CI, 0.74–0.95) and 0.98 (95% CI, 0.97–0.99) in GPT-4 (Fig. 1). Additionally, the time required to process 100 studies was shorter in GPT-3.5 (1.0 min) than in GPT-4 (1.5 min) (mean difference 0.45 min, 95% CI, 0.33 to 0.58, $p < 0.001$) (Fig. 2).
**Conclusions:** Our study demonstrated that the specificity of LLM-assisted citation screening using GPT-3.5 was remarkably lower than that of GPT-4, with comparable sensitivity between the two models in the primary analysis. In addition, GPT-3.5 had a significantly shorter processing time than GPT-4. GPT-4 may be the more optimal LLM for citation screening in systematic reviews given the higher specificity and the negligible small difference in processing time between the two models.

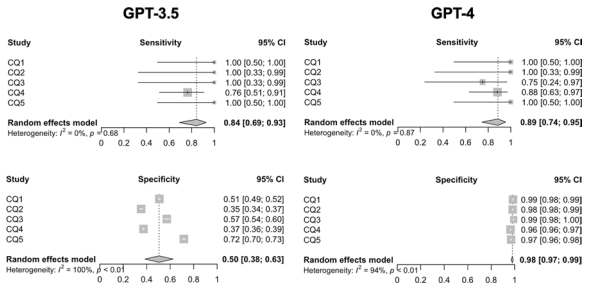

**Fig. 1 (abstract 000499)** Comparison of GPT-3.5 and GPT-4 in accuracy of large language model-assisted citation screening in the primary analysis

The primary analysis used results of the included publications for qualitative analysis, using the conventional method as the standard reference. In the upper panel, the individual sensitivity for each clinical question (CQ) and integrated sensitivities across CQ1-5 are compared between GPT-3.5 and GPT-4, with confidence intervals and inconsistency values (I2). In the lower panel, the individual specificity for each CQ and integrated specificities across CQ1-5 are compared between GPT-3.5 and GPT-4, with confidence intervals and inconsistency values (I2).

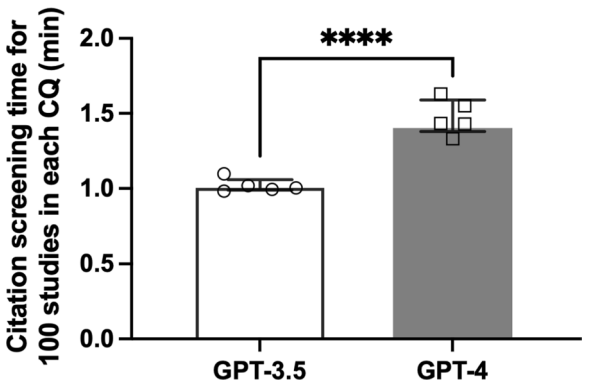

**Fig. 2 (abstract 000499)** Comparison of citation screening time for 100 studies using the large language models between GPT-3.4 and GPT-4

The difference in processing time was 0.45 min (95% confidence interval [0.33 to 0.58], $p < 0.001$). An unpaired $t$ test was used for the analysis.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000500

**Introduction:** In patients with acute sICH while on antiplatelet therapy, it is essential to identify the platelet dysfunction in a timely manner in the setting of urgent neurosurgical intervention. TEG-PM is designed to assess platelet inhibition due to antiplatelet therapy in a quick and reliable way. We do not have local data for our patients with sICH on aspirin and/or clopidogrel.
**Objectives:** We aimed to assess the ability of TEG-PM to detect platelet dysfunction accurately in patients with sICH on aspirin and/or clopidogrel.
**Methods:** This is a prospective observational study in patients presenting with sICH in Neuroscience Intensive Care Unit (NICU) in Singapore. Patients admitted to NICU from August 2022 to December 2023 were categorized into those on antiplatelet therapy (aspirin and/or clopidogrel prior to admission) and those without (control group). Patients on anticoagulants were excluded. TEG-PM was performed within 6 h after symptom onset and repeated within 1 h in those patients who received platelet transfusion. The clinicians were blinded to the TEG-PM results and the results were not used to determine the need for platelet transfusion.
**Results:** A total of 45 patients consented to participate in the study. They had a median age of 63 years, and majority were male ($n = 31$, 69%). Twenty-four patients (53.3%) received antiplatelet therapy and 21 patients (46.7%) were in control group. Patients on antiplatelet therapy were on average older, more males in proportion, had significantly higher percentage of patients with ischaemic heart disease, arterial hypertension, stroke, and on statin than the control group (Table 1).
Twenty-nine patients (17 on antiplatelet, 77% and 12 control, 60%) were found to have platelet dysfunction as defined by the Arachidonic Acid Inhibition Rate, AAIR > 50% on presentation. There was a statistically significant difference in prevalence of platelet dysfunction (AAIR > 50%) between antiplatelet and control group (Chi-squared test $p$ value < 0.01). Five patients in antiplatelet group (22.7%) were found to be non-responders to aspirin with AAIR < 50%.
Antiplatelet group had higher inhibition to Arachidonic Acid (AA) and Adenosine Diphosphate (ADP) than control group (Table 2). Median AAIR for antiplatelet group was 92.1 (IQR 65.0–94.4) and 56.45 (IQR 11.8–92.1) in control [$p$ value 0.022], whereas median ADPIR were 38.65 and 11.6, respectively [$p$ value 0.069]. There is a trend towards a lower maximum amplitude (MA) in the antiplatelet group compared to the control group but this did not reach statistical significance.
**Conclusions:** This is the first prospective study using TEG-PM to determine platelet dysfunction in our local population in Singapore. TEG-PM is able to accurately detect platelet inhibition in our local cohort of sICH patients on antiplatelet therapy. This allows us to rapidly diagnose, correct platelet dysfunction, and optimize patients for neurosurgical intervention as needed. The use of TEG-PM in other neurosurgical diagnosis and other patient population warrants further investigation.

**Table 1 (abstract 000499)** Distribution of demographic and clinical characteristics of the study sample

| Characteristics | Total cohort (n = 45) | Either aspirin or clopidogrel (n = 24) | No anti-platelet therapy (n = 21) | P value |
|---|---|---|---|---|
| Age, mean (SD) | 63.2 (12.6) | 66.7 (11.8) | 59.3 (12.7) | 0.051 |
| Gender male, n (%) | 31 (68.9) | 20 (83.3) | 11 (52.4) | 0.055 |
| Weight, mean (SD) | 64.1 (14.7) | 61.9 (15.2) | 66.6 (14.1) | 0.306 |
| Presence of co-morbidities, n (%) | | | | |
| Ischaemic Heart Disease | 10 (22.2) | 8 (33.3) | 2 (9.5) | 0.077 |
| Arterial Hypertension | 38 (84.4) | 23 (95.8) | 15 (71.4) | **0.039** |
| Hyperlipidaemia | 33 (73.3) | 20 (83.3) | 13 (61.9) | 0.176 |
| Smoking | 5 (11.1) | 2 (8.3) | 3 (14.3) | 0.652 |
| Chronic Pulmonary Disease | 2 (4.4) | 2 (8.3) | 0 | 0.491 |
| Chronic Liver Disease | 1 (2.2) | 0 | 1 (4.7) | 0.467 |
| Stroke | 20 (44.4) | 16 (66.7) | 4 (19.0) | **0.002** |
| Diabetes Mellitus | 18 (40.0) | 11 (45.8) | 7 (33.3) | 0.543 |
| Chronic Kidney Disease | 7 (15.5) | 5 (20.8) | 2 (9.5) | 0.422 |
| Malignant neoplasm | 2 (4.4) | 1 (4.2) | 1 (4.8) | 0.999 |
| Medication history, n (%) | | | | |
| Angiotensin-Converting Enzyme Inhibitor (ACEI) | 7 (15.6) | 4 (16.7) | 3 (14.3) | 0.999 |
| Angiotensin Receptor Blocker (ARB) | 7 (15.6) | 4 (14.3) | 3 (10.0) | 0.999 |
| NSAIDs | 2 (4.4) | 2 (8.3) | 0 | 0.491 |
| Statin | 26 (57.8) | 19 (79.2) | 7 (33.3) | **0.003** |

**Table 2 (abstract 000499)** Comparison of TEG-PM parameters between study group and control

| Parameter | Either aspirin or clopidogrel (n = 24) | No anti-platelet therapy (n = 21) | P value |
|---|---|---|---|
| Maximum Amplitude (mm), median (IQR) | 63.5 (60.9 – 67.7) | 64.4 (61.7 – 67.0) | 0.389 |
| MA Fibrin, median (IQR) | 17.5 (11.6 – 19.8) | 14.4 (9.2 – 17.1) | 0.073 |
| MA ADP, median (IQR) | 45.6 (32.8 – 59.0) | 56.6 (38.3 – 63.2) | 0.287 |
| MA AA, median (IQR) | 23.6 (19.4 – 37.5) | 37.6 (18.0 – 56.9) | 0.075 |
| Arachidonic Acid Inhibition Rate AAIR, median (IQR) | 92.1 (65.0 – 94.4) | 56.5 (11.8 – 92.1) | **0.022** |
| Adenosine Diphosphate Inhibition Rate ADPIR, median (IQR) | 38.6 (17.6 – 75.5) | 11.6 (5.0 – 51.7) | 0.069 |

**Introduction:** Glucose control of ICU patients is complicated due to various diseases, different patient characteristics, and divergent treatment received during ICU stay. To deal with this challenge, machine learning prediction models are emerging to forecast glucose-related events.

**Objectives:** The aim of the study was to develop a real-time blood glucose prediction model to promote the precision insulin therapy.

**Methods:** Electronic medical records (EMR) data of a tertiary hospital were collected from September 2021 to September 2022. A total of 4092 ICU patients with 60,466 BG measurements were included for modeling to predict the blood glucose level in the next 5 min to 10 h. Demographics, comorbidities, vital signs, laboratory results, previous BG measurements, records of insulin injection, nutritional intake, and vasoactive inotropic score (VIS) were included as candidate predictor variables. The prediction model was externally validated using MIMIC-IV database.

**Results:** The root-mean-square error (RMSE), mean absolute percentage error (MAPE), and median absolute deviation (MAD) of the XGBoost prediction model are 33.59 mg/dL, 15.39%, and 23.92 mg/dL. The model also achieved higher percentage of Type A prediction in CEGA (75.67%) and lower percentage of clinically inappropriate predictions (0.29%). On external validation in MIMIC IV database, the model showed satisfactory performance in in terms of RMSE, MAPE, and MAD (36.97 mg/dL, 23.04% and 22.51 mg/dL).

**Conclusions:** Our study proposes a real-time blood glucose prediction model utilizing the XGBoost machine learning framework. The model could facilitate clinicians in understanding the real-time trend of patients' glucose level and making timely therapeutic decisions.

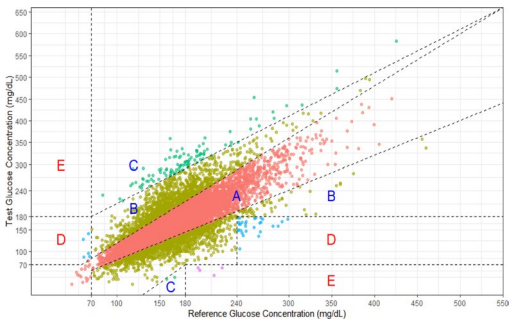

**Fig. 3 (abstract 000501)** Clarke error grid analysis (CEGA) for the XGBoost prediction model. Percentages of prediction in each region: Type A, 75.67%; Type B, 23.13%; Type C, 0.91%; Type D, 0.26%; Type E, 0.03% * Type A: predictions within 20% of the true values; Type B: predictions that are outside of 20% but would not lead to inappropriate treatment; Type C: predictions leading to unnecessary treatment; Type D: predictions that fail to identify a potentially dangerous hypoglycemic or hyperglycemic event; Type E: predictions that would confuse hypoglycemia for hyperglycemia and vice versa

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000502

**Introduction:** Group A Streptococcus (GAS) is one of the leading causes of death by a pathogen, with case fatality rates of 45% in GAS septic shock1. Since the 2022–2023 winter season, there has been a global resurgence in iGAS cases2. Several factors have been associated with increased risk of contracting iGAS such as diabetes mellitus, age older than 65 years, active wounds, malignancy, and substance use, in particular, injection drug use, alcohol, and tobacco use3. Most common and life-threatening complications of iGAS are respiratory failure requiring invasive mechanical ventilation (IMV), septic shock requiring vasopressors, necrotizing fasciitis, and in-hospital mortality (4). This retrospective cohort study aims to highlight an association between diabetic and non-diabetic populations with respect to the aforementioned iGAS complications.
**Methods:** An EPIC-powered electronic medical record database, SlicerDicer, was used to identify cases from a multi-center healthcare network throughout Illinois and Wisconsin. Inclusion criteria used were (1) age at admission greater than or equal to 18 years, (2) positive GAS blood culture, and (3) hospital admission between October 1st, 2022 and December 31st, 2023. Next, data were collected and de-identified with a secure collection system called REDCap. Data were collected by individual chart review of the 210 cases that met the inclusion criteria and stored in REDCap, where data analysis was conducted upon completion of data collection.
**Results:** The primary outcome of this study was in-hospital mortality secondary to GAS infection. Secondary outcomes included necrotizing fasciitis, septic shock, and respiratory failure requiring IMV. Of the 282,019 hospital admissions during that timeframe, 210 patients met the inclusion criteria. The diabetic (38.6%) and non-diabetic (61.4%) patients were then compared between primary and secondary outcomes. The in-hospital mortality for diabetics with iGAS was 8.6% compared to their non-diabetic counterparts (7.0%). Rates of respiratory failure requiring IMV in diabetics (9.9%) and non-diabetics (11.6%), septic shock requiring vasopressor support in diabetics (30.1%) and non-diabetics (26.4%), and necrotizing fasciitis in diabetics (6.2%) and non-diabetics (3.9%) were further analyzed.
**Conclusions:** In this multi-center study, we examined the most common iGAS complications that have been previously reviewed, with respect to diabetic and non-diabetic patient cohorts. We identified an association between having a pre-admission diagnosis of diabetes mellitus and having increased rates of iGAS complications, specifically in-hospital mortality (5), necrotizing fasciitis, and septic shock. Compared with the non-diabetic group, however, patients with diabetes had reduced respiratory failure rates requiring IMV.

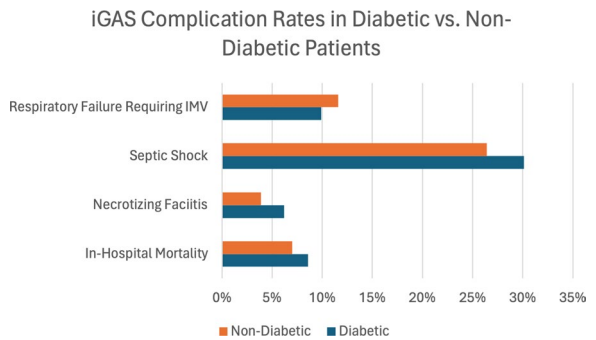

**Fig. 1 (abstract 000502)** iGAS complication rates (%) in diabetic vs. non-diabetic patients

**Introduction:** The Surviving Sepsis Campaign guideline recommends using empiric antimicrobials with methicillin-resistant *Staphylococcus aureus* (MRSA) coverage for adults with sepsis who are at high risk of MRSA, which is a best practice statement. Because the hosts are potentially immunocompromised, they could be vulnerable to multidrug-resistant (MDR) organisms.
**Objectives:** This study investigated the relationship between empiric MDR coverage with antipseudomonal antimicrobial agents and in-hospital mortality rates among septic patients at high risk of MRSA.
**Methods:** This was a nested case–control study using nationwide Japanese data from a medical reimbursement system from 2010 to 2017. Patients aged ≥ 18 years with new sepsis onset within 14 days of admission and using empiric antimicrobials with MRSA coverage were identified. We enrolled patients at high risk of MRSA with and without an antipseudomonal agent (MDR coverage) using propensity score matching based on baseline characteristics such as age, gender, comorbidities, ICU admission, and infection sites.

To investigate the relationship between MDR coverage and in-hospital mortality in patients at high risk of MRSA, we created a conditional logistic regression model. The model's adjusting variables included MDR coverage, the severity of acute organ dysfunction, and interaction terms.
**Results:** A total of 12,136 patients were included in this study. The median age was 74 (interquartile range, 63–82) years, and 7335 (60.4%) patients were male. The MDR coverage group experienced more acute organ dysfunction than the non-MDR coverage group (moderate: 34.0% vs. 24.3%; severe: 5.0% vs. 2.7%, $p<0.001$). The MDR coverage group had significantly higher crude in-hospital mortality compared to the non-MDR coverage group (22.9% vs. 16.7%, $p<0.001$). According to the conditional logistic regression model, MDR coverage, moderate, or severe acute organ dysfunction were significantly associated with in-hospital mortality (odds ratio [OR] [95% confidence interval (CI)] 1.49 [1.29–1.72], 2.65 [2.14–3.28], and 6.39 [3.81–10.7], respectively). The interaction between MDR coverage and severe acute organ dysfunction was statistically significant (OR [95% CI] 0.47 [0.25–0.88], $p$ for interaction = 0.02). Stratified by severity, in-hospital mortality reversed between moderate and severe (in-hospital mortality: mild 16% vs. 12%; moderate 32% vs. 27%; and 42% vs. 45%).
**Conclusions:** If an adult with sepsis is at high risk of MRSA, empiric concomitant antipseudomonal antimicrobial therapy may be beneficial if they have multiple acute organ dysfunctions.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000505

**Introduction:** Dexmedetomidine is used for the sedation of critically ill patients in intensive care. Several studies have also found that treatment with dexmedetomidine may contribute to a reduction in the duration of hyperactive disturbed behaviour and delirium in critically ill patients. Other studies have reported conflicting results including a limited reduction in the severity and duration of delirium when compared with other sedatives. We hypothesised that natural language processing (NLP) could be used to detect words and phrases, thereby identifying patients who experienced natural language processing diagnosed behavioural disturbance (NLP-Dx-BD) and possible delirium. And that NLP could be used to study the association between dexmedetomidine and the phenotypes of disturbed behaviour in critically ill patients.
**Objectives:** To study the association between treatment with dexmedetomidine and the phenotypes of NLP-Dx-BD in critically ill patients.
**Methods:** We obtained demographic data, medication records, outcomes, and electronic clinical progress notes for a cohort of critically ill patients. Using a previously validated NLP methodology, we scanned the clinical notes for words that indicated a patient may have exhibited hyperactive and/or hypoactive disturbed behaviour.
**Results:** We studied a cohort of 7525 patients. We found that 549 (7.3%) patients were treated with dexmedetomidine. Patients being treated with dexmedetomidine were younger (58.2 vs 64.2 years, $p<0.001$), more likely to be male (70.5% vs 60.7%, $p<0.001$), and to have higher APACHE III scores (58.0 vs 47, $p<0.001$). They were also more likely to be medical admissions (59.5% vs 50.6%, $p<0.001$). Further, they were significantly more likely to be on vasopressors or inotropes (85.4% vs 49.0%, $p<0.001$) and to be invasively ventilated (93.7% vs 58.8, $p<0.001$). Moreover, patients being treated with dexmedetomidine were more likely to screen positive for NLP-Dx-BD and possible delirium (96.2% vs 48.3%, $p<0.001$), more likely to be identified as having the hyperactive phenotype of NLP-Dx-BD (88.2% vs 25.2%, $P<0.001$) or the hypoactive phenotype of NLP-Dx-BD (83.2% vs 37.6%, $p<0.001$). Finally, patients receiving dexmedetomidine had significantly longer ICU length of stay (7.0 days vs 1.8 days, $p<0.001$) and hospital length of stay (18.1 days vs 9.5 days, $p<0.001$). Despite the greater illness severity of dexmedetomidine-treated patients, their hospital mortality was 9.7% vs. 9.1% in control patients ($p=0.64$).
**Conclusions:** Critically ill patients being treated with dexmedetomidine are highly likely to be screened positive for NLP-Dx-BD and possible delirium. Further, most NLP-Dx-BD positive patients were also screened positive for the hyperactive phenotype of NLP-Dx-BD. Finally, despite greater severity of illness, receiving vasopressor therapy and mechanical ventilation, patients treated with dexmedetomidine had equivalent hospital mortality to the control group. Further investigation of the association between treatment of delirium with dexmedetomidine and better than expected outcomes is warranted.

### 4-Octylitaconic acid alleviates sepsis-associated encephalopathy by suppressing microglial activation

Y. Wu, Z. Zheng, X. Wang, S. Yuan, J. Zhang
Department of Critical Care Medicine, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wu Han Shi, China

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000506

**Introduction:** Sepsis-associated encephalopathy (SAE) significantly elevates ICU patient mortality rates, posing a substantial challenge to clinical management [1]. SAE, a complication affecting the central nervous system of septic patients, may cause either widespread or localized neurological dysfunction. Despite its relative commonality in ICUs, the pathophysiology of SAE remains incompletely understood. Itaconate, a metabolite with potent anti-inflammatory properties [2], its role in central nervous system diseases remains unclear.
**Objectives:** To evaluate the therapeutic potential of 4-octyl itaconate (4-OI) in treating SAE and investigate its mechanisms of action.
**Methods:** Septic encephalopathy (SAE) was induced in C57BL/6 mice using cecal ligation and puncture (CLP) surgery. Experimental animals

were randomly divided into three groups: Sham (sham surgery), sepsis (CLP), and sepsis with 4-OI treatment (CLP + 4-OI). Post-CLP surgery, the CLP + 4-OI group received immediate intraperitoneal injection of 4-OI (50 mg/kg). Brains were collected 24 h after CLP, and cognitive abilities of mice were evaluated after the 7th day using the Morris water maze (MWM), Y-maze (YM), and open-field test (OFT). Immunofluorescence staining was employed to observe the activation status of glial cells in the hippocampal region, while DHE staining was used to assess oxidative stress in the hippocampal CA1 region.

**Results:** 4-OI significantly increased the 7-day survival rate of septic mice and improved their learning and cognitive functions. In the MWM test, septic mice exhibited decreased learning and memory abilities; however, 4-OI treatment significantly shortened the latency during the training period and increased the time spent in the target quadrant and platform crossings during the testing phase. In the YM, 4-OI increased the entries and duration of exploration of new arms by septic mice. Similarly, in the OFT, 4-OI treatment increased the time spent and the number of crossings in the central zone by septic mice. Compared to septic mice, 4-OI significantly reduced the activation level of glial cells in the hippocampal CA1 region and decreased the generation of reactive oxygen species (ROS).

**Conclusions:** This study demonstrates that 4-OI significantly improves the survival rate and cognitive function of septic mice by reducing glial cell activation and oxidative stress, thereby providing a potential new strategy for the treatment of SAE. These findings underscore the importance of exploring 4-OI as a therapeutic approach for SAE and lay the foundation for future clinical research.

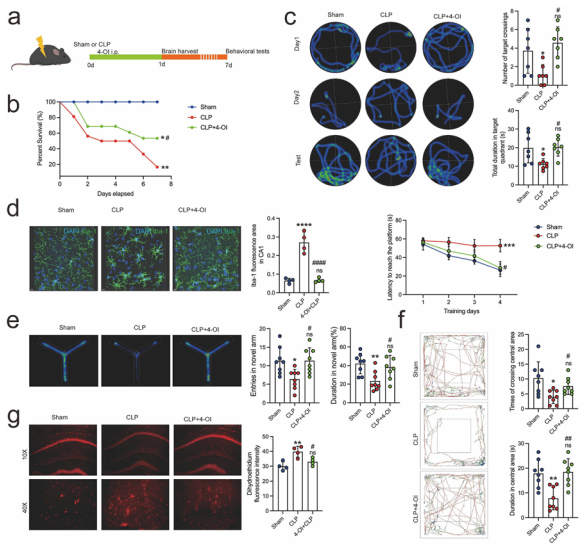

**Fig. (abstract 000506)** (a) Experimental Procedure: 4-Octyl itaconate (4-OI) was administered intraperitoneally (i.p.) to mice immediately after cecal ligation and puncture (CLP) at a dosage of 50mg/kg. Brain frozen sections were obtained 24 h post-CLP following perfusion with 4% paraformaldehyde. Behavioral assessments, including the Y-maze (YM), open-field test (OFT), and Morris water maze (MWM), were conducted 7 days post-CLP. (b) Survival Rate at Day 7 post-CLP: 4-OI significantly improved the survival rate of septic mice at day 7. (c) Comparative Analysis with CLP Group: 4-OI significantly improved mouse performance in the MWM, demonstrated by shortened latency period during the 4-day training, increased time spent in the target quadrant during testing, and increased number of platform crossings. (d) Immunofluorescence (IF) Analysis of Hippocampal CA1 Region: 4-OI significantly decreased the activation level of glial cells in the hippocampal CA1 region. (e) Increased Entries and Duration in Novel Arm in YM: 4-OI administration increased both the frequency and duration of entries into the novel arm in septic mice. (f) Increased Entries and Duration in Central Zone in OFT: 4-OI administration augmented both the frequency and duration of entries into the central zone in septic mice. (g) Decreased DHE Mean Fluorescence Intensity in Hippocampal CA1 Region of Septic Mice: Administration of 4-OI resulted in a decrease in the mean fluorescence intensity of dihydroethidium (DHE) in the hippocampal CA1 region of septic mice. Data are presented as mean ± standard deviation. Intergroup comparisons were performed using one-way analysis of variance. In comparison with the Sham group, $*p<0.05$, $**p<0.01$, $****p<0.0001$, ns: not significant; compared with the CLP group, $\#p<0.05$, $\#\#p<0.01$

**Introduction:** In the last few years, several studies have questioned the role or reliability of spontaneous breathing trial (SBT) in deciding extubation. Large observational data suggest that around 30% of patients are extubated without such a test and two RCT have questioned the need to pass an SBT to later sustain a successful extubation. Patients who fail an SBT are usually kept on the ventilator until they pass the SBT.

In the subgroup of patients who failed their first SBT in the WEANSAFE cohort, we aimed at evaluating, the impact of direct extubation despite SBT failure compared to the usual management consisting of sustaining invasive ventilation until patients pass a SBT.

**Objectives:** In a cohort of patients who failed their first SBT within 7 days of invasive mechanical ventilation, to compare the group of patients who were extubated despite failing SBT vs the group of patients who were not immediately extubated in terms of:

1. reintubation rate within 7 days of extubation;
2. total days of invasive ventilation, ICU length of stay, ICU and hospital survival.

**Methods:** Patients who fulfilled weaning eligibility criteria as defined by the WEANSAFE study (PEEP < 10 cm H2O, FiO2 < 0.5 and noradrenaline less than 0.2 mcg/kg/min) and who failed a first SBT within 7 days of mechanical ventilation start were selected if they also did not present limitations for reintubation. After this step, patients were split into those who were extubated after the very same SBT and those who were not. To estimate the probability of being extubated, we performed a propensity score matching (PSM) using optimal matching (which minimizes overall distance while selecting all the cases). To adjust for potential measured confounding, variables known to

influence the probability of being extubated and the outcomes at study were selected, such as age, cause of admission, and information at SBT such as oxygenation and respiratory rate during the trial. When data were missing, multiple imputation was conducted using Markov chains. Standardized mean differences (SMD) for continuous variables and differences in proportions for categorical variables were used to assess for balance after PSM. The outcomes were later assessed in the matched population using logistic regression for reintubation and survival rates and Wilcoxon tests for days of mechanical ventilation and ICU length of stay.

**Results:** 824 patients failed a first SBT of whom 207 (25%) were extubated immediately after. Before matching, patients who were immediately extubated were younger [61 (17) vs 65 (16) years, $p = 0.006$, SMD > 0.2], had been ventilated for a shorter time [2.7 (1.8) vs 3.1 (1.9), $p = 0.003$, SMD > 0.2] and respiratory rate at SBT was lower [20 (6) vs 22 (7), $p = 0.001$, SMD > 0.2]. Main reason for intubation (non-exclusive causes) was hypoxemic respiratory failure [132 (64%) vs 370 (60%) patients, $p = 0.38$], followed by sepsis [58 (28%) vs 166 (27%), $p = 0.83$]. Matching achieved good balance for all the covariates of interest as well as for the overall distance (Figure 1 & Table 1).

In the matched cohort, reintubation rate did not differ between groups [34 (16%) vs 35 (17%) patients, OR 0.97, $p = 0.90$], while the duration of invasive mechanical ventilation and the ICU length of stay were shorter in the group of patients with immediate extubation than in the group who remained intubated [5 (IQR 3–8) vs 9 (6–13) days, $p < 0.001$ and 9 (IQR 6–15) vs 13 (IQR 9–19) days, $p < 0.001$ respectively]. Finally, extubation after a failed SBT was associated with a lower ICU mortality [18 (9%) vs 35 (17%) patients, OR 0.46 (95% CI 0.26–0.86), $p = 0.01$] as well as a lower hospital mortality [33 (16%) vs 52 (25%) patients, OR 0.57 (95% 0.35–0.95), $p = 0.02$].

**Conclusions:** In this matched analysis, extubation after a first failed SBT in patients fulfilling weaning criteria was associated with a similar reintubation rates but with shorter duration of invasive mechanical ventilation and ICU length of stay. ICU and hospital mortality were also lower in this group.

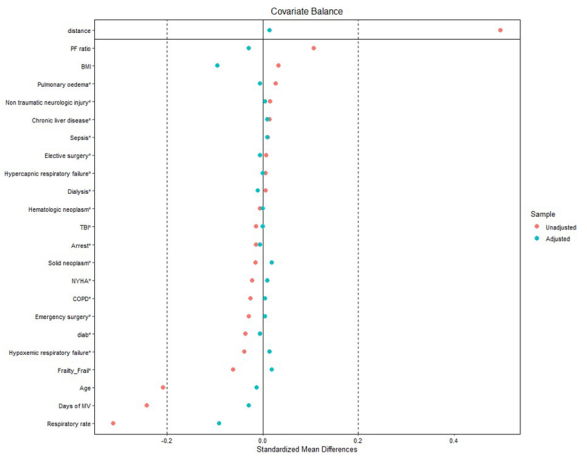

**Fig. 1 (abstract 000507)** Balance before and after propensity score matching in 207 pairs. Before optimal matching, patients who were extubated after a first failed spontaneous breathing trial were younger, had been ventilated for less time, and showed lower respiratory rate. Balance for each variable as well as overall balance was achieved with matching

**Table 1 (abstract 000507)** Characteristics of the matched population. Balance was assessed with standardized means in continuous variables and difference in proportions in categorical variables

**Introduction:** Stanford type A acute aortic dissection (AAAD) is a life-threatening condition. It is well known that inflammation is induced by the onset of AAAD. Some easy-available inflammatory markers like D-dimers or C-reactive protein (CRP) are not shown to relation to clinical outcome. Elevated White Blood Cell (WBC) count is also the marker of inflammation of acute aortic dissection. Although the relationship between WBC count and clinical outcomes of Stanford type B acute

aortic dissection has implied in a study, its usage for AAAD has not been well studied.
**Objectives:** This study aimed to explain the association of white blood cell (WBC) count with clinical outcomes.
**Methods:** We conducted a single-center retrospective study including patients with AAAD after emergency surgery. We divided patients into two groups according to the median value of the maximum white blood cell count measured within 24 h after ICU admission (a higher and lower WBC groups). The primary outcome was in-hospital mortality. The secondary outcome was ventilator-free days at day 28.
**Results:** Of 230 patients, median WBC (IQR) was 10.9 (8.9–13.1) k/uL. The overall in-hospital mortality was 6.1% and ventilator-free days was 26 (24, 27). Patients in the higher WBC group were younger, more male, and had a higher BMI than those in the lower WBC group. A multivariate logistic analysis adjusted for APACHE III score showed that higher WBC was associated with an increased risk of in-hospital mortality (adjusted odds ratio 6.87, 95% confidence interval 1.64–43.9, *P* value 0.018). A linear regression analysis adjusted for APACHE III and BMI found that higher WBC was associated with shorter ventilator-free days (Exp (β) 0.15, 95% CI 0.03–0.82, *P* value 0.030).
**Conclusions:** Our results indicate that elevated WBC count might be used as a predictor for increased risk of in-hospital mortality and shorter ventilator free days in AAAD.

*Intensive Care Medicine Experimental* 2024, **12(suppl 1):**000510

**Introduction:** Former Intensive Care Unit (ICU) patients frequently experience physical, mental, and cognitive health problems. Health problems that arise or worsen after critical illness and persist beyond acute care hospitalization are defined as the Post-Intensive Care Syndrome (PICS). ICU survivors indicate that physical, cognitive, and mental health problems have a major impact on their daily lives. Although the association between PICS and Health Related Quality of Life (HRQoL) appears logical, this has not been well demonstrated to date.
**Objectives:** To explore associations between the physical, cognitive, and mental PICS domains and HRQoL following an ICU admission.
**Methods:** Data were obtained from the MONITOR-IC; a longitudinal prospective multicenter cohort study including long-term outcomes of former ICU patients. At ICU admission, and 3 and 12 months post-ICU, patients completed questionnaires regarding physical problems (Physical complaints questionnaire), fatigue (Checklist Individual Strength), cognitive problems (Cognitive Failure Questionnaire), anxiety and depression (Hospital Anxiety and Depression Scale), post-traumatic stress (Impact of Event Scale), and HRQoL (European Quality of Life 5 Dimensions 5 Level Version). Composite scores were calculated for the physical domain (physical problems and fatigue), and the mental domain (anxiety, depression, and post-traumatic stress). Adjusted multivariable linear regression analyses were performed, including covariables (e.g., patient characteristics, disease severity, pre ICU HRQoL etc.) to explore associations between the physical, cognitive and mental domains of PICS, and HRQoL at 3 and 12 months post-ICU.
**Results:** Patients ($n=4092$) from seven Dutch ICUs were included between 2016 and 2020. At 3 months ($n=3368$), physical health problems ($b=-0.11$ (95% CI −0.13, 0.10), $p<0.001$), cognitive health problems ($b=-0.07$ (95% CI −0.10-, 0.05) $p<0.001$), and mental health problems ($b=-0.15$ (95% CI −0.17, −0.14) $p<0.001$) were negatively associated with HRQoL. Also at 12 months ($n=2950$), physical health problems ($b=-0.12$ (95% CI −0.13, −0.11), $p<0.001$), cognitive health problems ($b=-0.04$ (95% CI −0.06 −0.02) $p<0.001$), and mental health problems ($b=-0.14$ (95% CI −0.15, −0.12). $p<0.001$) were negatively associated with HRQoL.
**Conclusions:** PICS symptoms in all health domains (physical, cognitive, and mental) are negatively associated with a lower HRQoL 3 and 12 months post-ICU. PICS symptoms in the mental health domain seems to have the largest negative association. Daily ICU care and follow-up care should focus on preventing and mitigating health problems across all three PICS domains will improve long-term HRQoL.

*Intensive Care Medicine Experimental* 2024, **12(suppl 1):**000511

**Introduction:** After acute subarachnoid hemorrhage (SAH), tissue hypoxia has emerged among the factors contributing to secondary brain damage [1]. When available, brain tissue oxygenation (PbtO2) values can help clinicians tailoring the management of acute brain injured (ABI) patients.
**Objectives:** Our aim was to assess the association between arterial partial pressure of oxygen (PaO2) and PbtO2 in SAH patients.
**Methods:** A retrospective analysis of a prospectively collected cohort of all patients admitted after an aneurysmal SAH to the department of Intensive Care at Erasme Hospital (Bruxelles, Belgium) from January 2015 to October 2023, who underwent PbtO2 monitoring. The PbtO2/PaO2 ratio (BOx ratio) was calculated as previously proposed [2]. A BOx ratio below 0.15 was used to identify impaired oxygen delivery to brain tissue. Critical PbtO2 values were considered if below 20 mmHg.
**Results:** A total of 63 patients were included over the study period (mean age 55 ± 12 years—male gender 48%). Most patients exhibited severe neurological impairment, with a median Glasgow Coma Scale (GCS) score of 6 (3–13) on admission, along with higher Fisher score on initial CT scan. The median PbtO2 and BOx ratio for the entire cohort were 23 [21–26] mmHg and 0.20 [0.17–0.25], respectively. Overall, 3517 combined PbtO2 values and BOx ratios were available; 883 (25%) showed low PbtO2 values and 890 (25%) low BOx ratio (Figure 1). Cohen's k coefficient of agreement between PbtO2 and BOx ratio was 0.55, suggesting a moderate concordance [3].

**Conclusions:** Considering the BOx ratio together with absolute PbtO2 values in patients with SAH might help to better characterize tissue hypoxia.

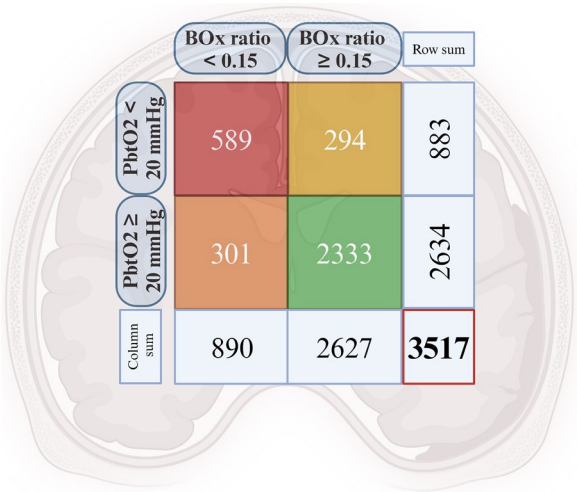

**Fig. 1 (abstract 000511)** Concordance of the BOx ratio and PbtO2 values in the study cohort

### Measurement of circulating nucleosomes in septic shock

F. Su[1], L. Dewachter[2], A. Moreau[1], F. Annoni[3], B. Garcia[1], G. Furlan[3], M. Savi[4], F. S. Taccone[3], J. L. Vincent[5]

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000512

**Introduction:** Blood nucleosome levels are commonly elevated in sepsis and can correlate with disease severity and outcome [1,2]. The primary method for quantifying circulating nucleosome levels is through Enzyme-Linked Immunosorbent Assay (ELISA). The performance of two commercially available ELISA kits in measuring circulating nucleosome concentrations was assessed in a clinically relevant septic shock model.
**Methods:** Sepsis was induced in 24 mechanically ventilated, hemodynamically monitored female sheep who underwent faecal peritonitis. The animals were randomly assigned to one of three groups: control, concurrent anti-histone treatment (CuT), and anti-histone post-treatment (PT) groups ($n=8$ each), following surgical preparation and stabilization. Anti-histone therapy involving sodium-*B*-*O*-methyl cellobioside sulfate was administered as a bolus (1 mg/kg) followed by continuous infusion (1 mL/kg/h). Treatment was started immediately after sepsis induction in the CuT group and 4 h thereafter in the PT group. The experimental period spanned 24 h. Plasma samples were collected at baseline and every 4 h for nucleosome measurements. Nucleosome levels were assessed using two commercially available ELISA kits (Nu.Q® H3.1 ELISA, Voltion, Snes, Belgium; Cell Death Detection ELISAPLUS, Roche, Mannheim, Germany) according to the respective manufacturer's protocols.
**Results:** Out of the 164 samples collected in this study, 34 samples analyzed using the Roche kit and none analyzed using the Voltion kit did not identify nucleosome. Over time, circulating nucleosome levels increased in the control group, when all measurement data were pooled together (Figure 1). Anti-histone therapy led to a significant decrease in nucleosome levels only in the CuT group as determined by the Roche kit (Figure 2). Conversely, significant decreases were observed in both treatment groups when using the Voltion kit. The coefficient of correlation between the two kits was 0.33 (95% CI: 0.19 to 0.47; $p<0.0001$).
**Conclusions:** Sepsis was associated with an increase in circulating nucleosome levels. Both the Roche and Volition ELISA kits demonstrated the potential of anti-histone therapy to reduce circulating nucleosomes in sepsis. However, the Volition kit outperformed the Roche kit, yielding more measurable samples and providing more accurate values.

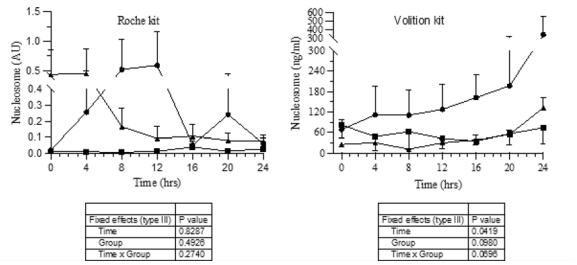

**Fig. 1 (abstract 000512)** Comparison of trends of circulating nucleosomes over time measured by Roche kit and Volition kit

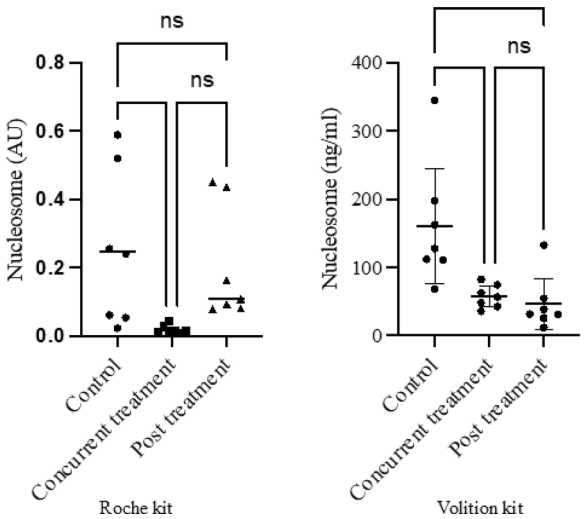

**Fig. 2 (abstract 000512)** Levels of circulating nucleosomes measured during anti-histone treatment and after treatment measured by Roche kit and Volition kit

**Introduction:** The COVID-19 pandemic in Pakistan revealed deficits in the availability of qualified critical care staff leading to the recruitment of non-traditional Intensive Care Unit (ICU) staff for patient management. High-fidelity simulation-based workshops were designed at the Aga Khan University Hospital (AKUH) to expeditiously train healthcare workers in the diagnosis, and management of COVID-19 patients.

**Objectives:** 1. To assess the baseline knowledge of physicians, nurses, and allied health workers required to work in COVID units. 2. To determine the level of subsequent improvement in knowledge after completion of the workshop using a structured pre- and post-assessment amongst the various participant groups. 3. To evaluate the impact of the course content on perception change, delivery method efficiency, teaching material efficacy, and applicability in a clinical setting.

**Methods:** Two distinct in-person workshops were developed and delivered for [1] physicians and [2] nurses and allied health workers, featuring small group lectures, case-based discussions, and simulation sessions. All participants completed pre- and post-tests comprising 30 multiple choice questions, with data analysed via paired t test comparison of pre- and post-test results. Subgroup analyses were done based on (i) designation, (ii) specialty, (iii) location, and (iv) level of care of participants' home institution. Feedback surveys, administered immediately after the course, assessed course content, delivery efficiency, and clinical efficacy. After 30 days, additional evaluation surveys were distributed among the participants to evaluate course impact, delivery efficiency, perception change, and clinical applicability.

**Results:** 569 candidates affiliated with 83 hospitals in 30 cities completed the workshops. Participants were predominantly males (65.6%), with non-trainee general physicians (30.6%) and registered nurses (24.1%) representing the largest groups.

Physicians' scores showed a 15.9% improvement from pre- to post-test (15.2 ± 4.4 (50.7%) to 20.0 ± 4.4 (66.7%) $p < 0.001$). For nurses and allied health workers, scores showed a 16.8% improvement (16.0 ± 6.0 (53.3%) to 21.2 ± 4.9 (70.1%) $p < 0.001$). The greatest improvement in mean scores by level of care was observed in secondary care (48.3%). Among designations, technicians showed the highest improvement (52.5%), followed by non-trainee general physicians (35.7%) and registered nurses (32.7%). By specialty, nephrology demonstrated the highest improvement in scores (72.2%), followed by emergency medicine (42.9%) and pediatrics (42.2%). Of 308 participants who completed the feedback form, 98.7% said that they would recommend this workshop to their peers. Of 386 participants who completed the 30-day evaluation, the topics taught on "Septic Shock" (13.3%) and "Diagnosis and Management of COVID-19 Patients" (12.6%) were stated to be the most beneficial in their clinical practice. Significant improvements were reported in knowledge (92.2%), confidence (91.7%), patient management (88.3%), and application in clinical settings (91.0%). Additionally, 366 participants reportedly managed over 7,150 COVID-19 patients after attending the workshops.

**Conclusions:** Our study underscored the impact of targeted educational interventions to tackle baseline critical care knowledge gaps among providers managing critically ill COVID-19 patients. This model can serve as a prototype for future interventions requiring rapid capacity building in similar situations.

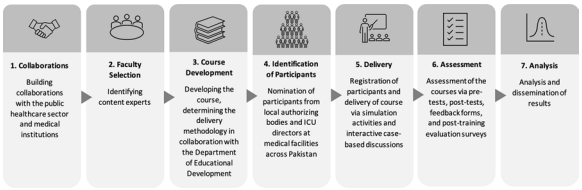

**Fig. 1 (abstract 000513)** Process flow of developing and delivering the simulation-based workshops

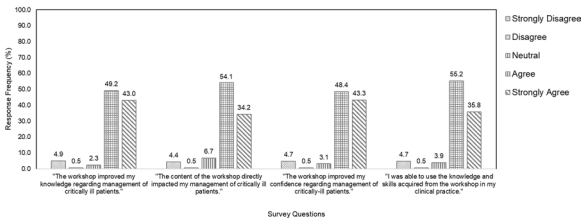

**Fig. 2 (abstract 000513)** Participant perceptions from the evaluation survey distributed 30 day post-course completion. $N = 386$ participants responded to these questions

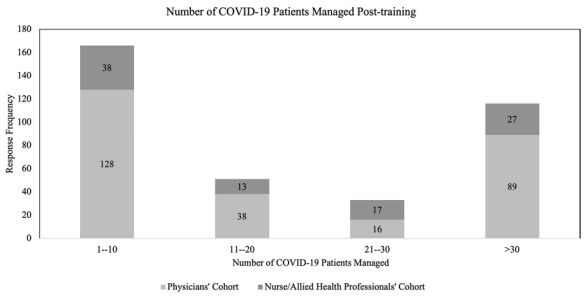

**Fig. 3 (abstract 000513)** Participant responses regarding the clinical impact of the simulation-based trained as found in the 30-day evaluation survey results. $N = 366$ participants responded to this question

**Introduction:** As lung ultrasound emerges as a standard tool to diagnose and monitor critically ill patients, it becomes imperative to gain insights into lung ultrasound appearances across patient with different characteristics in the Intensive Care Unit (ICU)[1]. The aim of this study is to describe lung ultrasound findings in various patient categories of invasively ventilated ICU patients within the first 24 h of starting mechanical ventilation. By delineating these typical ultrasound findings, we aim to assist clinicians in understanding typical lung ultrasound findings, which could aid in early recognition of pulmonary complications.
**Methods:** This is a post hoc analysis of a prospective observational study in invasively mechanically ventilated patients, the DARTS study [2]. Patients received a standard 12-region lung ultrasound examination within 48 h after initiation of mechanical ventilation.
For this analysis, patients were grouped based on reason for intubation: 'definite pulmonary problem' (pneumonia, ARDS, heart failure, asthma, COPD, and thoracic trauma), 'possible pulmonary problem' (sepsis, cardiac arrest, shock), or 'no pulmonary problem' (airway emergency, neurological conditions). Lung ultrasound findings, including lung aeration score and additional observations, were described for each group.
**Results:** After exclusion of two patients which did not fit any of the three categories, 322 patients were included [age: 60 (IQR: 20–90) years, 32% female, BMI 26.8 (IQR: 1.4–48.5)] in this analysis. At time of lung ultrasound examination, patients were mechanically ventilated for 20 (IQR: 11–28) hours when lung ultrasound examination was performed. Global lung aeration scores were 10 (IQR: 0–33), 6 (IQR: 0–21) and 2 (IQR: 0–19) for the definite pulmonary problem', 'possible pulmonary problem' or 'no pulmonary problem', respectively. Loss of aeration (B1, B2 or C-pattern) was most often observed in patients with 'a definite pulmonary problem', see Figure 1. Patients with 'possible pulmonary problem' and 'no expected pulmonary problem' show primarily A-pattern in the anterior and lateral regions. In all three groups, posterior C-patterns were found. In addition, pleural abnormalities were observed in all patients groups in the posterior regions. However, pleural abnormalities in the anterior and lateral regions were more prevalent in the 'definite pulmonary problem' group compared to the other two groups.
**Conclusions:** Patients who are invasively mechanically ventilated due to pulmonary pathology showed loss of aeration and pleural abnormalities in all lung regions in contrast to patients without pulmonary pathology. In addition, also patient without pulmonary pathologies frequently show loss of aeration in posterior regions. These study findings provide clinicians with a reference of typical presentations in a variety of intubated critically ill patients.

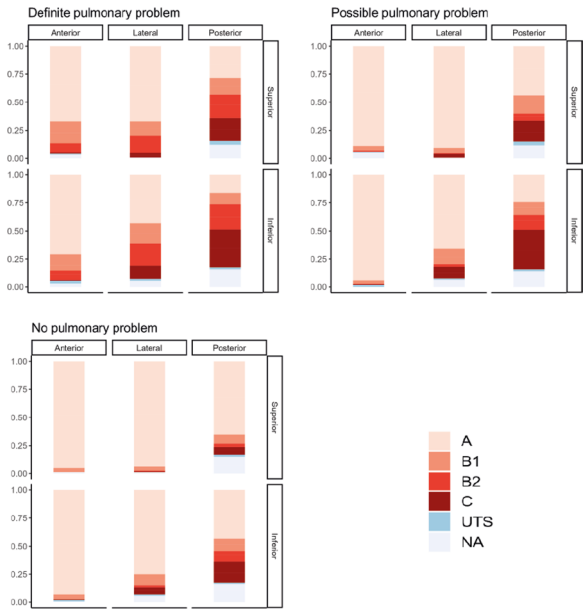

**Fig. 1 (abstract 000514)** Lung ultrasound patterns according to the lung ultrasound aeration score for different patient groups. Lung ultrasound consisted of assessment of 12 regions, six per hemithorax, of the thoracic cage. Each bar represents the superior or inferior part of the anterior, lateral and posterior regions on the thoracic cage. An "A-pattern," defined as horizontal repetitions of the pleural line (A-lines), was scored as 0. "B-patterns" were scored as 1 when more than two well-spaced B-lines were present that covered less than 50% of the pleural line or as 2 when B-lines covered more than 50% of the pleural line. A "C-pattern" was defined as an anatomical image of consolidation or as complete (or near-complete) loss of aeration that is larger than 2 cm and was scored as 3. NA: not available. UTS: unable to score

**Introduction:** Patients with COVID-19 pneumonia often develop acute respiratory failure (ARF) requiring respiratory support such as high-flow nasal cannula (HFNC), but some patients fail requiring invasive mechanical ventilation, what has been shown to increase mortality [1]. Metabolomic pathways related to failure in HFNC could be identified. This would allow for a better understanding of the pathophysiology of ARF due to COVID-19, as well as establishing possible therapeutic targets, guiding clinical decisions and not delaying orotracheal intubation (OTI) unnecessarily [2].
**Objectives:** To determine the metabolic alterations associated with failure in HFNC in patients with ARF due to COVID-19 and to generate a predictive model for this failure using clinical and metabolomic parameters.
**Methods:** A prospective unicentric study was carried out. Over the 1st to the 5th COVID-19 waves, critically ill patients with ARF due to COVID-19 that were admitted in the intensive care unit (ICU) and needed HFNC initial support were included. Patients were classified according to the success or failure of this therapy. The day they were admitted in the ICU, 138 biomarkers were determined for each patient and demographic, clinical, and analytical data were also recorded. The normality of the variables was verified using the K–S test; the quantitative ones were studied using the T-Student test and the qualitative ones were studied using the Chi2 test. A prediction model for HFNC failure was subsequently performed using a random forest-based analysis trying different combinations of the clinical and metabolomic parameters and obtaining different ROC curves.
**Results:** Among the 199 patients with COVID-19 who required HFNC, 118(59.3%) did not require OTI, while 81(40.7%) failed and were intubated. No significant differences were found in the demographic data or comorbidities except for age (56 ± 13 years vs. 60 ± 12 years, $p = 0.037$); in the success and failure groups, respectively. On the first day of HFNC, both groups presented differences in APACHE and SpO2/FiO2 (14 ± 6 vs. 16 ± 5, $p = 0.009$; and 168 ± 50 vs. 145 ± 66, $p = 0.009$ in these groups, respectively). Among the 111 metabolites studied, the ones that were significantly different were Octanoic (199 ± 112 µ/mL vs. 801 ± 167 µ/mL, $p = 0.003$), Anthranilic (11,918 ± 7478 vs. 16,180 ± 14,596, $p = 0.021$) and DAG180204 (290 ± 257 ng/mL vs. 385 ± 351 ng/mL, $p = 0.046$), in the group success and failure, respectively. The most accurate prediction model using fewer variables and with the possibility of clinical application was the one that included SpO2/FiO2, Octanoic and Anthranilic with an area under the curve (AUC) of 0.91(0.82–1) and a $p < 0.05$.
**Conclusions:** This predictive model for HFNC failure is accurate and could be applied in clinical practice to guide therapeutic decisions such as OTI decision. Event though, new studies using this model are needed to establish its usefulness for other causes of ARF and to validate its efficacy.

**Introduction:** New video-based technologies enable contactless continuous patient-friendly monitoring of vital signs in medical care. Both video-based heart rate (HR) and respiratory rate (RR) monitoring help to track changes in these vital signs to predict clinical deterioration earlier. These technologies are valid in controlled settings with healthy volunteers in whom the vital signs remain stable, but technical validation in clinical settings with changing trends of these vital signs remains limited (1).

**Objectives:** The objective of this study was to assess the validity of continuous video-based heart- and respiration rate monitoring in comparison with the reference standard in patients admitted to the intensive care (ICU).
**Methods:** A prospective observational study was performed in which measurements of HR and RR with a visible light (RGB) and an infrared (IR) camera were compared with continuous ECG and impedance pneumography monitoring on a standard patient monitoring system (Philips MX750) as the reference standards. Video-based HR relies on the principle of remote photoplethysmography (rPPG) by detecting subtle alterations in skin color induced by the cardiovascular pulse wave (2,3). Video-based RR analysis operates on the principle of discerning respiratory-induced motion patterns (4). The video data and reference data were synchronized to ensure alignment of their timestamps and 5-min data pairs were created for comparison. Outcome measures were the duration of valid video recordings and the agreement of HR and RR towards the reference standards reported as the bias and limits of agreement (LoA) and mean absolute error.
**Results:** In this preliminary analysis, 23 patients admitted to the ICU after cardiac surgery were included with a total video recording duration of 24.535 min. Valid video recording duration of HR and RR were 86.7% (4070 5-min data pairs) and 76,8% (3796 5-min data pairs), respectively. The bias and LoA of the video-based HR assessment were 2.73 [−24.73–19.26] with 87.7% of the 5-min data pairs falling within 5 beats/minute in comparison with the reference. Regarding RR, the bias and LoA were −0.85 [−9.84–8.14] with 81.7% of the 5-min data pairs falling within 3 breaths/minute in comparison with the reference.
**Conclusions:** These preliminary findings demonstrate the feasibility with a good agreement for continuous HR and RR measurements through video-based monitoring compared to the reference standard. Further efforts will concentrate on enhancing informative frame detection to improve coverage and validity, and continue developing more inexpensive off-the-shelf cameras as valid patient-friendly monitoring tools for clinical practice.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000521

**Introduction:** There are several recommendations how to perform weaning from mechanical ventilation (MV). However, such are not providing how to interpret hemodynamic changes during MV weaning.
**Objectives:** We evaluated hemodynamic changes during MV weaning including echocardiographic evaluation, and evaluated which parameters are significantly related with the result of MV weaning.
**Methods:** MV weaning trial was performed when patients showed alert mentality and achieved PFR > 200 mmHg with the positive end expiratory pressure of 5 cmH2O or lower. Echocardiography was performed before and after 30 min from weaning trial.
**Results:** A total of 160 patients (66.5 ± 15.3 years) were enrolled. The time from intubation to weaning trial was 8.0 ± 5.2 days and PFR before MV off was 286.8 ± 82.9 mmHg. One-hundred and six patients successfully weaned off MV at first weaning trial.
When we compared the condition before and during weaning trial of all patients, systolic blood pressure (131 ± 23 versus 135 ± 23, $p = 0.007$), left-ventricular end diastolic volume (LVEDV) (78.5 ± 82.3, $p < 0.001$), and tricuspid annular posterior systolic excursion (TAPSE) (20.5 ± 4.4 versus 21.5 ± 5.3, $p = 0.007$) were significantly increased. However, when we reanalyzed those parameters between groups, the increase of TAPSE was significant only among patients successfully wean-off MV. Increases of SBP and LVEDV were more prominent among patients failed to wean-off MV.
And, lower heart rate (91 ± 17 versus 100 ± 22, $p = 0.004$) and higher stroke volume (58.0 ± 16.0 versus 50.4 ± 16.8, $p = 0.017$) during weaning trial were significantly related with failed weaning of MV.
**Conclusions:** There were serial changes of hemodynamic parameters during MV weaning with increased venous return followed by increased LVEDV. The response of heart to those changes was different by the result of weaning trial. Lower heart rate with high stroke volume during weaning was one of the most important factors related with successful weaning.

### The role of intravenous albumin on fluid de-escalation in ICU patients

M. Faltys, A. Hararova, C. A. Pfortmueller
Department of Intensive Care Medicine, Inselspital, Bern University Hospital, University of Bern, Bern, Switzerland
**Correspondence:** M. Faltys
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000522

**Introduction:** Fluid resuscitation therapy for critically ill patients frequently leads to fluid accumulation [1]. Fluid accumulation with associated organ failure worsens critical care outcomes [2–4]. Fluid de-escalation aims to reduce fluid accumulation by active body fluid elimination [5,6]. Fluids can be actively removed from patients using diuretic therapy or via ultrafiltration when patients are receiving hemodialysis [1]. Intravenous albumin may augment fluid removal by increasing intravascular colloid oncotic pressure and promoting vascular refilling [7].
**Objectives:** To evaluate the impact of albumin infusion on total fluid balance during fluid de-escalation in hospitalized patients.
**Methods:** We conducted a systematic meta-analysis in alignment with the Cochrane, PRISMA, and MOOSE [8–10] guidelines (protocol registered to PROSPERO as CRD42022370029). We included randomized and non-randomized-controlled studies investigating the effect of adding Albumin to diuretic therapy or renal replacement therapy (RRT) on fluid balance during fluid de-escalation. We searched articles published on PubMed, Embase, and the Cochrane Library database until 12.12.2022. We excluded studies exclusively performed on patients with liver disease or traumatic brain injury. Two reviewers independently conducted title and abstract screenings, followed by

full-text reviews and data extraction. In case of disagreement, a third reviewer decided on inclusion. If the full text was unavailable, authors were contacted twice before their work was excluded. We calculated the effect size using the mean difference method, with the treatment effect (TE) determined as the difference in mean fluid balance between the intervention and control groups.

**Results:** We screened a total of 9225 studies and included 31 for full-text screening. Despite our repeated efforts, we could not obtain the full text for two articles. After full-text screening and data extraction, 4 studies were included in the analysis. The PRISMA flowchart is shown in Fig. 1.

All included studies examined the effect of albumin infusion in combination with furosemide. No identified study investigated the effect of added albumin during RRT on fluid balance for more than one session. The four studies (Table 1) included a total of 196 patients (118 patients in the intervention and 109 patients in the control arm). All studies were performed in the ICU setting. Two of the four studies were double-blinded randomized-controlled trials (RCT). Three out of four studies focused on patients with either hypoalbuminemia or -proteinemia.

The analysis revealed a fluid balance mean difference (MD) of −263 ml, with a 95% confidence interval (CI) spanning from −4326 ml to 3799ml ($p$ value = 0.90 for observed effect size different from zero, see Fig. 2).

Subgroup analysis of studies including only patients with hypoalbuminemia or -proteinemia ($n = 3$), as well as only RCTs ($n = 2$) showed similar Results: For the former, the fluid balance MD was-796ml (CI −6384 to 4791ml, $p$ value = 0.81). In the case of RCTs, the fluid balance MD was -1106ml (CI −7520 to 5308ml, $p$ value = 0.54).

**Conclusions:** This review indicates that the infusion of albumin alongside diuretic therapy has no discernible effect on the total fluid balance in ICU adult patients, according to the currently available evidence.

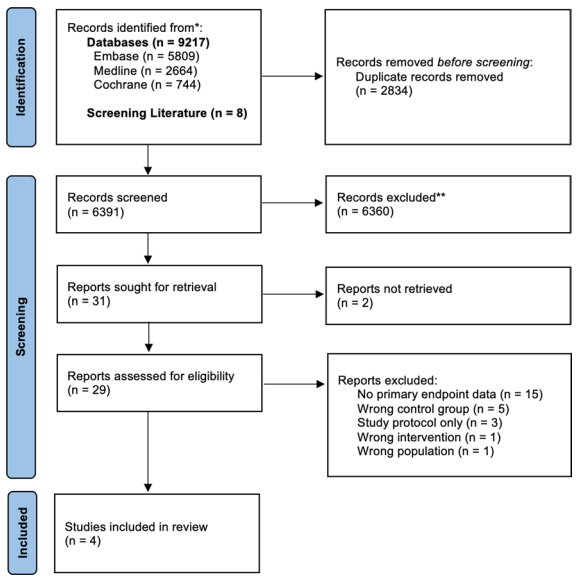

**Fig. 1 (abstract 000522)** PRISMA flow diagram

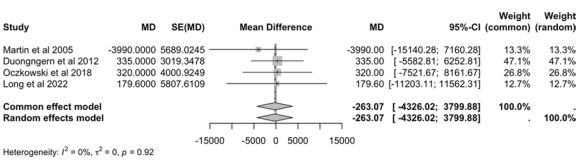

**Fig. 2 (abstract 000522)** Forest plot of the mean differences in fluid balance between intervention and control groups across included studies. The plot displays individual study estimates with their 95% confidence intervals (CIs) and the pooled estimate with their 95% CI. Each study is identified by the first author and the year of publication. The size of each square reflects the study's weight in the meta-analysis, and the diamond represents the pooled effect size

**Table 1 (abstract 000522)** List of the studies included in the meta-analysis

| Title | Author | Year of publication | Journal | Study type | Patients with hypoproteinaemia or -albuminaemia | Patient count (Control/intervention) |
|---|---|---|---|---|---|---|
| A randomized, controlled trial of furosemide with or without albumin in hypoproteinemic patients with acute lung injury | Martin et al | 2005 | Critical Care Medicine | RCT | yes | 40 (20/20) |
| Effect of albumin on diuretic response to furosemide in patients with hypoalbuminemia | Duongngern et al | 2012 | American Journal of critical care | retrospective | no | 31 (31/31) |
| Furosemide and albumin for diuresis of edema (FADE): a parallel-group, blinded, randomized controlled pilot trial | Oczkowski et al | 2018 | Journal of Critical Care | RCT | yes | 45 (21/24) |
| Albumin with furosemide versus furosemide alone for de-resuscitation after sepsis or septic shock | Long et al | 2022 | Critical Care Medicine | retrospective, abstract | yes | 80 (37/43) |

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000523

**Introduction:** Aneurysmal subarachnoid hemorrhage (aSAH) can cause delayed cerebral ischemia (DCI), typically within the first subsequent weeks due to multifactorial causes like vasospasm of intracranial vessels and disturbances of the microcirculation (1). Nimodipine (p.o. or i.v.) is known to be an evidence-based therapy for the prevention of this ischemic damage (2). Additional individualized treatment options to prevent the development of ischemia may also include intra-arterial administration of nimodipine (3). Various methods can be used to detect the onset of DCI, such as transcranial Doppler sonography (TCD), computed tomographic angiography (CTA), and digital subtraction angiography (DSA) (3,4). The biomarkers Glial fibrillary acidic protein (GFAP) and Ubiquitin carboxyl-terminal hydrolase L1 (UCH-L1) show promise for detecting intracranial damage (5), though their role in aSAH progression is still unclear.

**Objectives:** By comparison with traditional examination methods for the assessment of DCI, the aim is to investigate whether changes in marker levels allow earlier prediction of DCI.
**Methods:** The study is being conducted at University Hospital Regensburg. 15 patients have been included and analyzed to date. The concentration of the biomarkers GFAP and UCH-L1 was measured using chemiluminescent immunoassay analysis once a day for the first 14 days after aSAH. The following data will be collected: Doppler sonography results, radiological findings, neurological exams, surgical and interventional procedures, laboratory chemistry panel, nimodipine dosage, and intensive care monitoring.
**Results:** Blood samples of 15 patients were so far analyzed. Two patients received intra-arterial nimodipine after vasospasm was confirmed by CT-A and DSA, despite standard therapy. One patient showed increased UCH-L1 levels on day 6, with CT-A and DSA on day 7 confirming vasospasm and nimodipine intra-arterial treatment starting on day 8 (Figure 1). Another patient, diagnosed with vasospasm on day 5 by CT-A and DSA, also had rising UCH-L1 levels between days 2 and 5. Intra-arterial nimodipine was administered on day 6 for this patient as well (Figure 2).
**Conclusions:** It is difficult to clearly identify the onset of DCI. Two of the patients included so far showed clear vasospasms by CT-A and DSA despite standard therapy, which led to escalation of therapy. In both cases, diagnosis of vasospasm was preceded by increases in UCH-L1 levels. With intra-arterial nimodipine administration, the UCH-L1 values fell again in each case. As only 2 out of 15 patients in the patient collective evaluated so far were treated with intra-arterial nimodipine, a larger number of cases are necessary for a better assessment and statistical evaluation of this phenomenon. These initial indications of the potential usability of the biomarkers for the diagnosis of DCI encourage us in our plan to continue and optimize the analysis of the biomarkers in a larger patient collective.

**Introduction:** According to a recently published pilot study, a comprehensive change in the design of the ICU room could potentially reduce the incidence of delirium and influence circadian melatonin rhythms [1]. Changes in serum acetylcholinesterase (AChE) activity have been associated with a greater likelihood of being delirious [2]. Furthermore, AChE activity may serve as a real-time indicator of the state of the cholinergic system in these patients [3]. Basic research has shown that cholinergic markers, including AChE activity, exhibit natural fluctuations in accordance with the circadian rhythms of the body [4].
**Objectives:** To analyze if a multicomponent change in room design influences serum AChE activity in critically ill mechanically ventilated patients.
**Methods:** This is a secondary analysis of a proof-of-concept pilot study [1]. Two of the seven double bedrooms received extensive architectural modifications, including a new dynamic lighting system [5]. Patients were eligible for inclusion if they were mechanically ventilated and expected to remain in the ICU for at least 48 h. Patients with substantial recent exposure to the ICU were excluded [6]. Serum AChE activity was measured every 4 h for up to three 24-h assessment periods (AP-A, B, and C) using the *ChE check mobile* (Securetec Detektions-Systeme AG, Neubiberg, Germany). AP-B and C were initiated only if the patient's Richmond Agitation Sedation Scale (RASS) was -3 or greater. The influence of different lighting conditions (calculated as effective circadian irradiance [CEI], Ec) on serum AChE activity was analyzed using nonparametric multivariate analysis of longitudinal data.
**Results:** A total of 99 patients were enrolled. Sixty-four patients could be included in the data analysis ($n = 34$ patients in modified rooms, $n = 30$ in standard rooms). The median values of serum AChE activities in Figure 1 show different circadian behaviors between rooms with lower values for patients treated in standard rooms. The multivariate, nonparametric covariance analysis of longitudinal data revealed a significant influence of Ec on the course of serum AChE activity for AP-A, -B, and -C ($p < 0.0001$).

**Conclusions:** This preliminary analysis indicates that light therapy as part of a set of ICU room modifications may influence circadian serum AChE activity. Additional data analysis and larger studies are needed to confirm the hypothesis.

**Introduction:** Patients admitted to intensive care units present a high level of complexity due to the severity of their pathologies and require extensive monitoring and the use of multiple therapies and treatments. This complexity represents a significant challenge for clinicians, as they must integrate a large amount of information and manage it effectively to achieve the maximum benefit for the patient.
Sedation and analgesia (SA) are both primary treatments for critically ill patients, and its correct titration plays a fundamental role in patients' progression and the potential complications they may present (1).
Secondary use of data stored in Clinical Information Systems (CIS) allows the creation of support tools as real-time dashboards that can help to personalize and adjust treatments to achieve the maximum benefit for patients (2). The use of this dashboards to adjust SA in critical care patients can improve their outcomes and reduce associated complications.
**Objectives:** Design and implement a real-time SA dashboard from SIC data and validate it through internal audit (IA).
**Methods:** This study includes the design (1), implementation (2), and validation (3) of the dashboard for two Intensive Care Units (ICU) (26 boxes).

1. Variable selection: age, sex, days of admission, body mass index (BMI), measured RASS/prescribed RASS, EVN/ESCID, presence of restraints, CAM-ICU, BIS, TOF, renal and/or hepatic function, sedative drugs, opioids, and neuromuscular blocking agents, and dose-related to patient weight.
2. Extraction, transformation, and loading (ETL) of SIC data. Consensus on limits and alarm ranges, according to Clinical Practice Guidelines, and color-coded alerts.
3. Phase 1 of IA content dashboard. Errors are classified according to validated classification in previous studies (3, 4) (Plausibility, Conformance, or Completeness). In case of error, the origin is identified as configuration failure, professional registration error, or integration failure with devices or departments. Once the errors are identified, changes are implemented in the configuration according to them.
4. Phase 2 of IA.

**Results:** For 5 days, in phase 1 of IA, 67 cases (638 variables) were audited. 615 correct transfers (96.4%) and 23 errors were found. Type of errors: 12 plausibility errors (1.9% of errors regarding all evaluated variables); 7 completeness errors (1.1%), and 4 conformance errors (0.6%). The origin of the errors was configuration in 78.3%, professional registration in 13%, and integration failures with devices and departments in 4.4%. After correcting configuration errors, 17 cases (161 variables) were audited in second phase of IA (2 days). No errors were found.
**Conclusions:** It is possible to generate a reliable sedation and analgesia real-time dashboard from SIC data Configuration, guided by internal audit of information quality.

**Introduction:** The incidence of delirium in patients on mechanical ventilation may reach up to the 80% range during the hospitalization (1). Although most delirium studies have been conducted in mechanically ventilated patients, there are few studies investigating the relationship between pre- and post-extubation periods and delirium (2,3,4).
**Objectives:** In this study, we aimed to investigate and reveal at what stage of the extubation process delirium occurs, risk factors, and its association with sedation; and results of this study will offer a contribution to the prevention, treatment, and relief of symptoms.
**Methods:** The patients who were intubated and followed on a mechanical ventilator for at least 24 h in the intensive care unit, and whose extubation decision was made by the supervising physician, were enrolled in the study. The number of samples in our study was determined as 38 patients with 85% power analysis. To screen for delirium using CAM-ICU before extubation and during the 48-h period following extubation, demographic data, length of stay, duration of intubation, sedation, and results of arterial blood gas analysis were evaluated. Shapiro–Wilk test was used to investigate the suitability of the data for normal distribution and for two-way repeated-measures ANOVA test was used. IBM SPSS Statistics 21.0 program was used in the implementation of the analyses. The data were collected in three steps: pre-extubation, post-extubation at 24 h, and post-extubation at 48 h.
**Results:** Before extubation, among a total of 38 patients, 11 patients (28.95%) were identified as CAM-ICU positive. Those identified as CAM-ICU positive consist of 8 males (72.7%) and 3 females (27.3%). Patients diagnosed with delirium before extubation were generally younger (pre-extubation CAM-ICU (+) $55.18 \pm 22.44$ years; pre-extubation CAM-ICU (−) $64.89 \pm 18.46$ years), with relatively longer lengths of stay in the intensive care unit (6.15 days vs. 8.91 days) and durations of mechanical ventilation (3.96 days vs. 5.09 days) on average. Only 4 out of 19 patients (21.05%) who received sedation with dexmedetomidine were CAM-ICU positive before extubation. We observed a lower incidence of delirium in patients sedated with dexmedetomidine. We identified nine patients who were CAM-ICU(−) before extubation but became CAM-ICU (+) during the 48-h period following extubation, and it was determined that all of these patients had a PaO2/FiO2 ratio of less than 200 ($p < 0.05$). After extubation, CAM-ICU (−) was observed only in 4 patients with PaO2/FiO2 < 200. Throughout the study, we observed that 11 out of a total of 20 patients (55%) identified as CAM-ICU (+) received a negative score on the RASS, indicating a more prevalent hypoactive type of delirium.
**Conclusions:** Contrary to general literature data, based on the results of this study, we concluded that young male patients should be monitored more closely for delirium. The paO2/FiO2 ratio may be a suitable parameter for an objective score system that may predict delirium.

### Risk factors for mortality in radiological sub-phenotypes of severe ARDS patients on veno-venous ecmo: insights from the J-CARVE registry

**Introduction:** In a recent study utilizing the J-CARVE registry [1], a large multicenter database including chest CT data at the initiation of veno-venous extracorporeal membrane oxygenation (V-V ECMO), we previously developed three novel sub-phenotypes among patients with severe acute respiratory distress syndrome (ARDS) requiring V-V ECMO. These sub-phenotypes, characterized by Dry type (minimal lung edema), Wet type (pronounced lung edema), and Fibrotic type (presence of fibroproliferative changes on chest CT), were identified through latent class analysis. The aim of this study was to identify risk factors for mortality in these sub-phenotypes.
**Methods:** We retrospectively analyzed data of 544 adult patients with severe ARDS who underwent V-V ECMO between January 2012 and December 2022 across 24 intensive care units (ICUs). We conducted multivariate logistic regression analyses for each sub-phenotype to identify potential risk factors, focusing on clinical variables obtained within the first 24 h of initiating V-V ECMO support. The primary outcome was mortality at ICU discharge.
**Results:** Across all subtypes, an increase in age was associated with increased mortality in patients with severe ARDS requiring V-V ECMO (Dry type: adjusted odds ratio (AOR) 1.05 [95% confidence interval (CI) 1.00–1.10], $p = 0.026$; Wet type: AOR 1.03 [95% CI 1.00–1.06], $p = 0.017$; Fibrotic type: AOR 1.06 [95% CI 1.02–1.10], $p = 0.003$). For the Wet type, additional risk factors included the longer days from intubation to V-V ECMO initiation, and increased lactate and blood urea nitrogen levels (AOR 1.22 [95% CI 1.08–1.38], $p < 0.001$; AOR 1.17 [95% CI 1.04–1.32], $p = 0.002$; AOR 1.03 [95% CI 1.01–1.05], $p = 0.006$, respectively). In the Fibrotic type, longer days from intubation to V-V ECMO initiation and increased white blood cell counts were identified as risk factors for higher mortality (AOR 1.08 [95% CI 1.00–1.16], $p = 0.049$; AOR 1.06 [95% CI 1.01–1.11], $p = 0.007$, respectively).

**Conclusions:** Our findings revealed different risk factors associated with mortality across the previously identified sub-phenotypes of severe ARDS patients on V-V ECMO. These insights emphasize the necessity for tailored management strategies for each sub-phenotype during V-V ECMO intervention, potentially guiding more personalized and effective treatment approaches.

**Introduction:** Trauma is a leading cause of mortality and morbidity. Particularly, in cases of hemodynamic instability, the use of vasopressors and damage control surgery (DCS) are often necessary. However, the optimal timing of vasopressor use and its impact on clinical outcomes in trauma patients remains unclear.
**Objectives:** The aim of this study was to compare the clinical characteristics, hemodynamic parameters, surgical factors, and outcomes of trauma patients according to the timing of vasopressor use and the application of DCS.
**Methods:** This retrospective cohort study classified 380 trauma patients into three groups based on the timing of vasopressor use after admission: within 6 h (X1, $n=145$), 6–48 h (X2, $n=141$), and over 48 h (X3, $n=94$). Each group was further divided according to the application of DCS (X0: no DCS, X1: DCS). Demographics, injury severity, hemodynamic parameters, surgical factors, and outcomes were compared among the groups.
**Results:** The proportion of DCS was significantly different among the groups (X1: 7.2%, $n=10$; X2: 18.6%, $n=27$; X3: 41.7%, $n=40$; $p<0.001$), with the highest rate in the X3 group. Patients in the X3 group ($n=94$) had significantly higher injury severity scores (ISS) (26.0 vs 22.0 vs 22.4; $p=0.026$), lower initial systolic blood pressure (SBP) (81.4 vs 88.1 vs 82.9 mmHg; $p=0.134$), and higher 24-h transfusion requirements compared to the X1 ($n=145$) and X2 ($n=141$) groups ($p<0.001$). In the X2 group, patients who underwent DCS ($n=26$) had lower hemoglobin levels (9.1 vs 10.4 g/dL, $p=0.018$) and higher lactate levels (8.1 vs 5.6 mmol/L, $p=0.021$) compared to those who did not ($n=115$). Similar findings were observed in the X1 group (DCS, $n=10$ vs no DCS, $n=135$). The median abdominal AIS scores were 4, 3, and 2 in the X1, X2, and X3 groups, respectively ($p<0.001$). Mortality did not differ among the groups, but morbidity was slightly lower in DCS patients in the X2 (65.4% vs 61.7%) and X3 (45.0% vs 57.4%) groups.
**Conclusions:** In this study, delayed vasopressor use (> 48 h) was associated with higher injury severity, worse hemodynamic parameters, and increased need for DCS and transfusion. These findings suggest that early recognition and management of hemodynamic instability with vasopressors may be crucial in preventing the progression to more severe clinical states and the need for DCS. However, the timing of vasopressor use did not significantly impact mortality in this study. Future prospective studies are needed to establish evidence-based guidelines for the optimal timing of vasopressor use in trauma patients and its impact on clinical outcomes.

## 000532 Novel subtypes and differential response to muscle relaxants in patients with severe ARDS requiring V-V ECMO: potential for individualized management during V-V ECMO

M. Nishikimi, S. Ohshimo, S. Nobuaki
Department of Emergency and Critical Care Medicine, Hiroshima University, Hiroshima, Japan
**Correspondence:** M. Nishikimi
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000532

**Introduction:** Patients with severe ARDS requiring veno-venous extracorporeal membrane oxygenation (V-V ECMO) are a population with heterogeneous respiratory physiology. AQ28
**Objectives:** The aim of this study was to identify sub-phenotypes of severe ARDS requiring V-V ECMO and to evaluate the beneficial effect of muscle relaxants across sub-phenotypes.
**Methods:** We used the data from the Japan Chest CT for ARDS Requiring V-V ECMO Registry (J-CARVE registry [1]), a retrospective multicenter registry of adult patients with severe ARDS who received V-V ECMO. We performed a latent class analysis (LCA) for identifying sub-phenotypes of severe ARDS based on radiological and clinical findings at the start of ECMO support. Multivariate Cox regression analysis was conducted to investigate the association between the use of muscle relaxants within 48 h after the start of ECMO support and mortality by the sub-phenotypes. The primary outcome was the 90-day in-hospital mortality.
**Results:** Three sub-phenotypes were identified from data of a total of 544 patients with severe ARDS treated with V-V ECMO at 24 institutions across Japan: Dry type 185 (34%), Wet type 169 (31%), and Fibrotic type 190 (35%) (Figure). Patients with Fibrotic type showed an increased risk of 90-day in-hospital mortality compared with Dry type (adjusted hazard ratio [95% confidence interval] 1.83 [1.16–2.91], $p=0.010$) and Wet type (1.53 [1.04–2.27], $p=0.033$). Among the 320 patients who did not use muscle relaxants before ECMO support, the 90-day in-hospital mortality was 8.5% (4/47) and 15.9% (10/63) for Dry type ($p=0.24$), 26.7% (12/45) and 25.5% (14/55) for Wet type ($p=0.89$), and 34.8% (16/46) and 51.6% (33/64) for Fibrotic type ($p=0.08$), respectively. The use of muscle relaxants within 48 h after the start of V-V ECMO support decreased the risk of 90-day in-hospital mortality in patients classified into Dry or Fibrotic type (0.53 [0.30–0.93], $p=0.027$), while not in those classified into Wet type.
**Conclusions:** Three sub-phenotypes in patients with severe ARDS requiring V-V ECMO were identified. The use of muscle relaxants within 48 h after the start of V-V ECMO support may be beneficial only in patients classified as Dry or Fibrotic type**.**

## Neuro-prognostication using neuron-specific enolase after out of hospital cardiac arrest: a retrospective analysis from a tertiary referral and major trauma centre

N. Daines, M. Burgess, R. Gray, J. Porter
Intensive Care, Royal Sussex County Hospital, Brighton and Hove, United Kingdom
**Correspondence:** N. Daines
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000533

AQ29 **Introduction:** Neuron-specific enolase (NSE) is a well-established biomarker used in multimodal neuro-prognostication following out of hospital cardiac arrest (OHCA) [1]. Despite its widespread use for outcome prediction, the recommended cut-off values and time intervals for testing NSE remain uncertain due to variation observed between studies and different immunoassay techniques [2].
**Objectives:** This study investigated the utility of NSE as a predictor of 3-month survival following all cause OHCA in a real-world clinical setting.
**Methods:** A single-centre retrospective analysis of all patients admitted to the Royal Sussex County Hospital ITU over one calendar year (September 2022 to August 2023) with a diagnosis of OHCA. Clinical and outcome data were obtained from electronic patient records. NSE levels were measured by immunoassay (F.Hoffmann-La Roche Ltd, Elecsys® NSE).
**Results:** Of 66 admissions for OHCA eligible for inclusion, NSE data were available for 32. In 5 cases patients had died before reaching the time interval for performing NSE. In 16 instances NSE was not determined due to sample haemolysis. A total of 46 successful NSE tests were carried out, of which 22 were taken at 48 h and a further 24 taken at 72 h. There was minimal difference in predictive value between tests carried out at 48 and 72 h, as shown in Fig 1. Serum NSE results from all time intervals were both sensitive and specific in predicting outcome after OHCA, as shown in Fig 2 (area under ROC 0.898). As shown in Fig 1, median and mean average NSE were higher in the 72-h samples of non-survivors and lower in the 72-h samples of survivors when compared to the 48-h samples of each respective group.
**Conclusions:** In this study, an NSE of > 50 µg/L was ubiquitous with a non-survivable outcome following OHCA; however, an NSE < 50 µg/L while suggestive of survival was less sensitive. This may be partly explained as some non-survivors succumb for reasons other than hypoxic encephalopathy (for example aspiration, cardiogenic shock, arrhythmia, etc.) and so have comparatively low NSE results. Clinically NSE results were not interpreted in isolation but rather were used in combination with electroencephalography and computed tomography findings supportive of hypoxic encephalopathy.
A rising 72-h NSE was associated with a poor outcome. Conversely, a decrementing 72-h NSE was associated with survival. There may be an element of bias with regards to which patients are selected for neuro-prognostication using NSE. Some NSE samples could not be processed due to haemolysis, to which it transpires the test is especially susceptible.

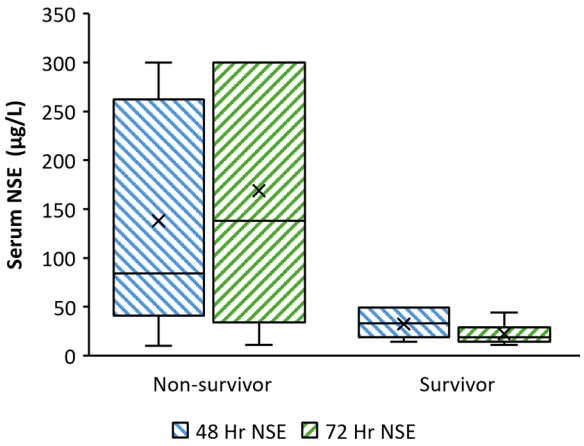

**Fig. 1 (abstract 000533)** Boxplot of serum NSE against survival outcome at 48 and 72 h intervals

.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000535

**Introduction:** Infective Endocarditis (IE) is associated with significant morbidity and mortality risk, despite advances in diagnosis and treatment. The poor prognosis associated with IE is due to the complications and risk of recurrence. The prevalence of IE caused by *Staphylococcus* and *Enterococcus* has increased. Ceftaroline fosamil (CPT-F), a fifth-generation cephalosporin, has activity against Gram-positive and -negative bacteria due to its inhibition of bacterial cell wall synthesis. CPT-F has been approved for the treatment of acute skin and soft-tissue infections and community-acquired pneumonia. Although clinical experience is limited, many observational studies have shown its effectiveness in the management of bacteremia and IE caused by Gram-positive microorganisms.
**Objectives:** This study aims to assess the efficacy, and treatment outcomes of CPT-F in patients diagnosed with IE, focusing on survival rates, and recurrence rates.
**Methods:** A retrospective review on 18 cases of IE treated with CPT-F. Patient demographics, clinical characteristics, including risk factors, type and location of IE, causative agents, and treatment were analyzed. Survival rate in the ICU, 30-day mortality, and recurrence of IE were included. Statistical analysis was performed with Stata 14.2. Categorical variables were presented as absolute frequencies and percentages, while continuous variables were expressed as mean (±standard deviation) or median (interquartile range) when necessary.
**Results:** The median age was 66.5 (61.75–75) years, 50% male and a median APACHE II score of 19.5 (13.5–28). Among the patients, cardiac valve prostheses (44.4%), diabetes mellitus (33.3%), endovascular devices (16.7%), and previous episodes of IE (11.1%) were prevalent risk factors. IE affected prosthetic and native valves equally (50%). The majority of cases involved a single valve (77.8%). In 88.88% of the cases, the endocarditis was on the left side, with the mitral valve being involved in ($N=10$) 52.6% of the cases. *Staphylococcus aureus* was the predominant pathogen: methicillin-sensitive ($N=8$, 44.4%) and -resistant ($N=4$, 22.2%), followed by *Staphylococcus epidermidis* ($N=3$, 16.7%). All the patients received CPT-F combined with at least one or more antibiotics, being daptomicine the most common adjunctive therapy (72.22%). CPT-F was used as rescue therapy in 55.6% and as first-line treatment in 44.4% of cases. The ICU survival rate was 83.3%, with a 30-day mortality rate of 22.2%. Recurrence of IE was observed in a minority of patients (22.3%), indicating effective infection resolution in 77.8% of the cases. No side effects were described during treatment.
**Conclusions:** CPT-F, particularly in combination with other antimicrobial agents, offers a viable therapeutic option for treating infective endocarditis, including cases involving methicillin-susceptible and -resistant *Staphylococcus aureus*, showing high survival rates and low recurrence. The study highlights the importance of tailored therapeutic strategies to manage this complex condition. Further prospective research is needed to validate these findings and refine treatment guidelines.

### Prediction of survival and neurological outcomes in ventricular fibrillation patients treated with extracorporeal cardiopulmonary resuscitation based on the acute kidney injury biomarkers

D. Fujita, A. Tsuruoka, H. Yoshida, H. Rinka
Emergency and Critical Care Medical Center, Osaka City General Hospital, Osaka, Japan
**Correspondence:** D. Fujita
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000536

**Introduction:** In recent years, acute kidney injury (AKI) biomarkers have been reported to be useful not only in the diagnosis of AKI and prediction of kidney replacement therapy (KRT) but also in predicting outcomes in critically ill patients. This study aimed to investigate whether prediction of survival and neurological outcomes are possible in patients with ventricular fibrillation (VF) who underwent extracorporeal cardiopulmonary resuscitation (ECPR). In Japan, only L-FABP and NGAL are covered by national insurance as AKI biomarkers.
**Methods:** This study was a monocenter retrospective observational study. Patients in ventricular fibrillation treated with ECPR admitted to our ICU and whose urinary L-FABP (uL-FABP) and urinary NGAL (uNGAL) were measured at ICU admission from July 2018 to March 2024 were selected from the medical records.
Patients were divided into two groups based on the median values of uL-FABP (μg/g.cre) and uNGAL (μg/g.cre), [L–L group (uL-FABP < 16,982.1) and L–H group (uL-FABP ≥ 16,982.1), N–L group (uNGAL < 1830) and N–H group (uNGAL ≥ 1830), respectively]. We analyzed the 28-day mortality using the log-rank test.
Furthermore, we examined the association with neurological outcomes using the Mann–Whitney U test and examined factors associated with poor neurological outcome using logistic regression analysis.
**Results:** A total of 46 patients were included in the study. The median age was 58 years, and 43 patients were male. 7 patients received KRT, 28 patients received IABP, and 6 patients received IMPELLA.
The median uL-FABP and uNGAL levels were 16,982.1μg/g.cre and 1830 μg/g.cre, respectively.
The Kaplan–Meier curves compared the 28-day prognoses of the L–L and L–H groups as well as the N–L and N–H groups are shown in Fig. 1(a,b).
No significant difference was observed between the L–L group and L–H group (Log rank $p=0.433$), whereas a significant difference was observed between the N–L group and N–H group (Log rank $p=0.046$). Both uL-FABP and uNGAL were significantly higher in the poor neurological outcome (Cerebral Performance Category = 3,4,5) group ($p=0.04$ and $<0.01$, respectively) (Fig. 2 a,b).
Factors associated with poor neurological outcomes were age (odds ratio 1.09, 95% C.I 1.01–1.18, $p=0.0223$) and uNGAL > 1830 (odds ratio 8.88, 95% C.I 1.59–49.70, $p=0.0129$).
**Conclusions:** AKI biomarkers such as uL-FABP and uNGAL may be useful in predicting survival and neurological outcomes in patients with VF treated with ECPR. However, due to the limited number of cases, further investigation is needed.

### Research capacity in Canadian community hospitals: an intrinsic descriptive case study

E. Orlando[1], A. Binnie[2], M. Law[1], J. Tsang[1]
[1]Niagara Health Knowledge Institute, Niagara Health, St. Catharines, Canada; [2]Department of Critical Care Medicine, William Osler Health System—Etobicoke General Hospital, Toronto, Canada
**Correspondence:** E. Orlando

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000538

**Introduction:** Canada's clinical research infrastructure is limited by a lack of community hospital (CH) engagement. CHs represent over 90% of Canadian hospitals, yet few participate in clinical research. Increasing research participation by CHs has the potential to accelerate trial enrollment, enhance study generalizability (1), and improve knowledge translation. Major barriers to CH research participation are a lack of (1) financial support and (2) mentorship (2). To address these issues, the COVID-19 Network of Clinical Trials Networks (NoN) provided 1 year of financial support to 14 CHs and recruited their research leads to participate in a CH-specific Working Group (WG).
**Objectives:** The purpose of this study was to: (1) describe the impact of NoN funding and WG on CH research participation, (2) identify actions to strengthen CH research activities, and (3) understand the impact of context on CH research participation.
**Methods:** We used an intrinsic descriptive case study methodology3 and collected data from multiple sources including WG minutes [$n=7$], email correspondence, NoN status reports [$n=21$]), and semi-structured interviews (physician leads [$n=7$] and research staff [$n=2$]). We used thematic analysis to identify themes that were mapped to the Consolidated Framework for Implementation Research (CFIR) domains, a useful framework for identifying barriers and facilitators to effective implementation.
**Results:** NoN funding enabled CHs to hire new research staff, sustain existing programs, increase active trials, and develop policies and procedures. WG membership also had a positive impact by facilitating reciprocal learning and networking (e.g., connecting with new trials and funding opportunities). Contextual factors were frequently cited as determining the success of CH research programs. These included: (1) clinical trial design, (2) health system characteristics, (3) CH context, and (4) individual team member characteristics. Themes and sub-themes aligned with all CFIR domains and many CFIR constructs, suggesting an opportunity to leverage implementation science strategies to tailor interventions to encourage CH research participation.
**Conclusions:** NoN funding and WG membership positively influenced research activities in CHs. Actions to continue this growth include: (1) identifying mechanisms to better connect CH researchers, (2) working with investigators to design clinical trials that facilitate CH participation, and (3) creating resources to support CHs in building and sustaining research programs, including in communities with low historic research participation. Our findings point to the importance of context, including local population characteristics, organizational research culture, provincial health system structures and research funding structures, that impact the success of CH research programs and should be considered in planning future interventions.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000539

**Introduction:** The evaluation of pupillary reactivity is crucial in assessing unconscious patients following cardiac arrest (CA). Automated pupillometry is known to provide more accurate assessments compared to human observation. The Neurological Pupil Index (NPi) has been recognized as an accurate index to predict unfavourable neurological outcome (UO). A new index, called the Quantitative Pupillometry Index (QPI), has emerged; however, there are no prognostic data on its application in CA patients.
**Objectives:** This study compared the prognostic value of NPi and QPI in unconscious patients post-CA.
**Methods:** This is a prospective ongoing observational single-center study, conducted at the Erasme University Hospital in Brussels (Belgium). We collected data from patients admitted to the Intensive Care Unit after successful resuscitation from CA between April 2023 and

January 2024. The inclusion criteria were age ≥ 18 years and a Glasgow Coma Scale < 9 on admission. Exclusion criteria included facial and/or ocular trauma, not allowing pupillometry, and pregnancy. Measurements of NPi (Neuroptics, California, USA) and QPI (Neurolight, IdMed, Marseille, France) were performed once at 24, 48, and 72 h after CA. All measures were collected by medical staff not directly involved in the clinical management of patients. The follow-up was performed using a semi-structured telephone interview or evaluated during follow-up visits; UO was considered as Glasgow-Pittsburgh Cerebral Performance Category (CPC) 3–5 at 3 months.
**Results:** 42 patients have been included so far, 36 of which had available follow-up data; UO occurred in 29 (80.5%) of patients. At 24 h, patients with UO showed a lower NPi (4.0 [3.2–4.4] vs 4.4 [4.05–4.6]; $p = 0.06$) and QPI (2 [1–3] vs 3 [3–4]; $p = 0.04$). Also, at 48 and 72 h, patients with UO showed a lower NPI (3.8 [3.3–4.3] vs 4.5 [4.4–4.7]; $p = 0.02$; and 3.6 [3.22–4.27] vs 4.6 [4.5–4.65]; $p = 0.04$, respectively) and a lower QPI (2 [0–3] vs 4 [3–5]; $p = 0.01$; 0 [0–4] vs 5 [5–5]; $p = 0.009$) than those with favourable outcome. The area under receiver-operating characteristic (AUROC) of QPI to predict UO was 0.73, 0.82, and 0.82 at 24, 48, and 72 h, respectively. A QPI ≤ 2 at 72 h showed a specificity of 100% (95%CI [40–100]%) and a sensitivity of 65% (95%CI [44–84]%). QPI and NPi showed a strong correlation over time ($r = 0.69$; $r = 0.66$ and $r = 0.66$ for 24, 48, and 72 h, respectively; $p < 0.001$).
**Conclusions:** In our study, QPI showed a good prognostic value in unconscious patients after cardiac arrest.

**Topic:** Cardiac arrest

### GPICS audit: speech and language therapy provision in a tertiary ICU setting

M. Papadaki, S. Oliver, F. Daniela
Speech and Language Therapy, Barking, Havering and Redbridge University Hospitals Nhs Trust, London, United Kingdom
**Correspondence:** M. Papadaki
*Intensive Care Medicine Experimental* 2024, **12(suppl 1):**000540

**Introduction:** People with intensive care needs who have difficulty with communication and/or swallowing require timely access to a Speech and Language Therapy (SLT) service. SLT assessment and intervention address the increasingly complex communication, swallowing, and tracheostomy weaning needs of patients. SLT is essential for performing instrumental assessments, such as Flexible Endoscopic Evaluation of Swallowing and videofluoroscopy, guiding timing for oral intake, early identification of laryngeal injuries, advising on speaking valve use, and contributing to weaning assessments and specialist tracheostomy tube selection.
**Objectives:** 1. To outline specific SLT standards and recommendations. 2. To measure any improvements or regression in compliance and analyse reasons for this. 3. To develop an action plan from the findings of the audit with a view to achieve overall improved compliance. 4. To motivate for additional resources and funding should the findings indicate that this would be beneficial to meeting standards and a greater compliance with recommendations.
**Methods:** Retrospective data were used in this audit to measure compliance. This included retrospective review of Careflow Connect data (a private, online robust network that stores patient information).

- The GPICS V2 Audit Toolkit was used to audit data.
- The patient list included all patients admitted to six critical care units across two hospital sites from January until August 2023.
- Information regarding availability of SLT over the audit period was established using local electronic rostering records and team annual leave calendars.
- Critical care discharge proformas were screened via Careflow to identify documentation of SLT handover when stepping down from a critical care unit.
- SLT's own clinical awareness was used to measure compliance where appropriate.

**Results:** GPICS Standards 1 and 2 were met, standard 3 was partially met, and standard 4 was not met due to the rotational aspect of one of the posts. Recommendations 2 and 3 were met due to the introduction of communication stations across our units ensuring patients and staff always have access to low-level communication resources. Recommendations 4, 5, and 6 were partially met, while recommendations 1 and 7 were not met. Without further increase in staffing levels, it is unlikely to have a positive change in the GPICS recommendations.
**Conclusions:** The outcomes of the GPICS audit 2023 conducted at BHRUT showed an overall partial compliance with standards and recommendations. This is a positive outcome overall to what is an ever-growing, evidence-based, patient-centred SLT service in our critical care and high dependency units.
Although there are greater factors out of the control of the SLT team such as financial constraints, a number of areas for service development have been identified and will be the focus with the aim of improving overall GPICS compliance and patient service provision in critical care.

### The importance of focused organ donation education and scope for improvement: An educational quality improvement project in a single centre District General Hospital (DGH) Intensive Care Unit (ICU)

J. Harding, J. Herzig, A. Myers, T. Samuels
Intensive Care Unit, East Surrey Hospital, Redhill, United Kingdom
**Correspondence:** J. Harding
*Intensive Care Medicine Experimental* 2024, **12(suppl 1):**000541

**Introduction:** Experience of training in organ donation varies greatly amongst ICU staff. Lack of education in this area has been shown to be a barrier to donation (1). By collating the views of staff on the ICU we aim to ascertain baseline understanding to tailor our education programme to the specific needs of the department.
**Objectives:** To investigate the impact of previous education and identify areas and methods of teaching to focus on in future training events.
**Methods:** An anonymous survey was sent to all nurses and doctors in ICU with a combination of multiple-choice questions, Likert scale rated questions, and free text questions.
Inferential statistics were produced using Fisher's exact test. All analyses were performed using R (version 4.3.2). Themes were extracted from the free text questions.
**Results:** 25 people responded to the questionnaire, with an even distribution of job roles and ICU experience. 48% of staff reported having had less than 2 h of formal training. This was higher for doctors than nurses (62% vs 31%, $p > 0.05$).
Respondents reported good theoretical knowledge of the donation process. Around 70% of respondents reported understanding how the 'opt out' scheme works, solid organ donation vs tissue donation, and donation after brain death vs donation after circulatory death.
60% of respondents reported feeling confident (answering agree or strongly agree) in when to refer patients for donation, with strong positive association with previous ICU experience ($p = 0.005$) and previous formal training ($p = 0.01$). Confidence was lower for management of patients after referral, with just 48% of respondents reporting feeling confident, again with strong positive association to previous formal training ($p = 0.02$). Just 24% of respondents reported feeling confident discussing donation with next-of-kin, and this was strongly associated with amount of formal training ($p = 0.0002$). For both questions with low confidence, association with training was stronger than association with ICU experience.

96% of respondents reported that they believed future training would be helpful. The most popular teaching format was interactive teaching in discussion-based sessions, with lecture-based sessions, simulation sessions and observation of the process also suggested. Popular topics were communication with next-of-kin and pre-operative optimization.
**Conclusions:** In general, the strongest association with staff confidence is with the amount of formal training received, with more training resulting in higher confidence.

Going forward, discussion-based teaching and simulation sessions should be included in the formal teaching programme. These are great methods for teaching topics, such as communication with next-of-kin and pre-operative management of patients (2).
More and consistent training is needed for all staff, but particularly doctors. It may be helpful to include a session on organ donation in departmental induction, as doctors rotate frequently and may otherwise miss formal teaching sessions.

### Hemoadsoption in rhabdomyolysis exploring the prognostic role of proenkephalin

L. Lovin[1], A. M. Cotae[1], C. Cobilinschi[1], R. Ungureanu[1], I. M. Grintescu[1], R. Ene[2], L. Mirea[1]
[1]Anesthesiology and Intensive Care I, Clinical Emergency Hospital, Bucharest, Romania; [2]Orthopaedics and Traumatology II, Clinical Emergency Hospital, Bucharest, Romania

*Intensive Care Medicine Experimental* 2024, **12(suppl 1):**000542

**Introduction:** Rhabdomyolysis (RM) is a severe clinical condition characterized by the breakdown of skeletal muscle fibers, leading to the release of intracellular contents into the bloodstream, including myoglobin (Mb), creatine phosphokinase (CK), and electrolytes. The resultant systemic effects like acute kidney injury (AKI) pose a significant challenge. In acute clinical settings, assessing kidney function on urine output, creatinine clearance, or Mb can cause delays in initiation of continuous renal replacement therapy (CRRT). A lot of research has been done on proenkephalin A 119–159 (PENK) as a novel kidney function biomarker.
**Objectives:** This article aims to assess the role of PENK in initiation of hemoadsorption for RM induced AKI. PENK is a freely filtered peptide that seems to correlate with glomerular filtration rate (GFR) [1]. High plasma PENK levels can be a sensitive biomarker for AKI and a risk factor for poor outcomes in critical illness and chronic kidney disease [1]. While high-volume hemofiltration is less accessible in acute clinical settings, CRRT with the addition of a hemoadsorber is easy, readily available and more efficient in elimination of Mb or CK [2].
**Methods:** This is a case series of 4 patients admitted to the intensive care unit (ICU) with RM following either crush syndrome (2 patients) or severe electrical injury (2 patients). We wanted to assess patients with a high risk factor for AKI that may benefit from early initiation of CRRT. CRRT with CytoSorb (CS) hemoadsorption was initiated in the first 4 h after ICU admission. In individuals with severe RM, CS may have a favorable impact on renal recovery. Removing musche cell waste products is essential to reduce the frequency and severity of AKI.
**Results:** All patients were admitted to ICU with a mean CK level of 116.940 U/L (86.006–149.021U/L) and were tested for plasma PENK with values over the established cut-off [3]. Two patients required emergency surgery for lower limb fasciotomy and one for upper limb amputation, respectively. The mean duration on CRRT was 36 h and significant improvement of RM syndrome was obtained with a mean reduction in CK levels after 48 h from admission of 87.25% (CK levels at 48 h: 5.415–27.629 U/L).
**Conclusions:** In comparison with currently available biomarkers, plasma PENK may be an accurate marker for early detection of AKI and is linked to accurate prediction of decline in renal function. Plasma PENK values measured on a point-of-care device may be especially helpful for critically ill patients with swiftly altering kidney function. This study confirms our belief that the adsorber should be installed as soon as possible to remove Mb and CK, and prevent ongoing renal failure.

### Impact of ambient air pollution on COVID-19 patients with shock: a multicenter retrospective study

S. Y. Chan[1], S. Kim[2]
[1]Department of Internal Medicine, The Catholic University of Korea, Yeouido St. Mary's Hospital, Seoul, Republic of Korea; [2]Division of Pulmonary, Allergy and Critical Care Medicine, Department of Internal Medicine, Yeouido St. Mary's Hospital, Seoul, Republic of Korea
**Correspondence:** S. Kim
*Intensive Care Medicine Experimental* 2024, **12(suppl 1):**000543

**Introduction:** Exposure to ambient air pollution has been associated with an increased risk of pneumonia, acute respiratory failure, or mortality (1, 2). Given the global pandemic of COVID-19 and its primary manifestation as a respiratory illness, understanding the relationship between air pollution and disease outcomes is crucial.
**Objectives:** To investigate the impact of ambient air pollution on the respiratory failure and mortality of COVID-19 patients presented with shock.
**Methods:** This multicenter, retrospective study was conducted using data from the Clinical Data Warehouse (CDW) of the Catholic Medical Center. Medical records of adult COVID-19 patients admitted to 8 university hospitals between January 2020 and December 2022 were extracted. Regional air pollutant levels of sulfur dioxide (SO2), carbon monoxide (CO), nitrogen dioxide (NO2), and particulate matters (PM10 and PM2.5) in South Korea were extracted from AIRKOREA data repository (www.airkorea.or.kr). Based on the hourly measured values, 3-day, 6-week, and 3-year mean averages of each air pollutant level were calculated and were matched to the patients' data according to their residential address. Meteorological factors, such as temperature, wind speed, and humidity, which were extracted from the Open Meteorological Data Portal, provided by the Korea Meteorological Administration Weather Data Service (https://data.kma.go.kr), were adjusted in the multivariable analyses. We represented the odds ratio by comparing the 4th quartile of each air pollutant exposure to the 1st quartile.
**Results:** Among 4,103 patients, we included 502 patients with shock, which was defined as starting of vasoactive drugs within 48 h. The median age was 75 years [IQR, 64.25–82.00], and 200 (39.84%) patients were female (Table 1). Of these, 244 (48.61%) patients started mechanical ventilation within 7 days, and the 30-day mortality rate

was 41.64%. The air pollutants significantly associated with respiratory failure within 7 days were the 3-day averages of CO and NO2 (Table 2; OR 2.45, 95% CI 1.22–4.92, $p = 0.0114$, and OR 5.11, 95% CI 2.34–11.19, $p < 0.0001$, respectively), and the 3-year averages of NO2 (OR 2.99, 95% CI 1.34–6.67, $p = 0.0073$). The 3-day averages of NO2, 6-week averages of CO, and 3-year averages of PM10 were associated with an increased risk of 30-day mortality (Table 3; HR 2.34, 95% CI 1.29–4.24, $p = 0.0053$; HR 3.65, 95% CI 1.27–10.49, $p = 0.0164$; and HR 1.79, 95% CI 1.03–3.12, $p = 0.0390$, respectively).

**Conclusions:** Short-term exposure to CO and NO2 levels was associated with an increased risk of respiratory failure within the first week in COVID-19 patients with shock. Short-term NO2 and intermediate-term CO exposure levels were also associated with 30-day mortality. Higher long-term exposure to PM10 showed an association with increased 30-day mortality.

**Introduction:** Compared to early strains, the Omicron variant exhibits a significant reduction in the severity [1]. Exploring the specific mechanisms behind the reduction in the severity of Omicron variant will contribute to investigating effective approaches for preventing and treating severe complications triggered by viral infections [2]. It will also provide a theoretical basis for the establishment of a real-time monitoring system for the virulence of future COVID-19 mutant strains, allowing for a more comprehensive understanding of viral

evolution and the formulation of corresponding prevention and control strategies.
**Objectives:** To clarify the cellular and molecular mechanisms underlying the reduction in the severity of Omicron infection.
**Methods:** To explore the unique immune characteristics of severe patients infected with the Omicron variant, single-cell RNA sequencing (scRNA-seq) was performed on bronchoalveolar lavage fluid (BALF) from severe Omicron patients and healthy volunteers. The sequencing data were combined with publicly available scRNA-seq data from severe patients infected with the wild-type strain to analyze the specific differences between Omicron severe patients and wild-type strain-infected severe patients. After identifying the key cells responsible for the decrease in Omicron severity, pbmc-derived macrophages and PMA-induced THP1 cell lines were infected with different titers of the wild-type strain and Omicron variant in the BSL-3 laboratory. RT-PCR, RNA-Scope, and immunofluorescence were conducted to assess the differences in infectivity of different strains in macrophages. Western Blot and Elisa were used to detect differences in pyroptosis levels in macrophages infected with different strains, and a stable cell system expressing different encoded proteins from the wild-type strain and Omicron variant was constructed to clarify the specific mechanisms underlying the differences in pyroptosis levels.
**Results:** Integrated scRNA-seq data showed that the number of macrophages in the BALF of Omicron severe patients was significantly reduced compared with the wild-type strain. The Omicron variant exhibited weakened infectivity towards macrophages compared to the wild-type strain but significantly enhanced pyroptosis levels. Further research revealed that the pyroptosis of macrophages induced by Omicron was mainly mediated by the NLRP3 inflammasome pathway. By constructing a stable cell system expressing different encoded proteins from the wild-type strain and the Omicron variant, we found that the difference in pyroptosis levels was caused by proteins other than the S protein.
**Conclusions:** The Omicron variant exhibits reduced ability to attack macrophages compared to the wild-type strain but can induce strong pyroptosis, which may be an important factor underlying the reduction in the severity among Omicron-infected patients.

**Introduction:** Osmotic therapy plays a crucial role in managing cerebral edema, yet optimal timing, dosage, and administration frequency lack quantitative clinical guidance. Decisions for osmotic therapy are often based on intracranial pressure (ICP) values but also on pupillary asymmetry.
**Objectives:** To investigate whether osmotic therapy improved the Neurological Pupil Index (NPi), obtained via an automated pupillometry, in acute brain injured patients.
**Methods:** Retrospective analysis of prospectively collected data of acute brain injured patients admitted to the Intensive Care Unit (ICU) and requiring ICP monitoring. The lowest NPi measured before and within 2 h after the administration of either 20% mannitol (1 g/Kg) or 4% hypertonic saline (HTS) was used for the analysis. Neurologic Pupil Index is a composite metric ranging from 0 to 5, with > 3 indicating normal. Repeated measurements were analyzed using Wilcoxon signed-rank tests.
**Results:** Among 18 patients (traumatic brain injury, $n = 10$, cerebrovascular diseases, $n = 8$—median age 42 [32–61] years), 172 osmotic therapies were administered during the ICU stay ($n = 149$, 86.6% being HTS). Median ICP values significantly decreased after osmotic therapy (from 16 [13–20] to 14 [11–18] mmHg; $p < 0.001$). Also, NPi values significantly increased after osmotic therapy (from 4.1 [3.8–4.5] to 4.2 [3.7–4.6]; $p = 0.003$). This effect was similar regardless of ICP values prior to the intervention. However, the largest improvement in NPi values was observed in patients with baseline NPi 3 (from 1.0 [0.0–2.5] to 2.3 [1.3–3.5]; $p < 0.001$).
**Conclusions:** In this study, NPi improved following osmotic therapy in acute brain injured patients, in particular when pupillary function was altered prior to the intervention.

**Introduction:** Subarachnoid hemorrhage (SAH) is a devastating condition associated with cerebral and systemic inflammation. The prognostic role of systemic inflammatory biomarkers such as C-reactive protein (CRP) and the neutrophil-to-lymphocyte ratio (NLr) have been studied in different pathologies such as sepsis or oncological conditions, but their role as prognostication markers after SAH has been poorly studied.
**Objectives:** To assess the prognostic role of CRP and NLr in non-traumatic SAH.
**Methods:** A retrospective single-center study of adult patients admitted with non-traumatic SAH to the intensive care unit (ICU) of a University Hospital from 2007 to 2023. Baseline information, clinical data, radiologic data, the occurrence of neurological and infective complications, as well as serum CRP and NLr levels during the first 7 days of ICU stay were collected. Unfavorable neurological outcome (UO) at 3 months was defined as a Glasgow Outcome Scale (GOS) of 1–3.
**Results:** Five hundred and forty-seven patients were included; 250 (45.7%) experienced UO. The highest serum CRP values during the first 7 days of ICU stay were significantly higher in patients with UO when compared to others (130 [56–220] vs 45 [20–100] mg/dl, $p > 0.001$). The highest NLr during the first 7 days of ICU was also significantly higher in patients with UO when compared to others (12.2 [7.9–17.6] vs 8.7 [5.2–13.4], $p > 0.001$). In the multivariate logistic regression model, the highest CRP value (OR 1.003 [95% CI 1.001–1.005]) was independently associated with the occurrence of UO, while the highest NLr (OR 1.020 [95% CI 0.994–1.041]) was not.
**Conclusions:** High CRP values had a significant prognostic value in SAH patients.

**Introduction:** Diurnal variation of analgosedation doses may worsen patient outcomes, including poor sleep quality, increased risk of failed spontaneous breathing trials, prolonged mechanical ventilation, prolonged coma, and delirium. Limited data describe factors associated with diurnal analgosedation drug dose variations in mechanically ventilated patients, particularly for those needing extracorporeal membrane oxygenation (ECMO).
**Objectives:** Our objective was to explore such factors comparing patients receiving ECMO with patients ventilated without ECMO.
**Methods:** We conducted a retrospective observational cohort of patients admitted to 5 Intensive Care Units (ICUs) including a commissioned ECMO unit (July 2021 to July 2023) at a tertiary academic centre in London, England. We collected data on all intravenous analgosedation (fentanyl, midazolam, and propofol) dosing commencing from the next 07:00 to 19:00 (day) or 19:01 to 06:59 (night-time) timepoints (whichever earliest) excluding bolus doses in the following 48 h. We generated multi-variable linear regression models for diurnal analgosedation dose variation with demographic and clinical independent variables selected a priori based on expert opinion and existing evidence.
**Results:** We included 1277 patients. Most patients were male (63.8%), median (IQR) age 58 (42–70) years; most common diagnosis cardiovascular failure (37.9%). Of these, 166 (12.9%) received ECMO support for a median (IQR) duration of 10 (6–20) days. Median (IQR) diurnal analgosedation dosing variation in ECMO vs non-ECMO patients for fentanyl and midazolam was 0 (−350 to 450) vs −60 (−675 to 300) micrograms ($p < 0.001$); 0 (−38 to 36) vs 6 (−23 to 30) milligrams ($p = 0.123$), respectively. Median (IQR) diurnal analgosedation dosing variation in ECMO vs non-ECMO patients for propofol was 60 (−300 to 480) vs −100 (−630 to 260) milligrams ($p < 0.001$).
In our multivariable linear regression models, we observed no diurnal variation associations with fentanyl and midazolam but did identify an association with lower night-time propofol doses with ECMO (216.41; 95% CI 108.45, 324.36). We also observed that higher night-time fentanyl doses was associated with older age (−5.17; 95% CI −7.53, −2.81) and lower night-time fentanyl dose with higher APACHE II (Acute Physiology and Chronic Health Evaluation) score (9.91; 95% CI 3.73, 16.07); higher night-time midazolam dose with higher admission SOFA (Sequential Organ Failure Assessment) score (−1.59; 95% CI −2.92, −0.25); lower night-time propofol dose with higher APACHE II score (6.35; 95% CI 0.56, 12.14). ICU mortality was 19.7%.
**Conclusions:** This study confirmed that there was no diurnal variation associated with ECMO for fentanyl and midazolam dosing but did identify an association with lower propofol dosing overnight in ECMO patients. Other variables associated with diurnal drug dose variation were age, APACHE II score, and SOFA score.

### RésiRéa study: identifying the factors involved in the resilience of intensive care patients

A. Mathieu[1], J. Reignier[2], A. Le Gouge[3], C. Vinsonneau[4], A. Laurent[5]
[1]Psychology, University of Burgundy, Dijon, France; [2]Médecine Intensive Réanimation, Nantes University Hospital Hotel-Dieu, Nantes, France; [3]Statistic department, Chru Hôpitaux De Tours, Hospital Bretonneau, Tours, France; [4]Intensive Care Unit, Hospital Center of Béthune Beuvry, Beuvry, France; [5]Psy-DREPI, University of Burgundy, Dijon, France
**Correspondence:** A. Mathieu
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000549

**Introduction:** The extreme intensity and suddenness of intensive care is a real somatic and psychological catastrophe for the patient and constitutes a major risk factor for psychological trauma. Resilience, which has been little studied in intensive care, is a dynamic phenomenon which involves adapting to traumatic situations by mobilising resources both internal and external to the individual to bounce back. In this context, the study of the resilience process represents a major challenge in reducing psychotraumatic disorders and improving patient support.
**Objectives:** The aim of this study is to gain a better understanding of the factors that promote or inhibit the resilience process in patients during and following their stay in intensive care.
**Methods:** In addition to the NUTRIREA-3 study, RésiRéa is a prospective, longitudinal study involving 42 intensive care units in France. At two different moments (3 months and 1 year after resuscitation),

patients hospitalised in a critical condition were asked to respond to 5 scales, including one assessing post-traumatic stress (IES-R) and resilience (CD RISC). Of the 380 patients included, 42 randomly identified patients underwent a semi-structured interview recorded by telephone 1 year after their hospitalisation. The interviews addressed 3 main themes: the experience of resuscitation and post-resuscitation, the difficulties encountered throughout the care pathway, and the coping skills and solutions found to overcome the difficulties. The interviews were transcribed and analysed using Nvivo software to produce a thematic analysis.
**Results:** The sample of 42 patients was made up of 19 women and 23 men. Of these patients, 52% presented significant psycho-traumatic symptoms between 3 months and 1 year after discharge. The patient's resilience is built up over 3 phases: resistance, reconstruction of identity, and a new sense of the experience. There are also factors that favour the resilience process, such as social support, knowledge of one's pathology or fighting spirit, and others that inhibit it, such as isolation, lack of verbalization, or incomplete recovery.
**Conclusions:** These results allow us to identify a model of resilience specific to the intensive care patient. This model can be used to inform the professionals involved in the patient's care of the factors which contribute to the development of resilience and reduce the risk of the psychological trauma becoming chronic.

*Intensive Care Medicine Experimental* 2024, **12(suppl 1):**000550

**Introduction:** Histopathological characterization obtained by transjugular liver biopsy (TJLB) may theoretically contribute to clarification of the exact aetiology of acute liver failure (ALF). However, it is unclear if the histopathological information obtained by performing TJLB is able to significantly contribute to diagnosis of ALF aetiology, therapeutic decision-making, and prediction of overall prognosis.
This study aimed to analyze safety and clinical significance of TJLB in patients with ALF.
**Methods:** This retrospective, monocentric study investigated safety and efficacy of TJLB in patients with ALF over a 10-year period at a large transplant-center. The predictive value of various clinical and laboratory characteristics as well as histopathological findings obtained by TJLB on the primary endpoint, 28-day liver-transplant-free survival, were evaluated by calculating uni- and multivariate Cox-proportional hazard regression models. Additional univariate logistic regression analyses were performed to explore the influence of degree of intrahepatic necrosis on the secondary endpoints intensive-care-unit (ICU) admission, need for endotracheal intubation, renal replacement therapy, and high-urgency listing for LTX.
**Results:** A total of 43 patients with ALF receiving TJLB were included into the study. All patients had manifest hepatic encephalopathy at the time of biopsy and 17 (39.5%) patients were already admitted to the ICU. TJLB was performed safely in all patients, but in the majority of cases, the biopsy only confirmed the initially already presumed ALF aetiology ($n = 41/43$ cases), and a change in specific therapeutic approach could be noted in none of the patients. None of the Ishak subscore categories showed a predictive value on liver transplant-free survival. While the majority of 31 patients (72%) had significant intrahepatic necrosis according to the Ishak score, the exact histopathological degree of intrahepatic necrosis in the TJLB specimen varied substantially in individual patients [Median (IQR): 60% (10–90)]. While the degree of intrahepatic necrosis showed significance in the univariate analysis ($p = 0.04$), it did not demonstrate a significant predictive effect on liver transplant-free survival in the multivariate analysis. Extent of intrahepatic necrosis was neither associated with later need for intubation and invasive ventilation, RRT or HU listing for LTX. Only consecutive ICU admission was more likely with higher extent of intrahepatic necrosis [Odds ratio (OR) 1.04 (95% CI 1–1.08), $p = 0.046$].
**Conclusions:** TJLB in ALF was safe but rarely led to a change in suspected diagnosis or significant change in therapeutic measures, suggesting that clinical assessment alone was often accurate and that additional histopathological findings served to rather confirm than substantially alter treatment planning. Future prospective studies could help to clarify the role of TJLB in the diagnostic and therapeutic approach of ALF.

*Intensive Care Medicine Experimental* 2024, **12(suppl 1):**000552

**Introduction:** The efficacy of invasive mechanical ventilation (IMV) in managing acute respiratory distress syndrome (ARDS) secondary to COVID-19 (C-ARDS) among patients aged over 75 with severe disease remains uncertain. This study aims to assess the healthcare costs for this demographic and evaluate the effectiveness of IMV in the older population in terms of hospital mortality.
**Objectives:** To describe the costs of care for patients over 75 years old with severe ARDS and to evaluate the risk factors associated with in-hospital mortality in this population.
**Methods:** Observational retrospective cohort study, encompassing all patients aged 75 or older diagnosed with severe C-ARDS and admitted between March 2020 and July 2021. The costs were measured in Colombian pesos; results are presented in dollars (1 US dollar = $4,000 Colombian pesos, the average representative rate for the study's development stage).
**Results:** The final analysis included 530 patients, with a median age of 81 years (interquartile range [IQR] 77–85), and recorded 397 deaths (75%). The average cost per patient was $4,955 standard deviation [SD] $5,600; 95% confidence interval [CI] $4,480 to $5,430). For patients undergoing IMV, the average cost was $8,630 (SD $6,532; 95% CI $ 8,073 to $ 9,186), significantly higher than $ 2,026 (SD $1,850; 95% CI $1,868 to $ 2,183) for those managed with alternative oxygen administration systems ($p < 0.000$). The average cost difference was $ 6,604 (95% CI $5,742 to $7,465, $p < 0.000$) (Table 1). Invasive mechanical ventilation was presented as the higher risk factor for in-hospital mortality (OR 3.88 CI 1.99 to 7.57, $p < 0.000$) Figure 1. The hospital mortality rate was notably higher in the IMV group compared to the other oxygen administration system group, with a difference of 13.8% (82.6% vs. 68.8%, 95% CI 6.6% to 20.9%, $p < 0.000$) Table 2.

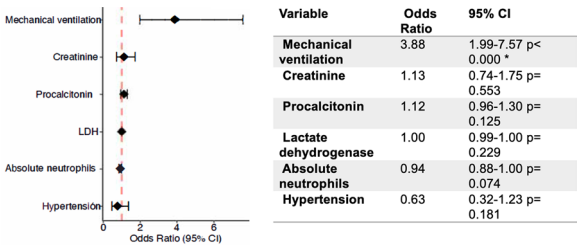
**Table 1 (abstract 000552)** Severe ARDS patient costs over 75 years in dollars

| Severe ARDS patient costs over 75 years in dollars | | | | | | | |
|---|---|---|---|---|---|---|---|
| | Total, patients ($n=530$) | | Survivors upon discharge ($n=133$) | | Deceased ($n=397$) | | Difference |
| | Average | Standard deviation | Average | Standard deviation | Average | Standard deviation | |
| Total cost | $4.955 ([CI] 95% $4.480–$5.430) | $5.600 | $5.860 ([CI] 95% $4670–$7049) | $6.997 | $4.652 ([CI] 95% 4155–$5148) | $5.051 | $1.208 ([CI] 95% $−80.76–2496) p = 0.066 |
| Severe ARDS patient costs over 75 years in dollars | | | | | | | |
| | Total, patients ($n=530$) | | Ventilated ($n=235$) | | Non-ventilated ($n=295$) | | Difference |
| | Average | Standard deviation | Average | Standard deviation | Average | Standard deviation | |
| Total cost | $4.955 ([CI] 95% $4.480–$5.430) | $5.600 | $8.630 ([CI] 95% $8.073–$9.186) | $6.532 | $2.026 ([CI] 95% $1.868–$2.183) | $1.850 | $6.604 ([CI] 95% $ 5.742–$7.465) $p < 0.0000$ |

**Table 2 (abstract 000552)** Difference in the proportion of hospital mortality between the IMV group and the other oxygen administration system group

| | Survivors | Deceased |
|---|---|---|
| Invasive mechanical ventilation | 41 (17.4%) | 194 (82.6%) |
| Not ventilated | 92 (31.1%) | 203 (68.8%) |
| Average proportion difference | 13.7%([CI] 95% 6.5%-20.9%, $p < 0.000$) | 13.8% ([CI] 95% 6.6%-20.9%, $p < 0.000$) |

**Conclusions:** The decision to utilize IMV in severe C-ARDS patients aged over 75 should be individualized due to its potential association with increased in-hospital mortality. Moreover, IMV was found to substantially escalate healthcare costs by over fourfold.



| Variable | Odds Ratio | 95% CI |
|---|---|---|
| Mechanical ventilation | 3.88 | 1.99-7.57 p< 0.000 * |
| Creatinine | 1.13 | 0.74-1.75 p= 0.553 |
| Procalcitonin | 1.12 | 0.96-1.30 p= 0.125 |
| Lactate dehydrogenase | 1.00 | 0.99-1.00 p= 0.229 |
| Absolute neutrophils | 0.94 | 0.88-1.00 p= 0.074 |
| Hypertension | 0.63 | 0.32-1.23 p= 0.181 |

**Fig. 1 (abstract 000552)** Multivariate analysis presenting the odds ratio (OR) for each covariate showed that the only significant OR was the use of invasive mechanical ventilation, with a value of 3.88 ([CI] 95% 1.99–7.57, $p < 0.000$). LDH = Lactate dehydrogenase

### Influence of patient age and gender on alarm-threshold changes in the intensive care unit: a retrospective observational study

**Introduction:** Bedside monitoring is crucial for the early identification of acute critical events characterised by abnormalities in vital signs, such as heart rate, blood pressure, and oxygen saturation. Alarm thresholds are set by medical personnel based on their experience and patient assessment, affecting overall alarm load [1, 2]. Nevertheless these threshold-based alarms, which are not automatically aligning with patient physiology, result in a high number of false-positive alarms. Previous research has shown that an excessive frequency of alarms contributes to "alarm fatigue" [3], which adversely affects patient safety [4]. This raises the question to which a patient's characteristics influence the threshold changes made by the operator and the resulting alarm load.
**Objectives:** Our aim is to analyze how different characteristics influence the amount of threshold changes and alarm load.
**Methods:** Following IRB approval (Ethics vote no. EA1/127/18), this retrospective analysis included adult patients admitted to a German ICU between July 2019 and June 2021, who stayed at least 24 h with annotated alarm data [5]. To ensure data quality and minimize the impact of extreme observations, we conducted outlier detection using Z-scores for the daily alarm load. Data points with a Z-score exceeding 3 or less than -3 were considered outliers and excluded from the analysis, resulting in a removal of 36 patients. In this study, we analyzed data from bedside monitors recording heart rate, blood pressure and oxygen saturation. The dataset provided details of a total of 318 180 alarm threshold changes for 1101 different patients with a total alarm load of 1 389 757 alarms. We defined 'alarm load' as the cumulative number of alarms triggered. The primary endpoint of this study is the frequency of threshold changes in different gender and age groups. In addition, the temporal pattern of these threshold adjustments in relation to patients' ICU admission were examined. Furthermore, the analysis aimed to reveal the distribution of total alarm incidence across gender and age groups compared to the threshold changes. Given the high volume of alarms, we opted for descriptive analysis over hypothesis testing, examining trends in thresholds and alarm rates by demographic and post-admission intervals.
**Results:** A breakdown of the threshold changes by physiological parameters reveals that 33 620 were related to heart rate (10.6%), 236 322 to blood pressure (74.3%) and 48 238 to oxygen saturation (15.2%). The mean age of the patient population was calculated to be 69.8 years with an average length of stay of 28.5 days. On average, each patient was associated with 1373.8 alarms and underwent 283.3 Threshold adjustments.

Further analysis reveals that older patients experience significantly more alarms and threshold adjustments. For example the age group 90–99 has on average 54.4% more threshold changes and 85.5% additional alarms compared to the age group 20–29. Furthermore, the data show a peak in both threshold changes and alarms on the second day after admission, indicating the most critical period for patient monitoring before a subsequent decline.

**Conclusions:** This study investigates the alarm load and threshold changes of blood pressure and heart rate parameters on an ICU of a large German University Medical Center. It turned out that older patients have a higher alarm load and undergo more frequent threshold changes, especially notable on the second day after admission. This indicates that the threshold values should be set more carefully, especially in older patients, to reduce the majority of the alarm load. The analysis shows that the second day after admission is particularly relevant for achieving this. Further research is needed to understand whether alarm thresholds are initially set inefficiently, particularly in older people, and whether better alarm threshold management can reduce the alarm load.

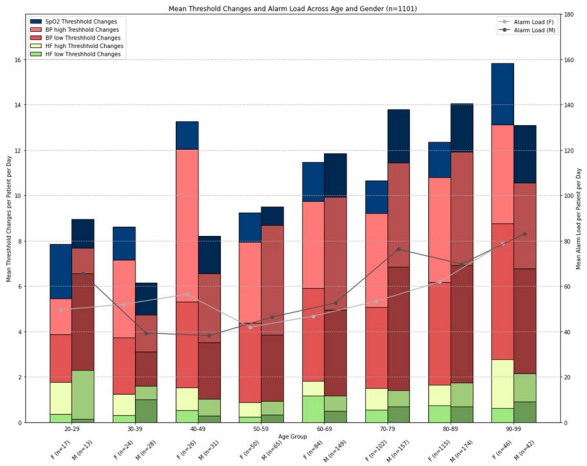

**Fig. 1 (abstract 000553)** Distribution of threshold changes and alarm load stratified by gender (F: female, M: male) and age (decade of life). Threshold changes are summarized for vital sign parameters routinely monitored on intensive care units: Blood Pressure (BP), Heart Frequency (HF), and Oxygen Saturation (SpO2). Alarm load is defined as the cumulative number of alarms triggered by deviations from preset parameter thresholds

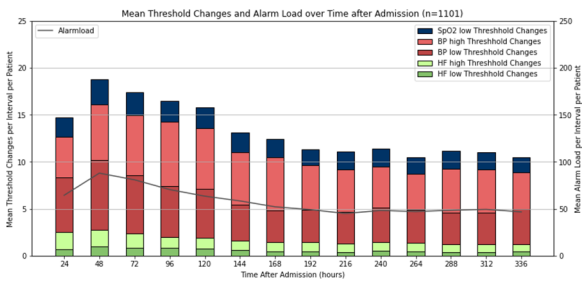

**Fig. 2 (abstract 000553)** Distribution of threshold changes and alarm load segmented into 24-h intervals following a patient's admission to the ward. Threshold changes are summarized for vital sign parameters routinely monitored on intensive care units: Blood Pressure (BP), Heart Rate (HF), and Oxygen Saturation (SpO2). Alarm load is defined as the cumulative number of alarms triggered by deviations from preset parameter thresholds

**Introduction:** Extracorporeal membrane oxygenation (ECMO) is increasingly employed to support patients with massive pulmonary embolism (PE) (1,2). However, the additional role of endovascular therapies (ET) (catheter-directed thrombolysis or thrombo-aspiration) to anticoagulation alone in patients receiving ECMO is unclear (3–5).

**Objectives:** Compare patients on ECMO for massive PE receiving ET and patients managed with anticoagulation alone.

Our primary outcome was reduction in vasoactive-inotropic score. Secondary outcomes and measures were changes in lactate concentration and right-ventricular function. We also report ICU mortality and complications.

**Methods:** Retrospective cohort study of patients presenting with massive PE to two high-volume ECMO centers in London, UK between 2014 and 2024. Patients receiving ET procedures (intervention group) were compared to those receiving anticoagulation alone (control group). Longitudinal physiological, echocardiographic, and radiographic data were extracted, including lactate, vasoactive-inotropic score (VIS), echocardiographic parameters, and clot burden at CT scan (6).

**Results:** We identified 26 patients receiving ECMO for massive PE. Sixteen patients (62%) underwent ET procedures, of whom 9 (56%) received USAT (ultrasound-accelerated catheter directed

thrombolysis), 4 (25%) received thrombo-aspiration, and 3 (19%) received both. Ten patients (38%) received anticoagulation alone.
There were no significant differences in baseline characteristics between groups (Table 1). Both groups demonstrated improvement in VIS, lactate, RV:LV ratio, TAPSE, EtCO2/PaCO2, and clot burden on CT (Figures 1 and 2). There were no differences between groups in the rate of improvement for any parameter. There was no difference in mortality between groups [31% for intervention group, 40% for controls ($p = 0.69$)] or complications.
**Conclusions:** In patients receiving ECMO for massive PE, endovascular treatment did not result in faster resolution of shock of right-ventricular function. The role of ET in this population supported by ECMO warrants further investigation.

| Baseline characteristics | Control (n=10) | Intervention (n=16) | p-value |

### Early administration of intravenous hydrocortisone prevent septic encephalopathy in patients admitted for sepsis: a randomised controlled study

M. Benlabed[1], S. Benlabed[2], R. Gaudy[3], A. Ladjouze[4]
[1]Anesthesiology, University of Lille, Lille, France; [2]Erasme Hospital, Université Libre de Bruxelles, Bruxelles, Belgium; [3]Anesthesiology and intensivecare, University of Lille, Lille, France; [4]Anesthesiology, Algiers University, Algiers, Algeria
**Correspondence:** M. Benlabed
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000557

**Introduction:** Some authors [1] investigated the effect of intravenous hydrocortisone (HC) on rats with septic encephalopathy (SE) and observed a significant improvement of brain injury. Therefore, we hypothesized that early administration of intravenous hydrocortisone in patients with sepsis [2] could prevent the incidence of SE.
**Objectives:** To evaluate the early intravenous (IV) administration of hydrocortisone on the incidence of SE, in patients with sepsis, from the first hour of ICU admission.
**Methods:** We enrolled 60 patients, 62 + −10 years old with sepsis admitted in ICU department of university hospital between 2017 and 2019.
All the patients had the same severity scores on admission, and were conscious with Glasgow score of 15, breathing spontaneously, hemodynamically stable, without signs of SE.
The patients were randomised into 2 groups of 30:
**The hydrocortisone group** (HC) receiving from the first hour of ICU admission a total dose of IV 200 mg HC spread over 24 h with boluses of 50 mg every 6 h and during 3 days.
**The control group** receiving saline as placebo with the same protocol as HC.
We recorded in the 2 groups the incidence of SE as delirium, agitation, epilepsy crisis or coma, Glasgow score every day, SOFA score day 1 and day 4, mean arterial pressure, blood lactate, C-reactive protein, the incidence of mechanical ventilation, ICU stay, hospital length of stay, and 28 day mortality.
**Results:** Statistical analysis used Mann–Whitney test and results expressed as Mean + -STD deviation.

**Table (abstract 000557)** Variables in relation with outcome in hc and control group

| Control group | | HC group | *P* |
|---|---|---|---|
| SE incidence % | 30% | 5% | 0.001 |
| MAP mmHG | 65 + −5 | 79 + −4 | 0.03 |
| LACTATE mmol/l Day1 | 3.1 + −0.2 | 2.8 + −02 | 0.12 |
| GLASGOW SCORE Day 4 | 10 + −2 | 15 + −1 | 0.001 |
| SOFA score day4 | 7 + −0.2 | 3 + −0.3 | 0.003 |
| ICU STAY (days) | 15 + −3 | 10 + −2 | 0.001 |
| 28 Day mortality | 50% | 25% | 0.001 |

**Conclusions:** We observed that hydrocortisone early administered decreases the incidence of septic encephalopathy in patients admitted

with sepsis and so improve survival. Glucorticoids could attenuate [3], and prevent the effect of cytokines on the brain.
A large randomised controlled study is needed to confirm these interesting results.

**Introduction:** Protective mechanical ventilation (PMV) is globally implemented; however, despite its application, mortality rates in COVID-19-related ARDS (C-ARDS) remain high.
**Objectives:** To describe the evolution of respiratory mechanics (RM) and ventilation parameters (VP) in patients with C-ARDS during the first 5 days of mechanical ventilation (MV).
**Methods:** A retrospective cohort study that describes the evolution of RM and VP in patients with C-ARDS during the first 5 days of MV. The evolution of VP over time was modeled using linear models fitted with generalized least-squares methods (GLS).
**Results:** A total of 995 patients were included and 664 patients died. Table 1 shows inflammatory markers, severity scores and oxygenation. The median age was 67 years [IQR 59–74]. GLS models are presented in Table 2 showing the average RM parameter on Day 0 and the average increase per follow-up day (Figure 1). Despite these differences, the observed changes in RM variables were not clinically significant.

**Table 1 (abstract 000558)** Summary of inflammatory markers, severity scores, and oxygenation index

| | Overall patients $n=995$ | Survivors $n=331$ (33.2%) | Non-survivors $n=664$ (66.7%) | *p* value |
|---|---|---|---|---|
| Median age [IQR] | 67 [59–74] | 61 [53–70] | 69 [62–76] | < 0.01* |
| PaO2/FiO2 | 59.2 [49–74.5] | 67.3 [55.9–86.1] | 55.3 [46.6–66.6] | < 0.01* |
| Leukocytes (cells × $10^6$/L) Median [IQR] | 9,335 [6832–13250] | 10,090 [7450–14140] | 9000 [6560–12535] | 0.003* |
| Procalcitonin (ng/ml) Median [IQR] | 0.55 [0.22–1.59] | 0.37 [0.16–1.04] | 0.68 [0.27–2] | < 0.01* |
| Ferritin (ng/ml) Median [IQR] | 1295 0.5 [847–2357] | 1142 [836–1569] | 1517 [860–2474] | 0.02* |
| Charlson Index Median [IQR] | 3 [2–3] | 2 [1–3] | 3 [2–4] | < 0.01* |
| SOFA Score Median [IQR] | 10 [8–10] | 9 [8–10] | 10 [9–10] | < 0.01* |

**Table 2 (abstract 000558)** Summary of GLS models. TV: Tidal volume, IBW: Ideal body weight, Cst: Static compliance, MP: Mechanical Power, ***p* < 0.05.**

| Model | TV | | TV adjusted to IBW | | DP | | Cst | | MP (Gattinoni) | | MP (Amato) | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Intercept | 415.24 [IC 95% (409.35–421.13)] | *p* | 7.17 [IC 95% (6.83–7.51)] | *p* | 12.00 [IC 95% (11.63–12.37)] | *p* | 37.75 [IC 95% (35.44–40.06)] | *p* | 16.46 [IC 95% (15.87–17.05)] | *p* | 65.78 [IC 95% (64.26–67.30)] | *p* |
| Coefficient 1 | 7.13 [IC95% (5.66–8.59)] | 0.00* | 0.12 [IC 95% (0.10–0.15)] | 0.00* | -0.05 [IC 95% (−0.18–0.07)] | 0.41 | 0.94 [IC 95% (0.03–1.85)] | 0.04* | 0.69 [IC 95% (0.50–0.88)] | 0.00* | 0.16 [IC 95% (−0.37–0.70)] | 0.54 |
| Coefficient 2 | −4.18 [IC95% (−11.42–3.05)] | 0.25 | 0.12 [IC 95% (−0.28–0.54)] | 0.54 | 0.34 [IC 95% (−0.11–0.79)] | 0.14 | -0.83 [IC 95% (−3.68–2.01)] | 0.56 | 0.75 [IC 95% (0.02–1.48)] | 0.04* | 1.99 [IC 95% (0.12–3.87)] | 0.03* |
| Coefficient 3 | −1.35 [IC95% (−3.17–0.46)] | 0.14 | −0.03 [IC 95% (−0.06–0.00)] | 0.05 | 0.18 [IC 95% (0.018–0.34)] | 0.02* | −0.87 [IC 95% (−1.99–0.24)] | 0.12 | −0.04 [IC 95% (−0.27–0.19)] | 0.72 | 0.57 [IC 95% (−0.09–1.23)] | 0.09 |

**Conclusions:** Differences in RM and VP are not clinically significant during the first 5 days of MV. Age, greater comorbidity burden, PaO2/FiO2, and inflammation impact mortality in C-ARDS.

*Intensive Care Medicine Experimental* 2024, **12(suppl 1):**000560
**Introduction:** Ceftazidime–avibactam (CTZ) and ceftolozane–tazobactam (CFT) are two antibiotics used in the treatment of nosocomial pneumonia (NN) caused by Gram-negative bacilli. The efficacy of these new β-lactams (BL) + β-lactamase inhibitors (BLIs) may be affected by their concentration at the site of infection.
**Objectives:** The aim was to assess the pharmacokinetics (PK) in plasma and epithelial lining fluid (ELF) of CTZ and CFT administered by continuous infusion (CI) in critically ill patients with NN, and to analyse the differences in lung penetration and clinical outcomes.
**Methods:** Randomized clinical trial conducted at the Surgical Intensive Care Unit (ICU) at the Hospital del Mar (June 2022–March 2024). Demographics, APACHE score at ICU admission, SOFA score at NN diagnoses, clinical cure, and 30-day all-cause mortality were recorded. After randomization, CTZ or CFT at conventional doses were administered by CI after an initial loading dose (LD) of 2000 mg. Plasma levels were determined at the following time points: after LD (Cmax), 1 h, 4 h, 8 h, and day 3 (Css_day3). On the third day, fibrobronchoscopy with bronchoalveolar lavage was performed once per subject, 2, 4, 6, or 8 h after the last infusion to determine drug concentrations in ELF. PK parameters were estimated from individual plasma concentrations and the composite ELF concentration–time profile. BL and BLIs levels were measured by HPLC in plasma and by mass spectrometry in ELF. The pharmacokinetic/pharmacodynamic (PK/PD) target for beta-lactams was 100% fT > 4 times the MIC (8 ceftazidime and 4 ceftolozane), and 100% fT > critical concentration, which was considered to be 1 mg/L for avibactam and 2 mg/L for tazobactam.
**Results:** Twenty patients were included, 10 in each arm. The clinical and PK characteristics of the patients are shown in Table 1. No significant differences were found in the plasma or ELF concentrations of BL or BLIs. Plasma BLs' concentrations after the LD are shown in Figure 1 and plasma BLIs concentrations after the LD are shown in Figure 2. Ceftolozane plasma and ELF AUC0-8 are 1731.6 mg*h/L and 376 mg*h/L, respectively; ceftazidime plasma and ELF AUC0-8 are 1795.2 mg*h/L and299, respectively; tazobactam plasma and ELF AUC0-8 are 225.6 mg*h/L and 38.1 mg*h/L, respectively, and avibactam plasma and ELF AUC0-8 are 242.4 mg*h/L and 39.4 mg*h/L, respectively. Pulmonary penetration is 21.7% for ceftolozane and 16.7% for ceftazidime, 16.89% for tazobactam, and 16.3% for avibactam. In both cases, concentrations of BLs in ELF remain 100% fT > 4 times the MIC for all susceptible bacteria and BLIs remain 100% fT > critical concentration in ELF in all cases.

**Table 1 (abstract 000560)**

| | Ceftolozane/tazobactam | Ceftazidime/avibactam | *p* |
|---|---|---|---|
| Gender male, *n* (%) | 6(60) | 9(90) | 0.121 |
| APACHE score* | 20.5 (17–22) | 16.5 (13–20) | 0.184 |
| SOFA score* | 4.5 (3–7) | 5 (3–8) | 0.848 |
| Estimated GFR at baseline (CKD-EPI) (mL/min/1.73 $m^2$)* | 92 (84.25–114.37) | 82 (43–86) | 0.058 |
| Mechanical ventilation, *n* (%) | 4 (40) | 5 (50) | 0.653 |
| BL plasma Css_day3 | 72.2 (61.8–104.4) | 74.8 (72.8–108.5) | 0.624 |
| BLI plasma Css_ day3 | 9.4 (7.6–17.3) | 10.1 (7.1–11.4) | 0.624 |
| BL ELF Css* | 45.8 (27.7–48.4) | 13.1 (10.8–46.7) | 0.067 |
| BLI ELF Css* | 4.46 (3.65–6.41) | 3,75 (2.28–8.04) | 0.630 |
| Clinical cure, *n* (%) | 9 (90) | 8 (80) | 0.531 |
| 30-days all-cause mortality, *n* (%) | 1 (12.5) | 2 (20) | 0.671 |

*Median (IQR). GFR, glomerular filtration rate
**Conclusions:** CTZ and CFT administered by CI achieve plasma and pulmonary levels sufficient to meet the established PKPD targets in critically ill patients with nosocomial pneumonia.

AQ34 **Introduction:** The use of critical care ultrasound (CCUS) is a core competencies of intensive care medicine. Whilst it has been over a decade since the key landmark publications, the most recent ESICM supported competencies for core skills for the general intensivists were published in 2021. Since then, the ESICM has conducted 2 courses (GENIUS) at the congress to educate and overcome of the barriers which have been reported by colleagues in achieving these competencies.
**Objectives:** To follow up the attendees from the 2 GENIUS ultrasound course with regards to their ongoing ultrasound skill development and progress.
To identify potential barriers for further development.
**Methods:** Online, focussed survey of all 60 participants that attended the 2022 & 2023 GENIUS course in Paris and Milan, respectively. The themes of the questions included basic demographics of the participants, professional development, and barriers since attending the course. Participants were also asked for suggestions on how the CCUS training could be improved.
**Results:** 27 participants, from all 5 continents, responded with 65% being of more than 5 years of experience in intensive care. The cardiac and lung modules were thought to be the most useful in their clinical practice and the neuro module being the least useful.
Despite having their confidence level in performing ultrasound examination improve after the course, the majority of respondents felt that their frequency of scanning was mostly unchanged.
67% of respondents continued to scan regularly as way to maintain competency. 22% have attended another ultrasound course/conference. Worryingly, 22% felt that they have not been able to maintain or develop their skills.
When asked about the barriers to developing their ultrasound skillset further, the top reasons provided were the lack of time to scan and the lack of local mentors to supervise bedside teaching.
To address these barriers, respondents felt that the ESICM could organise follow-up courses, develop a more formal pathway/certification, and provide 'observerships' in hospitals/institutions where POCUS is applied regularly.
**Conclusions:** These are the first 2 courses which incorporate the most recent ESICM competency guidelines on core CCUS. Whilst the immediate course feedback has been positive, this delayed survey provides an opportunity for responders to reflect and evaluate their clinical practice since their attendance.
It is interesting that whilst the majority felt that the course has improved their confidence in performing ultrasound scans of the heart and lung, the actual frequency of scanning did not increase. The lack of equipment, whilst mentioned was not the key determinant.
Neuro POCUS was deemed the most challenging and least useful. It would be important to highlight the utility of this modality at future educational events beyond the remits of the Neuro ICU.
The identified barriers to development are not new with participants recognising that attendance at a course merely being the first step to ongoing training/education. The lack of local mentors/trainers are significant challenges and need to be addressed. Arguably centralised courses, e.g., at conferences, may not be best placed to address this key issue.
Our survey has highlighted key areas of reflection and improvement in the delivery of European CCUS education. Importantly, it provides possible solution including use of online platforms.

### Infections and antibiotic use at the end of life

R. Curto[1], A. I. Oliveira[2], M. Quaresma[2], C. Lohmann[3], I. Correia[4], D. Rei[1], J. Gonçalves-Pereira[1]

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000562

**Introduction:** Infections are common at the end of life. The use of antibiotics may provide clinicians hope of a clinical resolution and significant recovery. However, in patients who are still deteriorating despite therapeutic efforts, and who have no significant hope of reversion of the clinical situation, end-of-life decisions are usually taken. Nevertheless, withdrawal of antibiotics is seldom made, and this, in addition to having side effects, may result in the emergence of multidrug-resistant microorganisms (MDR) [1]. A trial of time-limited antibiotic therapy (3 days) has been suggested as an effective alternative [2].
**Methods:** Retrospective, observational, multicenter, cohort study. Patients who were in the hospital for more than 72 h before dying were selected at a rate of 1 ICU patient per 5 Internal Medicine patients. The first 300 patients who died in the hospital during the year 2022 per center were included. Demographic, antimicrobial therapy, and microbiological data were collected.
**Results:** A total of 825 patients (54.9% men, mean age 77 years) died in one of the participating centers during the study period and were included in the study. Of these, 24% ($n=194$) were in the ICU at the time of death. Of the whole population, 17% had a clinical condition considered to be "end-of-life", before admission. Metastatic cancer was present in 15.9% and dementia in 16.6%. A Do Not Resuscitate (DNR) order was instituted before death in 73.6%, including 50.5% of ICU patients.
Only 34.2% ($n=282$) of patients were admitted because of suspected infection but as many as 609 (73.8%) patients received at least one antibiotic during hospitalization, during a mean of 9.1 days. At the time of death, 387 (46.9%) patients were still under antibiotic therapy, with a mean duration of 6 days. Among the ICU patients, these figures were even higher, and 163 (84%) received at least one antibiotic during their ICU stay, with a very high mean duration, 10.8 days; at the time of death, 133 (68.6%) were under antibiotic therapy already for a mean of 7.1 days, and more than half of the patients for more than 3 days. Large-spectrum antibiotics were used in the ICU 48% of the time (13.3% in the ward).
In only 13.1% of this population, symptom alleviation was reported.
**Conclusions:** Antibiotics, including large spectrum, are commonly used in the ICU and the ward. Even after a DNR order and in patients who are deteriorating, antibiotics are seldom withdrawn, and this seems even worse in the ICU. Time-limited antibiotic therapy is rarely used in this setting, although it may contribute to decreasing its burden without failing patients who might still benefit. This strategy should be included in stewardship programs.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000563

**Introduction:** Point-of-care ultrasound (POCUS) has undoubtedly revolutionized the practice of intensive care medicine (ICM), providing clinicians with a real-time diagnostic and monitoring tool. However, it remains largely unknown whether the use of POCUS is associated with improved patient outcomes. AQ35
**Objectives:** The study aimed to investigate whether incorporating a head-to-toe functional POCUS protocol, within the first 12 h from ICU admittance, could improve survival, compared to standard assessment alone. Secondary outcomes included: 1) changes in primary diagnosis, 2) need for further diagnostic investigations, 3) alterations in therapy management, and 4) changes in invasive procedures' indication.
**Methods:** This retrospective clinical study was conducted on critical care patients admitted to a mixed ICU. The control group consisted of patients admitted before the acquisition of an echograph for the department, who underwent standard assessment within 12 h from ICU admission. The treatment group comprised patients admitted after the acquisition of an echograph, who underwent a point-of-care functional ultrasound (POCUS) protocol in addition to standard assessment, within the same timeframe.
The POCUS assessment followed the "*BE SO SAFE-(D)*" protocol developed at our institution, encompassing transorbital, pulmonary, cardiac, and abdominal evaluations.
Data were propensity matched for age, sex, length of hospital stay, and SOFA, using SPSS (IBM, Armonk, NY) to ensure baseline comparability. Survival at 7 and 60 days was collected through clinical records or telephone interviews.
**Results:** After propensity matching, a total of 446 patients were evaluated, evenly divided between the control and treatment group. Mortality rates at 7 and 60 days differed significantly between the two groups: 7-day mortality was 22.3% in the treatment group versus 31.8% in the control group ($p=0.014$), while 60-day mortality was 38.1% in the treatment group versus 47.5% in the control group ($p=0.036$). Ultrasonographic findings led to changes in admitting diagnosis in 27.8% of patients, prompted further diagnostic tests in 5.6% of patients, altered medical treatment in 22.2% of patients, and changed the indication for an invasive procedure in 16% of patients (avoiding it in 1.2% and indicating it in 14.8%).
**Conclusions:** Our ultrasonographic protocol for rapid comprehensive patient assessment has improved the quality of healthcare by reducing mortality, enhancing diagnostic capability, and optimizing both medical and interventional treatment approaches. While further investigation is warranted, the systematic implementation of a POCUS protocol at ICU admission in critically ill patients may be a promising treatment option to consider.

### Clinical outcome of ceftazidime–avibactam in critically ill oncology patients with sepsis: experience from a tertiary care cancer hospital in eastern India

S. Mukherjee[1], P. S. Ghosh[1], S. Bhattacharya[2], S. Chatterji[3]

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000564

**Introduction:** Sepsis with multidrug-resistant organisms cause significant morbidity & mortality in cancer patients. Ceftazidime–avibactam (CZA) has evolved as an important treatment option against resistant bacteria, but lack of data in critically ill oncology patients is of concern against its widespread usage.
**Objectives:** The aim of this prospective observational study is to evaluate the clinical outcome of oncology patients in an intensive care unit (ICU) who have received CZA either as 'targeted' therapy (T) or 'empirically' (E) due to limited treatment option. The primary outcome was in-hospital mortality. Secondary outcomes were incidence of empirical usage of CZA, ventilator days and ICU days, microbiological failure, and secondary infection while on CZA and overall antibiotic consumption.
**Methods:** All cancer patients shifted to ICU due to sepsis during March–September 2023 and who received CZA, were included in this study, and data were collected as per protocol. The decision to start CZA was either microbiological (bacteria producing OXA 48 and NDM carbapenemase) or clinical (cultures negatives and clinical deterioration while on other antimicrobials). CZA was prescribed alone or in combinations (with aztreonam, polymyxins, tigecycline, etc.).
**Results:** Out of 75 patients, 29 were from haemato-oncology (38.7%) and the rest had solid organ malignancy. 59% were older than 60 years (Figure 1). Seven patients (9.3%) were already on CZA, and for the rest, median timing of initiation of CZA was 4 days after ICU admission. In pre-CZA microbiology, *Escherichia coli, Klebsiella* sp., and *Pseudomonas* sp. comprised 34 cases (43.3%), and in 41 cases (54.7%), CZA was started empirically. Sputum & blood are most common samples (70%). Significant number of patients were having multiorgan failure (Neutropenia—26%, ventilation—66%, shock—80%, and haemodialysis—19%). OXA-48 & NDM carbapenemases were identified in 32% of all clinical samples. In-hospital mortality was 50%; while mortality in patients not requiring CZA is 32%. Patients receiving 'empirical' therapy had higher in-hospital mortality—59% (E) vs 46% (T). Average duration of CZA was 7.6 days; for other combination antibiotics, it is 7.2 days. Average ventilator days were 11 days and ICU stay was 12.4 days. Microbiological failure was minimum. Post-CZA, 17.7% of clinical samples (both sterile and nonsterile) showed CZA-resistant pathogens (e.g., *Staphylococcus* sp, *Enterococcus* sp, *Acinetobacter* sp, *Candida* sp, *Trichosporon* sp, and *Aspergillus* sp).
**Conclusions:** Our oncology patient population receiving CZA had shown a high mortality, probably due to active malignancy, immunosuppression, and multiple organ failure. Culture negative patients with empirical therapy had shown poorer outcome (i.e., higher mortality) compared to targeted therapy group. Risk of superinfection with resistant bacteria and fungus in post CZA period is of significant concern.

### Microbial epidemiology and antibiotic therapy in ventriculitis

M. Monteiro[1], H. Veiga[2], S. Barbosa[2], A. Afonso[2], J. A. Paiva[2], E. Monteiro[2]
[1]Intensive Care, Unidade Local de Saúde Do Tâmega E Sousa, E.P.E., Guilhufe, Portugal; [2]Intensive Care Medicine, São João University Hospital, Porto, Portugal

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000566

**Introduction:** Most of the pathogenic agents contributing to central nervous system infections associated with external ventricular drains (EVD) are cutaneous-derived Gram-positive bacteria [1–2]. Despite this fact, recent reports indicate a change toward more Gram-negative infections and antibiotic-resistant organisms probably related to the growing complexity of neurocritical patients, prolonged hospitalization, and use of prophylactic antibiotics targeting gram-positive bacteria [1]. Additionally, the optimal duration of antimicrobial therapy in patients with ventriculitis is not well established [1,3].
**Objectives:** To characterize causative agents involved in ventriculitis associated with EVD and assess if guidelines compliance regarding antimicrobial duration impacts on outcomes.
**Methods:** We retrospectively collected data from medical files of patients with ventriculitis related to EVD admitted at a neurocritical care unit of a University Hospital from January 1st 2018 to December 31st 2023. The length of antibiotic therapy applied was compared to the one suggested by the Infectious Diseases Society of America (IDSA).
**Results:** In 28 of 54 patients with ventriculitis, a microorganism was isolated. Among microorganisms, 19 were Gram-positive and 11 Gram-negative bacteria (Fig. 1). Microorganisms most frequently found were coagulase-negative Staphylococci. Within this group, *Staphylococcus epidermidis* was the most commonly identified ($n=15$). Enterobacterales were the most common Gram-negative organisms isolated ($n=5$). In three patients, ventriculitis was attributed to polymicrobial infections and one patient had a *Candida albicans* ventriculitis.
Only 12 patients had an antibiotic time course in line with IDSA guidelines, despite similar baseline patients´ characteristics. There were no differences between the two groups regarding ICU and hospital lengths-of-stay; need and duration of invasive mechanical ventilation; ICU and hospital mortality and functional outcomes at 6 months (Table 1).

**Table 1 (abstract 000566)** Patient characteristics and outcomes according to IDSA guidelines for antibiotic duration

| Variable | Antibiotic duration according to IDSA | | *p-value* |
|---|---|---|---|
| | Yes ($n=12$) | No ($n=16$) | |
| Baseline characterization | | | |
| Age years, median (IQR) | 56 (28.5) | 68 (22) | 0.121* |
| Female, % | 42% | 31% | 0.698** |
| SAPS II, median (IQR) | 43 (20) | 50 (25) | 0.631* |
| Initial CGS, median (IQR) | 8 (3.5) | 8 (3.5) | 0.767* |
| IMV, % | 100% | 88% | 12 |
| Outcomes | | | |
| IMV days, median (IQR) | 33 (12.1) | 28.75 (41.15) | 0.609* |
| Antibiotic days, median (IQR) | 21 (7.5) | 24 (22) | 0.095* |
| ICU days, median (IQR) | 37 (24.5) | 42 (25.5) | 0.78* |
| ICU mortality, % | 0% | 13% | 0.492** |
| Hospital mortality, % | 17% | 38% | 0.236** |
| GOS 6 months, median (IQR) | 3 (2)*** | 2 (2)**** | 0.204* |

*Mann–Whitney. **Fisher's exact. ***Loss of follow up of 3 patients. ****Loss of follow up of 2 patients. *IMV* Invasive Mechanical Ventilation, *IQR* Inter Quartile Range, *GOS* Glasgow Outcome Scale

**Conclusions:** Gram-negative bacteria are responsible for more than one third of EVD-related ventriculitis. Duration of antimicrobial therapy doesn´t correlate with outcome.

### Comparison of neurosense/neurowave and sedline/masimo for measuring depth of sedation in the intensive care unit

S. Meerts[1], J. Poelaert[2], I. Ghijslings[3]
[1]Anesthesia and peri-operative medicine, UZ Brussel, Jette, Belgium; [2]Faculty of medicine and pharmacy, Universitair Ziekenhuis Brussel, Brussels, Belgium; [3]Anesthesie and peri-operative medicine, Intensive care unit, UZ Brussel, Jette, Belgium
**Correspondence:** S. Meerts
*Intensive Care Medicine Experimental* 2024, **12(suppl 1):**000568

**Introduction:** Sedation is often necessary during the treatment of critically ill patients on intensive care. Under- and over-sedation can occur and may cause potential side effects, such as awareness, agitation, and auto-extubation. Assessment of the depth of sedation (DoS) can be either done using a validated clinical DoS scale or with brain sedation monitors. Different DoS monitors have proprietary algorithms to calculate an index based on raw electroencephalogram (EEG) values to indicate the DoS. The SedLine® DoS monitor uses the patient state index (PSI) and the NeuroSENSE® DoS monitor uses the Wavelet-based central nervous system anesthetic value (WAVCNS). It is not known which index performs best at predicting the clinical DoS.
**Objectives:** The purpose of this study is to determine which of the two indices correlates best with the clinical Richmond Agitation Sedation Scale (RASS).
**Methods:** Thirty patients admitted to the intensive care unit (ICU) of the University Hospital of Brussels and sedated with propofol and remifentanil were included in the study. After skin preparation, the two brain sedation monitors were simultaneously attached to the patient's forehead. Each monitoring session consisted of two sequential monitoring periods where the duration of one trial was 35 min. The trial began with a 30-min "no touch" period, followed by recording the indices of both devices every five seconds for one minute. For the NeuroSENSE® monitoring device, the WAVCNS indices were recorded for both the left and the right hemispheres. Finally, the RASS score was evaluated for each patient. The prediction probability (PK) was calculated for each monitoring device.
**Results:** The study population consisted of twenty-one male and nine female patients, which together provided 180 data points per device. The PK of the PSI was $0.826 \pm 0.034$. The PK of the WAVCNS was $0.795 \pm 0.033$ for the left hemisphere and $0.809 \pm 0.032$ for the right hemisphere. The absolute differences between the PK of the PSI and the WAVCNS left, and right were 0.031 (95%CI −0.062; 0.0124) and 0.017 (95%CI −0.075; 0.109) respectively. As the confidence intervals of these absolute differences both cross zero, there is no statistical significant difference between the PK of both DoS monitors.
**Conclusions:** We compared the performance of the SedLine® DoS monitor PSI and the NeuroSENSE® DoS sedation monitor WAVCNS index in critically ill sedated patients in intensive care by calculating the prediction probability (PK), and could not find a superiority of one device over the other in predicting the clinical DoS as measured by the RASS.

### Impact of glucose in combination with ketogenic nutrition on ketosis and muscle weakness in septic mice

C. Lauwers[1], G. Van den Berghe[1], I. Derese[1], S. Derde[1], S. Vander Perre[1], J. Gunst[1], M. Casaer[1], L. Langouche[1]

*Intensive Care Medicine Experimental* 2024, **12(suppl 1):**000569

**Introduction:** Intensive care unit-acquired weakness (ICUAW) develops in over 40% of critically ill patients and impairs both short- and long-term morbidity and mortality. Reversal of the suppressed ketogenic pathways during sepsis attenuated muscle weakness in preclinical studies (Goossens et al. 2019). Nonetheless, the ketogenic potential of essential long-chain triglycerides (LCTs) during sepsis and its relation to glucose, a critical suppressor of ketogenesis, have not been investigated. Therefore, this study aimed to investigate the impact of a pure LCT emulsion with and without glucose on ketogenesis and muscle weakness in a murine model of sepsis.
**Methods:** In a centrally catheterized, fluid-resuscitated, and antibiotic-treated mouse model of chronic sepsis, abdominal sepsis was induced by caecal ligation and puncture (CLP). Septic mice receiving a standard total parenteral nutrition (composed of glucose, amino acids and LCTs providing 5.3 kcal/day; considered the standard of care) (TPN, $n = 15$) were compared to septic mice receiving a pure LCT emulsion (4.8 kcal/day; LCTs, $n = 16$) and a pure LCT emulsion supplemented with glucose (5.3 kcal/day, whereof 10% provided by glucose) (LCTs + glc, $n = 15$). Healthy control (HC) mice ($n = 17$) provided healthy reference values. Ex vivo muscle force (aurora scientific®) was measured as the primary outcome after 5 days. Plasma Ketone bodies (beta-hydroxybutyrate (BHB)) and insulin were measured by commercial assays. Muscle triglycerides were analysed by a commercial kit after hexane extraction. Metabolomics was assessed by LC–MS on muscle tissue.
**Results:** The survival rate was comparable between septic groups (TPN: 71.4%; LCTs + glc: 65.2%; LCTs: 61.5%) after 5 days of sepsis. Muscle force was similarly decreased in the TPN and LCTs + glc group, but declined even further in the LCTs group (TPN: 60.9%; LCTs + glc: 60.9%; LCTs: 33.1% of HC: 128.7 mN/mm$^2$, $p < 0.0001$). In contrast, LCTs infusion increased ketosis 65-fold in the LCTs and tenfold in the LCTs + glc groups as compared to the TPN group (median of 0.02 mmol/l, $p < 0.002$). Plasma insulin was decreased in both LCT groups, irrespective of the glucose load, in comparison with the TPN group ($p < 0.02$). Muscular triglyceride content, however, was maintained in the LCTs + glc group, but decreased in the TPN and LCTs group relative to HCs mice ($p < 0.004$). The metabolomics analysis showed a stepwise decrease in the relative abundance of muscular glycolytic intermediates in the TPN, LCTs + glc and LCTs groups, respectively.
**Conclusions:** A pure LCT emulsion moderately induced ketosis, but at a cost of muscular lipid content and glycolytic intermediates, potentially explaining the worsening of muscle weakness. Adding glucose to the LCT emulsion could prevent the latter, but also partially suppressed ketosis. Higher levels of ketosis alongside elementary glucose administration might be required to attenuate muscle weakness.

## Occult side effects of routinely intensive care treatment: impact of nimodipine and dexamethasone on neutrophil granulocytes

R. Kraus[1], K. Gross[1], A. Dejaco[1], M. Gruber[1], M. Kieninger[1]
[1]Department of Anaesthesiology, University Hospital Regensburg, Regensburg, Germany
**Correspondence:** R. Kraus
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000570

**Introduction:** Refractory cerebral vasospasms and secondary ischemia are among the major complications of aneurysmal subarachnoid hemorrhage (aSAH) [1]. In Neuro-ICUs, nimodipine (NIM), a calcium antagonist, is regularly administered to aSAH patients to diminish the occurrence of vasoconstrictions and to provide best possible protection against secondary ischemia [2]. Although the precise molecular mechanisms remain unclear, it is assumed that the interaction of NIM with neutrophil granulocytes (PMNs) also contributes to maintaining tissue perfusion and reducing the risk of further infarction [3].
Even though corticosteroids currently are not supported in routine use in aSAH patients [4], there are several (neuro)intensive care indications in which dexamethasone (DEX) is established, such as bacterial meningitis or ARDS (e.g. due to COVID) [5, 6]. One possible explanation for the positive influence on these disease patterns is the immunosuppressive effect of DEX. Moreover, in severe COVID DEX modulates immature PMNs and NETosis can even be seen as a marker for the severity of COVID progression [7, 8].
**Objectives:** This study aims to investigate the influence of NIM and DEX on neutrophil functions to uncover possible interactions. For this purpose, an established in vitro assay (3D µ-Slide chemotaxis model) is used to investigate the influence of NIM and DEX on neutrophil migration and NETosis [9].
**Methods:** PMNs were isolated from whole blood of healthy volunteer donors by centrifugation. Subsequently, live cell imaging was exerted for up to 10 h to examine PMN migration and NETosis (time for half-maximal NETosis (ET50NETosis)). Cells were investigated by light and fluorescence microscopy in type I collagen-filled (1.5 mg/mL) 3D µ-Slides. The collagen gel was blended with defined concentrations of NIM (500 ng/mL, dissolved in methanol) and DEX (75 ng/mL, dissolved in dimethyl sulfoxide) on the one hand and their drug solvents alone (methanol 3,1 ‰ and dimethyl sulfoxide 0.5 ‰) on the other hand. Due to water insolubility NIM and DEX require these specific solvents. NET formation was visualized using 4′,6-diamidino-2-phenylindole (DAPI). A chemotaxis gradient was established with N-formyl-met-leu-phe (fMLP).
**Results:** NIM prolonged neutrophil NETosis significantly ($p=0.005$; see Figure 1). Mean ET50NETosis in the presence of NIM ($n=7$) was $270\pm25.1$ min whereas mean ET50NETosis without NIM ($n=6$) was $230\pm25.1$ min. DEX prolonged NETosis, but did not reach significance ($p=0.071$; see Figure 2). Median ET50NETosis was in the presence of DEX ($n=3$) 351 min (range: 306–397 min). Median ET50NETosis without DEX ($n=6$) was 233 min (range 207–246 min). No significant influence of the selected drugs on neutrophil migration could be determined.
**Conclusions:** Nimodipine and Dexamethasone are drugs routinely used in intensive care and are associated with positive outcomes in various life-threatening conditions such as aSAH or ARDS. NETosis is more and more associated with development and worsening of such intensive care diseases [10]. Delayed NETosis observed in our study could explain molecularly why nimodipine and dexamethasone may have positive effects. Therefore, direct influence on neutrophil immune responses offers an attractive starting point for new treatment strategies and deserves attention in further research.

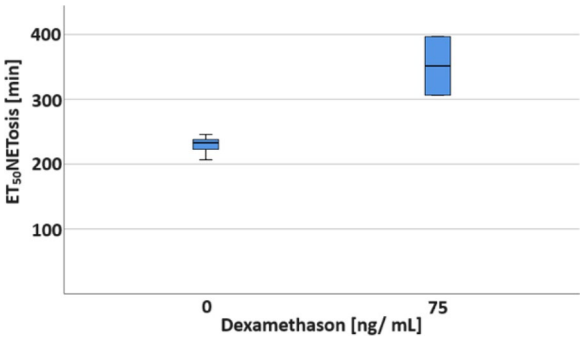

**Fig. 2 (abstract 000570)** Prolonged ET50NETosis in the presence of Dexamethasone did not reach statistical significance

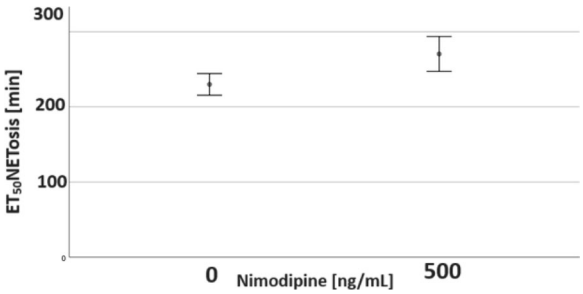

**Fig. 1 (abstract 000570)** Prolonged ET50NETosis in the presence of Nimodipine

### Intrathecal antibiotics in ventriculitis: a valid choice?

M. Monteiro[1], H. Veiga[2], S. Barbosa[2], C. Dias[2], E. Pereira[2], J. A. Paiva[2]; E. Monteiro[2]
[1]Intensive Care, Unidade Local de Saúde do Tâmega e Sousa, E.P.E., Guilhufe, Portugal; [2]Intensive Care, São João University Hospital, Porto, Portugal

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000571

**Introduction:** Intrathecal (IT) antibiotic administration is not a consensual procedure due to the potential harmful side effects. According to Infectious Diseases Society of America (IDSA) guidelines, IT antibiotics should be considered in cases of ventriculitis with poor response to systemic antibiotics (SA) [1]. In order to achieve adequate cerebrospinal fluid (CSF) concentrations, systemic antibiotics must cross the blood–brain, and blood-CSF barriers. Failure to achieve minimal bactericidal concentration can lead to infection persistence and the emergence of multi-resistant pathogens [2].
**Objectives:** To analyze and compare outcomes of ventriculitis associated with external ventricular drains (EVD) treated with IT antibiotics plus SA versus SA.
**Methods:** Retrospective analysis of medical record files from patients treated for EVD-associated ventriculitis admitted to a neurocritical care unit (NCCU) of a University Hospital from January 1st 2018 to December 31st 2023.
**Results:** Among the 54 EVD-related ventriculitis managed in NCCU, ten were treated with IT antibiotics. Antibiotic choice and dosage respect IDSA guidelines. Patients treated with IT antibiotics were significantly younger albeit with no other differences in baseline characteristics. Days of EVD, time under antibiotic therapy, and ICU length of stay were longer in the group of patients treated with IT antibiotics. We found no differences between groups regarding days of Invasive Mechanical Ventilation (IMV), ICU and Hospital mortality and Glasgow Outcome Scale at six months.

**Table 1 (abstract 000571)** Patient characteristics and clinical outcomes of patients treated with IT antibiotics

**Introduction:** Fluid management in the ICU is a cornerstone of care for mechanically ventilated patients, yet determining which patients are fluid-responsive can be difficult [1]. Hemodynamic indices such as cardiac output (CO), can provide insight into a patient's responsiveness when measured during a fluid challenge, thus guiding individual patient care. Often transthoracic echocardiography (TTE) is used to measure CO because the left ventricle outflow tract velocity time integral (LVOT VTI) correlates with stroke volume [2]. However, well-known limitations of TTE exist including the lack of continuous monitoring ability, necessary operator expertise, and potential image artifacts [1]. There remains a need for a non-invasive, operator-independent, continuous cardio-pulmonary monitoring system for mechanically ventilated patients.
**Objectives:** To evaluate non-invasive pulmonary blood flow (PBF) measurements provided by the VQm® System before and after a

passive leg raise (PLR) and a fluid bolus (FB) when compared to reference CO measurements from TTE LVOT VTI.
**Methods:** This is a single-site pilot study in Ontario Canada. The VQm® System calculates PBF through a modified differential Fick equation by administering a 3-breath inhaled bolus of CO2. The subsequent change in end-tidal CO2 is measured through a mainstream proprietary airway sensor distal to the patient's endotracheal tube, allowing for the calculation of all parameters in the differential Fick equation, including PBF, in real-time. For this study, patients started in a semi-recumbent position (torso elevated 45°) where baseline PBF and CO measurements were collected. The torso was then levelled and the legs were elevated (to 45°). Paired measurements were taken after 1 min while the legs remained elevated and again 5 min after the patient was placed back in the semi-recumbent position. Following an FB of 500 ml over 15 min a final paired measurement of PBF and CO was taken. A four-quadrant plot analysis was performed on the paired measurements to determine the concordance rate and assess the VQm® System's trending ability.
**Results:** Nine patients, 7 male/2 female, with a mean age of 60 (45–82) were recruited for this study. From the 9 patients, 13 data points fell outside of an exclusion zone of 10% and were included in the analysis. The concordance rate between the VQm® System PBF value and the TTE CO value before and after a fluid challenge was 69.2% (Fig. 1).
**Conclusions:** Results are promising for the trending ability of the VQm® System PBF value when compared to a reference CO value using TTE LVOT VTI measurements. Future work includes assessing the performance of the VQm® System as a predictor of fluid responsiveness in ICU patients.

## 000573 I
## Illness severity and number of patients admitted to critical care remains constant throughout the 7-day week

B. Barzi[1], E. Brunetti[1], S. Davey[2], T. Samuels[3], A. Myers[1], J. Mitchell[2]

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000573

**Introduction:** Critical care is a 7-day service throughout the world. However, in many intensive care units (ICU) across the UK, there can be fewer medical staff present at the weekend compared to the weekday[1]. To justify this there can be the misleading assumption that patients are 'less sick' when presenting over weekend or the number of patients admitted are fewer. To investigate this, we have examined the APACHE II score[2] for patients admitted to our unit in 2023.
Since 1985, the APACHE II score is measured within 24 h of admission and incorporates physiological measurements, like age and chronic disease.2 It is a standardised score assessing patients' deviation from normal and predicts mortality risk in critically ill patients. Its global use and accessibility make it suitable for comparing data worldwide.
**Objectives:** Assess if illness severity and number of admitted patients to our ICU across the 7-day week remains constant.
**Methods:** This is a retrospective single-centre study. We examined deidentified data for 656 patients selected between 01/01/2023 and 30/11/2023.
The data is presented using box plots for each day of the week. APACHE II scores are presented using median [IQR]. Inferential statistics were performed using the Kruskal–Wallis test and Chi-squared test. All analyses were carried out using R (version 4.3.2).
**Results:** The median APACHE II score in 2023 was 18. From Figure 1, the median APACHE II score for all 7 days appears consistent. The number of patients admitted per day is shown in Table 1. There is no evidence to suggest that the APACHE II score varies significantly across different days in 2023 ($p = 0.3$).
**Table 1 (abstract 000573).**

| | Mon | Tues | Wed | Thu | Fri | Sat | Sun |
|---|---|---|---|---|---|---|---|
| Number of patients | 92 | 109 | 95 | 113 | 95 | 89 | 91 |

In Table 2, the number of patients that were above and below the median APACHE II score for 2023 are presented according to whether they were admitted during the weekday or weekend. No significant association was found between the number of patients admitted on the weekday or weekend when separated according to above or below the median APACHE II score for 2023 ($p = 0.6$).
**Table 2 (abstract 000573).**

| | Weekday | Weekend |
|---|---|---|
| APACHE II > 18 | 223 | 85 |
| APACHE II ≤ 18 | 260 | 88 |

**Conclusions:** Our retrospective single-centre study demonstrates that there are no significant differences in APACHE II score across the 7-day week in 2023, and that the number of patients presenting according to the median APACHE II score for the year between the weekday and weekend was also not significant.
We recognise that our dataset is small and based on a single centre population which might lack generalizability due to limited sample diversity.
These findings challenge assumptions regarding reduced illness severity during weekends3, highlighting the importance of consistent staffing and resources in ICU settings.

## Guess the weight: the accuracy of estimated weights and the implications on aspects of clinical management in critical care

R. Mehta[1], S. Curran[1], J. Gaynor[1], L. Wandrag[1], R. Moodley[1], R. Davies[1], A. Wong[1]
[1]King's Critical Care, King's College Hospital, London, United Kingdom

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000574

**Introduction:** An accurate patient weight is a fundamental part of the initial assessment on admission to hospital, guiding therapy and progress in the ICU.
There are many challenges to weighing patients on the ICU: time constraints, unstable patients, staffing levels as well as lack and incorrect use of weighing equipment. Hence, most patient weights are estimated by the team on admission. However, published data has shown this to be grossly inaccurate, with differences of over 20% between actual and estimated weights in up to 15% of cases in critically ill patients.2
Weight is used routinely in multiple calculations; affecting many critical aspects—drug dosages, fluid balance monitoring, nutritional assessments as well as cardiac output studies.1,2
**Objectives:** 1. To identify the barriers to weighing patients on the ICU. 2. To assess the accuracy of healthcare professionals' (HCPs) estimates compared to the measured patient weight. 3. To describe the implications of therapy.

**Methods:** The study was conducted in a 16-bed mixed ICU. All patients were screened with patients excluded if they refused or the treating team judged them to be haemodynamically unstable.
Patients were weighed either using a hoist or chair device following a standardised unit weighing procedure. A diverse sample of HCPs was asked to estimate the individual patients' weight from the end of the bedspace (whilst blinded to the previously recorded or actual weight).
Descriptive analyses were performed. Bland–Altman analysis was used to assess agreement between the pooled estimated and measured weight.
**Results:** The study was conducted over 2 days and 13 patients were weighed. 8 were mechanically ventilated. 3 refused and 2 was deemed haemodynamically too unstable for weighing. Intubated patients were hoisted. There were no line dislodgement or unintended consequences of the weighing process.
30 HCPs as per Table 1 provided 297 estimations of weight.
.

**Table 1 (abstract 000574)** Breakdown of HCPs as assessors

| HCPs | No. of assessors |
|---|---|
| Nurses | 13 |
| Doctors | 6 |
| Pharmacists | 7 |
| Physiotherapists | 2 |
| Dieticians | 1 |
| Advanced clinical practitioner | 1 |

The median measured weight was 83.2kg (50.9–131kg). Figure 1 shows the percentage estimation errors for each patient. Pooled weight estimates were between 18.5% under to 16.9% over the measured weight. The differences between the pooled estimated and actual weight ranged from −22kg to + 10.3kg. Eight patients (62%) had a greater than 10% difference between the measured and estimated weight.
Figure 2 shows whether there is agreement between the measured and pooled estimated weight for each patient. The bias of 3.49 represents the mean difference between the two weights.
The measured weights led to therapy changes in 4 (30%) patients—3 had drug doses adjusted for anticoagulation and 1 had their nutrition plan revisited.
**Conclusions:** Our study shows that it is safe and feasible to weigh the majority of ICU patients and corroborates previously published work that the estimation of a patient's weight by HCPs is inaccurate. 62% of patients had a more than 10% margin of error, which has previously been shown to be the 'cut-off' of significance.2,3 30% of patients had therapies adjusted with potential avoidance of harm and/or treatment failures.
We intend to introduce a regular weighing programme in our department and acknowledge that the measured weight should also be interpreted with caution due to daily fluid shifts.

### Neurological prognosis in cardiac arrest: the role of somatosensory evoked potentials

L. Blanco[1], V. Osejo Altamirano[2], E. Renes Carreño[1], J. L. PerezVela[1], J. Ginestal[1], C. Galiano[1], A. J. Moneo González[1], H. Dominguez Aguado[1], M. C. Martín Delgado[1]

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000575

**Introduction:** Somatosensory evoked potentials (SSEPs) are a valuable tool in neurological prognosis following cardiac arrest (CA), offering significant advantages such as high specificity in diagnosing brain damage and minimal susceptibility to sedation effects. However, they have challenges such as technique availability and complexity of interpretation. Typically, the presence or absence of the N20 cranial wave is used to determine neurological prognosis in these patients.
**Objectives:** To assess the utility of SSEPs as a diagnostic tool in the neurological prognosis of CA.
**Methods:** A retrospective observational study was conducted on a prospective series of CAs treated in our centre between 2016 and 2023. SSEPs were performed on patients who remained comatose after 72 h of CA. Demographic, etiological, and outcome variables were collected, and results were presented as proportions and medians accompanied by interquartile range (IQR). Statistical analysis was performed using SPSS version 29.1.0.1.
**Results:** A total of 150 CA cases, both in-hospital and out-of-hospital, were included, of which SSEPs were conducted on 53 (35%) patients. The median age was 58 years (IQR 17), with 37 (7%) being male. 23 (43%) presented a shockable rhythm and the average time of CA until recovery of spontaneous was 25 min (IQR 18).
Among these 53 patients, 47 (89%) had poor neurological outcomes (CPC 3–5). Among those with poor neurological outcomes, 20 (43%) patients had preserved N20, 8 (17%) had unilaterally abolished N20, and 19 (40%) had abolished N20 bilaterally. Out of the 6 (11%) patients with good neurological outcomes, 5 of them (83%) had preserved N20, and only one patient had unilaterally abolished N20 (17%).
Stratifying by CPC level, among the 11 patients with CPC 1–3, 10 (91%) had preserved SSEPs and only one had a unilateral loss. In contrast, among the 39 CPC 4 patients, 15 (38%) had preserved N20, 19 (49%) had absent N20, and 5 had unilaterally absent N20 (13%). None of the 3 patients with CPC 5 had preserved SSEPs, with 2 (67%) showing bilateral absence and 1 (33%) unilateral absence.
In this series (including unilaterally abolished N20 as poor prognosis), SSEPs demonstrated a sensitivity of 60% (CI 95%: 44%-67%, specificity of 83% (CI 95%: 35–99%) (limited by the small number of patients with good prognosis), a positive predictive value (PPV) of 97%, and a negative predictive value (NPV) of 21%.
**Conclusions:** In our series, abolished SSEPs demonstrate high specificity and PPV, although sensitivity and NPV are not as high. Therefore, abolished SSEPs reliably indicate a poor prognosis, whereas preserved SSEPs do not assure a good neurological prognosis. It is noteworthy that although considered part of poor neurological prognosis, all patients with CPC 3 had preserved N20. Finally, further study is needed to explore the significance of unilaterally absent SSEPs, although in our series, they appear to be similarly associated with poor prognosis.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000576

**Introduction:** Multiple environmental and genetic factors influence the development of COVID-19 as a complex multisystem disease. According to the omnigenic model, the disease can be associated with a large number of variants in core (causal) and peripheral genes that are tightly linked in a regulatory network [1]. Disease-associated genes tend to be expressed at higher levels in those healthy tissues where alterations in these genes cause pathology. The identification of gene sets and associated rare pathogenic variants (high-impact variants)

is important for the diagnosis, prevention and treatment of diseases. Therefore, the study of the contribution of genes and variants associated with primary immunodeficiencies (PIDs) to the development of common infectious diseases remains a relevant and interesting area of research.
**Objectives:** Investigate the contribution of PID genes in severe critically ill COVID-19 patients.
**Methods:** We used whole-exome sequencing data from ≤45-year-old patients with severe ($n=9$) and non-severe COVID-19 ($n=11$) to evaluate the collective impact of rare high-impact variants (HIs) of PID genes on disease severity. The core PID gene list was taken from the International Union of Immunological Societies (IUIS) Committee of Experts 2022 Updated Classification. We curated gene lists of functional partners (FPs) of PID genes from protein–protein interaction networks using the STRING database tool version 11.5. Expression data of PID genes were obtained from the Human Protein Atlas (HPA).
**Results:** We generated three sets of genes, including 450 core PID genes (I), 4580 FPs of PID genes with a CIS (combined interaction score) of ≥0.9 (II—near-core peripheral genes), and 6445 FPs of PID genes with a CIS of 0.4 to 0.89 (III). The gene sets overlapped, so genes from set I were excluded from sets II and III, and so on. The burden of rare HI variants in PID genes and FPs in severe versus non-severe COVID-19 decreased in the sets I + II > I + II + III > all genes with rare HI variants in the cohort of 20 patients. PID-associated genes were more highly expressed than other genes in human peripheral blood cell subpopulations.
**Conclusions:** The cumulative effect of rare HI variants of PID core genes and near-core FPs of PID gene (II) contributed to the development of severe COVID-19. The higher level of PID gene expression in blood cell subpopulations is consistent with their functional importance for immune/hematological tissues so that disruption of PID genes will lead to severe consequences for the functionality of these tissues.

## Early brain CT as a prognostic method for neurological outcome in cardiac arrest

L. Blanco[1], E. Renes Carreño[1], J. L. PerezVela[1], J. Ginestal[1], C. Galiano[1], J. L. Flordelís Lasierra[1], N. Quílez-Trasobares[1], R. Ashbaugh-Lavesiera[1], M. C. Martín Delgado[1]
[1]Intensive care, University Hospital 12 de Octubre, Madrid, Spain
**Correspondence:** L. Blanco
*Intensive Care Medicine Experimental* 2024, **12(suppl 1):**000577

**Introduction:** CT scanning is a straightforward and accessible test that can provide insight into the neurological prognosis of cardiac arrest (CA). We propose that findings indicating a poor prognosis on an early CT scan will likely correlate with a poor neurological outcome, but the absence of findings does not predict a good long-term neurological outcome, as lesions may progress over time.
**Objectives:** To assess the usefulness of performing an early CT scan for neurological prognosis in CA.
**Methods:** A retrospective observational study was conducted on a prospective series of CAs treated in our centre between 2012 and 2023. Brain CT scans without contrast were performed in the early hours, with repeat scans in patients showing poor clinical response not explained by another cause. Demographic, etiological, and outcome variables were collected, and results were presented as proportions and medians accompanied by 25th and 75th percentiles. Statistical analysis was conducted using SPSS version 29.1.0.1.
**Results:** A total of 304 CAs, both in-hospital (41) and out-of-hospital (263), were included, with brain CT scans performed on 171 (56%) of them. Of these, 127 (74%) were male with a median age of 59 [52–72] years. The median time to return of spontaneous circulation was 25 [16–33]. Repeat imaging was done in 16 (9,4%) patients with initially normal CT scans.
Among the 171 patients initially scanned, 113 (66%) showed no acute pathological findings, 23 (13.5%) showed gray-white matter dedifferentiation (GWMD), 17 (9.9%) had cerebral edema, 9 (5,3%) had acute ischemic lesions, and 9 (5.3%) had other lesions. The diffuse lesion on the initial CT scan had a specificity of 100% and a sensitivity of 36% (PPV 100% NPV 47%) in the detection of severe brain damage.
Out of the 113 patients with initially normal CT scans, 52 (46%) had a good neurological outcome (CPC 1–2), while 57 (50.4%) had a poor neurological outcome (CPC 3–5); CPC could not be determined in 4 cases. Among the 58 (34%) patients with some pathological findings on the initial CT scan, only 4 (6.9%) had a good neurological prognosis, while 53 (91,3%) had a CPC 3–5; CPC could not be determined in 1 case.
Of the 16 patients with initially normal CT scans with a second CT scan done, 4 (25%) showed no findings on repeat CT scans; all of them had a CPC 3–5. The remaining 12 (75%) patients had lesions not previously described. Three (25%) patients with acute ischemic lesions had a CPC 1–2, while 5 patients had diffuse cerebral edema and 4 had haemorrhagic lesions, all with CPC 3–5.
**Conclusions:** Obtaining a normal result on an early post-CA brain CT scan is not useful for predicting the neurological prognosis of these patients, as lesions that progress in the following days may not be visible initially. Conversely, finding lesions on an early CT scan is often associated with a worse final neurological outcome. Most patients who underwent repeat brain imaging had a poor prognosis, possibly due to repeat testing for clinical deterioration.

## Clinical and respiratory mechanics characteristics related to mortality in patients with COVID-19 acute respiratory distress syndrome

C. Ortiz[1], B. Nahuelpan[1], P. Molina[1], J. Hidalgo[2]
[1]Intensive Care Unit, Regional Clinical Hospital of Concepción, Concepción, Chile; [2]Department of Statistics, Faculty of Sciences, University of the Bío-Bío, Concepción, Chile
**Correspondence:** C. ORTIZ
*Intensive Care Medicine Experimental* 2024, **12(suppl 1):**000578

**Introduction:** Covid-19 Associated Acute Respiratory Distress Syndrome (C-ARDS) was challenging when establishing therapeutic strategies in intensive care unit (ICU) with mortality varied among different regions of Latin America according to the progression of the pandemic [1–5]. Based on the implementation of the Protective Mechanical Ventilation Protocol (PMV), we evaluated the clinical variables associated with C-ARDS mortality in the first year of the pandemic in the ICU of a Chilean hospital.
**Objectives:** To assess the association between mortality and demographic, oxygenation and ventilatory variables in patients with C-ARDS in the ICU.
**Methods:** Causal, retrospective study. In 2020, 443 patients were admitted into ICU Guillermo Grant Benavente Hospital, in the pre-vaccination period. Inclusion criteria: C-ARDS diagnosis and PVM protocol. Non-intubated and incompletely registered patients were excluded, the final sample was 412 patients. Percentages, mean and SD are

presented for descriptive analysis. Odds Ratios(OR) are reported for qualitative association 95%CI. Significance was $p < 0.05$. Survival probabilities were estimated with a binary logistic regression, considering Driving Pressure (DP) as the principal predictor. APACHE II, PaFi, Body Mass Index (BMI) and age as secondary predictors.Ethical approval 200945 code.

**Results:** 412 patients were analyzed, 57% male, mean age 58.3 ± 13.5,BMI 31.1 ± 7.2, APACHE II 12.6 ± 6.3, 13.8 ± 6.1 days of PMV, Pafi 115 ± 29.1, DP 11 ± 1.5.51.2% required PMV in prone position with DP 11.3 ± 0.1 and Crs(static respiratory system compliance) 37.7 ± 8.7, total mortality 21.1%.Among the variables associated with mortality, DP is the most relevant(OR = 1.93, $p < 0.001$, 95% CI 1.53–2.44), followed by APACHE II (OR = 1.23, $p < 0.001$, 95% CI 1.16–1.30). Age is statistically significant (OR = 1.03, $p = 0.019$, 95% CI 1.01–1.06), PaFi index (OR = 1.00, $p = 0.94$, 95% CI 0.99–1.01) and BMI(OR = 1.01, $p = 0.58$, 95% CI 0.97–1.06) were not significant.

The logistic regression model applied corresponds to Prob(Mortality) = expM/(1 + expM),therein M = −13.24 + 0.2006 × APACHE II + 0.5879xDP-0.000457xPaFi + 0.013xBMI + 0.0329xAge. It was observed that when the DP exceeds 12cmH2O the probability of dying increases significantly ($p < 0.001$), (Figure 1; Table 1). When the Crs variable was incorporated into the formula in the prone position,did not significantly alter the predictive power of the formula($p = 0.09$).

**Table 1 (abstract 000578)** Predicted probability values for mortality according to demographics, oxygenation, and ventilatory variables

| DP Value* | 1-9 | 10 | 11 | 12 | 13 | 14 | 15 | 16 | 17 | 18 | 19 | 20 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Predicted probab** | <4.1 % | 7.2 % | 12.2 % | 20.0 % | 31.0 % | 44.8 % | 59.3 % | 72.4 % | 82.5 % | 89.5 % | 93.9 % | 96.5 % |

*DP ($cmH_2O$) proposal risk categories:low(green),moderate(yellow)and high(red).

**Variables:DP,Apache II,PaFi,BMI,Age.

*DP (cmH2O) proposal risk categories:low(green),moderate(yellow) and high(red)

**Variables:DP,Apache II,PaFi,BMI,Age

**Conclusions:** The evaluation of mortality in patients with C-ARDS identified DP as a main predictive variable, particularly when it exceeds 12 cmH2O. These findings emphasize the importance of developing clinical management strategies that focus on optimizing DP values to reduce mortality.

## The use of handheld devices in sustainable ultrasound training—boon or bane?

A. Wong[1], H. Farrah[1], J. V. Ramos[1], J. Gilroy[2]

**Introduction:** Competencies in Critical Care Ultrasound (CCUS) has been accepted as part of modern intensive care practice—it is part of both the ESAIC and ESICM competency documents. Achieving competency in this skillset requires a mixture of didactice knowledge, hands on practice, building a logbook of scans as well as mentored supervision and discussion. Despite this, significant barriers exist and only a small number of European countries have mandated it as part of their national training programme. In the UK and Netherlands, non-doctors

(nurses and physiotherapists) have been trained in ultrasound to improve patient care.
Handheld ultrasound (HHUS) devices have become increasingly popular and available as a way to improve access to CCUS from both a training and clinical perspective. Such devices are often allied with online platforms which facilitate learning and governance (individualized logbooks and quality assurance tools).
**Objectives:** To assess the impact of the addition of HHUS on training completion of CCUS Lung (UK programme). These include:

- Frequency of scanning
- Quality of images in logbook
- Speed of completion of competencies
- Barriers to completion

**Methods:** Two HHUS (Butterfly) were introduced in a single-centre critical care department with an established CCUS training programme. 25 healthcare professionals (doctors and allied healthcare providers) were invited to participate and provided individualised login to the device and online platform. Participation was completely voluntary with regular reviews by mentors as needed. Training scans were completely anonymised with no patient identifiers. Basic demographic data was collected by the participants. Information on scan frequency, quality etc. were collected from the cloud platform.
**Results:** 4 out of 25 participants completed the accreditation within the maximum 1 year allowed by the programme. All were allied healthcare providers. All 4 completed it within 6 months.
All 25 participants completed at least 5 scans logged. Only 7 of the 25 logged the halfway point (15 scans) by 3 months.
The various online videos/educational resources were only minimally accessed. There was no difference between those who ultimately completed and those who did not.
Barriers to completing competencies—lack of time to scan. Access to the 2 devices was not cited as a barrier.
Regarding online platform, both participants and trainers liked the ease of use and the fact that it can be accessed anywhere. The structured rating of scans was another positive comment by the trainer.
**Conclusions:** Despite its perceived benefits in encouraging colleagues to complete CCUS training, less than 20% did. This is inline with the 10–15% completion rate published in the literature. It is feasible to train non-doctors to achieve the same CCUS Lung competencies as doctors.
The lack of trainers and equipment, often cited as barriers in the literature, can/has been addressed by the introduction of HHUS. The biggest barrier in our study was the lack of time to practice and achieve the required number of scans (all done within the participants' time ie. not protected). This raises the wider issue of mandatory vs. optional. It could be argued that only by making the competencies mandatory and protecting time for learners to scan. The UK Society of Acute Medicine has mandated such an approach (0.5 day per week for all registrars to learn).
In conclusion, HHUS did not increase the completion rate of CCUS lung training in our institution. Whilst users were positive about the online platform, this was not significantly different between the 2 groups. Trainers found the review facility on the platform useful and it may have a role in the wider governance of POCUS scans in the ICU.
Our study adds to the discussion on the role of HHUS across critical care practice and further reflection on whether its the system or the individual which determines success.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000582

**Introduction:** Pulmonary embolism (PE) is associated with significant morbidity and mortality. Several lower dose thrombolytic dosing strategies have been employed as an attempt to better balance clot dissolution benefits with major bleeding risks. However, pharmacokinetic (PK) and pharmacodynamic (PD) data comparing these strategies to full dose (FD) are lacking.
**Objectives:** We aimed to evaluate differences in PD response to FD and lower dose alteplase treatments.
**Methods:** We performed a single center prospective open-label PK/PD pilot study of adults (≥ 18 years) admitted to the University of Colorado Hospital with acute PE and prescribed intravenous alteplase at a dose of either 100 mg (FD), 50 mg (half-dose [HD]), or a catheter-directed thrombolysis (CDT) approach (~ 1 mg/hr for 12–24 h). Peripheral blood sampling occurred immediately prior to alteplase administration and at 1, 2, and 4 h after start of treatment. For CDT, samples were taken at baseline, 1, 2, 4 h, at infusion end, and 2 h after treatment end. The primary outcome was a maximum reduction in

alpha-2 antiplasmin (A2A) activity from baseline. Additionally, percentage lysis at 30 min (LY30) via thromboelastography (TEG) and change in fibrinogen and D-dimer was evaluated.
**Results:** Twelve patients were included: median (range) age 62 years (23–82), 110.1 kg (77.7–158.8), 83% white, 50% female, high-risk PE ($n=4$), and intermediate high-risk PE ($n=8$). Alteplase 100 mg ($n=6$), 50 mg ($n=4$), and CDT (0.5 mg/hr ($n=1$) and 1 mg/hr ($n=1$) × 2 catheters × 12 h; $n=2$) were the initial thrombolytic strategies. All but one FD and all HD patients received a 10 mg bolus with the remaining dose administered as an infusion. One HD patient received a second 50 mg dose and one CDT patient underwent a second CDT treatment. Median baseline A2A activity in all patients was 103 (range 74–135) and reduced to a nadir of 15 (↓84%), 30.5 (↓74%), and 48 (↓60%) after FD, HD, and CDT alteplase, respectively (FD vs. HD, $p=0.17$). TEG LY30 was increased to 94.25% in FD, 87.6% in HD, and 37.35% in CDT ($p=0.06$). Fibrinogen was reduced by 49.8%, 50.2%, and 77.9% in FD, HD, and CDT groups ($p=0.98$). Median baseline D-Dimer was 29,012 (range 1620–199760) and increased to 58,840 after FD, and 286,880 after HD, and > 400,000 after CDT ($p=$NS).
**Conclusions:** Small differences in PD response were observed with FD and HD alteplase therapy. CDT had the least effect on A2A and TEG LY30, however D-Dimer increases and fibrinogen decreases were similar. Our findings highlight the need for PK/PD evaluations of new thrombolytic dosing strategies that can better retain benefits and minimize risk.

## Utility of the vasopressor inotrope socre as a prognostic factor for mortality in patients with distributive shock unresponsive to noradrenaline treated with arginine-vasopressin

S. Foradada Ubach[1], B. Vélez Jaigua[1], M. Lladó Vilar[1], L. Cornejo Fernández[2], A. Taché Sala[1]

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000583

**Introduction:** The use of arginine vasopressin (AVP), a non-catecholaminergic vasoconstrictor hormone, is recommended in septic shock when norepinephrine (NE) is between 0.25 and 0.5 ucg/kg/min and mean arterial pressure (MAP) ≤ 65 mmHg. The *vasopressor inotrope score* (VIS) is a score that allows us to quantify the intensity of cardiovascular support. There is no VIS to predict mortality.
**Objectives:** The objective of this study is to identify the value of VIS that is related to increased morbidity and mortality.
**Methods:** Observational and prospective study in a 24-bed 3rd level ICU, between November 2022 and September 2023. Inclusion criteria: patients ≥ 18 years old with a diagnosis of distributive shock and who met the criteria for AVP initiation were included. Variables, diastolic index shock (DIS), VIS, lactate, corticosteroid use, intra-ICU mortality and intra-ICU stay were analyzed (Table 1). Exclusion criteria: mortality during the first 24 h from ICU admission. The cut-off value of VIS with mortality was determined using ROC curves.
**Results:** 51 patients, 80.4% were men with a median age of 60 years. Intra-ICU mortality was 35.3%, and mean length of stay was 13 days. VIS values after AVP administration were statistically different at 24 and 48 h between survivor and non-survivor patients. Higher VIS clearance was observed at 24 and 48 h in survivor patients ($p<0.001$ and $p=0.002$, respectively). The cut-off point for VIS clearance at 24 h was 33.1% with a sensitivity of 77.8%, specificity of 81.8%, PPV of 87.1%, and NPV of 70%, AUC: 0.803 (image 1).The cut-off point at 48 h was 16.7%, with a sensitivity of 66.7%, specificity of 87.9%, PPV of 82.9%, NPV of 75%, AUC: 0.77 (image 2). Both at 24 h and 48 h, significant differences were observed between survivor and non-survivor patients in relation to the cut-off points found. No association between corticosteroids and VIS.

**Table 1 (abstract 000583).**

| | Evolution 24 hores | | | | Evolution 48 hours | | | |
|---|---|---|---|---|---|---|---|---|
| | Survivors | Non-survivors | Total | p-value | Survivors | Non-survivors | Total | p-value |
| AVP | 1 (0,6-1,7) | 1,3 (0,8-1,8) | 1,2 (0,6-1,8) | 0,422 | 0,96 (0-1,4) | 1,3 (0,8 - 1,8) | 1,2 (0,2-1,4) | 0,087 |
| NE | 0,4 (0,3-0,5) | 0,8 (0,6-1,4) | 0,5 (0,3-0,7) | < 0,001 | 0,3 (0,1-0,4) | 0,6 (0,4-1,1) | 0,3 (0,2-0,6) | 0,001 |
| VIS | 40 (29,6-56,9) | 78,8 (63,6-149,6) | 55,8 (33,1-76,6) | < 0,001 | 27 (13-42) | 63,5 (40-115,3) | 37 (16-58) | 0,001 |
| Δ VIS | 1,9 (-13-21,7) | -36,3 (-76,9 - -21) | -5,9 (-35,9-16,2) | < 0,001 | 15,9 (-1,2-36,2) | -17,4 (-40,3 -9,8) | 7,1 (-16,7-31,7) | 0,002 |
| % improvement VIS | 4,1 (-30,1-43,1) | -95,5 (-138,7- -31) | -18,4 (-101,9-35,5 | < 0,001 | 38,8 (-2,9-59,6) | -24,9(-102,3-20,1) | 19 (-25,6-55,5) | 0,001 |
| LACTATE | 17 (12-29,5) | 37 (16,8-91,3) | 22 (12-43) | 0,048 | 14 (8,5-24,5) | 26,5 (12,3-45,5) | 15 (9-28) | 0,016 |

**Conclusions:** A minimum increase in VIS of 33.1% at 24 h and 16.7% at 48 h identifies those patients with distributive shock at high risk of dying. Survivor patients have lower lactate, NE and VIS values at 24 and 48 h. VIS should be incorporated into hemodynamic management algorithms, allowing the identification of patients who would benefit from escalation or de-escalation of hemodynamic or mechanical circulatory support.

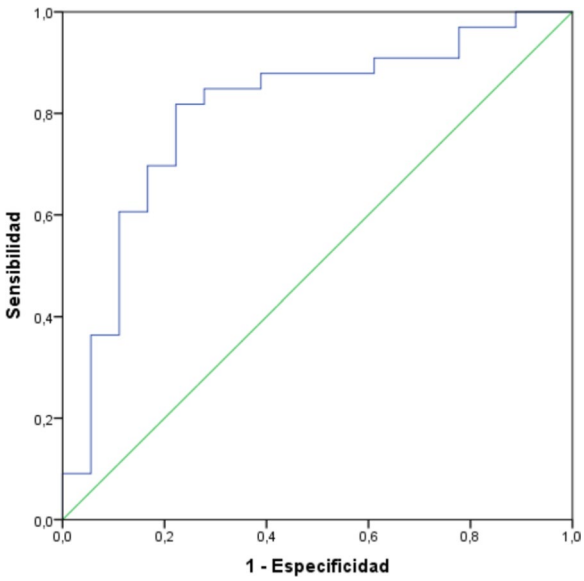

**Image 1 (abstract 000583)** ROC curve, cutt-off of the VIS at 24h

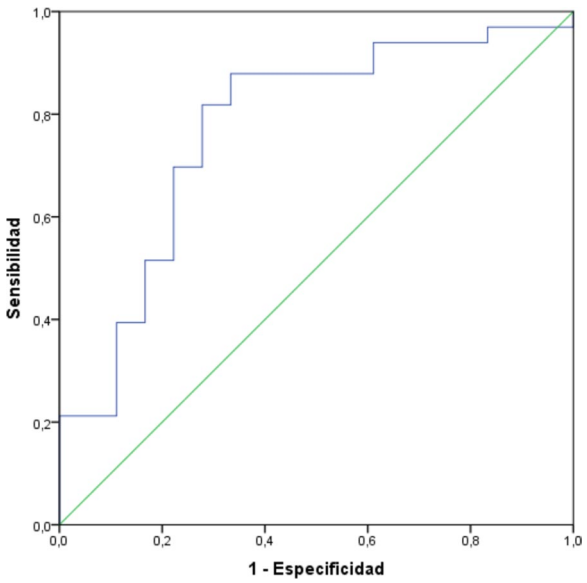

**Image 2 (abstract 000583)** ROC curve, cutt-off of the VIS at 48h

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000585

**Introduction:** The favorable pharmacokinetic (PK) profile of inhaled antibiotics, i.e. achieving high drug concentrations at the pulmonary site of action with limited systemic diffusion and side effects, represents the principal rationale for their use. However, among patients under mechanical ventilation, numerous factors have been described influencing the drug amount actually delivered to the lungs, but clinical pharmacokinetic data is limited.

**Objectives:** To perform large-scale population PK analysis of inhaled amikacin taking advantage of a randomized trial evaluating inhaled amikacin (20 mg/kg once a day for three days) to prevent ventilator-associated pneumonia.

**Methods:** Of 420 patients randomized to receive inhaled amikacin, a subset underwent sputum and plasma sampling randomly distributed over the 24 h following each nebulization. Various PK models were tested, with or without peripheral compartments and nonlinear elimination kinetics. Inter-individual and inter-occasion variabilities were assumed to follow a lognormal distribution. Covariate effects (age, sex, weight, oxygenation, ventilation mode, and settings, type of ventilator circuit, active humidification during nebulization, …) on PK parameters were evaluated using power or exponential functions and categorical models. Model selection was based on Bayesian information criterion, residue analysis, and accuracy metrics. The final model evaluation involved goodness of fit analysis, visual predictive checks, and assessment of prediction distribution errors and shrinkage.

**Results:** One to five plasma samples (total 638 samples) and 1 to 4 sputum samples (total 526 samples) were taken among 281 patients. In the sputum, concentrations were highest at the end of nebulization. Two distinct population pharmacokinetic models were established for sputum and plasma concentrations as these were not correlated. The sputum model was bi-compartmental, and the plasma model was mono-compartmental. In sputum, inter-individual variability was very high and no covariates, including ventilation parameters, were correlated with concentrations. The median maximum concentration was 7307 µg/g (80% range: 1684–12388 µg/g). The terminal half-life calculated from the model parameters was 7.9 h (80% range 4.0–303.3 h). The median concentration in sputum predicted 24 h after nebulisation was 236 µg/g (80% range: 6–507 µg/g). Concerning plasma concentration, the median maximal concentration was 2.0 mg/L (80% range: 0.7–4.5 mg/L). The median concentration in plasma predicted 24 h after nebulisation was 0.36 mg/L (80% range: 0.04–1.57 mg/L).

**Conclusions:** This large-scale population PK analysis confirmed the strong rational for inhaled antibiotic delivery. Surprisingly, none of the covariates believed to influence inhaled drug delivery based on preclinical data and small sample size studies, significantly influenced PK parameters in this large clinical study.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000586

**Introduction:** Sarcopenia and frailty, marked by muscle mass loss and quality decline, are pivotal factors impacting surgical outcomes. Current diagnostic approaches prioritize muscle mass assessment, often overlooking muscle quality. Ultrasound, although promising, lacks standardized criteria for sarcopenia diagnosis.
**Objectives:** This study assesses the reliability of AI-based software for ultrasound muscle quality evaluation, particularly focusing on the rectus femoris muscle. Validating AI-aided ultrasound could revolutionize sarcopenia assessment, refining surgical risk stratification and enhancing patient care.
**Methods:** In a cohort study, older adult trauma patients ($\geq 60$) underwent baseline sarcopenia evaluation using rectus femoris muscle ultrasound imaging. Transverse images were obtained on admission and discharge from 35 ICU patients, compared with age-matched healthy controls ($n = 975$). The AI software analyzed images to measure intramuscular adipose tissue (IMAT) and muscle parameters, including IMAT-index.
**Results:** IMAT-Index was measured in 29 patients (mean age: $73 \pm 1.4$), with 59% female and mean BMI of $29 \pm 1$. Cut-off IMAT-index for rectus femoris was 4.81%/cm$^2$. Frailty was observed in 44.8% ($n = 13$) and non-frailty in 55.2% ($n = 16$) of patients.
**Conclusions:** AI-assisted ultrasound presents a promising adjunct for frailty assessment and sarcopenia diagnosis in older adult trauma populations. Implementation of this technology could augment diagnostic precision and optimize patient care strategies, particularly in critical care settings.

### Hemophagocytic lymphohistiocytosis in adult critically ill patients in Intensive Care Unit: preliminary results from a systematic review with pooled analysis

R. Traversi[1], G. Arrigo[1], A. Busca[2], L. Rodigari[1], L. Brazzi[1], G. Montrucchio[1]

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000587

**Introduction:** Distributive shock burdened with Multiorgan Dysfunction (MODs) is a foremost cause of admission in the Intensive Care Unit (ICU). Hemophagocytic Lymphohistiocytosis (HLH) is a life-threatening hyperinflammatory syndrome caused by aberrantly persistently activated cytotoxic lymphocytes and macrophages with substantial clinical overlap with sepsis and MODs (1). Worldwide awareness of this condition is increasing, but currently, its overall frequency in ICU is unknown and probably underreported. Although international guidelines have been published (2), diagnosis, treatment and clinical management of this condition—especially in ICU—remain heterogeneous and inequitable.
**Objectives:** To increase awareness of HLH in ICU patients providing a pooled analysis of case reports and case series of literature.
**Methods:** We conducted a literature search of MEDLINE and EMBASE including studies, case series and case reports of adult patients diagnosed with HLH and admitted to ICU in the period 2006—January 2024. Source data of studies and case series were summarized and analyzed on an individual basis. Multivariable logistic regression analysis with use of stepwise selection was performed.
**Results:** In total, 148 patients from 128 case series and case reports were included. Population data and analysis are presented in Table 1. Overall ICU mortality was 47,5%.
The most common triggers include viral infection (52,41%) and namely EBV (19,59%) SARS cov 2 (14,86%), CMV (6,08%), disimmune disease, and hematologic malignancy.
Bone marrow biopsy (BMB) was performed in 73,97% of patients and guided treatment initiation in 83.81% of cases.
Treatment with etoposide (25,15%), tocilizumab (5,41%), Anakinra (16,33%), Penthaglobin® (2,03%), Cyclosporine (6,08%) and plasmapheresis (3,38%) didn't show a clear impact on mortality, while high-dose corticosteroids use (57,93%) showed a significative positive impact on survival in univariate analysis but did not in multivariate analysis.
**Conclusions:** Mortality of HLH in ICU is high. The most common triggers were viral infections, disimmune diseases, and hematologic malignancies. Patients with hematologic malignancies seem to represent a subgroup at higher mortality risk.
High-dose steroids appear to be the only treatment with statistically significant mortality reduction in univariate analysis but failed to obtain significance in multivariate analysis. Patients who needed invasive mechanical ventilation had a significantly higher mortality.
Early clinical suspicion of HLH during refractory distributive shock is pivotal, especially when a possible trigger is present. Although representative and widely used to guide clinical choices, BMB is not the only diagnostic tool that clinicians must consider as suggested by compound scores like HLH-2004 and HScore3.
Future studies prospectively investigating treatment tailored to critically ill HLH patients are highly warranted.

**Introduction:** Secondary complications accompanying severe traumatic injuries, particularly the emergence of multiorgan dysfunction syndrome (MODS), continue to be a significant and persistent cause of morbidity among hospitalized trauma patients. Interleukin-33 (IL-33) is a member of the IL-1 cytokine family and functions as an alarm signal in the immune system. The complete IL-33 protein necessitates enzymatic cleavage by proteases to produce its mature biologically active state. This active form can then bind to its specific receptor, the suppression of tumorigenicity (ST2) receptor, thereby initiating the activation of the nuclear factor kappa B (NF-κB) pathway across diverse innate and adaptive immune cell types. The elevated presence of IL-33 primarily within epithelial and endothelial cells contributes to its pro-inflammatory functions.

**Objectives:** This study aimed to evaluate the effectiveness of IL-33 as an indicator of the development of MODS in patients with trauma.

**Methods:** This study included patients with trauma admitted to our trauma center from July 2022 to July 2023. Using the Bio-Plex assay, IL-33 level was measured in blood samples over 4 days. Correlations with clinical and laboratory indicators, including initial IL-33 levels, were analyzed to identify the independent predictors of MODS in total patients and patients with injury severity score (ISS) over 16, respectively. After dividing the patients into the IL-33-positive and IL-33-negative groups, the factors showing significant differences between the 2 groups were analyzed.

**Results:** 87 patients were enrolled, 20 of whom developed MODS. The initial IL-33 levels were elevated in the MODS group compared to the non-MODS group. In the non-MODS group, IL-33 levels initially increased on the first day and then decreased, whereas the MODS group exhibited a consistent decline in IL-33 levels. In patients with detectable initial IL-33 levels, measurable levels correlated with higher abbreviated injury scale 5 scores and ISS. According to the multivariate analysis, in the entire patient cohort, ISS and DNI were identified as predictors of MODS, and in the patient cohort with an ISS greater than 16, lactate was confirmed as a predictor of MODS.

**Conclusions:** Initial IL-33 levels were higher in the MODS group and exhibited a rapid declining trend. This suggests that the net effect of the surged IL-33 at the initial presentation may act as a proinflammatory effect and that maintaining IL-33 after 1 day may have stronger anti-inflammatory effects on T regulatory cells, which may have a role in preventing MODS. The IL-33-positive group may be associated with higher ISS and AIS 5 score. Suggesting its potential as a dynamic biomarker for assessing trauma severity and the progression to MODS.

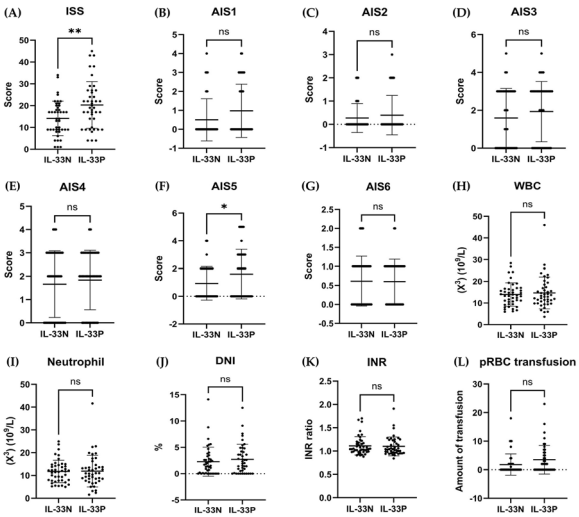

**Fig. (abstract 000589)** Injured patients stratified according to absence (IL-33N) or presence (IL-33P) at the initial presentation. **Introduction:** Prolonged corticosteroid use is associated with a higher mortality rate among patients with COVID-19 [1]. However, the relationship between lung involvement, mortality, and duration of corticosteroid therapy use remains unexplored.
**Objectives:** To evaluate whether chest computed tomography (CT) findings are associated with prolonged corticosteroid use and mortality among critically ill patients with COVID-19.
**Methods:** Patients were randomly selected from a dataset of hospitalized patients with COVID-19. Inclusion criteria were ICU admission and corticosteroid use. Subjects were divided into two groups according to the duration of corticosteroid therapy: short corticosteroid group (up to ten days) and prolonged corticosteroid group (more than ten days). Image analysis was conducted independently by two radiologists using a semi-quantitative method that scores 0–5 points according to the percentage of involvement in each lobe for each of the three elementary lung patterns associated with COVID-19, namely, ground-glass opacities, consolidations, and crazy-paving. The total CT score was calculated through the sum of scores for each lobe, ranging from 0 to 28 points, with higher scores indicating higher lung involvement [2]. For patients who underwent a second chest CT during hospitalization, the change in CT score over time was compared between groups. The primary outcome was the difference in radiographic patterns between groups with short and prolonged corticosteroid use. The secondary outcome was the difference in radiographic patterns between survivors and non-survivors.
**Results:** A total of 110 patients were included in the analysis, of which 54 received a short corticosteroid course, and 56 a prolonged course. The mean age was 54 and 63% of participants were male. Seventy-five patients underwent a second chest CT. Overall mortality was 23%, and no difference was detected between groups. Patients in the prolonged group presented higher scores for ground-glass opacities (median 15 IQR [9–19] vs 10 [4.2–15.7], $p=0.004$) in the first chest CT. Consolidation, crazy-paving, and total CT score values did not differ between groups. For the second chest CT, there was no difference for each of the three radiologic patterns, but the total CT score was higher for the prolonged group (median 20.5 IQR [13.7–25.2] vs 13 [8.5–21], $p=0.023$). The difference in CT score between first and second chest CT did not differ between groups with short or prolonged corticosteroid use. Survivors presented more reduction in the total CT score between the first and the second CT in comparison to non-survivors (mean -3.2 95% CI [−4.6 to −1.9] vs 0.15 95%CI [−2,4 to 2.7]; $p=0.049$].
**Conclusions:** Patients with prolonged corticosteroid use had more ground-glass opacities in the first chest CT and higher total CT scores in the second chest CT. Moreover, survivors presented a more pronounced reduction in the total CT score between the first and the second chest CT.

### Correlation between optic nerve sheath diameter and intracranial pressure in the patients with leptomeningeal seeding

S. Youn
Neurosurgery, Severance Hospital, Seoul, Republic of Korea
**Correspondence:** S. Youn
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000592

**Introduction:** Leptomeningeal seeding (LMS) refers to the metastasis of cancer to the arachnoid mater, cerebrospinal fluid (CSF), and pia mater. The tumor cell infiltration via LMS may cause hydrocephalus and increased intracranial pressure (IICP) as secondary complications. Clinical physicians often encounter the devastating results of sudden neurologic deterioration in patients with IICP signs with no radiologically definite hydrocephalus. Optic nerve sheath diameter (ONSD) is one of the useful diagnostic methods to detect IICP signs. However, the application of ONSD is not much reported in patients with LMS for diagnostic and/or prognostic purposes. We hereby share our experience with ONSD to analytically predict IICP in patients with LMS.
**Methods:** We have conducted a retrospective study of 79 patients with brain metastasis, who were admitted to our institution from 2015 to 2018. Patients with suspected LMS in the radiological findings were further selected for this study so that those who underwent ventriculo-peritoneal shunt or Ommaya catheter insertion with IICP but no definite mass effect were investigated. The study parameters were as follows: age, gender, primary tumor region, ONSD, presence of tumor cells in CSF cytology, ICP measurements, and overall survival. We analyzed the relationship between the ICP and ONSD measurements in conjunction with the findings of tumor cells in the CSF cytology. Then, we further analyzed whether there is any correlation between the actual ICP measurements and pre-operative ONSD.
**Results:** Of 79 patients, 49 patients were investigated. Those with incomplete medical records (n = 20) and ambiguous CSF cytology ($n=10$) were excluded from this study. Lung cancer was the most frequent primary tumor with brain metastasis ($n=17$, 43.6%) while the second most frequent primary tumor was breast cancer ($n=5$, 12.8%). According to the CSF cytology studies, the rate of positive findings of tumor cells was 66.7% ($n=26$). The ICP was higher in the patients with tumor cells in the CSF than those without ($25.0 \pm 15.3$ mmCSF vs. $13.46 \pm 8.0$ mmCSF, respectively; $p=0.013$). ONSD was also larger in the patients with tumor cells in the CSF than those without ($5.75 \pm 0.8$ mm vs. $5.12 \pm 0.6$ mm, respectively; $p=0.016$). According to the Pearson correlation analysis, the opening ICP and ONSD showed a positive correlation with a Pearson coefficient of 0.662 ($p=0.000$). Using the receiver operating characteristic (ROC) curve of ONSD and the positive finding rate of tumor cells in the CSF, we discovered that 100% sensitivity and 69% specificity were noted when the ONSD was 6.13 mm.
**Conclusions:** This study has demonstrated that the patients with positive findings of tumor cells in the CSF showed higher ICP. High ICP state of the patients with LMS was confirmed by the pre-operative measurement of ONSD. Indirectly, clinicians can also predict the presence of tumor cells in the CSF via the measurements of ONSD. In conclusion, the ONSD is a powerful non-invasive method to predict ICP in the patients with LMS, and this can further aid the clinicians to plan early ICP managements.

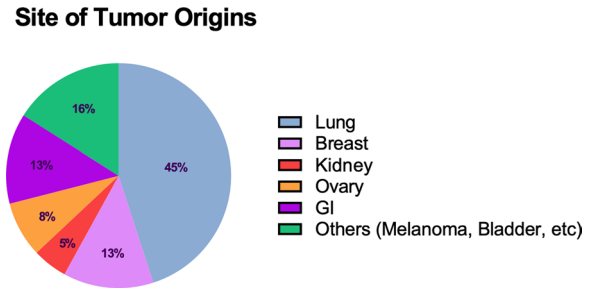

**Fig. (abstract 000592)** Of 69 patients, 39 patients were investigated. Those with incomplete medical records ($n = 20$) and ambiguous CSF cytology ($n = 10$) were excluded from this study

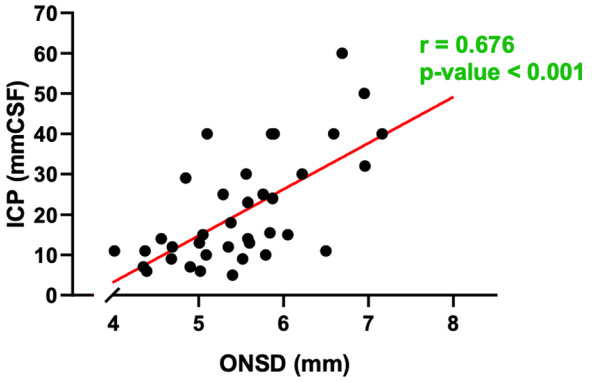

**Fig. (abstract 000592)** According to the Pearson correlation analysis, the opening ICP and ONSD showed a positive correlation with Pearson coefficient of 0.676 ($p < 0.001$)

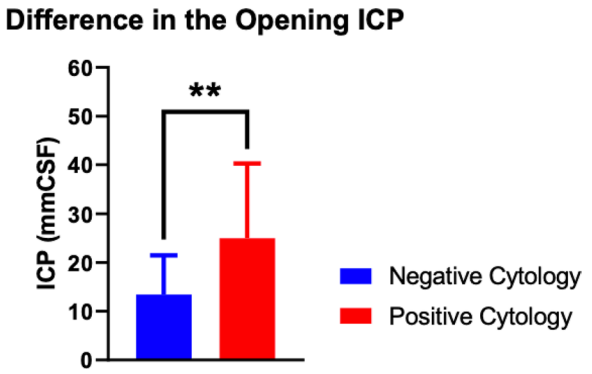

**Fig. (abstract 000592)** The ICP was higher in the patients with tumor cells in the CSF than those without (25.0 ± 15.3 mmCSF vs. 13.46 ± 8.0 mmCSF, respectively; $p = 0.013$)

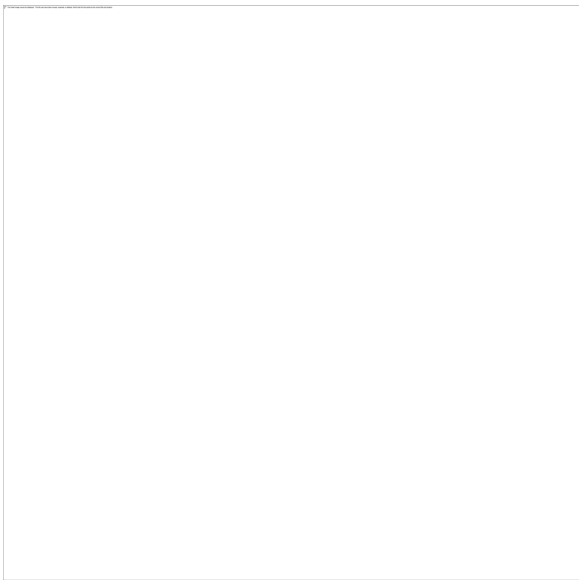

**Fig. (abstract 000592)** ONSD was also larger in the patients with tumor cells in the CSF than those without (5.75 ± 0.8 mm vs. 5.12 ± 0.6 mm, respectively; $p = 0.016$)

**Introduction:** Resuscitative Endovascular Balloon Occlusion of the Aorta (REBOA) is a balloon catheter that occludes the aorta via a transfemoral approach. It can effectively reduce bleeding and maintain central blood pressure; however, the effect on central blood pressure varies widely depending on several factors such as bleeding volume, cardiac function, and REBOA position. Optimal management of REBOA taking these factors into account is challenging even for experts. We hypothesised that a circulatory simulator could help optimise REBOA management.

**Objectives:** The aim of this study is to establish the REBOA simulator based on the fundamental REBOA characteristics from animal experiments and to investigate the influence of blood volume condition and cardiac function on central blood pressure under different REBOA placement positions.

**Methods:** In anesthetized beagle dogs ($N=11$), aortic pressure (AOP), right atrial pressure, and cardiac output were measured. REBOA was inserted through the left femoral artery. After inducing hypovolemic shock by blood withdrawal, the balloon was inflated at Zone 3 (below the renal arteries) and Zone 1 (descending aorta) to record haemodynamic changes. We used Simulink® (Mathworks Inc.) to perform the simulation. The four cardiac chambers were represented by a time-varying elastance. The systemic and pulmonary circulations were represented by resistance-compliance circuits, with the systemic circulation divided into three parallel circuits: central to Zone 1, between Zone 1 and Zone 3, and peripheral to Zone 3. Hypovolemic conditions were mimicked by blood volume loss and increased resistance. The effects of REBOA on haemodynamics were compared among baseline, Zone 1, and Zone 3 under various conditions of reduced stressed blood volume and left cardiac contractility.

**Results:** In animal experiments, the increases of AOP and vascular resistance by REBOA were significantly greater in Zone 1 than those in Zone 3 (Fig. 1A). Using the obtained data, we set the simulation parameters (Fig. 1B). The REBOA simulator demonstrated varying central blood pressure effects under different stressed blood volume, cardiac functions, and positions (Fig. 2). REBOA in normal hearts with 400 ml blood loss drastically elevated AOP (92.7, 149.3, 112.3 mmHg: Baseline, Zone 1, Zone 3). On the other hand, REBOA in hearts with low cardiac contractility and 1200 ml blood loss showed limited pressure elevation (25.3, 38.4, 29.9 mmHg: Baseline, Zone 1, Zone 3). In addition, REBOA in hearts with low cardiac contractility and 400 ml blood loss shifted the pressure–volume loop rightward (Fig. 3) and increased left atrial pressure (9.0, 15.7, 10.5 mmHg: Baseline, Zone 1, Zone 3).

**Conclusions:** The impact of REBOA on central blood pressure differs greatly depending on blood volume, cardiac function, and REBOA position. The REBOA simulator, which simulates central blood pressure effects in complex pathophysiological conditions, can help optimise REBOA management.

**Introduction:** Acute Respiratory Distress Syndrome (ARDS) is a critical illness with high mortality and morbidity in Intensive Care Unit (ICU) on a global scale. It has been highlighted that definitive strategies have not yet been established2 and patient quality of life (QOL) in post-ARDS presented significant deterioration due to impaired physical and cognitive function and mental disorders3-6. However, detailed daily data on the systematic implementation of ventilator strategy and evidence-based ICU care (e.g., the ABCDEF bundle, nutrition, ICU diaries, etc.)7, which is essential to guide clinicians on what we aim to achieve in daily clinical practice based on the disease severity and patient conditions, are lacking in the current literature8,9.

**Objectives:** This study aims to develop an international registry with data on the epidemiology, treatments, daily ICU care, and functional outcomes after hospital discharge.

**Methods:** This is an interim report of an international prospective cohort study, entitled "The ICU LIBERATION Study" endorsed by the European Society of Intensive Care Medicine (ESICM). As of 4th of April 2024, 167 ICUs across 29 countries have participated. This report included all consecutive adult ICU patients between June 2023 and March 2024 who were on an invasive or non-invasive ventilator within 24 h of ICU admission and for more than 48 h. The following essential data are collected daily: the disease severity and patient conditions (e.g., arterial blood gas result, Sequential Organ Failure Assessment Score, and respiratory mechanics such as plateau and driving pressure), ventilator settings, the implementation of the ABCDEF bundle, the amount of nutrition provided, and the introduction of ICU diary. The preliminary outcomes were hospital mortality and the incidence of physical impairments (evaluated by Barthel Index), cognitive impairments (by Mini-Mental State Examination), and mental disorders (by any of Hospital Anxiety and Depression Scale or Impact of Event Scale-Revised) at the 3-month follow-up performed by telephone. The feasibility of the daily-based registry was shown by the percentage of completion of daily data.

**Results:** A total of 523 patients with a mean PaO2/FIO2 ratio of 124 and PEEP of 9 were enrolled. The patient characteristics are demonstrated in Table 1. Of those, 332 patients were discharged and 204 patients have completed the 3-month follow-up with 7% follow-up loss. The hospital mortality was 36% and the mortality at 3-month follow-up was 39%. Of 204 patients, the incidence of physical and cognitive impairments and mental disorders at 3-month follow-up were 34%, 44%, and 25/%, respectively. The completion of essential daily data was 89% overall.

**Conclusions:** This is the first report from the ICU LIBERATION Study endorsed by ESICM. High mortality and high incidence of functional deterioration in ICU patients with ARDS were identified. The high completion of daily data will provide a deep understanding of the relationship between daily practice and patient prognosis in future analysis.

**Table 1 (abstract 000594)** Baseline characteristics

| Item | Overall (n=523) |
|---|---|
| Age, median [IQR] | 64.0 [46.0 - 75.0] |
| Sex (Male), n (%) | 351 (7%) |
| Body Mass Index, median [IQR] | 24.2 [21.2 - 27.8] |
| Clinical Frailty Scale prior to hospital admission, median [IQR] | 2.0 [1.0 - 3.0] |
| Barthel Index prior to hospital admission, median [IQR] | 100.0 [95.0 - 100.0] |
| Dementia scale prior to hospital admission, median [IQR] | 0.0 [0.0 - 0.0] |
| Swallowing function prior to hospital admission, median [IQR] | 7.0 [7.0 - 7.0] |
| Most likely cause of ARDS, n (%) | |
| Bacterial respiratory infection, n (%) | 251 (48%) |
| COVID 19, n (%) | 98 (19%) |
| Sepsis non respiratory, n (%) | 92 (18%) |
| Other viral respiratory infections,n (%) | 77 (15%) |
| Influenza, n (%) | 68 (13%) |
| Charlson Comorbidity Index, median [IQR] | 2.0 [0.0 - 4.0] |
| APACHEII, median [IQR] | 18.0 [10.0 - 24.0] |
| SOFA Sum Score, median [IQR] | 8.0 [5.0 - 11.0] |

### Evaluation of predictive tests associated with postoperative pulmonary complications in elderly patients undergoing hip surgery under general anesthesia: a retrospective observational study

E. Choi, S. L. Yoon, D. S. Kang, H. Jung
Department of Anesthesiology and Pain Medicine, Korea University Ansan Hospital, Gyeonggi-do, Republic of Korea
**Correspondence:** E. Choi
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000597

**Introduction:** Postoperative pulmonary complications remain a significant problem for elderly patients undergoing hip surgery under general anesthesia. To prevent this, various lung function tests are performed before surgery, but sometimes tests are performed inaccurately due to age or cannot be performed due to the patient's condition. Therefore, it is not known which test is most meaningful in predicting pulmonary complications after surgery.
**Objectives:** The aim of this study was to evaluate the predictive preoperative test associated with postoperative pulmonary complications in elderly patients undergoing hip surgery under general anesthesia.
**Methods:** A retrospective observational study was performed of patients aged 60 years or older undergoing hip surgery under general anesthesia at a tertiary care hospital from January 2018 to December 2022. The data collected included demographic information, laboratory tests, pulmonary function tests, pulmonary imaging tests including CT and X-ray, results of preoperative consultation with a pulmonologist, and postoperative outcomes. Afterwards, the statistical difference between the group that developed pulmonary complications after surgery and the group that did not, and the relationship between preoperative tests and the occurrence of postoperative complications were analyzed through regression analysis.
**Results:** 544 patients were divided into two groups: those that developed pulmonary complications (pulmonary complications group, PCG, $n=236$) and those that did not (control group, CG, $n=308$). The PCG was significantly older, included more emergency cases, and had significantly more patients with cardiovascular and renal diseases than the CG. In preoperative consultation with a pulmonologist, there were significantly more moderate to high-risk patients in the PCG. Laboratory tests showed significantly higher WBC and bilirubin levels, and lower aPTT in the PCG. ABGAs1, PFTs2, and operation data showed no difference. A multivariate logistic regression analysis revealed that moderate or higher risk given in preoperative consultations was associated with a 204% increase in pulmonary complications [odds ratio (OR): 2.045, $P=0.012$]. Increased WBC counts (OR: 1.000), decreased aPTT (OR: 0.932), and history of cardiovascular disease (OR: 0.281), were also associated with pulmonary complications ($P=0.001$).
**Conclusions:** In conclusion, preoperative pulmonary consultation with a pulmonologist of a moderate or higher risk was the best predictor associated with postoperative pulmonary complication in elderly patients undergoing hip surgery under general anesthesia.

### NEWS2 accuracy in predicting ICU admission in trauma patients based on their prehospital data set: a diagnostic study

G. Sabetian[1], M. Karajizadeh[2], M. R. yousefi[2], S. Paydar[2]
[1]Dept. of Critical Care Medicine, Trauma Research Center, Shiraz University of Medical Sciences, Shiraz, Islamic Republic of Iran; [2]Trauma Research Center, Shiraz University of Medical Sciences, Shiraz, Islamic Republic of Iran
**Correspondence:** G. Sabetian
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000598

**Introduction:** National Early Warning Score (NEWS2) is a scoring system designed to evaluate patients' clinical status. Studies have demonstrated its capability in predicting trauma patients' outcomes, including death and ICU admission (1, 2). NEWS2 is a feasible and quick way to determine and predict patients' outcomes using common vital signs and clinical status.
**Objectives:** In this novel study we aim to evaluate NEWS2 accuracy in predicting ICU admission in trauma patients based on their prehospital data set in the largest trauma center in southern Iran during 2023–2024.
**Methods:** Of 6905 trauma patients, 4191 were eligible for the study. Patients were divided into ICU admissions and admissions to wards other than ICU groups. Demographic data, vital signs, and Glasgow coma scale (GCS) were obtained in a prehospital setting. NEWS2 is

then calculated (3) and the two groups are compared. Mean and standard deviation are reported for variables. Area under the receiver operator curve, sensitivity, specificity, positive and negative predictive values, and odds ratio (OR) of NEWS2 are reported. P-value under 0.05 is considered significant.

**Results:** Of the 4191 patients, 541 have been admitted to ICU. Mean, and standard deviation of age, systolic blood pressure, respiratory rate, heart rate, SpO2, temperature, and GCS are 41.6 + 20.57, 129 + 18.59, 16.55 + 3.06, 87.77 + 16.9, 94.13 + 5.92, 36.77 + 0.39, and 14.48 + 1.99, respectively. Age and gender had no significant differences between the two groups. SBP, RR, HR, temperature, and GCS were significantly different between the two groups ($p < 0.001$). NEWS2 was significantly capable of predicting ICU admission in patients based on prehospital data set with cutoff point > 3 ($p < 0.0001$, AUC = 0.806, odd ratio = 13.75, 95% CI (11.22–16.86)) (Figure 1). Its sensitivity and specificity were 60.07, 95% CI (55.8–64.2) and 90.14, 95% CI (89.1–91.1), respectively. Positive and negative predictive values are 47.4 and 93.8, respectively (Table 1).

**Table 1 (abstract 000598)** ROC characteristics of NEWS2

| Characteristics | Values |
|---|---|
| Cutoff | > 3 |
| Area under the curve | 0.806 |
| Sensitivity (95% CI) | 60.07 (55.8–64.2) |
| Specificity (95% CI) | 90.14 (89.1–91.1) |
| Positive predictive value | 47.4 |
| Negative predictive value | 93.8 |
| Odd ratio (95% CI) | 13.75 (11.22–16.86) |

**Conclusions:** As demonstrated in this novel study, NEWS2 can effectively predict the need for ICU admission in trauma patients based on their prehospital data set. Studies have indicated that it takes roughly 4 min to calculate early warning scores including NEWS2 (4). Given its proper accuracy and ease of use, it seems to be a practical tool for managing and dispositioning the patients and in turn, reducing unexpected ICU admissions. Further meta-analysis and population-based studies are required to confirm these findings. Finally, using machine learning and advanced wearable vital signs monitoring devices, it is possible to utilize this scoring system in a way that can reduce mortality and morbidity of trauma patients.

**Introduction:** Intensive Care Unit (ICU) readmission among trauma patients presents multifaceted challenges within healthcare systems, including prolonged hospital stays, elevated complications of

hospitalization, and increased healthcare costs. (1,2) Despite extensive research efforts, ICU readmission remains a persistent concern, necessitating further investigation to better understand its determinants and implications.
**Methods:** This retrospective cohort study conducted at Emtiaz Hospital a level I referral trauma center in Shiraz City aimed to analyze ICU readmission rates among trauma patients over a three-year-period. Data were extracted from the Iranian Intensive Care Registry (IICUR), encompassing patient demographics, injury severity, physiological parameters, and clinical outcomes. Statistical analysis was performed using SPSS version 25.0, employing a range of methodologies such as descriptive statistics, T-tests, Mann–Whitney tests, Chi-square tests, and logistic binary regression.
**Results:** Among the 5273 patients discharged from the ICU during the study period, 195 (3.7%) experienced readmission during the same hospitalization. Notably, patients readmitted to the ICU exhibited a significantly higher mean age (54.83 years) compared to those who were not readmitted (47.08 years, $P<0.001$). Factors associated with ICU readmission included lower Glasgow Coma Scale (GCS) scores at admission and discharge, suggesting a correlation between neurological status and readmission risk. Furthermore, respiratory challenges emerged as a predominant cause of unplanned readmission, encompassing respiratory failure, hypoxic respiratory failure, respiratory distress, and respiratory infections such as pneumonia. Analysis of injury patterns revealed a higher frequency of poly-trauma and head and neck injuries among patients readmitted to the ICU.
**Conclusions:** This study underscores the significance of ICU readmission among trauma patients, with a notable readmission rate during the same hospitalization. By developing comprehensive guidelines and optimizing discharge processes, healthcare providers can potentially mitigate ICU readmissions and associated complications, ultimately enhancing patient outcomes and resource utilization in trauma ICU settings. This research contributes valuable insights to inform evidence-based practices and improve the quality of care delivery for trauma patients in intensive care settings.

### Factors associated with survival in patients with acute respiratory distress syndrome placed on prone position in a tertiary hospital in the Philippines

M. A. Lazaro, A. Maralit, R. M. Molina, A. M. Hernandez
Adult Critical Care Medicine, Asian Hospital and Medical Center, Muntinlupa, Philippines

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000601

**Introduction:** Acute respiratory distress syndrome (ARDS) remains to be the leading cause of mortality among critically ill patients worldwide. Lung protective ventilatory strategies are the mainstay treatment that aims to reduce the risk of ventilator-induced lung injury (VILI) by preventing overdistention and optimizing ventilation. Placing patients in the prone position is a well-studied approach to improve mortality among ARDS patients but despite evidence, it remains to be underutilized. At present, there are limited studies investigating the association of factors that affect survival among ventilated patients placed on prone and this study aims to determine these factors.
**Methods:** All mechanically ventilated ARDS patients that were placed on prone during a 5-year period were retrospectively reviewed. Baseline demographics, severity of illness, etiology of pneumonia, prone and ventilator strategies and respiratory mechanics were collected. Primary outcome was recorded as survival on the 28th day after the first prone. Adverse events while on prone position were recorded as secondary outcomes.
**Results:** A total of 117 patients were included in this study. Among those enrolled, 77(65.8%) patients died. Older age and higher SAPS-3 score were significantly related to 28-day survival. Non-survivors underwent longer prone duration, had worse lung mechanics (peak pressure, plateau pressure, driving pressure) post prone, and were placed on prone later after ARDS diagnosis. Survivors were on longer sedation days than non-survivors. Hemodynamic instability was the most common adverse event reported among non-survivors.
**Conclusions:** Elderly patients and those with more severe illnesses increase the risks for mortality among ARDS patients. Early initiation of proning may be beneficial to improve survival. Adverse events during proning such as hemodynamic instability can be an anticipated adverse event among patients placed on prone.

### Fallibility of PaO2/FIO2 and SaO2/FIO2 for assessing pulmonary function: a computer model

K. Haines[1], J. Downs[2], A. I. Wong[3], J. Räsänen[4]
[1]Department of surgery, Duke University, Durham, NC, USA, Durham, United States of America; [2]Department of Anesthesia, Professor, Gainesville, United States Minor Outlying Islands; [3]Department of Medicine, Duke University, Durham, United States

of America; [4]Department of Anesthesia, Professor, Tampa, United States of America
**Correspondence:** K. Haines
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000603

**Introduction:** Reliable measurements to assess pulmonary function have been debated for decades. PaO2/FIO2 and SaO2/FIO2 have been used to discriminate between Acute Lung Injury and ARDS and, recently, between mild, moderate, and severe ARDS. Almost all papers with ARDS diagnosis and/or treatment published in the last 15 years have incorporated analyses of PaO2/FIO2.
**Objectives:** In this study, we wished to determine the accuracy of assessing pulmonary function in patients with variable right to left intrapulmonary shunting of blood (Qsp/Qt) using PaO2/FIO2 and SaO2/FIO2. We also discuss the influence of other variables on PaO2/FIO2 and SaO2/FIO2 values.
**Methods:** A computer model was designed to calculate the PaO2/FIO2 and SaO2/FIO2 ratios for any FIO2 with an assumed value of Qsp/Qt. The model assumed normal values of hemoglobin, PaCO2, cardiac output, oxygen consumption, barometric, and water vapor pressures. We used the mathematical expression of the oxyhemoglobin dissociation curve described by Ruiz to generate SO2 and PO2 values from oxygen contents.
**Results:** PaO2/FIO2 and SaO2/FIO2 vary inconsistently with FIO2 at all levels of Qsp/Qt. Only when Qsp/Qt equals 0, does PaO2/FIO2 ratio remain relatively constant with variable FIO2. For Qsp/Qt values of 5–20%, PaO2/FIO2 decreased as FIO2 increased, until SaO2 was ~ 99%, then it increased in proportion to FIO2. However, for Qsp/Qt > 20%, PaO2/FIO2 decreased with increasing FIO2 and values were similar regardless of the degree of Qsp/Qt. SaO2/FIO2 analyses revealed similar results.
**Conclusions:** Our computational analysis demonstrates that PaO2/FIO2 and SaO2/FIO2 are an inaccurate means of assessing pulmonary function. When used in clinical situations, PaO2/FIO2 and $SaO_2/FIO_2$ are both affected by many variables and can lead to erroneous conclusions that affect therapy. Therefore, since it is doubtful that clinicians will cease using PaO2/FIO2 and SaO2/FIO2 ratios, it is essential that individual patient evaluations be made using a constant FIO2.

## Quantitative impact of traditional open surgery and minimally invasive surgery on first-night sleep status in intensive care unit patients: a pilot study

Z. Li[1], C. Shang[1], Y. Yang[2], Z. Zhao[3], Y. Gao[1]
[1]Department of Critical Care Medicine, Renji Hospital, School of Medicine, Shanghai JiaoTong University, Shanghai, China; [2]Department of Infection Control, Renji Hospital, School of Medicine, Shanghai JiaoTong University, Shanghai, China; [3]School of Biomedical Engineering, Furtwangen University, Guangzhou, China
**Correspondence:** Z. Li
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000605

**Introduction:** Impaired sleep quality is a commonly experienced stress by critically ill patients undergoing surgery, leading to physical and mental impairments and poor prognosis (1). Sleep disorders in these patients are influenced by the extent of surgical intervention and intensive care unit (ICU) instruments (2). Understanding the characteristics of postoperative sleep disorders is crucial for developing personalized perioperative treatment plans and improving prognosis.
Minimally invasive surgery (MIS) has emerged as an alternative to traditional open surgery (TOS), utilizing smaller incisions and potentially reducing surgical stress responses (3). However, due to the lack of quantitative sleep monitoring tools at the bedside, there is a lack of comparative studies on sleep quality after TOS and MIS.
The gold standard sleep monitor Polysomnography (PSG) is limited in the ICU due to electrode placement difficulties, movement concerns, and electrical artifacts(4). Subjective questionnaires like the Richards Campbell Sleep Questionnaire (RCSQ) are commonly used, sacrificing accuracy and quantification (5).
Modern wearable sleep monitoring wristbands equipped with the cardiopulmonary coupling technique and built-in analysis software have the potential to enhance monitoring capabilities by automatically assessing sleep status and stage, including sleep duration, light and deep sleep, rapid eye movement (REM) sleep, and wakefulness (6–8). However, there is currently limited data on sleep patterns in TOS and MIS surgery patients after recovery from anesthesia.
