FRACTURE PREVENTION: TIME TO MOVE BEYOND THE PRIMARY/SECONDARY DICHOTOMY?

E. V. McCloskey[1]

[1]Division of Clinical Medicine, School of Medicine and Population Health, Mellanby Centre for Musculoskeletal Research, University of Sheffield., Sheffield, United Kingdom

Primary prevention refers to actions aimed at avoiding the manifestation of a disease, including actions to modify behavioural and medical health risks (e.g. nutritional and activity interventions or use of vaccinations if appropriate). Secondary prevention deals with early detection of disease and interventions to deliver positive health outcomes (e.g. a reduction in risk of disease progression). The clinical management of chronic non-communicable diseases has frequently been separated into primary and secondary prevention. Secondary prevention is widely accepted, if not implemented, within clinical care—an event has happened that is often easily recognisable, usually if not always ensuring the presentation of the patient to a care provider and, finally, is seen to trigger a management pathway of investigation and treatment. This is often seen as the 'low hanging fruit' in medical care, but its implementation is often far from optimal as evidenced by a large and persisting treatment gap even in those with fracture.

The other concept of primary and secondary reflects the setting of the care provider; provision of event detection and management in primary care (GP, family physician, community settings) or in secondary care (hospital, specialist clinic etc). Events, by their nature, often lead to secondary care investigation and management with care in the immediate aftermath of the event often driven by established clinical protocols. However, the long-term care and management is then often transferred back to primary care; the latter requires excellent communication, education and understanding of the treatment goals so that long-term measures are provided and monitored to ensure the best possible outcome in individual patients.

Finally, the delineation of primary and secondary prevention is not totally an event driven phenomenon. While primary prevention is driven by the awareness of an increased risk in an individual prior to the event, the likelihood of an event in any individual, even in those with a first event, can vary markedly depending on the co-existence of other health conditions and risk factors. In this concept, the event can be seen as yet another risk factor to be considered, and rather than an automatic trigger for treatment should be seen as a trigger for risk assessment with subsequent treatment driven by the risk of future event. These different concepts will be addressed in this presentation.

PL2
OPTIMIZATION OF LIFELONG OSTEOPOROSIS MANAGEMENT

M. McClung[1]

[1]Oregon Osteoporosis Center, Portland, United States

Osteoporosis is a chronic condition requiring long-term, even lifelong therapy. Different strategies are appropriate at different stages of life and for different levels of fracture risk. During years of skeletal growth, being healthy with good nutrition and regular physical activity are important to optimize peak bone mass as is achieving normal puberty during adolescence. Identifying women at high risk for osteoporosis at the time of menopause provides the opportunity to prevent the rapid loss of bone mass and deterioration of skeletal microarchitecture that occurs at that time, thereby preventing postmenopausal osteoporosis. For patients with osteoporosis, general measures (good nutrition, maintaining strength and balance and fall prevention) are important but not sufficient to reduce fracture risk. Optimal therapy for patients who have already developed osteoporosis begins with an osteoanabolic agent to restore skeletal structure, followed by an anti-remodeling drug to maintain that benefit. Once a patient has achieved maximal benefit from therapy, intermittent bisphosphonate "maintenance" therapy is appropriate for long-term management. Optimization of skeletal health over the lifespan is an important consideration for all persons.

UNRAVELING THE VITAMIN D MEGATRIAL CONUNDRUM

B. Dawson-Hughes[1]

[1]Jean Mayer USDA Human Nutrition Research Center on Aging at Tufts University, Boston, United States

By now, it is generally recognized that the recent vitamin D mega-trials were null with respect to the effect of vitamin D supplementation on risk of falls and fractures. Most of these trials were planned and implemented concurrently and consequently did not "learn from one another". This presentation will address what we have learned and focus on the relevance of the megatrial findings to the global community. The context in which the trials were conducted—including the baseline 25-hydroxyvitain D [25(OH)D] levels of participants, their self-selected calcium intake, and the amounts of personal vitamin D and calcium supplements that participants were allowed to take during the mega-trials—will be considered.

In an early study, the landmark Chapuy trial published in 1992, the combination of daily vitamin D (800 IU) supplementation and calcium (1200 mg) supplementation in 3270 elderly, vitamin D- and calcium-deficient female nursing home residents dramatically reduced risk of hip fractures by 43% and other non-vertebral fractures by 32%. Smaller studies conducted soon thereafter identified a reduced risk of fractures in community dwelling older men and women who were not taking supplemental calcium or vitamin D. These studies were conducted before supplementation with vitamin D became the norm in the US. Supplementation was also occurring in other regions where megatrials were performed, as evidenced by the substantial baseline 25(OH)D levels in these trials. Additionally, calcium intake had been boosted by expanded food fortification in the US during the tenure of the VITAL mega-trial.

Nutrient intake has a distinctive relationship to function wherein inadequate intake impairs function, there is an optimal intake range in which function is maximal, and excess intake impairs function. The boundaries of the optimal 25(OH)D range for vitamin D are not precisely defined. The lower boundary for 25(OH)D appears to be around 20 ng/ml (50 nmol/L). The upper boundary is less clear although there is evidence that in may be in the range of 25(OH)D levels of 40–60 ng/ml. This concept is important to consider when choosing supplement doses and designing food fortification programs. Context is critically important as regions around the globe consider whether supplementation with vitamin D alone or in combination with calcium would be beneficial. We will review the 25(OH)D levels and calcium intake in different countries and regions compiled by the International Osteoporosis Foundation and consider strategies to optimize vitamin D and calcium intakes globally.

PL4
BONE, BIOCHEMISTRY AND BEYOND: NEW PARADIGMS IN CKD MDB

P. Ebeling[1]

[1]MD, Department of Medicine, School of Clinical Sciences, Monash University, Clayton, Victoria, Australia

CKD is commonly associated with ageing. Most have stage 1, 2 or 3 CKD with estimated glomerular filtration rates (eGFR) of ^{3}90 mLs/min, 60–89 mLs/min, and 30–59 mLs/min, respectively. However, many will have stage 4 CKD (15–29 mLs/min) and stage 5 CKD (< 15 mLs/min) or are on dialysis. CKD is associated with excess morbidity, including fractures, and mortality. There is an exponential increase in hip fractures with increasing CKD stage.

CKD-Metabolic Bone Disorder (MBD) occurs in stage 4 and 5 CKD, and is characterized by bone (renal osteodystrophy), soft tissue (calcifications), and mineral (phosphate, calcium, fibroblast growth factor-23, calcitriol, sclerostin, Dikkopf-1) abnormalities. Its pathological endpoints are increased cardiovascular risk, mortality and fractures.

Hip fracture incidence is increased at every age for patients with Stage 3b, 4 and 5 CKD. Mortality after any fracture is also increased in patients with CKD, being highest in patients with Stage 5 CKD. It is unclear whether conventional anti-osteoporosis drugs are either appropriate, or effective, in patients with CKD stages 4 and 5, which has led to therapeutic inertia. A reluctance to use anti-resorptive drugs also relates to the possibility of underlying adynamic bone disease and theoretical worsening of skeletal fragility. In adynamic bone disease, turnover is low, mineralization is normal, and volume is low, while in hyperparathyroidism, turnover is high, mineralization is normal, and volume is low. By contrast, in osteomalacia, turnover is low, mineralization is low, and volume is normal.

2017 KDIGO guidelines state the optimal PTH level is not known. Instead, they renew a focus on assessment of both fracture risk, using DXA, and bone turnover in individual patients with CKD Stage 3a–5D, if these results will impact treatment decisions. In patients with high turnover, an anti-resorptive drug ± vitamin D should be used, while in patients with low turnover, an anabolic drug ± vitamin D could be used instead. The use of calcitriol or other active vitamin D analogs is reserved for patients with CKD stages 4–5 with severe and progressive hyperparathyroidism. Data from large RCTs show both risedronate and denosumab reduce vertebral fractures in patients with milder CKD (stage 2–4 CKD for risedronate, and stage 2–3 CKD for denosumab). Denosumab use can also be associated with severe hypocalcaemia in stage 4 and 5D CKD patients even though it is cleared by the liver rather than the kidney. This can be corrected by administration of active vitamin D analogues and calcium. Denosumab has no adverse effect on kidney function in CKD. Data from the Fracture Prevention Trial show teriparatide is effective at reducing vertebral and nonvertebral fractures in patients with eGFR < 80 mLs/min. The renal risks of bisphosphonates are poorly explored in patients with CKD stages 3b–5D, which calls for caution in this group.

Trabecular bone score and alternative bone imaging techniques such as hip structural analysis and high-resolution peripheral quantitative computerised tomography (HR-pQCT) need further evaluation pending clinical implementation. FRAX® predicts fracture probability in all CKD stages. However, more evidence is required to determine whether adjustments to conventional FRAX® estimates must be made in stage 4 and 5 CKD. Regarding biochemistry, 2017 ECTS guidelines recommend combining PTH with bone specific alkaline phosphatase (BSAP) as the best non-invasive way to divide patients into high or low bone turnover. However, in cases with either low PTH, or low or intermediate BSAP levels, a bone biopsy may be required to exclude low turnover renal osteodystropy (due to either adynamic bone disease or osteomalacia). However, the inability to perform a bone biopsy should not preclude treatment in those a high risk of fracture.

In conclusion, it is critical that an individual and tailored approach to managing metabolic bone disorder is taken in patients with CKD.

PL5
BONE RESORPTION INHIBITORS BEYOND THE SKELETON

B. Abrahamsen[1,2]

[1]OPEN, University of Southern Denmark, Odense, Denmark,
[2]Department of Medicine 1, Holbæk Hospital, Holbæk, Denmark

Objective: Update the audience on recent developments on extraskeletal effects of inhibitors of bone resorption. The talk will focus on strong antiresorptive osteoporosis medications.
Methods: Narrative literature review of new basic, translational, RCT and observational studies.
Results: Uniquely among inhibitors of bone resorption, denosumab is a circulating humanized antibody which engages with immune cell signaling inside and outside the skeleton. By contrast, bisphosphonates home in on calcified tissues and spend only a short time in circulation before elimination. Despite the difference in kinetics, both classes of antiresorptives may exert clinically relevant effects outside the skeleton, either directly or indirectly mediated through reduced turnover. Hence, potential effects on heart rhythm, major cardiovascular events, muscle function and falls, pain syndromes, obesity, glucose metabolism, asthma, tumour macrophages, cancer events and inflammation have been reported in observational studies and in post-hoc analyses of clinical trials. For example, RCTs find a significantly reduced risk of falls with denosumab though there is not sufficient data to surpass the trial sequential monitoring boundary. In addition, intervention data support increased muscle strength with denosumab though the concept is supported by minimal animal data. A pilot study suggests denosumab could improve male fertility in some circumstances. Despite the kinetic profile favouring delivery to bone, bisphosphonates may also exert effects on soft tissue tumours and anti-inflammatory effects as well as potentially ameliorating chronic pain. Of particular note it remains controversial yet hugely important if and how potent antiresorptives can modify body composition and cardiovascular risk.
Conclusions: There is mounting indirect evidence and post-hoc trial evidence to support evaluating potent bone resorption inhibitors in clinical trials powered to assess non-skeletal outcomes of major public health impact such as frailty, falling, breast cancer, atherosclerosis and diabetes.
Disclosures: Institutional research grants and personal fees from UCB, Pharmacosmos and Kyowa-Kirin as well as speakers fees from Gedeon Richter and Amgen.

PL6
MANAGEMENT OF OSTEOPOROSIS IN MULTI-ETHNIC POPULATIONS

M. Chandran[1]

[1]Singapore General Hospital, Singapore, Singapore

Professor Manju Chandran
Senior Consultant and Director
Osteoporosis and Bone Metabolism Unit
Singapore General Hospital
Clinical Professor, DUKE NUS Medical School, Singapore
Chairperson, Asia Pacific Consortium on Osteoporosis (APCO)

- The meanings of ethnicity and race are complex, convoluted, and intertwined. Ethnicity is a complex social construct. *The descriptor can be employed as a supplement to a person's race and is* used to refer to social groups of a common ancestry and shared culture.
- There is evidence that variations in BMD and osteoporosis exist between major racial and ethnic groups. What reference database to use for defining osteoporosis based on T-scores is a matter of debate.
- There is also emerging evidence that racial and ethnic disparities in osteoporosis outcomes and management exist with many factors such as socio-demographics, biological risk factors, and health behaviors accounting for these differences
- Variations in ethnicity-specific fracture risk also exist.
- How does one determine intervention thresholds in populations that are multi-ethnic? Do we use ethnic specific intervention thresholds, or do we use a non-ethnic specific universal intervention threshold in that population?

This presentation will focus on 4 major issues

- Ethnic variations in BMD and their impact on T-scores.
- Fracture risk differences between ethnicities.
- Determining fracture risk probability-based intervention thresholds in multi-ethnic populations.
- Is it possible to circumvent ethnic disparities in osteoporosis assessment and management.

PL7
HOW SHOULD WE DEFINE SARCOPENIA? PAST, PRESENT AND FUTURE PERSPECTIVES

A. J. Cruz-Jentoft[1]

[1]Servicio de Geriatría. Hospital Universitario Ramón y Cajal (IRYCIS), Madrid, Spain

The term "sarcopenia", initially coined during a late-eighties conference on nutrition and body composition, aimed to describe the age-related decline in lean body mass—a surrogate measure of skeletal muscle mass. Subsequent research revealed that while measures of lean mass (commonly assessed via DXA or BIA) fell short in predicting functional outcomes—specifically mobility, one of the main functions of skeletal muscle—, muscle function emerged as a more reliable predictor.

Around 2010, consensus meetings across different continents published updated definitions of sarcopenia. Despite slight variations, these definitions agreed in including muscle function (usually defined by muscle strength and body physical performance) in the concept of sarcopenia. Consequently, sarcopenia was conceptualized as an organ insufficiency (muscle failure) characterized by reduced muscle mass, low muscle strength and reduced physical performance, using different frameworks and cut-off points. This functional redefinition swiftly demonstrated clinical significance, propelling research that established sarcopenia's predictive capacity for critical outcomes such as mortality, disability and falls. These new facts were incorporated to a second wave of key sarcopenia definitions, that emphasized the pivotal role muscle strength in this condition.

However, recent challenges have surfaced. First, disparities among definitions across continent seem to be hindering both research and the universal integration of sarcopenia detection and management into routine clinical practice. Second, the incorporation of new disciplines to sarcopenia research—where body composition assessment (typically via CT scans) are available but functional measures are lacking—has revived the erroneous attribution of the word sarcopenia to name a reduced muscle mass. This is an error, as low muscle mass not only defines sarcopenia, but also malnutrition and cachexia.

Encouragingly, major consensus groups have now united under an initiative named Global Leadership Initiative in Sarcopenia (GLIS). This collaborative effort has produced an updated conceptual definition of sarcopenia, aiming for global applicability, with an operational definition currently in development. These advancements will be presented at the conference.

PL8
SARCOPENIA MANAGEMENT: MUSCLE-TARGETED INTERVENTIONS FOR HEALTHY AGEING

A. Cherubini[1]

[1]Geriatria Accettazione geriatrica e Centro di Ricerca per l'invecchiamento IRCCS INRCA and Università Politecnica delle Marche, Ancona, Italy

Objective(s): To present evidence based interventions for the management of sarcopenia.
Material and Methods: Extensive literature review.
Results: There is currently no drug which is approved for the prevention and treatment of sarcopenia. Therefore, its management is based on non-pharmacological interventions. Overall all existing guidelines strongly recommend resistance training to improve muscle strength, muscle mass and physical function in sarcopenic older patients based on moderate quality evidence. A recent meta-analysis on 42 RCTs confirms that resistance exercise combined with balance or aerobic exercise can ameliorate strength and physical function, measured by means of different tests. Moreover, resistance exercise, with or without nutritional supplementation, and in combination with aerobic and balance exercises, has a positive impact on quality of life (moderate evidence). A protein rich diet is also recommended, although the quality of evidence is low. The referral of older patients with sarcopenia to a dietician or a nutritionist might be considered. An adequate intake of proteins should be preferably implemented in combination with exercise. Other non-pharmacological interventions, e.g. vitamin D or omega 3 polyunsaturated fatty acid supplements, still lack a sufficient level of supporting evidence.
Conclusion(s): A multicomponent personalized non pharmacological intervention based on resistance exercise training, alone or combined with other types, i.e. aerobic and balance exercise, associated with adequate nutrition, i.e. adequate intake of proteins, is recommended in sarcopenic older people. There are ongoing studies to identify drugs for the prevention and treatment of sarcopenia.

PL9
NEW PERSPECTIVES IN OSTEOARTHRITIS MANAGEMENT

A. Mobasheri[1,2,3,4]

[1]Research Unit of Health Sciences and Technology, Faculty of Medicine University of Oulu, Oulu, Finland, [2]Department of Regenerative Medicine, State Research Institute Centre for Innovative Medicine, Vilnius, Lithuania, [3]Department of Joint Surgery, First Affiliated Hospital of Sun Yat-sen University, Guangzhou, Guangdong, China, [4]World Health Organization Collaborating Center for Public Health Aspects of Musculoskeletal Health and Aging, Université de Liège, Liège, Belgium

Osteoarthritis (OA) is the most common form of arthritis and a major contributor to pain and reduced mobility globally. OA is a mechano-inflammatory characterized by the gradual breakdown of articular cartilage and other joint tissue structures, and the subsequent development of inflammation, pain, stiffness, and reduced joint function. New perspectives in OA management represent a shift from traditional symptom management with pharmacological pain medications toward more holistic, patient-centered, self-managed and science-driven approaches to address this common and debilitating joint condition. The European Society for Clinical and Economic Aspects of Osteoporosis, Osteoarthritis and Musculoskeletal Diseases (ESCEO) has recently performed a review of multimodal/multicomponent approaches for knee OA therapy (Veronese et al., 2022). The new perspectives aim to address expectations of patients, healthcare providers and regulators. The emerging approaches in OA management aim to improve patient outcomes, slow disease progression, and enhance overall quality of life. There is increasing emphasis on the importance of weight management, exercise, diet and lifestyle. Disease modification with disease-modifying OA drugs (DMOADs) remains a very challenging but active area of research and development. The identification and validation of specific biomarkers associated with OA can assist in early diagnosis and monitoring of disease progression. However, there are currently no biomarkers that can be used to predict patient responses to various interventions, thus highlighting a major gap in the availability of tools for developing individualized treatments and precision medicine. Regenerative medicine approaches, including stem cell therapies, gene therapies and platelet-rich plasma (PRP) injections, are being investigated for their potential to repair damaged joint tissues and promote healing, but none of these have been approved by regulators. In the absence of effective disease modifying and regenerative treatments, there is increasing recognition of lifestyle factors, such as diet, exercise, weight management, sleep quality and mental health in OA management. Lifestyle modifications can help reduce pain and improve function in OA patients, and behavioral interventions are gaining importance in pain management. Digital health and wearable technologies have the potential to transform clinical practice and the design of clinical trials. Mobile apps, wearable devices, and telemedicine can be used to monitor OA patients' symptoms, activity levels, and adherence to treatment plans. These technologies can provide real-time data to healthcare providers for more effective management and intervention. Digital technologies are also likely to impact on patient education and shared decision-making, empowering patients with better knowledge about their condition, allowing them to self-manage their symptoms (Healey et al., 2023), and involving them in shared decision-making processes, leading to better treatment adherence and patient satisfaction. In the future, OA management will involve multi-disciplinary teams and collaborative care models involving various healthcare professionals, such as rheumatologists, orthopedic surgeons, physical therapists, pain specialists, and nutritionists, can provide comprehensive and personalized care for OA patients. These new perspectives in OA management represent a shift toward more holistic, patient-centered, self-managed and science-driven approaches to address this common and debilitating joint condition. Continued research, innovation, and collaboration among healthcare providers, researchers, and patients are essential to further advance the field of OA management.

PL10
PRECISION MEDICINE APPROACHES IN THE ASSESSMENT OF FRACTURE RISK

N. Harvey[1]

[1]MRC Lifecourse Epidemiology Centre, University of Southampton, Southampton, United Kingdom

Established guidelines for the management of osteoporosis have traditionally focused on the question of treatment versus no treatment. However, we now have an enviable range of medications to improve bone mineral density across both antiresorptive and now anabolic mechanisms. Recent head-to-head studies have demonstrated superiority of teriparatide and romosozumab, compared with oral antiresorptives, both in terms of rapidity of onset and magnitude of effect. These findings have fuelled moves internationally, initially from ESCEO, supported by IOF, to promote a stratified approach to treatment, with choice of medication personalised according to baseline fracture risk. Different organisations espouse different definitions of very high fracture risk in this stratified approach, with the IOF-ESCEO favouring an absolute fracture probability threshold based on the European Guidelines using FRAX®. Whilst baseline fracture probability permits personalisation of treatment, with anabolics targeted to those at very highest risk, new understanding of genetic instruments for bone mineral density, and artificial intelligence approaches to risk assessment in big datasets, have suggested methods to stratify individuals at the level of healthcare systems. In future pathways linking together such assessments, it may be possible to identify those likely to be at high fracture risk on the basis of information held in a reimbursement database. These individuals could then be invited for subsequent clinical assessment and treatment, using FRAX and measurement of bone mineral density. In this presentation, I will review ways in which medication choices may be personalised to individuals, based on factors such as fracture risk, genetics and other considerations, and how these approaches might be synthesised into an integrated clinical pathway.

OC1
COMPARATIVE EFFECTIVENESS OF DENOSUMAB VERSUS BISPHOSPHONATES AMONG TREATMENT-EXPERIENCED POSTMENOPAUSAL WOMEN WITH OSTEOPOROSIS IN THE U.S. MEDICARE PROGRAM

J. R. Curtis[1], T. Aurora[2], Y. Liu[1], T.-C. Lin[3], L. Spangler[3], V. C. Brunetti[4], R. K. Stad[3], M. Mcdermott[3], B. D. Bradbury[3]

[1]University of Alabama at Birmingham, Birmingham, United States, [2]Foundation for Advancing Science, Technology, Education and Research, Birmingham, United States, [3]Amgen Inc., Thousand Oaks, United States, [4]Amgen Ltd., London, United Kingdom

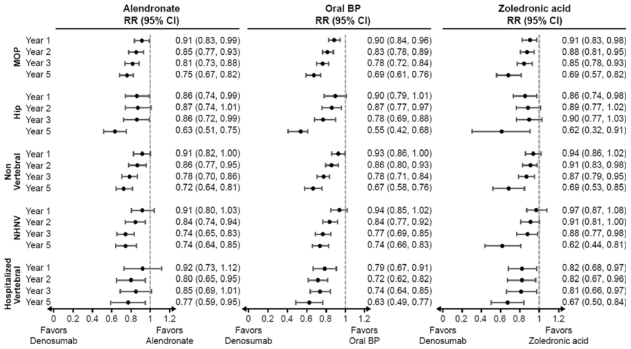
Objectives: Although clinical trials have shown that transitioning from bisphosphonates (BP) to denosumab (Dmab) increases bone mineral density at key skeletal sites more than remaining on BP, evidence from head-to-head studies evaluating fracture outcomes is lacking. This retrospective observational study compared the effectiveness of Dmab versus BP in reducing fracture risk among treatment-experienced women with postmenopausal osteoporosis (PMO) in the U.S.

Methods: Female Medicare fee-for-service beneficiaries $\geq$ 66 years of age with prior history of treatment with an oral BP, who newly initiated Dmab (n $\sim$ 108,000), a different oral BP (alendronate, ibandronate, or risedronate; n = 100,649), alendronate (Aln; n = 53,165), or zoledronic acid (ZA; n = 35,100) between Jan 1, 2012 to Dec 31, 2018 were followed from treatment initiation (index date) until the first instance of a fracture, treatment discontinuation (defined as the end of exposure + 60-day gap) or switch, Medicare disenrollment, death, end of available data (Dec 31, 2019), or 5 years post-index date. A doubly robust inverse-probability of treatment (weights estimated from multivariate logistic regression models) and censoring (weights estimated from multivariate Cox Proportional Hazards regression models) weighted function was used to estimate the relative risk (RR) associated with the use of Dmab compared with oral BP, Aln, and ZA for hip, nonvertebral (NV; includes hip, humerus, pelvis, radius/ulna, other femur), non-hip, nonvertebral (NHNV), hospitalized vertebral (HV), and major osteoporotic (MOP; nonvertebral and hospitalized vertebral) fractures for the overall study period and by year of follow-up.

Results: Over a maximum of 5 years of follow-up, Dmab reduced the risk of hip fracture by 45% (RR = 0.55; 95% CI 0.42–0.68), 37% (0.63; 0.51–0.75), and 38% (0.62; 0.32–0.91), and reduced the risk of MOP fracture by 31% (0.69; 0.61–0.76), 25% (0.75; 0.67–0.82), and 31% (0.69; 0.57–0.82) compared with oral BP, Aln, and ZA respectively (Figure). Similar results were observed for NV, NHNV, and HV fractures, with an increase in the magnitude of fracture risk reduction with increasing duration of exposure across all fracture outcomes.

Conclusion: In a large cohort of treatment-experienced women with PMO, we observed robust, clinically meaningful reductions in the risk of hip, NV, NHNV, HV, and MOP fractures for patients on Dmab compared to oral BP, Aln, and ZA; greater reductions in fracture risk were observed with longer duration of exposure.

Figure. Forest Plot of Relative Risk of Fracture Comparing Denosumab to Alendronate, Oral BP, and Zoledronic Acid



OC2
BMD RESPONSES AT THE LUMBAR SPINE AND TOTAL HIP IN PATIENTS RECEIVING ROMOSOZUMAB, DENOSUMAB AND ALENDRONATE: A POST HOC ANALYSIS OF THE RANDOMISED FRAME AND ARCH PHASE 3 TRIALS

F. Cosman[1], L. Gifre[2], K. Poole[3], F. Thomasius[4], B. Langdahl[5], P. R. Ebeling[6], J. P. van den Bergh[7], E. M. Lewiecki[8], J. Timoshanko[9], Z. Wang[10], C. Libanati[11]

[1]Columbia University, New York, United States, [2]Department of Rheumatology, Hospital Germans Trias i Pujol, Barcelona, Spain, [3]Department of Medicine, University of Cambridge, Cambridge, United Kingdom, [4]Frankfurter Hormon & Osteoporosezentrum, Frankfurt, Germany, [5]Department of Endocrinology, Aarhus University Hospital, Aarhus, Denmark, [6]Department of Medicine, School of Clinical Sciences, Monash University, Melbourne, Australia, [7]VieCuri Medical Center & Maastricht University Medical Center, Maastricht, Netherlands, [8]New Mexico Clinical Research & Osteoporosis Center, Albuquerque, United States, [9]UCB Pharma, Slough, United Kingdom, [10]Amgen Inc., Thousand Oaks, United States, [11]UCB Pharma, Brussels, Belgium

Objectives: To assess the proportion of postmenopausal women with osteoporosis (OP) achieving clinically meaningful improvements in BMD at both the total hip (TH) and lumbar spine (LS) over 1 year after treatment with romosozumab (Romo), denosumab (Dmab) or alendronate (ALN) using data from FRAME (NCT01575834) and ARCH (NCT01631214) studies. Correlations between overall change in LS and TH BMD for each treatment were also assessed.

Materialsand methods: For Romo/ALN comparisons, BMD data from ARCH were utilised; patients were randomised to Romo 210 mg monthly (QM) or ALN 70 mg weekly for 12 months.[1] For Romo/Dmab comparisons, BMD data from FRAME were utilised included women initially randomised to Romo 210 mg QM for 12 months and those initially randomised to placebo who then received Dmab 60 mg Q6M from months 12 to 24.[2] Because Dmab was initiated 1 year after Romo, inverse probability of treatment weighting was utilised to normalise differences in BL characteristics between Romo and PBO/Dmab groups.

Proportion of patients achieving $> 3\%$ and $> 6\%$ improvements in TH and LS BMD over 12 months was calculated, as previously reported.[3,4] Correlation between overall percentage improvement in LS and TH BMD was evaluated for each treatment using Pearson's correlation coefficient (r).

Results: Approximately twice as many women on Romo (72%) vs ALN (36%) had > 3% BMD gains at both sites. These proportions were 45% and 9%, respectively for > 6% BMD gains at both sites (Fig. 1). For Romo vs Dmab, 76% vs 40%, respectively, had > 3% BMD gains at both sites; 45% vs 8% had > 6% BMD gains at both sites (Fig. 2). Substantially greater proportions of patients failed to achieve improvements at either site with ALN and Dmab vs Romo, at both BMD gain thresholds. Correlations between percentage improvement in BMD at the LS and TH were stronger for Romo vs ALN (r = 0.43 vs r = 0.26) and Romo vs Dmab (r = 0.45 vs r = 0.25).

Conclusion: Substantially greater proportions of patients receiving Romo achieved concurrent, clinically meaningful BMD improvements of > 3%/ > 6% at both the LS and TH within 1 year compared with either ALN or Dmab; correlation between overall percentage improvements at both sites was also stronger with Romo. Data add to the body of evidence indicating the superiority of Romo in attaining simultaneous BMD improvements across relevant skeletal sites in patients with OP.

CARDIOVASCULAR SAFETY OF ROMOSOZUMAB IN OSTEOPOROSIS PATIENTS: A TRINETX MULTI-INSTITUTIONAL RESEARCH NETWORK ANALYSIS

C.-R. Li[1], H.-T. Lee[1], Y.-L. Deng[1]

[1]Taichung Veterans General Hospital, Taichung city, Taiwan

Objective: Romosozumab has been shown to enhance bone mineral density (BMD) and reduce fracture risk in humans by elevating serum biochemical markers of bone formation while simultaneously decreasing markers of bone resorption. However, given the potential link with acute coronary syndrome (ACS), this article focuses on a

comprehensive evaluation of romosozumab's cardiovascular safety profile. The goal is to ascertain the extent to which romosozumab may influence the risk of ACS, thereby ensuring a balanced understanding of its benefits and potential cardiovascular risks.

Material and methods: Utilizing the TriNetX database, alongside the RxNorm drug naming system and International Classification of Diseases-10 (ICD-10) codes, we identified 7634 adult osteoporosis patients treated with romosozumab. We designated the initial administration of romosozumab as the index event. Analytical statistics were employed to evaluate the safety profile, particularly focusing on the relationship between romosozumab and ACS within three years following the index event.

Results: In the logistic regression analysis, it was observed that the presence of chronic kidney disease (CKD) and essential hypertension are significant risk factors for ACS in patients treated with romosozumab. Specifically, CKD was associated with a two-fold increase in the risk (OR: 2.04; 95% CI 1.24–3.37, p = 0.005), while essential hypertension was linked to an approximately 82% higher risk (OR: 1.82; 95% CI 1.14–2.90, p = 0.011). Additionally, a subgroup analysis comparing patients receiving less than 12 doses to those receiving 13 to 24 doses of romosozumab within three years showed no significant difference in the risk of ACS (RR: 0.8; 95% CI 0.47–1.36), indicating that dosage within this range does not significantly alter the likelihood of ACS occurrence.

Conclusions: The present study uncovered a heightened rate of ACS in patients with CKD or essential hypertension who were treated with romosozumab. Moreover, the incidence of ACS showed no significant variance between patients administered fewer than 12 doses and those receiving 13–24 doses over a three-year period. For a comprehensive assessment of its risk-benefit balance, additional long-term and comparative research is crucial to substantiate these safety evaluations.

Disclosures: The authors of this manuscript have no conflict of interest to disclose.

THE COMPARATIVE EFFECTIVENESS AND CARDIOVASCULAR SAFETY OF ABALOPARATIDE AND TERIPARATIDE IN POSTMENOPAUSAL WOMEN NEW TO ANABOLIC THERAPY: UPDATE OF A REAL-WORLD RETROSPECTIVE ANALYSIS

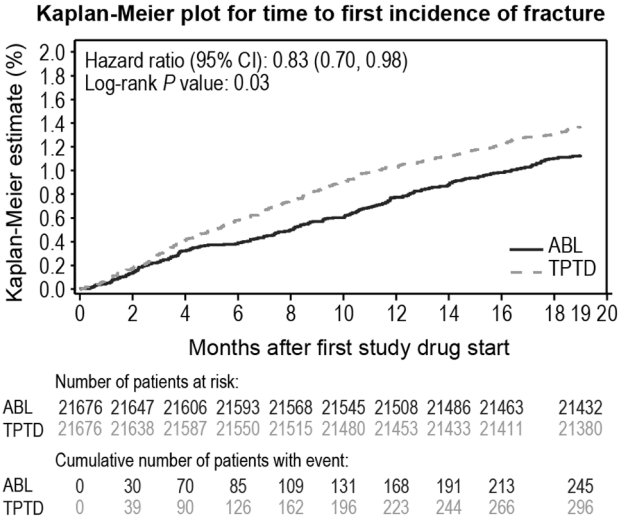
J.-Y. Reginster[1,2], R. Rizzoli[3], B. Cortet[4], Y. Wang[5], J. Chiodo[5], B. H. Mitlak[5]

[1]Epidemiology and Health Economics, University of Liège, Liège, Belgium, [2]WHO Collaborating Center for Epidemiology of Musculoskeletal Health and Ageing, Liège, Belgium, [3]University Hospitals of Geneva, Geneva, Switzerland, [4]Rheumatology, Lille University Hospital-Roger Salengro Hospital, Lille, France, [5]Radius Health, Inc, Boston, MA, United States

Objective: A prior real-world retrospective observational cohort study compared abaloparatide (ABL) and teriparatide (TPTD) treatment initiated between May 1, 2017 and Jul 31, 2019 (Cosman, *OI* 2022). The current study reexamined comparative effectiveness of ABL and TPTD following additional years of clinical experience; extending the study period through Dec 31, 2021 and includes a primary effectiveness analysis of time to first hip fracture.

Material and methods: Anonymized claims data from Symphony Health Patient Source, Osteoporosis Patient Transactional Datasets were accessed. Index date was the date of the initial prescription dispensed during the study period. Time to first hip fracture and other fracture endpoints were compared using a Cox proportional hazards model. *P* values were calculated using a log-rank test.

Results: Propensity matching was used to define study cohorts of women ≥ 50 years, new to anabolic therapy with ABL or TPTD (n = 21,676 per cohort) which were well matched on 73 baseline parameters. Median age was 67 years, 33.8% had a prior fracture at any time; 22.1% had a fracture in the year prior to index date. Over 18 months (+ 30 days follow-up), 245 (1.1%) women in the ABL and 296 (1.4%) in the TPTD cohort had a hip fracture (HR [95% CI] 0.83 [0.70, 0.98]; *P* = 0.03 [Figure]). Nonvertebral fractures were reported in 947 (4.4%) women in the ABL and 1078 (5.0%) in the TPTD cohorts (0.88 [0.80, 0.96]; *P* = 0.003). Major CV events were balanced between cohorts.



Conclusions: The current study doubles the exposure from the prior study and demonstrates that following 18 months of therapy, ABL was more effective than TPTD in reducing the incidence of hip fracture and nonvertebral fracture.

ZOLEDRONIC ACID AND DENOSUMAB ARE COMPARABLE IN DIABETIC OSTEOPOROTIC PATIENTS: A POPULATION-BASED COHORT STUDY

V. Rouach[1], H. Gortler[2], Y. Greenman[1], G. Chodick[3], I. Goldshtein[4]

[1]Institute of Endocrinology, Diabetes, Hypertension and Metabolism, Sourasky Medical Center, Tel Aviv, Israel, Tel Aviv, Israel, [2]Medical school, Sackler Faculty of Medicine, Tel Aviv University, Israel, Israel, Tel Aviv, Israel, [3]Epidemiology Department, School of Public Health, Sackler Faculty of Medicine, Tel Aviv University, Israel, Tel Aviv, Israel, [4]Maccabitech institute for research and innovation, Maccabi Healthcare Services, Tel Aviv, Israel

Background: Anti-resorptive therapies are the mainstay of osteoporosis management, but evidence of their efficacy in the diabetic population is limited and comparison between treatments is lacking. A retrospective analysis, presented at the American Society for Bone and Mineral Research (ASBMR) 2023 Annual Meeting, suggests that denosumab leads to greater reduction in fracture risk than zoledronic acid among treatment-naive postmenopausal women with osteoporosis. However, a recently published comparative study suggests higher mortality with denosumab versus oral bisphosphonates.

Aim: To assess the association between exposures to zoledronic acid or denosumab and outcomes of major osteoporotic fracture and mortality in osteoporotic patients with diabetes type 2.
Methods: The study population was identified by electronic records of a diabetes registry cross-linked with an osteoporosis registry of a large healthcare organization in Israel. Index date was at treatment initiation. The following data was collected: demographics, Comorbidity Index (CCI), diabetes complications, bone mineral density (BMD) T-scores, hemoglobin A1c levels, eGFR, purchase of statins and anti-resorptive agents. Exposure groups were matched by age, sex and eGFR. Kaplan-Meier curves were generated to assess the time to outcomes. Multivariable Cox's proportional hazards survival model was performed.
Results: A total of 27503 diabetic osteoporotic patients were identified, 13343 (48%) initiated treatment; 12214 (91.5%) started an oral bisphosphonate, 627 (4.7%) zoledronic acid and 502 (3.7%) denosumab. The median follow-up was 8.9 years.
Compared to zoledronic acid-treated patients, before matching the denosumab-treated patients were older (75.7 vs 71.9, $p < 0.01$), had longer diabetes duration (8.4 vs 7.2, $p < 0.01$), were more frequently treated with insulin (29.7 vs 23.9, $p = 0.02$) and had a lower eGFR (59.4 vs 75.3, $p < 0.01$). Male/Female ratio, BMI, CCI, smoking status, alcohol consumption, Hip BMD, HbA1c levels, microvascular complications, hypoglycaemic events and statins prescriptions were similar. After matching, 400 pairs of subjects treated with zoledronic acid or denosumab remained. The 5-year cumulative incidence of fracture and death events were similar in the two treatment groups (38 vs 31%, and 36% vs 41% respectively). We did not observe any significant differences in the risk of fracture HR = 1.17 (0.78–1.75) or death HR = 1.12 (0.87–1.44) between these two groups of treatments.
Conclusions: Our findings underscore the comparability of Zoledronic Acid and Denosumab in managing osteoporotic fractures and mortality among diabetic patients, offering valuable insights for treatment strategies in this vulnerable population.
Keywords: Anti-resorptive treatment, diabetes, osteoporosis, fracture prevention, mortality.

ANTIRESORPTIVE MEDICATION-RELATED JAW OSTEONECROSIS: AN EUROPEAN EUDRAVIGILANCE DATABASE-BASED RETROSPECTIVE COHORT STUDY

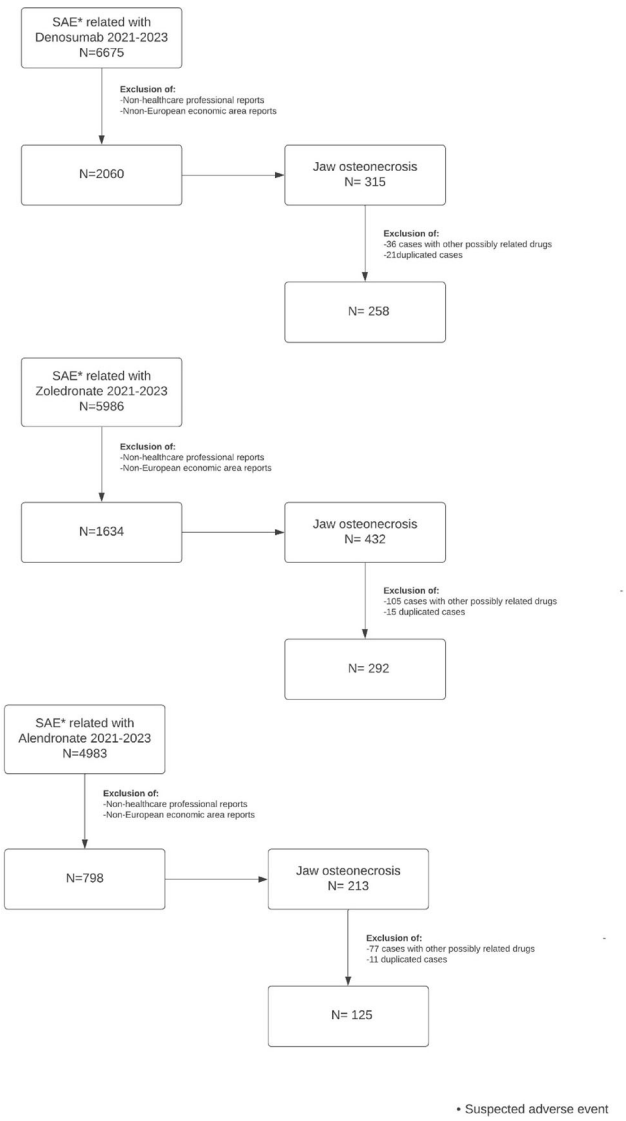
S. Ferreira Azevedo[1], C. Pinto Oliveira[1], A. R. Prata[1], I. Cunha[1], A. Barcelos[1]

[1]Rheumatology department, Hospital Infante D. pedro- Unidade Local de Saúde Região de Aveiro, Aveiro, Portugal

Objectives: To compare the occurrence of jaw osteonecrosis (JON) with denosumab, alendronate and zoledronate, by analyzing real-world data from the European EudraVigilance database.
Methods: Retrospective study using the EudraVigilance, including Suspected adverse reactions (SARs) related to denosumab, alendronate and zoledronate, between 2021–2023. Only SARs reported by healthcare professionals in the European Economic Area were included. A descriptive and comparative analysis was performed and the Reporting Odds Ratio (ROR) was calculated for each treatment.
Results: 17,644 (6675 denosumab, 4983 alendronate, and 5986 zoledronate-related) SARs were reported. 258 denosumab, 125 alendronate, and 292 zoledronate-related JON cases were included. (Fig. 1).
For all treatments, most patients were female between 65–85 years. The most common treatment indication was "Osteoporosis" for denosumab (58.5%) and alendronate (86.4%), while zoledronate was mostly prescribed in "Oncologic context" (69.2%).

Regarding denosumab reports, most patients had recovered or were recovering (56.9%), and the percentage of those not recovering was higher in the elderly (> 64 years) ($p < 0.05$). The percentage who recovered with sequelae was higher in patients older than 85 years ($p < 0.05$), and patients with "Oncologic context" recovered more frequently compared to patients with "Osteoporosis" ($p < 0.05$). Regarding the presence of seriousness criteria, most patients with "disability" did not recover ($p < 0.05$). In contrast with denosumab, most patients under alendronate or zoledronate did not recover (66.7%). While this percentage was higher in the elderly under alendronate ($p < 0.05$), no differences were found in the zoledronate group.

Comparing the risk of JON between the three treatments, based on the ROR, we found a higher risk with zoledronate [ROR 1.35 CI (1.14–1.59)]. The lowest risk was found for denosumab [ROR: 0.74 CI (0.63–0.68)]. The risk associated with alendronate treatment was equivalent to the others [ROR: 1.06 CI (0.86–1.31)].
Conclusion: In our analysis zoledronate treatment demonstrated a higher incidence of JON, while denosumab represented the safest drug. However, indication for the use of zoledronate was mostly an oncologic context, which implies a more intensive treatment. Therefore, our findings must be interpreted with caution. JON accounted for 12.5% to 17.9% of all SARs, in line with the current evidence of its infrequent occurrence.



OC7
CLINICAL IMPACT OF ACUTE SYMPTOMATIC VERTEBRAL FRACTURES IN THE UNITED STATES: AN OBSERVATIONAL STUDY

N. Binkley[1], M. Mcdermott[2], E. Yeh[2], J. Lane[3], J. Cheung[4], M. Amet[4], F. Cosman[5]

[1]University of Wisconsin, Madison, United States, [2]Amgen Inc, Thousand Oaks, United States, [3]Weill Cornell Medical College, New York, United States, [4]Adelphi, Bollington, United Kingdom, [5]Columbia University, New York, United States

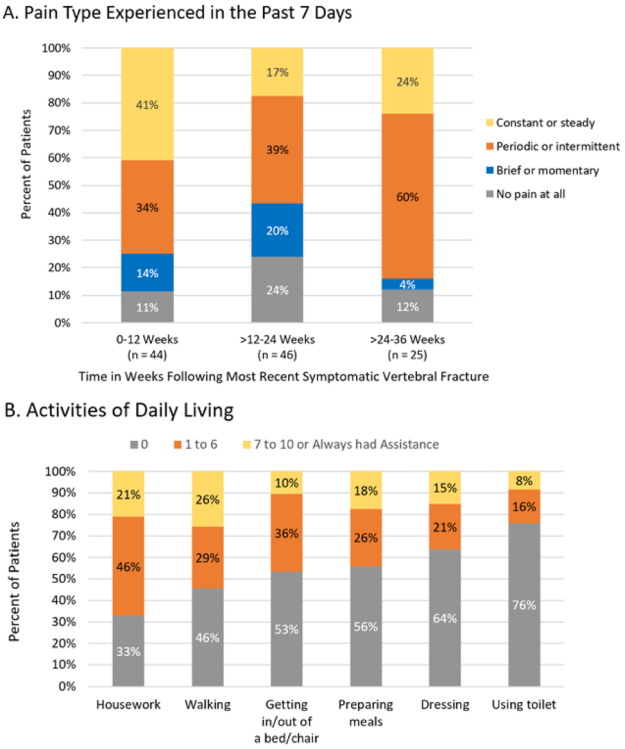
Objectives: To characterize pain status (frequency, severity, persistency) and effect on activities of daily living (ADLs) in patients with symptomatic vertebral fractures (VF).

Materials and methods: This was an observational, cross-sectional, survey of patients age $\geq$ 50 years with $\geq$ 1 symptomatic osteoporotic VF within the last 36 weeks (wks) confirmed by spine imaging, recruited from July 2022 to August 2023 at 7 clinical sites across the United States. Data were collected through a one-time patient survey and retrospective medical chart review, and analyzed descriptively. Patients described their pain level and pain characteristics.

Results: Of the 117 patients enrolled, most were postmenopausal women (82%), white (92%), and $\geq$ 60 years of age (95%); 38% of patients were recruited within 12 wks, 39% within > 12–24 wks, and 23% within > 24–36 wks of having a symptomatic VF. Index VF was confirmed by x-ray (56%), MRI (49%), CT scan (33%), and/or DXA (15%). As shown in Fig. 1A, within the first 12 wks of an acute symptomatic VF, pain was reported as constant/steady by 41% of patients. After 12 wks, the proportion who reported constant/steady pain was lower but still more than 20% in patients who had a VF > 24–36 wks earlier; at that time, more than 80% of patients reported at least intermittent pain. 43% reported high pain severity (between 7–10) within the first 12 wks following VF, and 30% and 36% reported high severity at > 12–24 wks and > 24–36 wks, respectively. The most common movements that increased pain were standing up (56%), bending down (54%), and lifting (43%). In general, patients reported a negative impact of VF on various ADL, with housework and walking being most impacted (Fig. 1B).

Conclusion: In this cross-sectional study, back pain persisted and affected ADL in the majority of patients after 24 wks. Even > 24–36 wks after a VF, 84% of patients experienced constant/steady or periodic/intermittent pain. ADLs that were difficult to complete required movements that patients often reported as precipitating pain. Acknowledging the study limitations of cross-sectional design and small numbers enrolled at different times from VF, particularly in the > 24–36-wk group, these data provide insight into the impact of VF on patients and emphasize the importance of VF prevention.

Figure 1 (A) Patient reported pain type experienced over 7 days **(B)** Patients' ratings on their ability to perform said activity on a scale of 1 to 10, with 0 = not limited at all and 10 = extremely limited.



OC8
MULTIMORBIDITY AND RISK OF FALLS, FRACTURES, AND JOINT REPLACEMENTS OVER TWO DECADES: FINDINGS FROM THE HERTFORDSHIRE COHORT STUDY

L. D. Westbury[1], C. Pearse[1], R. Rambukwella[1], K. A. Ward[1], C. Cooper[1], E. M. Dennison[1]

[1]MRC Lifecourse Epidemiology Centre, University of Southampton, Southampton, United Kingdom

Objective: While multimorbidity is known to be associated with risk of common musculoskeletal conditions, little is known about the relationship between comorbidity burden and the risk of subsequent development of conditions of musculoskeletal ageing, specifically risk of fractures, falls and joint replacements. We examined this in the community-dwelling Hertfordshire Cohort Study.

Material and methods: Data were analysed from 2997 individuals (age 59–73 at baseline). Outcomes (fractures, falls and lower limb joint replacements) were identified using ICD-10 and OPCS-4 codes from Hospital Episode Statistics data, available from baseline (1998–2004) until December 2018. Number of systems medicated (a marker of morbidity level) in relation to risk of outcomes was examined using sex-stratified Cox regression.

Results: Among both men and women, a greater number of systems medicated was related to increased risk of falls ($p < 0.001$) and lower limb joint replacements ($p < 0.003$). More systems medicated was only related to increased risk of fracture among women ($p < 0.001$ among women and $p = 0.186$ among men). Graded associations were observed for higher risks of fracture among women as the number of systems medicated increased. In contrast, a threshold effect was observed for falls among men and women with much higher risk of falls among men and women with at least two systems medicated compared to those who had less than two. Similarly, men and women with more than two systems medicated had much higher risks of a

lower limb joint replacement compared to those with two systems medicated or less.

Conclusions: Higher numbers of systems medicated was associated with increased risk of adverse health outcomes related to poor musculoskeletal health in older community-dwelling adults, with a threshold effect observed for falls and lower limb joint replacements. Intervention strategies to reduce multimorbidity among middle aged and older people may reduce the incidence of fractures, falls and joint replacements.

TEN-YEAR FOLLOW-UP OF FRACTURE RISK IN A SYSTEMATIC POPULATION-BASED SCREENING PROGRAMME: THE RISK-STRATIFIED OSTEOPOROSIS STRATEGY EVALUATION (ROSE) RANDOMISED TRIAL

T. G. Petersen[1], B. Abrahamsen[1], M. Højberg[2], M. J. Rothmann[3], T. Holmberg[4], J. Gram[5], M. Beck[6], K. E. Åkesson[7], K. M. Javaid[8], A. P. Hermann[9], K. H. Rubin[1]

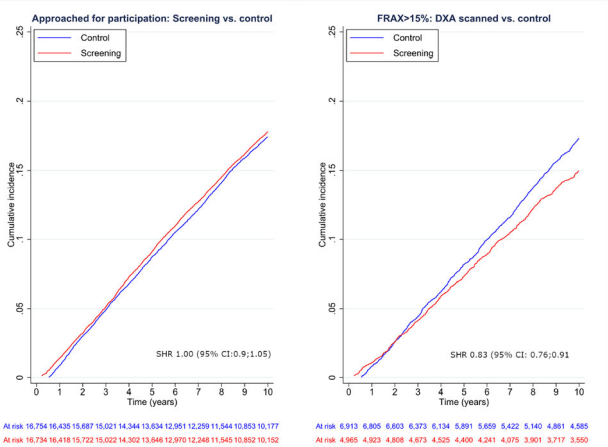
[1]Research unit OPEN, department of clinical research, University of Southern Denmark, Odense, Denmark, [2]Department of Internal Medicine, Hospital of Southern Norway, Arendal, Norway, Arendal, Norway, [3]Steno Diabetes Center, Odense University Hospital, Odense, Denmark, Odense, Denmark, [4]Centre for Childhood Health, Copenhagen, Denmark, Copenhagen, Denmark, [5]Department of Endocrinology, Esbjerg Hospital, University Hospital of Southern Denmark, Esbjerg, Denmark, [6]Department of Political Science and Public Management, University of Southern Denmark, Odense,, Odense, Denmark, [7]Clinical and Molecular Osteoporosis Research Unit, Department of Clinical Sciences, Lund University, Malmö, Sweden and Department of Orthopaedics, Skåne University Hospital, Malmö, Sweden, Lund, Sweden, [8]Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, University of Oxford, the United Kingdom, Oxford, United Kingdom, [9]Research Unit for Endocrinology, Odense University Hospital, Odense, Denmark; University of Southern Denmark, Odense, Denmark

Objective: Primary aim is to assess the effectiveness of the ROSE programme in reducing the incidence of major osteoporotic fractures (MOF) over a ten-year follow-up period. Secondary objective: impact on the incidence of hip fractures, all fractures, and mortality.

Material and methods: This ten-year follow-up of the ROSE randomized trial tested the effectiveness of a screening program utilizing the Fracture Risk Assessment Tool (FRAX) to select women for DXA scan to guide subsequent standard osteoporosis treatment. Women residing in the Region of Southern Denmark, aged 65–80, were randomised (single masked) into a screening or a control group and subsequently approached by a mailed questionnaire in 2010/11. Based on the questionnaire, women in the screening group with a FRAX value $\geq$ 15% were invited for DXA scanning. Fracture outcomes were derived from nationwide registers.

Results: During follow-up, 7355 MOFs were observed. No differences in MOF incidence were identified, comparing the 17,072 women in the screening group with the 17,157 controls in the intention-to-treat analysis (IRR 1.01, 0.95; 1.06). However, per-protocol, women DXA-scanned exhibited a 16% lower incidence of MOF (IRR 0.84, 0.76; 0.92) than controls with a FRAX value $\geq$ 15%. Similar trends were observed for hip fractures, all fractures, and mortality.

Conclusion: The ROSE program had no statistical significant effect on osteoporotic fracture incidence or mortality in the total screened population. However, it demonstrated a benefit in terms of risk reduction for women at moderate to high risk who underwent the DXA scan intervention. In other words, the intervention was effective in the prespecified moderate or high risk population (FRAX > 15%) in which DXA examination and a clinical path to treatment was offered, but the overall fracture burden in the community was not reduced by this strategy. Hence, the use of self-administered questionnaires as screening tools may not be an efficient approach for systematic screening due to the low and differential screening uptake.



OC10
ELEVATED FRACTURE RISK IN A DANISH COHORT WITH TYPE 2 DIABETES MELLITUS AND MICROVASCULAR DISEASES

M. Nasser[1], T. Grønborg[2], F. Kristensen[2], R. Thomsen[2], A. Vaag[3], J. Nielsen[1], K. Højlund[1], M. Olsen[4], P. Vestergaard[5], R. Eastell[6], M. Frost[1]

[1]Department of Clinical Research, University of Southern Denmark, Odense, Denmark, [2]Department of Clinical Epidemiology, Aarhus University Hospital, Aarhus, Denmark, [3]Steno Diabetes Center Copenhagen, Copenhagen, Denmark, [4]Department of Medicine and Steno Diabetes Center Zealand, Holbaek, Denmark, [5]Steno Diabetes Center North Denmark, Aalborg, Denmark, [6]Academic Unit of Bone Metabolism, University of Sheffield, Sheffield, United Kingdom

Objective: Microvascular diseases (MVD) in type 2 diabetes mellitus (T2D) are associated with alterations in the bone microarchitecture, but their association with fracture risk is unclear. We investigated whether MVD (retinopathy, nephropathy, and neuropathy) are associated with higher fracture risk in persons with recently diagnosed T2D.

Material and methods: We identified 10,491 persons with recently diagnosed T2D, enrolled in the Danish Centre for Strategic Research in Type 2 Diabetes cohort between 2010 and 2022. The primary outcomes were any hospital-diagnosed fracture (except facial and cranial), and major osteoporotic fractures (MOF), defined as clinical vertebral, hip, humerus, and forearm fractures, in persons with hospital-diagnosed MVD versus without MVD. We used Cox proportional hazard models to calculate crude and adjusted hazard ratios (aHRs).

Results: During a median follow-up of 7.6 years IQR (3.5; 9.7), the rates of any fracture were higher in persons with T2D and MVD versus no MVD (aHR 1.31; 95% CI [1.15; 1.51]), and a higher numerically rate was observed in men (aHR 1.41 [1.15; 1.72]) than women (aHR 1.21 [1.00; 1.46]) (p-interaction = 0.76). Similarly,

MOF rates were elevated in persons with MVD (aHR 1.33 [1.09; 161]), and a higher numerically rate was observed in men (aHR 1.43 [1.04, 1.96] than women (aHR 1.26 [0.98, 1.61]) (p-interaction = 0.80). The rates for any fracture and MOF were particularly highest in persons with neuropathy (aHR 1.49 [1.24; 1.78] and aHR 1.54 [1.19; 1.99], respectively).
Conclusion: Fracture risk is elevated in persons with T2D and MVD, particularly those with neuropathy.

OC11
ALARMING INCREASE IN BURDEN OF SPINAL FRACTURE IN THE MIDDLE EAST AND NORTH AFRICA: A 30-YEAR SECONDARY ANALYSIS OF THE GLOBAL BURDEN OF DISEASE STUDY 2019

A. H. Hoveidaei[1], A. Ghaseminejad-Raeini[2], M. S. Khonji[2], A. Azarboo[2], S. H. Hosseini-Asl[2], K. Pirahesh[2]

[1]Sports Medicine Research Center, Neuroscience Institute, Tehran University of Medical Sciences, Tehran, Iran, [2]School of Medicine, Tehran University of Medical Sciences, Tehran, Iran

Objective: Particularly in the elderly, spinal fractures are among the most frequent injuries associated with osteoporosis. Despite the region's ageing population, rising osteoporosis incidence, and devastating ongoing conflicts, the epidemiology and burden of spine fractures remain unexplored in the Middle East and North Africa (MENA). This investigation's primary goal was to look into the overall incidence and years lost due to disability (YLDs) of spinal fractures over the past thirty years in MENA, implementing data from the global burden of diseases (GBD) 2019.
Material and method: The incidence and YLD of spinal fractures in 21 MENA countries from 1990 to 2019 were examined in this cross-sectional study utilizing GBD data. Using a linear regression model, time-trend analysis was carried out, and the beta coefficient and P value were provided. Estimates were provided for various genders and age groups. Additionally, LOESS regression was used to examine the connection between the sociodemographic index and the prevalence of spinal fractures. Lastly, research was done on the distribution of spinal fracture causes. Python was utilized to create the graphs, and IBM SPSS was used to perform all analyses.
Results: The overall incidence rate of spinal fractures in MENA was 111.47 [82.24–157.55] in 2019. Both incidence ($\beta = 0.716$, p value < 0.001) and YLDs ($\beta = 0.616$, p value < 0.001) seemed to be increased annually since 1990, against the decreasing global trend. In general, spinal fractures were more frequent in males. However, in older population, females surpassed males. Although, Afghanistan had the highest incidence (301.15 [130.1–688.01]) and YLDs (20.27 [7.82–48.02]) rate in 2019, Saudi Arabia showed the most significant annual increase compared to other countries (For incidence = $\beta = 0.935$, for YLD = $\beta = 0.960$). Fracture burden had a negative correlation with SDI. The most frequent causes of spinal fractures were conflict and terrorism (33.13%), and falling (30.23%). In some of the countries such as Afghanistan, Palestine, and Syrian Arab Republic conflict and terrorism yielded more than 60% of incident fractures.
Conclusion: The study's findings indicate that the MENA region has an alarming spine fracture epidemiology. It seemed that war-related injuries played a significant role worsening the burden of this fatal fracture. Health professionals and legislators at all levels should be persuaded to include preventative techniques in the program by the gradual increase in spine fractures over the last 30 years.

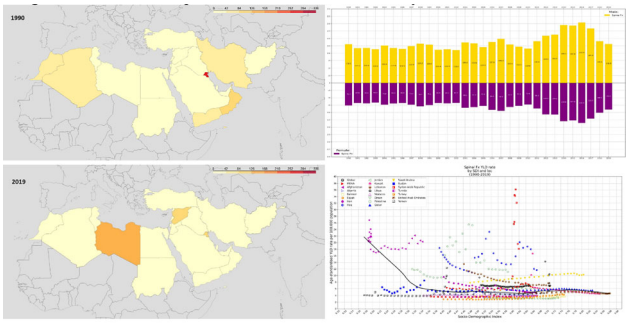


Figure 1. Age-standardized incidence rate of spinal fractures from 1990 to 2019 in male and females across MENA countries. The relationship between SDI and Incidence of spinal fracture is also exhibited.

OC12
DIMINISHING RETURNS OF FALL PREVENTION ON HIP FRACTURE WITH AGE

M. Lorentzon[1], H. Johansson[1], N. Harvey[2], E. Liu[3], M. Schini[4], L. Vandenput[3], E. McCloskey[5], J. Kanis[3]

[1]Sahlgrenska Osteoporosis Centre, Institute of Medicine, University of Gothenburg, Sweden, Mölndal, Sweden, [2]MRC Lifecourse Epidemiology Centre, University of Southampton, Southampton, UK, Southampton, United Kingdom, [3]Mary MacKillop Institute for Health Research, Australian Catholic University, Victoria, Australia, Melbourne, Australia, [4]Department of Oncology & Metabolism, Metabolic Bone Centre, Northern General Hospital, University of Sheffield, Herries Road, Sheffield, S5 7AU, UK, Sheffield, United Kingdom, [5]Centre for Metabolic Bone Diseases, University of Sheffield Medical School, UK, Sheffield, United Kingdom

Objectives: We have previously demonstrated in a meta-analysis of 40 cohorts including 606,715 women,[1] that a fall history during the last year was associated with an increased risk of hip fracture. An interaction was observed between fall history and age. The risk of hip fracture in those with a fall history was lower in an 80-year-old woman (HR (95% Confidence Interval) 1.30 (1.23–1.38)) than in a 50-year-old woman (HR 2.21 (1.68–2.90)). Thus, fall history is of lesser importance in the population with the highest hip fracture incidence. This study aimed to determine the population-attributable risk (PAR) for hip fracture due to increased fall risk in women.
Materialsand methods: Fall history associated attributable risk (AR, %) for hip fracture was calculated (100·(1–1/relative risk (HR))) for women per age stratum, using previously calculated HRs.[1] The population attributable risk (PAR,%) of hip fractures in the female population (50 years and older) that could be prevented if the fall history-mediated risk increase could be eliminated, was calculated as $100 \cdot P_{exp} \cdot (HR\text{-}1)/1 + P_{exp} \cdot (HR\text{–}1)]$ where P_{exp} was the exposed proportion of the population (i.e. the proportion fallers).
Results: The proportion of fallers increased progressively with age from 24.6% at age 50–54 years to 45.5% at age 90–94 years. In contrast, the AR due to falls decreased, from 54.8% at age 50–54 years to 8.3% at age 90–94 years, and the PAR, or the proportion of fractures in the total population that could be prevented if the risk increase induced by fall history was eliminated, diminished with age, from 23.9% in women 50–54 years old to 3.9% in women 90–94 years old (Figure).
Conclusions: Despite the increasing proportion of fallers with age, the importance of fall history as a risk factor for hip fracture in women diminishes markedly with age, which results in a much lower PAR in older than in younger women. These results suggest that preventing falls may be a more effective way to reduce hip fracture numbers in younger than older women, who are the most likely to sustain hip fractures.

Background: Knee Osteoarthritis (KOA) is a leading cause of disability with nearly a quarter of adults over 40 affected worldwide. Despite its widespread impact, no approved pharmacological solution exists to halt, slow, or reverse the progression of KOA. One of the main challenges in the KOA research aiming to find a cure is using total knee replacement (TKR) as an outcome, as many regulatory agencies rely on it to show the improvements in progression in knee osteoarthritis (KOA). However, the decision to undergo TKR is influenced by various factors beyond disease progression, such as education, income, and health insurance. To address these limitations, we recently validated a new outcome, namely, end-stage KOA (esKOA). A knee was classified as having esKOA if it met either of the following criteria: (1) Displaying moderate to severe KOA symptoms (defined as a combined WOMAC pain and disability score of 12 or above) in conjunction with the most severe radiographic KOA (i.e., KL grade = 4, the maximum KL grade); (2) Exhibiting intense KOA symptoms (a combined WOMAC pain and disability score of 23 or more) alongside persistent knee pain and either mild or moderate radiographic KOA (i.e., KL grade = 2 or 3). Unlike TKR incidence, esKOA is an endpoint that represents the advanced stage of KOA, independent of external factors influencing TKR decisions. Furthermore, an esKOA and change in esKOA predict the subsequent occurrence of TKR. Given the lack of a cure, tools that can predict the progression of KOA would be invaluable. Predictive tools can enhance the efficacy of clinical trials by identifying appropriate candidates and ensuring that participants are likely to show disease progression during the trial period.

Objectives: To enhance future trials that use esKOA as an outcome, our study focuses on developing and validating a machine-learning tool to identify individuals likely to develop esKOA within 2–5 years. We also aim to implement an online tool delivering the prediction of esKOA for 2 to 5 years based on the developed machine learning algorithm.

Methods: Using the Osteoarthritis Initiative (OAI) data, we trained the models with 3,259 participants and validated them with 616 participants. The Multicenter Osteoarthritis Study (MOST) data, consisting of 1,795participants, was employed for external validation. Our primary outcome was predicting the onset of esKOA at 2-to-2.5 years and 4-to-5 years. Our analysis considered 40 candidate predictors, including demographics, clinical history, physical examination, and X-ray evaluations. We also evaluated the models with top nine predictors among the 40 predictors. Using the models with nine predictors, we developed an online tool that predicts the probability of progression to esKOA at 2-to-2.5 years and 4-to-5 years.

Results: The Area Under Curve (AUC) obtained from external validation (i.e., MOST) using 40 predictors at 2.5 years was 0.861 (95% CI 0.832–0.886), and at 5 years was 0.854 (95% CI 0.830–0.877). The models with nine predictors showed comparable performance (Fig. 1). Using the nine predictors, we developed an online tool that can be found at the following link: https://eskoa.shinyapps.io/tool/.

Conclusion: Our study unveils a robust, externally validated machine learning tool proficient in predicting the onset of esKOA over the next 2 to 5 years. Our screening tool can lead to more efficient KOA trials.

MILD COGNITIVE IMPAIRMENT PREDICTS THE ONSET OF SARCOPENIA: A LONGITUDINAL ANALYSIS FROM THE ENGLISH LONGITUDINAL STUDY ON AGEING

F. S. Ragusa[1], L. Dominguez[2], L. Smith[3], F. Bolzetta[4], N. Veronese[1]

[1]University of Palermo, Palermo, Italy, [2]University of Enna Kore, Enna, Italy, [3]Anglia Ruskin University, Cambridge, United Kingdom, [4]ULSS 3 Serenissima, Venice, Italy

Objectives: To investigate whether MCI (mild cognitive impairment) predicts onset sarcopenia in a population of older adults.

Materialsand methods: In this retrospective study, using the data of the ELSA (English Longitudinal Study on Ageing) study, MCI was defined as the absence of dementia, preserved functional capacity and low in three objective cognitive tests. Sarcopenia was diagnosed as having low handgrip strength and low skeletal muscle mass index during follow-up. The longitudinal association between MCI at the baseline and incident sarcopenia was assessed using a multivariable

logistic regression model, reporting the data as adjusted odds ratios (OR) and 95% confidence intervals (95% CI).

Results: 3106 participants were included (mean age of 63.1 years; 55.3% males). People with MCI reported significantly lower mean handgrip strength values and Skeletal Mass Index (SMI) as well as a higher prevalence of obesity at baseline. At the baseline, 729 people were affected by MCI and during ten years of follow-up, 12.1% of the initial population included were affected by sarcopenia. In the multivariate analysis, adjusted for 18 potential confounders, the presence of MCI (OR = 1.236; 95% CI 1.090–1.596, p = 0.01) significantly predicted the onset of sarcopenia during follow-up.

Conclusion: The presence of MCI at baseline was associated with a higher incidence of sarcopenia at ten-years follow-up, demonstrating a probable role of MCI as predictor of onset sarcopenia in older adults.

COMPARATIVE EFFECTIVENESS OF YOGA AND STRENGTHENING EXERCISE FOR TREATING KNEE OSTEOARTHRITIS: A RANDOMISED CONTROLLED TRIAL (YOGA TRIAL)

B. J. Abafita[1], D. Aitken[1], A. Singh[1], S. Moonaz[2], C. Ding[1], S. Drummen[1], L. Blizzard[1], A. J. Palmer[1], G. Jones[1], K. L. Bennell[3], B. E. Antony[1]

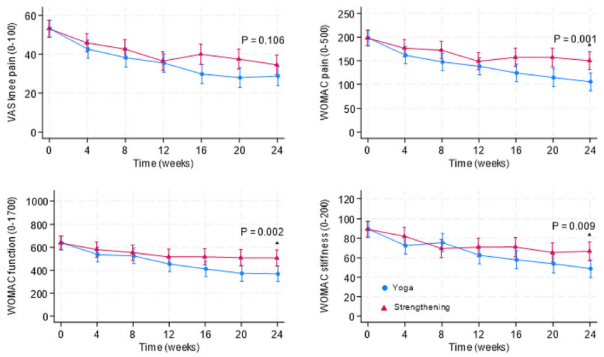
[1]Menzies Institute for Medical Research, University of Tasmania, Hobart, Australia, [2]Department of Clinical and Health Services Research, Southern California University of Health Sciences, Whittier, United States, [3]Centre for Health, Exercise and Sports Medicine, Department of Physiotherapy, School of Health Sciences, University of Melbourne, Melbourne, Australia

Objectives: There is little knowledge about the most effective type, frequency, and dosage of exercise for knee OA. There is also uncertainty about the effect that mind–body exercise, such as yoga, has on knee OA and to date no studies have directly compared yoga with strengthening exercise. We aimed to compare the effectiveness of a 24-week yoga program to a strengthening program in patients with knee OA.

Material and methods: The YOGA trial is an assessor-blinded (for non-patient-reported outcomes), randomised, active-controlled, superiority trial that included a pre-specified non-inferiority margin (visual analog scale (VAS) 10 mm). We recruited knee OA participants aged ≥ 40 years who fulfilled ACR clinical criteria with knee pain ≥ 40 mm on 100 mm VAS. Participants were randomly assigned to a 24-week yoga program or strengthening program, which both included two supervised sessions and one home-based session per week for 1–12 weeks, plus three home-based sessions per week from 13–24 weeks. The primary outcome was change in VAS knee pain over 12 weeks. Secondary outcomes included change in WOMAC scores, patient global assessment, OARSI-OMERACT response, physical performance measures, leg muscle strength, quality of life, depression, and neuropathic pain assessment over 12 and 24 weeks and change in VAS knee pain over 24 weeks.

Results: 117 were randomised to a yoga program (n = 58) or a strengthening program (n = 59). Change in VAS knee pain scores over 12 weeks (between group mean difference − 1.1 mm [95% CI − 7.8 to 5.7]) and 24 weeks (− 5.8 mm [95% CI − 12.8 to 1.2]) were not significantly different between the yoga and strengthening groups. For the secondary outcomes, the yoga group showed significantly greater improvements than the strengthening group over 24 weeks (between-group difference) for WOMAC pain (− 44.5 mm [95% CI − 70.7 to − 18.3]), WOMAC function (− 139 mm [95% CI − 228.3 to − 49.7]), WOMAC stiffness (− 17.6 mm [95% CI − 30.9 to − 4.3]), patient global assessment (− 7.6 mm [95% CI − 15.1 to − 0.2]), and quality of life (0.04 [95% CI 0.0 to 0.07]). Additionally, the yoga group had a significantly greater improvement than the strengthening group in depression (− 1.10 [95% CI − 1.99 to − 0.21]) over 12 weeks. Adverse events were common in both groups and mild in nature.

Conclusion: A 24-week yoga program was non-inferior to a strengthening program, as both groups reported pain reductions that were deemed clinically relevant over 12 weeks. The yoga group reported modestly greater improvements in several secondary outcomes including knee symptoms and quality of life over 24 weeks and depression over 12 weeks, supporting yoga as an effective treatment for knee OA.



Data are estimates from linear mixed-effects models. VAS = visual analogue scale; WOMAC = Western Ontario and McMaster Universities Osteoarthritis Index. VAS knee pain (0 to 100 mm). WOMAC pain (0 to 500 mm). WOMAC function (0 to 1700 mm). WOMAC stiffness (0 to 200 mm).

Figure 1. Mean VAS and WOMAC subscale scores (95%CI) in the yoga and strengthening exercise groups over 24 weeks.

OC16
RADIOGRAPHIC AND PAIN OUTCOMES FROM A PHASE 3 EXTENSION STUDY (OA-07) EVALUATING THE SAFETY AND EFFICACY OF REPEAT LORECIVIVINT INJECTIONS OVER 3 YEARS IN SUBJECTS WITH SEVERE KNEE OSTEOARTHRITIS

Y. Yazici[1], C. Swearingen[1], J. Tambiah[1], T. Mcalindon[2]

[1]Biosplice Therapeutics, Inc, San Diego, United States, [2]Tufts University, Boston, United States

Objectives: Evaluate the safety/efficacy of long-term lorecivivint (LOR) on severe knee osteoarthritis (OA) patient outcomes of medial joint space width (medial JSW)WOMAC Pain and Function.

Material and methods: Knee OA patients (medial JSW 1.5–4 mm) completing a 1-year trial (LOR 0.07 mg vs placebo [PBO]; OA-11, NCT 03928184) were enrolled into extension study OA-07. At Year 1, a repeat injection was given to blinded patients according to original OA-11 randomization. At Year 2, all patients received open-label LOR. Baseline-adjusted ANCOVA estimated differences between LOR and PBO outcomes on OA-07 baseline measures. Treatment effect at Month 36 was estimated using marginal comparison from baseline adjusted ANCOVA to last PBO observation prior to crossover.

Results: 276 patients (mean age 61.0 ± 8.2 years, Body Mass Index 31.8 ± 4.9 kg/m^2, female 62.7%, medial JSW 2.63 ± 0.69 mm, Kellgren-Lawrence [KL] 3 45.3%) were enrolled. Adverse event rates were similar between groups.

Comparing LOR to PBO:

In Full Analysis Set (FAS) completers:

- At 24 months, medial JSW: LOR − 0.11 (± 0.05) mm vs. PBO − 0.20 (± 0.05) mm (Δ = 0.09 mm, 95% CI [− 0.06, 0.23], P = 0.223) (Figure); LOR improvements observed in WOMAC

Pain Δ = − 5.18 (95% CI [− 10.28, − 0.08], P = 0.047) and WOMAC Function Δ = − 4.90 (95% CI [− 9.92, 0.13], P = 0.056).

- At 36 months, medial JSW: LOR vs. pre-crossover PBO measure, − 0.06 (± 0.08) mm, (Δ = 15 mm, P = 0.045).

In KL2 FAS completers:

- At 24 months, medial JSW: LOR 0.00 (± 0.06) mm (n = 38) vs. PBO − 0.08 (± 0.06) mm (n = 45) (Δ = 0.08 mm, 95% CI [− 0.09, 0.26], *P* = 0.354).
- At 36 months, medial JSW: LOR vs. pre-crossover PBO measure, 0.17 (± 0.11) mm, (Δ = 29 mm, P = 0.012).

Conclusions: In advanced knee OA patients, LOR 0.07 mg appeared safe. OA-07 met its primary objective with repeat LOR injections (× 3 over 3 years) showing medial JSW improvement vs. PBO. Beneficial LOR effects vs. PBO seen with pain/function outcomes and more pronounced in KL2 patients. PBO patients crossing to LOR showed benefits after 12 months, providing further evidence of efficacy. LOR continues to show promise as a potential disease-modifying knee OA treatment.

CURRENT SARCOPENIA DEFINITIONS ARE NOT VALID FOR PREDICTING FALLS AND POOR PHYSICAL FUNCTION IN URBAN DWELLING OLDER ADULTS IN SOUTH AFRICA, THE GAMBIA AND ZIMBABWE: RESULTS FROM THE MUFASSA STUDY

K. A. Ward[1], L. K. Micklesfield[2], L. Gates[1], T. Manyanga[3], M. K. Jallow[4], B. Cassim[5], Y. Madela[5], S. Crozier[1], C. Cooper[1], A. J. Burton[6], H. Wilson[6], R. A. Ferrand[3], C. L. Gregson[6]

[1]MRC Lifecourse Epidemiology Centre, Human Development and Health, University of Southampton, Southampton, United Kingdom, [2]SAMRC/Wits Developmental Pathways for Health Research Unit, School of Clinical Medicine, Faculty of Health Sciences, University of the Witwatersrand, Johannesburg, South Africa, [3]The Research Unit Zimbabwe, Harare Zimbabwe, Biomedical Training Research Institute, Harare, Zimbabwe, [4]MRC Unit The Gambia @ LSHTM, Banjul, Gambia, [5]Department of Geriatrics School of Clinical Medicine, University of Kwa-Zulu Natal, Durban, South Africa, [6]Musculoskeletal Research Unit, Bristol Medical School, University of Bristol, Bristol, United Kingdom

Objectives: To determine prevalence of sarcopenia, falls and impaired short physical performance battery (SPPB), and whether being sarcopenic is predictive of falls and low SPPB in older adults.
Methods: Population-based sample of sex- and age stratified participants (98% Black African) were recruited in Zimbabwe, (n = 1109), The Gambia (n = 1217) and South Africa (n = 962). All participants had hand grip strength, gait speed, sit-to-stand time and balance measured in the SPPB. Self-reported falls were documented. Prevalence of sarcopenia was defined as: (1) Sarcopenia Definition and Outcomes Committee (SDOC); men: grip strength < 35.5 kg and gait speed < 0.8 m/s; women: < 20 kg & < 0.8 m/s), (2) European Working Group on Sarcopenia II (EWGSOP II) probable sarcopenia; men low grip strength < 27 kg, women < 16 kg. Sensitivity and specificity of each definition to predict falls and low SPPB (< 8) were calculated.
Results: Overall, median (IQR) age was 60 (50, 71) years, 54% were women. Sarcopenia was more prevalent in men than women in all three countries using both SDOC *(men 18%; women 7%)* and EWGSOPII *(men 9%; women 3%)*. Overall, 19% had fallen in the last year, and 32% had a low SPPB. SDOC performed better than EWGSOPII, but sensitivity was low, with poor prediction of fallers *(men sensitivity 23%, specificity 83%; women sensitivity 9%, specificity 94%)* and low SPPB (*men sensitivity 58%, specificity 91%; women sensitivity 16%, specificity 99%)*. EWGSOP II Low grip strength as an indicator for probable sarcopenia performed worse: falls *(men sensitivity 12%, specificity 93%; women sensitivity 3%, specificity 98%)*; SPPB *(men sensitivity 27%, specificity 96%; women sensitivity 5%, specificity 99%)*.
Conclusion: Sarcopenia prevalence was low in women, contrasting with other populations across the globe. Both SDOC and EWGSOPII were poor predictors of falls and of low SPPB. They performed better in men than in women but not to an acceptable level for implementation. These data demonstrate current definitions are not fit for purpose for use in these countries. Determination of thresholds for poor physical function are required to fully understand the prevalence of poor functional ability and its consequences in older adults from African countries.

INCREASED RISK OF STROKE IN PATIENTS WITH OSTEOARTHRITIS IN A PROSPECTIVE COHORT OF MEN: THE STRAMBO STUDY

M. A. Auroux[1], R. Chapurlat[1], P. Szulc[2]

[1]Hospices Civils de Lyon, Lyon, France, [2]INSERM U1033, Lyon, France

Objectives: Osteoarthritis (OA) and cardiovascular disease share risk factors, including age, obesity, diabetes and the metabolic syndrome. The impact of osteoarthritis on cardiovascular and especially cerebrovascular outcomes is still debatted with some studies suggesting a causal role of OA in cardiovascular outcomes *(Zhao* et al., *Ost And Cart, 2022; Wang* et al., *Front Cardiovasc, 2022)*. The underlying mechanisms are yet not fully identified but possibly mediated partially by pro-inflammatory mediators secreted during the OA process, the genetic background and the limitation of physical activity induced by OA. Our aim was to assess the association between OA and the risk cardiovascular or cerebrovascular events in a cohort of older men followed prospectively for 8 years.
Material and methods: The STRAMBO study has involved men with age ranging from 60 to 87 years at baseline. We examined the relationship between joint replacement due to OA before baseline and incident cardiovascular events. Prior joint replacement due to fracture was not included. Major adverse cardio- and cerebrovascular event (MACCE)—were defined as an acute coronary syndrome (ACS), stroke or sudden death probably of cardiovascular origin. ACS comprised myocardial infarction, cardiac arrest and unstable angina necessitating emergency intervention). Events were self-reported by participants or their proxy and then confirmed by a health professional.
The association between OA and the risk of outcomes was assessed using a Cox model adjusted for age, BMI, occupational physical activity, smoking, ischaemic heart disease, hypertension, abdominal

aortic calcification, treatment with statins, treatment with vitamin K antagonists. Other potential relevant comorbidities such as diabetes or leisure physical activity were not included in the model because they were not significant predictors.

Results: The mean age and BMI of 816 men were 72 years and 27.6 kg/m^2. Among them, 49 men have reported joint replacement due to OA at baseline (18 knees, 30 hips, 6 shoulders, 6 men had two joint replacements). Men who had joint replacement were older and heavier. They more often self-reported high occupational physical activity, ischaemic heart disease, diabetes mellitus, and the treatment with beta blockers).

During the study period, 90 men had incident MACCE, with a median [interquartile range] follow-up time to event of 51.6 months [27.5; 71.0]. Men who sustained incident MACCE were at baseline older. They more often self-reported high occupational physical activity, ischaemic heart disease, diabetes mellitus as well as the treatment with vitamin K antagonists and with calcium channel blockers. The risk of MACCE among men with joint replacement due to OA was higher compared with the controls (HR = 3.12, 95% CI 1.74–5.58, $p < 0.001$). Men with OA had increased HR for stroke of 4.94 (95% CI 1.96; 12.42, $p < 0.001$) with a median follow-up time to event of 51.0 month [23.3; 72.9].

We did not observed such an association for ACS (HR = 1.30, 95% CI 0.49; 3.40, p = 0.60) or for myocardial infarction (n = 29, HR = 1.35, 95% CI 0.39; 4.68, p = 0.64).

Conclusions: Late stage OA, defined by joint replacement, was associated with an increased risk of stroke in a prospectively followed cohort of men, after adjustment for relevant confounders. Despite the observational nature of our work, our results support the concept that OA is also a marker of poor health and could play a role in cardiovascular events. Cardiovascular risk assessment could be considered in the management of OA patients. Our results are consistent with other studies linking OA and the cardiovascular risk.

Table 1: Participants characteristics according to the prosthesis

	Prosthesis (n = 49)	Controls (n = 767)	p*	p**

DXA-DERIVED HIP SHAPE IS PREDICTIVE OF HIP FRACTURE: A LONGITUDINAL STUDY FROM UK BIOBANK

S. Scott[1], A. Hashmi[1], R. Ebsim[2], F. R. Saunders[3], J. S. Gregory[3], R. M. Aspden[3], C. Lindner[2], T. Cootes[2], N. C. Harvey[4], J. H. Tobias[5], B. G. Faber[5], R. Beynon[5]

[1]University of Bristol, Bristol, United Kingdom, [2]Division of Informatics, Imaging and Data Science, University of Manchester, Manchester, United Kingdom, [3]Centre for Arthritis and Musculoskeletal Health, University of Aberdeen, Aberdeen, United Kingdom, [4]Medical Research Council Lifecourse Epidemiology Unit, University of Southampton, Southampton, United Kingdom, [5]Musculoskeletal Research Unit, University of Bristol, Bristol, United Kingdom

Objective: Despite major advances in osteoporosis management, hip fractures remain a notable consequence of bone fragility, with a one-year mortality rate of 20%. The aim of this study was to investigate whether dual-energy X-ray absorptiometry (DXA) derived hip shape is predictive of hip fracture, independent of bone mineral density (BMD).

Material and methods: Statistical shape modelling was applied on left hip DXA scans of participants in the UK Biobank (approved application 17295), a large prospective cohort linked to electronic healthcare records. Ten orthogonal hip shape modes (HSM) explained 86% of shape variance. Cox proportional hazard models were used to examine the longitudinal associations between each HSM and hospital diagnosed hip fractures. Adjustments were made for age, sex,

height, weight, and total hip BMD. A Bonferroni adjusted p-value threshold ($p < 0.005$) was used to account for the ten HSMs tested.
Results: Our study included 40,305 participants (mean age 63.7 years; 52.1% female; mean follow up time 5 years). 153 individuals (0.38%) had a hospital diagnosed hip fracture. HSM2, characterised by a narrower femoral neck and a higher femoral neck shaft angle (Fig. 1), showed strong evidence of an association to hip fracture (HR: 1.35, 95% confidence interval (CI): 1.14–1.59, p value 0.0005). In the fully adjusted model, the association was maintained (HR: 1.31, 95% CI 1.11–1.55, p value 0.002). There was no evidence for other HSMs being associated with hip fracture.
Conclusion: In this longitudinal study, we identified an association between DXA-derived hip shape and hip fracture that was independent of total hip BMD, showing that hip shape could be an important predictor of hip fracture. These findings suggest the potential for hip shape, derived automatically from DXA scans, to be included within risk assessment tools to further improve their predictive ability and targeted interventions to prevent hip fractures.

GREATER THIGH MUSCLE MASS MEASURED BY MRI IS ASSOCIATED WITH REDUCED INCIDENT FRACTURE RISK IN WOMEN, BUT NOT MEN: FINDINGS FROM THE UK BIOBANK

E. M. Curtis[1], S. D'Angelo[1], R. J. Moon[1], J. Paccou[2], N. R. Fuggle[1], E. M. Dennison[1], C. Cooper[1], K. A. Ward[1], N. C. Harvey[1]

[1]MRC Lifecourse Epidemiology Centre, University of Southampton, Southampton, United Kingdom, [2]Université Lille Nord-de-France, Lille, France

Objectives: Several studies have demonstrated that the modest predictive value of dual-energy x-ray absorptiometry derived appendicular lean mass (DXA-ALM) for incident fractures is attenuated (and potentially inverted) after adjustment for bone mineral density (BMD). We therefore investigated associations between a gold-standard measure of muscle quantity, MRI thigh muscle volume (MRI-TMV), and incident fractures.
Methods: In the UK Biobank Imaging Study participants underwent MRI examination, from neck to knees. Automated analysis was performed using the AMRA Profiler^{TM} system, to segment total thigh muscle volume (TMV), visceral adipose tissue (VAT) and abdominal subcutaneous adipose tissue (ASAT). We used Cox regression to calculate hazard ratio for any incident fractures per standard deviation greater MRI-TMV/height^2, in men and women separately, adjusting for age, Townsend deprivation score, ethnicity, prior fracture, alcohol consumption and smoking in all models, and then additionally for VAT, ASAT, body mass index (BMI) or heel quantitative ultrasound estimated (e)BMD. Participants were followed until first fracture, death, loss to follow-up or 30/9/2021.
Results: There were 25,117 participants (mean age 62.3 and 63.8 years in women and men respectively) with an MRI-TMV measure, undertaken between 2014 and 2018. There were 308 incident fractures in women (2.4%) and 200 in men (1.7%).
Greater TMV/height^2 was associated with decreased risk of any fracture in women [HR 0.82, 95% CI (0.70, 0.97)], but with a trend towards an increased risk of fracture in men [HR 1.17 (0.94, 1.46)]. Adjustment for measures of adiposity, such as VAT, ASAT or BMI did not change the observed associations in women but strengthened them in men [e.g. in men, with adjustment for BMI, HR 1.39 (1.07, 1.81)]. Adjustment for eBMD did not alter the findings.
Conclusions: The pattern of these findings is similar to that with DXA-ALM, supporting further investigation into possible causal, rather than measurement specific, associations between greater muscle mass and higher fracture risk in men. This work was undertaken using the UK Biobank resource under approved application 3593.

HIP GEOMETRY AND FRACTURE AMONG IRISH MEN AND WOMEN: THE DXA HIP PROJECT

M. Ebrahimiarjestan[1,2], E. E.[3], A. Brennan[4], L. Yang[5], T. Wang[6], C. Silke[2,7], M. O'Sullivan[2,7], M. Dempsey[8], M. Yu[1], J. Carey[2,9], G. O'Malley[10], A. Mcpartland[7], B. Rooney[10]

[1]Department of Industrial Engineering, Tsinghua University, Beijing, China, [2]School of Medicine, National University of Ireland, Galway, Ireland, [3]School of Management, Guangxi Minzu University, Nanning, China, Nanning, China, [4]School of Computer Science, National University of Ireland, Galway, Ireland, [5]Insight SFI Research Centre for Data Analytics, Data Science Institute, Galway, Ireland, [6]Nuffield Department of Medicine, University of Oxford, Oxford, United Kingdom, Oxford, United Kingdom, [7]Department of Rheumatology, Our Lady's Hospital, Manorhamilton, Ireland, [8]School of Engineering, National University of Ireland, Galway, Ireland, [9]Department of Rheumatology, University Hospital Galway, Galway, Ireland, [10]Department of Geriatric Medicine, Sligo University Hospital, Sligo, Ireland.

Background: Osteoporosis is one of the most prevalent non-communicable diseases worldwide manifest clinically as fractures. These can have devastating consequences, in particular hip fractures. Ireland has one of the highest rates of hip fracture in the world, yet few Irish studies examined the relationship between DXA biometrics and hip fracture.
Methods: We used data from a previously described research cohort, The DXA HIP Project, to perform a case–control study to examine the relationship between DXA femoral bone mineral density (BMD) and geometric parameters to hip fractures among adults $\geq$ 40 years in Ireland. First we compared clinical characteristics and DXA biometrics of hip fracture patients to two cohorts: (i) healthy control group and (ii) those with risk factors but without a hip fracture. Then we performed a case–control study matching by using the propensity

score matching method(1;4) for healthy controls for age, gender and body mass index (BMI) to each adult with a hip fracture.
Results: Clinical data and hip BMD were available for 29,110 subjects including 9108 healthy controls, 7748 subjects with major risk factors for fracture or osteoporosis and 691 cases of hip fracture. DXA derived advanced hip assessments (AHA) were available for 12,203 subjects including 4121 healthy controls, 7748 with major risk factors and 334 with a hip fracture. Adults with hip fractures were significantly older, had lower BMI, femoral neck and total hip BMD than those without hip fractures, but were twice as likely to be receiving osteoporosis medication, $p < 0.001$ for all comparisons. Similarly, among those subjects with available AHA those with hip fractures were older, had significantly lower BMI and BMD than both healthy controls and those with risk factors. In addition, subjects with hip fractures had significantly greater hip axis length (HAL) and buckling ratio (BR), but lower cross-sectional area (CSA), cross-sectional moment of inertia (CSMI) and strength index (SI), p value < 0.001. After matching, cases of hip fracture had significantly greater HAL and BR, but significantly lower femoral neck and total hip BMD, CSA and SI, p-value < 0.001. Although CSMI was also lower, the p value was greater than our pre-specified level at 0.028.
Conclusions: Irish adults with hip fractures are generally older and have lower BMI and BMD than healthy controls and those with other risk factors. Additional DXA hip geometric measures are also significantly associated with hip fractures in our population which could help in identifying those most at risk for hip fracture. Large prospective studies are needed to support these findings.

OC22
COST-EFFECTIVENESS OF RADIOFREQUENCY ECHOGRAPHIC MULTI SPECTROMETRY (REMS) FOR THE DIAGNOSIS OF OSTEOPOROSIS IN THE UNITED STATES

J.-Y. Reginster[1], M. Hiligsmann[2]

[1]University of Liège, Liège, Belgium, [2]Maastricht University, Maastricht, Netherlands

Objective: Radiofrequency Echographic Multi Spectrometry (REMS) is an innovative non-ionizing approach that has demonstrated a good level of accuracy and precision, supporting the use of this technology to enhance osteoporosis diagnosis in the clinical routine as an alternative to DXA. Given the increasing importance of economic considerations in healthcare decision-making, this study was designed to estimate the cost-effectiveness and economic consequences of an improved diagnosis with REMS followed by treatment in the United States.
Methods: A microsimulation-based Markov model was designed to estimate the cost (expressed in US$2022) per quality-adjusted life year (QALY) gained of REMS followed by treatment compared to no diagnosis/treatment in US women aged 50 years and over with osteoporosis. Women were classified as being at high risk (and receiving alendronate monotherapy for 5 years), or at very high risk (and receiving an anabolic treatment for 18 months (ie. abaloparatide) followed by alendronate 5 years). The potential impact of a 5% increase in the diagnosis and treatment of US osteoporotic women aged over 50 years through REMS was estimated in terms of QALY and life years gained and fractures prevented.
Results: REMS is associated with improved health outcomes (more QALYs and less fractures) and reduced fracture costs compared to no diagnostic. The incremental cost-effectiveness ratio of REMS was estimated at $50,167 per QALY gained, far below the US cost-effectiveness thresholds of $100,000–150,000. The cost per QALY gained remains favorable ($69,292 per QALY gained) when assuming that only 10% of people receiving REMS are treated. A 5% increase in the diagnosis and treatment of the osteoporosis women population at high and very high risk of fractures aged over 50 years with REMS would save about 30,000 life years (undiscounted), 43,500 QALY (ie. years in perfect health; discounted) and 100,000 fractures over lifetime.
Conclusion: REMS is a cost-effective strategy for the diagnosis of osteoporosis treatment in the US with substantial potential economic benefits.

EXTERNAL VALIDATION OF AI-DRIVEN BONE FRAGILITY DETECTION IN RADIOGRAPHS FROM MULTINATIONAL COHORTS

G. Gatineau[1], G. Nguyen[2], M. Degruttola[2], K. Hind[2], M. Kužma[3], J. Payer[3], G. Guglielmi[4], A. Fahrleitner-Pammer[5], D. Hans[1]

[1]Center of Bone Diseases, Rheumatology Unit, Bone and Joint Department, Lausanne University Hospital, & University of Lausanne, Lausanne, Switzerland, [2]Medimaps group SA, Plan-Les-Ouates, Switzerland, [3]Comenius University Faculty of Medicine, 5th Department of Internal Medicine, University Hospital, Bratislava, Slovakia, [4]Department of Clinical and Experimental Medicine, Foggia University School of Medicine, Foggia, Italy, [5]Medical University Graz, Department for Internal Medicine, Division for Endocrinology and Diabetology, Graz, Austria

Objective: Globally, over 9 million fragility fractures occur each year and one of the major challenges in the osteoporosis field is that most people who sustain a fragility fracture have not been assessed for osteoporosis, and/or are not receiving treatment. Therefore, additional approaches to identify those at risk are needed. This investigation aimed to evaluate a new AI-powered radiographic analysis tool designed to opportunistically identify individuals predisposed to an elevated risk of severe bone fragility, addressing a persistent clinical challenge within the domain.
Materialsand methods: A total of 4764 pairs of lumbar-spine X-ray DICOM and DXA scans (GE and Hologic systems), each acquired within 6-months interval, were identified from four multinational cohorts. A total of 3369 cases from three cohorts were allocated to the training and validation of a newly developed multi-stage AI-bone fragility detection tool (Medimaps Group, Switzerland). An independent internal test set comprising 300 cases was created, and the fourth cohort, consisting of 271 cases, served as an external test set. The identification of very high fragility risk relied on DXA parameters as the ground truth: BMD T-score $\leq$ -2.5 and trabecular bone score (TBS) $\leq$ 1.23. Uncertainties were calculated with a 95% confidence interval (CI) using binomial distribution approximations.
Results: The global sample mean age and BMI were 66.1 ± 10.8 years and 26.4 ± 5.0 kg/m^2 respectively. The prevalence of very high fragility risk was 17.5%. The AI tool's performance in the internal test set indicated an accuracy of 0.85 (95% CI 0.76–0.94), specificity of 0.91 (0.8–0.99), and sensitivity of 0.69 (0.53–0.84). The external validation demonstrated an accuracy, specificity, and sensitivity of 0.80 (0.69–0.87), 0.88 (0.77–0.99), and 0.62 (0.47–0.77), respectively.
Conclusion: This study validates the effectiveness of an automatic AI X-ray image processing application for the opportunistic screening of patients for very high fragility risk of lumbar spine, using DXA as the ground-truth. Its robust specificity underscores its capacity to reduce false-positive rates, emphasizing its clinical utility for efficient patient screening. While this study demonstrates promise, further development and validation will be beneficial, using larger and more diverse samples.

VITAMIN D METABOLITE RATIO (VMR) OFFERS THE BEST APPROACH TO EVALUATE FUNCTIONAL VITAMIN D DEFICIENCY: RESULTS OF THE SARCOPHAGE STUDY

A. Ladang[1], A.-S. Gendebien[1], S. Kovacs[1], C. Demonceau[2], C. Beaudart[3], C. Le Goff[1], J.-Y. Reginster[4], O. Bruyère[2], N. M. Al-Daghri[5], M. S. Alokail[4], E. Cavalier[1]

[1]CHU de Liège/Clinical chemistry, Liège, Belgium, [2]WHO Collaborating Centre for Public Health Aspects of Musculoskeletal Health and Aging, Division of Public Health, Epidemiology and Health Economics, University of Liège, Liège, Belgium, [3]Clinical Pharmacology and Toxicology Research Unit (URPC), NARILIS, Department of Biomedical Sciences, University of Namur, Namur, Belgium, [4]Protein Research Chair, Biochemistry Dept, College of Science, King Saud University, Riyadh, Saudi Arabia, [5]Chair for Biomarkers of Chronic Diseases, Biochemistry Department, College of Science, King Saud University, Riyadh, Saudi Arabia.

Backgrounds: The vitamin D metabolite ratio (VMR) has recently shown to be a best indicator of vitamin D deficiency than 25-hydroxyvitamin D (25(OH)VTD) alone. This study aims at validating these results in a large independent cohort of older individuals.
Methods: The SarcoPhAge cohort is a Belgian cohort of community-dwelling older adults. 25(OH)VTD and 24.25$(OH)_2$VTD were measured on 204 sera collected at the second follow-up using liquid chromatography-tandem mass spectrometry CDC certified method. VMR was calculated according the formula: VMR = (24.25($OH)_2$VTD/25(OH)VTD) × 100.
Results: According to cut-offs for vitamin D deficiency established in the literature, 35 individuals (17.2%), 40 individuals (19.6%) and 19 individuals (9.3%) had 25(OH)VTD < 20 ng/mL, 24.25$(OH)_2$VTD < 1.2 ng/mL and VMR < 4%, respectively. 25(OH)VTD, 24.25$(OH)_2$VTD and VMR were all independently associated with PTH but the best association was observed with VMR (rho: − 0.292; p value < 0.0001). When categorizing 25(OH)VTD, 24.25(OH)2VTD, and VMR into quartiles, it was observed that only 24.25(OH)2VTD and VMR exhibited a noteworthy elevation in PTH levels across quartiles (p = 0.002 and p < 0.0001, respectively). Additionally, VMR was independently associated with appendicular lean mass (rho: − 0.220; p value = 0.0018) and BMI (rho: − 0.173; p value = 0.0156) but not with fat mass.
Conclusions: In this study, we confirmed that VMR is the best biomarker to study functional deficiency of vitamin D.

CALCITRIOL SUPPLEMENTATION AFTER KIDNEY TRANSPLANTATION: RESULTS OF A DOUBLE-BLINDED, RANDOMIZED, PLACEBO-CONTROLLED TRIAL

P. K. Khairallah[1], S. S. Sammons[2], S. A. Agarwal[2], N. C. Cortez[3], M. F. Fusaro[4], M. P. Plebani[4], M. Z. Zaninotto[4], C. C. Cosma[4], T. N. Nickolas[2]

[1]Baylor College of Medicine, Houston, United States, [2]Columbia University, New York, United States, [3]University of Turin, Turin, Italy, [4]University of Padova, Padua, Italy

Objective: Vitamin D deficiency is highly prevalent following kidney transplantation (KT) and results in bone loss. We performed a randomized placebo-controlled trial of calcitriol administration in the 1st 12 months post-KT hypothesizing that calcitriol preserves bone quality and strength.
Methods: Participants > 18 yo undergoing a first KT were recruited from at Columbia University between 2013 and 2015. Participants were randomized 1:1 to either daily placebo or daily calcitriol 0.5 mcg. All participants received cholecalciferol 1000 IU daily. Participants had labs and imaging at baseline (pre-KT) and 12 months post-KT. Areal bone mineral density (BMD) was measured by DXA at the spine, hip and forearm. Cortical and trabecular volumetric BMD, microarchitecture, geometry, total bone strength, and vascular calcifications were measured by high resolution peripheral QCT (HRpQCT) at the radius and tibia. Primary analyses were intent to treat.
Results: The study included 32 and 29 participants in the calcitriol and placebo group respectively. In the calcitriol and placebo groups: mean ± sd age was 51 ± 14 and 51 ± 13 yrs; 67% and 70% were male; and 100% and 97% were Caucasian respectively. PTH declined − 63 ± 11% in calcitriol and − 62 ± 6% in placebo (p < 0.001 for both); there was no between-group difference (p = 0.9). BSAP increased 63 ± 36% in placebo and 9.6 ± 13.2 in calcitriol; CTX decreased by − 69 ± 7% in placebo and by − 77 ± 5% in calcitriol; there were no between-group difference for either (p = 0.8, p = 0.3, respectively). There were no within or between group differences in changes to areal BMD by DXA or to geometry, microarchitecture or mechanical estimates of bone strength by HRpQCT (Table 1). Hypercalcemia occurred in 39% and 3% in the calcitriol and placebo groups respectively (p < 0.001) but vascular calcification did not progress (p > 0.05).
Conclusion: Compared to placebo, calcitriol administration during the first 12 months of KT did not affect skeletal measures. These findings suggest that the addition of calcitriol to cholecalciferol in KT recipients does not improve skeletal health but causes hypercalcemia.

Objective: We investigated the effect of a standardized Fracture Liaison Service (FLS) intervention on subsequent fracture risk and mortality.
Material and methods: The study was a multicenter, pragmatic, stepped-wedge cluster-randomized trial. The intervention was introduced to three clusters with four months intervals starting May 2015 through December 2018 at seven Norwegian hospitals. The FLS intervention included medical treatment of osteoporosis for patients 50 years and older with a low-energy fracture. Based on data from the Norwegian Patient Registry, index fractures were assigned respectively to the control group (2011–2015) or intervention group (2015–2018). Rates of a subsequent fragility fracture (distal forearm fracture, proximal humerus fracture or hip fracture), and all-cause mortality were calculated. (Clinicaltrials.gov, NCT02536898).
Results: A total of 100,198 patients (mean age 69.6 years) suffered an index fracture of any type; 8,998 (9%) patients experienced a subsequent fragility fracture and 20,198 (20%) died. During a maximum of 4.7 years follow-up, FLS reduced the risk of any type of subsequent fragility fracture by 12% (hazard ratios (HR) 0.88, 95% confidence intervals (CI) 0.84–0.92) and mortality by 19% (HR 0.81, 95% CI 0.78–0.83). In additional analyses, the risk of a subsequent hip fracture was reduced by 24% (HR 0.76, 95% CI 0.71–0.81).
Conclusion: A standardized FLS intervention can reduce the risk of subsequent fragility fractures and mortality and may thereby contribute to a reduction in the global burden of fragility fractures.

PROTON PUMP INHIBITORS ASSOCIATED WITH INCREASED BONE TURNOVER MARKERS: RESULTS OF A LARGE OBSERVATIONAL COHORT STUDY

D. Fitzpatrick[1], R. Lannon[2], E. Laird[3], M. Ward[4], L. Hoey[4], C. F. Hughes[4], J. J. Strain[4], C. Cunningham[4], H. Mc Nulty[4], K. Mc Carroll[1]

[1]Mercer's Institute for Research on Ageing, St James's Hospital, Dublin, Ireland, [2]Mercer's Institute for Research on Ageing, Dublin, Ireland, [3]Department of Nutrition, Atlantic Technological University, Sligo, Ireland, [4]Nutrition Innovation Centre for Food and Health, University of Ulster, Coleraine, United Kingdom

Objective: Extensive research has found an increased risk of osteoporotic fracture with the long-term use of proton pump inhibitors (PPIs). Various factors have been postulated to explain the mechanism by which this occurs [1]. However few studies have examined the relationship between PPIs and bone turnover markers.
Materialsand methods: Participants were from the Trinity-Ulster-Department of Agriculture (TUDA) study, a large cross-sectional cohort of Irish adults aged $\geq$ 60 years. We excluded participants with a known diagnosis of osteoporosis or on treatment for osteoporosis. ANCOVA was used to compare mean levels of bone specific alkaline phosphatase (BAP) and tartrate-resistant acid phosphatase (TRAP 5b) in PPI users versus non-PPI users after controlling for age, sex, body mass index, timed up an go test, 25(OH)D, estimated glomerular filtration rate, parathyroid hormone, smoking, daily dairy intake, alcohol consumption, type 2 diabetes mellitus, current or past steroid exposure, and loop and thiazide diuretics.
Results: A total of 1657 participants met the inclusion criteria, of whom 31.3% (n = 519) were taking PPI medication. PPI users versus non-PPI users were of similar age (70.0 vs 69.7 years $p = 0.267$) though were marginally more likely to be female (54.1 vs. 49.2%, $p = 0.06$). Overall, PPI users versus non-PPI users had higher mean BAP and TRAP5b and this remained significant after multivariate adjustment (BAP 16.7 vs 15.2 μg/L, $p < 0.001$) and TRAP 5b (3.10 vs 2.94 μg/L, $p = 0.002$).
Conclusions: PPIs were associated with increased bone turnover markers. PPIs are known to inhibit calcium absorption by reducing gastric acid secretion which may lead to hyperparathyroidism. However, the increase in bone turnover markers we observed was independent of parathyroid hormone levels suggesting other additional mechanisms which deserves further investigation. These results highlight the importance of appropriate prescribing and deprescribing of PPIs especially in older adults at risk of fracture.

OC28
DISCONTINUATION OF BISPHOSPHONATES IN OLDER PEOPLE WITH COMPLEX HEALTH NEEDS: SELF-CONTROLLED CASE SERIES TO ASSESS FRACTURE RISK

D. Prieto-Alhambra[1], F. Dernie[2], A. Delmestri[1], T. Rathod-Mistry[1], E. H. Tan[1], A. M. Jödicke[1]

[1]NDORMS, University of Oxford, Oxford, United Kingdom, [2]Medical Sciences Division, University of Oxford, Oxford, United Kingdom

Objective: This study aimed to evaluate the effect of discontinuation of treatment with oral bisphosphonates (BP) on the risk of fractures in the post-discontinuation period in older patients.
Methods: We conducted self-controlled case series using UK primary care electronic health data (CPRD GOLD). All patients aged > 65 years and registered in the database for $\geq$ 1 year before study start

(01/01/2010) were included to the source population. Of those, people with a non-elective hospitalisation, or with frailty or polypharmacy in 2009 who didn't use BP in that year were selected. Among those, people with a new BP prescription and a fracture recorded during the study period were included. Exposure was defined as discontinuation of BP, with a treatment gap of > 90 days. Age-adjusted incidence rate ratios (IRR) were calculated to compare fracture rates during BP treatment vs. in the post-discontinuation period. The main analysis included all people irrespective of the duration of continuous BP use, while subgroup analyses required > 1 year of BP treatment prior to discontinuation. To test the robustness of our analyses we tested the assumptions of the SCCS model before progressing with the analyses and repeated our analyses with statins as negative control exposure to assess residual confounding.

Results: We included 171,048 BP-naïve people with complex health needs, of whom 6245 individuals started BP treatment during the study period. We observed 1262 fractures during 9796 person-years of treatment (event rate 128.8/1000 person-years [95% CI 121.7–136.0] and 942 fractures during 6428 person-years of follow-up post-discontinuation (event rate 146.6/1,000 person-years [137.2–156.1]), respectively. IRR of 0.94 [0.81–1.1] in the main analysis indicated no increased fracture risk after discontinuing of BP treatment,

However, for people with > 1 year history of continued BP therapy, our models showed increased fracture risk following treatment discontinuation (IRR of 1.26 [1.0–1.58]).

Negative control exposure analyses showed no association between statins and fracture risk.

Conclusions: Our study showed increased fracture risks when stopping BP in older people with complex health needs after > 1 year of continuous BP therapy. Further research focussing on the risk–benefit of stopping BP is needed.

GLOBAL BALANCE OF THE SPINE, AN INDEPENDENT CONTRIBUTOR TO PHYSICAL IMPAIRMENTS AND PREDICTOR OF INCIDENT FALLS IN OLDER ADULTS: THE SAFE 3-YEAR LONGITUDINAL COHORT STUDY

M. Hars[1], A. Faundez[2], M.-J. Begin[3], M. Terrien Ferey[1], J. Fechtenbaum[4], K. Briot[4], C. Roux[4], F. Herrmann[5], C. Graf[5], S. Ferrari[6], S. Genevay[7], S. Boudabbous[8], A. Trombetti[1]

[1]Division of Bone Diseases and Division of Geriatrics and Rehabilitation, Geneva University Hospitals and Faculty of Medicine, Geneva, Switzerland, [2]Division of Orthopaedics and Trauma Surgery, Geneva University Hospitals and Faculty of Medicine, and La Tour Hospital, Geneva, Switzerland, [3]Division of Endocrinology, Department of Medicine, Centre Hospitalier de l'Université de Montréal, Québec, Canada, [4]Department of Rheumatology, Cochin Hospital, Assistance Publique-Hôpitaux de Paris, Paris, France, [5]Division of Geriatrics and Rehabilitation, Geneva University Hospitals and Faculty of Medicine, Geneva, Switzerland, [6]Division of Bone Diseases, Geneva University Hospitals and Faculty of Medicine, Geneva, Switzerland, [7]Division of Rheumatology, Geneva University Hospitals and Faculty of Medicine, Geneva, Switzerland, [8]Division of Radiology, Geneva University Hospitals and Faculty of Medicine, Geneva, Switzerland

Objectives: Falls remain the leading cause of fractures in older adults and may result from several intrinsic and extrinsic risk factors. Among them, the role of the global balance of the spine (since recently easily evaluated with the advent of EOS® technology) has never been fully established. In the SAFE cohort, we aimed to determine the association between global balance of the spine, physical function and falls in community-dwelling older adults.

Material and methods: SAFE is an ongoing prospective 3-year longitudinal cohort study conducted in Geneva (Switzerland) among community-dwelling adults aged ≥ 65 years without history of instrumented spinal surgery. All subjects undergo at baseline and 3-year a comprehensive assessment battery including: full skeleton 2D/3D radiographs in the standing position by EOS® low-dose biplane X-ray imaging system, DXA imaging, and physical function tests. Prospective falls and fractures are also collected over the 3-year. Spino-pelvic parameters collected include, among others, the spino-sacral angle (SSA) and the C7-central sacral line (C7-CSL) distance for sagittal and coronal balance, respectively.

Results: Among the 110 subjects (mean age, 75 years; 76% female) included in the final cross-sectional analysis, 40 (36%) reported one or more falls in the past 12 months, 19 (17%) had a Short Physical Performance Battery (SPPB) score ≤ 9 and 8 (7%) were sarcopenic. Global sagittal balance was independently associated with physical performances after controlling for potential confounders (adjusted regression coefficient SPPB/SSA = 0.04, 95% CI [0.01–0.08]; p = 0.024). Global coronal balance was independently associated with both 1-year retrospective falls (OR C7-CSL/faller = 1.59, 95% CI [1.09–2.30]; p = 0.015) and 3-year incident falls (n = 66 first subjects in the longitudinal analysis; OR C7-CSL/faller = 2.25, 95% CI [1.24–4.08]; p = 0.008 and IRR C7-CSL/number of falls = 1.55, 95% CI [1.21–1.98]; p = 0.001), after controlling for potential confounders including age, sex, comorbidities, vertebral fractures and physical performances by SPPB score.

Conclusions: Our results suggest that global sagittal balance of the spine is an independent contributor to physical impairments in older adults, while global coronal balance is an independent predictor of incident falls. Further ongoing longitudinal analysis will fully reveal whether global balance of the spine relates to fractures and the role of compensating mechanisms.

OC30
A NOVEL DRUG COMBINATION WITH THERAPEUTIC POTENTIAL FOR SARCOPENIA

E. Mercken[1], J. Frickel[1], S. Huettner[1], J.-Y. Reginster[2,3], C. Tezze[4,5], M. Sandri[4,5,6], A. Beliën[1]

[1]Rejuvenate Biomed, Diepenbeek, Belgium, [2]WHO Collaborating Center for Epidemiology of Musculoskeletal Health and Aging, Liège, Belgium, [3]Protein Research Chair, Biochemistry Department, College of Science, King Saud University, Riyadh, Saudi Arabia, [4]Department of Biomedical Sciences, University of Padova, Padova, Italy, [5]Veneto Institute of Molecular Medicine, Padova, Italy, [6]Department of Medicine, McGill University, Montreal, Canada

Objectives: To determine the safety and efficacy of RJx-01, a novel drug combination identified using proprietary in-silico discovery (CombinAge™) and *C. elegans* screening/validation (CelegAge™) platforms, in the treatment of sarcopenia, an age-related progressive loss of physical performance and muscle strength that reduces mobility, diminishes quality of life, and increases risk of falls and morbidity.

Methods: RJx-01, consisting of metformin and galantamine, was tested in a Phase 1b randomized, double-blind, placebo-controlled study with 42 healthy males aged 65–75 placed in a full-length cast of the dominant lower extremity for 2 weeks to induce disuse atrophy. During the two weeks of casting and four weeks post-cast removal, 21 participants received RJx-01 and 21 received a placebo. Primary endpoints included safety and tolerability, and pharmacokinetics was assessed as the secondary endpoint. Exploratory endpoints relevant to

sarcopenia, including muscle strength and fatigue using the Biodex Dynamometer and inflammation, were evaluated.
Results: Rejuvenate Biomed recently identified and validated RJx-01 as a potential therapeutic for sarcopenia in worm and mouse pre-clinical models (1). In the Phase 1b trial, RJx-01 was found to be safe and well tolerated among the participants, with no severe or serious adverse events being reported. The RJx-01 proprietary formulation also exhibited high bioavailability. Compared to placebo, RJx-01 treatment significantly enhanced muscle strength and reduced muscle fatigue and inflammation during the recovery phase.
Conclusion: Preclinical studies indicate synergistic beneficial effects of RJx-01 in the treatment of sarcopenia-related phenotypes. The data of the Phase 1b clinical study supports a Phase 2 trial that determines the efficacy of RJx-01 in the treatment of sarcopenia.
Disclosures: EM, JF and SH are employees of Rejuvenate Biomed, and AB is CEO of Rejuvenate Biomed. JR is Chair of Rejuvenate Biomed's Scientific Advisory Committee. All other authors declare that there is no conflict of interest.

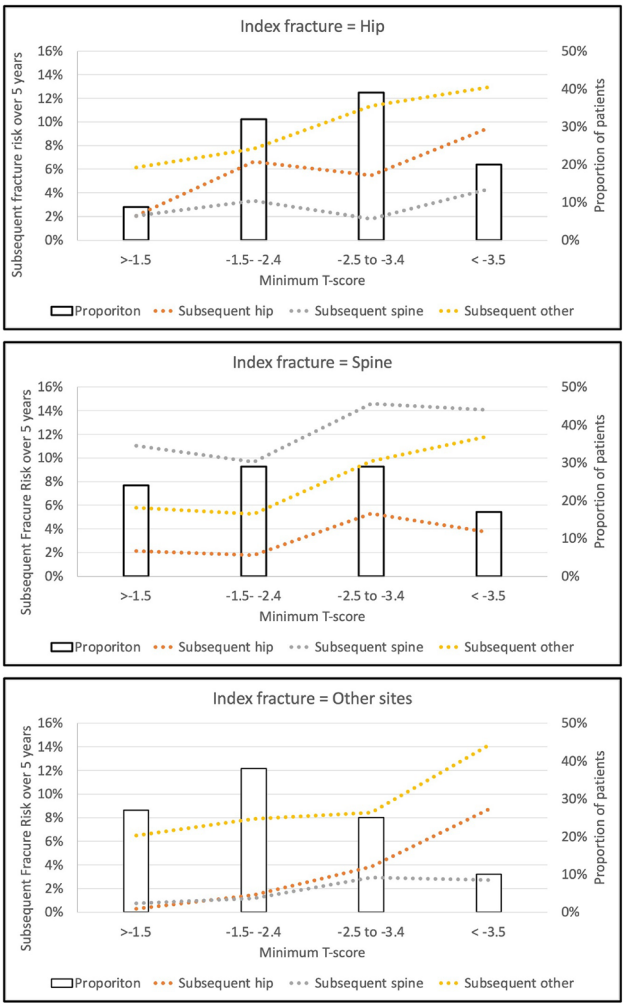
IMMINENT FRACTURE RISK AND MORTALITY DIFFER BY INDEX FRACTURE SITE AND BONE MINERAL DENSITY

R. Pinedo-Villanueva[1], M. K. Javaid[1], W. D. Leslie[2]

[1]University of Oxford, Oxford, United Kingdom, [2]Department of Medicine, University of Manitoba, Winnipeg, Canada

Objective: Data on imminent fracture risk and mortality after an index fracture are necessary to quantify the expected benefit from a fracture liaison service (FLS). This study describes the association between bone mineral density (BMD) measured after the index fracture and the risk of subsequent fractures and mortality.
Material and methods: The study population comprised women aged 50+ with an index fragility fracture of the hip, clinical spine, or other sites recorded within 2 years of subsequent DXA testing in the Manitoba BMD Program. The 5-year risk of subsequent hip, spine, and other fractures as well as mortality were ascertained.
Results: The study identified 566 women with a sentinel hip (mean age 73.4 yrs), 779 with a vertebral (69.9 yrs), and 3867 with other (66.4 yrs) fractures. The median time from fracture to DXA was under 0.5 yrs. The proportion of women with a lowest T-score ≤ -2.5 was 59%, 46%, and 35% for hip, spine, and other fracture sites, respectively. A significant interaction was observed between the index fracture site and minimum BMD category for subsequent hip fractures ($p = 0.001$) but not spine ($p = 0.09$) or other fracture sites ($p = 0.95$) (Figure). The 5-year mortality was 21.4%, 14%, and 7.9% for hip, spine, and other fractures, respectively. Mortality was significantly higher in those with lowest minimum T-score after spine or other fractures ($p < 0.001$), and uniformly high after hip fracture regardless of T-score ($p = 0.55$). The 5-year fracture risk was generally higher for lower T-scores, ranging from 1.3 times for fractures of spine to spine (11.1% for T-score > -1.5 vs 14.1% for T-score ≤ -3.5) to 30.8 times for other to hip (0.3% for T-score > -1.5 vs 8.7% for T-score ≤ -3.5) (Figure).
Conclusion: The 5-year risk of subsequent fracture and mortality differs by BMD measured after the index fracture and also by index fracture site. These data support a more refined approach to predicting the potential benefits from secondary fracture prevention.

Figure: Relationship between index fracture site, minimum T-score and subsequent fracture risk



OC32
EFFECT OF FRAXPLUS ADJUSTMENTS ON FRACTURE RISK RECLASSIFICATION IN OLDER SWEDISH WOMEN—RESULTS FROM THE SUPERB-STUDY

M. Zoulakis[1], H. Johansson[1], N. C. Harvey[2], K. F. Axelsson[1], H. Litsne[1], L. Johansson[1], E. Liu[3], M. Schini[4], L. Vandenput[5], E. V. McCloskey[6], J. A. Kanis[7], M. Lorentzon[1]

[1]University of Gothenburg, Department of Internal Medicine and Clinical Nutrition, Sahlgrenska Osteoporosis Centre, Gothenburg, Sweden, [2]MRC Lifecourse Epidemiology Centre, University of Southampton,, Southampton, United Kingdom, [3]Mary McKillop Institute for Health Research, Australian Catholic University, Melbourne, Australia, [4]Division of Clinical Medicine, School of Medicine and Population Health, University of Sheffield,, Sheffield, United Kingdom, [5]Mary McKillop Institute for Health Research, Australian Catholic University,, Melbourne, Australia, [6]MRC and Arthritis Research UK Centre for Integrated Research in Musculoskeletal Ageing, Mellanby Centre for Musculoskeletal Research, Sheffield, United Kingdom, [7]Centre for Metabolic Bone Diseases, University of Sheffield, Sheffield, United Kingdom

Objectives: FRAXplus allows adjustment of FRAX fracture probabilities for additional clinical information [currently, recency of osteoporotic fracture, high dose oral glucocorticoids, duration of type

2 diabetes mellitus, lumbar spine (LS) BMD, trabecular bone score (TBS), falls history in previous year, or hip axis length (HAL)]. We examined the impact of FRAXplus adjustments on the proportion of older Swedish women eligible for treatment using a major osteoporotic fracture (MOF) probability intervention threshold (IT) $\geq$ 26% (representing the risk in a 70-year-old Swedish woman with a previous fracture).

Materialsand methods: Ten-year MOF probabilities with femoral neck bone mineral density (BMD, Hologic) were calculated using the original FRAX tool and adjusted, where possible, by FRAXplus using data from the SUPERB cohort of 3028 Swedish women ages 75–80 years. Data on clinical risk factors (CRFs) and outcomes were collected using questionnaires and national registers over a follow-up period of 8 years. Incident MOFs were x-ray verified. The FRAXplus adjustment to MOF and hip fracture probabilities was only applied for one FRAXplus factor, with the most influential being used if more than one adjustment was possible. The net reclassification improvement (NRI) was calculated.

Results: In total, 90% (n = 2723) of the included women had their 10-year MOF probability adjusted, with the most common FRAXplus adjustment factors being HAL (30%), TBS (23%), fall history (20%), LS BMD (8%), and recent fracture (5%; Fig. 1). A similar pattern was observed for hip fracture 10-year probability. Of those below the IT using FRAX alone, 1785 remained below after FRAXplus adjustment, and within this group, 365(20.4%) women had an incident MOF. 339 women had their 10-year MOF probability uplifted above the IT using FRAXplus and in this group, 119 women (35.1%) had an incident MOF. There were 904 women with 10-year MOF probabilities above the IT using both the original FRAX tool and FRAXplus, and within this group, 324(35.8%) women had an incident MOF. The NRI (95% confidence interval) was 4.82% (1.87–7.77%); $p < 0.01$).

Conclusions: Using FRAXplus, a significant proportion of older women had their 10-year fracture probabilities uplifted above the IT, which reflected their elevated fracture risk more accurately.

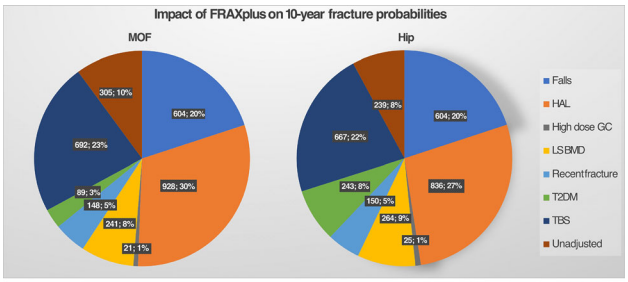


Figure 1. The impact of FRAXplus on 10-year MOF (left) and hip fracture (right) probabilities in older Swedish women in the SUPERB-cohort.

OC33
SMOKING HISTORY AND FRACTURE RISK: A META-ANALYSIS TO UPDATE THE FRAX® RISK ASSESSMENT TOOL

M. Schini[1], H. Johansson[2], N. C. Harvey[3], M. Lorentzon[4], E. Liu[5], L. Vandenput[5], J. A. Kanis[6], E. V. Mccloskey and The Frax Meta-Analysis Cohort Group[7]

[1]Division of Clinical Medicine, School of Medicine and Population Health, Mellanby Centre for Musculoskeletal Research, University of Sheffield, Sheffield, United Kingdom, [2]University of Gothenburg, Gothenburg, Sweden, [3]MRC Lifecourse Epidemiology Centre, NIHR Southampton Biomedical Research Centre, University of Southampton, Southampton, United Kingdom, [4]Sahlgrenska Osteoporosis Centre, Institute of Medicine, University of Gothenburg, Gothenburg, Sweden, [5]Mary McKillop Institute for Health Research, Australian Catholic University, Melbourne, Australia, [6]Centre for Metabolic Bone Diseases, University of Sheffield, Sheffield, United Kingdom, [7]Division of Clinical Medicine, School of Medicine and Population Health, Mellanby Centre for Musculoskeletal Research, University of Sheffield., Sheffield, United Kingdom

Objectives: Smoking has detrimental effects on health and is associated with an increased risk of fractures, thus current smoking is one of the risk factor the FRAX® tool. However, in this meta-analysis of international cohorts, the aim was to examine the relationship of smoking (current and past) with fracture risk, with a view to updating.

Materialsand methods: The risk of fracture associated with current smoking was estimated by an extended Poisson model applied separately to each of 57 prospective cohort studies. Covariates included time since start of follow up, current age, and in an additional model, BMD at the femoral neck. The results of the different studies were merged by using the inverse-variance weighted β-coefficients.

Results: The analysis included a total of 1 634 449 participants (60% female, mean age 60 years). Current smoking, documented in 12% of participants (15.3% men and 9.8% women), was associated with a significantly increased risk of any fracture in both men and women (Table). Current smoking was associated with a greater increase in fracture risk in men than in women. The hazard ratio (HR) was somewhat attenuated with the inclusion of BMD but remained statistically significant in all categories, suggesting that the risk is largely independent from BMD. When compared to non-smokers, there was little evidence for increased fracture risk amongst women who were past smokers for most fracture categories. In men, past smoking was significantly associated with fracture risk [1.11 (1.03, 1.18)]; however, the magnitude of the effect was lower than what was observed for current smokers [1.43 (95% CI 1.26, 1.62)].

Conclusions: Our results confirm an association between current smoking and increased fracture risk that is largely independent of BMD. The attenuation of the smoking associated fracture risk in past vs current smokers supports the skeletal benefits of smoking cessation. These data will be used to inform future iterations of FRAX.

***Table**: Hazard ratio (HR) and 95% confidence intervals (CI) for fractures in current smokers in men and women.*

QUANTITATIVE MOTION ARTEFACT GRADING IN HR-PQCT CLINICAL IMAGING: AN ALGORITHMIC APPROACH

T. Cox[1], S. Mahmoodi[1], L. D. Westbury[2], N. R. Fuggle[2], S. Lu[1], N. C. Harvey[2]

[1]Faculty of Engineering and Physical Sciences, Electronics and Computer Science, University of Southampton, Southampton, United Kingdom, [2]MRC Lifecourse Epidemiology Centre, University of Southampton, Southampton, United Kingdom

Objective: High-Resolution peripheral Quantitative Computed Tomography (HR-pQCT) is a three-dimensional imaging technique which captures detailed information on bone microarchitecture. Unfortunately, this increased resolution comes at the cost of increased sensitivity to motion artefact, assessment of which typically requires manual review. We therefore aimed to develop an algorithmic approach to automatically identify and quantify motion artefact.

Methods: Our approach was to detect motion artefact in a HR-pQCT scan by examining and exploiting the sinogram produced from the raw projection data. Unlike processed CT scans, sinogram data retain a temporal component, making it easy to detect shifts where, or more accurately when, subject motion has occurred during a scan. To detect these subtle shifts, we implemented a machine learning approach using the state-of-the-art U-Net neural network architecture to segment the areas of interest in the sinogram. Subsequently, we developed an algorithm to detect the number and severity of shifts that occurred across the scan and used this to calculate a quantitative measure of motion artefact.
Results: We tested our algorithm against manual gradings on 739 scans of children ages 6–10 years, in which the prevalence of motion artefact was high. Our preliminary results demonstrated that our approach more accurately assigned a high score to scans with high levels of motion artefact than existing methods. Specifically, our method captured each instance of subject motion across the entire scan, whereas previous work done by Sode et al. only captured net motion. However, our results were not perfect, and we aim to improve our algorithm to better capture all severities of artefact.
Conclusion: Our results show a better performance in accurately detecting motion artefact than existing methods and can be implemented to automatically check for motion artefact immediately when a HR-pQCT scan is taken. Additionally, our quantitative approach can be used to detect where artefact has occurred in a scan, which could be used to correct it.

FRACTURE RATE AND LOCATION IN ADULTS WITH HYPOPHOSPHATASIA WITH ONE VERSUS MULTIPLE ALPL VARIANTS: DATA FROM THE GLOBAL HPP REGISTRY

L. Seefried[1], K. Dahir[2], G. Martos-Moreno[3], K. Ozono[4], W. Högler[5], C. Rockman-Greenberg[6], S. Fang[7], A. Petryk[7], P. Kishnani[8], A. Linglart[9]

[1]University of Würzburg, Würzburg, Germany, [2]Vanderbilt University Medical Center, Nashville, United States, [3]Hospital Infantil Universitario Niño Jesús, IIS La Princesa, Universidad Autónoma de Madrid, CIBERobn, ISCIII, Madrid, Spain, [4]Osaka University, Suita, Osaka, Japan, [5]Johannes Kepler University Linz, Linz, Austria, [6]University of Manitoba, Winnipeg, Manitoba, Canada, [7]Alexion, AstraZeneca Rare Disease, Boston, United States, [8]Duke University Medical Center, Durham, United States, [9]Paris-Saclay University, AP-HP and INSERM, Paris, France

Objective: Hypophosphatasia (HPP), a rare, inherited disease associated with compromised bone mineralization, is caused by variants in the *ALPL* gene encoding tissue-nonspecific alkaline phosphatase (ALP). Fracture rates, locations, and the clinical implications of having 1 vs $\geq$ 2 *ALPL* variants are incompletely characterized in patients with HPP.
Methods: Adults in the Global HPP Registry (NCT02306720) with low ALP, $\geq$ 1 *ALPL* variant, and fracture data were included in the analysis. Fracture rate and distribution of fractures by location were determined for patients aged $\geq$ 18 to $<$ 50 (younger adults) and $\geq$ 50 years (older adults). Fractures and pseudofractures were combined for analysis; results were stratified by number of *ALPL* variants.
Results: The study population included 278 younger adults (75.2% females) and 249 older adults (72.3% females), with a history of fractures in 38.1% (younger adults) and 57.0% (older adults). Age-adjusted fracture rate per 100 person-years was 2.49 (95% CI 2.19, 2.82) in younger adults and 2.78 (95% CI 2.52, 3.06) in older adults. Metatarsal fractures were the most common fractures in younger adults (14.4% of patients and 25.6% of fractures) and older adults (19.3% and 17.5%), with similar rates in patients with 1 or $\geq$ 2 *ALPL* variants. Femoral fractures were more prevalent in those with $\geq$ 2 vs 1 *ALPL* variant (younger adults: 17.6% vs 1.2%; older adults: 46.9% vs 8.3%). Vertebral fractures were reported in 2.9% of younger adults and 9.2% of older adults.
Conclusions: Patients with HPP have relatively high rates of metatarsal fractures, and of femoral fractures in those with $\geq$ 2 *ALPL* variants. The vertebral fracture rate was lower in patients with HPP than in those with osteoporosis. These data suggest that fractures in patients with HPP have a distinct pattern compared with the general population or patients with osteoporosis.

OC36
IS THERE AN ASSOCIATION BETWEEN BIRTH WEIGHT OR GESTATIONAL AGE AND FRACTURE RISK IN YOUNG ADULTS?

H. T. Holltrø[1], T. I. L. Nilsen[1], B. Schei[2], I. Tronstad[2], A. Langhammer[3], M. Hoff[4]

[1]INB, NTNU, Norwegian University of Science and Technology, Trondheim, Norway, [2]ISM, NTNU, Norwegian University of Science and Technology, Trondheim, Norway, [3]HUNT, ISM, NTNU, Norwegian University of Science and Technology, Trondheim, Norway, [4]INB, NTNU, Norwegian University of Science and Technology/ St Olavs Hospital, University hospital in Trondheim, Trondheim, Norway

Objective: To examine the association between birth characteristics and fracture risk in a Norwegian cohort born 1967–1988.
Methods: Data on 6434 women and 4665 men who participated in the 3rd survey the HUNT Study, (HUNT3, 2006–08), were linked to the Medical Birth Registry of Norway and patient records at the regional hospitals. ICD9 and ICD10 was used to identify fractures of the wrist, humerus, hip, or spine from 01.01.1988 to 21.10.2021. Participants were followed from 01.01.1988 until the first fracture; date of death or end of follow-up. Cox regression was used for estimating hazard ratios (HR) between birth weight, gestational age, and fracture (95% CI) adjusted for birth year, sex, maternal age, and maternal morbidity.
Results: 539 fractures were observed (women 289 (4.5%), men 251 (5.4%)) during a median follow-up time of 33.8 years. Forearm fractures accounted for 61%. Mean age at fracture was 32.1 years (range 2.4–53.5). 389 (3.5%) had a birth weight $<$ 2.5 kg and 1362 (12.3%) were born small for gestational age (SGA). The adjusted HR for fracture among those with a birth weight $<$ 2.5 kg was 0.97 (0.55–1.71) compared to those born with a birth weight 3.5–3.9 kg and 1.01 (0.78–1.31) for SGA compared to those born appropriate for gestational age. In analyses excluding those with birthweight $<$ 2.5 kg, the HRs pr 100 g and one SD increase were 0.99 (0.97–1.00) and 0.93 (0.85–1.02), respectively.
Conclusion: In this study, we found no association between birth weight or gestational age and subsequent fracture risk in young adults.

Table 1. Incidence rate and hazard ratios (HR) of fracture according to birth characteristics

Variable	Number (%)	Person-year	Fractures (n)	HR, crude	HR Adjusted** (95% CI)	Trend-test
Birthweight, kg						
Continuous (per 100 g increase)	11,099 (100)	367284	539	1.00	0.99 (0.97-1.01)	1.00 (0.98-1.01)

Objective: Exposure to environmental factors during early life may provoke physical responses that have a lasting impact on skeletal development. We aimed to identify periods of susceptibility to air pollution in early life in relation to bone health outcomes at age six.
Material and methods: Data were from the Generation R study, a population-based pregnancy cohort study in Rotterdam, The Netherlands. In total, 9901 women with a delivery date from April 2002 until January 2006 were enrolled in the study. We estimated daily concentrations of nitrogen dioxide (NO2) and particulate matter (PM10, PM2.5 and PM2.5 absorbance) at the home addresses during pregnancy and childhood, using land-use regression models. Bone mineral density (BMD) and area-adjusted bone mineral content (aBMC) were measured by dual-energy x-ray absorptiometry (DXA) at age six. We performed distributed lag non-linear modelling (DNLM) adjusted for several socioeconomic characteristics to assess the associations between air pollution and bone health and identify windows of susceptibility.
Results: Among 5910 children, we identified windows of susceptibility from approximately 1 year to 4 years of age for PM2.5 and PM2.5 absorbance with BMD (e.g., – 10.3; CI– 15.8 to – 4.7 per 5 $\mu g/m^3$ increase in PM2.5) and for all air pollutants with aBMC (e.g., – 14.6; CI – 20.7 to – 8.4 per 5 $\mu g/m^3$ increase in PM2.5). Also, we identified a positive association between NO2 and PM2.5 absorbance during pregnancy with aBMC (e.g., 4.0; CI 1.4 to 6.6 per 10^{-5} m^{-1} increase in PM2.5 absorbance). Associations followed similar trends, but remained only statistically significant in boys, and not in girls.
Conclusion: Exposure to air pollution during childhood may have adverse impacts on bone health outcomes at age six, and between ∼ 1 to ∼ 4 years may be a critical period of higher susceptibility.

Funding: Erasmus MC, ZonMw, Ministry of Health, Welfare and Sport, European Union's Horizon, and Generalitat de Catalunya (CERCA Program).

Associations between exposure to air pollutants at pregnancy and childhood with measures of bone health at ~6 years of age (n = 5,910).

	Bone mineral density (BMD)		Area-adjusted bone mineral content (aBMC)	
Air pollutants	Lags	Estimate	Lags	Estimate
NO2 (Δ 10 $\mu g/m^3$)	--	--	Conception - 28 weeks of gestation	1.2 (95% CI 0.3 to 2.2)
	--	--	1.3 year - 3.9 years	-3.8 (95% CI -6.1 to -1.5)
PM10 (Δ 10 $\mu g/m^3$)	--	--	1.6 year - 3.9 years	-6.5 (95% CI -10.8 to -2.2)
PM2.5 (Δ 5 $\mu g/m^3$)	1.1 year - 4.1 years	-10.3 (95% CI -15.8 to -4.7)	9 months - 4.2 years	-14.6 (95% CI -20.7 to -8.4)
PM2.5 absorbance (Δ 10^{-5} m^{-1})	--	--	Conception - 1 months	4.0 (95% CI 1.4 to 6.6)
	1.3 year - 3.8 years	-7.8 (95% CI -13.1 to -2.5)	1.0 year - 3.9 years	-13.4 (95% CI -19.4 to -7.4)
	--	--	4.8 years - 5.5 years	5.4 (95% CI 1.8 to 9.0)

Estimates and 95% CI from distributed lag non-linear model, adjusted for maternal and paternal age, maternal and paternal educational levels, marital status, monthly household income, maternal smoking during pregnancy, child's sex and ethnicity, child's age, height, and bone free mass at the DXA scan visit, and year and month of conception. Associations after correction for multiple testing (P-value < 0.025). Abbreviations: CI, confidence interval; NO2, nitrogen dioxide; PM2.5, particulate matter with aerodynamic diameter <2.5μm; PM10, particulate matter with aerodynamic diameter <10μm; PM2.5 absorbance, absorbance of PM2.5 filters.

FAMILY HISTORY OF FRACTURE AND FRACTURE RISK: A META-ANALYSIS TO UPDATE THE FRAX® RISK ASSESSMENT TOOL

E. V. McCloskey[1], H. Johansson[2], E. Liu[3], M. Schini[4], L. Vandenput[3], N. C. Harvey[5], M. Lorentzon[6], W. D. Leslie[7], J. A. Kanis and The Frax Meta-Analysis Cohort Group[8]

[1]Division of Clinical Medicine, School of Medicine and Population Health, Mellanby Centre for Musculoskeletal Research, University of Sheffield., Sheffield, United Kingdom, [2]University of Gothenburg, Gothenburg, Sweden, [3]Mary McKillop Institute for Health Research, Australian Catholic University, Melbourne, Australia, [4]Division of Clinical Medicine, School of Medicine and Population Health, Mellanby Centre for Musculoskeletal Research, University of Sheffield, Sheffield, United Kingdom, [5]MRC Lifecourse Epidemiology Centre, NIHR Southampton Biomedical Research Centre, University of Southampton, Southampton, United Kingdom, [6]Sahlgrenska Osteoporosis Centre, Institute of Medicine, University of Gothenburg, Gothenburg, Sweden, [7]Department of Medicine, University of Manitoba, Winnipeg, Canada, [8]Centre for Metabolic Bone Diseases, University of Sheffield, Sheffield, United Kingdom

Objectives: To undertake a meta-analysis of international prospective cohorts to quantify the relationship between a family history of fracture and future fracture incidence, when adjusted for age, sex, time since baseline and femoral neck bone mineral density (BMD).
Materialsand methods: We investigated the relationship between family hip fracture or any fracture history and the risk of any clinical fracture, any osteoporotic fracture, major osteoporotic fracture (MOF) and hip fracture alone using an extended Poisson model in each cohort. Models were adjusted for current age, sex, BMD, and follow up time. The results of the different studies were merged using inverse weighted β-coefficients. We evaluated if the association between family fracture history differed age, follow-up time, and parental fracture origin (maternal vs. paternal) using traditional interaction terms.
Results: The interim analysis dataset comprised up to 281,893 men and women from up to 40 cohorts in 28 countries followed for a total of 2.42 million person-years. After adjustment for age and time since baseline, parental hip fracture was associated with higher risk of incident fracture across all fracture outcome categories in both men and women. The association was strongest for incident hip fractures alone [Hazard Ratio (95% CI): 1.40 (1.26–1.56) and 1.37 (1.05–1.80) in women and men respectively], and the increased fracture risk was similar by sex across all incident fracture categories. Associations were largely unchanged when additionally adjusted for BMD, did not vary by age or follow-up time, and were similar if the history of hip fracture was maternal or paternal. In a limited analysis of sibling history of hip fracture or any fracture, both demonstrated similar associations to those observed with parental history.

Conclusions: In this large international cohort meta-analysis, a family history of fracture is confirmed as a significant independent predictor of future fracture risk. While parental hip fracture appears the strongest factor for future hip fracture, the findings also suggest that a family history of other fractures might be appropriate for inclusion in future iterations of the FRAX tool.

SEX DEPENDENT ASSOCIATIONS BETWEEN BMI AND FRACTURE RISK: AN INTERNATIONAL META-ANALYSIS

N. C. Harvey[1], H. Johansson[2], E. V. McCloskey[3], E. Liu[4], M. Schini[5], L. Vandenput[6], M. Lorentzon[7], W. D. Leslie[8], J. A. Kanis[2], -. Frax Meta-Analysis Cohort Group[2]

[1]MRC Lifecourse Epidemiology Centre, University of Southampton, Southampton, United Kingdom, [2]Centre for Metabolic Bone Diseases, University of Sheffield, Sheffield, United Kingdom, [3]MRC Versus Arthritis Centre for Integrated research in Musculoskeletal Ageing, Mellanby Centre for Musculoskeletal Research, University of Sheffield, Sheffield, United Kingdom, [4]Mary McKillop Institute for Health Research, Australian Catholic University, Melbourne, Australia, [5]Division of Clinical Medicine, School of Medicine and Population Health, University of Sheffield, Sheffield, United Kingdom, [6]Sahlgrenska Osteoporosis Centre, Department of Internal Medicine and Clinical Nutrition, Institute of Medicine, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden, [7]Sahlgrenska Osteoporosis Centre, Institute of Medicine, University of Gothenburg, Gothenburg, Sweden, [8]Department of Medicine, University of Manitoba, Winnipeg, Canada

Objectives: In this international meta-analysis, we aimed to quantify the predictive value of body mass index (BMI) for incident fracture in men and women, and to investigate the relationship of this risk with femoral neck bone mineral density (BMD).

Materialsand methods: The interim analysis dataset comprised individual records of 172,059 men and women with BMD measured, from 51 cohorts in 20 countries. The total follow-up time was 1.4 million person-years. We investigated associations between WHO-defined BMI categories (Underweight: < 18.5 kg/m^2; Normal: 18.5–24.9 kg/m^2; Overweight: 25.0–29.9 kg/m^2; Obese I: 30.0–34.9 kg/m^2; Obese II: ≥ 35.0 kg/m^2) and risk of major osteoporotic fracture (MOF) or hip fracture (HF) alone using an extended Poisson model in each cohort. The covariates examined were age, sex, BMD, and duration of follow-up. The results of the different studies were merged by using the inverse-variance weighted β-coefficients.

Results: After adjustment for age and time since baseline, lower BMI was associated with a greater risk of incident fracture in both men and women. Thus, for underweight individuals compared with normal weight, the hazard ratio [95% CI] for HF was 2.30 [2.03–2.60] in women with an even more marked association in underweight men (HR 3.51 [2.05–5.99]) (Table). In both sexes, HF risk was lower in overweight and obese categories compared to normal weight. The pattern was similar for MOF but with a lower magnitude of effect for the increased risk in the underweight category.

Adjustment for femoral neck BMD T-score attenuated the increased risk associated with underweight and led to attenuation or inversion of the association in overweight and obese categories. Thus, after BMD adjustment, higher BMI category was progressively associated with greater hip fracture risk, with the association stronger in men than women. The pattern was similar for MOF.

Conclusions: In the largest ever meta-analysis undertaken to date, underweight was a consistent risk factor for HF and MOF. In contrast, overweight and obesity appeared protective for these fracture outcomes in models adjusted for age and follow-up time, but became risk factors after additional adjustment for femoral neck BMD, particularly in the highest BMI category. Notably, the effect of BMI extremes seemed greater in men than women. These findings will inform the next iteration of FRAX®.

Table. Hazard ratio for hip and major osteoporotic fracture [+ 95% confidence intervals] according to WHO-defined BMI category (adjusted for age and follow-up time).

Objective: To demonstrate similar efficacy, safety, and immunogenicity of CT-P41 and Prolia in postmenopausal women with osteoporosis (PMO).
Methods: This was a double-blind, active-controlled, Phase 3 study (NCT04757376) in PMO with lumbar spine BMD (LS-BMD) T-score of ≤ -2.5 to ≥ -4.0. A total of 479 patients were randomized (1:1) to receive 60 mg of CT-P41 or Prolia every 6 months. The primary efficacy endpoint was the percent change from baseline (%CFB) in LS-BMD at Week 52. The secondary efficacy endpoints were the %CFB in LS-BMD and in BMD at total hip (TH) and femoral neck (FN) and fracture incidence. Safety and immunogenicity were monitored during the study. Here, the results up to Week 52 in the CT-P41 and Prolia groups are presented.
Results: The therapeutic equivalence was demonstrated between the CT-P41 and Prolia groups in the mean %CFB in LS-BMD at Week 52 with 95% CIs for the treatment difference which was entirely within the predefined equivalence margins ($\pm$ 1.503%) (Table 1). The mean %CFB in BMD for LS, TH, and FN increased after each dosing and were comparable between groups. A new vertebral fracture was reported for 1 patient each at Week 26 in both groups. There was no hip fracture reported and the incidence of nonvertebral fracture was similar between groups (CT-P41: 0.8%; Prolia: 1.7%). The incidence of adverse events (AEs) (CT-P41: 75.7%; Prolia: 70.2%) and serious AEs (CT-P41: 2.9%; Prolia: 4.2%) were similar between groups. Most AEs were Grade 1 or 2 and were not related to study drugs. Most patients had at least one anti-drug antibody (ADA) positive result due to the sensitive assay but most of the ADA titer values were low. There was no patient with a positive neutralizing antibody result.

Table 1. Percent Change from Baseline in BMD for Lumbar Spine by DXA at Week 52 (ANCOVA)

Analysis Set Group	n / N	LS Mean (SE)	LS Mean Difference	95% CI of LS Mean Difference	Mean difference and 95% CI (CT-P41 – Prolia)

CT-P41	222 / 239[1]	4.9317 (0.31508)	-0.139	(-0.826, 0.548)	-0.826, 0.548
Prolia	212 / 238[1]	5.0706 (0.32714)			
Per-protocol Set					-0.973, 0.414
CT-P41	215 / 215[2]	5.0330 (0.31640)	-0.280	(-0.973, 0.414)	
Prolia	202 / 202[2]	5.3125 (0.33505)			-1.503% 0 +1.503%

Abbreviation: ANCOVA, analysis of covariate; BMD, bone mineral density; CI, confidence interval; DXA, dual-energy X-ray absorptiometry; LS, least square; SE, standard error.
1. The number of patients who had a BMD assessment result for lumbar spine by DXA at Week 52 / The number of patients in full analysis set.
2. The number of patients who had a BMD assessment result for lumbar spine by DXA at Week 52 / The number of patients in per-protocol set.

Conclusion: The therapeutic equivalence of efficacy was demonstrated between the CT-P41 and Prolia in PMO. The secondary efficacy, safety, and immunogenicity results supported the similarity of CT-P41 and Prolia. CT-P41 was well tolerated with a safety profile comparable to that of Prolia.

OP2-P1394
BISPHOSPHONATES SHOW NO ASSOCIATION WITH PREVENTING, SLOWING, OR DELAYING RADIOGRAPHIC CHANGES AND PAIN IN HIP OSTEOARTHRITIS: A FOUR-YEAR STUDY IN FEMALE ADULTS USING DATA FROM THE OSTEOARTHRITIS INITIATIVE STUDY

Z. Salis[1]

[1]Univ. of Geneva, Geneva, Switzerland

Objective: To investigate the potential impact of bisphosphonates on radiographic changes and pain in individuals with no or early stages of hip osteoarthritis (OA).
Methods: This study examined data from the Osteoarthritis Initiative (OAI), which included 4088 hips from 2,057 participants, predominantly with no or early stages of radiographic hip OA at baseline. Bisphosphonate users were identified as those who reported usage at least three times, including at baseline and during the subsequent 1-y, 2-y, 3-y, and 4-y follow-up visits. Non-users were participants who did not use bisphosphonates in the 5 y preceding the baseline and at subsequent follow-up visits. Generalized estimating equations were performed to assess the association between bisphosphonate use and outcomes relating to radiographic changes and pain in hip OA over a 4-y follow-up.
Results: The analysis revealed no statistically significant difference between bisphosphonate users and non-users concerning radiographic changes and pain in hip OA over 4 ys. Specifically, the odds ratios for the incidence and progression of radiographic hip OA were 0.58 (95% CI 0.27 to 1.22) and 0.80 (95% CI 0.49 to 1.32), respectively (Table 1). Furthermore, the odds ratios for the development and resolution of frequent hip pain were 1.04 (95% CI 0.76 to 1.42) and 0.99 (95% CI 0.72 to 1.36), respectively (Table 2).

Table 1. Association of bisphosphonate use and incidence and progression of radiographic hip OA, and worsening individual radiographic features of the hip OA, during 4-y follow-up in radiographic hip OA cohort, as shown in univariate and multivariable analyses.

* Defined as bisphosphonate use at least three examinations, including baseline and follow-up visits (1-year, 2-year, 3-year, and 4-year). ^Non-users were identified as those who did not use bisphosphonates in the preceding 5 years and at any of the examined time points. Multivariable analysis was adjusted for the baseline values of age, BMI, and analgesic use. CI: Confidence Interval; OA: Osteoarthritis.

Conclusion: The findings from this longitudinal study do not suggest an association between bisphosphonate use and the prevention, slowing, or delay of development and progression of radiographic changes or pain in hip OA among individuals with no or early stages of hip OA over a 4-y follow-up.

OP3
-P504 ROMOSOZUMAB AND DENOSUMAB COMBINATION THERAPY IN POSTMENOPAUSAL OSTEOPOROSIS

G. Adami[1], A. Fassio[1], D. Gatti[1], O. Viapiana[1], C. Benini[1], M. Rossini.[1]

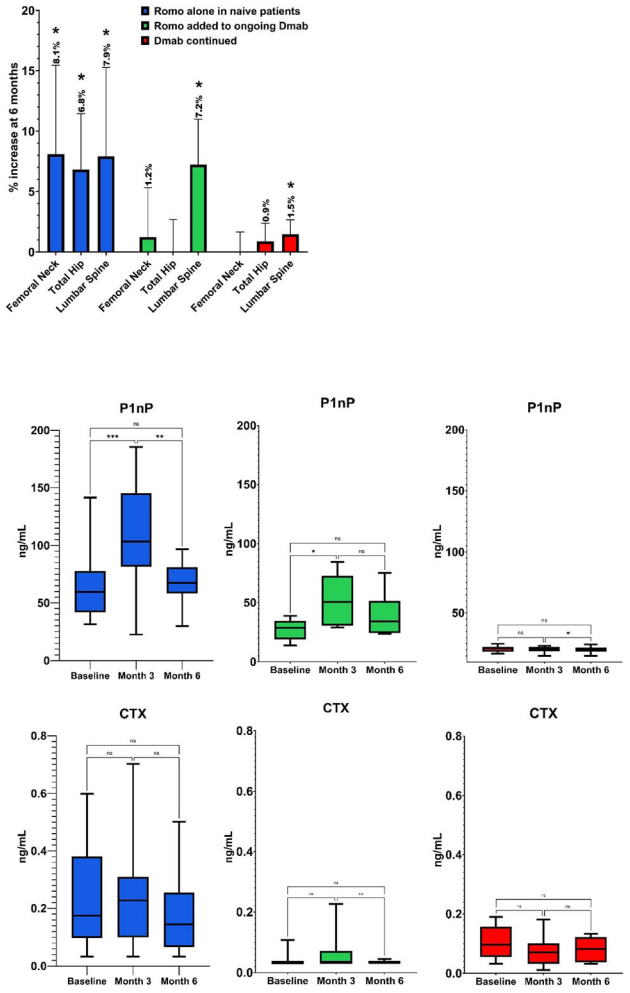
[1]Univ. of Verona, Rheumatology Unit, Verona, Italy

Objective: Optimization of sequential and combination treatment is crucial in shaping long-term management of postmenopausal osteoporosis (OP). We aimed to investigate the effectiveness of the combination of romosozumab to ongoing denosumab treatment.

Methods: We conducted a 6-month prospective observational study on postmenopausal women with severe OP receiving treatment with romosozumab either alone (in patients naïve to treatment) or in combination with ongoing long-term denosumab (> 2 y). We also included a group of patients with ongoing denosumab (> 2 y) as a control group to isolate the specific effects attributable to romosozumab, especially on bone turnover markers (BTMs) and calcium metabolism. We collected serum samples for BTMs, bone modulators and calcium phosphate metabolism at baseline, month 3 and month 6. BMD was assessed at baseline and after 6 months.

Results: 52 postmenopausal women (73 ± 9.6 y) with OP were included in the study. Nineteen received romosozumab alone, 11 received romosozumab combined to ongoing denosumab and 22 continued denosumab alone. Baseline characteristics did not differ significantly between groups at baseline (including FRAXplus

adjusted for recency of the fracture, 10y% fracture risk 37 ± 14 vs. 47 ± 16 vs. 33 ± 13, p NS). BMD increased significantly at all sites at 6 months of follow-up in the romosozumab alone group (femoral neck + 8.1%, total hip + 6.8% and lumbar spine + 7.9%). In contrast, BMD increased significantly only at lumbar spine in the combination group (+ 7.2%) and in the denosumab group (+ 1.5%) (Fig. 1). P1NP increased significantly in romosozumab groups at month 3 (+ 70.4% SD ± 64.5, p 0.0002 in romosozumab alone group; + 99.1% SD ± 100.,5 p 0.027 in combination group). CTX decreased (not significantly) in the romosozumab alone group, whereas was suppressed (< 0.033) at all time points in combination group and denosumab alone group (Fig. 2). We found a small decline in calcium concentration at month 3 in the romosozumab alone group (− 2.8% SD ± 3.8, p 0.037), which settled back to normal concentrations at month 6 (− 0.06% SD ± 4.1, p ns). Calcium did not change in the combination and denosumab alone groups. Sclerostin levels increased steeply in both romosozumab groups and Dkk1 did not change. After accounting for multiplicity using false discovery rate (Q value 5% of FDR), we found a significant positive association between baseline sclerostin levels and delta femoral neck BMD between baseline and month 6 in patients receiving romosozumab alone (r2 0.408, p 0.047).



Conclusion: Romosozumab added to ongoing denosumab resulted in an increase in P1NP and lumbar spine BMD, but not in femoral neck BMD. For patients on denosumab, using romosozumab as an additional treatment appeared to be useful in terms of bone formation markers and spine BMD vs. denosumab alone.

OP4-P512
RELATIONSHIPS BETWEEN SELF-PERCEIVED FRACTURE RISK AND FAMILY HISTORY IN THE HERTFORDSHIRE INTERGENERATIONAL STUDY: THE SAME OR DIFFERENT TO PERCEPTIONS REGARDING HEART DISEASE RISK?

G. Bevilacqua[1], L. D. Westbury[1], C. Cooper[1], E. M. Dennison[1]

[1]MRC Lifecourse Epidemiology Centre, Univ. of Southampton, Southampton, UK

Objective: Self-perceived fracture risk (SPR) has been associated with fracture independent of FRAX objectively calculated risk, and links to osteoporosis medication uptake. A family history of fracture is an important predictor of personal fracture risk. We examined correlates of SPR among UK community-dwelling individuals, aged 21–70 y. We also compared the relationship between SPR and family history of hip fracture with the relationship between self-perceived risk of heart disease and family history of myocardial infarction.
Methods: We studied 303 participants from the Hertfordshire Intergenerational Study. Participants indicated whether they thought that their risk of breaking a bone was 'much lower', 'a little lower', 'about the same', 'a little higher' or 'much higher' compared to others of the same sex. Potential correlates examined included sociodemographic and lifestyle factors, comorbidity level (assessed by number of systems medicated) and family history of hip fracture. Associations between these exposures and SPR were explored using ordinal logistic regression with adjustment for sex and age. Statistically significant correlates ($p < 0.05$) were then included in a mutually-adjusted model along with sex and age. Relationships were compared with those between self-perceived risk of heart disease and family history of myocardial infarction.
Results: Median (lower quartile, upper quartile) age of participants was 56 (43, 61) y. The only factors related to SPR in all analyses were personal fracture history and number of systems medicated. Relationships between SPR and family history of hip fracture were much weaker than relationships between perceived heart disease risk and family history of myocardial infarction ($p = 0.37$ vs. $p < 0.001$).
Conclusion: This analysis highlights differences in perception of risk of clinical outcomes among individuals with a family history of hip fracture vs. myocardial infarction. It suggests that better education around how a family history of hip fracture impacts individual risk might be beneficial to empower individuals to make positive lifestyle and healthcare choices at a point in the lifecourse when such change might have substantial benefit.

OP5-P674
TREATMENT WITH LORECIVIVINT LEADS TO IMPROVED LONG-TERM PATIENT ACCEPTABLE SYMPTOM STATE (PASS) COMPARED TO PLACEBO: DATA FROM PHASE 3 EXTENSION TRIAL

C. Swearingen[1], Y. Yazici[1], J. Tambiah[1], P. Conaghan[2]

[1]Biosplice Therapeutics, Inc, San Diego, USA, [2]Univ. of Leeds School of Medicine, Leeds, UK

Objective: Lorecivivint (LOR) has demonstrated beneficial effects on clinical outcomes in knee OA trials. A "patient acceptable symptom state" (PASS) also provides a clinically relevant assessment (Roos 2019). Year 1 results from a Phase 3 extension study, OA-07 (NCT04520607), with LOR 0.07 mg clinical outcomes including WOMAC Pain [0–100] and Function [0–100], were evaluated for PASS.
Methods: Severe knee OA patients (medial JSW 1.5–4.0 mm) who completed the parent trial were enrolled into the OA-07 extension. A

repeat injection according to original parent randomization (LOR/-placebo (PBO)) was given at OA-07 Year 1 start to blinded patients irrespective of symptom state. PASS is assessed with a 'yes/no' response to the question "Taking into account all the activities you have during your daily life, your level of pain, and also your functional impairment, do you consider that your current state is satisfactory?" at parent study baseline and end of OA-07 Year 1. PASS response and odds ratios (OR; 95% CI) between treatment groups were calculated using baseline-adjusted logistic regression. Differences between treatment groups were explored for patients with a positive PASS.

Results: 276 patients (mean age 61.0 ± 8.2 y, BMI 31.8 ± 4.9 kg/m^2, female 62.7%, Kellgren–Lawrence [KL] 3 45.3%, medial JSW 2.63 ± 0.69 mm) were enrolled. Adverse event data showed LOR appeared safe. Following the repeat injection, compared to PBO at end of Year 1: LOR treatment significantly increased odds of a 'yes' PASS response (LOR 103/121 (85.1%) vs. PBO 93/129 (72.1%), OR 2.45 [1.25, 4.78], P = 0.009) (Figure); patients with a 'yes' PASS response also reported improvements in WOMAC Pain (LOR − 6.8 (± 2.0) vs. PBO − 1.0 (± 2.1), t-test P = 0.049) and Function (LOR − 7.0 (± 1.9) vs. PBO − 2.4 (± 1.9), t-test P = 0.090).

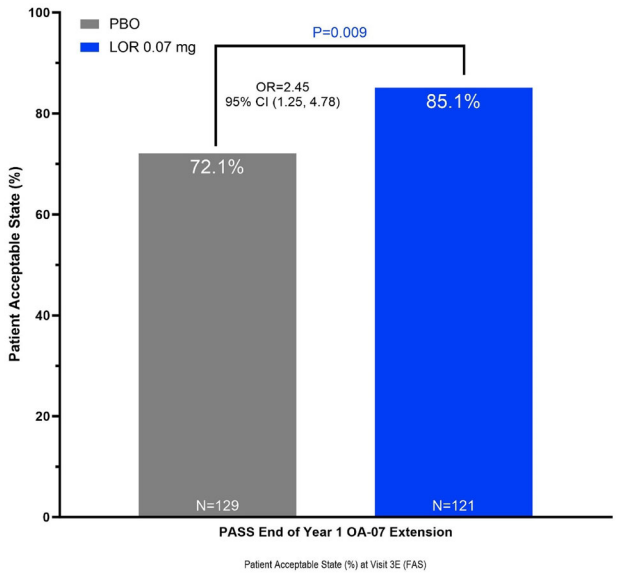


Figure. Patient Acceptable Symptom State between LOR and PBO at End of Year 1 Extension

Conclusion: Compared to PBO, LOR-treated Knee OA patients were significantly more likely to achieve a positive PASS 1 year after a second injection. Pain and function outcomes showed greater improvements for subjects reporting a positive PASS. These data suggest that LOR may provide long-term benefits for knee OA symptoms.

OP6-P1167
EFFECT OF ROMOSOZUMAB ON TISSUE THICKNESS-ADJUSTED TRABECULAR BONE SCORE (TBSTT) IN POSTMENOPAUSAL WOMEN WITH OSTEOPOROSIS AND DIABETES: RESULTS FROM THE ARCH STUDY

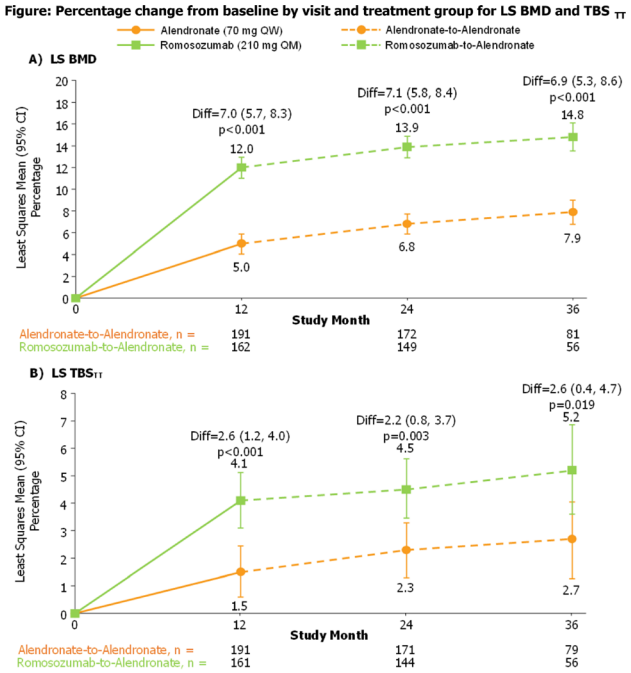
S. Ferrari[1], D. Betah[2], R. Feldman[3], B. Langdahl[4], M. Oates[2], J. Timoshanko[5], Z. Wang[2], R. Dhaliwal[6]

[1]Geneva Univ. Hospital, Geneva, Switzerland, [2]Amgen Inc., Thousand Oaks, USA, [3]MemorialCare Saddleback Medical Center, Laguna Hills, USA, [4]Aarhus Univ. Hospital, Aarhus, Denmark, [5]UCB Pharma, Slough, UK, [6]Massachusetts General Hospital, Boston, USA

Objective: Diabetes mellitus is associated with reduced bone strength and increased fracture risk.[1] TBS, a gray-level texture index derived from lumbar spine (LS) DXA scans, has been reported to be decreased in patients with diabetes and is associated with increased fracture risk, independent of BMD. In the ARCH trial (NCT01631214), romosozumab (Romo) significantly improved bone mass and bone strength, leading to superior fracture risk reduction vs. alendronate (ALN) alone.[2] We examined the effect of Romo-to-ALN vs. ALN-to-ALN on LS BMD and TBS in patients with diabetes in ARCH.

Methods: Postmenopausal women with osteoporosis and prior fracture were randomised 1:1 to Romo 210 mg monthly or ALN 70 mg weekly for 12 months (M), both followed by 24 M ALN 70 mg weekly. This post hoc analysis included participants with diabetes mellitus at baseline (BL) and LS DXA scan measurements at BL and ≥ 1 post-BL visit (Romo/ALN, n = 195; ALN/ALN, n = 165). BMD and TBS (determined by an updated TBS_{TT} algorithm; TBS iNsight^{TM} v4.0 [Medimaps][3] were assessed on LS DXA scans at BL, M12, M24, and M36.

Results: BL LS BMD was – 2.63 for Romo and – 2.89 for ALN; BL LS TBS_{TT} was 1.006 and 1.010, respectively. Romo led to significantly greater gains in LS BMD and TBS_{TT} at M12 vs. ALN; these were maintained after transition to ALN and persisted significantly at M24 and M36 vs. ALN alone (Figure). In the Romo/ALN group, the percentage of women with "normal" TBS values ($TBS_{TT} > 1.074$)[4] increased from 23.6% at BL to 50.0% at M36; those with "degraded" TBS values ($TBS_{TT} \leq 1.027$) decreased from 55.8% to 33.9% ($p < 0.001$). A similar trend, albeit with smaller improvement, was observed for ALN/ALN. TBS_{TT} changes were unrelated to LS BMD changes to M36 (Romo/ALN, $r^2 = 0.1493$; ALN/ALN, $r^2 = 0.0429$).



ALN: alendronate; BMD: bone mineral density; CI: confidence interval; Diff: percentage change from baseline for Romo treatment group minus percentage change from baseline for ALN treatment group; LS: lumbar spine; QM: monthly; QW: weekly; Romo: romosozumab; TBS: trabecular bone score; TBSTT: tissue thickness-adjusted trabecular bone score. LS BMD and TBSTT data were analysed based on repeated measures model adjusting for treatment, presence of severe vertebral fracture at baseline, visit, treatment-by-visit interaction, baseline BMD or TBS value as fixed effects, with machine type and baseline BMD or TBS value-by-machine type interaction as covariates, using either a compound symmetry variance covariance structure for BMD or an unstructured variance covariance structure for TBS.

Conclusion: In postmenopausal women with osteoporosis and diabetes, 12 M of Romo followed by 24 M of ALN significantly improved LS BMD and TBS as measured by TBS_{TT} (independently of BMD) to a greater extent than 36 M of ALN alone. These changes may reflect a greater improvement of bone strength by Romo vs. ALN in patients with diabetes.

OP7-P488
RELATIONSHIPS BETWEEN EARLY LIFE FACTORS AND OSTEOARTHRITIS PAIN: FINDINGS FROM THE HERTFORDSHIRE COHORT STUDY

F. J. Kirkham-Wilson[1], L. D. Westbury[1], N. R. Fuggle[1], F. Laskou[1], C. Cooper[1], E. M. Dennison[1]

[1]MRC Lifecourse Epidemiology Centre, Southampton, UK

Objective: Relationships between early life factors and musculoskeletal outcomes in later life have been well established, with previous reports suggesting that lower birthweight and weight at one year are associated with development of radiographic osteoarthritis (OA), specifically higher osteophyte number. Here we describe relationships between early life and development of pain among participants with knee OA (Kellgren–Lawrence grade $\geq$ 2) at baseline, who were followed up for around 10 years.

Methods: 75 men and 68 women were recruited in 1998–2004. Baseline knee radiographs were taken and graded according to Kellgren–Lawrence. A mean of 10.8 years later, participants were invited to another research clinic where follow-up radiographs were taken, and pain recorded using WOMAC questionnaires. Questionnaires were administered at both time points to detail lifestyle and anthropometric factors. The analysis sample was restricted to those with radiographic knee OA at HCS baseline (K&L $\geq$ 2 at either tibiofemoral or patellofemoral joint on either left or right side). We also excluded participants with a history of knee replacement at either baseline or follow-up.

Results: Mean (SD) age at baseline was 64.8 (2.8) years; mean (SD) BMI was 27.5 (4.2). 41.3% of men and 50% of women had pain (WOMAC pain score $>$ 0) at follow-up. Mean (SD) birthweight was 3.6 (0.6) kg and 3.5 (0.5) kg in men and women respectively. Greater weight at one year ($p = 0.01$) and greater infant weight gain ($p = 0.02$, independent of birthweight) were related to lower odds of knee pain at follow-up after adjustment for sex and follow-up time. For example, men with knee pain at follow-up had a mean weight at one year of 9.8 kg whereas this was 10.3 kg among men without knee pain at follow-up. Similarly, women with knee pain at follow-up had a mean weight at one year of 9.5 kg in contrast to 9.9 kg among women without pain.

Conclusion: Among subjects with baseline radiographic knee OA, greater weight gain in infancy was protective against pain associated with knee OA, attenuated after adjustment for follow-up osteophyte score. Our findings suggest associations between early life and both symptomatic and radiographic knee OA.

OP8-P935
INCREASED BONE MARROW ADIPOSITY IS RELATED TO HIGHER FRACTURE RISK AND LOWER BONE MINERAL DENSITY IN OLDER SWEDISH WOMEN

M. Zoulakis[1], K. F. Axelsson[1], H. Litsne[1], L. Johansson[1], M. Lorentzon[1]

[1]Univ. of Gothenburg, Dept. of Internal Medicine and Clinical Nutrition, Sahlgrenska Osteoporosis Centre, Gothenburg, Sweden

Objective: Recent research suggests that bone marrow adiposity (BMAT) is associated with osteoporosis and increased fracture risk. However, quantifying BMAT can be challenging mostly because the golden standard for assessment is by MRI, a method limited by low availability and high costs. We recently developed a method to quantify BMAT from HR-pQCT) images.[1] This method was able to explain up to 76% of the variation in the MRI-derived bone marrow fat fraction (BMFF) at the ultradistal tibia. This study aimed to investigate if BMAT, derived from HR-pQCT images, was associated with incident fractures and osteoporosis prevalence in older women.

Methods: In total, 2984 women aged 75–80 y, from the SUPERB cohort, participated in a population-based study between March 2013 to May 2016 and underwent a comprehensive assessment of bone characteristics including bone densitometry (DXA), and HR-pQCT measurements of the ultradistal tibia at baseline. The BMFF was measured as previously described[1] using HR-pQCT images at the ultradistal tibia. Follow-up of x-ray verified incident fractures data was completed in March 2023. Associations between BMFF, anthropometrics, and BMD, were investigated using correlations, linear and logistic regression. Cox regression was used to study the association between BMFF and incident fractures.

Results: BMFF was inversely associated with BMI ($r = -0.22$, $p < 0.001$) and with total hip BMD ($r = -0.50$, $p < 0.001$; $\beta = -0.43$, $p = 0.001$, after adjustment for age and BMI). During a median follow-up time of 7.3 (4.4, 8.4) y, 797 major osteoporotic fractures (MOF), 1069 any fractures, and 235 hip fractures occurred. Increasing

BMFF (per SD) was associated with increased risk of MOF (hazard ratio [HR] = 1.28, 95% CI 1.19–1.38), any fracture (HR = 1.23, 95% CI 1.16–1.31), and hip fracture HR = 1.34, 95% CI 1.17–1.53), All associations, except for hip fracture, remained significant after adjustments for clinical risk factors (CRFs) and femoral neck BMD (Figure).

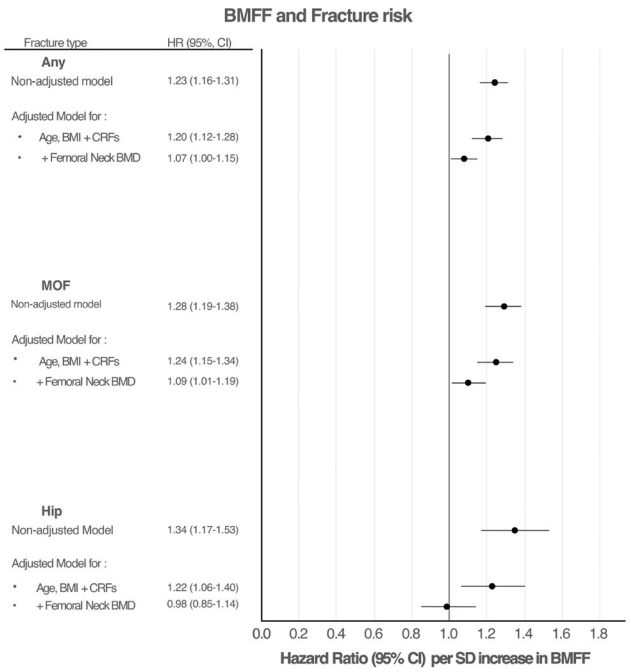

Figure. Forest plot of adjusted and non-adjusted Hazard Ratio (HR) and 95% Confidence Interval (95% CI) per SD increase in bone marrow fat fraction (BMFF) for : Any fracture, Major Osteoporotic Fracture (MOF) and Hip Fracture

Conclusion: Increasing BMFF was associated with lower BMD and with greater fracture risk in older Swedish women.

OP9-P321
HEALTH-RELATED QUALITY OF LIFE IN SARCOPENIA: CONTENT VALIDITY OF THE SARQOL QUESTIONNAIRE

C. Demonceau[1], B. Voz[2], O. Bruyère[1], J.-Y. Reginster[1], C. Beaudart[3]

[1]WHO Collaborating Centre for Public Health Aspects of Musculo-Skeletal Health and Ageing, Division of Public Health, Epidemiology and Health Economics, Univ. of Liège, Liège, [2]Dept. of Public Health, Univ. of Liège, Liège, [3]Clinical Pharmacology and Toxicology Research Unit, NAmur Research Institute for LIfe Sciences (NARILIS), Dept. of Biomedical Sciences, Faculty of Medicine, Univ. of Namur, Namur, Belgium

Objective: To enhance the evidence supporting the content validity for the Sarcopenia & Quality of Life (SarQoL) questionnaire, a patient-reported outcome measure specifically designed for assess health-related quality of life in individuals with sarcopenia.
Methods: Individual semi-structured interviews targeting the impact of sarcopenia on quality of life were conducted with 17 older Belgian older adults (i.e., aged 65 years and older) who met the EWGSOP2 criteria for the diagnosis of sarcopenia. Afterwards, structured cognitive interviews were conducted to rate the relevance of the current format of SarQoL. Transcripts were qualitatively analysed thematically according to the seven dimensions of the SarQoL questionnaire (i.e., physical and mental health, locomotion, body composition, functionality, activities of daily living, leisure activities and fears).
Results: The majority of the concepts elicited during the semi-structured interviews fit within existing SarQoL dimensions. Importantly, the seven dimensions of SarQoL were consensually considered as relevant by the participants. Some new emergent concepts were identified. While many of them (i.e. fear of the future, need of assistance with particular activities of daily living) could be considered as enrichments of existing dimensions or sub-concepts, other new concepts may highlight two potential dimensions not covered by SarQoL (i.e. self-realization and the adaptation/use of strategies). Cognitive interviews also highlighted that SarQoL items and instructions were clear and comprehensible.
Conclusion: SarQoL, in its current form, demonstrates good evidence of content validity for assessing health-related quality of life in patients with sarcopenia. To ensure SarQoL remains applicable across various individuals with sarcopenia, it is crucial to strike a balance between minimizing patient burden and considering the relevance of new elements. Taking this into account, we do not recommend adding new items or dimensions to SarQoL. Instead, we suggest improving the assessment of quality of life by concurrently incorporating additional validated scales. This would be beneficial for researchers or clinicians who aim to address dimensions such as self-realization and the utilization of adaptive strategies when evaluating the quality of life in a specific targeted sarcopenic population.

OP10-P360
WHAT IS THE EFFECT OF HORMONE REPLACEMENT THERAPY (HRT) ON PREVALENCE, INCIDENCE, AND SEVERITY OF OSTEOARTHRITIS (OA) OF THE KNEE, HIP AND HANDS? A SYSTEMATIC REVIEW

C. W. Hillman[1], K. Marino[2], O. O'Sullivan[1], S. Kluzek[1], R. Atkinson[3], A. Hassan[4]

[1]Univ. of Nottingham, Nottingham, [2]Keele Univ., Keele, [3]Nottingham Univ. Hospitals NHS Trust, Nottingham, [4]Institute of Sport, Exercise and Health (ISEH), London, UK

Objective: Osteoarthritis (OA) is a degenerative disease that can lead to pain, reduced mobility, quality of life and disproportionately affects women[1]. This review explores the effect of HRT on the prevalence, incidence or severity of hip, knee or hand OA in peri- or post-menopausal women.
Methods: A systematic review was performed using PRISMA guidelines and prospectively registered on PROSPERO and a search was conducted (7/10/22) on Medline. Two independent reviewers screened results, extracted the data, and conducted a quality assessment with the Risk of Bias In Non-randomized Studies—of Exposure (ROBINS-E) tool, with a third reviewer for arbitration. Studies were primary research using validated patient reported outcome measures (PROMs) or objective measures of OA.
Results: 27 studies were included, all observational in design. 11 studies assessed hip OA, 19 assessed knee OA, and 8 assessed hand OA. Methods of outcome measurement included radiographic measures (n = 16), joint replacement surgery (indicated by OA) (n = 9), healthcare records (n = 1), and PROMs (n = 1). Most studies (n = 17) were considered to have a'High Risk of Bias'. Positive correlations between HRT use and hip or knee replacement were observed across studies. Results were inconclusive for other outcome measures and the hand.
Conclusion: The included studies varied considerably in terms of confounder adjustment, exposure, and outcome measurement. Despite these limitations, use of HRT appears to be associated with an increased risk of receiving a knee or hip joint replacement indicated by OA. Informed by our critique of the literature, suggestions for high quality research, including appropriately analysed confounders,

appropriate exposure control and use PROMs alongside objective measures of disease are discussed.

OP11-P1091
GUT MICROBIOTA AND SHORT-CHAIN FATTY ACID SIGNATURES IN POSTMENOPAUSAL OSTEOPOROSIS PATIENTS: A RETROSPECTIVE STUDY

S. Li[1], Y. Zhang[1], C. Ma[1], Q. Dong[2], P. Sun[1]

[1]The First Affiliated Hospital of Guangdong Pharmaceutical Univ., Guangzhou, [2]Yunfu Hospital of Traditional Chinese Medicine, Yunfu, China

Objective: Studies have shown that gut microbiota (GM) and its metabolites, short-chain fatty acids (SCFAs), are associated with the development of postmenopausal osteoporosis (PMO). This study explored the clinical and laboratory evidence of the relationship of GM and SCFAs to PMO and attempted to determine the potential mechanism of action.
Methods: 18 patients (Collected from the First Affiliated Hospital of Guangdong Pharmaceutical University between January 2021 and August 2021) were included in this retrospective study, including 10 PMO women and 8 healthy young women as the healthy control (HC) group from Guangzhou, China. BMD was determined by DXA. The composition of GM and its metabolites, SCFAs, in the fecal samples were measured by 16S rRNA gene sequencing and gas chromatography/mass spectrometry (GC/MS) analysis, respectively.
Results: Compared with HC, PMO group had significantly decreased BMD in lumbar spines 1–4 (BMD_L) and femoral neck (BMD_F). 16S rRNA gene sequencing revealed that, compared with HC, PMO group had a markedly decreased abundance in Subdoligranulum, Norank_f_Muribaculaceae and Alistipes at the genus level. GC/MS analysis indicated that the concentration of propanoic acid significantly dropped in PMO group. Additionally, we found that Subdoligranulum, Norank_f_Muribaculaceae and Alistipes were positively correlated with BMD_L. Subdoligranulum and Norank_f_Muribaculaceae were also positively correlated BMD_F and propanoic acid, while Subdoligranulum is the only species that presented a strong correlation with the levels of acetic acid and butyric acid.
Conclusion: In postmenopausal women, there were evident changes in GM and SCFAs, and these changes were found correlated with patients' BMD. These correlations provide novel insights into the underlying mechanism of PMO development, representative of early diagnostic markers and therapeutic targets that may improve the bone health in postmenopausal women.

OP12-P1122
EXPECTED LOSS OF PRODUCTIVITY FOLLOWING FRAGILITY FRACTURES IN PATIENTS OF WORKING AGE

R. Pinedo-Villanueva[1], J. Griffin[2], L. Wiggins[2], N. Nicola[3], C. Jones[2], M. K. Javaid[1]

[1]Univ. of Oxford/ NDORMS, Oxford, [2]Royal Osteoporosis Society, Bath, [3]Sheffield Teaching Hospitals NHS Foundation Trust, Sheffield, UK

Objective: The economic impact of osteoporotic fractures has been extensively studied in terms of health and social care expenditures. However, their impact on productivity losses remains underexplored.
Methods: A survey targeting Royal Osteoporosis Society members was developed to gather data on demographic variables, fractures, and changes in employment status (following Office of National Statistics (ONS) classifications) after fracture. Annual loss of earnings was estimated by apportioning the total number of fractures in England (from National Hip Fracture Database and rule of 5) in people aged 50–67 y (from Oxfordshire Fracture Prevention Service) to each ONS occupation category according to the England 2021 Census. Expected numbers of fractured people by occupation were multiplied by corresponding% of those surveyed taking early retirement or stopping their job due to the fracture, with total loss estimated by applying annualised ONS 2023 weekly earnings.
Results: The survey, conducted from 15/08/2023 for 2 weeks, received responses from 354 adults aged 50–70 y (mean 67.9, 93% women) who reported a fracture. Prior to the fracture, 42.1% were in full-time paid employment, 29.3% in part-time employment, 5.2% were volunteers, 20.1% retired, and 3.4% unemployed. The most common job categories were professional (40.5%) and administrative (17.0%). 61.4% of respondents reported a change in employment after fracture, with 29.0% ceasing work, 24.1% taking early retirement, and 46.3% modifying their job, hours, or duties. Median duration of job absence was 8 weeks (IQR 42–90 d) for those who returned to work. The direct loss of earnings from fractures from early retirement and cessation of work was estimated to be £1.01 billion per annum.
Conclusion: This study provides an estimation of productivity losses resulting from fragility fractures in UK adults aged 50 y and over. Given the aging demographic and policies promoting extended workforce participation, the potential economic benefits of effective osteoporosis management in preserving employment and productivity warrant further exploration.

OP13-P228
THE ICARE FEASIBILITY STUDY: AN INTEGRATED COLLECTION OF EDUCATION MODULES FOR FALL AND FRACTURE PREVENTION FOR HEALTHCARE PROVIDERS IN LONG TERM CARE

A. Papaioannou[1], G. Ioannidis[1], L. Hillier[2], J. D. Adachi[1], A. Costa[3], G. Heckman[4], J. Hirdes[4], J. Holroyd-Leduc[5], S. Jaglal[6], S. Kaasalainen[7], A. Lau[1], C. Mcarthur[8], L. Kane[1], S. Marr[9], S. Straus[10], J.-E. Tarride[3], L. Thabane[1], M. Abbas[11], I. Rodrigues[12]

[1]McMaster Univ., Dept. of Medicine, Hamilton, [2]Geras Centre for Aging Research, Hamilton, [3]McMaster Univ., Dept. of Health Research Methods, Hamilton, [4]Univ. of Waterloo, School of Public Health Sciences, Waterloo, [5]Univ. of Calgary, Dept. of Medicine and Community Health Sciences, Calgary, [6]Univ. of Toronto, Dept. of Physical Therapy, Toronto, [7]McMaster Univ., School of Nursing, Hamilton, [8]Dalhousie Univ., School of Physiotherapy, Halifax, [9]Unity Health Toronto, Hamilton, [10]McMaster Univ., Unity Health Toronto, Hamilton, [11]McMaster Univ., Hamilton, [12]Univ. of Manitoba, Max Rady College of Medicine, Winnipeg, Canada

Objective: To determine the feasibility (recruitment rate and adaptations), with a subobjective to understand facilitators to and barriers of, implementing the PREVENT (Person-centred Routine Fracture PreEVENTion) model in practice. The model includes a multifactorial intervention on improving diet, exercise, environmental adaptations, hip protectors, osteoporosis medications, and medication reviews to treat residents at high risk of fracture. Our secondary outcomes were to determine if there was a change in knowledge uptake and in the proportion of fracture prevention prescriptions post-intervention.
Methods: We conducted a mixed methods longitudinal cohort study in three LTC homes across Ontario. A local champion was selected to guide the implementation of the model and promote best practices. We reported recruitment rates using descriptive statistics and implementation process using content analysis.

Results: Within 5 months, we recruited one for-profit and two not-for profit LTC homes, Home A (120 beds), Home B (425 beds), and Home C (240 beds) and one local champion from each home. We required two months to identify and train the local champion over three 1.5-h train-the-trainer sessions, and the local champion required three months to deliver the intervention to a team of healthcare professionals. Forty healthcare professionals across three LTC homes participated and 88% received education on the LTC recommendations. Homes A, B and C reported increases in the proportion of osteoporosis medication by 62%, 3%, and 42%, respectively before and after intervention. At baseline, 57% of LTC residents are at high risk for fracture, and 17% of these high risk residents are on osteoporosis medications. Benefits of the model include easy access to the Fracture Risk Scale, clear and succinct educational material, and an accredited continuing medication educational module for physicians. Challenges included misperceptions between the differences in fall and fracture prevention strategies and fear of perceived side effects associated with fracture prevention medications.
Conclusion: Our study found an increase in knowledge uptake and the proportion of fracture prevention prescriptions post-intervention. The next steps will be to determine if the adapted PREVENT model reduces the risk and rate of hip fractures in LTC.

OP14
-P754 ANXIETY AND DEPRESSION ARE ASSOCIATED WITH POOR HEALTH BEHAVIOURS AND INCIDENT FRACTURE AMONG WOMEN: FINDINGS FROM THE HERTFORDSHIRE COHORT STUDY

L. D. Westbury[1], G. Bevilacqua[1], C. Cooper[1], E. M. Dennison[1]

[1]MRC Lifecourse Epidemiology Centre, Univ. of Southampton, Southampton, UK

Objective: A recent systematic review has highlighted possible links between depression and fracture risk, but no information regarding possible explanatory health behaviours was available. In this study we used a well phenotyped community-dwelling cohort of older adults (the Hertfordshire Cohort Study) to consider these associations further.
Methods: Data from 2997 men and women, aged 59–73 y at baseline, were analysed. At baseline, mental health characteristics and health behaviours were ascertained through clinician-administered questionnaires. Anxiety and depression (mild or worse) were identified by scores of > 7 on the corresponding Hospital Anxiety and Depression Scale. Health behaviours included current smoking, alcohol consumption, diet quality and physical activity (Dallosso questionnaire). Incident fractures were identified using ICD-10 codes from Hospital Episode Statistics data, available from baseline (1998–2004) until December 2018. Health behaviours in relation to anxiety and depression were examined using logistic regression; anxiety and depression in relation to incident fracture were examined using Cox regression. All analyses were sex-stratified and adjusted for age; $p < 0.05$ was regarded as statistically significant.
Results: Prevalence of anxiety was 15% among men and 25% among women; prevalence of depression was 5% among men and 6% among women. Overall, 9% of men and 22% of women had a fracture during follow-up. Among men and women, poorer diet quality and lower physical activity were associated with depression; these health behaviours were also associated with anxiety among men. Current smoking was associated with anxiety and depression among women. Among women, anxiety (hazard ratio (95% CI): 1.34 (1.05, 1.72), $p = 0.019$) and depression (1.76 (1.18, 2.64), $p = 0.006$) were related to increased risk of incident fracture; among men, associations for anxiety ($p = 0.198$) and depression ($p = 0.265$) in relation to fracture were weaker.
Conclusion: Anxiety and depression were associated with increased risk of incident fracture among women, possibly due to their association with poor health behaviours, which are established risk factors for fracture. Preventive strategies are required to address poor health behaviours and mental health among older adults.

OP15-P863
BONE MINERAL DENSITY POST-TREATMENT FOLLOW-UP IN WOMEN WITH ENDOMETRIOSIS TREATED WITH RELUGOLIX COMBINATION THERAPY: SPIRIT PROGRAMME

M. McClung[1], N. Johnson[2], S. L. Ferrari[3], J. S. Perry[4], Y. Zhong[5], R. B. Wagman[5]

[1]Oregon Osteoporosis Center, Portland, USA, [2]Robinson Research Institute, Auckland, New Zealand, [3]Univ. of Geneva, Geneva, Switzerland, [4]Sumitomo Pharma American Inc., Brisbane, USA, [5]Sumitomo Pharma America Inc., Brisbane, USA

Objective: To evaluate BMD changes in women with endometriosis (EM)-associated pain who met prespecified bone loss criteria with relugolix combination therapy (Rel-CT: relugolix 40 mg, estradiol 1 mg and norethisterone acetate 0.5 mg) in the SPIRIT long-term extension (LTE) and underwent post-treatment follow-up (PTFU).
Methods: In the pivotal SPIRIT 1/2 studies, premenopausal women (18–50 y) with moderate-to-severe EM-associated pain were randomised 1:1:1 to receive once-daily Rel-CT, placebo or delayed Rel-CT (relugolix monotherapy/Rel-CT, 12 weeks each) for 24 weeks. Completers could enroll in the 80-week SPIRIT LTE to receive open-label Rel-CT for up to 104 weeks. BMD change was measured by DXA. Women who met protocol-specified BMD loss criteria compared with pivotal study baseline by Week104/the end of treatment were referred for PTFU DXA. BMD recovery was assessed with DXA at month (M)6 and M12 after treatment cessation. Women not meeting the recovery threshold at M6 ($\leq$ 1.5% at the lumbar spine and $\leq$ 2.5% at the total hip) were recommended for an additional scan at M12. BMD percent change from pivotal baseline to last on-treatment, M6 and M12 post-treatment, and last PTFU were summarised by anatomical location.
Results: Of 802 women who entered SPIRIT LTE, 171 (21%) women had protocol-specific BMD loss or BMD loss $> 3\%$ at the lumbar spine or total hip as compared with pivotal study baseline. Of women with BMD loss and underwent M6 or M12 PTFU at lumbar spine, there was evidence of recovery ($> 0\%$ change from last on-treatment DXA) to M6 or M12 PTFU DXA in 27/27 (100%) women previously treated continuously with Rel-CT, and in 21/28 (75%) women initially treated with placebo. Similar trends were observed at the total hip.
Conclusion: In women with EM-associated pain who met prespecified BMD loss criteria in the SPIRIT LTE, there was recovery or trend towards recovery after treatment cessation in all women who received continuous Rel-CT therapy for up to 2 years and in most women who transitioned from placebo to Rel-CT. The benefit/risk profile of Rel-CT remains favourable in women with EM for longer-term treatment.

OP16-P679
COMPARATIVE ANALYSIS OF TERIPARATIDE AND ROMOSOZUMAB IN PREVENTING SYMPTOMATIC SUBSEQUENT VERTEBRAL COMPRESSION FRACTURE AFTER CEMENTING

W.-H. Kao[1], Y.-H. Chiang[1], W.-C. Lo[1], M.-H. Wu[1], J.- H. Jiann-Her[1]

[1]Taipei Medical Univ. Hospital, Taipei, Taiwan

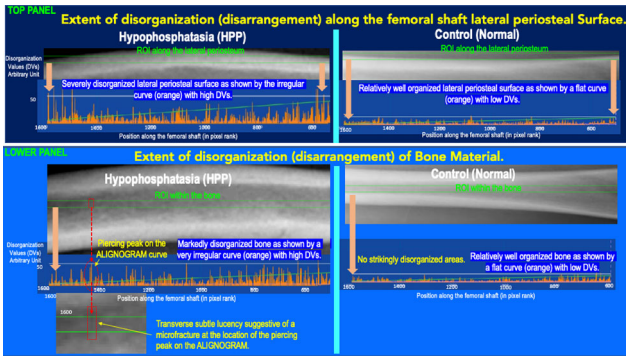
Objective: Subsequent vertebral compression fracture (SVCF) is a common and impactful complication. Because it usually occurs in the subacute phase (< 6 months after cementing of the primary VCF), the timing of prevention is critical. Teriparatide (TP) reduces fracture risk after 6 months but it did not show its effects in the subacute phase. Romosozumab (RM) with a quick onset time has the potential to prevent SVCF in the subacute phase. Our study compares their effectiveness in preventing symptomatic SVCF requiring another operation.
Methods: This retrospective observational study at TMUH includes 226 patients treated with either TP or RM after vertebroplasty or kyphoplasty due to OVCF from January 1, 2021, to June 27, 2023. The characteristics of the patients were reviewed. The primary outcome was a symptomatic SVCF requiring another operation. The secondary outcome was adjacent or non-adjacent fracture.
Results: This study included 118 and 99 patients in TP and RM groups, respectively. Between both groups, we find no significant difference in terms of age, gender, BMI, BMD, and underlying condition including HTN, DM, dyslipidemia, CKD, CAD, autoimmune disease, cancer, COPD, and OVCF at thoracolumbar junction. The rate of SVCF was 4.0% (4/99) in RM group compared to 14.4% (17/118) in TP group with statistically significant difference ($p = 0.01$). The subsequent adjacent fracture rate was 2.0% (2/99) in RM group vs. 11.9% (14/118) in TP group, showing a significant difference ($p = 0.005$). In contrast, no significant difference was observed in the rate of non-adjacent fracture ($p = 0.76$).
Conclusion: RM was associated with reduced symptomatic SVCF compared to TP especially in the subacute phase, highlighting RM's potential advantage in preventing SVCFs on adjacent levels.

OP17-P1136
STANDARD X-RAY IMAGES MAY POTENTIALLY BE USED TO QUANTIFY BONE DISORGANIZATION AND IDENTIFY PATIENTS WITH HYPOPHOSPHATASIA

R. Zebaze[1], C. Shore-Lorenti[1], Z. Simon[1], K. Djopseu[2], T. Makebeh[2], F. Milat[3], R. Ebeling[1]

[1]Dept. of Medicine, School of Clinical Sciences, Monash Univ., Melbourne, Australia, [2]Zeze Co, Yaounde, Cameroon, [3]Hudson Institute of Medical Research, Melbourne, Australia

Objective: The diagnostic issue is that low BMD and structural decay (e.g., cortical or trabecular deficits) are not key features of hypophosphatasia (HPP). Hence, a critical unmet challenge is the lack of a tool to accurately identify bone fragility in patients with HPP. We proposed that the loss of function mutations in tissue non-specific alkaline phosphatase leads to an impaired ability to properly organize (arrange, align) bone. This results in disorganized, damage-prone, and fragile bone. Thus, we hypothesized that quantification of the extent of bone disorganization identifies patients with HPP.
Methods: We studied 6 adult patients with HPP and 15 age- and sex-matched controls, Mean age 48 y (IQR 23–53). The extent of disorganization and features of the most misarranged areas were assessed using a novel validated tool (ALIGNOGRAM). This tool analyses femoral X-rays using AI and novel image processing algorithms.
Results: External shape: HPP patients had markedly more disorganized contours. Their periosteal surface was threefold more disorganized than that of controls; mean disorganization values (DVs) were respectively 3.04 (IQR = 0.21–7.25) in HPP vs. 1.0 (IQR = 0.07–2.53), ($P < 0.0001$). Moreover, the pattern of disorganization of the periosteum was distinctly (threefold) more irregular (Figure, top panel). Bone material was markedly ($\sim$ 3-fold) more disorganized in HPP; mean DVs ($\pm$ SEM) were 3.17 1.1(IQR = 2.37–4.03) in HPP vs. 1.1(IQR = 0.83–1.14) in controls, respectively $P < 0.0001$). Noticeably, there were many random tiny areas with excessively high DVs. They allowed us to identify relatively transverse subtle bands (barely visible unless detected by the tool). These bands were either small lucent lines suggestive of micro (early-stage) fractures, or opaque lines corresponding to micro-sclerosis. No strikingly disorganized areas were detected in controls (Figure, left lower panel).



Conclusion: Abnormal bone disorganization can be quantified from readily available X-ray images as a biomarker to identify HPP patients. This may offer a path for an easy, early routine identification of HPP patients in clinical and research settings. Detection of microfractures (early stage) offers the opportunity for early intervention which may revolutionize HPP treatment. Larger studies are underway.

OP18-P280
ASSESSMENT OF ADHERENCE TO ANTI-OSTEOPOROTIC MEDICATION (AOM) TREATMENT IN THE RISK-STRATIFIED OSTEOPOROSIS STRATEGY EVALUATION (ROSE) SCREENING PROGRAMME: A 10-YEAR FOLLOW-UP STUDY

T. G. Petersen[1], K. H. Rubin[1], M. K. Javaid[2], A. P. Hermann[3], K. Åkesson[4], B. Abrahamsen[5]

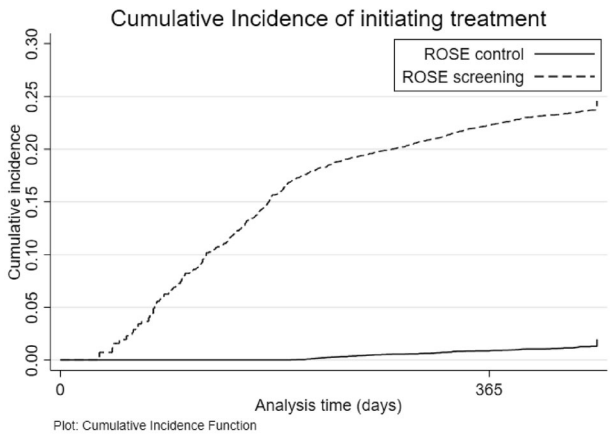
[1]Research Unit OPEN, Dept. of Clinical Research, Univ. of Southern, Odense, Denmark, [2]NDORMS, Univ. of Oxford, Oxford, UK, [3]Research unit of Endocrinology, Odense Univ. Hospital, Odense, Denmark, [4]Clinical and Molecular Osteoporosis Research Unit, Dept. of Clinical Sciences Malmö, Malmö, Sweden, [5]Dept of Medicine, Holbæk Hospital and OPEN, SDU, Denmark

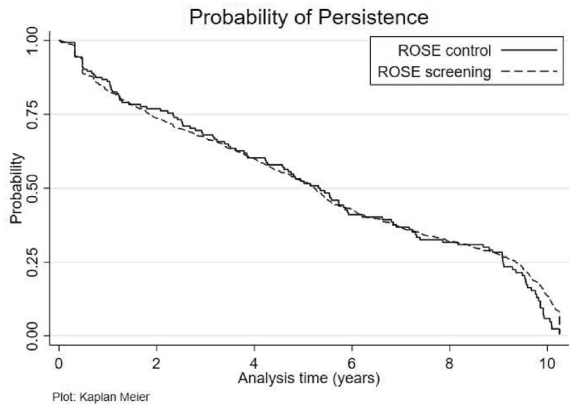
Objective: The ROSE screening programme RCT (Rubin, Osteoporos Int 2018;29:567) offers a comprehensive approach to risk assessment and initiation of anti-Osteoporotic medication (AOM). However, a screening programme's feasibility depends on adherence

to treatment and this could be poorer in those screened as opposed to women actively seeking assessment and treatment. We aimed to investigate the impact of the ROSE screening programme on long-term adherence to AOM treatment.

Methods: Women aged 65–80, residing in the Region of Southern Denmark 2010–2011, were randomized into a screening or a control group. Based on questionnaire data, women in the screening group with a 10-year fracture risk (FRAX^{TM}) of $\geq$ 15% were invited for DXA scanning, following standard AOM treatment in case osteoporosis was identified. We assessed initiation, medication possession ratio (MPR), and persistence to AOM treatment using information on filled prescriptions and in-hospital treatment assi from Danish nationwide registers. Survival analyses, with a maximum follow-up of 10 y, were applied to evaluate differences between the groups.

Results: Among the 15,505 women eligible for the analyses, 971 (6.26%) initiated AOM within one year after the intervention. Significantly more participants in the screening group started on AOM (HR 5.14 (95% CI 4.29; 6.16)) compared to controls (Fig. 1). Persistence was good with 50% remaining on treatment for 5 y or longer and 75% for 2 y or more, with equally good persistence in the screening group (Fig. 2).





Conclusion: Nonadherence presents a significant challenge in osteoporosis. The study demonstrates that the ROSE programme increases initiation of AOM treatment and that screened subjects exhibit similar levels of adherence once they have initiated medication compared to those not screened.

Disclosures: Grant/research support: UCB (MKJ, BA), Kyowa-Kirin (BA). Consultant/advisory activities: UCB (MKJ,APH,BA), Amgen (MKJ,APH,BA), Gedeon Richter (APH,BA), Abbvie (MKJ), Besin Healthcare (MKJ), Sanofi (MKJ), Kyowa-Kirin (BA), Pharmacosmos (BA).

OP19-P1013
EFFECT OF EIGHT MONTHS OF BALLISTIC AND CONVENTIONAL RESISTANCE EXERCISE TRAINING ON BONE STRENGTH IN POSTMENOPAUSAL WOMEN: THE REPROOF STUDY

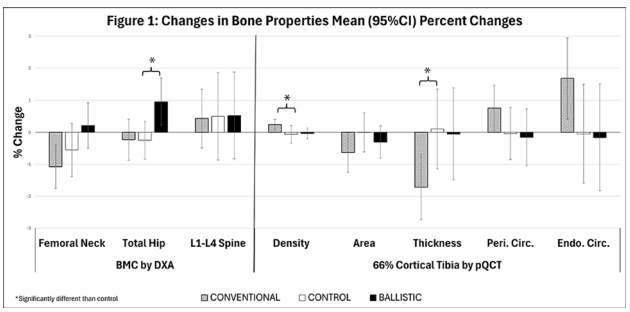
O. Caliskan[1], E. A. Marques[1], J. P. Folland[1], K. Brooke-Wavell[1]

[1]Loughborough Univ., Loughborough, UK

Objective: High-load, progressive resistance training (RT) is recommended for osteoporosis (OP) prevention. Fast ballistic RT involves moving as explosively as possible with a light/moderate load, attempting to launch the load, if possible, to maximize power production throughout the whole movement, but effects on BMD are unknown. We aimed to investigate the influence of ballistic and conventional RT, relative to control, on BMC and BMD in postmenopausal women.

Methods: The resistance exercise programme on risk of osteoporosis and osteoarthritis in females (REPROOF) was an 8-month RCT involving healthy, postmenopausal (> 4 y) women (50–70 y), randomised to ballistic (BRT), conventional (CRT) resistance training and control (CON) groups. Both RT groups attended similar sessions twice a week with hack squats and unilateral calf raises. One repetition maximum (1RM) was measured monthly and used to determine undulating periodized loads between 20–50% 1RM in BRT and 60–80% 1RM in CRT. Both hips and lumbar spine were measured by DXA (GE iDXA), and the tibia was measured by pQCT (Stratec XCT-2000L). Group comparisons were made by regression adjusting for baseline.

Results: 109 women were randomised. 82 completed the study; 63.1 $\pm$ 3.7 y; 24.5 $\pm$ 3.5 kg m^{-2}. Femoral neck T-score $-$ 1.0. DXA scans were available in 28 BRT, 29 CRT and 25 CON and pQCT in 27 BRT, 26 CRT and 23 CON. Mean adherence was $\sim$ 98% in RT groups. BRT showed significant improvements; total hip BMC by mean (95% CI) 0.33 (0.07, 0.59) g (p = 0.02) and BMD by 0.008 (0.001, 0.014) gc m^{-2} (p = 0.02) compared to CON. CRT increased cortical density by 3.18 (0.05,6.31) gcm^{-2} (p = 0.05) but reduced cortical thickness by $-$ 0.07 ($-$ 0.13, $-$ 0.01) mm (p = 0.03) relative to CON in (Fig. 1).



Conclusion: Ballistic RT increased total hip BMC and BMD. This contrasts with previous findings that high-load RT is necessary for bone adaptation. Ballistic RT was feasible in healthy postmenopausal women and may have a role in OP prevention.

OP20-P142
CALCIUM (CA) ISOTOPE COMPOSITION IN SERUM AND URINE FOR THE ASSESSMENT OF BONE CALCIUM BALANCE (BCAB): RESULTS FROM A POSTMARKET SURVEILLANCE CLINICAL FOLLOW-UP STUDY ON 2409 PARTICIPANTS

A. Eisenhauer[1,2], A. Heuser[1,2], J. Oehme[2], M. Lutz[2], M. Müller[2,3]

[1]GEOMAR Helmholtz-Centre for Ocean Research, [2]Osteolabs GmbH, [3]Univ. Clinic Schleswig–Holstein, Kiel, Germany

Objective: Ca isotope marker (CIM) measured in serum (δ44/42Ca-serum) and urine (δ44/42Ca-urine) has been demonstrated in earlier studies to be a sensitive, reliable, and minimal invasive BCaB marker. This study aimed to confirm the validity of the CIM approach to a larger randomized number of people not selected based on specific criteria, but rather showing a wide range of diseases and therapies.
Methods: The 2409 participants of this surveillance study were undergoing CIM testing in 2020–2023. Urine was self-collected, while blood was collected in doctor's office and stored for transport in suitable containers. Individual data were reported: current medical conditions, the last 4 years fracture history, current medication, and intake of supplements, e.g., vitamin D and Ca. Chemical preparation procedures followed standardized procedures. Ca isotopes were measured using a Neptune Plus (Thermo Fisher Scientific) applying a medium mass resolution.
Results: Factors affecting the musculoskeletal metabolism were sensitively reflected by a change in the CIM value in serum and urine. Osteoporosis, osteolytic metastases, hyperthyroidism, specific medications, and antihormone therapies associated with a negative BCaB were reflected by CIM values below the threshold value. Osteoprotective medications such as bisphosphonates, denosumab, and romosozumab, which are associated with a positive BCaB, were reflected by CIM values above the threshold values. The study revealed also that vegans show the highest CIM values possibly reflecting a low Ca intake with increased PTH secretion.
Conclusion: CIM values qualify as a strong and independent marker reflecting BCaB. The high CIM sensitivity allows the early risk assessment of diseases interfering with the musculoskeletal system before symptoms appear. Furthermore, CIM qualifies for near real-time therapy monitoring to ensure sufficient osteoprotective therapy and contributes to a general reduction in fracture risk.

World Congress on Osteoporosis, Osteoarthritis and Musculoskeletal Diseases (WCO-IOF-ESCEO 2024): ESCEO-OARSI Symposium Abstracts

ESCEO-OARSI1
IMMUNOMETABOLIC ALTERATIONS LINKING OBESITY, DIABETES, OSTEOARTHRITIS AND OSTEOPOROSIS

A. Mobasheri[1,2,3,4]

[1]Research Unit of Health Sciences and Technology, Faculty of Medicine University of Oulu, Oulu, Finland, [2]Department of Regenerative Medicine, State Research Institute Centre for Innovative Medicine, Vilnius, Lithuania, [3]Department of Joint Surgery, First Affiliated Hospital of Sun Yat-sen University, Guangzhou, Guangdong, China, [4]World Health Organization Collaborating Center for Public Health Aspects of Musculoskeletal Health and Aging, Université de Liège, Liège, Belgium

Immunometabolism is a new interdisciplinary field that explores the links between the immunology and metabolism. Although immunometabolism immune has traditionally focused on understanding how cellular metabolic processes influence immune cell function (and vice versa), there is increasing interest in the role of immunometabolic alterations in musculoskeletal disorders, including osteoarthritis (Mobasheri et al., 2017; Zheng et al., 2021) intervertebral disc degeneration (Francisco et al., 2022). There is also emerging evidence to link immunometabolism to subchondral bone changes in osteoporosis. Immunometabolic processes play crucial roles in regulating the activities of musculoskeletal and immune cells within the joint. Osteoporosis is a bone disorder characterized by reduced bone density and increased susceptibility to fractures. While osteoporosis is primarily considered a skeletal disorder, there is growing recognition of the intricate interactions between bone metabolism and systemic metabolism in addition to ageing, hormonal changes, nutrient deficiency and the inflammatory processes that arise as a consequence of obesity, diabetes, insulin resistance, and metabolic syndrome. In the context of osteoarthritis, which is the most common form of arthritis, there is also increasing recognition that immune cells and inflammatory processes contribute to disease pathogenesis. In addition to pro-inflammatory mediators secreted by activated chondrocytes, macrophages, synovial fibroblasts and subchondral bone cells undergo immunometabolic reprogramming in osteoarthritis, resulting in a shift from oxidative phosphorylation toward glycolytic metabolism to meet the increased energy demands associated with the low-grade inflammation within the joint. Broadly, the activation of immune cells in articular cartilage and subchondral bone involves metabolic reprogramming. Mitochondrial dysfunction has been observed in osteoarthritis, further promoting the process of oxidative stress. The metabolites derived from immunometabolic alterations in cellular metabolism, include reactive oxygen species and lipid mediators that can influence the inflammatory responses in the joint. Since ageing is the number one risk factor for both osteoporosis and osteoarthritis, it is important to highlight that cellular senescence also promotes altered metabolism and can contribute to inflammation within the joint. This presentation will discuss the key immunometabolic alterations that occur as a consequence of ageing and diabesity in osteoporosis and osteoarthritis. Targeting obesity and immunometabolism, and the interplay between adipokines and metabolic factors represents a potential avenue for therapeutic interventions in both diseases by modulating metabolic dysfunction in joint tissues.

ESCEO-OARSI2
IMPACT OF OSTEOPOROSIS AND OSTEOARTHRITIS AS COMORBIDITIES IN THE AGING POPULATION

E. Dennison[1]

[1]MRC Lifecourse Epidemiology Centre, Southampton, United Kingdom

Over the coming years, the number of people over the age of 65 is projected to increase substantially. By 2050, 2 billion people will be over 60 years of age, up from 1 billion in 2020 according to the World Health Organization. Conditions of musculoskeletal aging are common; it has been estimated that over 50% American adults > 50 years have osteoporosis or osteopenia, while an estimated 240 million individuals worldwide have symptomatic osteoarthritis (OA), including 10% of men and 18% of women age 60 and older. Meanwhile an increase in life expectancy and a subsequent ageing population have led to a higher prevalence of other chronic, non-communicable diseases that sit alongside conditions of musculoskeletal aging. The World Health Survey carried out between 2002 and 2004 in 70 countries worldwide showed that about 50% of middle-aged (50–64 years) to older (≥ 65 years) adults were multimorbid, having two or more non-communicable diseases, approximately a quarter had three, and one tenth have four or more non-communicable diseases.

There has been a recent interest in whether the existence of musculoskeletal diseases of aging alongside other health conditions might increase risk of adverse events. For example, studies have considered whether the existence of OA as a comorbidity existing with other medical conditions might heighten the risk of adverse outcomes among these individuals, with evidence from one study suggesting that this is indeed the case for risk of hospitalization for most medical conditions, excluding chronic obstructive pulmonary disease, citing 20 more hospitalisations for ambulatory-care sensitive conditions per 10 000 person-years in OA compared with non-OA persons. Similarly, of the comorbid long term conditions studied among Biobank participants, osteoporosis was most strongly associated with adverse outcomes in participants with rheumatoid arthritis compared with those without rheumatoid arthritis or long term conditions, namely a twofold increased risk of all-cause mortality (HR 2.20, 95% CI 1.55 to 3.12) and threefold increased risk of major adverse clinical event (HR 3.17, 95% CI 2.27 to 4.64).

ESCEO-WHO1
WHO SYMPOSIUM ON BONE HEALTH AND AGEING

J. T. Amuthavalli[1]

[1]Coordinator of Bone Health Initiatives, Ageing and Health Unit, Maternal, Newborn, Child, Adolescent Health and Ageing, World Health Organization, Geneva, Switzerland

Introduction: The World Health Organization (WHO), in partnership with the European Society for Clinical and Economic Aspects of Osteoporosis, Osteoarthritis, and Musculoskeletal Diseases (ESCEO) and the International Osteoporosis Foundation (IOF), is working on an evidence-based public health strategy to optimize bone health and prevent fractures among older persons. This initiative aims to contribute to the betterment of the health and well-being of older persons worldwide.

The Bone Health Expert Working Group (BOHEG) was established by WHO to advance technical work in the following areas:

- Developing global estimates on fracture and osteoporosis.
- Reviewing evidence-based interventions to prevent fractures.
- Creating an economic model for an investment case in fracture prevention and care.
- Providing guidance to countries on strengthening national health information systems by integrating osteoporosis and fractures into routine data monitoring.
- Providing guidance to countries on using data to design evidence-informed policies and programs to reduce the risk of fractures in older people.

To this end, the symposium will provide an update on ongoing technical work, present preliminary findings, and discuss future plans.

Chairpersons:

Dr Anshu Banerjee, Director, Maternal, Newborn, Child, Adolescent Health and Ageing, World Health Organization, Geneva, Switzerland

Dr Rene Rizzoli, Chair of WHO-BOHEG and emeritus professor of medicine at the University Hospitals of Geneva, Switzerland

ESCEO-WHO2
SYSTEMATIC REVIEW OF MEASUREMENT PROPERTIES OF INSTRUMENTS TO MEASURE THE QUALITY OF LIFE OF OLDER PERSONS WITH SARCOPENIA AND OSTEOPOROSIS

S. Sabico[1], J. A. Thiyagarajan[2], S. De Baets[3], N. Veronese[4], V. Knoop[5]

[1]Chair for Biomarkers of Chronic Diseases, Biochemistry Department, College of Science, King Saud University, Riyadh, Saudi Arabia, [2]Department of Maternal, Newborn, Child, Adolescent Health and Ageing, World Health Organization, Geneva, Switzerland, [3]Department of Rehabilitation Sciences, Faculty of Medicine and Health Sciences, Ghent University, Ghent, Belgium, [4]Geriatrics Section, Department of Internal Medicine, University of Palermo, Palermo, Italy, [5]Department of Gerontology, Vrije Universiteit Brussel (VUB), Brussels, Belgium.

Introduction: Over the past decades, several tools have been developed and validated to assess quality of life (QoL) in older people with musculoskeletal diseases. To assist various stakeholders in making informed decisions about the most appropriate patient-reported outcome measures (PROMs) to assess QoL, a systematic literature review was performed to comprehensively assess the measurement properties of the different QoL questionnaire available in the scientific literature.

Methods: A systematic review of QoL instruments identified for osteoporosis and sarcopenia was performed using the COSMIN guidelines for systematic reviews of patient-reported outcome measurements. The literature search was conducted up to June 2023 in MEDLINE (Ovid), Embase, PsycINFO (Ovid), and AMED (Ovid). The methodological procedure was in accordance with PRISMA2020 guidelines. Both the quality and the strength of evidence were considered to recommend the use of a QoL questionnaire for sarcopenia or osteoporosis (GRADE). Additional factors were also considered to formulate the final recommendations (i.e. resource requirement, feasibility, acceptability, equity and human rights). The protocol for this research has been registered on PROSPERO CRD42023458414.

Results: A total of 70 studies were deemed relevant for inclusion in this systematic literature review. In these studies, 11 QoL instruments were identified: 1 for sarcopenia (the SarQoL) and 10 for osteoporosis (ECOS-16, IOF-QLQ, JOQOL, OPAQ, OPTQoL, OQLQ, QoLOS-NVFX, QUALEFFO, QUALIOST, and the Triple-Q questionnaire), sometimes presented in different versions. Sample size ranged from n = 30 to n = 1477 with mean age ranging from 59.9–82 years. Thirty-six studies (51%) recruited only women.

Conclusion: The selected studies of the systematic review will be evaluated for content validity and the measurement properties of tools summarized to complete the GRADE evidence. It will be submitted for discussion to the World Health Organization Bone Health Group for final recommendation and publication.

ESCEO-WHO3
SYSTEMATIC REVIEW OF MEASUREMENT PROPERTIES OF INSTRUMENTS TO ASSESS RISK OF FRACTURE IN OLDER PERSONS—AN UPDATE

G. Honvo[1]

[1]Consultant, Ageing and Health Unit, Department of Maternal, Newborn, Child and Adolescent Health and Ageing, World Health Organization (WHO), Geneva, Switzerland

In March 2023, the World Health Organization (WHO) and the European Society for Clinical and Economic Aspects of Osteoporosis, Osteoarthritis and Musculoskeletal Diseases (ESCEO) launched the WHO Bone Health initiative for advancing WHO work in the field of bone health. The ultimate goal of this initiative is to develop a public health strategy to prevent fracture among adult populations. One of the key deliverables of the agreement between WHO and ESCEO is to conduct a systematic review of studies evaluating instruments to assess the risk of fractures in adults, including older adults, and to critically apprise the measurement properties of these tools. Since the development of the review protocol and its registration in PROSPERO in September 2023, some important steps have been accomplished, including the completion of the title and abstract screening phase. The objective of this presentation is to give an update of this systematic literature review, by presenting the current preliminary data collected and tools retrieved, and to discuss the next steps towards the completion of this important research.

World Congress on Osteoporosis, Osteoarthritis and Musculoskeletal Diseases (WCO-IOF-ESCEO 2024): EUGMS-ESCEO Symposium Abstract

EUGMS-ESCEO1
OPTIMIZING FRACTURE PREVENTION AND REHABILITATION IN FRAIL OLDER PERSONS: THE EXERCISE AND PHYSIOTHERAPY PERSPECTIVE

D. Skelton[1]

[1]ReaCH, School of Health and Life Sciences, Glasgow Caledonian University, Glasgow, United Kingdom

There is a large body of research that has informed evidence based practice in optimising fracture prevention and rehabilitation in frailer older people [1]. However, there are many barriers to delivery, uptake and adherence to individually tailored, multicomponent exercise programmes. To target frailty and sarcopenia we need to implement supervised progressive resistance training, if we want to focus on fracture prevention we need to implement weight bearing impact and specific balance challenging activities. The World Falls Guidelines also remind us that these interventions need to be a minimum of $3 \times$ pw and for > 12 wks [2]. Supervised delivery of such interventions is lacking in most countries and even where this support exists, uptake and adherence is poor. There is growing evidence that for some individuals, the prescription needs to start with breaking up prolonged periods of sitting and increasing volume of light activity, to support self efficacy with additional behaviour change techniques to progress on, over time, to more effective prescriptions [3]. People with diagnosed osteoporosis should be as active as possible and only avoid activities with a high risk of falls if they are naïve to those activities [4] and strength and balance exercise should be key components [5]. Older adults with multiple long-term conditions are willing to engage in resistance exercise if they are appropriately supported [6]. Physiotherapy input is warranted for the very frail/comorbid/high risk fallers but specific training can support transition to community exercise instructor support to ensure sustainable behaviour change and effective dose over time.

SICOT-ESCEO-IOF1
TRENDS IN THE MANAGEMENT OF OSTEOPOROTIC PELVIC FRACTURES

M. P. J. Teuben[1]

[1]MD/PhD, Traumasurgeon, Dept. of Traumatology University Hospital, Zurich, Switzerland

Osteoporotic fractures of the pelvis are common in the geriatric population. An ageing population and improved diagnostics will further increase the incidence of these fractures in the future.

In contrast to high-energy pelvic trauma (which occurs in the younger population), fragility fractures are associated with minor injuries in combination with fragile bone structures. Given the differences between the two types of pelvic trauma, different treatment protocols are required. Historically, non-operative management of osteoporotic fractures has been the preferred treatment in geriatric patients. Non-operative management requires a multidisciplinary team and frequent reassessment. Delaying surgerymay put patients at risk of developing immobilization-related complications such as infection, thrombosis and muscle loss. The aim of management in the geriatric patient with pelvic injury is to achieve early mobilization. Surgical treatment may help to achieve this. Surgery for pelvic fractures has evolved over time and minimally invasive procedures have become the standard of care. Further improvements in screw and plate designs, 3D imaging techniques and intraoperative navigation have led to improved accuracy of surgical fixation and lower complication rates. This also provided the impetus for a shift towards early operative treatment of osteoporotic pelvic fractures.

SICOT-ESCEO-IOF2
WILL A TREATMENT PROTOCOL INCLUDING OF CLASSIFICATION PROVIDE CLEAR GUIDELINES FOR OSTEOPOROTIC THORACOLUMBAR SPINE FRACTURES MANAGEMENT? CAN WE AVOID OVERTREATMENT OR UNDERTREATMENT?

N. Trajkovska[1], J. Saveski[1], I. Hasani[2]

[1]Clinical Hospital Acibadem Sistina, Skopje, North Macedonia, [2]University Clinic for Traumatology, Medical Faculty, Skopje, North Macedonia

Objective: Osteoporotic spine fractures (OSF) are major worldwide growing health problem, leading cause of pain, disability, impaired quality of life and morbidity in the elderly.
The best treatment is prevention, treating causes, correcting calcium and vitamin D, exercise program…

Medical treatment includes hormonal replacement, bisphosphonates, calcitonin, raloxifene, teriparatide… Nonsurgical treatment includes bedrest, cast/brace, analgesia…

If conservative treatment fails, surgery—minimally invasive (vertebroplasty or kyphoplasty) or invasive, open approach to the spine is indicated.

The fracture acuity is evaluated with MRI. Appropriate time for surgery is 3 weeks to 3 months after injury, unless dealing with pseudoarthrosis or late neurological deficits.

When facing this group of patients, it is usually hard to choose adequate treatment. It is a real challenge to find balance between overtreatment and undertreatment, since both are trigger for future complications.

Material and methods: We have evaluated retrospectively patients with OSF treated in our hospitals from June 2020 to June 2023. The diagnostic protocol, the OF classification and score, the chosen treatment, the results, the need of surgery after fail of previous treatment were analysed.
Results: We have found the OF classification and OF score reliable tool for choosing adequate treatment. The score incorporates level of pain, bone density, acuity of the fracture, neurological deficits and general health status, beside the classification.
Discussion: Because of number of comorbidities that geriatric patients have, it is crucial to apply treatment protocol in clinical setting for treating OSF while trying to do no harm.
Conclusion: When dealing with OSF it is imperative to use OF classification and OF score for choosing appropriate treatment in order to lower the incidence of complications and additional surgical procedures in elderly. Undertreating or overtreating them leads to complications, local and systemic.

SICOT-ESCEO-IOF3
OSTEOPOROTIC HIP FRACTURES

I. Hasani[1], J. Saveski[2], N. Trajkovska[2]

[1]University Clinic for Traumatology, Medical Faculty, Skopje, North Macedonia, [2]Clinical Hospital Acibadem Sistina, Skopje, North Macedonia

Although very important Osteoporotic Hip Fractures, because almost 1/3 of our geriatric patients are fatal, are the most contemned fractures in our everyday praxis and most neglected ones, often operated by the youngest surgeons or residents under supervision. Geriatric hip fractures are often in the shadow of other young injured patients on the wards and also often subject to nonstandard treatment in the same centers. There is also documented substantial hospital variation in adherence to evidence-based guidelines used for the treatment of hip fractures. Non-permanent following of the guidelines puts the patients at a significant risk of inequality in treatment and poor outcomes.

Fast-track strategy, Insisting on separate orthogeriatric departments, with standardized treatment and fast-track strategy for hip fracture patients, and its implementation is very beneficial for osteoporotic–geriatric hip fractures!

Unrealized needs for osteoporotic hip fractures are implant stability and bone implant anchorage!

Advances in the locking concept of the nails; anchorage with double screws or PMMA augmentation, and rigid femoral neck system for treating neck fractures have been introduced recently dramatically changing the perspective of patients with osteoporotic hip fractures.

Even though these fractures are the "beginning of the end" for almost 1/3 in the first year, of the injured frail and elderly injured; decreasing the excess mortality should be every surgeon's target for enabling our beloved oldies to live beside us as much as possible.

World Congress on Osteoporosis, Osteoarthritis and Musculoskeletal Diseases (WCO-IOF-ESCEO 2024): ESCEO Symposium Abstracts

ESCEO1
REMS: HOW DOES IT WORK AND WHAT DO WE MEASURE?

A. Diez-Perez[1]

[1]Hospital del Mar Institute of Medical Investigation, Barcelona, Spain

REMS (Radiofrequency Echographic Multi-Spectrometry) is a measurement that allows bone health status assessment and fracture risk prediction by means of a rapid ultrasound scan on reference axial sites of the skeleton. It operates in the following steps: ultrasound scan (software guided); B-mode image reconstruction; and radiofrequency signal analysis (with automatic identification of bone interfaces and ROIs on raw signals).

The acquisitions are performed at the lumbar vertebrae and the femoral neck and the data analyzed allowing the identification of target bone structures within the sequence of echographic images acquired on the patient by performing a number of steps on each acquired frame. These results are compared with a reference database yielding quantitative parameters (BMD, T-score and Z-score) and qualitative parameters (fragility score). This Fragility Score is dimensionless and measures bone fragility in a scale from 0 to 100, where 100 indicates the maximum similarity with the fractured model (i.e. maximum bone fragility) and vice versa. These levels are then used for the calculation of the 5-year risk of fracture (hip and major).

REMS automatically eliminates raw signals that belong to calcifications, osteophytes and other artifacts. The acquisition is fast (80 s for spine and 40 for femur), convenient for the patient and the operator, operator's training easy, the selection of ROIs is automatic (independently of the operator), accessible (portable) and radiation free.

REMS automatically eliminates raw signals that belong to calcifications, osteophytes and other artifacts avoiding the overestimation of lumbar BMD associated to DXA.

The technique has been evaluated, showing for BMD measurements high sensitivity and specificity ($> 91\%$, good diagnostic agreement with DXA and the intra-operator CV is 0.323–0.38% with an inte-roperator CV of 0.48–0.54. For Fragility Score the intra-operator CV is 0.43–0.49 and the inter-operator CV 0.64–0.73.

Ongoing development is in progress for the measurement of muscle strength and the results show a vey high correlation with hand grip strength values ($r = 0.95$, $p < 0.0001$).

In summary, REMS is a novel technique for the measurement of BMD (BMD, T-score) and bone fragility (Fragility Score), is radiation-free, can be used for mass screening or diagnosis and for short-term follow up and has a good accuracy and precision. Since is portable can be used in ambulatory settings and private offices as well as at the bedside. Avoids some artifacts of DXA and new developments (Fragility Score, Muscle Strength) may expand the clinical applicability of the technique.

ESCEO2
WHAT IS THE CONTRIBUTION OF REMS TO THE MANAGEMENT OF POST-MENOPAUSAL OSTEOPOROSIS?

N. Harvey[1]

[1]MRC Lifecourse Epidemiology Centre, University of Southampton, Southampton, United Kingdom

Radiofrequency echographic multi-spectrometry (REMS) is a novel technology based on the analysis of raw unfiltered ultrasound signals acquired during an echographic scan of either the lumbar spine or femoral neck. Its output can be taken as a REMS BMD T-score or a Fragility Score measure. Measures are derived from the comparison of echographic spectra of osteoporotic versus normal bone and have been demonstrated in several studies to be well calibrated with DXA BMD at the corresponding site. Discrimination of past or future fractures appears similar between REMS and DXA BMD T-score with the novel Fragility Score measure potentially yielding somewhat greater performance. The technique systematically removes effects of artefacts such as osteophytes, a property which has been validated to a limited extent in clinical studies. Given the non-ionising nature and portability of the technology, REMS is likely to provide novel opportunities to broaden access both within and without healthcare settings. More information is needed about the predictive capacity of these measures in relation to DXA BMD and FRAX probability, together with dependency on other risk factors, in order to fully understand the role of the technology in the broader context of fracture risk assessment.

ESCEO3
WHAT IS THE CONTRIBUTION OF REMS IN THE MANAGEMENT OF MUSCULOSKELETAL HEALTH, OUTSIDE OF POST-MENOPAUSAL OSTEOPOROSIS?

M. L. Brandi[1]

[1]Metabolic Bone Diseases Unit, Dep. of Surgery and Translational Medicine, University of Florence, Florence, Italy

Objective: Although musculoskeletal diseases are more often observed in elderly people and/or post-menopausal women; younger-adults, pregnant women or secondary osteoporosis should be included in the comprehensive prevention measures: widespread BMD and muscle disease evaluation in this population are commonly lacking, due to very limited research focus. In this context, the aim of this work is to illustrate the contribution of Radiofrequency Echographic Multi Spectrometry (REMS) in the management of musculoskeletal health outside of post-menopausal osteoporosis.

Material and methods: An up-to-date peer-reviewed research on the REMS application outside of well-known post-menopausal osteoporosis.

Results: Several clinical studies confirmed REMS diagnostic validity and show that, thanks to its radiation free nature and high precision, it can be applied for prevention programs, early diagnosis in clinical practice, risk fracture prediction and short-term monitoring. REMS can be used in various categories of fragile patients, both for primary and secondary osteoporosis.

Scientific evidences demonstrated a BMD reduction in pregnant women with respect to non-pregnant ones and from the first to the third trimester of pregnancy. REMS can be successfully applied in young subjects suffering from Anorexia Nervosa with previous vertebral fragility fractures confirming a high risk of bone fragility in these patients. Furthermore, clinical data confirmed that REMS investigation improved osteoporosis diagnosis also in individuals suffering from type II Diabetes or chronic kidney diseases (CKD), including patients undergoing kidney transplant and peritoneal dialysis (PD). Lastly, REMS diagnosis is not affected by osteoarthritis-related bone deformities nor by the presence of aortic calcifications, that in contrast, induce an artefactual BMD alteration with standard DXA. This technique allows reliable estimation of muscle strength in both pathological and healthy subjects, in order to monitor the onset and evolution of diseases like sarcopenia by early detecting the corresponding tissue deteriorations through dedicated REMS parameter.

Conclusion: On the base of the mentioned evidences, REMS can improve the management of musculoskeletal health and fracture risk in the clinical routine as stated in the Italian Health Ministry Guidelines, also outside of post-menopausal osteoporosis by reaching as well subjects who wouldn't have access to DXA.

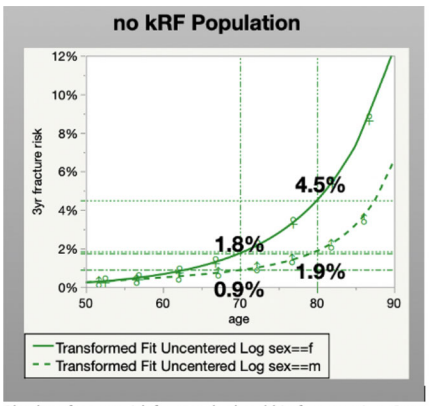
ESCEO-DVO1
THE NEW DVO OSTEOPOROSIS GUIDELINE 2023—A PARADIGM SHIFT FOR THE GERMAN SPEAKING COUNTRIES

F. Thomasius[1,2,3]

[1]Frankfurter Hormon and Osteoporosezentrum, Frankfurt, Germany, [2]Chairwoman of the DVO Guidelines Commission, Frankfurt, Germany, [3]President of the German Society for Osteology, Frankfurt, Germany

The key recommendations of the completely revised 2023 Guideline for the Prevention, Diagnosis and Treatment of Osteoporosis in Postmenopausal Women and Men over 50 Years of Age (1) of the German Dachverband Osteologie (DVO, an association of 20 societies for skeletal research in Germany, Austria and Switzerland) have changed. Following the highest level of evidence and strict quality criteria (DELBI, OXFORD, and SIGN) and approved as S3 guideline by the AWMF (Association of the Scientific Medical Societies of Germany; No 183-001), this guideline is based on a comprehensive systematic literature review (2267 publications) to address PICO questions (Population-Intervention-Comparison-Outcome) most relevant to clinical practice. Fracture risk, based on hip and vertebral fracture risk, now is derived for a 3-year time horizon instead of 10-years. The absolute fracture risk for vertebral and hip fractures is shown in Fig. 1. Other changes include (1) the prioritization of 33 clinical risk factors, (2) the omission of a fracture risk threshold for initial diagnostics if any of these clinical risk factors is present in a medically relevant constellation, (3) the introduction of a three-tiered fracture risk-based therapy threshold (removal of the requirement for a T-Score < -2), separating indications for antiresorptive versus osteo-anabolic treatment. These changes represent a paradigm shift in the diagnostic and therapeutic approach to osteoporosis, aiming at more comprehensive patient-specific diagnostic and therapeutic guidance to reduce the substantial diagnostic and treatment gap that exists for osteoporotic patients.



Absolute fracture risk for vertebral and hip fractures in a German health insurance data set; clinical risk factors are not included. F female, m male (1)

(1) DVO-German Guideline for the diagnosis and therapy of osteoporosis, Version 2.1, 13th Nov 2023, https://register.awmf.org/de/leitlinien/detail/183-001, last access 12th Feb 2024,

ESCEO-DVO2
DISEASE MANAGEMENT PROGRAM OSTEOPOROSIS—A POLITICALLY DECIDED STRUCTURED CARE PROGRAM FOR GERMANY

A. Kurth[1]

[1]Dep. of Orthopaedic and Trauma Surgery, Marienhaus Klinikum, Mainz, Germany

Disease management programs (DMPs) are structured treatment programs for chronic diseases that aim to optimize medical treatment in the long term and improve and maintain the quality of life of those affected. Further aims are to avoid complications and consequential damage or concomitant illnesses as far as possible.

DMPs include regular medical appointments with consultations and examinations as well as the provision of background information, for example through training courses. Medical practices that offer treatment as part of the DMP osteoporosis must meet certain requirements and comply with defined quality standards.

This is also intended to improve cooperation between the various specialist disciplines and facilities that care for a patient, for example between general practitioners and specialists, clinics and rehabilitation facilities.

Once osteoporosis has been diagnosed, the coordinating doctor can enrol the patient in the DMP and draw up an individual treatment plan based on the DMP guidelines.

This includes drug treatment (anti-resorptives, osteoanabolic agents, calcium and vitamin D) and other therapeutic measures, training appointments and regular check-ups.

The individual treatment steps, examination and treatment results are regularly documented.

Participation in a DMP has advantages for patients and doctors:

The doctors involved must take an interest in the subject of osteoporosis and undergo further training, thereby gaining continuously—updated knowledge, even for the care of complex cases of osteoporosis.

With the correct indication for enrollment in the DMP osteoporosis, colleagues no longer have to deal with the cost pressure for their therapy.

The documented information on the course of the disease and the therapy avoids duplicate examinations and incorrect medication. Furthermore, all therapists and doctors are required to coordinate their measures with each other.

Special training programs and structured exercise programs can make it easier for chronically ill osteoporosis patients to be well informed and actively involved in their treatment and to actively do something for their bone health in addition to drug therapy.

As medical knowledge is constantly growing, the specifications for the DMP osteoporosis must be regularly updated.

As the DVO's osteoporosis guidelines are updated every three years and therefore incorporate the latest evidence for diagnosis and treatment, it can be assumed that this content will also be taken into account when the DMP is updated.

ESCEO-DVO3
A NEW CASE FINDING ALGORITHM ACCORDING TO FRACTURE RISK

C.-C. Glüer[1], K. Engelke[2], F. Thomasius[3], W. D. Leslie[4]

[1]Christian-Albrechts-Universität zu Kiel, Section Biomedical Imaging-Department of Radiology and Neuroradiology-UKSH,, Kiel, Germany, [2]Friedrich Alexander University Erlangen Nürnberg, Department of Medicine 3, Erlangen, Germany, [3]Frankfurter Hormon- und Osteoporosezentrum, Frankfurt, Germany,

[4]Departments of Internal and Radiology, University of Manitoba, Manitoba, Canada

As key element of the 2023 DVO osteoporosis guidelines, a new fracture risk algorithm is now used for case finding of patients in need of therapy. Treatment decisions are based on fracture risk estimates derived from (i) a base risk of subjects without any clinical risk factors (cRFs), (ii) cRFs present in a patient, selected from 33 literature-validated cRF candidates, (iii) estimation of 3-year risk of fracture, (iv) considering incident hip fracture (HF) or vertebral fracture (VF), along with (v) DXA at total proximal femur and lumbar spine.

In order to assess whether an expanded list of cRFs, 3 yr risk instead of 10 yr risk, and inclusion of DXA of the spine would increase predictive power, we have tested corresponding more complex risk assessment models in the Manitoba BMD registry, for women only. Risk performance was based on Cox proportional hazard models. As presented at ASBMR 2023, AUCs of ROC analysis increased substantially and significantly (0.848 vs 0.830 for HF and 0.766 vs 0.727 for VF) when adding additional cRFs to the basic set (which included age, BMI, parental hip fracture, smoking, alcohol, glucocorticoid, RA and prior fracture). DXA of the spine added predictive power over DXA of the total hip for vertebral fracture prediction only. When comparing full models including cRFs and DXA for 3 yr and 10 yr follow-up, AUCs were larger for the 3 yr model (0.884 vs 0.825 for HF and 0.795 vs 0.771 for VF). These results motivated us to implement the new algorithm, first in a simplified version restricted to inclusion of only the patient's two strongest cRFs and limited to DXA of the total hip. Patients with a combined 3 yr-risk of HF or VF exceeding 3% should consider antiresorptive medication; if the risk exceeds 5% they should receive antiresorptive medication, and if the risk exceeds 10%, osteanabolic medication is recommended. An outline of the risk assessment algorithm will be presented.

ESCEO-DVO4
MEDICAL EDUCATION IN OSTEOLOGY CARE: FROM BASIC RESEARCH TO CLINICAL COMPETENCE CERTIFICATION

R. Schmidmaier[1]

[1]Department of Medicine IV, LMU University Hospital, LMU Munich, Munich, Germany

Objective: To reduce the treatment gap of osteoporosis by evidence based medical education.

Material and methods: Presentation of current medical education research issues and of the competence based DVO curriculum for certification in clinical osteology.

Results: There is a large treatment gap in osteoporosis, which is mainly due to diagnostic errors. Most of these are cognitive errors. Studies have shown that more than 80% of diagnostic errors are related to the diagnostic process, not only to lack of knowledge. Diagnostic competence can be fostered by scaffolding, either representational or process-related. However, effects are dependent on learner prerequisites. Therefore, future studies will focus on individualized adaptive scaffolding. The German-speaking umbrella organization of scientific osteology organizations (DVO) provides a structured, competence-based curriculum that leads to a stepwise certification in excellent osteology care. Residents may achieve the "certificate for general osteoporosis care" after a specialized 2-day training course. Medical specialists may achieve the "certificate for specialized osteoporosis care" after hands-on training and additional CME courses. The certificate "osteologist DVO" additionally requires extensive diagnostic skills and at least three years of supervised practice. All certificates need to be updated after five years by proofing intensive patient care and CME.

Conclusions: Evidence based medical education in osteology care may reduce the treatment gap in future. Prospective, multicentre intervention trials are needed to proof this.

Acknowledgements: I am grateful to the members of the DVO and to the organizers of the osteology certification curriculum (OSteology ACademy, OSTAK).

Disclosures: Chairman of the DVO (Dachverband Osteologie). Funding by the German Research Foundation (DFG), DFG Research Unit FOR2385.

World Congress on Osteoporosis, Osteoarthritis and Musculoskeletal Diseases (WCO-IOF-ESCEO 2024): Meet-the-Experts Abstracts

MTE1
COMPLEX OSTEOPOROSIS: CASE HISTORIES

E. Dennison[1]

[1]MRC Lifecourse Epidemiology Centre SO16 6YD, Southampton, United Kingdom

This interactive meet the professor session aims to cover discussion of many of the challenging management situations faced by clinicians who care for patients with metabolic bone disease. Discussion will be grounded in available literature and will include discussion of management of patients with Duchenne muscular dystrophy; women receiving therapy for breast cancer; patients with a history of eating disorders and young adults with osteogenesis imperfecta. Participants are invited to share their thoughts and personal experience.

MTE2
GUIDELINES FOR MANAGEMENT OF HYPOPARATHYROIDISM

M. L. Brandi[1]

[1]Fondazione FIRMO and Observatory for Fragility Fractures, Florence and University San Raffaele, Milan, Italy, Florence, Italy

Hypoparathyroidism (HypoPT) is a rare disorder characterized by hypocalcemia in the presence of a low or inappropriately normal parathyroid hormone level. HypoPT is most commonly seen after neck surgery, which accounts for approximately 75% of cases, whereas approximately 25% have HypoPT due to nonsurgical causes.

The 2022 International Task Force guidelines for chronic HypoPT was published in the Journal of Bone and Mineral Research. These guidelines update the original guidelines published in 2016, and include new information from literature published since then.

This clinical practice guidelines address the prevention, diagnosis, and management of HypoPT and provides evidence-based recommendations. The HypoPT task forces included four teams with a total of 50 international experts including representatives from the sponsoring societies.

The guidelines also enlisted a number of areas needing further studies.

This together with the astonishing pharmacological developments in this area open to a revision of these guidelines in the future.

By now these guidelines are intended to frame the diagnosis and care of patients with chronic hypoparathyroidism for at least the next five years.

MTE3
MACHINE LEARNING AND COMPUTER VISION—THE FUTURE OF FRACTURE RISK ASSESSMENT?

N. Fuggle[1]

[1]Associate Professor, MRC Lifecourse Epidemiology Centre, University of Southampton, Southampton, United Kingdom

Identifying those individuals at risk of fracture is key to effective management of osteoporosis as identification can lead to treatment, treatment can lead to reduction in fractures and reduction in fractures to improvements in quality of life for our patients.

Effective tools exist for the assessment of fracture risk. These include FRAX® which uses a combination of clinical risk factors and bone mineral density to provide a 10-year risk of major osteoporotic fracture and hip fracture. FRAX® is easily deployable and has been tailored to the vast majority of countries across the globe.

'Machine learning' refers to the use of computer systems which are able learn and adapt without requiring specific, prescriptive instructions but by developing algorithms and mathematical models to independently analyse and make inferences from data.

'Computer Vision' is the field of computer science which examines the ability of computers to identify patterns and objects in images via interpretation of shape, texture and other features.

There has been a recent explosion of research which is attempting to identify whether machine learning and computer vision can contribute to fracture prediction in a way which may be complementary to FRAX® and other fracture prediction tools.

In this session we will introduce the basic concepts of computer vision and look examine the research which is attempting to use these techniques in the field of fracture prediction.

MTE4
AN INTEGRATED APPROACH TO NUTRITION IN MUSCULOSKELETAL DISEASE

N. Veronese[1]

[1]Associate Professor in Geriatrics and Internal Medicine, University of Palermo, Palermo, Italy

Nutrition plays a pivotal role in the management and prevention of musculoskeletal diseases, encompassing conditions such as osteoporosis, osteoarthritis, rheumatoid arthritis, and sarcopenia. This lecture will discuss an integrated approach to nutrition aimed at optimizing musculoskeletal health and function.

Firstly, dietary factors influencing bone health are explored, including calcium, vitamin D, protein, and other micronutrients. Adequate intake of these nutrients is essential for bone mineral density and fracture prevention, for example. Furthermore, the interplay between inflammation, oxidative stress, and dietary patterns in arthritis will be examined. A diet rich in anti-inflammatory foods, such as fruits, vegetables, and omega-3 fatty acids, may mitigate symptoms and disease progression in rheumatic conditions.

Moreover, sarcopenia, characterized by age-related muscle loss and decreased strength, is addressed in relation to protein intake, amino acids, and resistance exercise. Optimizing protein quality and quantity, along with regular physical activity, are paramount for preserving muscle mass and function. Additionally, the impact of obesity on musculoskeletal health is discussed, highlighting the importance of weight management strategies and dietary modifications in reducing joint stress and inflammation.

Furthermore, the role of personalized nutrition interventions and supplementation in musculoskeletal disease management is emphasized. Tailoring dietary recommendations based on individual needs, genetic predispositions, and metabolic factors can enhance treatment outcomes and quality of life for patients. Moreover, emerging research on nutraceuticals, such as collagen peptides and polyphenols, suggests potential therapeutic benefits in supporting joint health and cartilage integrity.

In conclusion, an integrated approach to nutrition is essential for optimizing musculoskeletal health across the lifespan. By addressing dietary factors that influence bone density, inflammation, muscle mass, and weight management, healthcare professionals can empower individuals to prevent and manage musculoskeletal diseases effectively. Future research should continue to explore the intricate relationship between nutrition and musculoskeletal health, ultimately

paving the way for personalized dietary interventions and improved clinical outcomes.

MTE5
"OMICS" IN THE FUTURE OF BONE HEALTH ASSESSMENT

E. Cavalier[1,2]

[1]PhD, EuSpLM, Liege, Belgium, [2]Head, Department of Clinical Chemistry, University of Liege, CHU de Liege, Liege, Belgium

In the ongoing quest to unravel the molecular complexities underlying osteoporosis, researchers have turned to omics sciences, including genomics, proteomics, and metabolomics, for a more nuanced understanding.

Genomics offers insights into the genetic factors contributing to osteoporosis susceptibility. Understanding genetic predispositions allows for more accurate risk assessments, although it's essential to acknowledge the multifactorial nature of the disease.

Proteomics, with its focus on the entire protein complement, provides valuable information about the dynamic interplay of proteins involved in bone metabolism. While offering promising avenues for therapeutic exploration, it's important to recognize the challenges of translating proteomics findings into clinical applications.

Metabolomics, examining small molecules and metabolic pathways, complements the picture by identifying potential biomarkers and metabolic alterations associated with osteoporosis. However, the intricacies of linking metabolomic changes to disease mechanisms necessitate cautious interpretation.

Integrating these omics approaches presents a comprehensive but evolving perspective on osteoporosis. Recognizing the limitations, such as the need for larger-scale validation studies and addressing the complexities of translating research findings to clinical practice, is crucial.

In navigating the omics era of osteoporosis research, a balanced acknowledgment of both the advancements and the challenges is paramount. While omics sciences hold promise for deepening our understanding, caution and ongoing scrutiny are essential to ensure the responsible and realistic application of these insights in clinical settings.

MTE6
GUIDELINES FOR MANAGEMENT OF PRIMARY HYPERPARATHYROIDISM

M. Lazaretti-Castro[1]

[1]PhD, Professor Endocrinology, Escola Paulista de Medicina, Universidade Federal de Sao Paulo, Sao Paulo, Brazil

Primary hyperparathyroidism (PHPT) currently ranks as one of the most prevalent endocrine disorders. It is classically defined by hypercalcemia accompanied by inappropriate levels of parathormone. The clinical presentation of PHPT has evolved since its initial description in the early twentieth century. Originally considered a rare and severe disease, it has transformed into a highly prevalent and less symptomatic condition[1].

This transformation is primarily attributed to the widespread adoption of routine serum calcium testing, especially in developed countries. Additionally, the aging global population has also contributed, as asymptomatic cases are more commonly observed in the elderly. Surgical intervention remains the curative and preferred treatment for symptomatic presentations. However, in cases with minimal symptoms or asymptomatic forms, the decision for surgery must carefully consider the benefit-to-risk ratio and the increased risk for failure[2].

In recent decades, significant progress has been achieved in various aspects of PHPT, encompassing genotypic/phenotypic correlations, as well as novel diagnostic and therapeutic approaches. Due to the unique characteristics associated with the epidemiology, diagnosis, and management of PHPT, multiple expert groups have developed guidelines. Notably, the 5th International Workshop[3], featuring researchers from different countries, was recently published and will serve as the foundation for our discussion.

The routine screening of osteoporotic patients includes the exclusion of PHPT, as one of its classical clinical manifestations adversely affects bone structure and quality, thereby increasing the risk of fractures. Conversely, secondary hyperparathyroidism is a prevalent condition often encountered during osteoporosis investigations, leading to confusion and misdiagnosis. These complexities require extensive discussions to avoid inappropriate approaches.

MTE7
HOW CAN WE OPTIMIZE FRACTURE HEALING?

A. Kurth[1]

[1]Dep. of Orthopaedic and Trauma Surgery, Marienhaus Klinikum, Mainz, Germany

Osteoporosis drugs play a significant role in managing bone health and fracture healing in individuals with osteoporosis. Osteoporosis is a condition characterized by weakened bones, increasing the risk of fractures. Fracture healing can be compromised in individuals with osteoporosis due to poor bone quality and density. Here's how osteoporosis drugs may impact fracture healing:

Antiresorptive Drugs work by inhibiting bone resorption, thereby slowing down bone loss. Common antiresorptive drugs include bisphosphonates (such as alendronate, risedronate, zoledronate), selective estrogen receptor modulators (SERMs) like raloxifene, and denosumab (a monoclonal antibody targeting RANKL). While these medications can help prevent further bone loss and reduce fracture risk in osteoporosis patients, they may also affect bone remodeling during fracture healing. Some studies suggest that long-term use of bisphosphonates, for example, might delay fracture healing due to their suppressive effect on bone turnover. However, the clinical significance of this delay in healing remains a topic of debate.

Anabolic agents such as teriparatide and abaloparatide work by stimulating bone formation, thereby increasing bone density and strength. These drugs are often used in individuals with severe osteoporosis or those who have experienced fractures despite treatment with antiresorptive medications. Anabolic agents may have a

positive impact on fracture healing by promoting bone formation and remodeling, potentially accelerating the healing process. Preclinically, Scl-Ab (Romosozumab) rich osteogenic effects and has shown positive effects on bone healing in rodent models. However, two clinical have and failed to show positive effects in the femur and tibia.

Some treatment approaches involve combining antiresorptive and anabolic drugs to maximize bone density and strength while minimizing the risk of fractures. This combination therapy may offer benefits in both preventing fractures and supporting fracture healing, though more research is needed to fully understand its effects.

The timing of osteoporosis drug initiation in relation to fracture occurrence may influence fracture healing. Initiating treatment promptly after a fracture occurs may help optimize bone healing and reduce the risk of future fractures.

The impact of osteoporosis drugs on fracture healing may vary depending on individual factors such as age, overall health, severity of osteoporosis, and the specific characteristics of the fracture. Healthcare providers must consider these factors when determining the most appropriate treatment approach for each patient.

In summary, while osteoporosis drugs play a crucial role in managing bone health and reducing fracture risk, their effects on fracture healing can be complex and may vary depending on the specific medication, timing of treatment, and individual patient factors.

MTE8
CRITICAL ROLE OF EXERCISE IN POST FRACTURE MANAGEMENT

O. Bruyère[1], D. Pinto[2]

[1]WHO Collaborating Center for Public Health aspects of musculoskeletal health and ageing, Division of Public Health, Epidemiology and Health Economics, University of Liège, Liège, Belgium,
[2]Department of Physical Therapy, Marquette University, Milwaukee, United States

Fractures are a significant health problem, often requiring comprehensive management strategies to ensure optimal recovery and long-term outcomes. This presentation will examine the central role of exercise in post-fracture management, highlighting its multiple benefits in enhancing rehabilitation and preventing complications. The presentation will begin with an exploration of the physiological effects of fractures on the musculoskeletal system, highlighting the potential for muscle wasting, joint stiffness and overall functional decline. The importance of early mobilisation and the incorporation of targeted exercise programmes in mitigating these adverse effects will be highlighted. A detailed review of evidence-based exercise interventions tailored to specific fracture types will follow. From weight-bearing exercises for lower extremity fractures to range-of-motion exercises for upper extremity injuries, the lecture will provide practical insights into designing rehabilitation programmes that optimise healing and restore function. In the broader context of global rehabilitation, the session will extend its focus beyond exercise to include physiotherapy, nutrition and education. Participants will gain a comprehensive understanding of how the synergy between these elements contributes to a holistic and effective approach to post-fracture care. The integration of technology and innovative approaches will also be explored, providing healthcare professionals with actionable insights to optimise patient outcomes in the evolving landscape of post-fracture rehabilitation.

MTE9
TRANSGENDER MEDICINE: KEY CHALLENGES IN THE MANAGEMENT OF MUSCULOSKELETAL DISEASE

J.-M. Kaufman[1]

[1]Department of Endocrinology, Ghent University Hospital, Ghent, Belgium

Transgender or trans persons are people with experienced gender identity not aligned with their assigned sex at birth: trans men are assigned female at birth but self-identify as male; trans women are assigned male at birth but identify as female; non-binary trans persons identify as neither exclusively male or female. In addition to social transition, trans persons may seek gender-affirming medical care, i.e. hormonal treatment and/or surgery inducing and maintaining body changes more congruent to the self-identified gender. Gender-affirming hormonal treatment (GAHT) in trans men consist of testosterone treatment; GAHT in trans women consist of a testosterone-lowering drug [GnRH analogue (GnRHa), cyproterone acetate or spironolactone] and estradiol. Hormonal treatment of transgender adolescents consists of suppression of pubertal development with a GnRHa followed, if gender dysphoria persists, by GAHT usually from around age 16y. Hormonal treatment in non-binary trans people, who represent a substantial proportion (up to 20%) of trans persons, tend to be tailored to the individual needs of the trans person (e.g. partial masculinisation, partial feminisation) using various non-standardized treatment regimens. Considering the major role of sex steroid hormones in the regulation of both body composition and bone homeostasis, the potential musculoskeletal impact of GAHT deserves attention.

Trans women before initiation of any treatment have a lower lean mass, muscle area and strength, and lower areal (DXA) and volumetric (peripheral QCT) bone mineral density (BMD), a smaller cortical bone size and a higher prevalence of low BMD and osteoporosis compared to healthy cis men. This deficit has been attributed to lifestyle-related factors, particularly a low level of physical activity. During long-term GAHT, there is further modest decrease of muscular mass and physical performance towards values comparable to those in cis women, while pretreatment BMD is well maintained or slightly increased. Fracture risk in trans women $\geq$ 50 y is greater than in cis men and like that in cis women. In treatment naïve trans men muscle mass and strength tend to be slightly greater and BMD is not different compared to cis women. Muscle mass and strength increase, and BMD is maintained, while cortical bone size might slightly increase during long-term GAHT with testosterone. Adolescent trans girls but not trans boys have a lower lean body mass before initiation of treatment, which increases upon GHAT in trans boys and changes only modestly in trans girls. Pretreatment BMD is decreased in trans girls but not in trans boys. GnRHa monotherapy impairs physiologic pubertal BMD increase, resulting in decrease of BMD Z-scores both in trans girls and boys. Upon initiation of GAHT BMD and Z-scores increase with at least partial recovery. Nevertheless, there is a high prevalence of low BMD in young adult trans girls. There is no reliable data on the musculoskeletal effects of individualized, non-standardized GAHT applied in non-binary trans people.

In conclusion, GAHD in adult trans persons according to current guidelines has no detrimental musculoskeletal effects, whereas there is still a knowledge gap as to the longer-term effects on bone health in adolescents. Bone health deserves attention in adult and adolescent trans women because of increased risk of low BMD and osteoporosis. In addition to the general bone health-promoting measures such as adequate intake of calcium and vitamin D, adequate physical activity, avoidance of alcohol and smoking, strategies to optimize bone health include monitoring of adequacy of sex steroid exposure and patient compliance for GAHT. Systematic DXA screening is not advised, but in presence of risk factors for osteoporosis the threshold to perform

DXA should be low, in particular in trans women. Moreover, close monitoring is advisable for non-binary trans persons on individualized GHAT schemes often involving steroid hormone dosages suboptimal for maintenance of musculoskeletal health. Treatment decisions for trans persons with high fracture risk scan be based on the guidelines for osteoporosis in the general population.

MTE10
ACHIEVING OPTIMAL MUSCULOSKELETAL HEALTH IN HIV

E. Biver[1]

[1]Service of Bone Diseases, Geneva University Hospitals and Faculty of Medicine, Geneva, Switzerland

Life expectancy of people living with HIV (PLWH) is now close to that of the HIV-uninfected population. As a result, age-related musculoskeletal conditions, including osteoporosis and sarcopenia, are increasing in PLWH. However, most studies investigating musculoskeletal health in PLWH were performed before the latest developments in antiretroviral therapies (ART). Osteoporosis in PLWH is mainly driven by a combination of classical risk factors of bone fragility, very widespread in this population, and risk factors specific to HIV. Most of bone loss occurs during virus replication and during immune reconstitution at ART initiation, which both increase osteoclast activity. Abnormalities in bone formation and mineralization have also been shown in histomorphometric studies in untreated PLWH. The risk of fracture is higher in PLWH and increases about 10 years earlier compared to the general population. Measurement of bone mineral density (BMD) is the first line tool for assessing fracture risk in postmenopausal women, men above 50 years, and other PLWH with clinical risk factors for osteoporosis. FRAX underestimates fracture probability in PLWH. General preventive measures to optimize musculoskeletal health include the promotion of physical activity, a balanced diet, the cessation of toxic habits when applicable, and the prevention of obesity and falls in elderly PLWH. Calcium and vitamin D supplementation should be considered as ART initiation, since it may attenuate bone loss at this stage. In case of indication for anti-osteoporotic drug, bisphosphonates remain the reference option. Bone-protective ART regimens improve BMD to a lesser extent than bisphosphonate, and increase body weight compared to other regimens, and without available data on their influence on the incidence of fracture.

MTE11
DENOSUMAB CESSATION: A PRACTICAL APPROACH IN LONG-TERM TREATMENT

E. M. Curtis[1]

[1]MRC Lifecourse Epidemiology Centre, University of Southampton, Southampton, United Kingdom

Denosumab is a well-established treatment for osteoporosis with excellent efficacy and safety data to ten years follow-up. It is prescribed in a variety of situations, from first line anti-osteoporosis treatment to a follow-on from other antiresorptives or from anabolic therapy. However, studies have suggested that, in some patients, stopping denosumab therapy is associated with an increased risk of vertebral fractures without offering an alternative treatment.

In this session, we will discuss the choice of patients in whom denosumab treatment is most appropriate, together with duration of treatment, benefit/risk balance, and considerations around transition to anabolic treatments or bisphosphonates. The attendee will gain a better understanding of the position of denosumab in the context of long-term anti-osteoporosis treatment.

MTE12
QUALITY OF LIFE ASSESSMENT IN SARCOPENIA-LESSONS FOR COHORT AND CLINIC

C. Beaudart[1,2]

[1]Department of Biomedical Sciences, Clinical Pharmacology and Toxicology Research Unit, Namur Research Institute for Life Sciences (NARILIS), Faculty of Medicine, University of Namur, Namur, Belgium, [2]WHO Collaborating Center for Public Health aspects of musculo-skeletal health and ageing, Division of Public Health, Epidemiology and Health Economics, University of Liège, Liège, Belgium

As global life expectancy continues to rise, sarcopenia presents itself as a significant public health challenge. The various consequences of sarcopenia, ranging from the development of physical disability to nursing home admission, depression, hospitalisation, and even mortality, are anticipated to significantly impact the health-related quality of life (HRQoL).

In response to this, health services have redirected their focus toward improving patient's HRQoL, and the heightened attention given to patients participating in research studies has led to many initiatives shifting towards patient-centred research. In the realm of interventional clinical studies targeting sarcopenia, it becomes imperative to holistically assess the impact of interventions on patients' HRQoL. Patient-Reported Outcome Measures (PROMs) emerge as invaluable tools for capturing patients' perspectives on their health and experiences. Government regulatory agencies, including the Food and Drug Administration (FDA) and the European Medicines Agency (EMA), have advocated for the incorporation of Patient-Reported Outcomes Measurements as primary or secondary outcomes in interventional studies.

In the field of sarcopenia, on specific PROM for measuring HRQoL has been developed in 2015 by Beaudart et al. The SarQoL questionnaire can be found at http://www.sarqol.org, and stands as the only validated, sarcopenia-specific HRQoL instrument in the scien tific literature. In December 2023, an individual patient-data meta-analysis including all observational studies using SarQoL to assess quality of life in sarcopenia has been published. This analysis, encompassing 32 studies (including 10 unpublished data studies), revealed a substantial decrease in HRQoL among sarcopenic indi viduals compared to their non-sarcopenic counterparts (Mean Difference = − 12.32; 95% CI = [− 15.27; − 9.37]). However, sig nificant heterogeneity was observed, prompting subgroup analyses that highlighted the impact of regional differences, clinical settings, and diagnostic criteria on the observed variations. The moderate level of evidence, as assessed by GRADE, underscores the importance of recognizing these nuanced factors when interpreting the relationship between sarcopenia and HRQoL measured by the SarQoL questionnaire.

This meta-analysis provides valuable insights into the specific domains of HRQoL affected by sarcopenia and reinforces the significance of employing condition-specific instruments for a more accurate assessment of patient experiences. This IPD-meta-analysis also provides important HRQoL measurement values that can be used as endpoints in clinical studies. Using PROMs in interventional clinical studies on sarcopenia would contribute to a more comprehensive understanding of clinically perceived benefits, fostering an assessment of treatment efficacy.

MTE13
PHOSPHATE WASTING FOR THE OSTEOPOROSIS DOCTOR

J. Bubbear[1]

[1]Royal National Orthopaedic Hospital, Stanmore, United Kingdom

Phosphate wasting disorders are uncommon, but may present in the osteoporosis clinic with low bone density, fractures and/or pain. Blood phosphate levels are influenced by intestinal absorption, renal reabsorption and excretion as well as distribution between intracellular spaces, extracellular phosphate and the storage pool of phosphate in bone. Causes of a low phosphate are broad and include both genetic causes, which can present late in life, and acquired causes. Rare genetic causes include X-linked hypophosphataemia and Hereditary hypophosphataemia with hypercalcuria. There is a wide range of acquired causes that will be discussed including hyperparathyroidism, medications and more rarely Tumour induced osteomalacia. It is important to have a structured approach to assessment of a low serum phosphate to identify the cause and instigate appropriate treatments. This can reduce the time to diagnosis for rarer causes of a low phosphate and ensure that treatment is appropriate.

Learning objectives of this interactive workshop are:

- To understand phosphate metabolism.
- To have a structured approach to investigating for underlying causes of a low serum phosphate.
- To be aware of treatment options for a low serum phosphate including the use of Burosumab in X-linked hypophosphataemia and some cases of Tumour-induced osteomalacia.

MTE14
MANAGEMENT OF GIOP (GLUCOCORTICOID-INDUCED OSTEOPOROSIS) IN LATIN AMERICA

O. D. Messina[1]

[1]IRO Medical Research Centre, Collaborating Centre WHO, Buenos Aires, Argentina.

Guidelines and recommendations developed and endorsed by International Osteoporosis foundation (IOF) are intended to provide guidance for particular pattern of practice for physicians who usually prescribe glucocorticoid (GC) therapy and not to dictate the care of a particular patient and are intended to promote a desirable outcome but cannot guarantee any specific outcome. In 2022 a panel of Latin American (LATAM) experts specialized in osteoporosis with recognized clinical experience in managing GIO patients and authors of several publications in this field met to produce evidence—based LATAM recommendations for the diagnosis and management of GIO. These guidelines are particularly intended to general practitioners and primary care physicians who prescribe GC in LATAM countries. These recommendations were based on systematic literature review using MEDLINE, EMBASE, SCOPUS and COCHRANE Library Database during the period from 2012 to 2021. Based in this methodology fifty statements was made according to Oxford Centre for the Evidence—Based Medicine (EBM) criteria. Among five GIO guidelines and Consensus initially identified, two of them (American College of Rheumatology 2017) and the Brazilian guidelines (2021) were selected for comparison considering the latter as the most current guidelines in LATAM region. Based on his methodology fifty statements were issued.(1, 2, 3)

Algorithm of diagnosis and management of GIO is depicted in Fig. 1.

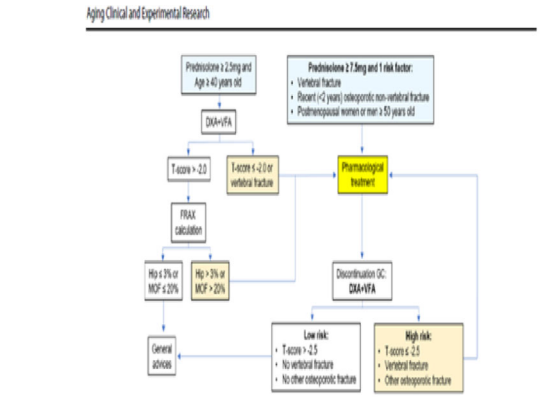

Fig. 1 Algorithm of diagnosis and management of glucocorticoid-induced osteoporosis. For women age 70 years and above, the intervention threshold set by NOGG is a MOF 10-year probability of 20% (or hip fracture probability of 4.8%) Assessment thresholds between which a BMD test would be undertaken to refine the probability assessment lie between 11 and 24%. Figure adapted from original article of Messina et al. [22]

- Table 1 depicts a comparison between ACR 2017 and Brazilian Guidelines 2021.

	ACR Guide 2017	Brazilian Guide 2020
Who should start prevention/treatment of GIOP?	All adults taking prednisone ≥ 2.5 mg/day for ≥3 months	All adults taking prednisone ≥ 5 mg/day for ≥3 months
Lifestyle changes for prevention/treatment of GIOP?	Smoking cessation; adequate diet; limit alcohol intake; weight bearing exercise	Smoking cessation; limit alcohol intake; avoid low body weight and sedentarism
Calcium/Vitamin D intake optimized to:	1000 to 1200mg/600 to 800IU per day. Reach serum 25OHD of 20 ng/mL	1000mg/500IU per day
Perform risk evaluation	Within 6 months of starting GC	Within 3 months of starting GC
BMD test to whom?	Adults < 40 years with a history of fragility fracture or severe risk factors All adults > 40 years	All the patients
Fracture risk stratification		
FRAX to evaluate fracture risk (**Adults ≥ 40 years**)	FRAX with GC dose adjustment	Brazilian FRAX model
High fracture risk	Prior fragility fracture T-Score ≤ -2.5 10-year risk of MOF ≥ 20% or ≥ 3%	Not available
Moderate fracture risk	10-year risk of MOF 10-19 % or >1% and <3%	Not available
Low fracture risk	10-year risk of MOF <10% or ≤1%	Not available
Adults < 40 years		
High fracture risk	Prior fragility fracture	Not available
Moderate fracture risk	Hip or spine Z-Score <-3, or Rapid bone loss (≥ 10% in 1 year) or continuing GC ≥ 7.5mg/day	Not available
Low fracture risk	None of the above risk factors	Not available
BMD threshold to prevent or treat men on GC	Not available	Prevention: T-Score ≤ 1 Treatment: T-Score ≤ 1.89
Vertebral fracture detection	Clinical assessment	X-Ray or DXA vertebral fracture assessment
Recommendations for special populations		
Children	Included	Included
Women of childbearing potential	Included	Included
People with organ transplant	Included	Not included
Patients on inhaled GC	Not included	Included
Patients on IV pulse GC	Not included	Included
Preferred initial pharmacological intervention for patients with moderate/high fracture risk	Oral bisphosphonates	Not stated
IV-Bisphosphonates; teriparatide; denosumab	Recommended for prevention and treatment	Recommended for prevention and treatment
Duration of pharmacological intervention	Discussed	Discussed
Definition of treatment failure	Discussed	Not discussed

GC= Glucocorticoid; BMD= Bone mineral density; 25OHD: 25-hydroxyvitamin D; MOF=

- Table 2 show a risk stratification of fractures in adults receiving GC therapy from ACR

Table 2 Risk stratification of fractures in adults receiving GC therapy from ACR guidelines

Fracture risk	High	Moderate	Low
Adults <40 years	History of osteoporotic fracture(s)	Hip or spine Z score <-3 or Rapid bone loss of ≥10% (at the hip or spine) over 1 year and Continuing GC treatment of ≥7.5 mg/day for ≥6 months	None of the above risk factors other than GC treatment
Adults ≥40 years	History of osteoporotic fracture(s) Hip or spine T-score ≤ -2.5 in men age ≥50 years and postmenopausal women FRAX® (GC adjusted) 10-year risk of major osteoporotic fracture ≥20% FRAX® (GC adjusted) 10-year risk of hip fracture ≥3%	FRAX® (GC adjusted) 10-year risk of major osteoporotic fracture 10 - 19% FRAX® (GC adjusted) 10-year risk of hip fracture >1% and < 3%	FRAX® (GC adjusted) 10-year risk of major osteoporotic fracture <10% FRAX® (GC adjusted) 10-year risk of hip fracture ≤1%

Table adapted from Buckley L et al. [6]

- Fig. 2 show the LATAM GIO panel proposal for pharmacological therapies according to fracture risk stratification

OPTIMISATION OF HIP FRACTURE SERVICES: LESSONS FROM THE REDUCE STUDY

C. Gregson[1]

[1]University of Bristol, Bristol, United Kingdom

Substantial variations remain in the delivery of hip fracture care across the United Kingdom despite well-established standards and guidelines. We aimed to predict adverse patient outcomes following hip fracture from modifiable hospital-level organisational factors and use findings to develop implementation tools to improve national hip fracture service delivery.

We used a national record-linkage cohort of 178,757 patients (age $\geq$ 60 years) with a hip fracture in England and Wales (2016–19). We linked patient-level hospital admissions, National Hip Fracture Database and mortality data with 231 metrics from 18 hospital-level organisational-level audits and reports. Multilevel models identified organisational factors, independent of patient case-mix, associated with patient outcomes: length of hospital stay, emergency 30-day readmission, 120-day mobility recovery, days in hospital and health costs over 365-days, and mortality (30- and 365-day) in 172 hospitals across England and Wales.

Over one-year patients with mean (SD) age 83 (8.6) years, spent 31.7 (32.1) days in hospital, costing £14,642 (£9,017), and 50,354 (28.2%) died. We identified 46 key organisational factors independently associated with one or more patient outcome, of which 13 were (a) associated with cost and/or bed-day savings over one year, (b) consistently associated with other positive patient outcomes, and (c) potentially modifiable. Factors included weekend physiotherapy provision (mean saving per patient/year: £676 [95% CI £67–1285]), orthogeriatrician assessment (£529 [£148–910]), direct admission to a hip fracture ward (3.4 [− 0.36 to 7.07] days), regular dissemination of audit data to staff (0.85 [0.30–1.39] days). These data have informed the development of a hospital-specific cost–benefit calculator, with model business cases for service improvement, specialty checklists, audit and 'how to' guides for complex care delivery.

All hospitals should try to provide the best available hip fracture care equally across the country. We identified multiple, potentially modifiable, organisational factors associated with important patient outcomes following hip fracture. Our practical and freely-available toolkit should help reduce variation in service delivery.

CSA-OC2
BONE MARROW ADIPOSITY: NEW UNDERSTANDING IN OSTEOPOROSIS PATHOGENESIS

J. Paccou[1]

[1]Department of Rheumatology, Lille University Hospital, Lille, France

Purposeofpresentation: This presentation focuses on the recent findings regarding bone marrow adipose tissue (BMAT) concerning bone health. We summarize the variations in BMAT in relation to age, sex, and skeletal sites, and provide an update on noninvasive imaging techniques to quantify human BMAT. Next, we discuss the role of BMAT in patients with osteoporosis and interventions that affect BMAT.

Recentfindings: There are wide individual variations with region-specific fluctuation and age- and gender-specific differences in BMAT content and composition. The Bone Marrow Adiposity Society (BMAS) recommendations aim to standardize imaging protocols to increase comparability across studies and sites. Water-fat imaging (WFI) seems an accurate and efficient alternative for spectroscopy (1H-MRS). Most studies indicate that greater BMAT is associated with lower bone mineral density (BMD) and a higher prevalence of vertebral fractures. The proton density fat fraction (PDFF) and changes in lipid composition have been associated with an increased risk of fractures independently of BMD. Therefore, PDFF and lipid composition could potentially be future imaging biomarkers for assessing fracture risk. Evidence of the inhibitory effect of osteoporosis treatments on BMAT is still limited to a few randomized controlled trials. Moreover, results from the FRAME biopsy substudy highlight contradictory findings on the effect of the sclerostin antibody romosozumab on BMAT.

Summary: Further understanding of the role(s) of BMAT will provide insight into the pathogenesis of osteoporosis and may lead to targeted preventive and therapeutic strategies.

CSA-OC3
STATE-OF-THE-ART IN HYPOPHOSPHATASIA: RECENT RECOMMENDATIONS FROM INTERNATIONAL WORKING GROUPS

M. L. Brandi[1,2]

[1]Fondazione FIRMO and Observatory for Fragility Fractures, Florence, Italy, [2]University San Raffaele, Milano, Italy

Hypophosphatasia (HPP) is an inborn error of metabolism caused by reduced or absent activity of the tissue non-specific alkaline phosphatase (TNSALP) enzyme, resulting from pathogenic variants in the ALPL gene. Clinical presentation of HPP is highly variable, including lethal and severe forms in neonates and infants, a benign perinatal form, mild forms manifesting in adulthood, and odonto-HPP. Diagnosis of HPP remains a challenge in adults, as signs and symptoms may be mild and non-specific. Disease presentation varies widely; there are no universal signs or symptoms, and the disease often remains underdiagnosed or misdiagnosed, particularly by clinicians who are not familiar with this rare disorder. The absence of diagnosis or a delayed diagnosis may prevent optimal management for patients with this condition.

The diagnosis of hypophosphatasia (HPP) is made on the basis of integrating clinical features, laboratory profile, radiographic features of the condition, and DNA analysis identifying the presence of a pathogenic variant of the tissue nonspecific alkaline phosphatase gene (ALPL). Often, the diagnosis of HPP is significantly delayed in both adults and children, and updated diagnostic criteria are required to keep pace with our evolving understanding regarding the relationship between ALPL genotype and associated HPP clinical features.

No formal diagnostic guidelines currently existed before for the diagnosis of this condition in children, adolescents, or adults. The International HPP Working Group is a comprised of a multidisciplinary team of experts from Europe and North America who have expertise in the diagnosis and management of patients with HPP.

Following consensus meetings, agreement was reached regarding the major and minor criteria that can assist in establishing a clinical diagnosis of HPP in adults and children.

These results will be presented and discussed at the WCO meeting.

World Congress on Osteoporosis, Osteoarthritis and Musculoskeletal Diseases (WCO-IOF-ESCEO 2024): Committee of National Societies Abstracts

OCs1
- P175 VARIATIONS IN HOSPITAL LENGTH OF STAY AND PERFORMED SURGICAL PROCEDURES AFTER HIP FRACTURES

A. Gasparik[1], L. Lorenzovici[1], M. Cevei[2], D. M. Farcas[2], D. Stoicanescu[3]

[1]Univ. of Medicine and Pharmacy of Tg Mures (UMFST), Tirgu Mures, [2]Universitatea Oradea, Oradea, [3]Univ. of Medicine V Babes Timisoara, Timisoara, Romania

Objective: The number of days spent in hospital (LoS) for osteoporosis and consequent fractures is higher than for myocardial infarction, stroke, breast cancer and chronic obstructive pulmonary disease. While most hip fractures are treated surgically, the LoS as well as the procedures performed to repair the fracture vary widely depending on many factors. Our aim was to define the patient and hospital characteristics that impacts these output variables.
Methods: We performed a retrospective study including 5993 inpatients registered during the years of 2018–2019 in 7 Romanian counties, with femoral neck, pertrochanteric, and subtrochanteric fractures. The following variables were registered: demographic characteristics of the patients, diagnosis code, duration of hospital stay, therapeutic procedure, hospital category (clinical, county, municipal), county where the surgery was performed, and in-hospital death.
Results: Regression analysis was used to examine variations in duration of care, procedures performed and death while controlling for patients' gender, setting (urban/rural), diagnosis, hospital category and region. Average age was 77.2 y (86% 65 +), mean length of hospital stay was 13.3 d (varied between 9.6-Vaslui and 14.6-Arad county). Urban residents and men spent significantly more days in the hospital (p .000 and .019). LoS was significantly longer also among older patients, in subtrochanteric fractures and *county* hospitals. The other analyzed dependent: the surgical procedure significantly correlated (when controlled for diagnosis 72.0, 72.1, 72.2 codes) with the following variables: urban vs. rural setting, diagnosis, type of hospital, age, length of care and in-stay death. Some of the variations observed are consistent with the international epidemiological data. Urbanity/rurality and gender dependence is noted in the literature for fracture incidence, LoS and mortality, however, no data was found for procedure choices based on patient gender and setting. The seemingly unexplainable variations raise the question of possible arbitrary (subjective/preferential) and professionally unjustifiable health technology choices.
Conclusion: Our study revealed that Los is significantly higher among men, urban residents and when hospitalized in a county unit. High variations are observed among fixation procedures depending on gender, setting, and hospital category. Exploring these complex patterns, the causes of the variations, solutions might be identified for optimal medical choices, reduction of prolonged care and a better resource allocation.

- P317 LESSONS FROM RICO: RISK COMMUNICATION IN OSTEOPOROSIS STUDY

C. Beaudart[1], M. Sharma[2], S. Silverman[3], M. Hiligsmann[4]

[1]Clinical Pharmacology and Toxicology Research Unit (URPC), NARILIS, Dept. of Biomedical Sciences, Faculty of Medicine, Univ. of Namur, Namur, Belgium, [2]The OMC Research Center, Beverly Hills, USA, [3]Cedars-Sinai Medical Center, UCLA, Los Angeles, USA, [4]Dept. of Health Services Research, Care and Public Health Research Institute (CAPHRI), Maastricht Univ., Maastricht, Netherlands

Objective: There is a close and strong relationship between the quality of fracture risk communication and the initiation of osteoporosis treatment and adherence. RICO was a global study, run in 2022, involving 332 participants at risk of fracture aiming to improve fracture risk communication and to understand patients' willingness to initiate treatment based on their perception of fracture risk.
Methods: Semi-structured interviews were conducted in 11 centres, 9 countries around the world (UK, Belgium, the Netherlands, Spain, Japan, Canada—Hamilton and Montreal, Argentina, Mexico, USA—Los Angeles and Spokane). The participants' Fracture Risk Decision Point (FRDP) was established as the fracture risk at which a participant was willing to initiate therapy. For that, participants were shown 8 distinct scenarios—each with a hypothetical FRAX score and a standard 40% fracture risk reduction upon use of a medication with minor, transient side effects. In each scenario, participants were asked whether they would hypothetically agree to initiate the medication.
Results: The major finding of RICO study was that participants expressed a strong willingness to receive communication about their fracture risk. Globally, they preferred visual to numeric presentations of FRAX data. Among the format presented, colored stoplight was preferred to icon array. Median FRDP was below the national treatment threshold in all eight countries which use FRAX®-based treatment thresholds in a clinical setting. Moreover, 75.7% of all participants demonstrated FRDP below their respective treatment threshold. Patients who demonstrated higher levels of numeric literacy also showed a significantly higher median FRDP (i.e. 10%) compared to those with a lower level of numeric literacy (i.e. FRDP of 5%, $p < 0.001$). FRDP was not influenced by age or history of fracture. Among participants who agreed to initiate medication with an hypothetical 40% of fracture risk or less, a weak and negative correlation was found between FRDP and age ($r = -0.153$, $p = 0.007$).
Conclusion: Fracture risk communication with FRAX may be improved with visual presentation and use of both 2- and 10-year time frame. The RICO team is currently developing a fracture risk communication tool.

- P498 FROM PIXELS TO PREVENTION: AI-POWERED DIGITAL RADIOGRAMMETRY DEMOCRATIZES OSTEOPOROSIS DIAGNOSIS.

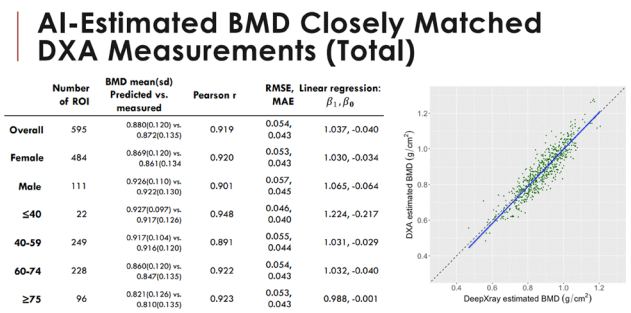
F. Shau-Huai[1], L. Cheng Wei[2], L. Chia-Hung[2], J. Yu-Ming[2], T. Qingzong[2], L. Yen-Jun[3]

[1]Dept. of Orthopedics, National Taiwan Univ. Hospital Yun-Lin Branch, Douliu, [2]Alpha Intelligence Manifolds, Taipei, [3]Radiology Dept., Far-Eastern Memorial Hospital, New Taipei City, Taiwan

Objective: BMD, assessed through DXA, is the gold standard for diagnosing osteoporosis. However, the availability of DXA remains a challenge, especially in rural areas. This study investigates the estimation of BMD from standard pelvic radiographs as an alternative.
Methods: The study employed deidentified data from Far Eastern Memorial Hospital and three primary care clinics in Taiwan, including 2235 patients with 2321 paired pelvic radiograph-DXA samples. The BMD values obtained from standard DXA scan within ± 6 months of the Xray imaging time were used as the ground truth value for AI model training. A hip landmark model was developed to extract radiogrammetric parameters, such as Cortical

Thickness Index and Femoral Neck Width. Test-time intensity augmentation and ablation studies were performed to assess feature contributions. An AI-augmented radiogrammetric BMD estimation model was developed based on the RegNet neural network architecture while incorporating radiogrammetric features. The model was trained with paired Xray-DXA data from 85% of the patients. The remaining 15% of patient data was reserved for model performance testing. Pearson correlation and RMSE between model-predicted and DXA-measured BMD were evaluated. Binary classification performance of the model for osteoporosis was also assessed.

Results: In the test set of 595 hip x-ray-DXA BMD pairs (81.3% female, mean age 61.4 y), the prevalence of osteoporosis was 24.7%. The Pearson correlation between predicted total hip BMD and measured BMD was 0.919. Subgroup analysis for female and male showed correlations of 0.920 and 0.901, respectively. Correlations remained strong across age groups. Predicted femoral neck BMD and measured BMD correlated at 0.868. Using a T-score ≤ -2.5 as the cutoff, the positive predictive value was 0.903, the negative predictive value was 0.907, and the ROC AUC was 0.950.



Conclusion: The AI model estimates BMD by radiogrammetry rather than absorptiometry, providing a robust and accurate BMD estimate that is highly correlated with DXA-measured BMD. This correlation allows rapid classification of osteoporosis according to established criteria. In addition, the implementation of an opportunistic screening strategy can expand diagnostic coverage, particularly benefiting rural areas.

OCs4
- P660 VERTEBRAL FRACTURES BY DXA: IS THE CURRENT DEFINITION ADEQUATE?

J. L. A. Morales Torres[1], J. Romero Ibarra[1], J. Morales Vargas[2]

[1]Hospital Aranda de la Parra, [2]Morales Vargas Centro de Investigacion, Leon, Mexico

Objective: Osteoporotic vertebral fractures (VF) indicate reduced bone strength and predict new fractures. Their identification in patients with suspected osteoporosis (OP) by DXA-based Vertebral Fracture Assessment (VFA) improves current definition of OP[1]. We aimed to describe the frequency of VF in patients referred to an osteodensitometry (ODM) center using the commonly accepted definition.

Methods: We included patients referred for an ODM study, who underwent a VFA as they met criteria for it[2]. VFA studies were performed on a GE-Lunar, iDXA device. We report the frequency of VF defined as a loss of vertebral body height of $\geq 20\%$ in one or more segments[1]. The characteristics of those with and without VF are compared by Student's t-test.

Results: We included 1226 patients (91.9% women) with a mean age of 74 ($\pm$ 8.5) y, seen since the end of 2021. Of these, 807 (65.8%) had at least one VF and 419 (34.2%) had none. Their characteristics are summarized in Table 1. Mean BMD is significantly lower in the VF population.

Table 1. Characteristics of the patients included

	No fracture (n=419)	With fracture (n=807)	P
Mean age	73.2 (±8.28)	74.82 (±8.71)	0.0017
Mean height	154.1(±10.41)	152.1(±8.39)	0.0003
Mean Weight	64.67(±13.56)	62.84(±11.91)	0.0136
Spine BMD (± SD)	1.028 (±0.207)	0.982 (±0.214)	0.0003
Spine BMD (± SD)	0.854 (±0.164)	0.777 (±0.152)	0.0001

Conclusion: Prevalence of VF in the community is 19.2 for women and 9.8 for men in Mexico[3]. Findings of this report exceed that. Population referred to ODM is more likely to have OP but, is the 20% limit adequate to define the presence of a fracture? Current paradigm prompts to consider all patients with a VF as having OP and requiring pharmacological therapy[1]. We found a high frequency of VF by VFA. According to the current definition, all such patients should be considered candidates for OP treatment.

- P754 ANXIETY AND DEPRESSION ARE ASSOCIATED WITH POOR HEALTH BEHAVIOURS AND INCIDENT FRACTURE AMONG WOMEN: FINDINGS FROM THE HERTFORDSHIRE COHORT STUDY

L. D. Westbury[1], G. Bevilacqua[1], C. Cooper[1], E. M. Dennison[1]

[1]MRC Lifecourse Epidemiology Centre, Univ. of Southampton, Southampton, UK

Objective: A recent systematic review has highlighted possible links between depression and fracture risk, but no information regarding possible explanatory health behaviours was available. In this study we used a well phenotyped community-dwelling cohort of older adults (the Hertfordshire Cohort Study) to consider these associations further.

Methods: Data from 2997 men and women, aged 59–73 y at baseline, were analysed. At baseline, mental health characteristics and health behaviours were ascertained through clinician-administered questionnaires. Anxiety and depression (mild or worse) were identified by scores of > 7 on the corresponding Hospital Anxiety and Depression Scale. Health behaviours included current smoking, alcohol consumption, diet quality and physical activity (Dallosso questionnaire). Incident fractures were identified using ICD-10 codes from Hospital Episode Statistics data, available from baseline (1998–2004) until December 2018. Health behaviours in relation to anxiety and depression were examined using logistic regression; anxiety and depression in relation to incident fracture were examined using Cox regression. All analyses were sex-stratified and adjusted for age; $p < 0.05$ was regarded as statistically significant.

Results: Prevalence of anxiety was 15% among men and 25% among women; prevalence of depression was 5% among men and 6% among women. Overall, 9% of men and 22% of women had a fracture during follow-up. Among men and women, poorer diet quality and lower physical activity were associated with depression; these health behaviours were also associated with anxiety among men. Current smoking was associated with anxiety and depression among women. Among women, anxiety (hazard ratio (95% CI): 1.34 (1.05, 1.72), $p = 0.019$) and depression (1.76 (1.18, 2.64), $p = 0.006$) were related to increased risk of incident fracture; among men, associations for

anxiety (p = 0.198) and depression (p = 0.265) in relation to fracture were weaker.

Conclusion: Anxiety and depression were associated with increased risk of incident fracture among women, possibly due to their association with poor health behaviours, which are established risk factors for fracture. Preventive strategies are required to address poor health behaviours and mental health among older adults.

OCs6
- P952 BONE MINERAL DENSITY AND HAND GRIP STRENGTH IN POSTMENOPAUSAL WOMEN WITH FOREARM FRACTURES

I. Stets[1], A. Iniushyna[1], D. Kurylo[1], A. Musiienko[1], N. Grygorieva[1]

[1]D. F. Chebotarev Institute of Gerontology, NAMS of Ukraine, Kyiv, Ukraine

Objective: Forearm fractures (FF) are one of the important osteoporotic fractures that increase the risk of other osteoporotic fractures in the future and lead to temporary or even permanent decrease in a patient's functional capabilities. The study aimed to assess BMD and hand grip strength in postmenopausal women depending on previous FF.

Methods: 150 postmenopausal women (average age 66.9 ± 8.5 y) were examined and divided into 2 groups. Group I consisted of 75 persons without any previous fractures and Group II included 75 females with previous FF (age at the time of the fracture 57.1 ± 10.1 y, duration of the period after a fracture—10.0 [2.0–16.0] y). BMD, T, and Z-scores of the lumbar spine, hip, femoral neck, and radius were measured using DXA (Hologic Discovery WI, USA, 2016). Muscle strength was assessed by handgrip strength of both hands using a spring hand dynamometer.

Results: The women of both groups did not differ significantly by age and height; however subjects with FF had a significantly lower body mass (67.4 ± 11.7 and 79.8 ± 14.9 kg, respectively), BMI (25.8 ± 4.0 and 30.1 ± 5.4 kg/m^2), age of menopause (48.1 ± 4.5 and 50.3 ± 3.4 years, for all parameters $p < 0.001$) and higher duration of postmenopausal period (19.2 ± 9.4 and 16.1 ± 8.5 y, $p < 0.05$). BMDs of the lumbar spine, hip, femoral neck, and radius of females with FF were significantly lower than the parameters of subjects without fractures.

Despite the absence of the BMD differences at broken and unbroken forearm (0.535 ± 0.089 and 0.538 ± 0.090 g/cm^2, respectively, 0.622 ± 0.060 g/cm^2 for Group I), significantly lower muscle strength was established at the side of broken forearm (16.0 [12.0–20.0] kg) compared to other hand (18.0 [15.0–23.0] kg, $p < 0.001$).

Conclusion: Women with previous FF had lower mass, BMI, and age of menopause and worse BMD parameters compared to females without previous fractures. Despite the absence of the BMD differences at the broken and unbroken forearm, hand grip strength was worse at the side of the broken forearm, which confirms the negative FF consequences for a long time after the fracture.

OCs7
- P1181 ORTHOGERIATRIC CO-MANAGEMENT FOR OLDER PATIENTS WITH A MAJOR OSTEOPOROTIC FRACTURE: AN OBSERVATIONAL PRE-POST STUDY

S. Janssens[1], A. Sermon[2], M. Deschodt[1], K. Fagard[1], M. Cerulus[3], H. Cosyns[3], J. Flamaing[1], M. Herteleer[2], M. Dejaeger[1]

[1]Dept. of Public Health and Primary Care, Division of Gerontology and Geriatrics, KU Leuven, [2]Dept. of Development and Regeneration, Division of Locomotor and Neurological Disorders, KU Leuven, [3]Dept. of Geriatric Medicine, Univ. Hospitals Leuven, Leuven, Belgium

Objective: To evaluate if nurse-led orthogeriatric co-management in patients with a major osteoporotic fracture results in better outcomes than inpatient geriatric consultation.

Methods: This single-center observational pre-post effectiveness study took place at the traumatology ward of the University Hospitals Leuven in Belgium. We evaluated 108 patients aged 75 y and older hospitalized with a major osteoporotic fracture in each cohort (usual care group with inpatient geriatric consultation vs. nurse-led orthogeriatric co-management). The intervention included proactive geriatric care, a patient's self-reported evaluation of premorbid status, a comprehensive geriatric evaluation followed by multidisciplinary interventions, and systematic follow-up. The primary outcome was the proportion of patients having one or more in-hospital complications. Additionally, a process evaluation of the intervention's core components and adherence to proactive geriatric care processes was performed.

Results: After controlling for confounding variables in a multivariable logistic regression model, the odds for any in-hospital complication in the intervention group decreased by 51% compared to the usual care group (OR = 0.49 (95% CI 0.26–0.92), p = 0.027). Delirium incidence decreased by 13% (34 vs. 21%; p = 0.003). Furthermore, the incidence of congestive heart failure and pneumonia decreased by 3% (p = 0.269) and 5% (p = 0.119), respectively. No differences were observed in the incidence of deep venous thrombosis, pulmonary embolism, myocardial infarction, urinary tract infection, and in-hospital mortality. Adherence to the intervention's core components was as follows: completion of a self-reported questionnaire to map premorbid status (38%), multidimensional evaluation (100%), development of an individual care plan (100%), and systematic follow-up (81%). Regarding the proactive geriatric care processes, screening for dysphagia and daily food intake were introduced in clinical practice (0% vs. 70%, 0% vs. 52%), more patients received a laxative if they did not pass stool (67 vs. 94%), and more patients received calcium-vitamin D supplements (20 vs. 58%), all significant with $p < 0.001$.

Conclusion: Implementation of nurse-led orthogeriatric co-management resulted in significantly higher fidelity to proactive geriatric care processes and in a significant reduction of in-hospital delirium incidence and an overall reduction in in-hospital complication rate.

OCs8
- P1355 UNITING THE DICHOTOMY BETWEEN PRIMARY AND SECONDARY PREVENTION OF OSTEOPOROSIS: A COMMUNITY-BASED INTERVENTION

Y. El Miedany[1], A. Gadallah[2], M. Sarhan[3], M. Elgaafary[2], A. Ahmed[3]

[1]Canterbury Christ Church Univ., Canterbury, UK, [2]Ain Shams Univ., Cairo, Egypt, [3]Egyptian Food Bank, Cairo, Egypt

Objective: Osteoporotic fractures, are associated with consequent negative impacts on health, quality of life, functional ability as well as independence. The overarching goal of treating osteoporotic patients is to reduce the incidence of fractures, yet interventions that support early detection of osteoporosis and prevention of osteoporotic fractures are underutilized. Recently, a groundbreaking collaboration between the WHO with ESCEO and the IOF for the prioritization of osteoporosis and fragility fracture prevention within global healthcare policy. In concordance with this new approach, this project has been launched to lay the groundwork for a national approach for prevention of osteoporosis and fragility fractures in Egypt. Aims: 1. to set up a national program implementing "Targeting to Treat" approach to

identify and treat subjects at high or very high risk of fragility fracture in care homes in Egypt. 2. To assess the applicability of using a comprehensive questionnaire for assessing the risk of fractures in older adults in the community. 3. To evaluate the evidence on interventions for preventing fracture in older adults.

Methods: This is a national quality improvement program adopting a Plan, Do, Study, Act (PDSA) cycle methodology. The project is a joint activity provided by the Egyptian Food bank and the Egyptian Academy of Bone and Muscle Health in collaboration with the ministry of Social Solidarity. All older adults living in care homes in Egypt, aged 50-years and above have been invited to join this project of primary prevention of osteoporosis. A list of eligible patients was generated through the national record. Every participant has been invited to complete a questionnaire to assess for Fracture risk, Falls risk, Sarcopenia Risk, functional disability, as well as comorbidities and current medications intake. US scan of the heals will be carried out for every enrolled person. Patients at high/very high fracture risk will be subjected to DXA scan. Rehabilitation program will be provided by local physio teams under supervision of the Rehab physicians to reduce sarcopenia and fall risk. Patient education and counselling program will be provided by the treating doctors. This work describes the protocol of the activity which has been set up in Cairo and Giza as an initial phase. Blood tests for Vitamin D serum levels and bone profile will be assessed for all subjects enrolled in this work. Supplement therapy will be provided for those participants wherever required.

Results: Reviewing the self-completed questionnaire will facilitate the recognition of subjects at high/very high fracture risk, high falls risk as well as sarcopenia risk. The patients will be stratified according to the underlying pathology and risk factors. Rehab program will be set up to tackle these risk factors. The Egyptian food bank will provide food and vitamin D supplement to the elder in need, identified based on their lab tests. Osteoporosis therapy will be offered according to national guidelines to the patients according to their fracture risk. Regular monitoring of the patients will be carried out to check for the progress of the falls and sarcopenia status as well as adherence to therapy.

Conclusion: This community intervention program of screening for osteoporosis, falls and sarcopenia along with continued medical care and patient education is expected to result in a significant improvement in the musculoskeletal healthcare in the care homes that we hope to expand to cover all the care homes at the national level. Providing comprehensive pharmacological as well as non-pharmacological management is expected to reduce the risk of developing fragility fractures.

OCs9
- P839 HAND GRIP STRENGTH IN PATIENTS WHO DIAGNOSED WITH TYPE 2 DIABETES MELLITUS IN MONGOLIAN FAMILY HEALTH CENTER

M. Jaalkhorol[1], E. Jamsranjav[1], E. Radnaa[2], B. Bat-Orgil[3], G. Ochirdorj[1], O. Bold[4]

[1]Univ. of National Medical Sciences, [2]Buyant Onoshilogoo Hospital, [3]Singapore School, [4]National Center for Communicable Diseases, Ulaanbaatar, Mongolia

Objective: Despite the many clinical studies in Mongolia, no study has measured the hand grip strength (HGS) of citizens diagnosed with diabetes mellitus. The present study aimed to measure the HGS of people diagnosed with type 2 diabetes mellitus (T2DM) at family health centers in Ulaanbaatar city.

Methods: The study was conducted using a cross-sectional survey and included 347 participants over age 40 who had T2DM in the family health center. Hand grip strength was measured using a digital dynamometer (TKK-5101; Takei Scientific Instruments, Tokyo, Japan). HGS was measured by a handheld dynamometer with maximum effort; two attempts were made with each hand. HGS was defined according to the Asian Working Group for Sarcopenia (AWGS) criteria as low handgrip strength (< 18 kg for females). Relationships between variables were assessed by Pearson's linear correlation coefficient.

Results: We recruited 347 participants whose mean age was 59.87 $\pm$ 8.93 y. 59.9% (n = 208) of the participants were women and 40.1% (n = 139) were men. 81.3% of the participants had hypertension, 42.1% had cardiovascular disease, 36.0% had ophthalmic disease, 28.2% had kidney disease, and 26.8% had rheumatoid arthritis. By age group, the grip strength of the right hand in men was the highest in the 40–49 age group (32.23 $\pm$ 9.33 kg), while in women the highest was in the 40–49 age group (20.66 $\pm$ 5.62 kg). The median male grip strength of the participants was 30.5 kg, with a minimum value of 9 kg and a maximum value of 53 kg, while the average left-hand grip strength was 28 kg, with a minimum value of 2.5 kg and a maximum value of 50 kg. Age and diabetic variables were significantly correlated with handgrip strength in male patients ($r = 0.237$, $p < 0.001$). A strong positive correlation was found in females between handgrip strength and pregnancy diabetes ($r = 0.865$, $p < 0.001$). Also type 2 diabetes duration, occurrence of leg ulcer and rheumatoid arthritis, and handgrip strength were significantly associated.

Conclusion: The average hand grip strength of both hands significantly differed between age groups, decreasing with age. There were significant sex differences in HGS within each age group, favoring men.

OCs10
- P506 MACHINE LEARNING TO CHARACTERIZE BONE BIOMARKERS PROFILE IN RHEUMATOID ARTHRITIS

G. Adami[1], D. Gatti[1], C. Benini[1], O. Viapiana[1], A. Fassio[1], M. Rossini[1]

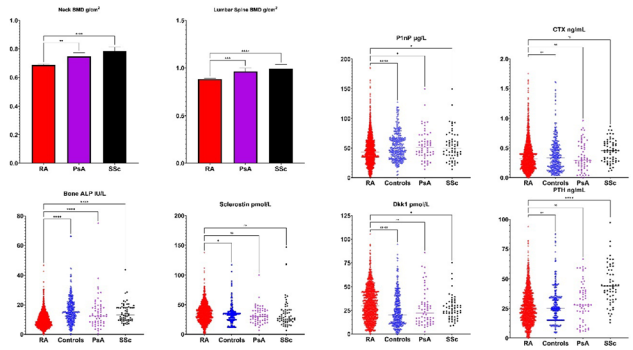
[1]Univesity of Verona, Rheumatology Unit, Verona, Italy

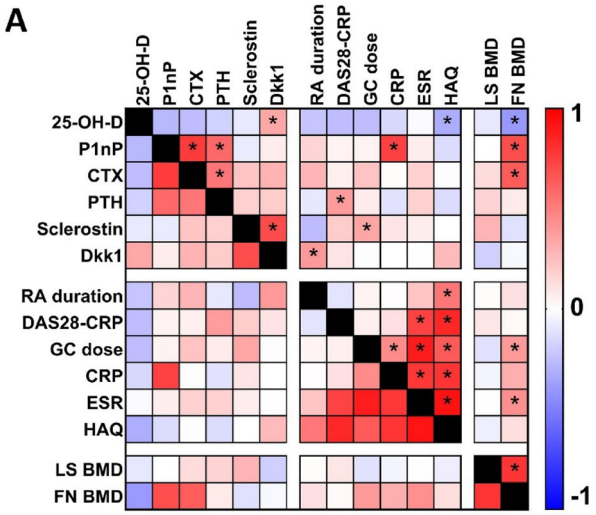
Objective: Bone metabolism is disrupted in rheumatoid arthritis (RA); however, the bone metabolic signature of RA is poorly known. The objective of the study is to further characterize the bone metabolic profile of RA and compare it to psoriatic arthritis (PsA), systemic sclerosis (SSc) and healthy controls.

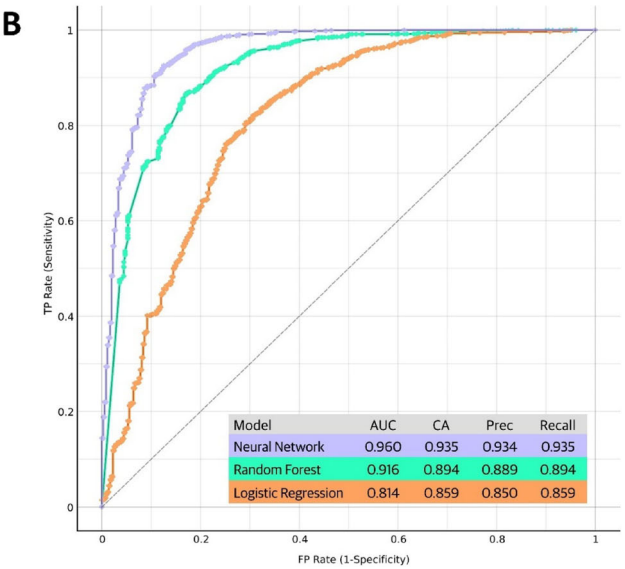
Methods: We did a cross-sectional case–control study on consecutively enrolled patients and age-matched controls. We collected clinical characteristics, serum biomarkers related to bone metabolism and BMD. A multiple correlation analysis using Spearman's rank correlation coefficient was conducted within the RA patient group to investigate associations between biomarker levels and clinical variables. Machine learning (ML) models and principal component analysis (PCA) was performed to evaluate the ability of bone biomarker profiles to differentiate RA patients from controls. We ran three different ML models (random forest, neural network, logistic regression) considering the following features in addition to all serum biomarkers tested: cumulative glucocorticoid intake, age, gender, CRP levels, csDMARD and b/tsDMARD use. To assess the performance of these machine learning models, we employed standard evaluation metrics, including classification accuracy (CA), precision, recall, and receiver operating characteristic (ROC) curves with area under the curve (AUC) analysis. We implemented cross-validation (10 folds, stratified) to ensure the robustness of our models and mitigate overfitting.

Results: A total of 1883 participants were included in the analysis, comprising 1462 RA patients, 60 PsA patients, 62 SSc patients, and 359 age-matched healthy controls. We found significantly lower

BMD in RA patients compared to PsA, and SSc groups. RA patients exhibited higher Dkk1, sclerostin and lower P1nP and B-ALP levels compared to controls. No significant differences in CTX levels were noted. Figure 1 shows the relevant markers. Correlation analysis revealed associations between bone biomarkers and clinical variables (Fig. 2A). PCA and ML highlighted distinct biomarker patterns in RA which can effectively discriminated bone biomarkers profile in RA from controls (Fig. 2B).







Conclusion: Our study helped uncover the distinct bone profile in RA, including changes in bone density and unique biomarker patterns. These findings enhance our comprehension of the intricate links between inflammation, bone dynamics, and RA activity, offering potential insights for diagnostic and therapeutic advancements in managing bone involvement in this challenging condition.

World Congress on Osteoporosis, Osteoarthritis and Musculoskeletal Diseases (WCO-IOF-ESCEO 2024): Non-Sponsored Symposium Abstracts

NSS1
UNMET GOALS OF TREATED PATIENTS

M. McClung[1,2,3]

[1]Endocrinology-Oregon Osteoporosis Center, Portland, United States, [2]Clinical Investigator, Portland, United States, [3]IOF Board of Directors, Portland, United States

Osteoporosis is a chronic condition characterized by low bone mass (bone mineral density) and disordered skeletal microarchitecture that results in increased risk of fracture. The objectives of treating our patients with osteoporosis is to increase bone strength and to reduce the risk of fracture. Patients need reassurance that the treatment they take is having the desired effect. Unfortunately, we do not have a metric that identifies each fracture that the treatment prevents. Furthermore, even our most effective therapies only reduce overall fracture risk by about 50%. Patients are often disappointed when fractures occur while on therapy, but we must help them appreciate that none of our therapies prevent all fractures, and that the risk of subsequent fractures is reduced while patients remain on therapy.

Our common measures of success include changes in either biochemical markers of bone turnover or bone mineral density. Changes in bone markers are more a measure of treatment compliance than of efficacy whereas the magnitude of treatment-related changes in BMD correlate with the efficacy of therapy to reduce fracture risk. (1) Ofttimes, for a variety of reasons (poor compliance with dosing rules, nutritional deficiency or especially previous osteoporosis therapy, BMD responses to therapy are not observed. In a large observational study, these predictors of treatment failure were identified: poor SF 36 vitality score, two or more falls in the past year and history of prior fracture.(2) Obviously, each of these is a well-known risk factor for fracture.

The concept of goal-directed therapy proposes choosing an appropriate surrogate treatment objective—more commonly a specific BMD target.(3) Such an approach informs choices of both initial therapy and follow-on therapy. When confronted with a fracture on therapy or an inadequate BMD response, the patient should be re-evaluated for possible secondary confounding conditions and compliance should be reassessed before making decisions about continuing or changing therapy. An IOF Working group provided empiric definitions of treatment failure necessitating a change in therapy, including having multiple fractures while on therapy or having a single fracture combined with either significant bone loss or inadequate change in markers of bone turnover. (4) There is scant data about the effects of changing therapy on fracture risk. Understanding the effects of continuing or changing therapy is necessary to make that decision.

NSS2
IMPROVING EFFICACY AFTER POOR OUTCOMES

B. Muzzi Camargos[1,2]

[1]Gynecology-Densitometry-Rede Mater Dei, Belo Horizonte, Brazil, [2]IOF Committe of Scientific Advisors, Belo Horizonte, Brazil

A fracture is an undesirable outcome. Treatments do not eliminate fracture risk: but reduce it. Treatment failure is defined as two or more incident fractures while on antiosteoporosis medications. (1,2)

Self-reported fragility, higher FRAX, recent falls, comorbidities, fractures, glucocorticoids, arm-assisted assist standing, and weight loss are variables associated to suboptimal response to treatment. Multivariable modeling identified 03 independent predictors associated to treatment failure: worse SF-36 score, $\geq$ 2 falls in the past year, and prior fracture. (3)

From these three, two of them are modifiable. SF-36 reflects physical activity and mental wellness. Improvements here shall addresse homecare, physiotherapy, nutrition and psychotherapy. Propensity to falls includes home-safety measures, balance training, management of drugs and routines potentially linked to falls. IOF provides a website on nutrition, exercises and safety measures recommended for fracture prevention; at https://www.buildbetterbones.org.

Although precise thresholds for bone suppression rate isn't established, lower-than-placebo CTX-1 levels are found in patients on antiresorptive treatment. Poor compliance is suspected when bone turnover markers are not reduced by antiresorptive therapy. Bone turnover markers are also helpful, when denosumab is discontinued. Bone formation markers, like P1NP, showed good correlation to anabolic agents. (4,5)

Bone mineral density (BMD) is a surrogate marker of fracture risk reduction and treatment response. It has been used in pivotal clinical trials. Long-term bisphosphonate users significantly improve their BMD mostly at first 3–5 years. Later then, BMD curve trends to a *plateau*. DMAB has demonstrated a sustained BMD gain through 10 years, with no evidence of *plateau* effect. BMD potentially trends down quickly at DMAD withdrawal. Romosozumab has shown remarkable BMD improvements, and may offer the largest BMD accrual on the first year of treatment. BMD follow-up on treatment can also reassure medication effect or arise concerns about failure if bone loss occurs. (6)

In conclusion, close individual care, biochemical tests and imaging assessment should be performed before switching medications, if an incident fracture occurs during osteoporosis treatment.

NSS3
CLINICAL PERSPECTIVES AFTER A FRACTURE: COULD IT BE ANY WORSE?

G. Altamar[1,2,3]

[1]Specialist in Internal Medicine and Geriatrics, Cali, Colombia, [2]Professor of Geriatrics in Valley University, Cali, Colombia, [3]President of Colombian Osteoporosis Association-ACOMM, Bogota, Colombia

Osteoporosis is a disease with low bone mass that leads to decreased bone strength and an increased risk of low trauma fractures. The primary aim of therapeutic intervention in osteoporosis is to prevent fragility fractures and their consequences. The available osteoporosis therapies (OT) reduced in trials the risk of fracture by 30–50%. Health professionals must expect incident fractures despite pharmacological treatment. Treatment failure is defined as two or more incident fractures while on OT. Its frequency is variable and depends on epidemiology differences between studies. It's been identified as risk factors to treatment failure: lower SF- 36 vitality score, two or more falls in the previous year, and prior fracture. Even more, the characteristic of patients who suffer major osteoporotic fractures despite treatment to bisphosphonates are number of comedications, dementia, prior fracture, and ulcer disease. In patients with rheumatoid arthritis daily glucocorticoid dosage, immobilization and inflammatory activity of disease are factors to failure. In the retrospective part of the ICARO study, being older and more frequently had multiple vertebral deformities were characteristics for inadequate response to treatment.

Considerations about the diagnosis, choice of initial therapy, and pharmacological adherence are necessary when there is a failure at the OT. If the diagnosis corresponds to primary osteoporosis, an adequate differential diagnosis was made, pharmacological therapy included adequate intake of calcium and vitamin D, associated with non-pharmacological therapy, and the patient is not in the group of who abandon therapy in the first year, other questions need to be considered: do we need specific treatments tailored to the needs of different patients? Frailty elderly people, severe chronic diseases like chronic obstructive pulmonary disease with respiratory insufficiency, heart failure, and dementia were no included in pivotal studies. Patients with polypharmacy and severe disability probably has difficulties to remain adherent to the treatment.

It's time to ask ourselves if the pharmacological current options could be not sufficient and if clinical repercussions of treatment failure, could it be any worse.

PSORIATIC DISEASE. MUSCULOSKELETAL MANIFESTATIONS

L. Athanassiou[1]

[1]Department of Rheumatology, Asclepeion Hospital, Voula, Athens, Greece

Psoriatic disease is a multifaceted disease which affects all organ systems, amongst those the musculoskeletal system and the skin. The disease has major comorbidities, including the metabolic syndrome. Patients may present with obesity, diabetes mellitus type 2 and arterial hypertension. The disease is an autoinflammatory disease and has a course with flares and remissions. Psoriatic disease presents with psoriatic arthritis and psoriasis. Psoriatic arthritis affects the enthesis, ie the area where tendons attach to the bone. Enthesitis, arthritis, spondylitis are manifestations of psoriatic arthritis. Most patients present with psoriasis and later on may develop psoriatic arthritis. However, in some cases psoriatic arthritis is the first manifestation and later on psoriasis may appear. Pain due to arthritis and enthesitis is a major therapeutic challenge in patients with psoriatic disease. Management of musculoskeletal manifestations is a major issue in the long-term management of psoriatic disease.

NSS5
PSORIATIC DISEASE. COMORBIDITIES

I. Kostoglou-Athanassiou[1]

[1]Department of Endocrinology, Diabetes and Metabolism, Asclepeion Hospital, Voula,, Athens, Greece

Psoriatic arthritis and psoriasis are systemic autoinflammatory diseases which are recently known as psoriatic disease. The disease has a variety of phenotypes and is well known for the involvement of all organ systems. The disease is characterized by an elevated risk of metabolic syndrome, characterized by abdominal obesity, hypertension, hyperglycemia, hyperuricemia and hyperlipidemia. Psoriatic disease and the associated metabolic syndrome may be related to the presence and overexpression of inflammatory cytokines. This association of a systemic inflammatory disease which affects the joints and the skin with the metabolic syndrome confers an increased cardiovascular risk. In addition, the severity of the metabolic syndrome is associated with increased severity of the psoriatic disease and the need for treatment modulation. Fatty liver disease may also accompany psoriatic disease. Inflammatory bowel disease may also be observed in psoriatic disease. Uveitis may also be a manifestation of psoriatic disease. In patients with psoriatic disease the various components of the metabolic syndrome should be therapeutically targeted to decrease the cardiovascular risk.

NSS6
PSORIATIC DISEASE. PSYCHOSOCIAL IMPLICATIONS

Y. Athanassiou[1]

[1]Trinity College, Dublin, Ireland

Psoriasis and psoriatic arthritis are known to occur after a major stress. The disease itself may cause depression. Psoriasis is related with disturbed social integration due to skin involvement and skin lesions. Thus, psoriatic disease may cause psychiatric problems and psychological problems such as depression. The emergence of novel therapeutic agents which cause remission of skin lesions has really improved quality of life in psoriatic disease patients. There is an urgent and unmet need for the discovery of agents which may induce permanent remission of the skin disease and alleviate psychiatric and psychological problems and significantly improve quality of life in psoriatic disease patients.

NSS7
PSORIATIC DISEASE AND REHABILITATION

Y. Dionyssiotis[1]

[1]Spinal Cord Injury Unit, University of Patras, Patras, Greece

Psoriatic disease affects the musculoskeletal system and the skin. The disease is an autoinflammatory disorder and belongs to the spondyloarthritis spectrum. Enthesitis, arthritis, spondylitis are manifestations of the disorder. A program of exercise supervised appropriately may greatly benefit patients with psoriatic disease. Exercise performed under supervision may have a pain alleviating effect. Exercise also strengthens the muscular system and may improve movement and function in the patient. Exercise may also have a beneficial effect on osteoporosis, which may accompany the disorder. Exercise may also be a supplementary measure for the management of depression which may also be observed in psoriatic disease patients. Physiotherapy in the form of exercise for the prevention of ankylosis and preservation of joint function is important for the management of the disease.

NSS8
PSORIATIC DISEASE. CURRENT TREATMENT AND EMERGING THERAPIES

P. Athanassiou[1]

[1]Department of Rheumatology, St. Paul's Hospital, Thessaloniki, Greece

Psoriatic disease which includes psoriasis and psoriatic arthritis is an autoinflammatory disease. Nowadays many drugs are available for the treatment of both psoriasis and psoriatic arthritis. Conventional disease modifying antirheumatic drugs, biologic agents, biosimilars, Janus kinase inhibitors, interleukin-23 inhibitors and small molecules are available for the management of psoriatic disease. It is important to take into account the presenting features of the patients when choosing treatment. The presence of peripheral arthritis, axial disease, enthesitis, dactylitis, skin and nail disease should be considered when choosing medication for every patient. The presence of inflammatory bowel disease and uveitis should also be considered, as these manifestations are part of the spondyloarthritis spectrum. It is the responsibility of the caring physician to apply these new available agents in the therapeutic regimen and to choose the right treatment for each individual patient. Patients' views should also be taken into account and be part of the decision-making process. It is also important that each treatment should be evaluated during the course of the disease and specific alterations made according to the response of the patient to the therapeutic regimen.

NSS9
IMPLEMENTING PHYSICAL ACTIVITY FOR COMMUNITY-DWELLING SENIORS DURING PERIODS OF ISOLATION

F. Buckinx[1,2]

[1]WHO Collaborating Center for Public Health aspects of musculoskeletal health and ageing, Division of Public Health, Epidemiology and Health Economics, University of Liège, Liège, Belgium, [2]Institut Universitaire de gériatrie de Montréal (IUGM), Montréal, Canada

Physical inactivity and sedentary lifestyles affect more than 50% of the older adults. Isolation periods such as the COVID-19-related lockdowns have imposed sedentariness and limited seniors' mobility and engagement in physical activity, which could precipitate or accelerate frailty or loss of functional capacities.

However, maintaining or improving the physical fitness is of critical importance as our population ages. Fortunately, previous studies have shown that pragmatic web-based tools integrating physical activity (PA) programs that are adapted to older adults' functional capacities are potential solutions to prevent their physical decline. Moreover, 50% of seniors use the Internet daily and own a tablet, computer or smartphone. Therefore, the implementation of remote PA using web technology could be a solution to maintain the health of older adults while avoiding physical contact and the risk of contagion. In times of limited physical activity due to pandemics, home-based exercises could be an alternative to counteract physical inactivity and to keep older adults fit and healthy. Therefore, it was important to assess whether distance-training in PA helps to counteract the lockdown deleterious effects (sedentary/inactivity) in pre-disabled seniors.

NSS10
SHORT- AND LONG-TERM EFFECTS OF 4 ONLINE REMOTE PHYSICAL ACTIVITY INTERVENTIONS ON PHYSICAL PERFORMANCES DURING ISOLATION PERIODS IN COMMUNITY-DWELLING OLDER ADULTS

M. Aubertin-Leheudre[1,2]

[1]UQAM, Faculté des sciences, Département des sciences de l'exercice, GRAPA, Montréal, Canada, [2]Centre de recherche de l'institut Universitaire de Gériatrie de Montréal (CRIUGM), Montréal, Canada

Context: Aging, chronic disease and periods of involuntary isolation increase the risk of physical inactivity, which can contribute to physical decline among older adults. Online technology could be an innovative solution to promote physical activity habits in this context.
Objectives: Thus, we aimed to: (1) Examine the short term acceptability, feasibility and health effects of 4 modalities of 12-weeks (3 sessions/week) web-based PA interventions in older adults and; (2) Explore the long-term effects of these remote modalities on active lifestyle and physical performance.
Methods: *Aim-1*: 129 inactive community-dwelling older adults were randomized in 4 modalities: full Live (LLL; n = 38); full Recorded (RRR; n = 45); Live-Recorded-Live (LRL; n = 22) *or* Recorded-Live-Recorded (RLR; n = 24). *Aim 2:* Among this number, 60 (46%: 14 men and 47 women) agreed to participate in the unplanned follow-up evaluation.
Conclusion: In short-term, web-based PA interventions using a decisional tree to prescribe adapted levels are safe, feasible and

acceptable during isolation periods. However, PA interventions which included a higher rate of live sessions appear to be more effective for maintaining or improving physical health. In long-term. Finally, our long-term follow-up analyses show that these exercise training modalities help to maintain motivation levels towards PA practice, which seems to allow the observed beneficial effects to persist over time and mitigate the effects of detraining (post vs. + 1 year). Our analyses also show that the remote exercise groups with higher interactive training rations (LLL and LRL) maintained better PA habits, which seem to help limit age-related physical decline (pre vs. + 1 year).

Overall, these results support the potential of virtual remote modalities as a tool to promote the practice of PA in older adults and allow aging well and more specifically the modalities with greater live training ratios (level of sedentary lower, higher level of physical activity and higher level of retention).

NSS11
UNDERSTANDING OLDER ADULTS' PREFERENCES FOR ENGAGING IN REMOTE INTERVENTIONS FOR IMPROVING PHYSICAL FUNCTION: THE RAMP INTERNATIONAL CONSUMER DELPHI PROCESS

D. Scott[1,2]

[1]Institute for Physical Activity and Nutrition (IPAN), School of Exercise and Nutrition Sciences, Deakin University, Burwood, Australia, [2]School of Clinical Sciences at Monash Health, Monash University, Clayton, Australia

As digital health interventions rapidly evolve, understanding the preferences and needs of older adults is crucial for designing effective strategies for remotely supporting this population to maintain physical function. This presentation will discuss the findings of the RAMP (Remote Assessment and Management of Physical Function) international consumer Delphi process, a project which has engaged with 654 older adults across 15 countries to understand their perspectives on physical function and remote interventions to support its maintenance, by facilitating self-management and collaboration with health professionals.

This modified Delphi process has demonstrated that older adults view physical function as a health priority integral to maintaining independence and quality of life, and that they would value greater support to manage their physical function. It is unclear however how this can most effectively be provided; while the vast majority of older adults are confident that they would be able to use digital technologies to participate in physical function management, there is low agreement on the types of digital health interventions that they would like to engage with (e.g. synchronous supervised versus asynchronous unsupervised exercise training). This appears to reflect a lack of exposure to digital health interventions and that there is no 'one size fits all' approach to remote management of physical function.

The findings from the RAMP study provide valuable insights for health professionals, policymakers, and digital health developers on tailoring remote interventions to align with the expectations and capabilities of older adults.

NSS12
HOW CAN THE RECENTLY WORLD FALLS GUIDELINES BE IMPLEMENTED TO REDUCE FRACTURE RISK IN OLDER PEOPLE

T. Masud[1]

[1]Consultant Physician and Honorary Professor of Geriatric Medicine, Nottingham University Hospital NHS Trust, Nottingham, United Kingdom

In the pathogenesis of fractures, particularly hip fractures, the most important determinants are bone fragility (osteoporosis) and the propensity to fall. Therefore, fracture prevention requires not only treating osteoporosis with drugs but also assessment of falls risk and to implement interventions that have been proven to reduce falls risk. The recently published World Falls Guidelines (Montero-Odasso et al., Age Ageing 2022) were a collaboration of 96 world experts from 39 countries that provide a practical framework for this implementation. The algorithm produced in the guidelines that applies to community dwelling older people and which stratifies falls risk into low risk, intermediate risk and high risk will be discussed. Gait speed and the Timed Up and Go Test have a pivotal role in the stratification. The appropriate interventions for each risk group will be presented. Education on fall prevention measures, physical activity, and exercise that focuses on balance and strength training have important roles in fall prevention across the risk groups. Older people considered at high falls risk should be offered a comprehensive multifactorial assessment with a view to co-design and implement personalized multi-domain interventions. Older people who have already suffered from a fragility fracture are by definition at a high risk of further fractures, and timely falls prevention measures in this group is of utmost importance. Fracture liaison services have an important role to play in these patients and implementing the World Falls Guidelines within these services should be a key goal.

NSS13
SCREENING FRAILTY EASILY IN PRACTICE: VALIDATION OF SIMPLER FRIED FRAILTY SCALE IN DIFFERENT EUROPEAN COUNTRIES

F. O. Kayhan[1]

[1]Associate Professor, Health Sciences University, Gazi Yaşargil Education and Research Hospital, Department of Internal Medicine, Geriatrics section, Diyarbakir, Turkiye

Frailty has been defined as a state of increased vulnerability due to a decline in reserve capacity, resulting in a limited ability to cope with everyday or acute stressors. Frail individuals are more susceptible to adverse health outcomes, including falls and fractures. The prevention of fractures and frailty are related concepts in the context of dependency and mortality, particularly in the older population. Fried frailty scale is the very first and most commonly used assessment scale for an operational definition of physical frailty with its demonstrated success as a predictor of mobility limitations and mortality. Fried frailty scale includes five components, among which three or more were defined as frailty: unintentional weight loss (10 lbs in the past year), self-reported exhaustion, weakness (grip strength), slow walking speed, and low physical activity. This definition proved the benefit of use as shown to be independently predictive (over three years) of incident falls, worsening mobility, disability, hospitalization, and death. However, it needs significant time, devoted personnel, and some equipments, precluding its use in everyday practice. Simpler Fried Frailty Scale is a self-reported version of this scale and is a quick and easy-to-use frailty screening tool. It proved to be useful in some settings and validation studies in different languages and

settings are going on. In this speech, we will introduce and outline the success of the Simpler Fried Frailty Scale as a practical user-friendly tool to identify frail and risky patients for adverse outcomes including fractures. Thereby, we aim to introduce/enhance its easy use in the practice of clinicians involved in the management of osteoporosis.

NSS14
CAN AND HOW MEDICATION REVIEW HELPS US PREVENTING FURTHER FRACTURES?

G. Bahat[1]

[1]Professor, Istanbul University, Istanbul Medical Faculty, Department of Internal Medicine, Division of Geriatrics, Capa, Istanbul, Turkiye

Osteoporotic fragility fractures most commonly occur due to traumas that develop secondary to falls. Falls are common in older adults occurring in about 1/3 of older adults residing in the community and half of the nursing home residents. Among several causes of falls, polypharmacy and inappropriate medication use come front as significant contributors of falls in older adults which can mostly be managed by focused medication review.

Use of drugs that have anticholinergic effects, drugs that cause confusion, balance problems, orthostatic hypotension, those that contribute to urinary incontinence, and those have greater metabolic risks in older adults (e.g. some anti-hypoglycemic drugs) frequently contribute or emerge as the factor(s) causing falls ending with osteoporotic fragility fractures. On the other hand, ignorance of use and misuse of "antiosteoporotic medications and calcium, vitamin D (in case of need)" are also common in older adults emerging as a significant contributor to osteoporotic fractures. Hence, medication review, focused on both the use of fracture risky medications and underuse/misuse of required medications, is an essential and must-do management strategy to decrease fractures. A variety of screening tools to optimize medication use in older adults are available. Some tools provide very practical recommendations to be easily used by clinicians involved in the management of osteoporosis. In this speech, we will outline the major drugs that are commonly responsible for/contribute to falls/fractures and stress the common types of underuse/misuse of pharmacological treatments with the help of the most current and easily accessible medication screening tools in practice, i.e. STOPP/STARTv3 and TIME criteria.

NSS15
VIRTUALLY ALL FRACTURE SITES ARE ASSOCIATED WITH ADVERSE POST-FRACTURE OUTCOMES

J. R. Center[1,2], D. Alarkawi[1,2], T. Tran[1,2], D. Alajlouni[1,2], J. D. Adachi[3], C. Berger[4], J. A. Eisman[1,2], D. Goltzman[5], D. A. Hanley[6], R. Josse[7], S. Kaiser[8], C. S. Kovacs[9], L. Langsetmo[10], J. C. Prior[11], D. Bliuc[2,12], R. D. Blank[1]

[1]Bone Epidemiology Clinical and Translation Science, Garvan Institute of Medical Research, Sydney, Australia, [2]Clinical School, St Vincent's Hospital, School of Medicine and Health, UNSW, Sydney, Australia, [3]Department of Medicine, McMaster University, Hamilton, Ontario, Canada, [4]CaMos National Coordinating Centre, McGill University,, Montreal, Canada, [5]Department of Medicine, McGill University, Montreal, Canada, [6]Department of Medicine, University of Calgary,, Calgary, Canada, [7]Department of Medicine, University of Toronto,, Toronto, Canada, [8]Department of Medicine, Dalhousie University, Halifax, Nova Scotia, Canada, [9]Faculty of Medicine, Memorial University, St. John's, Newfoundland, Canada, [10]School of Public Health, University of Minnesota, Twin cities, Minneapolis, United States, [11]Department of Medicine and Endocrinology, University of British Columbia,, Vancouver, Canada, [12]Bone Epidemiology Clinical and Translation Science, Garvan Institute of Medical Research,, Sydney, Australia

The FRAX model identifies fractures at 4 sites—hip, vertebrae, proximal humerus, and distal radius—as major osteoporotic fractures (MOF). This leads to the misconception fractures at other sites are either not "osteoporotic" or not important. We analysed post-fracture adverse outcomes based on the definitions of proximal (fractures of the axial skeleton and the appendicular skeleton proximal to the elbows and knees) and distal (fractures of appendicular sites distal to the elbows and knees) in multiple large cohorts. Non-MOF fractures are common and associated with adverse post-fracture outcomes. We propose that proximal versus distal fracture is a more useful distinction than MOF versus non-MOF.

In the Dubbo Osteoporosis Epidemiology Study (DOES) and Canadian Multicentre Osteoporosis Study (CaMos), non-MOFs comprised 40% of all initial fractures, resulting in 39% of all subsequent fractures, including 25% of all subsequent hip fractures and 22% of all subsequent vertebral fractures. They also resulted in 38% of all fracture-associated deaths. Multiple studies have shown that fractures at most sites increase the risk of subsequent fracture $\sim$ 2-fold. The risk of subsequent fracture is comparable for non-hip, non-vertebral (NHNV) proximal and distal sites. Both proximal and distal fractures increase the risk of a subsequent hip or vertebral fracture, albeit to a lesser degree than initial hip and vertebral fractures.

Increased mortality is underappreciated following fracture at NHNV sites. In contrast to subsequent fracture risk, proximal but not distal fracture sites are generally associated with increased premature mortality, ranging from 30% to over 2-fold. However, even distal fractures are associated with increased mortality in some subgroups.

Disability is a significant fracture outcome that is not restricted to MOFs. In the few studies that have considered non-hip fractures, disability, decline in quality of life and admission to residential aged care occurred after fractures at all sites. Outcomes are worst for hip, vertebral and pelvic fractures, but both lower and upper limb fractures are associated with a $\sim$ 2-fold increased risk of institutionalization.

In summary, non-MOFs contribute to the burden of subsequent fractures, disability and post-fracture mortality.

NSS16
ASSOCIATION BETWEEN SPECIFIC MULTIMORBIDITY CLUSTERS AND THE RISK OF FRACTURE AND POST-FRACTURE CONSEQUENCES

T. Tran[1,2,3], D. Bliuc[1,2], B. Abrahamsen[4,5,6], W. Chen[1], J. A. Eisman[7,8], L. Hansen[9], P. Vestergaard[10,11,12], T. V. Nguyen[3,8,13], R. D. Blank[1], J. R. Center[1,2,8]

[1]Garvan Institute of Medical Research, Sydney, Australia, [2]Faculty of Medicine, UNSW, Sydney, Australia, [3]School of Biomedical Engineering, University of Technology, Sydney, Australia, [4]Department of Medicine 1, Holbæk Hospital, Holbæk, Denmark, [5]Department of Clinical Research, Odense Patient Data Explorative Network, University of Southern Denmark, Odense, Denmark, [6]Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences University of Oxford, Oxford, United Kingdom, [7]Faculty of Medicine, UNSW Sydney, Sydney, Australia, [8]School of Medicine Sydney, University of Notre Dame Australia, Sydney, Australia, [9]Kontraktenheden, Noth Denmark Region, Denmark, [10]Department of Clinical Medicine, Aalborg University, Aalborg, Denmark, [11]Department of Endocrinology, Aalborg University Hospital, Aalborg, Denmark, [12]Steno Diabetes Center North Jutland, Aalborg, Denmark, [13]Tam Anh Research Center,, Ho Chi Minh City, Vietnam

Objectives: To define specific multimorbidity clusters and quantify the association between the multimorbidity clusters and the risk of fractures and mortality.

Material and methods: 1.7 million Danish adults born on or before 1/1/1950 were followed for fractures and death. 32 predefined chronic diseases and fractures were identified from the Danish National Hospital Discharge Register. Death was ascertained from the Danish Register on Causes of Death. We used latent class analysis to identify multimorbidity clusters, Cox's proportional hazards regression to determine association between specific multimorbidity clusters and fracture risk, and relative survival analysis to quantify excess mortality attributable to the combination of multimorbidity and fractures at specific sites.

Results: 793,815 men (age: 64 ± 10) and 873,524 women (65.5 ± 11) were included. Pre-existent chronic diseases grouped into low-multimorbidity (80.3% in men, 83.6% in women), cardiovascular (12.5%, 10.6%), malignant (4.1%, 3.8%), diabetic (2.4%, 2.0%) and hepatic clusters (0.7%, men only). These clusters distinguished individuals with advanced, complex, or late-stage disease from those with earlier-stage disease. During a median follow-up of 14 years (IQR: 6.5, 14), 95,372 men and 212,498 women sustained an incident fracture. Multimorbidity was associated with fracture independent of age and sex. The association between these specific multimorbidity clusters and fracture risk equalled or exceeded that of either the individual chronic diseases most prevalent in each cluster or of counts-based comorbidity indices (Figure). Prespecified sensitivity analysis accounting for competing risk of death yielded consistent results. The combination of multimorbidity clusters and fracture compounded mortality, conferring much greater risk than either alone, though they had only modest impact on recurrent fracture risk.

Conclusions: Multimorbidity clusters may provide greater insight into fracture risk than individual diseases or counts-based comorbidity indices. The compound contribution of multimorbidity to post-fracture excess mortality highlights the need for more comprehensive approaches in these high-risk patients. Our approach could also be used to examine other sentinel health events.

Figure. Specific multimorbidity clusters and their individual components and fracture risk

Jacqueline Center has been on a medical advisory board for Amgen and given educational talks for Amgen and Teva.

Measured poor physical performance is associated with increased fracture risk. However, whether self-assessed limited mobility is associated with fracture is unknown.

This study aimed to determine the association between self-reported limited mobility and 5-year fracture risk.

45 and Up is a prospective population-based cohort study with questionnaire data linked to mortality and hospital records. A cohort of 122,233 women and 110,365 men with baseline questionnaire data on limited mobility at 1 km self-assessed as "Not at all," "A little" and "A lot" was selected. Fracture events were ascertained from hospital records. Fracture risk was estimated using gender-specific Cox proportional hazards models adjusted for age, weight, falls, and prior fracture.

Approximately 22% of women and men reported limited mobility (12%—"A little" and 10%—"A lot") at baseline. During the first 5 years of follow-up, 6867 women and 4155 men experienced a minimal trauma fracture. Individuals with fracture were older, had more comorbidities, falls and prior fractures and were more likely to report limited mobility. After multivariable adjustment, limited mobility was associated with ~ 32% to > 2-fold greater fracture risk ["A little": 1.32 (1.23–1.41), and 1.46 (1.34–1.59); "A lot": 1.59 (1.49–1.71) and 2.02 (1.86–2.21), for women and men, respectively] (Figure). Limited mobility was significantly associated with fracture risk at all sites. The magnitude of association for all degrees of limited mobility was highest for hip (HR 2.16–3.34) followed by vertebral (HR 1.56–2.21) and non-hip non-vertebral fracture (HR 1.20–1.71).

All degrees of self-reported limitation in mobility are associated with increased fracture risk over and above known fracture risk factors. This study suggests that this simple assessment may be a useful clinical tool to select candidates who would benefit from osteoporosis investigation.

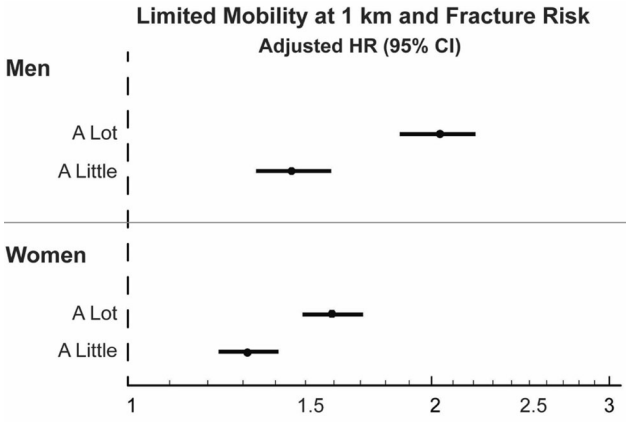

Figure Association between different degrees of limited mobility at 1 km and fracture risk adjusted for age, weight, prior fracture and falls in 45 and Up cohort

NSS18
FUNCTIONAL ASSESSMENT OF VITAMIN D STATUS BY A NOVEL METABOLIC APPROACH

M. Herrmann[1]

[1]Medical University of Graz, Clinical Institute of Medical and Chemical Laboratory Diagnostics, Graz, Austria

Determining serum 25-hydroxyvitamin D [25(OH)D], 24,25-dihydroxyvitamin D [24,25(OH)2D] and the vitamin D metabolite ratio (VMR) allows the identification of individuals with a low vitamin D metabolite profile. Here, we evaluated if such a functional approach provides superior diagnostic information to serum 25(OH)D alone.

25(OH)D, 24,25(OH)2D, and the VMR were determined in participants of the DESIRE (Desirable Vitamin D Concentrations, n = 2010) and the LURIC (Ludwigshafen Risk and Cardiovascular Health, n = 2456) studies. A low vitamin D metabolite profile (vitamin D insufficiency) was defined by a 24,25(OH)2D concentration < 1.2 ng/mL (< 3 nmol/L) and a VMR $< 4\%$. Parathyroid hormone (PTH) and bone turnover markers were measured in both cohorts, whereas 10-year mortality data was recorded in LURIC only.

The median age in DESIRE and LURIC was 43.3 and 63.8 years, respectively. Median 25(OH)D concentrations were 27.2 ng/mL (68.0 nmol/L) and 15.5 ng/mL (38.8 nmol/L), respectively. Serum 25(OH)D deficiency, defined as < 20.2 ng/mL (< 50 nmol/L), was present in 483 (24.0%) and 1701 (69.3%) participants of DESIRE and LURIC, respectively. In contrast, only 77 (3.8%) and 521 (21.2%) participants had a low vitamin D metabolite profile. Regardless of the serum 25(OH)D concentration, a low vitamin D metabolite profile was associated with a significantly higher PTH, accelerated bone metabolism, and higher all-cause mortality than an unremarkable vitamin D metabolite profile.

The personalized assessment of vitamin D status using a functional approach better identifies patients with accelerated bone metabolism and increased mortality than the use of a fixed 25(OH)D cutoff of 20 ng/mL (50 nmol/L).

NSS19
1,25(OH)2D AND 1,24,25(OH)3D—EXPANDING OUR KNOWLEDGE ON VITAMIN D CATABOLISM BEYOND VMR

E. Cavalier[1,2]

[1]PhD, EuSpLM, Liege, Belgium, [2]Head, Department of Clinical Chemistry, University of Liege, CHU de Liege, Liege, Belgium

An increasing body of research is revealing the dynamic nature of vitamin D metabolism, highlighting a diverse range of potentially active metabolites. The degradation pathway is gaining attention, particularly with a focus on the key enzyme, CYP24A1, which is intricately regulated. Notably, 24,25(OH)2-vitamin D and the ratio of vitamin D metabolites are emerging as novel indicators of vitamin D functional deficiency.

CYP24A1 also governs the catabolism of 1,25(OH)2D into 1,24,25(OH)3D. The latter can also be produced through the 1-alpha hydroxylation of 24,25(OH)2D by CYP27A1. Traditionally, 1,24,25(OH)3D production has been viewed as the initial step before complete degradation into calcitroic acid. However, recent studies have challenged this perception, revealing that this metabolite binds up to 40% to the vitamin D receptor (VDR) similar to 1,25(OH)2D. Moreover, it facilitates increased intestinal transport and calcium mobilization from bone, potentially through bone resorption, leading to enhanced bone cell proliferation and osteocalcin synthesis.

Unfortunately, the measurement of this metabolite is complex, and only a limited number of laboratories possess the capability to do so. Nonetheless, reanalysis of samples from the Calgary study demonstrated a dose-related increase in 1,24,25(OH)3D in groups receiving daily doses of 400, 4000, and 10,000 IU of vitamin D, contrary to 1,25(OH)2D. Interestingly, a dose-related reduction in bone density at the distal radius and tibia, along with a slight loss of bone strength, was observed with the higher doses, suggesting that metabolites other than 1,25(OH)2D may play a significant role.

While many studies have focused solely on 25(OH)D, associating clinical outcomes with the increase of this less active metabolite, a re-evaluation incorporating other metabolites such as 24,25(OH)2D and 1,24,25(OH)3D, measured via LC–MS/MS methods on remnant samples, could enhance our understanding of vitamin D's mode of action and prompt a reconsideration of our clinical perspective on this age-old vitamin.

NSS20
THE BURDEN OF HIP FRACTURES AND THE NEED FOR QUALITY INDICATORS

R. E. López Cervantes[1]

[1]Orthopedic Surgeon at Osteoporotic Fractures Clinic-CFO, Guadalajara, Mexico

Hip fractures represent a growing public health concern in Mexico, and the understanding of their epidemiology and outcomes across various healthcare systems are crucial. The epidemiological data reveal a concerning trend of underscoring the urgency for effective secondary prevention measures, notable distinctions in patient care quality, rehabilitation outcomes and morbi-mortality of the fragility fracture patients across the different healthcare systems. These differences emphasize the need for a unified approach to enhance the quality of hip fracture management across the diverse healthcare systems in Mexico.

Drawing lessons from international experiences, the use of quality indicators has proven invaluable in optimizing patient care in various countries. Quality indicators have demonstrated their effectiveness in improving outcomes, reducing complications, and enhancing the overall quality of life for individuals post-hip fracture.

As bone health experts globally grapple with the escalating burden of hip fractures, this project serves as a clarion call for the establishment and implementation of quality indicators tailored to the Mexican context. By fostering collaboration and sharing best practices, this initiative seeks to improve the standard of hip fracture care, ultimately mitigating the impact of this expanding health crisis on the Mexican population.

NSS21
KEY QUALITY INDICATORS FOR HIP FRACTURE CARE: WHAT TO MEASURE AND WHY

J. F. Torres-Naranjo[1]

[1]Centro de Investigación Ósea y de la Composición Corporal, CIO. Universidad de Guadalajara, Guadalajara, Mexico

This presentation explores critical hip fracture care quality indicators, emphasizing the significance of thoughtful selection based on health outcomes, feasibility, and adaptability to specific contexts.

The lecture will focus on several key aspects, discuss the crucial role of prompt surgical intervention in hip fracture cases, highlight the impact of critical indicators such as time to surgery on patient morbidity, mortality, and overall recovery, and emphasize how these indicators serve as a fundamental benchmark for quality care. Examine the importance of collaborative efforts among diverse healthcare professionals in caring for hip fracture patients, discuss the challenges and benefits of fostering multidisciplinary collaboration within specific institutional settings, and stress the need for tailored approaches based on individual patient needs and institutional capabilities.

The presentation will underscore the crucial consideration of not only the relevance of indicators in terms of health outcomes but also their feasibility and applicability to diverse institutional scenarios. We will share insights on how these carefully selected indicators contribute to improved patient outcomes and efficient resource utilization within healthcare systems.

By the end of the lecture, attendees will gain a comprehensive understanding of the rationale behind selecting specific quality indicators for hip fracture care, empowering them to make informed decisions tailored to their respective healthcare institutions' unique challenges and capabilities.

NSS22
IMPLEMENTING QUALITY INDICATORS IN NATIONAL HEALTHCARE SYSTEMS: CHALLENGES AND SUCCESS STORIES

J. C. Viveros García[1,2,3]

[1]Internal Medicine-Geriatrics-Orthogeriatric, Leon, Mexico, [2]Chair Elect Regionalization Committee, Leon, Mexico, [3]Fragility Fracture Network, Leon, Mexico

This presentation will focus on the current state of health systems in developing economies, particularly Latin America and Mexico, mainly in those barriers to their adoption and implementation. We will talk about how, after developing the indicators, the most important health system in Mexico has begun its introduction in some traumatology and orthopedics hospitals. After this, the rest of the healthcare system will follow.

We will describe how heterogeneity in health systems represents one of the most important barriers, as well as some strategies to try to overcome these problems. We will take examples of countries with robust indicator projects, and how they have managed to overcome some of the barriers and current states of said projects.

At the end of the talk, the audience will be able to learn about the challenges of an indicators project in a country like Mexico, as well as how the participants in said project have sought to solve these problems to improve the quality of care.

NSS23
BONE HEALTH AND HORMONAL CONTRACEPTION

R. Bonassi Machado[1,2,3]

[1]Associate Professor of Gynecology, Faculty of Medicine of Jundiai, São Paulo, Brazil, [2]President of Brazilian Specialized Committee in Contraception of FEBRASGO, São Paulo, Brazil, [3]President of SOBRAC–Brazilian Climacteric Society, São Paulo, Brazil

Estrogens are major determinants of bone mass, affecting the acquisition of peak bone mass during adolescence and young adult age and modulating bone mineral density (BMD) and the risk of osteoporosis later in life. Hormonal contraceptives induce a reduction of estrogen and a suppression of progesterone endogenous production by the ovaries. In these women, circulating levels of sex steroids are mainly determined by the dosages present in the contraceptive formulation. If the formulation of the contraceptive is insufficient to grant adequate sex steroid levels, bone tissue metabolism might be affected.

Short-term and long-term steroid contraceptive systems are widely employed in adolescents and premenopausal women; they could induce variation in bone metabolism, but whether these changes increase the overall fracture risk is not yet clear. In adolescent girl, combined oral contraceptives could have a deleterious effect on bone health when their onset is within three years after menarche and when they contain ethinyl estradiol at the dose of 20 mcg. In perimenopausal women, steroid contraceptives seem not influence bone health nor increase osteoporotic fractures risk in menopause. The oral progestogens intake is not related to negative effects on skeletal health. Depot medroxyprogesterone acetate (DMPA) induces a prolonged hypoestrogenism with secondary detrimental effect on healthy bone but progestin-based implants and intrauterine devices have not negative effect on bone health. Contraceptive choice should be tailored evaluating any possible effect on bone health. Clinicians should always perform precontraceptive counselling to identify any coexisting condition that may affect bone health.

NSS24
HOW TO MANAGE THE EARLY NEGATIVE IMPACT OF PREMATURE OVARIAN INSUFFICIENCY ON BONE HEALTH?

J. M. Soares Júnior[1,2,3]

[1]Associate Professor of Gynecology and Head of Obstetrics and Gynecology Department of Medical School of University of São Paulo, São Paulo, Brazil, [2]President of National Specialized Committee of FEBRASGO, São Paulo, Brazil, [3]Vice-President of Federacion Latina De Endocrinologia Ginecologica (FLEG), São Paulo, Brazil

Over 200 million women worldwide suffer from osteoporosis, and postmenopausal women are more vulnerable to the disorder and its serious consequences, including osteoporotic fractures. Preventive measures have not received as much attention as symptomatic treatment to date. Furthermore, as women age, their ovaries produce fewer eggs and less estrogen, which is linked to postmenopausal osteoporosis. Estrogen has a well-established effect in bone remodeling after many years of research. Estrogen contributes to the resorption and strengthening of bones. In addition, premature ovarian insufficiency (POI) is definite when menopause is stable before the age of

40, and the world prevalence is around 2% of the population. Women with POI are exposed to a long period of estrogenic deficiency, which potentially brings higher health bone risk. Most of the studies revealed lower bone density in both the femoral neck and lumbar spine of women with POI compared with healthy women. POI Bone mass had the tendency to remain stable in women treated with estrogen and progestin therapy. However, in women already with bone loss, the therapy—in the doses most frequently used—was not able to revert the loss. Higher doses of estrogen seem to have a positive impact on BMD, as did combined oral contraceptives used continuously. Also, the interruption of HT for longer than one year was linked to significant decrease of bone mass. Although HT brings clear benefits, further studies are needed to establish its long-term effects, as well as doses and formulations with better protective effects on the bone mass of these women. In addition, a holistic therapy with a calcium-rich diet, adequate exercise, sufficient sun exposure, and hormonal therapy is necessary to maintain bone health.

NSS25
BONE HEALTH AND OSTEOPOROSIS SCREENING IN GYNECOLOGIC CANCER SURVIVORS

A. Orcesi Pedro[1,2,3]

[1]Professor of post-graduate Course of Department of Obstetrics and Gynecology from University of Campinas-UNICAMP Medical School, São Paulo, Brazil, [2]Vice-President of National Specialized Committee on Osteoporosis of FEBRASGO, São Paulo, Brazil, [3]Member of the Regional Advisory Board of International Osteoporosis Foundation-Latin America, São Paulo, Brazil

Over the past decades, the incidence of early-onset cancers, often defined as cancers diagnosed in adults under 50 years of age, has increased in multiple countries. Among these, gynecological cancers (cervix and corpus uteri, ovary, vulva and vagina) affect a growing number of women globally, with approximately 1.4 million women diagnosed in 2020. Depending on tumor type and stage, treatments include hysterectomy with or without bilateral salpingo-oophorectomy, radiotherapy, and chemotherapy. These can result in loss of ovarian function and, in women under the age of 45 years, early menopause, which increases the risk of osteoporosis and fragility fractures among other health implications. Also, a growing availability of testing for pathogenic gene variants such as BRCA1/2 and Lynch syndrome, impacts on an increasing number of women undergoing risk-reducing salpingo-oophorectomy (RRSO), which in most cases will be before age 45 years and will induce surgical menopause with the same health consequences. regarding bone loss in women with gynecologic cancers are overall lacking compared to other cancer populations. Consequently, guidelines for osteoporosis screening in women with cancer are largely based on data generated among non-gynecologic cancer survivors. The overall aim after gynecological cancer treatment is prevention of adverse health consequences from early surgical menopause and optimization of long-term physical and emotional health. Retrospective reviews following surgical menopause demonstrated that 56% had osteopenia and 12% had osteoporosis. Prospective studies after RRSO suggest that HRT improves bone density and strength but not to baseline levels. The optimal dose and delivery system of HRT to prevent osteoporosis and fracture is not known. Current guidelines on early menopause are considered an indication for baseline bone mineral density with dual-energy X-ray absorptiometry (DXA) testing within the first year with repeat 1–2 years later. If baseline DXA shows mild osteopenia, repeat every 2 years thereafter or if normal, a repeat study should be considered in 3–5 years. The Fracture Risk Assessment Tool (FRAX) can be used to calculate 10-year fracture risk in women over 40 years. Management to detect and prevent osteoporosis include monitoring bone mineral density and aiming for nutrition orientation, adequate physical activity to specific age groups, call attention to lifestyle habits, fall prevention and when necessary, provide hormone replacement therapy (HRT) to those without contraindications or consider bone-protective therapy according to general guidelines of osteoporosis treatment. Systemic hormone therapy is well established as the most effective treatment for vasomotor symptoms, genitourinary symptoms and to prevent bone loss. However, the role of hormone receptors in many gynecological cancers and their treatment pose a challenge to the management of menopausal symptoms after cancer. An individualized approach taking into account age, tumor type, stage and concomitant therapies and morbidities is of extreme importance. Besides individualization of treatment, additional secondary health benefits (treatment of vasomotor symptoms, genitourinary syndrome of menopause, sexual dysfunction, and quality of life on symptomatic hypoestrogenic women), side effects, contraindications, cost and likelihood of adherence should be carefully considered. It is important to highlight that HRT can also use simultaneously with other medications for osteoporosis (e.g., bisphosphonates, denosumab or teriparatide) based on clinical needs and judgment.

NSS26
CHARACTERIZING BODY COMPOSITION AND BONE HEALTH IN TRANSGENDER INDIVIDUALS RECEIVING GENDER-AFFIRMING HORMONE THERAPY

E. S. Ferreira Filho[1,2,3,4]

[1]Assistant physician of Gynecology Division of Hospital das Clinicas from Medical School of University of São Paulo-USP, São Paulo, Brazil, [2]PhD in progress at Medical School of University of São Paulo-USP, São Paulo, Brazil, [3]Member of Brazilian Specialized Committee in Contraception of FEBRASGO, São Paulo, Brazil, [4]Affiliated member of the European Society of Contraception and Reproductive Health (ESC), Ternat, Belgium

Transgender people are those whose gender identity is different from sex assigned at birth. Unfortunately, they have been chronically neglected by health professionals, and revindications from these individuals' brought attention to the necessary care in academic and healthcare environments. It is historical reparation to include the topic in discussion spaces at congresses, scientific publications, undergraduate and postgraduate courses. Since few is known about body composition and bone health in transgender individuals, this seminar will address the main issues on the subject, focusing on the interpretation of bone mineral density assessment and the impact of gender-affirming hormone therapy on bone health of transgender adolescents and adults.

NSS27
DIAGNOSIS OF FIBROMYALGIA SYNDROME ON THE BASIS OF EVIDENCE BASED MEDICINE

A. Winkelmann[1,2]

[1]Physical and Rehabilitation Medicine (PRM)-Day Clinic for Fibromyalgia, Munich, Germany, [2]Department of Orthopaedics and Trauma Surgery, Musculoskeletal University Center Munich (MUM), University Hospital, Munich, Germany

Objective(s): The diagnosis of FMS is the most important and helpful factor in the course of the disease for the majority of FMS patients1. Diagnosis can improve the quality of life, reduce visits and health care costs[2,3]. Differential diagnosis should be considered and comorbidities should be diagnosed. The correct diagnosis of FMS

with the detection of comorbidities and relevant factors for restrictions of the activities of daily life within the framework of the biopsychosocial model is the key for an individual therapy with the aim of the best possible function and quality of life with FMS[4, 5, 6]. There is controversial discussion, how best to diagnose fibromyalgia syndrome (FMS). There is still a difference between criteria-based FM diagnosis (CritFM) and doctor's FM diagnosis (MDFM)[7].

Material and methods: Reviews, meta-analysis, guidelines and recommendations with the keywords fibromyalgia and diagnosis were reviewed by PubMed-listed publications until January 15, 2024.

Results: The ACR criteria from 1990, 2010 and the revised versions from 2011 and 2016 show an evidence-based process for optimizing the diagnosis of FM[8, 9, 10, 11]. In 1990, the criteria for characterizing FM were developed for clinical studies. The 2010 and 2011 criteria were developed for clinical use as preliminary diagnostic criteria and were initially implemented with graded questions on fatigue and functional complaints. The use of a "generalized pain criterion" in the revised criteria from 2016 eliminates the misclassification of regional pain syndromes as fibromyalgia. The revised ACR 2011/2016 criteria achieved a specificity of 90/87% and a sensitivity of 86/84% (medians). The criteria such as AAPT Diagnostic Criteria for Fibromyalgia 2019 with several dimensions provide an overview of the actual and future development of evidence-based diagnostic criteria[6]. A complete physical examination is required before the diagnosis of FM.[5]

Looking for mental health factors, e.g. depression disorders are more relevant than pain perceived factors for FM severity and quality of life, therefore it is important within the diagnostic process with the view to individual management strategies for best possible quality of life and participation in daily with FMS.[12, 13, 14]

Conclusion: Although the guidelines allow different options for diagnosing FM, the ACR criteria with the revised versions from 2011/2016 are still the gold standard. Don't forget to think about differential diagnosis, comorbidities and factors within the biopsychosocial model.

NSS28
PHARMACOLOGICAL MANAGEMENT OF FMS ON THE BASIS OF EVIDENCE BASED MEDICINE

F. Dincer[1,2,3,4]

[1]Professor of Physical and Rehabilitation Medicine, Ankara, Turkiye, [2]President Turkish Society of Rehabilitation Medicine, Ankara, Turkiye, [3]ESCEO Scientific Advisory Board Member, Ankara, Turkiye, [4]ESPRM Chair Musculoskeletal Disorders Com., Ankara, Turkiye

Objective: Fibromyalgia syndrome(FMS) is a common musculoskeletal condition characterised, by chronic widespread musculoskeletal pain disorder and reduced pain threshold, with hyperalgesia and allodynia, that is often accompanied by fatigue and disrupted sleep, cognitive disturbance, and multiple somatic symptoms.

Material and methods: In this lecture; Pharmacological Management of Fibromyalgia Syndrome will be mentioned in details, depending to evidence based medicine guidelines and upto date literature.

Results: EULAR has published, Evidence based recommendations about; management of FMS twice and updating it every ten years (2),(3). In Evaluating Evidence; pain, sleep, fatigue, DAL are taken into, consideration.(2),(3)
In our last EULAR-guideline we used, G.R.A.D.E-Grading of Recommendations Assessment Development and Evaluation: This is a four-point scale: strong for/weak for/weak against/strong against; or allowing a recommendation 'use only for research.(2).

In our EULAR guideline most of the following pharmaceutical agents are accepted as, weak for with level of, evidence Ia, except Tramadol Ib.(2).

Amitriptyline (at low dose), (level of evidence-1a), Serotonin-noradrenalin reuptake inhibitors-SNRI-duloxetine or milnacipran, (level of evidence-1a), tramadol, (level of evidence-1a) pregabalin, (Level of evidence-1a); cyclobenzaprine (level of evidence-1a).

The following pharmaceutical agents, SSRI-Selective serotonin reuptake inhibitors, Monoamine oxidase inhibitors, NSAIDs-are accepted as weak against, sodium oxybate, growth hormone, corticosteroids, strong opioids, cannabinoids as strong against.

Dizner et al. mentioned about Pharmacological treatment of FMS including several drugs approved by, FDA and EULAR Recommendations(1). Drug treatments in FMS must take into account the potential risk of adverse effects, including cognitive disturbances. Recommended drugs include pain modulators such as serotonin and noradrenaline reuptake inhibitors (SNRI):duloxetine and milnacipran; low doses of tricyclic antidepressant agent amitriptyline; and antiepileptic agent pregabalin. Non-recommended drugs for FMS include simple analgesics (acetaminophen, metamizole/dipyrone), nonsteroidal anti-inflammatory drugs, glucocorticosteroids, growth hormone, strong opioids, and sodium oxybate.

Duloxetine, milnacipran, pregabalin, and amitriptyline are potentially effective medications for fibromyalgia. Nonsteroidal anti-inflammatory drugs and opioids have not demonstrated benefits for fibromyalgia and have significant limitations.(4).

According to Giorgi et al., although ketamine, vitamin D, and hormone therapy have shown promise in reducing FM symptoms, a meta-analysis has shown that vitamin D supplementation is more effective, than placebo in reducing Fibromyalgia-Impact-Questionnaire-Scores(but not visual analogue scale scores) Finally, further research is needed to optimise their use.(5).

Duloxetine and pregabalin are the most effective drugs for managing FMS as they lead to the greatest improvement, in symptoms and the lowest rate of adverse events requiring study discontinuation. Amitriptyline is more effective in improving sleep, fatigue, and the overall quality of life. However, pregabalin should not be used in FMS patients with retinal nerve fibre layer damage such as those with diabetic retinopathy or glaucoma (5).
Conclusion: In the management of Fibromyalgia, best results are achieved by application of both pharmacological and non-pharmacological procedures.

NSS29
NON-PHARMACOLOGICAL MANAGEMENT OF FMS ON THE BASIS OF EVIDENCE BASED MEDICINE

D. Popa[1,2,3]

[1]Clinical Rehabilitation Hospital Felix Spa, Oradea, Romania,
[2]Romanian Society of Rehabilitation Medicine, Oradea, Romania,
[3]UEMS-PRM delegate, Oradea, Romania

FMS is one of the most common generalized pain syndromes, resulting in a consistent social burden and decreased quality of life. It is well known that FMS patients have substantial impairment in their functional abilities, with impaired performance in everyday activities. The objective of the presentation is to synthesize the comprehensive scientific information available on this topic and to highlight the best evidence with implications for ensuring the best care for the management of people with FMS. The literature available draws attention to a variety of non-pharmacological interventions for the management of FMS, including education, exercise, physical modalities, psychological therapies, balneotherapy, acupuncture, etc., direct transcranial electrical stimulation and much more, focusing on their effectiveness on the most common manifestations of the syndrome as pain, fatigue, sleep, depression and the disease specific quality of life, classified as key symptoms of FMS, according to the Results Measures in Clinical Rheumatology Studies (OMERACT). The exact number and types of non-pharmacological therapies that could be used for the treatment of FMS are not fully known to date and there is no widely accepted definition and classification of these the interventions. However, non-pharmacological interventions appear to be used more frequently than drugs as first-line treatment in recent guidelines. Given the diversity of the type of non-pharmacological therapy used, a discussion on the mechanism of action of each would not be possible in this presentation. With regard to non-pharmacological approaches based on evidence, a certain type of exercise and physical modalities, education, some psychological approaches, brain stimulation, balneotherapy and acupuncture benefit from reliable research conducted through several systematic reviews and meta-analyses. The findings of the available research suggest that several non-pharmacological interventions are effective in FMS and various interventions improve different specific outcomes. Of these, exercise has been shown to be most effective by improving most of the FMS-related outcomes. However, it has also been noted that there is a strong limitation in these research due to the high heterogeneity in terms of methodology, sample size, terminology and description of intervention. However, the abundance of non-pharmacological approaches in the management of FMS, most of which are part of the PRM's specialist tools demonstrates the role of PRM specialists in the management of this highly disabling syndrome.

KDIGO: WHAT'S NEW IN CKD-MBD

T. Nickolas[1]

[1]Columbia University, New York, United States

Chronic kidney disease mineral and bone disease (CKD-MBD) is a systemic disorder of bone and mineral metabolism that occurs in patients with CKD. In comparison to the general population, persons with CKD-MBD have higher rates of bone loss, fractures and cardiovascular events. Rates of fracture and cardiovascular events increase in parallel with severity of kidney dysfunction. Currently, there are no approved therapies to mitigate the effects of CKD-MBD, and contemporary management strategies to prevent adverse clinical events are controversial and/or have unproven clinical efficacy.

The Kidney Disease: Improving Global Outcomes Working Group (KDIGO) published Clinical Practice Guidelines for the diagnosis, evaluation, prevention, and treatment of CKD-MBD in 2009 and 2017. In October 2023, KDIGO held a Controversies Conference to review new lines of evidence both to support current strategies or to provide rationale to update strategies on the evaluation and management CKD-MBD.

This talk will focus on the data supporting the KDIGO recommendations for the diagnosis and management of bone disease in patients with CKD. There will be an emphasis on studies published since the 2017 guidelines, how future guideline updates may be effected by the current state of the literature, and how the field can address scientific and clinical knowledge gaps so that effective therapeutics and management strategies can be developed and implented.

NSS31
THE ASSOCIATION BETWEEN VERTEBRAL FRACTURES AND VASCULAR CALCIFICATIONS IN PATIENTS WITHOUT AND WITH CKD

M. Fusaro[1,2]

[1]National Research Council (CNR), Institute of Clinical Physiology (IFC), Pisa, Italy, [2]Department of Medicine, University of Padova, Padova, Italy

Despite Skeletal Fragility in CKD having been known since 1966, the nephrology community has poorly investigated this severe complication. CKD patients with moderate chronic renal failure (glomerular filtration rate < 45 mL/min) have a risk of hip fractures two-fold that of the general population, indicating a tight correlation between skeletal fragility and renal failure (1–3). In end-stage renal failure the incidence of hip fracture is at least 4 times higher than in the general population (4–6).

Few studies have been carried out on vertebral fractures (VFs) in CKD patients. In the secondary hyperparathyroidism by CKD is mainly affected cortical bone. We found VF prevalence to exceed 50% in hemodialysis patients (55%), similar to that of a control group affected by primary osteoporosis, and similar to the 50% prevalence reported for osteopenia postmenopausal women or in a renal transplant cohort with a prevalence of 57% (7–9). Noteworthy, there is a bidirectional link between VFs. and Vascular Calcifications (VCs), even more marked in CKD patients than in the general population. (10). Furthermore, VFs are strongly associated to higher mortality (11). In the last September, there has been KDIGO Controversies Conference on Chronic Kidney Disease–Mineral and Bone Disorder: Progress and Knowledge Gaps Towards Personalizing Care meeting, with an update, chair Professor Markus Ketteler.

Furthermore, Bone Biopsy histomorphometric analysis is the gold standard for the diagnosis and classification of different forms of renal osteodystrophy, indeed it is the only technique able to provide comprehensive information on static and dynamic parameters of turnover, cortical and trabecular microarchitecture, and mineralization defects. In particular, in clinical practice, bone biopsy yields relevant indications to support therapeutic choices in CKD impacting the management and prognosis of uremic patients.

Objective of the symposium will be to provide all participants with an in-depth and thus educational growth on prevention, diagnosis, and therapy of osteoporosis in the chronic kidney disease based on the latest evidence in the literature, but also offer the necessary tools to create a fruitful multidisciplinary collaboration, which is essential to improve care for our patients.

NSS32
BONE BIOPSY: HOW, WHEN, AND WHY PERFORM IT IN CKD PATIENTS?

M. Haarhaus[1]

[1]Karolinska Institutet, CLINTEC, Division of Renal Medicine, Stockholm, Sweden

Chronic kidney disease (CKD) is a state of premature aging. Features of senescence, including cardiovascular disease and increased skeletal fragility, are common manifestations of CKD. Fracture risk and cardiovascular mortality are multifold higher in CKD than in the age-matched general population. While primary and secondary forms of osteoporosis frequently coincide with CKD, CKD-associated complex disturbances of mineral metabolism, termed CKD – mineral and bone disorder (MBD), increase bone fragility even further.

CKD-MBD is characterized by biochemical alterations of mineral metabolism, vascular pathology, and disturbed bone metabolism. Based on bone histomorphometry, skeletal manifestations of CKD-MBD are described as disturbances of bone turnover, mineralization, and volume, collectively termed renal osteodystrophy (ROD).

Management of CKD-MBD differs largely, depending on its biochemical, vascular, and skeletal manifestations. Non-invasive diagnostic criteria have been developed to support therapeutic decision making, however, regarding ROD, non-invasive methods lack the ability to sufficiently differentiate between high and low turnover and absence or presence of disturbed mineralization. Thus, an iliac crest bone biopsy for histomorphometric analysis has been described as the gold standard for diagnosis of ROD. Despite its ability to diagnose different forms of ROD with high precision, a bone biopsy has several disadvantages, rendering it not an optimal diagnostic tool for every day clinical practice. Furthermore, expertise to perform classical histomorphometry is rare, causing long waiting times for diagnostic results.

It is thus of importance to integrate bone biopsies in a wider armament of diagnostic tools for the management of manifestations of CKD-MBD. Acknowledging the exceptionally high burden of fragility fractures and cardiovascular disease in CKD, recent development has shifted from a nihilistic to a more active approach to therapy and prevention despite the paucity of large interventional trials specifically targeting the CKD population. While earlier clinical guidelines specified clear indications for bone biopsies, based on pathophysiological considerations, current guidelines are less specific, but define indications by the relevance of the biopsy for clinical decision making.

I will discuss recent developments within skeletal diagnostics for CKD-MBD with a strong orientation towards the clinical management of its main manifestations, i.e. fragility fractures and cardiovascular disease. I will further discuss current clinical indications for bone biopsies in cKD and how to integrate results into the clinical management of patients with CKD.

NSS33
EPIDEMIOLOGY OF VD IN RHEUMATIC DISEASES

P. Clark[1]

[1]Director Clinical Epidemiology Unit, Federico Gomez Hospital, UNAM, Mexico, Mexico

Vitamin D has been a hot spot over the last 2 or 3 decades not only in its effects on bone and mineral metabolism. Its deficiency can lead to rickets, osteomalacia and osteoporosis, mainly mediated by secondary hyperparathyroidism, but also to the possible association of this pro hormone in many diseases in which, the immune system is compromised as in the case of the rheumatic diseases.

Various effects on several components of the innate and adaptative immune system has been reported as the effects of VDR activation the proliferation, function and differentiation of immune cells: however, the role of VD either in prevention or/and treatment of rheumatic diseases is inconclusive due to several confounders as the coexistence with comorbidities, lack of sun exposure or outdoor activities.

There are few epidemiological studies regarding the epidemiology of VD deficiency and rheumatic diseases. In a recent review from *N. Charoenngam (Vitamin D and Rheumatic Diseases: a Review of Clinical Evidence. Int. J. Mol, Sci 2021, 22)* some data are found:

In Rheumatoid Arthritis, multiple observational studies have shown the association of VD status with the incidence and severity of RA. Women in the highest tertile of VD intake had lower risk for RA by 33% compared with those in the lowest tertile. In Systemic Lupus Erythematosus, a low level of serum 25 (OH)D has been associated with deficiency in many case–control studies. Nonetheless in the Nurses' Health Studies I and II, of 186,389 women and 190 incident SLE patients, there was no association between VD intake and risk of incident SLE.

Regarding the Spondyloarthropathies, low levels of serum 25 (OH)D have been observed in patients with AS and IBD compared with healthy individuals.

In Gout and Hyperuricemia, a meta-analysis of 7 cross sectional studies in individuals with increased serum uric acid has been associated with deficiency/insufficiency of VD.

In Osteoarthritis and other rheumatic diseases, as well as in fibromyalgia some studies found the association of disease with low levels of VD.

This association, however, still controversial since the reported literature is controversial, while some studies find this correlation some other don't. The primary studies as well as meta-analysis have

several methodological limitations and further studies carefully designed are needed to find the evidence of this clinical question.

NSS34
VITAMIN D AND SYSTEMIC LUPUS ERYTHEMATOSUS, ANTIPHOSPHOLIPID SYNDROME, AND SYSTEMIC SCLEROSIS

J. L. A. Morales Torres[1]

[1]Rheumatologist, Hospital Aranda de la Parra, León, Mexico

Immunomodulatory effects of Vitamin D (VD) are well recognized, beyond its importance on bone homeostasis. Effects on immune cells, through interactions with VD Receptor expressed on them, are well known. Patients with Systemic Lupus Erythematosus (SLE); antiphospholipid syndrome (APS) and systemic sclerosis (SS), show a higher frequency of VD insufficiency and deficiency, when compared with healthy controls, and hypovitaminosis D is associated with more active disease and cardiovascular risk in SLE; more thrombotic events in APS and with clinical and serological features of SS. Although randomized clinical trials of supplementation with VD in those diseases are scant and results inconsistent, it is generally accepted that patients with SLE, APS and SS should maintain a serum 25-OH-D level of at least 30 ng/ml to preserve bone health and possibly 40–60 ng/ml for immune and overall health.

NSS35
VITAMIN D LEVELS IN PATIENTS WITH RHEUMATOID ARTHRITIS

O. D. Messina[1]

[1]IRO Medical Research Centre, Buenos Aires, Argentina

Rheumatoid arthritis (RA) ia an autoimmune disorders marked by characteristic chronic inflammation of joints in addition of systemic manifestations. Vitamin D is really an hormone rather than a vitamin with immunomodulatory properties and its deficiency has a significant role in the clinical course of RA. Vitamin D deficiency was observed in up to 50% of the patients with RA. Vitamin D deficiency is significantly correlated with disease severity of RA and with DAS28 values.

Main reasons of VtD low levels are, nutritional factors long term glucocorticoid therapy and age related factors in patients with RA. The nuclear vitamin D receptor (VDR = for 1'25) = H = 2D3 is expressed by many cells within the immune system both in innate and adaptive immunity.

Lee et al. showed a correlation between VitD levels and RA activity and published a meta analysis with a deficiency of the 55.2% of patients with RA vs 33.2 in the general population. Cecchetti et al. shoed similar results in the COMEDRA study. It is advisable to maintain VitD serum levels: 30 ng-ml 75 nmol–Lt = and possibly: than 40 ng –ml to achieve maximal benefits from VitD actions in immune health and overall health.

NSS36
FOLLOW-UP THROUGH IMAGINOLOGICAL ASSESSMENT: ADXA, TBS, RX, VFA, 3D-DXA AND QCT

B. Muzzi Camargos[1]

[1]Rede Materdei Saúde, Belo Horizonte, Brazil

Patients eligible to receive bone anabolic therapy have peculiarities linked to degenerative diseases of the spine, fractures and advanced age compared to those patients eligible for oral bisphosphonates. These peculiarities imply on artifactual findings that may interfere with imaging assessment.

Areal DXA is specially affected by lumbar spine degenerative diseases and by calcification of abdominal aorta. Fractures within the L1L4 segment are common but can me neutralized by software resources. The DXA software is able to apply vertebra exclusion, thus reducing the influence of a crushed vertebra on the segment studied. The exclusion criteria is either visual or numerical. If there is a visible fracture or T-score discrepancy (above 1.0 SD T-score) within L1L4 segment, the corresponding vertebra shall be excluded. Other sites like proximal femur and forearm can be used for diagnosis when lumbar spine is impaired for DXA purposes.

TBS is less affected by degenerative diseases and than aDXA. However, it is also affected when there is a massive influence of these artifactual changes within the sites of interest. On primary osteoporosis, TBS predicts fracture independent of BMD and other CRFs, including FRAX. TBS adds predictive value alongside FRAX and/or BMD T-score and the greatest utility is for patients close to an intervention threshold. On secondary osteoporosis, TBS predicts fracture associated with secondary osteoporosis, such as in type 2 diabetes, chronic kidney disease and rheumatological conditions. TBS adds value when monitoring the skeletal response to aromatase inhibitors and glucocorticoids. TBS is useful for stratifying osteoporosis treatment and for monitoring individual response to treatments including denosumab, PTH/PTH analogues and romosozumab.

Plain radiographic X-ray and VFA are useful tools for spine fracture identification. VFA can be done in the same device of aDXA thus it is a practical and low radiation exposure method. VFA lacks precision when the vertebral fractures are in lower grade, classified as mild deformities within the vertebral body. This limitation is due the lower resolution. Plain X-ray radiographs are performed on a separate device from densitometers. But it is considered of higher resolution than aDXA. It allows radiographs to identify even mild compression vertebral fractures. VFA has limitations also on higher spine because of other structures and scoliosis. Patients on anabolic therapy usually have vertebral fractures assessed by CT and MRI or even plain radiographs. Therefore, VFA might be more useful on fracture-free and low density patients, not submitted to a thorough imaging investigation.

3D-DXA and QCT are analogue methods. The first one is a DXA-based method which based it's ROC curve on QCT images. Both target bone quality rather than bone density. Although well recognized, their clinical use is less popular than the othwer methods listed above.

NSS37
CLINICAL MANAGEMENT OF PATIENTS UNDER ANABOLIC THERAPY

A. M. Cheung[1]

[1]Staff, General Internal Medicine and Endocrinology, Department of Medicine and Joint Department of Medical Imaging University Health Network and Sinai Health System, Toronto, Canada

Anabolic therapies are revolutionizing osteoporosis treatment. We can now build bone tissue, rather than just preventing its loss. This session will address who should receive anabolic therapy based on various international guidelines, how long they should receive it for, and how to manage patients receiving anabolic therapy. We will also discuss what laboratory tests/ bone biomarkers may be helpful while on therapy, and things to look out for in the management of these patients. We will also discuss what therapies to consider after completion of the course of anabolic therapy, and whether and when to consider re-use of another course of anabolic therapy.

NSS38
HOW TO WRITE A NARRATIVE REVIEW

S. Sabico[1]

[1]Professor, King Saud University, Riyadh, Saudi Arabia

Among the literature reviews found in peer-reviewed journals, narrative reviews are undoubtedly the most common type and easiest to draft. As a survey of select, previously published data on a certain topic, narrative reviews also require less resources compared to original articles, with the exception perhaps, of consensus/position statements, a type of narrative review which requires an assembly of experts, usually commissioned by medical societies that will serve as practitioner guidelines for a specific disease. Narrative reviews published in high impact journals are almost always by invitation (solicited), but most journals encourage narrative reviews from early-career researchers. While narrative reviews are non-systematic and less rigorous, it should nevertheless be structured with a topic that is both timely and relevant to the intended audience. Conventionally, narrative reviews need to first have a defined scope and audience, a planned search of literature taking into consideration the level of evidence, time period and outcomes, to name a few. These selected studies can then be structured and synthesized according to themes and relevance, creating the backbone or outline of the review. Lastly, narrative reviews should conclude with statements that match the intended purpose, in light of the available evidence presented, highlighting the gaps that need further research.

NSS39
HOW TO WRITE A SYSTEMATIC REVIEW AND META-ANALYSIS

G. Honvo[1,2]

[1]Assistant Professor of Epidemiology and Public Health, University of Abomey-Calavi, Department of Biodemical Sciences, Abomey-Calavi, Benin, [2]Collaborator University of Liège, Division of Public Health, Epidemiology and Health Economics, Liège, Belgium

Systematic reviews play an important role in clinical medicine and clinical epidemiology, and particularly in the development of clinical guidelines. In fact, they are considered the highest level of evidence for informing clinical and public health decisions. As such, they have become one of the most important types of studies published in the scientific literature over the past decades. However, while there has been a dramatic increase in the number of systematic review articles, reports have shown decrease in the quality of these publications. This presentation aims to discuss how to write a good systematic review and meta-analysis article, and particularly errors to avoid (or good writing practices to adopt) in drafting systematic review manuscripts for submission to scientific Journals. Drawing from extensive experience in peer-reviewing systematic review and meta-analysis articles, as well as in handling this type of research papers as Academic Editor for scientific Journals, the speaker intends to share with the audience some major issues usually seen in systematic review and meta-analyses manuscripts, that should be avoided in preparing these manuscripts. The presentation will specifically cover issues related to guidelines for systematic reviews and meta-analyses, formulation of research question/objective, selection criteria, search strategies, data synthesis/analysis, and more generally the reporting of the methods section of a systematic review article.

NSS40
HOW TO WRITE AN UMBRELLA REVIEW

N. Veronese[1]

[1]Professor, University of Palermo, Palermo, Italy

An umbrella review is a review of systematic reviews or meta-analyses. Some researchers propose that a useful strategy in the rain of evidence. Writing an umbrella review involves a meticulous and structured approach to assimilate and evaluate a broad spectrum of evidence from previously conducted systematic reviews and meta-analyses. The initial step entails defining a well-focused research question to guide the literature search and inclusion criteria. Critical appraisal is fundamental in assessing the methodological quality and bias of the included reviews. Utilizing established tools, such as AMSTAR, helps in evaluating the rigor of each review, aiding in the selection of high-quality evidence. Transparency in reporting the search process, inclusion criteria, and methodological assessments is imperative to enhance the credibility and reproducibility of an umbrella review. Synthesizing evidence from diverse reviews requires a meticulous data extraction process. The umbrella review also provides an opportunity to explore sources of heterogeneity among reviews and potential biases. In the final stages, a comprehensive narrative or quantitative synthesis is crafted to present a cohesive overview of the evidence landscape. Emphasizing clarity and accessibility in conveying the findings ensures that the umbrella review serves as a valuable resource for clinicians, researchers, and policy-makers. In conclusion, crafting an umbrella review demands a rigorous and systematic approach from formulating a precise research question to synthesizing evidence and transparently reporting the methodology. This methodological precision enhances the utility of the umbrella review in guiding future research directions and informing evidence-based practice.

NSS41
WHAT IS 'CLINICAL AI' AND HOW IS IT USED IN OSTEOPOROSIS?

N. Fuggle[1]

[1]Associate Professor, MRC Lifecourse Epidemiology Centre, University of Southampton, Southampton, United Kingdom

The field of artificial intelligence is not new, but with the advent of high-speed computing, novel algorithmic architectures and large, multi-modal datasets, there is growing excitement around this technology and it's potential ability to impact healthcare.

In this session we will demystify the jargon which surrounds AI and look at the opportunities for deployment in clinical practice.

To date, the majority of examples of Clinical AI tools approved for use in clinical practice have been in the field of imaging, due to the presence of large libraries to supply training datasets and, in the UK, these include products to assist with mammography assessment and analysis of CT brain scans for the presence of ischaemic stroke.

A similar trend for the development of AI 'Software as a Medical Device' (SaMD) exists in the field of osteoporosis, although AI and machine learning have been used for the development of risk prediction algorithms, and the analyses of muti-omic datasets for potential therapeutic targets.

Imaging studies to date have focused on utilising DXA images to improve fracture prediction beyond bone mineral density (BMD), opportunistic measurement of BMD from routinely performed imaging, opportunistic identification of vertebral fractures from routinely performed imaging and the derivation of bone microarchitectural features from alternative imaging modalities.

Despite the excitement, there are substantial challenges which must be borne in mind and addressed as the field moves forward, including issues around data privacy, establishing clear lines of accountability and working towards explainability of these 'black boxes'.

NSS42
ETHICAL CONSIDERATIONS WHEN USING OF AI IN CLINICAL PRACTICE

I. The Artificial Intelligence Ethics Team[1]

[1]Alan Turing Institute, London, United Kingdom

The ethics of artificial intelligence is often depicted as relating to white robots interacting with humans via versions of Michelangelo's 'Creation of Adam' in which a mechanical digit connects with a human finger. However, the reality of the field lies not in robotics, but in the careful consideration of the ethical issues surrounding the development and deployment of mathematical algorithms or software which are used to perform tasks normally requiring human levels of intelligence, including weighing the benefits against the substantial risks.

There is a dualism to artificial intelligence with the same techniques used, on the one hand, to seek patterns in healthcare data to better understand human health and disease and, on the other hand, to expound disinformation and pose threats to cybersecurity. AI ethics is used to map the path between these potential benefits and possible harms via the consideration of ethical principles in this context.

Furthermore, as AI develops, the deferral of decision-making to these tools has the potential to lead a loss of autonomy, interpersonal interaction and human agency. At worst, AI has the potential to violate human rights, the the use of an individual's data without permission violating their right to privacy and the reproduction of unfair or discriminatory patterns in data entrenching health disparities and clinical biases, leading to discrimination.

Other ethical questions to consider in the present include:

- How will the current driving forces of AI excitement bear upon the use of AI by future generations?
- How will legal and regulatory frameworks stay abreast of the rapidly developing landscape of technological advancement?

Indeed, with the burgeoning excitement around the deployment of artificial intelligence in healthcare and clinical practice, must come a rigorous and thoughtful consideration of the ethical, regulatory and legal implications of using these tools and the development of frameworks which address the above questions, risks and concerns.

NSS43
ARTIFICIAL INTELLIGENCE IN OSTEOPOROSIS: INCLUDING A CASE STUDY OF VERTEBRAL FRACTURE DETECTION: AI FOR VERTEBRAL FRACTURE SCREENING: A UK PERSPECTIVE—FINDINGS OF THE ADOPT STUDY

K. Javaid[1]

[1]Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, University of Oxford, Oxford, United Kingdom

Fracture Liaison Services (FLSs) are widely endorsed for the provision of secondary fracture prevention in adults who have recently been diagnosed with a fragility fracture. Identifying patients with non-spinal fractures is relatively straightforward. However, there are unique challenges in the identification of adults with vertebral fractures, who are often at a very high fracture risk. The widespread use of CT scanning in general clinical practice represent a potential opportunity to help close this care gap. There is mounting evidence that a significant number of adults have radiological vertebral fractures that are not being reported or actioned to mitigate the patient's fracture risk. This oversight represents a missed opportunity to prevent avoidable fractures in the short and longer term.

Several AI models have been trained and tested to identify patients with moderate and severe vertebral fractures. However, there is a paucity of data describing implications from the real-world implementation of these models into routine clinical practice. The ADOPT study, funded by the UK NIHR, is a programme of work specifically designed to test the implementation and performance of an AI model for detecting vertebral fractures (Nanox-AI) across five public hospitals in the NHS. In this symposium, we will share insights around the specific challenges of obtaining local information governance approvals, integrating the software with local radiology systems, clinical training on the detection of vertebral fractures, patient co-production of clinical pathways and service improvement. We will also discuss the performance of the AI model in comparison with routine radiological reports and local radiology re-reading using different sensitivity and specificity settings of the AI model, including impacts on the local FLS workforce.

NSS44
GLOBAL EXPERIENCES IN FLS IMPLEMENTATION AND SECONDARY FRACTURE PREVENTION IN POLICY—ASIA–PACIFIC

M. Chandran[1]

[1]Singapore General Hospital, Osteoporosis and Bone Metabolism Unit, Department of Endocrinology, Singapore, Singapore

By 2050, the number of hip fractures is projected to increase to in the Asia Pacific region from 1.13 million in 2018, to 2.54 million in 2050, resulting in staggering projected costs of almost USD 13 billion[1,2]. Implementation of Fracture Liaison Services has seen an increase from 96 FLS mapped on the Capture the Fracture® Map of Best Practice at the beginning of 2020 to 227 at the beginning of 2024. Regional initiatives such as APCO provide resources for osteoporosis and fragility fracture management such as the Bone Health QI Toolkit launched in 2022[3]. Together, IOF and APCO are developing a 2023 update to the 2013 Asia–Pacific Bone Health Regional Audit, with work starting in 2023[2]. These efforts are promising, and must be continued with support from all levels of decision-making to prepare for the projected more than doubling of hip fractures in the region by 2050.

GLOBAL EXPERIENCES IN FLS IMPLEMENTATION AND SECONDARY FRACTURE PREVENTION IN POLICY—EUROPE

M. L. Brandi[1]

[1]Fondazione FIRMO and Observatory for Fragility Fractures, Florence, Italy

Fragility fractures are a major concern for public health in Italy with approximately 570,000 fragility fractures per year, with associated costs of €9.5 billion in 2019[1]. Guidelines have been developed for the diagnosis, risk assessment, treatment, and management of fragility fractures in Italy[2]. Recent initiatives to track the burden of fragility fractures have been developed, such as the Fragility Fracture Observatory which acts as a monitoring centre for the epidemiology of fragility fractures in Italy. Despite these encouraging advances, additional work needs to be done as more than 2 million Italian women at high risk of fracture remain untreated for osteoporosis and only 10% of Italian hospitals have a Fracture Liaison Service (FLS).

F. Buckinx[1]

[1]WHO Collaborating Center for Public Health aspects of musculoskeletal health and ageing, Division of Public Health, Epidemiology and Health Economics, University of Liège, Liège, Belgium

The SENIOR ("Sample of Elderly Nursing homes Individuals: an Observational Research") study is a prospective follow-up of a cohort of more than 600 people living in nursing homes in Belgium, which started in 2013. Its primary objective was to improve understanding of the risk factors, consequences, and dynamics of frailty. In addition, it aimed to explore strategies for managing frailty in order to reduce the incidence of adverse health events. This symposium will present the key findings from this cohort, enriched by the comprehensive annual collection of demographic, clinical, and anamnestic data.

First, the symposium will address the cross-sectional dimension, highlighting the prevalence of frailty using different diagnostic tools. The variables associated with frailty in the SENIOR cohort will be presented, with a particular focus on muscle strength, sarcopenia, and agism. The longitudinal aspect will then unfold, identifying adverse health events, key risk factors, and their interactions within the first three years of monitoring this cohort.

In addition, the symposium will emphasise the fundamental role of nutrition and physical activity in the management of frailty and present findings from the SENIOR cohort in these areas. In terms of nutrition, a meticulous investigation present precise energy intake using the food-weighing method, as well as revealing energy expenditure using indirect calorimetry in nursing home residents. In particular, it will shed light on the complex relationship between psycho-emotional factors and food intake. Shifting the focus on physical activity, the symposium will highlight the importance of promoting qualitative physical activities in nursing homes to improve residents' quality of life. It will consider strategies to improve the motivational context of group physical activity sessions. It will also explore the feasibility and impact of innovative physical activity programmes, based on the development of novel approaches such as a giant play mat or the organisation of competitions within nursing homes.

The richness of the demographic, clinical, and anamnestic data collected annually makes this cohort of great interest to the scientific community. The SENIOR study has the potential to fill important gaps in the frailty literature.

NSS49
SARCOPHAGE CONTRIBUTIONS TO SARCOPENIA, MALNUTRITION AND QUALITY OF LIFE

C. Beaudart[1]

[1]Department of Biomedical Sciences, Clinical Pharmacology and Toxicology Research Unit, Namur Research Institute for Life Sciences (NARILIS), Faculty of Medicine, University of Namur, Namur, Belgium

The Sarcopenia and Physical Impairment with Advancing Age (SarcoPhage) prospective cohort study, initiated in 2013 in Liège, Belgium, enrolled 534 community-dwelling individuals aged 65 years and older. The study initially aimed to evaluate the short and medium-term health and functional consequences of sarcopenia. Over a decade of meticulous follow-up with annual assessments, this study has produced over 25 scientific publications, prompting a comprehensive reflection on its diverse outputs and original data.

Pr. Charlotte Beaudart will present the study's most significant scientific achievements, with a focus on key findings that have shaped the field. First, early publications from the SarcoPhage study will be presented, as those investigated variations in sarcopenia prevalence using different tools for measuring muscle mass, strength, and physical performance, as well as diverse cutoffs for parameter assessment, yielding highly cited papers. Subsequently, this cohort study played a crucial role in developing, in 2015, the first health-related quality of life questionnaire tailored for sarcopenia, i.e. the SarQoL. Today, this questionnaire is available in 35 languages, widely employed by researchers and clinicians globally, and endorsed by the European Society for Clinical and Economic Aspects of Osteoporosis, Osteoarthritis and Musculoskeletal Diseases (ESCEO) as the sole validated health-related quality of life questionnaire for sarcopenia. Beyond assessing the repercussions of sarcopenia on physical parameters and quality of life, the SarcoPhage study also delved into malnutrition research. Significantly, the study revealed the profound impact of malnutrition on both the onset of sarcopenia and mortality. More recently, the study has also explored the World Health Organization's emerging concept of Intrinsic Capacities within its Healthy Ageing program.

In this symposium, an overview of the SarcoPhage Study will be presented, highlighting its pivotal scientific achievements and key findings. Emphasis will be placed on how these discoveries have contributed to advancing the broader research landscape on healthy ageing.

NSS50
THE SENIOR AND SARCOPHAGE COHORTS TO STUDY COVID AND LONG-TERM MORTALITY

C. Demonceau[1]

[1]WHO Collaborating Center for Public Health aspects of musculoskeletal health and ageing, Division of Public Health, Epidemiology and Health Economics, University of Liège, Liège, Belgium

The SENIOR ("Sample of Elderly Nursing homes Individuals: an Observational Research") and the SarcoPhAge (Sarcopenia and Physical Impairment with Advancing Age) are two Belgian prospective cohort studies with a duration of 8 and 10 years, respectively. While a direct comparison of these two cohorts is challenging due to inherent differences in their composition, this symposium offers a unique opportunity to place the results of both in parallel, taking advantage of the rich longitudinal data collected.

This symposium will first highlight the associations, or lack thereof, between frailty, sarcopenia and their related components in the context of the Covid-19 pandemic and how these factors may influence the incidence and severity of the Covid-19.

The symposium will also focus on long-term mortality within these cohorts. By using longitudinal data over different follow-up periods, we have identified factors associated with 8- and 10-year mortality, providing new insights for a comprehensive understanding of the dynamics of mortality in the older population.

The wealth of data provided by these cohorts not only offers new insights into the vulnerabilities and health trajectories of older people but also provide major information for tailoring public health interventions for older people in our communities.

NSS51
TREATMENT INDUCED OSTEOPOROSIS IN WOMEN WITH BREAST CANCER

P. Hadji[1]

[1]Head of the Frankfurt Center of Bone Health, Frankfurt, Germany

Osteoporosis is one of the most frequent diseases in postmenopausal women leading to an increased fracture risk due to the physiologic loss of the bone protective effects of estrogen. Hereby, several risk factors for fracture such as prevalent fracture, low BMD, age, family history, use of glucocorticoid use etc. have been identified. Additionally, the further reduction of endogenous estrogens with chemotherapy (CHT), GnRH-Analogues or aromatase inhibitors (AI) continuously increases fracture risk. Breast cancer (BC) on the other hand is the most frequent cancer type in women. Recent reports indicated a continuous increased incidence while mortality, due to early diagnosis and treatment improvements is decreasing. Dependent on specific tumor characteristics, radiation, chemotherapy (CHT), antibody treatment as well as endocrine treatment has been introduced into the adjuvant clinical treatment setting.

Some but not all of this cancer specific treatments interfere with bone turnover leading to an accelerate bone loss referred to as cancer treatment induced bone loss (CTIBL). Whereas CHT leads to an unspecific increased of bone resorption, Aromatase inhibitor (AI) reduces residual serum endogenous estrogen level and is associated with a decrease of bone mineral density (BMD) and increased fracture risk. Independent of the type of AI administered, bone loss is 2–3-fold increase compared to healthy, age matched postmenopausal controls. Therefore, several guidelines have emerged to help managing CTIBL in women with BC including strategies to identify and treat those at highest risk for fractures.

The lecture will summarize the current knowledge on CTIBL and fracturing risk and indicates current treatment guidelines and intervention options.

NSS52
THE IMPACT OF ANDROGEN DEPRIVATION THERAPY ON BONE HEALTH IN PATIENTS WITH PROSTATE CANCER

J. E. Brown[1]

[1]Division of Clinical Medicine, University of Sheffield, Sheffield, United Kingdom

Around 1 in 8 men will experience prostate cancer (PC) in their lifetime. Endocrine-based treatment including androgen deprivation therapy (ADT) has proven to be a mainstay of PC management for many years and many patients now receive ADT throughout their cancer journey. Whilst successful in reducing testosterone levels and improving PC survival, ADT is associated with negative impacts on bone health, leading to bone loss and consequent increased risk of osteoporotic fracture.

Many newer systemic therapies for PC have been introduced in recent years and patients may now live with their disease for many years, but these treatments may themselves cause detrimental effects on the skeleton. The long-term consequences of treatment are therefore of increasing importance. However, these PC patients are often not routinely referred to bone specialists for optimisation of their bone health, despite the fact that the resulting increased risks of osteoporotic fragility fractures (often requiring hospitalisation) represent substantial problems for patients and healthcare systems.

Bone loss (reduction in areal bone density) is easily measured using dual energy x-ray absorptiometry and more recent technology (eg high resolution peripheral quantitative computed tomography), shows that ADT not only reduces areal bone density, but also volumetric bone density and also impairs the mechanical properties of bone.

Bone loss can be prevented or repaired using bone targeted agents such as bisphosphonates or the fully humanised antibody, denosumab. The detailed guidance for managing the skeletal health of patients receiving ADT will be discussed in the light of current treatment pathways for PC patients.

NSS53
CURRENT GUIDELINE DEPENDENT TREATMENT OF BONE METASTASIS

C. Confavreux[1,2]

[1]INSERM UMR 1033-LYOS, Université Claude Bernard Lyon 1, Lyon, France, [2]Bone Metastasis Expert Center (CEMOS), Department of Rheumatology, Hospices Civils de Lyon, Lyon, France

Bone is the third most common site for solid cancer metastasis. Metastases to the bone can cause severe pain, pathological fractures of the long bones and spine, and may even lead to spinal cord compression or hypercalcemia. These complications can result in the suspension of oncological treatment, bed rest, loss of autonomy, and require specific and heavy care involving radiotherapy, surgery, or interventional radiology. Therefore, it is crucial for clinicians to take all necessary measures to prevent skeletal-related events. Along with local treatments and oncological therapy, the use of systemic anti-resorbing agents (ARA) such as zoledronic acid and denosumab has proven effective in reducing the occurrence of bone events in solid tumors.

Trials with ARAs were conducted approximately fifteen years ago, utilizing a 24-month monthly administration schedule in patients with a low survival expectancy. Today, we are witnessing remarkable progress in oncology that is improving patient survival and bone response. This progress is causing us to reconsider our use of ARAs in bone metastases, in order to optimize the balance between benefits and risks (such as osteonecrosis of the jaw and atypical fractures) and enable long-term bone management for patients. These developments raise new questions for rheumatologists. How to interact cross-functionally with the oncologist? How to evaluate and re-evaluate the risk of fracture? Is it possible to space out the treatment? Is it possible to suspend it? If so, what would be the procedures? The presentation will address these topics and emphasize the importance of collaborative work among physicians of different specialities, preferably during the Bone Metastasis Multidiciplinary Meeting.

VASCULAR-BONE NEXUS: A NARRATIVE REVIEW OF THE EVIDENCE FROM EPIDEMIOLOGICAL STUDIES AND RANDOMISED CONTROLLED TRIALS

J. R. Lewis[1]

[1]Edith Cowan University, Perth, Australia

Background: In older individuals at higher risk of musculoskeletal disorders, after the skeleton, the vasculature is often the next most calcified structure within the body. Epidemiological studies, genetic studies and randomised controlled trials link low bone mass and fractures with cardiovascular disease and vice versa.
Objectives: Perturbations of the vascular-bone nexus during aging and chronic disease can lead to accelerated bone loss and vascular calcification. It is essential to improve our understanding of these vascular-bone interactions to develop new ways to prevent bone loss and vascular calcification development as well as address the potential risk–benefit for therapeutic agents to treat both skeletal deterioration and cardiovascular disease. Insights from this bi-directional signalling between the blood vessels and the skeleton are therefore essential to maintain both bone and vascular health during ageing.
Results: We and others have published data identifying supporting this link and the overlap in cytokine regulation of bone and vascular phenomena. However, these signalling pathways and evidence from epidemiological studies and randomised controlled trials for the link remain to be poorly understood. This narrative review will discuss how and why vascular calcification develops and progresses, how and which blood vessels are commonly assessed for vascular calcification and the epidemiological evidence for the temporal nature of the relationship between vascular calcification and measures of bone health and fracture. The review will also discuss and summarise the effects of bone active medications on vascular calcification and cardiovascular events from randomised controlled trials and will discuss the latest advanced in the field of vascular-bone assessment and the clinical implications of this work.
Conclusions: This presentation will provide an overview of the current literature of the vascular-bone nexus including new advanced in the field, existing knowledge gaps and highlight areas for future research.

NSS55
BONE RESORPTION AS A SOURCE OF CALCIUM AND PHOSPHATE IN ATHEROSCLEROSIS

G. Klein[1]

[1]University of Texas Medical Branch/Department of Orthopaedic Surgery and Rehabilitation, Galveston, United States

Objective: Epidemiologic studies link chronic inflammatory conditions with coronary artery calcification and cardiovascular disease. Limited studies indicate reduced cardiovascular and overall mortality in patients using bisphosphonates. Since chronic inflammatory conditions cause bone resorption and bisphosphonates reduce bone resorption, bone resorption may provide the calcium and phosphate precipitating in coronary arteries. The aim of the study was to construct a mechanism whereby calcium and phosphate released from bone could deposit in coronary arteries.
Materialsand methods: Searching PubMed with key words: calcium, phosphate, inflammation, bone, coronary artery calcium, and calcium-sensing receptor (CaSR), I examined the fate of calcium and phosphate entering the circulation from resorbing bone, functional changes in the CaSR from children to adults, inflammatory effects of calcium in the circulation, and known effects of calcium and phosphate in small arteries.
Results: I reviewed 4 inflammatory conditions and burns, which are also accompanied by chronic inflammation: post-menopausal osteoporosis, spinal cord injury, osteoarthritis, and rheumatoid arthritis. Each of the four are associated with bone loss and increased coronary artery calcification. Children with inflammatory conditions up-regulate the CaSR in response to cytokines, causing hypocalcemic hypoparathyroidism with hypercalciuria. When fully grown, adults lose capacity of the CaSR to up-regulate in response to cytokines, possibly by CaSR inhibition by phosphate binding, resulting in persistence of resorbed calcium in the circulation. Calcium accumulation can increase chemokine production by immune cells and stimulate the NLRP3 inflammasome, thus perpetuating or intensifying an inflammatory response. Phosphate from resorbed bone also persists in the circulation due to a decline in Klotho with age and inflammation. In the arterial circulation, calcium-stimulated chemokines can initiate inflammation of lipid deposits and calcium can interact with the vascular endothelial CaSR to increase vessel tone, causing luminal narrowing. Phosphate can initiate osteoblastic differentiation of the vascular endothelium, producing hydroxyapatite which can incorporate the excess calcium and phosphate.
Conclusions: Bone is the likely source of calcium and phosphate precipitating in coronary arteries. Patients with chronic inflammation should have earlier assessment of cardiovascular function and earlier initiation of anti-resorptive treatment or a trial of calcimimetics to reduce coronary artery calcification.

NSS56
SARCOPENIA COMPONENTS AND DEFINITIONS: PREVALENCE, AGREEMENT AND PREDICTIVE CAPACITY REGARDING MORTALITY

L. Westbury[1]

[1]MRC Lifecourse Epidemiology Centre, University of Southampton, Southampton, United Kingdom

Sarcopenia is characterised by the excessive loss of muscle mass, strength and function with age. It is associated with physical disability, falls, and considerable healthcare costs. This lecture presents findings on the prevalence and agreement between sarcopenia definitions proposed by the Sarcopenia Definitions and Outcomes Consortium (SDOC) and the 2019 European Working Group on Sarcopenia in Older People (EWGSOP2), and examines their association with earlier mortality. For example, in a multinational assembly of Western cohort studies of community-dwelling older people, sarcopenia prevalence was low for EWGSOP2 (1.1%) and SDOC (1.7%); agreement was weak between these definitions (kappa statistic: 0.17) *(Westbury* et al*., JCSM 2023;14(1):565–75)*. However, both definitions were strongly associated with mortality (EWGSOP2 (hazard ratio (95% CI 1.76 (1.42, 2.18)), SDOC (2.75 (2.28, 3.31))).

Findings on the predictive capacity of sarcopenia components regarding mortality will also be presented. For example, in a pooled analysis comprising the Osteoporotic Fractures in Men Study, the Health, Aging and Body Composition Study and the Hertfordshire Cohort Study, grip strength (hazard ratio (95% CI) per SD decrease: 1.14 (1.10, 1.19)) and gait speed (1.21 (1.17, 1.26)) were strongly related to mortality after accounting for established mortality risk factors. However, inclusion of grip strength and gait speed in a Cox

model which already included these established risk factors only increased Harrell's Concordance Index from 0.69 to 0.70. This suggests that the use of these sarcopenia components for identifying older people at risk of earlier mortality may be limited.

NSS57
SARCOPENIA COMPONENTS AND DEFINITIONS AS PREDICTORS OF FRACTURE RISK

N. Harvey[1]

[1]MRC Lifecourse Epidemiology Centre, University of Southampton, Southampton, United Kingdom

FRAX is the most widely used fracture risk assessment tool which estimates an individual's 10-year probability of hip and major osteoporotic fracture. This lecture presents recent research exploring the relationship between sarcopenia components and definitions and risk of incident fracture after accounting for FRAX probability and BMD.

In the Osteoporotic Fractures in Men Study cohorts, higher gait speed (hazard ratio (95% CI) per SD increase: 0.85 (0.79, 0.90)), grip strength (0.77 (0.72, 0.82)) and appendicular lean mass index (0.85 (0.80, 0.90)) were associated with lower risk of incident major osteoporotic fracture *(Harvey* et al*., JBMR 2018;33(12):2150–7)*. Although associations were robust after adjustment for FRAX probability, the ALM index association was attenuated after adjustment for BMD. In contrast, greater pQCT calf muscle density was associated with lower risk of incident fracture, independent of FRAX probability, falls and femoral neck BMD *(Harvey* et al*., JBMR Plus 2022;6(12):e10696)*.

Sarcopenia status was predictive of incident major osteoporotic fracture for 10 out of the 11 definitions considered (hazard ratios: 1.39—2.07) *(Harvey* et al*., JBMR 2021;36(7):1235–44)*. Associations were robust to adjustment for FRAX probability (without BMD); but adjustment for BMD attenuated associations, especially for sarcopenia definitions based on DXA-derived ALM.

These findings suggest that whilst physical performance measures may have a role in fracture risk assessment, the predictive capacity of DXA ALM over and above BMD is limited. These findings also demonstrate a complex interplay between measures of bone, muscle strength, function, and quality, in determining fracture risk.

NSS58
PREVALENCE AND BURDEN OF SARCOPENIA IN SUB-SAHARAN AFRICA

K. Ward[1]

[1]MRC Lifecourse Epidemiology Centre, University of Southampton, Southampton, United Kingdom

Little is known about the prevalence and burden of sarcopenia and poor functional ability in low- and middle-income countries. Given the exponential rise in adults aged over 60 years in these populations, data are urgently required to inform potential burdens of disease in coming decades.

In earlier work, among 249 women and 239 men, aged 40 years and older from rural Gambia, the prevalence of sarcopenia was 20% (men) and 45% (women) according to the FNIH definition, and 19% (men) and 10% (women) according to EWGSOP *(Zengin* et al*., JCSM 2018;9(5):920–8)*. These prevalences differ greatly compared to Western populations of a similar age range. This suggests that currently accepted international definitions of sarcopenia may need refinement for application in this population.

The MUFASSA (Musculoskeletal Functional Ability in sub-Saharan Africa) programme of work has collated data on over 3000 community-dwelling men and women living in urban regions of The Gambia, Zimbabwe and South Africa. This lecture will review current gaps in knowledge and present recent research on the prevalence of sarcopenia and poor functional ability, and whether they predict falls, frailty and disability in three contrasting countries, at different stages of nutritional and epidemiological transition.

NSS59
CONSTRUCTION OF A PROJECT TO ASSESS THE RISK OF FALLS BASED ON WOMEN'S MUSCULOSKELETAL PHYSIOLOGY

O. De Matos[1]

[1]PhD, Postgraduate Program in Physical Education and Health, Federal University of Technology, Curitiba, Brazil

There are many measures being used to predict the risk of falls in research and clinical practice, and it is important to investigate the usefulness and consistency of these measures, even if it is to reduce the number of possible risk of falls indicators.

Although our research checks neuromuscular control in older people, our main line is women's health, and in this case we have monitoring from post-menopause to the elderly stage. With menopause, women lose their main protective hormone for protein synthesis, causing a rapid loss of bone and muscle mass due to low estrogen production.

We conclude that for an effective and objective treatment of bone and muscle loss, we need to evaluate the 3 phases of anabolism for these tissues, which are: the dietary profile, absorption capacity and nutrient fixation. Thus, I will have the opportunity to present at the congress how all these aspects are interconnected in a single project.

Topics:

- Population-ageing;
- Falls and expenses;
- Primary health care;
- Importance of musculoskeletal analysis since menopause;
- Physiological phases of anabolism: ingestion, absorption and fixation;

NSS60
DEVELOPMENT OF A FALL RISK ASSESSMENT PROTOCOL BASED ON MUSCULOSKELETAL AND COMPREHENSIVE ASSESSMENT: PROTOCOLS AND MAIN RESULTS

B. Lenardt[1]

[1]Professor and Master degree Student in Postgraduate Program in Physical Education and Health, Federal University of Technology, Curitiba, Brazil

Along these lines, our study analyzed variables associated with the risk of falls, mainly aspects of physical performance. Thus, the objective of the project is to develop the protocol to assess the risk of falls and fractures in frail elderly women. The protocol consists of evaluating the association of sleep disorders, history of falls, physical performance and body composition with bone mineral density to verify the conditions in which women can fall, especially at home, and promote early diagnosis as the main care for health. We are working with several validated tools to assess falls and sleep disorders and after statistical analysis and a pilot program, we developed a new

model with short questions and tests to be applied more easily in the Health Units of our province.

Topics:

- Research and objectives;
- Assessment protocols for risk of falls and fractures, sarcopenia, fragility and sleep disorders;
- Short protocol for risk of falls;
- Outcomes found.

NSS61
THE PRINCIPLES OF OSTEOGENIC LOADING

K. Brooke-Wavell[1]

[1]Human Physiology, School of Sport, Exercise and Health Sciences, Loughborough University, Loughborough, United Kingdom

It is well known that bone responds to mechanical loading by losing mass when unloaded and increasing mass when chronically overloaded. Mechanical loading is typically applied through exercise but not all types of exercise have been found to be effective. Preclinical studies have demonstrated that the degree of bone response is highly dependent on the characteristics of strain generated within bone in response to applied forces. These specific load parameters must be considered if the goal is to formulate an effective exercise prescription. The current talk will present evidence from animal and well-controlled human studies, that report the influence of loading parameters such as strain magnitude, strain rate, cycle number, rest, load frequency and load duration on the bone response to loading.

NSS62
TRANSLATION OF OSTEOGENIC PRINCIPLES INTO EFFECTIVE EXERCISE PRESCRIPTION

B. Beck[1]

[1]Musculoskeletal Anatomy, School of Health Sciences and Social Work, Griffith University and The Bone Clinic, Queensland, Australia

In many parts of the world, exercise continues to be considered merely an ancillary strategy for the management of osteoporosis. The four clear reasons for this scepticism are: 1. generic exercise interventions do not provide a notably effective stimulus in comparison to medications, 2. some patients are reluctant to exercise, 3. GPs don't receive adequate training in exercise prescription, and 4. a perception that exercise is not safe for people with weak bones. As it happens, those concerns can be easily managed. We have demonstrated in rigorous clinical trials that brief, high intensity resistance and impact training (HiRIT) exercise improves bone, muscle and function (all risk factors for fracture) in older women and men with low bone mass without incurring injury. Furthermore, growing evidence from clinical practice has moved bone-targeted exercise, from an ancillary strategy in the management of osteoporosis, to front-line therapy central to patient care.

NSS63
KNOWLEDGE, RISK PERCEPTION, AND IMPACT ON ENGAGEMENT IN THE PREVENTION OF MUSCULOSKELETAL DISEASES—THE FOCUS GROUP OF VITAMIN D

F. Kamberi[1,2], J. Jaho[1], T. Kokuri[3]

[1]Scientific Research Centre for Public Health, University of Vlore "Ismail Qemali", Vlore, Albania, [2]Member of Technical Advisory Group on RCCEIM at WHO Regional Office for Europe, Copenhagen, Denmark, [3]Charité-Universitätsmedizin, Berlin, Germany

Objective: The goal was to assess women's risk perceptions for musculoskeletal diseases based on their levels of vitamin D, knowledge, and awareness.

Material and methods: A focus group composed of 14 women who work indoors was conducted in June 2023. The serum levels of vitamin D were assessed, and a discussion in relation to vitamin D knowledge and risk perception for musculoskeletal diseases was held on the premises of the Scientific Research Centre for Public Health, Albania. All the participants gave their informed written consent to be part of the study.

Results: All participants were women, age $\geq$ 35, with 10 academic medical staff and 4 administrative staff. The mean levels in serum vitamin D were 16.78 $\pm$ 9.21 with an average BMI of 25.64 $\pm$ 4.38. Half of the participants did not go out with sun cream protection and had frequently rhinitis. 65% of participants experienced continued musculoskeletal pain and fatigue. Meanwhile, more than half of the participants had mood swings, depression, or sleep problems, as well as hair loss. Low risk perception and engagement in prevention in relation to musculoskeletal diseases were found.

Conclusions: To effectively prevent and manage musculoskeletal diseases, health education and prevention efforts should be tailored to specific target groups based on their health literacy level and access to reliable and scientific information sources.

Keywords: Vitamin D, knowledge, risk perception, engagement, target groups.

NSS64
SELF-EDUCATION IN CHRONIC PATIENTS WITH MUSCULOSKELETAL CONDITIONS

D. Mio[1,2]

[1]University of Belgrade, Belgrade, Serbia, [2]Health Journalist, Tirana, Albania

Objectives: To provide an overview of the impact of self-education on patient outcomes, the role of digital health tools in facilitating learning, and the importance of personalized self-management education plans in catering to the unique needs of individuals with chronic musculoskeletal conditions.

Material and methods: Through exploring and searching for articles on databases like PubMed and Google Scholar, using keywords like patient education and chronic musculoskeletal conditions," a database of selected articles was created, and a reference list was compiled.

Results: Findings reveal that successful self-education initiatives often incorporate a multidimensional approach, integrating educational resources, peer support, and healthcare professionals' guidance. Furthermore, data from patient intervention programs indicates a substantial impact on self-management skills following educational initiatives.

Conclusions: The positive impact on health literacy, self-management skills, and psychosocial well-being emphasizes the need for healthcare providers to prioritize educational interventions in the care continuum for individuals with chronic musculoskeletal conditions. Future research should continue to explore innovative educational approaches, ensuring a tailored and data-driven strategy for optimal patient outcomes.

Keywords: self-education, chronic patients, musculoskeletal conditions.

NSS65
PHYSIOTHERAPY IN OSTEOPOROSIS. PRACTICE BEHAVIORS AND PHYSIOTHERAPISTS' PERCEPTIONS IN ALBANIA

S. Sinaj[1], F. Kamberi[2], V. Ndreu[1]

[1]Faculty of Technical Medical Sciences, University of Medicine Tirana, Tirana, Albania, [2]Scientific Research Centre for Public Health, University of Vlore "Ismail Qemali", Vlore, Albania

Objective: This study's objective was to investigate the most common treatment modalities used by a random sample of physiotherapists practicing in Tirana for individuals with osteoporosis. Assess whether physical therapists have concerns about the use of manual therapy in individuals with osteoporosis, particularly fractures, as a complication of treatment.
Material and methods: This cross-sectional study included 104 physiotherapists in Tirana, Albania. The physiotherapists were evaluated using a questionnaire developed by the Albanian Association of Physical Therapists. Physiotherapists incorporated the osteoporosis treatment modality and the osteoporosis knowledge assessment test (OKAT).
Results: The questionnaire was completed by 97 physiotherapists. The percentage of reaction was 93% (97/104). The majority of the physiotherapists in the study (93%) used therapeutic exercises and posture re-education; only 15% used manual therapy. Ninety-five percent of respondents expressed reservations about using manual treatment. The most often reported issues were vertebral fractures and rib fractures.
Conclusions: According to the research, the majority of physiotherapists in Albania employ evidence-based approaches when treating persons with osteoporosis, whereas a tiny number use manual treatment and are concerned about its use. Fractures, particularly vertebral fractures, are of special concern to physiotherapists, although injury to other musculoskeletal tissues is also a worry. Manual treatment safety and effectiveness studies in this population are needed to guide therapeutic practice.
Keywords: Osteoporosis, therapeutic exercises, manual therapy, fracture.

NSS66
EVALUATION OF KNOWLEDGE ON THE IMPACT OF VITAMIN D ON OSTEOARTHRITIS

G. Sinanaj[1]

[1]Scientific Research Centre for Public Health, University of Vlore "Ismail Qemali", Vlore, Albania

Objective: This review study aims to provide an overview of studies that present the evaluation of knowledge on the influence of vitamin D on osteoarthritis.
Material and methods: This is a literature review that includes research conducted in the Google Scholar, PubMed, and Medline databases. Respecting the inclusion criteria, 27 articles were reviewed.
Results: The data show that the effect of vitamin D varies depending on the disease state; nevertheless, little is known about its role in the onset and progression of OA. Clinical data show that vitamin D has a minimal protective effect on cartilage volume loss or radiologic OA beginning, while it may have a preventative effect on joint discomfort. Vitamin D deficiency is a risk factor for increased knee osteoarthritis progression, and patients with knee osteoarthritis may benefit from increased appropriate dietary consumption. Vitamin D supplementation could be a safe technique to treat and prevent OA, but further research is needed to pinpoint the exact mechanism and final efficacy.
Conclusions: Vitamin D is important not only for bone health but also for general health.
Keywords: vitamin D, impact, osteoarthritis.

NSS67
PRIMARY HYPERPARATHYROIDISM. ETIOLOGY AND CLINICAL MANIFESTATIONS

I. Kostoglou-Athanassiou[1]

[1]Department of Endocrinology, Diabetes and Metabolism, Asclepeion Hospital, Voula,, Athens, Greece

Primary hyperparathyroidism (PHPT) is a common endocrinologic disorder. It leads to chronically elevated levels of serum calcium, decreased phosphate and increased parathyroid hormone concentrations. The disorder may be due either to the presence of one or more than one adenomas in the area of the parathyroid glands or to diffuse hyperplasia of the parathyroid glands. Parathyroid adenomas may also be ectopically located, mainly in the upper mediastinum. In earlier years PHPT was diagnosed late in the course of the disease when the renal and osseous manifestations of the disease were already present. Nowadays, the disease is diagnosed early in the course of the disease due to the measurement of calcium during routine biochemical evaluation. In many cases PHPT is diagnosed when it presents with minimal or no symptoms. PHPT may also present with normal calcium levels and inappropriately elevated levels of PTH. Following the diagnosis of PHPT localization of the parathyroid adenoma is performed by ultrasonography and scintigraphy. Management of primary PHPT is either medical with the use of calcimimetics or by surgery. The calcimimetic cinacalcet decreases calcium and parathyroid hormone levels. However, surgery is the only treatment with permanent results.

NSS68
PRIMARY HYPERPARATHYROIDISM AND PSYCHOLOGICAL IMPLICATIONS

Y. Athanassiou[1]

[1]Trinity College, Dublin, Ireland

Hypercalcemia associated with primary hyperparathyroidism is linked to mild neurologic alterations, such as personality change and depression. Severe hypercalcemia may result in confusion, psychosis, coma and in serious cases death. Neurologic and behavioral symptoms in patients with primary hyperparathyroidism were described early in the course of the in depth study of hyperparathyroidism. These symptoms were loss of energy, depression, disorentiation, memory problems. Later on it was observed that after successful surgery for the treatment of primary hyperparathyroidism neural and psychiatric symptoms improved. In conclusion, primary hyperparathyroidism is associated with neural, cognitive and psychiatric symptoms which improve after successful treatment of the disease. Main symptom of the disease, observed in most of the patients is depression.

NSS69
PRIMARY HYPERPARATHYROIDISM AND MUSCULAR MANIFESTATIONS

L. Athanassiou[1]

[1]Department of Rheumatology, Asclepeion Hospital, Voula, Athens, Greece.

Primary hyperparathyroidism was once considered a rare disorder. Patients were diagnosed in late stages of the disease with severe manifestations, such as osteitis fibrosa cystica or kindey stones. Nowadays many patients are diagnosed each year due to the availability of serum calcium measurement in the routine biochemical examination. Consequently, many patients are diagnosed in early stages of the disease with minimal serum calcium elevation and minimal or absence of symptoms. However, when the disease presents with obvious symptoms muscle weakness is observed in many patients. Muscle weakness usually improves after successful surgical treatment of the disease.

NSS70
PRIMARY HYPERPARATHYROIDISM AND OSTEOPOROSIS. THE ROLE OF EXERCISE

Y. Dionyssiotis[1]

[1]Spinal Cord Injury Unit, University of Patras, Patras, Greece

Primary hyperparathyroidism is associated with the development of osteoporosis. Patients present with low bone mass and subsequently low bone mineral density. Osteoporosis in the context of primary hyperparathyroidism affects mainly the axial skeleton and the risk of fracture is increased. Successful treatment of the disease, mainly surgical, results in improvement of bone mass and bone mineral density. As primary hyperparathyroidism affects all aspects of skeletal health, patients may benefit greatly from exercise. Exercise should be mild, as an increased risk of fracture exists. Exercise should be performed under guidance from physical therapy specialists. After successful treatment of the disease, exercise may accelerate bone mass improvement. In addition, exercise may improve quality of life in primary hyperparathyroidism as it improves general health, skeletal health and depression.

NSS71
PRIMARY HYPERPARATHYROIDISM AND OSTEOPOROSIS. MANAGEMENT

P. Athanassiou[1]

[1]Department of Rheumatology, St. Paul's Hospital, Thessaloniki, Greece

Primary hyperparathyroidism affects all aspects of skeletal health and causes osteoporosis. Osteoporosis in the context of primary hyperparathyroidism preferentially affects the axial skeleton. Osteoporosis increases the risk of fractures. Successful surgical treatment of primary hyperparathyroidism leads to bone mineral density improvement. In cases of primary hyperparathyroidism, when surgery is not indicated, such as in cases of parathyroid hyperplasia, alendronate may be used as it improves bone mass and osteoporosis and decreases calcium levels. The effervescent form of alendronate may also be successfully applied in cases of primary hyperparathyroidism. In cases of severe primary hyperparathyroidism, osteoporosis should be dealt with in order to improve bone health and decrease fracture risk.

NSS72
LONG-TERM TREATMENT OF OSTEOPOROSIS: WHAT'S UP ON 10-YEARS AFTER

G. Altamar-Canales[1,2,3]

[1]Professor of Geriatrics in Valley University, Cali, Colombia, [2]President of Colombian Osteoporosis Association-ACOMM, Bogota, Colombia, [3]Specialist in Internal Medicine and Geriatrics, Cali, Colombia

Registry trials for the bisphosphonates (BP) alendronate (ALE), risedronate (RIS), ibandronate (IBA) and zoledronic acid (ZOL); showed fracture risk reduction after 3 to 4 years of treatment. These trials were further extended to investigate long-term effects of BP treatment. The extension trials used bone mineral density (BMD) as a primary endpoint and fractures were considered adverse events or followed as exploratory endpoints. BP treatment showed fracture risk reduction and BMD gain. ALE and ZOL trials showed reductions on vertebral fracture risk after 10 and 9 years, respectively[1,2]. When BP therapy lasts 10 or more years, drug holidays may be considered[3]. Even considering rare adverse events like atypical femur fractures and osteonecrosis of the jaw, BP use is safe and effective throughout the years; with increased BMD and fracture risk reductions[4]. Denosumab (DMAB) is a monoclonal antibody and reduces fracture risk at 10 years of follow-up[5]. BMD was increased and new vertebral, hip, and nonvertebral fractures remained low on DMAB with continued BMD improvements over time[6]. Anabolic agents (teriparatide[7], abaloparatide[8], and romosozumab[8]) also reduce nonvertebral and vertebral fractures maybe in greater extent than anti-resorptives[9]. Anabolic medications will not be addressed because there is no available data beyond 5 years of treatment with these drugs.

DISCONTINUATION OF ANTI-OSTEOPOROSIS TREATMENTS: SHOULD WE DO IT, WHEN AND HOW

A. Medina-Orjuela[1,2]

[1]Assistant Professor Universidad Nacional de Colombia, Bogota, Colombia, [2]Endocrinologist, Hospital San José, San José, Colombia

Long-term bisphosphonate (BP) treatment has been associated with atypical femur fractures (AFF) and osteonecrosis of the jaw (ONJ).[1] Anti-resorptive effect of BP lasts beyond it's period of use due to it's strong binding to calcium ions. BP drug holiday concept aims to maintain a long-length fragility fracture reduction with minimum AFF risk. BP drug holidays may be considered at 3 to 5 years of treatment[2]. Between nitrogen-containing BPs; Zoledronic acid (ZOL) has conferred the most durable reduction in fractures, particularly after 06 infusions[2]. Besides BP' long-lasting properties, anti-resorption effect tend to cease progressively over BP drug holidays. A single dose of ZOL 5 mg and 5-yearly doses of 1.0 and 2.5 mg ZOL prevented bone loss at hip and spine for 8 to 10 years in older postmenopausal women.[3] Denosumab (DNB) is a monoclonal antibody approved for treatment of osteoporosis in 2010. DNB is an anti-resorptive agent recommended in almost all guidelines worldwide as first-line treatment in pacients at high risk of fractures[4]. DNB discontinuation lead to BMD reduction and higher risk of fracture.[5] Nevertheless, alendronate (ALE), and zoledronic acid (ZOL) mitigated BMD loss.[6] There is some concern also regarding bone anabolic therapy discontinuation. Teriparatide is approved for 18–24 months and antiresorptive treatment may be necessary to maintain densitometric gains achieved during it's use.[7] Patients who received alendronate presented 4.9% gain in lumbar spine BMD vs. placebo group, stressing the importance of following teriparatide therapy with an antiresorptive drug.[8] Besides the need of sequential anti-resorptive use after teriparatide, the fracture prevention persisted for as long as 31 months after teriparatide discontinuation.[9]

NSS74
RECOMMENDATIONS FOR OSTEOPOROSIS TREATMENTS BEYOND 10 YEARS

A. F. Coy Barrera[1]

[1]Internist-Endocrinologist, Fundación Santa Fé, Bogota, Colombia

As life expectancy expands, women are progressively more exposed to longer hypoestrogenic state and postmenopausal bone loss. Considering that the risk of osteoporosis lasts for the whole life, sequential management of osteoporosis medications frequently needed. Sequential therapy options are increasingly being addressed in clinical trials more often than combination therapies, with the first results showing benefits for the maintenance of stable BMD increases and fracture risk reduction. Hormone replacement therapy (estrogen, tibolone) and selective estrogen receptor modulators (raloxifene) help on postponing bisphosphonate (BP) therapy and is considered an early intervention on the management of postmenopausal osteoporosis. When the use of these agents is not posible, the choice is an oral BP. For patients at high risk of an osteoporotic fracture, oral bisphosphonates (BP) can be used. But, If the patient is considered at very high (or iminent) risk of fracture, oral BP shall be substituted by intravenous, and denosumab or bone anabolic agents (teriparatide, abaloparatide, romosozumab) may be an option. Anabolics like teriparatide, abaloparatide and romosozumab; or Denosumab shall be followed by a subsequent antiresorptive treatment. Regardless of the strategy adopted, follow-up should be maintained indefinitely to help prevent fractures. Dental hygiene should be emphasized given that most of the cases of ONJ were related to tooth extractions. The patient should have regular medical appointments to check BMD, calcium and vitamin D levels, along with keeping vitamin D and calcium supplementation. Bone turnover markers help monitor treatment response and shall be chosen accordingly to the drug mechanism of action.

NSS75
CHRONIC ARTHRITIDES AND BONE

H. G. Raterman[1]

[1]Rheumatologist Northwest Clinics, Amsterdam, Netherlands

Patients with inflammatory rheumatic diseases suffer from loss of bone quality and density. Underlying inflammatory processes of the IRDs have a negative influence on bone (i.e. bone loss and bone quality). As IRDs patients have an elevated fracture risk there is urgent need to prevent further loss of quality of life due to the ongoing due to the ongoing inflammation and bone loss.

Historically, patients with IRDs were treated with high doses of glucocorticoids, but nowadays there is a wide variety in treatment modalities influencing different targets in the inflammatory cascade of IRD patients. The main goal of treating IRDs like rheumatoid arthritis is to prevent structural damage by pivotal disease modifying anti-rheumatic drugs (DMARDs). Optimal treatment with antirheumatic drugs in IRDs may improve bone quality and density by counteracting the negative effects of inflammatory processes on bone in these patients.

In this lecture the influence of inflammation on bone loss will be discussed. Moreover, the potential positive effects on bone of conventional and biological antirheumatic drugs in IRDs will be highlighted.

NSS76
VITAMIN D IN PATIENTS WITH INFLAMMATORY RHEUMATIC DISEASES

W. Lems[1]

[1]Rheumatologist, Amsterdam UMC, Amsterdam, Netherlands

There are 4 reasons why adequate vitamin D levels are crucial for patients with inflammatory rheumatic diseases (IRDs) such as rheumatoid arthritis, spondyloarthropaties including psoriatic arthritis and SLE. Suboptimal treated with antirheumatic drugs in IRDs are associated with muscular weakness and bone loss /fractures, suboptimal or deficient vitamin D levels elevates fracture risks even further. Suboptimal treated with anti rheumatic drugs in IRDs may induce immobility and thus lack of sunshine, this also elevates fracture risks. Patients with SLE should avoid sunshine because of the sensitivity of their skin for sunshine, this may also elevate even further. Interestingly, basic studies suggest that active vitamin D reduces inflammatory processes.

All these 4 topics will be discussed ending with the statement (to be discussed) that clinicians should measure serum VitD levels in their patients with IRDs and, when in lower range or deficient, correct them into normal, or preferably in upper normal range.

NSS77
FIBROMYALGIA AND BONE

O. D. Messina[1]

[1]Rheumatologist, IRO Medical Research Centre, Buenos Aires, Argentina

Fibromyalgia (FM) is characterized by widespread musculoskeletal pain and tenderness with associated symptoms related to central sensitization syndrome (CSS) such as fatigue, unrefreshing sleep, cognitive dysfunction, anxiety and depression. Relationship between osteoporosis (OP) and FM showed mixed results, and was not fully studied in well designed controlled studies.

Rationale to link FM with OP and VitD disorders are related to low mobility, sedentary lifestyle, low sun exposure, probably sarcopenia and an increased trend to falls and fractures among patients with FM. Lichtenstein et al. conducted a case control study in Israel comparing FM patients and age matched controls and found a significant correlation between FM and OP (correlation coefficient 0.55 $P < 0.001$). A logistic regression for OP showed an odd ratio of 1.94 (95% CI, 1.83–2.06 $P < 0.001$) for FM compared to controls but not with fractures. The mean serum of IL-6 was significantly higher in patients with FM and low VitD levels in comparison with patients with FM and normal VitD levels. This study included 14,296 FM patients and 71,324 age and sex matched controls. Among FM patients 2424 (17%) were found to have OP vs 8592 (12%) among controls (correlation coefficient 0.55, $P < 0.001$). Higher BMI was the only protective parameter among patients with FM. Some meta analysis showed low levels of Vitamin D among patients with FM vs controls and a correlation between low levels of Vitamin D and FM severity measured by FIQ and clinical variables.

Epidemiological studies about sarcopenia and fractures in patient with FM are clearly lacking and are strongly warranted.

NSS78
SCOPE OF THE PROBLEM: BEYOND THE FEMALE ATHLETE TRIAD

S. Tuzun[1]

[1]Professor of Physical Medicine and Rehabilitation, Istanbul University, Cerrahpasa School of Medicine, Istanbul, Turkiye

Understanding and addressing bone health in athletes encompasses a blend of science, art and medicine. Excessive exercising in young women causes a risk for developing the Female Athlete Triad as a result of inadequate energy intake, which is called low energy availability (LEA). Although the literature on LEA has focused on female athletes, it has also been reported in male athletes. However, prevalence of LEA in male athletes is lower, and occurs among the same at risk sports as for female athletes: the weight sensitive sports in which leanness and/or weight are important due to their role in performance. In case of an imbalance between exercise and nutrition as seen in female /male athlete triad, bone mass is compromised and this can lead to stress fractures.

LEA in combination with Functional Hypothalamic Amenorrhea can occur from severe energy restriction, or increased energy expenditure. In females of reproductive age engaging in excessive exercise, the result may be menstrual cycle disorders when there is relative caloric deficiency due to inadequate nutritional intake for the amount of energy expended. Risk for low BMD is increased four times if body weight is below 85% of ideal body weight.

Estrogen deficiency is responsible for low bone mass. Amenorrheic athletes have lower BMD than eumenorrheic athletes, particularly at the lumbar spine. Stress fractures, occur at a much higher frequency in patients with exercise-induced amenorrhea. Repeated stress fractures

occur in up to 30% of ballet dancers and 32% of runners. They are more common in athletes with eating disorders. This is caused by low bone mass and the low-energy state, which leads to low bone turnover and/or favors a resorptive state. Bone loss is one of the most challenging issue in the management of low energy availability since reverse of it takes a longer than other symptoms like lack of energy and menstrual dysfunction. Although some recovery is possible, it is not clear if complete restoration is possible to return bone health equal to that of menstruating exercising women.

NSS79
ASSESSMENT OF BONE STRENGTH IN ATHLETES

J. J. Carey[1]

[1]Professor in Medicine, University of Galway, Galway, Ireland

Elite athletes are not normal people so the assessment of bone health in sports medicine is complex. Extreme body phsiques and performance put the musculoskeletal system under extreme stress. Poor bone health or excessive strain can have devastating consequences, and can be career ending for elite athletes, while good bone health is also essential for past or occasional athletes for general health and well-being. The importance of bone health assessments has gained greater recognition, while the identification of those at risk and the definition of normal is evolving. During this presentation Professor Carey will discuss the importance of central DXA and other methods to assess bone health in sports medicine, and how interpretation of results may differ between elite and past or occasional athletes.

NSS80
HOW REMS CAN BE HELPFUL TO ASSESS BONE IN SPORTS MEDICINE?

R. Matijevic[1,2]

[1]University of Novid Sad, Faculty of Medicine in Novi Sad, Novi Sad, Serbia, [2]Orthopaedic and Trauma Clinic, Clinical Center of Vojvodina, Vojvodina, Serbia

Radiofrequency echographic multispectrometry (REM) represents a cutting-edge technology with promising applications in sports medicine, particularly for assessing bone health. REMS is a non-ionizing technology that evaluates bone status by analysing raw, unfiltered native ultrasound signals, so-called radio frequency ultrasound signals, obtained during an ultrasound scan of the lumbar vertebrae and proximal femur. The analysis of native unfiltered ultrasound signals allows for information about the characteristics of bone tissue to be acquired.

REM allows early detection of microstructural changes in bones, such as stress fractures or microdamage, which are common in athletes due to repetitive stress and high-impact activities. Unlike conventional imaging techniques like X-rays, REM provides a more objective assessment of bone quality by analysing the bone's composition and architecture. This enables sports medicine practitioners to accurately gauge bone strength and resilience, crucial for injury prevention and performance optimization. Injuries like fractures are prevalent in sports, and monitoring bone healing is essential for athletes to safely return to play. It also offers a dynamic method to track the progress of bone healing over time, allowing healthcare professionals to adjust treatment protocols as needed and ensure optimal recovery.

By understanding each athlete's bone composition and structure, healthcare providers can tailor rehabilitation programs and training strategies to address specific needs and minimize the risk of reinjury. This quantitative approach facilitates longitudinal monitoring of bone changes and the evaluation of treatment efficacy over time. REM contributes to ongoing research in sports medicine by advancing our understanding of bone physiology and response to mechanical loading. By elucidating the underlying mechanisms of bone adaptation and injury, REM supports the development of novel interventions and preventive strategies for athletes.

NSS81
HOW TO MANAGE BONE LOSS IN ATHLETES?

R. Terlemez[1]

[1]İstanbul University-Cerrahpaşa, Cerrahpaşa Medical Faculty, Physical Medicine and Rehabilitation, Istanbul, Turkiye

Low energy availability, frequently results in hypoestrogenism and menstrual disruption, which have detrimental impacts on bone health and endothelial cell dysfunction. Athletes with unstable menstruation and/or low bone mineral density (BMD) are more likely to sustain bone stress injuries. Compared to eumenorrheic subjects, athletes with amenorrhea are two to four times more likely to experience a stress fracture.

Weightbearing activity was found to have a considerable effect on BMD, with site specific mechanical loading having a major impact on bone accretion. Both amenorrheic and eumenorrheic athletes had larger total cross-sectional area, trabecular area, and cortical perimeter at the distal tibia than non-athletes. Athletes with low BMD should modify their exercise to include weight training and/or cutting and jumping sports. A good balance between exercise and nutrition, as well as proper intake of calcium and vitamin D, are essential to avoid osteoporosis and bone stress injuries. Lower BMD and stress injuries are linked to the Triad's constituent parts. Therefore, after a stress injury has been recognized, evaluating and treating risk factors that may have an adverse effect on bone health should be a component of the treatment approach. Improving the already compromised bone health requires raising energy availability to prevent the inhibition of growth factors, reproductive hormones, and other vital hormones. Amenorrheic athletes have been found to enhance their BMD more with the resumption of their menses and weight gain.

Young athletes with significant bone loss have limited pharmacologic options. Oral contraceptive pills (OCPs) are frequently prescribed for athletes despite not being the recommended first line treatment. The studies on the effect of OCPs and bone health remain mixed and are frequently confounded by weight gain, which is known to improve BMD. Bisphosphonates use, in reproductive age has a potential teratogenic affect, since almost all of these medications have long half lives and are bound to the bone for years. In future, leptin hormone may have a role in the treatment of low BMD in athletes.

NSS82
QUALITATIVE ASPECTS OF PLATELET-RICH PLASMA INJECTIONS

J.-F. Kaux[1]

[1]MD, PhD, Physical and Rehabilitation Medicine Department, University and University Hospital of Liège, Liège, Belgium

Platelet-rich plasma (PRP) holds promise as a therapeutic agent due to its high concentration of platelets and growth factors. Its widespread use, especially in treating tendinopathies or osteoarthritis among athletes, is notable. However, scientific consensus regarding its efficacy remains elusive, partly due to variations in PRP preparation methods. This literature review examines key parameters affecting PRP quality, including anticoagulant selection, centrifugation speed, platelet concentrations, blood cell ratios, platelet activators, and the use of local anesthetics during infiltration. Additionally, exploring variables like ultrasound guidance during injections could offer further insights into optimizing PRP's therapeutic potential.

NSS83
NERVE ANAESTHESIA FOR PAINFUL PLATELET-RICH PLASMA INJECTION

L. Chimot[1]

[1]MD, CNAES, Clinique Brétéché, Nantes, France

Efficiency of PRP is conditioned by several factors. One of those described is the necessity to avoid local anaesthesia. Being sensitive to pH environment, platelets could be destroyed by the presence of these medications which have low pH. Unfortunately, intra-tendinous injection is a strongly painful procedure. There are some technic to attempt to deal with this problem. One of them is to provide regional anaesthesia which consists to stop the stimulation of the nerve which covers the sensitive territory of the tendon. To perform this anaesthesia, a number of issues must be addressed: nerve territory anatomy, available medications and their properties, patient consigns.

We would try to bring the necessary background to understand the concept of regional anaesthesia and to choose the best technic to obtain a no pain procedure.

NSS84
POST-PROCEDURE AFTER PLATELET-RICH PLASMA INJECTION FOR A TENDINOPATHY

M. Lamontagne[1]

[1]MD, PhD, Physical Medicine Department, University of Montreal Health Center, Montreal, Canada

After an intratendinous platelets rich plasma (PRP) injection, management and recommendations vary greatly from one physician to another. In the absence of studies comparing two different rehabilitation protocols, it is difficult to propose ideal rehabilitation following these injections. Although there is some consensus in the literature on the post-procedure protocol, the rationale for recommending it remains limited. In this context, we believe that a protocol based on the different phases of connective tissue healing, and on principles of optimized active tendon rehabilitation, using exercises favoring a progressive increase in the mechanical load applied to the tendon, remains the most appropriate approach. This presentation will propose a protocol and recommendations that can be used for the management of a patient after receiving a PRP injection for a tendinopathy.

NSS85
OSTEOPOROSIS AND CARDIOVASCULAR RISK: OLD FRIENDS?

A. Medina[1,2,3,4]

[1]Endocrinologist, Hospital San José, San José, Colombia, [2]Assistant Professor Universidad Nacional de Colombia, Bogota, Colombia, [3]Past President of Colombian Osteoporosis Association-ACOMM, Bogota, Colombia, [4]Member of Regional Board IOF, Bogota, Colombia

Introduction: The link between osteoporosis and cardiovascular disease (CVD) includes shared risk factors, common pathophysiological mechanisms, common genetic factors and a causal association. Osteoporosis and CVD commonly occur in advanced age, but age is not the only factor that is associated.

Results: Both diseases have similar risk factors, including diabetes, smoking, alcohol, sedentary lifestyle, ageing, menopause, and dyslipidemia which may simultaneously promote atherosclerosis and bone demineralization. Studies have shown that low bone mineral density (BMD) is a risk factor for cardiovascular mortality in both women and men. BMD loss at the hip increased mortality 1.3-fold in CVD being a significant predictor of cardiovascular mortality.

Discussion: Common pathophysiological mechanisms involving inflammatory cytokines, endogenous sex hormones, oxidized lipids, vitamin K deficiency, and vitamin D were implicated in the progression of the two conditions. Inflammatory cytokines play a role in all stages of atherogenesis from fatty streak formation to plaque rupture and increasing the resorption leading to bone loss. Osteoporosis and atherosclerosis are characterized by low grade chronic inflammation, therefore, the processes involved in the calcification of atheroma plaque are similar to them in bone remodeling with participation of common proteins in the bone matrix and atheromatous plaques as: osteoprotegerin, osteonectin, osteopontin and type 1 collagen. The mineral composition of calcified atherosclerotic plaques is like hydroxyapatite crystals located in the inorganic bone matrix.
Regarding the hormonal effect, estradiol increases the proliferation of endothelial cells, production of endothelium-derived factors such as nitric oxide and decreases the expression of leukocyte adhesion molecules. In bone, prevents resorption and increases formation. Androgens also seem to have a positive effect on bone and vascular health.

Vitamin K deficiency has been associated to atherosclerotic calcification and low bone mass involving matrix-gla protein and osteocalcin. Deficiency of Vitamin D is associated to CVD mortality. Vitamin D receptor (VDR) polymorphisms contribute to the risk of both osteoporosis and CVD. In end-stage renal disease, secondary hyperparathyroidism was also linked to increased risk for fractures and vascular calcification. Regarding, genetic factors, the Osteoprotegerin, matrix-gla protein, and apolipoprotein E (Apo E) genes have been invoked in both atherogenesis and bone loss.

Finally, the reduced blood flow caused by atherosclerosis, reduces intraosseous blood circulation in the lower extremities, altering bone metabolism in the hip and resulting in osteoporosis. CVD, in turn, might limit physical activity contributing to bone loss.

Conclusion: An understanding of these mechanisms that involve CVD and osteoporosis, will serve as a basis for using common preventive and therapeutic measures targeted at both diseases.

OSTEOPOROSIS AND DEMENTIA: WHERE ARE WE GOING?

G. Altamar[1,2,3]

[1]Specialist in Internal Medicine and Geriatrics, Cali, Colombia, [2]Professor of Geriatrics in Valley University, Cali, Colombia, [3]President of Colombian Osteoporosis Association-ACOMM, Bogota, Colombia

Introduction: Low bone mineral density (BMD) share risk factors with dementia, however, remains unclear whether low bone density itself may be causally linked to dementia or vice versa, we will review some associations between osteoporosis and dementia.
Results: Low BMD has been associated with time to Alzheimer's disease (AD) in a Chinese cohort study and all-cause dementia in the Framingham Heart Study (FHS) in women, but not men. Low BMD was also associated with brain structural changes and cognitive performance in FHS. In elderly women, the decline in femoral neck BMD was associated to decline in cognitive screening. Recently, a meta-analysis of baseline BMD showed higher BMD to have a significant protective association with incident dementia and a significant association of risk between prior bone loss and incident dementia in one of the studies implicated.
Discussion: The brain and bones are interconnected. The neurotransmitters affect bone homeostasis and sensory nerve innervation of bone, likewise bone act as an endocrine organ secreting osteocalcin, which impact the production of neurotransmitters affecting cognitive function. Alzheimer's disease (AD) is a neurodegenerative disease with extracellular aggregates of amyloid-beta peptide (Ab) derived from amyloid precursor protein (APP) and the presence of neurofibrillary protein. APP/Ab can directly damage skeletal remodeling by impacting osteoclast differentiation, decrease in osteoblastogenesis and loss of trabecular bone mass. Insufficient Wnt/b-catenin activation is possibly related to bone loss and brain pathology because its signalling contributes to osteoblast differentiation and promotes bone formation, synaptic junctions, and neuronal survival.
Other factors in common are low protein intake and sedentarism lead to reduced muscle strength, reduced bone mechanical strain with consequent accelerated bone loss. Osteosarcopenia is associated with malnutrition, cognitive deterioration, atherosclerosis, frailty, falls and fractures. Fragility fractures lead to consequences in mobility, quality of life, increased morbidity, and mortality in AD patients. Unfortunately, only 5% of hip fracture patients receive appropriate treatment for osteoporosis.

Exercise, prevention of falls and fortified nutrition are beneficial for improve gait, balance, strength, mobility and reduce falls and fractures in the patient with dementia and/or osteoporosis.
Conclusion: In AD, direct factors like amyloid pathology, abnormal brain-bone interconnection, Wnt/b-catenin signaling deficits, low protein intake, sedentarism, are associated to osteoporosis and fractures.

TREATMENTS FOR OSTEOPOROSIS AND CARDIOVASCULAR EVENTS: WHAT DO WE KNOW?

A. Román-González[1,2,3]

[1]Specialist in Internal Medicine-Specialist in Endocrinology, Medellin, Colombia, [2]Master in Neuroendocrinal Tumors, Medellin, Colombia, [3]Associate Professor Antioquia University -Hospital San Vicente Fundación, Medellin, Colombia

Introduction: Anti-osteoporosis drugs are commonly used for preventing and treating osteoporosis. However, some of these drugs have been associated with an increased risk of cardiovascular events.
Results: Anti-osteoporosis treatment is composed of two pharmacological groups, antiresorptives and osteoanabolics, the following is the evidence associated with cardiovascular risk.
Antiresorptivestherapies: Bisphosphonates are the most widely used anti-osteoporosis drugs, slow down bone turnover. Some studies suggest an increased risk of atrial fibrillation, though others have not found this association. The overall evidence on the cardiovascular safety of bisphosphonates is mixed. Additionally, zoledronic acid was associated with lower mortality, but a clear explanation for this finding is lacking.
Denosumab, a monoclonal antibody inhibiting RANKL to reduce bone resorption, has conflicting evidence regarding cardiovascular risks. Some studies suggest an increased risk of major adverse cardiovascular events (MACE), while others report neutral effects. Although this side effect appears infrequent, further research is needed. Recent research suggests an increase in mortality. However, this may be explained by type I error.
Osteoanabolictherapies: Romosozumab, a monoclonal antibody inhibiting sclerostin and a newer anti-osteoporosis drug, is more effective than bisphosphonates in reducing fracture risk. However, some studies suggest an increased risk of myocardial infarction and stroke. Heterogeneous evidence exists across basic, clinical, population, and genetic studies, and this side effect seems rare. More research is needed to confirm these findings, and further phase IV studies may provide clarification.
Teriparatide and Abaloparatide, bone-forming agents acting through PTHR or PTHrp-mediated pathways, showed no evidence of increased cardiovascular risk. Some evidence even suggests cardioprotective roles.
Conclusion: The cardiovascular safety of anti-osteoporosis drugs is a complex issue. Evidence on the cardiovascular safety of bisphosphonates is mixed, denosumab may increase the risk of MACE or be neutral, and Romosozumab may increase the risk of myocardial infarction and stroke. On the other hand, PTH analogues seem neutral or even protective. The discontinuation of Odanacatib and findings from Romosozumab trials suggest a common link between osteoporosis mechanisms and cardiovascular risk. However, methodological issues or serendipitous findings may also explain these uncommon side effects. More research is needed to definitively determine the cardiovascular safety of these drugs, and phase IV studies may provide further clarification.

NSS88
BONE FRAGILITY AND OSTEOPOROSIS IN YOUNG ADULTS

L. Seefried[1]

[1]Orthopedic Department of the University Hospital at the Julius-Maximilians University Würzburg, Germany, Würzburg, Germany

While osteoporosis with progressive aging is a well-established condition with clear-cut diagnostic and therapeutic implications, the management of bone fragility and osteoporosis in younger adults still imposes extensive challenges. Operational definitions of this so early-onset osteoporosis in the age range of 20–50 years by ISCD and IOF both include a low BMD with a Z-score $\leq$ -2.0 or T-score $\leq$ -2.5, respectively, along with a low-trauma fracture or secondary cause of osteoporosis.

In terms of appropriate diagnosis, it is therefore important to cover a wide range of potential secondary causes in order not to miss any specific reasons, which are critical to further guide appropriate management treatment. In addition to medical history, radiographs, biochemical investigations, bone mineral density assessment and a bone biopsy in specific cases, genetic testing should be generously considered to identify potential underlying causes or predisposing factors.

Growing scientific evidence supports the notion that heterozygous alterations in genes otherwise causing recessive monogenic diseases of mild variants in genes associated with dominant skeletal dysplasias play an important role in many patients experiencing osteoporotic manifestations not sufficiently explainable otherwise. Specifically variants in genes related to type I collagen biosynthesis and key regulatory proteins of canonical WNT signaling like LRP5 and WNT1, the X-chromosomally located actin-binding plastin-3 protein (PLS3) and more recently sphingomyelin synthase 2 (SGMS2), critical for signal transduction in sphingomyelin metabolism, have recurrently been identified in such conditions. This also applies to cases of pregnancy and lactation associated osteoporosis.

While treatment is currently taking advantage of compounds established and primarily approved in the context of postmenopausal osteoporosis, a better understanding of the aforementioned monogenic disorders will help to integrate and adopt experiences from the management of these rare disorders to more common cases early onset osteoporosis.

NSS89
ASSESSMENT OF BONE HEALTH IN PREGNANCY

V. A. Degennaro[1], T. Ghi[1]

[1]Department of Medicine and Surgery, Obstetric and Ginecology Unit, university of Parma, Italy, Parma, Italy

Background: Women's bones are subjected to considerable change throughout pregnancy due to the concurrence of several factors. While the higher level of estrogen and vitamin D promote the formation of bone tissue, the fetal uptake of maternal calcium destined to skeletal development leads to maternal bone resorption. Furthermore, some recognized hormonal factors may concur to reduce the mineralization of maternal bone during pregnancy, such us the rise of parathyroid hormone-related protein or progressive increase level of oxytocin which activates the osteoclast and stimulates the calcium transport to the fetus. Moreover, lifestyle may have a negative impact on the bone mass during pregnancy. The physical activity or the sun exposure may be lower than usual in pregnant women, particularly in the third trimester. On this basis, the World Health Organization (WHO) recommends an extra dietary calcium intake of 200 mg/day for pregnant women compared to non-pregnant women. Based on the concomitant effect all of these factors, a net reduction of women's bone mineral density is purported to occur during pregnancy. However, this alleged demineralization of maternal bone during pregnancy has never been demonstrated or quantified due to lack of an appropriate method of BMD assessment which can be safely employed across gestation. Actually, the dual-energy X ray absorptiometry (DEXA), which is still widely considered as the gold standard method in determining the amount of bone loss, is limited by the potential harmful effect of radiation during pregnancy. Recently, an innovative ultrasound-based technique has been introduced in the clinical practice for an accurate assessment of BMD in the central site, such as the femoral neck or the lumbar spine. This method, known as Radiofrequency Echographic Multi Spectrometry (REMS), has been shown to be as reliable as DEXA in the diagnosis of osteoporosis among non-pregnant women.

The aim of the present work is to assess the BMD of the femoral neck by means of Rems technology, to objectify the reduction of BMD in pregnancy.

Methods: A review of the literature on the use of REMS technology in pregnancy was performed.

Results: In this prospective case–control observational study, a non-consecutive group of pregnant women with uncomplicated pregnancy at or $>$ 37 weeks were enrolled. The study subjects were submitted to a sonographic examination of the proximal femur with Radiofrequency Echographic Multi Spectrometry (REMS) technology to quantify the BMD of the femur. The BMD values obtained in the study group were compared with those of a control group of non-pregnant women matched for age, ethnicity and pre-pregnant body mass index (BMI). Overall, 78 pregnant women at 39.1 $\pm$ 1.5 weeks were assessed. Compared with non-pregnant women, the femoral BMD values measured in pregnancy using REMS were significantly lower (0.769 $\pm$ 0.094 g/cm^2 vs 0.831 $\pm$ 0.101 g/cm^2, p = 0.0001) with a mean BMD reduction of 8.1%. The femoral neck BMD presented a positive correlation with the pre-pregnant woman's BMI (p = 0.0004) and a negative correlation with the maternal age (p $<$ 0.0001). In addition, a lower femoral neck BMD in Caucasian ethnicity compared with non-Caucasian was noted (p $<$ 0.0001). In another study, over a period of seven months, a total of 65 participants underwent bone mineral density measurement at the femoral neck at first and third trimester of the pregnancy using REMS. A significant reduction of the bone mineral density at the femoral neck (0.723 $\pm$ 0.069 vs 0.709 $\pm$ 0.069 g/cm^2; p $<$ 0.001) was noted with a mean bone mineral density change of -1.9 $\pm$ 0.6% between the first and third trimester of pregnancy. At multivariable linear regression analysis, none of the demographic or clinical variables of the study population proved to be independently associated with the maternal bone mineral density changes at the femoral neck.

Conclusion: In this review of the literature a decrease BMD in pregnant women has been objectively demonstrated thank to REMS technology which is able to identify and quantify femoral BMD loss non-invasively during pregnancy. Furthermore, REMS technology is a safe and valid approach for monitoring bone health during and after pregnancy. Further studies are needed to promptly identify and follow

up with pregnant women who show transient osteoporosis and or decreased bone density in order to preserve bone health.

NSS90
MANAGEMENT OF BONE FRAGILITY IN PREGNANT WOMEN

M. L. Brandi[1]

[1]Fondazione FIRMO and Observatory for Fragility Fractures, Florence and University San Raffaele, Milan, Italy, Florence, Italy

Pregnancy-and lactation-associated osteoporosis (PLO) is a rare condition characterized by fragility fractures, most commonly vertebral. These complications appear in the third trimester of pregnancy or nearly post partum. The incidence is unknown.

The problems to be faced are diagnosis and therapy of this disorder.

In order to contribute to the recognition of this disorder the Observatory on Fragility Fractures Italy launched in 2023 a multicenter clinical study to evaluate the risk of fractures in 7 major gynecological centers in Italy. The protocol includes evaluation of bone biomarkers and bone density with the REMS technology. A dedicated fracture risk questionnaire has also been developed. The project will be presented and discussed during the meeting.

The therapy of fragility fractures in PLO is a complicate issue. The presentation will include the analysis of pharmaceutical approaches in this disease with an eye to future guidance efforts.

NSS91
INTRODUCTION IN SARCOPENIA

P. Athanassiou[1]

[1]Department of Rheumatology, St. Paul's Hospital, Thessaloniki, Greece

Sarcopenia is a geriatric syndrome with progressive loss of mass, quality and function of skeletal muscles associated with aging. Its prevalence may reach 30% for people over 60 in European populations. Sarcopenia is a multifactorial process: some factors lead to the development of sarcopenia and its associated negative effect on physical function. The loss of skeletal muscle fibers secondary to the reduced number of motor neurons appears to contribute significantly to the disorder, which may further include reduced levels of hormones (particularly GH, IGF-1, MGF, and testosterone), lack of protein and calories of the diet, oxidative stress, inflammatory processes etc. Sarcopenia requires a rehabilitation program to improve physical performance but also nutritional interventions: protein supplementation combined with exercise, leucine-enriched amino acids and vitamin D supplementation, as adjunctive therapy.

NSS92
SARCOPENIA IN METABOLIC DISEASES

I. Athanassiou-Kostoglou[1]

[1]Department of Endocrinology, Asclepeion Hospital, Voula, Athens, Greece

There is a lack of studies with outcome interventions to counteract sarcopenic obesity. However, there are recommendations for sarcopenia and/or weight loss. Strength exercise combined we proper diet demonstrated positive effects on muscle function and combination of a dietary weight loss intervention and additional protein supplements may reduce body fat. Nutrition is a common factor in both entities: sarcopenia and obesity, although interventions differ due to different pathophysiological mechanisms causing the problem: inadequate nutrition vs. excess consumption is the case. The problem is how to increase muscle mass in a situation of energy deficit. During weight loss, which is effective in reducing fat mass, skeletal muscle mass may also be lost and consequently reduced. Higher protein intakes prevent muscle mass loss, especially when combined with an exercise intervention. Exercise programs containing strength and aerobic exercise in combination with dietary weight loss program may possibly have positive effects on sarcopenic obesity.

NSS93
SARCOPENIA IN DIABETES MELLITUS

Y. Dionyssiotis[1]

[1]2nd Physical Medicine and Rehabilitation Department, National Rehabilitation Center EKA, Athens, Greece

The analysis of body composition for assessing the health and nutrition of the individual is a useful test. Diseases such as diabetes mellitus may be associated with adverse changes in body composition. However, there is a lack of studies that examine the association of sarcopenia in patients with type 2 diabetes mellitus (T2DM). To examine this relation individuals who visited endocrinological outpatient clinics, aged 20–80 years (n = 35), to assess the presence of sarcopenia in type 2 diabetes mellitus (T2DM) in comparison with controls. Appendicular skeletal mass (ASM) and other parameters such as total fat and total muscle mass (in kg) were calculated. The skeletal muscle index (SMI) was calculated as ASM divided by the square of the body height in meters. Low muscle mass is defined as SMI < 7.0 kg/m^2 in males and SMI < 5.7 kg/m^2 in females. Low physical performance was defined as a walking speed of < 0.8 m/s. The incidence of sarcopenia was significantly higher in patients with T2DM than in healthy subjects (27% vs 20%, $p = 0.01$ for sarcopenia) and higher in elderly participants (70 years and over) vs. younger (40% vs. 12%, $p < 0.001$). Walking velocity was significantly lower in patients with T2DM than in controls men and women (1.02 ± 0.34 vs. 1.25 ± 0.15, $p < 0.001$) and (1.01 ± 0.22 vs. 1.27 ± 0.12, $p < 0.001$), respectively. The prevalence of sarcopenia in patients with T2DM is moderate and gradually increases significantly in older men.

NSS94
SARCOPENIA IN NEUROLOGICAL DISORDERS

Y. Dionyssiotis[1]

[1]2nd Physical Medicine and Rehabilitation Department, National Rehabilitation Center EKA, Athens, Greece

Muscle decay and dysfunction are seen in ageing, but in neurological disorders with muscular atrophy, muscle loss can be seen also at younger ages. The pathophysiology of sarcopenia in neurological diseases is complicated. One factor is unloading of affected skeletal muscle, and consequently deconditioning which occurs in any muscle that is not active. Low muscle mass can be explained by neurogenic injury, both due to muscle atrophy and disturbed regulation by the central nervous system. A neurological disability causes inactivation and, consequently, unloading of affected skeletal muscle. The danger of decline in capacity for physical activity begins immediately after the injury. Disuse, spasticity, and microvascular damage, contribute to the induction of the marked morphological and enzyme histochemical changes seen in the paralyzed skeletal muscle leading to altered functional properties and atrophy. Motoneuron death and muscle denervation must contribute to the severe atrophy that is

measured in muscles after SCI. Malabsorption leads to protein deficits and muscle catabolism. Hormonal disturbances of the thyroid, hypercortisolism and insulin resistance lead to sarcopenia resulting from protein deficiency.

NSS95
THE CRITICAL SHIFT TO A PROACTIVE APPROACH TO BONE HEALTH

P. D. Cummings[1]

[1]Director of Bone Health Clinic TOCA at Banner, Scottsdale, United States

As the proportion of older individuals across the world increases, the prevalence/incidence of osteoporosis is rising and the economic burden of fragility fractures is growing. Current models for the identification of osteoporotic fracture patients are reactionary; predicated to responding only after the initial fracture in hopes of preventing a secondary fracture. This myopic view of bone health care leaves patients suffering and health care costs spiraling out of control. Imagine never having your high blood pressure checked, and instead waiting for a heart attack or a stroke as your first symptom of heart disease. We are at a critical state and our focus needs to change. Education, identification, and treatment of bone health are archaic, costly, and limited in exposure. They also fail to understand that bone health requires a *Cradle to Grave* mentality.

NSS96
OPTIMAL CLINICAL PARADIGM: 4-PILLAR EVALUATION, INTEGRATED PROFILE, AND MULTIDISCIPLINARY CARE PLAN

R. Patel[1]

[1]Bone Health Specialist TOCA at Banner, Scottsdale, United States

Bone Health Solutions operates in a closed-loop system designating an orthopaedic surgeon working in concert with an Advanced Practice Provider to be the champions for patients with bone health concerns. This care model attempts to eliminate the current problem of fragmented care as orthopaedic surgeons and their staff are already managing the treatment of patients with fragility fractures and preventing future fractures is a natural extension of the treatment phase. Additionally, our program utilizes a Bone Health Educator who is responsible for educating physicians and their staff across a variety of healthcare settings to raise awareness about bone health and patients that may be at a high risk for fracture.

Our clinic uses the Optimal Clinical Paradigm and 4-Pillars assessment to address six critical steps to the evaluation and comprehensive management of patients with regards to Bone Health. The first step is to identify all patients at high risk for fracture from local health care systems, not just those presenting to the Emergency Department. Second is to capture those patients to ensure they are evaluated by a dedicated bone health specialist. Third is to evaluate the patient by performing a comprehensive examination that assesses all aspects of bone health and its potential underlying causes and manifestations. Fourth is to use our 4-Pillar system to diagnose any underlying Biological, Functional, Behavior and Environmental factors that may be contributing to the development or enhancement of their underlying bone health that may place them at high risk. Fifth is to develop an individualized treatment plan involving a multidisciplinary team. The final step is prevention, which involves sustainable educational programs throughout the community.

NSS97
BONE HEALTH SOLUTIONS

P. D. Cummings[1]

[1]Director of Bone Health Clinic TOCA at Banner, Scottsdale, United States

Bone Health Solutions was created to either replace the current FLS programs or augment them depending upon the community they serve. We believe that our Optimal Clinical Paradigm through Bone Health Solutions completely addresses all aspects of bone health care and ultimately decreases the "Patient Care Gap". Data is currently being collected and it is hypothesized that a greater reduction in secondary fractures will occur due to a standardized, less fragmented system. Additionally, it is proposed that patient adherence will increase because of multi-disciplinary treatment, a shared decision-making plan and better education. This program sets the framework to create a more proactive approach to bone health and to better capture patients before they fracture.

NSS98
VITAMIN D STATUS AND DIVERSE MEDICAL PRACTICES IN MEXICO AND LATIN AMERICA

P. A. Garcia-Hernandez[1]

[1]Hospital Universitario "Dr. José E. González" UANL, Professor of Internal Medicine and Endocrinology, Nuevo Léon, Mexico

While vitamin D deficiency has been extensively documented globally, recent years have seen more data from countries near the Equator, including Latin America. Several studies in Latin American countries indicate an overall observed prevalence of vitamin D deficiency at around 35%, with a higher prevalence as age increases, particularly among the elderly. National surveys reveal this deficiency to be more common among older women than men, and levels below 15 ng/ml have been associated with increased mortality. Nevertheless, there are significant differences in prevalence rates related to age, gender, country, latitude, season, and year of publication.

The healthcare systems in the region display considerable diversity, incorporating a mix of public and private services. Despite notable improvements in some countries, unequal access to healthcare persists, primarily due to limitations in economic resources and infrastructure challenges. The duality in financial systems, drawing contributions from public and private sources, underscores the complexity of addressing public health issues such as vitamin D deficiency. The lack of coherent medical information and the limited consensus among specialists in the region further complicate the management of this issue. Notably, some medical practices need to consistently consider exploring vitamin D status, potentially impacting the prescription and guidance of treatments by healthcare professionals, with the associated inconsistency and even low adherence to medical recommendations among the population.

To overcome these challenges, it is imperative to promote collaboration among experts, encourage research to understand patterns of vitamin D deficiency, and enhance continuous medical education to establish a clear consensus and ensure the availability of accurate information. These measures are essential for effectively addressing vitamin D deficiency and improving bone and overall health in the Latin American population.

NSS99
GLOBAL AND REGIONAL DYNAMICS: HETEROGENEITY IN VITAMIN D SUPPLEMENTATION ACROSS LATIN AMERICA

H. Gutierrez-Hermosillo[1]

[1]PHD, Hospital Aranda de la Parra, Department of Geriatrics' Coordinator, Leon, Mexico

Recent data shows hypovitaminosis D is common in Asia, Eurasia, Western Europe, Africa, and the Americas. The IOF LATAM recent report concludes that in the region, as much as 75% of the population has low Vitamin D (VD) levels.

Most of the countries in Latin America have a combined health system, sometimes making access to new technologies or treatments different for those who work in public or private areas; Mexico is not an exception.

Before the COVID-19 pandemic, the prevalence in Mexicans across different ages was as high as 71%, being more pronounced as age increases- in contrast to other continents where it seems to be more prevalent in the younger population- and almost universal among the very old. Recently, we described that those Mexicans with levels below 15 ng/ml have an increased risk of death.

There are many explanations for this high prevalence of hypovitaminosis D, including low sun exposure even in countries like Mexico, where there are sunny days almost all year, urban–rural disparities, darker skin in the population, aging of the population, Government regulations regarding VD added to the food are present only in one-third of the countries in the region, some medical practices among physicians where there have been described that a high percentage do not consider hypovitaminosis D a medical problem, nor identifying the different presentations of VD they have available in their countries or being confused of which of the many presentations to prescribe in their patients having several options (daily, weekly, monthly, tablets, gel caps, etc.).

As part of the development of the Mexican Consensus on Vitamin D, a survey is taking place in several Latin-American Countries and Spain among Medical Doctors and there is a significant percentage that does not measure VD levels in their patients; some others only measure it in those they consider at high risk, most of them do not identify a therapeutic goal or in whom to initiate supplementation.

During the pandemic, there were changes in the intake of various nutrients, including VD, and in the Mexican population, there is data that showed that the serum levels increased significantly; the ingestion of VD compounds can explain this.

Therefore, with all this information, several medical associations in Mexico have focused on developing the National Joint Position.

NSS100
FORMULATING UNITY: MEXICO'S APPROACH TO THE NATIONAL JOINT POSITION ON VITAMIN D SUPPLEMENTATION IN ADULTS

J. F. Torres-Naranjo[1]

[1]Centro de Investigación Ósea y de la Composición Corporal, CIO. Universidad de Guadalajara, Guadalajara, Mexico

Vitamin D is crucial in numerous physiological processes beyond maintaining calcium homeostasis. Specialist involvement in Vitamin D prescription underscores its growing clinical importance. However, a lack of consensus on optimal doses and protocols poses a challenge in maximizing benefits while minimizing risks. Addressing this gap is crucial for advancing standardized Vitamin D supplementation practices in healthcare.

This lecture offers insights into the meticulous process of formulating Mexico's national joint position, presented as a regional model. It explores how this national joint position addresses and mitigates heterogeneity within the Latin American context.

Since this national position aimed to harmonize approaches across medical disciplines, a multidisciplinary expert panel was formed, involving specialists from diverse clinical disciplines, including endocrinologists, gynecologists, geriatricians, internists, orthopedic surgeons, and rheumatologists from National Medical Organizations: AMMOM, AMEC, AMG, CMIM, CMO, CMR, CONAMEGER, FEMECOG, and FEMECOT. The panel aimed to address variations in vitamin D supplementation approaches and concentrated on three main areas: the necessity of medical vitamin D supplementation for the general population or specific groups, the need for serum vitamin D level determination to identify suitable candidates for supplementation, and define precise dosages, and the general guidelines for initiating and evaluating the response to medical vitamin D supplementation.

Over the consensus process, substantial differences among expert panel members emerged on specific aspects due to diversity in the formation and approaches. To overcome this, the methodological team compiled an evidence report from relevant clinical evidence. A consensus opinion was formed, and an anonymous peer review process was conducted over four rounds.

The consensus is pivotal in unifying perspectives on vitamin D supplementation in Mexico. This interdisciplinary approach resolves discrepancies and establishes clear guidelines for clinical practices. The proposal extends this approach to the Latin American Region, recognizing documented heterogeneity in medical practices.

NSS101
THE IMPACT OF MENOPAUSE AND HIV ON MIDLIFE BONE HEALTH

T. Madanhire[1]

[1]The Biomedical Research and Training Institute, Harare, Zimbabwe

Improved access to HIV treatment means that more women in Africa are now aging and reaching menopause. Taken together, this means that there is a coh improved access to HIV treatment means that more women in Africa are now aging and reaching menopause. Taken together, this means that there is a cohort of elderly women living with HIV at risk of chronic comorbidities. We identified 450 urban-dwelling South African women aged 40–60 years with and without HIV and followed them for five-years and determined whether HIV infection modifies the effect of menopause on bone mineral density (BMD). At baseline, mean age was 49.5 years, 14% of the women were living with HIV and two in five were postmenopausal. I will describe differences in BMD and osteoporosis (T-score by HIV status at baseline and the change in menopausal status over the five-year period. In addition, I will also show that BMD losses after follow-up are higher among women identified to be living with HIV status at baseline. I will also describe how transitioning from pre- to post-menopause was associated with greater BMD losses in women living with HIV than HIV negative women, novel findings in the African context. Therefore, women living with HIV may be at greater risk of menopause-related osteoporotic fractures such that HIV services should consider routine bone health assessments among midlife women as part of HIV-care delivery.

NSS102
THE CHALLENGES OF POOR MUSCULOSKELETAL HEALTH IN THE GAMBIA

K. Ward[1]

[1]MRC Lifecourse Epidemiology Centre, University of Southampton, Southampton, United Kingdom

Over coming decades, the greatest rise in ageing populations will be seen in Africa. Inevitably there will be a concominent rise in non-communicable diseases, of which musculoskeletal diseases form a major part. Despite this, conditions such as osteoporosis and sarcopenia, and consequent falls and fractures remain low priority for healthcare spending. The Gambia, West Africa, is one of the lowest income countries in the world (in 2022 gross domestic product per capita was 840 USD). Whilst healthcare expenditure has risen over recent years, there remains a challenge for public healthcare facilities to meet the rising demands of an older population.

The Gambian Bone and Muscle Ageing Study (GamBAS) is a prospective observational study in Black African men and women aged $\geq$ 40 years (ISRCTN17900679). Fractures-E3 (https://wellcomeopenresearch.org/articles/8-261/v1) is a multi-country study of fracture epidemiology, ethnography and economic impact across The Gambia, Zimbabwe and South Africa. The community prevalence sur ver of FE3 has two study locations in urban and rural The Gambia. This talk will review findings from both GamBAS and Fractures-E3 Gambia work. Both studies have collected detailed assessments of bone and muscle, together with functional ability, medical history and blood samples. This talk will focus on the epidemiology of osteoporosis, vertebral fractures and associated risk factors. These data are the first of their kind in West Africa and provide important evidence to address barriers in diagnosis and access to care in older people in the country.

NSS103
HIP FRACTURE INCIDENCE AND OUTCOMES IN ZIMBABWE

C. Gregson[1,2]

[1]Professor, University of Bristol, Bristol, United Kingdom, [2]The Biomedical Research and Training Institute, Harare, Zimbabwe

In Southern Africa, rapidly ageing populations are increasing demands on healthcare services. In 2021 there were an estimated 212,830 women and 208,607 men aged $\geq$ 40 years living in Harare, equating to 16.2% of the city's population. Over 2 years we identified 243 hip fracture cases, with a mean age 71 years, most presented to public rather than private hospitals, with a fragility fracture. High-impact trauma e.g., traffic accidents, was generally only seen in younger men. I will describe the estimated current and future hip fracture incidence in Zimbabwe which we found to be similar to rates previously reported in Black South Africans. I will share emerging findings from one-year follow-up of the incident cases, describing how late presentations, comorbid HIV and malnutrition are all common. Non-operative management was also common and associated with high mortality, potentially reflecting surgical and financial challenges and/or multimorbidity. Understanding barriers to care will be important to inform future healthcare delivery, as demands on an already over challenged healthcare system are predicted to increase and fracture services will need to respond.

NSS104
THE ECONOMIC IMPACT OF HIP FRACTURE IN ZIMBABWE AND SOUTH AFRICA

N. Mafirakureva[1], P. Ishumael[2], P. Mushayavanhu[2], J. Masters[3], H. Wilson[4], F. Paruk[5], B. Cassim[6], R. Ferrand[2], C. Gregson[7], S. M. Noble[8]

[1]Sheffield Centre for Health and Related Research (SCHARR), Division of Population Health, School of Medicine and Population Health, University of Sheffield, Sheffield, United Kingdom, [2]The Research Unit Zimbabwe, Harare Zimbabwe, Biomedical Training Research Institute, Harare, Zimbabwe, [3]NDORMS, University of Oxford, Oxford, United Kingdom, [4]Musculoskeletal Research Unit, Bristol Medical School, University of Bristol, Bristol, United Kingdom, [5]Department of Rhuematology, School of Clinical Medicine, University of Kwa-Zulu Natal Durban, Durban, South Africa, [6]Department of Geriatrics School of Clinical Medicine, University of Kwa-Zulu Natal Durban, Durban, South Africa, [7]The Biomedical Research and Training Institute, Harare, Zimbabwe, [8]Population Health Sciences, Bristol Medical School, University of Bristol, Bristol, United Kingdom

Despite rapidly ageing populations and projected increases in hip fractures, data on hip fracture-related healthcare resource use and costs in sub-Saharan Africa are limited. The worldwide average health and social care cost in the first year post hip fracture was reported as US$43,669 per patient in a 2017 systematic review, with inpatient care costing US$13,331. Costs were highly variable, reflecting different contexts, variation in methodology, elements of care and patient populations. Data on costs associated with hip fractures are important for quantifying demands on healthcare services, informing accurate cost-effectiveness analyses, and for guiding policy decisions on priority setting, planning, and budgeting. As part of the Fractures-E3 study, we collected healthcare resource utilisation data and costs for cohorts of hip fracture patients in South Africa, The Gambia, and Zimbabwe. This talk will describe the first estimates of the direct healthcare costs associated with the acute management of hip fractures in South Africa and Zimbabwe. We will also discuss the methodological challenges associated with estimating these costs in sub-Saharan African settings.

NSS105
WHY; INTRODUCTION TO PPI, OVERVIEW OF IMPACT AND PROGRESS

A. Adebajo[1]

[1]Faculty of Medicine, Dentistry and Health, University of Sheffield, Sheffield, United Kingdom.

Patient and public involvement and engagement (PPI/E) is research being carried out by researchers alongside members of the public rather than to, about, or for them (National Institute for Health Research, UK). PPI/E as a concept is not new, and it has gained support in recent years due to increased awareness and commitments placed on researchers by funding agencies, patient groups, regulators, reimbursement agencies/HTAs and scientific societies. Notably, the dynamic, heterogeneous and multifaceted nature of lived experiences encourages researchers to partner with patients early and during

research if their primary aim is to learn from patients and effectively improve health for all. This session will focus on why PPI/E is imperative to improve/impact health for all.

NSS106
WHAT; PPI ARTICLE COLLECTION AS A GLOBAL RESOURCE

C. Fitzpatrick[1]

[1]Senior Editor, BMC Medicine, London, United Kingdom

Musculoskeletal and rheumatic healthcare practitioners play a reciprocal role in developing strategies to involve patients as authentic partners in clinical practice and research; however, many researchers express needing knowledge and resources to contact, plan and/or manage meaningful PPI. In June 2023, BMC Rheumatology and BMC Musculoskeletal Disorders (part of Springer Nature) published an Article Collection on 'Patient and public involvement (PPI) in rheumatic and musculoskeletal research' to provide a constructive learning experience and involve public partners more effectively. All papers championing PPI were welcomed and considered. The Article Collection is a global resource of musculoskeletal-related examples ranging from research priority setting through to guideline implementation & community partnerships for multi-modal management. This session will share available PPI resources and where to find them as part of the special collection, highlighting examples from which tailoring to suit different musculoskeletal diseases may be undertaken. Article Collection link:https://www.biomedcentral.com/collections/PPI-RMD

NSS107
HOW; IMPLEMENTING PATIENT PARTNERSHIPS

M. De Wit[1]

[1]Patient Research Partner, Stichting Tools, Amsterdam, Netherlands

Practical examples for involving patients in health research. There is increasing emphasis on patient-centred research to support the development, approval and reimbursement of health interventions that best meet patients' needs. Through a structured, collaborative process the group generated practical guidance to facilitate optimal patient involvement in basic, translational and clinical research. Patient involvement is a relational process. Principles will be shared based on lessons learned through applied experience. This session will focus on partnering with patients, and sharing an example of applied principles to facilitate optimal patient engagement.

NSS108
WHERE WE ARE GOING; PPI OPPORTUNITIES

A. Botto-Van Bemden[1,2,3,4,5]

[1]Global Patient Ambassador, Patient and Public Involvement, Musculoskeletal Research International, Inc., Miami, United States, [2]EUPATI Fellow, EUPATI, Utrecht, Netherlands, [3]Patient Partner, Patient Focused Medicines Development, Clinical Research Experts, LLC., Tampa, United States, [4]Chairperson, Patient Registry, International Cartilage Repair and Joint Preservation Society, Zurich, Switzerland, [5]Member Engagement Co-Chair, Patient-Centered Special Interest Group, ISPOR- The Professional Society for Health Economics and Outcomes Research, Lawrenceville, United States

Patient preferences are a type of patient experience data (PED). Including patient preferences stimulates innovation in medical product development, patient-focused drug development/PFDD or patient focused medicines development/PFMD. Industry prioritizes attributes that matter most to patients, driving creation of more patient-focused interventions and technologies. Incorporating patient preferences explicitly into HTA and regulatory decision-making is a transformative concept in healthcare that not only promotes patient-centric care but also has significant global implications & enormous opportunities. By taking into account the full spectrum of diverse needs and preferences of patients, stakeholders can make more accurate and informed decisions about which treatments should be available for patients. This session will focus on upcoming PPI opportunities with PED dossiers, HTAs and regulators.

NSS109
HYPERTHYROIDISM. ETIOLOGY AND CLINICAL MANIFESTATIONS

I. Kostoglou-Athanassiou[1]

[1]Department of Endocrinology, Diabetes and Metabolism, Asclepeion Hospital, Voula,, Athens, Greece

Hyperthyroidism is a frequent thyroid disorder which may be due to a variety of causes. Hyperthyroidism includes the increase in thyroid hormone levels either directly from the thyroid or from extrathyroidal sources. Hyperthyroidism may have an autoimmune etiology, may be

due to hormone production from autonomous or toxic adenomas, or to thyroid inflammation which causes tissue destruction, and, finally, from extrathyroidal hormone production, such as in the ovaries or to excessive thyroid hormone intake. From the history and the clinical picture, depending on the severity of hyperthyroidism, there usually exist weight loss, tachycardia and rarely atrial fibrillation, fatigue and muscular weakness and rarely periodic paralysis, excessive sweating, gastrointestinal and neuropsychiatric disorders, goiter and other manifestations. Finally, in Graves' disease extrathyroidal manifestations may be found, such as ophthalmopathy and pretibial myxedema. Laboratory evaluation includes the measurement of thyroid hormones in the blood, where T_3 and T_4 are elevated, rarely T_4 is normal and TSH is decreased.

NSS110
HYPERTHYROIDISM. PSYCHOSOCIAL IMPLICATIONS

Y. Athanassiou[1]

[1]Trinity College, Dublin, Ireland

Stressful life events may lead to the development or exacerbation of Hashimoto's thyroiditis and Graves' disease. Financial crises or bereavement may lead to the development of Graves' disease and severe hyperthyroidism. Additionally, hyperthyroidism itself may have psychological and psychiatric implications. The disease leads to depression and severely affects quality of life. Management of hyperthyroidism in the cases related to bereavement may lead to quick recovery and in many instances full remission of the disease. Successful management of hyperthyroidism leads to improvement of psychological disturbances and quality of life.

NSS111
HYPERTHYROIDISM AND SARCOPENIA

L. Athanassiou[1]

[1]Department of Rheumatology, Asclepeion Hospital, Voula, Athens, Greece

Overt hyperthyroidism causes proximal limb muscle weakness which improves after correction of the disease. Subclinical hyperthyroidism may also cause a degree of muscle weakness. This muscle weakness may be significant if it is observed in aging patients, who already have muscle loss. Sarcopenia, a syndrome which is currently under intense scientific investigation, is considered a main risk factor for morbidity and mortality among adults. Thyrotoxicosis may contribute to its development. Indices of sarcopenia such as grip strength, as a measure of muscle strength, appendicular skeletal muscle mass as an index of muscle quantity and gait speed as an index of physical performance were found to be impaired in patients with thyrotoxicosis. Thus, thyrotoxicosis may be associated with sarcopenia. Successful treatment of hyperthyroidism leads to improvement of muscle mass and muscle function.

NSS112
HYPERTHYROIDISM AND OSTEOPOROSIS. PATHOPHYSIOLOGY AND MANAGEMENT

P. Athanassiou[1]

[1]Department of Rheumatology, St. Paul's Hospital, Thessaloniki, Greece

Thyroid hormones are essential for normal skeletal development and normal bone metabolism in adults. However, increased thyroid hormone levels may have detrimental effects on bone metabolism and bone structure. Severe hyperthyroidism increases bone turnover, decreases bone mass and subsequently bone mineral density. Subclinical hyperthyroidism, which is defined as low TSH levels and free T_4 and T_3 levels within the normal range, which may have minimal symptoms or may be completely asymptomatic leads to decreased bone mass and bone mineral density. Hyperthyroidism may lead to an increased risk of fractures. Medical or surgical successful management of hyperthyroidism may ameliorate bone mass loss and may lead to improvement in bone mineral density. In cases of long-standing hyperthyroidism, osteopenia and osteoporosis should be managed with vitamin D and calcium supplementation as well as with the administration of agents such as bisphosphonates as well as denosumab. The administration of alendronate and the effervescent formulation of alendronate may lead to successful management of osteoporosis in the context of long-standing hyperthyroidism.

NSS113
OSTEOPOROSIS AND THE SPINE: KEY STATISTICS AND AN OVERVIEW OF THE NATIONAL SPINE HEALTH FOUNDATION'S KEY PATIENT AND HEALTH CARE PROFESSIONAL INITIATIVES

T. Schuler[1,2]

[1]President, National Spine Health Foundation, Reston, United States, [2]Founder, Virginia Spine Institute, Reston, United States

- Fractures caused by osteoporosis most often occur in the spine (and in the United States, there are 1.5 million vertebral compression fractures that occur each year)
- The age- and sex-specific prevalence of osteoporosis in patients undergoing spine surgery goes up markedly as people age, particularly in females (from 27.8% for women from age 50–59 to 75.4% for women from age 70–79)
- The efforts that the National Spine Health Foundation (which Dr. Schuler founded) is driving to educate patients and health care professionals on the need to identify, diagnose, and treat vertebral compression and spine fractures (both surgically and through anti-osteoporotic medications)
- His work as a leading spine surgeon and how he addresses spine and bone health in his patient population
- The opportunity to disseminate and create patient education tools in support of the recently released North American Spine Society (NASS) Diagnosis and Treatment of Osteoporotic Vertebral Compression Fractures in Adults clinical practice guideline through the members of the National Spine Health Foundation Spine Health Coalition (which includes the Cervical Spine Research Society, Lumbar Spine Research Society, National Spine Health Foundation, North American Spine Society, and Setting Scoliosis Straight Foundation)

NSS114
A SPINE SURGEON PERSPECTIVE ON THE NEED FOR PERIOPERATIVE SPINE AND BONE HEALTH OPTIMIZATION

P. Anderson[1,2]

[1]Co-Chair, National Spine Health Foundation Spine & Bone Health Task Force, Renson, United States, [2]University of Wisconsin School of Medicine, Madison, United States

- Gaps in spine surgeon awareness of the need to conduct perioperative spine health optimization before surgery as a crucial step for improving patient outcomes and reducing complications (which includes a thorough bone health assessment) given the

high prevalence of osteoporosis in patients undergoing spine surgery
- Why spine surgeons should establish care pathways to systematically identify and diagnose osteoporosis in their practices (which may include the establishment of a Fracture Liaison Service program or other means to ensure patients are assessed before surgery)
- The need for vertebral compression fractures to be treated as equally aggressively as hip fractures, with medications including anabolics
- Opportunities for spine/orthopaedic surgeons to work more effectively with bone health specialists to maximize patient care and improve outcomes

NSS115
SPINE AND BONE HEALTH PATIENT EDUCATIONAL GAPS AND NEEDS

R. Roy[1]

[1]Chief Executive Officer, National Spine Health Foundation, Renson, United States

- Key messages that are most effective with patients to educate them on the connection between spine and bone health (including prevention of osteoporosis, how it is treated, and why bone health is such an important component of spine health)
- How to get patients to understand the potential need to delay surgery (to ensure their bones are strong enough to increase the chances of having a good surgical outcome)
- A review of the targeted patient education NSHF is providing to educate and activate patients to take action in talking with their health care professionals regarding spine and bone health, including the most effective written, digital, and social media content
- Successful approaches to empowering patients to ask their health care professionals about spine and bone health

NSS116
A EUROPEAN PERSPECTIVE ON KEY SPINE SURGEON GAPS IN THE DIAGNOSIS AND TREATMENT OF OSTEOPOROTIC PATIENTS

E. Najjar[1,2]

[1]Member, North American Spine Society Continuing Medical Education Committee Member, Illinois, United States, [2]Associate Spinal Specialist, Centre for Spinal Studies & Surgery, Nottingham University Hospitals, Nottingham, United Kingdom

- Economic and personal impact of vertebral fractures, a national and global challenge
- UK National Institute for Health and Care Excellence (NICE) guidelines for early assessment and tailored interventions
- The effect of osteoporotic fractures on spinal global sagittal alignment
- The effect of bone quality on mechanical failure following spine surgery
- Integrating bone quality assessment into decision making and surgical planning in spine surgery

NSS117
GCS IN THE TREATMENT OF RHEUMATOID ARTHRITIS. FRIENDS ?

O. D. Messina[1]

[1]Rheumatologist, IRO Medical Research Centre, Buenos Aires, Argentina

Low dose glucocorticoids (GC) therapy is widely used in rheumatoid arthritis (RA) but the balance of benefit (short term) and harm (long term) is still unclear. GC was first used at the Mayo Clinic in a patients with RA by Hench et al. with spectacular results but after some time of enthusiasm many side effects were evident. In the GLORIA trial (glucocorticoid low-dose in rheumatoid arthritis) pragmatic double-blind randomized trial compared 2 years of prednisolone, 5 mg/day to placebo in patients aged > 65 years with active RA added to disease-modifying treatments including 14% on biologics. Disease activity was 0.37 points lower on prednisolone (95% CL, $p < 0.0001$), joint damage progression was 1,7 points lower (95% CL 0.7 $p = 0.003$). 60% vs 49% of patients experienced the harm outcome adjusted relative risk 1.24 (95% CL 1.04, $p = 0.02$) with the largest contrast in non severe infections. Add on low dose prednisolone has beneficial long-term effects in senior patients with established RA. this suggest a favourable balance of benefit and harm. However other studies using short term GC as a "bridging therapy "at high dose showed no long –term benefit with regard to pregression of radiographic damage at I year. One study by Wassenberg et al. showed than beryloe doses, lower than 5 mg of prednisolone given over 2 years in combination with background DMARDs therapy substantially decreased radiographic progression in early RA at low risk.

Many years ago a Dutch study by M Boers, the COBRA study showed that the combination of prednisolone and MTX and SSZ during the first six months was superior to SSZ alone with less articular damage and less disease activity. In a recent study Lotte van Ouwerkerk et al. compared the use of GC over time in patients with RA who were or were not treated initially with GC as a "bridging therapy ", combining data from BeSt, CareRA and COBRA trials. In randomized trials comparing GC bridging and no GC bridging, bridgers had more rapid clinical improvement, fewer DMARD changes and similar late use of GC compared with non bridgers. GC bridging per protocol resulted, as could be expected in higher cumulative GC over 2 years.

Future research will develop new molecules with less side effects modulating transrepression and transactivation. Some years ago deflazacort, an oxazoline derivative of prednisolone showed less side effects although its equipotency compared with traditional GC was questioned and not definitively established. However deflazacort is approved and prescribed in several European, Latin American and Asian countries.

NSS118
GLUCOCORTICOIDS "FOE"

G. Adami[1]

[1]Medical Doctor presso Azienda Ospedaliera Universitaria Integrata Verona, Verona, Italy

Glucocorticoids are widely used to treat common inflammatory diseases, including inflammatory rheumatic musculoskeletal diseases (iRMDs) such as rheumatoid arthritis and connective tissue diseases. More than 1% of the overall population uses glucocorticoids in chronic as part of the treatment of their condition, and, as a result, glucocorticoid-induced osteoporosis (GIOP) is the most common form of secondary osteoporosis. Glucocorticoids have various detrimental effects on bone. In the early phases, glucocorticoids can

increase osteoclasts activity and, simultaneously, can decrease osteoblasts functionality. Later in the treatment course, glucocorticoids are associated with an overall suppression of bone turnover with osteocyte apoptosis and microarchitectural damage. In aggregate, glucocorticoids cause a rapid reduction in bone mineral density (BMD), which is only partially preventable by anti-osteoporosis medications. Furthermore, by damaging bone microarchitecture, glucocorticoids alter the BMD fracture threshold; in other words, glucocorticoid users tend to fracture at osteopenic or even normal T-scores.

NSS119
MANAGING EGFR AND BONE

R. Keen[1]

[1]Consultant in Metabolic Bone Disease, Royal National Orthopaedic Hospital, Brockley Hill, Stanmore, United Kingdom

Dr Keen will discuss the clinically pertinent management of osteoporosis in people with chronic kidney disease. The attendees will be equipped with latest data on guidelines and data on pharmacological management of osteoporosis in the context of kidney disease.

NSS120
MANAGING AROMATASE INHIBITOR INDUCED BONE LOSS

M. K. Nisar[1,2,3,4]

[1]Consultant Rheumatologist & Physician, Luton, United Kingdom, [2]Director of Research & Development, Luton, United Kingdom, [3]Secretary to East Anglian Rheumatology Society, Luton, United Kingdom, [4]Luton & Dunstable University Hospital, Luton, United Kingdom

Dr Nisar will discuss the guidelines encompassing latest data on aromatase inhibitor induced bone loss in women with breast cancer and how the latest consensus guidelines have provided real world evidence of their efficacy in improving bone health and fracture prevention.

NSS121
OSTEOCALCIN (OC) "OLD"-NEW MARKER—CAN IT BE PROGNOSTIC FOR CVD?

B. Miskic[1], V. Cosic[2], S. Sokolovic[3], M. Knezevic-Pravecek[4], I. Bitunjac[5], K. Cvitkusic-Lukenda[4]

[1]GH drJ Bencevic, Slav. Brod, Slavonski Brod, Croatia, [2]Faculty of Dental medicine and health, University of Osijek, Osijek, Croatia, [3]University clinic Sarajevo, Sarajevo, Bosnia & Herzegovina, [4]GH dr.J.Bencevic SL.Brod, GH dr.J.Bencevic SL.Brod, Croatia, [5]GH dr.J.Bencevic SL.Brod, SL.Brod, Croatia

Objective: Cardiovascular diseases have been the leading cause of death worldwide for a long time. systematic analysis of modern literature. Systematic analysis of modern literature from the scientific databases (2013–2023.) define osteocalcin as a potential biomarker of cardiovascular status. Its increased values are associated with a potentially protective mechanism against the development of cardiovascular diseases (CVD). Contradictory in the pathogenitic mechanism of CVD leaves a lot if possibilities for research.
We concluded a short -term pilot study on the association of OC levels with acute myocardial infarct (AMI) and Heart failure (HF) in the Department of cardiology, in GH Slav. Brod, Croatia.
Materialsand Methods: We investigated serum level of osteocalcin in the patients (N25) with (AMI) and (N23) patients with (HF) comparable with age AMI 51 ± 3,6, IC 54 ± 5,3 and sex. Female (N8) AMI; (N7) and HF. and correlation between level of troponin, N-terminal proBrain Natriuremic Peptide (NT-proBNP) and other bone markers. Those with diseases affecting bone status were excluded.
We used the SPSS 28.0.1 package.
Results: Tropinin level (ng/L) was statistically significant between those two categories: AMI and HF, $p < \mathbf{0.001}$ Nt-proBNP (pg/ml) correlated with stage of HF but level of osteocalcin β-Crosslabs (ng/ml), vitamin D (nmol/L), Parathyroid hormon (pg/ml) and calcium were not very different between groups.
Conclusion We found slightly higher, statistically insignificant levels of OC in subjects with AMI. The reason for the insignificant difference may be the small number or great scale of results. From our results its cannot be ruled out whether OC is a significant predictor of CVD and by what mechanism. Large randomized well-designed double-blind studies with clear hypotheses are needed to gain insight into the real role of OC in CVD.

NSS122
THE HIDDEN UPSTAIRS BETWEEN BONE DENSITY AND CARDIOVASCULAR MORTALITY

H. Bassiouni[1]

[1]Update Rheumatology Foundation, Cairo, Egypt

Objective: Cardiovascular disease (CVD) and osteoporosis are common age-connected conditions associated with high morbidity, mortality, and disability. Accumulating biological and epidemiological evidence holds up a link between the two conditions namely low bone mass and CV disease. The aim of the present work is to review the relation between both conditions.
Observations: Atherosclerotic calcification and bone mineralization split a number of intriguing common aspects. It is now conceded that arterial tissue calcification is not merely a passive process of calcium phosphate precipitation or adsorption in advanced atherosclerosis, but alternatively is a highly organized process that is mastered by mechanisms similar to those involved in bone mineralization. Literature suggests that low BMD and bone loss seems to be risk factors for cardiovascular mortality in both genders. A number of studies have studied the link between BMD and cardiovascular morbidity. In the Health, Aging, and Body Composition (ABC) Study, it was noted that the volumetric BMD (vBMD) measures of the spine were notably and inversely associated with prevalent CVD in both genders, and areal BMD (aBMD) of the trochanter was related to CVD in women. Further browsing in papers suggested that there were more relevant associations between osteoporosis and CVD in women proposed by the MORE trial which highlighted that osteoporosis was a strong predictor of incident cardiovascular events in postmenopausal women maverick of age and other traditional cardiovascular risk factors. An inverse relationship was found in women between bone mass and various measures of subclinical disease in many publications. Cross-sectionally, vascular calcification, in both the aorta and the coronary arteries was found to disagree if correlated with bone density and directly related to vertebral and hip fractures, chiefly in white postmenopausal women.
Conclusion: CVD and osteoporosis increase with aging. Historically, these two conditions were considered unrelated and their coexistence was attributed to unconventional age-related processes. Currently, an increasing body of biological and epidemiological evidence has furnished support for a link between the two conditions far from age and shared risk factors. It is suggested that common molecular, cellular, and biochemical processes are implicated in their pathogenesis and warrants further clarifying studies.

NSS123
OSTEOPOROSIS AND CARDIOVASCULAR DISEASES: A CASE-SERIES STUDY

S. Sokolovic[1], I. Sokolovic[1]

[1]Society for Osteoporosis in Federation of Bosnia and Herzegovina, Sarajevo, Bosnia & Herzegovina

Introduction: Osteoporosis is associated with increased risk for cardiovascular morbidity and mortality. On the other hand, cardiovascular disorders may reflect bone and mineral dysregulation. This risk is particularly observed in postmenopausal women and elderly male. The estrogen deficiency plays a major role in women for osteoporosis and cardiovascular diseases. Both vitamin D and minerals have another important influence in both. The BMD, hyperlipidemia, diabetes contribute to and in cardiovascular diseases. The pro-inflammatory cytokines, osteoprotegerin act in the same time on bone and vascular calcifications. Both entities share the similar pathophysiology processes, clinical manifestations, prevention of the same risk factors and some novel therapies.
Material and methods: A case series study was implemented. Total of 16 postmenopausal women were included in a study. No males were included. The cardiovascular risk factors, bone mineral density (BMD), arterial hypertension, arterial stiffness, coronary calcium score and vitamin D level were analysed. Multi slice CT scan (MSCT) was diagnostic procedure for CHD.
Results: Among 16 patients, there were 9 suffering from the severe Osteoporosis and Coronary Heart Disease, while other 7 subjects did not have either severe osteoporosis or any other heart disease. Osteopenia was included.

Severe Osteoporosis (9pts)		No Osteoporosis/Osteopenia (7pts)
Average age	57y/o	65y/o
Average BMD	3,4	1,6
Coronary Calcium score:	368	18
LAD Stenosis	≥70%	≤ 50%
Vitamin D:	6,9 ng/ml	28 ng/ml
Blood pressure/Pulse: 146/94mmHg/78/min		102/88mmhg/84/min
Arterial stiffness /Vascular age	8 years older	3 years younger

Conclusion/discussion: Patients with osteoporosis and with no manifested CVD should be examined for silent heart disease. Patients with manifested CVD should be examined for osteoporosis.

NSS124
PREVENTION OF HIP FRACTURES

B. Duyur Cakit[1]

[1]MD, Professor, University of Health Science Ankara Training and Research Hospital, Department of Physical Medicine and Rehabilitation, Ankara, Turkiye

Osteoporosis is a major public health problem that affects millions of people worldwide. A frequent and serious consequence of osteoporosis is a hip fracture leading to high morbidity, excess mortality, substantial costs and decreased quality of life. Several risk factors are known to predispose individuals to hip fractures, including: female gender, older age, a high number of comorbidities, low cognitive function, previous spine or hip fracture and poor neuromuscular function. Falls in older adults are a highly prevalent problem.

Sarcopenia is identified as one of the most common comorbidities associated with femoral neck fracture. Preventive interventions are needed to reduce the number of hip fractures. Several interventions have been described to reduce the risk of hip fractures including regular exercises, drug treatments (e.g. calcium, vitamin D and antiresorptives/anabolics) and/or the use of hip protectors. Since more than 90% of the hip fractures are the result of a fall, hip protectors could be an interesting strategy/intervention for preventing hip fractures. Shock-absorbing flooring may also minimise fall-related injuries. In conclusion, preventing fractures in older community-dwelling adults requires careful consideration of an individual's estimated fracture risk, life expectancy, and health priorities. Clinicians must consider pharmacologic and non-pharmacologic interventions to reduce fracture burden in this vulnerable population.

NSS125
ANTIOSTEOPOROTIC AGENTS AND FRACTURE HEALING

P. Borman[1]

[1]MD, Professor of PMR, University of Ankara Medipol, Faculty of Medicine, Department of Physical Medicine and Rehabilitation, Ankara, Turkiye

Osteoporosis poses a significant public health concern, characterized by compromised bone strength and an increased risk of fractures. There is an intricate relationship between antiosteoporotic agents and the process of fracture healing. As osteoporotic fractures are associated with delayed and impaired healing, understanding the impact of pharmacological interventions becomes crucial. Antiosteoporotic agents, including bisphosphonates, selective estrogen receptor modulators, denosumab, and anabolic agents such as teriparatide, are commonly prescribed to manage osteoporosis and prevent fractures. While these medications primarily focus on bone density improvement, emerging evidence suggests their potential influence on the fracture healing process. While a number of studies using osteoporotic animal models have shown a detrimental impact on fracture healing, clinical evidence regarding whether fracture healing is impaired in the presence of osteoporosis is complicated by numerous associated conditions including advancing age. The mechanism of some anti-osteoporotic medications creates concern about a potential detrimental impact on fracture healing, while others appear to enhance fracture healing. There are still large gaps in the understanding of the potential effect of anti-osteoporotic drugs on fracture healing, although based on present knowledge a recent or present fracture should not be considered as a contraindication to such treatment. The current evidence indicates that the beneficial effects of anti-osteoporosis treatment exceeds any concerns about possible adverse consequences on fracture healing in most circumstances. The current literature, highlighting the mechanisms by which antiosteoporotic agents may impact fracture healing, shedding light on potential therapeutic implications and areas for future research will be discussed in this session.

NSS126
REHABILITATION OF HIP FRACTURES

A. Yaman[1]

[1]MD, Specialist of PMR, Ankara Etlik City Hospital, Department of Physical Medicine and Rehabilitation, Ankara, Turkiye

Hip fractures represent a significant health challenge, particularly among the elderly, often resulting from falls or trauma. The rehabilitation process following a hip fracture is crucial for restoring functionality, independence, and overall quality of life. Key aspects of

hip fracture rehabilitation encompass early postoperative care, physical therapy, and the psychosocial elements which are essential for a successful recovery.

The initial phase of hip fracture rehabilitation begins with educating patients and their caregivers about the importance of compliance with rehabilitation protocols, medication management, and lifestyle modifications are crucial. The postoperative care with early mobilization is encouraged to prevent complications associated with immobility and to promote circulation. Physical therapy plays a central role in hip fracture rehabilitation, aiming to rebuild strength, improve balance, and enhance mobility. Progressive exercises, tailored to the individual's capabilities, target the hip muscles and surrounding areas. Weight-bearing exercises, gait training, and balance drills are essential components, gradually reintroducing patients to daily activities. The use of adaptive devices like walker or cane, and assistive technology is integral to hip fracture rehabilitation. As psychological impact of a hip fracture, including fear of falling and anxiety about mobility, can impede progress, psychosocial aspects of hip fracture rehabilitation are critical for a holistic recovery. In addition, safe and supportive environment modifications enhance patient confidence and facilitate a smoother transition back to independent living.

As a conclusion; a comprehensive individualized approach that combines early postoperative care, targeted physical therapy, adaptive technologies, psychosocial support, environmental modifications, and patient education is essential for achieving optimal outcomes and contribute significantly to restoring functionality and enhancing the overall well-being of patients.

NSS127
HEALTH ECONOMICS OF OSTEOPOROSIS: THE MISSED INTERVENTIONAL THRESHOLD

Y. El Miedany[1]

[1]Consultant Rheumatologist, Canterbury Christ Church University, Kent, United Kingdom

Healthcare systems face considerable challenges to meet the population healthcare needs. This is of particular interest in low- and middle-income countries (LMICs) who have markedly fewer resources than those in high income countries. Therefore, the strategy in which the existing resources are assigned across competing priorities is critical in affecting the level of the health is generated overall, who receives healthcare interventions and who goes without. There are several tools of economic evaluation to facilitate and help policy makers in the process of resource allocation (e.g. cost-effectiveness analysis (CEA). The central factor is to consider both the effectiveness of the intervention versus its cost to be able to determine whether the health gains offered by an intervention are large enough relative to its costs and consequently warrant adoption. This involves some notion of the value that should be achieved by an intervention, which is most frequently represented using a cost-effectiveness threshold. This presentation is for healthcare professionals who are interested in health economics and would like to learn more about approaches to implementing it in standard practice. It will give an introduction of health economics and cost benefit analysis in a trial to make this challenging topic easy. This will include health economics evaluations, outcomes as well as modelling, Quality Adjusted Life Year (QALY), the incremental cost-effectiveness ratio (ICER), willingness to pay threshold and its implementation in osteoporosis and fragility fractures management.

NSS128
DIRECT COST OF OSTEOPOROTIC HIP FRACTURES

W. El Wakil[1]

[1]Lecturer Rheumatology and Rehabilitation, Alexandria University, Alexandria, Egypt

Osteoporosis and its associated fragility fractures not only have a major impact on health and quality of life but also impose a significant economic burden on the health system. The economic costs of a disease can be used to estimate the disease burden whether at the national or global levels. The costs in the economy can stratified into two sections, direct and indirect costs. The direct costs are the treatment costs, whereas the indirect costs are the costs associated with the days off from work due to illness.

Among the different components of health care systems, hospitals are facing a shortage of resources as a challenge, and every type of shortage of resources leads to a competition. Under such a condition and competition, only the organizations that could reduce the costs while paying attention to the quality of services provided can be successful. Therefore, cost information can be of great value in optimizing resource allocation, modifying budgets, reducing waste costs, and making more efficient use of available resources. The objective of every cost detection and cost management system is to provide accurate and practical information to help organizations deliver quality services under a competitive setting. This presentation will discuss the large treatment gap among those at high risk for fragility fractures at the international as well as national levels, direct as well as indirect costs of hip fractures, and approaches to implement the annual costs of hip fractures, calculated through construction of a Continuum-Care Episode, as a confounder in the health policy decision-making.

NSS129
ECONOMIC EVALUATION OF FRACTURE LIAISON SERVICE (FLS): THE EGYPTIAN EXPERIENCE

M. Toth[1,2]

[1]H. Senior Clinical Lecturer, King's College London, London, United Kingdom, [2]Medicine, Dartford, Kent, United Kingdom

With populations ageing, the burden of fragility fractures on healthcare systems around the world is on the rise, resulting in a spiral of increased patient disability, loss of independence, and early mortality within the older population. Given that patients with a fragility fracture are at substantially high risk of subsequent fractures, effective secondary fracture prevention is of critical importance. In this regard, Fracture Liaison Services (FLS) have been shown to be an optimal way to systematically identify, assess, treat, and monitor patients who have recently sustained a fragility fracture, and they have been proven to reduce the risk of subsequent fractures in numerous studies and reviews. This presentation will discuss the health benefits and budget impact of the national Fracture Liaison Services (FLS) in Egypt and its potential effectiveness in shaping positive patient outcomes and help drive policy decisions. Markov model has been assessed through five health states (with and without osteoporosis treatment, subsequent hip, subsequent major fracture, and death). A time horizon of 10 years and a 1-year cycle duration was used. Clinical and economic variables were estimated from the literature and Egyptian clinical practice. Effectiveness was measured in life-years gained (LYG) and quality-adjusted life years gained (QALYs). Implementing FLS at a national level in Egypt, has benefited patients' outcomes, through a significant reduction in subsequent fragility fractures and gains in quality of life, whilst at the same time reducing hospital bed days, surgeries, need for institutional social care, and their associated costs.

World Congress on Osteoporosis, Osteoarthritis and Musculoskeletal Diseases (WCO-IOF-ESCEO 2024): Posters Abstracts

P101
EXAMINING TREATMENT TARGETS AND EQUITY IN BONE-ACTIVE MEDICATION USE WITHIN SECONDARY FRACTURE PREVENTION: A SYSTEMATIC REVIEW AND META-ANALYSIS

A. A. Ali[1], E. H. Huszti[1], S. N. Noordin[2], U. A. Ali[2], J. S. Sale[1]

[1]Institute of Health Policy, Management & Evaluation, Univ. of Toronto, Toronto, Canada, [2]Dept. of Surgery, Aga Khan Univ., Karachi, Pakistan

Objective: This review seeks to evaluate the proportion of fragility fracture patients screened in secondary fracture prevention programs who were indicated for pharmacological treatment, received prescriptions for bone-active medications, and initiated the prescribed medication. Additionally, the study aims to analyze equity in pharmacological treatment by examining various equity-related variables including age, sex, gender, race, education, income, and geographic location.

Methods: We conducted a systematic review to ascertain the proportion of fragility fracture patients indicated for treatment who received prescriptions and/or initiated bone-active medication through secondary fracture prevention programs. We also examined treatment indications reported in studies and eligibility criteria to confirm patients who were eligible for treatment. To compute the pooled proportions for medication prescription and initiation, we carried out single group proportional meta-analysis. We also extracted the proportions of patients who received prescription and/or began treatment based on age, sex, race, education, income, location, and chronic conditions.

Results: This review includes 122 studies covering 114 programs. The pooled prescription rate was 77%, and the estimated medication initiation rate was 71%. Subgroup analysis revealed no significant difference in treatment initiation between the Fracture Liaison Service and other programs. Across all studies, age, sex, and economic status were the consistent equity variables reported in relation to treatment outcomes. Our data indicated no age-specific or income-related differences in the treatment proportions. Nine studies examined sex-related differences, and 44% of them found that females tended to be more likely to receive prescription and/or initiate treatment compared to men.

Conclusion: This review identified and described 122 studies encompassing 114 secondary fracture prevention programs. The pooled proportions for treatment outcomes may not fully reflect the targets reached by various programs. However, computing treatment proportions for eligible patients allowed us to compare them with international standards. The present review emphasizes the need for standardized reporting guidelines in post-fracture interventions. A thorough documentation of study population and treatment proportions would improve the applicability of findings. Moreover, considering equity stratifiers in the analysis of post-fracture outcomes will help address inequities and improve the overall quality of programs.

P102
THE ASSOCIATION BETWEEN MULTIMORBIDITY AND TREATMENT OF HIGH RISK FRAGILITY FRACTURE PATIENTS IN AN ONTARIO COORDINATOR-BASED FRACTURE SCREENING PREVENTION PROGRAM

A. A. Ali[1], E. H. Huszti[1], S. N. Noordin[2], J. S. Sale[1]

[1]Institute of Health Policy, Management & Evaluation, Univ. of Toronto, Toronto, Canada, [2]Dept. of Surgery, Aga Khan Univ., Karachi, Pakistan

Objective: This study investigated the association between multimorbidity and pharmacological treatment rates in high risk patients who were screened through Ontario Coordinator-based Fracture Screening Prevention Program (FSPP).

Methods: We conducted a retrospective cohort study to determine the magnitude of association between multi-morbidity and bone-active medication prescription and initiation rates. All high risk patients who were enrolled in the FSPP and screened at one of the 40 FSPP sites between June 1, 2017, and June 30, 2022 were included in the study. The FSPP collects information on seven chronic disease categories including heart disease (stroke, heart attack), diabetes, respiratory disease (asthma, COPD, emphysema), arthritis (rheumatoid arthritis, osteoarthritis), cancer, high blood pressure, and high cholesterol. We created an ordinal variable of multimorbidity by summing the total number of chronic conditions available in the dataset. Multi-morbidity was classified into four categories: (1) no chronic condition; (2) one chronic condition; (3) two chronic conditions; and 4) three or more chronic conditions. To investigate the association between treatment rates and multimorbidity, we created multivariable logistic regression models to compute adjusted odds ratios (AOR) along with their corresponding 95% CIs.

Results: Among 27,148 patients in the FSPP during study duration, 11,245 were identified as high risk. Patients with two chronic conditions demonstrated a 26% higher odds of receiving a medication prescription, and those prescribed bone-active medications had a 57% increased odds of initiating the treatment compared to individuals without chronic conditions. Significant predictors included age, sex, marital status, and living location.

Conclusion: Our analysis did not reveal any disparities in pharmacological treatment for patients with two or more chronic conditions screened through the FSPP. Instead a greater burden of health issues was associated with an increased likelihood of receiving treatment within the FSPP. The systematic identification of high risk patients for future fractures, appeared to eliminate disparities in treatment prescription and initiation rates based on multimorbidity. This underscores the program's success in ensuring that patients with a more complex health profile, characterized by multiple chronic conditions, receive the necessary attention and care within the FSPP.

P103
PREDICTIVE VALUE OF TRABECULAR BONE SCORE ADJUSTED FRAX FOR VERTEBRAL FRACTURES IN POSTMENOPAUSAL TYPE 2 DIABETIC WOMEN: A CROSS-SECTIONAL STUDY

A. A. Mousa[1], H. Abdelhay[1], M. Roshdy[1], S. Sameh[1]

[1]Specialized Medical Hospital, Mansoura Univ., Egypt, Mansoura, Egypt

Objective: Among the several comorbidities that affect postmenopausal women with diabetes, increased fracture risk is a relatively under covered complication. Individuals with T2DM exhibit higher BMD, which complicates the assessment of fracture risk. The most frequent type of osteoporotic fractures is vertebral

fractures (VFs), and is associated with future VFs and non-VFs. We aimed to evaluate the predictive value of fracture risk assessment (FRAX) tool adjusted with TBS in assessment of postmenopausal type 2 diabetic patients with VFs.

Methods: 125 postmenopausal type 2 diabetic women from Diabetes Clinic of Specialized Medical Hospital, Mansoura Univ. were included. DXA scan on vertebrae using TBS was done. For each patient, the FRAX algorithm for major osteoporotic fracture (MOF) and for hip fracture (HF) with BMD was computed, together with TBS-adjusted FRAX.

Results: 27.2% of the patients had morphometric VFs. BMD and FRAX with BMD did not differ; while TBS and TBS adjusted FRAX was statistically higher in patients with VFs compared to those without VFs. Based on the receiver operating characteristic (ROC) curve**,** the best curves to identify subjects with VFs were: age (area under the curve (AUC) 0.64; p = 0.02, duration of menopause (AUC 0.67; p = 0.008), TBS (AUC 0.63; p = 0.03), TBS-adjusted FRAX MOF (AUC 0.64; p = 0.01 with a threshold of 3%) and TBS-adjusted FRAX HF (AUC 0.63; p = 0.04 with a threshold of 20%).

Table 1. Characteristics associated with vertebral fractures in postmenopausal diabetic patients

Characteristics	Patients with VFs	Patients with no VFs	P value
Number (%)	34(27.2)	91(72.8)	
Age (y)	65 (55-79)	59 (53-61)	0.002
Duration of menopause (y)	16 (10-25)	13 (4-29)	<0.005
Duration of diabetes (y)	18(12-22)	14(10-21)	0.016
History of non VFs (%)	17.6	16.4	0.181
BMI (kg/m^2)	30.1 (26.4-33.9)	32.8 (22.6-45.7)	0.279
HbA1c (%)	8.2 (7.8-9.3)	7.9 (6.4-9.5)	0.637
Lumbar spine, T-score	−1.93±0.99*	−1.81± 1.18*	0.338
Lumbar spine BMD, g/cm^2	0.82± 0.11*	0.85±0.13*	0.944
Femoral neck, T-score	−2.04±(0.93*	−1.93 ±0.77*	0.817
Femoral neck BMD (g/cm^2)	0.62± 0.11*	0.63 ±0.10*	0.078
FRAX-MOPF (%)	4.9 (2.9-8.9)	4.6 (1.2-11.5)	0.788
FRAX-HF (%)	1.84±2.52*	2.08±2.92*	0.590
TBS	1.132 (1.109–1.154)	1.200 (1.192–1.207)	<0.0001
TBS adjusted FRAX-MOPF (%)	7.9 (5.3-16.5)	5.5 (4.1- 8.7)	0.002
TBS adjusted FRAX-HF (%)	5.36±6.27*	2.39±2.20*	<0.001

Data are presented as the median (Q1, Q3) or as mean±standard deviation*
BMD=bone mineral density, BMI=body mass index, FRAX-HF=10-y probability of hip fracture by fracture risk assessment tool, FRAX-MOF=10-y probability of major osteoporotic facture by fracture risk assessment tool, TBS=trabecular bone score, VF=vertebral fracture

Table 2. Area under the curve (AUC), sensibility and specificity for ROC curves that identify subjects with vertebral fractures (p value<0.05)

	Sensitivity (%)	Specificity (%)	AUC (95%CI)	p value
Age (y)	50	76	0.64 (0.52–0.76)	0.02
Duration of menopause (y)	40.6	89.6	0.67 (0.54–0.79)	0.008
Duration of diabetes (y)	23.3	66	0.62 (0.51–0.78)	0.01
TBS	31.6	84	0.63 (0.51–0.76)	0.03
TBS adjusted FRAX-MOPF (%)	51	94.5	0.64 (0.52–77)	0.01
TBS adjusted FRAX-HF (%)	22	75	0.63 (0.50–0.75)	0.04

FRAX-HF=10-y probability of hip fracture by fracture risk assessment tool, FRAX-MOF=10-y probability of major osteoporotic facture by fracture risk assessment tool, TBS=trabecular bone score.

Conclusion: TBS, TBS-adjusted FRAX MOF and TBS-adjusted FRAX HF but not FRAX with BMD could identify vertebral fractures in postmenopausal diabetic women.

P104
COGNITIVE IMPAIRMENTS IN RHEUMATOID ARTHRITIS PATIENTS RECEIVING ADEQUATE PSYCHOPHARMACOTHERAPY OF ANXIETY AND DEPRESSIVE DISORDERS: OUTCOMES OF THE 5-YEAR PROSPECTIVE STUDY

A. Abramkin[1], T. Lisitsyna[1], D. Veltishchev[2], O. Seravina[2], O. Kovalevskaya[2], S. Glukhova[1], E. Nasonov[1]

[1]V.A. Nasonova Research Institute of Rheumatology, [2]Moscow Research Institute of Psychiatry, Serbsky NMRC PN MoH, Moscow, Russia

Objective: To assess the baseline rates and 5-y outcomes of cognitive impairments (CI) in patients with rheumatoid arthritis (RA) and comorbid anxiety and depressive disorders (ADD) receiving conventional antirheumatic drugs and biologics with or without adequate psychopharmacotherapy (PPT) in 5-y prospective study. To compare clinical, demographical characteristics, ADD severity and prevalence in RA patients depending on CI outcomes.

Methods: 128 RA-patients (pts) were enrolled, 86% were women with a mean age of 47.4 ± 11.3 (M ± SD) y. All pts met the full ACR criteria for RA. Disease activity was assessed using DAS28, mean RA activity was high (5.27 ± 1.78) at baseline. ADD were diagnosed in 123 (96.1%) of RA-pts in accordance with ICD-10 in semistructured interview by a licensed psychiatrist. Severity of depression and anxiety was evaluated with MADRS and HAM-A. CI were diagnosed during clinical and psychological examination using the battery of pathopsychological and projective techniques including remembering the ten words, indirect (relational) memorization with pictograms, incomplete-sentence test, Wechsler scale, Raven's Progressive Matrices. According to test results, CI were classified as memory deficit (mechanical and/or or relational), impaired logical thinking (distortion, decrease of generalization process), impairments in memory and logical thinking or normal cognitive function. Patients missing 1 or more cognitive test results were excluded from the analysis. Biologics treatment duration varied from 1 to 6 y, antidepressants from 6–96 weeks. CI outcomes were considered favourable in cases with no CI diagnosed throughout the study or in cases of reversal of cognitive impairments (memory and/or logical thinking). Cases with CI remained unchanged throughout the study or CI newly diagnosed after 5 y were considered unfavourable. RA-pts with ADD were divided into the following treatment groups: 1—conventional disease-modifying antirheumatic drugs (DMARDS) (n = 39), 2—DMARDs + PPT (sertraline or mianserine) (n = 43), 3—DMARDs + biologic DMARDs (bDMARDS) (n = 32), 4—DMARDs + bDMARDs + PPT (sertraline or mianserine) (n = 9).

Results: At baseline CI were diagnosed in 25 (64.1%) patients in 1st group, 35 (81.4%) in 2nd, 24 (75%) in 3rd and 6 (66.7%) in 4th. At 5-y endpoint 83 RA-pts were assessed, 18 cases excluded due to absence of one or more cognitive tests performed, 65 included in analysis (1st group—22, 2nd—14, 3rd—20, 4th—9). 16 cases were considered as favourable outcomes (18.2%, 35.7%, 15% and 44.4% for groups 1–4 respectively, $p > 0.05$), 49 as unfavourable. Total percent of favourable outcomes was significantly higher in PPT (2 and 4) than in no PPT (1 and 3) groups (39.1 vs. 16.7%, p = 0.045, RR 1.97, 95% CI 0.61–6.32). Patients with favourable vs. unfavourable CI outcomes had similar clinical and demographical characteristics, including disease activity, CRP level,% of extraarticular RA manifestations, GC usage, but were characterised by lower major depression prevalence (12.5 vs. 46.9%), lower baseline depression levels by Montgomery–Asberg scale (18 ± 6.7 vs. 21.6 ± 6.9), major decrease of depression symptoms after 5 y (− 6.5 [− 11.0; − 4.0] vs. − 1.0 [− 8.0; 1.0]), higher rates of remission of anxiety and depressive symptoms after 5 y (44 vs. 12.8%, $p < 0.05$). Favourable CI outcomes significantly correlated with remission of

anxiety and depressive symptoms at 5-y follow-up (r-Spearman's 0.35, p = 0.002).
Conclusion: CI rates are associated with depression levels and tend to remain unchanged or deteriorate in a majority of RA patients with ADD in long-term perspective. Adequate PPT and remission of ADD symptoms is associated with favourable CI outcomes after 5 y.

P105
MEMORY IMPAIRMENT IN PATIENTS WITH RHEUMATOID ARTHRITIS WITH COMORBID ANXIETY AND DEPRESSIVE DISORDERS

A. Abramkin[1], T. Lisitsyna[1], D. Veltishchev[2], O. Seravina[2], O. Kovalevskaya[2], S. Glukhova[1], E. Nasonov[1]

[1]V.A. Nasonova Research Institute of Rheumatology, [2]Moscow Research Institute of Psychiatry, Serbsky NMRC PN MoH, Moscow, Russia

Objective: To assess the baseline rates and 5-y outcomes of cognitive impairments (CI), including memory loss, in patients with rheumatoid arthritis (RA) and comorbid anxiety and depressive disorders (ADD) receiving conventional antirheumatic drugs and biologics with or without adequate psychopharmacotherapy (PPT) in 5-y prospective study. To assess factors associated with impaired memory after 5 y.
Methods: 128 RA-patients (pts) were enrolled, 86% were women with a mean age of 47.4 ± 11.3 (M ± SD) y. All pts met the full ACR criteria for RA. Disease activity was assessed using DAS28, mean RA activity was high (5.27 ± 1.78) at baseline. ADD were diagnosed in 123 (96.1%) of RA-pts in accordance with ICD-10 in semi-structured interview by a licensed psychiatrist. Severity of depression and anxiety was evaluated with MADRS and HAM-A. CI were diagnosed during clinical and psychological examination using the battery of pathopsychological and projective techniques including remembering the ten words, indirect (relational) memorization with pictograms, incomplete-sentence test, Wechsler scale, Raven's Progressive Matrices. According to test results, CI were classified as memory deficit (mechanical and/or or relational), impaired logical thinking (distortion, decrease of generalization process), impairments in memory and logical thinking or normal cognitive function. Patients missing 1 or more cognitive test results were excluded from the analysis. Biologics treatment duration varied from 1–6 y, antidepressants from 6 to 96 weeks. RA-pts with ADD were divided into the following treatment groups: 1—conventional disease-modifying antirheumatic drugs (DMARDs) and/or biologic DMARDs (bDMARDS) and no PPT (n = 71), 2—DMARDs and/or bDMARDs + PPT (sertraline or mianserine) (n = 52). Stepwise logistic regression analysis was performed to assess factors associated with memory deficits after 5 y.
Results: At baseline CI were diagnosed in 90 (73.2%) patients, 49 (69%) patients in 1st group and 41 (78.9%) in 2nd, difference between groups nonsignificant. Logical thinking was impaired in 36 (50.7%) vs. 27 (51.9%), memory in 44 (62%) vs. 39 (75%), including mechanical memory deficit in 4 (5.6%) vs. 1 (1.9%), relational memory deficit in 17 (23.9%) vs. 18 (34.6%), impairments in both mechanical and relational memory in 23 (32.4%) vs. 20 (38.5%), combined memory and logical thinking impairments in 31 (43.7%) vs. 23 (44.2%) for 1st and 2nd groups respectively, $p > 0.05$. At 5-y endpoint, 83 RA-pts were assessed and 74 (42 in 1st group and 32 in 2nd) included in analysis. After 5 y, CI rates in 1st (no PPT) group increased from 69 to 85.7% and in 2nd (PPT) decreased from 78.9% to 62.5%, between-group significance p = 0.021 (85.7% vs. 62.5%, RR 1.93, 95% CI 0.63–5.9). Rates of logical thinking impairments in both groups increased (from 50.7 to 69.1% in 1st group and from 51.9 to 59.4% in 2nd), mechanical memory remained unchanged 3 (7.1%) vs. 1 (3.1%), relational memory deficit remained in 1st and decreased in 2nd group, 10 (23.8%) vs. 6 (18.8%), mechanical and relational memory deficit increased in 1st and decreased in 2nd group. 20 (47.6%) vs. 10 (31.3%), total memory deficit rates slightly increased in 1st group (from 62 to 78.6%, $p > 0.05$) and significantly decreased in 2nd (from 75 to 53.1%, p = 0.034), significance between groups p = 0.041 (78.6% vs. 53.1%, RR 1.56, 95% CI 0.59–4.13). According to univariate logistic regression, age, major depression, cholesterol level, longer duration of depression symptoms were positively associated, and RF, ACCP, anxiety spectrum disorders, baseline hemoglobin level, anxiety level (HAM-A score) and remission of depression symptoms after 5 y were negatively associated with memory deficit after 5 y ($p < 0.3$). These variables were subjected to multivariate logistic regression: cholesterol level were positively associated (OR 2.1, 95% CI 1.2–3.6, $p < 0.001$) while hemoglobin levels (OR 0.98, 95% CI 0.96–1.0, p = 0.08) and remission of anxiety and depression symptoms (OR 0.18, 95% CI 0.05–0.62, $p < 0.001$) negatively associated with memory impairments after 5 y.
Conclusion: Memory deficit, along with impaired logical thinking, is highly prevalent in RA patients with comorbid ADD. Rates of logical thinking impairments tend to increase in most patients and remain stable in antidepressants treated group. Memory function shows improvement after PPT and remission of ADD symptoms. Multiple regression shows cholesterol levels to be associated with higher risk of memory impairments after 5 y, and PPT and hemoglobin levels to be associated with lower risk. PPT of ADD and hemoglobin levels may play a protective role in regulation of memory function in RA patients with ADD.

P106
LOGICAL THINKING IMPAIRMENTS IN PATIENTS WITH RHEUMATOID ARTHRITIS WITH COMORBID ANXIETY AND DEPRESSIVE DISORDERS

A. Abramkin[1], T. Lisitsyna[1], D. Veltishchev[2], O. Seravina[2], O. Kovalevskaya[2], S. Glukhova[1], E. Nasonov[1]

[1]V.A. Nasonova Research Institute of Rheumatology, [2]Moscow Research Institute of Psychiatry, Serbsky NMRC PN MoH, Moscow, Russia

Objective: To assess the baseline rates and 5-y outcomes of cognitive impairments (CI), including logical thinking impairments, in patients with rheumatoid arthritis (RA) and comorbid anxiety and depressive disorders (ADD) receiving conventional antirheumatic drugs and biologics with or without adequate psychopharmacotherapy (PPT) in 5-y prospective study. To assess factors associated with logical thinking impairments after 5 y.
Methods: 128 RA-patients (pts) were enrolled, 86% were women with a mean age of 47.4 ± 11.3 (M ± SD) y. All pts met the full ACR criteria for RA. Disease activity was assessed using DAS28, mean RA activity was high (5.27 ± 1.78) at baseline. ADD were diagnosed in 123 (96.1%) of RA-pts in accordance with ICD-10 in semi-structured interview by a licensed psychiatrist. Severity of depression and anxiety was evaluated with MADRS and HAM-A. CI were diagnosed during clinical and psychological examination using the battery of pathopsychological and projective techniques including remembering the ten words, indirect (relational) memorization with pictograms, incomplete-sentence test, Wechsler scale, Raven's Progressive Matrices. Patients missing 1 or more cognitive test results were excluded from the analysis. CI were classified as logical thinking impairments (distortion, decrease of generalization process), memory deficit (mechanical and/or or relational) or combined memory and logical thinking impairments. Biologics treatment duration varied from 1–6 y, antidepressants from 6–96 weeks. RA-pts with ADD were divided into the following treatment groups: 1—conventional disease-modifying antirheumatic drugs (DMARDs) and/or

biologic DMARDs (bDMARDS) and no PPT (n = 71), 2—DMARDs and/or bDMARDs + PPT (sertraline or mianserine) (n = 52).

Results: At baseline CI were diagnosed in 90 (73.2%) patients, 49 (69%) patients in 1st group and 41 (78.9%) in 2nd, difference between groups nonsignificant. Logical thinking was impaired in 36 (50.7%) vs. 27 (51.9%), memory in 44 (62%) vs. 39 (75%), and combined memory and logical thinking impairments—31 (43.7%) vs. 23 (44.2%) for 1st and 2nd groups respectively, $p > 0.05$. At 5-y endpoint, 83 RA-pts were assessed and 74 (42 in 1st group and 32 in 2nd) included in analysis. After 5 y. CI rates in 1st (no PPT) group increased from 69 to 85.7% and in 2nd (PPT) decreased from 78.9% to 62.5%, between-group significance p = 0.021 (85.7 vs. 62.5%, RR 1.93, 95% CI 0.63–5.9). Rates of logical thinking impairments in both groups increased (from 50.7 to 69.1% in 1st group and from 51.9 to 59.4% in 2nd), memory loss slightly increased in 1st group (from 62 to 78.6%, $p > 0.05$) and significantly decreased in 2nd (from 75 to 53.1%, p = 0.034), significance between groups p = 0.041 (78.6 vs. 53.1%, RR 1.56, 95% CI 0.59–4.13). According to univariate logistic regression, female gender, DAS28, cholesterol levels, myocardial infarction in anamnesis, major depression (against minor depression and anxiety disorders), baseline depression severity (MADRS score), lower baseline anxiety levels (HAM-A score) and nonremission of depression symptoms after 5 y were associated with logical thinking impairments after 5 y ($p < 0.3$). These variables were subjected to multivariate logistic regression: only baseline major depression was associated with logical thinking impairments after 5 y (OR 3.17, 95% CI 1.265–7.929, p = 0.014).

Conclusion: CI are highly prevalent in RA patients with comorbid ADD. While CI rates tend to deteriorate in most patients, PPT and remission of ADD symptoms is associated with improvement in memory function, but not in logical thinking. Only major depression was independently associated with logical thinking impairment after 5 y.

P107
IS DEPRESSION ASSOCIATED WITH DIFFICULT TO TREAT RHEUMATOID ARTHRITIS?

A. Abramkin[1], T. Lisitsyna[1], D. Veltishchev[2], O. Seravina[2], O. Kovalevskaya[2], A. Borisova[1], S. Glukhova[1], E. Nasonov[1]

[1]V.A. Nasonova Research Institute of Rheumatology, [2]Moscow Research Institute of Psychiatry, Serbsky NMRC PN MoH, Moscow, Russia

Objective: To compare demographical characteristics, disease activity, patient-reported outcomes and depression severity in rheumatoid arthritis (RA) patients with depression with or without difficult-to-treat RA (D2T RA) and patients with no depression and no D2T RA. To determine factors associated with D2T RA phenotype.

Methods: 92 RA-patients were enrolled, all met the full ACR criteria for RA and were resistant to conventional DMARDs, 11 met EULAR definition for difficult-to-treat RA. Disease activity was assessed using DAS28 in all patients, functional limitations with HAQ questionnaire, fatigue with FSS scale, quality of life with EQ-5D scale, pain intensity with VAS pain, depression severity with PHQ-9 questionnaire. Depressive disorders were diagnosed in 84 (91.3%) of patients in accordance with ICD-10 in semistructured interview by a licensed psychiatrist. Patients were divided into the following treatment groups: 1—depression + D2T RA (n = 11), 2—depression and no D2T RA (n = 73), 3—no D2T RA and no depression (n = 8). Linear regression analysis was performed to determine factors associated with D2T subgroup of RA patients.

Results: Depression + D2T patients (group 1) were characterized by longer RA duration, higher RF titer, GC treatment duration, cumulative GC dosage, PGA, EGA, pain VAS, FSS and HAQ scores, the lowest quality of life (Table 1). Nondepressed patients with no D2T (group 3) had the lowest PGA, EGA, pain VAS and FSS scores. Depressed patients with no D2T (group 2) were older compared to groups 1 and 3 and demonstrated the interim results for the rest of the variables assessed. According to correlation analysis, age, RA duration, BMI, GC usage and depression severity by PHQ-9 score correlated with D2T subgroup of RA patients (Pearson's $R > 0.1$). Those variables were subjected to linear regression analysis. According to multinominal linear regression, age (B = 0.3), PHQ-9 (B = 0.31) score and GC usage (B = 0.4) were significantly associated with D2T subtype of RA, $R^2 = 0.189$, $p < 0.005$, ROC-curve AUC 0,74, $p < 0.005$.

Table 1. Clinical and demographical characteristics of RA patients by groups.

	Group 1 (depression+D2T), n=11	Group 2 (depression, no D2T), n=73	Group 3 (no depression, no D2T), n=8	Between-group difference (p)
Age	34 [30; 46]	52 [40; 59]	36 [30; 41]	P2-1, 2-3 <0,05
RA duration (months)	120 [72; 144]	60 [30; 120]	72 [60; 216]	P1-2, 1-3 <0,05
BMI	23,5 [18,3; 26,8]	25,2 [22; 30,5]	23,8 [18; 27,3]	P>0,05
RF (IU/ml)	122,5 [9,1; 261]	53,5 [10,6; 175]	42,3 [13,2; 148,9]	P1-3<0,05
Duration of GC usage (months)	46 [23; 72]	13,5 [4,5; 44]	9,8 [0; 132]	P1-2<0,05
Cumulative GC dosage (g)	6,3 [3,9; 16,2]	2,4 [0,75; 7,65]	2,925 [0; 41,6]	P1-2<0,05
Morning stiffness duration (h)	105 [60; 180]	120 [60; 180]	45 [20; 300]	P>0,05
SJC	8 [6; 10]	9 [6; 11]	7 [3; 15]	P>0,05
PJC	10 [8; 17]	12 [10; 18]	11 [7; 18]	P>0,05
PGA VAS	72 [60; 80]	60 [50; 70]	45 [40; 50]	P1-3, 2-3<0,05
EGA VAS	50 [50; 60]	58 [50; 60]	40 [35; 45]	P1-3, 2-3<0,05
Pain VAS	79 [50; 80]	70 [50; 80]	50 [40; 60]	P1-3, 2-3<0,05
DAS 28	5,7 [5,2; 6,25]	5,9 [5,3; 6,35]	5,22 [4,18; 6,83]	P>0,05
SDAI	33,4 [28,2; 42]	36,7 [29,6; 44]	27,1 [22,2; 35,4]	P>0,05
CRP (mg/l)	30,4 [12,3; 49,6]	27,5 [17,8; 49]	20,1 [18,3; 30,6]	P>0,05
ESR (mm/h)	56 [35; 66]	46 [28; 72]	34 [25; 40]	P>0,05
EQ-5D	0 [-0,02; 0,59]	0,52 [0,08; 0,59]	0,55 [0,26; 0,59]	P1-2, 1-3<0,05
FSS	5,84 [3,8; 6,78]	5,22 [3,9; 6,11]	3,4 [3; 4,1]	P1-3, 2-3<0,05
HAQ	1,75 [1; 2]	1,375 [1; 1,875]	1,188 [0,5; 1,5]	P1-3<0,05
PHQ-9	11 [6; 17]	8 [5; 12]	5,5 [3,25; 8,5]	P1-3<0,05

Conclusion: D2T RA subtype is mostly characterized by demographic variables (age, RA duration), patient-reported outcomes (quality of life, functional limitation, global health VAS) and depression level (PHQ-9), not clinical disease activity indexes and/or CRP level. Regression model shows younger, GC usage and depression level by PHQ-9 to be associated with D2T RA. Psychopharmacotherapy of depression may show potential to improve PROs and improve RA treatment response.

P108
NUMERICAL-DIGITAL APPROACH FOR BONE PROPERTIES EVALUATION

O. Gerasimov[1], A. Akhmetzyanova[1], K. Sharafutdinova[1], D. Sabirova[1], M. Baltin[1], T. Baltina[1], O. Sachenkov[1]

[1]Kazan Federal Univ., Kazan, Russia

Objective: To develop numerical-digital approach for bone properties evaluation. Such approach allows estimating stress–strain state of bone and even specifying bone tissue Young's modulus using CT data. In contrast to common approaches, the proposed method does not require reconstruction of bone geometry.

Methods: The approach is based on finite element method. An eight node hexahedral element with linear approximation was modified. CT data was used as an objects digital prototype [1]. So, hexahedral elements stiffness matrix was integrated regarding to CT data [2]. Meshing of the study area can be easily built by filtering the circumscribed regular mesh [3]. Fore and hind limbs of male Vietnamese swine with 8th week spinal cord injury (SCI) were investigated.

Results: Numerical results showed a significant difference in the mechanical behavior of the forelimbs and hind limbs. So, the restored Young's modulus was about 2.57 ± 0.1GPa and 1.12 ± 0.11 GPa, respectively. To validate results the bones was tested in the same conditions as in numerical simulation. Then stress–strain curve was built and compared to numerical stress–strain curve. Coefficient of determination was equal to 0.9985.
Conclusion: CT based simulation is gold standard in modern biomechanics. But, reconstruction of bone geometry and further meshing is labor-intensive process. Proposed approach allows reducing the preparing model time. Moreover the modified finite element allows taking into account structural anisotropy in simulation, and this explains the good agreement with experiment.

P109
HIGH PREVALENCE OF SARCOPENIA IN OLDER PATIENTS WITH TYPE 2 DIABETES MELLITUS IN SAUDI ARABIA: A CROSS-SECTIONAL STUDY

A. Alfaifi[1], M. Almalki[2], U. Almohareb[1], I. Brema[1], A. Alobedollah[1], S. Abdulhamid[3], F. Alshahrani[4], M. Almohaya[1]

[1]Obesity, Endocrine and Metabolism Center, King Fahad Medical City, Second Health Cluster, [2]Obesity, Endocrine and Metabolism Center, King Fahad Medical City, Second Health Cluster. College of Medicine, Alfaisal Univ., [3]Research Center, King Fahad Medical City, [4]College of Medicine, King Saud Bin Abdulaziz Univ. for Health Sciences, Riyadh, Saudi Arabia

Objective: Sarcopenia is prevalent amongst the geriatric population, and confers a risk of physical disability, diminished quality of life, and increased mortality. Previous evidence showed a wide range of prevalence in patients with type 2 diabetes mellitus (T2DM), ranging from 7–30% in different populations; local studies about its prevalence are lacking. We aimed to estimate the prevalence of sarcopenia among older patients with T2DM in Saudi Arabia.
Methods: We prospectively evaluated patients treated for T2DM at a tertiary center in Riyadh, Saudi Arabia. Muscle strength assessed using hand grip testing (Jamar Plus dynamometer) and physical performance tested by a 4 m walk gait speed test. Appendicular skeletal muscle index (ASMI) by body composition using DXA machine. Sarcopenia definition and cut-off values of each category were applied according to the EWGSOP2 recommendations.
Results: Total of 75 patients with T2DM were included (37 females, 38 males). Mean age 60 y ± 5 and mean diabetes duration of 15 y (mean HgbA1C of 8.1% ± 1.4%). Low hand grip strength observed in 65.7% of males and 70% of females. A 69% of males and 88.5% of females showed poor physical performance. Interestingly, males had a significant lower muscle mass ASMI (kg/m^2) compared to females (35.7 vs. 5.7%, p-value 0.004) when EWGSOP2 cut-off values applied. In 41.6% of males and 60% of females, sarcopenia has been confirmed by presence of two criteria according to EWGSOP2 definition.
Conclusion: These data indicate high prevalence of sarcopenia in older patients with T2DM in Saudi Arabia. Clinicians need to be aware about these associations and its risk factors. This will allow early recognition and addressing appropriate therapeutic strategies to prevent further negative consequences.

P110
FRACTURE LIAISON SERVICE IN DUBAI HEALTH

A. Alshaali[1], S. Abd El Aziz[1], A. Aljaziri[1], M. Elsherbiny[1], T. Farid[1], M. Hammam[1], M. Elnoamani[1]

[1]Dubai Health, Dubai, United Arab Emirates

Osteoporosis is a disease classified by the alteration of bony microarchitecture and the loss of its structural integrity and predisposition to fracture. Following an osteoporotic fracture, it is common to have a second fracture referred to as a secondary fracture. Secondary fracture prevention remains a major problem in most countries following the treatment of hip fracture, vertebral fracture, distal radius fracture, proximal humerus fracture, and other fragility fractures. A systematic review showed that fracture liaison services from Arab countries are still lacking and such service will help in closing the gap for prevention and management of secondary fracture. A Fracture Liaison Service (FLS) has started in Dubai Health in February 2023. It aims to screen patient with fragility fracture for osteoporosis and provide appropriate management.

P111
CLINICAL AND DENSITOMETRIC RESPONSE TO BISPHOSPHONATE THERAPY IN OSTEOPOROSIS PSEUDOGLIOMA SYNDROME: CASE REPORT

A. Alturkistani[1], M. Almohaya[1]

[1]Obesity, Endocrine and Metabolism Center, King Fahad Medical City, Riyadh, Saudi Arabia

Osteoporosis pseudoglioma syndrome (OPPG) is a rare autosomal recessive disease caused by mutation in gene LRP5 (LDL receptor-related protein) on chromosome 11q13.4. This protein helps in regulation of BMD and development of retina. Patient with OPPG usually present with decrease bone density and early onset of blindness.

We report the clinical, radiological and genetic findings of patient with OPPG in Saudi Arabia, and also we highlight the clinical and densitometric improvement observed with bisphosphonate administration.

A 14-year-old male was referred to the metabolic bone clinic for further evaluation of low-trauma multilevel severe vertebral compression fractures. He was born with severe visual impairment of both eyes. He is offspring of non-consanguineous parents and family history was unremarkable. Workup for other secondary causes of low bone mass was normal. CT scan demonstrated severe diffuse bone demineralization with multilevel non-acute compression fractures. DXA scan showed BMD of lumbar spine (L1–L4) 0.726 g/cm^2, BMD of dual femur neck mean 0.751 g/cm^2 and BMD of dual femur total mean = 0.697 g/cm^2. Genetic testing showed mutation in exon 6 LRP5 gene (homozygous) that is confirmed the diagnosis of OPPG. Oral alendronate 70 mg weekly was initiated in 2019. After 2 y of oral bisphosphonate therapy, his BMD values improved significantly by 9.5% in lumbar spine area, 9.8% in total dual femur areas. Later, BMD values declined by 3.8% at lumbar spine area due to compliance issues and lack of supply, therefore patient was switched to zoledronic acid 5 mg yearly. Patient continued to have an increase in his BMD values (increased by 7% in lumbar spine and 10.5% in total dual femur areas) over 2 y administration of zoledronic acid with no reported adverse events.

This is the first reported case of OPPG in Saudi Arabia. Long term bisphosphonate therapy showed clinical and densitometric improvement. These clinical and radiological findings may help the clinicians to consider OPPG in the differential diagnosis of young patients with fractures and congenital visual impairment and to consider an early intervention with bisphosphonate therapy.

P112
ASYMPTOMATIC HYPOPHOSPHATASIA: A CLINICAL CASE REPORT

A. Asanova[1], E. Drachuk[1], E. Pigarova[1], L. Dzeranova[1]

[1]Endocrinology Research Centre, Moscow, Russia

Hypophosphatasia is a rare hereditary metabolic disease caused by alkaline phosphatase (ALP) deficiency as a result of a mutation in the *ALPL* gene, which is accompanied by impaired bone mineralization and musculoskeletal manifestations in the form of bone deformities, frequent fractures, tooth loss, bone and muscle pain, decrease in muscle strength. The disease can manifest in utero, in childhood or in adulthood. An early age of onset is usually associated with a more severe disease, and a late age—with a mild course of the disease. Relatively little data is available on the prevalence and clinical features of hypophosphatasia in adults.

Casereport: An 18-year-old female (weight 56 kg, height 160 cm, BMI 21.9) with complaints of general weakness and dizziness, pain in the legs and joints, periodic darkening in the eyes, itching of the knuckles. Development in childhood and adolescence proceeded without any special features. Considers herself sick since the age of 16, when swelling and tenderness of the left ankle and knee joints appeared without x-ray changes. At the same time, the patient was diagnosed with infectious mononucleosis, after which she noted an increase in general weakness, periodic increases in body temperature in the mornings and evenings to 37.2 °C, loss of appetite, lightheadedness, pain in the bones and joints. When examining CRP, ASLO, RF—negative, biochemical indicators, parameters of bone and calcium-phosphorus metabolism were normal except for the detected decrease in ALP to 13–15 U/l (40–150) and a pronounced deficiency of vitamin D—9 ng/ml (30–100). The diagnosis of hypophosphatasia was confirmed genetically—a pathogenic nucleotide variant chr1:21563115C>A was detected in a heterozygous state in the ALPL gene. According to X-ray densitometry of the whole body, BMD, taking into account the skull, corresponds to the age norm: − 0.5 SD (according to the Z-criterion); BMD excluding the skull corresponds to the age norm: − 0.7 SD (according to the Z-criterion). According to lateral morphometry, no data were obtained for vertebral deformities and compression fractures. There were no fractures. Teeth, hair, nails—without any features. A detailed collection of family history revealed similar symptoms of joint pain in the mother with a decrease in ALP to 20 U/l (35–105).

Conclusion: Despite the low activity of alkaline phosphatase, the patient does not have the characteristic clinical manifestations of hypophosphatasia (mild form), which can be confirmed by the absence of manifestations in the mother. The regarded symptoms may also be a consequence of previous mononucleosis. The influence of other genetic, epigenetic or non-genetic factors on the course of the disease may explain cases in which it is difficult to establish a relationship between the genotype and phenotype of a given pathology.

P113
LUPUS NEPHRITIS: IS THE KIDNEY BIOPSY CURRENTLY NECESSARY IN THE MANAGEMENT OF LUPUS NEPHRITIS?

A. Aseeva[1], Y. Nikishina[1], K. Solovyev[1]

[1]Federal State Research Institution (FSRI) named after V. A. Nasonova, Dept. of SLE, Moscow, Russia

Objective: Lupus Nephritis (LN) is an immune-complex mediated glomerulonephritis affecting up to 60% of all SLE patients during the disease course. A kidney biopsy is indicated in SLE patients when proteinuria stably reaches or overcomes the level of 500 mg/24 h or spot urine protein to creatinine ratio (UPCR) > 500 mg/g (50 mg/mmol), especially with impaired renal function or active urinary sediment, and is generally recommended to evaluate the inflammatory findings but also to rule out other etiologies of renal involvement and to guide the need of immunosuppressive therapy. We aimed to investigate the histopathologic findings in first-time renal biopsies from SLE patients and evaluate the type and occurrence of histopathological findings other than LN as these may lead to a risk of inadequate therapeutic interventions.

Methods: 64 SLE patients who had a first-time onset of renal involvement from 24/11/2020 up to 24/10/2022 and subsequent renal biopsy were included in the study. All patients fulfilled the Systemic Lupus Erythematosus International Collaborating Clinics (SLICC) disease classification criteria (1) for SLE and were biopsied on clinical indication, i.e., proteinuria > 0.5 g/d or active SLE in combination with a rise in plasma creatinine, decrease in glomerular function or new onset proteinuria with concurrent active urine sediment.

Results: In total, 64 patients (female 51 (76%), Male (15 (24%) with first time presentation of renal involvement who had been subject to renal biopsy were included. The median age at the time of biopsy was 35.34 ± 11.19 y. For more patient baseline characteristics (Table 1). Fifty-two (81%) had findings consistent with LN according to ISN/RPS classification system [2]. Four patients (6%) had Class I–II, 19 (30%)—Class III, 13 (20%)—Class IV, 8 (12%)—Class V, 2 (3%)—Class VI, 3 (4%)—Class III ± V, 3 (4%—Class IV ± V. Twelve patients (19%) did not have histological changes in accordance with LN. Of these, 3 had thrombotic microangiopathy, 5 had IgA nephropathy, 4 were later found to be ANCA-positive and were re-diagnosed with concomitant ANCA-associated vasculitis. Of the 12 non-LN patients, all had proteinuria > 0.5 g/day, 2 had new-onset low-grade proteinuria and concurrent active urine sediment, 2 had new-onset low-grade proteinuria with concurrent increasing SLE disease activity, and 5 patients had isolated persistent low-grade proteinuria.

Table 1. Baseline characteristics, 64 patients

Age (y) Mean (SD)	
SLE duration at biopsy (y); M (IQR)	0.7 (0.4 – 7.3)
Systolic blood pressure (mm Hg); Mean (SD)	127.5 (20.8)
Ethnicity	
Caucasian; n (%)	58 (90%)
Asian; n (%)	6 (10%)
Diagnosis according to ISN/RPS	
Class I-II	4 (6%)
Class III	19 (30%)
Class IV	13 (20%)
Class V	8 (12%)
Class VI	2 (3%)
Class III±V	3 (4%)
Class IV±V	3 (4%)
TMA	3 (4%)
Vasculitis	4 (6%)
IgA nephropathy	5 (7%)

Conclusion: We demonstrate that renal histopathology confirmed other causes than LN in a significant proportion (19%) of SLE patients with signs of renal involvement. Since these patients may need other therapeutic interventions than patients with classic LN, we can conclude that the renal biopsy is important in order to guide the choice of therapeutics.

P114
A REVIEW ON THE ASSOCIATION OF CARDIOVASCULAR LIPID PROFILE WITH OSTEOPOROSIS, BONE MINERAL DENSITY AND OSTEOPOROTIC FRACTURES

A. Auyong[1], C. S. Goh[2], S. B. Ang[3], S. D. Satvinder[3]

[1]Lee Kong Chian School of Medicine, [2]Ministry of Manpower Singapore, [3]Duke-NUS Medical School, Singapore, Singapore

Objective: This systematic review is to evaluate the association between total cholesterol (TC), triglycerides (TG), low-density lipoprotein (LDL) and high-density lipoprotein (HDL), and osteoporosis in postmenopausal women, defined by either BMD or the presence of osteoporotic fractures.
Methods: A systematic literature search was conducted in PubMed, Embase and Web of Science from inception to December 2023. Studies that met the eligibility criteria were assessed for quality and data were extracted and synthesised.
Results: 32 articles were shortlisted for analysis—23 cross-sectional studies, 8 case–control studies and 1 cohort study. LDL had the greatest association with osteoporosis, followed by HDL, then TC and TG. A positive correlation refers to an unhealthier lipid level (increased for LDL, TC and TG, decreased for HDL) correlating with lower BMD and increased osteoporosis risk. The results of the papers are as below:

Lipid Level	n	Positive Correlation (%)	Inverse Correlation (%)	No correlation (%)
LDL	28	14 (50.0%)	2 (7.14%)	12 (42.9%)
TC	28	9 (32.1%)	3 (10.7%)	16 (57.1%)
TG	29	9 (31.0%)	4 (13.8%)	16 (55.2%)
HDL	30	10 (33.3%)	4 (13.3%)	16 (53.3%)

A majority of papers were noted to contain mixed results across the different lipid levels, with few papers coming to a consensus on the association of the whole lipid profile with osteoporosis. The exclusion criteria, in terms of pre-existing medical conditions, drugs and definition of menopause also varied significantly. Stratifying results by geographical regions, outcome measure and study type did not reveal significant differences in results.
Conclusion: There is a positive correlation between an increased LDL level, and BMD and osteoporotic fractures. The relationship between HDL, TC and TG, and osteoporosis is inconclusive. Future studies might be improved through standardised population criteria and study designs, to confirm the relationship between cardiovascular lipid profile and osteoporosis.

P115
PERFORMANCE EVALUATION OF AN ARTIFICIAL INTELLIGENCE-BASED SOFTWARE FOR OPPORTUNISTIC DETECTION OF VERTEBRAL COMPRESSION FRACTURES ON CT SCANS

A. Ayobi[1], D. Chow[2], J. Soun[2], P. Chang[2], C. Castineira[1], J. Kiewsky[1], M. Mahfoud[1], C. Avare[1], Y. Chaibi[1]

[1]Avicenna.AI, La Ciotat, France, [2]Univ. of California Irvine, Irvine, USA

Objective: To evaluate the performance of an artificial intelligence (AI)-based application designed to automatically screen CT scans with unsuspected VCF in order to assist physicians in the assessments of musculoskeletal diseases.
Methods: We conducted a retrospective, multicenter and blinded study on chest-abdominal-pelvis CT scans performed for other clinical indications than for thoraco-lumbar vertebral compression fractures assessment. The ground truth (GT) was established by three senior board-certified radiologists who defined by majority agreement if the scans were positive for VCF. The same data was processed by CINA-VCF (Avicenna.AI, La Ciotat, France), an AI software intended to passively notify positive VCF cases. The sensitivity, specificity, positive and negative predictive values (PPV, NPV) were calculated and the discrepancies between the AI and the experts were analyzed. Furthermore, the cases with VCF that were not mentioned in the clinical report but that were correctly detected by the algorithm were analyzed.
Results: A total of 317 opportunistic scans were analyzed (mean age: 70.1 yo ± SD: 9.2, 51.7% female, 37.8% positive). The AI sensitivity and specificity were 92.5% [86.2–96.5%], 95.4% [91.5–97.9%], respectively. PPV and NPV were 92.5% and 95.4%. False negatives were caused by very slight compressions (n = 4), Shmorls's nodes (n = 2), uniform compressions (n = 2) and severe artifacts (n = 1). False positives were due to Schmorl's node (n = 4), disc calcifications (n = 1), L5 natural deformation (n = 1), osteophytes (n = 1), mild compressions (n = 1) and Scheuermann's disease (n = 1). An example of a true positive, false negative and false positive is shown in Fig. 1. Among the 120 positive cases according to the GT, 76/120 (63.3%) were not mentioned in the clinical report. The algorithm was capable of detecting 67/76 cases. This indicates that 55.8% (67/120) of the patients with VCF could have been additionally identified by using the AI software.

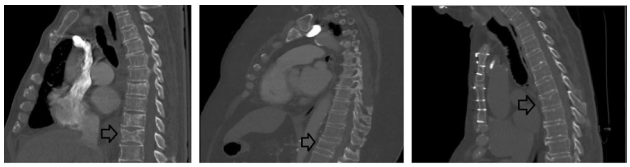

Figure 1. Example of a true positive, a false negative caused by a mild deformation and a false positive caused by a Schmorl's node.

Conclusion: This accurate AI tool may impact the early analysis of vertebral fractures, reducing the rate of undiagnosed scans. In addition, using routine CT to opportunistically detect VCF with AI may improve the diagnostic workflow of musculoskeletal diseases, such as osteoporosis.

P116
OSTEOPOROSIS AND FRACTURE RISK AFTER THE PROCEDURE IN PATIENTS UNDERGOING CHOLECYSTECTOMY: A SYSTEMATIC REVIEW AND META-ANALYSIS

A. Ghaseminejad-Raeini[1], A. Shirinezhad[1], A. Azarboo[1], K. Pirahesh[1], S. H. Hosseini-Asl[1], A. H. Hoveidaei[2]

[1]School of Medicine, Tehran Univ. of Medical Sciences, [2]Sports Medicine Research Center, Neuroscience Institute, Tehran Univ. of Medical Sciences, Tehran, Iran

Objective: Cholecystectomy has been associated with declining vitamin D absorption, raising concerns about osteoporotic fracture risk and lower BMD. There was no aggregate study to pool all the controversial findings in this regard. This study aimed to systematically review the increased incidence of osteoporosis and fracture in cholecystectomy patients.
Methods: A systematic literature search was conducted across major databases to identify relevant studies. Inclusion criteria comprised studies investigating osteoporosis and fracture outcomes in patients who underwent cholecystectomy. The Joanna Briggs Institute (JBI) Risk of Bias Tool was employed to evaluate the methodological

quality of included studies. Meta-analysis of hazard ratios was conducted when available, using R.

Results: Our search yielded 8 studies (624,290 cholecystectomy and 2,006,246 controls) meeting the inclusion criteria. The meta-analysis revealed a 1.08-fold increase in the fracture risk among post-cholecystectomy compared to normal patients. In descriptive synthesis of osteoporosis incidence, some studies showed an association with cholecystectomy (aHR [95% CI] = 1.23[1.14–1.32]). On the other hand, some studies reported the aforementioned outcomes to show no difference in cases and controls (aHR [95% CI] = 1.00 [0.97–1.03]). By the same token, BMD was lower in cholecystectomy cases (T score of femur: -0.5 ± 0.8 vs. 0.19 ± 1.1, p = 0.001—lumbar spine: -1.5 ± 1.0 vs. -0.9 ± 1.0, p = 0.004).

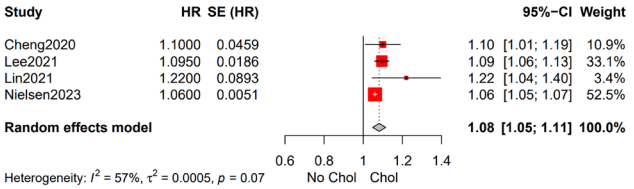

Figure 1. Fracture risk in patients having cholecystectomy compared to the normal control population.

Conclusion: Our findings suggest a significant association between cholecystectomy and increased risks of fractures. Although debatable, cholecystectomy seems to be associated with higher osteoporosis risk and worse BMD status, as it should be interpreted with caution. These findings underscore the importance of considering vitamin D supplementation and close follow-up in patients undergoing cholecystectomy, with further research warranted.

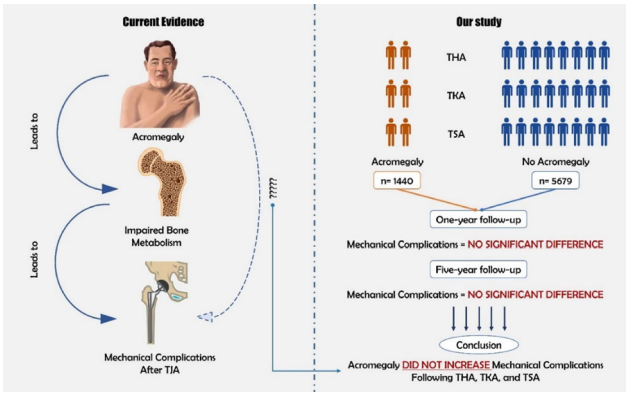
P117
MECHANICAL COMPLICATIONS AND REVISIONS IN JOINT ARTHROPLASTY FOR ACROMEGALIC PATIENTS: A MATCHED-CONTROL NATIONWIDE STUDY

J. D. Conway[1], A. Ghaseminejad-Raeini[2], A. H. Hoveidaei[3], A. Bahrami[4], S. Esmaeili[5], M. S. Khonji[2], B. O. Nwankwo[6], A. Azarboo[2]

[1]International Center for Limb Lengthening, Rubin Institute for Advanced Orthopedics, Sinai Hospital of Baltimore, Baltimore, USA, [2]School of Medicine, Tehran Univ. of Medical Sciences, Tehran, Iran, [3]Sports Medicine Research Center, Neuroscience Institute, Tehran Univ. of Medical Sciences, Tehran, Iran, [4]School of Medicine, Kashan Univ. of Medical Science, Kashan, Iran, [5]Sina Univ. Hospital, Tehran Univ. of Medical Sciences, Tehran, Iran, [6]Howard Univ. Hospital, Dept. of Orthopaedic Surgery and Rehabilitation, Washington, USA

Objective: Increased physical function and pain relief from osteoarthritis and arthritis are two benefits of total joint arthroplasty (TJA). There have been variations in the results of TJA in individuals with endocrinological conditions such as Cushing's illness and Diabetes Mellitus, according to earlier research. One of the main risk factors for osteoarthritis is acromegaly, a chronic hormonal disorder. Severe cases might be treated with TJA. Due to their higher rate of OA, comorbidities, and fracture risk, it is imperative to look into TJA results in individuals with acromegaly. There is a substantial knowledge gap, however, as there are notably few controlled trials assessing TJA outcomes in individuals with acromegaly.

Methods: We used data from the PearlDiver national database to analyze data for this retrospective matched-control research. Using a combination of Current Procedural Terminology (CPT) codes and International Classification of Diseases (ICD) codes from versions -9 and -10, the Patient Records Database covering the years 2010–2022 was utilized to identify acromegalic patients who underwent total hip arthroplasty (THA), total knee arthroplasty (TKA), and total shoulder arthroplasty (TSA). Individuals with a history of osteoporosis in the past and short follow-up periods were not included. Using matching based on confounding variables, nonacromegalic control groups were chosen.



Results: A total of 1440 patients—665 THA, 618 TKA and 157 TSA—were found to have acromegaly. Postoperative revision after THA (OR (1-y) = 0.76 [0.42–1.28], OR (5-y) = 0.68 [0.42–1.06]), TKA (OR (1-y) = 0.89 [0.48–1.55], OR (5-y) = 0.78 [0.49–1.17]), and TSA (OR (1-y) = 0.19 [0.02–1.40], OR (5-y) = 0.32[0.10–1.07]) did not significantly differ from the control group. Furthermore, one or five years following the procedure, individuals with acromegaly showed no significant rise in risk of mechanical problems.

Conclusion: In comparison to matched control groups, the data showed no significant association between acromegaly and the incidence of revisions or mechanical issues. When medically warranted in patients with acromegaly, orthopedic surgeons may contemplate undertaking similar procedures with comparable expectations, thanks to the valuable understanding that our data fill. In addition, additional research with a more narrow focus on functional results might be beneficial.

P118
GLOBAL AND REGIONAL EPIDEMIOLOGY OF BONE FRACTURES IN THE PAEDIATRIC AND ADOLESCENT POPULATION: A 30-YEAR COMPREHENSIVE ANALYSIS OF THE GLOBAL BURDEN OF DISEASES STUDY 2019

A. H. Hoveidaei[1], A. Ghaseminejad-Raeini[2], A. Azarboo[2], K. Pirahesh[2], S. Esmaeili[3], S. H. Hosseini-Asl[2]

[1]Sports Medicine Research Center, Neuroscience Institute, Tehran Univ. of Medical Sciences, [2]School of Medicine, Tehran Univ. of Medical Sciences, [3]Sina Univ. Hospital, Tehran Univ. of Medical Sciences, Tehran, Iran

Objective: Fracture epidemiology in the pediatric population, although being a major health issue, has rarely been investigated in the existing evidence. This study aimed to Inspect the global and regional trends of pediatric fractures' incidence and burden from 1990 to 2019.

Methods: The primary data source for this analysis was the Global Burden of Disease study (GBD). The study reported key indices, including incidence and years lived with disability (YLD) of fractures in the pediatric population (0–19 y), for all GBD regions, presented both as rates and numbers. Time-trend analysis was performed using joinpoint regression reporting average annual percent change (AAPC).

Results: Global incidence and YLD of pediatric fractures were 48.30 million (95%UI = 40.64–57.69) and 1.45 million (95% UI = 0.97–2.06), respectively in 2019. A significant downward trend was

observed in both incidence (AAPC = − 0.61% [95% CI = − 1.07 to − 0.15%]) and YLD rate (AAPC = − 0.73% [95% CI − 1.01 to − 0.36%]) from 1990–2019. Those aged 15–19 y had the highest incidence and YLD in 2019. Male cases were predominant across all years. Fracture of radius and ulna was the most common type of pediatric fracture worldwide in 1990 and 2019. However, the highest YLD was observed in those with fractures of patella, tibia, fibula, or ankle. In 2019, pediatric fracture incidence was higher in Australasia and Central Europe. Unlike global incidence, an upward trend was seen in Western Europe, Australasia, and Southern Latin America. The most common injury causes were falls (41.86%) and exposure to mechanical force (15.18%) in 2019.

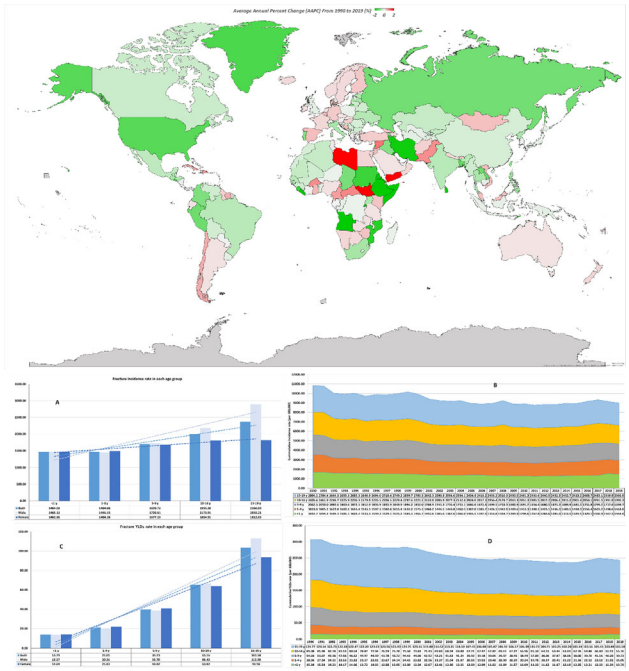


Figure 1. Average Annual Percent Change (AAPC) of bone fracture incidence in paediatrics (above) and age and sex distribution of YLD and incidence in these cases (below).

Conclusion: Global pediatric fracture incidence and YLD demonstrated a slight decline over time across genders and age groups. In regions like Western Europe, Australasia, and Southern Latin America, targeted interventions by health policymakers are crucial to mitigate underlying causes. Orthopedic surgeons should anticipate better management strategies, focusing on the most affected fracture sites in their respective regions.

P119
RETHINKING THE ROLE OF FORMAL PHYSICAL THERAPY IN GLENOHUMERAL OSTEOARTHRITIS: A NATIONWIDE STUDY IN THE USA

J. D. Conway[1], A. H. Hoveidaei[2], A. Ghaseminejad-Raeini[3], F. Moosaie[3], F. Kanaani Nejad[4], M. S. Khonji[3], M. N. Gilotra[5], B. O. Nwankwo[6], A. Azarboo[3]

[1]International Center for Limb Lengthening, Rubin Institute for Advanced Orthopedics, Sinai Hospital of Baltimore, Baltimore, USA, [2]Sports Medicine Research Center, Neuroscience Institute, Tehran Univ. of Medical Sciences, Tehran, Iran, [3]School of Medicine, Tehran Univ. of Medical Sciences, Tehran, Iran, [4]Anesthesiology and Critical Care Research Center, Shiraz Univ. of Medical Sciences, Shiraz, Iran, [5]Dept. of Orthopaedics, Univ. of Maryland School of Medicine, Baltimore, USA, [6]Howard Univ. Hospital, Dept. of Orthopaedic Surgery and Rehabilitation, Washington, USA

Objective: A prevalent degenerative joint condition affecting the middle-aged and elderly is glenohumeral osteoarthritis (OA), which has a major negative impact on the quality of life of patients. This condition can be managed using a variety of interdisciplinary, nonoperative, and operative techniques. Preoperative physical therapy has been suggested by the clinical practice guidelines based on the opinions of professionals, despite the lack of data to support its effectiveness. Finding out if adding physical therapy to a nonoperative method would effectively manage the course of OA and possibly save patients from needing total shoulder arthroplasty (TSA) surgery is the goal of this USA-wide study.
Methods: We made advantage of PearlDiver, a national database with over 100 million patients in it. Using ICD-9, ICD-10, and Current Procedural Terminology (CPT) codes, individuals diagnosed with glenohumeral OA between 2010–2022 made up this retrospective cohort. The rate of total surgical arthroplasty (TSA) at two and five years was compared between patients who underwent physical therapy (PT) within a year of being diagnosed with glenohumeral OA and patients who did not receive PT. Additionally, patients with and without corticosteroid injection within a year of diagnosis were also compared. To account for possible confounding variables, multivariable logistic regression was utilized.
Results: The study consisted of 5,200,419 patients with glenohumeral OA. Among patients with corticosteroid injection, patients who received PT had significantly higher 2- and 5-year TSA rate compared to those without PT (2-y TSA: 0.46 vs. 0.24%, OR [95% CI]: 2.06 [1.82, 2.35] and 5-y TSA: 0.80 vs. 0.44%, OR [95% CI]: 2.05 [1.86, 2.25]). Similar association was also significant among patients without corticosteroid injection (0.24 vs. 0.11%, OR [95% CI]: 2.42 [2.31, 2.54] and 0.50 vs. 0.24%, OR [95% CI]: 2.37 [2.29, 2.45], respectively).
Conclusion: The findings of this study indicate that individuals who did physical therapy as a part of their nonoperative treatment had a 2 to 2.4-fold increased probability of requiring TSA. In light of the potential association between the expedited deterioration of the glenohumeral joint and the increased rate of TSA, from now on, orthopedic surgeons and physical therapists need to proceed with caution when recommending preoperative physical therapy as a technique for managing glenohumeral OA.

P120
EFFICACY AND SAFETY OF ASFOTASE ALFA IN PATIENTS WITH HYPOPHOSPHATASIA: A SYSTEMATIC REVIEW

A. Ghaseminejad-Raeini[1], S. Esmaeili[2], A. Shirinezhad[1], A. Azarboo[1], A. H. Hoveidaei[3]

[1]School of Medicine, Tehran Univ. of Medical Sciences, [2]Sina Univ. Hospital, Tehran Univ. of Medical Sciences, [3]Sports Medicine Research Center, Neuroscience Institute, Tehran Univ. of Medical Sciences, Tehran, Iran

Objective: Hypophosphatasia (HPP) is a rare hereditary metabolic disorder characterized by inadequate activity of tissue nonspecific alkaline phosphatase (TNSALP). Asfotase alfa, a recent development, aims to address complications associated with HPP. This study systematically reviews existing evidence regarding the safety and efficacy of asfotase alfa in treating HPP.
Methods: We conducted a systematic search following the PRISMA guidelines across databases, including PubMed, Scopus, Web of Science, and the Cochrane Library. Inclusion criteria comprised studies assessing the impact of asfotase alfa on diverse complications in HHP patients, comparing them to untreated control groups or baseline

conditions. Acceptable study designs encompassed observational (cohort, case–control, cross-sectional), clinical trials, and case series (with a minimum of 5 patients). Two independent reviewers conducted screening, data extraction, and quality assessment.

Results: Fourteen studies, encompassing 271 treated HPP patients (58% female), were included. The studies comprised 8 multicenter clinical trials, 2 single-center clinical trials, 3 case series, and 1 cohort. Among these, 4 studies investigated patients aged 18 years and older, while 5 studies focused on those under 5 years old. Treatment durations in the studies varied from 13 weeks to 7 years. Asfotase alfa treatment has demonstrated notable improvements across various aspects. Eight studies highlighted improvements in mineralization and BMD, with five studies underscoring enhancements in respiratory status. Moreover, pain reduction was reported in five studies, with one study noting a non-significant decrease. Growth enhancement was documented in three studies, and enhanced walkability was emphasized in four studies, while improved muscle strength was reported in five studies. Additionally, two studies delved into the treatment's impact on the quality of life. Notably, three studies observed the normalization of plasma pyridoxal phosphate (PPI) and pyridoxal 5'-phosphate (PLP) levels due to treatment. The most frequently reported adverse events comprised injection site reactions in seven studies and pyrexia in two studies.

Conclusion: Asfotase alfa treatment has demonstrated noteworthy significance, especially in improving mineralization, walking ability, and respiratory status among HPP patients. Although the majority of patients experienced some adverse events, most of these incidents were not complicated. The results show heterogeneity, hindering a precise conclusion. To enhance our understanding of the efficacy and safety of asfotase alfa, further longitudinal research with a larger sample size is essential.

P121
HORMONES OF ADIPOSE TISSUE ON WEIGHT LOSS IN PATIENTS WITH RHEUMATOID ARTHRITIS

A. Bacumova[1], L. Aref'Eva[1], L. Sivordova[2]

[1]Volgograd State Medical Univ., [2]Federal State Budgetary Institution, Zborovsky Research Institute of Clinical and Experimental Rheumatology, Volgograd, Russia

Objective: Overweight in patients with rheumatic diseases is a condition that prolongs chronic inflammation and promotes synthesis and secretion of pro-inflammatory factors [1,2,3]. We investigated the relationship the effect of weight loss over 5 kg on the clinical manifestations of arthritis and hormones of adipose tissue serum levels in patients with rheumatoid arthritis (RA).

Methods: We observed 80 female patients with RA (EULAR/ARA 2010 criteria) ranged in age from 39–69 y (mean age 51.72 $\pm$ 5.83 y) and the control group (60 healthy persons). Fetuin A, nesfatin, hemerin, leptin, adiponektin, resistin, visfatin level was determined by commercial test systems.

Results: As overweight patients were recruited in the study, hypocaloric diet low in animal fats and physiotherapy has been recommended to all participants. The positive dynamics in body weight loss over 5 kg within 3 months has been achieved by 34 patients (27.2%). In RA patients with weight loss, a significant decrease in the serum level of pro-inflammatory cytokines ($p < 0.01$) and an increase in the quality of life according to the EQ-5D-5L ($p < 0.001$) index were observed. This fact is probably explained by the decreased activity of inflammatory process after RA therapy and weight reduction.

Conclusion: Thus, these findings suggest that there is a possible role of tissue pro-inflammatory cytokines in the pathogenesis of rheumatoid arthritis.

RIGHT CARE, FIRST TIME: OSTEOARTHRITIS, MENTAL HEALTH, AND SLEEP DISTURBANCES

C. Walker[1], A. Bajaj[2]

[1]Viatris, Hatfield, UK, [2]Viatris, Bengaluru, India

Multiple studies demonstrate that 20–25% of osteoarthritis (OA) patients experience affective disorders including depression or anxiety however the impact of comorbid depression on the treatment of OA has not been as well evaluated. OA also commonly associates with significant sleep disturbances, particularly in the elderly and negative bidirectional effects of pain on depression and sleep disturbances are potentially overlooked.

Chronic pain and mental health: OA is associated with persistent and chronic pain as a primary symptom of the disease. Multiple studies have shown that chronic pain depicts a fundamental risk factor for the development of depression and disturbances in sleep. Being female, higher baseline WOMAC pain and dysfunction score and having two or more painful sites, increase the risk of depression. Ageing is a risk factor for OA, but not a risk factor for depression, with ageing also reportedly being linked to an increased likelihood of poorer sleep (both quantity and quality). Systematic reviews have revealed that OA patients diagnosed with anxiety and/or depression experienced more pain, had frequent hospital visits, took more medication, and reported less optimal outcomes. Also, depression and anxiety were found to be predictors of complications after primary total joint arthroplasty and have been associated with higher healthcare costs, extended length of hospital stay, or increased postoperative mortality after TKA/THA (Total Knee/Hip Arthroplasty).

What can we do? Depression may serve as a better predictor of disability than radiographic degenerative joint changes and indicate amplified pain and functional disability. Routine psychological screening could be beneficial for OA patients. Early diagnosis, counselling on mood and sleep hygiene, psychological support, exercise, antidepressant pharmacotherapy and/or problem-solving treatment and interdisciplinary collaboration should be a part of the core management strategy in OA patients.

Conclusion: Depression and sleep disturbances increase the health-related burden of OA. Greater attention to these comorbidities and overall health among patients with OA is warranted. Detecting and managing mental health issues, and chronic sleep disturbances could pave the way for better management of OA.

P123
ARTIFICIAL INTELLIGENCE IN MUSCULOSKELETAL HEALTH: THE WHAT, HOW AND WHY?

A. Bajaj[1], C. Walker[2], R. Chiaese[3], S. Er[4]

[1]Viatris, Bengaluru, India, [2]Viatris, Hatfield, UK, [3]Viatris, Monza, Italy, [4]Viatris, Istanbul, Turkey

Use of artificial intelligence (AI), and machine learning (ML) has increased in numerous critical medical sectors, significantly impacting patients' and practitioners' lives. AI-aided systems are increasingly available for diagnosis, management and physiotherapy

rehabilitation in musculoskeletal conditions providing benefits to the patient and efficiencies for healthcare systems.

Applications of AI in Musculoskeletal Health: AI helps monitor and track pain triggers and assists patients and healthcare professionals in the identification of the most effective coping mechanisms. Mobile apps rather than manual approaches have been found to be more useful by patients to track joint pain, stiffness and buckling of knees potentially assisting in early diagnosis. New AI-enabled tools can also monitor patient's mental health and warning signs by capturing brief voice samples and analyzing them for signs of depression or anxiety. Therapists accessing data from AI apps can easily and remotely monitor patients' conditions. AI can also be helpful in orthopaedic surgeries to help decide whether to perform surgery, preoperatively estimate the risk of complications or mortality, the functioning of the prosthesis, as well as predict the duration of hospital stay, with accuracy and reliability.

Limitations of AI: To maximize the usefulness of AI the quality of data must be safeguarded, and the quantity of data maximized to avoid drawing erroneous conclusions. Additionally, AI can't reliably provide a causality assessment for chronic painful conditions.

Conclusion: AI systems that are practical, solution-driven, cost-effective, and easily accessible are the goal for large patient populations. Cutting-edge AI-imaging and ML technologies are potentially beneficial in lowering pain and enhancing functional impairment in patients with musculoskeletal diseases. The use of some technologies may be challenging in older age groups but is not insurmountable when help is provided.

P124
CORRELATION BETWEEN DXA AND HR-PQCT IN OSTEOGENESIS IMPERFECTA: PRELIMINARY FINDINGS IN A COHORT OF ADULT PATIENTS

S. Gazzotti[1], R. Sassi[1], E. Schileo[2], G. Fraterrigo[2], A. Moroni[3], M. Miceli[1], M. P. Aparisi Goméz[4], F. Taddei[2], L. Sangiorgi[3], A. Bazzocchi[1]

[1]Diagnostic and Interventional Radiology, IRCCS Istituto Ortopedico Rizzoli, Bologna, Italy, [2]Bioengineering and Computing Laboratory, IRCCS Istituto Ortopedico Rizzoli, Bologna, Italy, [3]Dept. of Medical Genetics and Rare Orthopaedic Diseases, and CLIBI Laboratory, IRCCS Istituto Ortopedico Rizzoli, Bologna, Italy, [4]Dept. of Radiology, Auckland City Hospital, New Zealand

Objective: To evaluate the correlation between areal BMD (aBMD) measured by DXA and HR-pQCT parameters in adults with osteogenesis imperfecta (OI).

Methods: The present report includes preliminary data from 14 adult patients (mean age: 36 y) with OI enrolled in an ongoing prospective study. aBMD was measured with DXA (Hologic QDR Discovery Wi) at the lumbar spine, hip, forearm (1/3 and ultradistal radius), and total body. HR-pQCT (XtremeCT II, SCANCO Medical), a noninvasive modality that couples high resolution and low dose in vivo to gain insight into bone microarchitecture, was performed at the distal radius and tibia using a fixed offset protocol and automatic contouring with standard XtremeCT II evaluation. A p-value < 0.05 was considered significant.

Results: DXA classified 4 out of 14 patients included in our cohort as having normal BMD. However, HR-pQCT revealed widespread deteriorations in most parameters of density and microstructure, enabling the identification of different bone phenotypes, despite the relative clinical homogeneity of the sample population. Total volumetric BMD measured by HR-pQCT at the distal radius correlated well with DXA-aBMD at the ultradistal radius ($r = 0.75$; $p = 0.002$) and this relationship predominantly reflected agreement in the cortical rather than trabecular compartment. There were limited associations between DXA-aBMD at central sites (lumbar spine and hip) and HR-pQCT parameters at both the distal tibia and radius. Nevertheless, some significant correlations were found between DXA-aBMD at the hip (femoral neck and/or total femur) and several trabecular HR-pQCT parameters at the distal tibia.

Conclusion: In adults with OI, there is initial evidence of site-specific agreement between DXA and HR-pQCT in the measurement of BMD values. Moreover, HR-pQCT may be able to provide information on bone quality that complements DXA evaluation at central sites. Additional patients will be included in this ongoing study, to validate our preliminary results and clarify the potential role of HR-pQCT in the characterisation of bone fragility in OI.

P125
SHORT-CHAIN FATTY ACIDS (SCFAS) ENHANCES BONE HEALTH IN POSTMENOPAUSAL OSTEOPOROSIS

A. Bhardwaj[1], L. Sapra[1], R. K. Srivastava[1]

[1]All India Institute of Medical Sciences (AIIMS), New Delhi, India

Objective: Short-chain fatty acids (SCFA), the primary metabolites produced by intestinal microbiota, have an impact on both innate and adaptive immunity. It has been demonstrated that high fiber diet, the primary fermentable source of SCFA, reduces the degeneration of bone in rheumatoid arthritis. Based on these facts we were interested in investigating the effect of SCFAs (acetate, propionate and butyrate) in regulating bone health in postmenopausal osteoporosis (PMO). We aimed to investigate the role of SCFAs on bone health under estrogen-deficient conditions.

Methods: In vitro assays for osteoclastogenesis and osteoblastogenesis in the presence and absence of different concentrations of SCFAs were performed. Coculture assays of SCFAs primed Treg along with osteoclast/osteoblast were done to assess the immunoporotic potential of SCFAs. To further evaluate the mechanism of probiotics-induced prevention of bone loss in vivo, female C57BL/6 mice were randomly divided into the following groups viz. Sham, ovx (ovariectomized), ovx + probiotics (*L. rhamnosus*, and *B. longum*-10^9 CFU/d). At day 45 mice were sacrificed and bones (SEM, μCT); small intestine, large intestine, bone marrow, and mesenteric lymph nodes (flow cytometry); serum and fecal content (ELISA and HPLC) were harvested to assess the immunomodulatory role of SCFAs on ovx-bone loss.

Results: Ovariectomized condition led to enhanced bone loss in female mice as confirmed by SEM and μCT data. HPLC data showed that ovx mice had significantly lower fecal SCFA levels than the sham group, thereby confirming the potential role of SCFAs in regulating bone health. Next, we investigated the mechanism underlying SCFAs-modulation of bone remodeling via various in vitro assays. We observed that SCFAs significantly inhibit osteoclastogenesis along with promoting osteoblastogenesis in a dose-dependent manner. Furthermore, SCFAs were found to enhance the differentiation of Tregs significantly. Interestingly co-cultures of SCFAs primed Tregs with BM-osteoclast precursors inhibited osteoclastogenesis along with simultaneously enhancing osteoblastogenesis. Lastly, we confirmed that probiotics such as *L. rhamnosus* and *B. longum* prevent bone loss by restoring the level of SCFAs in ovx mice.

Conclusion: Altogether, our results for the first time propose SCFAs as potent regulators of bone health under ovx conditions thereby offering a mechanistic link between the "gut-immune-bone" axis. Our results have immense clinical implications in proposing the therapeutic potential of SCFAs in managing bone loss under osteoporotic conditions in the clinics.

P126
RISK GROUPS FOR LOW VITAMIN D: CHANGING THE PARADIGM IN CLINICAL PRACTICE

A. Bleizgys[1]

[1]Vilnius Univ., Faculty of Medicine, Vilnius, Lithuania

It is well established that musculoskeletal diseases, e.g., osteoporosis or rickets, can be caused by vitamin D insufficiency or deficiency. Therefore, those illnesses are considered risk factors for low vitamin D, i.e., such patients should be tested for their serum 25-hydroxyvitamin D levels that are the best marker of vitamin D status in clinical practice. However, there are many diseases and conditions that can themselves impair vitamin D metabolism, or dramatically increase requirements for this vitamin that cannot be met via natural sources (synthesis in the skin and from food). In addition, there's some evidence that low vitamin D levels might contribute to the development of certain extraskeletal diseases. Clinicians should be familiar with the variety of risk factors that can help suspect low vitamin D in certain patients and, via vitamin D supplementation, replete their vitamin D stores, expecting improvement of at least the condition of musculoskeletal system.

P127
STRESS FACTORS IN SYSTEMIC LUPUS ERYTHEMATOSUS (SLE) AND ANTIPHOSPHOLIPID SYNDROME (APS) PATIENTS COMPARISON

A. Borisova[1], T. Lisitsyna[1], D. Veltischev[2], T. Reshetnyak[1], O. Seravina[2], O. Kovalevskaya[2]

[1]V.A. Nasonova Research Institute of Rheumatology, [2]Serbsky NMRC PN MoH, Moscow, Russia

Objective: Stress factors in childhood and in a period before the manifestation of SLE and APS symptoms predispose and precipitate the development of rheumatic diseases. We aimed to describe predisposing and precipitating stress factors in SLE and APS patients.
Methods: 181 patients: 69 with SLE (60 women and 9 men), 55 with SLE and secondary APS (40 women and 15 men) and 57 with PAPS (37 women and 20 men), the median age of which was 31.0 [22.0; 41.0], 40.0 [32.0; 48.0] and 41.0 [35.0; 46.0] years, respectively, were consecutively enrolled in the study. Stress factors were detected by psychiatrist in semistructured interview in accordance with ICD10.
Results: Early childhood stressors were detected significantly more often in patients with SLE compared to PAPS and SLE + APS: 53 (76.8%) vs. 31 (54.4%), p = 0.006 and vs. 33 (60.0%), p = 0.03, respectively. Childhood stressors are also more typical for patients with SLE than PAPS: 55 (79.7%) vs. 36 (63.2%), p = 0.03. In particular, SLE patients were exposed to parental deprivation significantly more often than patients with SLE + APS (54 (78.3%) vs. 34 (61.8%), p = 0.04) and PAPS (54 (78.3%) vs. 32 (56.1%), p = 0.007); and also—a threat to safety in childhood was more common in SLE compared with PAPS (10 (14.5%) vs. 1 (1.75%), p = 0.01) and in adolescence compared with SLE + APS (11 (15.9%) vs. 2 (3.64)%), p = 0.02) and with PAPS (11 (15.9%) vs. 3 (5.26%), p = 0.05). Among childhood traumas, chronic stress factors predominated in patients with SLE: 60 (86.9%) vs. 34 (59.6%), p = 0.0005 in patients with SLE compared with PAPS and 40 (72.7%) vs. 34 (59.6%), p = 0.04 in patients with SLE + APS compared with PAPS. Stressful events at the onset of SLE were detected in 69.6%. At the same time, in patients with SLE + APS, chronic (18 (51.4%) vs. 12 (25.0%), p = 0.01) family stress predominated (17 (48.6%) vs. 10 (20.8%), p = 0.008), and in patients with SLE—acute stress (34 (70.8%) vs. 15 (42.9%), p = 0.009), including losses (7 (14.6%) vs. 0, p = 0.02). Multiple significant stressful events (cumulative stress load) before rheumatic disease were noted significantly more often in patients with SLE compared to patients with PAPS (32 (46.4%) vs. 13 (22.8%), p = 0.005) and SLE + APS (32 (46.4%) vs. 14 (25.5%), p = 0.01). Stressful events at the onset of APS were observed in 56.4% of patients. In patients with PAPS, acute stress situations prevailed compared with SLE + APS (23 (74.2%) vs. 14 (48.4%), p = 0.03), and in patients with SLE + APS, compared with PAPS, chronic (16 (51.6%) vs. 7 (22.6%), p = 0.02).
Conclusion: Compared with APS, SLE patients were more often exposed to stressors in childhood. At the same time, stressful events in childhood in patients with SLE were more often chronic. More than 2/3 of SLE patients and slightly more than half of APS patients experienced stressful event within a year before the onset of the disease. Multiple stressful events were observed in SLE patients much more often than in APS patients during life before the disease. The stress related predisposition and chronic stress precipitation could be a common pathogenesis factors for the development as the rheumatic disease, as the anxiety-depressive spectrum disorder, diagnosed in most SLE and APS patients.

P128
PATIENT AND PUBLIC INVOLVEMENT (PPI) IN MUSCULOSKELETAL RESEARCH: A PRAGMATIC REVIEW WITH RESOURCES FOR OPTIMIZING INTEGRATION OF PATIENT EXPERIENCE DATA (PED)

A. Botto-Van Bemden[1], A. Arumugam[2]

[1]Patient and Public Involvement, Musculoskeletal Research International, Inc., Miami, USA, [2]Univ. of Sharjah, Dept. of Physiotherapy, Sharjah, United Arab Emirates

Objective: Patient and public involvement (PPI) is essential for Patient-Centered care and Patient-Focused Medicines Development. Proper PPI ensures optimal integration of Patient Experience Data (PED), helping to ensure patients' expectations, needs and preferences are met. It is essential to ensure competence of the research team by capacity building with available tools and resources on PPI. This brief review aims to prompt PPI access and action by briefly summarizing the most relevant PPI resources.
Methods: This pragmatic review summarizes the most relevant best practices, checklists, guidelines and tools for optimizing PPI in musculoskeletal research. Practical resources for PPI in various stages of research projects are reviewed- conception, co-creation, design (including qualitative or mixed methods), execution, implementation, feedback, authorship, acknowledgement and remuneration of patient research partners, and dissemination and communication of research findings.
Results: A resource table with links to various tools and referenced material for PPI in various stages of research was created.
Conclusion: Gaps in research and challenges in care management create PPI opportunities for researchers and patient research partners (PRPs) to co-create meaningful studies and/or research development programs by setting research priorities together, developing protocol designs and research partnerships that are fit for purpose, improving recruitment and research awareness, team competence and capacity building, dissemination and sharing of results, actionable insights for improved access and regulatory approval, etc. Successfully optimizing integration of PPI research opportunities will require a shift in mindset for most and capacity building for all stakeholders.
Acknowledgement: We thank each patient partner for their contributions creating PPI tools and resources and all PPI stakeholders who encouraged and continue to encourage patient partnership.

P129
THERAPEUTIC REHABILITATION STRATEGIES IN RHEUMATOLOGICAL SYNDROMES IN THE NEOPLASTIC PATIENT

A. Bumbea[1], R. Traistaru[1], V. Caimac[1], O. Rogoveanu[1], A. Musetescu[1]

[1]Univ. of Pharmacy and Medicine of Craiova, Craiova, Romania

Objective: To establish a strategy to approach the neoplastic patient with rheumatoid syndrome.
Methods: Some nonspecific rheumatoid syndromes (1) can be secondary to a neoplastic pathology. Malignancy can determine multiple paraneoplastic phenomena, the substrate being chronic inflammation and the procoagulant status, the latter can also produce a stroke (2). We included a number of 20 patients (2013–2023) who presented with clinical aspects of rheumatoid arthritis or lupus-like syndromes secondary to a diagnosed neoplasia. The evaluation of these patients highlighted specific rheumatoid clinical aspects, moderate inflammatory biological syndrome. The rehabilitation consisted in the application of TENS on selected areas, as therapy allowed for the neoplastic patient. They were evaluated initially and at 3 months using the VAS scale and the ADL scale. All patients received combined anti-algesic therapy such as paracetamol, NSAIDs and recovery therapy.
Results: Patients with combined therapy showed a 31.4% reduction in rheumatoid syndrome with improved functionality. Biological tests were slightly influenced, but functionality improved by an average of 39.3%. The evaluation at 3 months maintained the same results.
Conclusion: The combined therapy of analgesics, low doses of nonsteroid and TENS therapy brings improvements in the quality of life of neoplastic patients with rheumatoid syndrome.

THE COMPLEX THERAPEUTIC APPROACH OF THE PAINFUL SHOULDER IN THE STROKE PATIENT USING REHABILITATION TECHNIQUES AND BOTULINUM TOXIN

A. Bumbea[1], R. Traistaru[1], V. Caimac[1], A. Turcu Stiolica[1]

[1]Univ. of Pharmacy and Medicine of Craiova, Craiova, Romania

Objective: To develop a complex therapeutic plan that includes the injection of botulinum toxin into the spastic muscles and a rehabilitation program for the painful shoulder in the patient with stroke and spasticity.
Methods: It is known from the literature that patients with spasticity benefit from botulinum toxin therapy, which allows the application of rehabilitation programs with superior results (1). Thirty patients with stroke and spasticity of the upper limb who presented pain and limited mobility at the shoulder level were studied. The patients were evaluated using the VAS scale, the Ashworth spasticity scale, and functional assessment of the shoulder. All patients received specific rehabilitation treatment, ultrasound applications, massage and physical therapy. The group was divided into two groups, Group A, which included 15 patients who received botulinum toxin treatment for spastic shoulder muscles. Group B received only rehabilitation treatment.
Results: It was found that group A that received botulinum toxin had a favorable functional evolution and a reduction in pain quantified on the VAS scale with a reduction of approximately 43.6%, compared to group B where the improvement was only 19.45%.
Conclusion: Spasticity therapy with botulinum toxin applied to patients with spasticity combined with upper limb rehabilitation program and shoulder pain had a much improved evolution.

P131
COMPREHENSIVE APPROACH TO THE MANAGEMENT AND TREATMENT OF ADULTS WITH X-LINKED HYPOPHOSPHATEMIA (XLH)

A. C. Polonsky[1]

[1]Hospital Centenario, Rosario, Argentina

Objective: X-linked hypophosphataemia (XLH) is an X-linked dominant disorder caused by mutations in PHEX[1]. XLH is the most common genetic form of hypophosphatemic rickets and osteomalacia. Its incidence has been estimated at 3.9–5 cases per 100.000 live births[2]. The mutations or chromosomal derangements affecting the phosphate regulating endopeptidase homolog, X-linked (PHEX) gene on the X chromosome lead to elevated levels of the hormone FGF23, resulting in renal phosphate wasting, impaired 1a-hydroxylation of 25-hydroxyvitamin D and consequently, chronic hypophosphatemia, impaired skeletal mineralization and rickets[2]. Patients usually develop clinical symptoms during the first or second year of life[1]. The clinical features include those common for hypophosphatemic rickets, short stature, waddling gait, and leg bowing in growing children, in addition to muscle weakness. Fatigue and chronic pain become more prevalent in older children and particularly adults[2]. Even adults with milder forms usually develop symptoms in their third or fourth decade, which may include bone and joint pain, fatigue, enthesopathy (commonly involving the hips and anterior spinal ligament), pseudofractures, dental complications and early osteoarthritis. These complications ultimately cause chronic pain, impaired mobility, loss of productivity and lower quality of life. Other complications include hearing loss, overweight and obesity has also been observed in XLH. The diagnosis of XLH relies on the combination of clinical, radiographic, biochemical and genetic features. Conventional management of XLH involves phosphate supplementation and active vitamin D (calcitriol). While conventional therapy can help manage bone pain, children with XLH can still develop significant lower limb deformity and often have short stature[3]. Burosumab is a neutralizing antibody to FGF23 and is superior to conventional management of the condition in both adults and children[3]. We aimed to evaluate the clinical and biochemical characteristics of a cohort of adult patients with XLH and evaluate the best therapeutic option.
Methods: A total of 11 adult patients were recruited, of which 8 had a diagnosis of XLH confirmed in childhood. The other two were diagnosed because they had a family member with the disease and a molecular study was performed to confirm the presence of XLH. Clinical follow-up, disease sequelae, laboratory, and therapeutic alternatives were carried out for one year. Only 8 of the 11 patients were evaluated until the end of the study.
Results: All the patients studied have a common characteristic of deformities in their limbs to a greater or lesser extent, decreased hearing, mostly mild, and dental disorders. Everyone complains of pain, both at rest and during movement. Only two patient underwent treatment without interruptions since childhood, but the majority stopped during adolescence. One of the patients, despite having had orthopedic surgeries in childhood and dental disorders, was diagnosed at the age of 64 years, also presenting postmenopausal osteoporosis, which is why we believe it is urgent to start therapy with burosumab. As seen in the Table, not all participants carried out the controls as established. From the results obtained, an increase in the

phosphataemia value is evident in those patients who started with phosphorus salts but not in RTP. An increase in PTH is also evident as a consequence of conventional treatment.

Conclusion: Treatment for adults with XLH typically focuses on symptom management, including bone deformities and osteoarthritis. A multidisciplinary approach involving orthopedics, physiotherapy, and pain management is crucial for improving quality of life. Regular monitoring and adjustment of phosphate and vitamin D therapy are essential to maintain optimal levels and prevent complications. Burosumab, a monoclonal antibody approved for XLH treatment, has generally positive feedback. The problem with burosumab in my country is that it is so expensive, which can pose challenges for patients in terms of accessibility and affordability. The medical team must evaluate the cost–benefit relationship. It's understandable that some adult XLH patients may experience fatigue or reluctance regarding ongoing medical care from childhood. The weariness from

years of treatments and appointments can impact motivation to adhere to medical recommendations. In these cases, addressing patients' concerns and emotions is crucial. To improve treatment adherence in adult patients with XLH, it is crucial to implement strategies that facilitate the integration of the therapeutic regimen into their daily lives. Some suggestions include: continuous education, psychological support, simplification of the regimen, reminders and follow-up, family involvement, regular monitoring, treatment personalization. These combined measures can contribute to better treatment adherence in adult patients with XLH. It is essential to work collaboratively with the medical team and consider the preferences.

P132
COMPARATIVE PERFORMANCE OF CNN MODELS IN DETECTING FRACTURES IN X-RAY IMAGES

A. Chatsirisupachai[1], P. Nonthasaen[1], P. Achararit[1]

[1]Princess Srisavangavadhana College of Medicine, Chulabhorn Royal Academy, Bangkok, Thailand

Objective: This research confronts the public health challenge posed by osteoporotic fractures by comparing the effectiveness of convolutional neural networks (CNNs) in image classification vs. object detection tasks. We aimed to elucidate which method is more effective for fracture detection, which is critical in assessing fracture risk in osteoporosis.

Methods: We employed a FracAtlas dataset [1] with 717 abnormal scans out of 4,083 x-ray images. To achieve a balanced representation of fracture cases, 200 images with fractures and 200 without were designated for testing and validation, respectively. Classification models included MobileNetV3, Xception, and EfficientNetV2M, while object detection was performed with three variants of YOLOv8. For object detection, our evaluation criteria mirrored that of image classification—identifying at least one fracture correctly in an image was counted as a true positive, which aligns with clinical relevance where the detection of any fracture is the priority.

Results: Xception surpassed YOLOv8s in precision and F1-score, achieving 0.60 and 0.69, respectively, compared to YOLOv8s's 0.49 and 0.65. However, YOLOv8m achieved a superior recall rate, suggesting a decision between these models hinges on specific requirements. Although classification methods don't pinpoint fracture locations directly, using visualization tools like Grad-CAM enhances fracture detection in classification tasks, providing an efficient alternative to the traditionally more labor-intensive object detection methods.

Conclusion: In a domain traditionally favoring object detection, our study uncovers the promising capabilities of image classification for fracture identification. It offers a streamlined, efficient approach to osteoporotic risk assessment, advocating for a paradigm shift in fracture detection methods. Image classification, enhanced with visualization techniques, stands out as a viable, resource-efficient option.

CLINICAL AND LABORATORY PREDICTORS OF THE DEVELOPMENT OF CHRONIC PAIN AND EARLY STAGES OF PTSD OSTEOARTHRITIS AFTER KNEE INJURY

A. Chernikova[1], A. Karateev[1], M. Makarov[1], E. Bialyk[1], V. Bialik[1], V. Nesterenko[1]

[1]Nasonova Research Institute, Moscow, Russia

Objective: Chronic pain and post–traumatic arthritis are frequent complications of injuries that cause suffering, loss of function and disability. To date, no clear predictors of the development of these complications have been identified. We aimed to determine the clinical and immunological factors associated with the development of chronic pain and early stages of post-traumatic osteoarthritis after knee joint injury.

Methods: From August 2022 to January 2023, 100 people were examined at the V.A. Nasonova Research Institute, including 56 women and 44 men at an average age of 26.95 ± 11.64 y, with an average BMI of 26.95 ± 4.99, who suffered a knee joint injury with persistent pain for a month or more. All patients agreed to the study, which is confirmed by informed voluntary consent. The patients underwent a clinical examination, laboratory research methods (UAC, highly sensitive CRP) were performed. A questionnaire was conducted on the scales of HRSH, KOOS, HAQ, CSI, BPI, Pain DETECT, FACIT-F, FIRST, HADS, and an MRI examination was performed on a Philips, MULTIVA 1.5 T device.

Results: According to the results of the study, it was revealed that the pain when moving along the CRH was on average 5.21 ± 1.30, the pain at rest on the CRH was on average 1.72 ± 1.74, the night pain on the CRH was on average 1.55 ± 1.84. Functional impairment according to HRH was 4.44 ± 1.79. Assessment of knee joint function: KOOS total was 52.02 (13;87), KOOS symptoms 62.26 (4;56), KOOS pain 60.58 (25;92), KOOS activity 68.97 (22;100), KOOS sport 28.92 (0;95), KOOS quality of life 41.02 (0;100). The value on the Pain DETECT scale, which evaluates the presence of signs of neuropathic pain, averaged 6.26 ± 4.79. According to the FIRST questionnaire, the indicators are from 0–5 (on average from 0.93 ± 1.26), which indicates the presence of concomitant fibromyalgia in some patients. According to the CSI questionnaires, the average values were 23.55 ± 13.38. According to the catastrophization scale, 13.54 ± 11.20. According to the HADS scales assessing the level of depression and anxiety, the values were 4.37 ± 4.01-depression and HADS anxiety with values on average 5.42 ± 4. According to laboratory research methods, hemoglobin values averaged 116 ± 179 g/l. The level of ESRD was 0.2 ± 15.3 mg/l, and the level of ESR was 2 ± 23.

Conclusion: Some patients who have suffered a knee injury more than 1 month ago experience severe pain and have impaired joint function. In a number of patients, 26% (26 out of 100 people), of whom 18 are women, the remaining 8 are men, there are signs of neuropathic pain, central sensitization, increased BMI, psychoemotional disorders and fibromyalgia, which aggravates the course of the post-traumatic period. Patients with chronic pain after an injury need further follow-up to clearly identify predictors of the occurrence of this condition in order to predict the occurrence of post-traumatic osteoarthritis and the formation of correct treatment tactics.

P134
UPPER LIMB ORTHOPEDIC ASSESSMENT IN PARAPLEGIC AND TETRAPLEGIC PATIENTS AND CLINICAL OUTCOMES ON THE SHOULDER, ELBOW, WRIST AND HAND

A. Cliquet Jr.[1]

[1]Dept. of Orthopedics, Rheumatology and Traumatology, Faculty of Medical Sciences, UNICAMP, Campinas, SP, Brazil

Objective: Spinal cord injured individuals (SCI) do present joint lesions on their overused upper limbs, being wheelchair users and due to upper limb effort during daily activities such as transferring. This work aimed at providing an assessment on the orthopedic comorbidities as well as feasible approaches towards clinical improvements on the shoulder, elbow, wrist and hand.
Methods: MRI, disability of the arm, shoulder and hand (DASH) score, bone densitometry (DXA), plain radiography and clinical measurements such as active and passive range of motion were performed in patients attending the SCI Outpatient Clinic of the University Hospital, including those patients involved in Paralympic Sports. Rehabilitation protocols were applied.
Results: On the shoulder, 10% of the tetraplegic athletes (sample of 10 rugby players) did present tendinopathies against 30% of those sedentary ones (sample of 10 tetraplegics). Joint strength, endurance and function were improved (sample of 17 subjects) by protocols of the rehabilitation programme of specific physiotherapy training of the scapula muscles making use of elastic bands. Rugby training also improved bone mineral content in the arms. On the elbow joint, clinical and radiological abnormalities (osteoarthritis, subclinical acute and chronic pain) were noticed in SCI patients, assessed through bilateral X-ray exams, on 10 paraplegics and 10 tetraplegics, such comorbidities being more evident (90%) on the latter pathology. Related to wrist and hand, SCI patients (8 paraplegics, 6 tetraplegics) presented minimal radiological signs of osteoarthritis.
Conclusion: Regular wheelchair rugby enhances bone mass and sedentary tetraplegic individuals do present more risk of injury to the acromioclavicular joint. Elbow osteoarthritis, being a limiting disease to the patients, requires both, early diagnosis and treatment through rehabilitation techniques.

P135
ÉVALUATION OF BONE MINERAL DENSITY IN ALGERIAN PATIENTS WITH PLAQUE PSORIASIS: A CASE–CONTROL STUDY

A. Djebbari[1], A. Abiayed[2], S. Bennedjma[2], H. M. Houbi[3], S. Oulebssir[1], A. Beguiret[3]

[1]HCA Hospital Koubap, [2]HCA Hospital, [3]HCA Hospital, Kouba, Algeria

Objective: Psoriasis is a common chronic skin diseases, causing plaques. It is associated with many comorbidities. A link had been found between psoriasis and osteoporosis in some studies where various mechanisms may be involved, including increased inflammatory cytokines, such as interferon-gamma, IL-6, and TNFs. Moreover, psoriasis medications could cause abnormal BMD, which is measured by DXA as a gold standard method. Because the poverty of literature on the subject and the conflicting results in previous studies, for the first time in Algeria, we conducted a study to assess BMD in plaque psoriasis patients compared with a healthy control group to Improve the management of comorbidities associated with psoriasis. Our objectives were to evaluate the BMD measured by DXA in Algerian patients presenting a plaque psoriasis and identify associated factors with low BMD.
Methods: In this case–control study, 90 participants were enrolled from Algiers and Blida dermatology clinics University Hospital in Algeria between October 2019 and April 2022. The case group consisted 48 patients aged 20–65 from healthy subjects referred to these clinics for routine examination. Patients with psoriatic arthritis, chronic inflammatory diseases, endocrine disorders, a history of treatment with systemic drugs affecting BMD (including corticosteroids, disease-modifying antirheumatic drugs (DMARDs), and biologic drugs), individuals undergoing phototherapy, and those with a history of smoking and alcohol use were all excluded from the study. All participants were examined and evaluated for height, weight, BMI, medication history, pelvic fracture history, and chronic diseases. DXA was used to measure BMD at the 2nd and 4th lumbar vertebrae and the pelvis, and the results were categorized by T-score. The psoriasis area severity index (PASI) score was used to determine the severity of psoriasis.
Results: This study was conducted on 45 patients with a mean age of 47.23 ± 8.11 and 45 healthy controls with a mean age of 49.26 ± 6.7 to assess the relationship between BMD and plaque psoriasis. The mean T-score in the case and control groups were -0.56 ± 1.02 and -0.25 ± 0.65, respectively ($P = 0.325$). The mean T-score had a significant inverse correlation with an age of 42 y or above ($P < 0.001$), disease duration of more than 6 y ($P = 0.05$), and PASI score ($P < 0.001$), but had a positive correlation with sunlight exposure ($P < 0.001$), and overweight ($P < 0.001$).
Conclusion: Our study revealed that in Algerian patients, the mean T-score in patients with plaque psoriasis was significantly lower than the controls among those aged 42 or above. Furthermore, T-score had a significant inverse relationship with age, disease duration, and PASI score, but a significant direct relationship with overweight and sunlight exposure, so in addition to routine therapy we suggest treatments given to this group of plaque psoriasis patients to prevent osteoporosis.

P136
OBESITY IS THE MOST PREVALENT COMORBIDITY IN A NEWLY DIAGNOSED PSORIATIC ARTHRITIS POPULATION: ALGERIAN COHORT OF DERMATOLOGIC EARLY DETECTION

A. Djebbari[1], S. Bennedjma[2], S. Oulebssir[1], A. Abiayed[2]

[1]HCA Hospital Koubap, [2]HCA Hospital, Kouba, Algeria

Objective: Psoriatic arthritis (PsA) is a heterogeneous disease with articular extra-articular disease features. PsA is associated with important comorbidities: cardiovascular, gastrointestinal, infectious, malignant, and psychiatric. However, they are less studied in PsA compared to other chronic inflammatory arthritis. The aim of this study is to describe the prevalence of comorbidities in PsA newly diagnosed among a population of psoriasis screened by the PURE4 questionnaire recruited dermatology clinics.
Methods: Between 2019–2022, a multicenter cross-sectional trial including patients selected in dermatology clinics using PURE 4 questionnaire, and a diagnosis of PsA confirmed by CASPAR criteria. Data collected: demographical, clinical (affected joints, axial involvement, enthesitis, dactylitis), biological, and treatment related. Data on comorbidities and risk factors were collected according to the EULAR recommendations on reporting comorbidities in chronic inflammatory rheumatic diseases in daily practice.
Results: In all, 43 PsA patients were included: 14 (33%) women, mean age $\pm$ standard deviation 50.76 ± 12.39 y, 44% of patients with PsA had psoriatic nail disease and scalp involvement seen in 37%. With reference to the PsA type, 30% patients presented with polyarthritis, 44% with oligoarthritis, 39% with enthesitis, dactylitis in 23% and 13% with axial arthritis. Most of them had low or

moderate disease activity and 30% were taking a biologic. The most prevalent comorbidities were: obesity 18 (42%), dyslipidaemia 9 patients (21%), hypertension 7 (17%), diabetes 6 (14%) and ischemic heart disease 2 (4.65%). Cardiovascular events correlated with obesity ($p < 0.001$), smoking ($p < 0.001$), current moderate/severe psoriasis ($p = 0.01$) and PsA disease activity ($p < 0.01$). Regarding infectious comorbidities: 4 patients (9.3%) had a history of pulmonary infection, (4%) chronic viral hepatitis, of which 2 with B virus and 2 with C virus. One patient was diagnosed with neoplasia, but no correlation was identified with any of the clinical, biological or treatment related included variables. Only 4 patients (9.3%) were diagnosed with depression and 11.63% had inflammatory bowel disease.

Conclusion: PsA newly diagnosed is associated with a high prevalence of comorbidities, especially obesity and cardiovascular diseases. These comorbidities should be screened and taken into consideration in the therapeutic and management of PsA patients.

P137
EARLIER AGE OF PSORIASIS ONSET, HIGH CRP LEVEL AT DIAGNOSIS AND LOW EDUCATIONAL LEVEL ARE ASSOCIATED WITH DIAGNOSTIC DELAY IN PSORIATIC ARTHRITIS

A. Djebbari[1], A. Gouder[2]

[1]HCA Hospital Koubap, Kouba, [2]Hmruc, Constantine, Algeria

Objective: Psoriatic arthritis (PsA) is a chronic inflammatory disease characterized by cutaneous psoriasis, with peripheral and axial joint damage. Early diagnosis of PsA is important for improving long-term outcomes. Trends in diagnostic delay of PsA in Algeria (Africa) and factors associated with delay in diagnosis have not been well studied. Aims: (1) to determine the diagnostic delay in PsA in Algerian population from 2016–2022, and (2) to identify demographic and clinical characteristics associated with diagnostic delay in PsA.

Methods: We conduct a retrospective, population-based cohort of adult patients with PsA in Algeria from 2016–2022. All patients met the classification criteria. Diagnostic delay was defined as the time from any patient-reported PsA-related joint symptom to a physician diagnosis of PsA. Factors associated with delay in PsA diagnosis were identified through logistic regression models.

Results: 78 PsA were recruited from 2016–2022 with a physician or rheumatologist diagnosis. Mean (SD) age was 51.2 (14.8) y and 62% were male. Median time from symptom onset to physician diagnosis was 2.9 y (IQR 0.8–9.3). By 6 months, 10 (12.8%) received a diagnosis of PsA, 29 (37.1%) by 1 y, and 39 (50%) by > 2 y after symptom onset. No significant trend in diagnostic delay was observed over calendar time. Earlier age at onset of psoriasis symptoms ($p < 0.0001$), low educational level ($p < 0.001$) and higher CRP level were associated with a diagnostic delay of > 2 y, whereas patients with late onset psoriasis symptoms, high activity (PASI) were associated with a lower likelihood of delay.

Conclusion: Our study highlights that half of PsA patients had a diagnostic delay of > 2 y. Patients with younger age at psoriasis symptom onset, higher CRP level at psoriasis diagnosis or lower educational level before diagnosis were more likely to have a diagnostic delay of > 2 y, whereas patients with late onset psoriasis symptoms, high activity (PASI) were less likely to have a diagnostic delay.

P138
COMPARISON OF THE AVERAGE DAILY PRODUCTION OF VITAMIN D3 IN MOROCCAN MEN BETWEEN THE SUMMER AND WINTER SEASONS

A. E. El Maataoui[1], A. B. Belbo[1], D. M. Dandan[1]

[1]IBN Zohr Univ. Faculty of Medicine and Pharmacy Agadir, Agadir, Morocco

Objective: Hypovitaminosis D is a global health problem, even in countries with abundant sunlight. Despite Morocco's geographical location, the prevalence of vitamin D deficiency and insufficiency is reported to be high. In men and women, the prevalence of vitamin D deficiency was 4.4% and 8.6%, respectively. Also, the prevalence of vitamin D (25(OH)D) insufficiency was 85.2% and 77.4% in men and women, respectively. The aim of this study was to estimate the average amount of vitamin D3 produced by sunlight exposure in Moroccan adult men during summer and winter, based on their everyday outdoor ultraviolet doses.

Methods: This is a prospective study that recruited male participants exclusively and was conducted in both summer 2022 and winter 2023. All participants were Moroccan and resided in the Agadir area of Morocco (30.428° N). The sample size was calculated using the formula for sample size: $n = z^2 \times p(q)/d^2$. We included 324 men in the summer and 345 in the winter, all of whom were apparently healthy and from diverse socioeconomic backgrounds, ranging in age from 18–100 years old. Data were collected through a face-to-face interview questionnaire that assessed sun exposure variables for estimating the vitamin D3 produced by sunlight. The questionnaire also included sociodemographic and anthropometric variables, as well as medical history. The daily estimate of synthesized vitamin D3 was calculated using the following equation: estimate vitamin D3 (IU) per day = vitamin D dose (VDD) $\times$ (4900 IU) $\times$ skin type factor $\times$ fraction of body exposed $\times$ age factor.

Results: The study included participants aged 20–60, with 62.33% in the 20–40 age group and 23.31% in the 40–60 age group. Only 10.76% were over the age of 60. The majority of participants had Fitzpatrick skin type 3 (72.94%). During the summer period, vitamin D synthesis was below the recommended value of 600 IU/d for 0% of participants, between 600–1200 IU/d for 44.44% of participants, and $\geq$ 1200 IU/d for 55.55% of participants. During the winter period, 13.33% of participants had an average vitamin D synthesis below the recommended value of < 600 IU/d, while 74.20% had a synthesis between 600–1200 IU/d, and 12.46% had a synthesis of $\geq$ 1200 IU/d. The most important factors correlated with vitamin D production, in order of importance, are the amount of skin exposed to sunlight, the time of year, age, and duration of sun exposure.

Conclusion: In Moroccan men, the predictors of vitamin D3 production through sunlight exposure are the fraction of the body exposed, age, and season. These results do not correlate with the findings of Moroccan studies which have reported a high prevalence of vitamin D status insufficiency and the prevalence of vitamin D deficiency. All these studies used immunological techniques and not the reference technique for vitamin D determination.

P139
ONCE YEARLY ZOLEDRONIC ACID REDUCED THE RATE OF NEW CLINICAL FRACTURES AND IMPROVED SURVIVAL

S. Z. Zidan[1], A. E. Elsalmawy[2], M. M. Mouhsen[2], I. M. Malik[2], A. B. Butt.[2]

[1]North Middlesex Univ. Hospital, London, [2]Southend Univ. Hospital, Southend-on-sea, UK

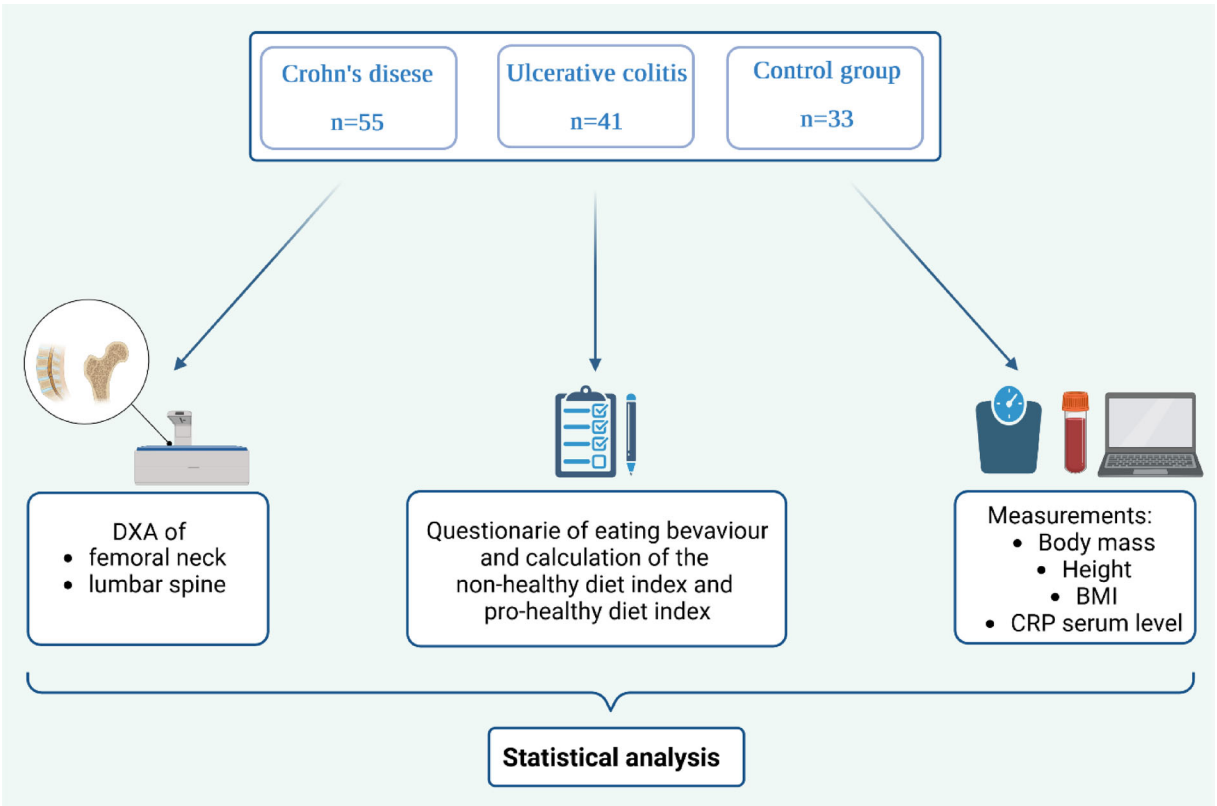
Objective: Hip fractures are associated with high mortality and a substantial economic burden. Given its association with older age and the rate of aging of the global population, hip fractures are likely to become even more frequent events to bring patients to healthcare systems worldwide,
Methods: In this study, 656 patients with a fragility hip fracture were treated in Southend University Hospital and North Middlesex hospitals between 2021–2022, the first group of 356 patients was assigned to receive yearly intravenous zoledronic acid (at a dose of 5 mg), and 300 patients did not receive it either due to low creatinine clearance, ongoing renal disease, or due to patient preference. The infusions were first administered during the admission after surgical treatment of a hip fracture. All patients (mean age, 80.2 y) received supplemental vitamin D and calcium. The median follow-up was 1 y. The primary endpoint was a new clinical fracture.
Results: The rates of any new clinical fracture were 8.6% in the zoledronic acid group and 13.9% in the second group, with a 35% risk reduction with zoledronic acid (P = 0.001); the respective rates of a new clinical vertebral fracture were 2.7% and 3.8% (P = 0.02), and the respective rates of new nonvertebral fractures were 7.6% and 10.7% (P = 0.03). In the safety analysis, 8 of 356 patients in the zoledronic acid group and 19 of 300 patients in the second group died. The most frequent adverse events in patients receiving zoledronic acid were pyrexia, myalgia, and bone and musculoskeletal pain. No cases of osteonecrosis of the jaw were reported, and no adverse effects on the healing of fractures were noted. The rates of renal and cardiovascular adverse events, including atrial fibrillation and stroke, were similar in the two groups.
Conclusion: An annual infusion of zoledronic acid during hospital admission after repair of a low-trauma hip fracture was associated with a reduction in the rate of new clinical fractures and improved survival.

P140
DOES THE QUALITY OF DIET AFFECT BONE MINERAL DENSITY IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE?

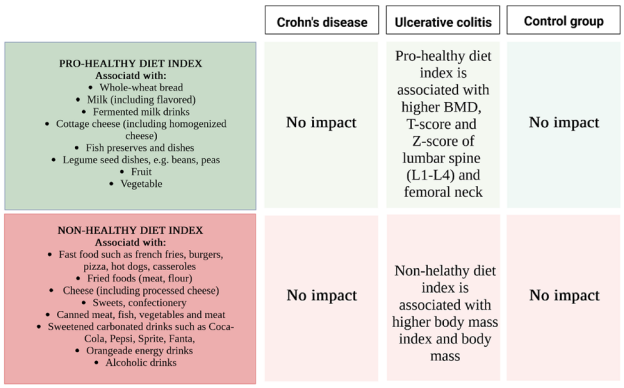
A. E. Ratajczak-Pawłowska[1], A. Szymczak-Tomczak[1], M. Michalak[2], A. M. Rychter[1], A. Zawada[1], K. Skoracka[1], A. Dobrowolska[1], I. Krela-Kaźmierczak[1]

[1]Dept. of Gastroenterology, Dietetics and Internal Diseases, [2]Dept. of Computer Science and Statistics, Poznan Univ. of Medical Sciences, Poznań, Poland

Objective: Looking for an association between BMD and diet quality among IBD patients.
Methods: We enrolled 96 IBD patients (55 with Crohn's disease—CD, 41 with ulcerative colitis—UC) and 33 healthy adults (control group—CG) at the age of 18–50, recruited at the Dept. of Gastroenterology, Dietetics and Internal Medicine, Poznan Univ. of Medical Sciences between 2020–2021. All subjects filled in the Questionnaire of Eating Behaviour (QEB), developed by the Polish Academy of Sciences, based on which pro-healthy and non-healthy diet indexes were calculated. Additionally, BMD, T-score and Z-score of the lumbar spine (L1–L4) and femoral neck (FN) were assessed using the Lunar DPX-Plus device (Lunar Inc., Madison, WI, USA). Finally, we carried out an appropriate statistical analysis. The summary of methods is presented in Fig. 1.



Results: Patients with UC and CD presented lower BMD, T-score and Z-score of L1–L4 and FN than the control group. Pro-healthy diet index was significantly higher among the control group than CD and UC. On the other hand, also non-healthy diet index was significantly higher among the control group than UC, but not CD. However, C-reactive protein concentrations were significantly lower among CG than CD and UC. We did not find differences between groups after dividing pro-healthy and non-healthy scores into low, medium and high categories. In the UC group, but not CD and CG, the pro-healthy index correlated positively with BMD, T-score and Z-score of L1–L4 and FN. Additionally, we find a positive correlation between non-healthy scores and BMI and body mass among UC patients. The summary is presented in the Fig. 2.



Conclusion: Chronic inflammation may affect the pro-healthy indexes characterised by, among other high intake of dairy, fruits, vegetables and whole grains. It should be noted that if IBD patients are following IBD-specific recommendations, the pro-healthy index can be lower. On the other hand, IBD patients avoided high-processed food, sweets and energy drinks, associated with a high non-healthy index. Nevertheless, a higher pro-healthy index is probably associated with a higher intake of nutrients, positively affecting BMD.

P141
CALCIUM, PHOSPHORUS AND MAGNESIUM INTAKE AND BONE MINERAL DENSITY IN INFLAMMATORY BOWEL DISEASE

A. E. Ratajczak-Pawłowska[1], A. Szymczak-Tomczak[1], M. Michalak[2], A. Zawada[1], A. M. Rychter[1], K. Skoracka[1], A. Dobrowolska[1], I. Krela-Kaźmierczak[1]

[1]Dept. of Gastroenterology, Dietetics and Internal Diseases, [2]Dept. of Computer Science and Statistics, Poznan Univ. of Medical Sciences, Poznań, Poland

Objective: To look for an association between calcium, phosphorus and magnesium intake and BMD in inflammatory bowel disease (IBD).
Methods: The study included 26 patients with Crohn's disease (CD), 30 ulcerative colitis (UC) patients and 31 healthy adults (control group) aged 18–50 y, recruited between 2020–2021. The dietary intakes of participants were assessed by a 4-d 24-h dietary recall, and these data were analysed by the DIETA 6.0 food analyser. We also assessed the BMD, T-score and Z-score of the lumbar spine (L1–L4) and femoral neck (FN) using the Lunar DPX-Plus device (Lunar Inc., Madison, WI, USA).
Results: CD patients presented a significantly lower calcium intake and significantly lower RDAs (recommended dietary allowances) coverage for calcium and phosphorus than healthy adults. We did not find significant differences in caloric intake between groups. Phosphorus and magnesium intakes, as well as the RDA coverage for magnesium were not significantly different among groups. Only 3.8%, 13.3% and 29.0% of patients with CD, UC and healthy adults, respectively, met the calcium needs. The RDA coverage for magnesium was also low and was 19.2%, 23.3% and 48.4% for CD, UC and the control group, respectively. CD and UC patients had lower T-scores and Z-scores of the FN and L1–L4. Among individuals with insufficient intakes of calcium or magnesium (< RDAs) or higher intake of phosphorus (≥ RDA), low BMD (including osteopenia and osteoporosis) was observed among CD and UC patients more often than controls. We did not find any correlation between calcium, phosphorus and magnesium intakes and BMD, T-score and Z-score of FN and L1-L4.
Conclusion: The diet of CD patients is poorer in calcium than healthy adults. However, the RDA coverage for calcium is low in both IBD patients and the control group. Among those with insufficient calcium and magnesium intake, the risk of low BMD is higher among CD and UC patients than in controls. Probably, IBD patients are more sensitive to nutrients deficiencies or other factors that affect patients' BMD. Although we did not find any significant correlations between calcium, magnesium or phosphorus intakes with bone parameters, we suppose that intake of these nutrients has an impact on bone, but we need studies including bigger groups.

P142
CALCIUM (CA) ISOTOPE COMPOSITION IN SERUM AND URINE FOR THE ASSESSMENT OF BONE CALCIUM BALANCE (BCAB): RESULTS FROM A POSTMARKET SURVEILLANCE CLINICAL FOLLOW-UP STUDY ON 2409 PARTICIPANTS

A. Eisenhauer[1,2], A. Heuser[1,2], J. Oehme[2], M. Lutz[2], M. Müller[2,3]

[1]GEOMAR Helmholtz-Centre for Ocean Research, [2]Osteolabs GmbH, [3]Univ. Clinic Schleswig–Holstein, Kiel, Germany

Objective: Ca isotope marker (CIM) measured in serum (δ44/42Ca-serum) and urine (δ44/42Ca-urine) has been demonstrated in earlier studies to be a sensitive, reliable, and minimal invasive BCaB marker. This study aimed to confirm the validity of the CIM approach to a larger randomized number of people not selected based on specific criteria, but rather showing a wide range of diseases and therapies.
Methods: The 2409 participants of this surveillance study were undergoing CIM testing in 2020–2023. Urine was self-collected, while blood was collected in doctor's office and stored for transport in suitable containers. Individual data were reported: current medical conditions, the last 4 years fracture history, current medication, and intake of supplements, e.g., vitamin D and Ca. Chemical preparation procedures followed standardized procedures. Ca isotopes were measured using a Neptune Plus (Thermo Fisher Scientific) applying a medium mass resolution.
Results: Factors affecting the musculoskeletal metabolism were sensitively reflected by a change in the CIM value in serum and urine. Osteoporosis, osteolytic metastases, hyperthyroidism, specific medications, and antihormone therapies associated with a negative BCaB were reflected by CIM values below the threshold value. Osteoprotective medications such as bisphosphonates, denosumab, and romosozumab, which are associated with a positive BCaB, were reflected by CIM values above the threshold values. The study revealed also that vegans show the highest CIM values possibly reflecting a low Ca intake with increased PTH secretion.
Conclusion: CIM values qualify as a strong and independent marker reflecting BCaB. The high CIM sensitivity allows the early risk assessment of diseases interfering with the musculoskeletal system before symptoms appear. Furthermore, CIM qualifies for near

realtime therapy monitoring to ensure sufficient osteoprotective therapy and contributes to a general reduction in fracture risk.

P143
CORTICAL AND TRABECULAR BONE INVOLVEMENT IN MEN1-ASSOCIATED PRIMARY HYPERPARATHYROIDISM

A. Eremkina[1], S. Pylina[1], A. Gorbacheva[1], L. Humbert[2], M. L. Picazo[2], N. Mokrysheva[1]

[1]Endocrinology Research Center, Moscow, Russia, [2]3D-Shaper Medical, Barcelona, Spain

Objective: Primary hyperparathyroidism (PHPT) is the most common MEN1 component. Data on the bone involvement in MEN1-associated PHPT (mPHPT) compared to sporadic one (sPHPT) remain contradictory. Aim of this study was to compare the severity of bone involvement in mPHPT and sPHPT.

Methods: A single-center retrospective study was conducted among young (< 50 y) age-matched patients in the active phase of PHPT (group 1—mPHPT, n = 22; group 2—sPHPT, n = 37). The analysis included the main parameters of calcium-phosphorus metabolism, bone remodeling markers, BMD assessment at three sites (femur, spine and forearm) using DXA, and the additional 3D-Shaper advanced analysis.

Results: The median duration of PHPT was comparable in both groups: mPHPT—1 y [0; 2] vs. sPHPT—1 y [0; 1], (p = 0.764, U-test). There were no differences in the main parameters of calcium-phosphorus metabolism, as well as in bone remodeling markers (osteocalcin, β-CrossLaps, ALP). The summary frequency of bone disease in mPHPT patients was higher than in sPHPT: 54 vs. 22% (p = 0.0085). Statistically significant differences were revealed in BMD and Z-values of the femoral neck, total hip, lumbar spine and radius 33% (except radius total), all of them were lower in mPHPT group ($p < 0.05$ for all). 3D-Shaper measurements in total hip region including cortical surface BMD, cortical volumetric BMD, cortical thickness, trabecular volumetric BMD, cortical and trabecular bone mineral content showed more severe changes in mPHPT ($p < 0.05$ for all). The groups differed also in areal BMD (p = 0.001).

Conclusion: mPHPT may be accompanied by a more severe decrease in BMD by DXA. The 3D-Shaper advanced analysis also confirmed more significant changes of both cortical and trabecular bone in mPHPT compared to sporadic disease.

P144
LONG-TERM BONE MINERAL DENSITY CHANGES IN KIDNEY TRANSPLANT RECIPIENTS TREATED WITH DENOSUMAB: QUASI-EXPERIMENTAL STUDY

A. F. Fassio[1], F. P. Pollastri[1], S. A. Andreola[2], D. G. Gatti[1], F. P. M. Ferraro[2], G. G. Gambaro[2], L. S. Stefani[2], C. B. Benini[1], G. I. Galvagni[1], R. M. Rossini[1], A. G. Adami[3]

[1]Rheumatology Unit, [2]Nephrology Unit, [3]Rheumatology Unit, Univ. of Verona, Verona, Italy

Objective: Data on the effectiveness of denosumab on osteoporosis after kidney transplantation are limited. We investigated the long-term BMD changes in kidney transplant recipients (KTRs) treated with denosumab compared to untreated KTRs. For these reasons, we performed a quasi-experimental study to investigate the long-term BMD changes over four years in KTRs receiving treatment with denosumab compared to a cohort of age and sex-matched untreated KTRs.

Methods: We enrolled KTRs treated with denosumab 60 mg/six months for 4 years. An untreated group of sex and age-matched KTRs with a 1:1 ratio was included. The primary outcome was BMD changes assessed by DXA over 4 years. Data on serum creatinine, alkaline phosphatase (ALP), PTH, and 25-hydroxyvitamin D were collected. All patients received oral cholecalciferol and calcium supplementation.

Results: 23 denosumab-treated KTRs were enrolled, and 23 untreated KTRs (Table 1). The median time from transplant to the start of denosumab was 4 y (range 0;24). The denosumab group showed a significant increase from baseline in BMD at the lumbar spine (LS) (9.0 ± 10.7%, $p < 0.001$), and total hip (TH) (3.8 ± 7.9%, p = 0.041). The untreated group showed a significant decrease at all sites (− 3.0 ± 7%, p = 0.041 at the LS; − 6.3 ± 9.2%, p = 0.003 at the TH; − 6.7 ± 9.3%, p = 0.003 at the FN) (Fig. 1, panels A and B). The between-group differences in percent BMD changes were statistically significant at all sites. Similar results were found for the respective Z-scores. The ALP serum levels significantly decreased from baseline only in the denosumab group, with a significant between-group difference (p = 0.032). No significant differences in serum creatinine, hypocalcaemic events or acute graft rejection rates were observed.

Table 1. Baseline characteristics of the two groups. Data are expressed as mean (SD) or absolute number (percentage). M, males; F, females, BMI, body mass index; T2DM, type 2 diabetes mellitus; DXA, dual-energy X-ray absorptiometry; GCs, glucocorticoids; SD, standard deviation; LS, lumbar spine; TH, total hip; FN, femoral neck; Ns, nonsignificant; 25OHD, 25-hydroxyvitamin D; ALP, alkaline phosphatase; PTH, parathyroid hormone. *defined as having a T-score < −2.5 at least one of the three sites. Square brackets show the reference range of normality.

	Denosumab (N=23)	Controls (N=23)	p-value
Sex (M:F)	10:13	10:13	Ns

FN T-score	−2.58 (0.52)	−1.98 (1.04)	0.002
LS Z-score	−1.62 (1.31)	−0.60 (1.50)	0.019
TH Z-score	−1.43 (0.53)	−0.61 (0.96)	0.001
FN Z-score	−2.58 (0.51)	−1.95 (1.02)	0.085
Number of osteoporotic subjects*	22 (95%)	9 (39%)	<0.001

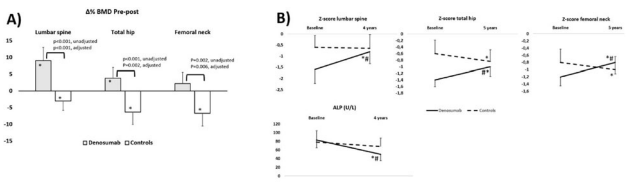

Figure 1: **panel A)** absolute BMD changes after four years of observation of the denosumab and control groups. Horizontal square brackets and the p-values show the between-groups differences, unadjusted and after adjustment for respective baseline Z-score, PTH and 25(OH)D. * p<0.05 *vs* baseline. **Panel B)** BMD and ALP changes expressed as Z-scores after four years of observation. Error bars show 95% confidence intervals. * p<0.05 vs baseline. # p<0.05 vs controls.

Conclusion: Four years of denosumab therapy were associated with increased BMD in KTRs, while untreated KTRs showed significant BMD losses at all sites.

P145
RADIOFREQUENCY ECHOGRAPHIC MULTI-SPECTROMETRY AND DXA FOR THE EVALUATION OF BONE MINERAL DENSITY IN SUBJECTS WITH AXIAL SPONDYLOARTHRITIS

A. F. Fassio[1], F. P. Pollastri[1], G. I. Galvagni[1], D. G. Gatti[1], C. B. Benini[1], O. V. Viapiana[1], R. M. Rossini[1], F. R. Ruzzon[1], A. G. Adami[2]

[1]Rheumatology Unit, [2]Rheumatology Unit, Univ. of Verona, Verona, Italy

Objective: Osteoporosis and bone loss represent a significant complication in axial spondyloarthritis (axSpA) [1]. Radiofrequency echographic multi-spectrometry (REMS) is a novel technique already validated in assessing BMD in postmenopausal osteoporosis [2]. It is characterized by its agile machinery and the absence of ionizing radiation. Additionally, REMS is robust against artifacts, which are known to affect DXA, especially at the lumbar spine (LS)—including aortic calcifications and osteophytes [3]. The aim of this real-life, cross-sectional, explorative study was to compare REMS with DXA in assessing BMD in patients affected by axSpA.
Methods: LS and femur scans were acquired using both techniques, including LS latero-lateral (LL) DXA scans. ANOVA for repeated measures was utilized to compare the differences in T-scores among DXA anteroposterior (AP), LL, and REMS scans at the LS, as well as between DXA and REMS T-scores at the total hip (TH) and femoral neck (FN). The correlation between the T-scores at the hip site was assessed using Pearson's correlation coefficient.
Results: A total of 55 patients were enrolled (Table 1). No significant differences were found between the BMD T-scores measured through DXA or REMS at the femur. At the lumbar spine, the DXA AP mean T-score was significantly higher than those obtained through LL DXA and REMS (Fig. 1). A strong positive correlation was observed between the T-scores obtained with the two techniques, both at the TH ($r = 0.80$, $p < 0.01$) and FN ($r = 0.77$, $p < 0.01$).

Table 1. Sample characteristics. Data expressed as mean (standard deviation).

Sample size	55
M:F	35:20
Age (y)	45.2 (13.6)
BMI (kg/m^2)	25.1 (4.8)
Disease duration (y)	9.5 (7.6)
r-AxSpA	60%
HLA B27	48%

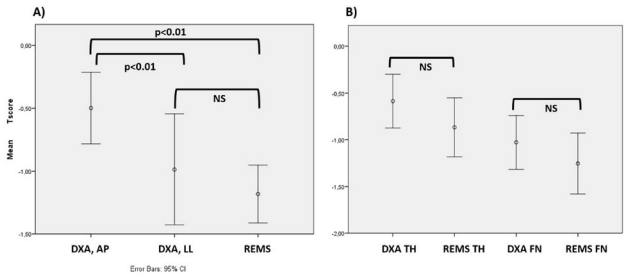

Figure 1: T-score comparison between the DXA and REMS techniques at the lumbar spine (panel A) and hip site (panel B).
Abbreviations: anteroposterior, AP; latero-lateral, LL; total hip, TH; femoral neck, FN; not significant, NS.

Conclusion: Our findings indicate a notable concordance between DXA and REMS in assessing T-scores at the femoral sites in SpA patients. Particularly at the LS, REMS may offer more precise BMD measurements in this distinct patient group, where DXA assessments are potentially confounded by the presence of syndesmophytes.

ROLE OF SIRT1, NOX4 AND FNDC5 IN AGE-RELATED MUSCULOSKELETAL DISEASES: A NEW PERSPECTIVE TO FIGHT CELLULAR AGING

A. Falvino[1], I. Cariati[2], R. Bonanni[3], B. Gasperini[1], A. Chiavoghilefu[4], A. Botta[1], V. Tancredi[2], U. Tarantino[4]

[1]Dept. of Biomedicine and Prevention, [2]Dept. of Systems Medicine, [3]Dept. of Biomedicine and Prevention, [4]Dept. of Clinical Sciences and Translational Medicine, Univ. of Rome Tor Vergata, Rome, Italy

Objective: Several molecular mediators play a key role in the aging process that characterizes osteoarthritis and osteoporosis by regulating cellular senescence, oxidative stress, and telomere shortening [1]. This study aimed to explore the different molecular mediators involved in the aging process. Specifically, we investigated the expression patterns of SIRT1, known to promote longevity, FNDC5, an exercise-induced myokine, and NOX4, an indicator of oxidative stress, in the muscle and cartilage bone tissues of osteoarthritic and osteoporotic patients, with the aim of identifying strategies to mitigate age-related musculoskeletal diseases [2–3].
Methods: Five osteoporotic patients and five osteoarthritic patients, undergoing hip arthroplasty for fragility fracture or coxarthrosis, respectively, were enrolled and classified following clinical and instrumental assessments. Surgical biopsies of bone, muscle, and cartilage tissues were used to perform histological, morphometric, and immunohistochemical analyses.
Results: Clinical and instrumental evaluations revealed significantly lower T-Score values in osteoporotic patients, with no age-related differences. Morphological and morphometric analyses demonstrated decreased bone volume, reduced trabecular thickness, and increased trabecular separation in osteoporotic compared to osteoarthritic bone tissue. Similar marked alterations were observed at the muscular and cartilaginous levels, including muscle fiber atrophy and the presence of hypertrophic chondrocytes. Immunohistochemical analysis revealed distinct expression patterns, with increased NOX4-positive cells and reduced FNDC5 and SIRT1-positive cells.
Conclusion: Cellular aging underlying age-related musculoskeletal disorders may result from altered expression patterns of SIRT1 and NOX4. Interestingly, a positive correlation between SIRT1 and FNDC5 expression levels suggests FNDC5 as a potential mediator of SIRT1's beneficial effects in musculoskeletal tissues.

EFFICACY AND SAFETY IN THE USE OF ROMOSOZUMAB IN POSTMENOPAUSAL WOMEN WITH SEVERE OSTEOPOROSIS AT HIGH RISK OF FRACTURE IN AN OUTPATIENT CASE SERIES FROM THE MARCHE REGION

A. Farina[1], E. Pingiotti[1], G. P. Martino[1], G. Bitti[1], S. Angelici[1]

[1]Internal Medicine, Ospedale Civile A. Murri, Fermo, Italy

Objective: To evaluate the efficacy and safety of the use of romosozumab (210 mg sc/28d) in postmenopausal women with severe osteoporosis at high risk of fracture in an outpatient series from the Marche region (1,2). Evaluation of patients treated in "real life" at a rheumatology center in the Marche (Rheumatology Outpatient Clinic c/o Internal Medicine Unit of Fermo).
Methods: Analysis on n. 6 postmenopausal women suffering from severe osteoporosis at high risk of fracture treated with romosozumab 210 mg sc/28d in association with calcium and vitamin D3. Demographic data, disease duration, comorbidities, and prior therapy were recorded at baseline. At baseline, at 3 months, at 6 months, at 12 months, the following variables were collected: hypocalcemia, dosage of vitamin D3, CTX, new fractures, cardiac complications (echocardiographic evaluation), cerebrovascular events; BP checks, cholesterol dosage, smoking abstention, bone densitometry based on the radiofrequency echographic multispectrometry (REMS) method. For each patient, adverse events and any suspension of therapy due to ineffectiveness or intolerance were recorded.
Results: No. 6 patients were included in the analysis with a median follow up of 9 months. The study demonstrated the maintenance rate is 85% at 6 months of all patients who have undergone therapy with romosozumab maintaining normal values of calcemia, vit d3, CTX, a picture of improvement in bone densitometric values with the REMS method in 75% (n. 4 patients) of the patients examined and a stability of the same values in the other 25% (n. 2 patients) Table; echocardiographic examination with normal EF values without episodes of heart failure. At 12 months, 85% of patients remain on therapy (1 suspended due to intolerance). The therapy was well tolerated and effective; general malaise and asthenia are reported in the vicinity of the therapy performed for a single patient.

N.	AGE	SPINAL FRACTURE	FEMORAL FRACT	REMS T0	REMS T 12 MONTHS	PREVIOUS THERAPIES
1	74	1		spinal -3 ; Femoral:-3.3	spinal:-2.6 ; Femoral:-3.0	ALENDRONATE
2	60	1		spinal: -2; Femoral.:-1	spinal: -0.9; Femoral:-0,2	ALENDRONATE
3	83	4		spinal:-3.3; Femoral:-3,4	spinal:-2.8; Femoral:-3,0	TERIPARATIDE,ALENDRONATE ,CLODRONATE
4	53	0		spinal: -2.9; Femoral:-2.8	spinal: -3.2; Femoral:-2.9	IBANDRONED
5	63	0	1	spinal.-0,6; Femoral.-1	spinal.-0.4; Femoral.-0.9	RESIDRONATO
6	69	0		spinal:-3; Femoral:-3	spinal:-2,7; Femoral:-3,9	ALENDRONATE , CLODRONATE

Conclusion: The data collected in the use of romosozumab in postmenopausal women suffering from osteoporosis at high risk of fracture, in our Marche case series, demonstrate an excellent maintenance rate and safety at twelve months. The data collected are limited by the small number of patients involved, but further morphological evaluations are planned to demonstrate the validity of this new therapy for osteoporosis.

P148
ASSOCIATION BETWEEN BODY MASS INDEX AND KNEE OSTEOARTHRITIS RADIOGRAPHIC STAGING IN ELDERLY PATIENTS

A. Fazaa[1], M. Rachdi[1], L. Ben Salem[2], S. Miladi[1], H. Boussaa[1], Y. Makhlouf[1], K. Ben Abdelghani[1], A. Laatar[1]

[1]Dept. of Rheumatology, Mongi Slim Hospital, [2]Family physician's office, La Marsa, Tunisia

Objective: Overweight is associated with higher mechanical load and exposure to systemic effects which could lead to cartilage damage. We aimed to assess the association between BMI and KOA grade based on Kellgren-Lawrence (K&L) criteria in elderly patients.
Methods: It's a cross-sectional study including patients aged $\geq$ 65 y, diagnosed with primary KOA according to the American College of Rheumatology criteria. Epidemioclinical data were gathered. BMI was calculated as weight in kilograms divided by squared height in meters. Based on the WHO's International classification, patients were placed into one of 3 BMI groups as follows: normal (18.5–24.9), overweight (25–29.9) and obese ($\geq$ 30). KOA grading was measured by K&L criteria from a conventional weight-bearing anteroposterior knee x-ray. Data analysis was performed using SPSS. The results were statistically significant if the p-value was < 0.05.
Results: 50 patients, 47 women (94%) and 3 men (6%) were enrolled. Mean age was 71.9 y [65–84]. All patients were retired. Their anterior professional activity was distributed as follows: 26 were housewives (52%), 5 had an office work (10%) and 19 had a physical labor (38%). Twenty-eight patients were married (56%), 20 were widower (40%) and two were divorced (4%). The most frequently noted comorbidities were high blood pressure (n = 42, 84%), diabetes (n = 15, 30%) and osteoporosis (n = 9, 28%). Mean disease duration was 98.4 $\pm$ 86.4 months [3–360]. Mean BMI was 29.9 $\pm$ 4.55 kg/m^2. 28 patients were obese (56%), 14 were overweight (28%) and 8 had normal BMI (16%). According to K&L criteria, mild (grade2) and moderate (grade3) KOA were observed in 24 (48%) and 26 (52%) patients respectively. In terms of gender, 12 women (25.5%) had a normal BMI, 13 (27%) were overweight and 22 (46.8%) were obese. All men were overweight and had a moderate KOA. A significant association between BMI and KOA grading was found (p = 0.01). In the normal BMI group, 6 patients (12%) had mild KOA and 2 (4%) had moderate KOA. However, in the overweight group, 10 (20%) patients had mild KOA while 4 (8%) had moderate KOA. In the obese group, 8 (16%) patients had mild KOA and 20 (52%) patients had moderate KOA. In patients with a BMI $\geq$ 25, statistically significant risk factor for KOA was age (OR = 1.15 [1.54–4.12], p = 0.04).
Conclusion: We found that a high BMI in associated with a more advanced radiological KOA. Therefore, improving BMI values toward normal in KOA older patients can help physicians have a better management of this common condition.

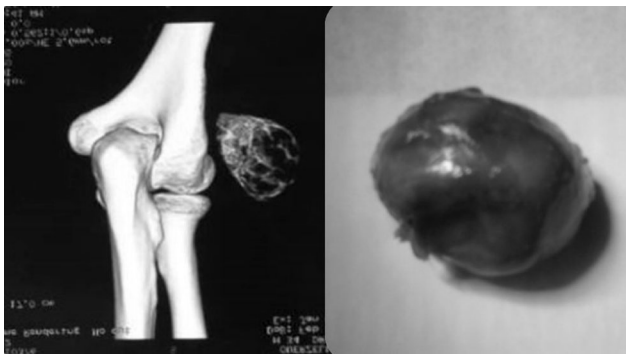
P149
A RARE CAUSE OF MYOSITIS OSSIFICANS: LOCALISATION AT THE ELBOW LEVEL

A. Fekih[1], J. Saadana[1], F. Chaouch[1], F. Boughattas[1], I. Aloui[1], I. Haddada[2], A. Abid[1]

[1]Orthopaedic Dept. Fattouma Bourguiba Univ. Hospital, Monastir, [2]Physical Medicine and Rehabilitation Dept. Taher Sfar Univ. Hospital, Mahdia, Tunisia

Myositis ossificans is rare and essential to be aware of as the appearance of ossifications within soft tissues, in young patients, always raises the concern of a local neoplastic process.
Casereport: This was a 34-year-old patient who consulted for a swelling of the left elbow that appeared 7 months after an accidental

electrification. Examination revealed a swelling opposite the lateral condyle measuring 6 cm in diameter, with little pain and no limitation of mobility or sensorimotor deficit. The standard X-ray was normal, and a complementary CT scan was in favour of an ossifying myositis of the extensor carpi muscles at the elbow. A biopsy of the lesion confirmed the diagnosis. Enucleation of the tumour was performed without incident. At the last follow-up, the patient was asymptomatic with normal elbow function.



Discussion: The etiopathogenesis of myositis ossificans is unclear, but it appears that a focus of muscle necrosis or a haematoma may be the cause of the lesion. Electrification is a rare cause. The most common sites are the quadriceps and biceps brachii. The differential diagnosis is with infectious and sarcomatous lesions. The natural evolution is regression without sequelae, with sometimes persistence of an intramuscular ossified nucleus, more or less voluminous. Treatment is essentially medical. Surgery is only indicated in case of functional or mechanical limitations.
Conclusion: The problem with myositis ossificans is early diagnosis, as the clinical and radiological presentation may raise fears of a local malignant process. However, if there is any doubt, a biopsy is required.

P150
ATYPICAL PHYSEAL FRACTURE-SEPARATION OF THE LOWER END OF THE TIBIA IN CHILDREN: A CASE REPORT

A. Fekih[1], J. Saadana[1], F. Chaouch[1], H. Ratib[1], I. Aloui[1], I. Haddada[2], A. Abid[1]

[1]Orthopaedic Dept. Fattouma Bourguiba Univ. Hospital, Monastir, [2]Physical Medicine and Rehabilitation Dept. Taher Sfar Univ. Hospital, Mahdia, Tunisia

Physeal fracture-separation of the lower end of the tibia and fibula are common in the paediatric population.
Casereport: A 12-year-old child was the victim of a sports accident resulting in a closed trauma of the right ankle. The radiological assessment concluded that the fracture was a physeal fracture-separation of the lower end of the tibia, type II according to the Salter and Harris classification on the front and side views, associated with a fracture of the lateral malleolus. Treatment consisted of external reduction followed by percutaneous pinning of the medial malleolus under fluoroscopic control. The result was satisfactory at 6 months with bone healing and correct ankle mobility.

Discussion: Injuries to the conjugal plates of the ankle can affect the growth of the limb. The literature describes the Mac Farland fracture, the Tillaux fracture and the Triplane fracture. The fracture described here is not one of these types. Classically, type I and II lesions were treated orthopaedically, whereas type III and IV lesions are treated surgically, even percutaneously, provided that anatomical reduction is achieved and that attempts to pin the conjugal plate are reduced. Some authors have found no significant difference in the occurrence of misalignment between open surgery and percutaneous treatment.
Conclusion: Physeal fracture-separation of the lower end of the tibia require appropriate and effective treatment to prevent complications.

P151
BIMALLEOLAR EQUIVALENT FRACTURES: A SERIES OF 30 CASES

A. Fekih[1], J. Saadana[1], F. Chaouch[1], H. Belgacem[1], I. Aloui[1], I. Haddada[2], A. Abid[1]

[1]Orthopaedic Dept. Fattouma Bourguiba Univ. Hospital, Monastir, [2]Physical Medicine and Rehabilitation Dept. Taher Sfar Univ. Hospital, Mahdia, Tunisia

Objective: The bimalleolar equivalent fracture is a fracture of the lateral malleolus in association with a medial osteo-ligament injury. It often goes unnoticed and requires adequate and rapid surgical management.
Methods: This is a retrospective study of 30 cases of bimalleolar equivalent fractures followed over a period of 7 y. The diagnosis was confirmed on radiographs of the ankle in front and in side by the Skinner test. Treatment was orthopaedic in minimally displaced or non-displaced fractures and surgical in displaced and off-center fractures by an external screwed plate more or less associated with screwing of the tibiofibular syndesmosis. We adopted Joy's scoring for assessing anatomical results and Vidal's radio-clinical scoring for assessing functional results.

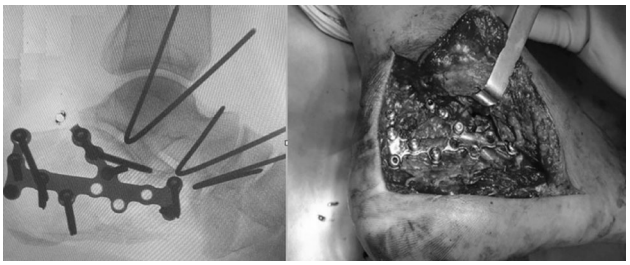
Results: The average follow-up was 3.5 y. Three fractures were open on the lateral side. Surgical treatment was indicated in 28 patients and orthopaedic treatment in the two remaining. Surgical treatment consisted of osteosynthesis of the lateral malleolus with a screw plate. In five cases, an internal approach was performed for ligament suture or reinsertion of a bone fragment. There were three early infectious complications; four delayed healing and five late complications (3 late sepsis, 1 post-traumatic arthritis and 1 malunion). The anatomical results were good in all cases. The functional outcome was good in 53.3% of cases and acceptable in 33.3%.
Conclusion: Bimalleolar equivalent fractures are uncommon in ankle traumatology; a well conducted treatment is the best guarantor of a good anatomical and functional outcome.

P152
CALCANEAL ARTICULAT FRACTURES: FUNCTIONAL VERSUS SURGICAL TREATMENT ABOUT A SERIES OF 80 CASES

A. Fekih[1], J. Saadana[1], F. Chaouch[1], A. Mdaoukhi[1], I. Aloui[1], I. Haddada[2], A. Abid[1]

[1]Orthopaedic Dept. Fattouma Bourguiba Univ. Hospital, Monastir, [2]Physical Medicine and Rehabilitation Dept. Taher Sfar Univ. Hospital, Mahdia, Tunisia

Objective: Articular fractures of the calcaneus present a real therapeutic challenge with considerable functional and economic impact. The treatment continues to be at the heart of the controversy between conservative treatment and osteosynthesis.
Methods: This is a retrospective comparative study over a period of 11 y, including 43 cases of articular calcaneal fractures treated functionally, and 37 cases treated surgically. Functional (return to work, time to weight-bearing, KITAOKA score) and radiological (time to consolidation, Bohler angle at last follow-up, Kellgren–Lawrence subtalar osteoarthritis score, assessment of the hind foot axis) results were collected at last follow-up.



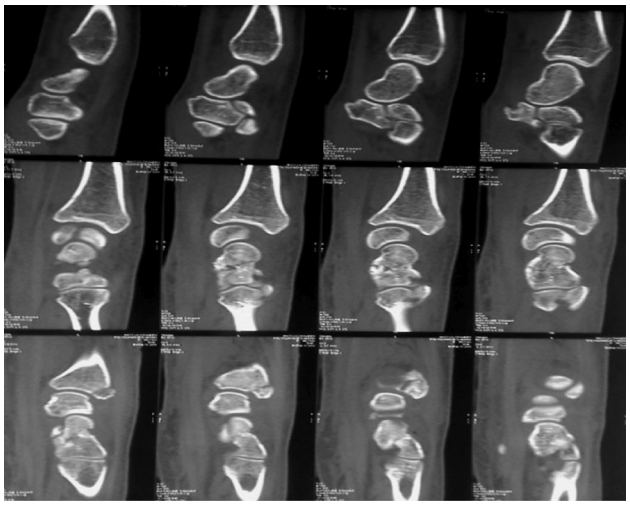
Results: The mean age was 36.5 y. Most fractures were classified as DUPARC V (41.3%). The mean initial Bohler angle was 14.3° in the functional treatment group vs. 11.4° in the surgical treatment group. Vertical sinking was the most frequent (52.5%). The KITAOKA score was comparable between the two groups, and the time to weight-bearing and return to work was shorter in the surgical group. Consolidation was achieved in all cases within an average of 12 weeks with no significant difference between the two groups. The mean Bohler angle at the last follow-up was 10.7° in the functional group vs. 21.7° in the surgical group. Subtalar osteoarthritis as assessed by Kellgren–Lawrence was more prevalent in functionally treated patients than in surgically treated patients.
Conclusion: We recommend surgical treatment whenever there is a zero or negative Bohler angle, varus of the greater tuberosity, mixed depression or external bone impingement.

P153
CONCURRENT FRACTURE OF THE TRIQUETRUM, CAPITATE BONE AND RADIAL EPIPHYSIS IN ADOLESCENTS: A CASE REPORT

A. Fekih[1], J. Saadana[1], F. Chaouch[1], A. Ltifi[1], I. Aloui[1], I. Haddada[2], A. Abid[1]

[1]Orthopaedic Dept. Fattouma Bourguiba Univ. Hospital, Monastir, [2]Physical Medicine and Rehabilitation Dept. Taher Sfar Univ. Hospital, Mahdia, Tunisia

Fractures of the carpal bones with the exception of the scaphoid are much rarer. Despite a better knowledge of these lesions and the increasing improvement of imaging procedures, these fractures are still often discover and treat with delay.
Casereport: This is an 18-year-old female patient who presented with a closed left wrist injury following a fall in hyperflexion. Standard radiology and a CT scan of the wrist showed a horizontal fracture of the capitate, an oblique fracture of the triquetrum and a compound fracture of the radial epiphysis. Orthopaedic treatment with a plaster cast cuff holding the thumb for 6 weeks was indicate. The evolution was favourable. After removal of the cast, a rehabilitation protocol was instituted. At the last follow-up, the patient had regained proper function of her wrist with full mobility.



Discussion: Triquetrum fractures are the most common carpal fractures after scaphoid fractures. They are often associated with other lesions such as fractures of the lower end of the radius and especially perilunate dislocation of the carpus. Capitate bone fractures were found in 1.4% of all carpal bone fractures. The association of these two fractures is rarely described in the literature. Well-conducted orthopaedic treatment often gives good results. Among wrist fractures, if the scaphoid fracture remains the most frequent injury, other fractures are by no means exceptional.
Conclusion: It is important to know how to look for and diagnose these injuries early, as it is at this stage that treatment is the simplest and most effective.

P154
CYCLOPS SYNDROME AFTER ANTERIOR CRUCIATE LIGAMENTOPLASTY: A TWO-CASE REPORT

A. Fekih[1], J. Saadana[1], F. Chaouch[1], H. Haj Taieb[1], I. Aloui[1], I. Haddada[2], A. Abid[1]

[1]Orthopaedic Dept. Fattouma Bourguiba Univ. Hospital, Monastir, [2]Physical Medicine and Rehabilitation Dept. Taher Sfar Univ. Hospital, Mahdia, Tunisia

Cyclops syndrome has been described as a loss of extension after anterior cruciate ligament (ACL) reconstruction due to proliferation of a fibrovascular nodule on the ACL graft.
Casereport: These were two patients operated on by ACL ligamentoplasty using a patellar tendon graft with simple postoperative recovery. Respectively at 4 and 6 months postoperatively, both patients recurred to gonalgia exacerbated by the extension of the knee. The diagnosis of suspected Cyclops syndrome was confirmed by MRI. Both patients were operated under arthroscopy. The graft had a good hold and the nodule was excised using the Shaver knife. At the last follow-up of one year, both patients were satisfied with full and painless knee mobility.

Discussion: Cyclops syndrome is a complication that can occur in up to 10% of patients who have undergone ACL ligamentoplasty. The onset of Cyclops syndrome can be early after ligamentoplasty, as early as the second month postoperatively. The pain is very characteristic and is provoked or aggravated by extending the knee. The diagnosis is essentially clinical and is confirmed by MRI. In the absence of a favourable spontaneous evolution, the treatment consists of arthroscopic debridement of the nodule. Sometimes a plasty of the intercondylar notch is necessary.
Conclusion: Cyclops syndrome is a complication of ACL ligamentoplasty, the origin of which is still controversial with a difficult calculation of the risk of occurrence. It represents an important factor of knee morbidity and the treatment consists of arthroscopic excision of the nodule.

P155
ENUCLEATION OF THE NAVICULAR BONE: A RARE LESION

A. Fekih[1], J. Saadana[1], F. Chaouch[1], A. Abbes[1], I. Aloui[1], I. Haddada[2], A. Abid[1]

[1]Orthopaedic Dept. Fattouma Bourguiba Univ. Hospital, Monastir, [2]Physical Medicine and Rehabilitation Dept. Taher Sfar Univ. Hospital, Mahdia, Tunisia

The severity of foot trauma varies greatly. Fracture-enucleation of the navicular bone is a very rare but serious entity requiring open reduction most often.
Casereport: This is a 25-year-old patient who consulted for a closed trauma of the left foot following a fall from a height of 3 m. X-ray followed by CT scan showed a comminuted fracture with dorsal enucleation of the navicular bone. The patient underwent emergency surgery with removal of the bone fragments and a bone graft was interposed with stabilisation by two pins. At two months postoperatively, the pins were removed after integration of the graft. At the last follow-up, the patient was asymptomatic with good mobility of the ankle.

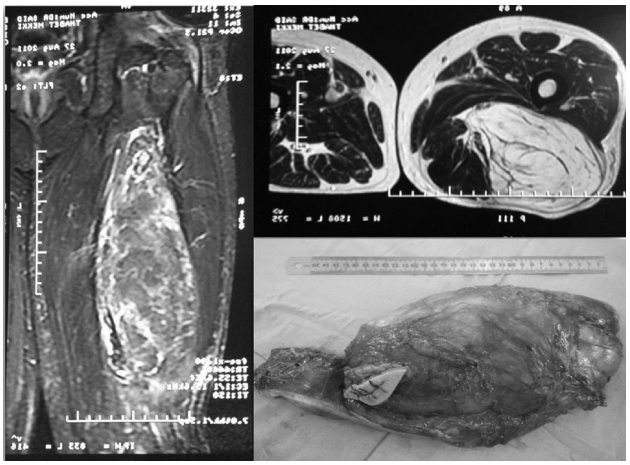
Discussion: Fracture-enucleation of the navicular bone is rare and results either from direct impact or indirectly from a fall on tiptoe resulting in crushing of the navicular bone between the head of the talus and the first cuneiform. A CT scan is necessary to better assess the injury. Treatment requires open reduction with screw fixation. Sometimes an immediate arthrodesis is indicate in case of significant comminution. The complications are bone necrosis and malunion. The evolution can be towards arthrosis or the appearance of a post-traumatic flat foot by collapse of the internal arch.
Conclusion: Enucleation of the navicular bone is a rare and serious lesion in functional terms. Talonavicular arthrodesis is the solution of choice provided that the length of the medial arch is preserved.

P156
GIANT LIPOSARCOMA OF THE THIGH: ABOUT TWO-CASE REPORT

A. Fekih[1], J. Saadana[1], F. Chaouch[1], F. Boughattas[1], I. Aloui[1], I. Haddada[2], A. Abid[1]

[1]Orthopaedic Dept. Fattouma Bourguiba Univ. Hospital, Monastir, [2]Physical Medicine and Rehabilitation Dept. Taher Sfar Univ. Hospital, Mahdia, Tunisia

Soft tissue sarcomas are rare especially liposarcoma which account for one-fifth of them. We report two case of giant liposarcoma of the thigh treated surgically with good outcome.
Casereports: Case 1: This was a 48-year-old man who consulted for a swelling of the right thigh of progressive onset. MRI showed fatty invasion of the biceps femoris with a discrete mass effect on the surrounding structures without any sign of local aggressiveness.
Case 2: A 68-year-old woman consulted for a rapidly increasing swelling of the left thigh. MRI concluded that the tumor was lipomatous in nature with central necrosis in the adductor fossa. Surgical biopsy of both patients was in favour of a well differentiated liposarcoma. The extension assessment was negative; the procedure was to operate on both patients with a carcinological excision. At the last follow-up of one year, the patients were doing well with no recurrence or secondary localization.



Discussion: Liposarcoma is often located in the deep tissues of the limbs, particularly in the thighs. The diagnosis of certainty is made by surgical biopsy. Treatment is mainly surgical with wide or radical resection. Neo-adjuvant chemotherapy with or without radiotherapy is an effective procedure for conservative resection.
Conclusion: Liposarcoma of the limbs is a rare lesion. MRI is the reference examination for locoregional extension assessment and post-treatment follow-up. Biopsy and anatomopathological examination remain the keys to diagnosis and management is multidisciplinary.

P157
ISOLATED FRACTURE OF THE TRIQUETRUM: ABOUT TWO CASES

A. Fekih[1], J. Saadana[1], F. Chaouch[1], H. Ratib[1], I. Aloui[1], I. Haddada[2], A. Abid[1]

[1]Orthopaedic Dept. Fattouma Bourguiba Univ. Hospital, Monastir, [2]Physical Medicine and Rehabilitation Dept. Taher Sfar Univ. Hospital, Mahdia, Tunisia

Isolated triquetrum fracture is rare in carpal bone trauma. It may go unnoticed and sometimes requires CT scanning for diagnosis.
Casereports: Case 1: This is a 38-year-old patient who consulted for closed trauma of the right wrist following a fall from a height with landing on the palm of the hand. X-ray showed a nondisplaced triquetrum fracture. Orthopaedic treatment with a plaster cast was indicated for one month.
Case 2: A 26-year-old patient consulted with open trauma of the right wrist following a fall on a sharp object. X-ray showed a displaced triquetrum fracture. The patient underwent emergency surgery with cross pinning of the triquetrum.

The evolution was favourable with consolidation of the fracture and normal mobility of the wrist for the first patient. For the second patient, despite the consolidation of the fracture, he still has discomfort when mobilizing the wrist.

Discussion: Isolated triquetrum fracture is rarely encountered and is classified as a corporal and parcel fracture. It is deceptively benign and very often associated with a fracture of the lower end of the radius or another carpal bone. Clinically, there is painful swelling of the wrist with reduced mobility. A radiological assessment is necessary to confirm the diagnosis, sometimes aided by CT scan. Treatment is usually orthopaedic, and surgical in the case of a displaced fracture. The evolution is generally favourable however; cases of pseudarthrosis or osteonecrosis have been reported.
Conclusion: Isolated triquetrum fractures are rare. The earlier the diagnosis the better the prognosis.

P158
OSTEOCHONDRITIS DISSECANS OF THE MEDIAL FEMORAL CONDYLE: A CASE REPORT OF CONCOMITANT INVOLVEMENT OF BOTH KNEES

A. Fekih[1], J. Saadana[1], F. Chaouch[1], H. Belgacem[1], I. Aloui[1], I. Haddada[2], A. Abid[1]

[1]Orthopaedic Dept. Fattouma Bourguiba Univ. Hospital, Monastir, [2]Physical Medicine and Rehabilitation Dept. Taher Sfar Univ. Hospital, Mahdia, Tunisia

Osteochondritis dissecans of the medial femoral condyle is a rare lesion even more so its bilaterality. We report a case of bilateral involvement in a young adult.
Casereport: This is a 35-year-old patient, a casual sportsman who consulted for bilateral gonalgia more accentuated on the right side. MRI showed osteochondritis dissecans of both medial femoral condyles in zone 2 on the frontal view and in intermediate zone C on the lateral view. According to Bedouelle's classification, the anatomopathological type of the lesion was type III in the left knee and type IV in the right knee. The patient was operated with screwing of the lesion on the left side and removal of the foreign body and Pridie perforations for the right side. At the last follow-up of two years, pain was significantly reduced with improvement in the mobility area of both knees.

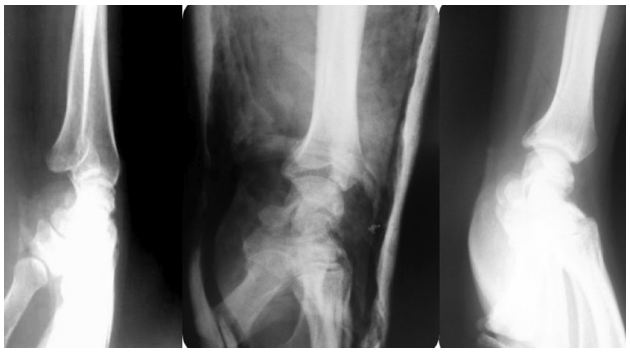
Discussion: Osteochondritis of the knee is often unilateral, but rare cases of bilateral involvement have been reported. The first step in treatment is to accurately assess the stage of injury. The reference examination is MRI. The therapeutic indications are based on the anatomo-radiological types (Bedouelle classification). The main therapeutic choices are orthopaedic treatment, perforations, refixing of the fragment, mosaicplasty and chondrocyte transplantation. The outcome depends on the type of the disease.
Conclusion: Although bilateral osteochondritis dissecans of the medial femoral condyle is a rare lesion, its management is the same as for unilateral involvement and it has benefited from new advances, notably chondrocyte transplantation.

P159
PALMAR DISLOCATION OF THE INFERIOR RADIO-ULNAR JOINT: A CASE REPORT AND LITERATURE REVIEW

A. Fekih[1], J. Saadana[1], F. Chaouch[1], A. Mdaoukhi[1], I. Aloui[1], I. Haddada[2], A. Abid[1]

[1]Orthopaedic Dept. Fattouma Bourguiba Univ. Hospital, Monastir, [2]Physical Medicine and Rehabilitation Dept. Taher Sfar Univ. Hospital, Mahdia, Tunisia

Palmar dislocation of the inferior radioulnar joint is poorly reported in the literature due to the rarity of this lesion, which goes unnoticed in half of the cases.
Casereport: This is a 46-year-old female patient who consulted for wrist trauma with possible wrist flexion and extension and painful pronosupination block. Radiography had shown a palmar dislocation of the inferior radioulnar joint and a fracture of the ulnar styloid. The patient had a reduction followed by cast immobilisation for six weeks. At the last follow-up, there was good wrist mobility with a slight decrease in clamping force.



Discussion: Distal radioulnar joint dislocation is an often-late diagnosed injury, going unnoticed in 50% of cases. Clinical examination will find retained mobility in flexion and extension with a marked decrease in pronation amplitude in the case of palmar dislocation, or even a blockage. The frontal radiograph shows a distal radioulnar superposition and the side will show a displacement of the distal ulna. In contentious situations, comparative x-rays or a CT scan can confirm the diagnosis. The first step in treatment is reduction under general anaesthesia followed by cast immobilisation. Irreducibility indicates a late diagnosis or interposition of the triangular carpal ligament requiring surgical treatment with dislocation and fixation by radioulnar pinning.
Conclusion: Early diagnosis based on clinical and radiological findings improves the prognosis of orthopaedic treatment, surgery being reserved for failures of the orthopaedic treatment and for irreducible forms.

P160
PARCEL FRACTURE OF THE TALUS IN CHILDREN

A. Fekih[1], J. Saadana[1], F. Chaouch[1], A. Ltifi[1], I. Aloui[1], I. Haddada[2], A. Abid[1]

[1]Orthopaedic Dept. Fattouma Bourguiba Univ. Hospital, Monastir, [2]Physical Medicine and Rehabilitation Dept. Taher Sfar Univ. Hospital, Mahdia, Tunisia

Parcel fractures of the talus in children are rare and usually result from violent trauma. The association with other foot and ankle injuries worsens the prognosis of these fractures, which must be managed early and appropriately.
Casereport: This was a 9-year-old child who had a fall from the stairs resulting in a closed right ankle injury. Examination found oedema over the anterior side of the tibio-talar joint and limited painful mobilisation of the ankle. X-ray and CT scan showed a patchy fracture of the articular surface of the talar trochlea. Treatment was surgical with open reduction and stabilisation with a mini screw driven under the cartilage. At the last follow-up, the fracture was consolidated with correct ankle mobility without discomfort to walking.

Discussion: Parcel fractures of the talar dome are most often osteochondral fractures. They should be investigated on radiographs and if necessary by CT scanning or MRI. Depending on the size and displacement of the fragment, treatment may be orthopaedic or surgical. A small fragment can be removed arthroscopically. If it is larger, it can be fixed by screw fixation.
Conclusion: Although talus fractures in children are rare, they are prone to complications that can be disabling. Their therapeutic management has clearly benefited from the progress of imaging and in particular CT scanning. The reduction must be as anatomical as possible to guarantee a better result.

P161
RESULTS OF SURGICAL TREATMENT OF SUPRA- AND INTRA-ARTICULAR FRACTURES OF THE DISTAL HUMERUS IN ADULTS: A SERIES OF 105 CASES

A. Fekih[1], J. Saadana[1], F. Chaouch[1], H. Haj Taieb[1], I. Aloui[1], I. Haddada[2], A. Abid[1]

[1]Orthopaedic Dept. Fattouma Bourguiba Univ. Hospital, Monastir, [2]Physical Medicine and Rehabilitation Dept. Taher Sfar Univ. Hospital, Mahdia, Tunisia

Objective: Supra-and intra-articular fractures of the distal humerus are serious and complex injuries given the difficulty of management and the potential consequences that can affect the elbow.
Methods: This is a retrospective study of 105 patients operated on for supra- and intra-articular fractures of the distal humerus. The approach was posterior via a transolecranial approach. Osteosynthesis was performed by an external fixation plate associated with internal column osteosynthesis (plate, screwing).

Results: Preoperatively, 26.6% of the fractures were simple classified as C1, 48.5%, had metaphyseal comminution classified as C2 and 24.9% had epiphyseal comminution classified as C3. 18 cases had a cutaneous opening. At the last follow-up, mean flexion was 120°, mean extension − 16°, mean pronation 82° and mean supination 73°. The mean MEPS score was 82.3 points. 36 cases had excellent results, 27 cases had good results, 19 cases had fair results and 23 cases had poor results. Five cases had postoperative infection, six patients had neurological complications mainly of the ulnar nerve, 10 cases had debricolage of the material, 49 cases had elbow stiffness, five cases had pseudoarthrosis of the focus and eight cases of the olecranon.
Conclusion: The prognosis of supra- and intra-articular fractures of the distal humerus in adult was considered very poor due to the frequent progression to elbow stiffness and osteoarthritis. Thanks to advances in osteosynthesis, the prognosis of these fractures has improved markedly, especially after the introduction of new implants that respect the anatomy of the humeral palette.

P162
THE LATERAL DISCOID MENISCUS: A TWO-CASE REPORT

A. Fekih[1], J. Saadana[1], F. Chaouch[1], A. Abbes[1], I. Aloui[1], I. Haddada[2], A. Abid[1]

[1]Orthopaedic Dept. Fattouma Bourguiba Univ. Hospital, Monastir, [2]Physical Medicine and Rehabilitation Dept. Taher Sfar Univ. Hospital, Mahdia, Tunisia

Lateral discoid meniscus is the most common congenital meniscal anomaly. It is often discovered at a young age and is rarely diagnosed in adulthood.
Casereport: These two patients aged 26 and 45 years consulted for gonalgia with external meniscal syndrome. Standard radiographs were normal, so an MRI was ordered and showed a discoid lateral meniscus with a transverse tear in both cases. Arthroscopy was performed to confirm the diagnosis of discoid lateral meniscus, which was type I according to Watanabe's classification in both cases. A meniscoplasty was performed to restore the meniscus to a near-normal shape. At the last follow-up of one year, the complaints of both patients were significantly reduced with normal knee function.

Discussion: The discoid meniscus is a meniscal malformation of variable frequency in the populations studied. It is usually external or lateral and can become symptomatic even if there is no associated lesion. Surgical intervention is then indicated and aims to restore physiology to the meniscus while removing any damaged areas. Maximum meniscal sparing must be the rule because of the deleterious long-term consequences on the cartilage of a total meniscectomy.
Conclusion: The main problem with a discoid meniscus is deciding when to operate. Indeed, the tendency in the case of a meniscus that is not very troublesome is often to wait. In the case of meniscus tears, conservative treatment by meniscoplasty is then indicated.

P163
THE MUSCULAR HYDATID CYST: A RARE LOCATION IN THE CALF

A. Fekih[1], J. Saadana[1], F. Chaouch[1], F. Boughattas[1], I. Aloui[1], I. Haddada[2], A. Abid[1]

[1]Orthopaedic Dept. Fattouma Bourguiba Univ. Hospital, Monastir, [2]Physical Medicine and Rehabilitation Dept. Taher Sfar Univ. Hospital, Mahdia, Tunisia

Hydatidosis is secondary to the development in humans of the larval form of the dog taenia: Echinococcus granulosus. It mainly affects the liver and lung and exceptionally the soft tissues.
Casereport: This is a 22-year-old female patient who consulted for a painful swelling of the calf that had been evolving for 6 months without any notion of trauma. The radiograph was normal and the MRI showed two cystic masses in the posterior compartment of the left calf related to ruptured hydatid cysts. Chest X-ray and abdominal ultrasound were normal; the patient was operated on with an internal approach allowing total resection of the cysts. At the last follow-up, there was no local recurrence and hydatid serology was negative.

Discussion: The muscular location of hydatid cysts is rare even in endemic countries.
Clinically, there is a latency of expression of these cysts, which present as inert tumours, progressively increasing in volume. Ultrasound and CT scans help to orientate the diagnosis by showing a more or less heterogeneous liquid image with visualisation of daughter vesicles. Pericystectomy is the surgical method of choice, but it is sometimes difficult to perform, especially in the absence of cleavage planes, deep cysts or in contact with vascular and nerve elements.
Conclusion: Soft tissue hydatid cyst is a rare localization with slow development and local extension. It should be considered especially in subjects from an endemic area and the necessary investigations should be requested in order to make an early diagnosis and avoid therapeutic errors.

P164
DIFFERENTIAL DIAGNOSIS AND TREATMENT OF MYOTONIC AND MYOFASCIAL SYNDROMES OF NECK PAIN

A. Filipovich[1]

[1]National Science and Practice Centre of Medical Assessment and Rehabilitation, Yukhnovka, Belarus

Objective: The dynamic monitoring of 195 patients with myotonic and myofacial syndromes of neck pain was done against the control group of 45 people.
Methods: MRI of cervical and vertebrocranial areas of spinal column, electromyography of 7 to 9 relevant muscles, finding of the "key" muscle and the overall computer aided assessment of osteomuscular, cardiorespiratory and oxygen transport system disorders.
Results: Clinical and electromyographic criteria for diagnosis of myotonic and myofascial syndromes of neck pain were identified based on the occurrence rates. The role of major system disorders in pathogenesis of neurological manifests of neck pain was studied. New therapeutic approaches to stopping pain and myotonic syndromes were developed; the effectiveness of early rehabilitation measures was demonstrated. The prevailing myotonic syndromes were identified which were the musculus obliquus capitis inferior syndrome (in 68, or 39.4% patients); superscapular area syndrome (33% of patients); musculus scalenus anterior and musculus scalenus medius syndromes (18.9%); musculus pectoralis minor syndrome (9.7%). Hypodynamia caused system disorders were noted in 78.3% patients including excessive body mass and fat content; reduced blood circulation rate and heartbeat volume and the pronounced decrease of PWC170. The most informative spondylographic findings were reduced thickness of posterior areas of intervertebral disks from CI to CVII (52.3 to 77.9% of patients), cervical lordosis impression (76.4%) and uncovertebral arthroses (58.2%).
Conclusion: The most seriously affected ("key") muscles in neck pain patients were found. Diagnosis and treatment strategies for neck pain patients were developed.

P165
TECHNICAL MEANS OF REHABILITATION FOR PATIENTS WITH LOW BACK PAIN

A. Filipovich[1]

[1]National Science and Practice Centre of Medical Assessment and Rehabilitation, Yukhnovka, Belarus

Methods: 78 patients with myotonic syndrome. Patients went through the clinical estimation of neurologic status, manual testing of muscles, CT and MRI of back bone lumbar department, interferential and needle electromyography of the most damaged muscular groups, dosed loading veloergometry, revasography of feet, and shins.
Results: Medical-rehabilitation complex on damaged extremity was approbated in 27 patients with MT syndrome. The complex included oral reception of katadolon (100 mg 3 times a day for 10 d), tractions on Fintrac-471 table (with force from 3 to 55 kg, a course of 8–10 sessions) and also acupuncture with use acupuncture points of general action with vascular autonomic nervous system orientation (G14, MJ6, E36, RP6, TR5, V40) and locally segmented points on the most damaged muscular groups (AT60, VB30 with deep introduction to piriform muscle; VB 34, VB41, F3).
Conclusion: After treatment damaged extremity pain has completely disappeared in 19 patients, pain essentially decreased and increased tolerance of physical activity in 6 patients. It is established, that katadolon shows not only analgesic and neuroprotective, but also myorelaxing action on muscles of pelvic girdle and feet in patients with acute and chronic pain syndrome.

P166
DIFFERENTIAL DIAGNOSIS AND TREATMENT OF MYOTONIC AND MYOFASCIAL SYNDROMS OF NECK PAIN

A. Filipovich[1]

[1]National Science and Practice Centre of Medical Assessment and Rehabilitation, Yukhnovka, Belarus

Methods: The dynamic monitoring of 195 patients with myotonic and myofacial syndromes of neck pain was done against the control group of 45 people. An extended neurological examination was carried out which included roentgenometry of cervical and vertebrocranial areas of spinal column, electromyography of 7 to 9 relevant muscles, finding of the "key" muscle and the overall computer aided assessment of osteomuscular, cardiorespiratory and oxygen transport system disorders.
Results: Clinical and electromyographic criteria for diagnosis of myotonic and myofascial syndromes of neck pain were identified based on the occurrence rates. The role of major system disorders in pathogenesis of neurological manifests of neck pain was studied. New therapeutic approaches to stopping pain and myotonic syndromes were developed; the effectiveness of early rehabilitation measures

was demonstrated. The prevailing myotonic syndromes were identified which were the musculus obliquus capitis inferior syndrome (in 68, or 39.4% patients); superscapular area syndrome (33% of patients); musculus scalenus anterior and musculus scalenus medius syndromes (18.9%); musculus pectoralis minor syndrome (9.7%). Hypodynamia caused system disorders were noted in 78.3% patients including excessive body mass and fat content; reduced blood circulation rate and heartbeat volume and the pronounced decrease of PWC170. The most informative spondylographic findings were reduced thickness of posterior areas of intervertebral disks from CI to CVII (52.3 to 77.9% of patients), cervical lordosis impression (76.4%) and uncovertebral arthroses (58.2%).

Conclusion: The most seriously affected ("key") muscles in neck pain patients were found. Diagnosis and treatment strategies for neck pain patients were developed.

P167
THE LONG TERM RESULTS OF TREATMENT AND REHABILITATION OF MULTIPLE SCLEROSIS PATIENTS

A. Filipovich[1]

[1]National Science and Practice Centre of Medical Assessment and Rehabilitation, Yukhnovka, Belarus

Methods: Long term results of treatment of multiple sclerosis were studied. The dynamic monitoring of 110 patients over the period of 1–1.5 years following the successful in-hospital treatment of MS was carried out. Clinical methods, CT and MRI of cerebrum and spinal cord, and a patented radioimmunobiological assay of the myelinotoxic activity (MTA) of blood serum were used.

Results: Four groups of patients were distinguished: group 1 (36 patients; 32.7%) – patients with low MTA level (4.56 × 0.7 units) after successful hormone therapy. No rehabilitation was required out afterwards. Group 2 included 41 patients (37.3%) with low MTA level (3.76 × 0.81) after hormone and corrector therapy; a rehabilitation course was carried out at a later stage. Group 3 consisted of 22 patients (20.0%) that required long term immunomodulating therapy due to a higher rate of demyelinisation (MTA = 19.2 × 0.43). The remaining 11 patients (group 4, 10.0%) with moderate rate of demyelinisation (16.4 × 0.52) were prescribed general health improvement therapy and rehabilitation based on intensive motional activity and physical exercise.

Conclusion: Hormone therapy helps to reduce the demyelinisation rate to acceptable level within 2 to 4 month. The subsequent rehabilitation helps to achieve the extended remission period. However, long time after treatment of acute MS the hormone therapy is not justified.

P168
PATHOGENESIS OF COGNITIVE NEUROSIS-LIKE DISORDERS IN PATIENTS WITH INITIALLY CHRONIC VIRAL ENCEPHALITIS

A. Filipovich[1]

[1]National Science and Practice Centre of Medical Assessment and Rehabilitation, Yukhnovka, Belarus

Methods: Brain MRI, research of cerebrospinal fluid and its dynamic, definition of a spectrum of 20 basic amino acids in blood serum and liquor.

Results: 126 patients with initial chronic viral encephalitis were surveyed. The most significant and informative appeared the decrease in free amino acids: serine (5.12 ± 0.15 mg/l; $P < 0.01$), glycine (6.59 ± 0.2 mg/l; $P < 0.001$), histidine (5.11 ± 0.12 mg/l; $P < 0.05$), alanine (12.93 ± 0.12 mg/l; $P < 0.001$), arginine (5.62 ± 0.09 mg/l; $P < 0.001$), tyrosine (5.08 ± 0.09 g/l; $P < 0.001$), meteonin (2.19 ± 0.12 mg/l; $P < 0.001$), phenylalanine (3.36 ± 0.14 mg/l; $P < 0.001$), lysine (6.94 ± 0.17 mg/l; $P < 0.001$), leucine (4.64 ± 0.14 mg/l; $P < 0.001$), threonine (6.2 ± 0.14 mg/l; $P < 0.001$), glutamic acids (2.99 ± 0.16 mg/l; $P < 0.001$) at simultaneous increase in concentration of tryptophan (7.36 ± 0.12 mg/l; $P < 0.001$). Among the connected amino acids in CMŽK the reliable increase, in comparison with control group healthy participants was observed, glycine (11.44 ± 0.13 mg/l; $P < 0.001$), histidine (6.12 ± 0.11 mg/l; $P < 0.001$), methionine (5.86 ± 0.07 mg/l; $P < 0.01$), lysine (19.42 ± 0.16 mg/l; $P < 0.001$), leucine (18.94 ± 0.14 g/l; $P < 0.01$), threonine (18.94 ± 0.14 g/l; $P < 0.001$), glutamic acids (9.69 ± 0.17 g/l; $P < 0.001$).

Conclusion: In pathogenesis of cognitive neurosis like disorders in patients with initial chronic viral encephalitis the great importance has the decrease in content of the majority free and bonded amino acids in cerebrospinal fluid and blood serum (alanine, glycine, glutamic acids, leucine, methionine, threonine, tryptophan, phenylalanine) at simultaneous increase of tryptophan, that it must be considered at carrying out of therapeutic actions.

P169
IMMUNOLOGICAL DISORDERS IN MULTIPLE SCLEROSIS PATIENTS WITH THE PRESENCE OF FOOD ALLERGY

A. Filipovich[1]

[1]National Science and Practice Centre of Medical Assessment and Rehabilitation, Yukhnovka, Belarus

Objective: 102 multiple sclerosis patients 19–33 years old were examined against the control group of 20 healthy people.

Methods: MRI and immunological studies.

Results: All patients on the level of IgE in blood serum of 20 basic food products are divided into four groups: the first (13 pers, 12.7%) with the absence of IgE in serum, second (29 pers., 28.5%) with the presence of IgE (threshold 0.35–0.69 IU/ml); third (45 pers., 44.1%) with a moderate increase in IgE (0.70–3.49 IU/ml); fourth (15 pers., 14.7%) with a significant increase in IgE (3.50–17. 49 IU/ml) in serum. Patients first group without clinical signs of apparent exacerbation of MS were observed in blood eosinophilia, and the brain MRI revealed hyperintense foci in a single T-2W mode, indicating the absence of active demyelinating process. Patients with the second group with a slow chronic course of MS were determined by individual eosinophils (18.1%), indicating that they have a weak allergic reaction. Identification of individual hypo-and hyperintense lesions on brain MRI evidence of chronic course of demyelinating process in the presence of rare clinical exacerbations was seen by us as secondary progressive MS. In the third group investigated the apparent worsening of the process of clinical signs detected a moderate increase in serum IgE (45 pers., 44.1%) in the presence of explicit eosinophilia (11.8%).

Conclusion: Markers of exacerbation of MS is the simultaneous moderate increase in serum IgE eosinophilia, and the appearance of new lesions on MRI brain.

P170
REHABILITATION TECHNOLOGY OF PATIENTS WITH SYMPTOMATIC EPILEPSY

A. Filipovich[1]

[1]National Science and Practice Centre of Medical Assessment and Rehabilitation, Yukhnovka, Belarus

Objective: 220 patients with symptomatic epilepsy were examined.
Methods: Neurological examination, MRI, EEG.
Results: Prepared technology rehabilitation of patients with symptomatic epilepsy caused by organic diseases of the central nervous system. The technology is intended for use by inpatient and outpatient offices rehabilitation, medical and rehabilitation expert committees, clinics, health resorts organizations in order to improve the outcome of the disease, prevent the development of disability or reduced the severity of violations, Disability formed under disability. The technology includes: selection of the object and the subject of rehabilitation of rehabilitation; expert-rehabilitation diagnostics; evaluation of rehabilitation potential, rehabilitation prognosis; medical examination (with evaluation categories and the degree of disability, the risk of disability); formation and practical implementation of individual rehabilitation programs; evaluation of the effectiveness rehabilitation and formation of further rehabilitation of the route.
Conclusion: With the formation of medical rehabilitation measures provided by the integrated use therapy, medical physical training, medication correction, physical therapy, dietetics, the organization "School of the patient."

P171
SOME ASPECTS OF REHABILITATION FOR PATIENTS WITH LOW BACK PAIN

A. Filipovich[1]

[1]National Science and Practice Centre of Medical Assessment and Rehabilitation, Yukhnovka, Belarus

Objective: Examination of 78 patients with myotonic (MT) syndrome of lumbar osteochondrosis.
Methods: Patients went through the clinical estimation of neurologic status, manual testing of muscles, CT and MRI of back bone lumbar department, interferential and needle electromyography of the most damaged muscular groups, dosed loading veloergometry, revasography of feet, and shins.
Results: It was established for the first time, that among MT-syndrome patients 54 (69.2%) an associated damage of two or more muscles prevailed. The most damaged ("key") muscles appeared to be gastrocnemius muscle (43; 55.1%), gluteus medius (42; 53.82%), quadriceps femoris (36; 46.2%), rectus abdominis and external oblique (32; 41.1%), peroneal muscle (29; 37.2%), piriform muscle (29; 37.2%), lumbar quadrate muscle (28; 35.9%), gluteus maximus (19; 24.3%), gluteus minimus (16; 20.5%), adductor (14; 17.9%) and abductor (9; 11.5%) thigh muscles. Medical-rehabilitation complex on damaged extremity was approbated in 27 patients with MT syndrome. The complex included oral reception of katadolon (100 mg 3 times a day for 10 days), tractions on Fintrac-471 table (with force from 3 to 55 kg, a course of 8–10 sessions) and also acupuncture with use acupuncture points of general action with vascular autonomic nervous system orientation (G14, MJ6, E36, RP6, TR5, V40) and locally segmented points on the most damaged muscular groups (AT60, VB30 with deep introduction to piriform muscle; VB 34, VB41, F3).
Conclusion: After treatment damaged extremity pain has completely disappeared in 19 patients.

P172
THE AQUEOUS EXTRACT OF *PEPEROMIA PELLUCIDA* (L) KUNTH IMPROVES BONE HEALTH IN RATS RECEIVING A THERMO-OXIDIZED PALM OIL-SUGAR SUPPLEMENT

A. Florence Nadine[1], N. Florence[1], G. Raceline[1], D. Jean[1], F. Rodrigue[1], D. Paul[1], D. Théophile[1]

[1]Dept. of Animal biology and Physiology, Faculty of Science, Univ. of Yaoundé I, Yaoundé, Cameroon

Peperomia pellucida (L) Hunth est une plante utilisée en médecine traditionnelle camerounaise pour le traitement des fractures. L'étude a examiné l'effet de l'extrait aqueux de plante entière de *Peperomia pellucida* chez des rats fracturés nourris avec un régime supplémenté en huile de palme thermo-oxydée et saccharose. Des rats mâles Wistar adultes ont reçu un régime alimentaire standard ou un supplément thermo-oxydé d'huile de palme et de saccharose pendant 112 jours. Ils ont été traités avec de l'eau distillée ou *Peperomia pellucida* aqueuse (100 et 200 mg/kg). Après 14 jours de traitement, les animaux ont été sacrifiés sous anesthésie et l'effet de l'extrait aqueux a été évalué sur certains paramètres biochimiques du sérum, des os et de l'hématologie. L'histologie au site du fémur a été réalisée. La combinaison de la fracture avec un régime thermo-oxydé à base d'huile de palme et de saccharose a induit une augmentation du calcium fémoral, du phosphore sérique et osseux, de l'ALP fémorale et une diminution de l'ALP sérique. L'extrait aqueux administré simultanément à l'alimentation complétée par de l'huile de palme thermo-oxydée et du saccharose a amélioré tous ces paramètres observés avec un effet marqué à la dose de 200 m/kg. L'histologie du fémur fracturé a montré la présence d'une structure de callosité osseuse très proche de celle de la normale. *Peperomia pellucida* peut être utilisé pour fabriquer un médicament traditionnellement amélioré et également utilisé dans une étude clinique pour le traitement des fractures de fragilité. *L'extrait* aqueux de P. *pellucida* possède des propriétés ostéo-inductives capables d'accélérer la cicatrisation osseuse chez les rats nourris avec une alimentation complétée par de l'huile de palme thermo-oxydée-saccharose.

P173
CENTRAL OBESITY AND IT RELATIONSHIP BETWEEN SARCOPENIA AND BONE MINERAL DENSITY IN OLDER MEN

A. G. Diaz[1], R. A. Salazar Muñoz[1], S. Capalbo[1], E. A. Aguero Zarate[1], M. D. Dell'Aquila[1], Z. Orellana Villa[1], N. Woniatczuk[1], M. Poch[1], S. P. Lucas[1]

[1]Universidad de Buenos Aires, Endocrinology, Hospital de Clinicas "Jose de San Martin", Buenos Aires, Argentina

Objective: To analyze the impact of obesity on muscle mass and BMD in men > 50 of Buenos Aires.
Methods: We analyzed 281 men (66.4 ± 8.6 y) participating in a community activity at a University Hospital. Participants completed questions about osteoporotic risk, chronic diseases and medications. Evaluation included height, weight, waist circumference (WC), grip strength (HG) by dynamometry, the Short Physical Performance Battery Test (sppb), body composition and BMD in femoral neck (by Lunar). Obesity was defined by BMI $\geq$ 30 kg/m^2, percentage of body fat (%BF) $\geq$ 28% or WC $\geq$ 102 cm. Sarcopenia was determined according to EWGSOP2 (ALM/ht^2 $\leq$ 7 kg/m^2 and HG < 27 kg) or SDOC (HG < 35.5 kg and gait speed < 0.8 m/s).
Results: The prevalence of sarcopenia varied between EWGSOP2 (2%) and SDOC (3.2%) (p = 0,007), reaching 6% and 10%, respectively, for those 80 + . Physical performance, muscle mass and BMD

showed significant decline with age (Table 1). Similar obesity prevalence was observed according to both BMI (32.1%) and WC (38.1%), while it was higher by %BF (72.2%)($p < 0.0001$). ALM/ht^2 positively correlated with BMI ($r = 0{,}604$, $p < 0.0001$) and WC ($r = 0.435$, $p < 0.0001$). However, men with obesity by WC showed prolonged sit-chair test performance ($p = 0.002$) and reduced grip strength ($p = 0.04$). No difference was found in physical performance between obese and non-obese group based on BMI or %BF. BMD and T-score were higher in obese men ($p = 0.001$). ALM/ht^2 correlated with BMD ($r = 0.31$, $p < 0.0001$) and T-score ($r = 0.31$, $p < 0.0001$). However, individuals with osteoporosis presented lower ALM/ht^2 and poorer sppb test ($p = 0.035$).

Table 1.

Age (y)	Grip strength (kg)	Sit-chair (seg)	Walking speed (m/seg)	sppb	ALM/ht^2 (kg/m^2)	T-score	%BF	WC (cm)
50-59	41.5±0.9*	10.2±0,3*	0.48±0.1*	11.4±0.1*	8.4±1.3*	-0.5±0.1*	32.1±0,7	99.4±1.5
60-69	39.5±0,9	10,8±0,3	0.48±0.2	11.1±0,1	8.4±0.9	-0.6±0.1	31.1±0.6	98.6±1,2
70-79	35.8±0.7	11.5±0.4	0.56±0,1	10.9±0,1	8.0±0.1	-1.0±0.1	31.2±0.8	97.9±1.4
80+	31.6±1.6*	13.8±0.9*	0.62±0.2*	9.8±0.4*	7.8±0.2*	-1.3±0.2*	32.9±1.5	97.5±2.3
*p	0.0001	0.001	0.014	0.0001	0.005	0.009	NS	NS

Conclusion: Despite of association between skeletal muscle mass and fat mass, central obesity appears to impact physical performance. Implementing lifelong interventions to manage central obesity could be important in preventing sarcopenia.

P174
PILOT STUDY: VITAMIN D LEVELS AND DENGUE FEVER—IS THERE AN ASSOCIATION WITH PROGNOSIS?

A. G. Mumbach[1], J. M. Roganovich[1], M. Martinez[2], M. L. Garcia[3], M. Ferreyra[4], V. Ferreyra[4]

[1]ADENO-CEIEMP, Posadas-Misiones, [2]BIOMED, Posadas, [3]Santorio Dr. Julio Mendez, Ciudad Autónoma de Buenos Aires, [4]Sanatorio integral IOT, Posadas- Misiones, Argentina

Objective: Dengue virus (DENV) is an infection transmitted by the bite of Aedes mosquitoes. The disease severity is variable and depends on several factors. Some studies have correlated vitamin D (VD)status and DENV outcomes. The objective of our study is to know if low levels of VD impact on DENV prognosis.
Methods: A retrospective cohort study was carried out. Taking data patients who had positive antigens to DENV and at least one measurement of VD in the last 3–6 months. Patients were grouped into DENV without alarm signs, DENV with alarm signs and Severe DENV. The variables were tested with parametric or non-parametric tests according to their distribution. Simple linear, multivariate, and logistic regressions were performed that were adjusted for confounders (comorbidities, age)-Stata18.0 Software was used.
Results: 52 patients were recruited aged in 49 ± 17 years old. The vitamin D mean value was 31.6 ± 13 ng/ml. 46.2% had VD under 30 ng/ml. Patients with highest VD levels presented less sign or symptoms (without alarm) against those with lower levels ($p < 0.01$) Table 1. In patients with alarm signs and severe DENV, values of VD were 22.1 ± 8 ng/ml and 20.5 ± 13 ng/ml respectively. Patient with VD levels < 30 ng/ml presented an OR of 11.1 to have DENV with alarm ($p < 0.01$ CI 2.89–83).

Table 1.

	Without alarm DENV (n: 34) *1	With alarm DENV (n:13) *2	Severe DENV (n: 5) *3	*p*
Age (y)	46.7±16.3	50.4 ±17.5	63±17	0.08
Vitamin D (ng/ml)	36.9±11.5	22.15 ±8	20.5± 13	<0.01
Comorbidities (n)	10	4	4	0.06

Dunn test: P*1 vs*2: <0.01, *1 vs*3: 0.003. *2 vs. *3: 0.44

Conclusion: Considering that this is a pilot study in order to program a prospective cohort study with a better number of patients and improving quality of design and execution, the results showed above encourage us to keep in the track of our objective and presume a possible association between VD levels and DENV evolution and prognosis.

P175
VARIATIONS IN HOSPITAL LENGTH OF STAY AND PERFORMED SURGICAL PROCEDURES AFTER HIP FRACTURES

A. Gasparik[1], L. Lorenzovici[1], M. Cevei[2], D. M. Farcas[2], D. Stoicanescu[3]

[1]Univ. of Medicine and Pharmacy of Tg Mures (UMFST), Tirgu Mures, [2]Universitatea Oradea, Oradea, [3]Univ. of Medicine V Babes Timisoara, Timisoara, Romania

Objective: The number of days spent in hospital (LoS) for osteoporosis and consequent fractures is higher than for myocardial infarction, stroke, breast cancer and chronic obstructive pulmonary disease. While most hip fractures are treated surgically, the LoS as well as the procedures performed to repair the fracture vary widely depending on many factors. Our aim was to define the patient and hospital characteristics that impacts these output variables.
Methods: We performed a retrospective study including 5993 inpatients registered during the years of 2018–2019 in 7 Romanian counties, with femoral neck, pertrochanteric, and subtrochanteric fractures. The following variables were registered: demographic characteristics of the patients, diagnosis code, duration of hospital stay, therapeutic procedure, hospital category (clinical, county, municipal), county where the surgery was performed, and in-hospital death.
Results: Regression analysis was used to examine variations in duration of care, procedures performed and death while controlling for patients' gender, setting (urban/rural), diagnosis, hospital category and region. Average age was 77.2 y (86% 65+), mean length of hospital stay was 13.3 d (varied between 9.6-Vaslui and 14.6-Arad county). Urban residents and men spent significantly more days in the hospital (p.000 and.019). LoS was significantly longer also among older patients, in subtrochanteric fractures and *county* hospitals. The other analyzed dependent: the surgical procedure significantly correlated (when controlled for diagnosis 72.0, 72.1, 72,2 codes) with the following variables: urban vs. rural setting, diagnosis, type of hospital, age, length of care and in-stay death. Some of the variations observed are consistent with the international epidemiological data. Urbanity/rurality and gender dependence is noted in the literature for fracture incidence, LoS and mortality, however, no data was found for procedure choices based on patient gender and setting. The seemingly unexplainable variations raise the question of possible arbitrary (subjective/preferential) and professionally unjustifiable health technology choices.
Conclusion: Our study revealed that Los is significantly higher among men, urban residents and when hospitalized in a county unit. High variations are observed among fixation procedures depending on gender, setting, and hospital category. Exploring these complex patterns, the causes of the variations, solutions might be identified for optimal medical choices, reduction of prolonged care and a better resource allocation.

P176
FRACTURE RISK IN A PATIENT WITH OSTEOPOROSIS AND MULTIPLE RISK FACTORS

A. Gherle[1], M. Cevei[1], D. Stoicanescu[2], M. S. Deac[1]

[1]Univ. of Oradea, Faculty of Medicine, Oradea, [2]Univ. of Medicine and Pharmacy "Victor Babes", Timisoara, Romania

Osteoporosis prevalence is significantly higher in patients who had hysterectomy with removal of ovaries. We present the case of a 61-year-old female patient who was diagnosed with postmenopausal osteoporosis after total hysterectomy with bilateral anexectomy for severe cervical dysplasia at 45 years. Her personal medical history revealed Hashimoto's autoimmune thyroiditis, hypothyroidism, normocalcemic hyperparathyroidism, C1-C2 and C3 cervical myelitis (Sylvian aqueduct stenosis from 2012). She was hospitalized for motor deficit, paraparetic type, balance difficulties, paresthesia in the lower limbs, and slight deficit in performing ADLs. The physical examination showed positive evidence of paresis in the lower limbs, slight spasticity-Ashworth 1. DXA performed in March 2021 revealed lumbar spine T-score: − 3.2; left hip T-score: − 1.4; right hip T-score: − 1.8. DXA from January 2023 showed lumbar spine T-score: − 3.3 left hip T-score: − 2.1 right hip T-score: − 2.3. 10 m walk test at admission: average steps 18.75; average time duration 12.65 s; step length 0.16 m; speed 0.79 m/s. 10 m walking test at discharge revealed: average steps 18.25; average time duration 11.98 s; step length 0.54 m; speed 0.74 m/s. Final 10 m walk test with drop-foot orthosis: average steps 16.5; average time duration 10.67 s; step length 0.6 m; speed 0.93 m/s. Grip strength measured with Jamar dynamometer showed left handgrip strength 10.5 kg and right handgrip strength 10.67 kg. The evolution under complex recovery treatment focused on individual physical therapy, occupational therapy and virtual reality-D-wall biofeedback, proprioceptive modulation therapy was favorable. The FRAX score revealed the ten year probability of major osteoporotic fracture was 37 and of hip fracture 6.4, a very high risk, the patient requiring immediate therapeutic interventions.

P177
THE IMPORTANCE OF ORAL HYGIENE: DOES PRIOR DENTAL IMPLANT PLACEMENT OR DENTAL CARIES WITHIN 1 YEAR OF PRIMARY TOTAL KNEE ARTHROPLASTY INCREASE MEDICAL COMPLICATIONS AND PERIPROSTHETIC JOINT INFECTIONS?

A. Gordon[1], R. Vakharia[1], M. Mont[2]

[1]Maimonides Medical Center, Brooklyn, [2]Rubin Institute of Advanced Orthopedics, Baltimore, USA

Objective: One of the leading causes of total knee arthroplasty (TKA) failure and reoperation includes periprosthetic joint infection (PJI). Historically, poor dental health and dental pathology have been considered a risk factor for development of PJIs. With few large comparative studies, there is a lack of consensus among orthopaedic surgeons and dentists regarding the influence of prior dental history and need for antibiotic prophylaxis in primary total knee arthroplasty (TKA) patients. Therefore, the objectives were to determine the association of dental caries or dental implant placement prior to TKA on: (1) medical complications; (2) healthcare utilization including lengths of stay (LOS) and readmission rates; and (3) implant-related complications including PJIs and healthcare expenditures.
Methods: A retrospective analysis was performed using a nationwide insurance claims database for primary TKAs from 2010 to 2020. Patients and complications were identified using International Classification of Disease, Ninth/Tenth Revision (ICD-9/10) and Current Procedural Terminology (CPT) codes. Patients undergoing primary TKA with a history of dental caries or dental implant placement within 1 year of TKA represented the study group (n = 1466). Patients without prior history of dental implant placement or caries represented the comparison cohort (n = 7328). Study group patients were case-matched in a 1:5 ratio by age and comorbidities. Primary outcomes of the study were to compare 90-day medical complications, healthcare utilization parameters (LOS, readmission rates), 2-year implant-related complications, and healthcare expenditures. Pearson's chi-square analyses were used to compare patient demographics of the two cohorts. Welch's t-tests were used to compare LOS and costs. Multivariate logistic regression models were used to calculate odds (OR) and 95% CIs of developing medical complications and being readmitted within 90-days following TKA adjusting for age, sex, geographic region, and matched comorbidities. Following a Bonferroni-correction, a p-value less than 0.005 was considered statistically significant.
Results: Patients with a history of dental implant placement or dental caries within 12 months of primary TKA had higher frequency of medical complications compared to case-matched patients (20.05 vs. 13.11%; OR: 1.66, $p < 0.0001$), including myocardial infarctions (2.52 vs. 1.23%; OR:2.08, $p = 0.0002$) and pneumoniae (2.52 vs. 1.24%; OR:2.06, $p = 0.0002$). LOS (3.28 vs. 2.98 d; $p = 0.255$), readmission rates (4.71 vs. 4.28%; $p = 0.470$), and incidence of PJIs within 2 years of surgery (3.14 vs. 2.63%; OR: 1.20, $p = 0.279$) were similar between groups. Within the 90-day episode of care interval, healthcare expenditures were significantly higher in patients with recent dental history ($19,363 vs. 17,980; $p < 0.001$).
Conclusion: Patients with dental caries or dental implant placement have higher 90-day medical complications, greater healthcare expenditures, and similar 2-year implant-related complications. Poor dental hygiene did not lead to increased implant infections, however this comorbidity may be reflective of overall poorer medical condition in these patients resulting in greater postoperative complications and increased healthcare expenditures. Addressing dental history in the preoperative period may assist orthopaedic arthroplasty surgeons in minimizing complications in this group of patients.

P178
THE ASSOCIATION OF PRIOR DENTAL PATHOLOGY ON MEDICAL COMPLICATIONS AND PERI-PROSTHETIC JOINT INFECTIONS FOLLOWING PRIMARY TOTAL HIP ARTHROPLASTY: A RETROSPECTIVE MATCHED-CONTROL ANALYSIS

A. Gordon[1], R. Vakharia[1], M. Mont[2]

[1]Maimonides Medical Center, Brooklyn, [2]Rubin Institute of Advanced Orthopedics, Baltimore, USA

Objective: One of the leading causes of THA failure and reoperation includes periprosthetic joint infection (PJI). Historically, poor dental health and dental pathology have been considered a risk factor for development of PJIs. With few large comparative studies, there is a lack of consensus among dentists and orthopaedic surgeons regarding the influence of prior dental implant placement or dental caries and need for antibiotic prophylaxis in total hip arthroplasty (THA) patients. Therefore, the objectives of this study were to determine the association of pertinent dental history (dental implant placement or caries) prior to THA on: 1) medical complications, 2) lengths of stay (LOS), 3) readmission rates, and 4) implant-related complications including PJIs.
Methods: A retrospective query was performed using a nationwide administrative claims database for primary THAs from 2010 to 2020. Patients and complications were identified using International Classification of Disease, Ninth Revision (ICD-9) and Current Procedural

Terminology (CPT) codes. Patients undergoing primary THA with a history of dental caries or dental implant placement before THA represented the study group (n = 3620). Patients without documented dental history including implants or caries represented the comparison cohort (n = 18,084). Study group patients were case-matched in a 1:5 ratio by age and comorbidities. Primary endpoints of the study were to compare patient demographics, 90-day medical complications, in-hospital lengths of stay, 90-day readmissions, in addition to 2-year implant-related complications. Pearson's chi-square analyses were used to compare patient demographics of the two cohorts. Welch's t-tests were used to compare LOS. Multivariate logistic regression models were used to calculate odds (OR) and 95% CIs of developing medical complications and being readmitted within 90-days following THA adjusting for age, sex, geographic region, and matched comorbidities. Following a Bonferroni-correction, a p-value less than 0.001 was considered statistically significant.

Results: Patients with a history of dental implant or dental caries had higher frequency and odds of medical complications compared to case-matched patients without a prior dental history (27.76 vs. 16.79%; OR: 1.88, $p < 0.0001$), including cerebrovascular accidents (1.19 vs. 0.41%; OR: 2.96, $p < 0.0001$), deep venous thromboses (1.22 vs. 0.47%; OR: 2.61, $p < 0.0001$), pneumonias (4.00 vs. 1.80%; OR: 2.29, $p < 0.0001$), and acute kidney injuries (4.64 vs. 2.17%; OR: 2.22, $p < 0.0001$). Lengths of stay (3.15 vs. 2.90 days; $p = 0.073$), readmission rates (8.31 vs. 7.96%; $p = 0.491$), and incidence of PJIs within 2 y of the index procedure (3.65 vs. 3.28%; OR: 1.11, $p = 0.271$) were similar between groups.

Conclusion: Patients with a dental implant placement or history of dental caries prior to primary total hip arthroplasty have higher 90-day medical complications but similar 2-year implant-related complications including PJIs. In-hospital LOS and 90-day readmission rates were similar between the two cohorts. These findings may help surgeons further understand and risk stratify patients with a pertinent dental history undergoing THA.

P179
THE EFFECT OF COVID-19 ON ELECTIVE TOTAL KNEE ARTHROPLASTY UTILIZATION, PATIENT COMORBIDITY BURDEN, AND COMPLICATIONS IN THE USA: A NATIONWIDE ANALYSIS

A. Gordon[1], R. Vakharia[1], M. Mont[2]

[1]Maimonides Medical Center, Brooklyn, [2]Rubin Institute of Advanced Orthopedics, Baltimore, USA

Objective: Total hip (THA) and knee arthroplasty (TKA) are two of the highest-volume elective surgeries performed in hospitals in the USA. Elective surgery was suspended as a result of the COVID-19 pandemic beginning in March 2020. The projected backlog of cases was estimated to take between 9 to 35 months to recover. Equally as concerning, delays for a total joint replacement doubled during the pandemic, ultimately diminishing the quality of life in these patients. As a result of the suspension of elective total joint arthroplasty and the lack of nationwide reporting utilizing a representative cohort, the primary purpose of the current study is to: (1) compare temporal trends in case volume of elective total knee arthroplasty (TKA) from 2019 (prepandemic) to 2020 in the USA, and (2) compare patient demographics and postoperative complications of those undergoing TKA before and after the pandemic origin.

Methods: Utilizing a multicenter, nationwide representative sample, a retrospective query of the 2019 to 2020 ACS-NSQIP database was conducted for patients undergoing elective TKA (Current Procedural Terminology code 27447). Nonelective and revision TKA cases were excluded. Cases involving polytrauma or infections were excluded by using International Classification of Diseases, 9 or 10 Revision codes. The primary outcome was to compare the annual case volume from 2019 to 2020. Secondarily, we compared admission quarters to understand the impact of the COVID-19 pandemic restrictions on TKA utilization over time. As admission quarter 1 (Q1) ends March 31, temporal trends in utilization, demographics, and lengths of stay (LOS) were compared pre-COVID (2019 to 2020Q1) with post-COVID (2020Q2-Q4). Demographics included age, gender, race, and comorbidity burden. Postoperative 30-day complications, mortality, and readmissions were compared by calendar year (2019 vs. 2020). To assess for significant differences in patient demographics between years and admission quarters, Pearson chi-square tests, student's T test, and analysis of variance (ANOVA) were used. Linear regression was used to evaluate changes in procedural volume over time. A significance threshold of $p < 0.05$ was used.

Results: A total of 121,415 patients underwent elective TKA in 2019 (N = 72,002) and 2020 (N = 49,413), a 31.4% decline. Patient demographics of all patients undergoing surgery in 2019 vs. 2020 calendar year were similar with respect to BMI, functional health status, ASA Class, and the presence of the following comorbidities (tobacco use, heart failure). The proportion of hospital-defined 'outpatient' TKAs in 2020 was significantly greater than 2019 (41.5 vs. 25.5%; $p < 0.001$). Elective TKA utilization declined by 65.1% in 2020Q2 and never returned to pre-pandemic baseline in 2020Q3-Q4. The average LOS was shorter in 2020 (1.56 vs. 1.87 days; $p < 0.001$). The proportion of same day discharge increased by quarter from 2019Q1–Q4 (6.2% to 8.6%) to 2020Q1–Q4 (8.7% to 17.1%). Total complication rates were similar in 2019 (4.84%) vs. 2020 (4.75%); $p = 0.430$. The incidence of major complications (3.1 vs. 3.0%; $p = 0.413$), infection complications (1.4 vs. 1.5%; $p = 0.422$), cardiac complications (0.24 vs. 0.27%; $p = 0.286$), pulmonary complications (0.66 vs. 0.61%; $p = 0.284$), hematology complications (1.4 vs. 1.3%; $p = 0.055$), renal complications (0.11 vs. 0.09%; $p = 0.297$), and Clavien Dindo IV complications (0.65 vs. 0.65%; $p = 0.959$) were similar. Only wound complications (0.20 vs. 0.29%; $p = 0.004$) were significantly higher during the pandemic year. The 30-day mortality (0.08 vs. 0.07%; $p = 0.858$), reoperation (1.0 vs. 1.0%;$p = 0.940$) and readmission (2.8 vs. 2.6%; $p = 0.053$) rates were no different between 2019 and 2020.

Conclusion: In the USA, there was a 31.4% decline elective TKA in 2020. Case volumes precipitously declined by 65.1% during the second quarter of 2020, before eventually leveling off at 80% of pre-pandemic baseline. Patient demographics of those undergoing elective TKA in 2020 were younger and less frail. There was a 1.5-fold increase in the number of surgeries performed in the outpatient setting in 2020 with rates of same day discharge doubling over the study period. Overall 30-day complication, readmission, reoperation, and mortality rates were not increased during Covid-19. Orthopedic surgeons may use this study to counsel patients about having surgery during COVID-19.

P180
THE INFLUENCE OF PRIOR DENTAL PATHOLOGY ON MEDICAL COMPLICATIONS AND PERIPROSTHETIC JOINT INFECTIONS FOLLOWING PRIMARY SHOULDER ARTHROPLASTY

A. Gordon[1], R. Vakharia[1], J. Choueka[1]

[1]Maimonides Medical Center, Brooklyn, USA

Objective: One of the leading causes of anatomic and reverse shoulder arthroplasty failure and reoperation includes periprosthetic joint infection (PJI). Historically, poor dental health and dental pathology have been considered risk factors for developing infections. Antibiotic prophylaxis before invasive dental procedures is a common practice in the USA. However, consensus regarding the influence of

prior dental pathology (DP) on postoperative complications in orthopaedic surgical patients, and specifically shoulder arthroplasty patients is lacking. The objectives of this study are to determine the association of DP prior to shoulder arthroplasty (SA) on: (1) medical complications, (2) lengths of stay (LOS), (3) readmissions, (4) implant-related complications including PJIs, and (5) healthcare expenditures.

Methods: Using a nationwide administrative claims database, we queried all patients undergoing primary shoulder arthroplasty from 2010–2020. Patients and complications were identified using International Classification of Disease, Ninth/Tenth Revision (ICD-9/10) and Current Procedural Terminology (CPT) coding. Patients with history of dental caries or dental implant placement prior to SA represented the study group (n = 1419). Patients without prior DP represented controls (n = 7062). Study group patients were 1:5 ratio matched to controls by age, sex, and comorbidities. The comorbidities chosen for matching were those that have been found to be prevalent among upper extremity arthroplasty patients. Outcomes assessed included 90-day complications, readmissions, LOS, 2-year implant-related complications, and healthcare reimbursements. Pearson's chi-square analyses were used to compare patient demographics of the two cohorts. Welch's t-tests were used to compare LOS and costs. Multivariable logistic regression models were used to calculate odds ratios (OR) of complications and readmissions while adjusting for age, sex, geographic region, and matched comorbidities. A p value < 0.003 was significant.

Results: Patients with DP had higher odds of 90-day medical complications compared to controls (OR: 1.74, $p < 0.0001$), including myocardial infarctions (2.2 vs. 0.8%; OR: 2.79, $p < 0.0001$), acute kidney injuries (8.3 vs. 4.6%; OR: 1.92, $p < 0.0001$), and pneumonias (8.7 vs. 5.3%; OR: 1.72, $p < 0.0001$. Readmission rates (1.97 vs. 1.54%; $p = 0.248$) and LOS (2.17 vs. 2.07 d; $p = 0.071$) were similar between groups. Overall 2-y implant-related complications were higher in patients with DP compared to controls (16.1 vs. 11.5%; OR: 1.38, $p = 0.0003$), including dislocations (6.4 vs. 4.5%; OR: 1.45, $p = 0.002$) and mechanical loosening (4.0 vs. 2.4%; OR: 1.67, $p = 0.001$), however PJIs were similar (2.2 vs. 1.9%; OR: 1.12, $p = 0.583$). Within the 90-day episode of care interval, healthcare expenditures were not significantly different in patients with recent history of dental work ($12,611 vs. 12,059; $p = 0.075$).

Conclusion: Patients with prior DP have higher 90-day medical complications and 2-year implant-related complications. Two-year incidence of PJIs were similar between groups. These findings can be helpful for shoulder surgeons as they counsel and risk stratify patients with a pertinent dental history.

P181
PRIOR KIDNEY STENT PLACEMENT IS ASSOCIATED WITH INCREASED MEDICAL COMPLICATIONS, READMISSIONS, IMPLANT-RELATED COMPLICATIONS, AND COSTS OF CARE FOLLOWING PRIMARY TOTAL KNEE ARTHROPLASTY

A. Gordon[1], R. Vakharia[1], M. Mont[2]

[1]Maimonides Medical Center, Brooklyn, [2]Rubin Institute of Advanced Orthopedics, Baltimore, USA

Objective: In the USA, approximately 100,000 ureteral stents are placed annually to manage upper urinary tract obstructions caused by urolithiasis and other genitourinary pathologies. These may be left in place for weeks, months, or even years and are a nidus for infectious complications. Infections following total joint replacements are costly for the healthcare system. Total joint arthroplasty surgeons are cognizant of reducing periprosthetic joint infections in patients with prior risk factors. A recent proposed risk factor for seeding non-native joints involves pathology from the urinary system, however the influence of prior ureteral stent placement has not been investigated. Therefore, the objectives of this study were to determine the association of a prior history of kidney stent placement prior to TKA on: (1) medical complications, (2) lengths of stay (LOS), (3) readmission rates, (4) implant-related complications including PJIs, and (5) healthcare expenditures.

Methods: A retrospective case–control study was performed using a private insurance claims database for primary TKAs from 2010 to 2020. Patients and complications were identified using International Classification of Disease, Ninth/Tenth Revision (ICD-9/10) and Current Procedural Terminology (CPT) codes. Patients undergoing primary TKA with a history of prior kidney stent placement represented the study group (n = 25,419). Patients without prior kidney stent placement represented controls (n = 127,080). Study group patients were 1:5 ratio matched to controls by age, gender, and comorbidities. Primary endpoints of the study were to compare patient demographics, in-hospital lengths of stay, 90-day medical complications, 90-day readmissions, 2-year implant-related complications, and healthcare expenditures. Pearson's chi-square analyses were used to compare patient demographics of the two cohorts. Welch's t-tests were used to compare LOS and costs. A multivariate logistic regression model was used to calculate odds (OR) and 95% CIs of developing medical complications and being readmitted within 90-days following TKA adjusting for age, sex, geographic region, and matched comorbidities. Following a Bonferroni-correction, a p value less than 0.001 was considered statistically significant.

Results: Patients with history of kidney stent placement had a four-fold higher frequency of 90-day medical complications compared to controls (43.93 vs. 11.25%; OR: 6.18, $p < 0.0001$), including myocardial infarctions (3.92 vs. 1.37%; OR:2.94, $p < 0.0001$), pneumoniae (3.78 vs. 1.28%; OR:3.03, $p < 0.0001$), venous thromboemboli (2.53 vs. 1.14%; OR:2.24, $p < 0.0001$), cerebrovascular accidents (1.01 vs. 0.39%; OR:2.60, $p < 0.0001$), and surgical site infections (1.70 vs. 1.14%; OR:1.50, $p < 0.0001$). LOS (3.2 vs. 2.9 days; $p = 0.213$) was similar between groups, however 90-day readmission rates (4.39 vs. 3.50%; $p < 0.0001$) were significantly higher for patients with prior kidney stent history. Overall 2-year implant-related complications (5.13 vs. 3.76%; OR: 1.38, $p < 0.0001$) and PJIs (2.62 vs. 2.19%; OR: 1.20, $p < 0.0001$) were higher in patients with a history of kidney stents. Within the 90-day episode of care interval, healthcare expenditures were significantly higher in patients with prior history of kidney stents ($17,391 vs. 15,985; $p < 0.001$).

Conclusion: Patients with a kidney stent placement prior to TKA have higher 90-day medical complications, increased 2-year implant-related complications, and greater healthcare expenditures. These findings may help surgeons risk stratify patients with a pertinent invasive urological history.

P182
DEPRESSION SCREENING WITHIN 3 MONTHS OF SHOULDER ARTHROPLASTY DECREASES MEDICAL COMPLICATIONS, HEALTHCARE EXPENDITURES, AND IMPLANT COMPLICATIONS IN PATIENTS WITH DEPRESSIVE DISORDER: A RETROSPECTIVE MATCHED-CONTROL ANALYSIS

A. Gordon[1], R. Vakharia[1], J. Choueka[1]

[1]Maimonides Medical Center, Brooklyn, USA

Objective: Depression is a multifactorial disease that affects 322 million people worldwide and is projected to be the highest cause of disability by 2040. Depression has been shown to be a risk factor for postoperative medical complications, readmissions, and increased healthcare utilization in orthopaedic surgery patients. There is no

reported optimal timing and interval for screening patients with depressive disorder. Therefore, we evaluated depressive disorder patients to determine if having a formal depression screen within 90 days of shoulder arthroplasty would influence postoperative outcomes. The aims were to compare depressive disorder patients with and without formal depression screening prior to shoulder arthroplasty (SA) and the influence on: (1) medical complications, (2) lengths of stay (LOS), (3) readmission rates, (4) implant-related complications including PJIs and (5) healthcare expenditures.

Methods: A retrospective query was performed using a nationwide administrative claims database for primary shoulder arthroplasty (anatomic and reverse) from 2010 to 2020. Patients and complications were identified using International Classification of Disease, Ninth Revision (ICD-9) and Current Procedural Terminology (CPT) codes. Patients undergoing primary shoulder (SA) arthroplasty with a history of depressive disorder were the population of interest. These patients were subsequently filtered by those who had a formal depression screen within 90 d of their procedure (n = 3566) vs. those who did not (n = 17,769). Patients with screening were 1:5 ratio matched to patients without formal screening by age, sex, anxiety disorder, COPD, Diabetes, Hypertension, Obesity, and Tobacco use. Primary outcomes of the study were to compare 90-day medical complications, lengths of stay (LOS), 90-d readmission rates, 2-y implant-related complications including periprosthetic joint infections (PJIs), and healthcare expenditures. Pearson's chi-square analyses were used to compare patient demographics of the screened vs. non-screened patients. Welch's t-tests were used to compare LOS and costs of care. Multivariable logistic regression models were used to calculate odds (OR) and 95% CIs of developing medical complications, implant-related complications, and being readmitted within 90-days following SA adjusting for age, sex, geographic region, and matched comorbidities. Following a Bonferroni-correction, a p value less than 0.005 was considered statistically significant.

Results: Patients with depression who did not undergo screening had threefold higher frequency and odds of 90-day medical complications compared to screened patients (28.08 vs. 7.26%; OR: 3.33, $p < 0.0001$), including myocardial infarctions (1.04 vs. 0.36%; OR: 2.37, $p = 0.003$), pneumonias (7.99 vs. 2.55%; OR: 2.88, $p < 0.0001$), deep venous thromboses (1.39 vs. 0.36%; OR: 3.25, $p < 0.0001$), pulmonary emboli (1.40 vs. 0.45%; OR: 2.62, $p = 0.0002$), transfusions (2.96 vs. 0.39%; OR: 6.67, $p < 0.0001$), acute kidney injuries (6.52 vs. 1.49%; OR: 4.08, $p < 0.0001$), and cerebrovascular accidents (2.70 vs. 0.93%; OR: 2.58, $p < 0.0001$). Readmission rates (3.48 vs. 3.97%; $p = 0.719$) and LOS (1.80 vs. 2.02 d; $p = 0.095$) were similar between patients screened vs. not screened. Overall 2-year implant-related complications were higher in patients without screening vs. those who were screened within 90 days of surgery (15.89 vs. 8.02%; OR: 1.93, $p < 0.0001$), including PJIs (2.05 vs. 0.93%; OR: 2.04, $p < 0.0001$). Within the 90-day episode of care interval, healthcare expenditures were significantly lower in depressive disorder patients screened within 3 months of surgery ($8,703 vs. $10,916; $p < 0.0001$).

Conclusion: Depressive disorder patients undergoing screening within 3 months of surgery appears to decrease overall 90-day medical complications and 2-year implant-related complications. Additionally, screening appears to decrease the 90-day episode of care interval expenditures by over $2000 in a matched population. These findings may be useful for shoulder arthroplasty surgeons in the 3 months prior to surgery as they may council their depressive disorder patients about the importance of having a recent screening by their physician.

P183
A NATIONWIDE ANALYSIS OF THE IMPACT OF SOCIOECONOMIC STATUS ON OUTCOMES AFTER TOTAL KNEE ARTHROPLASTY USING THE AREA DEPRIVATION INDEX: CONSIDERATION OF THE DISADVANTAGED PATIENT

A. Gordon[1], R. Vakharia[1], M. Mont[2]

[1]Maimonides Medical Center, Brooklyn, [2]Rubin Institute of Advanced Orthopedics, Baltimore, USA

Objective: Socioeconomic status (SES) has been demonstrated to be an important prognostic factor among patients undergoing surgery including total joint arthroplasty. Measures of socioeconomic disadvantage may enable improved targeting of measures to prevent and recognize potential increased healthcare utilization in these disadvantaged patients. The Area Deprivation Index (ADI) is a weighted index comprised of 17 census-based markers of material deprivation and poverty. The purpose of this study was to utilize a large nationwide administrative claims database to determine whether patients with high ADI (greater disadvantage) undergoing TKA is associated with differences in: (1) medical complications; (2) emergency department (ED) utilization; (3) readmission rates; and (4) costs of care.

Methods: A retrospective query of all primary TKA patients was performed using a large private insurance database from January 1st, 2010 to October 31st, 2020. Cohorts of interest were queried using Current Procedural Terminology (CPT) codes and International Classification of Disease, Ninth/Tenth Revision (ICD-9), ICD-10 codes. ADI is reported on a scale of 0–100 with higher numbers associated with greater disadvantage. Percentile was documented for each zip code for all states. The study group consisted of patients undergoing primary TKA in zip codes associated with high ADI (90%+) as established by previously published studies. The control cohort consisted of TKA patients who underwent surgery in zip codes not defined by the study group. Patients with high ADI were 1:1 propensity score matched to controls by age, gender, and Elixhauser Comorbidity Index (ECI). This yielded 225,038 patients in total evenly matched between the two cohorts. Primary endpoints of the study were to compare 90-day medical complications, 90-day ED utilization, 90-day readmission rates, and 90-day costs of care. A multivariable logistic regression model was used to calculate the odds-ratios (OR) and 95% CIs of ADI on 90-d medical complications, ED utilization, and readmission rates. A Shapiro-Wilks test was performed to assess for normality of distribution followed by Welch's T tests for the continuous variables lengths of stay and costs. Due to the ease of finding statistical significance with large database studies, a Bonferroni correction was performed to reduce the probability of a type I error. Thus, a p-value less than 0.003 was considered to be statistically significant.

Results: High ADI patients incurred significantly higher rates and odds of developing any medical complications (11.7 vs. 11.0%; OR: 1.05, 95% CI 1.02–1.09, $p = 0.0006$), including respiratory failures (0.36 vs. 0.29%; OR: 1.28, 95% CI 1.10–1.48, $p = 0.001$), acute kidney injuries (1.67 vs. 1.45%; OR: 1.15, 95% CI 1.08–1.23, $p < 0.0001$), and urinary tract infections (3.72 vs. 3.37%; OR: 1.11, 95% CI 1.06–1.16, $p < 0.0001$). Despite lower rates of readmissions in the study vs. control groups (2.91 vs. 3.46%), high ADI patients had significantly higher rates and odds of ED visits within 90 d (4.23 vs. 3.95%; OR: 1.07, 95% CI 1.03–1.12, $p = 0.0008$). Overall day of surgery ($12,210 vs. $9,653) and 90-d expenditures ($15,066 vs. $12,459) were higher in patients from a high ADI ($p < 0.0001$).

Conclusion: Socioeconomically disadvantaged patients have increased rates and odds of all 90 day medical complications. ED utilization was higher in socioeconomically disadvantaged patients despite lower readmission rates. Measures of neighborhood disadvantage, including the ADI, could potentially be used to inform healthcare policy and improve post-discharge care.

P184
CLINICAL CASE OF WRIST AND METACARPOPHALANGEAL JOINTS ARTHROPLASTY IN A PATIENT WITH IN RHEUMATOID ARTHRITIS

A. Gorelova[1], M. Makarov[1], S. Makarov[1], S. Maglevaniy[1], A. Khramov[1], A. Kolomatskaya[2], D. Ivanov[1], E. Byialik[1], V. Byalik[1], A. Logunov[1], A. Chernikova[1]

[1]V. A. Nasonova Research Institute of Rheumatology, [2]I. M. Sechenov First Moscow State Medical Univ., Moscow, Russia

We present a clinical case of a 48-year-old female patient with diagnosed rheumatoid arthritis since 2000. At the time of hospitalization, the patient was undergoing therapy with methotrexate 20 mg/week, methylprednisolone 4 mg/day, and upadacitinib 15 mg/d. Pain, deformities of the radiocarpal joint, and metacarpophalangeal joints (MCP) had been since the onset of the disease, with increased difficulty in self-care and intensified pain over the past 2 years. Conservative treatment (brace usage, NSAIDs) showed no significant improvement.

Clinical examination demonstrated severe pain (VAS 75 mm), volar-ulnar dislocation of the wrist bones, dislocation of the head of the ulna, limited range of motion (10° of extension and 15° of flexion), ulnar deviation of fingers 2–5, and a deficit in extension of MCP joints 2–5. X-ray findings revealed osteonecrosis of the wrist bones with signs of osteoarthritis (grade 3–4), osteonecrosis of heads of the metacarpal bones, and dislocations in the MCP joints. Considering the clinical presentation, the decision was to perform joint replacement and stabilization of the wrist joint as the first step.

During the surgery, a ceramic implant was used, and additional stabilization of the wrist joint was achieved with a tendon transfer. The postoperative period proceeded without complications, and immobilization in a volar plaster splint was maintained for 3 weeks. After splint removal, the patient engaged in movement rehabilitation. At the 6-month follow-up, the patient demonstrated 25° of flexion and extension, reduced pain (VAS 10 mm), and satisfaction with joint function. The second step involved standard joint replacement of MCP joints 2–5 using silicone implants and finger extensor apparatus plastic surgery according to the original method developed by the research institute. Dynamic observation of the patient is ongoing.

Wrist joint arthroplasty with a ceramic implants ensures function restoration of the wrist joint. MCP arthroplasty in combination with extensor plasty restores the lost functions of the hand and provides the improvement of life quality in patients with rheumatoid arthritis.

P185
MACRO-MICROSCOPIC PARAMETERS OF THE TIBIA, SPLEEN AND KIDNEYS IN JUVENILE RATS AFTER EXCESSIVE CAFFEINE INTAKE

A. Movenko[1], V. Luzin[1], A. Grishchenko[1], A. Tolstenko[1]

[1]FSBEI HI St. Luka LSMU of MOH of Russia, Lugansk, Russia

Objective: To investigate the influence of caffeine after 90-d intake on macro-microscopic parameters of the tibia, spleen and kidneys in juvenile rats.

Methods: 18 juvenile rats with initial body weight 130–140 g were distributed into 3 groups. The 1st group (K-90j) involved the intact animals, the 2nd group (C-90j) comprised the animals that received intragastric caffeine daily in dosage of 120 mg/kg. Animals of the 3rd group (CM-90j) received caffeine in the same way as 2nd group treated with subcutaneous injections of mexidol in dosage of 50 mg/kg of body weight daily. Upon expiration of observation terms, HE stained horizontal mid-shaft sections of the tibia were taken to morphometry. Sections of the spleen and kidneys at the hilum level were examined under 16 × magnification.

Results: In animals of the C-90j group by the 90th day, area of the compact substance of the tibial diaphysis was less than the K-90j group by 6.55%, and area of the bone marrow cavity increased by 6.74%. Area of the renal cortex increased by 13.40%, and area of the medulla by 10.10%. As a result, the cortical-medullary ratio exceeded the control values only by 90 d of the experiment by 3.09%. The area of the white pulp of the spleen and stroma increased by 4.81% and 5.10%, and area of the red pulp increased by 19.83%. In animals of the group CM-90j (in comparison with C-90j group), area of the cortical bone of the diaphysis increased by 4.73%, and area of the bone marrow cavity decreased by 4.45%. The area of the renal cortex decreased by 7.16%, and area of the medulla by 4.39%. Total area of the spleen was larger by 7.88%, and area of the red pulp by 12.88%.

Conclusion: Excessive 90-d caffeine intake results in decrease of bone formation and increased resorption in the diaphysis of the tibia, increased area of the cortical substances of the kidneys and white pulp of the spleen. Administration of mexidol to animals taking excessive caffeine results in restoration of macro-microscopic parameters of the studied organs.

P186
LUNG FUNCTION AFTER MENOPAUSE: INFLUENCE OF BONE MINERAL DENSITY

R. Martín Holguera[1], A. I. Turrión[2]

[1]Universidad de Salamanca, Facultad de Medicina, Departamento de Anatomía e Histología, [2]Hospital de Salamanca, Servicio de Reumatología, Salamanca, Spain

Objective: To compare spirometric results between nonmenopausal and menopausal women and to determine if there is an association of BMD with spirometric results.

Methods: We studied 112 healthy and nonsmoking women (57 menopausal). Spirometry and DXA were performed. A descriptive analysis of the variables was performed, and the differences in means of both groups were assessed using t-test for independent samples. Partial correlation and multiple linear regression analyses were performed to study the relationships between spirometric and BMD variables.

Results: The mean values of FVC and FEV_1 in the non-menopausal group were significantly higher ($p < 0.01$). In nonmenopausal women, no significant associations were found between BMD and spirometric parameters. In menopausal women we found, after performing partial correlations, a positive and very significant association between BMD in the lower extremities and FVC and FEV_1.

Conclusion: There is a very significant decrease in spirometric results in the menopausal group compared to those in the non-menopausal group, although the loss of BMD after menopause does not appear to play an important role in the accelerated decline in lung.

P187
LUNG FUNCTION AND BONE MINERAL DENSITY ON HEALTHY MEN

R. Martín Holguera[1], A. I. Turrión[2]

[1]Universidad de Salamanca, Facultad de Medicina, Departamento de Anatomía e Histología, [2]Hospital de Salamanca, Servicio de Reumatología, Salamanca, Spain

Objective: Several studies have demonstrated an association between osteoporosis and lung function in patients with chronic respiratory diseases. The target of the present study is to research whether there is an association between BMD and the spirometry results in a group of healthy nonsmoking men.
Methods: A group of 142 healthy and nonsmoking men was studied. Forced spirometry and DXA to quantify BMD were performed. Partial correlation and multiple linear regression analyses were performed to study the relationships between spirometric and BMD variables.
Results: The associations found between FEV_1 and FVC and BMD variables were positive and very significant ($p < 0.01$), after performing partial correlations adjusting for the confounding factors age and BMI. The FEV_1/FVC index showed no association with BMD. In the linear regression study, FEV_1 is the parameter with the highest coefficient of adjusted determination (R^2) for all BMD variables.
Conclusion: Osteoporosis has a higher prevalence in women, and it is more common for women to undergo densitometries to determine BMD. These tests are routinely performed during the perimenopause stage. However, this practice is not generalized among men, in which the diagnosis of osteoporosis is often delayed and takes place after the appearance of pathological fractures. Densitometry techniques such as DXA, which has been used in this study, are complex and not easily accessible. However, spirometry is a simple and low-cost technique which is routinely applied in general health check-ups and medical examinations in the workplace. The results of our study show that spirometry may help to detect men with a higher risk of osteoporosis and that spirometry results might be included as an individual risk factor in indexes that assess the risk of osteoporosis fracture.

SECONDARY PREVENTION OF OSTEOPOROSIS IN HIP FRACTURES IN ELDERLY PATIENTS: CLINICAL AND FUNCTIONAL PROFILE OF USERS

B. Miguel Ibáñez[1], C. Pablos Hernández[2], O. Martínez González[1], M. Ibáñez Martínez[1], C. C. Chacón Vélez[1], L. Blanco Ramis[1], M. Martín Martínez[1], C. Hidalgo Calleja[1], C. Montilla Morales[1], O. Compán Fernández[1], L. Lorenzo Rodríguez[1], J. V. Hernández Madrid[1], S. Gómez Castro[1], J. F. Blanco Blanco[3], A. González Ramírez[2], A. I. Turrión Nieves[1]

[1]Rheumatology Dept. of Univ. Healthcare Complex of Salamanca, [2]Geriatric Dept. of Univ. Healthcare Complex of Salamanca, [3]Traumatology Dept. of Univ. Healthcare Complex of Salamanca, Salamanca, Spain

Objective: To describe clinical characteristics of hip fractures, as well as falls, previous fractures, and anti-osteoporotic treatments in 609 elderly patients.
Methods: A descriptive, retrospective and observational study was conducted by analyzing demographic and clinical characteristics, and geriatric indexes of 609 patients who presented with low-impact hip fracture in 2022 and 2023.
Results: The average age of the patients was 87.29 y, with a range of 62–102 y and a predominance of women (456). During admission, a comprehensive geriatric evaluation of the situation prior to the fracture was completed. At a functional level the Barthel Index revealed that 437 patients had slight dependency in their daily life activities. Regarding their instrumental activities, 317 patients showed a score between 0–1. After their hip fracture, 445 patients received physical therapy in hospital and 190 patients required social interventions for their subsequent recovery. 327 patients had suffered falls over the last year. However, according to the Downton scale, 606 of them presented at least one risk factor for falls. Prior to their hip fracture, 155 patients had suffered a previous low-impact fracture. More than one previous fracture was found in 20 cases. Only 33 out of the 155 patients with previous fractures were receiving or had received antiresorptive or bone forming therapy. All the patients received anti-osteoporotic treatment as secondary prevention upon discharge.
Conclusion: Osteoporosis is an underdiagnosed and undertreated condition. Previous fractures often go untreated, which leads to new fractures that compromise the patients' quality of life, independence and survival. Falls very frequently cause fractures among the elderly population. Their primary prevention and an adequate osteoporotic treatment must be a priority in elderly care.

P189
HIP FRACTURES IN THE ELDERLY: EVOLUTION, READMISSION, REFRACTURE AND ONE-YEAR MORTALITY

B. Miguel Ibáñez[1], A. González Ramírez[2], O. Martínez González[1], M. Ibáñez Martínez[1], C. C. Chacón Vélez[1], L. Blanco Ramis[1], M. Martín Martínez[1], C. Hidalgo Calleja[1], C. Montilla Morales[1], O. Compán Fernández[1], L. Lorenzo Rodríguez[1], J. V. Hernández Madrid[1], S. Gómez Castro[1], J. F. Blanco Blanco[3], C. Pablos Hernández[2], A. I. Turrión Nieves[1]

[1]Rheumatology Dept. of Univ. Healthcare Complex of Salamanca, [2]Geriatric Dept. of Univ. Healthcare Complex of Salamanca, [3]Traumatology Dept. of Univ. Healthcare Complex of Salamanca, Salamanca, Spain

Objective: To describe the evolution in the first year of a cohort of elderly patients with osteoporotic hip fracture.
Methods: Observational, descriptive, longitudinal and prospective study of the refractures, readmission and mortality of 223 elderly patients hospitalized in 2022 for hip fractures from their discharge to December 2023.
Results: The mean age of the patients was 87.21 y, with a range of 62–102 y, and a predominance of women (169). After the hip fracture, anti-osteoporotic treatment was prescribed to all patients. The most common reason for readmission was a new fragility fracture (12). In half of these patients, the hip fracture had taken place more than 6 months prior, and there was total lack of adherence to the prescribed anti-osteoporotic treatment. In the series of 223 patients with hip fracture, 67 were readmitted within the first year of follow-up for the reasons included in Fig. 1. With regard to mortality (Fig. 1), 18 of the 41 registered deaths took place during the readmission, in half of these cases due to a respiratory infection.

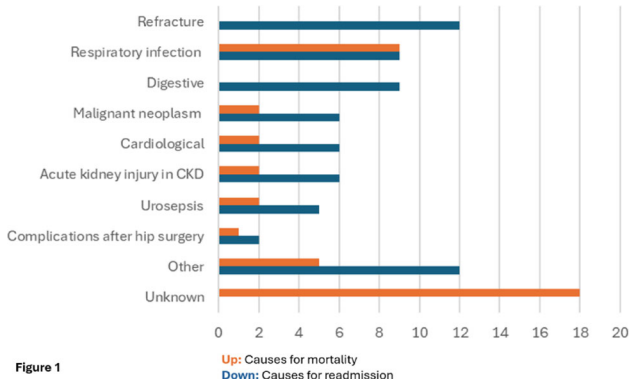

Figure 1

During their hospitalization for a hip fracture in 2022, a comprehensive geriatric assessment of the situation prior to the fracture was conducted. The patients who died in 2023 presented a worse functional outcome and performed fewer instrumental activities (Table 1).

Table 1. Geriatric indexes

		Living (182)	Dead (41)
Katz	N/A	3/1.65%	-
	A-B	94/51.65%	8/19.51%
	C-D-E	52/28.57%	24/58.54%
	F-G	33/18.13%	9/21.95%
Lawton Brody	N/A	4/2.2%	-
	0-1	79/43.41%	29/70.73%
	2-4	49/26.92%	10/24.39%
	≥5	50/27.47%	2/4.88%

Conclusion: The post-fracture mortality rate is in line with the published statistics, and it reveals that it is necessary to look for measures to prevent complications, help the patients recover their functional status prior to the fracture and monitor their adherence to the anti-osteoporotic treatment to prevent refractures.

P190
LONG-TERM SUSTAINED BENEFITS OF VISCOSUPPLEMENTATION WITH DIFFERENT MOLECULAR WEIGHT INTRA-ARTICULAR HYALURONIC ACIDS IN THE TREATMENT OF OSTEOARTHRITIS OF THE KNEE. HAV-OAK: A RETROSPECTIVE INDIAN COHORT STUDY OF MORE THAN 15 YEARS

A. K. Aggarwal[1], N. Aggarwal[1], J. Fitzpatrick[2]

[1]Institute of Rheumatology & Pain, Ghaziabad, India, [2]Univ. of Melbourne, Faculty of Medicines, Dentistry and Health Sciences, Parkville, Australia

Objective: Knee osteoarthritis (OA) is a progressive degenerative condition resulting in functional loss, pain, and discomfort. Viscosupplementation (VS) with intra-articular hyaluronic acid (IAHA) injections has been shown to have protective physiochemical functions and may confer disease-modifying, long-term effects in OA. However, conflicting guidelines, pooling of results for different molecular weight (MW) products, and a paucity of long-term clinical studies have resulted in a lack of confidence in the results of IAHA. The primary objective of the study was to determine the long-term sustained effects of vs. with different MW IAHA in Knee OA in maintaining functional improvement. The secondary objective was to determine the required interval between follow-up injections with different MW of VS.
Methods: We performed a retrospective analysis of a 15-year cohort from a single centre (India). The inclusion criteria were adults with b/l knee OA with functional reduction and radiological KL Grade III & IV, treated with Non-Animal Derived IAHA. Subjects were stratified into two groups based on the MW of the hyaluronic acid used: high MW—6–8 mg/ml—6 ml (HMW-HA), or very high MW—20 mg/ml—3 ml (VHMW-HA). The primary outcome measure was responder rates with improvement in WOMAC scores of $> 30\%$ from baseline vs. nonresponders. Those with a response lasting > 6 months after each injection were considered as sustained responders.
Results: A total of 2037 (female (F) 1467 (72.02%) and male (M) 570 (27.98%)) patients were treated. The total primary responders were 1496 (73.44%) with 1099 (74.91%) F and 397 (69.65%) M. Compared to HMW-HA, VHMW-HA had significantly higher primary responders (75.21 vs. 70.22%, $p = 0.015$) and significantly lower nonresponders (24.79 vs. 29.78%, $p = 0.015$). The sustained responders were 1186 (79.28%) of the primary responders. The sustained response was significantly greater with VHMW-HA vs. HMW-HA (85.54 vs. 67.06%, p-value < 0.0001). The average interval between the first and the third injections was significantly larger for VHMW-HA vs. HMW-HA—5.67 (median 25th–75th percentile—5.392–6.036) vs. 1.95 (median 25th–75th percentile—1.753–2.24) years. P-value < 0.0001.
Conclusion: 73.44% of responders justify treatment with IAHA. The sustained response with VHMW-HA was $>$ HMW-HA. VHMW-HA has a longer duration than HMW-HA.

P191
BONE FRACTURES AS A COMPLICATION OF OSTEOMALACIA DUE TO UNDIAGNOSED CELIAC DISEASE

A. K. Kukovic[1], N. Kravos Tramsek[1]

[1]Univ. Medical Centre Maribor, Dept. of Endocrinology and Diabetology, Maribor, Slovenia

Objective: We describe a case of osteomalacia secondary to long-standing untreated celiac disease, diagnosed after bone fractures and resistance to vitamin D treatment.
Methods: We present the case of a 54-year-old woman with no chronic conditions, who was referred to orthopedics due to groin discomfort and pain in her right hip persisting for three months. An MRI scan revealed fractures of the right pubic rami and greater trochanter of the left femur with associated bone edema. The patient denied any recent falls. She reported weight loss, fatigue, and night sweats, initially attributed to menopause. Physical examination was unremarkable except for malnutrition (BMI 16 kg/m^2). Blood tests showed anemia (Hb 87 g/L), hypocalcemia of 2.04 mmol/L, normal serum phosphate levels, albumins, elevated alkaline phosphatase (3.27 ukat/L). Further investigations, including CT scans of the thorax and abdomen and a bone lesion biopsy, did not confirm malignancy. Additional testing revealed severe vitamin D deficiency (10.3 nmol/L), elevated markers of bone turnover, and elevated i-PTH (120.3 ng/L). BMD measurement showed decreased values (T score left hip − 4.3 SD; lumbar spine -4.5 SD). SPECT revealed elevated osteoblastic activity in the skull, ribs, spine, femur, and tibia periosteum.
Results: The patient was diagnosed with osteomalacia. At follow up visit serum levels were still low, despite calcitriol and cholecalciferol treatment. Serological tests (endomysial antibodies and anti-transglutaminase IgA antibodies) and a digestive biopsy confirmed the

diagnosis of celiac disease. The patient was treated with a gluten-free diet and continued vitamin D supplementation.

Conclusion: Osteomalacia in adults results from decreased mineralization, associated with reduced bone density, loss of trabecular patterning, and variable thinning of the cortices, seen as pseudofractures on radiological images, commonly found near the femoral neck and pelvis. Osteomalacia with typical radiological changes is a rare first presentation of celiac disease in adults.

P192
IN VITRO EFFECTS OF A FOLLICLE-STIMULATING HORMONE RECEPTOR ANTAGONIST ON THE FORMATION AND ACTIVITY OF OSTEOCLASTS DERIVED FROM RAW264.7 MURINE MACROPHAGES

E. Scheepers[1], M. Naude[1], C. Newton[1], A. Kasonga[1]

[1]Univ. of Pretoria, Pretoria, South Africa

Low levels of oestrogen are known to be a major contributor to postmenopausal osteoporosis. However, decreases in oestrogen are also known to result in an increase in follicle-stimulating hormone (FSH) due to a decrease in negative feedback. Recent studies have demonstrated that this increase in FSH may play a role in bone loss by increasing osteoclast activity. These studies suggest that bone loss during perimenopause, where serum oestrogen levels are normal, may be caused by increasing FSH. Furthermore, hypogonadal FSH receptor (FSHR) knockout mice have been shown to be resistant to bone loss. FSHR is known to be expressed in several cells in the body, including bone-resorbing osteoclasts. While FSH antibodies have been shown to improve bone health in ovariectomized mice, there are currently no studies investigating the effects of small molecule FSHR antagonists on bone. Therefore, this study aimed to investigate the effect of an FSHR antagonist on osteoclast formation and activity.

RAW264.7 murine macrophages were differentiated into osteoclasts with the addition of 15 ng/mL RANKL. Western blotting confirmed the presence of the FSHR on the RAW264.7 cells. The cells were treated with FSH (50 ng/mL) and the activation of FSHR was confirmed by cyclic adenosine monophosphate (cAMP) ELISA. FSH (50 ng/mL) was shown to not affect the cell viability of undifferentiated RAW264.7 cells but did result in a small increase in osteoclast activity. The nonpeptide FSHR antagonist used in this study was shown to not affect cell viability at 1 pM–1 μM concentrations. However, the FSHR antagonist (1 nM–1 μM) decreased both the size and number of osteoclasts formed.

These results suggest that FSHR is expressed in RAW 264.7 murine macrophages, and non-peptide FSHR antagonists have the potential to decrease osteoclast formation and activity. Ongoing studies are investigating the mechanism of action of the FSHR antagonist in the RAW264.7 cells. These studies will shed further light on the potential of FSHR as a therapeutic target for postmenopausal osteoporosis.

P193
EFFECT OF DIALLYL TRISULFIDE ON OXIDATIVE STRESS MARKERS AND OSTEOCLAST FORMATION IN RAW264.7 MURINE MACROPHAGES

M. Mukozi[1], M. Visagie[1], A. Kasonga[1]

[1]Univ. of Pretoria, Pretoria, South Africa

In bone degenerative disorders, such as osteoporosis, over-active osteoclasts result in fragile bones that fracture readily. Inhibiting osteoclast activity represents a viable strategy to combat bone degeneration. Osteoclasts are large, multinucleated bone resorbing cells. RANKL binds to its receptor, RANK, on osteoclast precursors to stimulate differentiation and maturation into osteoclasts. Reactive oxygen species generation (ROS) as well as NF-kB and mitogen-activated protein kinase (MAPK) pathways are crucial for osteoclast differentiation and activation. Diallyl trisulfide (DATS) is a garlic-derived organosulfur compound that has demonstrated potent anti-cancer properties in vitro. However, the effects of DATS on osteoclast formation and function remains unknown. Therefore, the aim of this study was to determine the effects of DATS on osteoclast formation and function using RAW264.7 murine macrophages.

Using a resazurin assay, DATS (1–5 μM) was shown to have no effect on cell viability. RAW264.7 cells were then differentiated into osteoclasts using RANKL and stained for tartrate-resistant acid phosphatase (TRAP). DATS was shown to decrease the number TRAP positive osteoclasts formed. Western blotting analysis determined that DATS inhibited the activation of key MAPKs (Jun N-terminal kinase (JNK) and p38). However, DATS showed no effect on the activation of NF-kB. DATS was further shown to increase the expression of the antioxidative protein, nuclear factor erythroid 2-related factor 2 (Nrf2), while decreasing expression of the oxidative stress marker, nicotinamide adenine dinucleotide phosphate oxidase 1 (Nox1).

DATS was shown to be a potent inhibitor of osteoclasts through targeting MAPK signalling and ROS pathways. These results demonstrate that DATS may have potential as a therapeutic option in the treatment of osteoporosis. In addition, data obtained in the current study may potentially lead the identification of novel biochemical markers for improved future treatment strategies for bone disorders.

P194
EFFECTS OF CHRYSIN ON OSTEOCLASTOGENESIS IN RAW264.7 MURINE MACROPHAGES AND BONE METABOLISM IN SPRAGUE DAWLEY RATS

C. Mason[1], T. Nyakudya[1], A. Kasonga[1]

[1]Univ. of Pretoria, Pretoria, South Africa

Bone is a metabolically active tissue that is continuously resorbed and reformed by osteoclasts and osteoblasts respectively. Excessive osteoclast activity can lead to bone degenerative disorders such as osteoporosis. RANK signalling is crucial for osteoclast formation and function. RANKL binding to its receptor RANK will lead to the activation of nuclear factor of activated T-cells, cytoplasmic 1 (NFATc1), the master regulator of osteoclasts. Targeting RANK signalling in osteoclasts could offer a viable strategy in the treatment of osteoporosis. Chrysin is a bioactive phytochemical that has shown to possess several metabolic benefits, such as anticancer and antispasmodic properties. However, the effects of chrysin on bone remain unexplored. The aim of this study was to investigate the potential bone protective effects of chrysin.

Tartrate resistant acid phosphatase (TRAP) staining was conducted to determine the effect of chrysin on osteoclast differentiation. TRAP-positive cells of three or more nuclei were counted. qPCR was conducted to determine the effect on key osteoclast genes. Western blotting was conducted to determine the effect of chrysin on the RANK signalling pathways. μCT was performed was used to evaluate the tibia bones in Sprague Dawley rats who were fed a diet high in chrysin.

TRAP staining showed that chrysin (5–100 μM) significantly decreased the number of osteoclasts formed compared to the positive control. The IC50 (14 μM) was determined. qPCR analysis showed the NFATc1 expression was significantly inhibited at day 5, and TRAP expression at day 3 and 5. Western blot analysis showed a decrease in the phosphorylation of extracellular signal-regulated kinase (ERK), a key regulator of RANK signalling. However, the

analysis of the tibia bones showed that chrysin did not have any significant effects on bone health.

The results indicate that chrysin inhibits osteoclastogenesis through the inhibition ERK signalling leading to an inhibition of NFATc1 and TRAP genes. Further studies are needed to evaluate the in vivo effects of chrysin. These findings demonstrate the potential of chrysin as a therapeutic agent in bone degeneration.

P195
CORRELATION BETWEEN KNEE OA AND GRIP STRENGTH IN POSTMENOPAUSAL FEMALE

A. Kaur[1], G. Msp[1], R. Thakur[1], D. Wadhwa[1]

[1]MVP's College of Physiotherapy, Nashik, India

Objective: The preferred approach for assessing muscular strength necessary for diagnosing sarcopenia is hand grip strength, which has a positive correlation with quadruple movement strength. Individuals who are obese and sarcopenic are said to have an increased chance of developing knee osteoarthritis. Thus handgrip examination can be useful in assessing knee OA's functional and radiological outcomes. This study aimed to determine whether hand grip strength and radiographic and functional indications of osteoarthritis in the knee were related.
Methods: 53 postmenopausal female patients (mean age: 62.4 ± 8.6 y; range, 50–80 y) with bilateral persistent knee pain were included in the study. They were diagnosed with knee OA based on radiological and clinical findings in compliance with the 2019 American College of Rheumatology recommendations. The BMI, hand dominance, and patient demographics were noted. The Lower Extremity Functional Scale (LEFS) and WOMAC were used to evaluate the functioning of the knee OA. For the radiological evaluation of knee OA, the Kellgren-Lawrence (KL) grading system was used. The dynamometer was utilized to test the hand grip strength, and the findings were adjusted based on the BMI.
Results: A negative, moderate association was discovered between WOMAC and hand grip strength in the evaluation of the link between knee OA functioning and hand grip strength ($p < 0.05$). Furthermore, a moderately positive connection ($p < 0.01$) was discovered between the hand grip strength and the LEFS. There was no significant correlation between Kellgren–Lawrence grading and hand grip strength.
Conclusion: The results of the study demonstrate a functional and radiological relationship between hand grip strength and knee OA. In the functional assessment of knee OA, hand grip strength should be included in the WOMAC and LEFS. Additionally, new scales incorporating the assessment of hand grip strength should be created.

P196
IMPACT OF SQUARE STEPPING EXERCISE VERSUS BOSU BALL EXERCISE ON BALANCE IN A INSTITUTIONALIZED ELDERLY WITH LOW BONE MASS

A. Kaur[1], G. Msp[1], R. Thakur.[1]

[1]MVP's College of Physiotherapy, Nashik, India

Objective: Falls are a serious public health concern and one of the main causes of harm and mortality for older individuals. Even while falls are prevalent among the elderly, current studies have shown that those living in long-term care facilities had higher rates of falls than those living in the community. In senior people living in residential care facilities, balance becomes more compromised due to sedentary lifestyles, physical and mental impairments, and bodily damage that can lead to falls. Therefore, comparing the effects of Bosu ball exercise and square stepping exercise (SSE) on balance in an older population living in institutions was the primary objective of the research.
Methods: Thirty elderly individuals who were ambulatory and 60 years of age or older were randomly assigned to two groups in this study. Group A: SSEs. Group B: Bosu ball exercises. Variables: (i) dependent variables: balance. (ii) independent variables: square stepping exercises, Bosu ball exercises. Outcomes measure was Berg Balance Scale (BBS). Group A: SSEs for a period of 12 weeks, the SSE group participated the supervised group session thrice a week. SSEs, warmup and cool down activity exercises had been given during each session. SSE is performed on a thin, 100 × 250 cm felt mat that has been divided into 40 squares, each measuring 25 cm. Group B: Bosu ball exercise was given for thrice a week for 12 weeks with warm up and cool down exercise.
Results: The analysis of the data was done after 12 weeks. The balance score was assessed using a paired t-test within the group and an Independent sample t-test between the groups under the SSEs and Bosu ball exercises training. $P < 00.5$ was designated as the significant level for the P-value. This outcome demonstrated that there was no discernible difference in the BBS between the two groups at baseline treatment. (The P-value is 0.369). Following a 12-week exercise regimen, Group A's BBS increased (P-value = 0.016). Thus, the results indicated that Group A was more significant than Group B.
Conclusion: According to the study, the elderly population's balance significantly improved after receiving Bosu ball training. However, under SSEs training, improvement is significantly greater.

P197
COMPARATIVE ANALYSIS OF PERIPROSTHETIC FRACTURES IN TOTAL HIP ARTHROPLASTY BETWEEN PATIENTS WITH RHEUMATOID ARTHRITIS AND OSTEOARTHRITIS

A. Khramov[1], M. Makarov[1], S. Makarov[1], S. Maglevaniy[1], A. Gorelova[1]

[1]Nasonova Research Institute of Rheumatology, Moscow, Russia

Objective: Surgical treatment of patients with rheumatoid arthritis (RA) is associated with an increased risk of complications due to the presence of an inflammatory process, prolonged intake of glucocorticoids (GC), disease-modifying and genetically engineered biological drugs, reduced physical activity, functional disorders and severe osteoporosis. All this contributes to an increased risk of intraoperative complications, including periprosthetic fractures. We aimed to conduct a comparative analysis of periprosthetic fractures, which included intraoperative fractures of the large and small trochanter, as well as the acetabulum, during total hip arthroplasty (THA) in patients with RA and osteoarthritis (OA).
Methods: 1173 hip replacement operations were performed in patients with RA and OA in the period from 2002–2022 (OA: 709, RA: 484).
Results: A total of 41 (3.49%) periprosthetic fractures were diagnosed during THA. Of these: 23 (4.96%) fractures occurred in patients with RA; 18 (2.54%) in patients with OA. In most cases, osteosynthesis with intraosseous sutures, circular sutures with wire or plate was performed for the treatment of periprosthetic fractures (61.8%), and Wagner's long revision leg was also used. Osteosynthesis was performed more often in patients with OA (66.7%), less often in patients with RA (43.5%). Statistical analysis of the data revealed a significantly higher number of complications in the group of RA patients ($p = 0.0288$). Significant differences were also obtained in the analysis of each type of complications ($p < 0.05$).
Conclusion: Obtained results confirmed that the risk of periprosthetic fractures was 2 times higher in RA patients than in patients with OA. Therefore, these patients require a special approach, which includes in

the competent medical perioperative treatment of osteoporosis and careful handling of bone and surrounding soft tissues during the operation.

P198
DIURETICS AND OSTEOPOROSIS IN POSTMENOPAUSAL WOMEN

A. Kollcaku[1], J. Kollcaku[2], V. Duraj[1]

[1]"Mother Teresa" Univ. Hospital Center, [2]Specialities Health Center No. 3, Tirana, Albania

Objective: Loop diuretics increase bone turnover by augmenting urinary calcium excretion while thiazide diuretics lower calcium excretion. Estrogen cease appears to be an important risk factor in the development of osteoporosis in postmenopausal women. This study aimed to assess the role of diuretics usage in BMD in postmenopausal women.
Methods: It was a cross-sectional study already done in the capital city of Albania with the participation of 4789 postmenopausal women. All subjects were asked if they were using furosemide, hydrochlorothiazide, or other diuretics. They were screened for osteoporosis by using an ultrasound system, based on T-score values of BMD evaluation. Binary logistic regression was used to determine the relationship between osteoporosis and independent factors such as diuretics treatment in this study population.
Results: Osteoporosis was positively associated with diuretics treatment ($r = 0.007$, $p < 0.001$). Of the total number of subjects, 5.5% were using furosemide, 9.1% were using thiazide, and 4% were using other diuretics. On the other hand, 12% of the total number of women diagnosed with osteoporosis were using furosemide, 12.4% were using hydrochlorothiazide, and 8% were using other diuretics. We found a significant statistical correlation between osteoporosis and furosemide usage for P value < 0.001, osteoporosis and hydrochlorothiazide usage for P value < 0.007, and osteoporosis and other diuretics usage for P value < 0.001.
Conclusion: The study offers useful evidence of the diuretic effect on bone turnover. Loop diuretics are well known for their negative effect on bone turnover. This study suggests also that thiazide diuretics do not protect against osteoporosis in postmenopausal women.

P199
POSTMENOPAUSAL AND GLUCOCORTICOID INDUCED OSTEOPOROSIS

A. Kollcaku[1], J. Kollcaku[2], V. Duraj[1]

[1]"Mother Teresa" Univ. Hospital Center, [2]Specialities Health Center No. 3, Tirana, Albania

Objective: Glucocorticoids indicate bone turnover due to inhibition of bone formation early and increase of bone resorption later. Following initiation of glucocorticoids rapid bone loss occurs. The duration of glucocorticoid treatment plays a key role in bone loss. This study aimed to assess the role of duration of treatment with glucocorticoids in inducing osteoporosis in postmenopausal women.
Methods: It was a cross-sectional study in postmenopausal women and all subjects (4789) were screened for osteoporosis by using an ultrasound device. All subjects with T-score results below -2.5 were diagnosed with osteoporosis. Women were asked if they were using glucocorticoid therapy and treatment duration with less or more than three months. Binary logistic regression was used to determine the relationship between osteoporosis and independent factors such as glucocorticoid treatment duration in this study group.
Results: 13.9% of the total number of subjects diagnosed with osteoporosis were using glucocorticoid therapy for more than three months. We found a significant statistical correlation between osteoporosis and treatment with glucocorticoids for more than three months in postmenopausal women (OR: 1.52; CI 95% 1.46–1.94; $p = 0.02$).
Conclusion: The study offers strong evidence of a negative effect on bone turnover and the increased risk of inducing osteoporosis in the group of postmenopausal women who are going to use glucocorticoid treatment over three months.

P200
INTERVENTION FAILED TO STABILIZE ATLANTOAXIAL DISLOCATION IN A PATIENT WITH DIABETES AND ANKYLOSING SPONDYLITIS, AND OSTEOPOROSIS: A CASE REPORT

A. Kollcaku[1], J. Kollcaku[2]

[1]"Mother Teresa" Univ. Hospital Center, [2]Specialities Health Center No. 3, Tirana, Albania

Objective: Chronic kidney disease is associated with the deterioration of bone mass, which is called renal osteodystrophy. Patients with ankylosing spondylitis suffer from disease complications such as osteoporosis and are at risk for dislocation of the atlantoaxial joint. This case report aims to show how important is early detection of secondary osteoporosis, especially in patients with the risk of atlantoaxial joint dislocation, because of the risk of intervention failure.
Methods: The patient, a 56-year-old man, was diagnosed with chronic kidney disease 10 years ago due to the painkillers used for many years for ankylosing spondylitis. He started dialysis procedures at the same time. The patient complained of intensive cervical pain, extreme restriction of cervical mobility, and sensory disturbances in upper and lower limbs after one year of starting biological treatment with etanercept 50 mg once weekly. He was referred to the neurologist and an MRI of the cervical spine was ordered for him. Subluxation of the atlantoaxial joint was detected and bone deterioration of vertebras of the cervical spine. The patient was referred to intervention to stabilize the joint.
Results: Neurosurgical intervention already done failed to stabilize the joint subluxation because of the high grade of cervical spine osteoporosis.
Conclusion: Patients with atlantoaxial dislocation who suffer from osteoporosis are at high risk of failure to stabilize it by neurosurgical intervention. Early screening for secondary osteoporosis in patients with risk factors such as chronic kidney disease and ankylosing spondylitis is very important, especially in patients with long-term disease who are at risk for atlantoaxial joint sub/luxation.

P201
I.V. BISPHOSPHONATE PREVENTS PERIPROSTHETIC OSTEOPENIA AFTER IMPLANTATION OF A CEMENTLESS TOTAL HIP JOINT REPLACEMENT

A. Kurth[1], H. Arabmotlagh[2], C. Eberhardt[3]

[1]Dep. of Orthopaedic and Trauma Surgery, Marienhaus Klinikum Mainz, Mainz, [2]Spine Unit, Sana Klinikum Offenbach, Offenbach, [3]Arthroplasty Unit, St. Vinzenz-Krankenhaus, Hanau, Germany

Objective: Total hip arthroplasty (THA) is an effective intervention for end-stage osteoarthritis of the hip. But after surgery, loss of periprosthetic BMD has been reported, which may have a negative impact on implant survival, especially in patients with osteoporosis.

The early loss of periprosthetic bone density is mainly due to the initial local surgical irritation, but the postoperative relief of the operated leg is mainly due to the altered force flow ("stress shielding") through the prosthesis. Various studies have reported that bisphosphonates can effectively reduce periprosthetic bone density loss and prolong the survival time of implants. It is still unclear whether intravenous therapy is superior to oral bisphosphonate therapy in terms of preventing bone density loss.

Methods: 43 healthy patients were treated with cementless THA. Postoperatively, the patients were either treated with ibandronate 3 mg i.v. (twice with an interval of 3 months) (n = 23), or with Ca/Vit.D (n = 20). The periprosthetic bone density was determined by DXA measurements (Hologic 4500 plus) after 2, 4, 6 and 12 months in the regions n. Gruen (ROI) and compared with the baseline value one week after surgery. Furthermore, the results were compared with original data from a historical control group with oral alendronate 10 mg daily (Hennigs et al. Z. Orthop 2002). For the statistical analysis, an ANOVA test with a significance level of $p < 0.05$ was performed.

Results: In the control group, there was significant bone loss in the entire periprosthetic bone of up to 5% during the first few months. Ibandronate therapy completely prevented bone loss, while oral therapy reduced but did not prevent bone loss. The differences between the individual groups were statistically significant.

Conclusion: The study showed that i.v. bisphosphonate therapy with ibandronate after hip arthroplasty implantation can maintain periprosthetic BMD over 12 months and is superior to oral alendronate therapy. This confirms previous studies in which it was shown that osteointegration could be improved by the use of bisphosphonates in cementless implants. Influencing bone health with medication also shows positive effects on cementless arthroplasty and can possibly improve the longevity of the implants, even if there is a lack of conclusive studies.

P202
ARTHROPLASTY OF THE HIP IN OSTEOPOROTIC PATIENTS: A RECIPE FOR DISASTER?

R. Ene[1], A. L. Dimitriu[1], C. Georgescu[1], E. G. Popescu[1], B. Bolos[1]

[1]Clinical Emergency Hospital, Dept. of Orthopedics, Bucharest, Romania

Objective: As a result of low trauma, femoral neck fractures are very common in the elderly population. Usually, the fractures are Garden IV types, that require a form of arthroplasty (hemi or total) as surgical treatment [1]. In these cases, the presence of osteoporosis influences the implant stability [2], and may lead to implant failure of the acetabular cup or the femoral stem [3]. Of course, there is the obvious possibility of using cement, but this may affect the longevity of the implant in the more young and active population [4].

Methods: We evaluated 64 patients with femoral neck fractures Garden III and Garden IV types, that were operated in our clinic between July 2022 and February 2023. In 12 patients cementless bipolar arthroplasty was used, and in 52 patients total arthroplasty (24 cemented and 28 cementless). The decision of using cement was made either by the fact that the patients had severe osteoporosis, were elderly patients usually above 80 years old, or by the intraoperative assessment that shows a poor stability of probes. Septic patients were ruled out of the study, because the sepsis may be a cause of instability also [5].

Results: We noticed that 7 patients had mechanical failure (1 cemented cup became loose, 3 uncemented stems became also loose, and 3 cemented stems). Also, 5 patients returned to the clinic with periprosthetic fractures due to recurrent falls, and needed to be reoperated. We saw that smaller size stems were more prone to instability (up to size 9) and stem sizes above 10 were more stable. Out of these patients, 85% din not receive prior osteoporosis treatment, and they were instructed to do so after hip surgery. In the case of periprosthetic fractures, there were no difference between cemented vs. uncemented stems as protectors for periprosthetic fractures.

Conclusion: It appears that the use of bigger stem sizes is a factor of increased mechanical stability, but larger population groups need to be studied. Also, the cemented group seems to be more protected against instability of the implant, but a longer follow up needs to confirm this finding.

P203
CERVICAL SPINAL INJURY SECONDARY TO A SPORTS ACCIDENT ABOUT 29 CASES

A. Mahtout[1]

[1]Regional Univ. Military Hospital of Blida, Blida, Algeria

Objective: Trauma to the cervical spine can be differentiated from a therapeutic point of view, in two situations: The unstable spine (fracture + ligament rupture) where the potential neurological risk, medullary or radicular, guides in a completely hierarchical and validated way the conduct to be held on the ground and then at a distance. The microtraumatic spine where, as we know, the frequency of 'common' spinal pain, and the functional, socio-professional and athletic repercussions, which vary greatly from one patient to another for the same lesion, involve more diagnostic and therapeutic pathways. individualized and, for the majority, primarily or even solely conservative.

Methods: We report a series of 29 patients admitted as part of the emergency at the level of the neurosurgery department/central hospital of the army and treated surgically in emergency following various sports accidents. all the difficulty of management is based on the right indication:

- Should a great sportsman be operated on or not?
- If so, what is the benefit?
- And above all can he resume his sporting activity of competition?

Results: Of the 29 athletes who had spinal cervical lesions without medullary, 21 were indicated for surgery:

– 7 patients operated by an anterior approach with discectomy followed by placement of a cervical cage and anterior osteosynthesis on one level.
– 4 patients via the posterior route due to articular collisions, having benefited from fixation via the posterior route.
– 8 patients when to them were of orthopedic indication with installation of a cervical collar with a rigorous clinical radio control.

Conclusion: The surgical indication is always posed in front of spinal instability, this must be discussed at length and with the consent of the patient in athletes. orthopedic treatment is indicated when the elements of spinal stability are not compromised, otherwise surgery is the only therapeutic recourse. The management of high level athletes requires in-depth compression of the lesion mechanisms, careful reading of radiological images and multidisciplinary management, not only surgical but functional and rheumatological rehabilitation.

P204
SHOULD A SURGERY BE PERFORMED FOR CERVICO OSTEOARTHRITIC MYELOPATHIES DECOMPENSATED BY TRAUMA TO THE CERVICAL SPINE: ABOUT 37 CASES

A. Mahtout[1]

[1]Regional Univ. Military Hospital of Blida, Blida, Algeria

The incidence of the spinal cord trauma (SCT) in Algeria is 20 people/1000 inhabitants. SCT can lead to spinal cord injury without bone involvement, particularly when a narrow cervical canal (NCC) preexists. 75% of people over 65 have a narrow cervical canal, which is the most common risk factor for spinal cord injury. Furthermore, the cervical cord is more vulnerable because it is less well vascularized, particularly in the elderly population.

We report the experience of the neurosurgery department in the care of 37 patients with cervico osteoarthritic myelopathies whose ages are between 56–78 years old and who are victims of various accidents manifested by incomplete tetraplegia evaluated by the score by JOA. Our course of action was: hospitalization of patients; implementation of a therapeutic regimen based on corticoids 2 mg/kg/d associated with adjuvant treatment; the wearing of a cervical collar and not a minerva given the absence of spinal instability; and nursing. Reassessment of the JOA score on D3 post-trauma then patient discharge. Patients systematically reviewed in spine consultation at 1 month with a reassessment of the JOA.

The neurological and functional benefit of decompressive and stabilization surgery remains controversial. In our study, early surgery did not improve neurological and functional recovery and was not associated with fewer medical complications or shorter hospital stay. Moreover, there is no evidence in the literature to encourage routine early surgery in patients with SCT on NCC without vertebral fracture. In addition, potential preoperative complications must be taken into account, particularly in the elderly population. In the acute phase, the most frequent indications for surgery are the presence of signs of clinical and/or radiological instability. The criteria traditionally used in favor of remote surgery are worsening or stagnation of a neurological state after a phase of improvement.

P205
PLACE OF CURRENT IMPLANTS IN THE MANAGEMENT OF CERVICO OSTEOARTHRITIC MYELOPATHY (COM) ABOUT 150 CASES

A. Mahtout[1]

[1]Regional Univ. Military Hospital of Blida, Blida, Algeria

Cervico-osteoarthritic myelopathy is a cervical spinal cord suffering associating a narrowing of the dimensions of the cervical canal of osteoarthritis origin, the natural evolution of the pathology is towards progressive aggravation until tetraplegia. At present there is no medical treatment, so it is an almost exclusively surgical treatment that both decompresses the cervical spinal cord.

Casereport: We report a series of 150 cases collected in the neurosurgery department, carrying CAM at the operative stage and having benefited from decompression with the addition of prosthetic material, namely cervical prostheses. The whole difficulty of the management of CAM is to pose an indication for surgery at the right time, the addition of implants in this surgery has allowed on the one hand to restore spinal biomechanics but also to restore a function of lost neck mobility.

Conclusion: We are convinced that although the cost of acquisition is relatively high, the addition of cervical prostheses allows a restoration of function and a social and professional reintegration of patients.

P206
OS ODENTOIDEUM ABOUT 3 CASES

A. Mahtout[1]

[1]Regional Univ. Military Hospital of Blida, Blida, Algeria

Objective: Bone odentoidum or mobile odontoid process is one of the malformations of the cervico-occipital hinge. It is about a defect of union of the center of ossification of the odontoid on the body of the axis. The malformation exposes you to atlo-axoid instability and the risk of bulbo-medullary compression.

Methods: We report the observation of 3 active men whose age varied between 18–247 y with a notion of craniocervical trauma and who presented progressively in 2 y persistent cervical pain and stiffness with heaviness of the four limbs with discreet sphincter disorders.

Results: The clinical examination objectified spastic tetraparesis with associated sensory disturbances Lateral flexion and extension radiographs can provide useful information about C1–C2 instability. Computed tomography (CT or simple) is useful to define bony relationships at the base of the skull, C1 and C2. The degree of C1–C2 instability identified on cervical radiographs is not correlated with the presence of myelopathy. A sagittal diameter of the spinal canal at the C1–C2 level of 0.13 mm correlates with the myelopathy detected on clinical examination. MRI can show spinal cord compression and signal changes in the cord that correlate with the presence of myelopathy. To behave given the clinical examination, the patients show signs of deficit associated with imaging objectifying a compression of the bulb, a surgical indication is posed, the intervention consisted of an occipital craniectomy opening of the occipital foramen and the posterior arc of C1 followed by C3 occiput osteosynthesis using polyaxial rods and screws.

Conclusion: The mobile odontoid process or os odontoideum is a rare anomaly of the cervico-occipital hinge for which we will recall the clinical, radiological, etiological and prognostic aspects for an adequate management. Clinical examination revealed spastic tetraparesis with associated sensory disturbances. Cervical CT and MRI confirmed the odontoid-axoid dislocation, the CT on the one hand revealing a corticalized ovoid ossicle in place of the odontoid and the MRI on the other hand the myelomalacia. The therapeutic result was conclusive after surgical approach by posterior approach. The os odontoideum designates a small bone in a position cranial to the axis and independent of the odontoid. The embryonic, vascular or even traumatic origin are evoked to explain the pathogenesis. It can be discovered incidentally in asymptomatic patients or cause sudden death without the diagnosis being recognized. If symptomatic, the age of discovery is variable and the clinical signs are upper neck pain, neck stiffness, torticollis, spinal cord or cervical radicular compression syndrome without any notion of recent spinal cord injury. Standard radiographs, better cervico-occipital CT, show a rounded or ovoid ossicle, separated from the base of the odontoid and corticalized, unlike recent fractures of the odontoid. MRI shows the repercussions on the bulbo-medullary junction. The approach of choice is the posterior approach to decompress the nervous structures and stabilize the spine. Functional rehabilitation is essential. In asymptomatic subjects, prophylactic surgery is discussed after dynamic X-rays.

P207
EXPERIENCE IN X-LINKED HYPOPHOSPHATEMIC RICKETS IN THREE HOSPITAL CENTERS IN COLOMBIA: CASE SERIES

A. Medina[1], N. Camargo[2], M. A. Rueda[2], J. Gutierrez[2], A. Roman[2]

[1]Universidad Nacional de Colombia. Medicine Faculty, [2]Fundación Universitaria de Ciencias de la Salud, Medicine Faculty, [3]Universidad de Antioquia. Medicine Faculty, Bogota, Colombia

Objective: To describe the presenting characteristics as well as the clinical and biochemical response to treatment with burosumab of 5 patients with X-linked hypophosphatemic rickets (XLH) evaluated in three hospital centers in Colombia.
Methods: Case series from three hospitals where 5 patients with a diagnosis of XLH were included, in which genetical, clinical, radiological, biochemical studies and response to treatment with burosumab were analyzed.
Results: All patients were women with an average age of 50 y. Only two patients had been diagnosed with XLH since childhood, the remaining three were diagnosed in adulthood. Most frequent clinical manifestations were: short stature, in average 1.31 m, bone deformities, altralgias, stiffness, dental loss and oral abscesses. The most common radiological findings were pseudofractures and arthrosis of the hips or knees. Three patients presented fragility fractures and two of them with enthesopathies. The average baseline hypophosphatemia was 2.0 mg/dl, 1,25-dihydroxyvitamin D < 20 ng/ml, PTH 88 pg/ml and alkaline phosphatase(AP) 181 U/L. Only two patients had their tubular phosphorus reabsorption (TPR) and tubular phosphorus reabsorption adjusted to GFR (Tmp/GFR) Tmp calculated and were $< 85\%$ and 2.8 mg/dl respectively. Genetic confirmation of the PHEX gene mutation was performed in all patients.
Conclusion: XLH is a rare entity, which, given its rarity, presents limitations and delays of even years in diagnosis as well as in early treatment, leading to great morbidity and compromise in the quality of life of patients. Once treatment with burosumab, an anti-FGF23 monoclonal antibody, was initiated at a dose of 1 mg/kg body weight per month, clinical improvement and biochemical normalization were evident: serum phosphate increased to 2.5, 3.1 and 2.7 mg/dl on average in the following controls after starting treatment; as well as a decrease in mean PTH to 68.5 pg/L was evident. Pain, stiffness, and performance using the WOMAC improved after treatment compared to baseline. The average pain scale dropped from 8.25 to 2.25; the stiffness from 10.3 to 2.3 and the functionality test from 32.2 to 10.5. Thus in our experience, we had the opportunity to describe the clinical, biochemical and general performance improvement of all patients who received burosumab as targeted XLH therapy, starting from the first dose.

P208
IMPACT OF NOSOCOMIAL INFECTIONS ON CLINICAL OUTCOME AND AUTONOMY IN ELDERLY ORTHOPEDIC PATIENTS: A RETROSPECTIVE OBSERVATIONAL STUDY IN LONG-TERM RHEABILITATION FACILITIES

A. Medioli[1], C. Rizzi[1], C. Cucchetti[1], S. Orsucci[1], V. Di Cintio[1], N. Loubadi[1], G. Civardi[1], G. Aronica[1]

[1]Clinica Sant'Antonino, Piacenza, Italy

Objective: To verify whether nosocomial infection (NI) acquired during hospitalization have influenced the clinical outcome and autonomy in daily life activities upon discharge.
Methods: In a retrospective observational study, we evaluated the prevalence of NI during the hospitalization of patients admitted to long-term rehabilitation facilities using the patients' medical records. 2974 patients were admitted to hospital from January 1, 2021 to November 30, 2023. We selected 873 orthopedic patients and analyzed those who developed NI after the second day of hospitalization. The types of NI that occurred were analysed, correlating them with the number of days of hospitalization with the following scales: Barthel, Braden, ICA (index of healthcare complexity).
Results: In the cluster of 873 patients analyzed 313 contracted NI. The average age is comparable 79.83 for patients who have no counteract NI; 79.59 for patients with NI. The type of NI contracted are as follows: E. coli; Friedlander, Proteus mirabilis, Pseudomonas, Staphylococcal infection, Streptococcal infection, Other infections, Candidiasis, Clostridium difficilis, septicemia from E. coli, staphylococcal septicemia, septicemia due to other Staphylococci, Streptococcal septicemia, other septicemia, SARS CoV2 + . The data for patients who have not contracted NI are as follow: Barthel incoming average 37.75, median 37.41, standard deviation 2.82, Barthel outgoing average 59.47, median 60.31, standard deviation 8.11, ICA incoming average 17.75. median 18.37, standard deviation 1.08, ICA outgoing average 13.94, median 14.65, standard deviation 2.12, Braden incoming average 15.92, median 16.65, standard deviation 0.48, Braden outgoing average 17.73, median 17.83, standard deviation 5.02. Average hospital stay 28.40. Patient who has contracted NI: Barthel incoming average 27.39, median 27.62, standard deviation 1.23, Barthel outgoing average 46.29, median 42.07, standard deviation 6.15, ICA incoming average 18.99, median 18.63, standard deviation 0.67, ICA outgoing average 16.21, median, standard deviation 1.30. Braden incoming average 15.10, median 15.26, standard deviation 0.32, Braden outgoing average 16.42, median 16.19, standard deviation 0.36. Average hospital stay 30.31.
Conclusion: The data analyzed confirm that the days of hospitalization in patients who contracted NI have become longer. The frailty scales used on average confirm that in elderly orthopedic patients nosocomial infections worsen the outcome.

P209
VARIATION IN CIRCULATING LEVELS OF PERIOSTIN IN OSTEOGENESIS IMPERFECTA

A. Mercier[1], E. Gineyts[2], M. Millet[2], O. Borel[3], E. Sornay-Rendu[2], M. Auroux[1], P. Szulc[2], E. Fontanges[4], J.-C. Rousseau[2], R. Chapurlat[1]

[1]INSERM Unit 1033, Univ. of Lyon; Rheumatology Dept., Hôpital E. Herriot, Hospices Civils de Lyon, [2]INSERM Unit 1033, Univ. of Lyon, [3]INSERM Unit 1033, Univ. of Lyon, [4]Rheumatology Dept., Hôpital E. Herriot, Hospices Civils de Lyon, Lyon, France

Objective: Periostin (POSTN) interacts with type 1 collagen and the Wnt-β-catenin pathway, so it may play a role in the pathophysiology of osteogenesis imperfecta (OI). Higher POSTN levels have been associated with the risk of fractures in postmenopausal women. There is no biomarker for the severity of OI, and POSTN stands out as a promising candidate due to its straightforward measurement in serum through a standardized method. The primary aim is to investigate whether there is dysregulation of POSTN in OI. The secondary objective is to determine if POSTN levels correlate with the severity and various clinical and biological characteristics of the disease.
Methods: This is a secondary analysis of 60 adult patients from the miROI study cohort, including OI types 1 and 3. These patients were compared to 60 control individuals matched for age, sex, and BMI. The measurements were made using an ELISA in serum samples. We used a t-test for the primary comparison, and Pearson's correlation coefficient was computed to identify potential correlations between serum POSTN levels and clinical and biological characteristics.
Results: Serum POSTN levels were significantly higher in the OI group compared to the control group (mean = 798 vs. 712 ng/mL; $p = 0.016$) (Fig. 1). There was no correlation with severity variables,

such as the number of severe prevalent fractures, the ratio of height to wingspan, or the severity of scoliosis. However, a significant association with the presence of dentinogenesis imperfecta (DI) (mean = 819 vs. 685 ng/mL; p = 0.03) was observed.

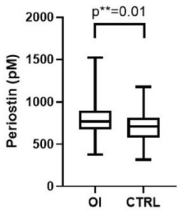

Figure 1: Box plot of the difference in circulating serum periostin levels between the Osteogenesis Imperfecta (OI) group and the control group (CTRL). P-value was calculated using a t-test

Conclusion: We have found that serum POSTN levels were higher in OI than in controls and were especially associated with the presence of DI. Considering POSTN role in collagen stability and in dentinogenesis, it may be considered as a factor in the pathophysiology of OI and a potential biomarker.

P210
OSTEOPOROSIS MANAGEMENT IN SPINAL CORD INJURY IN DEVELOPING COUNTRIES: THE MOROCCAN EXPERIENCE

A. Messouber[1], S. Skalli[1], S. Karkouri[1]

[1]Dept. of Physical Medicine and Rehabilitation, Rabat Univ. Hospital, Rabat, Morocco

Objective: Spinal cord injury (SCI) induces heightened bone turnover due to immobility, leading to an increased prevalence of osteopenia and osteoporosis, particularly below the injury site and in cases of complete injury. The BMD loss peaks within the initial four months, primarily affecting proximal femur, distal femur, and proximal tibia. This study aims to devise a standardized approach for managing osteoporosis in SCI patients, specifically tailored to the contextual constraints and resource limitations prevalent in developing countries.
Methods: An extensive literature review was conducted, analyzing relevant studies, guidelines, and expert opinions to identify evidence-based practices for preventing and treating osteoporosis resulting from immobility after SCI.
Results: While the fundamental principles of osteoporosis management are universal, addressing SCI-induced osteoporosis necessitates careful consideration of cost-effectiveness and safety for this patient subgroup. The main goal of osteoporosis management in SCI patients is prevention. A four-axis strategy is proposed:

- First, assessing bone outcomes through comprehensive evaluation of medical history and physical examination, as well as a standard laboratory and radiology tests, including baseline BMD measured via a Dual-energy X-ray Absorptiometry (DXA) scan.
- Second, implementing nutrition and lifestyle interventions such as a calcium-rich diet, sufficient sun exposure, and fall prevention education.
- Third, incorporating non-pharmacological interventions like early initiation of weight-bearing exercises, initially with a tilt table at least twice a week initially and decreased to once a week after six months.
- Finally, employing pharmacologic treatment involving calcium and vitamin D supplementation.

Conclusion: This work highlights the challenges associated with managing osteoporosis in SCI patients, emphasizing the role of weight-bearing activities in influencing bone metabolism. Considering economic constraints, the use of bisphosphonates in SCI patients requires compliance with specific indications and regulations. In light of current research, the proposed strategy appears readily implementable in developing countries, offering an effective means to enhance bone health outcomes in SCI populations.

P211
COMORBIDITIES, PHYSICAL ABILITIES AND POLYPHARMACY OF PATIENTS WITH UNILATERAL HIP FRACTURE (UHF) VERSUS SEQUENTIAL BILATERAL HIP FRACTURE (SBHF)

A. Michael[1], N. Obiechina[2]

[1]Russells Hall Hospital, Dudley, [2]Queens Hospital, Burton on Trent, UK

Objective: Hip fracture is a serious sequela of osteoporosis and falling, which could be due to plethora of diseases. It increases the risk of inpatient mortality, one year mortality, morbidity, and institutionalisation. Unfortunately, some patients, despite osteoporosis treatment, will fracture the other hip with potential worse outcome. The incidence of sequential bilateral hip fractures can range from 2–10% depending on the population studied. The aim of this study is to compare the profile and some clinical criteria of patients with unilateral hip fractures with those with sequential bilateral hip fractures.
Methods: Consecutive 137 unilateral hip fracture patients, and 23 sequential bilateral hip fracture patients were studied. Notes and electronic records were reviewed. Data collected include demographic data, comorbidities, medications, mobility and activities of daily living, AMT on admission, and discharge destinations. Some data were not available for all patients. Data collected on excel sheet and descriptive statistics were used. IBM SPSS 29 was used for statistical analysis. Risk estimates and chi-square were done to assess odds ratio.
Results: Summarised in the Table. A total of 137 unilateral hip fracture and 23 bilateral sequential hip fracture patients were analysed. There were 100 females (73%) and 37 males (27%) in the unilateral hip fracture group, whereas there were 20 females (87%) and 3 males (13%) in the sequential bilateral hip fractures group. Average age of the female patients was 82.2 and 83.5 in the unilateral and bilateral hip fracture groups respectively. Average age of the male patients was 78.3 and 79 in the two groups respectively. Patients with sequential bilateral hip fractures, compared to those with a unilateral hip fracture were older, with more females, and more percentage of patients has dementia (35 vs. 26%), malignancy (30 vs. 7%), cerebrovascular disease (43 vs. 30%), depression (22 vs. 7%), polypharmacy (95 vs. 30%) and hearing impairment (38 vs. 23%). They were more likely to be mobile with a frame (30 vs. 20%), to be dependant for ADLs (26 vs. 18%) and to be discharged to 24 h care (27 vs. 15%). However they had lower percentage of hypertension (48 vs. 61%), visual impairment (50 vs. 58%) and urinary incontinence (19 vs. 37%). Patients with sequential bilateral hip fractures were also less likely to be mobile unaided (22 vs. 39%), or to be independent for ADLs (39 vs. 45%) and had lower AMT on admission (5.8 vs. 6.8) and were less likely to be discharged to their usual residence (59 vs. 98%). None of the sequential bilateral hip fractures patients died in hospital.

Table.

Hip fracture	Unilateral Number (%)	Sequential bilateral Number (%)
Total number of patients	137	23
Female	100/137 (73%)	20/23 (87%)
Female age (y)	82.2	83.5
Male	37/137 (27%)	3/23 (13%)
Male age (y)	78.3	79
Comorbidities		
Dementia	35/137 (26%)	8/23 (35%)
Hypertension,	83/137 (61%)	11/23 (48%)
Osteoarthritis,	37/137 (27%)	6/23 (26%)
Previous osteoporotic fracture	21/137 (15%)	23/23 (100%)
Diabetes	18/137 (13%)	2/23 (9%)
Hypothyroidism	17/137 (12%)	2/23 (9%)
COPD	17/137 (12%)	2/23 (9%)
Malignancy	10/137 (7%)	7/23 (30%)
CVD, CVA or TIA	41/137 (30%)	10/23 (43%)
CKD	10/137 (7%)	2/23 (9%)
Depression	10/137 (7%)	5/23 (22%)
Visual affection	67/116 (58%)	9/18 (50%)
Hearing impairment	26/113 (23%)	6/16 (38%)
Urinary incontinence.	50/134 (37%)	4/21 (19%)
Polypharmacy (on more than 4 drugs)	41/137 **(30%)**	21/22 **(95%)**
On antihypertensive medications,	70/137 (51%)	12/21 (57%)
Diuretics	31/137 (23%)	8/22 (36%)
Antidepressants	18/137 (13%)	5/20 (25%)
Hypnotics	14/137 (10%)	1/22 (5%)
Antipsychotics	5/137 (4%)	2/22 (9%)
Admitted from		
Home	101/137 (74%)	15/23 (65%)
Residential home	22/137 (16%)	4/23 (17%)
Nursing home.	8/137 (6%)	2/23 (9%)
Sheltered accommodation	6/137 (4%)	1/23 (4%)
Mobility		
Unaided	53/137 **(39%)**	5/23 **(22%)**
With a stick	47/137 (34%)	7/23 (30%)
With a frame	28/137 **(20%)**	7/23 **(30%)**
Supervised	4/137 (3%)	1/23 (4%)
ADLs		
Independent	61/137**(45%)**	9/23 **(39%)**
Partially dependant	52/137 (38%)	8/23 (35%)
Dependant	24/137 **(18%)**	6/23 **(26%)**
Carers (for patients who were admitted from home)	36/101 (35%)	4/12 (33%)
high muscle tone	41/137 (30%)	7/20 (35%)
AMT on admission	**6.8** (for 96/137 patients)	**5.8** (for 17/23 patients)
Postoperative complication		
Delirium	15/137 (11%)	3/21 (14%)
Urinary tract inf.	16/137 (12%)	3/21 (14%)
Chest infection	14/137 (10%)	2/20 (10%)
TIA/Stroke	3/137 (2%)	1/21 (5%)
Discharge destination		
Usual residence	98/137 (72%)	13/22 **(59%)**
To rehabilitation	20/137 (7%)	3/22 (14%)
24 h care	10/137 **(15%)**	6/22 **(27%)**
Inpatient mortality	9/137 (7%)	None (0%)

Conclusion: Patients with sequential bilateral hip fractures were 3.9 times more likely to have moderate to severe frailty than the unilateral hip fracture patients (OR 3.9; CI 1.54–9.87, P = 0.005). They were much more likely to be on polypharmacy than those with unilateral hip fractures. Admission with the first hip fracture should trigger comprehensive geriatric assessment and multifactorial interventions to improve physical status, mobility and function and address frailty and polypharmacy.

P212
IS HYPOPHOSPHATASIA COMMON IN SUBJECTS DIAGNOSED WITH FIBROMYALGIA?

A. Mocritcaia[1], C. Chacur[1], E. González[1], M. B. Busso[1], T. Rodríguez[1], L. Polino[1], P. Peris[1]

[1]Hospital Clinic Barcelona, Barcelona, Spain

Objective: It has been suggested that hypophosphatasia (HPP), a rare bone disease with defective bone mineralization due to mutations in the alkaline phosphatase gene (*ALPL*), may be misdiagnosed as fibromyalgia (FM). Its wide clinical spectrum, which includes chronic pain syndrome, may partly explain this possible misdiagnosis. Therefore, it has been suggested that subjects diagnosed with FM should be screened for this condition. We aimed to analyze the prevalence of HPP in a cohort of patients with FM attended in a Rheumatology Dept.
Methods: Observational, retrospective study of a cohort of 713 patients diagnosed with FM in a Rheumatology Dept. from 2014–2021, who presented previous ALP levels determinations. Medical records (ALP levels, history of fractures and/or osteoporosis [OP], radiologic studies, pharmacological treatment, and comorbidities) were reviewed. Patients with at least 2 low ALP levels determinations were further prospectively evaluated. In these subjects, an additional study of bone metabolic parameters, ALP substrates (PLP: pyridoxal-5′-phosphate) and genetic testing for *ALPL* mutations were performed.
Results: 15/713 FM patients (2.1%) presented low ALP levels in at least 2 measurements; all were women (median age of 49 y). Serum calcium and phosphate levels were within the normal range in all subjects; 4 presented increased substrate PLP levels (> 96 nmol/l); none was receiving PLP supplementation. However, no mutations in the *ALPL* gene were observed in any of the 15 subjects. Of note, 4 had associated hypothyroidism, with 3 receiving hormonal replacement therapy with levothyroxine; one patient was receiving denosumab treatment for OP (this patient was evaluated because of low APL levels before the onset of treatment), and 2 other patients received low doses of glucocorticoids as treatment of systemic lupus erythematosus. None of these patients were receiving bisphosphonates and bone metabolism parameters were within the normal range in all of them.
Conclusion: In this cohort of patients with FM, although 2.1% presented persistent decreased ALP levels, they frequently presented comorbidities that may be associated with low APL levels, and none presented mutations in the *ALPL* gene. Our results indicate that HPP is rarely misdiagnosed as FM in a Rheumatology Department.

P213
EFFICACY OF AN ULTRASOUND-GUIDED ANALGESIC PROCEDURE IN THE THERAPEUTIC MANAGEMENT OF SYMPTOMATIC VERTEBRAL FRACTURES: PRELIMINARY RESULTS

A. Mocritcaia[1], A. Ponce[1], E. Gómez-Casanovas[2], N. Sapena[1], H. Flórez[1], A. Monegal[1], N. Guañabens[1], P. Peris[1]

[1]Hospital Clinic Barcelona, [2]BCTDR (Barcelona Centre Tractament Dolor Reumatológic), Spain, Barcelona, Spain

Objective: Osteoporotic vertebral fractures (VF) can lead to the development of chronic vertebral pain (CBP) and functional limitation. Vertebroplasty (VP) and/or kyphoplasty have shown effectiveness in reducing pain in these patients. Nevertheless, randomized clinical trial on these procedures have shown contradictory results, and thus, these procedures are not systematically recommended. Some studies suggest that blocking the spinal medial branch (SMB) could have a similar efficacy to VP. Hence, studies analyzing the utility of local anesthetic blockage techniques are needed. We aimed to analyze the effectiveness and feasibility of an ultrasound (US)-guided procedure in the vertebral column for treatment of refractory CBP associated with osteoporotic VF.
Methods: Observational study of patients with refractory CBP (visual analog scale [VAS] $\geq$ 7) associated with osteoporotic VF. US-guided blockage of the erector spinae muscle (involving blockage of the SMB) was performed with needle punction of the vertebral lamina of the fractured vertebra (2% lidocaine and 4 mg dexamethasone diluted in saline). Pain progression (VAS) was evaluated at 15 d, and at 1, 3, 6, and 12 months after the procedure. Clinical characteristics of patients were analyzed (age, gender, number and location of VF, pain duration, radiological studies, and procedure related side effects). We present the results of the 3-month follow-up.
Results: 12 patients (mean age 78 $\pm$ 7.4 y) were evaluated. Most (10/12) had CBP (VAS 8.8 $\pm$ 1.2 [range 7–10]) with a mean pain duration of 122.6 $\pm$ 126 weeks (range 2–365). 7 blockages were performed on dorsal vertebrae (D6 [2 cases], D7, D11, and D12 [3 cases]) and 5 on lumbar spine (L1 [2 cases], L3, L5 [2 cases]), showing overall pain improvement after 15 days (VAS 7.2 $\pm$ 1.7), 1 (6.8 $\pm$ 2.2), and 3 months (4.2 $\pm$ 1.9). Most of the patients evaluated (5/12) at 3 months showed significant improvement (VAS $\leq$ 4); 1 patient did not improve (had long-standing pain [1095 d] and lumbar VF), the latter likely associated with lower therapeutic response (Fig. 1). No procedure related complications were observed.

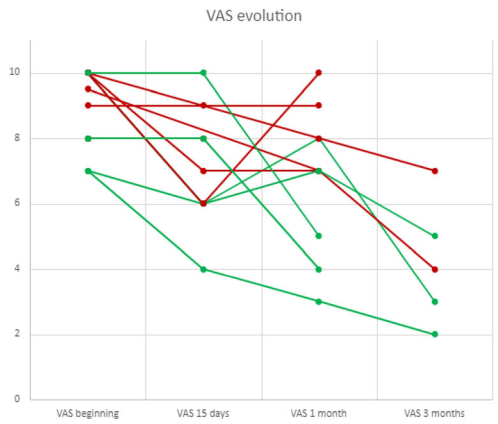

Figure 1. Evolution of pain (VAS) after a 3-month follow-up, according to the treated vertebra (dorsal in green, lumbar in red).

Conclusion: Our preliminary results suggest that a US-guided procedure in the lamina of the fractured vertebra may be a safe, effective, and feasible technique for treating refractory pain related to VF.

P214
STRUCTURAL HEART DISEASE IN PATIENTS WITH OSTEOGENESIS IMPERFECTA

A. Mocritcaia[1], C. Chacur[1], E. González[1], M. Ramos Jovani[1], A. García-Álvarez[1], H. Flórez[1], A. Monegal[1], N. Guañabens[1], P. Peris[1]

[1]Hospital Clinic Barcelona, Barcelona, Spain

Objective: Osteogenesis imperfecta (OI) is a genetic disorder characterized by connective tissue abnormalities with decreased bioavailability of collagen type I (COL1), bone fragility and increased susceptibility to fractures. While the bone OI phenotype is well described, less is known on the effects of OI in other tissues containing COL1, such as heart. Heart valves, chordae tendineae, annuli fibrosi, and the interventricular septum contain COL1, indicating the convenience to assess the presence of heart disease in OI subjects. We aimed to evaluate structural heart disease prevalence in a cohort of adult subjects with OI and its relationship with the severity of the disease and the COL1 genotype.
Methods: Retrospective study of 28 adult patients (> 18 y) diagnosed with OI. Clinical data (type and genetic mutation of OI, fracture history, presence of hearing loss, blue sclerae and/or dentinogenesis) were obtained from medical records. Laboratory, densitometric, and echocardiographic findings were also collected.
Results: Among the 28 patients (aged 19–78 years old) most with type I OI (26 type I, 1 type III, 1 type IV), 7 (25%) (median age: 32 years) exhibited echocardiographic alterations: diastolic dysfunction (1), left atrial dilatation (3, one with atrial fibrillation), aortic root dilatation (1; 38 mm), apical diverticulum (1) and significative valvulopathies (4; 14.3%). The former included 3 aortic insufficiencies (2 severe that required valve replacement and 1 moderate; 2 of these patients had a bicuspid aortic valve) and a moderate mitral insufficiency. These 4 subjects (aged 28–35) had type 1 OI, 3 were males, with several previous skeletal fractures (4–12), all had blue sclera, and none presented hearing loss nor dentinogenesis. The 2 subjects with severe valvulopathies also presented a marked low bone mass (Z-score < -4) and > 10 previous fractures. In the genetic test they showed *COL1A1* mutations affecting the glycine amino acid (p.(Gly200Asp) and p.(Gly221Arg), respectively.
Conclusion: Patients with OI may present cardiac involvement, especially heart valvular disease. Periodic screening with echocardiography seems essential to identify and manage potential severe heart complications in this disorder. Whether some mutations favor valvular disease needs further studies.

P215
SCAPULAR SPINE FRACTURE AFTER REVERSE SHOULDER ARTHROPLASTY MIMICKING A MALIGNANT TUMOUR OF THE SCAPULA: CASE REPORT AND LITERATURE REVIEW

A. Mocritcaia[1], H. Flórez[1], E. Muñoz-Mahamud[1], L. Peidro[1]

[1]Hospital Clinic Barcelona, Barcelona, Spain

Describe an unusual case of scapular spine stress fracture with non-union after reverse shoulder arthroplasty (RSA) mimicking a malignant tumour of the scapula. Review of acromion/scapular spine fractures (ASFs) after RSA and possible differential diagnoses.
Casereport: A 79-year-old female with osteoporosis (OP) treated with oral bisphosphonates underwent asynchronous bilateral RSA (right side 6/2011; left side 5/2018) secondary to rotator cuff arthropathy. In the 2-year follow-up after the left RSA, the patient reported having pain at the spine of the scapula since a few months ago. An X-ray showed no abnormalities. However, the report of a posterior MRI described high suspicion of a malignant lesion (great

bone proliferation surrounding the fracture), suggesting that metastasis or a primary tumor should be ruled out (Fig. 1A–B). A CT-guided biopsy was therefore performed showing cartilaginous proliferation without malignancy criteria, compatible with reactive changes associated with an evolved fracture. The study was completed with a CT scan, showing exuberant periscapular bone proliferation surrounding the fracture, without consolidation, suggesting non-union with a hypertrophic bone callus (Fig. 1C–D). With this diagnosis the patient was treated conservatively with favourable evolution (Fig. 1E).

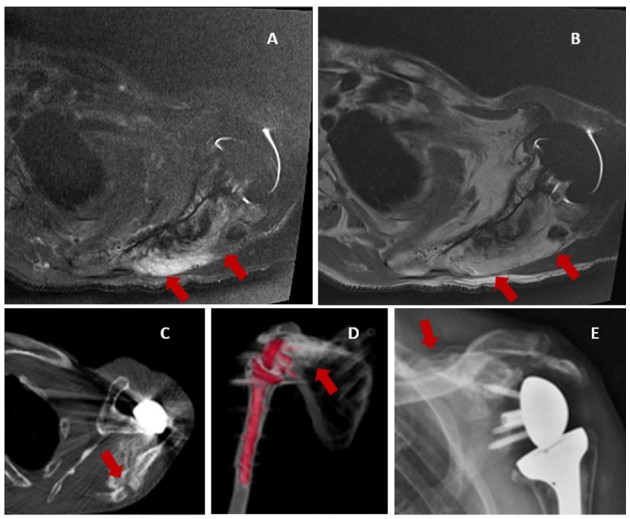

Figure 1. MRI images of the ASFs with exuberant periscapular bone proliferation surrounding the fracture line (A-B); CT images of left ASF with non-union (C-D); X-ray images of fracture consolidation one year after (E).

Conclusion: ASF following RSA (incidence: 0.8–11.2%) can significantly impact shoulder stability and function (1–3) and is the most frequent cause of pain after this procedure. Since OP is a well-known risk factor for the development of ASF, OP diagnosis and treatment may reduce the risk of fracture after RSA (2–3). Bone proliferation surrounding an ASF is very rare and can mimic a malignant scapular tumour. Thus, the differential diagnosis should include sarcomatous tumours (chondrosarcomas, Ewing sarcomas, osteosarcomas, among others), plasmacytomas and metastasis (4). Thus in the presence of pain and/or radiological alterations in the scapular spine after RSA in a patient with OP, a stress fracture should first be suspected. In the present case, the great bone proliferation surrounding the fracture indicate the need to rule out a malignant process.

THE ROLE OF THE ANDROGEN RECEPTOR IN SKELETAL MUSCLE SENESCENCE

A. Moretti[1], M. Di Donato[2], C. Sorrentino[2], G. Gentile[2], G. Castoria[2], A. Migliaccio[2], G. Iolascon[1]

[1]Dept. of Medical and Surgical Specialties and Dentistry, Univ. of Campania "Luigi Vanvitelli", [2]Dept. of Precision Medicine, Univ. of Campania "L. Vanvitelli", Naples, Italy

Objective: To analyze the role of rapid, nongenomic androgen action in skeletal muscle senescence as well as to investigate how androgen receptor (AR) signaling modulates age-related skeletal muscle mass changes.

Methods: Patients who underwent a primary total hip arthroplasty (THA) or a primary total knee arthroplasty (TKA) were considered eligible. In patients undergoing THA, a modified version of the Herdinge–Baur direct lateral approach was used to collect muscle biopsy from fibers of the gluteus medius. In patients undergoing TKA, a median parapatellar approach was done, and detached fibers from Vastus medialis were collected. We analyzed the expression of the AR in skeletal muscle biopsies and provided co-immunoprecipitation experiments to reveal the role of AR/Filamin A complex in skeletal muscle. To further investigate the effect of androgens on skeletal muscle senescence, we have exposed C2C12 myoblasts to H_2O_2. Finally, in search for a link between AR/FlnA complex and C2C12 cell senescence, we then used a stapled Rh-2025u peptide that specifically perturbs the androgen-induced AR/FlnA complexation.

Results: Twenty patients with a mean age of 63.1 ± 16.6 SD were enrolled. This cohort was split into two groups, young (< 58 y; mean age 46.5), and old (> 58 y; mean age 72.6). Lysate proteins derived from young subjects' (y) biopsies express higher levels of AR, as compared with older subjects (os). Moreover, a significant negative correlation between AR expression and age ($r = -0.7979$; $p < 0.0001$) was reported. Moreover, 75% and 25% of patients under 58 or over 70 y, respectively, exhibit the AR/Fln A complex association. Androgen pretreatment of cells prevents increases in multinucleated C2C12 fraction (i.e., a hallmark of cell senescence). These cells express a robust amount of the AR that undergoes Filamin A complexation upon androgen stimulation. Once assembled, such a complex prevents the senescence induced by oxidative stress in C2C12 cells. Moreover, the addition of the Rh-2025u stapled peptide, which specifically perturbs the AR/FlnA complex assembly, rescues the senescent phenotype even in the absence of oxidative stress, pointing to the critical role of this complex in muscle cell functions.

Conclusion: Our study provides new clues that entangle the role of the androgen-induced AR/FlnA complex assembly in skeletal muscle senescence. Findings in C2C12 cells and muscle biopsies from young or old subjects make the AR/FlnA complex a molecular signature for skeletal muscle health. Taken together, these findings suggest that specific perturbation of AR/FlnA complex assembly impairs the androgen effect and commits the cells towards senescence. Overall, our data indicate that FlnA has a permissive role in muscle cell trophism and strongly cooperates with AR in sustaining the androgen action on the health and wellbeing of skeletal muscle. Tracking and decoding the AR/FlnA complex might provide new hints for the identification of therapeutic candidates in sarcopenia, osteosarcopenia, and frailty.

P217
CLINICAL EVALUATION OF OSTEOPOROSIS IN A COHORT OF PATIENTS WITH EATING DISORDERS IN A THIRD LEVEL HOSPITAL

V. Siles-Guerrero[1], M. Novo-Rodriguez[1], A. Muñoz-Garach[1], I. Herrera-Montes[1], C. Novo-Rodriguez[1]

[1]Universitary Hospital Virgen de las Nieves, Granada, Spain

Objective: Osteoporosis is a relevant complication in patients with eating disorders as it affects a critical stage of skeletal development. The BMD is low and mainly trabecular bone is affected and is not always evaluated and will delay diagnosis. Duration of amenorrhea and malnutrition are related poor prognostic factors. Our aim was to analyse bone health, nutritional status and treatment received in a cohort of patients treated in a multidisciplinary unit for treating eating disorders.

Methods: We performed a descriptive observational study of a sample of 17 subjects admitted to our unit from 01/01/2022 to 01/01/2024. We studied analytical and nutritional parameters, DXA and treatment options. Statistical analysis was performed with SPSS.
Results: In our sample of patients, 91.66% were women, with mean age 31 ± 13.9 SD. Mean BMI was 15.4 ± 1.5 kg/m^2. 100% were diagnosed as anorexia nervosa. All our patients were on fertile age and had amenorrhea with a mean duration of 46 ± 44.1 SD months. Normal BMD was observed in 11.7%. Osteopenia (measured in lumbar spine, femoral neck or both) was found in 41.2% and osteoporosis (measured in same locations) appeared in 47.1%. In this last subgroup the mean Z-score in femoral neck was − 2.51 ± 0.82 SD and lumbar spine − 3.36 ± 0.79 SD and the BMD in femoral neck was 0.62 ± 0.12 g/cm^2 and lumbar spine 0.77 ± 0.13 g/cm^2. 100% of the patients, regardless of the DXA scores, received supplementation with calcium and vitamin D. 60% of the women with abnormal DXA received estrogen treatment, specifically when the amenorrhea was longer than 1 year. 62.5% of patients with osteoporosis diagnosis received antiosteoporotic treatment (40% risedronate and 60% teriparatide).
Conclusion: Low bone mass was frequently observed in our patients with eating disorders. It is underdiagnosed and probably undertreated due to lack of robust evidence of how best to predict and decrease future fracture risk. For this reason, it is essential to protocolize the monitoring of BMD considering that the current bases of treatment are renutrition, recovery of the menstrual cycle, supplementation with calcium and vitamin D and the establishment of antiosteoporotic treatment when necessary.

P218
OSTEOPOROSIS: A MANAGEMENT PROBLEM IN RHEUMATOID ARTHRITIS

A. Nistor[1], L. Groppa[1], E. Russu[1], L. Chişlari[1]

[1]"Nicolae Testemitanu" State Medical and Pharmaceutical Univ., Chisinau, Moldova

Objective: In recent years, researchers have been particularly interested in secondary osteoporosis (OP), which can develop at any age, in both men and women, and is a complication of many diseases, especially rheumatic diseases. However, the mechanisms of osteoporosis in rheumatoid arthritis (RA) are not well understood and disclosed. This is a comprehensive study of general and local regulators of bone tissue remodeling in RA patients, determination of the clinical and pathogenetic significance of the identified disorders.
Results: A decrease in BMD < -ISD according to the T-test (4.25 ± 0.78, $p < 0.01$) was found in a significant part of the examined RA patients (79.3%). It was shown that in menopausal patients and in those taking glucocorticosteroid hormonal drugs, this decrease was more significant (5.1 ± 0.41, $p < 0.01$). The L1-L3 section turned out to be the most informative in terms of diagnosing OP, which indicates the susceptibility of the trabecular part of the skeleton to the resorption process. The role of level disorders has been revealed pro-inflammatory cytokines—IL-1 and TNF, a decrease in the level of IL-2 cellular response regulator, initiating a disorder of bone metabolism, contributing to the manifestation of OP.
Conclusion: Osteoporosis was detected in 79.3% of the examined patients with RA. OP occurs 2 times more often in patients with RA than in controls. The obtained correlations between the content of interleukins in blood serum and the data of BMD and C-terminal telopeptides indicate their close relationship with the pathogenesis of the inflammatory process and bone resorption in patients with RA.

P219
EVALUATION OF STRUCTURE AND CAUSES FOR SWITCHING BDMARDS AND JAK INHIBITORS IN PATIENTS WITH RHEUMATOID ARTHRITIS

A. O. Bobkova[1], A. S. Potapova[1], P. A. Sholkina[1], A. E. Karateev[1], E. Y. U. Polishchuk[1], A. M. Lila[1]

[1]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia

Objective: To estimate the structure of bDMARDs and tsDMARDs in patients with rheumatoid arthritis (RA) as well as the reasons for changing this treatment.
Methods: A retrospective analysis of the therapy structure of bDMARDs and JAK inhibitors was performed in 591 RA patients with moderate or high disease activity (DAS28-CRP ≥ 3.2) and previous ineffectiveness of DMARDs. The most of them were women (83.1%), mean age 50.9 ± 14.1 y, average duration of disease 9 [5;16] y, RF positive 455 (77.1%) patients, ACPA positive 408 (69.0%) patients, DAS28-CRP 4.7 ± 1.0.
Results: Out of 591 patients with moderate and high activity RA, 441 (74.6%) patients had previously received bDMARDs or JAK inhibitors. Thus, the first line b/tsDMARD in the medical history was RTX—43.8%, TNFα inhibitors—38.9%, IL-6 inhibitors—7%, T-lymphocyte costimulation inhibitors—6.3%, JAK inhibitors—4.5%. Treatment was changed in 62.6% of cases (due to treatment failure—17.9%, adverse reactions—7.7%, nonmedical reasons—37%). The second biological drug was prescribed to 149 patients: TNFα inhibitors—41%, RTX—36.2%, IL-6 inhibitors—14%, T-lymphocyte costimulation inhibitor—6%, JAK inhibitors—12.8%. The leading reasons for switching b/tsDMARDs were treatment failure—32%, adverse reactions—7.4%, and nonmedical reasons—15.4%. A third line b/tsDMARD was received by 63 patients: TNFα inhibitors—38%, RTX—27%, IL-6 inhibitors—9.5%, T-lymphocyte costimulation inhibitor—7.9%, JAK inhibitors—17.5%. The structure of the reasons for switching third line biological therapy was similar to the data on second line b/tsDMARD: treatment failure—38%, adverse reactions—6.3%, nonmedical reasons—11.1%. Fourth line b/tsDMARD was administered in 28 patients: TNFα inhibitors 25%, RTX—10.7%, IL-6 inhibitors—28.6%, T-lymphocyte costimulation inhibitor—3.6%, and JAK inhibitors—32.1%, with an ineffectiveness in 46.7%, adverse reactions in 33.3%, and withdrawal for nonmedical reasons in 20% of cases. Finally, fifth line b/tsDMARDs were prescribed to 13 patients.
Conclusion: Five lines of b/tsDMARD were identified in our cohort of patients. In the structure of b/tsDMARDs TNFα and RTX placed the leading position as the first and second lines and a significant number of patients received JAK inhibitors as the fourth line. It is important to note that among the causes for switching first line b/tsDMARD, a large proportion are nonmedical reasons, and the causes for switching third and fourth line are treatment failure.

P220
SURVIVAL ANALYSIS OF BIOLOGICAL DMARDS AND JAK INHIBITORS IN RHEUMATOID ARTHRITIS PATIENTS REQUIRING SWITCHING OF TREATMENT

A. O. Bobkova[1], S. I. Glukhova[1], A. E. Karateev[1], A. S. Potapova[1], A. M. Lila[2]

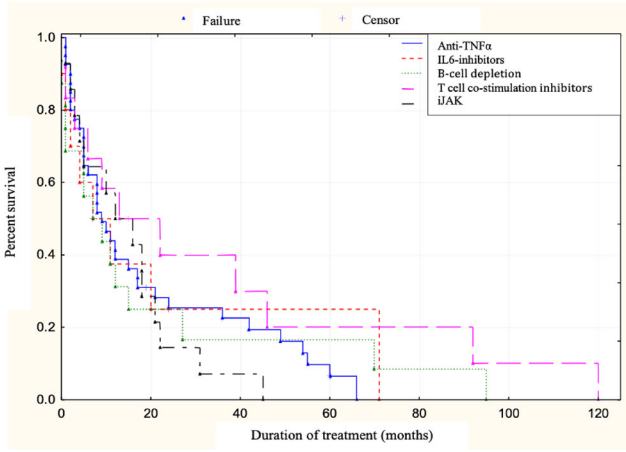
[1]V.A. Nasonova Research Institute of Rheumatology, [2]V.A. Nasonova Research Institute of Rheumatology, Dept. of Rheumatology Russian Medical Academy of Continuing Professional Education, Ministry of Health of Russia, Moscow, Russia

Objective: Approximately 40% of rheumatoid arthritis (RA) patients may respond inadequately to an initial biological treatment because of

primary nonresponse, loss of response, or intolerance. Following inadequate response to first line biological DMARDs (bDMARDs): anti-TNFs), IL-6 inhibitors, B-cell depletion agents, and T-cell costimulation inhibitors or Janus kinase inhibitors (iJAK), clinicians can consider switching to targeted drug with a different mechanism of action. This, in turn, may lead to an increase in refractory disease, which has been defined as difficult-to-treat RA (D2T) by EULAR in 2021. We aimed to evaluate the survival rates first bDMARDS and iJAK in RA patients requiring biologic therapy switching.

Methods: Between October 2022 and September 2023, 315 patients with a confirmed RA and treated with bDMARDs or iJAK were analyzed. There were 93 patients (29.5%), required switching (changing bDMARDs or iJAK to another drug class) due to nonresponse, adverse effect or intolerance therefore, all patients in the observed group finished treatment. The majority were women 86%, mean age 48 ± 13 y, median disease duration 11 [6; 17] y. The examined patients have RF-positive 71 (76%), ACPA-positive 66 (71%) tests, DAS28-ESR—5.9 ± 1.1, pain severity (VAS 100-mm) 67 ± 12. Among the 93 patients: 50 patients (53.8%) had first switching; 43 patients (46.2%) met D2T. The Kaplan–Meier estimator (Figure) was used to survival analysis of the first bDMARDs or iJAK. Patients were divided into 5 groups according to the mechanism of action of the drug. Whereby anti-TNFα group was 41 patients (44%), IL-6 inhibitors—10 patients (11%), B-cell depletion—16 patients (17%), T-cell costimulation inhibitor—12 patients (13%), iJAK—14 patients (15%).

Results: The obtained plot (Figure) shows that in our group of patients the longest duration of therapy was with T-cell costimulation inhibitors (120 months), a little less with B-cell depletion therapy. The median survival rate (in months) was anti-TNFα group—8,7 months, IL-6 inhibitors—7 months, B-cell depletion—7 months, T-cell costimulation inhibitor—13 months, iJAK—12 months. However, the median survival of therapy was not statistically different ($p > 0.05$) in the observed groups, which may indirectly indicate comparable efficacy of all classes of drugs. Regarding the distribution, most patients received anti-TNFα as first-line therapy.



Conclusion: Thus, all classes of bDMARDs and iJAK have comparable survival in our RA cohort, so a personalized approach to therapy selection is required. Consequently, switching to another drug class may be an effective treatment strategy.

P221
PREVALENCE OF OSTEOSARCOPENIA IN POPULATION AGED 50 YEARS AND OVER IN IRAN: THE RESULTS OF IRANIAN MULTICENTER OSTEOPOROSIS STUDY (IMOS)

A. Ghazbani[1], A. Aghakhani[1], N. Fahimfar[1], K. Khalagi[2], M. J. Mansourzadeh[1], M. Sanjari[1], N. Ostovar[3], F. Razi[4], F. Hajivalizadeh[5], K. Etemad[6], E. Hesari[1], S. Hajivalizadeh[1], G. Shafiee[7], R. Heshmat[7], N. Panahi[8], A. Ostovar[9]

Objective: Osteosarcopenia is a pathological state characterized by the concurrent decline in bone mass, indicated by osteoporosis or osteopenia, and the reduction in muscle mass and strength, known as sarcopenia. This study investigated the prevalence of osteosarcopenia in the population aged ≥ 50 y in Iran.

Methods: This study utilized samples from the Iranian Multicenter Osteoporosis Study (IMOS-2021). Individuals aged ≥ 50 y who participated in the IMOS, completed clinical and physical examinations. BMD and skeletal muscle mass were measured using DXA according to the standard protocol using HOLOGIC (Discovery and Horizon) devices. A BMD T-score of − 2.5 or lower and between − 1 and − 2.5 at either spinal, femoral neck or total hip sites were defined as osteoporosis and osteopenia, respectively. According to the EWGSOP-2 and AWGS, sarcopenia was detected by the presence of low muscle mass with low muscle strength in which was measured by handgrip strength, using a digital dynamometer. Subsequently, osteosarcopenia was characterized as the coexistence of osteopenia or osteoporosis, along with sarcopenia. The survey set analysis was carried out using the STATA statistical software, with the objective of determining the weighted prevalence of osteosarcopenia among adults in Iran.

Results: Overall, 1440 participants (54.4% women) with the mean age of 60.7 ± 8.0 y were included. Our results indicated that 8.7% (95% CI 7.2–10.5%) of participants had osteosarcopenia. The weighted prevalence of osteosarcopenia was 9.1% (95% CI 7.1–11.5%) in women and 8.3% (95% CI 6.2–11.1%) in men. The weighted prevalence of osteosarcopenia did not exhibit a statistically significant distinction between individuals residing in rural areas (7.6%, 95% CI 5.2–11.2%) and those living in urban areas (9.1%, 95% CI 7.3–11.2%). Considering the age range, the statistical analysis revealed a significant difference in the weighted prevalence of osteosarcopenia between individuals aged ≥ 65 y [16.8% (13.0–21.5%)] and aged < 65 y [5.4% (4.1–7.0%)].

Conclusion: Our results showed a relatively high prevalence of osteosarcopenia, particularly among individuals aged 65 y and older in Iran. Given the rapid expansion of the elderly demographic in Iran, it is anticipated that this matter will increasingly pose a significant public health challenge in the near future.

P222
PREVALENCE OF LOW BONE MASS IN MEN AND WOMEN AGED ≥ 50 YEARS OLD IN IRAN: KEY FINDINGS FROM THE IRANIAN MULTICENTER OSTEOPOROSIS STUDY (IMOS)

E. Hesari[1], K. Khalagi[2], N. Fahimfar[1], M. J. Mansourzadeh[1], A. Aghakhani[1], M. Sanjari[1], F. Hajivalizadeh[3], S. Hajivalizadeh[1], G. Shafiee[4], R. Heshmat[4], F. Farzadfar[5], F. Razi[6], N. Panahi[7], A. Raeisi[8], B. Larijani[9], A. Ostovar[1]

[1]Osteoporosis Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran Univ. of Medical Sciences, [2]Obesity and Eating Habits Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran Univ. of Medical Sciences, [3]Center for Non-Communicable Disease Control & Prevention, Deputy of Public Health, Ministry of Health and Medical Education, [4]Chronic Diseases Research Center, Endocrinology and Metabolism Population Sciences Institute, Tehran Univ. of Medical Sciences, [5]Non-Communicable Diseases Research Center, Endocrinology and Metabolism Population Sciences Institute, Tehran Univ. of Medical Sciences, [6]Metabolomics and Genomics Research Center, Endocrinology and Metabolism Molecular-Cellular Sciences Institute, Tehran Univ. of Medical Sciences, [7]Metabolic Disorders Research Center, Endocrinology and Metabolism Molecular-Cellular Sciences Institute, Tehran Univ. of Medical Sciences, [8]Dept. of Internal Medicine, Tehran Univ. of Medical Sciences, [9]Endocrinology and Metabolism Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran Univ. of Medical Sciences, Tehran, Iran

Objective: Iran has a rapidly aging population and a growing prevalence of geriatric syndromes. To estimate the prevalence of osteopenia and osteoporosis in a nationally representative, population-based study, we utilized data from the 4th round of the Iranian Multicenter Osteoporosis Study (IMOS-4), conducted in 2022.
Methods: The study employed a multistage, cluster random sampling method to select individuals aged 50 y and older from both urban and rural areas. BMD was measured in all participants by a trained operator using standard, calibrated Hologic DXA machines. A BMD T-score of − 2.5 or lower and between − 1 and − 2.5 at either spinal, femoral neck or total hip sites were defined as osteoporosis and osteopenia, respectively. We applied weights to account for sampling design, nonresponse, and poststratification to estimate the prevalence of osteoporosis and osteopenia by sex, age group and the area of residence.
Results: A total of 1435 individuals participated in the study, of which, 751(52.3%) were women. Total prevalence of osteopenia and osteoporosis were 48.7% (95% CI 45.7–51.7) and 31.1% (95% CI 28.4–33.9), respectively. The prevalence of osteoporosis was 23.6% (95% CI 19.9–27.5) and 37.4% (95% CI 33.6–41.4) among men and women ($P < 0.001$), 38% and 28.7% among rural and urban residents ($P = 0.010$), and 23.7% (95% CI 20.7–26.8) and 48.6% (95% CI 43.2–54.1) among those aged 50–65 and ≥ 65 years old ($P < 0.001$).
Conclusion: The prevalence of low bone mass in Iran is quite high, particularly among women, rural residents, and older individuals. Considering the rapid growth of the elderly population in Iran, this issue is expected to become a bigger public health concern in the near future.

P223
THE ASSOCIATION BETWEEN POOR NUTRITION AND OSTEOPOROSIS IN AN IRANIAN ELDERLY POPULATION: BUSHEHR ELDERLY HEALTH (BEH) PROGRAM

N. Fahimfar[1], A. Jamshidi[2], E. Madreseh[3], K. Khalagi[4], M. J. Mansourzadeh[1], M. Sanjari[1], G. Shafiee[5], I. Nabipour[6], H. Aghaei Meybodi[7], A. Farhadi[2], E. Hesari[1], S. Hajivalizadeh[1], N. Ostovar[8], B. Larijani[9], A. Ostovar[1]

Objective: Osteoporosis is characterized by the degradation of bone microstructures, resulting in an increased risk of fragility fractures. The risk factors for osteoporosis can be categorized as either modifiable or non-modifiable. The adoption of healthy lifestyle habits is widely recognized as a crucial modifiable factor in promoting optimal bone growth and healthy aging. The present study aims to assess the relationship between nutritional status, and the risk of osteoporosis in Iranian older adults.
Methods: The second stage of the BEH program provided the data for the current cross-sectional analysis. Nutritional assessment was assessed using the Mini Nutrition Assessment (MNA) and reported as mean ± standard deviations (SD). Considering the cutoff points of ≥ 24, the individuals were categorized as well nourished and poorly nourished. BMD was measured using DXA. Osteoporosis was described as having a BMD ≥ 2.5 (SD) below the average value of young Caucasian women, aged 20–29 y in either femoral neck, spinal, and total hip. Logistic regression model was used to investigate the association between nutritional status and osteoporosis, considering the other potential confounders.
Results: In all, 2419 (1165 men) participants aged ≥ 60 y were included. There were significant differences in MNA score between osteoporotic patients (23.1 ± 5.1) and participants with osteopenia (24.1 ± 5.0), and with healthy individuals (24.4 ± 5.26), both Ps < 0.001. Poor nutrition was associated to osteoporosis (OR: 1.25, 95% CI 1.01–1.55, P = 0.035), adjusted for potential confounders. Factors such as age (OR: 1.05, $p < 0.001$), fractures after age 45 y (OR: 1.95, $P < 0.001$), female sex (OR: 6.32, $P < 0.001$), drug abuse (OR: 2.05, $P = 0.029$), low physical activity (OR: 1.67, $P = 0.018$), polypharmacy ≥ 5 drugs (OR: 1.39, $P = 0.21$), cognitive disorders (OR: 1.53, $P < 0.001$), and disability (OR: 1.32, $P = 0.019$) were also associated with osteoporosis. BMI (OR: 0.89, $P < 0.001$), years of schooling (OR: 0.96, $P < 0.001$), and diabetes (OR: 0.58, $P < 0.001$) showed inverse association with osteoporosis.
Conclusion: Our research indicates the positive association of poor nutrition with osteoporosis, adjusted by the traditional risk factors.

Considering the growing number of elderly populations in the country, it seems necessary to have appropriate interventions to improve the nutritional status of the elderly.

P224
IS THERE A RELATIONSHIP BETWEEN BONE TURNOVER AND INSULIN RESISTANCE? EVALUATION OF AN OSTEOPOROTIC POPULATION TREATED WITH DENOSUMAB

A. P. Barbosa[1], I. Cosme[1], J. V. Rocha[1], F. Costa[1], E. Alves[1], F. Sampaio[1]

[1]Multidisciplinary Fracturary Osteoporosis Outpatient Clinic, Hospital Santa Maria, Lisboa, Portugal

Objective: Denosumab (Dmab), a monoclonal antibody against RANKL is a potent antiresorptive drug used to treat osteoporosis and osteoporotic fractures. Some studies have pointed to an association between RANKL/RANK signaling pathway and energy metabolism, and the downregulation of RANKL signaling seems to improve hepatic insulin sensitivity and glucose metabolism in both mice and humans. We aimed to evaluate the effects of Dmab on bone remodeling markers and on the glucose and insulin metabolism and to study the possible associations between bone turnover and glucose/insulin resistance.
Methods: Retrospective study of patients with severe osteoporosis, treated at least 6 months with Dmab. Bone remodeling markers (CTX, P1NP, BAP, osteocalcin) and fasting insulin and glucose were analysed before (T0) and after (T1) Dmab treatment. HOMA-IR (fasting insulin mcU/ml $\times$ fasting glucose mmol/l/22.5) was calculated in T0 and T1. Adequate statistical tests were used and $P < 0.05$ was considered significant.
Results: 22 patients (19 women), 75.7 $\pm$ 9.8 years old, treated with Dmab during 20.8 $\pm$ 10.6 months. Three had type 2 diabetes (DM2). The results of bone markers in T0/T1 were, respectively: P1NP 43.2 $\pm$ 17.5/21.4 $\pm$ 9.7 ng/ml ($P < 0.01$); CTX 0.4 $\pm$ 0.2/0.1 $\pm$ 0.1 ng/ml ($P < 0.01$); osteocalcin 19.8 $\pm$ 8.6/10.5 $\pm$ 4 ng/ml ($P < 0.01$); BAP 12.8 $\pm$ 5.7/8 $\pm$ 1.9 μg/l ($P < 0.01$). That corresponds to decreases of: P1NP 49.5%, CTX 25%, osteocalcin 53%, BAP 62.5%. Regarding glucose metabolism in T0/T1, the reductions were, respectively: glucose (98 $\pm$ 22.1/94.2 $\pm$ 18 mg/dl; P = 0.1), insulin (14.9 $\pm$ 22.1/11.3 $\pm$ 9.7 μU/ml; P = 0.4) and HOMA-IR (3.9 $\pm$ 6.3/2.8 $\pm$ 2.9; P = 0.4). There were no significant correlations between glucose, insulin and the bone markers in T0 and T1 in both diabetics and nondiabetics.
Conclusion: In this group of patients with severe osteoporosis, Dmab reduced bone turnover markers and simultaneously glucose and insulin resistance. This anti-osteoporotic treatment can also be useful in the prevention/treatment of DM2.

P225
BODY COMPOSITION AND CALCIUM METABOLISM IN POSTMENOPAUSAL TYPE 2 DIABETIC WOMEN

A. P. Barbosa[1], B. Dalpizol[2], L. Aguiar[2], J. Ferreira[2], M. R. Mascarenhas[3], M. Bicho[2], A. Inácio[2]

[1]CEDML-Endocrinology, Diabetes and Metabolism Clinic of Lisbon, [2]Genetics Laboratory, Faculty of Medicine, Lisbon Univ., [3]Environmental Health Institute, Associate Laboratory TERRA, Faculty of Medicine, Lisbon Univ., Lisbon, Portugal

Objective: Diabetic bone disease has been described as a complex chronic complication of people with type 2 diabetes (DM2) because it is associated to osteoporotic fractures, but not with increased bone turnover markers nor reduced BMD. So, its pathogenesis is still in debate and it seems that bone quality can be compromised. We aimed to evaluate the BMD, the bone turnover markers, and the calcium metabolism parameters in a DM2 population by comparison with a population without the disease.
Methods: A group of 47 DM2 postmenopausal women was compared with a control group (N = 176) of similar age, stature and time since menopause. Anthropometric parameters were evaluated and BMI (kg/m^2) was calculated. BMD (g/cm^2) at L1–L4 and proximal femur and lean and fat masses were analyzed by DXA (QDR Discovery, Hologic). Patients were categorized as normal, low bone mass and osteoporosis according to ISCD criteria. Fasting blood samples were collected for calcium, phosphorus, PTH, 25(OH)-vitamin D, osteocalcin, bone alkaline phosphatase and CTX. Adequate statistical tests were done with SPSS 28 version and statistical significance was considered for $P < 0.05$.
Results: The DM2 group had higher total fat (30.65 vs. 27.56 kg, P = NS) and lean masses (43.44 vs. 41.39 kg, P = 0.04), BMD at the femoral neck (0.838 $\pm$ 0.136 vs. 0.780 $\pm$ 0.128 g/cm^2, P = 0.007) and at the total femur (0.949 $\pm$ 0.137 vs. 0.902 $\pm$ 0.136 g/cm^2, P = 0.04). We found no significant differences between the DM2 and the control group, regarding the levels of: calcium (9.4 vs. 9.4 mg/dL), phosphorus (3.6 vs. 3.5 mg/dL), 25(OH)-vitamin D (17.5 vs. 16.0 ng/mL), osteocalcin (6.5 vs. 8.4 ng/mL), bone alkaline phosphatase (10.0 vs. 11.0 mcg/L), CTX (0.24 vs. 0.29 ng/mL). However, PTH was significantly lower in DM2 (35.4 vs. 48.4 pg/mL, $P < 0.001$). We did not find correlations of PTH with BMD nor with bone markers.
Conclusion: This study shows that this population of DM2 postmenopausal women has not increased bone turnover and has a higher cortical bone mass. We can also hypothesize that the lower PTH levels may play a protective role, reducing the expected increase in the postmenopausal bone resorption.

P226
VITAMIN D STATUS AND SEASONAL VARIATIONS IN SERUM 25-HYDROXYVITAMIN D LEVELS IN CHILDREN WITH CEREBRAL PALSY

A. Halasheuskaya[1], A. Pachkaila[1], E. Rudenka[2]

[1]Institute of Advanced Training and Retraining of Healthcare Personnel of Belarusian State Medical Univ., [2]Belarusian State Medical Univ., Minsk, Belarus

Objective: To assess vitamin D status and seasonal variation in serum 25-hydroxyvitamin D (25(OH)D) levels in children with cerebral palsy (CP).
Methods: The study included 93 patients with CP (41 girls and 52 boys) aged from 2–18 y (median age—9.9 (7.4; 13.1) y) who were examined at the Republican Center for Pediatric Osteoporosis. None of the patients had previously received vitamin D supplementation. 47 (50.5%) of all children were ambulatory (GMFCS levels I-III), 46 (49.5%) of all children were nonambulatory (GMFCS levels IV–V). 37 (39.8%) of all children were taking antiepileptic drugs. The level of 25(OH)D was determined by electrochemiluminescence. Vitamin D status was assessed according to international recommendations: normal if 25(OH)D $\geq$ 30 ng/ml, insufficiency—20–29 ng/ml, deficiency— $<$ 20 ng/ml, and severe deficiency— $<$ 10 ng/ml.
Results: The median 25(OH)D level was 16.2 (11.2, 19.8) ng/ml (range 2.3–44.3 ng/ml). Severe deficiency, deficiency and insufficiency of vitamin D were detected in 16.1%, 59.2% and 17.2% of children, respectively (total—92.5%). There were no significant differences in 25(OH)D levels among patients based on their age, gender, ambulation, or history of anticonvulsant drug use. Comparison of vitamin D levels in different seasons showed that the highest median serum 25(OH)D level was found in summer (20.2 (15.7; 28.9)

ng/ml), and the lowest one was in winter (12.1 (8.8; 16.8) ng/ml), ($p < 0.001$). The median values of 25(OH)D in spring and autumn did not differ significantly ($p > 0.05$) and were 16.0 (11.3; 18.1) ng/ml and 15.9 (11.5; 21.4) ng/ml, respectively. The prevalence of vitamin D deficiency and insufficiency was 100% in winter, 96.4% in autumn, 90.9% in spring, 80% in summer.

Conclusion: The results of our study revealed a high prevalence of vitamin D deficiency and insufficiency and significant seasonal variations in serum 25(OH)D levels in children with cerebral palsy who did not receive vitamin D supplementation. The obtained data determine the need to optimize measures to prevent vitamin D deficiency in children with CP.

P227
MELORHEOSTOSIS: A RARE SCLEROSING BONE DYSPLASIA

A. Halasheuskaya[1], A. Pachkaila[1], V. Vadzianava[1]

[1]Institute of Advanced Training and Retraining of Healthcare Personnel of Belarusian State Medical Univ., Minsk, Belarus

We present a case of a rare skeletal dysplasia. Melorheostosis is a rare sclerosing bone dysplasia that affects both cortical bone and adjacent soft tissue structures in a sclerotomal distribution.

Casereport: We present a case of melorheostosis in an 8-year-old boy with scleroderma-like skin lesions at the onset of the disease and a description of the dynamics of the disease over the next 10 y of observation. From the age of 6 y the patient had a scleroderma-like skin lesion in the area of the right thigh. At the age of 7 (after an injury) deformity of the second toe of the right foot appeared, and even later–slight hardening and swelling of the tissues of the right thigh, discrepancy in the length of the lower extremities and compensatory scoliosis. At 8 y of age radiography of the pelvis and lower extremities demonstrated the presence of extensive, irregular endosteal hyperostosis in the diaphyses of the right femur and right tibia. The diagnosis was verified: Melorheostosis, polyostotic form. Since the age of 10 he was periodically bothered by unexpressed pain in the right lower limb, limited range of motion in the right knee joint, shortening of the affected limb by up to 3 cm, compensatory lameness and compensatory right-sided thoracolumbar scoliosis. The patient received conservative treatment: NSAIDs (for pain relief), physiotherapeutic treatment, physical therapy, massage. Further observation showed a gradual and steady progression of the radiological manifestations of the disease. By the age of 18 the patient had spread of the melorheostotic lesion to the pelvic bones with the formation of secondary coxarthrosis of the right hip joint, grade 3.

Conclusion: The dynamics of the development of the disease in the patient in the presented clinical case indicates a gradual, steady progression of clinical and radiological manifestations of melorheostosis over time. There is currently no effective specific treatment for the described skeletal dysplasia. The used treatment is symptomatic and requires the participation of a multidisciplinary team of specialists.

P228
THE ICARE FEASIBILITY STUDY: AN INTEGRATED COLLECTION OF EDUCATION MODULES FOR FALL AND FRACTURE PREVENTION FOR HEALTHCARE PROVIDERS IN LONG TERM CARE

A. Papaioannou[1], G. Ioannidis[1], L. Hillier[2], J. D. Adachi[1], A. Costa[3], G. Heckman[4], J. Hirdes[4], J. Holroyd-Leduc[5], S. Jaglal[6], S. Kaasalainen[7], A. Lau[1], C. Mcarthur[8], L. Kane[1], S. Marr[9], S. Straus[10], J.-E. Tarride[3], L. Thabane[1], M. Abbas[11], I. Rodrigues[12]

[1]McMaster Univ., Dept. of Medicine, Hamilton, [2]Geras Centre for Aging Research, Hamilton, [3]McMaster Univ., Dept. of Health Research Methods, Hamilton, [4]Univ. of Waterloo, School of Public Health Sciences, Waterloo, [5]Univ. of Calgary, Dept. of Medicine and Community Health Sciences, Calgary, [6]Univ. of Toronto, Dept. of Physical Therapy, Toronto, [7]McMaster Univ., School of Nursing, Hamilton, [8]Dalhousie Univ., School of Physiotherapy, Halifax, [9]Unity Health Toronto, Hamilton, [10]McMaster Univ., Unity Health Toronto, Hamilton, [11]McMaster Univ., Hamilton, [12]Univ. of Manitoba, Max Rady College of Medicine, Winnipeg, Canada

Objective: To determine the feasibility (recruitment rate and adaptations), with a subobjective to understand facilitators to and barriers of, implementing the PREVENT (Person-centred Routine Fracture PreEVENTion) model in practice. The model includes a multifactorial intervention on improving diet, exercise, environmental adaptations, hip protectors, osteoporosis medications, and medication reviews to treat residents at high risk of fracture. Our secondary outcomes were to determine if there was a change in knowledge uptake and in the proportion of fracture prevention prescriptions post-intervention.

Methods: We conducted a mixed methods longitudinal cohort study in three LTC homes across Ontario. A local champion was selected to guide the implementation of the model and promote best practices. We reported recruitment rates using descriptive statistics and implementation process using content analysis.

Results: Within 5 months, we recruited one for-profit and two not-for profit LTC homes, Home A (120 beds), Home B (425 beds), and Home C (240 beds) and one local champion from each home. We required two months to identify and train the local champion over three 1.5-h train-the-trainer sessions, and the local champion required three months to deliver the intervention to a team of healthcare professionals. Forty healthcare professionals across three LTC homes participated and 88% received education on the LTC recommendations. Homes A, B and C reported increases in the proportion of osteoporosis medication by 62%, 3%, and 42%, respectively before and after intervention. At baseline, 57% of LTC residents are at high risk for fracture, and 17% of these high risk residents are on osteoporosis medications. Benefits of the model include easy access to the Fracture Risk Scale, clear and succinct educational material, and an accredited continuing medication educational module for physicians. Challenges included misperceptions between the differences in fall and fracture prevention strategies and fear of perceived side effects associated with fracture prevention medications.

Conclusion: Our study found an increase in knowledge uptake and the proportion of fracture prevention prescriptions post-intervention. The next steps will be to determine if the adapted PREVENT model reduces the risk and rate of hip fractures in LTC.

P229
WHAT IS THE BEST TREATMENT OPTION FOR OSTEOPOROSIS IN YOUNG WOMEN WITH A HISTORY OF GYNECOLOGICAL CANCER? A SYSTEMATIC REVIEW

A. V. Gueldini[1], L. Costa-Paiva[1], A. Pedro[1]

[1]Univ. of Campinas, Campinas, Brazil

Objective: To evaluate the best treatment option for osteoporosis in young women with a history of gynecological cancer.

Methods: The present systematic review was carried out using the keywords 'gynecological cancer' and 'young women' and 'osteoporosis treatment'; keywords were combined with Boolean operators. Breast cancer survivors were excluded. Eligible studies were identified by a systematic literature search of PubMed, Cochrane Library,

Web of Science, Embase, and Scopus with no language or date restriction up to 25 January 2024. To be included in this systematic review, eligible studies had to be randomized clinical trials (RCTs) and nonrandomized studies of intervention comparing osteoporosis outcomes of women who had gynecological cancer underwent osteoporosis treatments compared to patients not exposed to these strategies.
Results: From 656 articles, 7 studies were included for qualitative analysis. Not all studies had a matching criterion or the same design between the study population and the controls, and these criteria often differed between studies. In addition, there is no trial comparing different types of medication treatment (hormone replacement therapy vs. bisphosphonates or denosumab) with the worst outcome in this population, the occurrence of fragility fractures.
Conclusion: Our results showed that there is a gap in the literature on what would be the best treatment option for osteoporosis in young women who are survivors of any type of gynecological cancer. Therefore, during the treatment of gynecological cancer, strategies should be implemented to mitigate these risks. The risk of bone density loss and osteoporosis in gynecological cancer should be recognized, prevented, and diagnosed early to reduce the incidence of osteoporotic fractures. Proper calcium and vitamin D intake, outdoor activity recommendations, and regular BMD measurements may improve the quality of life of gynecological cancer patients. In addition, larger scale prospective studies should be carried out to investigate the factors that affect the long-term, as well as the short-term effects of osteoporosis treatment in gynecological cancer patients.

P230
IMPACT OF FALL-RISK INCREASING DRUGS (FRIDS) ON FALL RISK, FEAR OF FALLING, AND FALLS IN OLDER ADULTS

A. Pereira[1], P. Pires[1], J. Costa[2], M. Veríssimo[3], O. Ribeiro[1]

[1]Cintesis-Center for Health Technology and Services Research, Dept. of Education and Psychology, Univ. of Aveiro, Aveiro, [2]Research Center in Physical Activity, Health and Leisure, Faculty of Sport, Univ. of Porto, Porto, [3]Faculty of Medicine, Univ. of Coimbra, Coimbra, Portugal

Objective: Deprescribing fall-risk-increasing drugs (FRIDs) is part of multifactorial fall prevention strategies for older adults. This study explores the relationship between FRIDs and fall-related outcomes in older adults.
Methods: Cross-sectional study of 509 community-dwelling older adults (mean age = 76.0 y, SD = 6.8), data collection including demographic and clinical characteristics, falls history, fear of falling using the Fall Efficacy Scale (FES-I) and basic functionality using the Timed Up and Go test (TUG). Statistical analyses employed chi-square tests, Mann–Whitney and Kruskal–Wallis tests, Student's T-test, and ANOVA with a significance level of 5%.
Results: 24.6% of participants experienced falls the previous year, and 26.2% exhibited a high fall risk (TUG). Fear of falling (FES-I) was high in 44.8% of participants. Most (73.1%) used at least one FRID, with 43.4% taking one, 19.8% taking two, and 9.9% taking three or more. Common FRIDs included diuretics (41.2%), benzodiazepines (23.4%), and antidepressants (18.7%). Notably, 29.1% of men used alpha-blockers for prostate hyperplasia. High fall risk was prevalent in those using benzodiazepines (32.8 vs. 24.2%, $p = 0.042$), antiepileptics (45.0 vs. 25.4%, $p = 0.050$), opioids (40.5 vs. 25.1%, $p = 0.034$), and high ceiling diuretics (56.9 vs. 22.8%, $p < 0.001$). A significant association existed between the number of FRIDs and high fall risk ($p = 0.005$). No significant association was found between FRID use and falls in the last year. Higher fear of falling was associated with antipsychotics, antidepressants, opioids, and diuretics, with increasing fear tied to a higher number of drugs ($p = 0.011$).
Conclusion: This study highlights the intricate association between FRIDs and an increased fall risk and fear of falling in older adults. Understanding these associations is vital for targeted deprescribing interventions to reduce fall-related outcomes.

P231
INFLUENCE OF CENTRAL SENSITIZATION ON DISEASE ACTIVITY, SEVERITY OF CLINICAL MANIFESTATIONS IN RHEUMATOID ARTHRITIS PATIENTS WITH INITIAL FAILURE OF DMARDS

A. Potapova[1], A. Karateev[1], E. Polishchuk[1], A. Bobkova[1], P. Sholkina[1], E. Filatova[1], A. Lila[1]

[1]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia

Objective: To evaluate the relationship between psychoemotional disturbances, severity of clinical manifestations and presence of central sensitization in rheumatoid arthritis.
Methods: The study group consisted of 509 RA patients (according to the ACR/EULAR 2010 classification criteria) with moderate or high disease activity (DAS28-CRP ≥ 3.2) and insufficient efficacy or intolerance to csDMARDs, biological drugs (bDMARDs), and JAK inhibitors. We used inquirers such as the Central Sensitization Inventory (CSI) questionnaire to identify signs of CS, PainDETECT questionnaire to screening neuropathic pain symptoms (NPS), HADS questionnaire to identify anxiety and depression, HAQ questionnaire to evaluate functional status, FSS questionnaire for fatigue and FIRST questionnaire for signs of fibromyalgia.
Results: Signs of CS (CSI ≥ 40) were detected in 57.2% of the examined patients and median value was 42 [32; 53]. It was found that patients with CS have worse health status (Patient's Global Assessment)—64.6 $\pm$ 13.5 and 53.5 $\pm$ 16.8, $p = 0.001$ respectively) and more prolonged morning stiffness—90 [30; 180] and 60 [20; 120] min., $p = 0.001$, greater number of painful joints—8 [5; 12] and 7 [4; 10], $p = 0.005$, worse functional state according to HAQ (1.65 $\pm$ 0.7 and 1.08 $\pm$ 0.5, $p = 0.001$) and higher disease activity according to DAS28-CRP (4.9 $\pm$ 1.0 and 4.6 $\pm$ 0.9, $p = 0.001$) vs. patients without signs of CS. There was also a clear relationship between CS and a high probability of having NPS (Pain DETECT > 18)—34.5% and 10.3%, $p = 0.001$, clinically significant anxiety and depression (HADS > 11)—29.0% and 5.1%, $p = 0.001$ and 26.3% and 4.2%, $p = 0.001$, respectively, fatigue (FSS)—96.5% and 70.4%, $p = 0.001$, signs of fibromyalgia (FIRST ≥ 5)—38.4% and 6.1%, $p = 0.001$.
Conclusion: The presence of signs of CS in RA significantly affects many symptoms of the disease, being associated with higher pain intensity, fatigue, impaired function, increased incidence of NPS, depression, anxiety and fibromyalgia.

P232
CENTRAL SENSITIZATION (CS) IS A PHENOMENON TO DETERMINE THE PATHOGENESIS OF CHRONIC PAIN, REDUCED RESPONSE TO DMARDS, AND DEVELOPMENT OF DIFFICULT TO TREAT RHEUMATOID ARTHRITIS (RA)

A. Potapova[1], A. Karateev[1], E. Polishchuk[1], A. Bobkova[1], P. Sholkina[1], A. Lila[1]

[1]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia

Objective: To determine the effect of central sensitization on clinical response to biological therapy in RA patients.

Methods: We assessed the presence of CS in 591 patients with moderate or high activity of RA (DAS28-CRP $\geq$ 3.2) using the Central Sensitization Inventory (CSI) questionnaire. The majority were women—83.1%, mean age 50.9 $\pm$ 14.1 y, with previous failure of DMARDs. The examined patients have RF-positive 455 (77.1%), ACPA-positive 408 (69.0%) tests. The average duration of RA in the study group was 9 [5; 16] y, DAS28-CRP—4.7 $\pm$ 1.0, pain severity (VAS) 6 [4; 7], fatigue according to FSS questionnaire ($\geq$ 27)—499 (84.4%), HAQ 1.4 $\pm$ 0.7. Medical history analysis showed, 97.5% of patients received csDMARDs, more often methotrexate—65.7%, less often sulfasalazine—16.9%, hydroxychloroquine—8.5%, and leflunomide—5.2%. Biological drugs were previously received by 74.6% of patients. At the time of inclusion in the study, csDMARDs were taken by 81.8% of patients, bDMARDs—63.1%, and JAK inhibitors—6.2%. More than half of the patients (52.8%) were taking glucocorticoids, all patients were taking NSAIDs. Initially, the result of CSI questionnaire more than 40 (CSI^{3}40) was detected in 56.3%, the median was 42 [32;53]. During hospitalization, patients were prescribed bDMARDs—70.6% (TNFα inhibitors—26.6%, IL6-inhibitors—6.5%, RTX 38.4%) and JAK inhibitors—8.87%, replacement of DMARDS without bDMARDs and JAK—29.4% of patients. The clinical response was assessed by PASS according to the data of telemedicine monitoring after 6 months.
Results: PASS-positive was registered in 57% (65.1% for bDMARDs and JAK inhibitors, 40% for csDMARDs. The presence of CS (CSI $\geq$ 40) was associated with the worst response: PASS-positive—42.3%, PASS-negative—57.7%, (p = 0.001).
Conclusion: The presence of CS significantly reduces the efficacy of therapy with csDMARDs and biological agents. The presence of CS is associated with severer pain, fatigue, and poor quality of life.

P233
REDUCING THE NEED FOR GLUCOCORTICOIDS AGAINST THE BACKGROUND OF THERAPY WITH BDMARDS AND IJAK IN RHEUMATOID ARTHRITIS: REAL CLINICAL PRACTICE

A. Potapova[1], A. Karateev[1], E. Polishchuk[1], A. Bobkova[1], E. Filatova[1], A. Lila[1]

[1]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia

Objective: Clinical guidelines for the treatment of rheumatoid arthritis (RA) recommend reducing the use of glucocorticoids (GCs) due to the high risk of associated complications. We aimed to determine the frequency of GC cancellations and dose reductions in real clinical practice, while taking into account active RA therapy.
Methods: The study group consisted of 303 patients with RA reliable according to ACR/EULAR criteria (women 79.9%, age 52.8 $\pm$ 13.3, disease duration 9 [4; 16] y, DAS28-CRP 4.9 $\pm$ 1.0, RF positive 77.4%, ACCP positive 70.3%), who were prescribed or changed therapy with DMARDs, bDMARDs or iJAK due to disease exacerbation and ineffectiveness of previous treatment. All patients initially received GC (7.7 $\pm$ 3.8 mg/d prednisolone equivalent). After adjustment of therapy, 42.9% of patients received methotrexate, 27.6% leflunomide, 29.5% sulfasalazine, hydroxychloroquine, or a combination with an NSAID, 63.7% bDMARDs, and 7.2% iJAK. The need for GC intake was assessed by a telephone survey conducted 6 months after the start of follow-up.
Results: Telephone survey was possible in 274 persons (90.4%). There was a significant decrease in pain intensity (numerical rating scale, NRS 0–10) from 6.3 $\pm$ 1.4 to 4.3 $\pm$ 2.4 ($p < 0.001$), fatigue (NRS) from 6.7 $\pm$ 2.3 to 5.2 $\pm$ 2.1 ($p < 0.001$), and functional impairment (NRS) from 5.4 $\pm$ 2.1 to 3.9 $\pm$ 2.0 ($p < 0.001$). A positive PASS index (symptom status acceptable to patients) was noted in 139 patients (50.7%). GC cancellation was noted in 19.7%, dose reduction in 25.9%, maintaining the same dose in 42.7%, and dose increase in 11.7%.
Conclusion: Against the background of intensive RA therapy, including combination of DMARDs with bDMARDs or iJAK, complete withdrawal or reduction of GC dose was achieved in less than half of patients (45.6%) after 6 months.

P234
EVALUATION OF VITAMIN D METABOLISM, CALCIUM AND PHOSPHATE HOMEOSTASIS IN PATIENTS WITH CKD5 UNDERGOING HEMODIALYSIS WHEN GIVEN A SINGLE HIGH DOSE (150,000 IU) OF CHOLECALCIFEROL

A. Bondarenko[1], A. Povaliaeva[1], A. Zhukov[1], Z. Zuraeva[1], M. Ovcharov[1], V. Ioutsi[1], E. Pigarova[1], L. Dzeranova[1], Z. Belaya[1], L. Rozhinskaya[1]

[1]Endocrinology Research Centre, Moscow, Russia

Objective: To assess parameters of vitamin D and mineral metabolism and their response to a loading dose of cholecalciferol (150,000 IU) in hemodialysis patients (CKD5D), as compared to healthy individuals.
Methods: Thirty CKD5D patients were compared to 30 healthy volunteers. Serum levels of vitamin D metabolites, free 25(OH)D, vitamin D-binding protein (DBP), PTH, FGF-23, calcium (Ca), albumin and phosphorus (P) were assessed before and 7 d after 150,000 IU cholecalciferol administration. Blood sampling was performed before hemodialysis. Vitamin D metabolites were measured by UPLC-MS/MS.
Results: Initial levels of free 25(OH)D (4.78 [3.88; 5.26] vs. 5.61 [4.01; 7.31] pg/mL), and DBP (280 [229; 320] vs. 265 [242; 293] mg/L) were comparable ($p > 0.05$). The basal level of albumin-corrected Ca (2.11 [2.04; 2.17] vs. 2.30 [2.25; 2.35] mmol/L) was significantly lower, while P (1.56 [1.28; 1.98] vs. 1.19 [1.06; 1.30] mmol/L), PTH (199.5 [105.6; 321.5] vs. 42.4 [36.1; 61.7] pg/mL) and FGF-23 (21.0 [8.9; 27.6] vs. 0.4 [0.3; 0.6] pmol/L) levels were higher in CKD5D patients ($p < 0.05$). CKD5D patients were also characterized by lower levels of 25(OH)D3 (7.1 [3.7; 13.5] vs. 18.2 [12.2; 22.9] ng/mL), 24,25(OH)2D3 (0.05 [0.05; 0.07] vs. 1.33 [0.60; 2.10] ng/mL), and 1,25(OH)2D3 (18 [12; 43] vs. 39 [31; 56] pg/mL) ($p < 0.05$). After the cholecalciferol treatment in a single high dose (150,000 IU) we observed a significant increase in free 25(OH)D, 25(OH)D3 and 24,25(OH)2D3 ($p < 0.05$) within the CKD5D and control group, while 1,25(OH)2D3 levels did not change significantly in either group ($p > 0.05$). The CKD5D group showed an increase in albumin-corrected Ca levels (p = 0.031) and a decrease in PTH levels (p = 0.043) during the follow-up. However, FGF-23 and P levels remained unchanged ($p > 0.05$). Free 25(OH)D levels (5.91 [4.21; 6.50] vs. 8.90 [6.51; 13.05] pg/mL) at the second visit were significantly lower in CKD5D than in controls ($p < 0.05$). Initial significant differences in the levels of Ca, P, FGF-23, PTH, DBP and vitamin D metabolites between the groups persisted after the cholecalciferol load.
Conclusion: CKD5D patients display distinctive disturbances in vitamin D metabolism. A loading oral dose of 150,000 IU cholecalciferol is effective and safe in reducing PTH in CKD5D patients with a tendency towards calcium normalization, without increasing phosphorus levels.

P235
A DESCRIPTIVE LONGITUDINAL EXPLORATION OF THE BONE HEALTH AND BONE HEALTH SCREENING PATTERNS OF ADULTS WITH AN INTELLECTUAL DISABILITY IN IRELAND

A. Power[1], P. Mccallion[1], M. Mccarron[1], E. Burke[1]

[1]Trinity College Dublin, Dublin, Ireland

Objective: To longitudinally examine the bone health status, bone health screening patterns and factors that negate screening in adults with an intellectual disability over the age of 40 in Ireland and identify changes over time.
Methods: This research study was conducted with data generated from a large longitudinal study examining ageing among people with intellectual disability in Ireland. Ethics was approved by the TCD faculty of health sciences and all participating service providers. Each participant provided informed consent. Data used in this study extends from 2009–2020. Health domains explored include doctor's diagnosis of osteoporosis and healthcare utilisation.
Results: The prevalence of doctor diagnosed osteoporosis increased from 8.1% at Wave 1 to 21% at Waves 4. Simultaneously, DXA attendance increased from 16.8% at Wave 1 to 44.8% at Wave 4, Among the strongest predictors for attending DXA were residing in supported accommodation and aged > 65 y. Factors that negate DXA attendance include difficulty walking and not troubled with pain.
Conclusion: Osteoporosis is rising in prevalence among this vulnerable and high-risk cohort and despite increased attendance at DXA access remains relatively poor implying the prevalence of low BMD is likely to be largely underestimated. Recommendations for clinical practice and future investigation:

- Further research is warranted in people within the < 50 age category and people residing independently or with family as they were underrepresented in this study.
- Healthcare staff training and awareness is required in relation to bone health among people with intellectual disabilities emphasising the unique issues pertinent to bone health screening and people with intellectual disability.
- Improved policy and protocol provision to guide bone health promotion, associated risk factor identification and screening protocols or algorithms are required.

P236
VALIDATION OF QUANTITATIVE ULTRASONOGRAPHY FOR OSTEOPOROSIS DIAGNOSIS IN POSTMENOPAUSAL WOMEN COMPARED TO DXA

A. R. Singh[1]

[1]King George's Medical Univ., Lucknow, India

Objective: BMD is an essential indicator for diagnosing osteoporosis and evaluating the success of osteoporotic treatment. DXA, quantitative ultrasonography (QUS), and quantitative computed tomography (QCT) are frequently used for measuring BMD. The objective of the study was to evaluate the ability of QUS to screen for osteoporosis and bone density in postmenopausal women by calibrating it against DXA.
Methods: This cross-sectional study was conducted at the Dept. of Orthopedics and Trauma Center of the tertiary care center, Lucknow. A total of 90 patients visited this department from August 2017 to July 2018 for the present study. BMD in the same patient was evaluated by using DXA and ultrasonography methods. Data were entered in Microsoft Excel and analyzed by using SPSS Software.
Results: According to linear regression analysis, T neck was found statistically significant with T QUS ($p < 0.001$) and z QUS ($p < 0.001$). T lumbar and T wrist were found statistically significant with T QUS ($p < 0.001$) but not with z QUS ($p > 0.001$). Z neck was found statistically significant with T QUS ($p < 0.001$) and z QUS ($p < 0.001$). Z lumbar was found statistically significant with T QUS ($p < 0.001$) but not with z QUS ($p > 0.005$). Z wrist was not found statistically significant with T QUS ($p > 0.005$) or with z QUS ($p > 0.005$).
Conclusion: In the present study, we found that QUS can be used as a screening tool for detecting osteoporosis by measuring BMD in contrast to DXA. QUS also can be used to predict the DXA values for osteoporosis and to detect osteoporosis.

P237
USE OF REMS TECHNOLOGY FOR BONE HEALTH STATUS EVALUATION AFTER HORMONAL THERAPY IN TRANSGENDER SUBJECTS

A. Russo[1], C. Stomaci[2], P. Pisani[3], F. A. Lombardi[3], F. Conversano[3], R. Franchini[3], M. Di Paola[3], S. Casciaro[3]

[1]Dept. of Endocrinology, San Lorenzo di Borgo Valsugana Hospital, Trento, [2]Dept. of Biological and Environmental Sciences and Technologies, Univ. of Salento, Lecce, [3]Institute of Clinical Physiology, National Research Council, Lecce, Italy

Objective: Sex steroid hormones exert their effect on bone metabolism and musculoskeletal unit by the interaction with specific nuclear receptor expressed in the bone tissue, by regulating the continuous bone physiological remodeling inducing anabolic effects. The investigation of the long-term effect of gender affirming hormone therapy (GAHT) on bone metabolism assumes an important challenge. Radiofrequency echographic multispectrometry (REMS) is a nonionizing technology used to assess the bone health status and fracture prediction by the analysis of the reference axial sites: lumbar spine (LS) and femoral neck (FN). REMS has been widely validated in comparison with DXA, showing good accuracy and precision ($> 90\%$), therefore represents a valid technology to monitor bone health status in a short-term period. Consequently, the aim of this preliminary clinical study is to follow-up the bone health of transgenders subject within 1 y from the treatment starting by using REMS in order to understand the impact of GAHT on bone health status.
Methods: A total of 5 transgender patients were enrolled in the Endocrinology department of the hospital San Lorenzo di Borgo Valsugana, Trento (Italy). The study population included 3 assigned male at birth (AMAB) in therapy with oestradiol valerate 2 g/die and cyproterone acetate 25 mg/die; and 2 assigned female at birth (AFAB) in therapy with testosterone 25 mg/die. Patients underwent LS-DXA scan before the initiation of GAHT, and subsequently, REMS technology has been used to monitor bone health status after patient's therapy initiation.
Results: All the results were collected in the following Table:

	AMAB LS
	T-SCORE TOT ± DS
DXA	-1.8 ± 1.8
REMS	-0.3 ± 0.3

	AFAB LS
	T-SCORE TOT ± DS
DXA	0.9 ± 0.4
REMS	0.5 ± 0.4

The results show an increase of T-score values in AMAB after estrogen treatment starting, and no effect on bone in AFAB subjects after GAHT; this phenomenon can be explained considering on one hand the protective effect of estrogen therapy in AMAB subjects against bone loss, and on the other hand the combined effect of the decrease of estrogen together with the increase of testosterone in AFAB ones.

Conclusion: These preliminary results demonstrate the suitability of REMS for the bone health status monitoring in these subjects and show, as expected, the positive impact of estrogen therapy in AMAB subject's bone loss.

P238
PRP THERAPY IN OA KNEE: MY EXPERIENCE (A SERIES OF 350 CASES–380 KNEES)

A. S. Bhatia[1]

[1]Dr Bhatia's Bone & Joint Care Clinic, Chandigarh, India

Objective: Osteoarthritis (OA) is a major source of disability, pain, and economic burden worldwide. Genetic, biochemical, and mechanical factors are responsible for the complex multifactorial epidemiology of the disease. Abnormal joint biomechanics, age, gender, joint injury, and high BMI, along with a strong genetic basis, are associated with OA development. Presently, OA is the eighth most common disease in males world over and the fourth most common disease in females [1]. Previously, OA was believed to be caused by the mechanical degradation of cartilage. But now the understanding is, this a complex of, mechanical, chemo- inflammatory, the pathophysiology is complex inter play leading to the production of matrix metalloproteinases (MMPs), nitric oxide (NO), and prostaglandins (PGs), leading to matrix degradation [2]. The catabolic effects of interleukins secreted by chondrocytes, mononuclear cells, osteoblasts, and synovial cells interfere with the activity of growth factors and reduce the synthesis of aggrecan, which is the key constituent of the matrix providing resilience to cartilage [3]. IL-1β, the proinflammatory cytokine, is a major protagonist in inducing arthritic changes, as evident by its increased levels in the synovial fluid of affected joints [4–5]. Intra-articular injection of platelet-rich plasma (PRP) has been broadly considered for cartilage repair, as it could enhance matrix synthesis thanks to the properties of its growth factors (mostly PDGF and TGFβ) [6–8]. To evaluate the efficacy of PRP intra-articular injections in OA knee patients. A series of 123 patients with different grade of OA. Assessing the recovery on VAS and WOMAC scale.

Methods: 8 ml of patient's blood taken in two tubes containing 0.5 ml of sodium citrate (38% w/l). Centrifuged at the 4000 rpm for 20 min. Let sample rest for about 5 min, about 5–6 ml of PRP is extracted. Patient shifted to operation theatre. After proper skin sterilisation and knee draping. This PRP is injected into the knee joint. 2nd injection of PRP repeated after one month. The patient's progress is assessed after the second injection. First case done 4 y. Back and last case included 6 months back (today-26/12/23). Recovery assessed with VAS and WOMAC scale. Four aspects of WOMAC sore taken into consideration: (1) pain at night, (2) rising from sitting, (3) walking on flat surface, (4) ascending and descending stairs, (5) performing light domestic duties, and (6) performing heavy domestic duties.

Results: In the series 350 cases–380 KNEES of taking into consideration the severity of OA as per K&J classification—Grade 2 (minimal) moderate joint reduction, Grade 3 (moderate) severe joint space reduction with subchondral sclerosis, Grade 4 (severe) large osteophytes, marked narrowing of joint space, severe sclerosis and definite deformity of bone ends. BMI of the patient, age of the patient showed: (1) pain at night 95–100%, (2) rising from sitting 86–100%, (3) walking on flat surface 85–100%, (4) ascending and descending stairs 60–90%, (5) performing light domestic duties 70–96%, and (6) performing heavy domestic duties 60–95%. Across various Grade of OA (Grade 2 to 4). Patients were also instructed for regular exercises to strengthen their thigh muscles and lifestyle changes to bring their body weight in permissible levels as per their height.

Conclusion: PRP therapy in moderate to severe OA knee showed good to excellent results in improving pain during rest, pain free walk, climbing stairs. Patients who do not want TKR is worth trying. Up to two years follow patients are happy and pain free.

P239
BONE MICROARCHITECTURE IMPAIRMENT IN PATIENTS WITH SJÖGREN'S DISEASE IS ASSOCIATED WITH DAMAGE INDEX

A. S. Franco[1], I. H. Murai[1], T. H. Yang[1], L. Takayama[1], V. L. N. Bonoldi[1], V. F. Caparbo[1], L. K. N. Guedes[1], D. S. Domiciano[1], S. G. Pasoto[1], C. P. Figueiredo[1], R. M. R. Pereira[1]

[1]Division of Rheumatology, Hospital das Clinicas HCFMUSP, Faculdade de Medicina, Universidade de Sao Paulo, Sao Paulo, Brazil.

Objective: To assess bone microarchitecture parameters and their associations with systemic disease activity and damage index in women with Sjögren's disease (SjD).

Methods: A cohort of 106 women with SjD (mean ± SD age: 49.6 ± 9.2 y and BMI: 28.1 ± 5.5 kg/m^2) was recruited from a tertiary hospital in Sao Paulo, Brazil. Exclusion criteria were immunomediated diseases, hepatitis B/C, sarcoidosis, IgG4-related disease, head and neck radiotherapy and/or medications that affect bone metabolism. Bone microarchitecture at the distal radius and distal tibia was assessed using HR-pQCT. Systemic disease activity and damage index were measured by ESSDAI and SSDI, respectively. Spearman's correlation coefficient was used to analyze the relationship between bone parameters and SjD-related indices. A multivariate generalized linear model (GLM) was used to explore the effects of ESSDAI and SSDI on bone variables that showed $P < 0.10$ in the bivariate analysis. The significance level was set at 5%.

Results: The parameters had the following median (IQR): ESSDAI 1 (1–3), SSDI 2 (1–3) and disease duration 7 (4–14). SSDI was directly correlated with disease duration ($\rho = 0.22$; $P = 0.02$). At the radius, SSDI was inversely correlated with cortical area (Ct.Ar) ($\rho = -0.21$; $P = 0.04$), cortical volumetric BMD (Ct.vBMD) ($\rho = -0.23$; $P = 0.02$), and positively correlated with cortical porosity (Ct.Po) ($\rho = 0.33$; $P < 0.01$). At the tibia, negative correlations were observed between SSDI and Ct.Ar ($\rho = -0.31$; $P < 0.01$), total vBMD ($\rho = -0.26$; $P = 0.01$), trabecular number (Tb.N) ($\rho = -0.23$; $P = 0.03$), cortical thickness ($\rho = -0.23$; $P = 0.02$) and Ct.vBMD ($\rho = -0.40$; $P < 0.01$). In addition, SSDI was positively correlated with trabecular separation (Tb.Sp) ($\rho = 0.22$; $P = 0.03$), Ct.Po ($\rho = 0.39$; $P < 0.01$) and pore diameter ($\rho = 0.31$; $P < 0.01$). Multivariate GLM with adjustment for age, disease duration and cumulative prednisolone dose showed significant associations between SSDI and Ct.Po at the radius ($\beta = 0.35$; $P < 0.01$) and tibia

($\beta = 0.21$; $P = 0.02$) and Tb.N ($\beta = -0.23$; $P = 0.03$) at the tibia. No significant associations were observed between ESSDAI and bone microarchitecture.

Conclusion: In this cross-sectional study, damage index was independently associated with bone microarchitecture impairment in women with SjD. The findings suggest that SSDI could be a useful and feasible tool for estimating the extent of bone involvement in SjD, highlighting the importance of investigating bone health in this disease.

P240
PHYSICAL ACTIVITY IS ASSOCIATED WITH BONE MICROARCHITECTURE, BONE BIOMECHANICAL PROPERTIES, AND MUSCLE STRENGTH IN SJÖGREN'S DISEASE PATIENTS

A. S. Franco[1], T. H. Yang[1], I. H. Murai[1], L. Takayama[1], V. L. N. Bonoldi[1], V. F. Caparbo[1], L. K. N. Guedes[1], D. S. Domiciano[1], R. M. R. Pereira[1], S. G. Pasoto[1], C. P. Figueiredo[1]

[1]Division of Rheumatology, Hospital das Clinicas HCFMUSP, Faculdade de Medicina, Universidade de Sao Paulo, Sao Paulo, Brazil

Objective: To analyze the correlations between physical activity (PA) and bone microarchitecture, bone biomechanical properties, muscle strength, and disease-related parameters in women with Sjögren's disease (SjD).

Methods: A cohort of 106 women with SjD (mean ± SD age: 49.6 ± 9.2 y and BMI: 28.1 ± 5.5 kg/m^2) was recruited from a tertiary hospital in Sao Paulo, Brazil. Exclusion criteria were other immunomediated diseases, hepatitis B/C, sarcoidosis, IgG4-related disease, head and neck radiotherapy and medications that affect bone metabolism. Bone microarchitecture and biomechanical parameters (S: stiffness and F.load: estimated load to failure) at the distal radius and distal tibia were assessed using HR-pQCT and finite element analysis, respectively. Handgrip strength was evaluated using a dynamometer. Questionnaires were used to quantify PA levels (Baecke Questionnaire of Habitual PA), systemic disease activity (ESSDAI), damage index (SSDI) and functional capacity (HAQ). The sample was divided into tertiles of PA levels according to the total activity index. Differences between tertiles were assessed using the Kruskal–Wallis test or generalized linear model. Spearman's correlation coefficient was used to evaluate the relationship between the total activity index and all dependent variables. The significance level was set at 5%.

Results: The median (IQR) total activity index was 7.5 (6.4–8.4), ESSDAI: 1 (0–3), SSDI: 2 (1–3) and HAQ: 0.3 (0–0.7). The mean ± SD handgrip strength was 17.1 ± 6.4 N. The total activity index significantly differed ($P < 0.01$) when comparing the lower: 5.5 (5.2–6.2), middle: 7.5 (6.9–7.7), and upper: 8.7 (8.4–9.5) tertiles of PA levels. At the radius, PA levels were directly correlated with cortical area ($\rho = 0.28$; $P < 0.01$), total volumetric BMD ($\rho = 0.21$; $P = 0.03$), cortical thickness ($\rho = 0.22$; $P = 0.03$), S ($\rho = 0.29$; $P < 0.01$), and F.load ($\rho = 0.28$; $P < 0.01$). At the tibia, positive correlations were shown for S ($\rho = 0.21$; $P = 0.04$) and F.load ($\rho = 0.21$; $P = 0.04$). Handgrip strength was significantly correlated with PA levels ($\rho = 0.32$; $P < 0.01$). Tertiles of PA levels significantly differed for handgrip strength ($P < 0.01$), S ($P = 0.02$) and F.load ($P = 0.02$) at the radius. No significant correlations were observed with any other variables.

Conclusion: In women with SjD, PA levels were positively correlated with bone and muscle strength. The findings highlight the importance of PA as a feasible tool in multifaceted management to counteract SjD-induced bone impairment.

P241
UTILITY OF TRABECULAR BONE SCORE IN THE EVALUATION OF LUNG TRANSPLANT CANDIDATES

A. Sherman[1], A. Shokrekhuda[1], D. Kalbi[1], K. Chun[1]

[1]Montefiore Medical Center, Albert Einstein College of Medicine, Bronx, USA

Objective: The present study sought to investigate the value of TBS, in conjunction with DXA, for the evaluation of BMD and microarchitecture in lung transplant candidates.

Methods: A retrospective review of 191 DXA scans of patients undergoing lung transplantation at a large, urban, academic medical center was performed. All patients underwent BMD screening using DXA. TBS iNsight software was applied to DXA images of the lumbar spine (L1 through L4 vertebrae). DXA and TBS measurements were standardized by T-scores using population-based reference data and applied to established cutoffs for osteopenia, osteoporosis, partially degraded bone, and degraded bone. Pathologic bone requiring medical intervention was defined at DXA or TBS T-score < -1.0.

Results: DXA and TBS T-scores were found to be moderately correlated, $r = 0.50$, $p < 0.001$. However, TBS T-scores ($M = -1.97$, $SD = 1.31$) were, on average, significantly lower than DXA T-scores ($M = -0.79$, $SD = 1.56$), $t(190) = 11.17$, $p < 0.001$. There were 153 cases (80.1%) for which the TBS T-score was less than the corresponding DXA T-score. Significantly more patients had pathologic bone requiring medical intervention according to TBS (72.3%) than DXA (47.6%), exact McNemar's $p < 0.001$. Differences in the observed rates of osteopenia (36.6%), osteoporosis (11.0%), partially degraded bone (38.7%), and degraded bone (33.5%) were also statistically significant, exact McNemar's $p < 0.001$. Three times the number patients were found to have degraded bone by TBS compared to osteoporosis by DXA, exact McNemar's $p < 0.001$.

Conclusion: Osteoporosis and impaired trabecular microarchitecture are extremely common among lung transplant candidates. A substantial proportion of patients remain at risk of fracture through degraded bone despite normal BMD. TBS offers promise as a simple, noninvasive, and inexpensive screening adjunct to DXA in this unique and vulnerable population.

P242
GENDER AND RACIAL/ETHNIC DIFFERENCES IN BONE MINERAL DENSITY AND MICROARCHITECTURE AMONG LUNG TRANSPLANT CANDIDATES

A. Sherman[1], A. Shokrekhuda[1], D. Kalbi[1], K. Chun[1]

[1]Montefiore Medical Center, Albert Einstein College of Medicine, Bronx, USA

Objective: To compare gender and racial/ethnic differences in BMD and microarchitecture among lung transplant candidates using DXA and TBS.

Methods: A retrospective cohort of 191 lung transplant candidates undergoing DXA and TBS screening was analyzed. The sample had a modest male predominance (61.8%) and relatively diverse racial/ethnic composition (46.3% Hispanic, 29.4% White, 21.9% Black, 2.4% other). DXA T-scores were standardized using the manufacturer's Caucasian, gender-matched reference population (1). TBS T-scores were calculated with reference to an established Caucasian, female cohort (2).

Results: Male ($M = -0.67$, $SD = 1.50$) and female patients ($M = -0.99$, $SD = 1.65$) had statistically equivalent mean DXA T-scores, $t(189) = 1.40$, $p = 0.16$. However, female patients

(M = − 2.40, SD = 1.50) had significantly lower mean TBS T-scores than male patients (M = − 1.71, SD = 1.10), t(189) = 3.58, $p < 0.001$. There was a significant main effect of race/ethnicity on DXA T-score, F(2, 153) = 6.78, p = 0.002. By contrast, race/ethnicity did not significantly impact TBS T-score, F(2, 153) = 0.17, p = 0.84. Hispanic patients (M = − 1.13, SD = 1.56) had significantly lower DXA T-scores than Black (M = − 0.12, SD = 1.68), p = 0.003, and White patients (M = − 0.40, SD = 1.13), p = 0.03. There was no significant difference in DXA T-scores between White and Black patients, p = 0.67.

Conclusion: Gender-matched referencing appears to mitigate disparities in patients undergoing DXA but does not yet exist for TBS. TBS was less sensitive in detecting degraded bone microarchitecture in men, possibly due to standardization by a female cohort. This study also underscored known issues with using Caucasian reference standards for DXA. TBS, however, was found to be particularly robust against racial/ethnic differences.

P243
CTX LEVEL MIGHT BE ASSOCIATED WITH THE INCREASE IN BONE MINERAL DENSITY IN OSTEOPOROTIC SUBJECTS TREATED WITH DENOSUMAB

A. Shinkov[1], J. Vlahov[2], M. Angelova[1], D. Petrova[1], I. Yankova[1], J. Petrova[1], R. Kovatcheva[1]

[1]Medical Univ. Sofia, Medical Faculty, Dept. of Endocrinology, [2]Sofiamed Hospital, Sofia, Bulgaria

Objective: The role of the bone metabolic markers in the treatment and follow-up of postmenopausal osteoporosis is still controversial. It is assumed the initial marker levels and their continuous suppression might be related to the effect of the antiresorptive therapy. The aim of the study was to explore the association of CTX levels with the effect of the treatment with denosumab on the BMD.

Methods: 120 postmenopausal women with osteoporosis and high fracture risk were enrolled. Baseline BMI, BMD at lumbar spine (BMD-L) and proximal femur (BMD-N and BMD-T) and serum CTX were measured. All participants started standard of care treatment with denosumab 60 mg every 6 months. BMD and CTX were followed-up at months 12 and 24 months. The relative changes in the BMD and the CTX were calculated and correlations were explored.

Results: 119 subjects attended the month 12 visit and 91 subjects the month 24 visit. At Month12 BMD-L increased by 6.2% (2.4–8.4), BMD-N by 1.1% (0.1–2.4), BMD-T by 1.2% (0–2.9), all $p < 0.001$. At month 24 BMD-L increased by 8.5% (5.9–11.2), BMD-N by 1.8% (0.7–4.2) and BMD-T by 2.7% (1.1–3.8), all $p < 0.001$). The baseline CTX was 0.54 (0.2) ng/ml and was decreased by 76% (58–85) at Month12 and by 75% (54–84) at Month24. The change in BMD at any site was not associated with the age or the BMI. The increase in BMD-L at Month24 but not Month12 was weakly correlated to the baseline CTX (r = 0.24, p = 0.047) when controlling for age and BMI. No association was found between the CTX and the change in BMD-N or BMD-T. The increase in BMD-L at Month24 correlated with the reduction in CTX (r = 0.31, p = 0.22).

Conclusion: Baseline CTX levels show weak correlation with the increase in BMD but only at the lumber spine. The continuous suppression of CTX at Month24 correlates better with the BMD-L increase and might serve as a prognostic factor for the clinical efficiency of denosumab. Further research is needed to corroborate these observations.

FRACTURE LIAISON SERVICE: CAN WE REALLY CHANGE PATIENT'S OUTCOMES?

A. Silva[1], A. M. Monteiro[1], A. R. Lopes[1], A. Pinto[2], M. Silvério-António[1], M. Magalhães[3], A. R. Cruz-Machado[1], A. M. Silva[2], A. Tirado[2], J. C. Romeu[1]

[1]Rheumatology and Metabolic Bone Diseases Dept., Hospital de Santa Maria, EULAR Center of Excellence in Rheumatology Research, Centro Hospitalar Universitário Lisboa Norte, Lisbon Academic Medical Center, [2]Orthopaedics and Traumatology Dept., Centro Hospitalar Universitário Lisboa Norte, [3]Unidade de Saúde Familiar do Parque, Agrupamento de Centros de Saúde Lisboa Norte, Lisbon, Portugal

Objective: To describe the initial results of a single centre type A Fracture Liaison Service (FLS) care.

Methods: On May 2023, we reviewed the clinical charts of patients referred to the FLS program between 01.2020 to 06.2022. We considered an intervention group (IG)—patients effectively evaluated—and a control group (CG)—those who were not.

Results: 507 patients were referred to the FLS program and most of them—393 (77.5%)—were formally evaluated, while 114 were not (CG) for several reasons, such as nonfulfillment of requirements or discharge prior to the FLS team evaluation. 79.6% of the IG and 76.3% of the CG were female, most had a proximal femur fragility fracture (FF) (99.4% and 99.1%) with a mean age at FF diagnosis of 83.1 ± 8.8 and 81.9 ± 10.8 years, as well as a median follow-up time of 17 [11–24] and 15 [3.75–25] months, respectively. In the IG, antiresorptive therapy was recommended to 341 patients (86.8%), but only 161 (47.2%) had complied: alendronate in 69 patients (54.8%), zoledronate in 68 (39.3%) and denosumab in 24 (57.1%). Out of the treated patients, 1/3 on alendronate and denosumab and half on zoledronate have discontinued the treatment. The IG and CG were similar at baseline, with differences at the level of autonomy prior to the fracture (p = 0.018); number of previous FF (p = 0.002) and length of hospitalization (p = 0.001), all lower in the CG. The frequency of antiresorptive therapy initiation was higher in the IG ($p < 0.001$), but no differences were found in the number of readmissions, new FF or deaths, although there was a favorable trend in the last two outcomes for the IG.

Conclusion: FLS care was not associated with a significant reduction in subsequent fractures, in line with previous studies with a follow-up ≤ 2 y. Our FLS program began in the critical period of the COVID-19 pandemic, with a reduced accessibility to health care, which can explain, at least partially, the lack of benefit regarding the reduction of new FF and deaths. Nevertheless our results seem promising and we will keep working to improve clinical outcomes.

P245
LONG-TERM EFFECTS OF DENOSUMAB IN A PATIENT WITH SYMPTOMATIC PRIMARY HYPERPARATHYROIDISM

D. Grigorie[1], A. Badici[1], A. Sucaliuc[1]

[1]National Institute of Endocrinology, Bucharest, Romania

Objective: Denosumab can be used to increase bone density in patients who choose not to have surgery, but who meet specific guidelines (1). We aimed to observe long-term (3 y) effects of

denosumab on BMD, hypercalcemia and bone turnover markers in a patient with primary hyperparathyroidism (PHPT) and osteoporosis.
Methods: A 73-year-old woman with surgical menopause (at age 48) was diagnosed with PHPT in 2011, based on total serum calcium of 11.7 mg/dl and increased PTH of 242 pg/ml; she had osteoporosis by DXA at all three sites: LS T-score − 3.2 SD, femoral neck − 2.5 SD, one-third radius − 3.9 SD with a Z-score at − 2.2 SD; serum C-telopeptide was 1 ng/ml. There were no fractures, and a small stone was seen in the right kidney. On ultrasound a small left inferior parathyroid adenoma was seen, confirmed on subsequent surgery. She denied surgery and agreed to receive treatment with denosumab for three years. Finally, she wished to be operated on, and a 0.95 g adenoma of the left inferior parathyroid gland was removed with cure.
Results: After 3 y of denosumab the BMDs increased at all sites: + 4.5% at the LS, + 6.5% at the FN and by 9% at one-third radius. The effects on serum calcium were variable, with rebound before next dosage. Serum CTX also had variable suppression (nadir at 0.15 ng/ml after 3 dosages) with a tendency of minimal suppression in the third year (0.75 ng/ml). In the three years after the surgical cure BMD increased by 5.1% at the LS and by 6.6% at the FN.
Conclusion: Denosumab is an efficacious treatment for osteoporosis in PHPT patients who choose not to have surgery. The changes were similar after surgery.

P246
DOES COMORBIDITY IMPACT ON THE PREVALENCE OF OSTEOPOROSIS IN PATIENTS WITH RHEUMATOID ARTHRITIS?

A. T. Mamasaidov[1], A. A. Ansarova[2], E. V. Kalinina[2], A. R. Babaeva[2], K. S. Solodenkova[3]

[1]Osh State Univ., Faculty of Medicine, Osh, Kyrgyzstan, [2]Volgograd State Medical Univ., Volgograd, Russia, [3]Sechenov Univ., Moscow, Russia

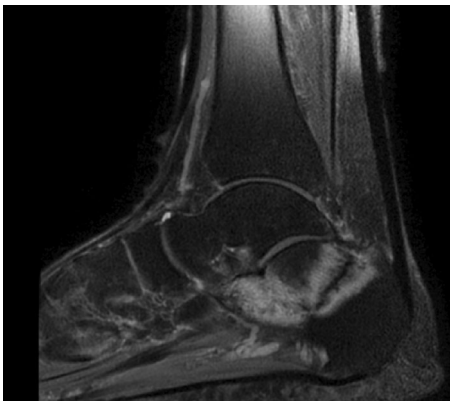
Objective: To assess the relationship between the presence of comorbid pathology, as well as the use of glucocorticoids (GC), on the one hand, and the presence of osteoporosis (OP), on the other hand, in patients with rheumatoid arthritis (RA).
Methods: We investigated 264 patients with a definite diagnosis of RA (ACR/EULAR criteria, 2010), aged from 26–79 y (average age 58.21 ± 2.09), women predominated (211 people—79.92%). The duration of RA in 82.58% of patients exceeded 5 y, the average duration was 12.14 ± 3.26 y. Based on the submitted medical documentation and the standard examination of patients, the presence and spectrum of comorbid pathology and radiologically proven OP were analyzed. The influence of comorbidity, as well as GC therapy on the development of OP, was assessed by the frequency of registration of OP in patients with and without concomitant diseases and GC therapy using the χ^2 criterion.
Results: Comorbid pathology was observed in 218 patients with RA, which amounted to 82.58%. The range of concomitant diseases was represented by cardiovascular pathology (in 73.48% of patients), gastrointestinal and liver diseases (48.48%), anemia (29.92%), kidney and urinary tract diseases (33.33%), respiratory diseases (17.04%), type 2 diabetes mellitus (8.33%). The frequency of use of systemic GCs turned out to be quite high—68.94%; in individuals with comorbidity, the cumulative dose of GCs was significantly higher (6.89 vs. 3.16 g, $p < 0.01$). Systemic OP was diagnosed in 58.33% of RA patients, while 7.95% had a history of osteoporotic fractures. Systemic OP was significantly more often recorded in comorbid patients than in patients without comorbidity (138 people—63.3% vs. 16 people – 34.78%, $\chi^2 > 4.0$, $p < 0.05$). Along with this, an association of OP with the use of GC therapy was observed: in patients receiving GC at a dose of > 5 mg in terms of prednisolone, OP was recorded with a frequency of 74.73 vs. 21.95% in the group that did not receive GC ($\chi^2 > 4.0$, $p < 0.05$).
Conclusion: Comorbid pathology occurs in the vast majority of RA patients and is associated with the duration and intensity of GC therapy. Systemic OP is recorded in more than half of patients with advanced or late stage RA. A direct connection was found between the presence of comorbidity and the prevalence of OP, as well as between the long term GC therapy and the development of systemic OP.

P247
THE CASE OF MULTIPLE STRESS FRACTURES IN A PATIENT WITH RHEUMATOID ARTHRITIS AND OSTEOPOROSIS SUCCESSFULLY TREATED BY TERIPARATIDE

A. Tarasova[1]

[1]Hadassah Moscow, Moscow, Russia

The patient is a 77 years old generally healthy woman with a history of low activity rheumatoid arthritis on methotrexate 15 mg a week previously treated with methylprednisolone. She first presented at the age of 72 years old. At that moment she was already diagnosed osteoporosis with radius fracture treated for several years by alendronic acid. Her main complaint was knee pain during walking and MRI showed stress fracture of her left tibial plateau. She received zoledronic acid infusion twice. After that her DXA T-score was − 2.7 in femoral neck and − 1.8 in L1–L4. In 2021 DXA result was stable and even improved in hip (− 2.4). Left knee MRI in June 2021 showed the same picture of stress fracture with massive bone oedema and right heel MRI also showed stress fracture which was new. Nevertheless the patient decided to stop therapy for a while though she continued to experience painful symptoms in her legs. She presented again in 2022 with severe knees and right heel pain on walking. She was using crutches and NSAIDs and opioid analgesics had only mild effect. Left knee MRI was remarkable by slight decrease of bone oedema though tibial deformity and subchondral fragmentation increased with no signs of active synovitis. Right heel MRI at the same time was remarkable for increase of fracture line and also slight bone oedema decrease with no signs of active synovitis.



Haemoglobin was slightly decreased (11,7 g/dl), ESR was elevated up to 84 mm/h. Blood sugar was slightly elevated up to 6.7 mmol/l though HA1c was 5.6. BUN and calcium were normal. The patient had normal BMI and showed no signs of rheumatoid arthritis activity. She was recommended to start teriparatide in the standard dose daily and 1000 mg of calcium and 2000 IU of vitamin D. In a month her pain totally disappeared, she continued using crutches to let fractures heal. 6 months later MRI showed the same picture. In July 2023 the patient was diagnosed B-cell lymphoma and treated with R-CHOP mini. Haematologist didn't insist on stopping teriparatide. In October 2023 the patient experienced a severe fall on her side but didn't break any bone. In December 2023 her PET-CT showed signs of fractures consolidation.

P248
CASE PRESENTATION OF A PATIENT WITH POST COVID ARTHRITIS

A. Todorovic[1], D. Draskovic-Radojkovic[2], G. Tulic[3]

[1]Medigroup,General Hospital, [2]Naya Medic, [3]Unversity Clinic Center of Serbia-Clinic of Orthopaedic Surgery and Traumatology, Belgrade, Serbia

Reactive arthritis can occur after various infections, even if joint pain was not initial symptoms. Arthritis that develops after COVID-19 may be the result of long COVID, or it may be a temporary side effect of the COVID-19 vaccine. Patients reported new-onset fatigue, myalgia, arthralgia, arthritis, muscle weakness, etc. According to a 2021 study Trusted Source, post-COVID-19 arthritis may occur as a result of inflammation, which is part of the body's natural immune response. The symptoms of reactive arthritis include inflammation, swelling, and pain in the joints.

Casereport: We present a case of a 25 year patient, soccer player, who was hospitalized on January 13, 2023, Rheumatology Clinic KCS with severe pain in the groin, tingling in the upper legs and swelling of the right knee and pain in the right ankle joint for the past 3 days. The complaints suddenly arise and led to the inability to walk. The patient stated that he had been suffering from COVID for several months before the symptoms appeared, he was on antibiotic therapy for 3 weeks. Examination: limited movements in both hips, arthritis of the right knee, contracture of 10°, painful of the ankle joint, positive Menels sign right, no arthritis of the other joints. Blood analyses: IgG AB for spike protein—1484 AU/ml, CRP—104, /l, HLAB27 positive peripher SpA. Echosonographic of joints: an anechoic effusion, 60 ml of clear synovial fluid. MRI: no signs of inflammation of the SI joints, synovitis of the left hip. Therapy was prescribed: pronison tbl 20 mg, sulafasalizin 2 × 2 g/d. Result no reduction in pain. Next therapy: high doses of sodium ascorbate, EGCG and glutathione intravenously twice weekly.

Result: After 6 weeks of therapy all pain was gone, he could walk normally and after 3 months he started to play soccer again.

Conclusion: This case illustrates difficulties in standard therapy of reactive arthritis after post-COVID and that antioxidative therapy could help to enhance immune answer due to higher oxidative stress in professional sportiest.

P249
FACTORS AFFECTING PATIENT ACCESS AND ENGAGEMENT WITH SURGICAL CARE SERVICES FOR HIP FRACTURE IN THE GAMBIA: AN ETHNOGRAPHIC STUDY USING A SOCIAL-ECOLOGICAL MODEL

A. Touray[1], J. Badjie[1], S. Drew[2], R. Chingono[3], C. Zinyemba[3], R. Gooberman-Hill[2], L. Gregson[2], A. Ward[4], K. Marena[5]

[1]Medical Research Council The Gambia @London School Hygiene and Tropical Medicine, Banjul, Gambia, [2]Musculoskeletal Research Unit, Translational Health Sciences, Bristol Medical School, Univ. of Bristol, London, UK, [3]The Health Research Unit Zimbabwe, Biomedical Research and Training Institute, Harare, Zimbabwe, [4]MRC Lifecourse Epidemiology, Human Development and Health, Univ. of Southampton, London, UK, [5]Orthopaedic unit, Edward Francis Small Teaching Hospital, Banjul, The Gambia

Objective: To investigate the delivery of hip fracture care across rural and urban settings in The Gambia, focusing on patient pathways from injury to access and utilisation of healthcare and traditional bone setter services.

Methods: An ethnographic approach was used to collect in-depth data through semistructured face-to-face interviews and participant observations over a period of 29 months between March 2021 and August 2023. A total of 77 purposively sampled participants were recruited from five study sites, comprising 40 hip fracture patients and 37 carers who were all family members of the patients. Data were analysed inductively using the framework method, and a socio-ecological model guided analysis.

Results: Participants were aged 23–100 y, most (n = 27; 77%) patients were female. The hip fracture care pathway was complex due to medical pluralism. Multiple factors influenced patients' access and engagement with surgical care, encapsulated through four themes: individual patient characteristics (e.g., age of patients) interpersonal relationships (e.g., family influence) institutional factors (availability of surgical equipment), and community factors (e.g., traditional bone setter patronage). The most common barriers to accessing surgical care were the strong belief in traditional bone setters and the inability

of patients to afford surgical fees and implants costing 180–1120 USD.

Conclusion: Patients are challenged during their care-seeking journey to navigate a complex pathway of care. In The Gambia, to improve access to, and engagement with surgical care for hip fracture patients, greater awareness of traditional bone setter practice and its influence on successful hip fracture management, is needed. The costs of surgical fees and implants are more than the annual salary of many Gambians. Health policy reforms that focus on enabling patients, who cannot afford surgical treatment, to access government hospital care. Is much needed.

P250
PAIN SYNDROME AND BONE MINERAL DENSITY IN ADULT PATIENTS WITH OSTEOGENESIS IMPERFECTA FROM THE REPUBLIC OF BASHKORTOSTAN

D. Valeeva[1], A. Tyurin[1], R. Khusainova[2]

[1]Internal Medicine Dept., Bashkir State Medical Univ., Ufa, [2]Medical Genetics Dept., Bashkir State Medical Univ., Endocrinology Research Centre, Moscow, Russia

Objective: Osteogenesis imperfecta (OI, Q78.0) is an inherited connective tissue disorder characterized by bone fragility under minimal loading. The characteristics of the bone system of adult patients with OI are of interest, which served as the purpose of our study.

Methods: We examined 64 patients with OI from the Republic of Bashkortostan (age 24.75 ± 5.31 y), the control group—40 healthy individuals of comparable sex and age. We evaluated the pain syndrome by visual analog scale (VAS), and 12 patients with OI had bone densitometry on Lunar Prology device.

Results: Blue sclerae occurred in 45 patients (70.3%), the number of fractures ranged from 3–50 (mean 13.11 ± 10.85). The mean BMD was 1.045 ± 0.208 g/cm^3, with a Z-score of − 0.375 ± 1.43. Back pain was reported by 67% of patients and joint pain by 92%. In the control group, the mean age was 22.96 ± 0.76 y. Fractures were rare and associated with significant external impacts. Back pain was noted by 63% of the subjects, joint pain—47%. The average level of BMD was 1.159 ± 0.082 g/cm^3, Z-criterion was 0.97 ± 0.606. The comparative analysis of the examined parameters revealed statistically significant differences in the level of BMD and Z-criterion ($t = 2.85$; $p = 0.0067$ and $t = 4.34$; $p = 0.0001$, respectively). The frequency of back pain syndrome was comparable in both studied groups, joint pain was statistically more frequently reported by patients with OI ($\chi^2 = 5.54$; $p = 0.019$).

Conclusion: Adult patients with OI are characterized not only by a reduced level of bone density, but also by the presence of joint pain without association with recent fractures.

P251
SPECIFICS OF HEPATITIS B VIRUS SEROLOGIC MARKER TESTING IN PATIENTS WITH RHEUMATOID ARTHRITIS

V. A. Aleksandrov[1], L. N. Shilova[2], E. A. Zagorodneva[3], I. Y. Alekhina[4], A. V. Aleksandrov[1]

[1]Volgograd State Medical Univ., Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky, Volgograd, [2]Volgograd State Medical Univ., Dept. of Hospital Therapy, Volgograd, [3]Volgograd State Medical Univ., Dept. of Laboratory Diagnostics, Volgograd, [4]Stavropol State Medical Univ., Dept. of Hospital Therapy, Stavropol, Russia

Objective: Most antirheumatic drugs have an inhibitory effect on the immune system. So one of the complications of disease-modifying antirheumatic drugs (DMARDs) may be the reactivation of hepatitis B virus (HBV) replication in rheumatoid arthritis (RA) patients. We aimed to evaluate the extent of testing for HBV serologic markers in RA patients before DMARD treatment.

Methods: Clinical and laboratory examination of 146 patients with RA aged 24–62 y with negative results for HBV surface antigen (HBsAg-) detection was performed. All patients were screened for antibodies to HBV nuclear antigen (anti-HBcIgG) and antibodies to HBsAg (anti-HBs). 73.3% of patients were taking methotrexate, 52.7% were taking corticosteroids, and 11% were taking genetically engineered biological drugs.

Results: 29 patients were positive for anti-HBs and 13 RA patients were positive for anti-HBcIgG. In 9% of patients, baseline serologic tests indicated prior hepatitis B infection (HBsAg-, anti-HBs+/anti-HBcIgG+, n = 11; HBsAg-, anti-HBs-/anti-HBcIgG+, n = 2). According to clinical guidelines, patients previously exposed to HBV should be monitored for HBV antigens during DMARD treatment. Preliminary hepatitis B virus DNA (HBV DNA) detection by PCR was performed in only 15 (10%) patients with RA, with the vast majority of patients seropositive for anti-HBs+ only and one patient anti-HBc+. Patients with RA with latent HBV infection or anti-HBc-positive patients may experience HBV reactivation during DMARD treatment; more attention should be paid to detecting not only HBsAg and anti-HBs but also anti-HBc.

Conclusion: RA patients seropositive for anti-HBc need additional screening detection of hepatitis B virus DNA as well as regular testing for HBV DNA by PCR during DMARD treatment.

P252
COMORBIDITY AND VITAMIN D STATUS IN PATIENTS WITH RHEUMATOID ARTHRITIS

A. V. Rudenka[1], A. E. Buglova[1], T. D. Tiabut[1], G. A. Babak[2], K. A. Laurukevich[3], Y. V. Muryna[4]

[1]Belarusian State Medical Univ., Minsk, [2]Clinical Hospital #1, Minsk, [3]Brest Regional Clinical Hospital, Brest, [4]Minsk Clinical Consulting and Diagnostic Center, Minsk, Belarus

Objective: Rheumatoid arthritis (RA) is autoimmune disease characterized by chronic joint inflammation. Given the proposed role for vitamin D as an immune regulator, hypovitaminosis D may be associated with immune-mediated inflammatory diseases including RA. The purpose of this study is to evaluate incidence of comorbidities, serum 25(OH)D and to analyze relationship between patients' RA characteristics and vitamin D status.

Methods: 156 patients with RA were enrolled: 139 women (mean age 60.1 ± 13.7 y) and 17 men (mean age 58.8 ± 13.4 y). Assessment of clinical status included swollen (SJC) and tender (TJC) joint counts, physician's (PhGA) and patient's global assessments of disease activity (PGA), pane assessment by visual analogue scale (VAS). Serum levels of rheumatoid factor (RF), C-reactive protein (CRP), total vitamin D (25(OH)D) were determined. RA disease activity was calculated using DAS28 (disease activity score), SDAI (Simplified Disease Activity Index) и CDAI (Clinical Disease Activity Index). Statistical analysis was carried out using the Statistica 10 program for Windows.

Results: The most frequent comorbidities were cardiovascular diseases (79 patients), endocrine (51 patients), and gastrointestinal diseases (58 patients). 4 patients underwent joints replacement. Osteoporosis was detected in 51 patients (39.9%), osteopenia in 39 (30.5%), 38 patients (29.6%) had normal BMD. 25 patients (16%) had history of fractures. Mean 25(OH)D levels were 25.2 ± 13.2 ng/ml. Normal vitamin D, insufficiency and deficiency were observed in 47

(30.3%), 45 (28.7%) and 64 (40.7%) patients. Low levels of vitamin D were associated with higher rates of RA activity according to the DAS28, SDAI and CDAI indices, as well as with greater number of painful joints. Patients with concomitant diseases (n 105) differed statistically significantly from patients without comorbidities (n 51) in age, age of onset of the disease, PhGA, PGA, CDAI, SJC and TJC. There were no statistically significant differences in 25(OH)D concentrations between groups.

Conclusion: Hypovitaminosis D was observed in majority of patients with RA and was associated with higher RA activity. Vitamin D supplementation should be administered in patients with RA for potential immunomodulatory purposes and for prevention and treatment of bone metabolic disorders.

P253
TUMOR-INDUCED HYPOPHOSPHATEMIC OSTEOMALACIA: CASE REPORT

A. V. Rudenka[1], T. L. Karonova[2], K. A. Yakovanko[2], E. V. Rudenka[1], A. E. Buglova[1]

[1]Belarusian State Medical Univ., Minsk, Belarus, [2]Almazov National Medical Research Centre, St. Petersburg, Russia

Tumour-induced osteomalacia (TIO) is a rare paraneoplastic disorder caused by tumours secreting FGF23. Clinical manifestations of TIO develop slowly and are represented by symptoms of osteomalacia including bone pain, fragility fractures, and muscle weakness.

Casereport: 35-year-old woman with neither significant past medical history nor a relevant family history was referred to our clinic with complains of severe weakness, bone pain, pain in the spine, hip joints, muscles tremors, limited movement, "unruly legs," limitation of movements in the hip joints, decrease in height by 8 cm since 2019. Considers herself sick since 2019, when bone pain first appeared, avascular necrosis of both femoral heads was diagnosed on MRI and autologous bone grafting was performed. The first metabolic disorders were also detected in 2019: calcium 2.11 mmol/l (normal value 2.15–2.55), phosphorus 0.44 mmol/l (normal value 0.87–1.45). Other laboratory findings PTH: 78 pg/ml; normal value 15–68.3, alkaline phosphatase 238 U/l; normal value 35–105, 25(OH)D 22.1 ng/ml, normal value 30–50 ng/ml. Chest CT: multiple rib fractures, fractures of acromion. Osteoscintigraphy: multiple foci of bone destruction. Malignancy, parathyroid pathology, myeloma were excluded. There was a progressive decrease in bone mineral density from 2019–2021 (Z score—2.6). Considering the persistent decrease in phosphorus (from 0.36 to 0.59) and calcium (from 2.04 to 2.2) in the serum, it was assumed that the patient might have TIO. Tubular reabsorption of phosphorus was normal (94.3%) and 99mTc bone scan did not reveal SSTR-positive receptor tissue. Multiple sites of hyperexpression of SSTR in bones with probable primary FGF23 tumor site were identified in the lateral condyle of the right tibia on 68 Ga-DOTATATE PET/CT scan. Laboratory testing showed increased FGF23 level (328 kRU/L, normal 26–110 kRU/L). Patient was treated with phosphorus, calcium and vitamin D supplements, bisphosphonates and non-steroidal anti- inflammatory drugs without significant improvement as new locus of aseptic necrosis of the right humeral head occurred. Investigation with targeted examination of the suspicious area is planned to determine further treatment strategy including burosumab administration.

Conclusion: TIO is an underdiagnosed disease, leading to disability and mortality, whose awareness should be increased among physicians for timely and proper management of patients.

P254
EFFECTS OF EXTRACORPOREAL SHOCK WAVE THERAPY ON PATIENTS WITH TRIGGER FINGER

R. Nartea[1], A. Voicu[2], S. A. Nica[3], B. I. Mitoiu[4]

[1] "Carol Davila" Univ. of Medicine and Pharmacy, National Institute of Rehabilitation, Physical Medicine and Balneoclimatology, [2]Emergency Clinical Hospital "Prof. Dr. Agrippa Ionescu", [3]"Carol Davila" Univ. of Medicine and Pharmacy, National Institute of Rehabilitation, Physical Medicine and Balneoclimatology, [4]"Carol Davila" Univ. of Medicine and Pharmacy, Emergency Clinical Hospital "Prof. Dr. Agrippa Ionescu", Bucharest, Romania

Objective: Tendons that flex the fingers and thumb are affected by the trigger finger, which usually causes a locking or catching sensation when bending and straightening the digits. A trigger finger can affect anyone, but it is more common in middle-aged active people with occupations that involve heavy lifting, repetitive motions, grasping, gripping, or applying force with the fingers and thumbs (farming or gardening, industrial work, and racket sports, so on) [1–3]. Also, people with particular medical problems, such as gout, diabetes, metabolic syndrome, rheumatoid arthritis, osteoarthritis, amyloidosis, and thyroid disease have an increased risk of developing trigger finger [1–4]. We conducted a study that aims to investigate the effectiveness, safety, and potential benefit of using extracorporeal shockwave therapy (ESWT) as an alternative option for the treatment of trigger finger.

Methods: Sixteen patients, who were 2nd grade according to Quinnel classification and diagnosed with trigger finger, were included in this prospective cohort clinical study. Sixteen patients with trigger fingers were applied to 10 sessions, twice a week, for 3 weeks of rESWT (2000 impulses, 2.5 bars, 10–15 Hz). Pain scores (Numeric Pain Rating Scale), general functional capacity (Quick-DASH), range of motion, grip strength with Jamar Dynamometer, and pinch strength were evaluated before treatment, after treatment, and 3 months after the treatment.

Results: Pinch strength measurements using a dynamometer show a progressive improvement in pinch strength over time. Average pinch strength: 3.6 units represent the baseline pinch strength in the initial moment. After 3 weeks of intervention, there is a noticeable increase in average pinch strength of 4.5 compared to the initial moment. A pinch strength value of 5.7 indicates a significant enhancement in pinch strength compared to both the initial and second moments. Overall, the increasing trend in average pinch strength from the initial moment to the third moment suggests a positive response to the ESWT treatment received.

Conclusion: The results indicate that individuals experienced a progressive improvement (p-value 0.00022) in their pinch grip strength over the three-time points.

P255
REHABILITATION TREATMENT IN A PATIENT WITH FRACTURE OF THE LEFT HUMERAL DIAPHYSIS WITH LEFT RADIAL NERVE PARALYSIS, TREATED ORTHOPEDICALLY AND SURGICALLY: CASE PRESENTATION

D.-M. Dimulescu[1], B.-I. Mitoiu[2], A. Voicu[3], G. Chiriţi[1]

[1]Univ. of Medicine and Pharmacy "Carol Davila", National Institute of Rehabilitation Physical Medicine and Balneoclimatology, [2]Univ. of Medicine and Pharmacy "Carol Davila", Emergency Clinical Hospital "Agrippa Ionescu", [3]Emergency Clinical Hospital "Agrippa Ionescu", Bucharest, Romania

To highlight the role of a complex physical-kinetic treatment, applied to a patient with a spiroid fracture of the middle third of the left humeral diaphysis, initially treated orthopedically, after 2 weeks of metal osteosynthesis (screw plate), with paralysis of the left radial nerve.
Casereport: We present the case of a 63-year-old patient presented for: mixed pain of the left arm, referred to the left shoulder and elbow, marked functional impotence on all axes of motion, at the elbow joint, respectively left wrist-hand complex, predominantly on extension and supination. From the pathological history we note: the patient suffered, following a fall from her own height, a spiroid fracture of the middle third of the left humeral diaphysis, immobilized in the first phase, the patient refused surgery, after 2 weeks, due to the accentuated algic syndrome, metal osteosynthesis (screw plate) was performed—June 2023, followed by paralysis of the left radial nerve. Physical-kinetic treatment was instituted, which included: Curapuls on the left arm, electrostimulation with exponential currents on the extensor and supinator muscles of the forearm and left wrist-hand complex, ultrasound, laser therapy with analgesic and myorelaxant effects, interferential currents on the distal of the left upper limb. The physiotherapy program included: analytical movements, passive mobilizations, passive-active mobilizations of the left upper limb, followed by ergotherapy exercises. The patient underwent repeated inpatient and outpatient treatments, with improvement of the algic syndrome, without significant improvement of active mobility on extension and supination. Repeat electromyography was recommended and it was decided to ablate the osteosynthesis material 4 months after the operation (November 2023), after which the patient continued the ES and physiotherapy programme, in hospital, outpatient and at home. Following the applied physical-kinetic treatment, pain relief was obtained, with VAS score decrease from 9 points, at admission, to 6 points, at discharge, mobility improvement on extension and supination at the distal extremity of the left upper limb, muscle strength increase on the forearm extensors and of the wrist-hand complex.
Conclusion: The applied physical-kinetic program led to the improvement of the algo-dysfunctional syndrome at the level of the distal extremity of the left upper limb, increase of muscle strength at the level of the extensors and supinators of the forearm, wrist and left hand; the evolution was favorable also from the point of view of professional reinsertion, the patient being a seamstress and resuming her activity.

P256
RESULTS OF THE REHABILITATION PROGRAM FOR A PATIENT WITH COMPLEX REGIONAL PAIN SYNDROME IN THE HAND REGION

B. I. Mitoiu[1], A. Voicu[1], R. Nartea[2], G. Chiriti[2], D. M. Dimulescu[2]

[1]Emergency Clinical Hospital "Prof. Dr. Agrippa Ionescu", [2]National Institute of Rehabilitation, Physical Medicine and Balneoclimatology, Bucharest, Romania

To highlight the results of the rehabilitation program in case of a patient with complex regional pain syndrome type I post comminuted fracture in the right distal epiphysis radius.
Casereport: We present the case of a 54-year-old patient, right-hander, chef cook, BMI 26.3 kg/m^2, with Complex regional pain syndrome type I post comminuted fracture in the right distal epiphysis radius by falling down stairs, conservative treatment of fracture because the patient refused surgery, Osteoporosis in the lumbar spines, score T = − 3 at bone density test 05.2023, in treatment with bisphosphonates and alfacalcidol, major depressive syndrome after the death of the husband, treated 7 y ago, who is hospitalized in the rehabilitation department complaining of right wrist and hand pain, predominantly mechanical, of high intensity VAS 8/10, accompanied by paresthesia, finger II–V, associating pain at cervical and lumbar level, mechanical character, VAS 5/10, in the context of professional overload. Local examen reveals trophic and color changes in the skin of the fist-hand complex, active and passive limited range of motion in wrist and fingers joints, limited hand and fingers prehension, swelling and functional impotence at the same level. During the hospitalization the evolution was favorable, with significant improvement of pain syndrome, VAS 3/10 at the level of hand, and 1/10 at cervical and lumbar spine levels, and trophic skin changes was observed with modest improvement of mobility in the wrist joint and MCF II–V joint and increased muscle strength in the case of fingers pinch.
Conclusion: After an intensive rehabilitation program, pain decreased significantly and functional outcomes, such as active and passive range of motion and strength, revealed significantly better results compared to pretreatment but the whole dysfunctional picture of the patient are still issues to be treated in a long-term care program.

P257
CASE REPORT: MULTIDISCIPLINARY TEAM APPROACH IN CASE OF A PATIENT WITH RHEUMATOID ARTHRITIS MUTILANS

B. I. Mitoiu[1], A. Voicu[1], S. A. Nica[2], D. M. Dimulescu[2], G. Chiriti[2]

[1]Emergency Clinical Hospital "Prof. Dr. Agrippa Ionescu", [2]National Institute of Rehabilitation, Physical Medicine and Balneoclimatology, Bucharest, Romania

The importance of a multidisciplinary medical team in the case of a patient diagnosed with seropositive rheumatoid arthritis 40 years ago.
Casereport: We present the case of a patient, aged 60 y, with the following medical history: seropositive rheumatoid arthritis mutilans diagnosed at the age of 21, stage IV for which she underwent treatment, initially csDMARDs and after bDMARDs, last cure in June 2019, bilateral arthritis mutilans hands and feet, right spinal canal stenosis surgery in 2015 and 2019 by hemilaminectomy l3–l4–l5, spondylolisthesis l5-s1, bilateral coxarthrosis, bilateral gonarthrosis, osteopenia, iatrogenic Cushing syndrome, labile hypertension, chronic ischemic cardiomyopathy, dyslipidemia with hypercholesterolemia, hypothyroidism, right renal microlithiasis, bilateral inguinal hernia repair, major depressive syndrome, hospitalized accusing left low back pain that radiates to plantar level, progressively worsened in the last 2 weeks, VAS 10/10, chronic paresthesia in legs and feet, especially left one, hands and knees polyarthralgia, and functional incapacity for walking in pain context. Following the local examination, important changes are noted for all spine levels with reversal of physiological curvatures, and at the level of peripheral joints, leading to a high degree of disability. From functional point of view, the patient is able to walk assisted, on short distance using the zimmer frame, with difficulty, and on long distance using the wheelchair, requiring help to perform daily activities. During hospitalization, analgesic, myorelaxant, antidepressant,

gastroprotective treatments ware administered, without significant improvement of symptoms. The patient was transferred to the neurosurgery department where the surgical treatment of the left L4 disc herniation was performed with favorable evolution and symptomatology improvement, followed by a rehabilitation program in a specialized clinic.
Conclusion: Rheumatoid arthritis is an autoimmune disease with a strong negative impact on quality of life, especially from a functional point of view. However, cases of rheumatoid arthritis mutilans are increasingly rare due to early diagnosis and new treatment methods.

P258
REHABILITATION PROGRAM BENEFITS IN INCREASING THE QUALITY OF LIFE FOR PATIENTS WITH OSTEOPOROSIS ASSOCIATED WITH STROKE

B. I. Mitoiu[1], M. D. Alexe[1], A. Voicu[1], S. A. Nica[1]

[1]Univ. of Medicine and Pharmacy Carol Davila, Bucharest, Romania

Objective: To present the importance of rehabilitation procedures associated in the management plan for the patients that suffer from osteoporosis and stroke in order to increase their quality of life.
Methods: After reviewing the medical database in order to have an actualized and modern perspective of the impact of complex and personalized rehabilitation treatment for our patients with stroke and osteoporosis we can present the next most important aspects.
Results: Osteoporosis is a common bone disease characterized by fragility of the bones and requires a long term treatment. When osteoporosis coexist with other pathologies that also affect the skeleton and motor function the therapeutical management must be individualized and monitored frequently. Worldwide each year, 12.2 million people have a stoke, and among them around 5 million remain with different degrees of disabilities. After stroke, patients complain mostly of a decrease in motor and sensory level and also in visual and cognitive functions. In the first months after stroke they have a high risk of fall injuries and 37% of them have a least one episode of fall and all this leads to a diminished quality of life. Due to the lack of mobility and uncertainty in movement patients after a stroke episode tend to limit their physical activities and taking in consideration that more than 60% of them have over 70 years old it is mandatory to measure the bone density among all other clinical and paraclinical tests, in order to identify osteoporosis in due time.
Conclusion: Osteoporosis therapeutical management includes a healthy lifestyle, specific medication and not the last, the rehabilitation personalized treatment. Modern individualized rehabilitation should be focused on increasing bone and muscular strength. This nonpharmacological and noninvasive treatment consist in physical therapy procedures, nutrition counseling and occupational therapy. Most important in gaining bone and muscle strength it is the active part of rehabilitation which consist in personalizes exercises, using also vibration platforms, which can improve also the level of independence and the quality of life for our patients.

P259
ANALYSIS OF CHRONIC PAIN SYNDROME IN GERIATRIC PATIENTS

M. V. Tchikovskaya[1], D. G. Gubin[1], A. Y. Moshkina[1], Z. V. Kuimova[1], D. A. Elfimov[1]

[1]Federal State Budgetary Educational Institution of Higher Education "Tyumen State Medical University" of the Ministry of Healthcare of the Russian Federation, Tyumen, Russia

Objective: Chronic pain syndrome (CPS) is an important medical and social problem, since in elderly people persistent pain leads to an increased level of suffering, decreased cognitive functions and earlier mortality. An important goal of the state policy in the field of health protection is: to improve the health of the population by ensuring the availability of medical care by creating legal, economic and organizational conditions for the provision of medical services. The purpose of the study was to develop measures to improve the organization of medical care for geriatric patients with CPS in a polyclinic institution.
Methods: We analyzed 300 outpatient patient records in the department of medical and social assistance (MSA) of the Tyumen polyclinic. There were 3 groups of patients depending on their age: group I from 65–74 y (33.3%); group II 75–84 y (33.3%); group III 85 y and older (33.3%). The average age in: Group I is 69 years old; Group II is 80 years old; Group III is 91 years old.
Results: As part of the study of CPS localizations, it was revealed that: headaches (HA) are characteristic of patients of group I in 60% (n = 60) of cases, II in 63% (n = 63), III in 70% (n = 70); back pain (BP) occurred for patients of group I in 70% (n = 70) of cases, II in 72% (n = 72), III in 75% (n = 75); pain in large joints (PLJ) was in group I in 68% (n = 68) cases, II-th in 74% (n = 74), III-th in 82% (n = 82); pain in small joints (PSJ) were in patients of group I in 34% (n = 34) cases, II-th in 37% (n = 37), III in 42% (n = 42); arm pain (AP) of a non-articular nature occurred in patients of group I in 25% (n = 25) of cases, II in 30% (n = 30), III in 35% (n = 35); leg pain (LP) of a non-articular nature were in patients of group I in 46% (n = 46) cases, II in 51% (n = 51), III in 53% (n = 53); other localizations were characteristic of patients of group I in 3% (n = 3) cases, II-th in 4% (n = 4), III-th in 5% (n = 5). The types of pain had the following values: nociceptive pain in group I was in 65% (n = 65) of cases, II in 67% (n = 67), III in 69% (n = 69); neuropathic pain of group I in 20% (n = 20) of cases, II in 22% (n = 22), III in 24% (n = 24); nociplastic pain in group I in 15% (n = 15) of cases, II in 11% (n = 11), the III-th in 7% (n = 7). Hypesthesia to touch was in patients of group I in 11% (n = 11) of cases, II in 15% (n = 15), III in 17% (n = 17). Hypesthesia to needle pricking occurred in elderly people from group I in 10% (n = 10) of cases, II in 14% (n = 14), III in 15% (n = 15). The appearance or intensification of pain when running a finger over the skin was observed among patients of group I in 10% (n = 10) of cases, II in 11% (n = 11), III in 12% (n = 12). The frequency of pain syndrome was: daily in group I in 35% (n = 35) cases, II in 45% (n = 45), III in 48% (n = 48); several times a week in group I in 34% (n = 34) cases, II-th in 31% (n = 31), III-th in 28% (n = 28); 1 time a week and less often in the I-th group in 17% (n = 17) cases, II-th in 13% (n = 13), III-th in 10% (n = 10); 1 time per month and less often in the I-th group in 14% (n = 14) of cases, II-th in 11% (n = 11), III-th in 14% (n = 14). Analgesics were taken in group I in 68% (n = 68) of cases, II in 75% (n = 75), III in 77% (n = 77). Restrictions in daily life due to pain were experienced in group I in 57% (n = 57) of cases, II in 72% (n = 72), III in 80% (n = 80). In women, chronic pain was detected more often than in men (90 vs. 80%).
Conclusion: The importance of the staff of the MSA department has an important place in the rehabilitation of geriatric patients with CPS: conducting health schools, regular assessment of pain syndrome on scales, the use of auxiliary means for pain relief and patient adaptation. The older a person gets, the higher the frequency and intensity of the pain syndrome, but the symptoms of CPS could reduce the intake of analgesics. The low effectiveness of analgesics may be due to neuropathic and nociplastic mechanisms of pain chronization. HA and BP had the highest localization frequency. Patients observed in the department of geriatric MSA often (99%) have CPS. Patients are provided with free medicines, means of care, technical means of rehabilitation.

ULTRASOUND DUPLEX VASCULAR SCANNING IN CHILDREN WITH LEG LENGTH DISCREPANCY ASSOCIATED WITH CONGENITAL VASCULAR MALFORMATIONS

A. Zyma[1], R. Viderko[1], Y. Guk[1], L. Chernuha[2], A. Cheverda[1], T. Kincha-Policschuk[1], J. E. Herzenberg[3], D. G. Steawart[4], Y. Demyan[5], S. Martsyniak[1], O. Skuratov[1]

[1]SI "The Institute of Traumatology and Orthopedics" by NAMS of Ukraine, Kyiv, Ukraine, [2]National Scientific Center of Surgery and Transplantology named after O.O. Shalimova National Academy of Sciences of Ukraine, Kyiv, Ukraine, [3]International Center for Limb Lengthening, Baltimore, USA, [4]Children's Bone And Spine Surgery, Las Vegas, USA, [5]Transcarpathian Regional Children's Hospital, Mukacevo, Ukraine

Objective: The influence of the regional blood flow disturbance on the formation of the limb length discrepancy (LLD) remains insufficiently studied in patient with CVM. We aimed to investigate changes in regional blood flow based on color duplex angioscanning (CDA) of arteries in the lower extremities and to establish their association with LLD in patients with CVM.
Methods: The study included 36 patients with CVM at two hospitals. The patients were divided according to the working classification scheme of the CVM "VASC + T": arteriovenous (AVM)—23, venous—7, capillary—4, lymphatic—2. CDA of the arteries, veins, capillaries and lymphatics of the lower extremities and soft tissues of the knee joint was performed; blood flow velocity and pulsatility index (Pi) were evaluated.
Results: LLD was diagnosed in 26 (72.2%) patients, further broken down into overgrowth of the affected limb in 21 (58.3%), and undergrowth in 5 (13.8%) patients. In patients with diffuse form of AVM, overgrowth of the affected limb was 2.76 ± 1.54 cm, with similar amounts of LLD in the femur—1.13 ± 0.55 cm; and in the tibia—1.62 ± 1.2 cm. ($p = 0.192$). In the case of diffuse form AVM, increase blood flow velocity of the posterior tibial artery, decrease in the Pi of the popliteal and posterior tibial arteries of the affected limb was found ($p = 0.05$). An increase in the total overgrowth of the affected limb with an increase blood flow velocity on the superficial femoral artery was established, as well as an increase in the elongation of the affected limb, with a decrease in Pi on the superficial femoral, popliteal and posterior tibial arteries ($p = 0.05$).
Conclusion: In patients with the diffuse form of AVM, there was a statistically significant increased blood flow velocity in the posterior tibial artery, and a decrease in the peripheral resistance (Pi) of the popliteal and posterior tibial arteries. Overgrowth of the affected limb with increase blood flow velocity on the superficial femoral artery and with decreased Pi in the superficial femoral, popliteal and posterior tibial arteries suggests a relationship between changes in regional blood circulation and LLD.

P261
IMPORTANCE OF CORRELATION BETWEEN SARCOPENIA, NUTRITIONAL STATUS AND BONE MINERAL DENSITY

A.-D. Nedelcu[1], L.-E. Stanciu[2], I. Abdula[1], A.-B. Uzun[1], D. Oprea[2], M.-G. Iliescu[3]

[1]Hospital Rehabilitation Unit, Balneal Sanatorium of Techirghiol, Romania, Ovidius Univ. Faculty of Medicine Doctoral School, [2]Hospital Rehabilitation Unit, Balneal Sanatorium of Techirghiol, Romania. Dept. of Medical Rehabilitation, Faculty of Medicine, Ovidius Univ. of Constanta, [3]Hospital Rehabilitation Unit, Balneal Sanatorium of Techirghiol, Romania, Ovidius Univ. Faculty of Medicine Doctoral School. Dept. of Medical Rehabilitation, Faculty of Medicine, Ovidius Univ. of Constanta, Constanta, Romania

Objective: Sarcopenia can accentuate the vulnerability of the musculoskeletal system, having significant consequences on muscle and adipose tissue and involving important dysfunctions, especially in the context of association with decreased BMD.
Methods: The study carried out over 4 months (January–April 2023) included 200 patients admitted to The Balneal and Rehabilitation Sanatorium Techirghiol, evaluated by standard methods for diagnosing sarcopenia. In confirmed cases, the individuals' BMI, bone density scanning (DXA), and fracture risk (FRAX) were evaluated, and the data underwent statistical analysis.
Results: Among the 200 patients, the diagnosis of sarcopenia was confirmed in 85 patients, and 42% of them presented, by BMI calculation, sarcopenic obesity. The DXA testing performed on the 85 patients with sarcopenia, identified that 14% of the patients had osteoporosis, and 25% of them associated sarcopenic obesity. Depending on gender, 60% of women and 40% of men had sarcopenia. Sarcopenic obesity is present in 20% of women and 55% of men, and all patients with osteoporosis are female. Calculation of the FRAX score indicates that 58% of patients with osteoporosis have an increased risk of fracture. The obtained results are consistent with literature studies. The incidence of sarcopenia is increased. Women are more prone to osteoporosis and men to sarcopenic obesity. Muscle tone disorders are associated with decreased BMD. Adipose tissue confers protection on BMD. Calculating the FRAX score is important, considering the functional consequences determined by the fracture that may occur in these patients, requiring specific therapeutic measures.
Conclusion: A comprehensive assessment of the osteoarticular and muscle conditions in patients with sarcopenia is essential, considering the coexistence between muscle tissue decrease, adipose tissue excess, and the change in BMD that occurs with aging.

P262
CHALLENGES IN DIAGNOSIS: UNUSUAL MANIFESTATIONS OF SYSTEMIC SCLEROSIS—A CASE STUDY

A.-E. Minea[1], M. Minea[2], M.-L. Groşeanu[3]

[1]Carol Davila Univ. of Medicine and Pharmacy, Bucharest, [2]Ovidius Univ. Faculty of Medicine Doctoral School, Hospital Rehabilitation Unit, Balneal Sanatorium of Techirghiol, Constanţa, [3]Saint Mary Clinical Hospital. Carol Davila Univ. of Medicine and Pharmacy, Bucharest, Romania

Systemic sclerosis (SS) is a rare disease and the major key in the treatment is early diagnosis. We present a case of a 43-year-old male with acute and atypical SS onset with incomplete Raynaud and polyarticular involvement.
Casereport: The patient admitted in June 2022 to the hospital accused inflammatory pain and swelling of small joints of hands, knees, ankles, which started 2 months prior, when he suffered from a left superior lobe pneumonia. He also described paraesthesia in the hands if exposed to cold and persistent sub-febrility. From the medical history we specify: hypertension, dyslipidaemia, recurrent occurrences of pneumonia, bilateral lung nodules and hilar adenopathy which first raised suspicion of Sarcoidosis and scapulo-humeral, sternoclavicular and vertebral bone condensations suggestive for osteopoikilosis. The clinical exam underlined pain in wrists' (RCC) palpation, reduced elasticity of the fingers' skin on both hands and the left palm, discrete "puffy fingers", painful swelling in both RCC, left proximal interphalangeal (PIP) III, right PIP IV, metacarpophalangeal (MCP) III, MCP IV joints and in both ankles,

and positive patellar tap bilaterally. The investigations showed inflammatory syndrome (CRP = 12.76 mg/dl), negative anti CCP antibodies and anti SAFL anti-bodies profile, normal levels of LDH, CPK, but the extended ANA profile indicated positive anti SCL 70 antibodies, > 200 UI/ml, with negative anti-centromere, anti-dcDNA, anti-Sm anti-bodies, gamma globulins = 23%. The capillaroscopy showed nonspecific minor abnormalities. The patient was diagnosed with VEDOSS (very early diagnosis of SS), treatment with methotrexate (MTX) and prednisone was initiated, with regular monitoring. He had a positive evolution, with remitted knee arthritis after 12 weeks of MTX, thereby, prednisone was withdrawn in March 2023.

Conclusion: Our patient has a peculiar form of SS (puffy fingers, incomplete Raynaud, high levels of anti SCL 70 antibodies) with acute poli-articular onset. Still, considering the presence of anti-SCL antibodies associated with poor prognosis, close monitoring is recommended. Another particularity of the case is the association of osteopoikilosis, a rare inherited condition, this linkage of pathologies being atypical itself.

P263
DISCORDANCE BETWEEN AN INCIDENTAL FRACTURE AND DXA WITH SUPPRESSED BONE TURNOVER MARKERS AMID ALENDRONATE FOR OSTEOPOROSIS

A.-I. Trandafir[1], A.-M. Gheorghe[1], O.-C. Sima[1], A. Ghemigian[2], G. Voicu[3], E. Petrova[2]

[1]PhD Doctoral School, Carol Davila Univ. of Medicine and Pharmacy & C.I. Parhon National Institute of Endocrinology, [2]C.I. Parhon National Institute of Endocrinology & Dept. of Endocrinology, Carol Davila Univ. of Medicine and Pharmacy, [3]C.I. Parhon National Institute of Endocrinology, Bucharest, Romania

The first line of treatment for osteoporosis in postmenopausal women is frequently bisphosphonates. The decision is based on guidelines, local reimbursement protocols, side effects, efficacy, patients' compliance and adherence. (1–10) We aim to present a female patient undergoing treatment for osteoporosis with discordances between incidental fractures and DXA results.

Casereport: A 63-year-old female is admitted for osteoporosis evaluation. The personal medical history includes a multinodular goiter with euthyroidism, controlled arterial hypertension, dyslipidemia, and chronic venous insufficiency. She entered menopause at 50. 2 years prior weekly alendronate was started (lumbar DXA T-score of -2.6SD). Currently, thyroid function was still normal TSH = 1.18 μUI/mL (normal: 0.5–4.5), FT4 = 14.69 pmol/L (normal: 9–19), with negative thyroid antibodies. Bone turnover markers (BTM) are suppressed in terms of formation-osteocalcin = 5.55 ng/mL (normal: 15–46), alkaline phosphatase = 42 U/L (normal: 38–105), and P1NP = 20.39 ng/mL (normal: 20.25–76.31), and resorption-CrossLaps = 0.10 ng/mL (normal: 0.33–0.782) with normal PTH = 27.86 pg/mL (normal: 15–65), and total serum calcium = 9.63 mg/dL (normal: 8.4–10.3). DXA showed an increase of lumbar L1-4T-score = − 2.2 SD, Z-score = − 0.7 SD, femoral neck T-score = − 1.3 SD, Z-score = − 0.4 SD. Yet, an incidental vertebral L2 fracture was detected at plane X-ray. Despite recommendations to switch, she opted to continue with the same regime.

Conclusion: This case highlights the gap between T-score increase and suppressed BTM, on one hand, and an incidental fracture, on the other hand under medication. Moreover, the decision of therapy is mandatory to take into consideration the patient's preference and access to a certain drug.

AUTOIMMUNE THYROID DISEASE AND MENOPAUSAL OSTEOPOROSIS: DUAL ELEMENTS FOR A COMMON ENDOCRINE MANAGEMENT

A.-I. Trandafir[1], O.-C. Sima[1], A. Dumitrascu[2], A.-M. Gheorghe[1], E. Petrova[3]

[1]PhD Doctoral School, Carol Davila Univ. of Medicine and Pharmacy & C.I. Parhon National Institute of Endocrinology, [2]C.I. Parhon National Institute of Endocrinology, [3]C.I. Parhon National Institute of Endocrinology & Dept. of Endocrinology, Carol Davila Univ. of Medicine and Pharmacy, Bucharest, Romania

Despite some pathogenic traits that involve autoimmune mechanisms in primary osteoporosis (a topic that is still on open issue), levothyroxine (LT4) overtreatment for autoimmune thyroid disease (ATD)-related hypothyroidism might represent an additional fracture risk during menopause.[1–10] We aim to present such a case.

Casereport: This is a 49-year-old lady known with autoimmune hypothyroidism. She was first diagnosed with myxedema 2 y prior and started LT4 replacement. After 6 months since LT4 initiation, overtreatment was confirmed based on TSH = 0.03 μUI/mL (Normal: 0.5–4.5). Since she entered spontaneous menopause by the age of 42, DXA scan was done and confirmed osteoporosis: lumbar L1–4 BMD = 0.877 g/cm^2, T-score = − 2.5 SD, Z-score = − 1.6 SD; femoral neck BMD = 748 g/cm^2, T-score = − 2.1 SD, Z-score = − 1 SD. She also associated at that point a high bone turnover as reflected by serum P1NP = 89.3 ng/mL (Normal: 20.25–76.31), and CrossLaps = 0.719 ng/mL (Normal: 0.162–0.436). Opportunity window for hormone (estrogens) replacement therapy was considered out, thus anti-osteoporotic medication was recommended, which the patient refused and she continued with cholecalciferol 1000–2000 UI/d and a mildly reduced dose of LT4. Currently, thyroid function is normal: TSH = 1.69 μUI/mL and FT4 = 15.92 pmol/L (Normal: 9–19) under T4 therapy 100 μg/d. A mild vitamin D deficiency is revealed by 25-hydroxyvitaminD = 21.6 ng/mL (Normal > 30) with normal serum calcium and PTH, as well as still increased P1NP = 90.4 ng/mL, and CrossLaps = 0.556 ng/mL. BMD continued to decrease: L1–4 BMD = 0.805 g/cm^2, T-score = − 3.1 SD, Z-score = − 2.1 SD; total hip BMD = 0.726 g/cm^2, T-score = − 2.2 SD, Z-score = − 1.3 SD. Hence, oral twice monthly risedronate was offered in addition to 2000 IU/d cholecalciferol and LT4 replacement.

Conclusion: Overtreatment with LT4 for ATD represents a synchronous element to concur to bone loss in association with early menopause. Adherence to anti-osteoporosis medication and its early initiation might help the overall bone status.

P265
IMPACT OF COVID-19 PANDEMIC RESTRICTIONS: ONE STEP FORWARD IN TAKING THE DECISION OF BISPHOSPHATES DRUG HOLIDAY?

A.-I. Trandafir[1], O.-C. Sima[1], A. Dumitrascu[2], A.-M. Gheorghe[1], E. Petrova[3]

[1]PhD Doctoral School, Carol Davila Univ. of Medicine and Pharmacy & C.I. Parhon National Institute of Endocrinology, [2]C.I. Parhon National Institute of Endocrinology, [3]C.I. Parhon National Institute of Endocrinology & Dept. of Endocrinology, Carol Davila Univ. of Medicine and Pharmacy, Bucharest, Romania

Restrictions amid COVID-19 pandemic limited the access to periodic checkup in some instances or the patients voluntarily avoided medical evaluations for prior chronic conditions, including the subjects being under specific medication against osteoporosis.[1–10] We aim to introduce a female patient that stopped her therapy for osteoporosis under these specific circumstances.

Casereport: This is a 62-year-old woman who received monthly alendronate and oral vitamin D for 5 y; she started at the lowest T-score at lumbar spine of − 2.6 SD followed by a 3-y treatment gap amid COVID-19 pandemic. She associated chronic Hashimoto's thyroiditis with controlled hypothyroidism under daily levothyroxine replacement and hypercholesterolemia. She had spontaneous menopause at the age of 50. Her medical family history also included her mother with menopausal osteoporosis. The latest prepandemic assessment included central DXA: lumbar L1–4: BMD of 0.862 g/cm^2, T-score of − 2.6SD, Z-score of − 1.8SD; total hip BMD of 0.862 g/cm^2, T-score of − 1.3, Z-score of − 0.3SD. After 3-y drug holiday, she was reassessed and blood assays showed adequate thyroid hormone substitution with normal TSH of 3.17 µUI/mL (normal: 0.5–4.5) in association with a mild vitamin D insufficiency in terms of 25-hydroxyvitamin D of 26 ng/mL (normal > 30), normal total serum calcium (9.1 mg/dL, normal: 8.4–10.2), and PTH (31.72 pg/mL, normal: 15–65), and nonsuppressed bone turnover markers. No incidental fracture was detected at plane lumbar-thoracic profile X-ray. Lumbar BMD-DXA decreased at 0.833 g/cm^2, T-score of − 2.8SD, Z-score of − 1.9SD; but not total hip BMD of 0.862 g/cm^2, T-score of − 1.3, Z-score of − 0.2SD. It was decided to resume taking weekly alendronate and continue with vitamin D replacement (2000 UI/d), and similar levothyroxine doses, respectively.

Conclusion: Frequent monitoring of osteoporosis is essential, while establishing the adherence to medical recommendations is also mandatory, particularly when taken into consideration the potential impact of COVID-19 pandemic to regular assessments.

PITFALLS OF SEQUENTIAL THERAPY IN LONG TERM MENOPAUSAL OSTEOPOROSIS

A.-I. Trandafir[1], A.-M. Gheorghe[1], E. Petrova[2], O.-C. Sima[1], A. Dumitrascu[3]

[1]PhD Doctoral School, Carol Davila Univ. of Medicine and Pharmacy & C.I. Parhon National Institute of Endocrinology, [2]C.I. Parhon National Institute of Endocrinology & Dept. of Endocrinology, Carol Davila Univ. of Medicine and Pharmacy, [3]C.I. Parhon National Institute of Endocrinology, Bucharest, Romania

Long term osteoporosis requires a complicate sequence of therapy across menopausal life span and prior second- or even third line medication such as strontium ranelate (SR) might be found in one individual' medical history.[1–10] Our purpose is to introduce such case of complicated osteoporosis management.

Casereport: This is a 63-year-old female patient admitted for the assessment of thyroid and bone status. Her medical history consists of benign thyroid nodules, gastroesophageal reflux disease, vitamin D deficiency, and osteoporosis. She entered menopause at 50. More than a decade ago, she was treated with SR for 4 y. At first evaluation, DXA confirmed osteoporosis: L1–L4 BMD = 0.748 g/cm^2,T-score = − 3.6SD, Z-score = − 2.3SD, total hip BMD = 0.638 g/cm^2, T-score = − 3SD, Z-score = − 2SD with an improvement after 4 y to L1–4 BMD = 0.821 g/cm^2, T-score = − 3SD, Z-score = − 1.3SD, total hip BMD = 0.702 g/cm^2, T-score = − 2.4SD, Z-score = − 0.9 SD, but she suffered a double patellar fracture that was considered a fragility fracture. After stopping SR for a few years, she re-stated therapy with intravenous ibandronate every 3 months and achieved a mild suppression of bone formation marker osteocalcin = 14.96 ng/mL (normal:15–46), and resorption marker CrossLaps = 0.26 ng/mL (normal:0.33–0.782) with an increase of T-score to − 2.4SD at lumbar DXA after 1 y. Currently, thyroid function is normal with stationary ultrasound traits, as well as mineral metabolism, including PTH = 32.64 pg/mL (normal:15–65) and 25-hydroxyvitamin D. Bone turnover markers remained suppressed after another year of the same drug: osteocalcin = 12.94 ng/mL, P1NP = 15.39 ng/mL (normal:20.25–76.31), and CrossLaps = 0.18 ng/mL, but a decreased of BMD-DXA in terms of L1–L4 BMD = 0.866 g/cm^2, T-score = − 2.6SD, Z-score = − 0.8SD, total hip BMD = 0.7 g/cm^2, T-score = − 2.4SD, Z-score = − 0.8SD. A switch to yearly 5 mg zoledronate was done, despite not having an incidental vertebral fracture, in addition to vitamin D supplementation.

Conclusion: SR might not be a current first line option, but this may represent a part of an otherwise complicated picture of long time therapy for osteoporosis.

BILATERAL NODULAR ADRENOCORTICAL DISEASE AND DECISION MAKING FOR ANTIOSTEOPOROTIC MEDICATION

A.-I. Trandafir[1], E. Petrova[2], A.-M. Gheorghe[1], O.-C. Sima[1], A. Dumitrascu[3]

[1]PhD Doctoral School, Carol Davila Univ. of Medicine and Pharmacy & C.I. Parhon National Institute of Endocrinology, [2]C.I. Parhon National Institute of Endocrinology & Dept. of Endocrinology, Carol Davila Univ. of Medicine and Pharmacy, [3]C.I. Parhon National Institute of Endocrinology, Bucharest, Romania

One-third of apparently non-secreting adrenal tumors (NSAT) associate autonomous cortisol secretion (ACS) with negative bone impact. Whether bilateral adrenal involvement is more prone than unilateral disease for this issue is yet an open matter.[1–5] We aim to introduce a female with NSAT and osteoporosis including strategic decisions such as drug holiday (DH) and teriparatide (TPT) transition.

Casereport: This is an 83-year-old female who was admitted for an adrenal and bone evaluation. Her medical history includes menopause at 44 and osteoporosis since the age of 67. She was diagnosed with bilateral sporadic nodular adrenocortical disease (largest diameter of the right tumor = 2.73 cm, respectively, of 1.86 cm on the left) with inconsistent suppression of post-dexamethasone test-based morning cortisol (values between 1 and 5 μg/dL over the years). She was treated with alendronate for 6 y; DXA results with lowest values at lumbar spine: L1–4 BMD = 0.812 g/cm^2, T-score = − 2.9SD, Z-score = − 1SD. Following 1 y DH, she resumed alendronate for 2 y followed by 2-y TPT. TPT was started at DXA showing lumbar bone loss to BMD = 0.75 g/cm^2, T-score = − 3.5SD, Z-score = − 1.9SD; but not at femoral neck BMD = 0.735 g/cm^2, T-score = − 2.2SD, Z-score = − 0.3SD. After 2-y TPT, no incidental fracture was detected, bone turnover markers (BTM) were normal: osteocalcin = 28.7 ng/mL (Normal:15–46), CrossLaps = 0.278 ng/mL (Normal:0.33–0.782), as well as PTH = 24.09 pg/mL (Normal:15–65). DXA improved to: L1–4 BMD = 0.917 g/cm^2, T-score = − 2.1SD, Z-score = − 0.2SD; femoral neck BMD = 0.814 g/cm^2, T-score = − 1.6SD, Z-score = 0.5SD. She continued with IV ibandronate then self-decided to take a 1-y break followed by drug resumption. Currently, a normal phosphorus-calcium profile is confirmed, including formation BTMs: osteocalcin = 18.21 ng/mL, and P1NP = 25.71 ng/mL (Normal: 20.25–76.31), and suppressed resorption BTM CrossLaps = 0.28 ng/mL. While novel fractures were not identified, T-score remained decreased (but did not reach the best nadir) of − 2.8 (lumbar), and − 2.6 (femoral neck). Low TBS confirmed a degraded microarchitecture (1.098).

Conclusion: No genetic testing was feasible for NSAT, neither adrenal venous sampling; anyway, the patient did not take into consideration an adrenalectomy, while the adrenal imaging features remained stationary during bone surveillance and associated challenges.

P268
BONE MICROSTRUCTURE CASE STUDY: TRABECULAR BONE SCORE IN DIABETES-RELATED BONE FRAGILITY AMID MENOPAUSE

A.-I. Trandafir[1], D.-E. Barbulescu[2], C.-T. Visan[2], A.-M. Gheorghe[1], O.-C. Sima[1], E. Petrova[3]

[1]PhD Doctoral School, Carol Davila Univ. of Medicine and Pharmacy & C.I. Parhon National Institute of Endocrinology, [2]C.I. Parhon National Institute of Endocrinology, [3]C.I. Parhon National Institute of Endocrinology & Dept. of Endocrinology, Carol Davila Univ. of Medicine and Pharmacy, Bucharest, Romania

Type 2 diabetes mellitus (DM) has a major epidemiologic impact thus any complication that increases the disease burden should be taken into consideration very early such as bone fragility. DM impacts bone microarchitecture, as reflected by TBS, in addition to the bone loss resulting from menopausal state. [1–5] Our purpose is to introduce such a case.

Casereport: A 59-year-old lady was reassessed for bone health since 1 y prior she received an osteoporosis diagnosis [DXA showed lumbar (L1–4) BMD = 0.871 g/cm^2, T-score = − 2.5, Z-score = − 2.5, with a low TBS = 1.044; femoral neck BMD = 0.890 g/cm^2, T-score = − 1.1, Z-score = − 0.6]. Weekly oral alendronate was started. Moreover, she had a history of postsurgical hypothyroidism (for a benign condition), arterial hypertension, dyslipidemia, type 2 insulin-dependent DM, and mixed anxiety-depressive disorder. On current admission, uncontrolled hypothyroidism [TSH = 40.42 μUI/mL (normal:0.5–4.5), FT4 = 5.41 pmol/L (normal:9–19) under LT4 50 μg/d] and DM [fasting glycaemia = 198 mg/dL (normal:70–100), and glycated hemoglobin A1c = 7.8% (normal < 5.9)] are detected. Mineral metabolism is normal: total serum calcium = 10 mg/dL (normal:8.4–10.3), phosphorus = 2.94 mg/dL (normal:2.5–4.5), PTH = 22.76 pg/mL (normal:15–65), except for suppressed osteocalcin = 6 ng/mL (normal:15–46), and CrossLaps = 0.091 ng/mL (normal:0.33–0.782). BMD increased to L1–4 BMD = 0.904 g/cm^2, T-score = − 2.3, Z-score = − 2.2, and femoral neck BMD = 0.874 g/cm^2, T-score = − 1.2, Z-score = − 0.5. She continued with the same regime including 1000 UI/d cholecalciferol that allowed a normal 25-hydroxyvitamin D in addition to adjustment of LT4 and insulin dose.

Conclusion: Despite poor glycemic control, DXA-BMD and TBS results improved showing that specific anti-osteoporotic medication might act against menopause-related and DZ-associated components, as well. In this case, long-term medication for mixed anxiety-depressive disorder might become an additional fracture risk.

P269
BISPHOSPHONATES HOLIDAY: BETWEEN PATIENT'S COMPLIANCE AND REIMBURSEMENT PROTOCOLS

A.-I. Trandafir[1], C.-T. Visan[2], D.-E. Barbulescu[2], A.-M. Gheorghe[1], O.-C. Sima[1], E. Petrova[3]

[1]PhD Doctoral School, Carol Davila Univ. of Medicine and Pharmacy & C.I. Parhon National Institute of Endocrinology, [2]C.I. Parhon National Institute of Endocrinology, [3]C.I. Parhon National Institute of Endocrinology & Dept. of Endocrinology, Carol Davila Univ. of Medicine and Pharmacy, Bucharest, Romania

Bisphosphonates holiday (BPH) is recommended in low-risk osteoporosis or high-risk side effects to specific drugs against osteoporosis. Under certain circumstances a pseudo-holiday means that the patient was no longer compliant, neither the individual had access to prescription.[1–5] Our purpose is to introduce a female who underwent a total thyroidectomy due to a benign thyroid disease and has a long history of osteoporosis.

Casereport: A 79-year-old female is hospitalized for a thyroid and bone status evaluation. She associates hypothyroidism following total thyroidectomy for a benign multinodular goiter, chronic ischemic cardiomyopathy, and controlled arterial hypertension. She had spontaneous menopause at the age of 50. The bone assessment started 2 decades prior when she was identified with osteopenia and followed intermittent vitamin D supplementation; then, at 66, she started oral monthly 150 mg ibandronate for 2 y with a BMD improvement, hence, a BPH was recommended for 1 y and self-continued for another 2 y (calcium and vitamin D were intermittently administered) since the patient did not come to be assessed. A decision of resuming ibandronate for another year was done, and then switched to alendronate for 5 more years due to reimbursing protocol based access. An improvement of BMD-DXA was confirmed [(L1–L4)BMD = 1053 g/cm^2, T-score = − 1.1, Z-score = − 0.6; femoral neck BMD = 0.713 g/cm^2, T-score = − 2.3, Z-score = − 0.4] and, since the subject had no fragility fracture, BPH was decided once again. After 2 more years, BMD lumbar BMD decreased (0.959 g/cm^2, T-score = − 1.7, Z-score = − 0.1), while femoral neck BMD did not (0.806 g/cm^2, T-score = − 1.7, Z-score = − 0.3). The thyroid panel continued to be normal [TSH = 1.58 μUI/mL (normal:0.5–4.5)] under LT4 with normal mineral metabolism and adequate vitamin D levels in terms of 25-hydroxyvitamin D = 32.4 mg/dL. At this point, bone turnover markers(BTM) panel remained suppressed [osteocalcin = 9.55 ng/mL (normal:11–46), CrossLaps = 0.131 ng/mL (normal:0.33–0.782)], but, due to lumbar BMD trend, a decision of resuming the antiresorptive drug was done.

Conclusion: Discordances between BMD changes at different central DXA sites or between BMD decrease and BMTs' suppressed profile makes the decision of prolonging BPD more difficult. Due to long standing history of sequential treatment against osteoporosis, a personalized medicine remains the main clue of real-life clinical approach.

P270
NOT TAKING VITAMIN D IS THE MAIN REASON FOR ITS DEFICIENCY IN THE POPULATION (REVIEW OF HOSPITAL MATERIAL)

A.-M. Borissova[1], L. Trifonova[1], E. Mollova[1], J. Vlahov[1], R. Mekova.[1]

[1]Sofia Univ. St Kliment Ohridski, Sofia, Bulgaria

Objective: The level of vitamin D in the Bulgarian population depends on various risk factors and seasonal dynamics, but also on the traditions of regular intake of this vitamin. We aimed to investigate the relationship between vitamin D deficiency and the available risk factors, the role of the season and the regularity of vitamin D substitution.

Methods: 199 patients who were regularly admitted to the Clinic of Endocrinology, University Hospital Sofiamed were examined on a random basis. with the mandatory condition being to have a tested level of vitamin D [25(OH)D] using a standard assay in a central laboratory on the day of the sampling.

Results: 74.5% of the examined patients have a BMI > 25 kg/m^2. For the entire group, the average level of eGFR is 81.24 ml/min; eGFR < 60 ml/min had 15.6%, which are similar to the general population. With gastrointestinal resp. liver diseases are 43%, and 15% take antidepressants. The level of vitamin D in general for both seasons and separately for winter and summer was low: 23.49 ± 10.861 ng/ml, winter—19.68 ± 8.65 ng/ml, summer—27.04 ± 11.48 ng/ml, $p < 0.001$. Distribution of patients according to the level of vitamin D: Normal (≥ 30 ng/ml)—54 (27.1%); Insufficient (10–30 ng/ml)—125 (62.8%); Deficiency (< 10 ng/ml) – 20 (10.1%). Only 58 (29.1%) patients take vitamin D, the remaining 141 (70.9%) do not. The patients who do not take vitamin D (141, 70.9%) are divided into two groups—never took it—38 (27%) and did not take it for "months"—103 (73%). From the group of patients taking vitamin D (58, 29.1%)—11 (19%) take 1000 IU/d and 47 (81%) take 1000–4000 IU/day.

Conclusion: There are several risk factors that determine a low level of vitamin D. Seasonality also has an expected effect. The most important cause of vitamin D deficiency remains the lack of systemic substitution among the population, which is clearly reflected in the hospitalized patients—71% do not take and of them 27% have never taken vitamin D. The medical community faces a very important task—education and creating traditions in vitamin D substitution that will have important population health implications.

P271
INCIDENTAL TOXIC MULTINODULAR GOITRE DURING BISPHOSPHONATES DRUG HOLIDAY: INTERFERENCES WITH RESUMPTION OF ANTI-OSTEOPOROTIC REGIME

A.-M. Gheorghe[1], A.-I. Trandafir[1], A. Ghemigian[2], O.-C. Sima[1], G. Voicu[3], E. Petrova[2]

[1]PhD Doctoral School, Carol Davila Univ. of Medicine and Pharmacy & C.I. Parhon National Institute of Endocrinology, [2]C.I. Parhon National Institute of Endocrinology & Dept. of Endocrinology, Carol Davila Univ. of Medicine and Pharmacy, [3]C.I.Parhon National Institute of Endocrinology, Bucharest, Romania

Hyperthyroidism (even mild) may increase bone loss and complicate the outcome in patients on bisphosphonates drug holiday.[1–10] We aim to introduce such a case.

Casereport: A 70-year-old patient known with osteoporosis for prior 6 y, for which she had been treated with bisphosphonates for 3 y (alendronate for 1 y, respectively, 2 more years of oral ibandronate) followed by a 3-y drug holiday was admitted for suspected thyrotoxicosis. She entered menopause of 56. She associated controlled high blood pressure and continued with daily 1000 UI cholecalciferol for the last years. Initial DXA showed: lumbar L1–L4 BMD = 0.781 g/cm^2, T-score = − 3.2, Z-score = − 1.4, total hip BMD = 0.758 g/cm^2, T-score = − 2, Z-score = − 0.3. On current admission, subclinical hyperthyroidism is confirmed: TSH = 0.03 μUI/mL (Normal:0.5–4.5), freeT4 (thyroxine) = 17.8 pmol/L (Normal:9–19) with negative thyroid antibodies; thyroid ultrasound showed multinodular goiter with the largest nodule of 3.3 cm. Vitamin D deficiency was identified: 25-hydroxivitamin D = 9.83 ng/mL (Normal > 30) with normal (nonsuppressed) bone turnover markers: of resorption-CrossLaps = 0.549 ng/mL (Normal:0.33–0.78), and of formation osteocalcin = 23.46 ng/mL (Normal:15–46), and alkaline phosphatase = 64 U/L (40–150). Initial lumbar T-score (premedication) of − 3.2 improved at drug holiday initiation and currently remained so: DXA based lumbar L1–L4 BMD = 0.876 g/cm^2, T-score = − 2.5,

Z-score = − 0.6, total hip BMD = 0.732 g/cm^2, T-score = − 2.2, Z-score = − 0.5. No prevalent fracture was found on plane spine X-ray. A decision of starting anti-thyroid medication (thiamazole 10 mg/d) was associated with increased vitamin D replacement (2000 UI/d) and resumption of oral bisphosphonates due this thyroid-related risk factor.

Conclusion: Despite favourable evolution during drug holiday in terms of DXA and no incidental fracture (yet, with no suppression of bone turnover markers), resuming bisphosphonate treatment may be taken into consideration in selected patients with other risk factors such as subclinical hyperthyroidism.

P272
SINGLE VERTEBRAL FRACTURE IN A PATIENT WITH HISTORY OF LOCAL RADIATION TERAPY

A.-M. Gheorghe[1], A.-I. Trandafir[1], A. Dumitrascu[2], O.-C. Sima[1], E. Petrova[3]

[1]PhD Doctoral School, Carol Davila Univ. of Medicine and Pharmacy & C.I. Parhon National Institute of Endocrinology, [2]C.I. Parhon National Institute of Endocrinology, [3]C.I. Parhon National Institute of Endocrinology & Dept. of Endocrinology, Carol Davila Univ. of Medicine and Pharmacy, Bucharest, Romania

Ionizing radiation used during treatment of various types of cancers, including uterine carcinoma, may alter bone microarchitecture and, hence, increase the risk of fragility fractures.[1–10] We aim to introduce the case of a patient with osteoporosis and a history of radiation.

Casereport: A 70-year-old woman was admitted for bone status assessment due to intermittent non-specific bone pain for the last months. Her medical history included pelvic radiation therapy (cobalt therapy and brachytherapy) for uterine cancer 20 y prior (and menopause by the same age). A contrast computed tomography exam performed 5 y prior identified herniated L4–L5, and L5-S1 discs, and a vertebral fracture at lumbar L5 level. Central DXA showed osteopenia (the lowest T-score was at lumbar spine of 1.1SD). She did not continue investigations; neither started any drug against osteoporosis and followed intermittent vitamin D therapy. On current admission, bone turnover markers showed normal, as follows: resorption marker CrossLaps = 0.68 ng/mL (normal: 0.33–0.78), and formation marker osteocalcin = 20.29 ng/mL (normal: 15–46). Central DXA (GE Lunar Prodigy device) confirmed osteoporosis based on: L1–L4 BMD = 0.856 g/cm^2, T-score = − 2.6, Z-score = − 0.4, femoral neck BMD = 0.738 g/cm^2, T-score = − 2.2, Z-score = − 0.2. No other secondary cause of osteoporosis was identified, except for a mild vitamin D deficiency: 25-hydroxivitamin D = 28.5 ng/mL. Despite no incidental fracture was detected, and the patient remained on remission for her prior malignancy, oral monthly alendronate was recommended in addition to daily cholecalciferol 2000 UI/d, 3 months followed by 1000 UI/d.

Conclusion: Whether local bone effects in terms of single vertebral fracture are due to radiation therapy or this stands as solitary complication amid primary osteoporosis is difficult to be distinguished; yet, specific therapy against osteoporosis might help.

P273
PRIOR HISTORY OF GRAVES' DISEASE: IS THERE A CLUE FOR BONE FRAGILITY?

A.-M. Gheorghe[1], A. Dumitrascu[2], O.-C. Sima[1], A.-I. Trandafir[1], E. Petrova[3]

[1]PhD Doctoral School, Carol Davila Univ. of Medicine and Pharmacy & C.I. Parhon National Institute of Endocrinology, [2]C.I. Parhon National Institute of Endocrinology, [3]C.I. Parhon National Institute of Endocrinology & Dept. of Endocrinology, Carol Davila Univ. of Medicine and Pharmacy, Bucharest, Romania

Long term uncontrolled hyperthyroidism may lead to loss of cortical bone mass and probably sarcopenia in a selected subgroup of patients, particularly seniors. Adequate anti-thyroid treatment is essential for reducing fracture risk in these patients.[1–10] We aim to introduce a case of osteopenia in a patient with a long history of partially controlled Graves' disease and an incidental spontaneous vertebral fracture.

Casereport: A 65-year-old patient was diagnosed with Graves' disease 15 y prior; over the years, she was partially compliant to the recommendations and the condition' evolution highlighted several episodes of remission and relapse. She entered physiological menopause by the age of 50; her medical family history is irrelevant. Currently, she complains of nonspecific myalgia. The patient had been treated with methimazole, but stopped taking her medication one year prior to this presentation. Her thyroid evaluation showed normal spontaneous thyroid function: TSH = 0.9 μUI/mL (normal:0.5–4.5), freeT4 = 9.93 pmol/L (normal:9–19); thyroid ultrasound revealed micronodular hypoechoic pattern. She has positive TSH receptor antibodies (TRAb) = 2.97 UI/L (normal < 1.75), but also anti-thyroperoxidase antibodies (TPO) = 158 UI/mL (normal < 35). Bone turnover markers were mildly suppressed: CrossLaps = 0.209 ng/mL (0.33–0.78), osteocalcin = 13.69 ng/mL (15–46). DXA revealed osteopenia with lowest T-score at femoral neck: lumbar L1–L3 BMD of 1.364 g/cm^2, T-score = 1.7SD, Z-score = 3SD, femoral neck BMD of 0.826 g/cm^2, T-score = − 1.5SD, Z-score = − 0.2SD. An incidental mild lumbar L4 fracture was confirmed at screening X-ray. The patient received treatment with 2000 UI of vitamin D due to suboptimal levels [25-hydroxivitamin D = 27.5 ng/mL (normal ≥ 30)] for 3 months with myalgia improvement followed by a dose reduction and started oral bisphosphonates.

Conclusion: The combination of positive serum stimulating (TRAb) and blocking thyroid antibodies (TPO) might be a clue for episodes of spontaneous thyroid function normalization alternatively with thyrotoxicosis relapse that (if left untreated) might contribute to an

increased fracture risk. Muscle complains may accompany a thyroid dysfunction or hypovitaminosis D.

P274
BONE STATUS AFTER FOUR YEARS OF BIPHOSPHONATE DRUG HOLIDAY

A.-M. Gheorghe[1], A.-I. Trandafir[1], O.-C. Sima[1], A. Dumitrascu[2], E. Petrova[3]

[1]PhD Doctoral School, Carol Davila Univ. of Medicine and Pharmacy & C.I. Parhon National Institute of Endocrinology, [2]C.I. Parhon National Institute of Endocrinology, [3]C.I. Parhon National Institute of Endocrinology & Dept. of Endocrinology, Carol Davila Univ. of Medicine and Pharmacy, Bucharest, Romania

Bisphosphonates drug holiday (DH) is chosen to reduce risk of atypical fractures in selected cases. Assessing fracture risk during HD is important for taking the decision to resume treatment if needed. Sometimes this decision is a matter of individual management rather than general guideline.[1–9] We introduce a female with a 4-y DH.

Casereport: A 78-year-old lady was admitted for bone status assessment after 4 y of DH. Her medical history included total thyroidectomy for Graves' disease associated with a papillary thyroid carcinoma, and premature menopause at 38 (no replacement therapy). The patient had been treated with bisphosphonates for 7 y (risedronate for 3 y, IV ibandronate for 2 y, and alendronate for 2 y) with an increase of bone mass. Her DXA after 7 y showed: lumbar L1–L4 BMD = 0.977 g/cm^2, T-score = − 1.7, Z-score = 0.5, femoral neck BMD = 0.673 g/cm^2, T-score = − 1.6, Z-score = − 0.4. After 1-y DH, bone turnover markers (BTM) remained suppressed: CrossLaps = 0.22 ng/mL (normal:0.33–0.78), osteocalcin = 14 ng/mL (normal:15–46), while DXA showed similar results: 3% lumbar BMD loss (< LSC). She only returned for a checkup amid early post-pandemic months (after a total 4-y DH), BTM were still decreased: CrossLaps = 0.31 ng/mL, osteocalcin = 13.16 ng/mL. DXA remained stationary: L1–L4 BMD = 0.947 g/cm^2, T-score = − 2, Z-score = 0.4. Of note, she continued to have adequate 25-hydroxyvitamin D levels under supplementation, a mild TSH suppression therapy with oral thyroxine for her prior thyroid malignancy, while she had no fracture. A decision of prolonging DH was done with indication of 1-y reassessment.

Conclusion: No incidental fracture, suppressed BTM, and stationary DXA-BMD might be convincing elements for prolonged DH despite TSH suppression therapy and early menopause in a osteoporotic senior.

Hospital, [4]Thoracic Surgery Dept., "Dr. Carol Davila" Central Military Emergency Univ. Hospital & Thoracic Surgery II Discipline, Carol Davila Univ. of Medicine and Pharmacy, Bucharest, Romania

Papillary thyroid carcinoma increases the risk of osteoporosis, but it is unclear whether the effect is sole due to TSH-suppressive therapy. Even though hypothyroidism reduces bone turnover, there is insufficient data regarding a possible correlation with BMD and fracture risk.[1–5] We aim to introduce a case of osteoporosis in a patient with overt hypothyroidism caused by thyroidectomy for a differentiated thyroid carcinoma.

Casereport: A 57-year-old lady was admitted for a planned thyroid and bone evaluation. Her medical history included total thyroidectomy for differentiated thyroid carcinoma, vitamin D deficiency treated with 2000 UI daily for the past 3 y, and osteoporosis at central DXA (GE Lunar Prodigy device): lumbar L1–L4 BMD of 0.959 g/cm^2, T-score of − 2, Z-score of − 1.3, left femoral neck BMD of 0.664 g/cm^2, T-score of − 2.7, Z-score of − 1.7. She was not compliant to any anti-osteoporotic drug. On current admission, the thyroid panel showed insufficient treatment with levothyroxine 100 μg/d: TSH of 26.95 μUI/mL (normal: 0.5–4.5), freeT4 (thyroxine) of 8.73 pmol/L (normal: 9–19). Bone turnover markers showed reduced resorption and formation: CrossLaps of 0.32 ng/mL (normal: 0.33–0.78), respectively, osteocalcin of 15.9 ng/mL (normal: 15–46). Her 25-hydroxyvitamin D level was 43.7 ng/mL (normal: 30–100). DXA showed loss of bone mass: lumbar L1–L4 BMD of 0.962 g/cm^2, T-score of − 2, Z-score of − 1.1, left femoral neck BMD of 0.612 g/cm^2, T-score of − 3.1, Z-score of − 2. The patient received treatment with 5 mg annual zoledronate, and her levothyroxine dose was gradually increased with lifelong follow-up.

Conclusion: Whether thyroid carcinoma and associated management is an independent risk factor for osteoporosis and the influence of hypothyroidism on bone metabolism remain open issues.

P276
THALASSEMIC ENDOCRINE DISEASE: THALASSEMIA BONE DISEASE IN A PATIENT WITH MINOR BETA TYPE

A.-M. Gheorghe[1], A.-L. Ioan[2], A.-I. Trandafir[1], O.-C. Sima[1], E. Petrova[3]

[1]PhD Doctoral School, Carol Davila Univ. of Medicine and Pharmacy & C.I. Parhon National Institute of Endocrinology, [2]C.I. Parhon National Institute of Endocrinology, [3]C.I. Parhon National Institute of Endocrinology & Dept. of Endocrinology, Carol Davila Univ. of Medicine and Pharmacy, Bucharest, Romania

Thalassemic endocrine disease is challenging; a distinct subgroup with minor type might display similar traits with major thalassemia. In patients with beta thalassemia the development of osteoporosis is multifactorial and it includes vitamin D deficiency. In addition, poor compliance to treatment may worsen the outcome.[1–5] We aim to introduce a case of osteoporosis in a patient with minor thalassemia and persistent vitamin D deficiency.

Casereport: This is an 82-year-old female patient admitted for a bone status assessment. Her medical history included minor thalassemia and one year of glucocorticoid treatment for chronic obstructive pulmonary disease. She was known with osteoporosis and severe vitamin D deficiency (25-hydroxivitamin D of 7.32 ng/mL, normal: 30–100), with consequent secondary hyperparathyroidism (PTH of 65.39 pg/mL, normal: 15–65) for 4 y, but had abandoned alendronate and vitamin D treatment after first year. On admission, she had persistent vitamin D deficiency (25-hydroxivitamin D = 7.48 ng/mL, normal: 30–100), and secondary hyperparathyroidism (PTH of 67.62 pg/mL, normal: 15–65). DXA was inconclusive for the lumbar region due to multiple low-trauma vertebral compression fractures and showed hip osteopenia scores: total hip BMD of 0.746 g/cm^2, T-score of − 2.1, Z-score of − 0.4. Serum bone turnover markers showed reduced resorption: CrossLaps of 0.28 ng/mL (normal: 0.33–0.78) with normal bone formation markers such as osteocalcin of 19.40 ng/mL (normal: 15–46). The patient received treatment with vitamin D 2000 UI daily and alphacalcidol 1 μg daily. She refused any specific medication against osteoporosis.

Conclusion: Patient's adherence to anti-osteoporosis medication might be impaired by the multiple comorbidities and associated drugs. There is a need for further research focused on the impact of minor thalassemia on bone metabolism. Modern perspective stands for thalassemia bone disease typically involving the major type, but minor thalassemia might be taken into consideration in certain subgroups.

P277
OSTEOPENIA IN AN ELDERLY FEMALE WITH IRRITABLE BOWEL SYNDROME UNDER SULFASALAZINE TREATMENT

A.-M. Gheorghe[1], A.-L. Ioan[2], O.-C. Sima[1], A.-I. Trandafir[1], E. Petrova[3]

[1]PhD Doctoral School, Carol Davila Univ. of Medicine and Pharmacy & C.I. Parhon National Institute of Endocrinology, [2]C.I. Parhon National Institute of Endocrinology, [3]C.I. Parhon National Institute of Endocrinology & Dept. of Endocrinology, Carol Davila Univ. of Medicine and Pharmacy, Bucharest, Romania

Gastrointestinal diseases including irritable bowel syndrome (IBS) may impair bone metabolism due to chronic inflammation, malabsorption, and calcium and vitamin D deficiencies. However, sulfasalazine has been showed to increase bone formation. [1–5] We aim to introduce a case of osteopenia in a patient with IBS in treatment with sulfasalazine, associating autoimmune thyroiditis.

Casereport: An 83-year-old female patient was admitted for skeleton health evaluation. Her personal medical history included: IBS for which she had been treated with sulfasalazine for 5 y, and, also, autoimmune Hashimoto's thyroiditis with adequate levothyroxine substitution. On current admission, the thyroid panel under levothyroxine 75 μg/d revealed a TSH of 0.58 μUI/mL (normal: 0.5–4.5), with freeT4 (thyroxine)of 13.59 pmol/L (normal: 9–19), high thyroid peroxidase antibodies titter > 1000 UI/mL (normal: 0–5.61) and the cervical ultrasound identified multinodular goiter with hypoechoic pattern. The patient had normal serum levels of calcium of 9.7 mg/dL (normal: 8.5–10.2), phosphorus of 4.1 mg/dL (normal: 2.5–4.5) and parathormone of 25.67 pg/mL (normal: 15–65), with mild vitamin D insufficiency (25-hydroxivitamin D of 27.5 ng/mL, normal: 30–100). Bone turnover markers showed increased resorption: CrossLaps of 0.86 ng/mL (normal: 0.33–0.78), with normal formation in terms of serum osteocalcin of 35.9 ng/mL (normal: 15–46). DXA showed osteopenia with higher scores before starting sulfasalazine: lumbar L1–L4 BMD of 0.946 g/cm^2, T-score of − 1.9, Z-score of 0.1, femoral neck BMD of 0.712 g/cm^2, T-score of − 2.3, Z-score of 0.1. No vertebral fracture was detected at screening lumbar-thoracic X-ray. The patient continued with vitamin D 2000 UI/d and periodical checkups.

Conclusion: IBS and consequent malabsorption may be among the factors leading to bone loss; hence, in this case, the status quo of the bone health may be related to the therapy over the latest 5 years with sulfasalazine.

EFFICACY OF ANTIRESORTIVE TREATMENT IN OSTEOPOROTIC OLDER ADULTS: RESULTS OF A NESTED CASE–CONTROL STUDY

B. A. Cedeno-Veloz[1], E. Lopez[2], M. Gutiérrez-Valencia[2], L. Leache-Alegría[2], L. C. Saiz-Fernandez[2], A. M. Rodriguez-Garcia[1], R. Ramirez-Velez[3], M. Izquierdo[3], N. Martinez-Velilla[1]

[1]Geriatric Dept., Hospital Universitario de Navarra (HUN), [2]Unit of Innovation and Organization, Navarre Health Service, [3]Dept. of Health Sciences, Public Univ. of Navarra, Pamplona, Spain

Objective: Osteoporosis, often dubbed a "silent epidemic," poses serious health risks including disability, fractures, and increased mortality, particularly due to hip fractures. Despite extensive research and advancements in bone health assessments and treatments, the predictability of hip fracture risk and the effectiveness of treatments like antiresorptives remain unclear in older adults. These treatments, thought to enhance bone density, have not shown definitive advantages in reducing hip fracture risk in this population. Cohort studies offer insights but leave critical questions about the real-world effectiveness of these treatments in preventing hip fractures, especially in elderly women, unanswered.

Methods: This study, utilizing the Spanish primary care database BIFAP from January 1, 2010, and December 31, 2021; focused on women aged 75 or older with osteoporosis. Participants were followed until hip fracture (potential case), cancer diagnosis (excluding basal cell skin carcinoma), death from any cause, loss of follow-up, or the end of the study period. Exclusions included history of cancer (excluding basal cell skin cancer), Paget's disease, rheumatoid arthritis, polymyalgia rheumatica or ankylosing spondylitis, a history of hip fracture from high-impact trauma, and patients on oral corticosteroid treatment for more than 3 months. Exposure to antiresorptive drugs was the main focus, with users categorized based on timing since last prescription. Up to 10 controls was selected per case. Additional variables like prior fractures and medication history were considered. Statistical methods included logistic regression to compare fracture risks among different user groups, with adjustments for potential confounders and subgroup analyses based on fracture history and age.

Results: We compared cases (n = 2057) and controls (n = 19,257). The analysis was stratified into different user categories: Current Users (CU; patients exposed to antiresorptive on the index date or when $\leq$ 1 y has elapsed since the last prescription until the index date), Past Users (PU; when more than 3 y have elapsed since the last prescription until the index date), Recent Users (RU; when between 1 and 3 y have elapsed since the last prescription until the index date), and Never Users (NU; no time before the index date had received treatment with antiresorptive drugs) (Table 1).

Table 1. Association between exposure to antiresorptive and the risk of hip fracture

	Cases (n=2057), n (%)	Controls (n=19257), n (%)	OR (95%CI)	Adjusted OR (95%CI)
CU vs. PU+RU+NU				
Current users	301 (6.9%)	4039 (93.1%)	ref	ref
past users + recent user + never users	1756 (10.3%)	15236 (89.7%)	1.27 (1.11, 1.46)	1.35 (1.17, 1.55)
CU+RU+PU vs. NU				
Never users	1390 (9.2%)	13761 (90.8%)	ref	ref
Current user + recent user + past user	667 (10.8%)	5514 (89.2%)	1.14 (1.02, 1.27)	1.01 (0.90, 1.13)
CU vs. Others

Recent users	150 (14.9%)	857 (85.1%)	1.30 (1.07, 1.57)	1.12 (0.91, 1.37)
Past users	216 (25.9%)	618 (74.1%)	2.06 (1.70, 2.48)	1.91 (1.57, 2.33)
According interval between OP diagnosis and hip fracture				
<2 y n=11397				
Current users	66 (2.5%)	2594 (97.5%)	ref	ref
PU+RU+NU	328 (3.8%)	8409 (96.2%)	1.44 (1.07, 1.93)	1.48 (1.10, 2.00)
2-5 y n=7076				
Current users	126 (9.8%)	1154 (90.2%)	ref	ref
PU+RU+NU	713 (12.3%)	5083 (87.7%)	1.22 (0.98, 1.52)	1.34 (1.06, 1.69)
>5 y n=2859				
Current users	109 (27.3%)	291 (72.8%)	ref	ref
PU+RU+NU	715 (29.1%)	1744 (70.9%)	1.14 (0.86, 1.50)	1.13 (0.84, 1.51)

Abbreviations: CU: current user, NU: never user, PU: past user, RU: recent user

1. CU vs. PU + RU + NU: Current users showed a lower percentage of hip fractures compared to the combined group of past, recent, and never users. The adjusted odds ratio (OR) indicated a statistically significant increased risk in the PU + RU + NU group with OR 1.35 (1.17, 1.55).
2. CU + RU + PU vs. NU: When combining current, recent, and past users against never users, the latter group had a higher percentage of hip fractures. However, the adjusted OR suggested no significant difference in risk with OR 1.01 (0.90, 1.13).
3. CU vs. Others (RU, PU, NU): Current users had the lowest percentage of hip fractures among all groups. The adjusted ORs for recent, past, and never users progressively increased, indicating a higher risk compared to current users.
4. Analysis by exposure time: We also analyzed data based on the interval between osteoporosis diagnosis and hip fracture. The results varied with the time intervals (< 2 years, 2–5 y, > 5 y), showing different risk patterns among current users and the combined group of past, recent, and never users.

Conclusion: Current use of antiresorptive medications is associated with a reduced risk of hip fracture compared to past, recent, or never use. The risk varies with the duration since osteoporosis diagnosis, highlighting the importance of ongoing medication adherence for fracture prevention.

P279
EVALUATION OF PRECISION MEDICINE WITH BIOMARKERS IN FRACTURE RISK PREDICTION: PROTOCOL OF A COHORT STUDY

B. A. Cedeno-Veloz[1], A. M. Rodriguez-Garcia[1], S. Domínguez-Mendoza[1], M. Fernández-González[2], G. Gutierrez-García[3], J. Preciado-Goldaracena[4], F. Zambom-Ferrasi[2], N. Martinez-Velilla[1]

[1]Geriatric Dept., Hospital Universitario de Navarra (HUN), [2]Navarrabiomed, IdiSNA, Navarra Institute for Health Research, Pamplona, Navarra, [3]Navarrabiomed Biobank, Pamplona, Navarra, [4]Dept. of Pharmacology, Hospital Universitario de Navarra (HUN), Pamplona, Spain

Objective: Osteoporosis, a systemic skeletal condition characterized by reduced bone density and quality, leads to increased fragility and fracture risk. Current clinical guidelines focus on high fracture risk detection but face limitations in older adults. This study aims to bridge knowledge gaps by evaluating blood biomarkers related to osteoporosis' molecular mechanisms, proposing a patient-specific risk stratification tool for more precise treatment approaches, emphasizing the need for new biological markers in clinical contexts.

Methods: The study is designed as an observational cohort, focusing on patients referred to the geriatric unit at the University Hospital of Navarra. Recruitment spans 2024–2025, with follow-up of two years. It includes women over 75 y at high risk of fracture (defined as a patient with osteoporosis and fragility fracture in the 2 y prior to assessment), with specific exclusion criteria (impossibility to walk, life expectancy < 2 y and no terminal illness). The methodology includes initial clinical evaluations, blood sample (serum will be collected and 46 biomarkers were analysed in serum analysis on the Olink platform analyses), ultrasound bone densitometry and body composition with bioimpedanciometry. Periodic for follow-ups include both telephonic and in-person (Fig. 1). Main outcome will be frailty fracture incidences. Secondary outcomes such as time to first fracture, with a particular interest in hip and vertebral fractures. Prognostic variables include changes in FRAX scores, BMD, and factors related to frailty and sarcopenia will be also evaluated. Biomarkers are a central study variable, analyzed for changes over the study period. Covariates include demographic, lifestyle, anthropometric, geriatric, nutritional, functional, and biochemical variables. Statistical methods involve descriptive comparisons, multivariate logistic regression, and principal component analysis. Quality control measures are in place for data integrity, and ethical considerations align with current regulations.

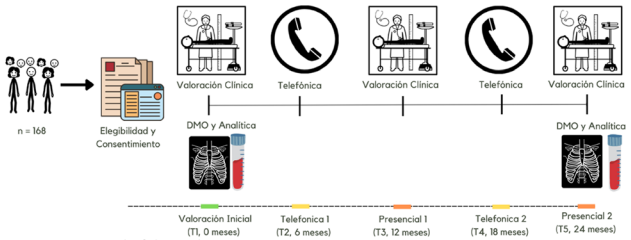

Figure 1. Protocol of the study

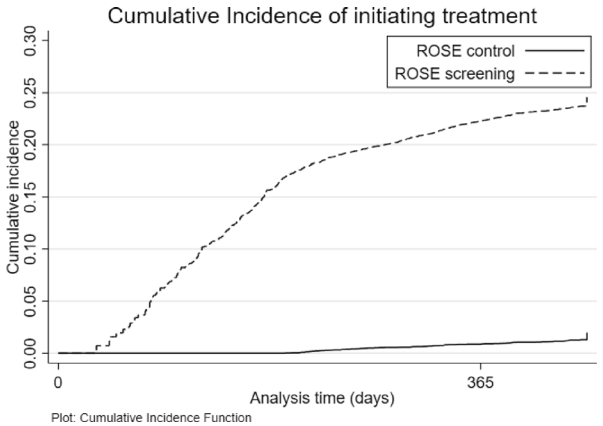
Results: Historically, predicting the risk of osteoporosis-related fractures has been suboptimal. It's crucial to develop new strategies for understanding, predicting, and addressing osteoporosis from the perspective of precision medicine, as traditional treatment approaches for high-risk patients are inadequate for tackling systemic deterioration in bone microstructure. The European Society for Clinical and Economic Aspects of Osteoporosis, Osteoarthritis and Musculoskeletal Diseases (ESCEO) has proposed relevant biomarkers for musculoskeletal health research. Analytical technologies are increasingly detailing molecular and cellular alterations in osteoporosis and patient variability. Our group has preliminary results on distinct biomarkers in fractured and non-fractured patients, linked to fracture risk via the FRAX scale, moving beyond just associating biomarkers with osteoporosis to fracture risk. However, these findings are from small, cross-sectional studies or male-only studies, needing validation in longitudinal studies with more female representation, the most affected group. While the identification of proteins and metabolic pathways involved in bone metabolism regulation across populations has improved, the precise understanding of biological mechanisms underlying low BMD remains incomplete.
Conclusion: The purpose of our update study will be to determine the real-life evidence of precision medicine with biomarkers in fracture risk prediction.

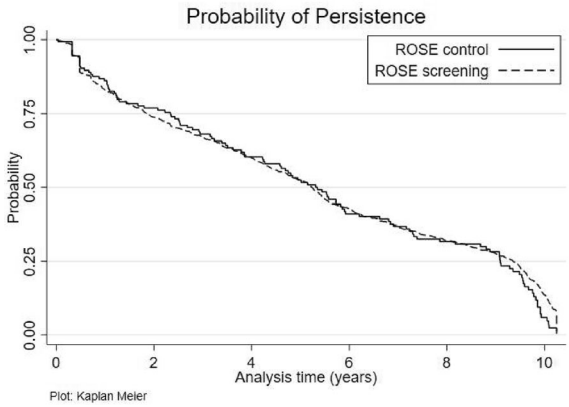
P280
ASSESSMENT OF ADHERENCE TO ANTI-OSTEOPOROTIC MEDICATION (AOM) TREATMENT IN THE RISK-STRATIFIED OSTEOPOROSIS STRATEGY EVALUATION (ROSE) SCREENING PROGRAMME: A 10-YEAR FOLLOW-UP STUDY

T. G. Petersen[1], K. H. Rubin[1], M. K. Javaid[2], A. P. Hermann[3], K. Åkesson[4], B. Abrahamsen[5]

[1]Research Unit OPEN, Dept. of Clinical Research, Univ. of Southern, Odense, Denmark, [2]NDORMS, Univ. of Oxford, Oxford, UK, [3]Research unit of Endocrinology, Odense Univ. Hospital, Odense, Denmark, [4]Clinical and Molecular Osteoporosis Research Unit, Dept. of Clinical Sciences Malmö, Malmö, Sweden, [5]Dept of Medicine, Holbæk Hospital and OPEN, SDU, Denmark

Objective: The ROSE screening programme RCT (Rubin, Osteoporos Int 2018;29:567) offers a comprehensive approach to risk assessment and initiation of anti-Osteoporotic medication (AOM). However, a screening programme's feasibility depends on adherence to treatment and this could be poorer in those screened as opposed to women actively seeking assessment and treatment. We aimed to investigate the impact of the ROSE screening programme on long-term adherence to AOM treatment.
Methods: Women aged 65–80, residing in the Region of Southern Denmark 2010–2011, were randomized into a screening or a control group. Based on questionnaire data, women in the screening group with a 10-year fracture risk (FRAX^{TM}) of $\geq$ 15% were invited for DXA scanning, following standard AOM treatment in case osteoporosis was identified. We assessed initiation, medication possession ratio (MPR), and persistence to AOM treatment using information on filled prescriptions and in-hospital treatment assi from Danish nationwide registers. Survival analyses, with a maximum follow-up of 10 y, were applied to evaluate differences between the groups.
Results: Among the 15,505 women eligible for the analyses, 971 (6.26%) initiated AOM within one year after the intervention. Significantly more participants in the screening group started on AOM (HR 5.14 (95% CI 4.29; 6.16)) compared to controls (Fig. 1). Persistence was good with 50% remaining on treatment for 5 y or longer and 75% for 2 y or more, with equally good persistence in the screening group (Fig. 2).





Conclusion: Nonadherence presents a significant challenge in osteoporosis. The study demonstrates that the ROSE programme increases initiation of AOM treatment and that screened subjects exhibit similar levels of adherence once they have initiated medication compared to those not screened.

P281
RISK FACTORS OF URATE DEPOSITS IN WOMEN WITH ASYMPTOMATIC HYPERURICEMIA

B. B. Bengana[1], G. H. Guerboukha[1], B. A. Boukabous[1], L. S. Lefkir[1]

[1]Univ. Hospital of Benimessous, Rheumatology Dept., Algiers, Algeria

Objective: This study marks a milestone by focusing on gout, a disease often studied in men but neglected in women. It explores the prevalence of urate deposits detected by ultrasound exclusively in women with asymptomatic hyperuricemia (AH). The aim is also to evaluate risk factors associated with these deposits, such as the double contour (DC) sign and tophus but within an exclusively female population.
Methods: For this analysis, musculoskeletal ultrasounds were performed on female participants, divided into two groups: with and without AH. The knee, ankle, and first metatarsophalangeal (MTP1) joint, as well as certain tendons, were examined. Demographic, clinical, and biological data from both groups were compiled to study risk factors associated with urate deposits detected by ultrasound, focusing particularly on the double contour sign and tophus.
Results: The results involved 93 women (48 with AH and 45 without AH). The double contour sign was more common in the knee and ankle joints in those with AH (knees: 7/48 vs. 1/45; ankles: 5/48 vs. 0/45). The most common ultrasound manifestations at the MTP1 joints were tophus and the double contour sign (tophus: 3/48 vs. 0/45; DC: 8/48 vs. 2/45). Risk factors identified for the double contour sign were advanced age and renal function issues (OR, 2.67, $p = 0.01$; OR, 1.71, $p = 0.022$ respectively). As for tophus, it was associated with high uricemia levels (OR, 2.32, $p = 0.023$).
Conclusion: This study reveals that one in six women with AH had ultrasound signs of urate deposits. Advanced age and renal issues were associated with the double contour sign, while tophus was linked to high uricemia levels.

P282
PAINFUL SWELLING OF THE FINGERS REVEALING POLYOSTOTIC MELORHEOSTOSIS

B. B. Bengana[1], B. I. Boukrara[1], G. H. Guerboukha[1], L. S. Lefkir[1]

[1]Univ. Hospital of Benimessous, Rheumatology Dept., Algiers, Algeria

Melorheostosis is a rare sclerosing bone dysplasia, with approximately 400 known cases worldwide. Often monomelic, its etiopathogenesis remains poorly understood. This process typically begins in childhood or adolescence, manifesting as irregular cortical hyperostosis, characterized by a candle wax-like appearance on imaging, mainly affecting the lower limb.
Casereport: We present the case of a 31-year-old patient, S.L, with a history of type 2 diabetes and thyroidectomy under levothyroxine. Since the age of 17, she has had unilateral hypertrophy of the left upper limb affecting the 4th finger and forearm. Over the past 6 months, she has developed hyperesthesia throughout the left forearm and intermittent mechanical pain in the 4th finger, improved by NSAIDs. Clinical examination revealed no limitation of the left shoulder, elbow, or wrist joints. Laboratory results for phospho-calcium, renal, and inflammatory parameters were normal. X-rays and CT scans showed linear candle wax-like hypercondensation along the humeral and radial diaphyses, carpal bones, metacarpal bones, and phalanges. Scintigraphy revealed intense tracer uptake in the 3rd and 4th rays of the hand, as well as in the bones of the left forearm and humerus.
Discussion: Melorheostosis is a congenital disease with insidious onset, observed in our patient during adolescence and affecting multiple bones of the upper limb. Radiologically, the characteristic appearance of melorheostosis presents as linear candle wax-like hypercondensation along the bones. Bone scintigraphy shows moderate uptake in the areas of condensation, allowing assessment of disease extent. Its progression can lead to refractory pain, deformities, and joint stiffness. Treatments remain largely nonstandardized, primarily focused on symptomatic relief with analgesics, NSAIDs, bisphosphonates, and colchicine.
Conclusion: Polyostotic melorheostosis remains exceptional. The diagnosis relies on the candle wax appearance of the long bone cortices. Its management remains complex due to the absence of specific treatment.

P283
AN ENIGMATIC CASE OF GORHAM-STOUT DISEASE WITH RECURRENT PLEURISIES

B. B. Bengana[1], T. H. Touaher[1], L. S. Lefkir[1]

[1]Univ. Hospital of Benimessous, Rheumatology Dept., Algiers, Algeria

Gorham-Stout disease is a spontaneous and massive osteolysis resulting from local proliferation of small blood or lymphatic vessels, leading to progressive destruction and resorption of bone tissue. It is a rare and sporadic disease, with approximately 350 identified cases worldwide. We report a case of Gorham-Stout disease in a young man revealed by suspicious osteolysis of the shoulder.
Casereport: Mr. S.F., 34 years old, was hospitalized for management of diffuse lytic osteopathy. Beginning in 2010, he experienced lingering moderate pain in the right arm, with recurrent pleurisies requiring periodic punctures, indicating chylothorax. MRI revealed a fluid lesion in the humerus, radius, and ulna. In 2023, following ischemia of the right upper limb, amputation was performed, with histopathological examination concluding hemangioendothelioma, ruling out other malignant pathologies. Clinical examination noted fair general condition with diffuse pain predominating in the lower limbs and anterior thoracic region. Laboratory findings showed inflammatory syndrome, anemia at 8.3 g/dL; renal, hepatic, and phosphocalcic tests were normal. Chest X-ray showed bilateral moderate pleural effusion. Whole-body CT: generalized lytic osteopathy affecting the entire skeleton (ribs, lower angles of scapulae, iliac wings, vertebral bodies). Bone scintigraphy: increased uptake in the sternum, tip of the left scapula, right costal arch, and pelvis. Subsequently managed in pneumology with pleural punctures and oxygen therapy. Prescribed bisphosphonate therapy.
Discussion: Therapeutic management is complex due to the lack of curative treatment. Our patient had Gorham-Stout disease affecting all bones of the body, with recurrent chylothorax requiring frequent punctures, associated with pulmonary acidosis requiring oxygen therapy limiting surgical intervention. Unfortunately, the patient died due to respiratory decompensation.
Conclusion: Gorham-Stout disease, rare and causing significant disability, can compromise life prognosis mainly through pulmonary complications. Diagnosis and management remain complex and poorly understood.

P284
SAFETY OF GAM-COVID-VAC (SPUTNIK V) COMBINED VECTOR VACCINE IN PATIENTS WITH IMMUNOINFLAMMATORY RHEUMATIC DISEASES

A. Kulikov[1], N. Muravyeva[1], B. Belov[1]

[1]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia

Objective: Patients with immunoinflammatory rheumatic diseases (IRD) are at high risk of developing COVID-19. Vaccination should be an effective method of preventing this disease. However, vaccination may be unsafe in IRD patients.
Methods: The study included 222 patients with IRD (171 women, 51 men, age 49 ± 15,5 y, duration of disease 10.6 ± 9.2 y)—the main group and 111 people without any IRD (84 women, 27 men, age 37,2 ± 15,7 y)—the control group. 145 patients received disease-modifying antirheumatic drugs (mainly methotrexate—69), 81 were treated with biologics (mostly with rituximab—58). 64 took glucocorticoids, 10 did not receive therapy. All participants were vaccinated with both components of Gam-COVID-Vac and interviewed by a research doctor with a unified questionnaire.
Results: After the introduction of the first dose pain at the injection site without limitation of limb movements (22.5 and 34.2%, $p = 0.023$), weakness (28.4 and 43.2%, $p = 0.007$), fever (24.8 and 51.4%, $p < 0.001$), arthralgia or myalgia (10.8 and 31.5%, $p < 0.001$), headache (7.7 and 15.3%, $p = 0.03$) and chills (4.1 and 27.9%, $p < 0.001$) were significantly less common in the main group. After the administration of the second dose pain at the injection site without limitation of limb movements (14.4 and 26.1%, $p = 0.01$) and arthralgia or myalgia (10.4 and 18.9%, $p = 0.03$) were also less common in the main group, but no significant differences were obtained for other adverse events (AEs). A significant difference was revealed between two groups in the number of patients with local and systemic AEs after the introduction of the first (22.1% and 44.1%, respectively; $p < 0.001$), second (14% and 29.7%, $p = 0.007$) components and both doses (35.6 and 21.6%, respectively; $p = 0.01$). There were no exacerbations of IRD and the occurrence of autoimmune phenomena after complete immunization.
Conclusion: According to our data, the Safety of Gam-COVID-Vac in patients with IRD is satisfactory.

P285
SAFETY OF GAM-COVID-VAC (SPUTNIK V) COMBINED VECTOR VACCINE IN PATIENTS WITH RHEUMATOID ARTHRITIS

A. Kulikov[1], N. Muravyeva[1], B. Belov[1]

[1]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia

Objective: Patients with rheumatoid arthritis (RA) are at high risk of developing COVID-19. Vaccination should be an effective method of preventing this disease. However, vaccination may be unsafe in RA patients.
Methods: The study included 119 RA patients (109 women, 10 men, age 52.9 ± 14.7 y, duration of disease 11.3 ± 8,8 y)—the main group and 111 people without any immunoinflammatory rheumatic diseases (84 women, 27 men, age 37.2 ± 15.7 y)—the control group. 90 patients received disease-modifying antirheumatic drugs (mostly methotrexate—54), 58—biological drugs (mainly rituximab—48). All participants received two doses of Gam-COVID-Vac and were interviewed by a research doctor with a unified questionnaire.
Results: Local and systemic adverse events (AEs) were observed both in the main group and in the control group. There were no significant differences between two groups in the frequency of local reactions after both components. There was a significant difference between two groups in the frequency of weakness (26.1 and 43.2%, $p = 0.007$), fever (18.5% and 51.4%, $p < 0.001$), arthralgia or myalgia (7.6 and 31.5%, $p < 0.001$), chills (5 and 27.9%, $p < 0.001$) and headache (4.2% and 15.3%, $p = 0.005$) after administration of the first (but not the second) component of the vaccine. A significant difference was revealed between the main group and the control group in the number of patients with local and systemic AEs both after the introduction of the first component of the vaccine (21.8 and 44.1%, $p < 0.001$) and after the second (14.3% and 29.7%, $p = 0.005$). After administration of the two components of the vaccine, a higher number of patients without any AEs were detected in the main group compared to the control group (34.5 and 21.6%, $p = 0.03$). Exacerbation of RA in main group are not marked.
Conclusion: According to our data, the safety of Gam-COVID-Vac in RA patients is satisfactory.

P286
SAFETY OF GAM-COVID-VAC (SPUTNIK V) COMBINED VECTOR VACCINE IN PATIENTS WITH SPONDYLOARTHRITIS

A. Kulikov[1], N. Muravyeva[1], B. Belov[1]

[1]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia

Objective: Vaccination remains one of the most effective methods of preventing infectious diseases, but it can be unsafe in patients with spondyloarthritis (SpA) who probably have a high incidence of COVID-19.
Methods: The study included 62 SpA patients (36—ankylosing spondylitis, 16—psoriatic arthritis, 10—undifferentiated SpA, 27 women, 35 men, age 39.5 ± 11.6 y, duration of the disease 11.2 ± 8.3 y)—the main group and 111 people without any immunoinflammatory rheumatic diseases (84 women, 27 men, age 37.2 ± 15.7 y)—the control group. 30 patients received disease-modifying antirheumatic drugs (17—methotrexate), 12—biological drugs (8—TNFα inhibitors), 17—only nonsteroidal anti-inflammatory drugs. All participants were vaccinated with two doses of Gam-COVID-Vac and interviewed by a research doctor with a unified questionnaire.
Results: Local and systemic adverse events (AEs) occurred in both groups. After the introduction of the first (9.7 and 34.2%; $p < 0.001$) and second (6.5% and 26.1%; $p < 0.001$) components of the vaccine there was a significant increase in the frequency of pain without restriction of movement in the control group. There was a significant difference between two groups in the frequency of fever (35.5% and 51.4%, $p = 0.045$), arthralgia or myalgia (12.9 and 31.5%, $p = 0.007$) and chills (1.6 and 27.9%, $p < 0.001$) after administration of the first (but not the second) component of the vaccine. Also, significant difference was noted between two groups in the number of patients with local and systemic AEs after the introduction of the first component of the vaccine (16.1 and 44.1%, $p < 0.001$) and after the second (11.3% and 29.7%, $p = 0.006$). After complete immunization, the percentage of patients without any AEs was significantly higher in the main group—40.3% and 21.6%, $p = 0.009$. There was no exacerbation of SpA.
Conclusion: According to our data, the safety of Gam-COVID-Vac in patients with SpA is satisfactory.

P287

INFLUENCE OF LOW MUSCLE MASS ON PHYSICAL PERFORMANCE TESTS IN FRAIL OLDER WOMEN

B. C. C. Lenardt[1], A. Maoski[1], G. Furlan[1], I. C. De Lima[1], M. C. Souza[1], L. Amaral[1], T. Yamaguishi[1], O. De Matos[1]

[1]Federal Univ. of Technology Parana, Curitiba, Brazil

Objective: To evaluate the correlation between low muscle quantity and physical performance in frail older women.
Methods: the sample consisted of 53 women aged 60 or over, classified as normal (N = 23) and pre-frail and frail (N = 30) by the functional clinical vulnerability index (IVCF-20). DXA was used for total mass, total lean mass, appendicular lean mass adjusted for BMI (ASM/BMI) and adjusted for height squared (ASM/H^2), BMD and T-score value. The physical performance tests were handgrip strength (HGS), single-leg stance (SLS) and Short Physical Performance Battery (SPPB). For statistics, descriptive analysis, nonparametric Mann–Whitney U, Spearman correlation and linear regression analysis were used.
Results: When comparing the results of the physical tests between the groups, the frail group presented the lowest results, with a moderate and significant correlation between IVCF and ASM/BMI. While for the normal group, lean mass showed a correlation between ASM/H^2 and an inverse and moderate correlation with the single-leg stance.

Table 1. Correlation test for both groups

Normal group (n=23)			
		r_s	(p)
Lean mass	Total mass	0.686	0.000**
Lean mass	HGS	0.416	0.048*
Lean mass	ASM/H^2	0.603	0.002**
HGS	Age	-0.422	0.045*
IVCF	SLS	-0.493	0.017*
ASM/H^2	Total mass	0.500	0.015*
ASM/BMI	Neck T-score	-0.526	0.010**
ASM/BMI	Lumbar BMD	-0.416	0.049*
Frail group (n=30)			
Total mass	HGS	0.439	0.015*
Total mass	BMI	0.502	0.005**
Total mass	ASM/H^2	0.615	0.000**
IVCF	ASM/BMI	0.376	0.041*
SPPB	Age	-0.594	0.001**
ASM/H^2	Age	-0.444	0.014*

The main influence between the variables was 14.7% of IVCF on ASM/BMI and 14.1% on lean mass for the frail group. For the same group, SPPB presented moderate and inverse correlation with age. HGS showed a greater correlation with muscle mass for both groups.
Conclusion: We conclude that it is very important to use the classification to verify cognitive and functional conditions in older people. The physical tests used are important to analyze the risk of falls, but for this study HGS was the test that had the greatest statistical relationship with lean mass.

P288

ASSOCIATION BETWEEN FALL RISK TOOLS WITH TRABECULAR BONE SCORE (TBS) AND FRACTURE RISK ASSESSMENT TOOL (FRAX) IN OLDER WOMEN WITH LOW BONE MINERAL DENSITY

B. C. C. Lenardt[1], A. Maoski[1], O. De Matos[1]

[1]Federal Univ. of Technology Parana, Curitiba, Brazil

Objective: verify the relationship between fall risk instruments with TBS and FRAX in women with low BMD.
Methods: The sample consisted of 24 women aged 60 or over, classified according to BMD analysis as normal (N = 06) and low BMD (N = 18). The following were used: fracture risk assessment instrument (FRAX), TBS by DXA. The physical performance tests carried out were the Short Physical Performance Battery (SPPB) and the Functional Reach Test (FRT). For statistics, Shapiro–Wilk analysis was used to verify the sample distribution, t-test to compare variables between groups, Pearson correlation and linear regression analysis.
Results: When comparing groups, the variables did not show a statistically significant difference. Therefore, to verify the association between the variables, only the low BMD group (n = 18) was used.

Table 1. Correlation between TBS and physical performance tests (n=18).

Variables		r	P	Regression analysis%)
TBS absolute	SPPB	-0,560	0,016*	31,4
TBS absolute	FRT	-0,674	0,002**	45,4
TBS Spine	SPPB	-0,526	0,025*	27,6
TBS Spine	FRT	-0,758	0,000**	57,5
TBS Hip	FRT	-0,614	0,007**	37,7

Table 2. Correlation between TBS and FRAX (n=18).

Variables		r	P	Regression analysis (%)
TBS Spine	FRAX Hip	-0,580	0,012*	33,6
TBS Neck	FRAX Hip	-0,770	0,000**	59,3
TBS Neck	FRAX Major	-0,556	0,017*	30,9
TBS Hip	FRAX Hip	-0,731	0,001**	53,4
TBS Hip	FRAX Major	-0,535	0,022*	28,6

BMD did not show a significant correlation with any other performance variable, TBS or FRAX. Regarding bone analysis, TBS demonstrated an important correlation and influence on performance tests and on all FRAX sites. TBS Spine correlated with total hip FRAX. TBS Spine had moderate and inverse association with FRAX hip, while TBS Neck had an association with FRAX total Hip and FRAX major.
Conclusion: For this study, TBS was important not only because of its relationship with FRAX, but also because it is related to fall risk tests. Therefore, we conclude that the association of fall risk assessment tools with TBS and FRAX can more efficiently predict the risk of falls and fractures for this population.

P289
RISK FACTORS INFLUENCING PERIPROSTHETIC FRACTURE AND MORTALITY IN ELDERLY PATIENTS FOLLOWING HEMIARTHROPLASTY WITH A CEMENTED COLLARLESS POLISHED TAPER STEM FOR AN INTRACAPSULAR HIP FRACTURE

B. C. Chen[1], C. S. Scott[2], N. C. Clement[2]

[1]Second Affiliated Hospital of Soochow Univ., Suzhou, China, [2]Royal Infirmary of Edinburgh, Edinburgh, UK

Objective: To evaluate the incidence of reoperation (all cause and specifically for periprosthetic fracture [PFF]) and mortality, and associated risk factors associated with these following a hemiarthroplasty incorporating a cemented collarless polished taper slip stem (PTS) for management of an intracapsular hip fracture.
Methods: This retrospective study included hip fracture patients aged 50 years and older treated with Exeter (PTS) bipolar hemiarthroplasty between 2019–2022. Patient demographics, place of domicile, fracture type, delirium status, ASA grade, length of stay and mortality were collected. Reoperation and mortality were recorded up to a median follow up of 29.5 months. Cox regression was performed to evaluate independent risk factors for reoperation and mortality.
Results: The cohort consisted of 1619 patients with a mean age of 82.2 y (SD 8.8, range 50–104) and 1100 (67.9%) were females. In total 29 (1.8%) patients underwent a reoperation. Twelve (0.7%) patients sustained a PFF during the observation period (United Classification System [UCS]-A n = 2; UCS-B n = 5; UCS-C n = 5), of whom 10 underwent surgical management. Perioperative delirium was independently associated with the occurrence of PFF (Hazard ratio (HR) 5.92, p = 0.013) and surgery for UCS-B PFF (HR 21.7, p = 0.022). Neither, all-cause reoperation nor PFF related surgery were independently associated with mortality (HR 0.66, p = 0.217 and HR 0.38, p = 0.170, respectively). Perioperative delirium, male sex, older age, high ASA grade and pre-fracture residential status were independently associated with mortality following hemiarthroplasty ($p < 0.001$).
Conclusion: The cumulative incidence of PFF at 4-years was 1.1% in elderly patients following cemented taper slip hemiarthroplasty for a hip fracture. Perioperative delirium was independently associated with a PFF, and more specifically with UCS B and C PFF. However, reoperation for PPF was not independently associated with patient mortality after adjusting for patient specific factors.

P290
LATERAL WALL THICKNESS (< 20.5 MM) IS NOT ASSOCIATED WITH REVISION RISK OF MEDIALLY STABLE INTERTROCHANTERIC FRACTURES FIXED WITH A SLIDING HIP SCREW

B. Chen[1], A. Duckworth[2], L. Farrow[3], N. Clement[2]

[1]Second Affiliated Hospital of Soochow Univ., Suzhou, China, [2]Royal Infirmary of Edinburgh, Edinburgh, UK, [3]Univ. of Aberdeen, Aberdeen, UK

Objective: To determine whether lateral femoral wall thickness (LWT) < 20.5 mm was associated with increased revision risk of intertrochanteric fracture (ITF) following sliding hip screw (SHS) fixation when medial calcar was intact. Additionally, the study assessed the association between LWT and patient mortality.
Methods: This retrospective study included ITF patients aged over 50 years treated with SHS fixation between 2019 and 2021 at a major trauma centre. Demographic information, fracture type, delirium status, ASA grade, length of stay (LoS) were collected. LWT and tip apex distance (TAD) were measured. Revision surgery and mortality were recorded at a mean follow-up of 19.5 months (range 1.6–48 months). Cox regression was performed to evaluate independent risk factors of revision surgery and mortality.
Results: The cohort consisted of 890 patients with a mean age of 82 y (SD 10.2). Mean LWT was 27.0 mm (SD 8.6), and there were 213 (23.9%) patients with LWT < 20.5 mm. Twenty patients (2.2%) underwent a revision surgery following SHS fixation. Adjusting for covariates, LWT < 20.5 mm was not independently associated with an increased revision or mortality risk. However, factors that were significantly more prevalent in LWT < 20.5 mm group (residence in care home (HR = 1.84, $p < 0.001$) or hospital (HR = 1.65, p = 0.005), and delirium (HR = 1.32, p = 0.026)) were independently associated with increased mortality risk. The only independent factor associated with increased risk of revision was older age. (HR = 1.07, p = 0.030).
Conclusion: LWT was not associated with risk of revision surgery in patients with an ITF fixed with SHS when medial calcar was intact, after adjusting for the independent effect of age. Although LWT < 20.5 mm was not an independent risk factor for mortality, patients with LWT < 20.5 mm were more likely to be from care home or hospital and have delirium on admission which were associated with a higher mortality rate.

P291
BLOOD FLOW RESTRICTION WITH DIFFERENT LOAD LEVELS IN PATIENTS WITH KNEE OSTEOARTHRITIS: A RANDOMIZED CLINICAL TRIAL

B. Dias[1], R. A. Jardim[1], E. A. Teixeira[1], K. Rodrigues[1], A. Matos[1], N. Iosimuta[1]

[1]Federal Univ. of Amapa, Macapa, Brazil

Objective: To evaluate whether blood flow restriction with low load (BFR + LL) and no load (BFR + rest) are noninferior to high-intensity resistance exercise (HIRE + BFR placebo) for improving muscle strength and reducing pain in patients with knee osteoarthritis (OA) over a 3-week period.
Methods: This clinical trial is a non-inferiority, three-arm, randomized, controlled study conducted with 24 patients of both sexes with knee OA, aged 50 years or older. Participants were randomly allocated to three exercise groups (BFR + LL, n = 8; BFR + rest, n = 8, and HIRE + BFR placebo, n = 8). The treatment protocol spanned 3 weeks with interventions occurring twice a week, each session lasting 40 min, totalizing six sessions. Each session began with 5-min warmup on a bicycle, followed by strengthening exercises performed through knee extension (3 sets of 8 repetitions). The BFR + LL group used lower load (30%RM) than the HIRE + BFR placebo group (80%RM), while BFR + rest group do not perform strengthening exercises. Participants were assessed before and after treatment using the visual analogue scale (VAS) for pain and strength of the right quadriceps muscle was estimated using the 7–10 repetition maximum (7–10RM) test on the chair extensor. Repeated measures ANOVA was applied for statistical analysis (level of significance set at $p \leq 0.05$), using SPSS software.
Results: The average age of the sample was 56.8 (± 8.85) y, with 66.7% of sample being female. All groups increased muscle strength after 3 weeks of intervention (p = 0.046), with higher gain in muscle strength in the BFR + LL group compared to the BFR + rest group (p = 0.024). No statistically significant differences were observed between treatments in reducing pain ($p > 0.05$).
Conclusion: The results of this study demonstrated that a BFR combined with low-intensity resistance exercise lead to similar effects to conventional high-intensity strength training on muscle strength in patients with knee OA in short term. Thus, the BRF associated with low load could be an alternative to traditional treatment for knee OA, being more comfortable modality and potentially increasing patient treatment adhesion.

P292
DENOSUMAB-RELATED OSTEONECROSIS OF THE JAW IN A PATIENT WITH OSTEOPOROSIS AND RHEUMATOID ARTHRITIS: TREATMENT CHALLENGE OF A RARE COMPLICATION

B. Fernandes Esteves[1], R. M. Ferreira[1], M. Bernardes[1], P. Santos[2], L. Costa[1]

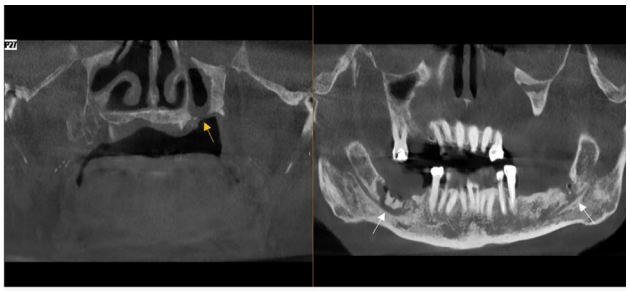
[1]Rheumatology Dept., [2]Stomatology Dept., Centro Hospitalar Universitário São João, Porto, Portugal

Osteonecrosis of the Jaw (ONJ) is a rare and severe complication of anti-resorptive agents. Treatment of Denosumab-Related Osteonecrosis of the Jaw (DRONJ) in patients with Osteoporosis (OP) remains challenging. The following case aims to highlight the lack of common agreement for anti-osteoporotic treatment in patients with DRONJ.

We describe a case of an 83-year-old woman, with a 16-y history of rheumatoid arthritis, with pulmonary involvement, under rituximab and 5 mg/d of prednisolone, and fractured OP (rib fracture). For OP treatment, she received ibandronic acid from 2007–2012, with a good densitometric response. In 2021, due to a high fracture risk, frequent falls and an eGFR of 30 ml/min/1.73m^2, denosumab 60 mg every 6 months was initiated. The patient received 3 doses, the last one being in December 2022. One month later, she went to the emergency department (ED) with left sided odontalgia for 2 weeks. In the ED, spontaneous detachment of approximately 3 cm of maxillary bone from the left upper arcade was observed, with bone exposure at the level of the 2nd quadrant. She had areas of bone exposure in the 2nd, 3rd, and 4th quadrants. Cone-beam computed tomography confirmed DRONJ stage 3 changes. Denosumab was suspended, a course of antibiotics was started and oral hygiene measures were reinforced. She refused surgery.

The treatment of ONJ can be conservative or surgical. Teriparatide has shown benefits in the treatment of medication-related ONJ. However, the majority of studies are limited to bisphosphonate-related ONJ. After discontinuation, denosumab has a rebound effect associated with a decrease of BMD, requiring sequential treatment. However, the use of teriparatide after denosumab has demonstrated bone mass loss and increased fracture risk. The major therapeutic obstacle in DRONJ is the subsequent anti-osteoporotic therapy. To the authors' knowledge, there are no studies proposing anti-osteoporotic therapy after DRONJ.

Photograph of the detachment of approximately 3cm of maxillary bone from the upper left arcade.



Patient's CBCT presenting stage 3 ONJ. In the 2nd quadrant (yellow arrow) extension to the maxillary sinus. In the 3rd and 4th quadrants (white arrows) extension to the mandibular canal.

P293
EXPLORING THE LINK BETWEEN MUSCULAR SENESCENCE AND OSTEOPOROSIS

B. Gasperini[1], A. Falvino[1], I. Cariati[2], R. Bonanni[1], V. V. Visconti[1], V. Tancredi[2], A. Botta[1], U. Tarantino[3], S. Grillo[3]

[1]Dept. of Biomedicine and Prevention, [2]Dept. of Systems Medicine, [3]Dept. of Clinical Sciences and Translational Medicine, Univ. of Rome Tor Vergata, Rome, Italy

Objective: Osteoporosis is a condition characterized by low mineral density and deterioration of bone tissue microarchitecture, resulting in increased bone fragility and increased risk of fractures. Cellular senescence and the consequent characteristic senescence-associated secretory phenotype (SASP) are crucial factors contributing to the pathogenesis of the disease [1]. Given the interconnection between bone and muscle tissue, this study aims to investigate the correlation between the expression pattern of genes associated to cellular senescence and SASP phenotype with osteoporosis in muscle tissues from OP patients [2,3].
Methods: 6 osteoporotic (OP) and 6 osteoarthritic patients (OA) were enrolled, who underwent surgery for fragility fracture and coxarthrosis, respectively. Subsequently, muscle tissue biopsies were collected for RNA extraction. The expression of *CDKN1A*, *CDKN2*, *IL-6* and *FAS* genes was assessed by quantitative real time-polymerase chain reaction (qRT-PCR) in muscle tissue from OP and OA individuals.
Results: The mRNA levels of two markers of cellular senescence, *p16* and *p21* were higher in the OP patients compared with the OA individuals ($p = 0.0303$; $p = 0.0043$), thus indicating the premature aging of muscle tissues in OP. We then investigated the expression profile of *IL-6* and *FAS* genes whose encoded proteins have been associated with SASP. Interestingly, we found a significant upregulation of both genes in OP muscle ($p = 0.0260$; $p = 0.0043$), in accordance with the expression of cellular senescence biomarkers.
Conclusion: These preliminary results show a potential link between muscular senescence and osteoporosis. These data provide additional insights into the molecular mechanisms underlying osteoporosis, highlighting the importance of considering cellular senescence and SASP as potential therapeutic targets.

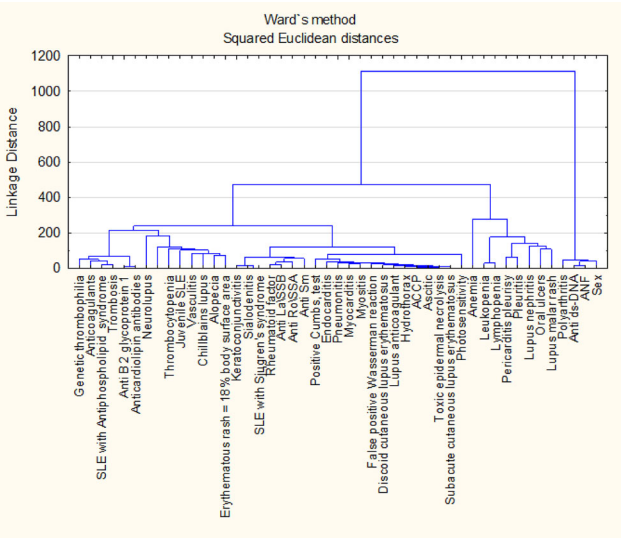
CLINICAL AND IMMUNOLOGICAL PHENOTYPES OF SYSTEMIC LUPUS ERYTHEMATOSUS IDENTIFIED BASED ON CLUSTER ANALYSIS

B. Issayeva[1], E. Aseeva[2], S. Solovyev[2], S. Glukhova[2], S. Issayeva[1], M. Saparbayeva[1], M. Bizhanova[1], A. Amanzholova[1]

[1]Asfendiyarov Kazakh National Medical Univ., Almaty, Kazakhstan, [2]Rheumatology, Federal State Research Institution (FSRI) named after V.A. Nasonova, Moscow, Russia

Objective: To identify clinical and immunological variants (phenotypes) of systemic lupus erythematosus (SLE) using cluster analysis.
Methods: The study included 400 patients with diagnosis of SLE according to the 2012 SLICC classification criteria. Patients underwent laboratory and immunological workup according to accepted standards of medical care for patients with SLE, and therapy was prescribed in accordance with disease activity (using SLEDAI 2 K).
Results: Among patients, most were females (ratio of men and women—1:10), and people of young age (34.2 ± 11.5 y), with an average duration of illness of 6 [3; 12] y. In 98 (25%) patients with SLE, the disease debuted before the age of 18 y. L nephritis (LN) was detected in 192 (48%) patients, SLE with antiphospholipid syndrome (APS) in 48 (12%), SLE with Sjogren's syndrome in 44 (11%). For cluster analysis 30 clinical, 4 laboratory, 12 immunological and 10 therapeutic parameters were selected and a dendrogram was constructed with the calculation of the Euclidean distance using the Ward method. As a result, five clusters of SLE were identified: with the development of LN; with predominantly extrarenal manifestations; SLE combined with APS; SLE combined with Sjıgren's syndrome; SLE with childhood onset (up to 18 y of age). Clusters differed in clinical, laboratory and immunological parameters, as well as in therapy.



Conclusion: Cluster analysis data made it possible to group the selected signs into five clinical and immunological variants (phenotypes) of SLE. Identification of SLE phenotypes as a set of characteristics that, individually or in combination, make it possible to determine differences between patients based on clinical, laboratory and immunological parameters, variants of the onset and course of the disease, response to therapy and prognosis, will contribute to a personalized approach in choosing the therapy, improving its long-term results, as well as quality of life and prognosis in patients with SLE.

P295
LONG-TERM RESULTS OF THERAPY WITH RITUXIMAB AND BELIMUMAB IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

B. Issayeva[1], A. Mesnyankina[2], E. Aseeva[2], N. Nikishina[2], S. Issayeva[1], M. Saparbayeva[1], M. Bizhanova[1], A. Amanzholova[1]

[1]Asfendiyarov Kazakh National Medical Univ., Almaty, Kazakhstan, [2]Rheumatology, Federal State Research Institution (FSRI) named after V.A. Nasonova, Moscow, Russia

Objective: To evaluate the effectiveness of combination therapy with rituximab (RTM) and belimumab (BLM) in patients with SLE with long-term follow-up.
Methods: 12 patients with SLE (1 M/11F) of high and moderate disease activity, 9 of them with skin-joint manifestations, others had kidney damage, peripheral nervous system, vasculitis. Patients received RTM at a dose of 500–2000 mg with premedication of 6-methylprednisolone, and then BLM was prescribed according to the standard scheme of 10 mg/kg once a month. The patients were divided into two groups depending on the time of evaluation of long-term results. In the first group, data were analyzed 7–9 y after the initiation of RTM (4 people). In the second group of 8 patients after 2–4 y. The efficacy and tolerability of therapy, the activity of SLE, as well as the dose of oral glucocorticoids (GK) were evaluated.
Results: Against the background of combination therapy, a clinical and immunological response was obtained in 11 out of 12 patients one year later (initially, the Me of SLEDAI-2 K was 10 [9.5;14.5] points, 6 and 12 months after the initiation of BLM, Me was 4 [2;6] points, $p < 0.008$). Patients who started receiving RTM + BLM within 0–2 y from the moment of the debut of SLE responded better to therapy, and a more significant improvement in clinical and laboratory parameters was achieved. Subsequently, BLM therapy was limited, on average, to two years with the achievement of stable remission. This therapy allowed the use of medium and low doses of GK as an initiating therapy for exacerbation of SLE, followed by their decrease in dynamics. Clinical remission was achieved and persists in 7 patients, in three exacerbations were observed at different times after the withdrawal of BLM, the effect eluded in one patient, and another had no effect on combination therapy.
Conclusion: The achievement of the most pronounced positive result can be assumed in patients for whom RTM + BLM therapy is initiated as early as possible from the moment of diagnosis (0–2 y). BLM infusions should preferably be carried out according to the recommendations once a month, without long breaks between injections for at least 2 y, and if possible, continue for a long time until a lasting effect is achieved. The use of low doses of GK and their elimination is a very real and achievable goal, however, careful monitoring of patients is required in order to identify early symptoms of exacerbation.

P296
EFFICACY AND SAFETY OF CANNABIS EXTRACT FOR THE TREATMENT OF OSTEOARTHRITIS: A SYSTEMATIC REVIEW OF PRE-CLINICAL AND HUMAN STUDIES

B. J. Abafita[1], A. Singh[1], B. E. Antony[1]

[1]Univ. of Tasmania, Hobart, Australia

Objective: There is increasing interest in the use of various cannabis extracts for the treatment of chronic pain, including OA. This systematic review aimed to evaluate the safety and efficacy of various cannabis extracts for the treatment of OA in both preclinical and human studies.

Methods: A comprehensive literature search was conducted using electronic databases, including Ovid Medline, Embase, CINAHL and Cochrane central register for controlled trials, to identify relevant studies published up to 2023. Studies that investigated the efficacy and safety of cannabis extract for the treatment of OA in pre-clinical and clinical settings were included. The risk of bias of the included studies was assessed using the Cochrane risk of bias tool, independently by two researchers.
Results: Twenty-six (20 pre-clinical and 6 clinical) studies were included in this systematic review. The majority of the studies (n = 20) evaluated the effect of cannabis extract using OA models in both animal and cell studies, as well as in domestic animals with spontaneous OA. These studies assessed the effect of cannabis extract on structural changes (n = 8), modulation of pro-inflammatory effects (n = 8), and pain (n = 13) in OA models. Six clinical studies were also included, which investigated the effect of cannabis extract on pain, quality of life, and functional limitations in individuals with OA. Pre-clinical studies consistently demonstrated chondroprotective, chondrogenerative, and anti-inflammatory effects of cannabis extract in mouse and human chondrocyte models. Additionally, cannabis extract demonstrated analgesic effects by reducing hyperalgesia and mechanical/thermal allodynia in OA animal models. However, the evidence from human studies demonstrated a lack of benefit of cannabis extract in OA. Meta-analysis of four randomized controlled trials (RCTs) found no evidence of improvement in pain (standard mean difference [SMD]: − 0.13; 95% CI = − 0.35 to 0.1). The only RCT reporting quality of life found no evidence of improvement (between group difference 0.03; 95% CI − 0.11 to 0.18). Only one RCT reported on the functional limitation (− 0.1; 95% CI − 1.2 to 2.5) and found no difference between cannabis extract and placebo in OA. Adverse events were mild in severity; however, Meta-analyses of 5 studies indicated that the cannabis extracts group had 7% higher adverse events.
Conclusion: There is consistent evidence from pre-clinical studies to support the chondroprotective, anti-inflammatory, and analgesic effects of cannabis extracts in the OA. However, meta-analyses of limited clinical studies using cannabis extract show no beneficial effects on pain, function, and quality of life in OA.

P297
ROMOSOZUMAB IN THE TREATMENT OF PATIENTS WITH OSTEOPOROSIS AND VERY HIGH RISK OF FRACTURE: A WINDOW OF OPPORTUNITY

B. L. L. Llado[1], L. B. Bernacer[2], A. C. Conesa[3], A. M. Martinez[4], A. C. Cirera[5]

[1]Son Llátzer Univ. Hospital, Palma de Mallorca, [2]Univ. Clinic Hospital of Valencia, Valencia, [3]Univ. General Hospital of Castelló, Castellón, [4]Univ. Hospital Doctor Peset, Valencia, [5]Univ. Hospital Complex of Cartagena, Murcia, Spain

Objective: Osteoporosis (OP) is a chronic disease with decreased BMD and increased risk of fragility fractures (FF), which significantly aggravates morbidity and mortality. OP patients at very high risk of fracture (VHRF) are at increased risk of FF in the two years following incident fracture (imminent risk) and require a more aggressive diagnostic and therapeutic approach. To define the baseline demographic, clinical, biochemical and densitometric characteristics of patients treated with Romosozumab in actual clinical practice. We aimed to evaluate changes in BMD, antifracture effect and changes in bone mineral turnover markers and to assess tolerability and adherence to treatment.
Methods: Multidisciplinary multicenter study with Rheumatology, Internal Medicine and Rehabilitation services, observational, retrospective of a cohort of OP patients with VHRF referred to a Bone Metabolism Unit. Period: October 01, 2022 to December 31, 2023. Criteria: Patients with hip fractures, single or multiple vertebral fractures and patients with VHRF according to SEIOMM criteria, in whom treatment with romosozumab is initiated. Comorbidities, OP and fracture risk factors (FF), bone metabolism parameters, BMD, fractures and pharmacological treatments were analyzed.
Results: A total of 189 women were included, with a mean age of 74 y (42–93). 96% had ≥ 1 recent FF. 76.2% had historical FF (1FF (57.1%), ≥ 2 FF (19.1%)). GFR 73.43 ml/min, calcium 9.3 mg/dL (7.9–10.7), VitD 26.05 ng/mL (5–85), PTH 81.10 pg/mL (16–227), BMD hip − 2.69 (− 5.30 − 0.50), BMD lumbar spine − 2.65 (− 5 − 0.50). History of DM (15.3%), HT (23.8%), CKD 3.2%, neoplasia 14.8%. Of the patients with a history of previous FF (144), 57.7% were on antifracture treatment (51 (29.9%) bisphosphonates, 53 (28%) denosumab, 29 (15.3%) teriparatide, 1 (0.5%) MSRE) and 42.3% were naïve patients who started treatment with romosozumab. Good tolerance was reported during treatment with romosozumab.
Conclusion: A change in the model of care is required that includes the identification and assessment of fracture risk in patients with OP with the aim of identifying those with VHRF and reducing the imminent risk of fracture. A paradigm shift focused on patients with VHRF and based on sequential treatment initiating with a dual-acting osteoformer (romosozumab) provides a new therapeutic option in OP patients with VHRF. A longer-term follow-up is required after completion of the complete 1-y treatment to assess the effectiveness in terms of bone mass gain and the anti-fracture effect.

P298
ROMOSOZUMAB IN DENMARK: A REGISTRY STUDY ON OSTEOPOROSIS PATIENTS

B. Langdahl[1], M. Lorentzon[2], T. T. Borgen[3], C. Alstad[4], E. Bajtner[4], A. Rieem Dun[5], T. Kaarill[4], M. Konradsen[6], E. Tsitlakidis[4], A. Moayyeri[7]

[1]Dept. of Endocrinology, Aarhus Univ. Hospital; Dept. of Clinical Medicine, Aarhus Univ., Aarhus, Denmark, [2]Sahlgrenska Osteoporosis Centre, Dept. of Internal Medicine and Clinical Nutrition, Univ. of Gothenburg; Geriatric Medicine, Sahlgrenska Univ. Hospital; Mary McKillop Institute for Health Research, Australian Catholic Univ., Gothenburg, Sweden, [3]Vestre Viken Hospital Trust, Drammen Hospital, Drammen, Norway, [4]UCB Pharma, Brussels, Belgium, [5]Quantify Research, Stockholm, Sweden, [6]Quantify Research, Copenhagen, Denmark, [7]UCB Pharma, Slough, UK

Objective: Romosozumab was approved in the European Union in December 2019 for the treatment of severe osteoporosis (OP) in postmenopausal women at high risk of fracture and has been reimbursed in Denmark since September 2020. This study is the first to describe the profile of patients selected for romosozumab treatment in Denmark.
Methods: We performed a retrospective cohort study based on data from Danish administrative registries. The study population comprised female patients aged ≥ 50 receiving OP medication during the period September 2020 to October 2023.[1] The study included three cohorts: (i) patients with severe OP treated with romosozumab, (ii) patients with severe OP not treated with romosozumab, and (iii) patients who did not have severe OP and were not treated with romosozumab. Patients were considered as having severe OP if they had sustained a fracture at any skeletal site in the three years before the index date (BMD data were not available in the dataset). The characteristics investigated in the three cohorts included: age, index treatment, comorbidities, OP treatment history, dispensing of drugs that increase risk of falling and fracture, fracture history, and use of glucocorticoids.

Results: Overall, 149,395 patients were included; patient characteristics for each cohort are shown in the Table. In patients treated with romosozumab, we generally observed a younger age and lower instances of comorbidities and glucocorticoid use. Of the 622 patients treated with romosozumab, 277 (44.5%) had not received any prior treatment for OP.

Table. Patient characteristics at index

	Patients treated with romosozumab	Patients not treated with romosozumab	
	Severe OP patients (N=622)	Severe OP patients (N=37,831)	Patients without severe OP (N=110,942)
Age at index, mean ± SD	69.3 ± 8.5	75.8 ± 9.9	72.4 ± 9.7
Index treatment, n (%)			
Oral bisphosphonates[a]	0 (0)	24,897 (65.8)	80,238 (72.3)
Injectable bisphosphonates[b]	0 (0)	7,913 (20.9)	19,268 (17.4)
Denosumab	0 (0)	3,775 (10.0)	10,887 (9.8)
Teriparatide	0 (0)	1,173 (3.1)	253 (0.2)
Raloxifene	0 (0)	50 (0.1)	241 (0.2)
Estrogen	0 (0)	23 (0.1)	55 (0.0)
Romosozumab	622 (100)	0 (0)	0 (0)
OP treatment history, n (%)			
Oral bisphosphonates[a]	282 (45.3)	17,833 (47.1)	58,788 (53.0)
Injectable bisphosphonates[b]	77 (12.4)	3,921 (10.4)	11,181 (10.1)
Denosumab	19 (3.1)	2,638 (7.0)	9,142 (8.2)
Teriparatide	21 (3.4)	1,689 (4.5)	577 (0.5)
Raloxifene	<5 (NA)	76 (0.2)	331 (0.3)
Estrogen	8 (1.3)	386 (1.0)	1,673 (1.5)
Romosozumab	0 (0)	0 (0)	0 (0)
OP treatment naive	277 (44.5)	15,594 (41.2)	36,984 (33.3)
Total Charlson-Quan comorbidity index, mean ± SD	0.4 ± 0.9	0.9 ± 1.4	0.9 ± 1.4
Prevalence of comorbidities, n (%)			
Cardiovascular disease[c]	13 (2.1)	5,449 (14.4)	10,865 (9.8)
Diabetes[d]	9 (1.4)	2,230 (5.9)	4,150 (3.7)
Malignancy	40 (6.4)	4,406 (11.6)	21,803 (19.7)
Drugs that increase risk of falling and fracture,[e] n (%)	551 (88.6)	35,209 (93.1)	92,856 (83.7)
Fracture history in the past 3 years, n (%)			
Hip	79 (12.7)	8,626 (22.8)	0 (0)[f]
Spine	64 (10.3)	4,238 (11.2)	0 (0)[f]
Non-hip non-spine	303 (48.7)	22,547 (59.6)	0 (0)[f]
Osteoporosis with pathological fracture[g]	335 (53.9)	12,338 (32.6)	0 (0)[f]
Fracture history in the past >3 to 5 years, n (%)	112 (18.0)	8,084 (21.4)	9,691 (8.7)
Use of glucocorticoids,[h] n (%)	42 (6.8)	5,556 (14.7)	21,038 (19.0)

[a]Includes: alendronate, etidronate and risedronate. [b]Includes: ibandronate and zoledronate. [c]Includes: myocardial infarction, congestive heart failure, peripheral vascular disease, cerebrovascular disease. [d]Includes: diabetes without chronic complication, diabetes with chronic complication. [e]Includes: antipsychotics (lithium excluded), anxiolytics, hypnotics and sedatives, antidepressants, vasodilators used in cardiac diseases, antihypertensives, diuretics, beta blocking agents, calcium channel blockers, renin-angiotensin system inhibitors, alpha-adrenoreceptor antagonists, dopaminergic agents, opioids. [f]Severe OP was defined as sustaining a fracture in the last three years – any patients with a history of fracture in the past three years would therefore have been included in one of the 'severe OP' cohorts. [g]Hospitals only. Mostly used for patients with fragility vertebral fractures, but may also include patients with hip fracture as fragility vertebral and hip fractures are diagnostic for osteoporosis in Denmark irrespective of BMD [h]Definition of previous glucocorticoid use is based on minimum one dose equivalent to ≥450 mg prednisolone within a three-month time window within the baseline period.

Conclusion: This study provides insight into the patterns and influencing factors of romosozumab use in routine clinical practice across Denmark. Of note, many patients who received romosozumab did so as their initial treatment for OP, which suggests the recommendation for use of osteoanabolic agents as the first line of treatment in high fracture risk patients is being followed.

CLOSING THE OSTEOPOROSIS DIAGNOSIS GAP: INSIGHTS FROM A FEASIBILITY STUDY INTO OPPORTUNISTIC SCREENING FROM WRIST X-RAYS

R. Meertens[1], B. Lopez[2], T. Bean[3], N. Ashley[3], J. Da Palma Lopes[3], P. Lewis[3], J. Shrivastava[3], A. Radcliffe[2], W. Vigers[1]

[1]Univ. of Exeter, Exeter, [2]IBEX Innovations Ltd., Sedgefield, [3]Royal Cornwall Hospital, Truro, UK

Objective: Feasibility study aimed at assessing patient flow from a wrist X-ray to DXA assessment in cohorts presenting with and without a fracture. The primary objectives were to: evaluate whether referral rates to DXA align with the anticipated prevalence of osteoporosis; and explore the practicalities of implementing opportunistic screening software (IBEX BH) which measures wrist bone density from a standard X-ray.

Methods: Anonymised data from the Royal Cornwall Hospital Trust (RCHT) radiology information system (RIS) was audited to assess the rate of DXA referrals for patients over 50 attending for a wrist X-ray. Two cohorts were assessed: those presenting with a fracture and those without. A 6-week random sample of anonymised wrist X-rays were analysed using IBEX BH which measures bone density at the ultra-distal and distal third regions. The outputs were used to assess the likely pick-up rate that could be achieved if the software were part of future service provision.

Results: Between August 2021 and July 2022, 2719 patients had a wrist X-ray which could have been assessed by IBEX BH. 983 (36.2%) presented with a fracture. 192 (19.5%) were referred to DXA within one year, compared to 129 (7.4%) in the non-fracture group. In the fracture group referred to DXA, 54 (28.1%) were recommended treatment, compared to 33 (25.6%) in the non-fracture group. IBEX BH returned a T-score at the ultra-distal region on 86% of the 64 images extracted from the system. 33% of patients were identified as at-risk of central osteoporosis.

Conclusion: The study evidenced that there was a large cohort of patients that received a wrist DR and did not get referred to DXA, evidencing that there is an underserved group of patients who could benefit from opportunistic screening. The study also confirmed for that IBEX BH enables radiology to offer this service improvement, supporting the drive to close the osteoporosis diagnosis gap.

Acknowledgment: The authors extend their appreciation to RCHT.

Disclosure: IBEX Innovations have a commercial interest in the adoption of IBEX BH.

P300
DETRIMENTAL EFFECTS OF PROTON PUMP INHIBITORS ON BONE MINERAL DENSITY ARE NOT MEDIATED BY CHANGES IN SERUM CALCIUM OR PTH IN PATIENTS WITH INFLAMMATORY RHEUMATIC DISEASES: A CROSS-SECTIONAL STUDY

A. Palmowski[1], Z. Boyadzhieva[1], P. Hoff[2], S. Hermann[1], B. Muche[1], D. Simon[1], G. Krönke[1], E. Wiebe[1], F. Buttgereit[1]

[1]Charite Universitätsmedizin, Dept. of Rheumatology, [2]Endokrinologikum, Berlin, Germany

Objective: In a previous study, we found daily proton pump inhibitor (PPI) intake to be associated with decreased BMD of the femoral neck and the lumbar spine in patients with inflammatory rheumatic diseases (IRMDs) even after comprehensive adjustment for confounders [1]. The underlying pathomechanism is unclear. Similar findings in other populations in the past were repeatedly explained by decreased intestinal calcium absorption and increased levels of intact serum

PTH [2, 3]. We aimed to assess whether daily PPI use is associated with changes in serum calcium or PTH in patients with IRMDs.

Methods: We used cross-sectional baseline data from the single-center Rh-GIOP cohort [4]. Patients with IRMDs have been prospectively enrolled since 2015. Included patients receive DXA scans, laboratory testing and complete bone-health-related questionnaires. This study excluded patients with hyperthyroidism and multiple myeloma as treatable causes of secondary osteoporosis. The exposure—daily PPI use—was ascertained by a combination of self-reporting by patients and chart review. Co-primary outcomes were serum levels of calcium and PTH. Analyses were based on general linear models, considering complete cases only. As part of a gate-keeping procedure, adjusted analyses were performed for the respective outcomes only if unadjusted analyses identified statistically significant differences between PPI users and non-users. For adjustment, we used (1) a conventional multiple regression approach and (2) inverse probability of treatment weighting. Potential confounders were based on findings from literature review and expert opinion and included age, BMI, self-reported degree of physical activity, smoking status, presence of diabetes mellitus type I or II, chronic kidney disease stage (based on the estimated glomerular filtration rate), cumulative and current glucocorticoid (GC) dose and serum C-reactive protein. For weighting, included covariates were allowed to affect the outcome only [5], so 25-OH-vitamin D deficiency was additionally included. A sensitivity analysis excluded patients with a prior diagnosis of hyperparathyroidism.

Results: 1504 patients (75.3% women; mean age 62.6 ± 13.1 y; 49% with daily PPI use) were included (Table 1). Most patients (79.6%) received vitamin D3 supplements and were within normal ranges as measured by 25-OH-vitamin D3. Missingness regarding exposure and outcome variables was as follows: PPI use: 0%; calcium: 7%; PTH: 17%. In the unadjusted analyses, serum PTH was higher in PPI users (difference = 2.49 pg/mL; 95% CI 0.23–4.74; p = 0.031). Serum calcium was similar in PPI users and non-users and omitted from further adjusted analyses. After adjustment for confounders, statistically significant differences in serum PTH between PPI users and non-users vanished with both adjustment procedures (Fig. 1). In the conventional multiple regression model, age, BMI, chronic kidney disease stage and current GC intake were statistically significantly associated with serum PTH. These results were consistent in the sensitivity analysis which excluded patients with a prior diagnosis of hyperparathyroidism.

Table 1. Patient characteristics stratified by proton pump inhibitor use. Numbers are n (%), mean (standard deviation) or median [interquartile range]. PPI, proton pump inhibitor; GC, glucocorticoid. Figure 1. Differences between proton pump inhibitor users and non-users in serum calcium, PTH and phosphate (numbers are estimated marginal means from general linear models). Error bars represent 95%CIs. PPI, proton pump inhibitor.

Conclusion: In our cohort of patients with IRMDs, the previously observed reduction in bone density with PPI does not seem to be mediated by changes in serum calcium or PTH. Prior studies with such findings might have been subject to confounding.

DOES COXARTHROSIS PREDISPOSES INTRACAPSULAR OR EXTRACAPSULAR HIP FRACTURE?

B. Mur Molina[1], L. A. Hernandez-Sanchez[1], A. Gil González[2], B. Alonso Alvarez[1], S. Miranda Bautista[1], B. Palomino Aguado[1]

[1]Hospital Universitario Ramón y Cajal, [2]Fundación Jiménez Díaz, Madrid, Spain

Objective: Evaluate the relationship between the degree of coxarthrosis and the type of fracture pattern of hip fracture.

Methods: Retrospective analytical study. We included all patients admitted for proximal femur fracture in our Hospital between January 2021 and January 2022. Demographic data, age, functional status (trough Bartel index (BI) and gait evaluation scale), type of femur pattern fracture, presence of coxarthrosis and its severity according to Kellgren's radiological classification scales and Lawrence and Tonnis on the fractured side.

Results: 240 patients were included (78.5% women). The average age was 86.9 y (SD 8.7). Functionally, they presented mild dependence (BI 70, SD 24) and independent ambulation (FAC 3.5 SD 1.3). 83.5% lived at home. The most common types of fracture were displace intracapsular fractures (41.9%) and pertrochanteric (41.5%), followed by subtrochanteric (14.1%) and nondisplaced intracapsular fracture (2.5%). The 34.4% of patients presented minimal coxarthrosis in the x-ray on admission, 45.6% moderate coxarthrosis, 14.5% severe coxarthrosis and 5.4% doubtful coxarthrosis. Of the patients who presented coxarthrosis severe 71.4% suffered an extracapsular fracture (pertrochanteric or subtrochanteric) and 26.6% an intracapsular fracture. Of the patients with non-severe coxarthrosis (85.4%), 52.9% suffered an extracapsular fracture, while 47.1% presented an intracapsular. A relationship was evident statistically significant between the degree of coxarthrosis (severe vs. not severe) and fracture pattern (extracapsular vs. intracapsular) $p = 0.042$.

Conclusion: In our study patients with severe radiological coxarthrosis presented more frequently extracapsular fractures of hip fracture.

P302
CASE OF OSTEOPOROSIS IN MAN DUE TO LOW TESTOSTERONE

B. Rexhepi-Kelmendi[1], M. Rexhepi[1]

[1]Univ. Clinical Centre of Kosova, Rheumatology Clinic, Prishtina, Kosovo, Albania

Men's osteoporosis is a dangerous condition that is underdiagnosed, undertreated, and frequently made worse by fragility fractures and the morbidity and mortality they cause.

Although testosterone plays a very little influence in bone health when compared to other parameters like estradiol levels, male hypogonadism is linked to fragility fractures and low bone mass.

Case report: We describe the case of a 50-year-old man who presents with low back pain, developed several spinal compression fractures several years ago, and was followed from orthopedic surgeon and physiatrist. In 2023 was admitted in Rheumatology Clinic and diagnosed with listhesis at L5/S1, asymmetrical lysis at L3, and a right L5/S1 disc bulge with limited S1 nerve root contact after he presented with chronic low back discomfort. The patient had osteoporosis as determined by DXA, despite the fact that he did not exhibit any clear risk factors for bone fragility (lumber spine: T-score—2.8 standard deviation [SD]; femoral neck: T-score—1.2 SD). Serum 25-hydroxyvitamin D level was deficient (16 ng/mL), testosterone was very low 2.3 ng/mL (3.50–8.60), PTH was 50.87 pg/ml. Rehabilitation and therapeutic medication intervention from rheumatologist and endocrinologist were started.

Conclusion: Even though low back discomfort doesn't seem typical, it should be extensively checked for severe bone diseases if it does not go away.

P303
IMMUNOGENICITY OF INACTIVATED TRIVALENT INFLUENZA SPLIT-VACCINE IN PATIENTS WITH ANKYLOSING SPONDYLITIS AND PSORIATIC ARTHRITIES

M. M. Baranova[1], N. V. Muravyeva[1], B. S. Belov[1]

[1]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia

Objective: To study the immunogenicity of inactivated trivalent influenza split-vaccine in patients with ankylosing spondylitis (AS) and psoriatic arthritis (PsA).

Methods: The open prospective study included 28 patients with AS and 12 patients with PsA; 34 males; mean age 40.5 ± 10.5; mean disease duration was 2.55 ± 1.93 y. At the moment of inclusion in the study, the disease activity in patients with AS according to the BASDAI index was 2.55 ± 1.93; disease activity in patients with PsA according to the DAPSA index – 12.47 ± 7.06. The majority of patients (72.5%) received immunosuppressive therapy: 22 biological disease-modifying anti-rheumatic drugs (bDMARDs) ± conventional DMARDs, 7 methotrexate/leflunomide, 1 tofacitinib. 22 people without immuno-inflammatory rheumatic disease were in the control group (CG). Inactivated trivalent influenza split-vaccine was injected in an amount of 1 dose (0.5 ml) into the deltoid muscle of the shoulder against the background of anti-rheumatic therapy. The level of

antibodies (AT) of class G to hemagglutinin (HA) of influenza A(H1N1), A(H3N2) and influenza B was assessed at baseline (visit I), 1–3 months (visit II) and 6 months (visit III) after vaccination.

Results: At the first, second and third visits the levels of AT, determined in units of optical density, were (M ± σ): 0.58 ± 0.19; 0.78 ± 0.17; 0.71 ± 0.18 for AT to HA of influenza A(H1N1), 0.76 ± 0.26; 1.01 ± 0.21; 0.93 ± 0.22 for AT to HA of influenza A(H3N2), 0.79 ± 0.18; 0.95 ± 0.09; 0.9 ± 0.11 for AT to HA of influenza B. In the CG, similar levels were: 0.88 ± 0.31; 1.04 ± 0.24; 0.95 ± 0.28 for AT to HA of influenza A(H1N1), 0.78 ± 0.32; 0.98 ± 0.31; 0.85 ± 0.3 for AT to HA of influenza A(H3N2), 0.89 ± 0.16; 0.86 ± 0.15; 0.92 ± 0.15 for AT to HA of influenza. After vaccination the levels of AT to HA of influenza A (H1N1), A (H3N2) and B were significantly ($p < 0.006$) higher compared to baseline values in both groups (patients with SpA and CG). The baseline level of AT to HA of influenza A (H1N1) was higher in the CG than in the group of patients with AS and PsA ($p = 0.0006$), later these differences remained (pII = 0.0002, pIII = 0.006). The levels of AT to HA of influenza A(H3N2) and influenza B were comparable between groups at all three visits.

Conclusion: The data obtained indicate sufficient immunogenicity of the inactivated trivalent influenza split-vaccine in patients with AS and PsA, including those receiving immunosuppressive therapy.

P304
FREQUENCY AND STRUCTURE OF SERIOUS INFECTIONS IN PATIENTS WITH SPONDYLOARTHROPATHY TREATED WITH VARIOUS ANTI-RHEUMATIC DRUGS

M. M. Baranova[1], N. V. Muravyeva[1], B. S. Belov[1]

[1]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia

Objective: To determine the frequency and structure of serious infections (SIs, defined as life-threatening infections requiring hospitalisation and intravenous antibiotic therapy) in patients with spondyloarthropathy (SpA) treated with various anti-rheumatic drugs.

Methods: The one-time retrospective study considered the 332 SpA patients (206 ankylosing spondylitis, 98 psoriatic arthritis, 26 undifferentiated SpA, 2 inflammatory bowel disease-related arthritis; 190 males; mean age 39.5 ± 12.1; median disease duration 9 [4;16] y). The patients were interviewed by a research physician with the completion of a unified questionnaire in the period from 2020–2021. Additional information was obtained from medical records. 60% of patients have never smoked. The Charlson comorbidity index was 0 in 157 patients, 1 in 79 patients, 2 in 37 patients, 3 and more in 59 patients. 102 (31%) treated with biological disease-modifying anti-rheumatic drugs (bDMARDs) as monotherapy or in combination with conventional DMARDs/steroids. 112 (34%) have not received immunosuppressive therapy.

Results: The overall incidence of SIs was 63. The most frequent infections (63.5%) were respiratory tract infections (pneumonia, n = 21, including the caused Sars-CoV-2, n = 12; acute bronchitis, n = 2; acute tonsillitis, n = 9; acute sinusitis, n = 5; acute otitis, n = 2; Sars-CoV-2 without lung damage, n = 1), followed by gastrointestinal infections (n = 9), skin and soft tissue infections (n = 6), urinary tract and genital infections (n = 5). Festering arthritis, tuberculosis and neurotoxicosis were single cases. Treatment with tumour necrosis factor inhibitors (OR 2.25, 95% CI 1.22–4.14; p = 0.01) and bDMARDs (OR 1.94, 95% CI 1.06–3.55; p = 0.03) were associated with SIs.

Conclusion: Given the potential danger of SIs, their study in patients with SpA is very relevant. In addition, taking into account the leading place of respiratory tract infections in the structure of SIs in SpA patients, issues of their prevention (including vaccination) require special attention, especially among patients receiving bDMARDs.

P305
IMMUNOGENICITY AND CLINICAL EFFICACY OF 23-VALENT PNEUMOCOCCAL POLYSACCHARIDE VACCINE IN PATIENTS WITH ANKYLOSING SPONDYLITIS AND PSORIATIC ARTHRITIES

M. M. Baranova[1], N. V. Muravyeva[1], B. S. Belov[1]

[1]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia

Objective: To study the immunogenicity and clinical efficacy of 23-valent pneumococcal polysaccharide vaccine (PPV-23) in patients with ankylosing spondylitis (AS) and psoriatic arthritis (PsA).

Methods: The open prospective study included 51 patients with AS and 25 patients with PsA; 55 males; mean age 41.5 ± 11.5; mean disease duration was 11.0 ± 8.4 y. At the moment of inclusion in the study, the disease activity in patients with AS according to the BASDAI index was 4.3 ± 2.0; disease activity in patients with PsA according to the DAPSA index—23.8 ± 17.9. The majority of patients (65.8%) at the time of inclusion in the study received immunosuppressive therapy: 15 methotrexate, 2 leflunomide, 21 TNFα inhibitors (including in combination with conventional disease-modifying anti-rheumatic drugs—DMARDs, n = 9), 11 IL-17 inhibitors (including in combination with conventional DMARDs, n = 5), 1 tofacitinib. PPV-23 was injected in an amount of 1 dose (0.5 ml) into the deltoid muscle of the shoulder against the background of anti-rheumatic therapy. Initially (visit I), 1 (visit II), 3 (visit III) and 12 (visit IV) months after vaccination, the level of antibodies to pneumococcal capsular polysaccharide was assessed using the EIA PCP IgG kit (TestLine Clinical Diagnostics s.r.o., Czech Republic). The clinical efficacy of PPV-23 was evaluated after 12 months.

Results: The dynamics of antibody concentration to pneumococcal capsule polysaccharide is presented in the Table.

Table 1. Concentration of pneumococcal antibodies in patients with AS and PsA, U/ml, Me [25th, 75th percentiles]*.

Visit I (n=71)	Visit II (n=60)	Visit III (n=60)	Visit IV (n=59)
50.7 [23.6; 137.5]	149.4 [59.0; 247.7]	88.1 [37.5; 232.3]	113.2 [41.6; 206.3]

*pI-II,I-III,I-IV≤0,002

After 1, 3 and 12 months after vaccination, a significant increase in the concentration of antibodies to pneumococcal capsular polysaccharide was observed compared with the initial indications. Vaccination against pneumococcal infection was effective in 98.7% of patients: after 12 months of observation, there were no clinical and radiological symptoms of the lower respiratory tract infections. In one patient, 3 weeks after vaccination with PPV-23, the development of bilateral polysegmental pneumonia, presumably of bacterial etiology, was documented. In this patient, the post-vaccination period was insufficient for the formation of a full-fledged immunity. In addition, another genesis of pneumonia is not excluded, since microbiological examination of sputum has not been carried out.

Conclusion: The data obtained indicate sufficient immunogenicity and clinical efficacy of PPV-23 in patients with AS and PsA. Further studies are needed to assess the effect of the therapy on the immunogenicity of PPV-23, as well as the clinical efficacy of this vaccine.

P306
INTERCONNECTION OF BONE LOSS, OSTEOPOROSIS, AND ASEPTIC LOOSENING IN JOINT ARTHROPLASTY: A COMPREHENSIVE REVIEW

B. S. Bolos[1], E. Popescu[2], C. E. Georgescu[2], A. L. Dimitriu[3], R. Ene.[3]

[1]Bucharest Emergency Clinical Hospital-Orthopaedics and Traumatology Dept., Carol Davila Univ. of Medicine and Pharmacology, [2]Bucharest Emergency Clinical Hospital-Orthopaedics and Traumatology Dept., [3]Bucharest Emergency Clinical Hospital-Orthopaedics and Traumatology Dept., Carol Davila Univ. of Medicine and Pharmacology, Bucharest, Romania

Objective: As the world's population ages and life expectancies rise, musculoskeletal disorders and diseases like osteoporosis, fractures, and bone metastases are becoming more common. Bone reactions to orthopedic implant materials are crucial determinants of the implant's success. This article underscores the importance of a holistic approach in managing osteoporosis-related complexities for successful joint replacement.
Methods: Based on a comprehensive review of the literature on the materials and biocompatibility of orthopedic implant, examining factors such as material composition, surface properties and tissue reactions.
Results: Currently, orthopedics uses two main types of implants: osteosynthesis devices for fracture repair and prosthetics for joint replacements. These implants' success relies on their mechanical properties and their interaction with the surrounding biological environment. Because of its great strength, low density, and superior corrosion resistance, titanium and titanium alloys are preferred structural materials. However, alternative metallic alloys not based on titanium are used in orthopedic implants. Because of their great mechanical qualities, excellent wear resistance, and resistance to corrosion, Co and Cr are extremely compatible and frequently utilized as orthopedic implant materials in clinical procedures like hip and knee replacement. (2) Complications related to these orthopedic biomaterials and bone can arise in some clinical outcome from several factors such as: inflammation and infection (3), implant loosening (4), stress shielding (5), allergic reactions (6), poor biocompatibility, material wear and debris (7) which must be correlated with biological status of the patient. The intricate relationship among bone loss, osteoporosis, and aseptic loosening, particularly in the context of joint arthroplasty, nowadays are critically evaluated. Osteoporosis, a systemic skeletal disorder characterized by decreased bone density and microarchitectural deterioration, emerges as a key precursor to bone loss, amplifying the challenges in orthopedic procedures. Aseptic loosening is a complication often observed in joint replacements and is the cause of revision of major arthroplasties. Several theories on the cause of aseptic loosening have been proposed but the most principal factors are wear debris particles that simulate a local inflammatory response and osteoclastic bone resorption, sometimes related to endocrine disorders (4,7). Preoperative assessment of bone health is crucial for osteoporotic patients undergoing joint replacement.
Conclusion: In context of joint replacement, osteoporosis poses challenges related to bone quality, affecting the stability and long-term success of prosthetic implants. Understanding how varied materials influence tissue reactions is crucial for advancing implant technology and optimizing patient outcomes. Orthopedic implants play a pivotal role in restoring function and improving the quality of life for individuals with musculoskeletal conditions. For a metallic material to be suitable as biomaterial, it should meet a series of desired properties ranging from mechanical to biocompatibility (not toxic to environmental cells and tissues, quickly integrated in the body, corrosion resistant).

P307
EFFECTIVENESS OF GLOBAL POSTURAL REEDUCATION IN CHRONIC LOW BACK PAIN

B. S. Bouden[1], Z. S. Zanned[1], R. L. Rouached[1], B. A. Ben Tekaya[1], M. I. Mahmoud[1], S. O. Saidane[1], A. L. Abdelmoula[1]

[1]Rheumatology Dept., Charles Nicolle Hospital Tunis, Tunis, Tunisia

Objective: Chronic low back pain (LBP) is one of the most common musculoskeletal disorders. It represents a healthcare issue as it is often associated with loss of work productivity and thus huge economic burden. Several physiotherapeutic strategies may be used during the treatment. We aimed to compare global postural reeducation (GPR) to a conventional rehabilitation protocol for improving pain, flexibility, function, and psychological impact in patients with chronic LBP.
Methods: A randomized, controlled, clinical trial with a single blinded examiner was conducted. Patients with chronic LBP were randomly allocated to 2 groups: group control received the conventional rehabilitation protocol alone and group GPR received the conventional protocol associated to GPR. Both groups were followed a 3 sessions per week over a period of 4 weeks. Evaluations were performed at the start of the study and 4 weeks after. We used the Oswestry scale to assess disability, visual analog scale (VAS) to evaluate pain and the Hospital Anxiety Depression the (HAD) scale in its Arabic validated version to evaluate depression.
Results: We included 26 patients with common LBP (13 in the control group and 13 in the GPR group). Mean age was 45 y in the control group and 46 y in the GPR group. Mean duration of back pain was 18 months. Mean body weight was 73 kg [60–88] in the control group and 72 kg [60–87] in the GPR group. 84.61% were obese or overweight (BMI $\geq$ 25). All the patients had a sedentary lifestyle. The GPR associated group demonstrated significant statistical improvements in the VAS ($p = 0.01$), lumbar mobility ($p = 0.02$) and Oswestry scale ($p = 0.04$) at the four weeks' evaluation. Likewise HAD score decreased significantly in the GPR group (11–3.6; $p = 0.01$).
Conclusion: GPR associated to the conventional rehabilitation seems to be an effective tool in the management of common LBP and its related psychological impact.

P308
CASE REPORT IN A PATIENT WITH OSTEOGENESIS IMPERFECTA

B. T. Todorova[1]

[1]Univ. Clinic of Endocrinology, Diabetes and Metabolic Disorders, Skopje, North Macedonia

Osteogenesis imperfecta is a genetic disease manifested by increased bone fragility, low bone mass and other manifestations of connective tissue. 85–90% are associated with pathogenic variants of the COL1A1 and COL1A2 genes. It is mostly inherited as an autosomal dominant disorder. The incidence is 1:20,000 live births.
Casereport: A 22-year-old female patient. She was diagnosed with nanosomy at the age of 5, and MRI scan confirmed the diagnosis of

empty sella syndrome with ectopic neurohypophysis. Due to thyroxine deficiency, she was put on levothyroxine. The GnRH activity at the age of 13 was low, therefore puberty was induced with combined oral contraceptives (ethynyl estradiol/drospirenone). The first sign of OI (curvature of the legs) was noticed at the age of 12. She has blue sclerae, a triangular face. Several doses of growth hormone were given due to hypopituitarism. It prevented the occurrence of fractures. However, in the postpubertal period, the patient marks multiple fractures in the upper and lower extremities. (1). Fractures: Condition after a fracture of the right radius in the distal part and the styloid process of the right ulna conservatively resolved with plaster immobilization (2017 year), Fractura et VLC phalangis distalis digiti mani IV lat. dex., Contusio reg. phalangis digiti minimi l. dex. (2015 year), St post conquasatio dig. IV, V manii dex (2015 year), St. post fracturam radii part distalis (2014 year). Positive family history-cousin, nephews of cousin with osteogenesis imperfecta. The DXA scan revealed low bone density, and the genetic testing confirmed the diagnosis of type I OI. The patient was started on treatment with Ibandronic acid and supplements containing calcium, vitamin K and vitamin D3. She responded adequately to the therapy and, at the age of 27, wanted to achieve pregnancy. She was informed about the pattern of inheritance of OI, but still wanted to proceed. The patient was started on GnRH replacement therapy and in-vitro fertilization was performed. She delivered a healthy female newborn via cesarean section on the 39th gestational week.

Conclusion: OI is a diagnostic challenge and can often be masked by other conditions. Prompt evaluation of multiple fractures is essential for establishing the correct causative agent. Multidisciplinary approach is the cornerstone of patient management.

P309
ROLE OF EDUCATIONAL PROGRAMS IN PREVENTION OF FRACTURES IN PATIENTS WITH OSTEOPOROSIS

B. Zavodovsky[1], L. Sivordova[1], Y. Polyakova[1], E. Papichev[1], Y. Akhverdyan[1]

[1]Federal State Budgetary Institution "Zborovsky Research Institute of Clinical and Experimental Rheumatology", Volgograd, Russia

Objective: The problem of osteoporosis (OP) is of great socio-economic importance [1, 2]. The aim of the study. The aim of our study was to evaluate the effect of compliance in patients with osteoporosis on the incidence of new low-traumatic fractures.

Methods: Design: Prospective study in two stages. The analysis included outpatient records of 2236 patients aged 40–92 y.

Results: According to the results of the first stage of the study, it was shown that 715 patients (31.98% of all included in the study) applied once, of which 115 had a history of low-traumatic fractures. These patients made up the I control group. Of these, 509 (71%) had low bone mass. But these patients refused to study at the school for patients and did not seek treatment, 26.51% patients reported new low-traumatic fractures. The remaining 68.02% of all included in the study were fully examined and regularly observed at the Osteoporosis Center. Of these, 82.97% patients had low bone mass. These patients were trained in the school of osteoporosis and were prescribed anti-osteoporotic therapy. Of these, 62.12% fully complied with the recommendations of doctors, these patients constituted the II group (highly compliant patients). Among these patients, only 11 new low-traumatic fractures (1.4%) were registered. Group III (low compliance patients) consisted 37.88% who only partially complied with the recommendations of doctors. In this group, 8.79% were identified new low-traumatic fractures.

Conclusion: The education of patients with OP in schools for patients is of great importance in the prevention of new fractures.

P310
ADVANTAGES OF INTRA-ARTICULAR THERAPY WITH SODIUM HYALURONATE IN THE THERAPY OF GONARTHROSIS

B. Zavodovsky[1], L. Sivordova[1], Y. Polyakova[1], E. Papichev[1], Y. Akhverdyan[1]

[1]Federal State Budgetary Institution "Zborovsky Research Institute of Clinical and Experimental Rheumatology", Volgograd, Russia

Objective: Diseases of the musculoskeletal system (MSS) occupy third place in the structure of morbidity in the Russian Federation. The most common form of MSS pathology is osteoarthritis (OA), and its prevalence is increasing every year [1,2]. We aimed to assess the dynamics of pain syndrome during the sodium hyaluronate solution in comparison with the bioactive concentrate of small sea fish in patients with osteoarthritis (OA) knee joint.

Methods: Prospective, comparative, randomized, single center study, 12 months. The study included 180 patients with gonarthrosis. 50 patients were intra-articularly injected with sodium hyaluronate solution. 30 patients—bioactive concentrate of small sea fish (BACSSF), intra-articularly. 100 patients—BACSSF, intramuscularly.

Results: The most rapid and pronounced decrease in the VAS index was obtained with the use of sodium hyaluronate: in the 1st week by 31%, in the 2nd week—48%, by the 3rd month − 49.1% ($p < 0.001$). The effectiveness of therapy remained after 12 months: the level of the VAS index was − 19.9 mm (− 32%) ($t = 47.23$; $p < 0.001$). In other groups, the speed, degree of pain reduction and duration of the effect were also significant ($p \leq 0.05$), but the effectiveness of therapy was statistically significantly lower. In addition, intra-articular administration of sodium hyaluronate provided a significant reduction in the need for NSAIDs ($p < 0.001$).

Conclusion: Thus, a domestically produced synovial fluid prosthesis, made without the use of animal raw materials, completely purified from hyaluronidases, can be recommended to reduce pain in grade I–III gonarthrosis.

P311
EVALUATING THE IMPACT OF DIVERSE FACTORS ON THE DETERIORATION OF TWO-MINUTE WALKING AND TIME-UP-AND-GO TEST PERFORMANCES: A COMPREHENSIVE EVALUATION OF AT LEAST A 5-YEAR FOLLOW-UP STUDY ON PRIMARY TOTAL KNEE ARTHROPLASTY PATIENTS

P. Ruangsomboon[1], C. Anusitviwat[2], A. Unnanuntana[1]

[1]Dept. of Orthopaedic Surgery, Faculty of Medicine, Siriraj Hospital, Mahidol Univ., Bangkok, [2]Dept. of Orthopedics, Faculty of Medicine, Prince of Songkla Univ., Songkhla, Thailand

Objective: The 2-min walk test (2MWT) and timed up-and-go test (TUG) are performance-based tests (PBTs) used alongside patient-reported outcome measures (PROMs) to assess functional recovery after total knee arthroplasty (TKA). This study examined PBTs and

PROMs over a minimum 5-year follow-up period after TKA and identified factors associated with declined PBTs.
Methods: We tracked a TKA cohort who were previously involved in a prior 2MWT study conducted between 2013–2015. Participants' PROMs (modified WOMAC), modified Knee Score, Oxford Knee Score, Numeric Pain Rating Scale) and PBTs (2MWT and TUG) were evaluated during a minimum follow-up of 5 y. Analysis of variance (ANOVA) assessed PBTs and PROMs at various time points. Survivorship, indicated by no need for subsequent surgery, was analyzed using the Kaplan–Meier (KM) survival estimator. A generalized linear mixed model identified potential risk factors for PBT deterioration.
Results: The latest follow-up time was 7.4 $\pm$ 2.3 y. The mean age of the 126 participants was 77.8 years, with 89.7% women. The 2MWT and TUG exhibited nonsignificant functional decline, while all PROMs remained stable. Only hospitalization for complex medical conditions or recent trauma worsened the PBTs. KM analysis indicated a 98.8% survivorship at 7.6 y.
Conclusion: The PBTs of the patients significantly worsened after hospitalization for complex medical illnesses or recent trauma at the midterm follow-up. These factors should be considered when assessing postoperative function after TKA.

P312
EARLY HIP FRACTURE SURGERY WITHIN 24 HOURS DID NOT REDUCE THE MORTALITY RATE BUT RESULTED IN A LOWER LENGTH OF STAY AND REDUCED THE NEED FOR POSTOPERATIVE PAIN RESCUE

A. Unnanuntana[1], C. Anusitviwat[2], V. Lertsiripatarajit[3], P. Riawraengsattha[3], M. Raksakietisak[3]

[1]Dept. of Orthopaedic Surgery, Faculty of Medicine, Siriraj Hospital, Mahidol Univ., Bangkok, [2]Dept. of Orthopedics, Faculty of Medicine, Prince of Songkla Univ., Songkhla, [3]Dept. of Anesthesiology, Faculty of Medicine, Siriraj Hospital, Mahidol Univ., Bangkok, Thailand

Objective: There was no report on the results of early hip fracture surgery within 24 h and comparison between early and late surgery in patients who underwent hip fracture surgery in Thailand. This study was conducted to explore the postoperative complications and mortality rates following early hip fracture surgery and to compare the outcomes between patients who received early and late hip fracture surgery.
Methods: The hip fracture patients who underwent operative treatment were retrospectively reviewed. Patients aged more than 50 y with at least 12 months of follow-up were included. Patients diagnosed with multiple fractures, fractures from high-energy trauma, pathological fractures, or insufficient data were excluded. The comprehensive management from a multidisciplinary care team was applied to all patients. The postoperative complications, in-hospital, 30-d and 1-y mortality rates after hip fracture surgery were analyzed and compared between the early surgery within 24 h and later than 24 h.
Results: A total of 276 patients were included in this study. Most patients (77.9%) underwent surgery within 24 h. Patients with early surgery had a shorter length of stay (6 (4, 9) vs. 8 (7, 13), $p < 0.001$) and needed fewer rescue analgesia 24-h postoperatively (15.8 vs. 27.9%, $p = 0.032$). The 30-d and 1-y cumulative mortality rates were only 1.1% and 2.5%. The two most common postoperative complications were anemia (43.1%) and acute kidney injury (32.6%). There were no statistically significant differences in mortality rates and postoperative complications between early and late surgery.
Conclusion: Hip fracture patients who underwent surgery with a multidisciplinary care team had low overall mortality rates. Early surgery could shorten the length of hospital stay and reduce postoperative pain. However, surgery within 24 h did not have a positive effect on the mortality and complication rates of hip fracture patients.

GORHAM STOUT DISEASE: PRELIMINARY STUDY ON THE INVOLVEMENT OF THE ENDOCANNABINOID SYSTEM AND AUTOPHAGY IN THIS EXTREMELY RARE SYNDROME

C. Aurilia[1], G. Palmini[2], S. Donati[1], I. Falsetti[1], G. Galli[1], T. Iantomasi[1], L. Funaro[3], G. Picchioni[3], M. L. Brandi[2]

[1]Dept. of Experimental and Clinical Biomedical Sciences, Univ. of Florence, [2]Fondazione Italiana Ricerca sulle Malattie dell'Osso, F.I.R.M.O Onlus, [3]Stabilimento Chimico Farmaceutico Militare (SCFM), Agenzia Industrie Difesa (AID), Florence, Italy

Objective: Gorham-Stout Syndrome (GSD) is an extremely rare bone disease characterized by the onset and progressive osteolysis, especially in the upper part of the skeleton. The pathogenesis is still unknown and present therapies are only intended to limit the syndrome progression. Recently, the PI3K/AKT/mTOR signaling pathway and aberrations in the *ATG101* gene have been identified as potential molecular pathways involved in the GSD pathogenesis. Recently, it has been reported that the Endocannabinoid System (ES) could regulate the autophagy process. Therefore, in this study we investigated the possible involvement of ES and autophagy process in the pathogenesis of GSD.
Methods: First, we established and characterized two primaries cell lines, signed as BMSC-GS-1 and BMSC-GS-2, obtained from a healthy and pathological bone marrow bioptic samples from a GSD patient. After, we evaluated the ALP activity and hydroxyapatite deposition, through fluorimetric assay. Finally, we analyzed the expression levels of ES components and autophagy genes in the two cell lines both under normal conditions and during osteogenic differentiation, by using TaqMan technology.
Results: Both the cell lines show the mesenchymal phenotype. The spectrofluorimetric analyses revealed that BMSC-GS-2 line exhibit lower ALP enzyme activity and hydroxyapatite deposition than the BMSC-GS-1 line. The molecular analyses showed not only the presence of the ES components (i.e., *CNR1*, *CNR2*, and *NAPE-PLD*) in the BMSC-GS1 line, but also a positive modulation of them during the osteogenic differentiation process. Same results have been obtained regarding the expression levels of autophagy genes (i.e., MAPLC3B, BECN1, and ATG5) in both the BMSC-GS-1 and BMSC-GS-2 lines, during osteogenic differentiation.
Conclusion: This preliminary study showed for the first time whether and how ES and the autophagy may be involved in the GSD pathogenesis. To date we are evaluating the possible presence and modulation of ES components expression in BMSC-GS-2 cells during osteogenic differentiation. This will allow to identify new cellular targets that can be used for the development of targeted therapies, such as the ES that could pave the way to the development of therapies focusing on the isolation and use of natural molecules contained in therapeutic Cannabis. Further studies needed.

P314
USE OF PATIENT-REPORTED OUTCOME MEASURES AND PATIENT-REPORTED EXPERIENCE MEASURES WITHIN INTERVENTIONAL STUDIES AIMING AT THE MANAGEMENT OF SARCOPENIA: RESULTS FROM A SYSTEMATIC LITERATURE REVIEW

G. D. Doza[1], S. van Heden[1], F. Oliveira Felix[1], V. Singh[1], C. Beaudart[2]

[1]Dept. of Biomedical Sciences, Faculty of Medicine, Univ. of Namur, [2]Dept. of Biomedical Sciences, Clinical Pharmacology and Toxicology Research Unit, Namur Research Institute for Life Sciences (NARILIS), Faculty of Medicine, Univ. of Namur, Namur, Belgium

Objective: Sarcopenia, age-related muscle decline, affects the mobility and independence of elderly individuals. Its prevalence varies across populations, with severe consequences such as increased risk of falls, fractures, depression, and even mortality, ultimately reducing overall quality of life. Current interventions involve a multifaceted approach, including nutrition, exercise, and pharmacology. The global increase in life expectancy emphasizes the growing importance of sarcopenia as a public health challenge. Patient-reported outcome measures (PROMs) and Patient-reported experience measures (PREMs) provide crucial insights for evaluating intervention effectiveness. The aim of this review is to identify all sarcopenia-designed interventional studies that used a PROMS/PREMS as the primary or secondary outcome, identify the different PROMS/PREMS used within those studies and summarize the effects of sarcopenia-designed interventions on PROMS/PREMS of sarcopenic participants.
Methods: A systematic search of databases (Medline, EMBASE, Review- Cochrane Central of Register of Controlled Trials and PsychINFO (Via Ovid)) was conducted in September 2023. The review followed the Preferred Reporting Items for Systematic Review and Meta-Analyses (PRISMA) statement, and the protocol was registered on the Open Science Framework (https://osf.io/zxgwm/). Risk of bias was measured using the Cochrane 2.0 risk of bias tool.
Results: The systematic review identified 17 RCTs as sarcopenia-designed interventional studies that used a PROM as primary or secondary outcome. PROMs were exclusively used in these studies (i.e., no PREMS were reported) and covered the assessment of various aspects, including quality of life (15/17, 88.2%) depressive symptoms (3/17, 17.6%) sleep quality/disturbance (2/17, 11.8%) and loneliness/social isolation, daytime sleepiness, insomnia impact (all reported in 1/17, 5.9%). Except of SarQoL, which is a specific health-related quality of life questionnaire for sarcopenia, all other PROMs identified were generic. Interventions included medication (11.8%), nutritional supplementation (35.3%), exercise Programs (23.5%) and a combination of exercise and nutritional supplements (29.41%). None of the included RCT contained any high risk of bias. The effect of sarcopenia-designated interventions on PROMs showed considerable heterogeneity.
Conclusion: heterogeneity in outcome measures underscores the need for standardization in sarcopenia research by developing a Core Outcome Set (COS). COS in sarcopenia studies would ensure consistent and comparable findings, ultimately enhancing the reliability and effectiveness of interventions.

P315
TOWARDS DEVELOPING A CORE OUTCOME SET (COS) FOR SARCOPENIA INTERVENTION STUDIES

S. van Heden[1], O. Bruyère[2], J.-Y. Reginster[2], M. Surquin[3], D. Sanchez-Rodriguez[3], C. Beaudart[1]

[1]Clinical Pharmacology and Toxicology Research Unit (URPC), NARILIS, Dept. of Biomedical Sciences, Faculty of Medicine, Univ. of Namur, Namur, [2]WHO Collaborating Center for Public Health Aspects of Musculo-Skeletal Health and Ageing, Division of Public Health, Epidemiology and Health Economics, Univ. of Liège, Liège, [3]Medicine Dept., Geriatrics Dept., Brugmann Univ. Hospital, Université Libre de Bruxelles, Brussels, Belgium

Objective: In recent years, there has been a significant surge in clinical research focused on sarcopenia, driven by its recognized reversibility. The interest in developing effective interventions is underscored by the need for well-defined outcomes, currently impeded by the absence of a standardized set of outcomes, known as Core Outcome Sets (COS). Utilizing COSs harmonizes assessment criteria, facilitating the comparative analysis of diverse interventions. Establishing a sarcopenia-specific COS is crucial to augment the precision and effectiveness of clinical trials in this field. This project aims to develop a COS for intervention studies in sarcopenia, designed to address unmet needs in sarcopenia research and clinical practice and to pave the way for the development of effective treatments for the disease.
Methods: The methodology for this study adheres to the recommendations outlined in COS-STAD and COS-STAP. The study protocol has been registered in the database of the COMET initiative (https://www.cometinitiative.org/Studies/Details/2991). A Working Group (WG) will be assembled to collaborate on this project, consisting of individuals with sarcopenia, clinicians, and researchers. Subsequently, the study will progress through three key phases. Firstly, the development of an outcome list will be pursued through two distinct methods: a systematic literature review following PRISMA guidelines and semi-structured interviews with 5 to 10 participants aged 65 years and older, diagnosed with sarcopenia. The literature review will comprehensively identify potential outcomes reported in phase III clinical trials on sarcopenia, while the interviews will delve into the values and preferences of the participants. Following the outcome list development, a two-round modified Delphi process will be initiated, engaging key stakeholders to identify and prioritize relevant outcomes. Finally, a consensus meeting involving the Working Group will be convened to validate the results.
Results: Ongoing project, results are not available yet.
Conclusion: A core outcome set of sarcopenia would improve the efficiency of research and allow direct and indirect comparisons of sarcopenia clinical trials. This protocol aims to define the scope and methodology, stakeholder involvement, procedures and consensus processes of the COS for sarcopenia intervention trials. Our ultimate goal is to improve the lives of people with sarcopenia.

P316
THE SOCIETAL COSTS AND HEALTH UTILITIES OF KNEE OSTEOARTHRITIS IN THE NETHERLANDS

Charlotte Beaudart[1−2], Annelies Boonen[3−4], Tim A E J Boymans[5], Pieter J Emans[5], Mickael Hiligsmann[6]

[1]Department of Biomedical Sciences, Clinical Pharmacology and Toxicology Research Unit, Namur Research Institute for Life Sciences (NARILIS), Faculty of Medicine, University of Namur, Namur, Belgium, [2]WHO Collaborating Centre for Public Health Aspects of Musculo-Skeletal Health and Ageing, Division of Public Health, Epidemiology and Health Economics, University of Liège, Liège, Belgium, [3]Department of Internal Medicine, Division of

Rheumatology, Maastricht University Medical Centre, Maastricht, Netherlands, [4]Care and Public Health Research Institute (CAPHRI), Maastricht University, Maastricht, Netherlands, [5]Department of Rheumatology, Maastricht University Medical Center, Maastricht, The Netherlands, [6]Department of Health Services Research, Care and Public Health Research Institute (CAPHRI), Maastricht University, Maastricht, The Netherlands

Objective: To estimate the average annualized healthcare costs, societal costs and health utilities associated with knee osteoarthritis using data from the Maastricht Study (DMS).
Methods: The twelve-month costs per patient and health utilities related to knee osteoarthritis for the year 2022 were measured utilizing data from the DMS, an observational, prospective, population-based cohort developed in the South of the Netherlands, with an overrepresentation of individuals with diabetes. Participants who completed the baseline assessment of the DMS and for whom all relevant variables for these analyses were collected were included. The identification of knee osteoarthritis was based on the clinical criteria developed by the American College of Rheumatology (ACR). Costs were assessed throughout a resource-use questionnaire, completed by participants. Cost prices were based on Dutch costing guidelines. Healthcare costs, non-healthcare costs, total societal costs and health utilities (measured by EQ5D) were compared between patients with knee osteoarthritis and those without. Analyses were adjusted on age, gender (female), educational level (high) and presence of type II diabetes (yes).
Results: 7928 individuals were included in our analyses (50.6% of women, mean age of 59.4 years, 20% of people with type II diabetes) of whom 970 (i.e. 12.2%) were identified with knee osteoarthritis. Patients with knee osteoarthritis were more often of female gender, older and with lower educational levels compared to patients without knee osteoarthritis. Moreover, they had a higher prevalence of diabetes (i.e. 29.1%) compared to those without knee OA (i.e.18.8%). Globally, the presence of osteoarthritis was significantly associated with higher use of general practitioners, medical specialists and paramedics as well as higher paid home care and informal care received and higher productivity losses (all p-values < 0.05 both in univariate and multivariate models). This resulted into significantly higher annual societal costs per patient for patient with knee osteoarthritis (i.e. €4747.4 (95% CI 3736.4; 5985.4)) compared to those without knee OA (i.e. €2633 (95% CI 2345.6; 2942.6), $p < 0.001$)). Lower utility values were found for patients with knee osteoarthritis (i.e. 0.83 (95% CI 0.82; 0.84)) compared to those without knee osteoarthritis (i.e. 0.92 (95% CI 0.91; 0.92), $p < 0.001$). When stratifying the population based on the presence of type II diabetes, knee osteoarthritis remains associated with higher costs and lower health utilities, even among patients suffering solely from knee osteoarthritis without diabetes.
Conclusions: These findings emphasize the substantial economic and health burden associated with osteoarthritis.

P317
LESSONS FROM RICO: RISK COMMUNICATION IN OSTEOPOROSIS STUDY

C. Beaudart[1], M. Sharma[2], S. Silverman[3], M. Hiligsmann[4]

[1]Clinical Pharmacology and Toxicology Research Unit (URPC), NARILIS, Dept. of Biomedical Sciences, Faculty of Medicine, Univ. of Namur, Namur, Belgium, [2]The OMC Research Center, Beverly Hills, USA, [3]Cedars-Sinai Medical Center, UCLA, Los Angeles, USA, [4]Dept. of Health Services Research, Care and Public Health Research Institute (CAPHRI), Maastricht Univ., Maastricht, Netherlands

Objective: There is a close and strong relationship between the quality of fracture risk communication and the initiation of osteoporosis treatment and adherence. RICO was a global study, run in 2022, involving 332 participants at risk of fracture aiming to improve fracture risk communication and to understand patients' willingness to initiate treatment based on their perception of fracture risk.
Methods: Semi-structured interviews were conducted in 11 centres, 9 countries around the world (UK, Belgium, the Netherlands, Spain, Japan, Canada—Hamilton and Montreal, Argentina, Mexico, USA—Los Angeles and Spokane). The participants' Fracture Risk Decision Point (FRDP) was established as the fracture risk at which a participant was willing to initiate therapy. For that, participants were shown 8 distinct scenarios—each with a hypothetical FRAX score and a standard 40% fracture risk reduction upon use of a medication with minor, transient side effects. In each scenario, participants were asked whether they would hypothetically agree to initiate the medication.
Results: The major finding of RICO study was that participants expressed a strong willingness to receive communication about their fracture risk. Globally, they preferred visual to numeric presentations of FRAX data. Among the format presented, colored stoplight was preferred to icon array. Median FRDP was below the national treatment threshold in all eight countries which use FRAX®-based treatment thresholds in a clinical setting. Moreover, 75.7% of all participants demonstrated FRDP below their respective treatment threshold. Patients who demonstrated higher levels of numeric literacy also showed a significantly higher median FRDP (i.e. 10%) compared to those with a lower level of numeric literacy (i.e. FRDP of 5%, $p < 0.001$). FRDP was not influenced by age or history of fracture. Among participants who agreed to initiate medication with an hypothetical 40% of fracture risk or less, a weak and negative correlation was found between FRDP and age ($r = -0.153$, $p = 0.007$).
Conclusion: Fracture risk communication with FRAX may be improved with visual presentation and use of both 2- and 10-year time frame. The RICO team is currently developing a fracture risk communication tool.

P318
A MULTIMODAL APPROACH TO AMELIORATE ACUTE PHASE REACTION INDUCED BY ZOLEDRONIC ACID

C. Chen[1], L. Kang[2], S. Lin[1], T. Lee[1], C. Ho[1]

[1]Kaohsiung Medical Univ., [2]National Cheng Kung Univ. Hospital, Kaohsiung, Taiwan

Objective: Zoledronic acid is an effective medication for anti-osteoporosis. However, acute phase reaction (APR) following zoledronic acid infusion is a problematic issue that hinders the drug adherences. To overcome this, a case–control retrospective study was conducted to validate the effectiveness of our novel protocol, which consist of glucocorticoids, NSAIDs and acetaminophen, on APR prevention.
Methods: This case–control retrospective study was conducted to validate the effectiveness of our novel protocols of multimodal anti-APR approaches for APR alleviation induced by zoledronic acid. The protocol includes intravenous glucocorticoid before zoledronic acid and oral glucocorticoid and NSAID for 3 d.
Results: There were 467 patients in the protocol group and 407 patients in the control group. There is no significant difference in the incidence of APR. After administration of protocol, 66 (14.13%) patients who experienced APR had their symptoms controlled completely, while 21 (4.49%) patients had their symptoms partially relieved. There were only 12 (2.57%) patients had their APR symptoms persisted after administration of the prevention protocol. Overall, 434 out of 467 patients (92.93%) are free from symptoms of

APR in the protocol group; while 339 out of 407 patients (83.29%) are free from symptoms of APR in the control group.
Conclusion: A multimodal anti-APR approaches of glucocorticoids, NSAIDs, and acetaminophen can effectively prevent and control zoledronic acid-induced APR.

P319
BONE PROTECTION IN A FRACTURED WORLD: A CLOSED LOOP AUDIT OF BONE PROTECTION PRESCRIPTION POST HIP FRACTURE AT DISCHARGE AND 12 MONTHS ON IN A MODEL FOUR HOSPITAL IN THE WEST OF IRELAND

C. Conlon[1], M. S. Memon[1], C. Small[1], R. Waters[1]

[1]Univ. Hospital Galway, Galway, Ireland

Objective: To assess practice of prescribing of bone protective treatment in a post hip fracture patient cohort at the time of discharge and at one year post discharge.
Methods: A closed loop audit in the form of a retrospective review of prescribing of bone protective medications post hip fracture was undertaken in a model four hospital in the west of Ireland. The Plan-Do-Study-Act tool was utilised to guide this audit, the standard being audited against was the fifth Irish Hip Fracture Standard. Each cycle of the audit looked at a one month period namely August 2021 and subsequently August 2022 with a follow up at one year to assess adherence. The inclusion criteria being aged sixty-five or above with a hip fracture within the time period of the study, those with fracture of shaft of femur were excluded. The data was analysed using Microsoft Excel and ethical approval was obtained in advance.
Results: There were 32 patients in the first cycle of the audit and 18 patients in the second cycle. The majority of the cohort in the first and second cycle were female, 23(74%) and 16(89%), with a mean age of 81 years. The first cycle demonstrated that 21(65%) were prescribed bone protective treatment with 8(31%) on treatment one year post hip fracture. The second cycle demonstrated that 9(50%) were initiated on bone protection on discharge with 7(78%) on treatment at the one year juncture.
Conclusion: This timely audit demonstrates suboptimal adherence to the Irish Hip Fracture Standards and will serve as the impetus for redesigning our orthogeriatric service with an emphasis on education of staff and ensuring prescription of bone protective medications at the time of discharge. Notably the second cycle demonstrates that whilst prescription of bone protection has disimproved adherence for those prescribed these agents has in fact improved since the first cycle. The results of this audit will drive change in the orthogeriatric service.

P320
COMPARATIVE EFFECTS OF ROMOSOZUMAB VERSUS TERIPARATIDE IN POSTMENOPAUSAL WOMEN WITH INTERTROCHANTERIC FRACTURE AFTER SURGERY: A RETROSPECTIVE SINGLE CENTER ONE-YEAR STUDY

C. Coppola[1], A. Randazzo[2], S. Balzano[3], D. Agnusdei[4]

[1]Dept of Orthopedics & Traumatology, Trauma Center-Ospedale del Mare, General Hospital, ASL NA1 Center, Italian NHS, Naples, [2]Dept of Rehabilitation Medicine-Ospedale del Mare, General Hospital, ASL NA1 Center, Italian NHS, Naples, [3]Dept. of Economics & Law, Univ. of Cassino (FR), Cassino, [4]Indipendent Scientific Consultant, Siena, Italy

Objective: In the elderly, the occurrence of a proximal femur fracture is a serious event, charged with a 20–33% of mortality risk within 1–2 years after surgery; furthermore, within one year from the event, there is an increased risk (up to 55%) for a further fragility fracture. In order to prevent this fracture cascade, international scientific societies and health authorities guidelines suggest to start bone anabolic therapy immediately after surgery. Romosozumab (ROMO) is a monoclonal antibody that inhibits Sclerostin (anabolic effect) and increases RANKL expression (antiresorptive effect), thus increasing bone mass. Teriparatide (TPTD), a N-terminal rhPTH peptide, was the first anabolic agent, approved since 2003 for the treatment of severe Osteoporosis. The aim of the present study is to compare the effects 12 months of these two treatments in osteoporotic women with intertrochanteric fractures, on BMD and other functional parameters.
Methods: The study was performed from January 2023 for 12 months at the Trauma Center of "Ospedale del Mare" in Naples. Sixty postmenopausal women, age (67–83), were selected to enter the study; other inclusion criteria were: BMI 23–26, BMD T-score between -2.5 and -4, ASA score 2, and AO31 A2-A3 femoral fracture type fixed by nail. The study population was divided into two groups: 30 patients were treated with ROMO 210 mg/month sc, and 30 patients with TPTD 20 mcg/day, respectively. BMD, by DXA, was measured after surgery, and at the end of treatment period; functional parameters, such as Timed Up and Go (TUG) test, SF-36 Health Status Questionnaire and Self-reported Hip Pain, by modified Harris Pain score, were measured at 3, 6, and 12 months of treatment.
Results: In the ROMO group, compared to baseline, BMD increased by 11.2% at the lumbar spine (LS), 3% at the total hip (TH), and 3.1% at the femoral neck (FN). In the TPTD group BMD increased by 6% at LS, and a decrease of 0.5%, and 0.2% at TH and FN, respectively. In the ROMO group, the TUG test showed a reduction between 15 to 30 s after 3, 6 and 12 months of treatment compared with the TPTD group. Self-reported hip pain, measured by the modified Harris Hip pain score, significant improved ($P < 0.0001$), as well as the SF-36 questionnaire ($P = 0.003$), expression of the Health-related QoL. During the treatment period, in both groups there were no drug related side effects.
Conclusion: This is the first study to show a clinical and functional comparison in osteoporotic patients, after hip surgery, of two anabolic treatment, ROMO and TPTD. The results clearly show that both drugs are safe and effective in the secondary prevention of further fractures; in particular, the ROMO group showed a significant increase in BMD, and a significant functional recovery, compared with TPTD group. In these specific population, based on our results, ROMO should be then considered as first choice treatment, in order to get stronger metabolic and functional outcomes.

P321
HEALTH-RELATED QUALITY OF LIFE IN SARCOPENIA: CONTENT VALIDITY OF THE SARQOL QUESTIONNAIRE

C. Demonceau[1], B. Voz[2], O. Bruyère[1], J.-Y. Reginster[1], C. Beaudart[3]

[1]WHO Collaborating Centre for Public Health Aspects of Musculo-Skeletal Health and Ageing, Division of Public Health, Epidemiology and Health Economics, Univ. of Liège, Liège, [2]Dept. of Public Health, Univ. of Liège, Liège, [3]Clinical Pharmacology and Toxicology Research Unit, NAmur Research Institute for LIfe Sciences (NARILIS), Dept. of Biomedical Sciences, Faculty of Medicine, Univ. of Namur, Namur, Belgium

Objective: To enhance the evidence supporting the content validity for the Sarcopenia & Quality of Life (SarQoL) questionnaire, a patient-reported outcome measure specifically designed for assess health-related quality of life in individuals with sarcopenia.
Methods: Individual semi-structured interviews targeting the impact of sarcopenia on quality of life were conducted with 17 older Belgian older adults (i.e., aged 65 years and older) who met the EWGSOP2

criteria for the diagnosis of sarcopenia. Afterwards, structured cognitive interviews were conducted to rate the relevance of the current format of SarQoL. Transcripts were qualitatively analysed thematically according to the seven dimensions of the SarQoL questionnaire (i.e., physical and mental health, locomotion, body composition, functionality, activities of daily living, leisure activities and fears).

Results: The majority of the concepts elicited during the semi-structured interviews fit within existing SarQoL dimensions. Importantly, the seven dimensions of SarQoL were consensually considered as relevant by the participants. Some new emergent concepts were identified. While many of them (i.e. fear of the future, need of assistance with particular activities of daily living) could be considered as enrichments of existing dimensions or sub-concepts, other new concepts may highlight two potential dimensions not covered by SarQoL (i.e. self-realization and the adaptation/use of strategies). Cognitive interviews also highlighted that SarQoL items and instructions were clear and comprehensible.

Conclusion: SarQoL, in its current form, demonstrates good evidence of content validity for assessing health-related quality of life in patients with sarcopenia. To ensure SarQoL remains applicable across various individuals with sarcopenia, it is crucial to strike a balance between minimizing patient burden and considering the relevance of new elements. Taking this into account, we do not recommend adding new items or dimensions to SarQoL. Instead, we suggest improving the assessment of quality of life by concurrently incorporating additional validated scales. This would be beneficial for researchers or clinicians who aim to address dimensions such as self-realization and the utilization of adaptive strategies when evaluating the quality of life in a specific targeted sarcopenic population.

P322
HISTOLOGICAL, CLINICAL AND INSTRUMENTAL EVALUATION OF SARCOPENIA IN OSTEOARTHRITIC PATIENTS

C. Greggi[1], M. Montanaro[1], A. Chiavoghilefu[2], S. Gino Grillo[2], C. Prezioso[2], A. Mauriello[1], R. Iundusi[1], E. Gasbarra[1], U. Tarantino[1]

[1]Univ. of Rome "Tor Vergata", [2]Policlinico Tor Vergata, Rome, Italy

Objective: Among the major aging-related diseases of the musculoskeletal system are osteoarthritis and osteoporosis. Very often, these two conditions may be accompanied by a concomitant progressive and generalized loss of skeletal muscle mass and strength, known as sarcopenia. Therefore, the purpose of the present study was to investigate muscle quality and function in osteoarthritic patients, to identify any differences from patients also suffering from osteoporosis or osteopenia.

Methods: Patients undergoing prosthetic hip replacement surgery affected by osteoarthritis (OA) and patients affected also by osteoporosis or osteopenia (OA/OP/Ope) were enrolled. The Harris Hip Score (HHS) was calculated to assess joint function degree, and the standard diagnostic procedure for sarcopenia was then followed. Muscle quality in terms of contraction velocity was also assessed by tensiomyographic examination, and finally, histomorphometric examination, and immunohistochemical analysis (IHC) for identification of type II muscle fibers were performed.

Results: HHS was lower in the OA/OP/Ope patients' group. Evaluation of sarcopenia by performing the 30'' chair stand test and the Timed Up and Go Test (TUG) showed lower muscle strength in the same group of patients. Similarly, performance of the Short Physical Performance Battery (SPPB) showed a lower level of muscle performance in the OA/OP/Ope group than in the OA patients. Tensiomyographic analysis revealed that the muscle contraction capacity of OA/OP/Ope patients was lower than that of the OA group. Confirming these findings, histological analysis showed that the muscle tissue of this group of patients was characterized by reduced-diameter muscle fibers, a larger amount of adipose tissue and larger inter-fiber spaces. In addition, the percentage of type II fibers was lower in the OA/OP/Ope group than in the OA patients.

Conclusion: In OA patients, the concomitant osteoporotic condition worsens the degree of hip joint function and muscle qualitative and functional status. In addition, the tensiomyograph proves to be a potential and valuable new instrumental strategy for the diagnosis of sarcopenia, since in a noninvasive modality, it appears to confirm the finding obtained by invasive modality on muscle biopsy.

P323
RELATION BETWEEN ADIPONECTIN LEVELS AND BONE LOSS IN ANOREXIA NERVOSA: A PROSPECTIVE STUDY

C. Guillot[1], C. Philippoteaux[1], O. Ghali[2], J. Vignau[3], C. Chaveau[2], B. Cortet[1]

[1]Univ. of Lille/Rheumatology/Salengro Hospital/Lille Univ. Hospital, Lille, [2]Univ. of Littoral Cote d'opale/Research/Salengro Hospital/Lille Univ. Hospital, Boulogne, [3]Univ. of Lille/Psychiatry/Fontan Hospital/Lille Univ. Hospital, Lille, France

Bone loss in anorexia nervosa is a complex phenomenon with only partial understanding of its underlying mechanisms. Recent studies suggested the involvement of bone marrow adiposity and adipokines, such as adiponectin, in bone involvement.

To explore the potential relationship between adiponectin levels and bone parameters, we conducted a prospective observational study in a cohort of anorexic patients at the Lille University Hospital (France) from September 2013 to December 2016. The study involved three stages: V0 (inclusion), V1 (midpoint at 1 or 2 years post-inclusion), and V2 (end of follow-up at 5 or 6 years). At each stage, BMD measurements, biological tests (including total and high molecular weight (HMW) adiponectin), and clinical assessments were performed.

A total of 184, 91, and 55 patients were evaluated at V0, V1, and V2, respectively. The mean age at enrollment was 23 years, with an average disease duration of 5 years. Amenorrhea was present in 72.3% of patients. Mean BMI was 16.8 kg/m^2 at V0, 17.8 kg/m^2 at V1, and 18.2 kg/m^2 at V2. Osteoporosis prevalence in BMD was 70/184 patients (n = 38%), 38/91 patients (n = 41.8%), and 38/55 patients (n = 40%) at V0, V1, and V2, respectively, with a predominant involvement of the femoral neck. For all patients, BMD at the total hip decreased significantly from V0 to V2 (-0.009 ± 0.008 g/cm^2 to 1.05%, $p < 0.0001$), whereas BMD at the lumbar spine increased significantly (0.043 ± 0.010 g/cm^2 or + 4.92%). Adiponectin data were collected for 106, 66, and 51 patients at V0, V1, and V2, respectively. No significant differences in adiponectin levels were observed between V0, V1 and V2. Moreover, adiponectin level was independent of bone status. In multivariate analysis, at baseline, several factors were associated with osteoporosis at the lumbar spine including BMI (p = 0.02), bone alkaline phosphatase level (p = 0. 01) and adiponectin level (total and HMW (p = 0.01). At the total hip site, duration of amenorrhea (p = 0.03), BAP level (p = 0.02) and adiponectin level total and HMW (p = 0.02) were found.

Extended follow-up demonstrated bone loss at the total hip in anorexic patients, despite weight gain. Factors associated with these findings included adiponectin levels (total and HMW), suggesting the need for further research to elucidate the role of adiponectin in anorexia nervosa related bone loss.

P324
FROM ATHENS TO LONDON: THE 15-YEAR HISTORY OF IOF ANTHEM POWERED BY JOHAN SEBASTIAN BACH

C. Günther[1]

[1]Orthopädische Fachklinik, Dept. Osteology, Schwarzach, Germany

Objective: In order to increase public awareness and knowledge about the osteoporosis, novel measures are necessary. I use the "ESCEO-IOF Song" for many years in the fight against osteoporosis. On its fifteenth anniversary, I would like to put a spot on my experiences with it.

Methods: 1. In front of the J.S. Bach memorial in Leipzig I had an idea on October 25, 1992, which I shortly presented in a one minute presentation at the Osteoporosis World Congress 1993 in Hong Kong and named it "J.S. Bach Rule of Osteoporosis Prevention". 2. At the World Osteoporosis Day on October 20, 2007, I presented an "IOF-Osteoporosis-Song" in a German version in Bad Füssing, Germany, which was using the IOF topics of the World Osteoporosis Days from 2004–2008. These topics were converted into lyrics and music, arranged by Gert Fischer (Leipzig) and musically accompanied by the brass ensemble of the world famous "Leipziger Gewandhausorchester".

Results: After agreement of the "Neue Bach-Gesellschaft Leipzig (NBG)" and the choirmaster of the "Leipziger Thomanerchor" Prof. Georg Christoph Biller (September 20, 1955–January 27, 2022) I used the "Bach Rule" in over 1900 osteoporosis lectures. The NBG published this rule for its 3800 members worldwide. In a pilot survey of 350 listeners to this osteoporosis lecture, 349 (99%) liked this "Bach Rule". The German version of IOF-Song 2007 has been published in the magazine "Mobiles Leben" (4/2007) of the "Kuratorium Knochengesundheit", a former member of the IOF. The song was also presented at the 2nd International Educational Symposium in Bratislava/Slovakia on September 30, 2008 and the English version had its world premiere at ECCEO 9 in Athens, Greece on March 18, 2009. The song was also translated into Chinese at the 18th International Osteoporosis Symposium in Beijing/China at April 17, 2010. And we produced a CD "IOF-Song—Fighting Against Osteoporosis". Ten years later, I reported on the Ten Years Of Experience In Fighting Osteoporosis With the ESCEO-IOF-Song Powered By Johann Sebastian Bach at the poster session of the WCO-IOF ESCEO on April 6, 2019 in Paris, and was then invited by Prof. Kanis to the opening ceremony of the WCO in Barcelona in 2020 and in Berlin in 2021, both of which fell victim to COVID-19.Ultimately, I was supposed to perform the "ESCEO-IOF song" at the IOF board meeting on May 4, 2023 at the WCO IOF-ESCEO in Barcelona as "IOF Anthem", but this was prevented by a rib fracture that I suffered in the immediate run-up to the congress. Meanwhile I used the "ESCEO-IOF-Song against Osteoporosis" in the last fifteen years since 18th March 2009 in over 200 lectures with a total of more than 50 000 listeners, and it is a great honor and pleasure for me to finally be able to perform the IOF Anthem at the opening ceremony of the WCO IOF-ESCEO 2024 on April 11, 2024 at 6:55 p.m. at the Hilton London Metropole—accompanied by playback by the "Brass ensemble of the Leipzig Gewandhaus Orchestra" under the direction of Karl-Heinz Georgi.

Conclusion: 1. The "J.S. Bach Rule for Osteoporosis Prevention" has proved itself in almost two thousand lectures and therefore, hopefully increased the public awareness of the disease. 2. The German version of the "IOF-song 2007" shows a very good acceptance, and many osteoporosis support groups have asked for the text and tune, using it for education and raising public awareness. 3. The English version of the "ESCEO-IOF-Song against Osteoporosis" at ECCEO 9 in Athens—incl. the CD—experienced a good acceptance and was published on the website of IOF and ESCEO (see: Google: ESCEO—IOF Song Part 2). 4. Last but not least I hope, that the "Bach-Rule of Osteoporosis Prevention" and the "IOF Anthem" can also remember my honoured surgical colleagues from all over the world: "Don´t forget the prevention of osteoporosis!" 5. "Music is a greater revelation than all wisdom and philosophy," says Ludwig van Beethoven!

P325
THE LIGNANS METABOLITES, ENTEROLACTONE AND ENTERODIOL, MAY PREVENT OSTEOPOROSIS AND OSTEOCLAST DIFFERENTIATION BY AKT SIGNAL PATHWAY

C. H. Hou[1], P. C. Chen[2]

[1]Dept. of Orthopedic Surgery, National Taiwan Univ. Hospital, [2]School of Life Science, National Taiwan Normal Univ., Taipei City, Taiwan

Objective: Bone remodeling is a physiological process crucial for maintaining bone health, ensuring calcium balance, and strengthening bones. It involves three main cell types: osteoclasts, osteoblasts, and osteocytes. Osteoporosis increases the risk of fractures, raises mortality rates, reduces quality of life, and leads to increased healthcare costs. Current treatment strategies primarily focus on inhibiting osteoclast activity, such as bisphosphonates and hormone replacement therapy/selective estrogen receptor modulators (SERMs), but these methods have potential risks. Lignans, a type of phytoestrogen, mimic estrogen's effects and have a certain degree of bone-protective properties. Upon ingestion in the human digestive system, lignans are metabolized by gut microbiota, leading to the formation of two significant byproducts known as enterodiol (END) and enterolactone (ENL). However, the actual effect of these metabolites on bone loss prevention remains unclear.

Methods: The cell cytotoxicity of END and ENL was evaluated by alamar blue cell viability assay. The osteoclasts precursor cells RAW264.7 were stimulated with RANKL (50 ng/mL) to induce osteoclastogenesis, with the addition of different concentrations of END and ENL (0–100 μM). The signal pathway involved in the effects of END and ENL on osteoclastogenesis was assessed by western blot.

Results: Our preliminary findings indicate that END and ENL possess the ability to inhibit osteoclast differentiation, suggesting their potential in treating osteoporosis. Additionally, our observations reveal that when administered simultaneously, END and ENL significantly suppress Akt signaling pathways compared to the MAPK pathway during osteoclast differentiation.

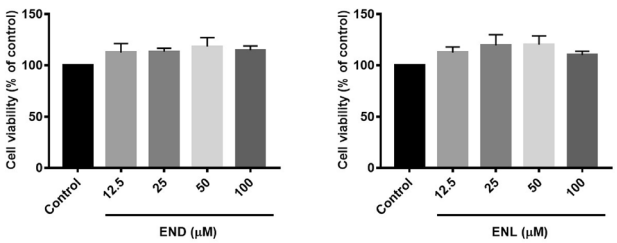

Figure 1. The cell viability of END and ENL on RAW264.7.

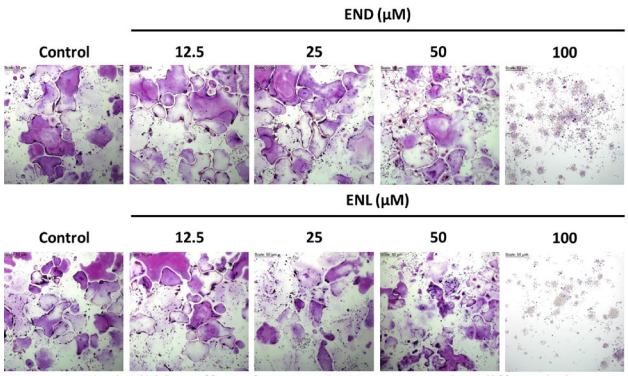

Figure 2. The inhibition effect of END and ENL on osteoclast differentiation.

Conclusion: This research project is dedicated to unraveling the underlying molecular mechanisms responsible for the inhibitory effects of END and ENL on osteoclast differentiation, suggesting its potential application on osteoporosis therapy.

P326
OSTEOPENIA: MORE ROUTES TO INCREASE BONE FRAGILITY?

C. Horvath[1], E. Csupor[2], E. Hosszu[3], T. Leel-Össy[1], S. Meszaros[1]

[1]Dept. of Internal Medicine & Oncology, Semmelweis Univ., [2]Budavar Health Center, [3]2nd Dept. of Pediatrics, Semmelweis Univ., Budapest, Hungary

BMD derived T-score below -2.5 is considered as diagnostic threshold for osteoporosis. However, former publications issued that 40% of fragility fractures occur in patients with osteopenia (T-score between -1 and -2.5). Adequate treatment is barely available for osteopenic patients, as -2.5 or lower T-score is required to initiate therapy, although antiresorptive drug treatment has been proven efficient in osteopenia as well.

Our trial included 2028 osteopenic women (66.8 ± 10.3 y) suggested to bone densitometry. History of fragility fractures was recorded (n = 787). DXA scans were performed (GE Lunar Prodigy, WI, USA) and BMD (g/cm^2) was assessed at the L1-L4 vertebrae, hip and radius. At least one of the three sites needed to result in osteopenia while patients with T-score below − 2.5 at any site were excluded. The 10-year probability of hip and major osteoporotic fractures was calculated by the traditional FRAX tool. In the fractured patients the FRAX calculation was repeated with disregarding the previous fracture as a risk factor.

The incidence of at least one fragility fracture was 34% in the total group. No differences in age, BMI, BMD and T-score has been found between the fractured and non-fractured patients. Both hip and major osteoporotic fracture probability were higher in the fractured subgroup (MOP 13.9 vs. 7.3%, $p < 0.001$; FRAX-HIP 4.8 vs. 2.2%, $p < 0.001$) than in non-fractured participants. FRAX calculated without previous fracture in the fractured subgroup remained still higher than that of non-fractured persons (MOP 9.4%, $p < 0.001$ and HIP: 3.3%, $p < 0.004$).

Considering the scale of osteopenia from − 1.0 to − 2.5, FRAX-HIP and FRAX-MOP increased in the non-fractured patients. In fractured patients the facture incidence was growing with extent of osteopenia from 29 to 45%, however, the fracture probabilities remained stable in all level of osteopenia, calculated even with minding or ignoring the previous fracture as risk factor.

We hypothesize that osteopenic condition may contain not only lower bone mass but other non-mass deteriorations of bone, resulting in excess fragility.

P327
IMPACT OF A SECONDARY PREVENTION PROGRAM FOR FRAGILITY FRACTURES AT THE ORTHOGERIATRIC CLINICAL CARE CENTER AT THE FUNDACIÓN SANTA FE DE BOGOTÁ, 2014–2020

C. M. Olarte[1], A. M. López[2], J. Tihanyi Feldman[1], A. Libos Zabala[1], D. Morales[2], A. Patiño[2], R. Pesantez[1], J. Salavarrieta[1], V. Sanint[2]

[1]Orthopaedics, Hospital Universitario Fundación Santa Fe de Bogotá, [2]Geriatrics, Hospital Universitario Fundación Santa Fe de Bogotá, Bogotá, Colombia

Objective: To characterize the secondary prevention program for fragility hip fractures in patients older than 65 years, determine adherence to treatment and its effect on the appearance of new fractures in the established follow-up period.
Methods: A descriptive retrospective cohort study was carried out. Patients older than 65 y with a fragility hip fracture treated by an Orthogeriatric Clinical Care Center between May 2014 and April 2020 who completed a one-year follow-up were included.
Results: A final sample of 290 patients was obtained (226 women and 64 men) with an average age of 82.27 y. It was found that 84.5% of patients received indications to start osteoporotic management prior to hospital discharge and only 35.2% started the treatment in the first 6 postoperative months. 16.6% (n = 48) of patients presented a new fracture, with no significant difference between those who started their osteoporosis treatment in a timely manner. Out of the 48 patients, 5 patients (10.4%) met therapeutic failure criteria.
Conclusion: Most patients (84.5%) received indications for starting osteoporotic treatment before hospital discharge, nevertheless 35.2% started it during the first 6 postoperative months. 16.6% of patients presented a new fracture during follow up, of which only five met therapeutic failure criteria. No significant differences were found between the presence of new fractures and early initiation of osteoporotic management. However, literature shows that prompt and timely osteoporotic treatment reduces the incidence of new fractures, thus measures must be implemented to strengthen the adherence and surveillance of patients to the indicated treatment.

P328
VITAMIN D STATUS AND OSTEOPOROSIS IN PORTUGUESE PATIENTS WITH INFLAMMATORY BOWEL DISEASE: ASSOCIATION WITH CLINICAL FEATURES

C. Marques Gomes[1], M. Diz Lopes[1], I. Santos[2], B. M. Fernandes[1], F. Magro[3], M. Bernardes[1], L. Costa[1]

[1]Rheumatology Dept., Centro Hospitalar Universitário de São João, Porto, [2]Rheumatology Unit, Centro Hospitalar Tondela-Viseu, Viseu, [3]Gastroenterology Dept., Centro Hospitalar Universitário de São João, Porto, Portugal

Objective: To assess the prevalence of vitamin D deficiency in a Portuguese cohort of patients with inflammatory bowel disease (IBD). To evaluate the association of demographic, clinical and analytical features with vitamin D serum levels and differences between patients with and without osteoporosis (OP).
Methods: Monocentric retrospective study. All patients included had IBD. Demographic, clinical and analytical data were collected at the time of the first visit in the Rheumatology department (V1). Correlations between continuous variables were evaluated by Spearman rank test and Pearson's correlation coefficient; Mann–Whitney U and T-student tests were used in the comparison analysis between groups.
Results: 244 patients were included, mostly female (57.4%), with a mean age at V1 of 46.65 (± 13.46) y. 184 (75.4%) patients had

Crohn's disease (CD) and 60 (24.6%) had ulcerative colitis (UC). 41 patients (16.8%) had osteoporosis (T score ≤ -2.5 or Z-score ≤ -2.0 in DXA, according to age ≥ 40 or < 40 y, respectively) and 10 (4.1%) had previous fragility fractures. 192 (78.7%) patients exhibited low levels of 25-hydroxyvitamin D (25(HO)VitD (< 30 ng/mL), 17 (6.9%) were taking calcium and/or vitamin D supplements. Of all the parameters evaluated, serum levels of 25(HO)VitD correlated positively with hemoglobin (Hb; $r = 0.151$, $p = 0.023$) and total calcium ($r = 0.135$, $p = 0.045$) and negatively with erythrocyte sedimentation rate (ESR; $r = -0.232$, $p < 0.001$). Among patients with osteoporosis, serum levels of 25(HO)VitD were lower ($p = 0.008$) compared to non-osteoporotic patients; except for age at V1, BMI and osteocalcin, no other statistically significant differences were observed (Table 1).

Table 1. Features related to vitamin D serum levels and osteoporosis (by DXA)

	25-HOVitD (ng/mL)	Osteoporosis (T-score ≤ 2.5 or Z-score ≤ 2.0)*		
		Yes (n=41)	No (n=194)	
Age at V1 - mean±SD	*r=-0.420; p=0.529*	48.73±14.75	42.78±12.84	***p=0.035***
BMI - mean±SD	*r=-0.136; p=0.590*	23.81±4.32	25.93±4.57	***p=0.008***
Duration of IBD - median (IQR)	*r=-0.850; p=0.201*	12.00 (14.00)	9.50 (9.30)	*p=0.104*
Hemoglobin - median (IQR)	***r=0.151; p=0.023***	14.00 (2.10)	14.00 (2.30)	*p=0.461*
Total proteins - mean±SD	*r=0.350; p=0.626*	72.00±5.48	73.28±5.33	*p=0.199*
Albumin - median (IQR)	*r=0.121; p=0.710*	41.70 (4.30)	42.80 (4.50)	*p=0.122*
Beta-CTX - median (IQR)	*r=-0.120; p=0.079*	0.38 (0.26)	0.36 (0.27)	*p=0.135*
Osteocalcin - median (IQR)	*r=-0.850; p=0.217*	23.20 (15.80)	19.00 (11.60)	***p=0.030***
Total calcium - median (IQR)	***r=0.135; p=0.045***	4.70 (0.30)	4.70 (0.20)	*p=0.730*
CRP - median (IQR)	*r=-0.119; p=0.073*	3.30 (7.20)	2.50 (5.30)	*p=0.303*
ESR - median (IQR)	***r=-0.232; p<0.001***	16.00 (29.00)	14.50 (19.00)	*p=0.132*
Ferritin - median (IQR)	*r=-0.30; p=0.671*	153.75 (240.30)	85.00 (130.80)	*p=0.061*
25-HVitD (ng/mL) - median (IQR)	---	15.00 (13.00)	19.00 (13.00)	***p=0.008***
25-HVitD deficency - n (%)	---	---	---	*p=0.054*
≤ 30 ng/mL (n=189)	---	38 (92.7)	151 (77.8)	---
> 30 ng/mL (n=36)	---	2 (4.9)	34 (17.5)	---
Sex, median - n (%)	---	---	---	*p=0.863*
Female	---	23 (56.1)	112 (57.7)	---
Male	---	18 (43.9)	82 (42.3)	---
Under VitD supplements – (n=15, %)	---	3 (7.3)	11 (5.7)	*p=0.842*

Footnote: Beta-CTX: beta-carboxy-terminal type-1 collagen crosslinks; BMI: body mass index; CRP – C reactive protein; DXA: Dual-energy X-ray absorptiometry; ESR: erythrocyte sedimentation rate; 25(HO)VitD: 25-hydroxy vitamin D; IBD: inflammatory bowel disease; IQR: interquartile range; SD: standard deviation; V1: first visit at rheumatology department; *considering age at V1 (≥40 or <40 years old, respectively)

Conclusion: Lower total body mineral density has been found in patients with IBD which may increase OP and pathological bone fractures risk due to several mechanisms. This study reveals higher prevalence of OP in comparison with the general Portuguese population and an association of OP with vitamin D deficiency across patients with IBD. On the other hand, our results show significant correlations between clinical/analytical variables and vitamin D levels: positive correlation of 25(HO)VitD with Hb and negative correlation with ESR, suggesting a potential link to inflammatory state.

P329
FRACTURE RISK ASSESSMENT BASED ON FRAX® ALGORITHM IN PORTUGUESE PATIENTS WITH INFLAMMATORY BOWEL DISEASE: ASSOCIATION WITH CLINICAL FEATURES

C. Marques Gomes[1], M. Diz Lopes[1], I. Santos[2], B. M. Fernandes[1], F. Magro[3], M. Bernardes[1], L. Costa[1]

[1]Rheumatology Dept., Centro Hospitalar Universitário de São João, Porto, [2]Rheumatology Unit, Centro Hospitalar Tondela-Viseu, Viseu [3]Gastroenterology Dept., Centro Hospitalar Universitário de São João, Porto, Portugal

Objective: To assess the prevalence of osteoporosis and proportion of treated patients in an IBD cohort. To evaluate the association of demographic, clinical and analytical features with fracture risk.

Methods: Monocentric retrospective study. All patients included had IBD. Demographic, clinical and analytical data and BMD by DXA (total hip, femoral neck and lumbar spine) were collected at the time of the first visit in the Rheumatology outpatient center (V1); for patients over 40 years old, major (MFR) and hip (HFR) fracture risk was assessed (based on FRAX-Portugal); proportion of patients with indication of therapy for OP was calculated (according to Portuguese recommendations). Correlations between continuous variables were evaluated by Spearman rank test and Pearson's correlation coefficient and Mann–Whitney U test was used in the comparison analysis between groups.

Results: 244 patients were included, mostly female (57.4%), with a mean age at V1 of 46.65 (± 13.46) y; 184 (75.4%) patients had Crohn's disease and 60 (24.6%) had ulcerative colitis. Regarding IBD treatment, 12 patients (4.9%) were taking glucocorticoids at V1 and 185 (75.8%) had been previously treated with glucocorticoids. Of all patients, 33 (14.1%) had DXA T-score ≤ -2.5 (osteoporosis), 10 (4.1%) had previous fragility fractures. Concerning to individuals ≥ 40 years old (Table 1), serum levels of total proteins and albumin correlated negatively with HFR ($r = -0.194$, $p = 0.035$) and MFR ($r = -0.187$, $p = 0.026$), respectively. Erythrocyte sedimentation rate (ESR) correlated positively with MFR ($r = 0.175$; $p = 0.045$), ferritin correlated positively with MFR ($r = 0.214$; $p = 0.017$) and HFR ($r = 0.206$; $p = 0.022$); β-CTX correlated positively with MFR ($r = 0.221$; $p = 0.010$). Of interest, serum levels of 25(HO)VitD correlated negatively with β-CTX ($r = -0.255$; $p = 0.004$). Fifteen patients (10.1%) had an indication for osteoporosis treatment (no differences between genders, $p = 0.848$); only 3 were undergoing treatment with bisphosphonates.

Table 1. Patients ≥ 40 years old (n=148): features related to major and hip fracture risk assessed by FRAX®Port.

	Major fracture risk (%)	Hip fracture risk (%)
Age at V1	**r=0.593; p<0.001**	**r=0.439; p<0.001**
BMI	**r=-0.212; p=0.010**	**r=-0.317; p<0.001**
Age at IBD diagnosis	**r=0.271; p<0.001**	**r=0.180; p=0.030**
Hemoglobin	n.s.	n.s.
Total proteins	n.s	**r=-0.194; p=0.035**
Albumin	**r=-0.187; p=0.026**	n.s.
Beta-CTX	**r=0.221; p=0.010**	n.s.
Osteocalcin	**r=0.236; p=0.006**	n.s.
25(HO)VitD	n.s.	n.s.
CRP	n.s.	n.s.
ESR	**r=0.175; p=0.045**	n.s.
Ferritin	**r=0.214; p=0.017**	**r=0.206; p=0.022**
Calprotectin	n.s.	n.s.
Sex, median (IQR)	n.s.	n.s.
Female (n=90)	2.10 (2.30)	0.30 (0.90)
Male	1.95 (2.10)	0.35 (1.00)
Previous fracture, median (IQR)	**p<0.001**	**p<0.001**
Yes (n=10)	9.90 (10.70)	4.10 (9.10)
No	1.90 (1.90)	0.30 (0.80)
Exposition to GC, median (IQR)	**p=0.005**	n.s.
Yes (n=114)	2.20 (2.30)	0.35 (1.00)
No	1.30 (1.40)	0.20 (0.60)
IBD type	n.s.	n.s.

Conclusion: This study shows a higher prevalence of OP in comparison with the general Portuguese population and an important number of untreated patients with high FR. It also reveals significant associations between clinical variables and FR in IBD patients: inflammatory state (positive correlation of FR with ESR and ferritin) and nutritional status (albumin correlated negatively with FR).

P330
THE EFFECTS OF THE MOTOR CONTROL HOME ERGONOMICS ELDERLIES' PREVENTION OF FALLS (MCHEELP) PROGRAMME IN PATIENTS WITH SARCOPENIA: A PILOT STUDY

M. Tsekoura[1], C. Matzaroglou[1], S. Xergia[1], E. Tsepis[1], Y. Dionnysiotis[2], V. Sakellari[3], E. Billis[1]

[1]Dept. of Physiotherapy, Univ. of Patras, Rio, [2]Medical School, Univ. of Patras, Spinal Cord Injury Rehabilitation Clinic, Univ. General Hospital Patras, Rio, [3]Dept. of Physiotherapy, Univ. of Western Attica, Athens, Greece

Objective: The objective of this study was to investigate the effects of a three month 'Motor control Home ergonomics Elderlies' Prevention of falls' (McHeELP) programme on muscular, functional/physical performance and fear of falling across older adults with sarcopenia.
Methods: Patients with sarcopenia participated in the present study. The definition of sarcopenia was performed according to the criteria reported by EWGSOP2. The exercise programme included a package of exercises divided into 6 domains [1 (warm up) and 5 motor control domains]. In addition, all participants received a booklet, with basic advice and tips on modifying the interior and exterior of their home environment (kitchen, bedroom, living room, bathroom and stairs of the home). The pre- and post-intervention measurements were recorded while taking into account a series of tests and measurements which included in the hand grip strength, bioimpedance analysis, muscle mass, functionality and fear of falling.
Results: A total of 12 participants [men (n = 4) and women (n = 8)] with a mean age of 74.95(SD = 5) years completed the study. Results showed significant differences before and after the programme in terms of the participants' functionality ($p < 0.001$), balance ($p < 0.05$) and fear of falling ($p < 0.001$).
Conclusion: The present study revealed that the McHeELP programme has positive effects on functionality, balance and fear of falling which are essential components for falls prevention. Future studies need to be developed and implemented in order to improve clinical implications and reduce the burden of falls reduce the burden of falls in patients with sarcopenia.

P331
RELIABILITY OF A PHOTOGRAMMETRY TECHNIQUE USING THE LEONARDO ANALYSIS SYSTEM FOR THE EVALUATION OF THE ANGLE Q OF THE LOWER LIMB

E. Livieratou[1], G. Kokalidis[1], S. Lampropoulou[1], Z. Dimitriadis[1], C. Matzaroglou[1], K. Fousekis[1], E. Tsepis[1], M. Tsekoura[1]

[1]Dept. of Physiotherapy, Univ. of Patras, Rio, Greece

Objective: To investigate the reliability of the photogrammetry technique in the evaluation of lower limb Q angle using the Leonardo (postural lab) system.
Methods: Participants (aged 18 y and above) were recruited from the University of Patras. An assessment of test–retest and inter-rater reliability was conducted. The procedure included photography and static analysis on the Leonardo PL800 postural analysis system and evaluation of Q-angle by photogrammetry. Reliability was tested using the intraclass correlation coefficient (ICC) to examine the degree of correlation of values between the two measurements, the first completion and the repetitive completion of the instrument. The study protocol was approved by the Ethical Committee of the University of Patras, Greece.
Results: 59 adults (mean age of 21.2 ± 1.8 y) participated to assess the test–retest reliability and 29 adults (mean age of 20.8 ± 2 y) to assess inter-rater reliability. The reliability of repeated measures was excellent for the right leg (ICC 0.97 95% CI 0.95–0.98) and for the left leg (ICC 0.88 95% CI 0.79–0.92). Good inter-rater reliability was recorded for both the right leg (ICC 0.73 95% CI 0.51–0.85) and the left leg right (ICC 0.7 95% CI 0.6–0.85).
Conclusion: Photogrammetry demonstrated to be a reliable method using the Leonardo posture analysis system for the evaluation of lower limb Q angle. New research studies are needed to investigate both the reliability and validity of the system at other body sites.

P332
ULTRASOUND EVALUATION OF DIAPHRAGM IN HEALTHY ADULTS

I. Aravantinou[1], A. Skoura[1], C. Matzaroglou[1], E. Billis[1], M. Tsekoura[1]

[1]Dept. of Physiotherapy, Univ. of Patras, Rio, Greece

Objective: To evaluate the thickness of the diaphragm by ultrasound and correlate it with gender, anthropometric characteristics and physical activity level.
Methods: Diaphragmatic thickness assessment was performed in the Clinical Physical Therapy and Research Laboratory (CPR Lab) using 2D real-time ultrasound (Versana Active, General Electric). The measurement was performed in the diaphragm juxtaposition zone, in the right hemithorax in Brightness Mode (B-Mode), through the acoustic window of the liver, in the region of the 8th–10th intercostal space and between the anterior and mid axillary line, with the echosounder oriented parallel to the anteroposterior plane. All measurements were made in the supine position with the torso in 30°–40° reclination, knees bent at 70°–80° and arms bent behind the neck at (a) maximum diaphragmatic inhalation and (b) the corresponding maximum diaphragmatic exhalation. Thickness was defined as the ratio (Th at End Inspiration—Th at End Expiration)/(Th at End Expiration), where Th: diaphragm thickness. The procedure was repeated 3 times for each measurement and the mean value was kept. The research study was approved by the Ethics Committee of the University of Patras.
Results: 49 healthy adults older than 18 y (mean age 24.4 ± 7.8) and without respiratory disorders participated in this study. The majority of participants were female (n = 29; 59.2%), nonsmokers, with a mean BMI of 23.4 ± 2.7, and diaphragm thickness of 102.6 ± 36.8 mm. For females the thickness was 94.3 ± 35.3 mm and for males 108.4 ± 37.4 mm. The thickness at peak expiration recorded a moderate to high correlation with gender ($r = 0.42$, $P = 0.02$) and BMI ($r = 0.46$, $P < 0.01$). Diaphragm thickness as defined by (Th at End Inspiration—Th at End Expiration)/(Th at End Expiration) recorded moderate correlation with depth of inspiration ($r = 0.4$, $P < 0.001$) and expiration ($r = 0.4$, $P < 0.001$) but not with other parameters.
Conclusion: Diaphragm thickness is an important evaluation parameter for different population groups. In the present study no significant associations with gender, anthropometric characteristics were recorded. Future studies in a larger sample of participants are required to make correlations with more parameters.

P333
ENHANCED PAPER GRIP TEST: CLINICAL APPLICABILITY AMONG COMMUNITY DWELLING OLDER ADULTS

M. Tsekoura[1], P. Chatzistergos[2], E. Billis[1], C. Matzaroglou[1], N. Chockalingam[2], E. Tsepis[1]

[1]Dept. of Physiotherapy, Univ. of Patras, Rio, Greece, [2]Centre for Biomechanics and Rehabilitation Technologies, Staffordshire Univ., Stoke-on-Trent, UK

Objective: To investigate the clinical applicability of the enhanced paper grip test (EPGT) for assessing foot muscle strength in community dwelling older adults.
Methods: Community dwelling older adults > 60 years of age enrolled in this pilot study. After providing their informed consent, participants were interviewed to assess comorbidities, medication use, and history of falls. EPGT force was recorded for both feet using the same standardized protocol for all participants (1,2). Participants were seated comfortably without shoes and socks. The card was placed underneath the participant's foot. They were instructed to start gripping the card and then a highly experienced physiotherapist started pulling the dynamometer until the card was fully removed from underneath. The test was repeated three times per foot, and the highest value was recorded. Clinical applicability was assessed in community-dwelling adults of both genders. After the testing all participants answered 3 questions: (i) Do you have any complain; (ii) Did you find the procedure easy; (iii) Do you feel safe during the measurement? The study was approved by the Ethics Committee of the University of Patras.
Results: A convenience sample of 30 community-dwelling adults (70.6 ± 5.8 y) was recruited for clinical applicability testing. Most of the participants were women (n = 21; 70%) and without a self-reported history of falling (n = 4, 13.3%). The test and the data obtained was performed in < 5 min. All participants performed the test easily, safely and with no complaints. Mean score on EGPT was 16.1 ± 4.2 N.
Conclusion: EGPT is easy to use and it is a clinical applicable measurement of the strength of the hallux grip. Further research is required in a larger sample size of older adults with different pathologies.

REAL-TIME DIAGNOSTIC ULTRASOUND AS A MEANS OF BIOFEEDBACK TRAINING IN TRANSVERSUS ABDOMINUS RE-EDUCATION OF PATIENTS WITH NON-SPECIFIC LOW BACK PAIN

C. Matzaroglou[1], N. Taxiarchopoulos[1], M. Tsekoura[1], S. Lampropoulou[1], E. Billis[1], J. Gliatis[2]

[1]School of Health Rehabilitation Sciences, Dept. of Physiotherapy, Univ. of Patras, Patras, Greece, [2]Dept. of Orthopedic Surgery, Univ. Hospital of Patras, Patras, Greece

Objective: The ultrasound-guided imaging of activation/contraction of the deep abdominal muscles (such as transervsus abdominis) is useful for assisting deep muscle re-education, which is often dysfunctional in nonspecific low back pain (NSLBP). Thus, this pilot study aimed to evaluate the use of real-time ultrasound (US) as a feedback device for transverse abdominis (TrA) activation/contraction during an exercise program in chronic NSLBP patients.
Methods: 55 chronic NSLBP patients were recruited and randomly assigned to a US-guided (n = 30, 24 women, 48.4 ± 3.55 y) or control group (n = 25, 21 women, 47.8 ± 5.22 y). The same motor control-based exercise program was applied to both groups. All patients received physiotherapy twice per week for seven weeks. Outcome measures, tested at baseline and post-intervention, included Numeric Pain Rating Scale, TrA activation level (measured through a pressure biofeedback unit-based developed protocol), seven established motor control tests, Roland-Morris Disability Questionnaire and Hospital Anxiety and Depression Scale.
Results: For each group, all outcome variables yielded statistical differences post-intervention ($p < 0.05$), indicating significant improvements. However, there were no significant group x time interactions for any of the outcomes ($p > 0.05$), thus, indicating no superiority of the US-guided group over the control.
Conclusion: The addition of US as a visual feedback device for TrA re-education during a motor control exercise program was not proven superior to traditional physiotherapy.

GAIT IMPAIRMENT AND QUALITY OF LIFE IN PATIENTS WITH MULTIPLE SCLEROSIS IN WESTERN GREECE

E. Trachani[1], E. Diakatou[1], A. Mpouta[1], E. Tsiamaki[1], C. Matzaroglou[1], E. Chroni[1]

[1]Univ. of Patras, Patras, Greece

Objective: To clarify how the gait disorders in Multiple Sclerosis (MS) affect the quality of life in a sample of patients living in West Greece.
Methods: 38 patients with MS (mean age: 43.61 ± 10.75 y, 24 females) were evaluated by means of EDSS, Timed 25-Foot Walk (T25FW), MS Quality of Life-54 (MSQoL-54)[1] and MS Walking Scale-12(MSWS-12)[2].
Results: There was a moderate linear correlation between EDSS subgroups and the T25FW ($p = 0.013$, $r = 0.398$) and MSWS-12 ($p = 0.00$, $r = 0.544$). Moreover, a negative correlation was found between the T25FW and the MSQoL-54 (physical health: $r = -0.385$, mental health: $r = -0.368$). Finally, there was a positive correlation between the physical health composite of the MSQoL-54 and the mental health composite ($r = 0.458$).
Conclusion: Walking disorders in patients with MS in West Greece have a negative effect on their quality of life and also on their mental health, in accordance with the current literature[3–4].

P336
CROSS-CULTURAL ADAPTATION OF THE "NORTH STAR ASSESSMENT" SCALE FOR LIMB-GIRDLE MUSCULAR DYSTROPHY

S. Lampropoulou[1], A. A. Lala[1], M. M. Troullaki[1], V. M. Pratsinaki[1], I. A. Gedikoglou[2], C. Matzaroglou[1], E. Billis[1], E. Chroni[3]

[1]Physiotherapy Dept., Univ. of Patras, [2]Univ. of Patras, Dept. of Physiotherapy, [3]Unit of Neuromuscular Diseases, Patras Univ. General Hospital, Patras, Greece

Objective: The "North Star Assessment" scale (NSAD), is a newly developed, reliable tool for the evaluation of the functional deficits in patients with limb-girdle muscular dystrophy (LGMD) (1) but it hasn't yet been adapted into Greek. The aim therefore, of this research, was to translate and cross-culturally adapt the NSAD scale into the Greek language. A pilot test of the adapted scale was a second aim of this study.
Methods: Following permission by the developers of the scale (MJ), the NSAD was adapted according to international guidelines (forward & backward translation, by four independent translators) (2). The pre-final NSAD-GR was distributed to a convenient sample of 8 experienced physical therapists (range of 2–10 y of clinical experience with neurological patients) in order to assess the comprehension of the translated content and it was piloted in 2 patients with LGMD (1 male & 1 female, age of 31 and 41 y, respectively).
Results: Upon completion of the translation, the semi-final form of the Greek adaptation of the NSAD was revealed which has kept the structure, the form and the outline of the original English scale intact. The pilot study of the NSAD-GR, was an important step in clarifying a few commands of the translated version. Pre-final NSAD-GR was found to be adequate, comprehensible and easy to use by physical therapists and patients alike.
Conclusion: For validation of the final form of the NSAD scale into Greek, further research is recommended, with a larger sample of patients and domestic physiotherapists, for a thorough screening of its psychometric features.

Acknowledgments: Initially, we would like to that thank Dr Meredith James for the access to NSAD files and for giving us the permission for the adaptation of the scale into the Greek language. We would also like to thank Prof Elisabeth Chroni, the Director of the Neuromuscular Unit of the University Hospital of Patras, in Greece, who granted us the space of the unit that meets all the specifications for conducting our research.

P337
THE ROLE OF THE PHYSIOTHERAPIST AS A MEMBER OF THE MULTIDISCIPLINARY TEAM OF A MODEL CENTRE OF EXPERTISE IN RARE DISEASES

S. Lampropoulou[1], G. Andrikopoulou[1], E. Billis[1], C. Matzaroglou[1], E. Trachani[1], E. Chroni[2]

[1]Physiotherapy Dept., Univ. of Patras, [2]Unit of Neuromuscular Diseases, Patras Univ. General Hospital, Patras, Greece

Objective: Healthcare interdisciplinarity, powered by diverse scientific knowledge, is vital (1). Greece's sole rare neuromuscular diseases centre (NMDU) emphasizes interdisciplinary collaboration. The recent physiotherapist inclusion highlights their value, but research gaps persist on their team role. This study aims to investigate the physiotherapist's impact on patient care quality within the multidisciplinary team, of a model centre of expertise on rare diseases.
Methods: Fifteen staff members of the NMDU (8 women and 7 men, aged 44 $\pm$ 10 years old), participated in the survey. 33 patients of the Unit (16 women and 14 men, aged 51 $\pm$ 14 years old), also participated. The survey was firstly conducted by creating two questionnaires to assess the role of the physiotherapist and then distributing them to the staff and patients of the NMDU.
Results: The data collection showed that the physiotherapist has multiple roles within the NMDU, such as assessment (80%), and long-term follow-up of patients (86%). In addition, he/she participates in conducting research (54%), and has the theoretical background (67%), to provide motivation to patients (66%). The physiotherapist's presence in the NMDU is considered necessary (93%). In the future, the need for expanding the responsibilities of the physiotherapist, such as working with external physiotherapists (87%) and providing physiotherapy sessions in the NMDU (93%) is highlighted.
Conclusion: Physiotherapist's role in the NMDU is essential, blending theory, clinical expertise, interdisciplinary training and research skills, for quality patient's care. Future improvements would include extending the physiotherapist presence in the unit and sharing knowledge from research with the community.

P338
THE EFFECT OF A TELEREHABILITATION PROGRAMME ON BALANCE, GAIT AND PHYSICAL PERFORMANCE IN INDIVIDUALS WITH PARKINSON'S DISEASE

E. Brouma[1], C. S. Chatzivasilis[1], I. Papakosta[1], P. Papadopoulos[1], M. Nikolopoulou[1], E. Trachani[1], S. Xergia[1], S. Lampropoulou[1], C. Matzaroglou[1]

[1]Physiotherapy Dept., Univ. of Patras, Patras, Greece

Objective: Telerehabilitation for the management of motor dysfunctions in Parkinson's disease (PD) has gained considerable interest in recent years but it is limited by the use of not easily accessible devices for most patients.
Methods: A convenience sample of n = 6 patients with PD, consisting of 2 women and 4 men aged 64 $\pm$ 11 years was randomly divided into 2 equal groups, receiving a remote therapeutic exercise program twice a week for 8 weeks. The experimental group followed the program via video-conferencing with live guidance from the physiotherapist, whereas the control group performed a similar unsupervised program via a standard exercise booklet. Assessments were conducted at baseline, at the end of the 4 weeks intervention and one month later (follow-up). The main outcome measures were balance (Mini Balance Evaluation Systems Test, Activity-specific Balance Confidence Scale), gait (Functional Gait Assessment, Freezing of Gait Questionnaire) and physical performance (Short Physical Performance Battery). Secondary outcome measures were posture abnormalities such as the Total (TCC) and Upper Camptocormia Curve (UCC) and Drop Head (DHA) angles (PL0800 Leonardo, Chinesport Italy), quality of life (Parkinson's Disease Quality of Life Questionnaire) and intrinsic motivation (Intrinsic Motivation Inventory).
Results: Balance and physical performance was improved in both groups after the end of the intervention, but the change was not statistically significant ($p > 0.05$). Significant improvement in freezing of gait was observed only in the intervention group ($p < 0.05$).

Quality of life and interest/enjoyment in activity also improved in both groups ($p \leq 0.05$), with no statistically significant difference between groups ($p > 0.05$). TCC and DHA angles decreased in both groups but not statistically significant ($p > 0.05$). Functional gait did not improve in either group ($p > 0.05$).

Conclusion: Remote rehabilitation through videoconferencing and via booklet seems to have a positive effect on balance, physical performance, quality of life, intrinsic motivation for exercise, TCC and DHA in patients with PD. However, studies with a larger sample size are needed to strengthen the results of this study.

P339
ADHERENCE OF PATIENTS WITH PARKINSON' S DISEASE TO A NOVEL REMOTE REHABILITATION PROGRAM

S. Lampropoulou[1], C. S. Chatzivasilis[1], E. Brouma[1], I. Papakosta[1], P. Papadopoulos[1], M. Tsekoura[1], C. Matzaroglou[1], E. Trachani[1]

[1]Physiotherapy Dept., Univ. of Patras, Patras, Greece

Objective: Chronic neurological patients suffer from decreased motivation and exercise adherence over time (1). The aim of this study was to evaluate patients' adherence to a novel remote home exercise program guided by an exercise booklet (2).

Methods: In this single-blinded clinical trial, patients with Parkinson's disease were voluntarily enrolled in a remote hourly intervention, twice a week, for 8 weeks, which consisted of therapeutic exercises to improve posture, balance and gait. The exercises were delivered through a leaflet which was explained and given to the patients at their initial visit in the lab for the baseline assessments. Adherence was evaluated with the Exercise Adherence Rating Scale (EARS) as the main measurement outcome, while the motivation was also reported through the Intrinsic Motivation Index (IMI), the balance through the mini-Balance Evaluation Systems Test (mini-BESTest), the gait with the Functional Gait Assessment (FGA) and the freezing effect during gait with the Freezing of Gait Questionnaire (FOG-Q). Assessments were conducted pre- and post the intervention and one month after the completion of the program.

Results: Three patients (2 men and 1 woman, age 68 ± 6 y) diagnosed with Parkinson's Disease for 17 ± 11 months participated in this study. The patients' adherence to the intervention presented a steady but not statistically significant improvement up to the completion of the intervention ($p > 0.05$) (Fig. 1). According to patient reports, the freezing of gait had a statistically significant decrease ($p = 0.05$), while the other outcome measures despite the trend of improvement, did not present a significant differentiation ($p > 0.05$).

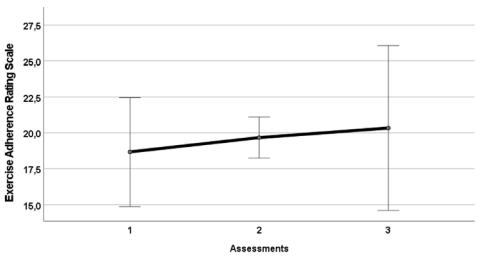

Figure 1. Improvement of the adherence of the patients in a remote rehabilitation program, delivered with an exercise leaflet. The assessments were performed 1: before the intervention (baseline), 2: at the end of the intervention and 3: one month after the end of the intervention (follow up) (n=3).

Conclusion: The trends of improvement in adherence, gait and balance combined with the intrinsic motivation suggest that an exercise program on a regular basis, even remotely, could be extremely beneficial for patients' functionality. Further research on the field of remote rehabilitation on chronic neurological patients using larger samples, is considered necessary.

P340
POSTURAL CONTROL AND LOWER LIMB FUNCTIONALITY IN PATIENTS WITH MULTIPLE SCLEROSIS AFTER A PILATES REHABILITATION PROGRAM COMPARED TO A CONVENTIONAL PHYSIOTHERAPY PROGRAM

S. Lampropoulou[1], D. N. Provata[1], I. Papakosta[1], E. Brouma[1], P. Papadopoulos[1], K. M. Kravvariti[1], C. Matzaroglou[1], E. Trachani[1]

[1]Physiotherapy Dept., Univ. of Patras, Patras, Greece

Objective: The Pilates method although effective in improving muscle recruitment, symmetrical body posture, breathing control, strengthening the abdominal muscles, it is not fully investigated whether it can help with lower extremity functionality and balance problems in multiple sclerosis (MS). The aim therefore, of this study is to investigate whether the Pilates method, compared to conventional physiotherapy, is more effective in improving postural control and lower limb functionality in patients with MS.

Methods: Patients with MS were randomly divided into two groups, undertaking a Pilates intervention program or a conventional physiotherapy program. Both programs were delivered in hourly-sessions, for 2 times/week, for 8 weeks. Assessments were conducted before the intervention (baseline), at the midpoint of the intervention (4 weeks) and 8 weeks after its completion (follow-up). The lower limb functionality was also assessed via the Fugl-Meyer Sensorimotor Assessment (FMA) scale. The balance was assessed via the mini Balance Evaluation System Test (mini-BESTest), the ability of walking in various conditions was assessed with the Functional Gait Assessment (FGA). Other secondary outcome measures included the assessment of fatigue with the Fatigue Severity Scale (FSS), the fear of falling with the Fall Efficacy Scale-International (FES-I) and the patients' quality of life with the Short Form Health Survey (SF-12).

Results: Eight patients with MS participated in the study (3 men, 5 women, mean age 46 ± 10 y), and were equally divided into the two groups. Lower limb balance and functionality improved after the intervention and showed significant progress in both groups between assessments ($p < 0.05$). Similarly, gait as well as the lower limb motor function were significantly improved for both groups ($p < 0.05$). Fatigue was reduced and quality of life was optimized ($p < 0.05$). No significant differences were found between the two groups ($p > 0.05$).

Conclusion: The beneficial effect of Pilates appears to be significant in improving the main deficits of patients with MS, but was not found to be superior to conventional physiotherapy. Further research is needed to confirm these results.

P341
FUNCTIONAL RETRAINING OF ADULT PATIENTS WITH FACIOSCAPULOHUMERAL MUSCULAR DYSTROPHY: A PILOT CLINICAL STUDY

M. Nikolopoulou[1], K. M. Kravvariti[1], C. Matzaroglou[1], E. Billis[1], E. Chroni[2], S. Lampropoulou[1]

[1]Physiotherapy Dept., Univ. of Patras, [2]Unit of Neuromuscular Diseases, Patras Univ. General Hospital, Patras, Greece

Objective: Facioscapulohumeral muscular dystrophy (FSHD) is an inherited condition within the spectrum of neuromuscular disorders, which is characterized by weakness and atrophy of the muscles in face, upper extremities, the pelvic girdle and trunk. There are significant research gaps regarding the effectiveness of the therapeutic exercise protocols (1,2). Therefore, this research aims to investigate the effectiveness of a functional retraining program in those patients.
Methods: This study constitutes a pilot clinical trial, involving pre- and post-intervention assessments in adults with FSHD. The intervention involved ten 45-min sessions, once a week, for 10 weeks and included muscle strengthening exercises, balance enhancement, selective muscle activation, walking and hand dexterity improvement (Fig. 1). The intervention's effectiveness was evaluated through the Revised Upper Limb Module (RULM), the 6-min walk test (6MWT), the expanded Hammersmith Functional Motor Scale (HFMSE), the muscle power in shoulder, hip, hand and ankle muscles as well as the active Range of Motion (ROM) in shoulder and ankle joints.

Figure 1. Examples of strengthening, fine mobility and dual task exercises.

Results: Four adults (3 men and 1 woman, 38 ± 9 years old), with FSHD participated in the study. The mean total distance walked during the 6MWT was increased by 17 ± 12 m ($p > 0.05$) (Fig. 2). The active ROM of shoulder's flexion and abduction increased in both sides, with a range of 27–40°. Additionally, the ankle flexion increased 3° in both sides. The strength improved mainly in shoulder's muscles for about 1 level at the Oxford scale (from 2 + to 3 +). No changes yielded in the muscles' power of hip, ankle and hand. The overall functional motor ability and hand dexterity improved but did not reach any significant change post the intervention ($p > 0.05$).

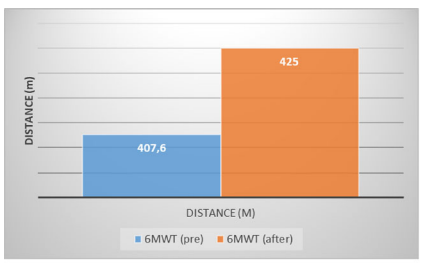

Figure 2. The graph shows the average distance walked by the 3 ambulatory patients at the initial and final assessment, using the 6MWT.

Conclusion: Due to small sample none of the outcomes reached significance, however, the improvements revealed in muscle power, active ROM, walked distance, body functional ability and hand dexterity, support the importance of a functional exercise intervention in these patients. A bigger sample and dose of the program during the week, may lead to more prominent improvements.

P342
A REVIEW ON KINETIC AND KINEMATIC CHANGES IN GAIT OF PATIENTS WITH PARKINSON'S DISEASE

S. Lampropoulou[1], N. Menegakis[1], S. I. Spyrou[1], C. Matzaroglou[1], E. Trachani[1], T. Bania[1]

[1]Physiotherapy Dept., Univ. of Patras, Patras, Greece

Objective: To investigate the gait alterations in Parkinson's disease patients through motor and kinematic analysis and to examine whether there is a correlation with the assessment through scales.
Methods: The scientific articles used to conduct this review were selected through authoritative databases, PubMed, Google Scholar, Medline, Scopus, Cochrane. A selective search was done for recent articles, from 2011 onwards for better validity and reliability of the information.
Results: The Vertical Ground Reaction Force has been reported to be changed particularly with the disease progression, where the waveform tends to become flat. Both flexion moments in all joints and power production were found to be increased, whereas the administration of medication did not seem to affect these factors in particular (1). Regarding the kinematic analysis, each joint is studied separately, as well as the spatiotemporal factors. In general, both the upper and lower limbs and the trunk showed a reduced range of motion trajectory and a position of excessive flexion and reduced extension predominated. In addition, reduced oscillation and asymmetries between the sides have been found in the upper limbs, especially at an early stage (2). Through the study of spatiotemporal factors it has been reported that the mean gait velocity and rate have decreased as well as a significant decrease was found in the variable in the swing phase. On the contrary, there was an increase in the support phase. At an advanced stage, these factors change even more markedly. The above kinetic and kinematic changes have been found to correlate with the bradykinesia as this is usually assed by the Unified Parkinson' s Disease of Rating Scale (UPDRS) III scale and the motor characteristics of movement performance speed, amplitude and rhythm (3). These correlations are not absolute as the resulting data are semi-quantitative and their results are non-linear showing high variability, which needs further study to clarify.
Conclusion: Kinetic and kinematic changes have been extensively studies in Parkinson's Disease. However, little is known about their correlations with the functional ability of these patients. Further research in associating these changes with the functional assessment scales would be of great value.

INTELLIGENT APPROACHES ENHANCE THE CLINICAL VALUE OF ELECTROPHYSIOLOGICAL MEASUREMENTS FOR SPINAL INJURY PROGRESSION PREDICTION

C. Matzaroglou[1], D. Chrysanthakopoulou[2], C. Koutsojannis[2], E. Trachani[1], M. Adamidou[2]

[1]School of Health Rehabilitation Sciences, Dept. of Physiotherapy, Univ. of Patras, [2]Health Physics & Computational Intelligence Laboratory, Physiotherapy Dept., School of Health Rehabilitation Sciences, Univ. of Patras, Patras, Greece

Objective: Spinal cord injury (SCI) is a severe condition caused by damage or trauma to the spinal cord. SCIs can result in a range of symptoms, including paralysis, loss of sensation, and loss of bowel and bladder control [1]. Over the years, various assessment scales have been developed to help healthcare professionals diagnose and monitor SCIs, assess the severity of the injury, and develop effective treatment plans, as these types of injuries vary to a great extent [2]. The rehabilitation and recovery of individuals with spinal cord injuries are usually complex and require collaboration among several healthcare professionals, aiming to improve the function and quality of life [3]. The purpose of this review is to provide a comprehensive guide of all the SCI's assessment tools, including their purpose, scoring system, and limitations. Moreover, it highlights the integration and importance of electrophysiology as far as the information it can reveal and the potential to revolutionize the diagnosis, prognosis, and treatment of spinal cord injuries using artificial intelligence approaches.
Methods: For this review article, a comprehensive search was conducted in the period from 01/12/2022 until 30/7/2023, on published medical literature using several electronic databases including Medline, Google Scholar, Science Direct, Sci-Hub, and PubMed. The research used keywords such as spinal cord injuries, spinal cord injury scales, evaluating tools for spinal cord injuries, somatosensory evoked potentials, electrophysiology in spinal cord injuries, artificial intelligence, and machine learning in SCI.
Results: This study resulted in a comprehensive guide of all the SCI's assessment tools, including their purpose, scoring system, and limitations. Some scales describe the type and the spinal level of the damage but do not assess the functional abilities, such as Frankel Scale and ASIA Impairment Scale, while others are focused on assessing daily life activities but are missing data about movement quality, like Functional Independence Measure Scale and Spinal Cord Independence Measure Scale. Also, some scales are more suitable for incomplete SCIs, like Lower Extremities Motor Score, Walking Index for Spinal Cord Injury Score, and Barthel Scale, while others are focused on evaluating the muscle tone – Ashworth Scale. Studies using somatosensory evoked potentials (SSEPs) have made steady progress since Dawson's initial description. The introduction of information technology has allowed for digital analysis, leading to the rapid scaling of SSEP and other Central Nervous System studies in the clinical field. Recent research has highlighted the multifaceted utility of SSEPs in understanding and managing neurological conditions. SSEPs offer objective and continuous monitoring, complementing subjective behavioral assessments, and hold promise in standardizing injury progression in research settings. Furthermore, SSEPs provide valuable insights in rodent models, facilitating comparisons between distinct SCI pathophysiology and monitoring motor function alterations post-injury. In clinical trials, standardized reporting guidelines for electrophysiological outcome measures are deemed necessary, while tailored SSEP assessments hold the potential to enhance SCI diagnosis, patient categorization, and therapeutic evaluation. Additionally, SSEPs offer insights into spinal cord reperfusion injury monitoring and aid in diagnosing focal spinal diseases. These findings collectively underscore SSEPs' pivotal role in advancing both research and clinical practices in neurological disorders and SCI management. Based on reliable data, this research concludes that with the assistance of Artificial Intelligence in the analysis of electrophysiological measures and somatosensory evoked potentials, Biomarkers and Bio-signals from neurophysiological indicators will eventually lead to the use of a unified tool model that will provide a personalized prediction of the restoration outcome of individuals with spinal cord injury, combined with imaging methods.
Conclusion: Therefore, it is of great importance to widely develop intelligent tools that will predict the walking ability and autonomy of a patient with SCI, i.e., a model predicting the progress of rehabilitation based on artificial intelligence for analyzing, somatosensory evoked potentials and biomarkers due to the valuable information they can offer in established clinical and imaging examinations. In that way, the diagnosis and prognosis of each patient will not be based on linear models that may not fully estimate data and do not consider the complex behavior of variables that often exist in biological conditions, especially in the case of spinal cord injuries where the variety of injuries is limitless. It is important to set correct parameters, as creating such a valuable AI tool which can maximize the importance of electrophysiology and somatosensory evoked potentials data in collaboration with other useful tests and tools already existing. To give this tool a greater extent, it is crucial to build it with information not only from the existing damage of a SCI or information from just hospitalization and recovery periods but also data from the progression of the condition. The follow-up should last forever after a spinal cord trauma, and the data should be collected annually to strengthen its importance.

VITAMIN D DEFICIENCY IN ORTHOPEDIC PATIENTS IN DIFFERENT LATITUDES. COMPARING GERMAN AND GREEK POPULATIONS

A. Mamilos[1], G. Maier[2], Z. Alsofy[3], P. Drees[4], K. Kafchitsas[5], J. Gliatis[6], C. Matzaroglou[6]

[1]Institute of Pathology, Univ. of Regensburg, Regensburg, Germany, [2]Pius-Hospital, Univ. Hospital of Orthopaedic Surgery, Carl-Von-Ossietzky-Univ., Oldenburg, Germany, [3]Dept. of Neurosurgery, St. Barbara-Hospital, Academic Hospital of Westfälische Wilhelms-Univ. Münster, Hamm, Germany, [4]Dept. for Orthopaedic Surgery, Univ. Hospital Mainz, Univ. of Mainz, Mainz, Germany, [5]Dept. of Spine Surgery, Asklepios Orthopedic Clinic Lindenlohe, Schwandorf, Germany, [6]Dept. of Physiotherapy, School of Health Rehabilitation Sciences, Univ. of Patras and Dept. of Orthopedic Surgery Univ. Hospital of Patras, Patras, Greece

Objective: Lack of vitamin D can cause bone demineralization, bone mass loss and secondary hyperparathyroidism, bone fractures, and osteoporosis [1]. The preventive role of vitamin D is not evidently proven for the case of fractures [2, 3], but vitamin D plays a crucial role in the development and maintenance of a healthy skeleton throughout life [4]. Vitamin D regulates skeletal homeostasis [5] and the immune system [6]. Hypovitaminosis D increases the risk of respiratory and periprosthetic infections, whereas vitamin D supplementation may reduce the risk of influenza or an infection [7, 8]. Although data is currently not sufficient, there are studies, including a randomized clinical pilot study, that suggest a prophylactic potential of vitamin D for COVID-19 patients [9]. Hypovitaminosis D can

increase the risk of cardiovascular diseases, type 2 diabetes, and mental illness. Vitamin D plays a pivotal role in calcium metabolism and bone mineralization. Sufficient vitamin D levels are important for the health and functionality of the musculoskeletal system. Hypovitaminosis D is a phenomenon affecting orthopedic patients worldwide.

Methods: This study researched whether most orthopedic patients in two different cities of different countries had hypovitaminosis D, whether there was a correlation between sunshine hours and vitamin D serum levels, and whether hours of sunshine alone were enough to achieve vitamin D sufficiency among orthopedic patients regardless of their activities. In total, 500 patients in Greece and 500 patients in Germany, admitted to orthopedic surgery departments of 2 hospitals, were analyzed regarding their 25-OH-D serum levels between 1 January 2013 and 31 December 2013. The tested population was set to electively undergo an orthopedic operation. The study was conducted in accordance with the Declaration of Helsinki and approved by the Institutional Review Board of the University of Patras (protocol code 4052 and date of 13 March 2017). In Regensburg and Patras, upon admission, all patients signed to grant consent that their personal, medical, and laboratory data may be retrospectively anonymously analyzed for further studies. Blood was extracted on the day of admission for elective surgery, regardless of the kind of elective operation (no fasting serum). The mean age of the patients was 59 years old. Age was categorized into 4 groups (30 years and younger, 31–50 years old, 51–69 years old, and 70 years and older).

Results: The mean sunshine hours throughout the year were also calculated. Both the German and Greek groups showed hypovitaminosis D. Older patients were more affected. Although there were more hours of sunshine in Greece, Greek orthopedic patients also showed hypovitaminosis D. Hypovitaminosis D affects orthopedic patients independent of their latitude. As shown in other studies, there is a wide prevalence of vitamin D deficiency among the world's population; Hernigou et al. describe vitamin D deficiency as a common phenomenon. In our study, a high percentage of the population in both Germany and Greece, without consideration of their medical history, showed hypovitaminosis D. More than 50% of the tested patients showed not only a 25-OH-D insufficiency but also a deficiency. The lowest values of 25-OH-D in serum were among the patients aged 70 years or more. As shown above, 25-OH-D values increased during the summer months, in which the most sunshine hours were measured. The correlation between sunshine hours and 25-OHD seems to be stronger in the Greek population. The strong correlation in the German population seems to be due to the low status in winter rather than the peak in summer. However, the patients still did not achieve scores of 25-OH-D above 30 ng/mL.

Conclusion: Supplementation of vitamin D may be considered among orthopedic patients to achieve sufficient levels in serum. Sufficient vitamin D levels may be helpful for the treatment of orthopedic patients, reduce the negative effects of operations or postoperational settings.

EFFECT OF THERAPEUTIC EXERCISE PROTOCOL, ON PAIN AND FUNCTION IN PATIENTS WITH LUMBAR DISC DISEASE WITH CLINICAL LOW BACK PAIN AND/OR SCIATICA

C. Matzaroglou[1], A. Evangelatou[2], E. Billis[2], M. Tsekoura[2], E. Trachani[2], S. Lampropoulou[2], M. Adamidou[3], C. Koutsojannis[3], J. Gliatis[4]

[1]Dept. of Physiotherapy, School of Health Rehabilitation Sciences, and Unit of Neuromuscular Diseases Univ. Hospital of Patras, [2]School of Health Rehabilitation Sciences, Dept. of Physiotherapy, Univ. of Patras, [3]Health Physics & Computational Intelligence Laboratory, Physiotherapy Dept., School of Health Rehabilitation Sciences, Univ. of Patras, [4]Dept. of Orthopedic Surgery, Univ. Hospital of Patras, Patras, Greece

Objective: Chronic low back pain is a common cause of disability and has considerable medical, social, and economic implications. An estimated 80% of the population suffers an episode of low back pain at some time in their lives and 5–10% of patients develop persistent back symptoms, while there are potentially many sources of low back pain including the spinal facet and sacroiliac joints) the intervertebral disc is one of the most common. A variety of methods have been used to treat low back pain of unspecified etiology, however, research [1,2,3] seems to focus on the association of a condition such as lumbar disc herniation with the symptomatology of low back pain and sciatica. The aim of this study was to test the effect of a specific therapeutic exercise protocol under the supervision and guidance of a qualified physiotherapist, in patients with lumbar disc herniation with clinical low back pain and/or sciatica who did NOT have neurological complications.

Methods: Therapeutic exercise was applied as an interventional method which can be used to improve the clinical picture of the patients. 61 patients with intervertebral disc herniation in the lumbar spine underwent a special therapeutic exercise for 50 min/d, twice a week for 6 months. The investigation took place in a specially designed physiotherapy room. The evaluation tools used were: 1. A visual analogue scale of pain (VAS) consisting of a 10 cm long horizontal line marked "absence of pain" at one end (0) and "worst possible pain" at the other end (10); 2. The keele STar Back screening Tool questionnaire which aims to identify predictive markers (both physical and psychosocial risk factors) for persistent, inhibitory pain in the TMJ, as well as to categorize patients into risk groups and guide treatment; 3. The Roland-Morris Disability Index, a questionnaire that assesses the disability index of each patient; 4. The Oswestry Disability Index (O.D.) a questionnaire that assesses limitations of various activities of daily living; and 5. The Hospital Anxiety and Depression scale (HADS) which is a scale to detect symptoms of depression and anxiety. These parameters were reassessed at the month and quarter since the implementation of the exercise protocol.

Results: There was significant improvement in all parameters after the intervention The VAS scale improved by 46.2%, the keele STar Back screening Tool improved 58.3%, the Roland–Morris Disability Index improved 64.2%, the O.D.I improved 67.4% and the HADS scale improved 46.2% in anxiety and 61% in depression. All the above parameters showed improvement after the end of the interventions with a percentage significant change before and after the intervention.

Conclusion: The specific therapeutic protocol of the study, accompanied by specific therapeutic exercises [Fig. 1] aimed at dynamic stabilization [4,5] of the lumbar spine, as well as stretching, had a positive effect on patients with lumbar disc herniation. The protocol helped and improved mobility and stability of the lumbar spine and reduced the patients' symptomatology. There were only positive clinical effects on the patients' functionality and mental health.

Finally, it should be noted that the treatment protocol was applied to patients who did not have neurological deficits.

TOWARDS A SYSTEM DYNAMICS MODEL FOR PREVENTION AND TREATMENT OF KNEE OSTEOARTHRITIS

S. A. Xergia[1], C. Matzaroglou[1], N. Liveris[1], C. Tsarbou[1], E. Tsepis[1], E. Billis[1], M. Tsekoura[1], J. Kvist[2], J. Gliatis[3], G. N. Papageorgiou[4]

[1]Dept. of Physiotherapy, Univ. of Patras, Patras, Greece, Patras, Greece, [2]Physiotherapy, Linköping Univ., Linköping, Greece, [3]Dept. of Orthopaedics, Univ. of Patras, Patras, Greece., Patras, Achaia, Greece, [4]Dept. of Management and Marketing, SYSTEMA Research Centre, School of Business Administration, Cyprus, Nicosia, Cyprus

Objective: Osteoarthritis (OA) is a serious chronic disease mostly affecting the knee joint. Despite the many efforts for developing strategies to prevent and control osteoarthritis (OA), the disease is on the rise[1]. Current methods are inadequate to deal with the high complexity and the multiple factors associated with the disease.
Methods: This paper proposes the development of the dynamic knee osteoarthritis simulation (DYNAMIKOS) model as a decision-making tool for health policy-makers to effectively deal with OA. The model is based on the system dynamics (SD) approach[2,3], which is incorporated for the case of the primary and secondary prevention of knee osteoarthritis (KOA). The paper goes through the main qualitative and quantitative procedures that are necessary in order to formulate and validate the DYNAMIKOS model. The first step is to identify the main factors affecting KOA and particularly, develop a causal loop model for the risk factors involved. This is followed by a series of group modeling building (GMB) workshops with experts and stakeholders. Next, a questionnaire survey is designed to collect retrospective data from a representative sample of KOA patients using experimental and control groups. Exploratory and confirmatory Factor Analysis would allow for structural equation modeling (SEM) to be applied before the final system dynamics model is developed.
Conclusion: The proposed DYNAMIKOS model could be used for effectively analyzing the complex interrelationships among the multiple factors that constitute the spread of KOA. In this way plausible prevention strategies could be implemented for effectively managing and leading the potential eradication of KOA.

MORPHOMETRIC SCIATIC NERVE CHARACTERISTICS IN LOW BACK PAIN WITH UNILATERAL RADICULOPATHY CAUSED BY DISC HERNIATION: AN ULTRASOUND IMAGING EVALUATION

C. Matzaroglou[1], A. Kolovou[2], Z. H. Dailiana[3], M. Tsekoura[4]

[1]Dept. of Physiotherapy, School of Health Rehabilitation Sciences, and Unit of Neuromuscular Diseases Univ. Hospital of Patras, Patras, [2]Dept. of Orthopaedic Surgery, Faculty of Medicine, School of Health Sciences, Univ. of Thessaly, Larissa, [3]Dept. of Orthopaedic Surgery, Faculty of Medicine, School of Health Sciences, Univ. of Thessaly, Larissa, [4]School of Health Rehabilitation Sciences, Dept. of Physiotherapy, Univ. of Patras, Patras, Greece

Objective: The word sciatic has Greek origin. Sciatic nerve (SN) is unique because it is not only the longest, but also the thickest nerve in the body. It has an extensive origin from lumbosacral plexus formed by the ventral rami of L4-S3 spinal nerves in the pelvic region [1,2,3,]. Ultrasonography [US], has been used recently to characterize median and ulnar nerves but is seldom used to characterize the lower extremity nerves as sciatic nerve. The reference standard for normal and pathologic lower extremity nerves has not been established.
Methods: 55 healthy volunteers with 110 sciatic nerves, aged 20–89 years old, were studied with US and compared with 59 volunteers' patients with 118 sciatic nerves aged 26–77 years old, which complained about sciatica, and they identified it with lumbar disc prolapse in MRI. Age, sex, height, weight was recorded, and the size and morphology of sciatic nerve were obtained at every predetermined sites. These data provide basic clinical data for the use of ultrasound for the future diagnosis, treatment, and prognostic evaluation of peripheral neuropathy of sciatic nerve [Fig. 1]. The statistical calculations were performed using Sigma Stat Plus software. A Spearman's rank-order correlation model was used in assessing the statistical significance of associations at 0.05 and 0.01 confidence, levels. The rationale for correlation coefficient analytical model in this study was to ascertain parameters positively and negatively correlated with herniated disc, and the chronicity of the symptoms of sciatica.
Results: The mean size of sciatic nerves were 0.578 ± 0.034 cm^2 in males and 0.488 ± 0.03 cm^2 females respectively. Pearson's correlation analysis showed that the mean size was correlated with height and weight. There was no difference in mean size among the different

ages. Women had smaller size of the sciatic nerves than men. Also, the "pathologic sciatic nerves have morphology of "edema", and the size were smaller [Fig. 2]. The statistical calculations were performed using Sigma Stat Plus software. Peripheral nerve ultrasonography is a reliable and reproducible diagnostic method in the hands of experienced examiners. Normal values for the sciatic nerve nerves are provided by our study but with not enough statistical power. Thus, reference values of Sciatic nerve of the lower extremity can facilitate the analysis of abnormal nerve conditions and give useful information and prognostic parameters in patients with sciatica and established nerves disc herniation.

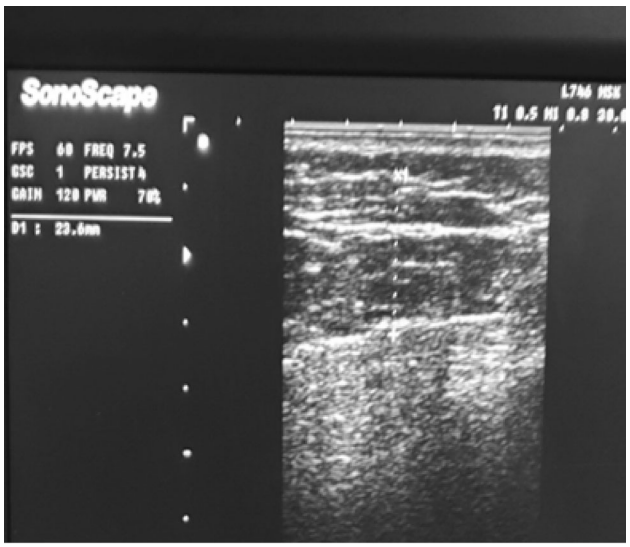

Figure 1. Normal sciatic nerve

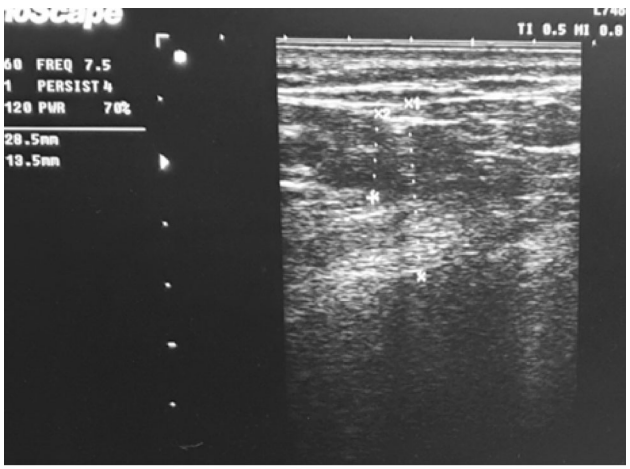

Figure 2. Sciatic nerve with morphology of "edema"

Conclusion: The abnormal nerve conditions and morphologic characteristics give useful information and prognostic parameters in patients with sciatica and established nerves disc herniation. Sciatic nerve unfortunately presents significant variations, its topography, and divisions [4,5]. The topographic variation shows sex effect due to differences in the dimension of pelvis that makes for the adaptability of female pelvis for pregnancy and childbirth. There are a lot of limitations in this study because SN shows substantial variations with landmark structures in the gluteal region [6]. Different population studies have highlighted some of these variations, most of which are variations in relation to piriformis [6,7].

OSTEOPOROSIS-PROVOKED IN MYASTHENIS GRAVIS OF GLYCOCORTICOIDS GCS USAGE: OUR DATA AND LITERATURE REVIEW

C. Matzaroglou[1], A. Marouda[2], E. Matzaroglou-Heristanidu[3], K. Kafchitsas[4], E. Chroni[5]

[1]Dept. of Physiotherapy, School of Health Rehabilitation Sciences, and Unit of Neuromuscular Diseases Univ. Hospital of Patras, Patras, Greece, [2]School of Health Rehabilitation Sciences, Dept. of Physiotherapy, Univ. of Patras, Patras, Greece, [3]Faculty of Medicine, School of Health Sciences, Univ. of Patras, Patras, Greece, [4]Dept. of Spine Surgery, Asklepios Orthopedic Clinic Lindenlohe, Schwandorf, Germany, [5]Dept. of Neurology, Unit of Neuromuscular Disorders, Univ. of Patras, Patras, Greece

Objective: Myasthenia Gravis (MG) is an autoimmune neuromuscular disorder caused by antibodies that target the postsynaptic muscle membrane. The clinical feature of MG is a fluctuating marked weakness limited to the voluntary muscles with an initial manifestation of focal weakness. The main treatment is corticosteroid administration with improvement of muscle strength in all cases of MG [1,2,3]. The main course of treatment includes corticosteroids, yet they carry various side effects, with osteoporosis being particularly significant. Monitoring entails DXA examinations to evaluate bone density and examining biochemical markers such as osteocalcin, alkaline phosphatase, and vitamin D. This study aimed to define how corticosteroids, considering both duration and dosage, impact the wellbeing of patients. More specifically, we examined alterations in bone density and biochemical markers, exploring potential correlations among individuals with MG.

Methods: To assess this risk, we performed a case–control study including the patients in our Unit of Neuromuscular Diseases in University Hospital of Patras, between 2020–2023. Following the study selection, we compared data related to DXA measurements and bone turnovers Multivariate conditional logistic regression estimated odds ratios (ORs) among MG patients using oral glucocorticoids GCs vs. non-users. Adjustments were made for comorbidities and comedications.

Results: In our data identified 38 cases. Major osteoporotic fracture risk was found in 34/38 MG patients currently using oral GCs compared to MG patients (4) not on oral GCs. Cases were all subjects aged between 18–53 years old, who had sustained a major osteoporotic fracture (MOF) between January 1, 2020, and December 31, 2023. MOF was defined as a fracture of the hip, radius/ulna, vertebrae. In literature, 4 studies retrieved regarding MG, in patients of average age 55 years of both sexes. In a study with a population of 283 MG [4] patients receiving corticosteroids (50% with history of fractures and 50% without), DXA showed lower bone density values in subjects with fractures, while the alkaline phosphatase value showed no difference. In another study, comparing patients with MG and control group, it was found that the level of 25(OH)D was lower

in the first group, while alkaline phosphatase, calcium and phosphorus showed no differences in the two groups. In DXA measurement, low bone density values were found in MG patients. In a study focused on the effect of vitamin D, 33 MG patients were enrolled, with 23 receiving corticosteroids and divided into 2 subgroups: those receiving vitamin D and calcium supplementation, and those not. Measurements showed vitamin D and calcium deficiency in unsupplemented patients. A study [5,6] involving 80 MG patients and 62 controls examined the effect of cumulative corticosteroid dosing over 13 y. DXA testing showed low bone density (especially in the hip region) in MG patients compared to healthy subjects and in postmenopausal women compared to premenopausal women. MG patients also showed low osteocalcin.

Conclusion: Patients' osteoporosis is affected by the severity of MG with symptoms being associated with the likelihood of fractures. The risk of osteoporosis increases in case of low vitamin D [7]. Cumulative glucocorticoid use increases the likelihood of osteoporosis, especially in women. In conclusion, glucocorticoid-induced osteoporosis aggravates the quality of life of patients with MG. To avoid osteoporotic fracture, neurologists have to consider shortening the duration of glucocorticoids treatment for MG.

P349
COMPLEMENT FACTOR H-RELATED PROTEIN-5 ENHANCES OSTEOBLAST DIFFERENTIATION

C. N. Son[1], J. H. Lee[1]

[1]Dept. of Rheumatology, Uijeongbu Eulji Medical Center, Eulji Univ. School of Medicine, Uijeongbu, South Korea

Objective: Complement factor H-related protein-5 (CFHR5), a member of the human factor H protein family, has been identified as an enhancer of complement activation. The impact of complement activation on bone and joint has been recognized as arthritis and osteomyelitis. Thus, we conducted a study to compare the effect of CFHR5 on the differentiation of osteoblasts.

Methods: We examined the mineralization of osteoblast cell line (MC3T3-E1 cells) treated with various dose of CFHR5 (0–1000 ng/mL) during osteoblast differentiation. To measure bone mineralization, alkaline phosphatase (ALP) activity and alizarin red S (ARS) was assessed in CFHR5-treated MC3T3-E1 cells for two distinct periods: the early period (1, 3, 7, and 10 d) and the late period (14, 21, and 28 d). Additionally, the levels of RUNX2 and OPN in CFHR5-treated MC3T3-E1 cells were observed by western blotting.

Results: The highest increase in ALP activity was observed in MC3T3-E1 cells at a concentration of 1000 ng/mL for 10 d. Moreover, the expressions of RUNX2 and OPN were significantly increased in treatment with 1000 ng/mL CFHR5 as comparison to that of control. Accordingly, ARS staining exhibited a notable increase in CFHR5 treated cells, indicating that augmentation of bone mineralization.

Conclusion: These findings suggest that CFHR5 promotes bone mineralization in MC3T3-E1 cells, and this effect is associated with the upregulation of RUNX2 and OPN expression.

P350
INSULIN-LIKE GROWTH FACTOR 2-FUSED LYSOSOMAL TARGETING CHIMERAS (ILYTAC) FOR DEGRADATION OF RANKL TO PROTECT OSTEOPOROSIS

C. P. Zhou[1], W. W. Gui[1], G. L. Wang[2], X. H. Lin[1]

[1]Dept. of Endocrinology and Metabolism, [2]Dept. of Orthopedics, Sir Run Run Shaw Hospital, College of Medicine, Zhejiang Univ., Hangzhou, China

Objective: IGF2 is closely associated with the occurrence and development of osteoporosis, with bone marrow mesenchymal stem cells being the main source of IGF2. This study investigates the role of IGF2 deficiency in inducing osteoporosis by constructing a mesenchymal stem cell-specific *Igf2* knockout mouse model. Additionally, the study explores the feasibility of using anti-RANKL@iLYTAC technology (Banik et al., 2020; Zhang et al., 2023), a lysosome-targeted protein degradation technique based on IGF2 fusion protein modules, to treat osteoporosis by selectively degrading the pathogenic protein RANKL in osteoclasts.

Methods: Single-cell sequencing datasets from 13 organs were collected from public databases for integrated single-cell sequencing analysis to examine the expression profile of IGF2 in different organs and tissues. A mesenchymal stem cell-specific *Igf2* knockout mouse model ($Prrx1\text{-}Cre^{+}Igf2^{fl/fl}$) was constructed using the *Cre/LoxP* system and the mesenchymal stem cell-specific Prrx1-cre tool mouse. Femurs of knockout and control mice were subjected to H&E staining and μCT scanning to observe changes in bone microstructure. Bone marrow mesenchymal stem cells (BMMSCs) were extracted for flow cytometry identification. Mouse-derived IGF2(mIGF2) protein was cloned, synthesized, and purified. Anti-RANKL@iLYTAC was formed by incubating the IGF2 protein with anti-RANKL, a monoclonal antibody drug used to treat osteoporosis, which inherently binds to the Fc domain of commercial IgG antibodies. Confocal laser scanning microscope (CLSM) was used to observe the process of iLYTAC(or IGF2-Z) transporting proteins to lysosomes for degradation. Western blot analysis was performed to validate the degradation effect on RANKL, as well as changes in autophagy proteins LC3 and SQSTM1/p62.

Results: Analysis of single-cell sequencing databases from 13 different organs indicated specific high expression of IGF2 in mesenchymal stem cells. We successfully constructed and identified the mesenchymal stem cell-specific *Igf2* knockout mouse model. μCT scanning of the femurs showed a decrease in trabecular number, BMD, and trabecular separation (Tp.Sp), as well as a decrease in cortical bone density (TMD) in the mesenchymal stem cell-specific *Igf2* knockout mice. CLSM revealed effective enrichment of RANKL in lysosomes after treatment with anti-RANKL@iLYTAC. Western blot analysis demonstrated that anti-RANKL@iLYTAC significantly activated autophagy levels and effectively degraded RANKL.

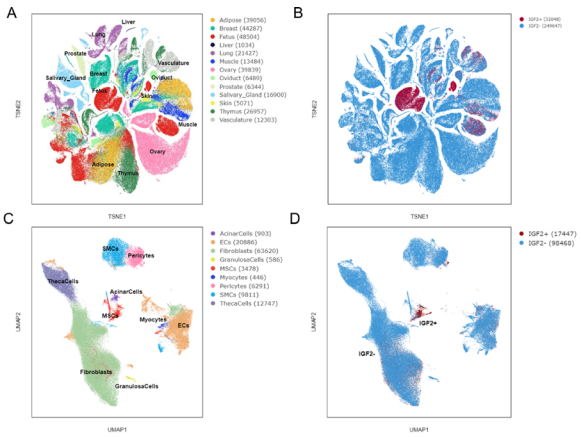

Figure 1. The analysis of integrated single-cell sequencing datasets from 13 different organs demonstrates that Igf2 exhibits high expression in mesenchymal stem cells. A. tSNE visualization analysis of the first-level clustering of single-cell transcriptomic sequencing results from 13 organs. B. Distribution of Igf2 across the 13 organs. C. UMAP visualization analysis of the second-level clustering of stromal cells. D. Specific high expression of Igf2 in the subpopulations of mesenchymal stem cells within stromal cells.

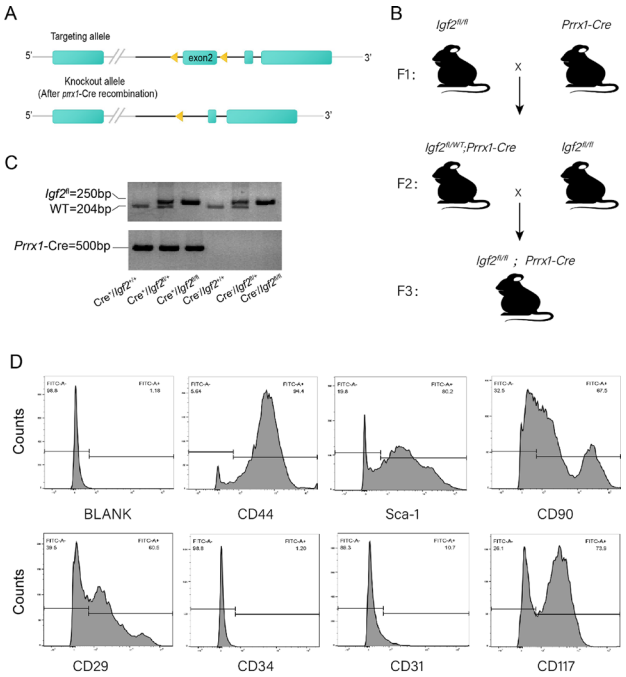

Figure 2. (A-C) The construction of *Prrx1-Cre*$^{+}$*/Igf2*$^{flox/flox}$ mouse. (D)Flow cytometry identification of BMMSC: CD44^{+}, Sca-1^{+}, CD34^{-} and CD31^{-}.

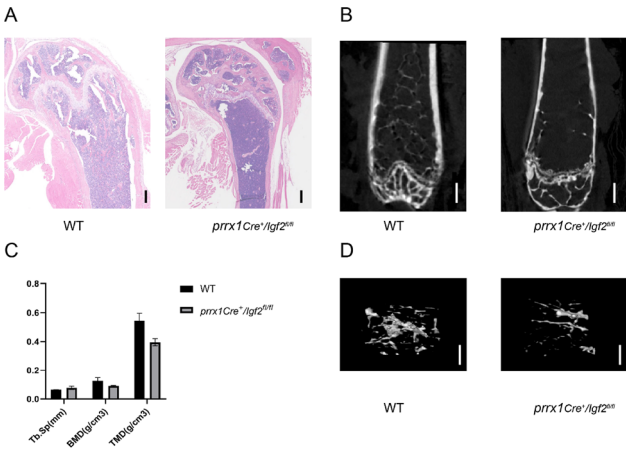

Figure 3. IGF2 deficiency promotes osteoporosis. (A)The representative of H&E staining in femora from *Prrx1-Cre*$^{+}$ *Igf2*$^{flox/flox}$ mice and WT mice. Scale bars: 500 μm. (B-D) Representative μCT images (B,D) and quantitative μCT analysis of bone mass and microarchitecture (C) in femora from *Prrx1-Cre*$^{+}$ *Igf2*$^{flox/flox}$ mice and WT mice. Scale bar: 1 mm.

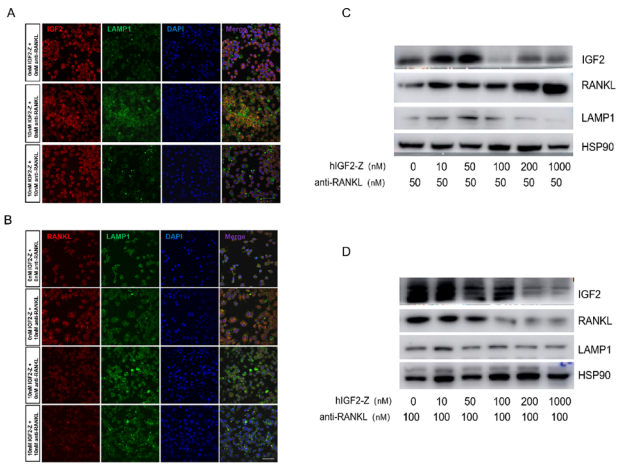

Figure 4. (A-B) CLSM images show the enrichment process of IGF2 and RANKL into lysosomes by 10nM anti-RANKL@iLYTAC. IGF2: red; RANKL: red; LAMP1: green. Scale bar=10μm (C)WB analysis of concentration-dependent human IGF2-Z(hIGF2-Z) and Anti-RANKL (fixed at 50 nM) on inducing RANKL and LAMP1 variation from cells *in vitro*. (D)WB analysis of concentration-dependent hIGF2-Z and anti-RANKL@iLYTAC (fixed at 100 nM) on inducing RANKL and LAMP1 variation from cells *in vitro*.

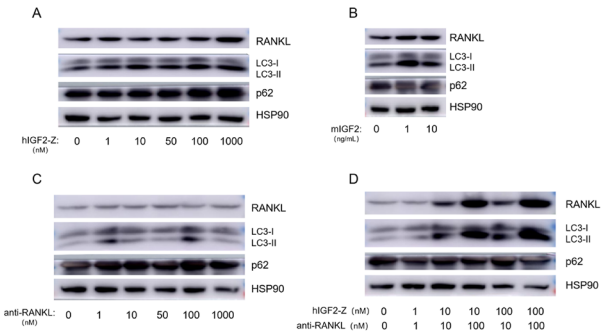

Figure 5. (A)WB analysis of RANKL, LC3 and p62 in hIGF2-Z from 0-1000nM from cells *in vitro*. (B)WB analysis of RANKL, LC3 and p62 in synthesized mIGF2 from 0-10nM from cells *in vitro*. (C)WB analysis of RANKL, LC3 and p62 in Anti-RANKL from 0-1000nM from cells *in vitro*. (D) WB analysis of RANKL, LC3 and p62 in Anti-RANKL@iLYTAC from cells *in vitro*.

Conclusion: IGF2 is specifically highly expressed in mesenchymal stem cells. Mesenchymal stem cell-specific *Igf2* knockout mice effectively induce symptoms of osteoporosis. In vitro treatment of cells with Anti-RANKL@iLYTAC showed effective targeted transport of RANKL to lysosomes and its subsequent degradation by activating lysosomal autophagy. These findings suggest that iLYTAC technology, with IGF2 as a universal module, may be an effective novel approach for treating osteoporosis.

HIP CARISKORE: A CLINICAL TOOL FOR IMPROVING THE APPROPRIATENESS OF ECHOCARDIOGRAPHY IN ORTHOGERIATRIC PATIENTS

C. Properzi[1], V. Gemo[1], F. Perini[1], M. Baroni[1], C. Ruggiero[1]

[1]Geriatric and Orthogeriatric Unit, SM Misericordia Hospital, Univ. of Perugia, Perugia, Italy

Objective: The hip fracture requires surgical repair within 24–36 h. Cardiovascular risk assessment is recommended by the ACC/AHA guidelines in the presence of organ-specific symptoms, clinical signs and history of disease. In clinical practice, the request for transthoracic echocardiography (TTE) is often performed in the absence of symptoms and as a screening for cardiac disease that would rarely change perioperative management. This behavior results in unnecessary additional examinations and potential surgical delay. The purpose of this study is to develop a clinical practice score based on clinical-instrumental elements for improving the appropriateness of requesting and performing TTE in the preoperative phase.

Methods: Prospective observational study conducted in 385 orthogeriatric patients consecutively admitted to the Orthogeriatric Unit of Hospital of Perugia from January to September 2023. The Hip CaRiskore was defined by a multidisciplinary evaluation and included the following criteria: unknown systolic murmur, METs < 4, overload alterations on EKG. The simultaneous presence of the three criteria was a prerequisite for the TTE request. The study evaluated whether Hip CaRiskore determines valid criteria for requiring TTE, the likelihood that it reveals cardiac pathology that could modify medical or anesthesiologic management, and whether it is able to reduce unnecessary use of TTE and consequently delayed access to surgery.

Results: Of the 385 participants, patients' TTE with positive Hip CaRiskore were more likely to detect disease (43.24% for moderate-severe aortic stenosis and 29.73% for moderate-severe mitral regurgitation) compared with patients TTE with systolic murmur (23.62% and 14.96% respectively) and negative Hip CaRiskore (4.31% and 6.03% respectively). We analyzed the association with moderate-severe aortic stenosis of Hip CaRiskore and systolic murmur and we obtained that Hip CaRiskore predicts moderate-severe aortic stenosis with a higher probability (49%) than systolic murmur (36%).

Conclusion: By integrating ACC/AHA guidelines with Hip CaRiskore, we can improve the appropriateness of TTE request, reducing resource use and delay in access to surgery without sacrificing patient safety.

P352
PREVIOUS BISPHOSPHONATE THERAPY AND BASELINE SERUM P1NP AS INDICATORS OF SIX-MONTH BONE MINERAL DENSITY RESPONSE TO ROMOSOZUMAB: REAL WORLD DATA FROM A METABOLIC BONE SERVICE IN ENGLAND

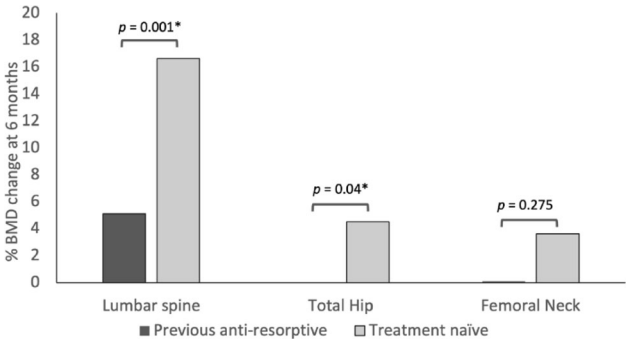
C. Rakieh[1], T. Roberts[1], J. Cole[1], M. K. Javaid[2], B. Tins[3], C. Mennan[1], D. E. Powell[1]

[1]Metabolic Bone Disease Unit, Robert Jones and Agnes Hunt Orthopaedic Hospital, Oswestry[2]NDORMS, Univ. of Oxford, Oxford, UK, [3]Radiology Dept., Robert Jones and Agnes Hunt Orthopaedic Hospital, Oswestry, UK

Objective: To describe real-world patient acceptability of romosozumab in an English patient population and assess the percent change in BMD at 6 months.

Methods: Patients attending a metabolic bone centre in England in 2023 were included in this retrospective single centre study. Women aged > 50 y with a major osteoporotic fracture (MOF) within two years and a BMD T-score $\leq$ -2.5, at the lumbar spine (LS), total hip (TH), or femoral neck (FN) were considered eligible according to the national guidelines. BMD measurements and serum P1NP levels were measured at baseline (prior to treatment) and at month 6.

Results: Of the 124 patients offered romosozumab, 105 (85%) agreed to start treatment between January-December 2023. Data at 6 months were available for 17 patients: mean age 73.2y $\pm$ 9.9, 82% with a vertebral fracture and 52.9% with additional non-vertebral MOF including 29.4% with a hip fracture, 9 (53%) patients were treatment-naïve, and 8 (47%) had previous bisphosphonates (4 alendronate, 1 risedronate, and 3 zoledronate). At 6 months, a significant BMD gain of 10.9% was observed at LS ($p < 0.001$), while FN and TH demonstrated modest BMD gains of 2.4% and 2.3%, respectively, which were not statistically significant ($p > 0.05$). Treatment-naïve patients showed significantly greater gains in BMD at LS (16.6 vs. 5.2%, $p = 0.001$) and TH (4.5 vs. $-$ 0.02%, $p = 0.04$) compared with those on previous bisphosphonates (Figure). Strong positive correlations were found between baseline P1NP and BMD %change at the LS ($r = 0.75$, $p < 0.001$) and FN ($r = 0.78$, $p < 0.001$) with a weaker positive correlation at the TH ($r = 0.49$, $p = 0.059$).



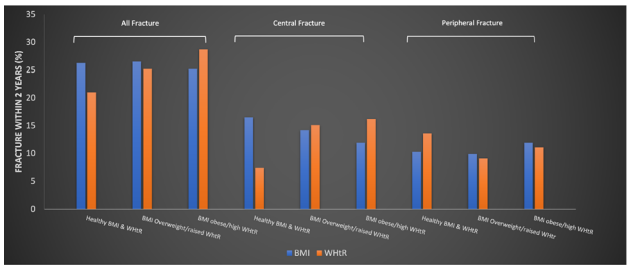
Conclusion: This real-world data demonstrates, for the first time, a high patient acceptability of romosozumab with rapid BMD gains in an English patient population. The changes in BMD observed at 6 months are comparable to those reported in the ARCH trial. However, the BMD response is blunted by previous bisphosphonate therapy, which highlights the importance of osteoporosis treatment sequence for optimal patient management. P1NP at baseline may play a role in patient selection, but more data is needed to explore this area.

P353
THE RELATIONSHIP BETWEEN CENTRAL ADIPOSITY MEASURED BY WAIST TO HEIGHT RATIO, BMI OBESITY AND RECENT OSTEOPOROTIC FRACTURE: A CROSS-SECTIONAL STUDY

C. Rakieh[1], D. E. Powell[1], C. Mennan[1], B. Tins[2], T. Roberts[1], M. K. Javaid[3]

[1]Metabolic Bone Disease Unit, Robert Jones and Agnes Hunt Orthopaedic Hospital, Oswestry, [2]Radiology Dept., Robert Jones and Agnes Hunt Orthopaedic Hospital, Oswestry, [3]NDORMS, Univ. of Oxford, Oxford, UK

Objective: To assess the relationship between BMI, waist to height ratio (WHtR), and the prevalence of recent osteoporotic fracture including all, central, and peripheral fractures within 2 y.
Methods: A cross-sectional retrospective, single-centre study assessing consecutive female patients aged > 50 years old who attended a BMD scan at a UK metabolic bone service in 2023. Recent osteoporotic fractures within 2 years were assessed for: all fracture, central fracture (spine, hip, rib, pelvis, and proximal humerus) and peripheral fracture (distal humerus, forearm, distal femur, proximal tibia/fibula, and ankle). A logistic regression analysis was performed to assess the association between fracture sites, WHtR groups (healthy 0.4–0.49, raised 0.5–0.59, and high central adiposity ≥ 0.6), and BMI groups (healthy 18.5–24.9, overweight 25–29.9, and obese ≥ 30).
Results: 515 patients were included: mean age (y) 71.2 ± 10.4, mean BMI 27.5 ± 5.9, mean WHtR 0.58 ± 0.08, mean total hip T-score -1.35 ± 1.14, prevalence of recent fracture was 26% including 14.4% central fracture. Significant differences in fracture distribution were found between BMI and WHtR classification systems ($p < 0.01$) (Figure). When adjusted for total hip BMD, patients with high central adiposity had significantly higher rates of all (OR 2.1, 95% CI 1.1–4.2) and central fracture (OR 4.2, 95% CI 1.6–11.1) compared to those with normal central adiposity. These significant associations were independent of BMI and age. BMI categories showed opposite association with central fracture with a tendency to fewer central fracture in those who were overweight and obese, but the changes did not reach statistical significance. BMI values, however, demonstrated a significantly negative association with central fracture, OR 0.91, 95% CI 0.85–0.99. No significant associations were found between either BMI and WHtR categories and peripheral fracture.



Conclusion: These results indicate a clear discordance between BMI and WHtR associations with a recent central fracture. Central adiposity appears to be a potential risk factor for central fracture. More data is needed to confirm these results and evaluate the added value of using central adiposity in routine fracture risk assessment.

P354
ENHANCED INFLAMMATORY TH17 CELLS DURING LEPROSY REACTIONS AUGMENT BONE LOSS

C. Saini[1], L. Sapra[1], A. Bhardwaj[1], V. Ramesh[2], P. Puri[3], R. K. Srivastava[1]

[1]Dept. of Biotechnology, All India Institute of Medical Sciences, Delhi, [2]Dept. of Dermatology, ESI College and Hospital, Faridabad, [3]Dept. of Dermatology, SJH, Delhi, India

Objective: Osteoporosis in type 1 reactions (T1R) of leprosy is an inflammatory condition. Leprosy reaction itself and steroid treatment to cure it can modulate bone health. Th17 cells are associated with inflammation in both leprosy T1R reactions and bone loss. Thus, their role in leprosy-mediated bone loss needs to be deciphered. We aimed to assess the role of Th17 cells in patients with leprosy T1R reactions.
Methods: This study involved 10 patients with leprosy reaction (T1R-S) treated with steroids (prednisolone) and 10 non-reaction (NR) patients (borderline tuberculoid) attending the leprosy clinics in the Department of Dermatology, Safdarjung Hospital, New Delhi, India. For the recruitment of patients, BMD was measured in the spine, femur, neck and forearm by DXA. PBMCs were stimulated with *MLSA (Mycobacterium leprae sonicated antigen)* for 48 h. By using flow cytometry, we identified Th17 cells in the peripheral blood mononuclear cells. Gene expression of cytokines, such as *IL-17A and TGF-β* and *RUNX2, P1NP* (osteoblast markers) was further examined using real-time PCR (q-PCR) in the stimulated PBMCs of both type of leprosy patients.
Results: T1R-S patients had significantly ($p < 0.05$) higher percentages of IL-17A-producing Th17 ($CD3^+CD4^+$ $CCR6^+IL\text{-}17^+$) cells as compared with non-reaction (NR) patients. Of interest, T1R-S showed significantly ($p < 0.002$) lower percentages of Treg cells ($CD3^+CD4^+CD25^+FOXP3^+$) than NR patients. Surprisingly, osteoblast markers (*RUNX2* and *P1NP*) showed a significant ($p < 0.02$) positive correlation with IL-17 cells. Moreover, inflammatory cytokines IL-17A mRNA expression were significantly ($p < 0.01$) high in T1R-S patients in stimulated PBMC as compared to NR patients. On the other hand, TGF-β was significantly ($p < 0.03$) high in NR as compared to T1R-S patients.
Conclusion: Participants with leprosy reactions and steroid treatment have enhanced levels of pathogenic/inflammatory Th17 cells, which could lead to leprosy-reaction-mediated bone loss. The study has clinical implications with respect to the management of bone health in leprosy disease conditions.

P355
BILATERAL TRANSIENT OSTEOPOROSIS OF THE HIP: A NEGLECTED CAUSE OF HIP PAIN DURING PREGNANCY

C. Soares[1], H. Hugo[1], M. Maria[1], A. Anita[1], S. Susana[1], D. Daniela[1]

[1]Unidade Local de Saúde do Alto Minho, Ponte de Lima, Portugal

In pregnancy and lactation women need to supply an increased amount of calcium daily, supported by increased intestinal absorption in pregnancy and maternal bone resorption during lactation. Assim, changes in bone microarchitecture may occur, temporarily reducing skeletal strength.

We report a case of a 39-year-old woman, who presented at the Rheumatology department two weeks post-cesarean delivery with bilateral coxalgia. The patient without relevant personal history, reported the onset of left mechanical hip pain from 33 weeks of pregnancy with a progressively worsening accompanied by limited mobility and an inability to walk, requiring the use of crutches for ambulation. After delivery, similar complaints arose on the right side. There was no history of trauma or other accompanying symptoms. The patient promptly underwent a hip x-ray which showed a decrease in bone density in the left hip. Later, the MRI revealed bone edema in femoral heads and acetabulum (Fig. 1). The hemogram and phospho-calcium metabolism were normal and the acute phase parameters were negative. Bone densitometry, carried out 2 months after delivery, showed a T-score of -1.8 at the femoral neck and at the lumbar spine. The diagnosis of transient osteoporosis of the hip (TOH) was established and the patient underwent analgesia and rest with a later gradual increase in the load.

In the follow-up appointment, 7 months later, she was asymptomatic, and the X-ray showed normalization of the previously detected changes in bone density. Pregnancy is a recognized risk factor for TOH, especially in the last trimester. Clinically it presents as a sudden and progressive onset of back, groin, hip, or lower extremity pain that can affect joint mobility and typically worsens with weightbearing. MRI is the imaging test of choice and typically TOH resolves in the first year after delivery with conservative strategies.

Figure 1. Coronal-STIR sequence shows a signal hyperintensity of the femoral head and neck bilaterally, left acetabulum, and in the external obturator and adductor muscles.

CO-DESIGNING AN OSTEOPOROSIS EDUCATION PROGRAM WITH CONSUMERS FOR MULTICULTURAL COMMUNITIES IN AUSTRALIA

C. Tang[1], B. Brady[2], D. Lim[3], B. Sidhu[2], W. Chen[4], S. Carter[5], T. Wong[6], J. Center[4]

[1]Institute of Health and Sport, Victoria Univ., Melbourne, [2]South Western Sydney Local Health District, Liverpool, [3]Centre for Improving Palliative, Aged and Chronic Care through Clinical Research and Translation (IMPACCT), Univ. of Technology Sydney, Ultimo, [4]Garvin Institute of Medical Research, Darlinghurst, [5]Faculty of Medicine and Health, Univ. of Sydney, Sydney, [6]No affiliation (consumer), Sydney, Australia

Objective: Older people of Asian descent experience a high risk of osteoporosis (OP). Lack of culturally appropriate resources to support diagnosis and management of the condition can hinder their ability to self-manage. This study partnered with consumers from Mandarin, Cantonese and Vietnamese speaking backgrounds and health professionals to co-design a culturally appropriate osteoporosis education and self-management program.
Methods: The study was conducted in Greater Western Sydney, one of the most culturally diverse regions in Australia. Eleven consumers with lived experience of OP, representing three language groups, and 12 health professionals were recruited. Using the experience-based co-design approach, interviews and workshops were first conducted separately with consumers and health professionals to explore the challenges experienced along the journey of OP diagnosis and management. Subsequently, two workshops were held, where consumers and health professionals worked in collaboration to develop OP resources. Challenges in the journey of care were analysed using an interpretive phenomenological approach while a categorical analysis was conducted in the second phase of the study to highlight the key touchpoints that guided the development of the OP resources.
Results: Challenges in the journey of care included (i) lack of access to reliable sources of information related to bone health, (ii) OP viewed by consumers as a normal part of ageing, and (iii) the lack of opportunity to discuss matters related to bone health with their health professionals. Three key components were identified for the development of resources: (1) the need for multi-media resources, (2) consumer-friendly in-language written materials and (3) involvement of community health workers for dissemination.
Conclusion: The findings highlighted what people from multicultural communities want in an OP resource and provided a practical guide for the key components of such a resource.

P357
EVALUATING THE IMPACT OF A CO-DESIGNED OSTEOPOROSIS EDUCATION PROGRAM (MINDSET) FOR MULTICULTURAL COMMUNITIES IN AUSTRALIA

C. Tang[1], B. Brady[2], B. Sidhu[2], D. Lim[3], W. Chen[4], S. Carter[5], T. Wong[6], J. Center[4]

[1]Institute of Health and Sport, Victoria Univ., Melbourne, Melbourne, Australia, [2]South Western Sydney Local Health District, Liverpool, Australia, [3]Centre for Improving Palliative, Aged and Chronic Care through Clinical Research and Translation (IMPACCT), Univ. of Technology Sydney, Ultimo, Australia, [4]Garvin Institute of Medical Research, Darlinghurst, Australia, [5]Faculty of Medicine and Health, Univ. of Sydney, Sydney, Australia, [6]No affiliation (consumer), Sydney, Australia

Objective: Osteoporosis (OP) education programs are effective for improving older people's knowledge about the disease. Using a co-designed OP education program—MultIcultural commuNities co-DeSigned ostEoporosis Toolkit (MINDSET), this study aimed to evaluate the reach, acceptability, feasibility and effects of this program on older people from three selected language groups (Mandarin, Cantonese and Vietnamese).
Methods: The study was conducted in Greater Western Sydney, one of the most culturally diverse regions in Australia between October 2022 and June 2023. Ten bilingual community health workers were

trained to deliver the MINDSET program to people from the three selected language groups in the community. The reach of the program was evaluated based on the number of attendees of the program and the number of community sessions. Feasibility and acceptability were evaluated via a study-specific questionnaire administered to workshop participants appraising their satisfaction with the program. All attendees were required to complete a pre-post OP Knowledge Assessment Tool (OKAT), a validated outcome measure to evaluate osteoporosis-related knowledge.

Results: A total of 157 participants (n = 98 Mandarin/Cantonese-speaking and 59 Vietnamese-speaking) were recruited for the study. All groups highly rated the intervention for its feasibility and acceptability, with 90% of participants stating that they would likely/very likely recommend the program to others. There was also a significant improvement in pre-post scores on the OKAT in both the Mandarin/Cantonese group (mean difference 2.3, 95% CI 1.4–3.1) and the Vietnamese group (mean difference 2.1, 95% CI 1.3–2.9).

Conclusion: The findings provide preliminary evidence that MINDSET is an acceptable, feasible and effective community-based education program to improve OP-specific knowledge. Future research needs to evaluate if such community-based programs can be further adapted to facilitate behaviour changes towards positive OP management.

P358
EXPLORING SELF-CARE EXPERIENCES IN OSTEOPOROTIC PATIENTS: A SYSTEMATIC REVIEW

C. Tedesco[1], V. Bernalte Martí[2], G. Pucciarelli[3], E. Vellone[3], E. Basilici Zannetti[3], N. Cittadini[3], A. Pennini[3], U. Tarantino[4], R. Alvaro[3]

[1]Dept. of Biomedicine and Prevention, Univ. of Rome Tor Vergata, Rome, Italy, [2]Dept. of Nursing, Faculty of Health Sciences, Univ. of Jaume I, Castellón de la Plana, Spain, [3]Dept. of Biomedicine and Prevention Univ. of Rome Tor Vergata, Rome, Italy, [4]Dept. of Orthopaedics and Traumatology Policlinico Tor Vergata Foundation, Univ. of Rome Tor Vergata, Rome, Italy

Objective: To summarize knowledge about experiences in self-care behaviors, according to Riegel's middle range theory of self-care (1), in patients affected by osteoporosis.

Methods: A systematic review was conducted to identify qualitative and mixed methods studies, through database research performed on 6 databases (PubMed, Web of Science, ProQuest, CINAHL, Scopus, and Cochrane) until June 2023, with 27 papers identified. The methodological quality of the articles was ensured using the JBI Critical Appraisal Tool for Qualitative Research (2).

Results: The three dimensions of self-care appear to be recognised in the articles, as seen in Fig. 1. The most addressed dimension of self-care in this review is 'maintenance', principally associated with adherence to therapy; 'management' mainly related to the management of symptoms, and 'monitoring' predominantly related to instrumental tests. A relevant cross-cutting topic that emerges is the relationship with healthcare professionals. For every main dimension of self-care, several subthemes were identified: This implication could help researchers better understand the specific self-care experience in osteoporosis. In detail, for self-care 'maintenance' seven subthemes have been identified, while for 'management' and 'monitoring' four have emerged (Fig. 1).

	SELF-CARE MAINTENANCE	SELF-CARE MONITORING	SELF-CARE MANAGEMENT
SUBTHEMES →	ADHERENCE/NON-ADHERENCE TO THERAPY ATTITUDES TOWARD THERAPY RELATIONSHIP WITH HEALTHCARE PROFESSIONALS DIET PHYSICAL ACTIVITY FRACTURE RISK REDUCTION LIFESTYLE CHANGES	DIAGNOSTIC AND INSTRUMENTAL TESTS PERCEPTION OF SYMPTOMS AND RISKS INTERPRETATION OF TEST RESULTS RELATIONSHIP WITH HEALTHCARE PROFESSIONALS	MEDICATION MANAGEMENT PROACTIVE ACTIONS FOR MANAGEMENT SYMPTOMS AND DISEASE MANAGEMENT BARRIERS AND FACILITATORS IN MANAGEMENT

Figure 1. Dimensions of self-care addressed by each study

Conclusion: The findings of this review point towards the implementation of educational interventions related to self-care maintenance, monitoring, and management that should be encouraged; They should be led by specially trained health professionals, particularly nurses, providing specific information to avoid incompleteness and confusion. These aspects are also supported by the literature (3–7). Consequently, more education in the area of self-care behaviours could contribute to the empowerment of the patient and to the improvement of quality of life: maintaining a self-care attitude could allow osteoporotic patients to live a more stable and controlled life.

P359
STANDARDIZATION OF TOTAL BODY COMPOSITION PARAMETERS BY DUAL-ENERGY X-RAY ABSORPTIOMETRY AND ITS IMPACT ON BODY COMPOSITION-DERIVED DIAGNOSTICS: THE OSTEOLAUS COHORT

C. Vendrami[1], G. Guillaume[1], E. Gonzalez Rodriguez[1], O. Lamy[2], D. Hans[1], E. Shevroja[1]

[1]Interdisciplinary Center of Bone Diseases, Rheumatology Unit, Bone and Joint Dept., [2]Internal Medicine Unit, Medicine Dept., Lausanne Univ. Hospital and Univ. of Lausanne, Lausanne, Switzerland

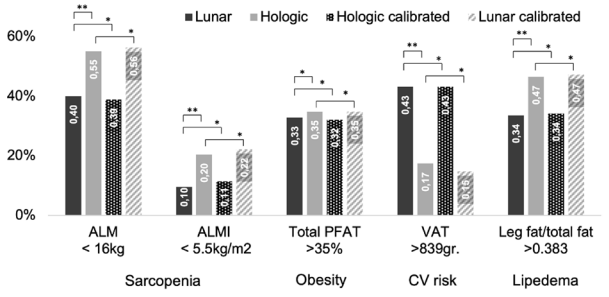
Objective: To standardize body composition (BC) parameters between the latest generation of DXA: Hologic Horizon A System™ and GE Lunar iDXA™; and to assess the impact of this standardization on the prevalence of BC derived diagnostics.

Methods: This study includes 926 postmenopausal women with whole body DXA assessment on each device, during the same day, following the ISCD guidelines. Participants were 72.9 ± 6.9 y,

measured 160.3 ± 6.6 cm and weighted 66.1 ± 12.7 kg. The dataset was split in a train (80%) and test (20%) subsets, stratified for age, height and weight; the standardization equations were derived from the train set and evaluated in the test set. We performed visual (Bland–Altman) and numerical (Pearson/Spearman, t-test/Wilcoxon) comparisons for each DXA-device measure. The standardization equations were derived following backward stepwise multiple linear regressions. Their performance was assessed in both datasets using r-squared and mean absolute error. The impact of this standardization on diagnostics of sarcopenia, lipedema, cardiovascular risk and obesity was assessed in the test set using relative risk (RR), accuracy, kappa score and McNemar tests.

Results: Total and regional body mass were similar ($p > 0.05$) and highly correlated (0.97–0.99) between devices. Bone mineral content (BMC) was higher for all regions in Lunar ($p < 0.05$), while fat and lean mass differed based on the region. Regression equations showed high performance metrics in both datasets. The RR of sarcopenia was 1.37 and 2.13 higher ($p < 0.05$) in Hologic using appendicular lean mass (ALM) and ALM/height^2, respectively; lipedema was 1.39 higher ($p < 0.05$) based on leg fat/total fat; cardiovascular risk was 0.40 lower ($p < 0.05$) based on visceral adipose tissue mass; obesity was not different ($p > 0.05$) based on percent fat. After standardization, these classification differences disappeared, accuracies and kappa scores increased (Fig. 1).

Figure 1: Prevalence of clinical diagnosis cut-offs per devices before and after standardization



Legend: p-value from McNemar test: p*>0.001, p**<0.001; ALM: Appendicular Lean Mass; ALMI: ALM/height^2; PFAT: percent fat; VAT: Visceral Adipose Tissue

Conclusion: This is the first and largest study to standardize DXA devices comprising all BC regions and parameters, including with an internal validation step. Differences in DXA devices and software impact BC assessment. Up to twofold differences in prevalence were seen in BC derived diagnostics. Providing inter-DXA-devices standardization equations addresses this issue. External validation is further needed. Further studies and disease definitions shall consider device differences.

P360
WHAT IS THE EFFECT OF HORMONE REPLACEMENT THERAPY (HRT) ON PREVALENCE, INCIDENCE, AND SEVERITY OF OSTEOARTHRITIS (OA) OF THE KNEE, HIP AND HANDS? A SYSTEMATIC REVIEW

C. W. Hillman[1], K. Marino[2], O. O'Sullivan[1], S. Kluzek[1], R. Atkinson[3], A. Hassan[4]

[1]Univ. of Nottingham, Nottingham, [2]Keele Univ., Keele, [3]Nottingham Univ. Hospitals NHS Trust, Nottingham, [4]Institute of Sport, Exercise and Health (ISEH), London, UK

Objective: Osteoarthritis (OA) is a degenerative disease that can lead to pain, reduced mobility, quality of life and disproportionately affects women[1]. This review explores the effect of HRT on the prevalence, incidence or severity of hip, knee or hand OA in peri- or post-menopausal women.

Methods: A systematic review was performed using PRISMA guidelines and prospectively registered on PROSPERO and a search was conducted (7/10/22) on Medline. Two independent reviewers screened results, extracted the data, and conducted a quality assessment with the Risk of Bias In Non-randomized Studies—of Exposure (ROBINS-E) tool, with a third reviewer for arbitration. Studies were primary research using validated patient reported outcome measures (PROMs) or objective measures of OA.

Results: 27 studies were included, all observational in design. 11 studies assessed hip OA, 19 assessed knee OA, and 8 assessed hand OA. Methods of outcome measurement included radiographic measures (n = 16), joint replacement surgery (indicated by OA) (n = 9), healthcare records (n = 1), and PROMs (n = 1). Most studies (n = 17) were considered to have a'High Risk of Bias'. Positive correlations between HRT use and hip or knee replacement were observed across studies. Results were inconclusive for other outcome measures and the hand.

Conclusion: The included studies varied considerably in terms of confounder adjustment, exposure, and outcome measurement. Despite these limitations, use of HRT appears to be associated with an increased risk of receiving a knee or hip joint replacement indicated by OA. Informed by our critique of the literature, suggestions for high quality research, including appropriately analysed confounders, appropriate exposure control and use PROMs alongside objective measures of disease are discussed.

P361
FACTORS RELATED TO FUNCTIONAL PROGNOSIS AFTER FRAGILITY HIP FRACTURE

C. Y. Chu[1], Y. Chan[1], Y. K. Tan[1], S. T. Yip[1], N. F. Lui[1], K. L. Tiu[2], K. B. Lee[2], W. Li[2], K. K. Li[2]

[1]Occupational Therapy Dept., [2]Dept. of Orthopedics & Traumatology, Queen Elizabeth Hospital, Hong Kong, SAR China

Objective: Fragility hip fracture often leads to a decline in functional capacity in elderly patients. Functional outcome could be influence by a variety of factors. Understanding those factors may help occupational therapists intervene early to improve patient's recovery and facilitate discharge and triage planning. We aimed to identify factors related to functional prognosis after fragility hip fracture.

Methods: Patients aged 60 or above who suffered from fragility hip fracture and attended Fragility Fracture Day Rehabilitation Program (FFDR) after hospital discharge in between September 2022 to October 2023 were recruited in this retrospective study. All subjects underwent either conservative or operational intervention during the hospital stay. Occupational therapists, allied with doctors, nurses and physiotherapists, provide education on bone health, fall prevention and rehabilitation training in the FFDR. Demographics including age, gender, cognitive status measured by Abbreviated Mental Test (AMT), discharge destinations, length of stay in acute hospitals and post-fracture duration were collected and studied as independent factors. Functional status at premorbid and community phase was measured by Modified Barthel Index (MBI). Data were collected by occupational therapists at acute admission to hospital after the fracture occurrence and during subjects' first attendance to FFDR after hospital discharge. Each subject's functional outcome was determined by the discrepancy in MBI score between the post-discharge status and premorbid status. Pearson's correlation was used to analyze the correlation between the independent factors and the functional

outcome. Factors that show association were further studied by regression analysis.

Results: 141 subjects aged from 61–101 (mean age: 84) were recruited in the study. The mean reduction in MBI among all subjects was 20. Age ($r = 0.336$, $p < 0.001$) and cognitive status in post-operative stage ($r = -0.377$, $p < 0.001$) are correlated with functional outcome. Both of them are significant predictors of functional outcome ($p < 0.005$).

Conclusion: Age and cognitive status are found to be related to post-fracture functional prognosis. Patients with older age or poor cognitive status tend to have a poorer functional prognosis after fragility hip fracture. This could help early identification of those with greater odds of poor functional outcome. Measures for better care planning like carer education and home modification could be initiated at the early stage of rehabilitation.

P362
VALIDATION OF THE OSTEOPOROSIS SELF-ASSESSMENT TOOL FOR ASIA AND TAIWAN FOR THE PREDICTION OF OSTEOPOROTIC FRACTURE RISK

C.-C. Li[1], L.-C. Ou[2], Y.-F. Chang[3], C.-S. Chang[3], Z.-J. Sun[4], T.-T. Cheng[5], C.-H. Wu[6]

[1]Institute of Allied Health Sciences, College of Medicine, National Cheng Kung Univ., Tainan, [2]Dept. of Family Medicine, Kaohsiung Medical Univ. Hospital, Kaohsiung, [3]Dept. of Family Medicine, National Cheng Kung Univ. Hospital, College of Medicine, National Cheng Kung Univ., Tainan, [4]Dept. of Family Medicine, National Cheng Kung Univ. Hospital Douliu Branch, College of Medicine, National Cheng Kung Univ., Yunlin, [5]Division of Rheumatology, Allergy, and Immunology, Dept. of Internal Medicine, Kaohsiung Chang Gung Memorial Hospital, Kaohsiung, [6]Institute of Gerontology, Medical College, National Cheng Kung Univ., Tainan, Taiwan

Objective: Patients with low bone density face an increased risk of future fractures and should be actively screened for mitigating this risk. Considering the inadequate feasibility of DXA, identifying high-risk groups through simple questionnaires for further bone density measurements is plausible. Currently, the commonly used tools for this purpose include the osteoporosis self-assessment tool (OSTA), the osteoporosis self-assessment tool for Taiwan (OSTAi) and the male osteoporosis self-assessment tool for Taiwan (MOSTAi). This study aimed to evaluate the sensitivity and specificity of these tools for predicting the 10-year risk of major osteoporotic fractures by comparing them with the FRAX score without BMD.

Methods: This study enrolled subjects surveyed from 2009 to 2010 in two communities in Taiwan. The OSTA, OSTAi and MOSTAi were calculated, and lumbar/hip BMD was measured via DXA, accordingly. The ability of cross-sectional comparisons to predict osteoporosis (T-score ≤ -2.5) was also analyzed. This study also linked to Taiwan's National Health Insurance Research Database to confirm major osteoporotic fracture data within 10 years to evaluate the cutoff values of OSTA (≤ -1), OSTAi (≤ -1), MOSTAi (≤ 11) and FRAX scores ($\geq 20\%$) for detecting future fractures in the real world.

Results: A total of 1976 participants were identified in the study. The participants were mostly female (52.8%), with a mean age of 65.4 y. In contrast with those of MOSTAi (sensitivity/specificity = 0.53/0.62), the OSTA (0.82/0.88) and OSTAi (0.86/0.89) have high sensitivities for detecting the risk of osteoporosis (T-score ≤ -2.5). In women, the OSTA (0.80) and OSTAi (0.86) have high sensitivities for determining the probability of major osteoporotic fractures at 10 years compared to the FRAX-MOF risk without BMD (0.35). However, the FRAX MOF risk without BMD (0.07) and MOSTAi (0.46) had low sensitivities in men.

Conclusion: In women, the necessity of bone density measurements and 10-y major osteoporotic fractures can be screened with either the OSTA or OSTAi, but the use of the MOSTAi needs to be further modified for men.

P363
CARDIOVASCULAR FUNCTION AND HEART RATE VARIABILITY PREDICT SARCOPENIA RISK IN THE ELDERLY

C.-F. Huang[1], P.-W. Hsu[2], Y.-L. Wang[3], S.-S. Lee[3], W.-H. Hsu[3], T.-Y. Mao[3]

[1]En Chu Kong Hospital, National Yang Ming Chiao Tung Univ., Chaoyang Univ. of Technology, Taichung, [2]Lo-Hsu Medical Foundation Lotung Pohai Hospital, Yilan County, [3]Chaoyang Univ. of Technology, Taichung, Taiwan

Objective: The identification and management of sarcopenia in older adults has become a major health issue. The aim of this project is to collect straightforward and noninvasive measurements of cardiovascular function, along with heart rate variability features, to create a model that can forecast the probability of developing sarcopenia.

Methods: The study was done in central Taiwan and had 418 participants (105 men, 313 females) with a mean age of 73.32 ± 8.81 y. The study incorporated a 3-min assessment of cardiovascular function and heart rate variability, along with a screening for sarcopenia utilizing metrics such as appendicular skeletal muscle index, grip strength, and walking speed as per the guidelines set by the Asian Working Group for Sarcopenia 2019 (AWGS 2019) (Fig. 1).

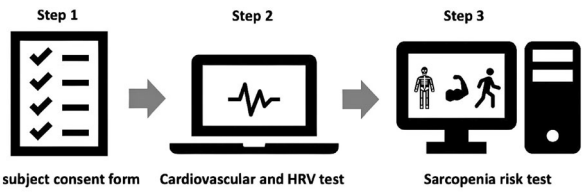

Figure 1. Flowchart of research process

Results: A significant correlation was seen between the appendicular skeletal muscle index, grip strength, walking speed, cardiovascular performance, and heart rate variability. The primary factors used to predict the likelihood of sarcopenia by logistic regression analysis were age, reflection index, dicrotic elasticity index, and high-frequency power. The analysis had an overall accuracy of 70.10%, with a sensitivity of 81.30% and a specificity of 54.07%.

Conclusion: This study showed that simple and noninvasive 3-min evaluations of cardiovascular function and heart rate variability can effectively forecast the probability of developing sarcopenia in older persons. This method can be employed to quickly detect the risk of sarcopenia in electronic equipment and prevent the development of sarcopenia in elderly individuals.

P364
ORAL BISPHOSPHONATES FOR ONE-YEAR POSTFRACTURE TREATMENT ARE ASSOCIATED WITH LOWERED LONG-TERM MORTALITY AND REFRACTURE: ADHERENCE MATTERS

C.-H. Wu[1], C.-C. Li[2], Y.-F. Chang[3], T.-W. Tai[4], S.-Y. Lin[5], C.-H. Chen[6]

[1]Institute of Gerontology, Medical College, National Cheng Kung Univ., Tainan, [2]Institute of Allied Health Sciences, College of Medicine, National Cheng Kung Univ., Tainan, [3]Dept. of Family Medicine, National Cheng Kung Univ. Hospital, College of Medicine, National Cheng Kung Univ., Tainan, [4]Dept. of Orthopedics, National Cheng Kung Univ. Hospital, College of Medicine, National Cheng Kung Univ., Tainan, [5]Orthopaedic Research Center, College of Medicine, Kaohsiung Medical Univ., Kaohsiung, [6]Dept. of Orthopedics, Kaohsiung Medical Univ. Hospital, Kaohsiung Medical Univ., Kaohsiung, Taiwan

Objective: Osteoporosis is a gradual condition that leads to the weakening of bones, increasing susceptibility to fractures, particularly among elderly people. A range of anti-osteoporosis medications are designed to mitigate fracture risk and even mortality. Studies have shown that the 1-y persistence rate for oral bisphosphonates is usually estimated to be less than 50%, while less than 50% of patients have a medication possession rate of $\geq$ 80%. Poor adherence to osteoporosis medications resulted in an approximately 50% reduction in the potential benefit observed in clinical trials. This real-world evidence study aimed to investigate the impact of one-year adherence to anti-osteoporosis medication on long-term mortality and major osteoporotic refractures.
Methods: The study focused on individuals diagnosed with osteoporosis who had experienced significant fractures leading to hospitalization, as identified in Taiwan's National Health Insurance Research Database spanning from 2008–2019. All the users of oral bisphosphonates (daily or weekly alendronate, weekly or monthly risedronate) within only one-year timeframe were selected and compared with the nonusers of any anti-osteoporosis medications. Survival outcomes were analyzed using Cox model analysis, adjusted with age, sex and Charlson comorbidity Index. Major osteoporotic refractures were censored from officially documented medical records.
Results: A total of 142,935 patients (14,070 users vs. 128,865 nonusers) were identified in the study from 2008–2019. The patients were mostly female (71.5%), and the mean age was 72 y. The follow-up duration was from 2009–2019. In general, the users of oral bisphosphonates exhibited a suboptimal medication possession ratio (MPR) (0.30 ± 0.24). Compared with nonusers, one-year oral bisphosphonate users seemed to have higher long-term mortality (HR 1.06, 95% CI 1.03–1.09), but those maintaining a superior MPR ($\geq$ 0.8) experienced a markedly reduced risk of mortality (HR 0.84, 95% CI 0.75–0.94) and major fracture (HR 0.69, 95% CI 0.64–0.74). However, an MPR between 0.5–0.8 had no significant impact on long-term mortality (HR 0.97, 95% CI 0.89–1.04), even users with a low MPR (< 0.5) had poor long-term mortality (HR 1.09, 95% CI 1.06–1.12).
Conclusion: One year of oral bisphosphonate use after fracture treatment with high adherence is associated with substantially lower long-term mortality and major osteoporotic refracture.

P365
ASSESSING DENOSUMAB'S ROLE IN PREVENTING BONE DENSITY LOSS IN OSTEOPOROSIS PATIENTS ON CORTICOSTEROIDS

C.-R. Li[1], H.-T. Lee[1], Y.-L. Deng[1]

[1]Taichung Veterans General Hospital, Taichung City, Taiwan

Objective: Osteoporosis frequently develops as a significant complication in patients undergoing corticosteroid therapy, which is recognized as a major drug-induced cause of this bone condition. This complication is particularly relevant for patients with rheumatologic and immunologic disorders, who often require long-term corticosteroid use. In existed literature, denosumab has shown promise, primarily by increasing bone density and reducing the incidence of fractures in patients with osteoporosis. This article aims to investigate the long-term effectiveness of denosumab in patients with osteoporosis who are also receiving corticosteroid therapy.
Methods: Between 2013–2022, a total of 390 patients with osteoporosis undergoing denosumab treatment for at least 18 months were enrolled in this study. Denosumab was administered as a subcutaneous injection of 60 mg every 6 months. The patients were categorized into two groups: those receiving corticosteroid treatment and those not receiving corticosteroid treatment. The primary outcomes assessed were BMD and TBS, measured at the lumbar spine and femoral neck. Additionally, secondary fracture events occurring within the 18-month follow-up period were also documented.
Results: After a follow-up period of at least 18 months, both the corticosteroid and non-corticosteroid groups exhibited improvements in the T-score of the lumbar spine. Specifically, the corticosteroid group showed a change from -2.1 ± 1.2 to -2.0 ± 1.3, which was statistically significant ($p < 0.001$). Similarly, the non-corticosteroid group demonstrated an improvement from -2.6 ± 1.2 to -2.4 ± 1.2 ($p = 0.003$). However, logistic regression analysis for secondary fractures revealed that corticosteroid administration remained a significant influencing factor (odds ratio: 1.69; 95% CI 1.11–2.56, $p = 0.014$), despite the administration of denosumab.
Conclusion: In our 18-month retrospective study, we noted a stabilization and slight improvement in BMD and TBS in corticosteroid-treated patients, suggesting denosumab's potential against corticosteroid-induced osteoporosis. Despite differences in secondary fractures between groups, these preliminary findings indicate denosumab's promise. Further long-term, comparative studies are essential to confirm its preventive efficacy in this demographic.

P366
ONE-YEAR ANTI-OSTEOPOROSIS MEDICATION THERAPY AND MUSCLE MASS CHANGES IN COMMUNITY-DWELLING OSTEOPOROTIC WOMEN

C.-Y. Wang[1], Y.-C. Lu[1], S.-H. Fu[2]

[1]National Center For Geriatrics and Welfare Research, National Health Research Institutes, [2]National Taiwan Univ. Hospital, Yunlin, Taiwan

Objective: Anti-osteoporosis medications (AOMs) offer proven benefits for bone health, yet their impact on muscle health is still under investigation. This study aims to investigate the impact of one of the AOMs, zoledronate, on muscle mass in osteoporotic women in rural communities.

Methods: This study was a subanalysis from the HOPE trail, a randomized controlled trial conducted in a rural community, aims to prevent disability through community-based integrated care intervention. In the present study, women aged 50 years and older diagnosed with osteoporosis were included. Those with a history of aAOM treatment were excluded. AOM used in this study was zoledronate. Participants were divided into two groups: a AOM treatment group (n = 136) and a control group (n = 134). Participants' appendicular skeletal muscle (ASM), handgrip strength (HS), the Short Physical Performance Battery (SPPB) assessment, and the Mini Nutritional Assessment (MNA) were measured at o, and 12 months.
Results: Participants had a mean age of 74.95 ± 7.42 in the AOM group, and 77.04 ± 8.64 in the control group. There were no significant differences in ASM, handgrip strength, SPPB score and the MNA score between treatment group and control group at baseline. Substantial enhancements in the physical condition were observed in both groups during the treatment period. At 12 months, the control group significantly improved in ASM (1.46 ± 3.77, $p < 0.001$) and HS (3.55 ± 8.51, $p < 0.001$), while the AOM group showed significant improvement in ASM (0.81 ± 4.33, $p = 0.036$) and handgrip strength 2.76 ± 8.48, $p < 0.001$). However, there were no statistically significant differences in the mean change between the treatment group and the control group in ASM (0.81 vs. 1.46, $p = 0.296$), handgrip strength (2.76 vs. 3.55, $p = 0.059$), SPPS score (0.42 vs. 1.08, $p = 0.302$), and MNA score (− 0.24 vs. − 0.35, $p = 0.406$), respectively.
Conclusion: In conclusion, community-dwelling osteoporotic women treated with AOM did not exhibit statistically significant differences in changes in ASM, handgrip strength, SPPS score, and MNA score in the first year.

P367
IMPACT OF CONTACT WITH THE ROYAL OSTEOPOROSIS SOCIETY SPECIALIST NURSE TELEPHONE HELPLINE ON CALLERS' INTENTION TO INITIATE OR CONTINUE OSTEOPOROSIS MEDICATION

D. A. Nelson[1], R. Stone[1], J. Thomson[1], E. Thomas[2]

[1]Royal Osteoporosis Society, Bath, UK, [2]Elizabeth Thomas Research, Stockholm, Sweden

Objective: To investigate the impact of contact with the Royal Osteoporosis Society's Osteoporosis Specialist Nurse Telephone Helpline (ROSHelp) on callers' intention to initiate or persist with osteoporosis treatment.
Methods: Data were gathered from a 2022 ROSHelp service audit. The ROSHelp annually handles over 13,000 enquiries from across the UK. Participants were recruited during helpline calls between 31 October and 2 December 2022, following a pilot study in 2021 that informed the research design. Validated surveys were administered electronically or by post 2 weeks after contact with ROSHelp to collect quantitative and qualitative data.
Results: Analysis included 273 returned surveys, constituting a 49% response rate. The majority of respondents were highly educated, affluent, white women aged over 60 y. 90% reported having osteoporosis, with 58% having experienced fracture(s). 66% of callers sought information regarding drug treatment, of whom 98% indicated improved understanding of their medication and its prescription rationale after the call. Additionally, 90% reported decreased concerns about treatment side effects, and 86% felt the call assisted them in taking decisions to start or continue treatment. Following the helpline interaction, 33% of those calling about medication opted against offered treatment, instead pursuing alternative treatment plans. Qualitative responses consistently highlighted callers' appreciation of specialist nurse expertise, empathetic support, and individualised assistance, with 10% citing barriers to accessing similar support through NHS sources.
Conclusion: The primary motivation for contacting ROSHelp is driven by a wish for greater comprehension of drug treatments, perhaps reflecting the complexity of therapies or current NHS pressures. Engagement with ROSHelp was found to enhance treatment understanding, alleviate concerns about side effects, and empower some participants to self-advocate for alternative therapeutic options. Interactions significantly influence callers' treatment perceptions in a positive manner, suggesting a role for ROSHelp in promoting medication adherence—bridging both information and treatment gaps, particularly for those facing barriers to accessing the information they need to make informed choices about treatment to reduce fracture risk.

P368
INFLUENCE OF HYPERHOMOCYSTEINEMIA AND ANTI-TNF TREATMENT ON TRABECULAR BONE SCORE AND BONE MASS DENSITY IN PATIENTS WITH RHEUMATOID ARTHRITIS

D. Anghel[1], O. -G. Petrache[1], I. -N. Nicolau[1], V. -C. Bojincă[2], A. Mihai[1]

[1]Dept. of Internal Medicine, "Dr. Carol Davila" Central Military Emergency Univ. Hospital, [2]Dept. of Internal Medicine, 'Sf. Maria' Clinical Hospital, Bucharest, Romania

Objective: To compare the effects of anti TNF-α agents (adalimumab, etanercept and infliximab) on TBS and BMD in patients diagnosed with rheumatoid arthritis (RA) and hyperhomocysteinemia.
Methods: 34 patients with RA were enrolled in this retrospective observational study. The data was collected chronologically (February 2022-February 2023) from the hospitalized patients in Central Military Emergency Hospital "Dr. Carol Davila", Dept. of Medicine 2, who were diagnosed with RA, and were prescribed biologic treatment and had undergone osteodensitometry (DXA). Patients with osteopenia were prescribed alfacalcidol and patients with osteoporosis were prescribed risedronate sodium, vitamin D and calcium lactate. Inclusion criteria: patients > 18 years old, diagnosed with RA (according ACR/EULAR criteria 2010). Exclusion criteria: history of anti-osteoporotic treatment, history of biological treatment, secondary causes of osteoporosis, other rheumatic inflammatory diseases than RA. Several parameters (TBS, DMO, homocysteine—HCY and vitamin D serum levels) were evaluated at baseline and after 12 months.
Results: We observed that treatment with anti TNF therapy had a positive influence on TBS. We found a significant correlation between TBS and Adalimumab therapy after 12 months ($p = 0.0003$). However, we found no significant correlation in patients treated with etanercept ($p = 0.06$) or infliximab ($p = 0.146$). A significant correlation was observed between TBS and HCY in both adalimumab ($p = 0.003$) and etanercept ($p = 0.004$) groups after 12 months of treatment. No significant correlation was found in the infliximab treated group ($p = 0.185$). Regarding BMD and anti TNF treatment, significant correlation was observed in the adalimumab group ($p = 0.0002$), in the infliximab group ($p = 0.0001$) and etanercept ($p < 0.0001$) group after 12 months.
Conclusion: Adalimumab improved BMD and TBS after 12 months of treatment. Hyperhomocysteinemia had a negative influence on TBS and BMD. It is important to evaluate and reduce homocysteine levels in order to prevent bone fragility.

P369
CHATGPT AMONG TUNISIAN PHYSICIANS: ARE RHEUMATOLOGISTS MORE ENGAGED?

W. Lahmar[1], D. Ben Nessib[1], H. Ferjani[1], F. Majdoub[1], L. Kharrat[1], D. Kaffel[1], K. Maatallah[1], W. Hamdi[1]

[1]Kassab's Institute of Orthopedics, Manouba, Tunisia

Objective: The emergence of sophisticated language models, such as Chat Generative Pre-Trained Transformer (ChatGPT), has generated curiosity across diverse domains, including the field of medicine. Developed by OpenAI, ChatGPT is an artificial intelligence (AI) driven chatbot utilizing Language Processing Models. The aim of this study was to explore the use of ChatGPT by the Tunisian physicians and more specifically the Tunisian rheumatologists.
Methods: This cross-sectional study (online questionnaire survey) was conducted over a 2-week period amongst rheumatologists and other specialty clinicians. An online questionnaire was developed, with multiple choice, using the Google Forms platform.
Results: The survey was completed by 174 physicians. The predominant responses were received from the family doctors (n = 43, 24.7%) followed by rheumatologists (n = 35, 20.1%). The mean age of participants was 30.29 ± 3.88 y [24–49], with an average experience of 4.28 ± 3 y [1–23]. Among them, 100 (57.5%) were residents in training, 45 (25.9) were university hospital doctors, 16 (9.2%) were public health doctors and 13 (7.5%) worked in the private sector. The majority of clinicians (n = 120, 69%) admitted being aware of ChatGPT and used it in their professional practice, including internal medicine (n = 9, 75%), family medicine (n = 36, 84%), and psychiatrists (n = 8, 89%). ChatGPT was used by physicians for medical writing, academic purposes, and clinical domain in 51% (n = 88), 10% (n = 18) and 13% (n = 23) of the cases, respectively. Most of rheumatologists (n = 23, 65%) used ChatGPT and some hesitated to use it due to factors like not feeling the need (n = 6), lacking experience (n = 3), and concerns about data reliability (n = 4). For those using AI, 17 admitted to employing ChatGPT for medical writing, and thus for grammar and spelling correction (n = 9), translation (n = 11), idea generation (n = 8), paraphrasing (n = 12), reference generation (n = 2), results interpretation (n = 1), and to enhance general writing style (n = 17). Only one person utilized ChatGPT for academic activities, primarily for evaluating pedagogical techniques and preparing medical teaching courses. In clinical activities related to diagnosis, monitoring, or therapy, only four rheumatologists used ChatGPT. Two considered it for etiological discussions, two for listing therapeutic alternatives, and one for aiding in follow-up and therapeutic decision-making. The majority, 23 individuals, admitted using ChatGPT with colleagues, 4 with students, 5 with superiors, 2 with scientific work evaluators, and 3 with patients. Respondents expressed concerns about ChatGPT's reliability (average 1.97 ± 0.9 [0–3]) on the Likert scale. Data confidentiality when using ChatGPT received an average of 2.27 ± 1.4 [0–4], while concerns about potential copyright law violations were evaluated at 2.15 ± 1.4 [0–4] by rheumatologists. When comparing rheumatologists to other clinicians, we found that they were similar in all other applications, including medical writing, academic domain, and clinical and therapeutic use. However, the rheumatologist users of ChatGPT were statistically younger (R: 29.11 + 3.7 years vs. NR: 30.59 + 3.87 y, p = 0.043) and used it for a longer time (R: 9.57 + 6.8 months vs. NR: 7.19 + 4.31 months, p = 0.045) than other clinicians.
Conclusion: In this exploration of ChatGPT's adoption among Tunisian physicians, particularly rheumatologists, we noticed a significant awareness and utilization of this AI-driven tool in medical practices.

P370
PATIENT DISSATISFACTION WITH CARE AMONG INDIVIDUALS UNDERGOING CONSERVATIVE TREATMENT FOR KNEE OSTEOARTHRITIS

D. Ben Nessib[1], W. Lahmar[1], H. Chaouachi[1], H. Ferjani[1], L. Kharrat[1], F. Majdoub[1], D. Kaffel[1], K. Maatallah[1], W. Hamdi[1]

[1]Kassab's Institute of Orthopedics, Manouba, Tunisia

Objective: Knee osteoarthritis (KOA) is the most common musculoskeletal disease. It has been suggested that conservative management of OA may be difficult and sometimes unsatisfying for both physicians and patients. To improve quality of care for KOA patients, quality indicator should be set to develop an evidence-based guidelines. We aimed to investigate the frequency of dissatisfaction in patients with KOA in our center and determine the associated factors.
Methods: This cross-sectional study included patients followed for KOA in a rheumatology department. Sociodemographic features (age, gender, educational level, socioeconomic status, social coverage), and clinical characteristics of KOA were collected. We asked patients about their satisfaction with the care for KOA provided in our center. Patients were categorized into two groups: Group 1 (G1): unsatisfied and Group 2 (G2): satisfied with care.
Results: A total of 87 patients were included with a mean age of 59.5 + 10.26 y [34–87], the sex ratio (female/male) was 11.42. Dissatisfaction with care was detected in 57 patients (66%). A notable female gender predominance was observed in both groups, but with no statistical difference (G1: 54(94%) vs. G2: 26(87%); p = 0.182). Patients in G1 were statistically older (G1: 61.02 ± 10.39 y vs. G2: .77 ± 9.5 y, p = 0.048). BMI differences between the two groups were observed, with no statistical significance (G1: 31.22 ± 6.7 vs. G2: 29.3 ± 6.2, p = 0.225). Lower educational level (G1: 44(77%) vs. G2: 22(74%), p = 0.689), lower socioeconomic status (G1: 26(46%) vs. G2: 18(60%), p = 0.202), and absence of social coverage (G1:30(53%) vs. 20(67%), p = 0.208) showed no significant differences between the two groups. Patients in G1 reported a higher pain intensity (5.91 ± 1.6) compared to G2 (4.63 ± 1.7), demonstrating a significant association with dissatisfaction (p = 0.001). Bilateral KOA (G1: 50(87%) vs G2:19(63%), p = 0.008) and bicompartmental and tricompartmental locations were also found to contribute significantly to dissatisfaction (G1: 37(65%) vs. G2: 12(40%), p = 0.026).While a delayed medical intervention (G1:2.05 ± 1.8 y vs. G2: 1.5 ± 1.6 y, p = 0.175) and therapeutic noncompliance (G1:14 (25%) vs. G2:1 (3%), p = 0.013) played a more substantial role in dissatisfaction, irregular follow-up (G1: 4(7%) vs. G2: 0, p = 0.137) and the absence of therapeutic education were not relevant factors (G1:10 (17%) vs. G2:2 (6%), p = 0.162). An indication for a total knee arthroplasty revealed a notable distinction, with 12% in G1 having an indication compared to none in G2 (p = 0.045).
Conclusion: Our study on patient dissatisfaction with conservative KOA treatment underscores the importance of personalized approaches based on factors like age, gender, and specific health conditions. We found that issues like delayed medical intervention and ensuring treatment compliance are crucial for overall satisfaction with KOA management.

P371
KNEE OSTEOARTHRITIS: EXPLORING THE RELATIONSHIP OF PAIN, FUNCTIONAL IMPAIREMENT WITH COMPARTMENTAL INVOLVEMENT

D. Ben Nessib[1], W. Lahmar[1], H. Chaouachi[1], H. Ferjani[1], L. Kharrat[1], F. Majdoub[1], D. Kaffel[1], K. Maatallah[1], W. Hamdi[1]

[1]Kassab's Institute of Orthopedics, Manouba, Tunisia

Objective: Knee osteoarthritis (KOA) is a prevalent musculoskeletal condition that significantly impairs patients' quality of life. Understanding the clinical characteristics and factors influencing functional outcomes in KOA is crucial for optimizing patient care. The study aimed to explore the relationship between clinical impact including knee pain and functional impairment and specific compartment of the knees in patients followed for KOA.
Methods:A cross-sectional study including patients followed for KOA. Clinical and radiological characteristics of KOA were collected. Pain intensity was assessed by the visual analogue scale (VAS). Functional impairment was assessed by the short form of the Knee Injury and Osteoarthritis Outcome Score (KOOS-PS) with a score ranging from 0 (no difficulty) to 100 (extreme difficulty).
Results: A total of 87 patients were included with a mean age of 59.5 ± 10.26 y [34–87], the sex ratio (female/male) was 11.42. The mean BMI was 30.58 ± 6.61. KOA was femoro-tibial in 40 cases (46%) and femoro-patellar in 18 patients (21%), the internal compartment was affected in 34 (39%) cases, a tricompartmental involvement was present in 29 patients (33%), and a bilateral KOA was found in 79% of cases (n = 69). Mean duration of follow-up of the disease was 4.38 ± 3 y. The mean VAS pain was 5.47 ± 1.75 [2–9]. The mean KOOS-PS score was 67 ± 14.76 [28–89]. A positive and significant correlation between the KOOS and VAS pain was found (r: 0.72; $p < 0.001$). There was no correlation between the KOOS and the duration of evolution (p = 0.43). The mean KOOS was significantly higher in patients with medial femoro-tibial involvement, either coexisting with lateral compartment involvement or no, compared to those with femoro-patellar compartment involvement alone (70.34 ± 12.71 vs. 63.98 ± 12.71, p = 0.005). However, pain intensity was notably higher in cases with femoro-patellar compartment involvement (5.08 ± 1.6 vs. 6.16 ± 1.63, p = 0.046). Patients exhibited comparable KOOS scores in the presence of bilateral involvement (70.26 ± 13.47 vs. 64.63 ± 15.38, p = 0.078), but reported higher pain levels (5.84 ± 1.79 vs. 5 ± 1.59, p = 0.026).
Conclusion: Pain intensity demonstrated a significant correlation with functional impairment, emphasizing the subjective experience of patients. The compartmental involvement analysis revealed nuanced associations, highlighting the heterogeneity of KOA presentations.

P372
FEAR OF FALLING IS ASSOCIATED WITH GAIT SPEED AFTER 3 MONTHS OF HOSPITAL DISCHARGE IN OLDER ADULTS WITH HIP FRACTURE SURGERY

M. Peres Ueno[1], L. L. C. Capato[1], J. Faria Junior[1], V. Sanchez Teixeira[1], A. S. F. Sundin Foltran[2], G. H. P. Pelinson[2], C. Pereira da Silva Herrero[3], D. Carvalho de Abreu[4]

[1]Ribeirão Preto Medical School, Univ. of São Paulo, [2]Dept. of Orthopedics and Hip Surgery, Santa Casa de Misericórdia de Ribeirão Preto, [3]Dept. of Orthopedics and Anesthesiology at the Ribeirão Preto Medical School, Univ. of São Paulo, [4]Dept. of Health Sciences, Ribeirão Preto Medical School, Univ. of São Paulo, Ribeirao Preto, Brazil

Objective: Fragility hip fracture is associated with osteoporosis, and hip fracture is the most serious fracture. After a hip fracture, patients commonly exhibit very low gait speeds. While various factors have been shown to influence the patients' functional outcome, this study aimed to provide new insights related to the influence of self-perception on the gait speed of older Brazilian adults three months after hip fracture surgery.
Methods: A prospective cohort study was undertaken, including twenty participants who were hospitalized in a public hospital due to a proximal femur fracture. Participants were followed from hospital admission until 3 months after discharge. Along with clinical and surgical variables, questionnaires of pre-fracture functional capacity (New Mobility Score), balance self-perception, and fear of falling were administered. Also, handgrip strength was assessed. Gait speed was evaluated 3 months after surgery by asking participants to walk a 10-m distance at their usual speed, with the time recorded over 5 central meters of the route. Linear regression analysis was used to determine a statistical model that best predicted gait speed (dependent variable), adjusted for age and sex.
Results: Of the 20 participants evaluated (mean age of 78 y), 75% were women, 50% had a transtrochanteric femoral fracture, and 50% underwent arthroplasty of the hip. The average length of hospital stay was 5 d. Fear of falling ($\beta = -0.51$; p = 0.037) explained 34% of the usual gait speed after 3 months of hospital discharge. New mobility score ($\beta = 0.47$; p = 0,030) and the handgrip strength ($\beta = 0.59$; p = 0.029) explained 35% of gait speed.
Conclusion: These preliminary findings may have important implications for clinical care in the acute scenario. The fear of falling may be an emerging prognostic factor for functional recovery, so future research may target patients who are afraid of falling to optimize the post-intervention management of high-risk individuals.

P373
BEYOND MUSCLE PAIN IN FIBROMYALGIA AND MYOFASCIAL PAIN SYNDROME

D. Cepoi[1], L. Groppa[1], E. Russu[1]

[1]State Univ. of Medicine and Pharmacy "Nicolae Testemitanu", Chisinau, Moldova

Objective: To compare the frequency of symptoms classically reported in fibromyalgia (FM) in the groups of FM and myofascial pain syndrome (MFS).
Methods: A total number of 160 patients with chronic musculoskeletal pain were examined and assigned to fibromyalgia and myofascial syndrome groups accordingly. The subjects were asked questions based on a standardized questionnaire.
Results: Presented in Table 1.

Table 1. Occurrence of symptoms other than muscle pain in FM and MFS groups.

Symptom	FM (M±SD)	MFS (M±SD)	p
Fatigue	0,85000±0,35932	0,66250±0,47584	0,010334
Sleep disorders	0,68750±0,46644	0,56250±0,49921	0,105142
Joint pain	0,83750±0,37124	0,68750±0,46644	0,013363
Headache	0,82500±0,38236	0,62500±0,48718	0,005342
Restless leg syndrome	0,52500±0,50253	0,43750±0,49921	0,299630
Paresthesia	0,81250±0,39277	0,71250±0,45545	0,131424
Memory problems	0,78750±0,41166	0,47500±0,50253	0,000046
Concentration issues	0,55000±0,50063	0,32500±0,47133	0,005900
Anxiety	0,83750±0,37124	0,53750±0,50174	0,000122
Depression	0,56250±0,49921	0,32500±0,47133	0,0039
Irritable bowel syndrome	0,50000±0,50315	0,12500±0,33281	0,000000
Interstitial cystitis	0,41250±0,49539	0,10000±0,30189	0,000016
Cold intolerance	0,63750±0,48376	0,32500±0,47133	0,000046

Conclusion: Patients with FM and MFS frequently associate non-muscular pain symptoms. Sleep disorders, restless leg syndrome, paresthesia, fatigue, joint pain, and headaches are frequently reported by both patients with FM and MFS. Symptoms that showed a higher

specificity for FM were Irritable bowel syndrome, Interstitial Cystitis, and Intolerance to cold.

P374
HIGHER LEVELS OF HIGH-DENSITY LIPOPROTEIN CHOLESTEROL ARE ASSOCIATED WITH LOWER BONE MINERAL DENSITY IN OLDER ADULTS

D. Fitzpatrick[1], E. Laird[2], R. Lannon[3], M. Ward[4], L. Hoey[4], C. F. Hughes[4], J. J. Strain[4], C. Cunningham[4], A. M. Molloy[4], H. Mc Nulty[4], K. Mc Carroll[1]

[1]Mercer's Institute for Research on Ageing, St James's Hospital, Dublin, Ireland, [2]Dept. of Nutrition, Atlantic Technological Univ., Sligo, Ireland, [3]Mercer's Institute for Research on Ageing, Dublin, Ireland, [4]Nutrition Innovation Centre for Food and Health, Univ. of Ulster, Coleraine, UK

Objective: Lipids appear to play an important role in bone metabolism. However, there are few studies examining the relationship between high density lipoprotein cholesterol (HDL), low density lipoprotein cholesterol (LDL), triglycerides and BMD with inconsistent results identified.
Methods: Participants were from the Trinity-Ulster-Department of Agriculture (TUDA) study, a large cross-sectional cohort of Irish adults aged $\geq$ 60 y. We excluded patients with a known diagnosis of osteoporosis and those on therapies for osteoporosis as well as patients on statins. We examined the association between HDL, LDL and triglycerides and BMD (as measured by DXA) at the neck of femur, total hip and lumbar spine controlling for age, sex, BMI, timed up and go test, 25(OH)D, eGFR, PTH levels, smoking, daily dairy intake, alcohol consumption, type 2 diabetes mellitus, current or past steroid exposure, and loop and thiazide diuretics.
Results: There were 871 participants who met the inclusion/exclusion criteria with a mean age of 70.0 $\pm$ years, of whom 62.5% were female. BMD at the total hip was negatively associated with HDL, which remained significant after multivariate regression ($\beta = -0.04$, $p = 0.003$). No significant association was found between HDL and lumbar spine BMD ($\beta = -0.03$, $p = 0.09$). We also did not find any significant association between LDL or triglycerides and BMD at any site.
Conclusion: This study demonstrated that HDL was an independent negative predictor of BMD at the total hip as identified elsewhere. Other research suggests this association may be mediated by genetic and dietary factors, sex hormone profiles as well as a potential direct interaction between HDL and bone metabolism. Further investigation to elucidate the factors underpinning this relationship is warranted.

P375
DIABETES ASSOCIATED WITH LOWER BONE TURNOVER MARKERS: A MECHANISM FOR INCREASED BONE MINERAL DENSITY IN DIABETICS

D. Fitzpatrick[1], R. Lannon[2], E. Laird[3], M. Ward[4], L. Hoey[4], C. F. Hughes[4], J. J. Strain[4], C. Cunningham[4], H. Mc Nulty[4], A. M. Molloy[4], K. Mc Carroll[1]

[1]Mercer's Institute for Research on Ageing, St James's Hospital, Dublin, Ireland, [2]Mercer's Institute for Research on Ageing, Dublin, Ireland, [3]Dept. of Nutrition, Atlantic Technological Univ., Sligo, Ireland, [4]Nutrition Innovation Centre for Food and Health, Univ. of Ulster, Coleraine, UK

Objective: Diabetes is associated with increased BMD though paradoxically an increased risk of fracture. Lower bone turnover markers (BTM) in diabetics are identified in some studies and may in part explain this relationship. We aimed to: (1) explore BTM in older adults with and without diabetes and (2) ascertain if lower BTM are associated with higher BMD.
Methods: Study participants were $\geq$ 60 y from a large cross-sectional study of Irish adults. Those with osteoporosis and/or on antiresorptives or anabolic medications were excluded. Diabetes was defined by self-report, use of diabetic medications or HbA1c $\geq$ 6.5%. ANCOVA was used to compare mean levels of bone specific alkaline phosphatase (BAP), CTX, osteocalcin and TRAP5b in patients with and without diabetes controlling for age, sex, BMI, estimated glomerular filtration rate, 25-hydroxyvitamin D, timed up and go, long-term or current steroid use, alcohol use, smoking, thiazide and loop diuretic use. The relationship between BTM and BMD (measured by DXA) at the lumbar spine and total hip were also explored in diabetics adjusting for the same covariates.
Results: Of the 2127 participants 17.7% (n = 375) had diabetes. The mean age of those with and without diabetes was 69.8 y, while diabetics were more likely to be male (54.7 vs. 40.6%, $p < 0.001$). Diabetics vs. non-diabetics had lower mean osteocalcin and CTX which remained significant after multivariate adjustment (osteocalcin: 12.2 vs. 15.9 ng/ml, $p < 0.001$), (CTX: 0.273 vs. 0.330 ng/ml, $p < 0.001$). No association was found between diabetes status and BAP or TRAP5b. In diabetics, both lower CTX and osteocalcin were associated with higher BMD at the spine ($p < 0.001$) and the hip ($p < 0.001$).
Conclusion: Patients with diabetes vs. non-diabetics had significantly lower CTX and osteocalcin as reported elsewhere. Furthermore, in diabetics CTX and osteocalcin were negatively associated with BMD. Lower CTX in diabetics may indicate reduced bone resorption, which could account for higher BMD. However, the relationship with osteocalcin may be more complex, as it appears to influence insulin secretion. Further research to understand how these changes in BTM may affect bone quality and fracture risk is required.

P376
IMPLICATIONS OF THORACIC MUSCLE INDEX AND CALF CIRCUMFERENCE IN SARCOPENIA DIAGNOSIS FOR OSTEOPOROTIC INDIVIDUALS POST-VERTEBROPLASTY

L. Fangying[1], D. Hong[1], Z. Liwei[1], Y. Citing[1]

[1]Orthopedic Dept., Taizhou Hospital of Zhejiang Province, Linhai, China

Objective: Diagnosing sarcopenia in elderly osteoporotic patients with vertebral fractures is challenging due to the traditional focus on extremity muscle mass rather than back muscle. Furthermore, back pain from fractures hampers physical function assessment. This study aimed to compare thoracic muscle cross-sectional area (T12 skeletal muscle index, T SMI) measured by CT and manually measured calf circumference (CC) for sarcopenia diagnosis in these patients.
Methods: This study involved patients with fragile thoracolumbar fractures who underwent vertebroplasty at two tertiary hospitals in southeastern China from January 2022 to June 2023. T12 SMI and CC were evaluated as indicators of muscle mass to diagnose sarcopenia. Postoperative variables, such as the visual analogue scale (VAS), Short Physical Performance Battery (SPPB), hospital stay duration, and vertebral refracture rate within 6 months, were compared between sarcopenia and non-sarcopenia groups diagnosed by the two methods.
Results: Out of 149 participants, the diagnostic concordance between T12 SMI and CC was 79.9%. The sarcopenia prevalence was 46.1% and 52.3% for T12 SMI and CC, respectively. CC's AUC was 0.735. Significant differences in diagnostic outcomes between the two methods were associated with sex ($p = 0.043$), BMI ($p < 0.001$), abdominal circumference (AC) ($p = 0.038$), and diabetes presence ($p = 0.043$). Binary stepwise regression analysis identified BMI

(p = 0.01) as the primary factor influencing CC diagnostic accuracy. T12 SMI-diagnosed sarcopenia significantly correlated with refracture (p = 0.033), whereas CC-diagnosed sarcopenia was significantly related to postoperative SPPB scores (p = 0.002).
Conclusion: CC may be unsuitable for diagnosing sarcopenia in obese osteoporotic patients. T12 SMI proves more predictive for refracture in patients with thoracolumbar fractures, while CC is more related to postoperative functional status.

P377
PAIN RELIEF AND IMPROVED QUALITY OF LIFE AFTER SWITCHING ORAL BIPHOSPONATE TREATMENT TO DENOSUMAB IN PATIENT WITH OSTEOPOROTIC MULTIPLE VERTEBRAL FRACTURES

D. Jovanovska-Jordanovski[1], V. Dimitrioski[1], S. Lazarevska[2], M. Jakimova[3], I. Bozhinovska[4]

[1]PHI Health Center Skopje, Polyclinic Jane Sandanski, [2]Center of Physical and Kinesitherapy Laser Med, [3]Private Orthopaedic Practise OrtoPlusPed, [4]Acibadem Sistina Hospital, Skopje, North Macedonia

Osteoporosis is a silent metabolic bone condition associated with natural loss of bone density with ageing. Vertebral body compression fractures are prevalent in older patients. Sometimes efficacy of the long term oral bisphosphonate treatment is diminished. Denosumab is alternative treatment for osteoporosis. This case report aimed to describe the beneficial effects of Denosumab in osteoporotic treatment as well as pain relief in patient with osteoporotic multiple vertebral fractures. After a long term therapy with oral bisphosphonates through comparison of the past and current DXA scans, X rays and CT findings we concluded that switching to Denosumab was a reasonable way for treatment of this patient.
Casereport: 71 years old female patient, 146.0 cm height, weight 60 kg, menopause at 46 y, + familiar anamnesis (mother), history of chronic back pain. A physical examination included labs, X-rays, CT and DXA scans. X-rays and CT findings of the thoracolumbar spine showed kyphoscoliosis, degenerative spondylarthrosis and polydiscopathy, compressive body fractures from Th9-L4.This patient after long term treatment with oral bisphosphonates was switched to denosumab. Comparing control labs and DXA scan results (f2023) T-score L1 2.4/L2 − 1.9/L3 − 0.3/L4 − 0.1/LF total T-score − 1.8 (wards − 2.8)/RF total T-score − 1.8 (wards − 2.8) showed relief of low back pain and improvement of quality of life after two administrated doses of denosumab beside analgesic therapy and brace support.
Conclusion: Denosumab has beneficial effects in osteoporotic treatment as well as pain relief and improved quality of life in patient with osteoporotic multiple vertebral fractures.

P378
MID-TERM RESULTS OF ARTHRODESIS OF THE 1ST METATARSOPHALANGEAL JOINT AND RESECTION ARTHROPLASTY OF THE HEADS OF THE LESSER METATARSAL BONES IN COMPARISON WITH JOINT-PRESERVING OPERATIONS ON THE FOREFOOT IN PATIENTS WITH RHEUMATIC DISEASES

D. Kapitonov[1], E. Bialik[1], L. Alekseeva[1], S. Makarov[1], M. Makarov[1], V. Bialik[1]

[1]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia

Objective: To compare the results of the Clayton-Hoffman (arthrodesis of the 1st metatarsophalangeal joint and resection arthroplasty of the heads of the lesser metatarsal bones) operation (CH) and joint-preserving operations (JP) on the forefoot in patients with rheumatic diseases (RD).
Methods: 143 patients with RD were included. The patients were randomized into 2 groups: the control group underwent CH surgery (70), the main group underwent JP (73) on the forefoot. To assess the outcome, we studied the change in pain intensity on the visual analogue scale (VAS), as well as the functional status of the foot on the AO FAS scale (for toes 1 and 2–5) before and 3 y after surgery. The results obtained were assessed by the dynamics of pain intensity according to VAS (0–10 mm—excellent; 11–30 mm—good; 31–40—satisfactory; $\geq$ 40 mm—unsatisfactory) and changes in the functional state of fingers 1 and 2–5 according to the AO FAS scale (91–100—excellent; 81–90—good; 71–80—satisfactory; < 70—unsatisfactory).
Results: The average value of pain intensity according to VAS before surgery was 62 ± 3 points (both groups), after—CH-10 ± 5, JP—11 ± 3 points, on the AO FAS scale for 1 finger 42 ± 3, for 2–5 fingers—47 ± 7 before operations, after CH—81 ± 3, JP—79 ± 2 for 1 finger and CH—80 ± 2, JP-70 ± 5 for 2–5 fingers. Three years after the operation, the results were as follows: according to VAS—Excellent—126 (CH-67; JP-59), good—6 (CH-5, JP-1) satisfactory -2 (CH-1, JP-1), unsatisfactory—9 (CH-5, JP-4). According to the AO FAS scale (1)—Excellent—34 (CH-16, JP-18), good—74 (CH-38, JP-36), satisfactory—16 (CH-14, JP-2), unsatisfactory—18 (CH-8, JP-10). On the AO FAS scale (2–5)—Excellent—34 (CH-24, JP-10), good—53 (CH-29, JP-24), satisfactory—20 (CH-16, JP-4), unsatisfactory—14 (CH-9, JP-11).
Conclusion: Performing joint-preserving operations on the forefoot in a group of patients with RD can improve functional indicators on the AO FAS scale (for 1 and 2–5 MCP joints) and reduce pain intensity according to VAS, increasing the quality of life of patients.

P379
CANADIAN FIRST NATIONS CARE GAP: OSTEOPOROSIS HEALTH CARE PROVIDER SURVEY HIGHLIGHTS

D. Kendler[1], J. Ybanez[2], S. Huang[3], R. Kherani[3]

[1]UBC Division of Endocrinology, [2]Prohealth Clinical Research, [3]UBC Division of Rheumatology, Vancouver, Canada

Objective: First Nations people have a high incidence of inflammatory arthritis. Inflammatory arthritis is a strong risk factor for osteoporosis. Although there are no data for British Columbia (BC), Canada, in other First Nations communities, studies have indicated increased osteoporosis and fracture risk amongst First Nations people. We developed a questionnaire to identify the osteoporosis perceptions and needs of health care providers (HCP) in First Nations communities in northern BC.
Methods: A literature review identified information on the prevalence, risk factors, and management of osteoporosis in Canadian First Nations populations. A questionnaire was created to assess the knowledge of physicians and nurses in each First Nations community. Questionnaires were accumulated through paper and electronic formats.
Results: Questionnaires were distributed to HCP in First Nations communities in conjunction with travelling rheumatology clinics in coastal BC communities of Heiltsuk Nation, Bella Bella, BC central coast; Nuxalk Nation, Bella Coola, BC central coast; and Nisga'a Nation, Nass Valley, BC northern coast. Of 18 returned questionnaires, 7 were from doctors and the remainder from nurses. Over half (52%) reported that they received no specific education on osteoporosis. The majority (73%) indicated that they see osteoporosis occasionally or frequently; however, 92% encountered fractures occasionally or frequently. Since fractures are frequent indicators of osteoporosis and future fracture risk, the absence of an osteoporosis diagnosis may indicate a lack of awareness of this risk. Over half

(57%) of respondents rarely or never refer patients for bone density. The most common perceived barriers to providing osteoporosis care include geographic (67%), mistrust (56%), financial (39%), and lack of access to required services (39%). 94% of respondents agreed or strongly agreed that enhanced access to osteoporosis care is required for First Nations communities in BC.

Conclusion: Our survey provides valuable insights into the osteoporosis-related needs of HCP in First Nations northern BC populations. Most significantly, there was overwhelming agreement amongst respondents of the need for strategies to enhance osteoporosis care in their communities. These data will pave the way for targeted interventions and improved osteoporosis healthcare practices for these communities.

P380
ASSOCIATION OF DIFFERENT DYSGLYCEMIA GROUPS WITH INCIDENT BONE FRACTURES IN MEN AND WOMEN: TEHRAN LIPID AND GLUCOSE STUDY

D. Khalili[1], H. Farzad[1], M. Tohidi[1], F. Azizi[2]

[1]Prevention of Metabolic Disorders Research Center, Research Institute for Endocrine Sciences, Shahid Beheshti Univ. of Medical Sciences, [2]Endocrine Research Center, Research Institute for Endocrine Sciences, Shahid Beheshti Univ. of Medical Sciences, Tehran, Iran

Objective: To investigate the association between different dysglycemia groups and long-term hospitalization-required incident fractures in adults, men and women aged $\geq$ 50 years old with more possible osteoporosis.

Methods: A total of 3309 participants (1711 women) were followed up for a median of 18 y. The incidence rate per 1000 person-year was calculated and a multivariate Cox proportional hazard model was applied to assess the hazard ratio (HR) of fracture for categories of impaired fasting glucose (IFG), impaired glucose tolerance (IGT), both IFG/IGT, newly diagnosed diabetes mellitus (NDM) and previously known diabetes (KDM). Covariates included age, BMI, waist circumference, smoking, hypertension, and steroid medications.

Results: Incident fracture was observed in 201 cases (114 women). The incidence rate was 3.4 (95% CI 2.8–4.2) and 4.3 (3.6–5.1) per 1000 person-year in men and women respectively. None of the categories of dysglycemia was associated with an increased risk of fracture in both men and women, meanwhile, KDM in men (HR = 0.20, 95% CI 0.05–0.84) and IGT in women (HR = 0.42, 0.17–1.06) were significantly associated with a lower risk of fracture. Among covariates, BMI (in kg/m^2) was associated with decreased risk (HR = 0.88, 0.82–0.95), waist circumference (in cm) with increased risk (HR = 1.05, 1.02–1.08) and also current smoking with increased risk (HR = 2.5, 1.0–6.3) in women.

Conclusion: In our population, dysglycemia was associated with a lower fracture risk with different patterns in men and women.

P381
JOINT INVOLVEMENT IN SYSTEMIC LUPUS ERYTHEMATOSUS: PREVALENCE AND SEROLOGICAL ASSOCIATIONS

O. Iaremenko[1], D. Koliadenko[1], K. Iaremenko[2]

[1]Bogomolets National Medical Univ., [2]Alexander Clinical Hospital, Kyiv, Ukraine

Objective: To investigate the prevalence and serological associations of joint involvement in a cohort of Ukrainian patients (pts) with systemic lupus erythematosus (SLE).

Methods: A total of 376 SLE pts (aged 36 (26–48) y; 86.4% females) were enrolled in the cross-sectional study. Pts were thoroughly assessed using SLE Disease Activity Index 2000 (SLEDAI-2K). Joint involvement was defined as arthralgias (mostly polyarthralgias) and/or arthritis detected by ultrasound or MRI, aligning chronologically with the onset of other SLE symptoms and lacking alternative causes. Laboratory assessments included traditional inflammatory markers (erythrocyte sedimentation rate (ESR), C-reactive protein (CRP)) and specific SLE autoantibodies. Additionally, 79 SLE pts were tested for serum levels of high-sensitivity CRP (hs-CRP), anti-CRP antibodies, IL-6, IL-10, and presepsin. Mann–Whitney test was used for statistical analysis.

Results: Joint involvement was observed in 316 (84%) of SLE pts. Disease activity index was significantly higher in pts with articular manifestations compared to those without such symptoms (SLEDAI-2K 11 (6–16) points vs. 8 (4–14) points, p = 0.01). SLE pts with joint involvement exhibited higher frequency of anti-double stranded DNA antibodies (anti-dsDNA) positivity (65 vs. 46%, p = 0.03), with no differences noted in other SLE autoantibodies. There were no significant variations between SLE pts with and without articular manifestations regarding levels of ESR (22 (11–41) vs. 22 (13–42) mm/h, p = 0.97), CRP (6 (0–24) vs. 6 (0–48) mg/L, p = 0.24), hsCRP (7 (5–17) vs. 6 (2–14) mg/L, p = 0.33), anti-CRP (7 (5–12) vs. 8 (5–11) ng/mL, p = 0.41), IL-6 (5 (2–17) vs. 5 (2–11) pg/mL, p = 0.76), and IL-10 (13 (3–31) vs. 3 (3–24) pg/mL, p = 0.58). However, presepsin levels were significantly lower in SLE pts with joint involvement (111 (87–153) pg/mL) compared to those without such manifestations (145 (122–175) pg/mL, p = 0.04).

Conclusion: Joint involvement (arthralgias and/or arthritis) is present in majority of SLE pts (84%) and is associated with higher disease activity and anti-dsDNA positivity. Our data did not find the association between joint involvement in SLE and levels of serum inflammatory markers and cytokines, except for lower presepsin levels.

P382
ABALOPARATIDE INCREASES DISTAL FEMUR BMD POST TOTAL KNEE ARTHROPLASTY

N. Binkley[1], D. Krueger[1], G. Borchardt[1], B. Nickel[1], P. A. Anderson[1]

[1]Univ. of Wisconsin, Madison, USA

Objective: Osteoporosis is common in total joint replacement patients and increases risk for adverse outcomes including revision surgery and periprosthetic fracture. Existing data indicate total knee arthroplasty (TKA) leads to rapid distal femur bone loss. We hypothesized that Abaloparatide (ABL) would mitigate this loss. The purpose of this preliminary analysis is to evaluate the effect of ABL begun $\sim$ 3 months prior to TKA on distal femur BMD.

Methods: Female and male TKA candidates age $\geq$ 55 y were enrolled in this open-label 18-month study. Those with clinical osteoporosis, defined as T-score ≤ -2.5, or < -1.0 with prior low-trauma fracture, received subcutaneous ABL up to 80 mcg daily. Subjects with osteopenia but without fracture comprised an untreated control (CON) group. BMD was measured by DXA at the lumbar spine, total hip, 0.3 radius and two distal femur regions of interest (ROIs) at screen ($\sim$ 3 months pre-TKA), 1-week pre-surg, 6 and 15-months post-surg. Distal femur BMD was measured at ROIs placed at 15% and 25% of femur length. Groups were compared at baseline by t-test. For this preliminary analysis in study completers (n = 14 ABL/27 CON) BMD change at all measured sites was assessed by ANOVA.

Results: All 58 subjects (29 ABL/29 controls) have been enrolled. Sex, mean (SD) age and BMI did not differ between ABL and CON groups; 3 vs. 7 male, 70.6 (7.1) vs. 68.5 (7.0) years and 31.4 (6.1) vs.

30.9 (4.6) kg/m^2, respectively. ABL group baseline BMD was lower ($p \leq 0.05$) at all measured sites. ABL was administered for a mean (SD) of 92 (56) days prior to TKA. At the 15% distal femur ROI, BMD percentage change from screening was higher than control ($p < 0.05$) at pre-surg, 6 and 15 months post-surg by 1.7%, 7.0% and 9.2%, respectively. Similarly, at the 25% ROI BMD change was greater ($p < 0.05$) at 6 (4.7%) and 15 months post-surg (5.9%). At 15 months post-surg, spine and total hip BMD change from baseline was greater ($p < 0.001$) in the ABL than CON group (6.3% and 6.3%, respectively).

Conclusion: In this preliminary analysis, ABL increased distal femur BMD, compared with control, in TKA recipients. This increase was demonstrable with $\sim$ 3 months of treatment.

P383
ASSOCIATION OF OSTEOGENESIS IMPERFECT AND COOLEY'S ANEMIA: AN UNPRECEDENTED SITUATION!

D. Lardjani[1], S. Djennadi[1], R. Hassani[1], L. Rezgui[1], M. Azzi[1], M. Djennane[1]

[1]Hospitalo Univ. Center, Tizi Ouzou, Algeria

Osteogenesis imperfecta (OI), or brittle bone disease, is characterized by bone fragility and osteopenia. It associates skeletal and extraskeletal signs. Cooley's anemia is homozygous form of β-thalassemia. We report a situation where these two pathologies coexist.

Casereport: 31-year-old female patient from a non-consanguineous marriage, with a family history of heterozygous β-thalassemia and OI. She has a homozygous B-thalassemia with iron chelation and transfusions complicated by hemochromatosis with primary amenorrhea, hypoparathyroidism and hepatomegaly, treated in rheumatology for OI type IV according to Sillence and Glorieux classification by intravenous bisphosphonates since the age of 18 years, stopped because of secondary hypocalcemia to the hypoparathyroidism. Physical examination reveals failure to thrive, gray skin, pectus carinatum, scoliosis, lower limbs curvature, yellow opalescent teeth and enlarged abdomen. Biology: Normocytic normochromic anemia, hypocalcemia, hypoparathyroidism, hypovitaminosis D, normal alkaline phosphatase and normal phosphatemia. Radiology: Diffuse demineralization, the pelvis in the heart of playing card, fish vertebrae, Looser fracture on the femoral shaft, hair-on-end appearance of the skull, a gridded appearance of the epiphyses. Bone densitometry: Z-score: $-$ 2.5 at the neck and spine. The patient received a treatment for hypocalcemia and hypovitaminosis D, then in addition intravenous bisphosphonate with tight control.

Discussion: OI is a rare genetic disorder with autosomal dominant or recessive transmission, caused by mutations in chromosomes 7 or 17 encoding the chains of type I collagen fibers, with polymorphic clinical expression, which is not particularly associated with other diseases. Cooley's anemia is also a genetic disease due to β globin gene mutation on the chromosome 11, it is autosomal recessive transmission. Like OI, it is not known to have any associations with other diseases.

Conclusion: The association of osteogenesis imperfecta and Cooley's anemia, which are two rare genetic diseases, is only a coincidence. With a distinct pathophysiology for each one, both forming a rather particular phenotype requiring a delicate therapeutic management.

EFFECTIVENESS OF OSTEOPOROSIS DRUGS IN PATIENTS WITH TYPE 2 DIABETES MELLITUS: A POPULATION-BASED COHORT STUDY

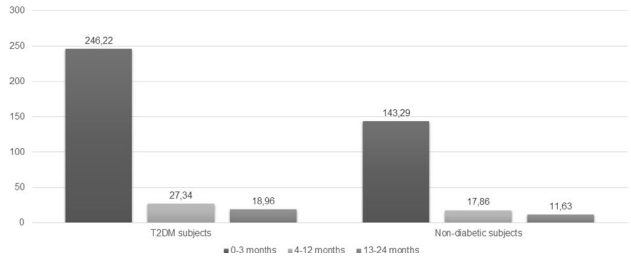
L. Gómez Rodríguez[1], J. L. Poveda[2], C. Carbonell-Abella[1], C. Reyes[3], M. A. Pou Giménez[1], C. Díaz Torné[4], D. Martinez-Laguna[1]

[1]Institut Català de la Salut. Primary Care, Barcelona, [2]Univ. of Navarra, Institute of Data Science and Artificial Intelligence (DATAI), Pamplona, [3]IDIAP Jordi Gol., Barcelona, [4]Rheumatology Dept., Hospital de Sant Pau, Barcelona, Spain

Objective: Patients with type 2 diabetes mellitus (T2DM) have an increased risk of fragility fractures. Contrarily, the tendency is to underestimate their risk, hence there is a lower prescription of osteoporosis drugs (OPD) compared to non-diabetics. In addition, the evidence for different OPD in these patients is limited. We aimed to analyze the differences between the incidence of new fractures in patients who receive an OPD, depending on the presence of T2DM or not.

Methods: Population-based cohort study conducted in the primary care setting. All subjects who initiated an OPD between 2012–2016 were selected from the SIDIAP database which contains anonymized clinical information of > 5.5 million patients in Catalonia. Those who had received an OPD in the previous 12 months, with a history of neoplasia, Paget's disease or HIV infection were excluded. Each T2DM subject was propensity-score matched up to 5 non-diabetic subjects. Each patient was followed until study end date, fracture event, date transferred out of the practice, or death. Fracture incidence rates were calculated in periods 0–3 months, 4–12 months, and 13–26 months.
Results: We identified 45,991 subjects who started a OPD (6,083 with T2DM and 39,908 non-diabetics), of whom 89.8% were women, mean age (SD) 69.1 (10.5) y. The most used OPD was oral bisphosphonate (80.6%), followed by denosumab (9.7%). 15.7% had a previous fracture. The baseline incidence rate of all fractures (0–3 months) was higher in T2DM patients than in those non-diabetics. Fracture incidence rates are shown in Fig. 1.

Figure 1: Fracture incidence rate per 1000 person-year, according to T2DM status.



Conclusion: Continued treatment with OPD was associated with reductions of fracture rates in both T2DM and non-diabetic subjects. Differences in early-treatment period fracture rates indicate that T2DM patients' individual fracture risk should be considered.

P386
FEATURES OF BONE TISSUE IN CHILDREN OF DIFFERENT GENDERS DEPENDING ON GROWTH INTENSITY, POLYMORPHISM OF THE VDR GENE AND VITAMIN D LEVELS

T. Frolova[1], D. Mcgovan[2], N. Osman[1], N. Stenkova[1], I. Siniaieva[1], A. Amash[1], O. Savvo[3], T. Khalturina[3], F. Leontieva[4]

[1]Kharkiv National Medical Univ., Kharkiv, Ukraine, [2]Spine &Orthopedic Surgery Associates, Nebraska, USA, [3]Kharkiv Regional Children's Clinical Hospital, Kharkiv, Ukraine, [4]Sytenko Institute of Spine and Joint Pathology of the National Academy of Medical Sciences of Ukraine, Kharkiv, Ukraine

Objective: To establish the densitometric characteristics of bone tissue in children taking into account gender, growth intensity, polymorphism of the VDR gene and vitamin D status.
Methods: 151 children aged 9–17 were examined, who were divided into two groups depending on gender (78 males and 73 females). Inclusion criteria: absence of chronic somatic and endocrine pathology, hereditary and genetic diseases. A general clinical examination, determination of the level of 25-(OH)-D, ultrasound densitometry (QUS), molecular diagnostics (BSML polymorphism of the VDR gene) were performed. The criterion for a growth spurt (GS) was a growth of 8 cm or more in the current year. Decreased bone density was defined as BMD Z-score ≤ -2.0 (The International Society for Clinical Densitometry 2019).
Results: Decreased BMD according to QUS was diagnosed in 44.87% of males (Z-score -2.29 ± 0.32) and 42.47% of females (Z-score -2.40 ± 0.31). In the group of males with growth spurts, a decrease in BMD was found in 52%; in the group of females with growth spurts, a decrease in BMD in 60%. All examined children had a deficiency or insufficient level of vitamin D, the average level of which was 40.30 ± 9.51 nmol/l. The average level of vitamin D in children with low BMD and without growth spurts was: in males—37.17 ± 9.04 nmol/l, in females—36.28 ± 9.04 nmol/l; with low BMD and growth spurts: males—41.42 ± 11.52 nmol/l, females—37.62 ± 12.75 nmol/l. When studying the BSML polymorphism of the VDR gene in children with low BMD, the following results were obtained: pathological mutations (heterozygous and homozygous) were found in 35.71% of males with growth spurts and 55.56% of males without growth spurts; 57.14% of females with growth spurts and 56.25% of females without growth spurts had pathological mutations.
Conclusion: The examined children have insufficient levels of vitamin D. Low BMD in the examined children during the period of intensive growth is not related to the status of vitamin D. But intensive growth is the reason for the decrease in BMD. Pathological mutations of the BSML polymorphism of the VDR gene were also not associated with low BMD in children with growth spurts, but were more common in females. Mineralization of bone tissue during the spurt period depends not only on the genetic component and the status of vitamin D, but also on the growth mechanisms, which are characterized by the discrepancy between the growth rate and the accumulation of bone mass.

P387
INCREASED PREVALENCE OF OSTEOPOROSIS AND DECREASED HIP BONE MINERAL DENSITY IN PATIENTS WITH ENDOCRINE AND NON-ENDOCRINE CAUSES OF HYPONATREMIA

D. Miljic[1], M. Nikolic-Djurovic[1], M. Doknic[1], S. Pekic[1], M. Stojanovic[1], Z. Jemuovic[1], I. Cekic[1], I. Jevtic[1], B. Kurcubic[2], S. Borozan[3], S. Vujosevic[3], M. Petakov[1]

[1]Clinic for Endocrinology, Diabetes and Metabolic Diseases, Dept. of Neuroendocrinology, Univ. Clinical Centre of Serbia, Belgrade, Serbia, [2]Faculty of Medicine, Univ. of Belgrade, Belgrade, Serbia, [3]Clinical Centre of Montenegro, Podgorica, Montenegro

Previous studies have shown that longer duration of hyponatremia is associated with an increased risk of osteoporosis, while even mild hyponatremia is an independent risk factor for decreased bone mineral density, risk of falls and fractures. We have conducted a retrospective cohort study, which included patients treated for chronic endocrine and non-endocrine causes of hyponatremia, over the last decade at the Department of Neuroendocrinology, Clinic for Endocrinology, Diabetes and Metabolic Disease of the University Clinical Centre of Serbia, who had osteodensitometric studies performed during their hospitalization. Clinical, biochemical, hormonal and osteodensitometric parameters of patients and age and gender matched control subjects, without hyponatremia, were analyzed and compared. 34 subjects participated in the study, 19 patients (11 women, 57.9%, 10/11 menopausal) mean age 62.8 ± 14.6 y, mean sodium level 127.2 ± 5.25 mmol/L and 15 healthy subjects (8 women, 53.3%, 6/8 menopausal) mean age 53 ± 15 y with no comorbidities and normal sodium levels. The most common endocrine cause of hyponatremia was adrenal insufficiency, which was secondary (pituitary) in 7 (36.8%) and primary (adrenal) in 3 (15.8%) patients, while the most common non-endocrine cause of hyponatremia was the syndrome of inadequate anti-diuresis (SIAD), caused by malignant disease in 5 (26.3%) or idiopathic in 4 (21%) patients. Decreased BMD was observed in 20 of 34 investigated subjects (58.8%), 13 (65%) had osteopenia (53.8% of patients with

hyponatremia compared to 46.2% of controls, $p < 0.05$), and 7 (35%) had osteoporosis (100% patients with hyponatremia vs. 0% controls, $p < 0.05$). Decreased BMD was significantly more prevalent in patients with hyponatremia compared to controls 73.7% (14/19) vs. 40% (6/15) ($p = 0.05$). However, no statistically significant difference was found in the prevalence of reduced BMD in patients with different causes of hyponatremia in endocrine vs. non-endocrine causes (70%(7/10) vs. 73.7%(7/9); $p > 0.05$). Patients with hyponatremia had significantly lower BMD and T-score values at total hip compared to controls (-1.53 ± 2 vs. -0.56 ± 0.9; $P = 0.05$), while statistical difference between the groups was not reached for mean values of T-score at lumbar spine (-1.4 ± 1.3 vs. -0.8 ± 0.9; $P = 0.08$). Our results confirm significantly higher prevalence of osteoporosis and decreased BMD in patients with hyponatremia, irrespective of its etiology, which is more evident at total hip than lumbar spine.

P388
INCIDENCE AND INFLUENCE OF VITAMIN D DEFICIENCY IN PATIENTS WITH OSTEOARTHRITIS: A SYSTEMATIC REVIEW

B. Neagu[1], A.-E. Cristea[1], D. Oprea[2], L.-E. Stanciu[2], M. Minea[1], C. Mihailov[3], M.-G. Iliescu[4]

[1]Hospital Rehabilitation Unit, Balneal Sanatorium of Techirghiol, Ovidius Univ. Faculty of Medicine Doctoral School, [2]Hospital Rehabilitation Unit, Balneal Sanatorium of Techirghiol, Dept. of Medical Rehabilitation, Faculty of Medicine, Ovidius Univ. of Constanta, [3]Dept. of Rheumatology, Faculty of Medicine, Ovidius Univ. of Constanta, [4]Hospital Rehabilitation Unit, Balneal Sanatorium of Techirghiol, Ovidius Univ. Faculty of Medicine Doctoral School, Dept. of Medical Rehabilitation, Faculty of Medicine, Ovidius Univ. of Constanta, Constanta, Romania

Objective: This systematic review aimed to search the current literature and provide evidence regarding the correlation between vitamin D deficiency and the severity of osteoarthritis (OA).
Methods: A systematic review was performed based on the PRISMA methodology. Studies were identified from the following databases: PubMed, Scopus, Web of Science, Cochrane, PEDro using the keywords: vitamin D deficiency and osteoarthritis, 25-hydroxyvitamin D deficiency and osteoarthritis. We included only articles written in English from the last 10 y, about patients suffering from OA, regarding the type of it and containing information about the serum level of 25(OH)D. Reviews, meta-analysis and articles about vitamin D deficiency in correlation with inflammatory rheumatic diseases or another serum biomarkers were excluded.
Results: The general search resulted in 1090 articles: 180 in PubMed, 469 in Scopus, 418 in Web of Science, 22 in Cochrane and 1 in PEDro, of which 22 studies fitted the inclusion criteria. The relationship between vitamin D and OA revealed a high incidence of lower vitamin D serum levels in patients with OA.
Conclusion: The goal was to review a select literature in order to present recently studies on degenerative diseases that show a high prevalence of vitamin D deficiency to sustain the major role of vitamin D in musculoskeletal system health maintenance. Even so, further studies are necessary to confirm the association between vitamin D deficiency and OA.

P389
ROLE OF SHORT REHABILITATION PROGRAMS IN OLDER ADULTS FOR IMPROVING MOBILITY AND PREVENTING FALLS

A. T. Vancea[1], A. A. Lupu[1], D. Oprea[1], L. E. Stanciu[1], M. G. Iliescu[1], I. Calatoiu[2], L. Spiru[3]

[1]Dept. of Medical Rehabilitation, Faculty of Medicine, Ovidius Univ. of Constanta, Constanta, [2]Faculty of Medicine, Ovidius Univ. of Constanta, Romania., Constanta, [3]Carol Davila Univ. of Medicine and Pharmacy, Bucuresti, Romania

Objective: This study emphasizes averting the risk of falling among older adults, focusing on a complex rehabilitation program at Techirghiol Balneal and Rehabilitation Sanatorium (TBRS), a famous location for rehabilitation in Romania. The primary objective was to assess changes in the risk of falling from admission to discharge and evaluate the short-term rehabilitation process's efficacy in mitigating this concern.
Methods: The research was conducted on 156 patients over 65, hospitalized for a rehabilitation program, using 12 d of physical procedures, such as physiotherapy, thermotherapy, massage, kinetotherapy, and hydrokinetotherapy in salty water from Techirghiol Lake, adapted to the main pathology, osteoarthritis. All the patients signed the informed consent for the study. Acknowledging the repercussions of fall-related injuries on the autonomy of the elderly, the study explores the role of a short-term rehabilitation program, using two evaluations, at admission and discharge, using the STRATIFY scale for assessing fall risk, the visual analogue scale (VAS) for self-reported pain and Functional Independence Measure (FIM) scores for motor and cognitive dysfunctions.
Results: Analysis of the study batch reveals substantial improvements in preventing the risk of falling through the short-term rehabilitation program. The study demonstrates a notable reduction in fall risk from admission to discharge, mean value of the STRATIFY scale decrease of -0.257. There is also a significant evolution of the general FIM score at discharge, in the sense of its increase, an aspect mainly due to the improvement of functionality at the locomotor level (mean value improvement of 1436 in patients' motor ability). The mean value of VAS decreases to -3.141 between the two moments of evaluation, indicating a significant reduction in pain intensity in the evaluated patients.
Conclusion: This research highlights the brief rehabilitation program's effectiveness at TBRS in diminishing the risk of falling and preserving independence among geriatric patients. The pairs of variables measured at admission and at discharge, indicate remarkable internal consistency with statistical significance (p-value < 0.001). Our study has practical implications for healthcare professionals, in implementing efficient fall prevention strategies.

P390
RELATIONSHIP BETWEEN DEPRESSIVE SYMPTOMS AND FRAILTY IN OLDER ADULTS

D. Orentaitė[1], A. Mastavičiūtė[1], V. Ginevičienė[1], J. Kilaitė[1], R. Dadelienė[1], I. E. Jamontaitė[1], E. Pranckevičienė[1], I. Ahmetov[1], V. Alekna[1]

[1]Vilnius Univ., Vilnius, Lithuania

Objective: Frailty and depression are two common syndromes among older adults. These geriatric syndromes are associated with a range of deleterious outcomes in older age such as lower quality of life, increased use of healthcare services, increased morbidity and mortality [1–3]. Scientific research about depressive symptoms associations with frailty in older adults are scarce. The aim of this

study was to investigate the relationship of depressive symptoms and frailty in community dwelling older adults.
Methods: This cross-sectional study was conducted on community dwelling older adults aged $\geq$ 65 y with normal cognition and mild cognitive impairment. A total of 51 older adults (78.4% women) with average age 77.82 $\pm$ 1.04 y were involved in this study. Exclusion criteria were chronic diseases with acute organ failure, musculoskeletal and nervous system diseases, restricting mobility. Cognitive status was evaluated using the Mini Mental State Examination (average was 27.49 $\pm$ 0.28). Geriatric Depression Scale (GDS) short form was used to measure depressive symptoms. Frailty was assessed using Fried's phenotype (robust [0 score] pre-frail [1–2 score] and frail [$\geq$ 3 score]). The relationship between variables was calculated using Spearman correlation coefficients with statistical significance $p < 0.05$. Data was analyzed using IBM SPSS Statistics 29.0.2.0 version.
Results: The average score of GDS was 3.2 $\pm$ 0.34. Depressive symptoms were observed in 46 of 51 patients, 31.4% of individuals having scored mild and moderate depression. The average score of Fried's phenotype criteria was 1.67 $\pm$ 0.22. The analyzed data showed that 25.5% of patients were robust, 49.1% of individuals were pre-frail and 27.5% frail. The analysis demonstrated a statistically significant moderate positive correlation between depressive symptoms and frailty ($r = 0.407$, $p = 0.003$).
Conclusion: The results of our study revealed that depressive symptoms and frailty were moderately correlated in community dwelling older adults.

P391
RELATION BETWEEN PERCEIVED WORK ABILITY AND CLINICAL CHARACTERISTICS OF THE DISEASE IN PATIENTS WITH RHEUMATOID ARTHRITIS

D. Petrovic[1], M. Perovic[1], P. Ostojic[1]

[1]Institute of Rheumatology, Belgrade, Serbia

Objective: Population aging leads to increased focus on work ability, preventing early employment termination and increasing work productivity of patients with rheumatoid arthritis (RA). We aimed to examine the perceived work ability of working patients with RA and its relation to the clinical characteristics of RA.
Methods: The sample included 103 patients, with an average age of 48 y and average disease duration of 5 y to the diagnosis and 7 y total. 75.9% of patients had positive RF and/or ACPA. Radiographic joint damage was determined in 62.8% of patients by hands and feet X-rays not older than a year. 67% of patients were treated with conventional synthetic disease-modifying antirheumatic drugs (csDMARD), while 33% of patients received biological drugs (bDMARD) or Janus kinase inhibitors (JAKi). Serbian version of the Work Ability Index (WAI) was used to assess perceived work ability. The WAI values were examined in relation to pain (assessed by VAS), functional capacity (HAQ), depression (BDI), fatigue (FACIT) and disease activity (DAS_{28}).
Results: The average WAI value was 42.1 $\pm$ 9.0. There was no difference in the average WAI value between groups of patients in relation to RF/ACPA seropositivity, presence/absence of structural joint damage, disease duration to the diagnosis, the total duration of RA or the type of applied therapy. A significant negative correlation was determined between perceived work ability and pain intensity ($r = -0.355$, $p < 0.001$), functional capacity ($r = -0.288$, $p = 0.003$), depression ($r = -0.303$, $p = 0.001$) and fatigue ($r = -0.293$, $p = 0.002$). A negative correlation was observed between DAS_{28} and WAI, but it was not statistically significant.
Conclusion: RA patients assessed their perceived work ability as very good on average. Depression, fatigue, severe pain and limited functional capacity were significantly associated with decreased perceived work ability. These results should be confirmed by larger randomized studies.

P392
COMBINING SYSTEMIC AND LOCAL OSTEOPOROSIS TREATMENTS IN OVARIECTOMIZED RATS

V. Stadelmann[1], E. Gerossier[2], U. Kettenberger[3], D. Pioletti[2]

[1]Dept. of Research and Development, Schulthess Klinik, Zurich, [2]LBO/EPFL, Lausanne, [3]flowbone SA, Lausanne, Switzerland

Objective: HA2, a novel, hydrogel-based, and highly injectable biomaterial for local bone strengthening, was combined with two systemic anti-osteoporosis treatments and a local bisphosphonate to assess combined effects on bone density in a rat model of osteoporosis.
Methods: 36 ovariectomized Wistar rats were randomly assigned to vehicle (VEH), alendronate (ALN), or PTH groups and underwent systemic treatment with those substances throughout the entire study. One week after treatment started, the 72 tibias of the rats were block-randomized into 3 sub-groups, and their plateaus were injected with either NaCl as control, HA2 or HA2-ZOL (with incorporated Zoledronate), excluding two times the same treatment in one animal. In vivo μCT scans of the proximal tibiae of all animals were acquired at baseline (week $-$ 1), immediately post-injection (week 0), and at 2, 4, 6, and 8 weeks thereafter. Changes in bone were evaluated within and outside the injected zone, which was identified on the post-injection scans. Histology was performed on the harvested bone samples.
Results: HA2 injections more than doubled local bone mass in the VEH animals within 4 weeks and tripled it in the ALN and PTH groups. Local bisphosphonate in HA2-ZOL strongly enhanced this effect in the VEH and PTH animals but less in combination with systemic ALN. HA2-ZOL also significantly slowed down the resorption of the newly formed bone, especially in the VEH and PTH animals. Neither HA2 nor HA2-Zol influenced bone outside the injected zone.
Conclusion: This study suggests that HA2, an injectable biomaterial capable of promoting new bone formation, could be a valuable addition to established anti-osteoporotic drugs, with and without an integrated bisphosphonate. It can increase bone density rapidly and significantly in regions at high risk of fracture.
Disclosures: UK and DP hold shares of flowbone SA.

P393
TREATMENT AND MANAGEMENT OF OSTEOPOROTIC FRACTURES IN MEN: A 8-YEAR STUDY OF REAL-WORLD CLINICAL PRACTICE IN A SINGLE-CENTRE (OSTEOPROM, PART III)

D. Pokšāne[1], I. Rasa[2]

[1]Rīga Stradiņš Univ. (RSU), Latvian Osteoporosis and Bone Metabolic Diseases Association (LOKMSA), [2]Riga East Clinical Univ. Hospital (RECUH), Latvian Osteoporosis and Bone Metabolic Diseases Association (LOKMSA), Riga, Latvia

Objective: The insufficient knowledge of male osteoporosis (OP) accounts for the lack of well-shared protocols for clinical management. The growing data on the pathophysiology of bone and epidemiological data of fracture in men are becoming available. We studied the BMD increase and the anti-fracture effectiveness of denosumab (Dmab) in the male cohorts (OsteoProM).
Methods: We conducted the single-centre real-world retrospective observational Study from 2014–2022. We collected RECUH Outpatient Clinic data from medical records and then manually analysed it. We analysed fracture risk factors, fracture incidences, BMD changes, laboratory data (Ca, vitamin D, iPTH), co-morbidities and concomitant medications. BMD of the lumbar vertebrae L1/L4 and the total mean hip by DXA scans were performed for the initial and final diagnoses of the Study. Statistical analysis was performed using IBM SPSS v29.0.
Results: We analysed 60 men with OP. The mean age was 64.2 ± 11.9 SD yrs and included: one patient aged 18–40 yrs, five patients aged 41–50 yrs, 15—aged 51–60 yrs, 21—aged 61–70 yrs, 13—aged 71–80 yrs, and five—aged > 80 yrs. Men with idiopathic OP were 75.0% (n = 45), glucocorticoid-induced OP—13.5% (n = 8) and secondary OP—11.5% (n = 7). Dmab increased BMD at lumbar spine L1/L4 by 80.0% and total mean hip by 76.9%. Before the Study started, pts with at least one fracture were 50%, mainly in the spine (63.3%) and also other fracture types—hip, forearm, and ribs. After the Study ended, three patients had at least one fracture. Men were divided into six groups according to injection (inj.) numbers from 1 to 13 inj. BMD by DXA was analysed in each inj. group.
Conclusion: Dmab is an effective anti-fracture medication, which significantly and promptly increases BMD in DXA scans at the lumbar spine and the total mean hip in men with and without fractures. Dmab is an appropriate clinical option in men with intolerance or contra-indications to bisphosphonates and is also a reasonable first-line treatment.

P394
VITAMIN D STATUS IN LATVIAN POPULATION IN 2023: RESULTS FROM TWO BIGGEST LABORATORY DATABASES

D. Pokšāne[1], I. Rasa[2]

[1]Rīga Stradiņš Univ. (RSU), Latvian Osteoporosis and Bone Metabolic Diseases Association (LOKMSA), [2]Latvian Osteoporosis and Bone Metabolic Diseases Association (LOKMSA), Riga East Clinical Univ. Hospital (RECUH), Riga, Latvia

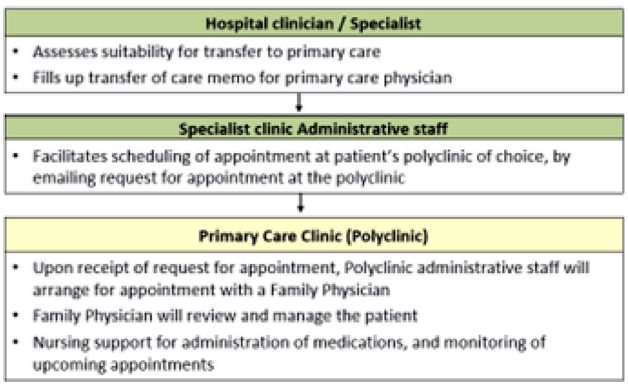
Objective: Vitamin D deficiency is a global public health problem. A decreased vitamin D level is a risk factor for many diseases and mortality rates in general. Due to that, the prevalence of vitamin D deficiency is an important topic in public health. The study aimed to evaluate the status of the total 25-hydroxy vitamin D (chemiluminescent assays) in adults in Latvia in 2023.
Methods: The retrospective study from January 2023 to December 2023 included data from 465,150 patients from two electronic databases: Central Laboratory Ltd. and E. Gulbja Laboratory Ltd. in 2023. Vitamin D deficiency was defined as < 20 ng/mL, insufficiency as 20–30 ng/mL, optimal level as 30–50 ng/mL, and excess of vitamin D as > 100 ng/mL. All data were analyzed in IBM SPSS v29.0.
Results: In 2023 in Latvia, 465,076 tests were done for a total of 25-hydroxyvitamin D tests—were women 68% (n = 318,214), men 32% (n = 146,862), and the mean age was 48 y. Vitamin D deficiency was found in 15.0% (n = 69,617) of the study cases, insufficient level in 30.7% (n = 142,920); 51.4% of patients had an optimal level of vitamin D (30–50 ng/mL in 42.8% (n = 199,345), 50–75 ng/mL in 10.3% (n = 47,774), 75–100 ng/mL in 1.0% (n = 4507)). Excess of vitamin D had 0.2% (n = 987) of the study population.
Conclusion: Vitamin D insufficiency and deficiency in the study population were almost as common as optimal levels of vitamin D. These results demonstrate the importance of electronic database analyses concerning vitamin D levels.

P395
RIGHT-SITING OSTEOPOROSIS PATIENTS ON DENOSUMAB TO PRIMARY CARE: EXPERIENCE FROM A SINGAPORE PRIMARY CARE CLUSTER

D. S. Choong[1], G. C. S. Tan[1], S. L. Kok[1], K. H. Koh[1], J. J. L. Chua[1], D. L. S. Tng[1]

[1]SingHealth Polyclinics, Singapore, Singapore

Objective: The model of care to 'right-site' patients with stable chronic disease from secondary care to primary care, supports Singapore's health strategy of "Beyond hospital to community"—one of the "Three Beyonds" that the Ministry of Health has embarked on to sustain quality healthcare amidst rising demand. Osteoporosis is a chronic disease managed in both primary care and secondary care. Anti-osteoporosis medications commonly used in Singapore include bisphosphonates and denosumab. Use of denosumab for osteoporosis remained mostly confined to specialty-care settings in Singapore's public healthcare system and is not routinely used by public sector primary care (polyclinic) physicians. A workflow was implemented to allow right-siting of patients on denosumab for osteoporosis to transition from hospital to polyclinics.
Methods: Patients suitable for discharge to primary care, according to inclusion criteria, were right-sited via workflow in Figure. Patients excluded were those with severe renal impairment, or had conditions requiring continuing specialist's care. The outcome measures were the number of patients transferred under this framework, the number of injections administered, and the number of referrals back to specialty centre.



Results: From July 2020 to December 2023, a total of 288 patients transferred from hospital to community settings under right-siting framework. A total of 721 denosumab injections were cumulatively administered under the right-siting framework. From 2021–2023, 17 patients were referred to specialty centre under predefined fast track criteria. A physician survey (n = 13) showed 84.7% of polyclinic physicians self-reporting at least moderate levels of confidence in managing patients on denosumab. The program was thereafter expanded to two other hospitals in late 2023.
Conclusion: The right-siting workflow created a structured framework to transition patients on denosumab to primary care. Such a framework grants patients convenience and enables primary care doctors to be familiar with its use.

Acknowledgements: The authors wish to thank the following colleagues from Singapore General Hospital, Dept. of Endocrinology for their invaluable guidance in this collaboration: Prof Manju Chandran, Ms Huang Xiaofeng, Ms Liu Xiaoming. Dr Jane Tan, Ms Wendy Foo, Ms Hannah Lye, Ms Nur Syarina Binte Shaari and all others from SingHealth Polyclinics who supported this right-siting pathway.
Disclosure: DS Choong has participated as panelist and received support to attend conferences by Amgen.

P396
EFFECT OF INTRODUCING A FRACTURE LIAISON SERVICE IN A SMALL HOSPITAL ON PATIENT OUTCOMES

D. Schweppenhäuser[1], M. Förtsch[2]

[1]Orthopedic Dept., ev. Krankenhaus Bad Dürkheim, Bad Dürkheim, [2]Ortho 1 a Ludwigshafen, Ludwigshafen, Germany

Objective: Patients aged over 50 with fragility fractures of wrist, proximal humerus, spine and proximal femur and patients aged over 80 with all fractures were treated in the hospital. They have a high imminent risk of a subsequent fracture. The aim was to describe the impact from introducing an FLS on readmission rates with fragility fractures in a small hospital.
Methods: In 2019 an FLS was implemented in a small hospital (235 inpatient beds) that is the only hospital in the region. The FLS identified adults fractures. All patients were referred to the local osteologist by the FLS coordinator for DXA and ongoing treatment. We compared the readmission rate and mortality for patients admitted in 2018 and 2022 using hospital records. Differences were tested using chi-square.
Results: In 2018, 217 patients with fragility fractures were treated in the hospital, mean age 77.2 and 257 in 2022 (mean age 77.9). There was a significant reduction in readmissions due to fracture and mortality but not readmissions due to other causes (Table). Of the 15 patients with a subsequent fracture in 2022, 5 were seen in the FLS and 9 had a treatment recommendation in discharge letter.

Table. Subsequent re-admissions and mortality over X years after index fragility fracture

Year	Total	Seen by FLS	Readmitted with fracture	Other readmission	Mortality
Pre FLS 2018	217	0	30 (13.8%)	52 (24.0%)	22 (10.1%)
Post FLS 2022	257	201 (78.2%)	15 (5.8%)	51 (19.8%)	12 ((4.6%)
p-value		n/a	0.003	0.28	0.02

Conclusion: Readmission rate due to fracture and mortality was significantly reduced after implementing the FLS but not readmissions for other reasons, which remained high. Further work is needed to characterise the performance of the FLS and explore other interventions to reduce readmission rates and long term sustainability of the benefits shown.

P397
BENEFITS OF PHYSICAL EXERCISE IN THE IMPROVEMENT OF HAND GRIP STRENGTH IN PATIENTS WITH OSTEOPOROSIS AND SARCOPENIA

D. Stoicanescu[1], M. S. Deac[2], M. Cevei[2], A. Gherle[2]

[1]Univ. of Medicine and Pharmacy "Victor Babes", Timisoara, [2]Univ. of Oradea, Faculty of Medicine, Oradea, Romania

Physical exercise and nutritional intervention are currently the known solutions for sarcopenia. We present the case of a 38 years old male patient, with a medical history of resuscitated cardio-respiratory arrest of unknown etiology in 2013 and secondary osteoporosis after immobilization. The patient is a wheelchair user requiring assistance in performing ADLs. The modified Ashworth scale measuring the increase of muscle tone revealed spasticity: Ashworth score 1 for both upper and lower limbs. Apraxia and dysarthria were also found. The John Health System Corporation scale established a high risk of falling, with 19 points. The patient's self-care capacity, functional independence and functional ambulatory category were assessed using the FIM, Barthel and FAC (Functional Ambulation Classification) scale, respectively. FIM scale score was 25 points out of 126, 19.84%. Barthel Index score was 5 points out of 100 indicating the patient was totally dependent. FAC score was 0 indicating nonfunctional ambulatory. The diagnoses of osteoporosis and sarcopenia were based on BMD, ALM and grip strength data. BMD determination using DXA from 21.06.2022 indicated: lumbar spine Z-score: -1.6; left hip Z-score:-2.6; right hip Z-score:-2.0; ALM was 0.47. Grip strength measured with Jamar dynamometer on 23.06.2022 showed left handgrip strength 20 kg and right handgrip strength 22 kg. The dynamometry performed on 25.10.2023 indicated left handgrip strength 17 kg and right handgrip strength 32 kg. The recommendations were: daily exercise intervention programs at home; follow recommendations related to the prevention of falls and fall-related injuries. Conclusion: Medical rehabilitation programs improved upper limbs functionality.

P398
INPATIENT TREATMENTS IN VERY ELDERLY PATIENTS WITH FRACTURE NECK OF FEMUR: A UNIQUE GROUP NEEDING SPECIAL CONSIDERATION

D. Veness[1], H. Griffiths[1], R. Noble[1], A. Ahmed[1], J. Chillala[1]

[1]MFT, Manchester, UK

Objective: The risk of further fractures after a fracture neck of femur is very high, with zoledronic acid showing reduction in refracture rate by a third. The National Osteoporosis Guideline Group NOGG in 2021 recommended zoledronate as first line after fracture neck of femur. When we looked at previous data in very elderly this showed 60% of patients were not receiving any treatments post fracture apart from vitamin D. This study looked at which inpatient treatments were being given to very elderly patients with fracture neck of femur on an orthogeriatric ward and how barriers to treatment can be improved for initial treatment and follow on treatments.
Methods: The records of all patients discharged from July 2023 to October 23 on Elm unit, Trafford (an orthogeriatric assessment and rehabilitation unit) were examined. Of these, 76 patients were identified for data collection including comments on those patients who did not have treatment and also how follow up infusions were planned.
Results: 65.8% of patients received zoledronate treatment as an inpatient, which is still a lower figure than expected target. 5.5% of patients received denosumab. Remaining patients had optmisation of vitamin D. The main reasons for nontreatment were refusal by patient /family due to concern of side effects and difficulty attending for future doses. This was particularly where Cr clearance was low and patients felt unable to attend secondary care for ongoing denosumab. 30% patients who required ongoing infusions with zoledronate did not have follow up for 2nd doses.
Conclusion: Uptake of bone health treatment is still not ideal in older patients who are high risk of refracture. Improved communication/ information to patients and families who decline treatment may improve uptake numbers. Denosumab requires attendance to hospital if Cr Cl < 30, this is a major barrier for our patients with limited mobility post hip fracture and guidelines need to be reviewed for this group of patients. Home zoledronic acid treatment needs to be a standard service offered. An improved pathway for follow up of

patients and ongoing infusions is required in the absence of a fracture liaison service.

P399
RETROWALKING—A NEW APPROACH TOWARD REHAB TRAINING FOR OSTEOARTHRITIS KNEE: A REVIEW

D. Wadhwa[1], V. Phalke, R. Kunkolol[1]

[1]Pravara institute of Medical Science, Loni, India

Everyone talks of arthritis but considering its implications; no one wants to suffer from it! Arthritis foundation of India has cited an interesting Chalo Chalein (come we will move) test that most of us can understand. American College of Rheumatology Diagnostic and Therapeutic Committee defined OA as 'A heterogeneous group of conditions that lead to joint symptoms and signs which are associated with defective integrity of articular cartilage, in addition to relative changes in the underlying bone at the joint margins'. The disease limits everyday activities, such as getting in and out of bed, dressing and climbing stairs. Patients with knee Osteoarthritis seems to develop their own gait pattern and try to unload the affected structures during gait. This prolonged usage of secondary gait compensation creates greater imbalances of muscle, progressively reducing muscle strength, endurance, flexibility and later ending to deformity. Whenever you encounter a difficult situation, stepping backward may boost your capability to deal with it effectively' written by Severine Koch. Retrowalking is sometimes referred to as backward walking, has been thought to be used already for several decades in Japan and Europe to get a physical workout, improve sport performance, promote balance and to stay mentally fit. Retrowalking is a new approach in physiotherapy and rehabilitation. It has emerged as a beneficial exercise in terms of lowering peak patellofemoral joint compressive force, trauma to the articular cartilage is reduced, increase quadriceps strength, reduction in adductor moment at knee; all these reduce the disability thus leading to improved function. It also has effect on improving strength of hip extensors leading to reduced hip flexion moment during stance phase and thus preventing abnormal loading at knee joint and, in turn, the disability Retrowalking is associated with increased cadence, decreased stride length and different joint kinematics as compared to forward walking and hence may offer some benefits over forward walking alone. Thus, Retrowalking a new approach for rehab training for osteoarthritis knee has numerous benefits and improves the functional activity.

P400
IMPACT OF RETROWALKING ON OSTEOARTHRITIS OF KNEE: A CASE STUDY

D. Wadhwa[1], V. Phalke, R. Kunkolol[1]

[1]Pravara institute of Medical Science, Loni, India

Osteoarthritis is a very common case and is regularly physiotherapy clinics. Mostly the affected population is elderly in whom prominent weakening and wasting of quadriceps and hamstrings muscle is seen. As the affected population is mostly aged, they can't bear the heavy weight which is needed for strengthening. Hence one such and intervention is needed which may be easy to perform and cause strengthening of these weak muscles. Retrowalking is one such intervention and has been proved beneficial in treating symptomatic osteoarthritis of knee.

Casereport: A case of 65 years old male is presented in the report who presented with pain and stiffness in knee which was sudden in onset. Diagnosed with osteoarthritis of knee for by Orthopaedician substantiated by radiograph grade 2. Assessed for any physical disorders which are contraindicated for exercises by using Physical Activity Readiness Questionnaire (PAR-Q). The patient fulfilling clinical criteria listed by the American College of Rheumatology: knee pain-7 NPRS and any three out of six: age 65 y, morning stiffness lasting > 30 min, crepitus on active motion, bony tenderness, no warmth on touch and Clark test was positive. Ranges and muscle strength of the knee joint were found to be reduced. Outcome measures—NPRS, WOMAC-CRD and Berg balance scale treatment. The patients received retrowalking on flat surface (distance 20 m) at their maximum pace with support of the wall for 10 min/session. The session—4 min of retrowalking following 2 min of rest time and then again 4 min of retrowalking. Conventional exercise like static and dynamic quadriceps, SLR, static hamstring and hamstring stretch was given. Total treatment—5 d/week for 3 weeks. Even the pain had subsided drastically with improvement in WOMAC CRD and Berg balance score ($p < 0.05$). Patient was very comfortable after completion of 3 weeks treatment.

Conclusion: The importance of the new intervention that is retrowalking and glorifies its benefits.

P401
EXPLORING THE SARCOPENIA CRITERIA IN ADULT PATIENTS WITH DIABETES

C.-J. Wen[1], R.-S. Yang[2], W.-J. Huang[1], K.-P. Lin[1], T.-H. Yang[3], D.-C. Chan[1]

[1]Dept. of Geriatrics and Gerontology, National Taiwan Univ. Hospital, Taipei, [2]Dept. of Orthopedics, National Taiwan Univ. Hospital, Taipei, [3]Dept. of Orthopedics, NTU BioMedical Park Hospital, NTUH Hsin-Chu Branch, HsinChu, Taiwan

Objective: Sarcopenia is defined by age-related decline of skeletal muscle mass plus low muscle strength and/or physical performance. The European Working Group on Sarcopenia in Older People (EWGSOP) and Asian Working Group for Sarcopenia (AWGS) have established practical clinical definitions and consensus diagnostic criteria. However, these criteria are specifically designed for older individuals. Therefore, our aim is to investigate sarcopenia criteria applicable to adults.

Methods: A total of 178 patients with diabetes, aged 20–65, were recruited at the National Taiwan University Hospital (NTUH). Muscle mass criteria were assessed using DXA and bioelectrical impedance analysis (BIA). Muscle strength was determined by measuring handgrip strength, and physical performance criteria were evaluated through the 6-m walk test and the 5-times sit-to-stand test. The research employed either 1 standard deviation below the mean or the 20th percentile of the study group as the criteria for determining the cut-off value.

Results: The mean age for the entire cohort was 52.3 ± 9.2 y with 45.5% female. The reference cut-off values were shown in the following Table.

			A	B
Muscle Mass				
Men	DXA	8.0±1.0[C]	6.9 kg/m^2	7.2 kg/m^2
	BIA	9.2±1.2	8 kg/m^2	8.3 kg/m^2
Women	DXA	6.4±1.0	5.4 kg/m^2	5.4 kg/m^2
	BIA	6.9±0.9	6 kg/m^2	6.1 kg/m^2
Muscle Strength				
Men	Handgrip	41.5±8.0	33.5 kg	35 kg
Women		27.9±5.9	22 kg	22.5 kg
Physical Performance				
Gait speed of the 6-meters walk		1.2±0.1	1.1 m/s	1.1 m/s
5-times sit-to-stand test		8.5±2.4	10.9 s	10.2 s

A. 1 standard deviation below the mean
B. the 20th percentile of the study group
C. mean± standard deviation

Conclusion: In this study, we determined the reference cut-off values of muscle mass, muscle strength and physical performance for adult patients with diabetes. In the future, we will endeavor to establish the reference cut-off values of sarcopenia for general adult population.

P402
COMPARISON OF THE MEAN BONE MINERAL DENSITY AND FRAGILITY SCORE OF THE LUMBAR SPINE ASSESSED WITH RADIOFREQUENCY ECHOGRAPHIC MULTISPECTROMETRY (REMS) BETWEEN WOMEN WITH AND WITHOUT SCOLIOSIS

E. Bischoff[1], F. Bischoff[2], S. Vladeva[3]

[1]Univ. "Prof. Dr. Assen Zlatarov" Burgas, Medical Faculty, [2]Rheumatology practice [3]Trakia Univ., Medical Faculty, Stara Zagora, Bulgaria

Objective: Fragility score (FS) is dimensionless parameter based on the innovative ultrasound examination of the lumbar spine and/or hip using REMS. FS evaluates the bone quality independently of bone density (BMD).
Methods: We assessed the FS of the lumbar spine of 42 women with REMS. Subjects were with mean age of 82 y and range 24–88 y. Women were considered to have scoliosis if their spine had a sideways curvature of at least 10°. Age, weight, height, BMI, BMD, T-score, Z-score and FS were compared between the subjects with and without scoliosis. Independent sample T-test was used to show if there are some statistically significant differences. The data collection was performed with an innovative JAVA tool, developed by Kirilov et al. [1,2].
Results: Women with scoliosis were significantly older (with mean age of 74 y) than those without scoliosis (51 y), $p < 0.001$. Height differed significantly between the two groups, $p = 0.02$ (159 cm for those with scoliosis and 164 cm for those without scoliosis). Weight and BMI didn't show any statistical significance. BMD, T-score and FS differed significantly between the both groups, $p < 0.001$. Women with scoliosis had lower BMD (0.774 g/cm^2), lower T-score (− 2.5 SD) and higher fragility score (58.5) of the lumbar spine compared to those without scoliosis (BMD = 0.945 g/cm^2, T-score = − 1.0 SD and FS = 26.1). Although Z-score didn't show any statistically significance.
Conclusion: Women with scoliosis demonstrated higher fragility score and in this way higher fracture risk.

P403
DETECTING LOOSENING OF LOWER EXTREMITY TOTAL JOINT ARTHROPLASTY WITH AN ACCURATE MACHINE LEARNING MODEL FOR CLINICAL DECISION MAKING

E. C. S. Chui[1], K. K. K. Mak[1], R. H. T. Ng[1], E. C. H. Fung[1], M. T. Y. Ong[1], R. M. Y. Wong[1], P. S. H. Yung[1]

[1]Dept. of Orthopaedics and Traumatology, Prince of Wales Hospital, Chinese Univ. of Hong Kong, Hong Kong, SAR China

Objective: Total joint arthroplasty is a common operation for treating knee or hip osteoarthritis (OA). The objective of this study was to develop an accurate machine learning model based on image analysis for detecting loosening of lower extremity total joint arthroplasty implants. The aim was to aid clinical decision making by providing a reliable tool for early detection and diagnosis of implant loosening.
Methods: A comprehensive dataset of image data, including X-rays, MRI and CT scans, was collected for training the machine learning model. The images provided detailed information about the status of the implants. The model was trained using a combination of image processing techniques and machine learning algorithms to accurately identify loosening of the implants.
Results: The developed machine learning loosening model exhibited an accuracy of 90% and a predictability of 0.92 in successfully detecting loosening of lower extremity total joint arthroplasty implants. It demonstrated remarkable proficiency in analyzing the provided image data and swiftly identifying instances of implant loosening. The model's impressive performance holds great promise for facilitating clinical decision-making in the early detection and management of implant loosening.
Conclusion: The novel image-based machine learning model presented in this study offers a reliable and accurate tool for detecting loosening of lower extremity total joint arthroplasty implants. Its high accuracy and predictability can aid clinicians in making informed decisions regarding further examinations or interventions. The model has the potential to improve patient care by enabling early detection and intervention for implant loosening.

P404
DEEP LEARNING NETWORK-BASED SPINE OSTEOPOROSIS DETECTION AND CLASSIFICATION SYSTEM BASED ON SIMULATED STANDARDISED BONE MINERAL DENSITY SCORE

E. C. S. Chui[1], K. K. K. Mak[1], R. H. T. Ng[1], E. C. H. Fung[1], M. T. Y. Ong[1], R. M. Y. Wong[1], P. S. H. Yung[1]

[1]Dept. of Orthopaedics and Traumatology, Prince of Wales Hospital, Chinese Univ. of Hong Kong, Hong Kong, SAR China

Objective: The focus of this specific study was on the implementation of deep learning algorithms for the classification of osteoporosis status using X-ray images of the spine, hip, and wrist. By harnessing the power of deep learning techniques, specifically employing the DenseNet architecture, the researchers aimed to develop a robust and precise algorithm capable of identifying and classifying osteoporosis in X-ray scans from these anatomical regions.
Methods: The study utilized a dataset consisting of 200 spine X-rays, 200 hip X-rays, and 200 wrist X-rays. These X-ray images were collected and curated for the purpose of training and evaluating the algorithm. To develop the classification algorithm, DenseNet was selected due to its ability to effectively capture intricate patterns and features from images. The training process involved feeding the labeled X-ray images into the DenseNet model. The network learned to extract meaningful features from the X-ray images and map them to the corresponding osteoporosis classes.

Results: The study demonstrated a high performance of the developed algorithm in classifying osteoporosis based on X-ray images. The developed algorithm exhibited a strong performance, achieving an impressive accuracy rate of up to 0.86, with a precision of 0.83 and specificity of 0.82. This accuracy metric indicates the proportion of correctly classified X-ray images compared to the total number of images in the dataset.
Conclusion: The application of AI and deep learning techniques to osteoporosis classification based on X-ray scans carries substantial implications for patient care. By accurately identifying individuals with osteoporosis through AI-based classification, healthcare professionals can intervene at earlier stages of the disease, implement tailored treatment plans, and potentially mitigate the potential complications associated with osteoporosis.

P405
INNOVATIVE WORKFLOW FOR THE IDENTIFICATION OF CATHEPSIN K CLEAVAGE SITES IN TYPE I COLLAGEN

J. J. Demeuse[1], P. Massonnet[2], M. Schoumacher[1], E. Grifnée[2], L. Huyghebaert[2], T. Dubrowski[2], S. Peeters[2], C. Le Goff[2], E. Cavalier[1]

[1]Univ. of Liège, [2]Univ. Hospital of Liège, Liège, Belgium

Objective: In this work, we propose a degradomics mass spectrometry-based workflow that combines protein digestion, Nano-LC-UDMS^E, and several software tools to identify cathepsin K cleavage sites.
Methods: Type I collagen standards were subjected to digestion by cathepsin K at various protein/enzyme ratios for different incubation times. The digested proteins were subsequently injected into the nanoAQUITY UPLC-system Nano-LC (Waters). Chromatographic separation was accomplished using a nanoEaseTM M/Z HSS T3, 100 Å, 1.8 µm, 300 µm × 150 mm Column (Waters). The identification of peptides was conducted using PEAKS X, employing a combination of database searching and de novo sequencing.
Results: This workflow not only identified previously known cleavage sites, but also discovered new ones. Multiple cleavage hotspots were found and described in type I α1 and type I α2 collagen, many of which coincided with pyridinoline crosslinks, known to stabilize the triple helix. Our results allowed us to establish a chronology of digestion and conclude that cathepsin K preferentially cleaves the extremities of type I collagen before the helical part. We also found that cathepsin K preferentially cleaves amino acid residues with long and hydrophobic lateral chains at the beginning of digestion, whereas no preferred amino acid residues were identified later in the digestion.
Conclusion: Our workflow successfully identified new cleavage sites and can be easily applied to other proteins or proteases.

P406
CONFOUNDING FACTORS OF THE EXPRESSION OF MTBI BIOMARKERS, S100B, GFAP AND UCH-L1, IN AN AGING POPULATION

E. Calluy[1], C. Beaudart[2,3], M. S. Alokail[4], N. M. Al-Daghri[5], O. Bruyère[2,6], J.-Y. Reginster[2,7], E. Cavalier[1], A. Ladang[1]

[1]Clinical Chemistry Dept., CHU de Liège, Univ. of Liège, Liège, Belgium, [2]WHO Collaborating Center for Public Health Aspects of Musculoskeletal Health and Aging, Division of Public Health, Epidemiology and Health Economics, Univ. of Liège, Liège, Belgium, [3]Clinical Pharmacology and Toxicology Research Unit (URPC), NARILIS, Dept. of Biomedical Sciences, Faculty of Medicine, Univ. of Namur, Namur, Belgium, [4]Protein Research Chair, Biochemistry Dept, College of Science, KSU, Riyadh, Saudi Arabia, [5]Chair for Biomarkers of Chronic Diseases, Biochemistry Dept., College of Science, KSU, Riyadh, Saudi Arabia, [6]Dept. of Sport and Rehabilitation Sciences, Univ. of Liège, Liège, Belgium, [7]Protein Research Chair, Biochemistry Dept., College of Science, King Saud Univ., Riyadh, Saudi Arabia

Objective: Mild traumatic brain injury (mTBI) is one of the most common conditions seen in emergency departments. Recently, guidelines have proposed the combined use of the measurement of biomarkers, namely S100b and the "GFAP-UCH-L1" mTBI test to rule out mTBI. As older adults are the most at risk for mTBI, this study evaluates confounding factors that influence the concentration of S100 Calcium Binding protein B (S100B), Glial Fibrillary Acidic Protein (GFAP), and Ubiquitin carboxyl-Terminal Hydrolase L-1 (UCH-L1) in older individuals.
Methods: The protein S100B and the "GFAP and UCH-L1" mTBI test were measured using Liaison XL (Diasorin) and Alinity I (Abbott), in 330 and 341 individuals with non-suspected mTBI from the SarcoPhAge cohort, respectively.
Results: S100B, GFAP and UCH-L1 were all significantly correlated with renal function while alcohol consumption, geriatric depression score (GDS), smoking habits and anticoagulant intake were not associated with any of those 3 biomarkers. BMI and age were associated with GFAP and UCH-L1 expression while sex and mini-mental state examination (MMSE) were only associated with GFAP. Additionally, according to the manufacturers' cut-offs for mTBI rule-out, only 5.5% of the subjects were positive for S100B whereas 66.9% were positive for the "GFAP-UCH-L1" mTBI test. All "GFAP-UCH-L1" mTBI positive tests were GFAP + /UCH-L1−. Among individuals with cystatin C > 1.55 mg/L, 25% were positive for S100b whereas 90% were positive for the mTBI test.
Conclusion: Our data show that confounding factors have a different impact on the positivity rate of the "GFAP-UCH-L1" mTBI test compared to S100B.

P407
ANATOMICAL DISTRIBUTION OF WORK-RELATED MUSCULOSKELETAL DISORDERS AMONG NURSES IN A HELLENIC AIR FORCE HOSPITAL GREEK HOSPITAL

S. Naoum[1], E. Chronopoulos[2], M. Kotsapas[3], D. Kotzias[1], K. Alpantaki[4], V. Giovanoulis[5], M. Piagkou[6], C. Koutserimpas[1]

[1]Dept. of Orthopaedics and Traumatology, "251" Hellenic Air Force Hospital, Athens, Greece, [2]Laboratory for Research of the Musculoskeletal System, School of Medicine, National and Kapodistrian Univ. of Athens, Athens, Greece, [3]General Hospital of Naousa, Orthopedic Dept., Naousa, Greece, [4]Dept. of Orthopaedics and Traumatology, "Venizeleion" General Hospital, Heraklion, Greece, [5]Dept. of Pediatric Orthopaedic Surgery, Robert Debré Univ. Hospital, Assistance Publique des Hôpitaux de Paris (AP-HP), Paris, France, [6]Dept. of Anatomy, School of Medicine, National and Kapodistrian Univ. of Athens, Athens, Greece

Objective: Nurses, as health professionals, are at high risk of work-related musculoskeletal disorders (WRMDs). The purpose of this prospective study was to record the anatomical distribution of the WRMDs and to evaluate the association between reported WRMDs and perceived caring behaviors in the nursing personnel in the Hellenic Air Force Hospital of Athens, Greece.
Methods: A total of 350 questionnaires were completed from 1 December 2022 to 30 March 2023. The Nordic Musculoskeletal Questionnaire for the evaluation of WRMSDs and the Caring Behaviors Inventory-24 (CBI-24) for the assessment of caring behaviors were used.

Results: At least one WRMSD was recorded to 259 participants (74%). Regarding the anatomical distribution of WRMD, low back (64.3%), neck (63.2%) and shoulder (58.4%) were the most common anatomical regions. The mean score of the CBI-24 scale was 5.06, while the mean "Connectedness" parameter was 4.59. Elbow WRMDs were significantly correlated with the lowest score in the "Knowledge and skills" parameter, as well as with the lowest overall nursing score. Linear regression analysis revealed that the lowest nursing care score was associated with the left-handed nurses of low hierarchical position, suffering from elbow WRMDs. Participants who continued working on regular basis despite their WRMDs, showed lower mean score on the parameters of "Respectful" and "Connectedness".
Conclusion: Nurses showed high percentage of WRMDs that negatively affected their perceived dimensions of caring behaviors. The most commonly affected anatomical region was the lower back. These findings could be used to prevent and deal with WRMSDs, reduce occupational hazards and improve hospital patient care.

P408
ANATOMY OF THE ARTIFICIAL HIP JOINT: SIZING AND BIOMECHANICS OF A NEW THREADED ACETABULUM COMPONENT

N. Christodoulou[1], K. Raptis[2], M. Piagkou[3], D. Kotzias[2], S. Naoum[2], E. Chronopoulos[4], C. Koutserimpas[2]

[1]Dept. of Orthopedics, Athens Medical Group, [2]Dept. of Orthopaedics and Traumatology, "251" Hellenic Air Force Hospital, [3]Dept. of Anatomy, School of Medicine, National and Kapodistrian Univ. of Athens, [4]Laboratory for Research of the Musculoskeletal System, School of Medicine, National and Kapodistrian Univ. of Athens, Athens, Greece

Objective: The uncemented threaded DELTA ST C cup was introduced in last few years. It has a hemispheric shell, consisting of Ti6Al4V titanium alloy. The purpose of the study was to assess the sizing of the acetabulum component, as well as the bone stock quality in patients undergoing total hip arthroplasty (THA).
Methods: The present study is a retrospective observational cohort study of a prospectively maintained database, evaluating 620 patients undergoing THA with the DELTA ST-C cup. Age, affected hip, primary diagnosis, bone stock quality and size of the acetabulum prosthesis were evaluated.
Results: The enrolled population's mean age was 69.3 y and most patients were female (64%). The affected side was the right hip in 287 (43.6%), while 333 (56.7%) patients replaced their left hip. Primary diagnosis was osteoarthritis in 437 patients (70.5%), avascular necrosis in 85 (13.7%), congenital or acquired deformity in 46 (7.4%), Fracture of the femoral neck in 46 (7.4%) and post-traumatic arthritis in 6 (1%). Regarding the bone stock quality of the acetabulum, it was normal in 555 (89.5%) while in 65 (10.5%) was porotic. As for the acetabular cup size, 50 mm was the mostly used (196;31.6%), followed by 52 mm (104;16.8%), 48 mm (85;13.7%), 54 mm (78;12.6%), 56 mm (59;9.5%), 46 mm (33;5.3%) 58 mm (26;4.2%), 44 mm and 60 mm (20;3.2%), respectively.
Conclusion: DELTA ST-C cup has recently been used in Greece and this is the first study aiming to record the size of this prosthesis in a sample of the south-eastern European, Greek population. Most DELTA ST-C cups were used for osteoarthritis management and the most commonly size used was 50 mm.

P409
SIZING AND BIOMECHANICS OF A NEW MINIMAL FEMORAL STEM: A RETROSPECTIVE OBSERVATIONAL COHORT STUDY

N. Christodoulou[1], M. Piagkou[2], K. Raptis[3], S. Naoum[3], D. Kotzias[3], E. Chronopoulos[4], C. Koutserimpas[3]

[1]Dept. of Orthopedics, Athens Medical Group, [2]Dept. of Anatomy, School of Medicine, National and Kapodistrian Univ. of Athens, [3]Dept. of Orthopaedics and Traumatology, "251" Hellenic Air Force Hospital, [4]Laboratory for Research of the Musculoskeletal System, School of Medicine, National and Kapodistrian Univ. of Athens, Athens, Greece

Objective: The MINIMA S stem was developed according to the principles of proximal-loading and extended metaphyseal geometry applied to a short stem. The purpose of the study was to assess demographics, the stem size as well as bone stock quality in patients undergoing total hip arthroplasty (THA).
Methods: The present study is a retrospective observational cohort study of a prospectively maintained database, evaluating 570 patients undergoing THA with the MINIMA S stem. Age, affected hip, primary diagnosis, bone stock quality and size of the stem were evaluated.
Results: The enrolled population's mean age was 69.3 y and most patients were female (64%). The affected side was the right hip in 249 (43.6%), while 321 (56.7%) patients replaced their left hip. Primary diagnosis was osteoarthritis in 402 patients (70.5%), avascular necrosis in 78 (13.7%), congenital or acquired deformity in 42 (7.4%), fracture of the femoral neck in 42 (7.4%) and post-traumatic arthritis in 6 (1%). Regarding the bone stock quality of the acetabulum, it was normal in 510 (89.5%) while in 60 (10.5%) was porotic. As for the size of the stem, no.6 was the mostly used (102;17.9%), followed by no.5 (84;14.7%), no.2 and no.4 (66;11.6%), no.7 (60;10.5%), no.3 (54;9.5%), no.8 (48;8.4%) no.1 (42;7.4%), no.9 (24;4.2%) no.10 (18;3.2%) and no.11 (6;1%).
Conclusion: The MINIMA S stem has recently been used in Greece and this is the first study aiming to record the size of this prosthesis in a sample of the Greek population. Most MINIMA S stems were used for osteoarthritis management and the most commonly size used was no.6.

P410
ANATOMICAL DISTRIBUTION OF HIP FRACTURES IN A TERTIARY GREEK HOSPITAL: A RETROSPECTIVE ANALYSIS OF 4000 ELDERLY PATIENTS OVER 65 YEARS OLD

K. Alpantaki[1], C. Chaniotakis[1], S. Naoum[2], D. Kotzias[2], E. Chronopoulos[3], K. Dretakis[4], M. Piagkou[5], C. Koutserimpas[2]

[1]Dept. of Orthopaedics and Traumatology, "Venizeleion" General Hospital, Heraklion, [2]Dept. of Orthopaedics and Traumatology, "251" Hellenic Air Force Hospital, Athens, [3]Laboratory for Research of the Musculoskeletal System, School of Medicine, National and Kapodistrian Univ. of Athens, Athens, [4]2nd Dept. of Orthopaedics, "Hygeia" General Hospital of Athens, Athens, [5]Dept. of Anatomy, School of Medicine, National and Kapodistrian Univ. of Athens, Athens, Greece

Objective: Hip fractures are considered a principal cause of morbidity and mortality among patients over the age of 65 years. The aim of the study is to evaluate the characteristics of elderly patients with hip fractures and the anatomical distribution of intracapsular and extracapsular hip fractures among genders and age groups treated surgically.

Methods: In this nine-year retrospective cohort study, the type of hip fractures, age, and the overall incidence among 4000 patients aged over 65, surgically treated at the "Venizeleio" General Hospital of Heraklion, Crete, Greece, were evaluated.
Results: Hip fractures were more frequent in women (× 2.9) rather than men. Most of the patients suffering from a hip fracture were over 75 years of age (62.3% in females and 59.3% in males). Regarding the anatomical distribution, the proportion of extracapsular and intracapsular fractures were 59.6% and 40.4% in men and 62.7% and 37.2% in women, respectively. Extracapsular fractures were found to increase dramatically with age in women (from 52.3% in patients younger than 75 compared to 58.8% in those older than 75), while in men they slightly increased with age (57.7% in patients older than 75, compared to 55.7% in those less than 75).
Conclusion: The pattern of hip fractures was found to differ between genders and age groups in the present patients' population. Most likely, these findings reflect differences in the nature and rate of bone loss, and frequency of falling events between males and females. The present findings have shown that the anatomical pattern of hip fractures among Cretan elderly is not different from other Western societies.

P411
SUBTROCHANTERIC FATIGUE FRACTURE OF BOTH SIDES IN A MILITARY CADET

C. Koutserimpas[1], M. Piagkou[2], S. Naoum[1], M. Kotsapas[3], D. Kotzias[1], K. Raptis[1], E. Veizi[4], K. Alpantaki[5], K. Dretakis[6], E. Chronopoulos[7]

[1]Dept. of Orthopaedics and Traumatology, "251" Hellenic Air Force Hospital, Athens, Greece, [2]Dept. of Anatomy, School of Medicine, National and Kapodistrian Univ. of Athens, Athens, Greece, [3]General Hospital of Naousa, Orthopedic Dept., Naousa, Greece, [4]Dept. of Orthopedics and Traumatology, Ankara City Hospital., Ankara, Turkey, [5]Dept. of Orthopaedics and Traumatology, "Venizeleion" General Hospital, Heraklion, Greece, [6]2nd Dept. of Orthopaedics, "Hygeia" General Hospital of Athens, Athens, Greece, [7]Laboratory for Research of the Musculoskeletal System, School of Medicine, National and Kapodistrian Univ. of Athens, Athens, Greece

Objectives Fatigue fractures are caused by a great variety of activities. A relatively common anatomical region of fatigue fractures is femur, representing approximately 11% of all these injuries. Nevertheless, simultaneous fatigue fractures of both femurs are considered to be an extremely rare clinical entity. This study consists of a case report of a male cadet with subtrochanteric fatigue fractures of both femurs.
Methods: An 18-year-old male cadet presented to the emergency department due to bilateral thigh pain. Clinical evaluation revealed diffuse bilateral thigh pain and mild swelling; hip flexion was minor weaker bilaterally. X-rays showed bilateral radiolucent signs in the medial cortex of both femurs at the subtrochanteric area. The serum laboratory examination was within normal limits Moreover, findings of mild bone oedema and increased radiotracer uptake were present at MRI and bone scintigraphy, respectively, at the medial cortex of the subtrochanteric area of both femurs.
Results: The diagnosis of bilateral fatigue femoral fractures was established. The patient was managed conservatively, since both fractures were incomplete and non-displaced. It was recommended that the patient protect weight bearing for 6 weeks and start gradual increase in activities. He could return to his military training after 3 months.
Conclusion: The typical symptoms of fatigue femoral fractures usually include pain, tenderness, and oedema in the thigh or groin area. However, since there is no traumatic history, these injuries might be misdiagnosed. MRI examination is considered to be the most sensitive and effective imaging method for early detection of these fractures, depicting bone marrow and/or periosteal or soft tissue oedema, while the fracture could be revealed in T1 weighted images.

P412
CAN SPONDYLODISCITIS LEAD TO DEVICE RELATED ENDOCARDITIS?

C. Koutserimpas[1], S. Naoum[1], E. Veizi[2], V. Giovanoulis[3], D. Kotzias[1], K. Raptis[1], K. Dretakis[4], K. Alpantaki[5], M. Piagkou[6], E. Chronopoulos[7]

Objective: Cardiac device-related endocarditis (CDRIE) is not a rare infection, while its diagnosis and management may be difficult. This study presents a case report with a complication of CDRIE, with a history of a previously eight-week spondylodiscitis.
Methods: A 72-year-old female presented with symptoms of intense back pain and spine MRI revealed spondylodiscitis of the 11th and 12th thoracic vertebrae, while both blood and sample cultures were negative. The patient was treated with empirical antibiotic therapy with intravenous daptomycin and meropenem, for 40 days, with successful clinical outcome. Eight weeks after the spondylodiscitis onset, signs of pocket infection were noted, including skin erythema, pain, edema, and purulent drainage in the pocket area, without symptoms of systemic infection. Transesophageal echocardiography did not reveal signs of endocarditis.
Results: PET/CT was performed, revealing an increased uptake from the pacemaker generator and the electrodes, signs indicative of CDRIE. The pacemaker was removed and a temporary one was fitted. Polymerase chain reaction (PCR) examination of several parts of the device revealed Corynebacterium spp, treated with vancomycin based on sensitivity testing for 40 days with a successful outcome.
Conclusion: CDRIE and spondylodiscitis are closely associated infections. Clinicians should be aware and suspicious for CDRIE in patients with spondylodiscitis, ordering the most appropriate exams and test for diagnosis and early treatment. Due to the fact that laboratory tests and cultures occasionally may not be helpful, PET/CT could be a quite important tool for the diagnostic procedure.

P413
MODIFIED ANTEROLATERAL MINIMALLY INVASIVE SURGERY (ALMIS) FOR TOTAL HIP RECONSTRUCTION

C. Koutserimpas[1], M. Piagkou[2], S. Naoum[1], D. Kotzias[1], I. Karaiskos[3], K. Kourelis[3], K. Raptis[1], E. Chronopoulos[4]

[1]Dept. of Orthopaedics and Traumatology, "251" Hellenic Air Force Hospital, [2]Dept. of Anatomy, School of Medicine, National and Kapodistrian Univ. of Athens, [3]Dept. of Orthopedics and Traumatology, "251" Hellenic Air Force General Hospital, [4]Laboratory for Research of the Musculoskeletal System, School of Medicine, National and Kapodistrian Univ. of Athens, Athens, Greece

Objective: To report the clinical outcomes as well as the complications from the ALMIS approach for total hip arthroplasty (THA).
Methods: The present study is a single-center retrospective observational cohort of 520 patients undergoing the ALMIS technique. The patients were followed-up for a minimum of 5 y. The time-period of the study was from January 2014 until December 2018, including all patients undergoing THA with the modified ALMIS at the Dept. of Orthopaedics at the 251 Hellenic Air Force General Hospital of Athens, Greece. Patients' demographics, including gender and age, as well as length of in-hospital stay (LOS) and transfusion rate were recorded. Range of motion (ROM), Harris hip score (HHS), Trendelenburg sign and surgery related complications were also evaluated.
Results: A total of 520 patients with a mean follow-up period of 6.6 y were enrolled in the study. The mean LOS was 3.01 d (SD 1.2) and a total of 6 (1.2%) patients required postoperative transfusion with one blood unit each. At the final follow-up, mean adduction was 23° (compared to 14.8° preoperatively; $p < 0.0001$), mean abduction 26.9° (17.8° preoperatively; $p < 0.0001$), mean flexion 121.5° (74.2° preoperatively; $p < 0.0001$), mean external rotation 25.1° (11.1° preoperatively; $p < 0.0001$) and mean internal rotation 18.6° (8.1° preoperatively; $p < 0.0001$). The median HSS at the final follow-up was 93, compared to the 45 preoperatively (p-value < 0.0001). In early postoperative period 37 patients (7.1%) had Trendelenburg sign with a mean of 5.7° (SD 1.4), but following rehabilitation, it was ameliorated and finally was permanent only in 2 cases. The mean satisfaction rate (1–10) was 9.3.
Conclusion: ALMIS hip approach is a modified surgical technique providing good visibility during acetabulum and femur preparation, revealed excellent clinical outcomes during midterm follow-up, by significantly improving hip range of motion and the HHS. Careful utilization of this technique, after adequate training should yield favorable outcomes, while minimal major complications should be expected.

P414
FACTORS AFFECTING PERSISTENCE OF DENOSUMAB TREATMENT IN PATIENTS WITH OSTEOPOROSIS: A RETROSPECTIVE COHORT STUDY

E. Costa[1], S. Paredes[1], D. Taverner[1], A. Pàmies[2], C. Tomas[3], D. Llop[4], C. Llop[5]

[1]Rheumatology Hospital Universitari Sant Joan de Reus, Reus, [2]Rheumatology Hospital Verge de la Cinta, Tortosa, [3]Rheumatology Hospital Comarcal de Amposta, Amposta, [4]Universitat Rovira i Virgili, Reus, [5]Pharmacy, Servei Català de la Salut, Tarragona, Spain

Objectives: Perseverance in pharmacological treatment for osteoporosis is a key factor in fracture prevention. Denosumab has demonstrated superior persistence compared to other anti-osteoporotic drugs in previous studies. Patient related factors may influence treatment persistence. We aimed to describe the characteristics of a cohort of patients undergoing denosumab treatment. To assess clinical and/or demographic characteristics that are significantly associated with treatment persistence.
Methods: Patients diagnosed with osteoporosis aged over 50, visited in Rheumatology outpatient clinics of three hospitals in Tarragona, who were prescribed denosumab between January 2013 and December 2023 and had received at least two doses of denosumab. Clinical and demographic data were collected from the patients' medical records. Logistical regression analysis was conducted to examine the relationship between different factors and treatment persistence. The variables studied included age, gender, polypharmacy, Charlson index, cognitive status, fracture risk, use of psychoactive drugs, previous osteoporotic fractures and previous osteoporosis treatments.
Results: A total of 854 patients were recruited. Patients lost to treatment due to death (130 patients) and withdrawal due to improvement according to medical criteria (108) were excluded. 616 patients were analyzed. The characteristics of these patients are shown in Table 1. A total of 468 patients continued with treatment (76%) while 148 discontinued it (24%). The mean follow-up time was 59 months (minimum 12–maximum 144). Variables significantly associated with lower treatment discontinuation were previous osteoporosis treatment (OR = 0.67; CI 0.48–0.93); polypharmacy with 5–10 drugs (OR 0.66; CI 0.45–0.95); polypharmacy with more than 10 drugs (OR 0.6; CI 0.37–0.97). The variable significantly associated with higher discontinuation was dementia (OR 1.96; CI 1.34–2.89).

Table 1. Characteristics of the analyzed population

	N = 616
Age (median, IQR)	81 (74 – 87)
Sex (n women, %)	560, 90.90%
Cognitive state (n, %)	
- Good	470, 76.30%
- Mild dementia	115, 18.66%
- Moderate dementia	30, 4.87%
Densitometry at diagnosis (yes, %)	416, 67.53%
Column densitometry values T-score (median, IQR)	-3.10 (-3.70 - -2.37)
Hip densitometry values T-score (median, IQR)	-2.50 (-2.90 - -1.90)
Vitamin D values before starting treatment ng/dl (median, IQR)	33.80 (28 – 44)
Osteoporosis risk (n, %)	
- High	263, 42.69%
- Very high	353, 57.31%
Charlson index (median, IQR	4 (3 – 6)
Psychoactive drugs (yes, %)	311, 50.49%
Corticoids (n, %)	
- Up to 5 mg prednisone	63, 10.22%
- More than 5 mg prednisone	27, 4.38%
- No	524, 85.06%
Polypharmacy (n, %)	
- Up to 5 different drugs	205, 33.28%
- Between 5 and 10	293, 47.56%
- More than 10	116, 18.83%
Previous osteoporotic fracture (n, %)	
- Other fractures	23, 3.73%
- Hip	122, 19.81%
- Vertebral	204, 33.11%
- No	186, 30.19%
Previous osteoporosis treatment (n, %)	
- IV Bisphosphonates	25, 4.06%
- Oral bisphosphonates	213, 34.58%
- Teriparatide	102, 16.56%
- No	274, 44.48%

Conclusion: The studied cohort comprises an aging population with high comorbidity, a significant presence of dementia, and polypharmacy. Denosumab treatment persistence is significantly influenced by patient's cognitive status, use of more than 5 drugs, and having received previous osteoporosis treatments. These factors should be considered when initiating long-term treatments, reevaluating the type of treatment, and reinforcing follow-up for these patients.

P415
VITAMIN D LEVEL IN PATIENTS WITH EARLY RHEUMATOID ARTHRITIS

E. Deseatnicova[1], L. Groppa[1], M. Curchi[1], E. Rusu[1]

[1]State Medical and Pharmaceutical Univ. Nicolae Testemitanu, Chisinau, Moldova

Objective: To determine vitamin D level as a function of disease activity in patients with early rheumatoid arthritis.
Methods: We investigated 50 patients with early rheumatoid arthritis and 50 healthy persons in control group matched by age and sex for serum 25(OH)vitamin D level (chemiluminescence immunoassay, serum). Deficiency was defined as < 20 ng/ml, severe deficiency as < 10 ng/ml. Simultaneously clinical and laboratory data were obtained to asses disease activity by DAS28-CRP index. Mean age of the patients was 53.12 ± 5.62 y.o., mean duration of rheumatoid arthritis symptoms was 9.8 ± 1.6 weeks. All the patients were rheumatoid factor and/or anti-CCP positive. The data were analyzed statistically.
Results: This observational case control study showed significantly lower mean 25(OH)vitamin D level in patients with early rheumatoid arthritis compared to healthy individuals, 14.2 ± 4.53 ng/ml vs. healthy controls 28.3 ± 6.58, $p < 0.001$. Severe deficiency was determined in 12.8% of cases of rheumatoid arthritis. Mean DAS28-CRP was 4.8 ± 0.36. High disease activity index correlated negatively with 25 (OH) vitamin D level, $r = -0.62$, $p < 0.001$. Severity of vitamin D deficiency correlated positively with the anti-CCP level, $r = 0.38$, $p < 0.05$.
Conclusion: Patients with early rheumatoid arthritis in our study had 25(OH)vit D deficiency in about 60% of cases. It correlated negatively with disease activity and positively with serum anti-CCP level. Early screening for vitamin D deficiency and its correction is highly recommended.

P416
ROLE OF VITAMIN D SUPPLEMENTATION IN THE MANAGEMENT OF PATIENTS WITH OSTEOARTHRITIS OF THE KNEE

M. Curchi[1], E. Deseatnicova[1], L. Groppa[1], A. Pascari-Negrescu[1]

[1]State Medical and Pharmaceutical Univ. Nicolae Testemitanu, Chisinau, Moldova

Objective: Vitamin D deficiency is a common problem worldwide. Optimal active vitamin D level is required for the metabolism and function of the osteoarticular and neuromuscular system. Normal vitamin D level was shown to reduce the risk of many chronic diseases. Low serum 25OH vitamin D levels are frequently found in osteoarthritis patients. We aimed to study the effect of vitamin D supplementation on clinical manifestations in knee OA.
Methods: Observational, case–control study of 70 patients with knee osteoarthritis radiological stage II according to Kellgren–Lawrence and vitamin D deficiency, divided into 2 equal groups. The patients of both groups received meloxicam 15 mg/d 1 month, local ointment diclofenac 50 mg/g 3 FTU (fingertip unit) per day, chondroitin sulfate 1500 mg + glucosamine sulfate 1500 mg/d 3 months. Group I patients were supplemented with cholecalciferol having vitamin D target level—50 ng/dl in 3 months, the dosage was calculated using web based calculator from Grassrootshealthnet project, group II no supplementation. In 3 months, patients of both groups were subjects of active supplementation.
Results: BMI—29.13 (95% CI 31.08–24.83) vs. 27.74 (95% CI 29.38–24.51) kg/m^2, $p > 0.05$. Patients of both sexes had no significant differences between vitamin D values (17.01 ± 5.15 ng/dl) and (17.74 ± 4.03 ng/dl) ($p = 0.862$). Patients with severe vitamin D deficiency < 10 ng/dl were 11.3%. The level of 25(OH) vitamin D at the end of the study- group I 36.72 ± 10.39 (95% CI 57.23–31.07) vs. group II 17.1 ± 6.2 (95% CI 12.67–26.14) ng/dl, $p < 0.05$. Pain by VAS group I was statistically significantly lower 3.2 ± 2.7 (95% CI 6.91–3.04) vs. 6.1 ± 1.3 (95% CI 8.32–4.29) ($p < 0.05$).
Conclusion: Supplementation and correction of serum vitamin D levels till middle optimal may be recommended for combination therapy and pain management in patients with knee OA.

P417
BONE MINERAL DENSITY IN PATIENTS WITH JUVENILE IDIOPATHIC ARTHRITIS

E. Dunayeva[1], A. Pachkaila[1], V. Vadzianava[1]

[1]Institute of Advanced Training and Retraining of Healthcare Personnel of Belarusian State Medical Univ., Minsk, Belarus

Objective: Juvenile idiopathic arthritis (JIA) is the most common rheumatic disease in children. JIA may be accompanied by a decrease in BMD and even the development of osteoporosis, especially in children with high disease activity or taking systemic glucocorticoids (GS).
Methods: 76 children (28 boys and 48 girls) with JIA aged 3–17 y participated in study. The median age of patients was 12.8 y (9.8; 14.6). The BMD study was carried out using DXA according to pediatric research programs (total body less head (TBLH) and lumbar spine (L1–L4)). BMD (g/cm^2) and BMD Z-score were analyzed. Z-score BMD values ≤ -2 SD were regarded as low BMD; osteoporosis was diagnosed in patients with a clinically significant history of fractures in combination with a Z-score BMD ≤ -2.0 SD or in children with vertebral compression fractures at the absence of a local pathological process or high-energy injury, regardless of BMD indicators (Official position in Pediatrics of the International Society of Clinical Densitometry, 2019).
Results: In the group of examined patients, the average TBLH BMD was 0.715 (0.618; 0.805) g/cm^2, TBLH Z-score 0.45 ($-$ 0.7; 1.475) SD, the average L1–L4 BMD was 0.626 (0.521; 0.785) g/cm^2, the average Z-score L1–L4 was $-$ 0.6 ($-$ 1.5; 0.2) SD. Normal BMD was detected in 84.2% (64/76) of the examined patients; low BMD was diagnosed in 11.9% (9/76) of children; osteoporosis was diagnosed in 3.9% (3/76) of patients (all these patients took systemic GS and had vertebral fractures).
Conclusion: Low BMD and osteoporosis were diagnosed in 15.8% of examined children with JIA. It is advisable to include BMD monitoring and spine imaging in the routine examination plan for children with JIA to detect low BMD early and to increase the effectiveness of measures to prevent osteoporosis in these patients.

P418
MODELLING FUTURE BONE MINERAL DENSITY: SIMPLICITY OR COMPLEXITY?

E. E.[1], J. Carey[2], T. Wang[3], M. Ebrahimiarjestan[4], L. Yang[5], M. Dempsey[6], M. Yu[4], W. Chan[7], B. Whelan[2], C. Silke[2], M. O'Sullivan[8], B. Rooney[9], A. Mcpartland[10], G. O'Malley[2], A. Brennan[11]

Engineering, Univ. of Galway, Galway, Ireland, [7]Dept. of Radiology, Wan Fang Hospital, Taipei Medical Univ., Taipei, Taiwan, [8]Univ. of Galway, Galway, Ireland, [9]Dept. of Geriatric Medicine, Sligo Univ. Hospital, Sligo, Ireland, [10]Dept. of Rheumatology, Our Lady's Hospital, Manorhamilton, Co. Leitrim, Manorhamilton, Ireland, [11]School of Computer Science, College of Science and Engineering, Univ. of Galway, Galway, Ireland

Objective: Osteoporotic fractures are a major global public health issue, driving up patient suffering and the expense of healthcare globally. BMD measurement is important to identify those with osteoporosis and assess their risk of fracture. This risk is related to both the absolute BMD and the change in this value over time. Predicting future BMD in individual patients is challenging which impacts clinical decisions such as when to intervene or repeat BMD measurement. Effective tools to support clinical practice are lacking.
Methods: We compared simple and complex deep learning models generated from longitudinal data collected on subjects with 2 or more hip DXA scans on the same machine between 2000–2018. A simple Z-score based method (ZBM) was used to predict an individual's BMD at their next scan based on the mean BMD and the standard deviation of the reference group, while a random forest (RF) model used time between scans and baseline DXA scan information. A more complex deep learning (DL)-based model was developed to cope with multidimensional longitudinal data, variables extracted from patients' baseline DXA scan, as well as features drawn from the ZBM model.
Results: 2948 white adults aged 40–90 y met our study inclusion: 2652 (90%) females and 296 (10%) males. Our hybrid DL model performed significantly better than the ZBM and RF in women. In contrast, the ZBM outperformed other models in men.
Conclusion: DL-based and statistical models have potential to forecast future BMD using longitudinal clinical data. These methods have potential to augment clinical decisions for when to repeat BMD testing in the assessment of osteoporosis.

P419
VALIDATION OF A NOVEL SCREENING TOOL FOR OSTEOPOROSIS: THE DXA MAP PROJECT

E. E.[1], J. Carey[2], L. Yang[3], T. Wang[4], C. Silke[2], M. O'Sullivan[5], A. Brennan[6], M. Dempsey[7], M. Ebrahimiarjestan[8], M. Yu[8], B. Whelan[2]

[1]School of Management, Guangxi Minzu Univ., Nanning, China, [2]School of Medicine, College of Medicine, Nursing and Health Sciences, Univ. of Galway, Galway, Ireland, [3]Insight SFI Research Centre for Data Analytics, Data Science Institute, Univ. of Galway, Galway, Ireland, [4]Nuffield Dept. of Medicine, Univ. of Oxford, Oxford, UK, [5]Univ. of Galway, Galway, Ireland, [6]School of Computer Science, College of Science and Engineering, Univ. of Galway, Galway, Ireland, [7]School of Engineering, College of Science and Engineering, Univ. of Galway, Galway, Ireland, [8]Dept. of Industrial Engineering, Tsinghua Univ., Beijing, China

Objective: Ireland has one of the highest illness burdens related to osteoporosis in Europe, but there is no national strategy to address this disease. Clinical guidelines recommending DXA scans for older adults with fractures or major risk factors are widely endorsed, but guidelines for screening healthy adults, particularly men, are not. The Osteoporosis Self-assessment Test-index (OSTi) is one of the simplest and most widely validated tools worldwide to identify men and women with osteoporosis. Several studies show this algorithm may outperform more complex tools including FRAX® for this purpose, but yet it is rarely used in clinical practice. Better screening tests are needed. The DXA MAP (Management Application Process) Project is a Health Research Board funded initiative to develop novel ways to improve DXA resource use. In this study we evaluated the performance of the DXA MAP tool and compared it to the OSTi tool among 'healthy' Irish adults referred for a DXA scan in the West of Ireland.
Methods: Cross-sectional study of patients referred for a DXA scan in West of Ireland. Collection and analyses of data for this study was approved by Institutions Ethics Committees. Combinations of age, gender, height and weight were examined using logistic regression and deep learning methods to derive a best fit model to identify those with a DXA diagnosis of 'osteoporosis' (T-score ≤ -2.5) at the femoral neck. Total hip BMD was later assessed in sensitivity analyses. We used accuracy, AUC, F1 and Mathews correlation coefficient to assess algorithm performance.
Results: 6729 (18.5%) of 36,321 white adults aged $\geq$ 20 y had a hip DXA available who had no prior fracture or other clinical risk factors for osteoporosis other than age. Included subjects were randomly divided into a derivation cohort (70%) and a validation cohort (30%). Mean age of both groups was 61.5 y (SD: 13), the majority of whom (> 87%) were female. Mean femoral neck T-score was -1.0 and mean OSTi was -1.9. In univariate analyses age and weight were the most important discriminators of osteoporotic BMD. Multivariate analyses showed the combination of all 4 variables was marginally better than OSTi in the derivation cohort (femoral neck AUC: 0.879 vs. 0.852) and validation cohort (0.860 vs. 0.841). Results of deep learning produced similar results (AUC: 0.855). Total hip BMD results were also similar for univariate, multivariate and machine learning analyses using the derivation and validation cohorts: OSTi: 0.861 vs. DXA-MAP: 0.869; OSTi: 0.854 vs. DXA-MAP: 0.866.
Conclusion: The DXA MAP Project represents a novel approach to identify Irish adults most likely to benefit from a screening DXA test for osteoporosis. These results can support a national programme to optimise DXA resources, and requires further validation among other populations.

P420
ACCURACY OF CENTRAL DXA DIAGNOSIS OF OSTEOPOROSIS: THE DXA HIP PROJECT

E. E.[1], J. Carey[2], L. Yang[3], T. Wang[4], C. Silke[2], M. O'Sullivan[5], A. Brennan[6], M. Dempsey[7], M. Ebrahimiarjestan[8], M. Yu[8], B. Whelan[2]

[1]School of Management, Guangxi Minzu Univ., Nanning, China, [2]School of Medicine, College of Medicine, Nursing and Health Sciences, Univ. of Galway, Galway, Ireland, [3]Insight SFI Research Centre for Data Analytics, Data Science Institute, Univ. of Galway, Galway, Ireland, [4]Nuffield Dept. of Medicine, Univ. of Oxford, Oxford, UK, [5]Univ. of Galway, Galway, Ireland, [6]School of Computer Science, College of Science and Engineering, Univ. of Galway, Galway, Ireland, [7]School of Engineering, College of Science and Engineering, Univ. of Galway, Galway, Ireland, [8]Dept. of Industrial Engineering, Tsinghua Univ., Beijing, China

Objective: 30 years ago the WHO published criteria for the diagnosis of postmenopausal osteoporosis. Multiple studies show the majority of fractures however occur among whose T-score is > -2.5, a phenomenon referred to as an epidemiologic paradox. Current collaborative publications of an International working group representing 9 international bone societies show opinion remains divided as to what constitutes an 'osteoporotic' fracture. We used the DXA HIP Cohort in Ireland to evaluate the sensitivity, specificity and accuracy of DXA for diagnosing osteoporosis using a major osteoporotic fracture as the gold standard.
Methods: We merged, cleaned and anonymised data from 4 DXA centres in the West of Ireland with hospital admission diagnoses and administrative as previously described. We examined the performance of central DXA testing to correctly diagnose osteoporosis using major osteoporotic fracture (MOF) as the disease. Multiple

subgroup analyses were also performed by gender, age, fracture site, and site of BMD measurement to capture the range of performance. We calculated sensitivity, specificity and accuracy using confusion matrices, and AUC.

Results: Data were available for 30,158 adults $\geq$ 40 y including 30% with a prior fracture and 19% with a MOF. Overall 25% had a white female T-score ≤ -2.5 including 22% without MOF and 38% with MOF. There was a considerable range in the sensitivity, specificity, and accuracy of DXA for diagnosing osteoporosis, summarised in the Table below depending on the site of fracture and BMD measurement, age, and gender of the population.

Table. Sensitivity, specificity and accuracy of lowest site BMD to Diagnose Osteoporosis.

Characteristic	Sensitivity	Specificity	Accuracy
Mean% (Range) for Men	35.2 (23.1 – 60.0)	81.7 (57.9 – 87.1)	73.1 (58.6 – 76.2)
Mean% (Range) for Women	38.2 (14.3 – 78.0)	77.5 (38.0 – 94.4)	69.8 (52.8 – 85.2)
Mean% (Range) Overall	37.8 (15.6 – 76.1)	78.0 (43.6 – 93.5)	70.2 (55 – 84.1)

*AUC values ranged from 0.517-0.771

Conclusion: Although central DXA measurement is recommended to make a diagnosis of osteoporosis in older men and postmenopausal women, the considerable variation in sensitivity, specificity and accuracy of such testing must also be taken into account.

Acknowledgement: This project was funded by the Health Research Board of Ireland: S.D.A.P.-2020-0001.

P421
COMPARATIVE CHARACTERISTICS OF LYSED LYMPHOCYTES XANTHINE OXIDOREDUCTASE PROFILES IN DISCOID AND SYSTEMIC LUPUS ERYTHEMATOSUS

E. E. Mozgovaya[1], S. A. Bedina[1], A. S. Trofimenko[1], S. S. Spitsina[1], M. A. Mamus[1], I. A. Zborovskaya[1]

[1]Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky, Volgograd, Russia

Objective: Discoid lupus erythematosus (DLE) and systemic lupus erythematosus (SLE) are chronic inflammatory diseases of the connective tissue. Typical discoid elements may occur in 25% of patients with SLE. In some cases, DLE can be an independent nosology. Wherein, unlike SLE, signs of internal organs damage are not detected and antinuclear antibodies are not determined in most cases. Oxidative stress are involved in pathogenesis of DLE and SLE. Development of oxidative stress is closely associated with the activation of xanthine oxidoreductase (XOR) enzyme system. We aimed to reveal the features of XOR activities profiles in lysed lymphocytes of DLE and SLE patients.

Methods: 31 patients with DLE, 56 patients with SLE, 35 apparently healthy individuals were enrolled in study. The activities of two forms of XOR (xanthine dehydrogenase (XDG; EC 1.17.1.4) and xanthine oxidase (XO; EC 1.17.3.2)) were measured in lysed lymphocytes.

Results: Compared to the control, activities of both XOR forms were decreased in lysed lymphocytes of DLE and SLE patients. Wherein XO and XDG activities were higher in DLE in contrast to subgroups of patients with low, moderate and high SLE activities. A pronounced decrease of XO activity was accompanied by a slight decrease of XDG activity in DLE, which may indicate the predominance of hypoxanthine and xanthine utilization by dehydrogenation. This direction has a positive meaning because it is accompanied by a reduction in the intracellular production of reactive oxygen species. In contrast to DLE, SLE was characterized by an increase in the ratio of XO/XDG activities with an increase in the degree of immune inflammation activity. Together with other factors, reactive oxygen species formed as a result of the catalytic activity of XO can have a damaging effect on cellular structures, participating in the development of associated with SLE activity lymphopenia.

Conclusion: Changes in XOR activities in lysed lymphocytes in DLE and SLE were unidirectional, but were more pronounced in the systemic form of the disease. Thus, DLE and SLE are characterized by some common changes in XOR activities. At the same time, lysed lymphocytes XOR profiles have distinctive features, which are characteristic for nosology.

P422
A DIFFERENTIATED APPROACH TO THE THERAPY OF CHRONIC PAIN IN OSTEOARTHRITIS CONSIDERING THE PHENOMENON OF CENTRAL SENSITIZATION

E. Filatova[1], E. Polishchuk[1], E. Taskina[1], L. Alekseeva[1], N. Kashevarova[1], A. Karateev[1], A. Lila[1]

[1]VA Nasonova Research Institute of Rheumatology, Moscow, Russia

Objective: Central sensitization (CS) and emotional-affective accretions play an important role in the formation of chronic pain syndrome in osteoarthritis (OA). We aimed to determine the therapeutic potential of different variants, analgesic therapy in patients with OA with signs of CS.

Methods: 90 patients with osteoarthritis of the knee and/or hip joints with chronic pain syndrome were included in the study. The somatosensory nervous system state, pain syndrome severity according to VAS, WOMAC index, pain neuropathic component severity according to DN4 questionnaire, CSI scale, anxiety and depression level according to HADS scale were evaluated before the study, as well as on study day 14 and 28. After screening, all patients were divided into three groups: Group 1 patients with chronic pain and signs of CS, without signs of organic lesions of the nervous system, depression and anxiety; Group 2 patients with chronic pain and signs of CS and signs of depression and anxiety without signs of organic lesions of the nervous system; Group 3 patients with OA with chronic pain and signs of somatosensory lesions. Each group of patients received differentiated therapy: Group 1—etoricoxib 60 mg/d + gabapentin 900 mg/d (300 mg 3 times a day); Group 2—etoricoxib 60 mg/d + duloxetine 60 mg/day; Group 3—etoricoxib 60 mg/d + gabapentin 900 mg/d + Motaren gel 2 times a day for local pain area.

Results: The clinical characteristics of the patients included in the study are presented in Table 1. Significant differences between the groups at the time of inclusion in the study were in the following indicators: duration of the disease, DN4 and CSI scores, anxiety/depression level. These differences were explained by the criteria for grouping patients. Against the background of three therapy schemes, considering pathogenetic aspects of the pain syndrome, positive dynamics was observed in all studied parameters in all groups.

Table 1. Clinical characteristics of patients.

	Group 1 (n=30)	Group 2 (n=30)	Group 3 (n=30)
Age (y)	50,0 [43,0;55,0]	51,0 [46,0;60,0]	69,5 [65,0;79,0]
Duration of OA (y)	3,5 [1,0;6,0]	6,0 [5,0;7,0]	12,0 [5,0;26,0]

Conclusion: This study demonstrates the need to develop an algorithm for a differentiated approach to the therapy of chronic pain in OA, considering the phenomenon of CS.

P423
EVALUATION OF THE EFFECT OF TOFACITINIB AND ADALIMUMAB ON CLINICAL MANIFESTATIONS AND ACTIVATION OF THE CENTRAL NERVOUS SYSTEM ACCORDING TO THE FUNCTIONAL MAGNETIC RESONANCE IMAGING IN PATIENTS WITH RHEUMATOID ARTHRITIS

E. Filatova[1], A. Karateev[1], A. Potapova[1], S. Morozova[2], E. Polishchuk[1], E. Luchikhina[3], V. Amirdzhanova[1], E. Zotkin[1], A. Lila[1]

[1]VA Nasonova Research Institute of Rheumatology, [2]Scientific Center of Neurology, [3]Regional Scientific Research Clinical Institute n.a. M.F. Vladimirsky, Moscow, Russia

Objective: Central sensitization (CS) is a phenomenon associated with nociplastic changes, characterized by a significant decrease in the pain threshold and hyperalgesia. CS often develops on the background of autoimmune inflammation and plays an important role in the development of chronic pain in systemic rheumatic diseases such as rheumatoid arthritis (RA). We aimed to evaluate the dynamics of chronic pain and neuroplastic changes in the central nervous system in patients with RA during therapy with the JAK inhibitor tofacitinib and the TNFα inhibitor adalimumab, depending on the presence or absence of signs of CS.

Methods: the study group consisted of 40 patients with RA, 87.5% women, age 46.6 ± 11.4 y, with moderate/high disease activity (DAS28-CRP ≥ 3.2) while taking methotrexate and severe chronic pain (≥ 50 mm on visual analogue scale, VAS), of which 20 patients had signs of CS (CSI ≥ 40, CS+), 20—had no signs of CS (CSI < 40, CS−). 20 patients (10 with CS+ and 10 with CS−) were prescribed tofacitinib (TOFA) per os 5 mg BID and 20 patients were prescribed adalimumab 40 mg subcutaneously once every 2 weeks. All patients underwent functional MRI of the brain (b-f-MRI) on the background of a nociceptive stimulus (hand squeezing a rubber ball) before and after 4 weeks of therapy.

Result: TOFA and ADA therapy provided a statistically significant reduction in RA activity (DAS28-CRP, CDAI, SDAI), as well as pain, fatigue (FACIT), depression (HADS) in the TOFA group and anxiety (HADS) in the ADA group, as well as count PainDETECT and CSI. There was a trend towards a higher analgesic effect of TOFA (according to BPI scales). There were no significant differences in the dynamics of RA activity and symptoms in patients with CS + and CS−. According to f-MRI data, during treatment with TOFA in patients with RA CS-, no significant differences in the activation of CNS structures were identified; in patients with RA CS + , significant changes in the activation of the brain cortex were revealed. During ADA therapy, significant differences were observed in the activation of the cerebral cortex in both patients with RA CS− and patients with RA CS + .

Conclusion: TOFA and ADA have a similar effect on the activity of RA and the severity of the main symptoms of this disease, regardless of the presence of CS. There are differences in the activation of the brain cortex when using TOFA in RA patients with and without CS.

P424
RESULTS OF SCREENING FOR HIGH RISK OF FRACTURES USING THE FRAX CALCULATOR

E. Gladkova[1], O. Lesnyak[1]

[1]Northwestern Mechnikov State Medical Univ., St. Petersburg, Russia

Objective: Screening for high fracture risk using the FRAX calculator has been shown to be effective in preventing fractures in older women (Merlijn et al., 2020). However, the effectiveness of screening in men and women of younger age has not been studied. The purpose of this study was to evaluate the effectiveness of screening for high fracture risk in men and women aged 40 years and older in primary health care facility.

Methods: The study was performed in the city polyclinic in St. Petersburg in 2017–2021. A high fracture risk was assessed in those who have sought medical care during this time and was determined if a subject suffered an osteoporotic fracture or if his/her 10-year probability of a major osteoporotic fracture according to FRAX calculation exceeded the therapeutic intervention threshold developed for Russia. Those with high fracture risk were recommended osteoporosis treatment. The fracture incidence was compared in high and low fracture risk groups in 2016 (before screening) and in 2022 taking into account mortality rate.

Results: 11,013 subjects were screened which amounted to 31.7% of the total population served. The high fracture risk was determined in 8.1% of men and 20.9% women. Of these, 99.6% of men and 84.8% of women were classified as high-risk based on fragility fractures alone. The fracture incidence in this group reduced from 570.1 per 10,000 in 2016 to 277.3 per 10,000 in 2022 ($p = 0.00001$). At the same time in low fracture risk group the fracture incidence increased from 126.4 per 10,000 in 2016 to 178.9 per 10,000 in 2022 ($p = 0.0048$). The difference was statistically significant when comparing the two groups ($p = 0.0068$). Men and women showed the same tendency for decreasing the frequency of fractures in the high risk group and increasing in the low risk group. In women at high risk of fractures, the incidence of fractures decreased from 576.9 in 2016 to 296.6 per 10,000 in 2022 ($p = 0.0001$), in men—from 524.2 to 138.9 ($p = 0.023$) for the same period of time.

Conclusion: The screening for high fracture risk in men and women of 40 years and older is effective in reducing fracture incidence.

P425
INCIDENCE OF IMMINENT SUBSEQUENT FRACTURE IN POSTMENOPAUSAL WOMEN AS CAPTURED IN PRIMARY CARE COMPARED TO HOSPITAL RECORDS IN UK AND SPAIN

X. Chen[1], T. Rashod-Mistry[1], G. Fabiano[1], A. Delmestri[1], A. Moayyeri[2], J. Warden[2], C. Reyes[3], R. Pinedo-Villanueva[1], E. H. Tan[1]

[1]Nuffield Dept. of Orthopaedics, Rheumatology, and Musculoskeletal Sciences, Univ. of Oxford, Oxford, UK, [2]UCB Pharma, Slough, UK, [3]Fundació Institut Universitari per a la recerca a l'Atenció Primària de Salut Jordi Gol i Gurina (IDIAPJGol), Barcelona, Spain

Objective: To compare the incidence of imminent subsequent fracture among postmenopausal women with fragility fractures as recorded in primary care vs. hospital setting.

Methods: We included women aged ≥ 50 y with fragility fracture of any site using SNOMED codes recorded in primary care databases from 1 April 2010 to 31 March 2018: Clinical Practice Research Datalink (CPRD Aurum, UK) and Sistema d'Informació per al Desenvolupament de la Investigació en Atenció Primària (SIDIAP, Spain), linked with hospital databases: Hospital Episode Statistics (HES) and Conjunt asic asic de dades (CMBD), respectively. We estimated the overall incidence rate (IR) of subsequent fracture in the two years after index fracture, as well as site-specific cumulative incidence, accounting for competing risk of death.
Results: A total of 48,108 and 143,992 women had index fractures recorded in CPRD and SIDIAP respectively, whereas 31,362 and 45,981 women had index fractures recorded in HES and CMBD, respectively. The overall IR (per 1,000 person years) of subsequent fracture was 1.6 times higher in primary care as compared to hospital setting in the UK (114 [95% CI 112–116] vs. 70 [67–72]), and 4.5 times higher in Spain (142 [95% CI 141–143] vs. 31 [30–32]). The number of fragility fractures recorded in both settings were more similar for hip fractures, but higher for vertebral and non-hip non-vertebral (NHNV) in primary care. As the hospital records in both countries did not include emergency room visits, most of non-hip fractures which do not need to be hospitalised are captured in primary care. The proportion of index fractures recorded in the hospital being hip fractures was higher in Spain than in the UK. The differences between the cumulative incidence of subsequent hip fractures according to fracture sites across database settings is presented in Table 1.

Table 1. Two-year cumulative incidence of imminent subsequent fracture in women aged 50 and above with an index fracture in primary care and hospital databases

		Cumulative incidence (95%CI)			
		Primary Care		Hospital	
Index fracture site	Subsequent fracture site	CPRD (UK)	SIDIAP (Spain)	HES (UK)	CMBD (Spain)
Hip	Hip	12% (11%, 13%)	24% (24%, 25%)	4.4% (4.0%, 4.8%)	3.1% (2.8%, 3.3%)
		Cumulative incidence (95%CI)			
		Primary Care		Hospital	
Index fracture site	Subsequent fracture site	CPRD (UK)	SIDIAP (Spain)	HES (UK)	CMBD (Spain)
	NHNV	7.5% (6.9%, 8.1%)	4.2% (4.0%, 4.5%)	5.5% (5.0%, 5.9%)	1.8% (1.6%, 2.0%)
	Vertebra	0.74% (0.56%, 0.97%)	0.60% (0.51%, 0.70%)	0.49% (0.37%, 0.65%)	0.31% (0.24%, 0.39%)
Vertebra	Hip	2.5% (2.0%, 3.1%)	1.4% (1.2%, 1.7%)	4.4% (3.4%, 5.6%)	2.3% (1.9%, 2.9%)
	NHNV	6.8% (6.0%, 7.7%)	5.1% (4.7%, 5.6%)	7.6% (6.3%, 9.1%)	2.0% (1.6%, 2.6%)
	Vertebra	18% (17%, 19%)	11% (10%, 11%)	2.8% (2.0%, 3.7%)	1.5% (1.2%, 2.0%)
NHNV	Hip	1.6% (1.5%, 1.7%)	1.4% (1.4%, 1.5%)	3.9% (3.7%, 4.2%)	2.2% (2.0%, 2.4%)
	NHNV	15% (15%, 16%)	19% (19%, 20%)	7.0% (6.6%, 7.4%)	2.9% (2.7%, 3.2%)
	Vertebra	0.75% (0.66%, 0.84%)	0.73% (0.68%, 0.79%)	0.71% (0.59%, 0.84%)	0.44% (0.36%, 0.53%)

Conclusion: Differences are likely due to a mix of the nature of fracture recording in each country/setting and possible re-recording of vertebral and NHNV fractures in primary care. Understanding these differences will help future research in generating reliable real-world evidence for osteoporosis using these databases.
Acknowledgments: This project was funded by UCB Pharma and Amgen Inc.

P426
EARLY-ONSET OSTEOPOROSIS IN A PATIENT DUE TO NOVEL MUTATION OF THE WNT1 GENE

E. Karaseva[1], A. Eremkina[1], R. Salimkhanov[1], A. Myakota[1], E. Sevostyanenko[1], N. Mokrysheva[1]

[1]Endocrinology Research Centre, Moscow, Russia

The WNT signaling pathway is recognized as an essential regulator of the bone remodeling process. Homozygous mutations in *WNT1* gene can lead to a rare inherited disorder known as osteogenesis imperfecta type XV and heterozygous mutations have been found in adults with early-onset osteoporosis (EOOP). We report a patient with EOOP and spinal fractures during her second pregnancy.
Casereport: A 32 year-old woman noted the severe back pain since the third trimester of her twin pregnancy, restricting movement. Post-delivery CT-scan revealed wedge-shaped collapse of multiple thoracic vertebrae: $Th_{4\text{-}5,7\text{–}9,11}$, but she continued breastfeeding. No risk factors, previously fractures or family history of osteoporosis were reported. Her first pregnancy was uneventful. DXA confirmed reduction BMD in the lumbar spine (Z-score − 3.5) and femoral neck (Z-score − 2.4). Blood tests excluded secondary causes of bone fragility, but showed elevated bone turnover markers (Ctx– 1.88 ng/mL (< 0.573), osteocalcin—52 ng/mL (< 43), ALP—112 U/l (42–98)). Vitamin D metabolites analysis showed only 25(OH)D deficiency—17 ng/ml. Genetic test identified a novel heterozygous missense mutation (chr12:48979468G > A, c.105G > A) in the *WNT1* gene, classified as a variant of uncertain significance. The patient received daily treatment with cholecalciferol 7000 IU for the initial 2 months, followed by 2000 IU, alfacalcidol 1 mcg, and Ca carbonate 1500 mg. Lactation was medically discontinued. In the 6-month follow-up, there was no evidence of new fractures. BMD increased at the lumbar spine (+ 25.7%) and femoral neck (+ 13.2%). Bone turnover markers normalized, and calcium-phosphate metabolism markers were within the normal range.
Conclusion: This case highlights a novel *WNT1* gene mutation causing EOOP. It emphasizes the importance of complex clinical, biochemical, radiologic and even genetic evaluation to identify the true cause of osteoporosis in young patients with multiple low-trauma fractures.

P427
ROLE OF ULTRASOUND EXAMINATION OF THE THIGH MUSCLE AND BIOIMPEDANCE ANALYSIS IN THE DIAGNOSIS OF SECONDARY SARCOPENIA IN PATIENTS WITH RHEUMATOID ARTHRITIS

E. Keledzhyyeva[1], E. Kulieva[1], V. Kaliberdenko[1], S. Khamidova[2]

[1]V.I. Vernadsky Crimean Federal Univ., Simferopol, Russia, [2]Tashkent State Pedagogic Univ. named after Nizami, Tashkent, Uzbekistan

Objective: Sarcopenia is an older-onset, progressive and generalized skeletal muscle disorder associated with an increased likelihood of adverse outcomes, including falls, fractures, and mortality. Sarcopenia at the present time is recognized as one of the five major risk factors for morbidity and mortality in people over 65 years old.
Methods: Diagnostic methods recommended by EWGSOP2 were used: SARC-F questionnaire, creatinine dilution test, ultrasound diagnostics (ultrasound) of the quadriceps femoral muscle (to determine the thickness and cross-sectional area of this muscle), determination of skeletal muscles mass using of DXA, determined the cross-sectional area of the psoas muscle using computed tomography, bioimpedance measurement, dynamometry, physical performance tests.

Results: The study involved 84 patients with rheumatoid arthritis; the control group consisted of 18 healthy people. The patients were divided into 4 groups. For each group, basic diagnostic methods were carried out, such as the SARC-F questionnaire, physical activity tests, dynamometry and one additional method: group A (22 patients)—basic diagnostic methods and DXA, group B (22 patients)—basic methods and bioimpedance measurement, group C (20 patients)—basic methods and CT-Scan of the cross-sectional area of the psoas muscle, group D (20 patients)—basic methods and ultrasound examination of the quadriceps femoral muscle (thickness and cross-sectional area).
Conclusion: Secondary sarcopenia was diagnosed in 81% of the examined patients. The most accessible and sensitive diagnostic methods at the DXA level can be considered bioimpedance measurement and ultrasound examination. CT-Scan also showed the feasibility of recommending the introduction of screening for sarcopenia, but due to its higher cost, it can be classified as an auxiliary diagnostic method.

P428
EVALUATION OF SONOGRAPHY EFFICIENCY IN THE DIAGNOSIS OF SUBACROMIAL PAIN SYNDROME

E. Keledzhyyeva[1], Y. Popenko[1], Y. Usachenko[1], N. Shadchneva[1], A. Useinova[1], E. Kulieva[1], V. Kaliberdenko[1], V. Yas[2]

[1]V.I. Vernadsky Crimean Federal Univ., Simferopol, Russia, [2]Ege Univ., Izmir, Turkey

Objective: Subacromial pain syndrome (SAPS) is defined as all nontraumatic, usually unilateral, shoulder problems that cause pain, localized around the acromion, often worsening during or subsequent to lifting of the arm. The purpose of the study is to determine the possibilities of using sonography in the diagnosis of compression of the suprascapular nerve in the development of the subacromial pain syndrome.
Methods: From 2020–2023, 47 patients aged 26–45 y were examined. Clinical examination of these patients revealed the presence of wasting of the muscles of the scapular region, in particular the supraspinatus and infraspinatus muscles in 12 people, wasting of the infraspinatus muscle in 39 people. All patients underwent ultrasound examination with a linear sensor with a frequency of 5–12 MHz. The results of the ultrasound examination were verified using MRI.
Results: In all patients, ultrasound examination revealed unilateral muscle wasting of the supraspinatus and infraspinatus regions in the form of a decrease in the thickness of the muscle component with a simultaneous moderate increase in the echogenicity of muscle tissue; the differences in the thickness of the muscle layer on the healthy and injured side were significant ($P < 0.05$). In 36 patients, a volumetric anechoic formation with a smooth, clear contour, round shape, size from 11–32 mm, localized in the projection of the location of the proximal (22 patients) and distal (6 patients) sections of the suprascapular nerve was detected.
Conclusion: An assessment of the condition of the suprascapular nerve, due to its small size and the complexity of visualization, may not be based on data on changes in its size, but on the presence of indirect qualitative and quantitative signs, such as a displacement of the position of the suprascapular nerve relative to the healthy side, the presence of space-occupying formations in the projection of the supraspinatus and infraspinatus fossa, the presence of a conglomerate of heterogeneous tissue in the thickness of the infraspinatus muscle above the projection site of the suprascapular nerve and hypotrophy of the supraspinatus and infraspinatus muscles. Thus, the reliability of the complex of ultrasound signs was 72%, specificity 96%.

P429
CHANGES OF BONE MINERAL DENSITY IN PATIENTS WITH PRIMARY COXARTHROSIS DEPENDING ON BMI

F. Ilchenko[1], S. Hryvenko[1], E. Kulieva[1], V. Kaliberdenko[1], E. Keledzhyyeva[1], N. Shadchneva[1], A. Useinova[1], L. Ametova[1]

[1]V.I. Vernadsky Crimean Federal Univ., Simferopol, Russia

Objective: Due to the facts, the overweight and obesity are among the main risk factors for osteoarthritis of different localization. In addition, the BMI is an important determinant that effects of BMD of the skeleton.
Methods: The analysis of BMD and calculation of BMI were performed in 248 patients with primary coxarthrosis, aged 45–87 y (of which 161 women—64.9%, 87 men—35.1%). Patients were calculated BMI according to the standard formula and DXA of the lumbar spine and proximal femur with a T-criterion assessment. Thus, the patients were divided into 3 groups: normal weight (18.5–24.9), overweight (25–29.9) and obesity (30–50.7).
Results: Among the patients of the studied groups, the frequency of reduced BMD was 84.6%—210 people (osteoporosis 44.2%—93 people, osteopenia 55.8%—117 people). There are no significant rank differences in BMD and BMI in all three groups ($p = 0.36$). The assessment of BMD in the lumbar spine is characterized by the absence of significant differences between all three groups ($p = 0.42$). There were also no significant differences in the values of BMD of the proximal femur depending on BMI ($p = 0.96$).
Conclusion: There is no direct correlation between BMD and BMI in patients with primary coxarthrosis.

P430
EVALUATION OF THE EFFECTIVENESS OF THE USE OF PLATELET-RICH PLASMA IN THE TREATMENT OF ELBOW JOINT ENTHESOPATHIES

S. Hryvenko[1], F. Ilchenko[1], E. Kulieva[1], E. Keledzhyyeva[1], N. Shadchneva[1], V. Kaliberdenko[1], E. Mureyko[2], E. Kondratiuk[1]

[1]V.I. Vernadsky Crimean Federal Univ., Simferopol, [2]N.N. Petrov National Medicine Research Center of Oncology, St. Petersburg, Russia

Objective: Epicondylitis of the shoulder is a common condition that affects up to 3% of the adult population. Being the most common cause of pain in the elbow joint, the disease mostly occurs in people of working age from 35–54 y.
Methods: From 2017–2023 we observed 100 patients of both sexes aged from 31–65 y, with clinical symptoms of internal and external epicondylitis without impairment of hand grip strength. The diagnosis of epicondylitis was made based on history and clinical examination. All subjects tested had at least one positive test (Mill's test, Cozen's test, Maudsley test, Golfer, Elbow test). Results were recorded using the Patent-Rated Tennis Elbow Evaluation (PRTEE) psychometric scale at 1, 6 and 12 months after the 2nd injection. The comparison group consisted of 50 patients who received betamethasone injections 2 times with an interval of 14 days. The main group included 50 patients who received 2 PRP injections with an interval of 14 d.
Results: During treatment, as well as follow-up, we did not notice any negative side effects after the administration of platelet-rich plasma (PRP) and betamethasone. With the administration of betamethasone, a decrease in pain and improvement in limb function was noted on days 1–2 after the first administration, whereas with the introduction of PRP, on days 3–6. The most pronounced clinical effect 12 months after treatment was found in patients who received PRP injections. Moreover, the result was maintained throughout the entire observation period in 43 (86.0%) patients. We found that the effect after using

PRP increased by 6 months with a slight tendency to decrease the effect by 12 months. It should be noted that 7 (14.0%) respondents in this group noted the absence of an effect at all periods of observation. Patients who received Betamethasone showed the lowest level of pain after 1 month, with a gradual trend towards a decrease in clinical effect after 6 months and an increase in clinical symptoms of the disease by 12 months after treatment. 5 (10.0%) patients noted a lack of effect after twofold use of betamethasone at all periods of observation. However, the results obtained in this group, 12 months after treatment, were still better than the initial data. It should be noted that early treatment results (1–2 months) were better with the administration of betamethasone, with a subsequent decrease in effectiveness. With the introduction of PRP, long-term (6–12 months) treatment results were better.

Conclusion: Our studies have shown high, up to 86.0%, effectiveness of our method for treating internal and external epicondylitis of the shoulder using PRP in comparison with glucocorticosteroids. The data obtained only confirm the need for further study of the effect of this promising cellular technology on tissues.

P431
THE ROLE OF C-TYPE NATRIURETIC PEPTIDE ON BONE METABOLISM

E. Kondo[1]

[1]Kondo Orthopaedic Clinic, Ikoma City, Japan

Objective: Recent studies have revealed that C-type natriuretic peptide (CNP) is a potent stimulator of endochondral bone growth. Nevertheless, the effect of CNP on bone turnover has not yet been well studied.

Methods: I investigated the bone phenotype of a mouse model with elevated plasma CNP concentrations (*CNP-Tg* mice). Furthermore, I performed an open and stabilized femoral fracture using 8-week-old *CNP-Tg* mice and compared the healing process with age-matched wildtype mice.

Results: μCT analysis revealed less bone in femurs, but not in lumber vertebrae, of young adult *CNP-Tg* mice than that of wildtype mice. Bone histomorphometry of the tibiae from 8-week-old *CNP-Tg* mice showed enhanced osteoblastic and osteoclastic activities, in accordance with elevated serum levels of osteocalcin and TRAP5b, respectively. In the healing process of mouse femoral fracture, CNP and its receptors, natriuretic peptide receptor-B (NPR-B) and natriuretic peptide clearance receptor are immunohistochemically expressed in hard calluses of wildtype mice, suggesting possible role of CNP/NPR-B signaling in fracture repair, especially in bone remodeling stage. On μCT analysis, rapid decrease in callus volume was observed in *CNP-Tg* mice followed by generation of significantly higher new bone volume with a tendency of increased bone strength. In addition, μCT analysis also showed that bone remodeling was accelerated in *CNP-Tg* mice, which was also evident from increased serum osteocalcin and TRAP5b levels in *CNP-Tg* mice at remodeling stage of fracture repair.

Conclusion: CNP activates bone turnover and remodeling in vivo and possibly accelerates fracture healing in mouse model.

P432
ACETABULAR BONE STOCK MSCT-ASSISTED QUANTIFICATION DURING DDH: APPLICATIONS TO THR

E. Kovbasa[1], A. Oliynik[2], D. Sinegubov[2], A. Altanets[3], K. Furmanova[4], A. Naumenko[4]

[1]Kharkiv Institute of Medicine and Biomedical Sciences, [2]Dnipro State Medical Univ., [3]KNE "Dnipro Clinical Municipal Hospital No. 4", [4]N1 Clinic, Dnipro, Ukraine

Objective: There was conducted preoperative assessment of acetabular medial wall bone stock in projection of the planned surgical implant bony bed accordingly to the developed MSCT-measuring technique to prevent THR complications.

Methods: There were revealed complex comparative MSCT-morphometric investigation of 32 normal hips and 65 hips with DDH as medial wall bone thickness assessment in projection of lig. teres bed and planned acetabular component's bony bed centre accordingly to the proposed MSCT-measuring technique; their correlation with femoral head's cranial migration, acetabular horizontal sphericity angle and centre-edge angle. Mann–Whitney test, Spearman's rank correlation coefficient were applied. Data presented as Me (95% CI), p value < 0.05.

Results: Acetabular medial wall thickness in the projection of lig. teres/acetabular component's bony bed centre was defined as: 4.3 mm (3.3; 4.8)/7.2 mm (6.2; 7.8) for normal hips, 9.95 mm (7.5; 11.6)/11.85 mm (9.8; 13.5) for Crowe I hips, 15 mm (1.7; 17.3)/15.7 mm (13.5; 17.3) for Crowe II hips and 15.45 mm (13.7; 19.8)/16.05 mm (12.8; 20.2) for Crowe III hips, respectively. Correlation of medial wall thickness in projection of acetabular component's bony bed centre with femoral head's cranial migration, horizontal sphericity acetabular angle and centre-edge angle was defined as: $r = 0.36$ ($p = 0.006$); $r = 0.36$ ($p = 0.007$); $r = -0.47$ ($p = 0.0007$), respectively. Weak correlation of acetabular medial wall bone stock in projection of acetabular component's bony bed centre with femoral head's cranial migration indicates the invalidity of the Crowe's DDH staging for THR's needs and the necessity of independent measuring of the index during individual preoperative planning.

Conclusion: Since conventional biplanar X-ray imaging is invalid for precise measuring of the aforementioned indices due to superimpositioning, the proposed MSCT-morphometric technique could be of help for individual safe implantation technique selection during THR preplanning for DDH.

P433
PREOPERATIVE MSCT QUALITATIVE ASSESSMENT OF ACETABULAR SPONGIOUS BONE FOR DDH

E. Kovbasa[1], A. Altanets[2], O. Loskutov[3], A. Alieksieiev[4], O. Goregliad[5]

[1]Kharkiv Institute of Medicine and Biomedical Sciences, Dnipro, [2]KNE "Dnipro Clinical Municipal Hospital №4", Dnipro, [3]MedinUA Clinic & Lab, Dnipro, [4]Univ. Clinic of National Medical Univ., Kiev, [5]KNE "Dnipro Clinical Municipal Hospital №16", Dnipro, Ukraine

Objective: There was conducted complex comparative MSCT-morphometric assessment of acetabular spongious bone X-ray density during DDH accordingly to the developed technique.

Methods: 32 normal hips and 65 hips with DDH were assessed via determining spongious bone tissue X-ray density (HU) accordingly to the developed method after preliminary DXA of the lumbar spine with the following excluding of patients with the signs of osteoporosis at the pre-analytical stage. The scanning procedure was performed using a calibration phantom Mindways VR QCT PRO (Mindways Software Inc., Austin, TX, USA). Mann–Whitney test, Spearman's rank correlation coefficient were applied. Data presented as Me (95% CI), p value < 0.05.
Results: There were defined physiological norm values of acetabular spongious bone X-ray density due as: 272 HU (238–306 HU) for supraacetabular area, 194 HU (172–216 HU) for anterior and 244 HU (220–268 HU) for posterior acetabular walls. All dysplastic hips showed increasing of X-ray density of supraacetabular area up to 334–428 HU depending the sectoral deficiency type. X-ray density loss is observed both for anterior/posterior acetabular walls in all sectoral deficiency subtypes. There were determined progressive increase of the X-ray density in supraacetabular area ($r = 0.89$, $p < 0.00001$) and steady decrease of anterior ($r = -0.85$, $p < 0.00001$) and posterior ($r = -0.75$, $p < 0.00001$) walls' ones are in correlation with the femoral head cranial displacement. The most severe loss of acetabular spongious bone X-ray density in all the zones was observed during the total sectoral deficiency subtype.
Conclusion: Proposed method of acetabular bone quality evaluation and conducted regularities should be taken into account for preoperative planning of acetabular component safe implantation during DDH.

P434
BONE MINERAL DENSITY IN CHILDREN WITH JUVENILE IDIOPATHIC ARTHRITIS

E. Kulieva[1], V. Kaliberdenko[1], V. Yas[2]

[1]V.I. Vernadsky Crimean Federal Univ., Simferopol, Russia, [2]Ege Univ., Izmir, Turkey

Objective: Juvenile idiopathic arthritis (JIA) is a chronic systemic connective tissue disease with an autoimmune mechanism of development that occurs in children under the age of 16. The JIA is characterized by involvement of vital organs in the process, formation of erosive-destructive polyarthritis, early disability of children and finally most significant manifestation of local and then generalized osteoporosis (OP). According to the WHO (2018) OP is a systemic skeletal disease characterized by a decrease of bone strength, which determines the high risk of fractures. OP in children with juvenile arthritis is initially local and then generalized, that the need to study the processes of bone remodeling with the identification of markers of its early diagnosis and correction.
Methods: The analysis of research scientific and literary materials of foreign authors working on the study about BMD in children with JIA.
Results: The decreasing of BMD in children with JIA is one of the significant problems of pediatrics, due to the high prevalence of this pathology, as well as the need for early detection of changes in BMD to prevent fractures. The cause of mineral changes in bone tissue is associated with the pathogenesis of JIA that activates in T- and B-cell immune reactions leading to hyperproduction of proinflammatory cytokines and destruction of bones, joints and other body tissues. The cytokines of JIA pathogenesis are divided into several groups, among which proinflammatory (IL-1, IL-6, IL-8, IL-17, TNFα, IFN-γ, chemokines) and anti-inflammatory cytokines (IL-4, IL-10, IL-13, growth factor). Hyperproduction of proinflammatory cytokines leads to damage to the synovial membrane of joints with subsequent destruction of cartilage and bones and, as a result, contributes to the development of generalized osteoporosis and erosive changes in joints.
Conclusion: The decreasing of BMD in children with JIA is close with the molecules of the immune system are involved in pathogenesis, like proinflammatory cytokines.

P435
EFFICACY OF DENOSUMAB IN CHINESE POSTMENOPAUSAL WOMEN: A RETROSPECTIVE COHORT STUDY

E. Lau[1], D. Lam[2]

[1]Hong Kong Center for Clinical Research, [2]Hong Kong Orthopaedic and Osteoporosis Center, Hong Kong, SAR China

Objective: To study the followings in Chinese postmenopausal women with osteoporosis, who were treated by denosumab for 3 year or more: BMD at the total hip and spine, total number of fractures, and adverse events from the treatment.
Methods: From 2011–2023, the records of osteoporosis postmenopausal women who received 6 monthly subcutaneous injection of denosumab was reviewed. Only women who received treatment for three years or more were included in this study. The following variables were used in the analysis: age, T-Score at baseline, annual BMD changes at the total hip and total spine, adverse events, number of fractures and site of fracture. Results were analyzed by SPSS.
Results: A total of 342 women were studied. The mean follow-up period was 6.1 y (SD = 2.9 years). All women had a T-Score of -2.0 or more at the total hip or spine at baseline. All were considered to have clinical indications for denosumab injection. The average annual increase in hip BMD was 1.5% (SD = 1.6%) and at the spine was 2.4% (SD = 2.9%). The following adverse events (AE) were considered as possibly related to denosumab. These included dizziness, slight dyspnea, tiredness and itchiness of skin. All AE were ranked as mild and none of these led to cessation of treatment. A total of 38 fractures occurred. The sites of fracture were: ribs (n = 8), forearm (n = 7), hip (n = 5), spine (n = 5), foot and ankle (n = 6), others (n = 7).
Conclusion: Denosumab was associated with a BMD increase that was in accordance with published clinical trials. It was considered a safe drugs in terms of adverse events.

P436
SERUM HEMOGLOBIN LEVEL, TYPE 2 DIABETES MELLITUS AND OSTEOPOROTIC RISK FRACTURE IN OLDER WOMEN

E. Lopez Gavilanez[1], M. Navarro Grijalva[1], N. Bautista Litardo[1], M. Hernandez Bonilla[1], M. Navarro Chavez[1], A. Segura Mestanza[1], R. Cedeño German[1]

[1]AECE Research Group, Association of Clinical Endocrinologists of Ecuador, Guayaquil, Ecuador

Objective: There is evidence of a continuous increase in fracture risk with decreasing hemoglobin levels, showing an almost linear association. This association has not been investigated in the Ecuadorian population. We aimed to evaluate whether there is an association between serum hemoglobin levels and the risk of osteoporotic fractures in Ecuadorian women with type 2 diabetes mellitus (T2DM) and without diabetes mellitus (DM).
Methods: We selected 386 women aged 60 years and older. We measured serum hemoglobin, ferritin, creatinine, vitamin B12 and vitamin D levels. We calculated the risk of major osteoporotic fracture (MOF) and hip fracture (HF) with the Ecuador-specific FRAX

model (version 4.1) and adjusted for rheumatoid arthritis (RA) in women with T2DM. We performed simple linear regression analysis (SLR) and multiple linear regression analysis (MLR) in both groups.
Results: In the whole sample n = 386 (with T2DM n = 190; without DM n = 196), mean age 70.7 ± 7.6 y. The baseline characteristics of each group are presented in Table 1. In the group with T2DM, the SLR model explains 2% and 4% of the variability in the risk of major osteoporotic fracture (p = 0.048; coeff b = – 0.321; SE = 0.161) and hip fracture (p = 0.005; coeff b = – 0.325; SE = 0.115), respectively. In the MLR model we found a significant association (p = 0.045; coeff b = – 0.136; SE = 0.068) between hemoglobin level and risk of hip fracture. In the group without DM, the SLR model explains 2% and 3% of the variability in the risk of major osteoporotic fracture (p = 0.047; coeff b = – 0.372; SE = 0.186) and hip fracture (p = 0.020; coeff b = – 0.3226; SE = 0.096), respectively. In the MLR model, we found no association between hemoglobin level and risk of major osteoporotic fracture or hip fracture.

Table 1. Baseline characteristics and results of the comparison of study groups.

Variables *	Without DM (n=196)	With T2DM (n=190)	*p* value	CI 95%
Age (yr)	70.8 ± 7.8	70.7 ± 7.4	0.897	-1.422; 1.622
Height (m)	1.5 ± 0.1	1.5 ± 0.1	1.000	-0.020; 0.020
Weight (Kg)	54.8 ± 12.8	61.4 ± 12.9	0.000	-9.172; -4.028
BMI (Kg/m^2)	25.8 ± 5.2	28.2 ± 5.5	0.000	-3.471; -1.329
Hemoglobin (mg/dL)	13.8 ± 1.4	13.2 ± 1.5	0.000	0.310; 0.890
Serum Creatinin (mg/dL)	0.7 ± 0.1	0.89 ± 0.88	0.003	-0.314; -0.066
Ferritin (ng/dL)	187.3 ± 190	211.7 ± 236.2	0.263	-67.235; 18.435
Vitamin B12 (pg/mL)	532.8 ± 265	601.5 ± 269.2	0.012	-122.162; -15.228
Vitamin D (ng/mL)	25.5 ± 28.9	25.5 ± 13.6	1.000	-4.543; 4.543
FRAX Score MOF	4.94 ± 3.55	4.09 ± 3.46 **	0.018	0.148; 1.552
FRAX Score HF	1.76 ± 1.83	1.98 ± 2.5 **	0.323	-0.657; 0.217

*mean ± SD; ** Adjusted Reumatoid Arthritis; MOF, Major osteoporotic fracture; HF, Hip fracture

Conclusion: In older Ecuadorian women with or without T2DM there is a moderate significant correlation between serum hemoglobin level and the risk of major osteoporotic fracture and hip fracture.

P437
CLINICAL OUTCOMES OF FRAIL ELDERLY PATIENTS AFTER DEPRESCRIPTION OF DENOSUMAB

E. M. Tam[1], C. C. M. Lau[1]

[1]Dept. of Medicine and Geriatrics, Tuen Mun Hospital, Tuen Mun, Hong Kong, SAR China

Objective: Current evidence does not support abrupt termination of denosumab for high-risk osteoporotic patients due to the rapid BMD decline after cessation. However, for frail elderly patients with poor functional status or limited life expectancy, denosumab may not provide additional clinical benefits. This study aims to look for any clinical fracture and fall admission in frail elderly within their surviving period for up to 3 y after deprescription of denosumab.
Methods: This is a retrospective case series. All elderly patients on denosumab for osteoporosis under the care of Tuen Mun Hospital Geriatric team, who subsequently had denosumab deprescribed between 2015–2020 due to doubtful clinical benefits because of advanced frailty or terminal illnesses were recruited. Exclusion criteria included patients who had denosumab discontinued due to treatment escalation to anabolic agents, or patient's refusal to treatment. Any occurrence of fracture and fall admission within 3 y of surviving period after deprescription were reviewed.
Results: A total of 30 patients were recruited with a median age of 85.5. 83.3% were female. 90% had previous history of fragility fracture. The median Clinical Frailty Scale was 7 (I.Q.R. 7–8) upon termination of denosumab. 24 (80%) had denosumab terminated due to frailty, 2 (6.7%) due to end stage renal failure, 1 (3.3%) due to malignancy. Only 5 (16.7%) had received bridging therapy with bisphosphonate for a median duration of 12 months. Among all 30 patients, none (n = 0) had had any clinical fracture or fall admission within their surviving period for up to 3 y after termination of denosumab. At 3 y, 21 (70%) had died with a median survival of 10 months, with pneumonia being the commonest cause (66.7%).
Conclusion: Clinical fractures and falls are unlikely to occur after termination of denosumab in elderly with advanced frailty or life-limiting diseases within their surviving period for up to 3 y, justifying deprescription due to limited benefits.

P438
THE RISK FACTORS OF OSTEOPOROTIC FRACTURES OVER 10 YEARS OF FOLLOW-UP IN WOMEN AGED OVER 50 YEARS IN THE SIBERIAN POPULATION

E. Mazurenko[1], O. Rymar[1], L. Shcherbakova[1], S. Malyutina[1]

[1]Research Institute of Internal and Preventive Medicine-Branch of the Institute of Cytology and Genetics, Siberian Branch of Russian Academy of Sciences, Novosibirsk, Russia

Objective: To study the frequency of osteoporotic fractures (OF) over 10 y of follow-up and risk factors for OF up in women aged over 50 y (Novosibirsk).
Methods: In 2003–2005, a screening examination of persons aged 45–69 (n = 9360) was carried out within the framework of the international project HAPIEE (Novosibirsk). The information was collected on OF during the last 12 months and risk factors for OF, registration of sociodemographic data, anthropometry, and a study of biochemical blood parameters. In 2017–2018 on the second examination (n = 828), data on the frequency of OF that occurred over 10 y of observation were retrospectively collected. The analysis included 340 postmenopausal women who were 50–69 years old at the 1st screening (2003–2005) of the project. Statistical analysis was carried out by SPSS package (v.13.0).
Results: Among studied 340 women (mean age 59.3 ± 5.1), OF occurred in 13.2% subjects during the 10-y follow-up. Women with a history of OF during 10 y of follow-up had lower weight (p = 0.021), BMI (p = 0.018), waist circumference (p = 0.037), hip circumference (p = 0.050) compared with women without OF. Women with OF were more likely to be overweight (BMI 25–30 kg/m^2) (p = 0.029), while women without OF were more likely to have BMIs characteristic of obesity (p = 0.004), as well as women with OF smoked more often (p = 0.032) and had falls in the last 12 months (p = 0.023) than women without OF. According to the results of a multivariate analysis in women, the risk of OF associated with a smoking (OR = 4.003 (95% Cl = 1.29–12.46), Ca consumption < 1000 mg/d (OR = 2.320 (95% Cl = 1.01–5.34), falls (OR = 2.834 (95% Cl = 1.07–7.53) while BMI is negatively associated with OF (OR = 0.914 (95% Cl = 0.85–0.99) independent of other factors.
Conclusion: In the studied sample of postmenopausal women aged over 50 y, a high frequency of new cases of OF over 10 y of follow-up was revealed, which amounted to 13.2%. The risk of OF increased 4 times with smoking, 2 times with Ca consumption < 1000 mg/d and a falls, and decreased with an increase in BMI.
Acknowledgement: The study was supported by State target №AAAA-A17-117,112,850,280–2.

P439
MINERAL DENSITY BONE TISSUE DISORDER IN CASE OF INFLAMMATORY BOWEL DISEASES: LITERATURE REVIEW

E. Myasoutova[1]

[1]Republican Clinical Hospital, Kazan, Russia

Inflammatory bowel diseases (IBD), which include Crohn's disease (CD) and ulcerative colitis (UC), are chronic, recurrent diseases of unclear etiology characterized by immune inflammation of the mucous membrane of the gastrointestinal tract (GI tract) with the development of local and systemic complications.

The purpose of this review is to study the frequency of development, risk factors and mechanisms of formation of a decrease in BMD in patients with IBD, the role and place of biochemical markers of bone remodeling and densitometry in determining the risk of developing such disorders.

In general, all effects on bone metabolism are realized through the main regulatory systems of osteoblastogenesis (canonical WNT signaling pathway) and osteoclastogenesis (RANKL/RANK/OPG).

The RANK/RANKL/OPG ligand receptor system is a key link in bone tissue homeostasis, directly regulating osteoclast differentiation and osteolysis. RANKL is produced by osteoblasts and activated T lymphocytes. This protein binds to a specific RANK receptor located on osteoclasts and dendritic cells. RANKL acts as the main stimulating factor in the formation of mature osteoclasts, therefore, an increase in its expression leads to bone resorption and, consequently, bone loss.

The main biochemical markers of bone remodeling, which are most justifiably determined in clinical practice, are osteocalcin and P1NP (markers of bone formation), β-Cross Laps (marker of bone resorption). The "gold standard" for the diagnosis of osteoporosis, based on the measurement of BMD, is considered to be densitometry of the lumbar spine and femoral neck DXA.

According to the scientific literature, the incidence of osteopenia and osteoporosis in patients with IBD varies from 22–77% and from 17–41%, respectively.

BMD disorders occur in more than half of patients with IBD. Some authors believe that IBD itself should also be considered as an independent risk factor for osteoporosis and osteoporotic fractures. However, today there are different points of view about the causes and specific risk factors for osteoporosis in CD/UC. Thus, according to a number of studies, the course of IBD has a particularly significant effect on the state of bone tissue, including their debut in adolescence, exacerbations of these diseases, eating disorders, decreased muscle and fat mass, taking systemic glucocorticoids and genetically engineered biological drugs.

P440
GENETIC DETERMINANTS OF TRANSFORMATION OF HYPERURICEMIA INTO GOUT

E. Panina[1], M. Eliseev[1], O. Zhelyabina[1]

[1]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia

Objective: To identify the association of genetic polymorphisms with the risk of the appearance of monosodium urate crystals (MSU), which have pro-inflammatory potential.
Methods: A single-center case–control study included patients aged ≥ 18 y with hyperuricemia (uric acid (UA) level > 360 μmol/L). The examination included collecting an anamnesis (including the use of urate-lowering drugs), examination, anthropometric data (height, weight, BMI), determination of the level of uricemia, ultrasound (GE Voluson E10 device, Austria) of the foot joints to identify deposits of MSU crystals. The presence of MSU crystals was considered reliable when the "double contour" sign, the "blizzard" symptom and the presence of periarticular/intraosseous deposits of MSU crystals were detected according to ultrasound. The diagnosis of gout was based on the 2015 ACR/EULAR criteria; patients who did not meet these criteria were diagnosed with asymptomatic hyperuricemia (AHU). All patients also had blood samples taken for genotyping of polymorphisms of the SLC2A9 (rs1014290), NLRP3 (rs10754558), TLR4 (rs2149356), IL-1β (rs1143623), ABCG2 (rs2231142) genes. Statistical analysis of the obtained data was carried out using the application package Statistica 12.0, Biostatistics (StatSoft Inc., USA).
Results: 166 patients with a mean age of 48.5 ± 12.3 y were included: 83 (50%) patients with AHU and 83 (50%) patients with gout. The groups are comparable by age and gender. BMI in both groups corresponded to obesity (30.0 ± 5.0 kg/m^2 in the gout group vs. 30.4 ± 7.2 kg/m^2). The average sUA level was 469.5 ± 85.7 μmol/l; in the group of gout it was expectedly higher (497.1 ± 95.5 vs. 440.9 ± 62.9 μmol/l) in the AHU group, p = 0.04). MSU crystals in the metatarsophalangeal joints were found in 17 (20.4%) patients with AHU and 57 (68.6%) patients with gout (p = 0.01), despite taking urate-lowering drugs in 64.7% of cases among the latter. Differences in the distribution of genotypes of the NLRP3 and ABCG2 genes between two groups were found to be approaching statistically significant (p = 0.049 and p = 0.059, respectively). The genotype–phenotype analysis revealed a statistically significant association of NLRP3 gene polymorphism with the risk of crystals in the metatarsophalangeal joints in gout (OR = 5.33 [1.22–24.85], p = 0.01), while in AHU such an association was not identified.
Conclusion: NLRP3 gene polymorphism is one of the factors responsible for the deposition of MSU crystals in gout, but not in AHU. Thus, it can be considered a predictor of the transformation of AHU into gout. However, larger studies of genotype–phenotype relationships are needed.

P441
CLINICAL FEATURES OF KNEE OSTEOARTHRITIS IN PATIENTS WITH GOUT AND ASYMPTOMATIC HYPERURICEMIA

E. Panina[1], M. Eliseev[1], O. Zhelyabina[1]

[1]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia

Objective: To study the characteristics of the knee joints osteoarthritis (OA) depending on the stage of hyperuricemia.
Methods: A single-center case–control study included patients aged ≥ 18 y with various stages of hyperuricemia (uric acid (UA) level > 360 μmol/L): asymptomatic hyperuricemia (AHU) or gout. The examination included collecting anamnesis (including taking urate-lowering drugs (ULD) and colchicine), anthropometric data (height, weight, BMI), determining the level of pain in knee joints using a visual analogue scale (VAS), blood test for UA levels, and performing radiography (TeleCord MT Plus device, Russia) of the knees joints to determine the radiological stage of OA according to Kellgren-Lawrence. The diagnosis of gout was based on the 2015 ACR/EULAR criteria; patients who did not meet these criteria were diagnosed with AHU. All patients underwent measurement of the HAQ, WOMAC, M. Lequesne and EQ-5D indices. Statistical analysis of the obtained data was carried out using the application package Statistica 12.0, Biostatistics (StatSoft Inc., USA).
Results: A single-center case–control study included 202 patients: 101 (50%) patients with AGU and 101 (50%) patients with gout. Patients from the AHU and gout groups were comparable in gender,

age (mean age 48.9 ± 13.7 y), height, weight and BMI (29.8 ± 5.3 kg/m^2), which corresponded to excess body weight. The frequency of taking ULD and colchicine, which were more often prescribed to patients with gout, differed as expected ($p < 0.01$). Laboratory examination showed significantly higher levels of UA in the gout group compared to the AHU group (448.41 ± 64.8 vs. 518.1 ± 52.6 μmol/L, respectively). Knee OA according to Kellgren-Lawrence was found in 61 (60.4%) patients with AHU and 53 (52.5%) patients with gout, however, advanced stages of OA (3 and 4 according to Kellgren-Lawrence) were more often found among patients with gout ($p = 0.002$).

Conclusion: Knee OA occurs in more than half of patients with elevated uric acid levels. In gout, it is characterized by more advanced radiological stages, and is also accompanied by more intense pain and functional impairment.

P442
CLINICAL FEATURES OF PATIENTS WITH CALCIUM PYROPHOSPHATE CRYSTAL DEPOSITION DISEASE IN THE PRESENCE OF HYPERURICEMIA

E. Panina[1], M. Eliseev[1], O. Zhelyabina[1]

[1]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia

Objective: To compare the incidence of cardiovascular diseases and conditions among patients with calcium pyrophosphate crystal deposition disease (CPPD) and hyperuricemia (HU) and CPPD without HU.

Methods: A single-center study included patients with a definite diagnosis of CPPD. All patients underwent history taking, examination, determination of joint pain using a visual analogue scale (VAS), phenotyping for acute or chronic arthritis and uricemia level. The level of hsCRP (norm < 5 mg/l), creatinine (norm < 106 μmol/l), serum uric acid (sUA) (norm < 360 μmol/l) was determined. GFR was calculated using the CKD-EPI formula. Concomitant diseases were recorded if there was a corresponding entry in the medical document. Statistical analysis of the obtained data was carried out using the application package Statistica 12.0. Biostatistics (StatSoft Inc., USA).

Results: The study included 258 patients over 18 years old with a definite diagnosis of CPPD: 155 (60.0%) women, 103 (40.0%) men; of these, 112 (43.4%) patients had an increase in sUA levels, 146 (56.6%) patients did not. A comparison of patients with CPPD and HU and CPPD without HU is shown in the Table below.

Comparable characteristics	HU (n=112)	Normouricemia (n=146)	p
Gender. m/f. n	42/104	61/51	<0.00001*
BMI >25 kg/m^2. n (%)	54 (48.2)	49 (33.6)	0.0041*
BMI >25 kg/m^2. n (%)	91 (81.3)	95 (65.1)	0.017*
AH. n (%)	86 (76.8)	75 (67.0)	<0.00001*
IHD. n (%)	39 (34.8)	35 (24.0)	0.056
AMI. n (%)	5 (4.5)	3 (2.1)	0.27
Stroke. n (%)	5 (4.5)	6 (4.1)	0.89
CHF. n (%)	22 (19.6)	11 (7.5)	0.039*
GFR <60 ml/min. n (%)	16 (14.3)	8 (5.5)	0.016*
DM 2 type. n (%)	21 (18.8)	16 (11.0)	0.077
CRP >2 mg/l. n (%)	70 (62.5)	73 (50.0)	0.045*
Chronic arthritis. n (%)	72 (64.2)	93 (43.1)	0.92
Acute arthritis. n (%)	31 (27.7)	33 (22.5)	0.35
Pain according to VAS. mm (M±SD)	57.8±13.1	55.6±15.4	0.075

*p <0,05

Conclusion: CPPD is often combined with HU. This combination predetermines a high likelihood of concomitant diseases and metabolic disorders (obesity, AH, CHF), as well as a chronic inflammatory process (hsCRP > 2 mg/l). The relationship between HU and the clinical manifestations of CPPD has not been identified. The frequency of arthritis attacks in the formed groups also did not differ, amounting to an average of 4 arthritis attacks per year in each group ($p = 0.98$).

P443
ANAKINRA IN THE TREATMENT OF CALCIUM PYROPHOSPHATE CRYSTAL DEPOSITION DISEASE

E. Panina[1], M. Eliseev[1], O. Zhelyabina[1]

[1]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia

Objective: To evaluate the effectiveness of a short course of anakinra in calcium pyrophosphate crystal storage disease (CPPD).

Methods: The prospective study included patients with a definite diagnosis of CPPD who did not respond to therapy with NSAIDs, colchicine, corticosteroids and disease-modifying drugs. The examination included anthropometry, determination of pain intensity on a visual analogue scale (VAS), the number of painful (PBS) and swollen (SPS) joints out of 44, and the disease activity index DAS44. The level of CRP and ESR were determined. Each patient was prescribed anakinra at a dose of 100 mg/d. in a week. If severe pain occurred, patients could take NSAIDs. Follow-up visits were scheduled at 1, 2, and 8 weeks after initiation of anakinra therapy. The dynamics of laboratory parameters and examination data were recorded. Statistical analysis of the obtained data was carried out using the application package Statistica 12.0, Biostatistics (StatSoft Inc., USA).

Results: 5 patients with a definite diagnosis of BDP were included: 4 (80%) women and 1 (20%) man. The average age among patients was 59.0 ± 6.4 y; the average BMI was 28.4 ± 6.9 kg/m^2, which corresponds to pre-obesity; the average PBS and SPS before anakinra administration was 5.2 [2.0; 8.0] and 2.0 [2.0; 2.0] respectively; the average pain level according to VAS was 60.0 ± 9.4 mm. The average values of inflammatory markers before treatment were: ESR: 35.6 ± 6.2 mm/h and CRP 5.9 ± 1.3 mg/l. After the end of treatment with anakinra, a decrease in the number of heart rate and heart rate was noted (3.2 [0.0; 4.0] and 1.2 [0.0; 2.0], respectively), pain intensity by 2 times, and the level of inflammatory markers: ESR 13.4 ± 6.1 mm/h and CRP 3.3 ± 1.9 mg/l. The average DAS44 index decreased by 1.75 times. However, upon closer examination of the treatment results, it was noted that in 2 patients the effect of anakinra therapy was incomplete—arthritis and elevated levels of laboratory markers of inflammation persisted.

Conclusion: Anakinra has a beneficial effect in the treatment of CPPD when other treatments are ineffective, but some patients do not respond to this therapy. Larger studies are required.

P444
WHAT FACTORS AFFECTED THE SELF-REPORTED HEALTH STATUS OF PATIENTS WITH RHEUMATOID ARTHRITIS IN REAL CLINICAL PRACTICE? SURVEY DATA

E. Polishchuk[1], A. Karateev[1], A. Potapova[1], E. Filatova[1], V. Amirdzhanova[1]

[1]V.A.Nasonova Research Institute of Rheumatology, Moscow, Russia

Objective: Patient acceptable symptom state (PASS) is a simple way to assess the health status and therapy effect from the patient's point of view and is well suited for clinical practice. We aimed to evaluate factors affecting PASS in RA patients in real clinical practice according to the survey data.
Methods: A survey of patients with RA was carried out using an electronic form of a questionnaire posted on the website of the V.A. Nasonova Research Institute of Rheumatology in the period from January to June 2023. A total of 945 people took part in the survey. 87.8% were female, mean age 46.3 ± 13.2 y, disease duration 6[3;14] y. Most of them (80.4%) were receiving conventional synthetic disease-modifying antirheumatic drugs (csDMARDs), 23.9%—biological DMARDs (bDMARD) and JAK inhibitors, 36.5% were receiving glucocorticoids (GCs) and 69.1% NSAIDs. The patients rated the severity of joint pain, fatigue, anxiety, depression, daily activity limitation, global health (GH) and global disease activity (GDA) in the past 2 weeks using a numerical rating scale (NRS) from 0–10 points. Patients' satisfaction with their condition was determined using the PASS. To do this, the patient answered "YES" or "NO" to the question, "Taking into account all you have to do during your daily life, your level of pain, and your functional impairment, do you consider that your current state is satisfactory?".
Results: According to the survey, 54.8% of patients were satisfied with their condition (PASS +). PASS " + " and PASS "−" patients were comparable in age (46.9 ± 12.7 and 45.6 ± 13.6 years, respectively, p = 0.08) and disease duration (6[3;14] and 6[2;13] years, respectively, p = 0.29), but in the group of PASS " + " they had significantly lower levels of pain, fatigue, anxiety, depression, were less restricted in daily activities and had significantly better GH and GDA scores ($p \leq 0.05$). The most significant factors associated with PASS "−" were severity of pain OR 2665 (95% CI 2072–3429), fatigue 2497 (1818–3430), anxiety 1683 (1395–2029), and depression 1537 (1308–1805) > 4 points on the NRS, intake of NSAIDs 1305 (1103–1544) and GCs 1185 (1029–1363); in contrast, bDMARD and JAK inhibitors intake were associated with PASS " + " 0.779 (0.647–0.938).
Conclusion: The most significant factors affecting self-assessment of RA patients' health status in real clinical practice were the severity of pain, fatigue, anxiety and depression.

P445
EFFICACY AND SAFETY OF CELECOXIB, DIACEREIN AND GLUCOSAMINE-CHONDROITIN COMBINATION FOR THE CONTROL OF MUSCULOSKELETAL PAIN ASSOCIATED WITH OSTEOARTHRITIS AND CHRONIC LOW BACK PAIN

E. Polishchuk[1], A. Karateev[1]

[1]V.A.Nasonova Research Institute of Rheumatology, Moscow, Russia

Objective: Co-administration of drugs with different mechanisms of action is an important approach to controlling musculoskeletal pain in rheumatic diseases. However, there are only a small number of studies evaluating the efficacy of this approach in real practice. We aimed to evaluate the efficacy and safety of the combined use of celecoxib, diacerein and glucosamine—chondroitin combination in osteoarthritis (OA) and chronic low back pain (LBP).
Methods: Data from a 3-month open-label observational study were analyzed. We included 1569 patients, 63.6% women and 36.4% men, age 58.7 ± 11.0 y, with knee OA, hip OA hand OA and chronic LBP experiencing moderate/severe pain (≥ 4 on a numeric rating scale, NRS 0–10) and requiring NSAIDs. Patients took celecoxib 400 mg/d with dose reduction to 200 mg/d and "on-demand" use after significant pain reduction; diacerein 100 mg/d and glucosamine 250 mg—chondroitin 200 mg 2 caps. 2 times daily. The results were assessed at 3 months using the dynamics of pain, fatigue, functional impairment (NRS) and the patient-acceptable symptom state (PASS) parameter.
Results: 80.2% of patients completed the 3-month treatment course, 4.4% discontinued treatment due to adverse events (AEs) and 15.4% were lost to follow-up. At 3 months, a reduction of ≥ 50% from baseline in the severity of pain on movement was observed in 83.4%, pain at rest in 83.7%, pain at night in 78.6%, functional limitation in 80.8%, fatigue in 83.4%. PASS was noted in 87.7% of patients. There was no significant difference in treatment outcomes for different localisations of OA and LBP: ≥ 50% pain reduction was achieved in 81.6% of knee OA patients, 82.2% of hip OA patients, 85.0% of hand OA patients, 88.1% of LBP patients. AEs were reported in 350 patients (22.4%), the most common being dyspepsia in 280 patients (17.8%). Diarrhoea was reported in 37 patients (2.4%). There were no serious complications requiring hospitalisation.
Conclusion: Combined therapy with celecoxib, diacerein and glucosamine-chondroitin significantly reduces symptoms of OA and LBP.

P446
COMPLEX DECISION-MAKING HIP REREVISION ARTHROPLASTY CASE OF PJI IN DIABETIC AND OSTEOPOROTIC ELDERLY MALE PATIENT

E. Popescu[1], C. E. Georgescu[1], A. Dimitriu[2], B. Bolos[1], R. Ene[2]

[1]Bucharest Emergency Clinical Hospital, Orthopaedics Dept., Bucharest, Romania, [2]Bucharest Emergency Clinical Hospital, Orthopaedics Dept., "Carol Davila" Univ. of Medicine and Pharmacy, Bucharest, Romania

Objective: THA is one of the most successful surgical procedures with documented survivorship at up to 25 years thus increasing the need for RHAs [1]. However, the increase of THA cases and the increase of life expectancy increases the RHA need with various causes such as infection, corrosion, wearing, poor osseointegration, periprosthetic fractures, therefore the demand for metallic materials in medical devices is large [2]. Ti-based materials combined with Co and Cr are highly compatible and are widely used as orthopedic implant materials in clinical practices such as hip joint and knee replacement due to their superior mechanical properties, good wear, and corrosion resistance [3] which leads to less inflammatory response [4] and hydroxyapatite coatings are widely used as a coating material for metal implants because of its bioactivity and osteoconductivity, which are similar to those of natural human bone [5,6,7]. Besides local factors the general factors provided by the patient, such as diabetes, smoking, alcohol abuse and osteoporosis as testosterone deficit increases bone resorption in male patients [8,9] can also influence the final outcome. The potential of biological fixation and improved implant designs have led to an increasing worldwide use of cementless components in revision THA including two-stage exchange procedures for PJI [10,11]. Interval between stages can range from 6 weeks to several months and PJI are very challenging for every surgeon skilled in prosthetic surgery and it's necessary to make an exact preoperative diagnosis and to treat them with the proper technique [12]. Our case report presents the challenges of

successfully treating the PJI and restore the limb functionality were represented by a multitude of local and general factors that influenced our decision making process in regards to the best available option for this patient.

Methods: We present the complex case of a diabetic, heavy smoking, alcoholic, osteoporotic normal BMI, 80 yo male patient with delayed onset *E. cloacae* ESBL positive PJI after cementless THA for femoral neck fracture and after a cemented femoral stem revision and ORIF for Vancouver A2 femoral fracture. The patient presented in our service at 8 months after his last surgery accusing the appearance of a thigh fistula, pain, fever and limb shortening on the affected side and with elevated ESR, CRP and Fibrinogen levels. We had a lot of tough treatment choices and investigations to make but we will further present the most important ones. The hardest first choice we had to make was represented by adopting the one stage vs. two stage revision approach regarding the fact that the patient had an ESBL + type of infection which was an indication for the two stage revision, but the patient already had osteoporosis which could also worsen with time with the two-stage revision wait interval increasing the osteoporosis levels the patient's risk for periprosthetic fractures and the fact that he was a non-compliant patient (he was not interested in any of the solutions for controlling the diabetes, smoking and alcohol ceasing or further osteoporotic treatment we provided no matter how hard we tried to make him understand that these are also connected to his overall orthopedic problem). We finally decided for the two stage revision approach using a Vancomycin and Gentamicin impregnated hip spacer and after 6 months we were able to plan for the second stage of the revision surgery without any local complications encountered in these months, when it was time for the second hard choice between cemented (primary stability, further antibiotics local delivery with the risk of non-union in case of a new fracture during the surgery) and cementless (secondary stability, bioconductivity advantages regarding his osteoporotic status), knowing that the periprosthetic fracture was still highly possible during the surgery so we finally decided on a cemented cup and cementless modular femoral stem option. Of course, during our second surgery he suffered a distal femoral diaphysis fracture which also needed ORIF in addition to the cementless modular stem.

Results: After the surgery the patient was finally convinced that the osteoporosis had a negative impact on his overall evolution, prolonging his rehabilitation protocol with a 2 month non weight bearing and started taking the specific treatment. We did not encounter any problems during the rehabilitation protocol, but we noticed a mild local inflammatory reaction at 5 days postop (skin redness) which was a scare, but 14 months after the surgery the ESR, CRP and Fib levels are normal (tested every 3 months interval), he has no pain and he recovered 85% of his lower limb mobility. The X-rays show no implant migration and the fracture is fully healed.

Conclusion: This case highlights the necessity to properly evaluate the patient specific risk factors and treatment options in order to address all possible scenarios and proper, up to date preoperative planning.

Abbrecccviations: THA-total hip arthroplasty, RHA-revision hip arthroplasty, Ti-titanium, Co-cobalt, Cr-chromium, PJI-prosthetic joint infection, ESR-erythrocyte sedimentation rate, CRP-C-reactive protein, ORIF-open reduction and internal fixation

P447
EFFICACY OF REHABILITATIVE TREATMENTS ON FUNCTIONALITY IN DAILY LIFE ACTIVITIES IN PATIENTS WITH FIBROMYALGIA: A SYSTEMATIC REVIEW OF RANDOMIZED CONTROLLED TRIALS

E. Prestifilippo[1], N. Marotta[2], R. Zito[1], I. Bartalotta[1], L. Lippi[3], M. Invernizzi[3], A. Ammendolia[1], A. De Sire[1]

[1]Dept. of Medical and Surgical Sciences, Univ. of Catanzaro "Magna Graecia", Catanzaro, [2]Physical and Rehabilitative Medicine, Dept. of Experimental and Clinical Medicine, Univ. of Catanzaro "Magna Graecia", Catanzaro, [3]Dept. of Health Sciences, Univ. of Eastern Piedmont "A. Avogadro", Novara, Italy

Objective: This study investigated the efficacy of rehabilitation interventions in relieving symptoms and improving functionality in individuals with fibromyalgia, a debilitating condition characterized by persistent pain. This systematic review and meta-analysis aimed to clarify the impact of diverse therapeutic methods, providing valuable insights into managing functional limitations associated with fibromyalgia.

Methods: The systematic literature review was conducted on PubMed, Scopus, and Web of Science. The focus was on randomized controlled trials (RCTs) involving fibromyalgia patients undergoing various rehabilitative interventions, including physiotherapy, transcutaneous electrical nerve stimulation (TENS), acupuncture, and more. The Fibromyalgia Impact Questionnaire (FIQ) measured outcomes, evaluating the condition's impact on daily activities. Cochrane Risk of Bias tool assessed RCTs' bias risks.

Results: A comprehensive screening identified 23 studies with 1283 participants, 660 in intervention and 623 in control groups. Seven approaches were studied, including exercise, hydrotherapy, acupuncture, low-level laser therapy (LLLT), electromagnetic therapy, TENS, whole-body vibration (WBV), and exergaming. Meta-analysis revealed significant FIQ-10 improvements with hydro-kinesitherapy, tMS, LLLT, and WBW (MD decrease of ES: − 11.74). Limited impact for electromagnetic therapy, exergames, and exercise. FIQ-8 showed a small but significant improvement (MD decrease of ES: − 7.95), while FIQ-R significantly improved with Physical Exercise/Therapy (MD decrease of ES: − 17.70). Risk of bias analysis found 86.3% high-quality randomization, 59% low risk for missing data, and an overall 46.5% low bias risk.

Conclusion: This systematic review highlights the efficacy of rehabilitative interventions in improving the functioning and daily life activities of fibromyalgia patients. Given the condition's debilitating nature, the findings advocate for integrating these approaches into a comprehensive care strategy, emphasizing tailored, multidisciplinary interventions to address fibromyalgia's complex challenges.

P448
EFFICACY OF OXYGEN-OZONE THERAPY IN COMBINATION WITH DIFFERENT REHABILITATIVE TREATMENTS ON PAIN IN PATIENTS WITH LOW BACK PAIN: PILOT RANDOMIZED CONTROLLED TRIAL

E. Prestifilippo[1], N. Marotta[2], A. Vimercati[1], S. Fasano[3], L. Lippi[4], M. Invernizzi[4], A. De Sire[5], A. Ammendolia[5]

[1]Dept. of Medical and Surgical Sciences, Univ. of Catanzaro "Magna Graecia", Catanzaro, [2]Physical and Rehabilitative Medicine, Dept. of Experimental and Clinical Medicine, Univ. of Catanzaro "Magna Graecia", Catanzaro, [3]Physical and Medical Rehabilitation Unit, Univ. Hospital "Renato Dulbecco", Catanzaro, [4]Dept. of Health Sciences, Univ. of Eastern Piedmont "A. Avogadro", Novara, [5]Dept. of Experimental and Clinical Medicine, Univ. of Catanzaro "Magna Graecia", Catanzaro, Italy

Objective: This pilot randomized controlled trial aimed to assess the efficacy of combination of oxygen-ozone therapy (O2O3) and proprioceptive neuromuscular facilitation (PNF) program vs. O2O3 plus Back School physiotherapy in terms of pain relief in low back pain patients.
Methods: Adults (age $>$ 18 y) with low back pain (with a numeric rating scale, NRS score $\geq$ 4) were randomized into two groups. Both groups received 8 sessions of intramuscular-paravertebral lumbar injections over 8 weeks, followed by physiotherapy. The study group underwent PNF rehabilitation, whereas the control group underwent Back School rehabilitation. Outcomes were: NRS for pain, Oswestry Disability Index (ODI) for disability, and EuroQol for quality of life at the following timepoints: T0 (baseline), T1 (after O2O3 therapy), T2 (after physiotherapy), and T3 (at 3 months at end of treatment).
Results: 20 patients (mean age: 65.3 $\pm$ 19.0 y) showed significant pain improvement in both groups at T3 (PNF: 8.5 $\pm$ 1.35 vs. 5.4 $\pm$ 2.3, p = 0.02; Back School: 7.9 $\pm$ 1.4 vs. 3.4 $\pm$ 2.0,p = 0.02). PNF group exhibited significant quality of life improvement at T1 (0.325 $\pm$ 0.226 vs. 0.625 $\pm$ 0.232, p = 0.04), while the Back School group showed non-significant change at T1 (0.479 $\pm$ 0.224 vs. 0.698 $\pm$ 0.176, p = 0.06). ODI significantly improved in both groups (PNF: T0–T1 p = 0.04, T0–T2 p = 0.03; Back School: T0–T1 p = 0.04, T0–T2 p = 0.03, T0–T3 p = 0.03). No significant between-group differences were observed.
Conclusion: O2O3 therapy demonstrated significant pain, disability, and quality of life improvement in all patients. Although there were no significant intergroup differences, intragroup improvements suggested the efficacy of O2O3 therapy independently from the following rehabilitation type in reducing low back pain.

P449
THE COMBINATION OF PSORIATIC ARTHRITIS WITH OSTEOPOROSIS

E. Russu[1], L. Liliana[1], L. Chişlari[1], A. Nistor[1], M. Homiţchi[2], L. Gonţa[3], L. Dutca[1]

[1]"Nicolae Testemitanu" State Medical and Pharmaceutical Univ., [2]"Timofei Mosneaga" Republican Clinical Hospital, Laboratory of Rheumatology, [3]Republican Diagnostic Center, Chisinau, Moldova

Objective: The prevalence of osteoporosis in psoriatic arthritis (PsA) is poorly understood, and the mechanism of its development has not yet been elucidated. It is assumed that the severity of the disease, the age of the patient, and chronic autoimmune inflammation may play a role in its pathogenesis in this disease. Aim of the study was to investigate the prevalence of osteoporosis in psoriatic arthritis.
Methods: 81 patients with PsA aged 32–59 y were examined, predominantly men under the age of 50 (70%), the mean age was 44.7 $\pm$ 5.5 y. Diagnosis was carried out in accordance with the CASPAR criteria.
Results: According to DXA osteodensitometry, osteoporosis and osteopenia (4.1 $\pm$ 1.3 vs. 3.4 $\pm$ 0.8, $p < 0.01$) are a common complication of PsA, its signs were detected in 60% of patients. Osteoporosis are more likely to develop in patients with high PsA activity ASDAS-CRP (3.9 $\pm$ 0.5 vs. 2.9 $\pm$ 0.3, $p < 0.01$), BASDAI (5.1 $\pm$ 0.7 vs. 3.5 $\pm$ 0.9, $p < 0.01$), severity, duration of the disease, rheumatoid-like form, systemic manifestations, receiving glucocorticosteroids per os and having a low BMI.
Conclusion: Osteoporosis is a common complication of psoriatic arthritis. The development of osteoporosis in this disease is associated with high activity, severity of the pathological process, and the use of glucocorticosteroids. Patients with psoriatic arthritis complicated by osteoporosis have more severe bone pain than patients without osteoporosis.

P450
BONE MINERAL DENSITY IN PCOS: NEW INSIGHTS INTO HYPERANDROGENISM AND HYPERINSULINEMIA

C. P. Lopes[1], G. A. R. Maciel[1], G. D. N. Maffazioli[1], E. S. Ferreira-Filho[1], R. F. Macchione[1], E. M. D. Neves[1], J. M. Soares-Junior[1], R. M. R. Pereira[2], E. C. Baracat[1]

[1]Disciplina de Ginecologia, Faculdade de Medicina FMUSP, Universidade de Sao Paulo, [2]Disciplina de Reumatologia, Faculdade de Medicina FMUSP, Universidade de Sao Paulo, Sao Paulo, Brazil

Objective: Polycystic ovary syndrome (PCOS) is a complex gynecological, reproductive, endocrine and metabolic disease whose pathophysiological mechanisms, such as chronic anovulation, hyperandrogenism, and hyperinsulinemia, may affect BMD (BMD). However, the impact of PCOS on bone metabolism is poorly understood. We aimed to analyze the BMD and body composition in patients with PCOS, where one of the criteria to be considered is hyperandrogenism, and to compare to women without the syndrome.
Methods: A cross-sectional study was carried out with 21 women with PCOS and 19 women without the syndrome. All women were using combined hormonal contraceptives. Statistical analysis was performed in the STATA program.
Results: The groups were homogeneous and there was no statistically significant difference in mean age (p = 0.91) and BMI (p = 0.10). The BMD in the PCOS and control groups were, respectively, 1.300 vs. 1.150 g/cm^2, p = 0.01 for lumbar spine, 1.068 vs. 0.920 g/cm^2, p = 0.01 for femoral neck and 1.135 vs. 0.964, p = 0.002 g/cm^2 for total femur. In our sample, there was higher BMD in all studied areas in PCOS subjects, who had higher testosterone levels. As for body composition, the percentage of total fat in the PCOS and control groups was 40.2 vs. 41.6%, p = 0.41, and the visceral adipose tissue component seemed to be higher in PCOS (785 vs. 474 g, p = 0.07), although not statistically significant. The analysis of bone characteristics among participants with PCOS, with and without insulin resistance, showed a decrease in BMD of the femoral neck only (1.124 vs. 0.950 g/cm^2, p = 0.01) in the group with insulin resistance, although it was not significant after controlling for BMI.
Conclusion: BMD in the total femur, femoral neck and lumbar spine of patients with PCOS was higher than those without the syndrome.

P451
A PROMISING STRATEGY FOR THE DIAGNOSIS, TREATMENT AND PREVENTION OF OSTEOPOROSIS: EMS STRATEGY

E. Shahrour[1]

[1]Tishreen Univ., Latakia, Syria

Objective: The challenges facing DXA in the assessment of osteoporosis call for more search for useful methods and strategies. A real scientific revolution to find appropriate solutions (radiological studies, genetic studies and bioinformatics applications) is ongoing. Recently, a new road map between ESCEO & WHO is interested in new strategies to improve the management of osteoporosis around the globe. There is no current application or tool that gives the complete picture of the status of the osteoporotic bone (1). For the picture to be complete, the strategies must give an idea about BMD, microarchitecture of trabecular bone, microarchitecture of cortical bone, environmental risk factors, genetic risk factors, clinical history, organic and inorganic bone formation, osteoblasts and osteoclasts. We need the balance between strength and flexibility of the bone to protect it against fracture. We need the balance between quantity and quality of bone.
Methods: EMS strategy.
1-Bioinformatics application includes results of (DXA, FRAX, GPS, TBS, CBS, CH, OCS, ICS, BCS).

DXA: Dual-Energy X-ray Absorptiometry: BMD.(2)
FRAX: Fracture Risk Assessment: Environmental Risk Factors.(3)
GPS: Genetic Polygenic Score: Genetic Risk Factors.(4)
TBS: Trabecular Bone Score: microarchitecture of trabecular bone.(5)
CBS: Cortical Bone Score: microarchitecture of cortical bone.
CH: Clinical History: Diagnostic Auxiliary Factors.
OCS: Organic Component Score: mechanism of bone matrix formation and elements included in it.(6,7)
ICS: Inorganic Component Score: mineralization mechanism and elements included in it.(8)
BCS: Bone Cell Score: Formation of bone cells and influencing factors.(8)
BCS, OCS, ICS can be obtained from the cellular pathways.
CBS can be obtained from DXA.
Gene classification in GPS App. must be according to their effect on molecular pathways, structure of (cortical/ trabecular bone), component of (organic/inorganic), bone cells(osteoblasts/ osteoclasts).
Bioinformatics application of Genetic Morphology(Morphological characteristics of carriers of the genetic defect). It may be added to the clinical story, as genetics will be involved in every detail in the future.

2-Bioinformatics application includes the exact effect of the current or discovered drugs by the following classification, effect on.

Molecular Pathways (WNT, BMP, NOTCH, RANKL/RANK/OPG)
Cortical bone/Trabecular bone
Organic component/Inorganic component
Osteoblasts/ Osteoclasts
Simple example: Most of the femur is cortical bone and most of the lumbar bone is trabecular bone. In the event that there is a problem in the femur, we go for treatments that affect the cortical bone. In the event of a problem in the lumbar bone, we use medications that affect the trabecular bone. This idea will be good to be associated with TBS osteo.

3- Bioinformatics application decides the optimal treatment and prevention methods for the patient by combining the results of the two previous applications.
Conclusion: EMS strategy fits with the global trends to follow precision medicine and individual treatment. Perhaps this strategy will be useful for diagnosing, treating and prevention for most diseases of the skeletal system.

P452
GENETIC ASSOCIATION BETWEEN SYMPTOMS OF MILD OSTEOGENESIS IMPERFECTA (OI) AND POSTMENOPAUSAL OSTEOPOROSIS

E. Shahrour[1], B. Al-Halabi[2], A. Dabboul[2], W. Al-Achkar[2], A. A. Hassan[1], A. Khamis[1], H. Yazigi[1]

[1]Tishreen Univ., Latakia, [2]Atomic Energy Commission, Damascus, Syria

Objective: Mild osteogenesis imperfecta OI and postmenopausal osteoporosis are both bone disorders. Mild OI may be associated with postmenopausal osteoporosis. According to NCBI, COL1A2rs72658152 (COL1A2G661S) is a pathogenic proven cause of the association between mild OI and postmenopausal osteoporosis. The challenges facing DXA and the treatment plans of the World Health Organization WHO for osteoporosis require a search for new diagnostic solutions such as genetic methods.
Methods: COL1A2rs72658152 was detected by Restriction Fragment Length Polymorphism RFLP and DNA sequencing on 150 EDTA blood samples from pre- and post-menopause women in Tishreen University Hospital. BMD was measured using DXA. A clinical examination was conducted for the participants. A questionnaire was filled out with information related to the study. Related-Samples McNemar Change Test, chi-square test, and binary logistic regression were used as a statistical method to estimate the correlation between mild OI and postmenopausal (osteopenia or osteoporosis) under 95% confidence level ($\alpha \leq 0.050$) as well as the correlation between (mild OI, postmenopausal osteoporosis or osteopenia) and some morphological characteristics under 95% confidence level ($\alpha \leq 0.050$).
Results: The significant change to the occurrence of mild OI with postmenopausal osteopenia or osteoporosis is 10.8% with a confidence level of 95% or more ($p \leq 0.05$). Strong asymptotic significance of the (2-sided) correlation is found between mild OI, on one hand, and postmenopausal osteopenia or osteoporosis on the other (chi-square = 29.066, $p = 0.000 < 0.05$). Mild OI has a significant impact on postmenopausal osteoporosis or osteopenia ($p = 0.000 < 0.05$). They are in a positive correlation relationship according to the nature of tendency slop (B = 1.758).
Conclusion: Mild OI is associated with postmenopausal osteopenia and osteoporosis with statistical significance with reasons other than COL1A2G661S, and no specific morphological characteristics are found. Postmenopausal osteoporosis is not a primary osteoporosis because there are causes for it to occur. This is contrary to the WHO classification.

P453
EMBODIMENT OF BIOINFORMATICS IN THE DIAGNOSIS AND TREATMENT OF OSTEOPOROSIS: EMS STRATEGY

E. Shahrour[1]

[1]Tishreen Univ., Latakia, Syria

The challenges facing DXA in the assessment of osteoporosis call for more research for useful methods and strategies. A real scientific revolution to find appropriate solutions (radiological studies, genetic studies, and bioinformatics applications) is ongoing [1]. Recently, a new road map was signed between ESCEO and WHO is interested in new strategies to improve the management of osteoporosis around the globe. There is no current application or tool that gives a complete picture of the status of the osteoporotic bone [2].

Material and methods: EMS strategy supports bioinformatics in diagnosing and treating osteoporosis through three bioinformatics applications that may be consistent with the goals of the new roadmap signed between ESCEO and WHO in February 2023. The first one organizes the results of various diagnostic tests currently available and other tests that must be worked on to give a complete picture of the bone. It should give an integrated picture about (BMD, microarchitecture of trabecular bone, microarchitecture of cortical bone, environmental risk factors, genetic risk factors, clinical history, organic and inorganic bone formation, osteoblasts, and osteoclasts). We need the balance between strength and flexibility of the bone to protect it against fracture. We need a balance between the quantity and quality of the bone. It includes results of (DXA, FRAX, GPS, TBS, CBS, CH, OCS, ICS, and BCS) [3]. The following is a definition of these terms:

DXA: dual-energy x-ray absorptiometry: BMD[4].
FRAX: fracture risk assessment: environmental risk factors[5].
GPS: genetic polygenic score: genetic risk factors [6].
TBS: trabecular bone score: microarchitecture of trabecular bone[7].
CBS: cortical bone score: microarchitecture of cortical bone.
CH: clinical history: diagnostic auxiliary factors.
OCS: organic component score: mechanism of bone matrix formation and elements included in it [1, 8].
ICS: inorganic component score: mineralization mechanism and elements included in it [9].
BCS: bone cell score: formation of bone cells and influencing factors [9].

BCS, OCS, and ICS can be obtained from the cellular pathways.

CBS can be obtained from DXA.

Gene classification in GPS app must be according to their effect on the molecular pathways, structure of (cortical/trabecular bone), component of (organic/ inorganic), and bone cells (osteoblasts/ osteoclasts) [3].

Bioinformatics application of the genetic morphology (morphological characteristics of carriers of the genetic defect). It may be added to the clinical story, as genetics will be involved in every detail in the future [10].

The other bioinformatics application focuses on the exact site of effect of the currently available medications and the medications that must be worked on in the future according to their effect on molecular pathways (WNT, BMP, NOTCH, RANKL/RANK/OPG), (Cortical bone/trabecular bone), (Organic component/inorganic component)(Osteoblasts/osteoclasts), etc. To illustrate with a simple example; most of the femur is cortical bone and most of the lumbar bone is trabecular bone. If there is a problem in the femur, we go for treatments that affect the cortical bone. In the event of a problem in the lumbar bone, we use medications that affect the trabecular bone. This idea will be good to be associated with TBS osteo.

Then correlating the results of the previous two applications to a single bioinformatics application which is the third one which may decide the optimal treatment and prevention methods for the patient. Results& **Conclusion**: That may fit with the global trends to follow precisely medicine and individual treatment. Perhaps this strategy will be useful for diagnosing, treating, and preventing most diseases of the skeletal system[3].

VALIDATION OF THE SWISS FRAX MODEL FOR FRACTURE RISK ASSESSMENT USING 10-YEAR FRACTURE DATA FROM THE OSTEOLAUS STUDY

E. Shevroja[1], C. Vendrami[1], G. Gatineau[1], E. Gonzalez Rodriguez[1], O. Lamy[1], D. Hans[1]

[1]Lausanne Univ. Hospital, Lausanne, Switzerland

Objective: FRAX provides the fragility fracture risk in the next 10 years. FRAX score threshold is currently recognized as reimbursement criteria for DXA acquisition and certain osteoporosis treatments in Switzerland. Further, Swiss national guidelines recommend its use in treatment decision-making. We aimed to investigate the FRAX performance at predicting the occurrence of incident major osteoporotic fractures (MOF) during 10 y of follow-up.

Methods: 944 Swiss postmenopausal women (mean age 62.7 $\pm$ 7.6 y) from the OsteoLaus cohort were included in this analyses. The participants had FRAX assessed at baseline, had undergone a DXA and had incident and prevalent MOF data at baseline and 4 follow-up visits every 2.5 y, with a total follow-up period of 10 y. T-tests were used to study the difference of FRAX adjusted for clinical risk factors (CRF) and of FRAX adjusted for BMD and TBS between fractured and non-fractured groups. FRAX sensitivity and specificity were assessed for cutoffs of 10%, 20%, and moderate and high risk age-adjusted cutoffs as recommended by the Swiss national guidelines.

Results: The 10-y MOF incidence in the low risk group (FRAXTBS $<$ 10%) was 10%, moderate risk (10 $<$ FRAXTBS $<$ 20%) was 25% and high risk (FRAXTBS $>$ 20%) was 48%; and for FRAXCRF the 10-y MOF incidence was 11.7%, 23% and 29%, respectively. Both FRAXCRF and FRAXTBS were significantly higher in the fractured group. The sensitivity of FRAXTBS cutoff 10% was 66%, specificity was 42%; the sensitivity of FRAXCRF cutoff 20% was 20%, specificity 7.5%. The sensitivity and specificity of the FRAXTBS age-dependent cutoff was 18% and 7%, respectively.

Conclusion: The fully adjusted FRAX model, comprising adjustment for CRF, BMD and TBS performs better in fracture prediction than the only CRF adjusted model. The age- dependent FRAX cutoffs used currently in Switzerland show a low sensitivity and specificity in the 10 years fracture prediction in the OsteoLaus cohort. Further analysis

will study more FRAX performance parameters; and take into account time dependent fracture occurrence and the possible effect of antiosteoporotic treatment use in FRAX performance.

P455
INFLAMMATORY PHENOTYPE OF OSTEOARTHRITIS AND METHOTREXATE

E. Strebkova[1], L. Alekseeva[1], E. Taskina[1], N. Kashevarova[1], E. Sharapova[1], A. Lila[1]

[1]V.A.Nasonova Research Institute of Rheumatology, Moscow, Russia

Objective: To study the effectiveness of methotrexate in patients with knee osteoarthritis (OA) and synovitis.
Methods: The prospective study included 19 patients (women) with knee OA (criteria of the ACR) I-III X-ray stage (Kellgren-Lawrence), aged 45–75 y (Me 60.0 (54;65) y), with knee pain > 40 mm according to VAS, who needed NSAIDs and clinically pronounced synovitis. Patients received methotrexate 15 mg once a week subcutaneously for 24 weeks. An individual card was filled out for each patient, including anamnesis and clinical examination data, assessment of pain in the knee joints according to VAS, WOMAC, ultrasound data of the knee joint.
Results: Patients had a statically significant decrease in pain according to VAS ($p < 0.05$) and all components of the WOMAC ($p < 0.05$) (Figs. 1-3) against the background of methotrexate therapy. 85.5% of patients responded to therapy according to the OMERACT-OARSI criteria. 10 patients showed a significant decrease in the thickness of the synovial membrane and signs of synovitis ($p < 0.05$) according to knee ultrasound in dynamics against the background of methotrexate therapy. The need for the use of NSAIDs has decreased against the background of methotrexate therapy. No serious adverse events have been reported.

Figure 1. Dynamics of knee pain by WOMAC

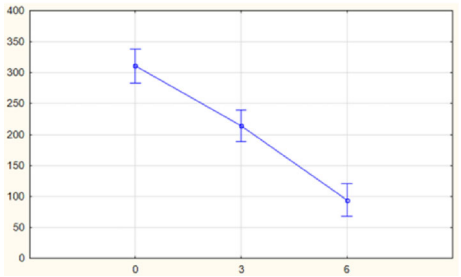

Figure 2. Dynamics of knee stiffness by WOMAC

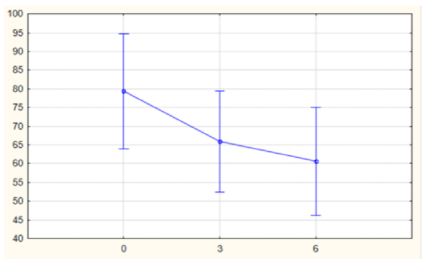

Figure 3. Dynamics of knee functional insufficiency by WOMAC

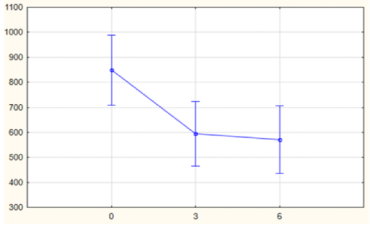


Conclusion: Methotrexate has a good clinical effect and a satisfactory safety profile in the inflammatory phenotype of knee OA.

P456
COMPARATIVE LABORATORY AND INSTRUMENTAL CHARACTERISTICS OF METABOLIC AND OSTEOPOROTIC PHENOTYPES OF KNEE OSTEOARTHRITIS

E. Strebkova[1], N. Kashevarova[1], L. Alekseeva[1], E. Taskina[1], N. Savushkina[1], E. Sharapova[1], K. Mikhailov[1], A. Khalmetova[1], A. Lila[1]

[1]V.A.Nasonova Research Institute of Rheumatology, Moscow, Russia

Objective: Comparative analysis of laboratory and instrumental indicators of metabolic (MetOA) and osteoporotic (OPOA) phenotypes of knee osteoarthritis (OA).
Methods: The study included 195 patients with MetOA (metabolic syndrome and/or type 2 diabetes mellitus) and 176 with OPOA (with reduced BMD: the presence of osteoporosis or osteopenia in the axial skeleton), with a reliable diagnosis of knee OA (criteria of the ACR) of stage I-III according to Kellgren-Lawrence.
Results: The patients of both groups did not differ in age and duration of the disease. During laboratory examination, patients with MetOA had statistically significantly high levels of inflammatory biomarkers (CRP, leptin), carbohydrate (glucose, insulin) and lipid metabolism (triglycerides), which indicates the role of low-level inflammation and metabolic disorders in this phenotype. According to the X-ray of the knee MetOA there was a greater narrowing of the medial articular gap, large lateral osteophytes of the femur and medial osteophytes of the tibia were detected; according to ultrasound data, there is a large thickness of the synovial membrane, compared with patients with OPOA. Osteitis was also more common in MetOA in the medial femur (MRI): (RR = 1.72, 95% CI 1.34–2.21, p = 0.0002), in the central tibia (RR = 2.85 95% CI 2.30–3.53, p = 0.0001). The results obtained confirm a more severe course in patients with MetOA (Table 1).

Table 1. Laboratory and instrumental indicators of patients with MF and OPF OA

Parameter	MetOA n=195	OPOA n=176	p
CRP, mg/l, Me	2,8 [1,5; 5,0]	1,1 [0,5; 1,9]	<0,001
Leptin, ng/ml,	45,2 [33,9; 73,0]	18,6 [12,9; 36,5]	<0,001
Osteitis in the medial part of the femur,%	33,3	11,2	<0,001
Osteitis in the central parts of the tibia,%	43,5	0	<0,001

Conclusion: In patients with MetOA, is noted that the course of OA is more severe than that of OPOA: worse indicators during instrumental and laboratory examinations. In OPOA, there are significantly smaller structural changes and lower rates of inflammatory response and metabolic disorders compared with MetOA.

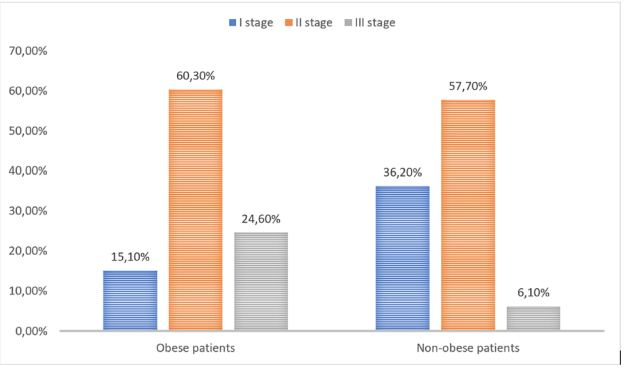
P457
EFFECT OF OBESITY ON STRUCTURAL CHANGES IN KNEE JOINTS IN OSTEOARTHRITIS

E. Strebkova[1], L. Alekseeva[1], E. Taskina[1], N. Kashevarova[1], N. Savushkina[1], E. Sharapova[1], K. Mikhailov[1], A. Khalmetova[1], D. Kudinsky[1], O. Alekseeva[1], A. Lila[1], T. Raskina[2], J. Averkieva[2], E. Usova[2], I. Vinogradova[3], O. Salnikova[3], A. Markelova[3]

[1]V.A.Nasonova Research Institute of Rheumatology, Moscow, [2]Kemerovo State Medical Univ., Kemerovo, [3]Ulyanovsk Regional Clinical Hospital No. 1, Ulyanovsk, Russia

Objective: To evaluate the effect of obesity on structural changes in knee joints in patients with osteoarthritis (OA).
Methods: The study included 495 patients aged 40–75 years with a reliable diagnosis of knee OA (ACR) of stage I–III (Kellgren–Lawrence) who signed an informed consent. The average age of the patients was 60.5 ± 8.33 y (from 40–75), the duration of the disease was 7 y (3–14).
Results: Obesity (BMI > 30 kg/m^2) was detected in 244 individuals (49.3%). Obese patients were more likely to have more severe stages of OA (Graph 1): stage III—24.6 vs. 6.1% (RR = 0.2, 95% CI 0.1–0.4, $p < 0.0001$); smaller sizes of the medial articular fissure, more massive osteophytes of the femur and tibia, more pronounced hypertrophy of the synovial membrane and tenosynovitis ($p < 0.05$ for all parameters). Osteitis (RR = 0.2, 95% CI 0.06–0.87, p = 0.03) and subchondral cysts (RR = 0.16, 95% CI 0.03–0.9, p = 0.04) in the medial tibia were more often detected in obese patients. Spearman correlation analysis ($p < 0.05$) confirmed the relationship between high BMI and osteitis in the medial tibia (r = 0.31), subchondral cysts in the medial tibia (r = 0.27), X-ray stages (r = 0.31), the size of osteophytes of the femur and tibia, hypertrophy of the synovial membrane (r = 0.27) and tenosynovitis (r = 0.22). Inverse relationships with the size of the medial articular gap (r = -0.21) were revealed.

Graph 1. Radiological stages of OA in obese and normal body weight individuals



Conclusion: Obese patients have more severe structural changes of the knee joints according to instrumental examinations. Direct links between obesity and osteitis, subchondral cysts, and osteophytosis have been found. Associations of high BMI and smaller sizes of the medial articular gap were revealed. The results of our work indicate the important role of obesity as a predictor of a more severe course of OA, which requires the development of algorithms for the treatment of patients with obesity and knee OA.

P458
INITIAL CLINICAL INSIGHTS: SELECTIVE DNA/NETS APHERESIS IN THE MANAGEMENT OF SYSTEMIC LUPUS ERYTHEMATOSUS

E. A. Aseeva[1], E. V. Nikolaeva[1], S. K. Solovyov[1], N. Y. U. Nikishina[1], E. T. Abdullin[2], T. M. Reshetnyak[1], E. G. Zotkin[1], N. S. Pokrovsky[3], A. M. Lila[1]

[1]Federal State Budgetary Institution Research Institute of Rheumatology named after V.A. Nasonova, [2]Moscow State Univ. named after. M.V. Lomonosov, [3]Federal State Budgetary Institution National Medical Research Center of Cardiology named after Academician E.I. Chazov, Ministry of Health of the Russian Federation, Moscow, Russia

Objective: Elevated levels of circulating cell-free DNA (cfDNA) and neutrophil extracellular traps (NETs) are associated with systemic lupus erythematosus (SLE) and may represent a new potential therapeutic targets. The first case report of the treatment of SLE using a new adsorption column for selective apheresis of cfDNA/NET will be reported. Our aim was evaluation of the efficacy and safety of therapeutic apheresis using adsorption column for selective cfDNA/NETs apheresis in patients with systemic lupus erythematosus (SLE).
Methods: Patient K., 56 years old with SLE (according to SLICC criteria, 2012) underwent three sessions of selective cfDNA/NETs apheresis a one-day interval between procedures, standard therapy with 6-methylprednisolone at a dose of 16 mg/d per/os was prescribed. Therapeutic apheresis procedures were carried out using new medical device for selective cfDNA/NETs apheresis to stop the exacerbation of the disease. The volume of treated plasma per one procedure was approximately 2 volumes of circulating plasma. General blood tests, biochemical parameters, immunological markers and disease activity (SLEDAI-2 K index) were assessed before and after the course of treatment.
Results: Significant positive dynamics were noted during the therapy: the SLEDAI-2 K index decreased from 32 (vasculitis, urinary casts, hematuria, proteinuria, rashes, low complement, increased antibodies to dsDNA, fever, leukopenia) to 12 (hematuria, pyuria, low complement, an increase in the level of antibodies to dsDNA) points, normalization of blood leukocyte levels, positive dynamics of renal function and decrease in immunological activity of the disease. The level of antibodies to dsDNA, to Sm, to C1q, LaSSB and anti-centromere antibodies decreased and increase in the C4 fraction of complement. There were no adverse reactions or complications during or after the procedure.
Conclusion: The first results with selective cfDNA/NETs apheresis column demonstrated a significant clinical and laboratory results in the treatment of severe exacerbation of SLE.

P459
COMPUTER-AIDED MULTI-POINT ANALYSIS OF TIBIOFEMORAL JOINT SPACES IN AN ANTEROMEDIAL OSTEOARTHRITIS (AMOA) KNEE MODEL: A PERSONALIZED APPROACH TO JOINT SPACE MAPPING

E. Tahir[1], Z. Zhi[1], D. G. Alemayehu[1], H. D. Wang[1], X. Ma[1]

[1]Dept. of Orthopedics, First Affiliated Hospital of Xi'an Jiaotong Univ., Xi'an, China

Objective: To introduce an efficient and easy-to-use CT-based 3D Joint Space Mapping (3D-JSM) protocol for quantifying multiple joint space widths (JSWs) within the tibiofemoral compartments relevant to disease progression.

Methods: Geometric 3D models of bones and tibiofemoral cartilages (TFC) were generated using data from CT and 3D MRI scans of a 62-year-old female with left knee AMOA. To extract 3D contours of the femorotibial joint space (FTJS), we employed multiplanar CT image analysis, region-of-interest (ROI) selection, joint space margin delineation, and surface patch extraction techniques using 3D modeling software. The extracted joint space curvatures were interpolated with 182-point nodes to establish a multi-point JSW construct. Point-to-point distances were then automatically computed for evaluating changes in width across the joint space. Multi-point JSW CT measurements for the medial compartment within the ROI were also compared with MRI-derived cartilage thickness measurements from the same patient.
Results: The curvatures of the 3D medial and lateral FTJS constructs were well-matched with multiplanar images and 3D bone model margins. There were 91 JSW values generated for each compartment (medial and lateral). The mean JSW in the medial compartment was 3.83 ± 2.65 mm. These results were very similar to the combined mean thickness of the TFCs derived from MRI (3.56 ± 2.06 mm). The lowest point-to-point distance was 1.478 mm (minimum JSW). Out of the 91 JSWs mapped on the medial side, a total of 8 JSWs were found to be less than 2-mm. These were all located along the anteromedial aspect and measured 1.478 mm, 1.622 mm, 1.713 mm, 1.803 mm, 1.834 mm, 1.853 mm, 1.868 mm and 1.887 mm respectively. In contrast, the mean JSW in the lateral compartment was 6.28 ± 2.50 mm, while the lowest point-to-point distance was 3.458 mm. From posterior to anterior, a trend of decreasing JSW was observed along the curvature of the joint space construct, more prominent on the medial side.
Conclusion: Multi-point analysis of JSW in accurate 3D patient-specific constructs can be useful for understanding morphological characteristics and local tissue environments in AMOA patients. As a result, more personalized treatment options could be designed, improving both clinical outcomes and procedural efficiency.

P460
MINIMALLY INVASIVE-PERCUTANEOUS SURGERY FOR TREATMENT OF MILD-TO-SEVERE GLUTEAL MUSCLE CONTRACTURE: A LESS-IS-MORE APPROACH

E. Tahir[1], Z. Zhi[1], D. G. Alemayehu[1], H. Wang[1], X. Ma[1]

[1]Dept. of Orthopedics, First Affiliated Hospital of Xi'an Jiaotong Univ., Xi'an, China

Objective: The aim of this study was to introduce a minimally invasive-percutaneous technique to achieve full-thickness fibrotic band release and to assess the clinical efficacy of this method.
Methods: 112 gluteal muscle contracture (GMC) patients (60 males, 52 females) aged between 16–44 y (mean age: 27.96 ± 4.67 y) were consecutively treated with minimally invasive-percutaneous surgery (MIPS). These were all bilateral cases, totaling 224 hips. As an adjunct to surgical planning, a dynamic musculoskeletal ultrasound (D-MSKUS) imaging protocol was implemented preoperatively. The safe zone and the optimal access points were established intraoperatively using an accurate and reproducible MIPS technique. The immediate functional improvement after fibrotic band division was assessed intraoperatively. Postoperative outcomes and complications were documented, and patient satisfaction was assessed through questionnaire. The clinical efficacy of MIPS was assessed using a standard GMC outcome evaluation scale at final follow-up.
Results: 224 hips were categorized as mild (42); slightly moderate (61); moderate (46); and severe (75) contractures. Two cases had bilateral recurrences following failed primary open surgery; both cases were treated with MIPS. The effective rate of full-thickness fibrotic band division with MIPS was 100% in all 224 hips. A maximum of three percutaneous access points were used, each only 3-mm. Mean operative time was 7.21 ± 3.78 min (unilateral). Compared to preoperative condition, there was significant functional improvement intraoperatively. Postoperatively, patients could actively overlap their legs whilst sitting and squat with their knees pressed together. Postoperative hematomas were reported in six cases; all were cured conservatively within three weeks. At the final follow-up, 165 hips had excellent results, 49 had good results, and 10 had fair results; the mean follow-up period was 2.5 y. No recurrences, infections, neurovascular injuries, or other long-term complications occurred. All patients were satisfied with the results of the surgery.
Conclusion: These findings suggest that MIPS can effectively cure mild-to-severe contractures in patients with GMC. The hallmark of this method is that it uses only two-to-three 3-mm percutaneous incisions to divide IMFBs across their full-thickness. By preserving gluteal muscle integrity, it significantly reduces surgical trauma, improves quality of life postoperatively, and facilitates faster functional recovery.

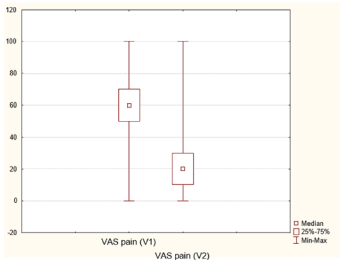
P461
EFFICACY OF BIOACTIVE CONCENTRATE OF SMALL MARINE FISH IN PATIENTS WITH CHRONIC LOW BACK PAIN

E. Taskina[1], A. Lila[1], L. Alekseeva[1], E. Strebkova[1], N. Kashevarova[1]

[1]V.A.Nasonova Research Institute of Rheumatology, Moscow, Russia

Objective: To study the efficacy of SYSADOA (bioactive concentrate of small marine fish (BCSMF) containing chondroitin sulfate, amino acids, peptides, sodium, potassium, calcium, magnesium, iron, copper and zinc ions) in patients with chronic low back pain (LBP) in a large open pilot prospective observational study.
Methods: We enrolled 10,047 patients between 40–75 years of age who had LBP for at least 12 weeks with a pain intensity > 30 mm on visual analogue scale (VAS). The median age was 60 (49–68) y, BMI was 27.9 ± 4.7 kg/m^2. The duration of the study is from 20–31 d, the number of visits is 2: visit 1 (V1)—the beginning of therapy, visit 2 (V2)—within 10 d after the completion of the 1st course of treatment. BCSMF was prescribed 1 ml intramuscular daily No. 20 or 2 ml intramuscular every other day No. 10. The effectiveness of treatment was assessed by the dynamics of pain (VAS), assessment of quality of life according to the EQ-5D and general health status (GHS) according to VAS.
Results: Against the background of one course of the BCSMF there was a significant decrease in pain intensity (V1—60 (50–70) and V2—20 (10–30) mm, $p < 0.0001$, Fig. 1), improvement in the quality of life according to EQ-5D ($p < 0.0001$) and GHS ($p < 0.0001$). The median reduction in pain (VAS) was 66.7%. A good response to therapy (pain reduction by 50% or more, n = 9789) was detected in 73%; pain reduction of less than 40 mm in 87.2% of patients. Older age, high pain intensity, poorer quality of life and concomitant pathology were associated with a lower effect of LBP therapy (pain reduction by less than 50%): coronary heart disease ($p < 0.0001$), chronic heart failure ($p < 0.0001$) and obesity ($p < 0.0001$).

Fig. 1 – Dynamics of muscle pain (on VAS) in patients with chronic low back pain



Conclusion: Although open and uncontrolled, this large pilot community-based study shows dramatic reductions in pain in patients with LBP treated with BCSMF. Taking into account and correcting factors associated with a less pronounced analgesic effect of the drug will improve the effectiveness of OA therapy.

P462
MAIN RISK FACTORS CAUSING PAIN IN EARLY OSTEOARTHRITIS: PRELIMINARY DATA

E. Taskina[1], L. Alekseeva[1], N. Kashevarova[1], E. Strebkova[1], E. Sharapova[1], N. Savushkina[1], O. Alekseeva[1], D. Kudinsky[1], N. Demin[1], A. Lila[1]

[1]V.A.Nasonova Research Institute of Rheumatology, Moscow, Russia

Objective: To identify the main risk factors associated with pain in early knee osteoarthritis (OA).
Methods: The study included 51 women with early knee OA, according to the criteria of ESCOA, who signed informed consent. The mean age of patients was 49 ± 10.4 y. An individual card was filled out for each patient, including anthropometric parameters, anamnesis, instrumental and clinical examination data. All patients underwent standard X-ray (Kellgren-Lawrence), ultrasound of the knee joints, laboratory examination.
Results: Every third patient (33.3%) had moderate or severe knee pain (≥ 40 mm according to VAS). Patients were divided into 2 groups, depending on the presence or absence of pain ≥ 40 mm according to VAS. Patients were comparable in age, disease duration. Patients with knee pain had higher BMI, indicators of WOMAC, general assessment of the patient's health status, worse data on the KOOS and DN4 ($p < 0.05$). Knee X–ray revealed larger sizes of osteophytes, knee ultrasound—synovitis (58.8 and 29.4%, OR = 1.9, 95% CI 1.01–3.7, p = 0.05), densitometry—higher values of total hip BMD, laboratory examination—higher values COMP ($p < 0.05$ for all values). Arterial hypertension (AH) (50 and 0%, OR = 11.5, 95% CI 1.6–83.9, p = 0.002), hypercholesterolemia (72.7 and 34.6%, OR = 2.2, 95% CI 1.17–4.15, p = 0.05) and metabolic syndrome (64.3 and 9.5%, OR = 6.75, 95% CI 1.7–26.7, p = 0.001) were in the presence of knee pain. The Spearman correlation analysis confirmed positive associations ($p < 0.05$ for all values) between the intensity of knee pain and all these factors. In the discriminant analysis, it was found that significant risk factors for the development of pain in early knee OA are: synovitis (clinically detectable), osteophytes (ultrasound data) and AH.
Conclusion: In a prospective study using a complex of clinical, laboratory and instrumental methods, it was shown that knee pain in early OA is caused by synovitis, the presence of osteophytes and AH. The identified risk factors should serve as a basis for the creation of individual targeted preventive and curative measures.

P463
CHANGES IN MORPHOMETRY OF OSTEOCHONDRAL UNIT IN PATIENTS WITH OSTEOARTHRITIS UNDERGOING CORRECTIVE OSTEOTOMY WITH PRP OR SVF POST-TREATMENTS DURING FOLLOW-UP

E. Tchetina[1], A. Prizov[2], A. Volkov[3]

[1]Nasonova Research Institute of Rheumatology, [2]Peoples Friendship Univ. of Russia, [3]Priorov National Medical Research Center of Traumatology and Orthopaedics, Moscow, Russia

Objective: To examine the long-term structural changes in the osteochondral unit in 20 patients with knee osteoarthritis (OA) undergoing high tibial osteotomy (HTO) with platelet-rich plasma (PRP) or stromal vascular fraction (SVF) post-treatments.
Methods: Six weeks after surgery the knees of 10 patients were injected with autologous PRP (PRP subgroup) while another 10 patients were injected with autologous SVF (SVF subgroup) and monitored during 1.5 years. Histological material containing bone and cartilage (2 mm in diameter and 2 cm long) was withdrawn at tibial and femoral sites during surgery and 1.5 y after HTO. Morphometric analyses of bone tissues were carried out using the MegaMorf12 software.
Results: Our analyses demonstrated an increase in articular cartilage height in case of both post-treatments and at both sites that can be considered as a positive outcome. Significant positive changes in the architecture of the subchondral and trabecular bones were also observed; however, SVF post-injection demonstrated higher reparative capacity related to bone volume, subchondral bone height, trabecular bone volume, and trabeculae parameters such as intertrabecular space.
Conclusion: The extent of correction obtained with HTO surgery in combination with PRP and SVF post-treatments resulted in significant improvements both at knee articular cartilage and at bone architecture in patients with OA. However, higher regenerative potential of SVF post-treatment was also noted. Our results might further improve treatment methods that facilitate better clinical outcomes of HTO therapy for patients with OA.
Acknowledgment: This study was funded by Russian Ministry of Education and Science (Project no. 1021062512064-0).

P464
POST-SURGERY PAIN DEVELOPMENT IS ASSOCIATED WITH PREOPERATIVE DISTURBANCES IN FATTY ACID TRANSPORT AND METABOLISM IN PERIPHERAL BLOOD MONONUCLEAR CELLS OF PATIENTS WITH END-STAGE KNEE OSTEOARTHRITIS

E. Tchetina[1], G. Markova[1], K. Glemba[1], M. Makarov[1]

[1]Nasonova Research Institute of Rheumatology, Moscow, Russia

Objective: To reveal the pre-operative metabolic differences in fatty acid metabolism in patients with knee osteoarthritis (KOA) associated with post-surgery pain development aiming to find intrinsic causes of chronic post-operative pain.
Methods: Peripheral blood of 26 healthy volunteers (55 ± 8.3 y) and 50 end-stage KOA patients (56.5 ± 8.9 y) undergoing knee joint replacement surgery was examined prior to surgery and 6 months' post-surgery. Nociceptive pain was assessed using VAS index whereas neuropathic pain, using DN4 and PainDETECT questionnaires prior to surgery. Functional activity was assessed by WOMAC. Pain indices after surgery according to VAS of 30% and higher were considered. Protein levels were quantified by ELISA. Total RNA was isolated from whole blood. Relative gene expression examination was performed with quantitative real-time RT-PCR prior to surgery.

Results: Out of 50 patients, pain complaints were obtained from 17 patients after 6 months post-surgery. No difference in the clinical pain-related and functional indices in the examined subsets of patients was observed at baseline. Prior to surgery the majority of the examined genes were significantly upregulated in all the examined patients compared to healthy controls. In contrast, FASN gene expression was comparable in KOA patients and healthy individuals. Patients who developed postoperative pain demonstrated significantly higher expression of ACLY and CPT1A genes compared to those who were satisfied with the results of surgery. At the same time, no differences were found in the expression of ACC1, MLYCD and FASN in both in both examined subsets was noted.
Conclusion: Postoperative pain development is associated with an increased transport of fatty acids into mitochondria, caused by overexpression of the CPT1A gene, as well as by accumulation of acetyl-CoA due to high expression of the ACLY gene, which can be assessed in the peripheral blood of patients with KOA before surgery.
Acknowledgment: This study was funded by Russian Ministry of Education and Science (Project no. 1021062512064-0).

P465
ROLE OF CLINICAL PARAMETERS AND CATHEPSIN S GENE EXPRESSION IN PREDICTING THE DEVELOPMENT OF POSTOPERATIVE PAIN IN PATIENTS WITH OSTEOARTHRITIS OF THE HIP JOINT

E. Tchetina[1], G. Markova[1], K. Glemba[1], M. Makarov[1]

[1]Nasonova Research Institute of Rheumatology, Moscow, Russia

Objective: To evaluate the significance of clinical traits and expression of the pain-related gene—cathepsin S and pro-inflammatory cytokines IL-1β, TNFα, and cyclooxygenase (COX)2 in the peripheral blood in prognosis of postoperative pain development in patients with osteoarthritis (OA) of the hip joint before arthroplasty.
Methods: The peripheral blood of 31 end-stage patients with OA (mean age 61.3 ± 9.8 y), before hip joint replacement, and 26 healthy volunteers were studied. Patients with OA were examined before and 6 months after surgery. Nociceptive pain was assessed using VAS index whereas neuropathic pain, using DN4 and PainDETECT questionnaires prior to surgery. Functional activity was assessed by WOMAC. Pain indices after surgery according to VAS of 30% and higher were considered. Protein levels were quantified by ELISA. Total RNA was isolated from whole blood. Relative gene expression examination was performed with quantitative real-time RT-PCR prior to surgery.
Results: Out of 31 patients, pain complaints were obtained from 12 patients (38.7%) after six months post-surgery. Preoperatively, gene expression of cathepsin S, IL-1β, TNFα, and COX2 was significantly higher in both patient subgroups compared with healthy controls. Moreover, neuropathic pain according to the DN4 questionnaire and the expression of the cathepsin S gene were significantly higher in patients who were dissatisfied with the outcome of arthroplasty and who retained pain syndrome, compared with the other examined patients. However, there was no significant differences in the expression of pro-inflammatory cytokine genes between the examined subgroups before arthroplasty.
Conclusion: The development of postoperative pain in patients with hip OA may be associated with impaired central sensitization while increased expression of the cathepsin S gene in the peripheral blood before surgery may serve as a prognostic biomarker of chronic pain persistence.
Acknowledgment: This study was funded by Russian Ministry of Education and Science (Project no. 1021062512064-0).

BONE MINERAL DENSITY IN POSTMENOPAUSAL WOMEN WITH RHEUMATOID ARTHRITIS

E. V. Brutskaya-Stempkovskaya[1], V. V. Prybylskaya[2], A. A. Trotskaya[2], N. A. Vasilyeva[3], M. L. Snitich[1], V. A. Sirik[1], Y. V. Dydyshko[1]

[1]Belarusian State Medical Univ., [2]Minsk Consulting and Diagnostic Center, [3]Republican Center for Medical Rehabilitation and balneotherapy, Minsk, Belarus

Objective: BMD decreasing in patients with rheumatoid arthritis is an immune-mediated secondary osteopathy. The development of osteoporosis is one of the significant complications of rheumatoid arthritis (RA), associated with the occurrence of low-traumatic fractures and an unfavorable course of the disease. Female gender, age over 50 y, and glucocorticosteroid therapy are risk factors for secondary osteoporosis in patients with RA.
Methods: A cross-sectional controlled study of 48 postmenopausal women with RA was conducted to assess BMD in postmenopausal women with RA. A comparison group included 25 postmenopausal women without RA. Exclusion criteria: age over 75 years, patients with a history of spinal injuries and diseases of the musculoskeletal system of functional classes III–IV, a decrease in GFR less than 30 ml/min, with concomitant diseases and conditions associated with a decrease in BMD. Examination: biochemical blood tests, DXA.
Results: Patients of both groups were comparable with anthropometric, anamnestic, laboratory data: glucose, cholesterol, TG, HDL, VLDL, AST, ALT, creatinine, total protein, calcium in blood serum ($p > 0.05$). The average age of the patients in the main group was 63.2 ± 6.77 y: in the control group—61.9 ± 5.23 y, U = 178.5, p = 0.165. Significantly decreasing BMD detected in patients of the main group compared with patients of the control group in the lumbar spine: T-score L2 (− 2.4 (− 2.8 to − 1.0) vs. − 1.1 (− 1.9 to − 0.2), U = 116.0, p = 0.003), T-score L3 (− 1.4 (− 2.0 to − 0.8) vs. − 0.1 (− 0.9 to 1.1) and in the proximal femur: T-score total hip L (− 1.0 (− 1.9 to 0.7) vs. − 0.1 (− 0.9 to 0.8), U = 113.5, p = 0.002), total hip R (− 1.1 (− 1.9 to − 0.8) vs. − 0.2 (− 0.9 to 0.5), U = 99.5, $p < 0.001$).
Conclusion: BMD decreased in the lumbar spine and proximal femur in postmenopausal women with rheumatoid arthritis compared postmenopausal women without rheumatoid arthritis.

P467
ASSOCIATION OF CHEMERIN WITH RHEUMATOID ARTHRITIS COMORBIDITY

E. V. Papichev[1], L. E. Sivordova[1], Y. U. R. Akhverdyan[1], Y. U. V. Polyakova[1], B. V. Zavodovsky[1]

[1]FSBI "RICER named after A.B. Zborovsky", Volgograd, Russia

Objective: To study the association between serum chemerin levels with rheumatoid arthritis comorbidity.
Methods: We enrolled 88 women with RA in our study. Standard clinical and laboratory examination was performed. Serum levels of chemerin, high-sensitive C-reactive protein (hsCRP), anti-citrullinated protein antibodies (ACPA), insulin and C-peptide levels were determined using ELISA. Homeostatic model assessment for insulin resistance (HOMA-IR) was calculated. Statistical analysis was performed using conventional methods with a software package Statistica 10.0.
Results: Median chemerin concentration was 463.5 [366–576.5] ng/ml. Chemerin concentration correlated with the age ($\rho = 0.232$; $p = 0.030$), weight ($\rho = 0.254$; $p = 0.017$) and BMI ($\rho = 0.212$; $p = 0.047$), but wasn't associated with serum levels of rheumatoid

factor, ACPA and DAS28. We observed positive correlation between serum chemerin levels with the number of tender joints (NTJ) from 28-joint counts ($\rho = 0.213$; $p = 0.046$) and hsCRP ($\rho = 0.273$; $p = 0.010$), and slightly above statistical significance with the number of swollen joints ($\rho = 0.210$; $p = 0.051$). Patients with type 2 diabetes mellitus (DM2) had higher chemerin concentration (598.0 vs. 479.5 ng/ml, U = 134.5; $p = 0.007$) and patients with cholecystectomy in anamnesis had lower (359.0 vs. 479.0 ng/ml, U = 123.5; $p = 0.043$). However, serum chemerin levels were not associated with blood glucose ($\rho = -0.02$; $p = 0.871$), serum insulin ($\rho = -0.10$; $p = 0.369$) and HOMA-IR ($\rho = -0.10$; $p = 0.353$), but were approaching statistical significance with C-peptide ($\rho = -0.20$; $p = 0.058$). Serum chemerin levels correlated with systolic and diastolic blood pressure (BP) ($\rho = -0.41$; $p < 0.001$ and $\rho = -0.27$; $p = 0.028$, respectively).

Conclusion: Chemerin concentration in women with RA correlates with age, weight, BMI, NTJ and hsCRP. Higher levels of chemerin were observed in patients with DM2 comorbidity and lower in patients comorbid with cholecystectomy in anamnesis. Chemerin levels correlates negatively with a systolic and diastolic BP.

P468
EFFECT OF SERUM ALBUMIN AND HEALTH-RELATED QUALITY OF LIFE ON POSTOPERATIVE RECOVERY IN ELDERLY HIP FRACTURE PATIENTS

W. Sirichativapee[1], E. Vanitcharoenkul[2], P. Chotiyarnwong[2], A. Unnanuntana[2]

[1]Orthopaedics Dept., Khon Kaen Univ., Khon Kaen, [2]Dept. of Orthopaedic Surgery, Faculty of Medicine Siriraj Hospital, Mahidol, Bangkok, Thailand

Objective: Over the last decade, global aging has surged, bringing increased age-related conditions. Osteoporosis, a precursor to fragility fractures, significantly impacts morbidity and mortality. Despite standard treatments, short-term studies reveal poor post-hip fracture outcomes, affecting mobility and quality of life. Malnutrition, often overlooked, affects 4% to 39.4% of elderly hip fracture patients, hindering recovery. This study aimed to establish the correlation between preoperative serum albumin levels and postoperative functional recovery in elderly hip fracture patients.

Methods: A retrospective analysis utilized data from the Fracture Liaison Service registry at a university hospital between 2016–2021. Serum albumin levels, measured upon admission, defined hypoalbuminemia as total albumin < 3.5 g/dL. Functional outcomes were assessed using Barthel index and EQ-VAS before discharge, at 3 months, and 1 year postoperatively. Multivariable logistic regression identified risk factors for poor Barthel index scores (< 60) at 1 y after surgery.

Results: A total of 1086 patients with mean age of 79.9 y and 75.8% were female, hypoalbuminemia prevalence in elderly patients with fragility hip fracture was 28.9%. Over a 1-y follow-up, all functional outcomes significantly improved compared to baseline. However, in hypoalbuminemia cases, EQ-VAS notably improved only within the initial 3 months post-surgery. Further analysis revealed low serum albumin (OR = 1.68, 95% CI 1.19–2.39; $p = 0.003$) and Charlson Comorbidity Index (CCI) ≥ 5 (OR = 3.80, 95% CI 1.49–9.70; $p = 0.005$) as factors associated with poor Barthel index scores. The risk of unfavorable functional outcomes was particularly pronounced with albumin levels below 3.8 g/dL (Youden index).

Conclusion: Our study confirms that preoperative serum albumin levels are a significant predictor of poor Barthel index scores one year after hip fracture surgery. Elevated CCI is also identified as a factor contributing to unfavorable functional outcomes. Addressing malnutrition, specifically correctable risk factors like hypoalbuminemia, in preoperative care is crucial for optimizing postoperative recovery and improving overall quality of life in elderly hip fracture patients.

P469
DYSLIPIDEMIA AND ITS RELATION WITH THE ACTIVITY OF THE DISEASE IN PATIENTS WITH SLE

E. Xherahu[1], T. Backa[2]

[1]Memorial Regional Hospital, Intern Dept., Rheumatology Clinic, [2]Mother Theresa Univ. Hospital Center, Tirana, Albania

Objective: To evaluate the association of dyslipidemia with disease activity in patients with SLE.

Methods: The study included 80 patients diagnosed with SLE hospitalized in the rheumatology service at the "Mother Teresa" University Hospital, Tirana during the period 2019–2021. All these patients met at least 4 of the 11 classification criteria for SLE, revised from the American College of Rheumatology (1997). Patients were divided into two different groups according to the SLEDAI-2k score, in the group of patients with SLE with low activity and with high activity. Dyslipidemia was defined as the presence of at least one of the following criteria: total CHOL $\geq$ 240 mg/dl, TG $\geq$ 180 mg/dl or combined hyperlipidemia. All patients underwent clinical evaluation and laboratory examination data were recorded on the lipid profile and immunological.

Results: Out of 80 patients (95.0% female), 59 patients (70% female) resulted with high activity SLE, SLEDAI-2k $\geq$ 6. Dyslipidemia was present in 45 patients (56.2%). In patients with high activity, hypercholesterolemia was in 23 patients (23.8%), and hypertriglyceridemia in patients with 29 patients (36.2%). In univariable logistic regression, dyslipidemia was associated with high disease activity index SLEDAI-2k (OR 6.00, 95% CI 1.90–18.86, $p < 0.002$). After further standardization for other risk factors for SLEDAI-2k, in multivariable logistic regressions, the association was significant (OR 12.75, 95% CI 2.44–66.42, $p < 0.02$).

Table 1

Independent predictors of SLEDAI-2k in univariable and multivariable logistic regression

	Univariable Logistic Regression			Multivariable Logistic Regression		
Variable	OR	95%CI	p value	OR	95%CI	p value
Age	0.99	0.96 – 1.03	0.94	0.97	0.91-1.03	0.46
Duration of disease	0.70	0.24- 2.01	0.51	1.09	0.95 -1.26	0.18
AntiDS-DNA	3.28	1.13-9.48	0.02	8.42	1.804-39.35	0.02
Hypokomplementemia	2.85	0.96-8.42	0.06	2.78	0.73-10.63	0.13
Proteinuria 24h	3.55	0.74-17.01	0.11	2.19	0.59-8.14	0.24
Dyslipidemia	6.00	1.90-18.86	0.002	12.75	2.44-66.42	0.02

Conclusion: Dyslipidemia was prevalent in female SLE patients, and was shown to be significantly associated with high disease activity. High levels of total Chol and TG in active SLE patients are considered as independent risk factors for premature atherosclerosis in these patients. Dyslipidemia as well as high disease activity increase the risk for atherosclerosis in patients with SLE. Dyslipidemia is an independent and modifiable risk factor of atherosclerosis.

P470
RISK FACTORS FOR RECURRENT FALLS IN A COHORT OF MIDDLE-AGED MEN AND WOMEN

E. Zaballa[1], S. D'Angelo[1], G. Ntani[1], K. Walker-Bone[2], E. Dennison[3]

[1]MRC Lifecourse Epidemiology Centre, Univ. of Southampton, Southampton, UK, [2]Monash Centre for Occupational and Environmental Health, Monash Univ., Melbourne, Australia, [3]MRC Lifecourse Epidemiology Centre, Univ. of Southampton, Southampton, UK, Southampton, UK

Objective: Falls cause disability, morbidity, and mortality across all ages. The number of falls that led to deaths and disability-adjusted life years steadily increased between 1990–2017, however most literature reporting predictors of falls focuses on people aged 65 and over. Specifically, there is a scarcity of studies evaluating risk factors for falls in community dwelling middle-aged people, thus this study addressed this evidence gap.
Methods: We used data from the Health and Employment After Fifty (HEAF) study, a longitudinal cohort that first recruited participants aged 50–64 in 2013–14. Information on health, finances, lifestyle, and employment was collected annually over 5 y. At each follow-up participants reported whether, in the preceding 12 months, they had experienced any falls. Recurrent fallers, i.e., participants who reported 2 or more falls in at least at two follow-ups were compared with those who did not. Risk factors for being recurrent fallers were explored with Poisson regression models with robust standard errors.
Results. In total 7437 people (54% women), mean age 58.7 ± 4.4 years old were included in the analysis. The prevalence of respondents reporting falling at least twice in the previous year was approximately 5% at each follow-up. While 6979 participants reported less than two falls, 458 (6.7%) were recurrent fallers. Adjusted models showed that recurrent falls were associated with: female sex (RR = 1.3; 95% CI 1.1–1.6), very slow self-reported walking speed (RR = 3.0; 95% CI 2.4–3.8), self-reporting fair or poor health (RR = 2.7 95% CI 2.1–3.4), depressive symptoms (RR = 1.8 95% CI 1.4–2.2), and not being in work (RR = 1.4 95% CI 1.2–1.8).
Conclusion: Recurrent falls are not uncommon in younger people (< 65 y) with several risk factors identified. Recognition of these may allow introduction of strategies to reduce this falls risk, and their sequelae.

P471
INFLUENCE OF WEIGHT STATUS ON BROADBAND ULTRASOUND ATTENUATION MEASURED AT THE CALCANEUS IN A GROUP OF YOUNG WOMEN

E. Zakhem[1], F. Francois[2], W. El Hawly[3], R. Hurdiel[4], T. Pezé[4], G. Zunquin[5], R. El Hage[6]

[1]Dept. of Physical Education, Univ. of Balamand, Kelhat, Deddeh El koura, Lebanon, [2]Dept. of Physical Education, Univ. of Balamand, Kelhat, Chekka, Lebanon, [3]Laboratoire Mouvement, Equilibre, Performance, Santé (MEPS), Université de Pau et des Pays de l'Adour, Campus Montaury, Anglet, France, Batroun, Lebanon, [4]Dept. STAPS, URePSSS-EA 4110, EA448, ULCO, Dunkerque, France, [5]Laboratoire Mouvement, Equilibre, Performance, Santé (MEPS), Université de Pau et des Pays de l'Adour, Campus Montaury, EA 4445, Anglet, Bordeaux, France, [6]Dept. of Physical Education, Univ. of Balamand, Kelhat, Kfarabida, Lebanon

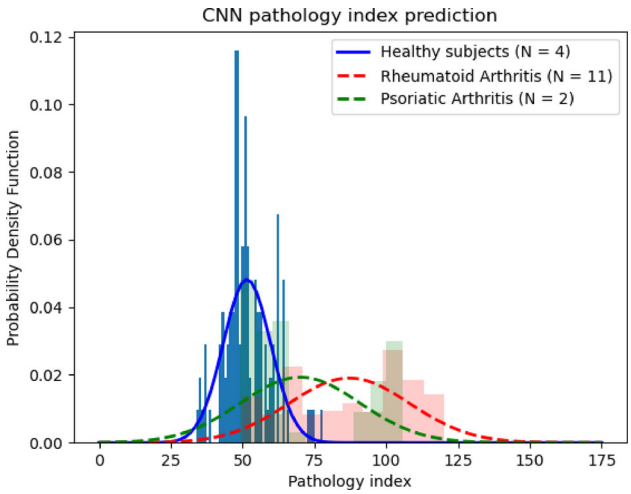
Objective: To investigate the effect of weight status on broadband ultrasound attenuation (BUA) measured at the calcaneus in a group of young women.
Methods: 369 young women [270 normal weight women (BMI < 25 kg/m^2) and 99 overweight women (BMI > 25 kg/m^2)] with an average age of 20.4 y participated in this study. Height, fat mass, lean mass, hip circumference and waist circumference were measured. Validated questionnaires were used to assess physical activity level, sleep quality and daily calcium intake. Broadband ultrasound attenuation (BUA) of the calcaneus was measured using a valid ultrasonometry device (Pegasus Smart Medlink®).
Results: BUA values were significantly higher ($p < 0.001$) in overweight group (76.6 ± 6.6) compared to normal weight group (74.4 ± 5.4).
Conclusion: Being overweight is associated with greater BMD values at the calcaneus level in young women. Therefore, being overweight seems to protect against osteoporotic fractures at the calcaneus in women.

P472
RADIOFREQUENCY ECHOGRAPHIC MULTI-SPECTROMETRY (REMS) FOR THE RECOGNITION OF MUSCULAR-TISSUE ALTERATIONS

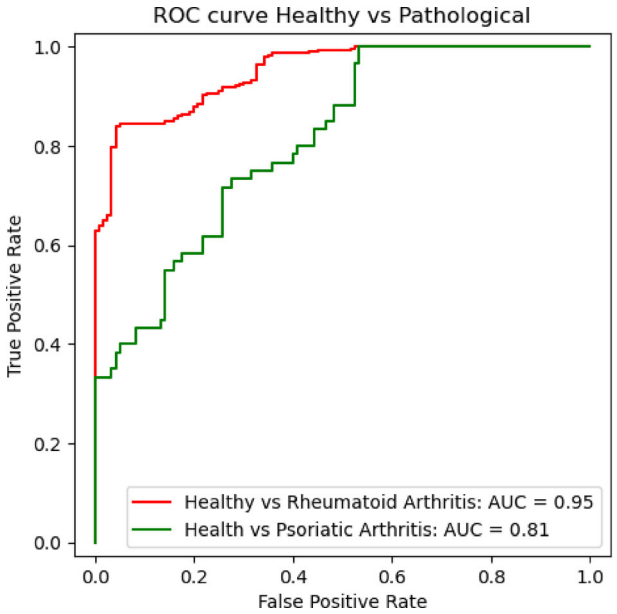
F. A. Lombardi[1], P. Pisani[1], C. Stomaci[2], L. Antelmi[3], E. Casciaro[1], R. Franchini[1], G. Luceri[3], M. Di Paola[1], F. Conversano[1], S. Casciaro[1]

[1]Institute of Clinical Physiology, National Research Council, [2]Dept. of Biological and Environmental Sciences and Technologies, Univ. of Salento, [3]R&D Dept., Echolight S.p.a., Lecce, Italy

Objective: The term "primary sarcopenia" was initially used to characterize the age-related loss of muscle mass in the elderly people. Sarcopenia has since been investigated in many clinical contexts as "secondary sarcopenia", identifying three primary pathogenic mechanisms: inflammatory response (e.g. rheumatoid arthritis (RA) and psoriatic arthritis (PA), etc.), malnutrition (e.g. malabsorptive conditions, etc.), and reduced physical activity (e.g. immobility/bed rest, etc.). Nowadays, it's important to note that ultrasound (US) techniques appear to have a strong position in this context. The ability of US to examine numerous aspects of muscle change makes it potentially helpful in the diagnostic work-up of sarcopenia. This study aims to use REMS technology to assess the pathological changes in muscular-tissue, specifically those of RA and PA subjects respect to healthy controls (HC).
Methods: A total of 17 subjects (4 HC, 11 with RA and 2 with PA) were enrolled and underwent a REMS acquisition of upper limb. The patient was acquired in a supine position with the linear probe placed transversely at the proximal third of the forearm, between the styloid process and the radius head. A novel dedicated pathology index (PI) based on the results of a classification algorithm, previously tuned on the REMS data of healthy subjects, was adopted to measure the PI on the HC, RA, and PA patients.
Results: Fig. 1 shows the histogram of PI measured for each category of subjects (HC, RA, PA), which appears to be well distinct and separated from each other.



In Fig. 2 are shown the results in terms of AUC: the algorithm is able to accurately separate images of HC from those with RA and PA, with AUC of 0.95 and AUC of 0.81 respectively for the HC vs. PA and HC vs. RA comparisons.



Conclusion: REMS is capable to discriminate the images of HC subjects from those with RA and PA. The study demonstrates that REMS technology can provide a dual assessment of muscle and bone health status.

P473
REMS TECHNOLOGY IN THE ASSESSMENT OF BONE HEALTH STATUS IN PATIENTS WITH PROSTATE CANCER

P. Pisani*[1], S. Casciaro*[1], F. R. Contaldo*[2], F. Conversano*[1], M. Di Paola*[1], R. Gifuni*[3], G. Guglielmi*[3], F. A. Lombardi*[1], M. Muratore*[4]

[1]Institute of Clinical Physiology, National Research Council, Lecce, [2]Dept. of Biological and Environmental Sciences and Technologies, Univ. of Salento, Lecce, [3]Dept. of Experimental and Clinical Medicine, Univ. of Foggia, Foggia, [4]ASL-LE, Ospedale Vito Fazzi, Lecce, Italy

Objective: In patients with prostate cancer (PCa), bone health impairment is observed, which is a frequent and harmful consequence of the high bone trophism induced by prostate cancer cells. This is also exacerbated by prolonged treatment with androgen deprivation therapy (ADT), leading to bone matrix loss (with a loss rate of 4.6%/y, up to about 10 times the normal loss) and the consequent increased risk of fractures. It is very important for this patient category to undergo constant monitoring of the bone health status. This study aims to assess the impact of prostate cancer on BMD, thanks to REMS technology (radiofrequency echographic multi-spectrometry) measurement.
Methods: A group of 35 Caucasian men with PCa and a group of healthy controls matched for gender, ethnicity, age and BMI, underwent REMS scans on the lumbar spine (LS). A t-test was then carried out to assess the difference in the values obtained between the two groups.
Results: The means ± standard deviations (SD) of age and BMI for subjects affected by PCa and healthy control are collected in the Table below:

Lumbar Spine	Age ± SD (y)	BMI ± SD (kg/m^2)
PCa	70.5 ± 6.7	25.8 ± 3.6
Healthy control	70.2 ± 6.6	25.5 ±2.5

The patients with PCa showed a significantly reduction of BMD values compared to the healthy control (0.944 ± 0.1 vs. 1.014 ± 0.1 g/cm^2, respectively p = 0.04) with a difference equal to 0.05 ± 0.10 g/cm^2.
Conclusion: The obtained results confirm, as expected, a significantly reduction of lumbar BMD in patients with PCa measured with REMS, due to the negative impact of PCa on bone health. This clinical aspect can be aggravated by the administration of androgenic deprivation therapies, which increase bone turnover and the risk of fractures. REMS technology, thanks to its diagnostic accuracy, reliability and high precision, effectively improves the management of this patient category and allows them to be short-term monitored in the with a constant follow up.

P474
SARCOPENIA KNOWLEDGE AND AWARENESS AMONG HEALTHCARE PROFESSIONALS IN SAUDI ARABIA

F. Alshahrani[1], Y. Alsulaiman[2], S. Alotieschan[3], S. Alammari[4], H. Alarfaj[4], M. Alshehri[5]

[1]King Saud bin Abdulaziz Univ. for Health Sciences, [2]King Fahad Medical City, [3]King Saud Univ. Medical City, [4]King Faisal Specialist Hospital and Research Center, [5]King Abdulaziz medical city, Riyadh, Saudi Arabia

Objective: Sarcopenia is a musculoskeletal disease in which muscle mass, strength, and performance are significantly compromised with age. Sarcopenia most commonly affects elderly and sedentary populations and patients who have comorbidities that affect the musculoskeletal system or impair physical activity (1). Sarcopenia has significant negative consequences personally, socially, medically, and economically, including an increased risk of falls, fractures, frailty, and mortality. Since sarcopenia is a silent and asymptomatic initial stage, Therefore, early assessment and subsequent interventions are important. For this, awareness among healthcare professionals is a prerequisite that requires adequate knowledge regarding the concept, diagnostic criteria, and optimal interventions. (2). We aimed to identify the healthcare professional's awareness and knowledge of sarcopenia in Saudi Arabia.
Methods: Cross-sectional study based on online self-administered questionnaire.
Results: Total of 189 healthcare professionals participated, more than 80% did not received any sarcopenia-related education in the past. Only 12% of participants were able to correctly identify the sarcopenia diagnostic criteria required for diagnosis.
Conclusion: The current study indicated that healthcare professionals had limited knowledge and awareness of sarcopenia, which could influence and impede the early diagnosis and treatment of sarcopenia in practice. Strategies to increase knowledge among healthcare professionals are crucial.

CERVICAL ARTHROSIS' IMPACT IN A TUNISIAN INDUSTRIAL REGION

F. Arfaoui[1], G. Nahdi[1], H. Ajlani[2]

[1]Faculty of Medicine of Tunisia, [2]Rheumatology Dept., Vasminet Hospital, Tunis, Tunisia

Objective: To evaluate the physical and psychological impact caused by cervical arthrosis and whether it affects the work ability of our patients.
Methods: This is a descriptive cross-sectional study carried out over a period of two months in a rheumatology unit including 60 patients, divided into two equal groups of workers and non-workers who have cervical arthrosis. We used the visual analog scale (VAS), the central sensitization inventory (CSI), the SF-12 and the neck disability index (NDI) scores to evaluate the physical and psychological impact and to type the pain in every group. The work ability index (WAI) was calculated in the working patients' group to evaluate the impact of cervicalgia on their work performance.
Results: The ratio-gender was ¼ in the two groups. The mean age in the workers group was 49.2 vs. 64.4 y in the other one. Most of the working patients have a manual job (92%), 68% work in the industry and 71% have been working for more than 10 y. Cervical neuralgia was associated to the cervicalgia in 46% of the working patients, of which 29% were unilateral, while it was more frequent (62%) and bilateral (56%) in the second group. Our patients had at least one other joint affected with osteoarthritis in more than 63% of the cases. The NDI mean score was higher in the workers' group and 42% of them had a complete disability. Central sensitization (CSI $\geq$ 40) was more frequent among the non-workers (89 vs. 83% in the workers' group). The SF-12 mean score was higher in the workers' group (36 vs. 34, and meant 70% of optimal in both groups). There was a significant association between the VAS and the CSI score, and VAS and NDI score in both of the groups; patients with high VAS had moderate to severe central sensitization and severe to complete neck disability. The quality of life (SF-12 score) was associated with the gender; male patients had lower SF-12 scores. Besides, SF-12 and WAI scores were associated with whether or not working patients had a cervical neuralgia or another joint-affection. As for the non-workers' group, the CSI and NDI scores were significantly associated with whether or not they had a cervical neuralgia. SF-12 score, VAS along with CSI and NDI scores were associated with the number of joints affected.
Conclusion: Cervical arthrosis can impact the life quality of patients, whether they were working or not. Thus, an adapted and personalized management is necessary to ease their pain and improve their prognosis.

P476
QUALITY OF LIFE OF TUNISIAN PATIENTS WITH CERVICAL ARTHROSIS

F. Arfaoui[1], G. Nahdi[1], H. Ajlani[2]

[1]Faculty of Medicine of Tunisia, [2]Rheumatology Dept., Vasminet Hospital, Tunis, Tunisia

Objective: To evaluate the type of the pain, the impact caused by cervical arthrosis and to determine the factors associated to a high neck disability.
Methods: This is a descriptive cross-sectional study carried out over a period of two months in a rheumatology unit including 50 patients who have cervical arthrosis. Patients' data was gathered through a pre-established questionnaires associated with an exhaustive examination and a radiological assessment. We used the visual analog scale (VAS) to evaluate the pain and the central sensitization inventory (CSI) to type the pain. The SF-12 and the neck disability index (NDI) were calculated to evaluate the physical and psychological impact of the pain.
Results: Most of our patients were women (80%). The mean age was 57.6 y. 92% of our patients had a manual job and 84% of them have been working for more than 10 y. 68% of the patients have at least one comorbidity. The most prevalent comorbidity was dyslipidaemia (36%). The average duration of progression of the cervicalgia was 1.8 y. 56% of our patients had cervical neuralgia associated to their cervicalgia, of which 46% were bilateral and the C6 topography was the most frequent (61%). 64% of the patients had at least one other joint affected with osteoarthritis. The totality of our patients was under medication: Non-steroidal anti-inflammatory and paracetamol. Physical rehabilitation was prescribed to 58% of them. None of our patients needed corticoid infiltration or surgery. The VAS mean of cervicalgia and radiculalgia were 6.2 and 3.8. respectively. The NDI mean score was 25.6 and 38% of the patients had a complete disability. CSI mean score was 47.92 and 86% had a central sensitization (CSI $\geq$ 40) of which 56% were moderate. The SF12 mean score was 35, which is 70% of optimal. There was a significant association between the VAS and the CSI score, as with the NDI score; patients with high VAS had central sensitization and severe to complete neck disability. Moreover we have found that the CSI and NDI scores were significantly associated with the duration of progression of the cervicalgia and whether or not a cervical neuralgia was associated. SF-12 score, VAS along with CSI and NDI scores were significantly associated with the number of joints affected. The quality of life was associated with the gender; male patients had the lowest SF-12 scores.
Conclusion: Cervical arthrosis can impact patients' quality of life, physically and psychologically, whether it was associated to a several-joint affection or not. Thus, an adapted and personalized management is necessary to ease their pain and improve their prognosis.

P477
VITAMIN D DEFICIENCY IN SUBJECTS WITH CHRONIC INFLAMMATORY DISEASES

F. Bischoff[1], S. Vladeva[2], M. Kovachev[3], E. Simeonov[3], H. Gigov[3]

[1]Rheumatology practice Stara Zagora, Stara Zagora, [2]Trakia Univ., Stara Zagora, [3]Medical Univ.-Pleven, Medical faculty, Pleven, Bulgaria

Objective: Vitamin D deficiency can occur in subjects with chronic diseases due to the known connection between vitamin D status and the activity of chronic inflammatory diseases. The aim of this work is to evaluate the vitamin D status in 63 patients suffering from chronic inflammatory diseases due to its importance for bone metabolism.
Methods: We assessed 63 patients with chronic inflammatory diseases. The mean age of the subjects was 54 $\pm$ 16 y, (range 27–75 y). 51 of the subjects (81%) were female and 12 were male (19%). 39 of 63 patients (61.9%) had rheumatoid arthritis (RA), 17 of 63 (27%) patients had psoriatic arthritis (PsA) and 7 of 63 patients (11.1%) had ankylosing spondylitis (AS). We analyzed the vitamin D_3 values of each subject and compared the mean vitamin D_3 values between the three groups. Low vitamin D_3 value was defined as a rate below 20 ng/ml. Data collection and transfer from the electronic health record was performed with an innovative JAVA tool, developed by Kirilov et al. [1,2].
Results: The mean vitamin D_3 rate was 24.3 $\pm$ 9.1 ng/ml (range 8.2–56.4 ng/ml). 20 of 63 subjects (31.7%) had low vitamin D_3 rate. The group with AS showed the lowest mean vitamin D_3 that was 19.1 $\pm$ 4.3 ng/ml with range 11.1–24.1 ng/ml. The mean vitamin D_3 in the group with RA was 23.9 $\pm$ 9.7 ng/ml. The mean vitamin D_3 in

the group with PsA was 27.5 ± 8.1 ng/ml. The differences in the mean vitamin D_3 values between the three groups were not statistically significant (p = 0.108).
Conclusion: Due to the common vitamin D deficiency in subjects with chronic inflammatory diseases, we recommend vitamin D determination in those patients.

P478
OPTIMIZING MUSCULOSKELETAL HEALTH IN AGING: A SYSTEMATIC REVIEW AND META-ANALYSIS ON THE EFFECTS OF NUTRITIONAL COUNSELING ON PHYSICAL PERFORMANCE AND MUSCLE STRENGTH

F. Buckinx[1], C. Brabant[2], O. Bruyère[2], N. Durieux[3]

[1]WHO Collaborating Centre for Public Health Aspects of Musculoskeletal Health and Ageing. Division of Public Health, Epidemiology and Health Economics, Univ. of Liège, [2]WHO Collaborating Centre for Public Health Aspects of Musculoskeletal Health and Ageing. Division of Public Health, Epidemiology and Health Economics, Univ. of Liège., [3]Research Unit for a Life-Course Perspective on Health and Education-RUCHE, Faculty of Psychology, Speech and Language Therapy and Educational Sciences, Univ. of Liège, Liège, Belgium

Objective: Nutritional counseling is emerging as a crucial component in promoting healthy eating habits and sustainable dietary practices in older adults. Despite its recognised importance, the specific influence of nutritional counseling on the musculoskeletal health in older adults remains uncertain. This study will provide a thorough synthesis of the effects of nutritional counseling compared to two different approaches: no intervention (lifestyle habits maintenance) and nutritional counseling combined with additional strategies such as nutritional supplementation and physical activity. The aim is to provide an understanding of how nutritional counseling impacts physical performance and muscle strength, thereby contributing to the optimisation of musculoskeletal health in the ageing population
Methods: This systematic review follows the JBI guidelines and a pre-defined protocol. It includes randomised and non-randomised controlled trials of people aged 65 years and older who received nutritional counseling and were assessed for physical performance or muscle strength. Extensive searches were conducted in a variety of resources. Study selection, data extraction and synthesis of results are being carried out by two researchers.
Results: Of the 1415 initial references, 1354 were included after removing duplicates. After screening of the titles and abstracts 1272 references were excluded. From the remaining 82 studies, a comprehensive full-text assessment will be conducted. Each retained study will undergo critical appraisal, and its characteristics will be detailed in a table. A narrative synthesis of the results will then be undertaken and a meta-analysis will be performed if there are studies that are sufficiently similar to be meaningfully pooled.
Conclusion: The comprehensive findings will be presented at the WCO-IOF Congress, providing a detailed overview of the impact of dietary advice on the musculoskeletal health of older adults.

P479
MITIGATING DECONDITIONING IN NURSING HOMES: A FEASIBILITY AND ACCEPTABILITY STUDY OF THE PUSH TOOL (PROMOTING THE AUTONOMY THROUGH EXERCISE IN NURSING HOME)

F. Buckinx[1], V. Libin[2], E. Peyrusqué[3], M. Aubertin-Leheudre[3], O. Bruyère[4]

[1]WHO Collaborating Centre for Public Health Aspects of Musculoskeletal Health and Ageing. Division of Public Health, Epidemiology and Health Economics, Univ. of Liège, Liège, Belgium, [2]Dept. of Sport and Rehabilitation Sciences, Univ. of Liège, Liège, Belgium, [3]Research center of the Univ. Institute of Geriatrics of Montreal, Montréal, Canada, [4]WHO Collaborating Centre for Public Health Aspects of Musculoskeletal Health and Ageing. Division of Public Health, Epidemiology and Health Economics, Univ. of Liège, Liège, Belgium

Objective: To assess the feasibility and acceptability of the PUSH (Promoting the aUtonomy through exerciSe in nursing Home) tool in nursing homes (NH).
Methods: This is a feasibility and acceptability pilot study carried out in 3 NH in the province of Liège, Belgium. The tool, through the establishment of individual abilities, assigns tailor-made exercise programmes to NH residents. To establish individual abilities, validated physical tests for muscle strength, balance and muscle endurance were assessed. Each PUSH programme includes two daily exercises combined with personalized walking or wheelchair distances. Participants were randomized into two modality groups: those who received external motivation (PUSH-EM) twice a week to complete the PUSH programme and those who did not (PUSH-NEM). In addition to socio-demographic characteristics, two acceptability indicators (adherence and satisfaction using a 4-point Likert scale) and two feasibility proxies (perceived difficulty using a 4-point Likert scale and usability using the validated SUS questionnaire) were assessed. The expected values were 80% for adherence and satisfaction, 68/100 for SUS and less than 40% for difficulty.
Results: 55 participants (PUSH-EM: n = 27 vs. PUSH-NEM: n = 28), aged 84.9 ± 7.5 years with 70.9% women and an MMSE score of 27/30 points were enrolled. The groups showed comparable adherence (PUSH-EM: 62% vs. PUSH-NEM: 63.2%; p = 0.82) and satisfaction (PUSH-EM: 91.7% vs. PUSH-NEM: 92.5%; p = 0.17). Regarding the feasibility, the groups were also similar [SUS questionnaire: PUSH-EM: 77.5 (66.9–83.1) vs. PUSH-NEM:77.5 (63.8–82.5); p = 0.75) and perceived difficulty: PUSH-EM: 33.3% vs. PUSH-NEM: 22.2%; p = 0.19)].
Conclusion: Although the adherence is slightly below the expected threshold (80%), the PUSH tool seems to be overall acceptable and feasible in NH, regardless of external motivation. Before implementing PUSH in larger scale to maintain autonomy, the assessment of its benefits is needed.

P480
ASSESSING GAMOTION'S ADAPTATION FOR REVALIDATION CENTERS: ENHANCING REHABILITATION PERSPECTIVES

F. Buckinx[1], C. Reggers[2], P. Frankinet[3], J.-Y. Reginster[1], O. Buyère[1]

[1]WHO Collaborating Centre for Public Health Aspects of Musculoskeletal Health and Ageing, Research Unit in Public Health, Epidemiology and Health Economics, Univ. of Liège, [2]Dept. of Sport and Rehabilitation Sciences, Univ. of Liège, [3]Musculoskeletal Medicine Service, CHU of Liège, Liège, Belgium

Objective: The GAMotion, a giant physical activity board game, was originally designed to promote physical activity in nursing homes. This study aims to evaluate the adaptability of the GAMotion for use in revalidation centers.
Methods: Patients and healthcare staff from the Esneux rehabilitation center were surveyed to assess their perspectives on the suitability of GAMotion (design and content) for patients undergoing rehabilitation at the center. The questionnaire comprised six closed questions rated on a 4-point Likert scale (not at all agree, disagree, somewhat agree, completely agree).
Results: Out of the 44 patients (61% men, 63.3 ± 13.1 years) surveyed, 30% had Parkinson's disease, 23% had experienced a stroke, and 73% could walk without technical support. Patients predominantly found GAMotion's design suitable (91% completely or somewhat agreed). They perceived exercises as tailored (84% somewhat or completely agreed) and easy to understand (77% somewhat or completely agreed). However, a majority felt exercise difficulty wasn't adjusted adequately (45%). Half were highly motivated (50% completely agreed). Twelve healthcare professionals (25% men, 32.3 ± 9.1 years, 92% physiotherapists) also participated. They generally found exercises suitable (75% completely or somewhat agreed). Opinions on the game square size varied (50% somewhat or completely agreed). Most observed correct exercise execution (92% somewhat or completely agreed). A majority believed GAMotion improved patients' motor capabilities (85% somewhat or completely agreed). All agreed that patients were motivated to use GAMotion.
Conclusion: Patients and healthcare professionals' positive feedback confirms GAMotion's applicability in rehabilitation. However, participants offered suggestions for improving GAMotion, including adding upper limb strengthening and increasing exercise difficulty, which could be considered in a new version.
Disclosure: FB is supported by the FNRS (Fonds National pour la Recherche Scientifique).

P481
A PROJECT OF OCCUPATIONAL THERAPY TO PREVENT SARCOPENIA IN ELDERLY PATIENTS

F. D'Amico[1], R. D'Amico[2]

[1]Univ. of Messina, Messina, [2]Rehabilitative Medicine Unit IRCCS Oasi, Troina, Italy

Objective: The aim of the integrated OT programme was to evaluate the prevalence of sarcopenia and osteoporosis in hospitalized patients in order to customize rehabilitation due to femoral fractures. Sarcopenia as a syndrome causes a progressive general muscle and muscle strength loss leading to increasing negative outcomes like disability and poor quality of life.
Methods: 73 elderly patients with femoral fractures have been hospitalized for 12 months. They have been assessed through a multifaceted (orthopedic-geriatric-rehabilitative) approach using MMSE, BADL, IADL, Barthel Index. Sarcopenia and osteoporosis were assessed through DXA bone densitometry. Sarcopenia presents: (1) muscle loss; (2) muscle strength loss; (3) reduced physical abilities. A diagnosis descends from presence of criterium #1 plus criterium +2 or #3. 27 patients with femoral fracture and sarcopenia (M #16, F #21, aged 82 ± 4) were included in the study.
Results: The standing position recovery for 43 patients started within 3 d after prosthesis surgery due to femoral fracture. They were dismissed after a 15/25-d hospitalization. 30 elderly subjects recovering from osteosynthesis regained the sitting position in 2–3 d, load tests were made between 7–14 d and they left the unit 30/45 d after admittance. At discharge 21 patients (M #9, F #12, aged 80 ± 3) affected by femoral fracture and sarcopenia were moved to the extended care unit for lack of assistance at home. There they followed an occupational therapy (OT) programme including aims like: (1) performing lower limbs mobilization through specific exercises; (2) working on muscle fibers type 2 to counterbalance the muscle loss. The group including patients following the programme was then compared to one including 8 subjects affected by femoral fracture and sarcopenia (mean age 77 ± 6) discharged and going home to their caregivers after femoral fractures. A 6-month individual OT programme at the extended care unit showed: (1) improvement in motor skills detected through scales scores (BADL 3.3/6 > 4.5/6—IADL 2.5/8 > 5.7/8—Barthel Index 50/100 > 90/100); (2) improvement both in muscle mass and muscle strength.
Conclusion: Aims of orthogeriatrics were: (1) improve mobilization and motor reactivation; (2) diagnosis and treatment in case of medical complications or comorbidity aggravation; (3) treatment of acute diseases postponing surgery; (4) customized physical activity programme at discharge. Effectiveness of a OT programme focused on motor reactivation and muscle strengthening aimed at patients discharged after femoral fractures and osteosynthesis, was evaluated. The occupational therapist approach was customized so that elderly patients continuing rehabilitation in residential structures regained self-assurance and independence.

P482
FRACTURE LIAISON SERVICES IN IRELAND: REPORT OF A 2ND NATIONAL DATABASE

F. Dockery[1], A. Glynn[1], R. Kiely[1]

[1]National Fracture Liaison Service Database, National Clinical Programme for Trauma and Orthopaedic Surgery, RCSI

Objective: Osteoporotic/'fragility' fractures are a major burden on healthcare and on society. In Ireland they occupy more bed days than cancer, heart disease or COPD and numbers are set to rise steeply, as Ireland has had the largest growth rate of older people within the EU. Fracture Liaison Service (FLS), a globally-recognised, evidence-based healthcare system is the gold standard for secondary fracture prevention and we established a national FLS database (FLS-DB) in 2020 to address fracture prevention.
Methods: Data on patients over 50 y with recent non-hip fragility fracture are captured by local FLS around the country using a web-based IT system. Data on fracture risks, falls risks, DXA, osteoporosis treatment, falls interventions and treatment adherence are recorded. Performance is measured against the International Osteoporosis Foundation (IOF) 'Capture the Fracture' Key Performance Indices.
Results: The 2nd national report for the calendar year 2022 included data from 9 FLS in Ireland. Each FLS is based in a Trauma hospital of which there are 16; the remaining 7 Trauma hospitals do not yet have a FLS. Data on 3195 fracture cases were submitted, vs. 2147 in 2021. This still represents just a third of expected fracture numbers at these 9 sites. Median patient age 69 y [50-100 y], 81% female. 35% were recommended osteoporosis drug treatment; 52% of these were of an injectable drug. Only a third of patients contacted after 4 months of their fracture could confirm they had started drug treatment as advised, highlighting the importance of this follow up call. Falls risk assessments and referral rates to exercise programmes were lower in 2022 than 2021. Though overall performance improved from 2021 in most fields, there was still a large amount of missing data and failure to meet the IOF standards.
Conclusion: The national FLS-DB is an important step towards making inroads into rising fracture numbers in Ireland. It may take a number of years of national data capture and benchmarking to impact performance however, as considerable improvements are needed in identification and management of fracture patients in Ireland based on the present data.

P483
CIRCULATING MIR-320A-3P AS POTENTIAL INDICATOR OF FRACTURE RISK IN OSTEOPOROTIC PATIENTS

F. Giusti[1], S. Donati[2], F. Marini[3], G. Palmini[3], C. Aurilia[2], I. Falsetti[2], G. Galli[2], F. Miglietta[1], T. Iantomasi[2], A. Isidori[4], L. Masi[1], M. L. Brandi[3]

[1]Metabolic Bone Diseases Unit, Univ. Hospital of Florence, AOU Careggi, Florence, [2]Dept. of Experimental and Clinical Biomedical Sciences, Univ. of Florence, Florence, [3]Fondazione Italiana Ricerca sulle Malattie dell'Osso (FIRMO Onlus), Florence, [4]Dept. of Experimental Medicine, Sapienza Univ. of Rome, Rome, Italy

Objective: The importance of microRNAs in controlling bone homeostasis and mineral metabolism has been stated. A growing number of studies have reported that several microRNAs regulate bone modelling and remodelling by modulating differentiation and activity of osteoblasts and osteoclasts. Deregulation of microRNA expression and/or activity has been associated with the occurrence of bone disorders, including osteoporosis (OP). In our previous study, we found that dysregulated serum levels of miR-320a-3p specifically correlated with fragility fracture, independently by BMD.
Methods: Cell-free total RNA containing primarily microRNAs, was extracted from sera of patients with OP fracture (PPOF) and of OP patients without any fragility fracture (PPONF). The presence of hemolysis in serum samples was assessed by spectrophotometry, evaluating the absorbance of free hemoglobin at 414 nm (A_{414}). Samples were considered hemolyzed if the A_{414} reading exceeded a value of 0.2. Differential miR-320a-3p expression was calculated by relative quantification using the $2^{-\Delta\Delta Ct}$ method, after normalization with miR-23a-3p and/or miR-21-5p. Real-Time qRT-PCR was performed in duplicate using the miRCURY LNA miRNA Probe PCR System. The diagnostic value of miR-320a-3p was calculated using Receiver Operating Characteristics (ROC) curve analysis. *p*-values less than 0.05 were statistically significant.
Results: No hemolysis was detected in our serum samples. The results of real-time qRT-PCR revealed that the expression levels of miR-320a-3p were remarkably reduced in the serum of PPOF patients compared to OP patients who did not experience any fractures. Receiver operating characteristic (ROC) curve analyses showed that serum miR-320a-3p levels normalized to miR-21-5p could discriminate PPOF from PPONF, with an area under the curve (AUC) value of 0.652 (sensitivity: 61%, specificity: 66%, cut-off value: 0.9490), while when its levels were normalized to miR-23a-3p showed an AUC value of 0.673 (sensitivity: 65%, specificity: 70%, cut-off value: 0.8815).
Conclusion: The downregulation of circulating miR-320a-3p is significantly associated with the occurrence of OP fractures. Additional studies are needed to confirm these data and to translate the use of serum miR-320a-3p as a prognostic indicator of fracture risk in OP patients into clinical settings.

P484
IMPROVING THE INTEGRATION OF FRAGILITY FRACTURE SERVICES MAY REDUCE THE SUBSEQUENT INCIDENCE OF MAJOR TRAUMA DUE TO LOW-ENERGY INJURY IN OLDER PEOPLE

F. Guerreiro[1], M. Baxter[1], S. Tilley[1]

[1]Univ. Hospital Southampton NHS Foundation Trust, Southampton, UK

Objective: Major trauma due to low-energy injury (MTLE) in the elderly population has become more common with higher mortality and increased frailty post-trauma. Fragility fracture prevention is known to provide a significant cost-saving to the healthcare system. This study analyses the incidence of prior fragility fracture or osteoporosis in the elderly population who subsequently sustained a low-energy major trauma event. The aim is to review whether fragility fracture prevention could reduce the incidence or improve outcome on MTLE patients.
Methods: The Trauma Audit & Research Network (TARN) database retrospective review on patients more than 65 years old with an Injury Severity Score (ISS) of more than 15 after a low energy injury, between 1 January 2021 to 31 December 2022 in a regional major trauma centre. Electronic health records were interrogated for evidence of previous fragility fracture, diagnosis of osteoporosis, and Fracture Liaison Service (FLS) review.
Results: 254 patients were included in the final analysis. Of these 132 (52%) were female, 122 (48%) were male with a mean age of 82.9 years old, range (65.1-103.7). There were 42 patients with evidence of previous fragility fracture, 25 patients with previous diagnosis of osteoporosis, 11 patients with both. There were 55 patients who had at least one of the factors (22%); therefore, there is an incidence of 22% of older patients presenting with major trauma who have a history of osteoporosis or fragility fracture. There is low proportion of patients with previous FLS review, 8 patients (3%). 31 patients had fragility fractures, no diagnosis of osteoporosis and no FLS review. This group has a high mortality rate at 45% in an average of 1.5 y (1.0–1.9). This cohort outcome could potentially be improved with FLS review at their index fragility fracture
Conclusion: Major trauma carries high morbidity and mortality in elderly frail patients. Although most factors may not be modifiable, there could be a potential scope to intervene a cohort with previous fragility fracture with FLS review.

P485
PERFORMANCE OF OSTEOPOROSIS SELF-ASSESSMENT TOOL FOR ASIANS (OSTA) IN IDENTIFYING POSTMENOPAUSAL WOMEN AT RISK OF OSTEOPOROSIS

F. Hajivalizadeh[1], M. Darman[1], K. Etemad[2], N. Fahimfar[3], K. Khalagi[3], A. Ostovar[4], R. Mirmoeini[5], N. Fayazi[5], F. Torkman Asadi[5], H. Ghajari[1]

[1]Non-Communicable Diseases Control and Prevention Office, Ministry of Health and Medical Education, Tehran, [2]Center for Noncommunicable Disease Control and Prevention, Ministry of Health (MOH), Tehran, [3]Osteoporosis Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran Univ. of Medical Sciences, Tehran, [4]Endocrinology and Metabolism Clinical Sciences Institute, Tehran Univ. of Medical Sciences, Tehran, [5]Non-Communicable Diseases Control and Prevention Office, Hamedan Univ. of Medical Sciences, Hamedan, Iran

Objective: The Osteoporosis Self-Assessment Tool for Asians (OSTA) score is one of screening tools has been developed to identify women at risk of osteoporosis. The objective of this study was to assess the performance of OSTA among women over 50 years old in Iran.
Methods: The study population was 953 women aged 50 or older living in Hamadan, one of the cities in the center of Iran. DXA was used as gold standard to measure BMD of participants. Osteoporosis in each area was defined as T-score ≤ -2.5 and osteopenia as $-1 >$ T-score > -2.5. The OSTA score calculated by subtracting age from weight and multiplying by 0.2. In the participants of the study, we compared the results of the OSTA with the osteoporosis status in total hip and neck of femur based on the BMD to assess the OSTA performance.

Results: The mean age of the participants was 70.43 with standard deviation 6.23. Out of 953 participants, 128 (13.43%) people had total hip osteoporosis and 446 (46.80%) had total hip osteopenia. More than half of the participants (55.36%) had neck of femur osteopenia and 18.17% had neck of femur osteoporosis. Evaluating the performance of OSTA for total hip osteoporosis showed that this risk assessment tool had a sensitivity 89.06%, specificity 47.27%, PPV 20.76%, and NPV 96.5%. Also, performance of OSTA for neck of femur osteoporosis showed a sensitivity 84.97%, specificity 48.46%, PPV 26.77%, and NPV 93.56%.
Conclusion: Overall, the OSTA had a good sensitivity to screen patients for hip and neck of femur osteoporosis. So, it is a suitable screening tool for use in the PHC where high sensitivity tools are needed.

P486
A BIBLIOMETRIC APPROACH TO THE SCIENTIFIC PRODUCTION ON FAMILIAL HYPOPHOSPHATEMIC RICKETS IN SCOPUS (2000–2022)

F. Hernández-García[1], H. Gil-Peña[2], J. Rodríguez Suárez[2], J. M. López García[1], R. Fuente Pérez[3], P. Oro Carbajosa[1], I. E. Corrales-Reyes[4]

[1]Univ. of Oviedo, Oviedo, Spain, [2]Hospital Universitario Central de Asturias, Oviedo, Spain, [3]Fundación Jiménez Díaz, Madrid, Spain, [4]Independent Researcher, Miami, USA

Objective: Hypophosphatemic rickets has been described as a disabling condition with a negative impact on physical functioning, activities of daily living, mental health, social life, and leisure activities. The most common cause are genetics such as X-linked hypophosphatemia. The evaluation of scientific production on familial hypophosphatemic rickets aids in understanding the research landscape, identifying opportunities for improvement, and promoting significant advancements in the knowledge and treatment of this medical condition.
Methods: An observational, descriptive, and cross-sectional study was conducted through a bibliometric analysis of scientific output on familial hypophosphatemic rickets, published in journals indexed in Scopus, during the 2020–2022. To retrieve the publications, Scopus was accessed on April 4, 2023, and an advanced search was performed using a filter by title, abstract and key words, source (journals), publication year, and type of articles (article and review). The terms used for the search were extracted from the PubMed Medical Subject Headings (MeSH) related to the disease included in the MeSH catalog. Additionally, an analysis of co-occurrence between countries and keywords was carried out with the VOSviewer software.
Results: The study found 1,269 articles on hypophosphatemic rickets (938 articles and 331 reviews). In total, they had received 39,548 citations with an H index of 95. The majority of the articles (76.9%) were published in high-impact journals (Q1 and Q2 journals). Scientific production shows a growing trend in recent years. The countries with the highest scientific production are the USA, Japan, and the UK, considering that middle and low-income countries contribute less to international scientific production.
Conclusion: The scientific production has shown sustained growth in recent years. USA solidifies itself as the country leading scientific production on hypophosphatemic rickets.

P487
POSSIBLE ENVOLVEMENT OF THE ENDOCANNABINOID SYSTEM IN THE ALTERED MINERALIZATION PROCESS IN MANDIBOLAR BONE FIBROUS DYSPLASIA

F. I. Falsetti[1], P. G. Palmini[2], A. C. Aurilia[1], D. S. Donati[1], M. F. Marini[2], M. L. Margheriti[3], G. G. Galli[1], Z. R. Zonefrati[2], I. T. Iantomasi[1], P. G. Picchioni[3], B. M. L. Brandi[2]

[1]Dept. of Experimental and Clinical Biomedical Sciences, Univ. of Florence, [2]Fondazione Italiana Ricerca sulle Malattie dell'Osso (F.I.R.M.O Onlus), [3]Stabilimento Chimico Farmaceutico Militare (SCFM)_Agenzia Industrie Difesa (AID), Florence, Italy

Objective: Fibrous bone dysplasia (FBD) is a rare bone disease in which bone mineralization is altered. The presence of the endocannabinoid system (ES) in bone has been demonstrated, and its possible role in bone mineralization process. Therefore, the aim of this work is to assess the alterations of the mineralization process in FBD and the involvement of ES.
Methods: First, we have evaluated the mesenchymal stem cell phenotype of the primary cell line isolated from a FBD lesion, marked as FD-1. We have evaluated the expression of the ES components genes and of osteogenic markers genes (OMGs) in normal growing conditions and in osteogenic differentiation process (OD) by TaqMan technology. The acquisition of the osteogenic phenotype has been evaluated through fluorometric assays and through cytochemical staining.
Results: The mesenchymal stem phenotype of FD-1 line and the presence of ES components under normal growing conditions has been confirmed. During OD we observed an increment of ALP activity at 14 days and a significant increase of HA deposits at 35 days. Data obtained revealed a positive modulation of OMGs in FD-1 line but, at the same time, the expression levels of OMGs resulted to be lower respect to those reported in a healthy pre-osteoblastic cell line induced to differentiate into osteoblasts. Our data revealed also that in FD-1 line under OD there is a modulation of ES components genes, like it has been observed in the healthy pre-osteoblastic cell line under OD.
Conclusion: We set up and characterized a primary mesenchymal stem cell line of FBD, reporting for the first time the presence of a stem cell population inside the FBD lesion. Our data not only confirmed that the osteoblastogenesis is altered in FBD, but also that there is a modulation of the ES components during this process which is different to that observed in healthy pre-osteoblastic cell line, leading to the hypothesis that the ES could be involved in FBD progression and representing a new way to understand the altered bone formation process of FBD.
Acknowledgments: Supported by Fondazione Ente Cassa di Risparmio di Firenze and by F.I.R.M.O Onlus.

P488
RELATIONSHIPS BETWEEN EARLY LIFE FACTORS AND OSTEOARTHRITIS PAIN: FINDINGS FROM THE HERTFORDSHIRE COHORT STUDY

F. J. Kirkham-Wilson[1], L. D. Westbury[1], N. R. Fuggle[1], F. Laskou[1], C. Cooper[1], E. M. Dennison[1]

[1]MRC Lifecourse Epidemiology Centre, Southampton, UK

Objective: Relationships between early life factors and musculoskeletal outcomes in later life have been well established, with previous reports suggesting that lower birthweight and weight at one year are associated with development of radiographic osteoarthritis (OA), specifically higher osteophyte number. Here we describe relationships between early life and development of pain among

participants with knee OA (Kellgren–Lawrence grade ≥ 2) at baseline, who were followed up for around 10 years.
Methods: 75 men and 68 women were recruited in 1998–2004. Baseline knee radiographs were taken and graded according to Kellgren- Lawrence. A mean of 10.8 years later, participants were invited to another research clinic where follow-up radiographs were taken, and pain recorded using WOMAC questionnaires. Questionnaires were administered at both time points to detail lifestyle and anthropometric factors. The analysis sample was restricted to those with radiographic knee OA at HCS baseline (K&L ≥ 2 at either tibiofemoral or patellofemoral joint on either left or right side). We also excluded participants with a history of knee replacement at either baseline or follow-up.
Results: Mean (SD) age at baseline was 64.8 (2.8) years; mean (SD) BMI was 27.5 (4.2). 41.3% of men and 50% of women had pain (WOMAC pain score > 0) at follow-up. Mean (SD) birthweight was 3.6 (0.6) kg and 3.5 (0.5) kg in men and women respectively. Greater weight at one year ($p = 0.01$) and greater infant weight gain ($p = 0.02$, independent of birthweight) were related to lower odds of knee pain at follow-up after adjustment for sex and follow-up time. For example, men with knee pain at follow-up had a mean weight at one year of 9.8 kg whereas this was 10.3 kg among men without knee pain at follow-up. Similarly, women with knee pain at follow-up had a mean weight at one year of 9.5 kg in contrast to 9.9 kg among women without pain.
Conclusion: Among subjects with baseline radiographic knee OA, greater weight gain in infancy was protective against pain associated with knee OA, attenuated after adjustment for follow-up osteophyte score. Our findings suggest associations between early life and both symptomatic and radiographic knee OA.

P489
WHAT IS THE ASSOCIATION BETWEEN REPRODUCTIVE FACTORS (EXCLUDING HRT USE) AND OSTEOARTHRITIS IN WOMEN?

K. Mcgill[1], J. Hammond[1], I. Shah[2], F. Kirkham-Wilson[1], R. Rambukwella[1], E. Dennison[1]

[1]MRC Lifecourse Epidemiology Centre, [2]Faculty of Medicine, Southampton Univ., Southampton, UK

Objective: Osteoarthritis (OA) is the most common form of arthritis. It becomes more prevalent in women around the age of menopause, leading to a higher prevalence in women compared to men in later life. It has therefore been suggested that the decrease in estrogen at menopause may be important in the pathophysiology of development of OA. The literature is conflicting however, especially around HRT use and OA, and a recent meta-analysis suggested that HRT use may actually be associated with an increased risk of joint replacement. In this systematic review we consider whether other reproductive factors are associated with an increased risk of OA.
Methods: Using PRISMA guidelines, a search strategy was generated to find articles using MEDLINE, CINAHL and Web of Science databases up to October 15, 2023. The articles were deduplicated using Endnote and imported to Rayyan where further deduplication was carried out. The titles and abstracts of the remaining articles were then screened independently by two reviewers, with final adjudication by a third reviewer. 14 papers, published over 26 years, were found to be relevant to the study. The papers were assessed for risk of bias.
Results: Of the 14 papers included, 4 were found to be of low quality. Sample size of populations studied ranged from 348 to 1134 680 with worldwide geographic variation. Hand, hip and knee OA outcomes were included. Increased parity was associated with increased risk of OA in 10 studies; use of the oral contraceptive pill was identified as a risk factor in 3 studies and spontaneous abortion and breast feeding were each associated as a risk factor in 2 studies. Relationships between higher parity and OA were observed in women of low/normal weight.
Conclusion: Several studies have suggested a positive association between several reproductive factors such as higher parity and OA. Further epidemiological analyses in newer cohorts are now required to support basic science research in this important subject area.

P490
COMPARISON OF FRAILTY SCREENING INSTRUMENTS ON PREDICTIVE OF DEPENDENCY IN THE OLDER INPATIENTS

F. O. Kayhan Kocak[1], M. Gürsu[2]

[1]Geriatric Medicine, Internal Medicine, Gazi Yaşargil Education and Research Hospital, Diyarbakır, [2]Internal Medicine, Bakircay Univ. Cigli Training and Research Hospital, İzmir, Turkey

Objective: Frailty and dependency in older patients can have significant implications for hospitalization. Older adults who are frail and dependent may face increased risks and challenges during hospital stays. The aim of this study is to evaluate the relationship between frailty screening instruments and dependency in Turkish older inpatients.
Methods: This cross-sectional study involving 127 subjects aged 65 years or older was conducted at tertiary hospital internal medicine inpatient clinic from September to November 2023. Frailty was defined by the Clinical Frailty Scale (CFS), the Seniors At Risk (ISAR) tool and Triage Risk-Screening Tool (TRST). Dependency was defined by Katz Index of Independence in Activities of Daily Living (ADL), The Lawton Instrumental Activities of Daily Living (IADL).
Results: A total of 127 subjects were examined, of which 72 (56.7%) were in the 75–101 years old subgroup with a median age of 82.5 y. There were 75 (59.1%) female subjects. According to the ADL and IADL, 44 (34.6%) and 91 (71.7%) were classified as dependency, respectively. Frailty was identified in 54 (42.5%), 108 (85.5%) and 73 (57.5%) patients according to CSF, ISAR and TRST, respectively. The AUC values of the CFS, ISAR and TRST were 0.969 (95% CI 0.942–0.996), 0.899 (95% CI 0.845–0.952) and 0.784 (95% CI 0.705–0.862) for predicting dependency in ADLs. The AUC values of the CFS, ISAR and TRST were 0.879 (95% CI 0.821–0.936), 0.760 (95% CI 0.677–0.843) and 0.737 (95% CI 0.648–0.827) for predicting dependency in IADLs.
Conclusion: Frailty, as measured by the CFS, is associated with an increased risk of adverse health outcomes, including dependency. The Clinical Frailty Scale is a valuable tool for assessing levels of frailty in older adults and, in place of the ISAR and TRST, can help healthcare providers anticipate and manage dependency issues during hospitalisation.

P491
ASSOCIATION BETWEEN FRAILTY SCALES AND THE LENGTH OF STAY AMONG OLDER PATIENTS

F. O. Kayhan Kocak[1], M. Gürsu[2], H. C. Fehmioğlu[2], B. Emekdaş[2]

[1]Geriatric Medicine, Internal Medicine, Gazi Yaşargil Education and Research Hospital, Diyarbakır, , [2]Internal Medicine, Bakircay Univ. Cigli Training and Research Hospital, İzmir, Turkey

Objective: Frailty is independently associated with morbidity and mortality among older patients. We investigated the relationship between frailty and length of stay in Turkish older inpatients.

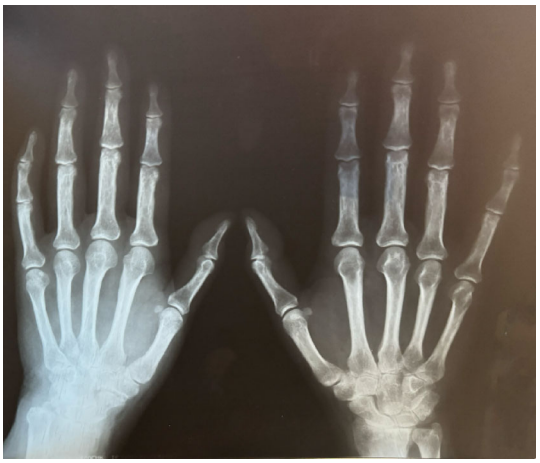
Methods: This cross-sectional study included 133 patients aged 65 years and older who were admitted from the emergency department to tertiary internal medicine inpatient unit between September 2023 and December 2023. Frailty status evaluated by the clinical frailty scale (CFS), the Seniors At Risk (ISAR) tool and Triage Risk-Screening Tool (TRST).
Results: The 133 participants (56 men, 42.1%) had a mean age of 76.8 ± 8.1 y, which ranged from 65–101. Frailty was present in 58 (43.6%), 114 (85.7%) and 76 (57.1%) of the patients according to CSF, ISAR and TRST, respectively. The mean length of stay was 6.6 ± 4.1 d. Three of the patients died during hospitalization. At the correlation analysis, we found that there was a positive correlation between the CSF score and length of hospital stay. ($p = 0.005$, $r = 0.244$). TRST and ISAR had no correlation with length of stay ($p > 0.05$, $r = 0.118$ and $p > 0.05$, $r = 0.116$, respectively).
Conclusion: We found that the frailty according to CFS is associated with a marked increase in length of stay in older patients. In the context of hospitalisation, the CFS, rather than ISAR and TRST, can play an important role in guiding healthcare decisions and providing appropriate care for older patients.

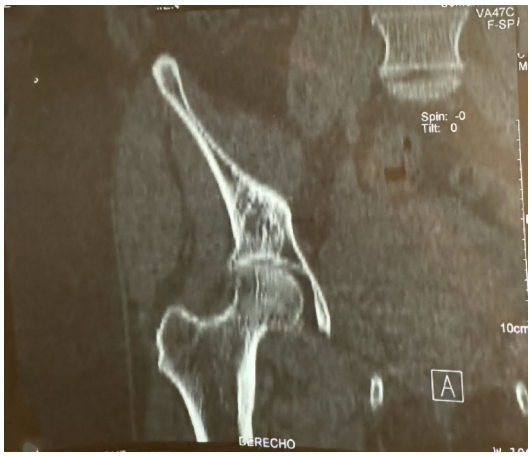
P493
RHEUMATOID ARTHRITIS AND POLYOSTOTIC PAGET'S DISEASE OF BONE: A CASE REPORT

F. Rivas Santirso[1], P. Rivas Calvo[2], J. González García[3]

[1]Rheumatology and Rehabilitation Clinic Doctores Rivas, [2]Rheumatology and Rehabilitation Clinic Doctores Rivas (Segovia) and San Pablo CEU Univ. (Madrid), [3]Radiodiagnosis Service, Recoletas Hospital, Segovia, Spain

Rheumatoid Arthritis (RA) is a systemic autoimmune disease of unknown cause that mainly causes inflammation with symmetric synovitis of the peripheral joints and usually does not involve the lumbar spine. Paget's disease of bone (PDB) is a progressive monostotic or polyostotic metabolic bone disease which is characterized by a focal abdormal bone remodeling, with increased bone resorption and new bone formation which is excessive and disorganized. RA has been associated with PDB in 1% of cases, but there are not many recent studies.
Casereport: A 61-year-old Caucasian woman who 6 months before going to the clinic had started with symmetrical polyarthritis affecting the shoulders, hands and knees, describing joint pain and stiffness mainly in the hands. Examination revealed synovitis in the carpi and knees. In laboratory tests: ESR, CRP, RF and CCP antibody values were significantly elevated. Serum alkaline phosphatase was 2 times as high as the upper normal limit. Analysis of the knee synovial fluid aspirate was consistent with inflammatory arthritis, no red blood cells or crystals and negative growth on bacterial culture. X-ray: showed symmetrical joint space narrowing and irregularities at the radiocarpal and intercarpal joints, more pronounced on the left hand. CAT scan: areas of mixed bone involvement, mainly blastic with lytic lesions affecting the vertebral bodies of L3–L4, iliac of the right left femoral shaft, trochanteric area and proximal third of the left femoral shaft. Bone scintigraphy with 99mTc: in the metabolic phase, shows pathological hyperfixation of the tracer radius in L3–L4, right iliac spine, right sacroiliac and proximal third of the left femur. Hyperfixation of the tracer in both shoulders, knees and significant pathological deposits in the wrists.





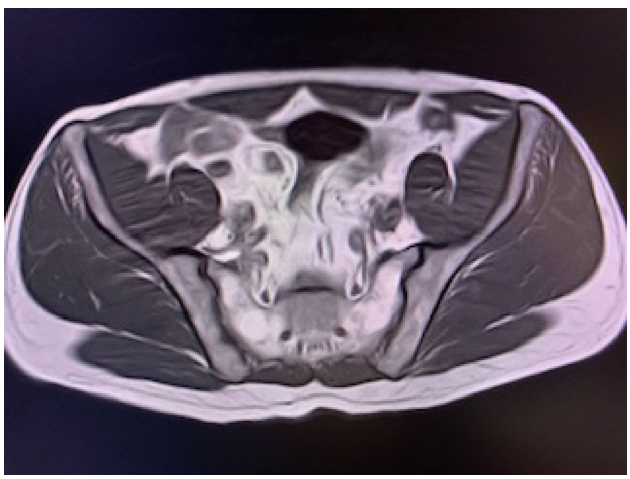
Conclusion: The diagnostic challenges associated with the rare coexistence of RA and PDB. Paget's disease of bone, should be considered as a new addition to the large family of osteoimmunological disorders. The cytokine profiles observed in this disease are also very similar to those observed in other osteoimmunological disorders that should probably be classified accordingly.

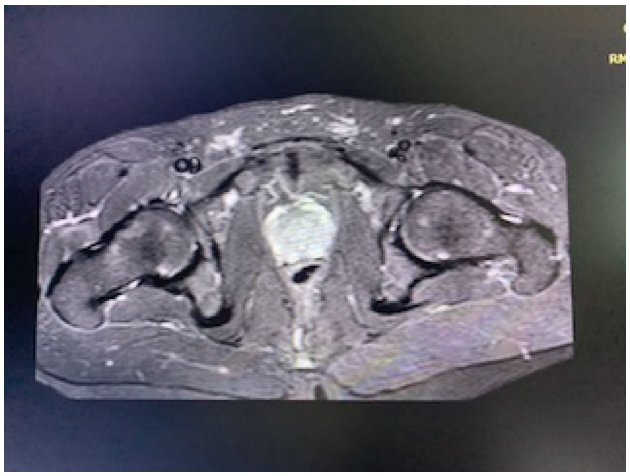
P494
ANKYLOSING SPONDYLITIS AND RADIOGRAPHIC EVIDENCE OF FEMOROACETABULAR IMPINGEMENT: A CASE REPORT

F. Rivas Santirso[1], P. Rivas Calvo[2], J. González García[3]

[1]Rheumatology and Rehabilitation Clinic Doctores Rivas, [2]Rheumatology and Rehabilitation Clinic Doctores Rivas (Segovia) and San Pablo CEU Univ. (Madrid), [3]Radiodiagnosis Service, Recoletas Hospital, Segovia, Spain

Ankylosing spondylitis (AS) is a chronic inflammatory disease of the axial skeleton with involvement of peripheral joints and non-articular structures. Main symptom is lower back pain; however, patients often present hip or groin pain misleading the clinician to think that the cause lies primarily in the hips. Hip involvement increases the burden and negative affects its prognosis of AS. Femoroacetabular impingement (FAI) has been recently identified as a major cause of early primary osteoarthritis (OA) of the hip. FAI refers to abnormal contact between the femoral head-neck junction or the acetabular rim. **Casereport**: A 38-year-old male who comes to the clinic with an inflammatory low back pain that has been going on for one year. He also reported alternating pain in the left buttocks and groin. He didn´t have systemic manifestations. His medical history included Achilles tendonitis and left plantar fasciitis. No family antecedents. Axial examination: no limitation of mobility or pain. Sacroiliac tests were positive bilaterally. Patrick's Faber and Fadir test were positive in the left hip with limitation to internal rotation. Laboratory: ESR: 34 mm/h (0–20); CRP: 12 mg/l (< 5 mg/l). HLA-B27+. The rest of the parameters (hemogram, RF, CCP-antibodies, biochemistry) were normal. X-rays: rectification of lumbar lordosis. Bilateral sacroiliitis, with subchondral sclerosis in both sacroiliac joints and partial effacement of the left and cortical erosion in the lower portion of the left joint. Loss of sphericity of both femoral heads with cam-type FAI and bilateral subchondral sclerosis. MRI: bilateral sacroiliitis with areas of signal change, pattern of edema in the subchondral bone marrow of sacral and iliac bone facets on both sides. Focal deformity in the anterosuperior contour of the cervico-capital femoral junction and increased alpha angle of both hips with cam impingement.





Conclusion: FAI pattern of hip involvement was seen in AS (36.7%), more frequent in male patients and associated with significantly greater grade of sacroiliitis (2.49 ± 1.19). Regarding type of FAI, pincer type was the most common pattern, followed by combined and cam types. Combined type FAI pattern had greater sacroiliitis score than pincer and cam-types.

P495
ASSOCIATION OF DYNAPENIA AND OBESITY WITH ALL-CAUSE MORTALITY: BIRJAND LONGITUDINAL AGING STUDY (BLAS)

M. Rahimi[1], F. Sharifi[2], M. Payab[3], M. Ebrahimpur[2], P. Ebrahimi[4], Z. Shadman[2]

[1]Endocrinology and Metabolism Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran Univ. of Medical Sciences, [2]Elderly Health Research Center, Endocrinology and Metabolism Population Sciences Institute, Tehran Univ. of Medical Sciences, [3]Non-Communicable Diseases Research Center, Endocrinology and Metabolism Population Sciences Institute, Tehran Univ. of Medical Sciences, [4]Tehran Heart Center, Tehran Univ. of Medical Sciences, Tehran, Iran

Objective: To evaluate the effect of dynapenia, obesity and all-cause mortality of community-dwelling older adults.
Methods: The results of this study were come from BLAS. This study is an aging cohort study on a community dwelling older adults (≥ 65 y) that started in 2018. The death occurrence was registered by telephone interview with the family of the participants during September 2018 to end of 2023. The death was approved by provincial death registry of Birjand University of Medical Sciences. Hand grip was measured six times (three times in each hand) the maximum values were considered as value of hand grip. Dynapenia were respectively defined based on grip strength (< 26 kg for men and < 16 kg for women). Obesity was defined by BMI categorization. Univariate and multiple Logistic regression models adjusted for age, gender and number of morbidities were used for assessing association between dynapenic obesity and death.
Results: Mean age of the 1354 participants was 69.77 ± 7.55 y and 703 subjects of the participants were female. In the model after adjustment for age and sex, dynapenia without obesity was associated with all-cause mortality (odds ratio 2.27; CI 95% 1.09–4.71, P = 0.027). In final model after adjustment for age, sex and number of morbidities dynapenia, obesity and dynapenic obesity were not associated with all-cause mortality.

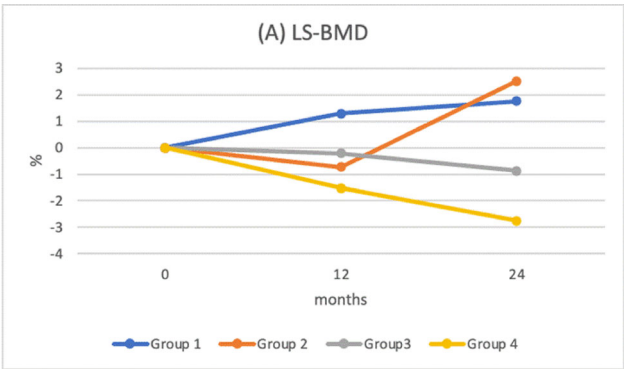
Conclusion: The risk of all-cause mortality may be higher in individuals with dynapenia but not obesity defines by BMI. Also, other factors such as presence of comorbidities may have a stronger effect on death.

P496
THERAPEUTIC STRATEGIES OF DENOSUMAB SEQUENTIAL THERAPY: A FOUR-ARMED MULTI-INSTITUTIONAL RANDOMIZED CONTROLLED TRIAL

F. Shau-Huai[1], L. Chia-Che[2], H. Chih-Chien[3], L. Chung-Yi[4], Y. Hung-Kuan[2], W. Chen-Yu[5]

[1]Dept. of Orthopedics, National Taiwan Univ. Hospital Yun-Lin Branch, Douliu, [2]Dept. of Orthopedic Surgery, National Taiwan Univ. Hospital, Taipei, [3]Dept. of Orthopedics, National Taiwan Univ. Hospital Yunlin Branch, Douliu, [4]Dept. of Public Health, College of Medicine, National Cheng Kung Univ., Tainan, [5]National Center for Geriatrics and Welfare Research, National Health Research Institutes, Yunlin, Taiwan

Objective: Denosumab, a RANKL inhibitor, is renowned for its long-term efficacy in improving BMD and reducing fracture risks. However, its discontinuation leads to a rapid rebound and BMD loss, necessitating effective follow-up interventions. This study aimed to evaluate four treatment regimens post-denosumab discontinuation in patients with osteoporosis.
Methods: The 2-y, multicenter, randomized controlled trial involved 101 postmenopausal women and men who had received biannual denosumab treatments for at least 2 y. The patients were randomized into four groups continued denosumab, zoledronate followed by denosumab, zoledronate for 2 y, and zoledronate followed by a supervised drug holiday. The primary outcome was the percent change from baseline at 24 months in BMD at various sites.
Results: An alternating regimen of denosumab and zoledronate could lead to a BMD enhancement (LS-BMD, 2.25%; IQR, 0.02–5.82%). A strategically timed zoledronate injection can maintain BMD for two years post-denosumab (BMD at the lumbar spine [LS-BMD], -0.71%; interquartile range [IQR], − 3.67% to 2.69%). However, a single zoledronate dose post-denosumab brings significant BMD loss (LS-BMD, − 2.76%; IQR, − 6.12% to 2.06%).



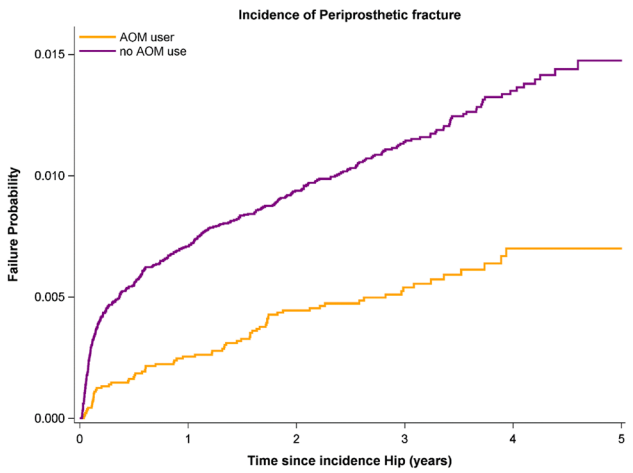
Conclusion: The study highlighted the "catch-up effect" in BMD upon resuming denosumab after a break, suggesting a potential reset in the body's response. Despite limitations like the short follow-up duration, the study provides novel insights into managing bone health post-denosumab discontinuation. Future studies should aim to validate the long-term therapeutic effect and the safety of the alternative regimen.

P497
PROGNOSIS OF PERIPROSTHETIC FRACTURES POST HIP FRACTURE: UNVEILING PROTECTIVE ROLE OF ANTI-OSTEOPOROTIC MEDICATION

F. Shau-Huai[1], Y. Hung-Kuan[2], H. Chih-Chien[3], Y. Rong-Sen[2], L. Chung-Yi[4], W. Chen-Yu[5]

[1]Dept. of Orthopedics, National Taiwan Univ. Hospital Yun-Lin Branch, Douliu, [2]Dept. of Orthopedic Surgery, National Taiwan Univ. Hospital, Taipei, [3]Dept. of Orthopedics, National Taiwan Univ. Hospital Yunlin Branch, Douliu, [4]Dept. of Public Health, College of Medicine, National Cheng Kung Univ., Tainan, [5]National Center for Geriatrics and Welfare Research, National Health Research Institutes, Yunlin, Taiwan

Objective: Periprosthetic fractures (PPF) near prior hip fracture fixation implants present formidable challenges due to intricate fracture patterns, implant presence, and compromised patient bone quality. Limited research exists on PPF prognosis in osteoporotic hip fracture patients. While anti-osteoporotic medication (AOM) effectively reduces secondary hip fracture risks, its impact on PPFs remains unexplored. Our study aims to address these gaps by assessing the influence of initiating AOM post-hip fracture on PPF occurrence and investigating PPF prognosis in a nationwide cohort of hip fracture patients.
Methods: This nationwide cohort study employs Taiwan's National Health Insurance Research Database (NHIRD) from January 1, 2016, to December 31, 2018, identifying 48,082 hospitalized hip fracture patients with concomitant procedures. Collected demographics include age, gender, comorbidities, and comedications. AOM use within one year post-hip fracture was examined. Primary outcome: periprosthetic fracture risk post-incident hip fracture. Secondary outcomes: subsequent osteoporotic fractures and PPF patient mortality. Fine and Gray's subdistribution hazard function explored risk factors and AOM effects on PPF.
Results: Among 48,082 patients with incident hip fractures, 30,182 (62.7%) were female, mean age 77.9 $\pm$ 10.7 y. Over 5 y, 443 (0.92%) developed PPF, with failure probability ranging from 0.58% (first year) to 1.25% (5-y follow-up). AOM users had lower cumulative PPF incidence at 5 y (0.53 vs. 1.08%). AOM post-hip fracture reduced PPF risk by 50% (HR = 0.5, $p < 0.0001$). Among 443 PPF patients, 22 (4.97%) had subsequent osteoporotic fractures, and 72 (16.25%) died within one year.



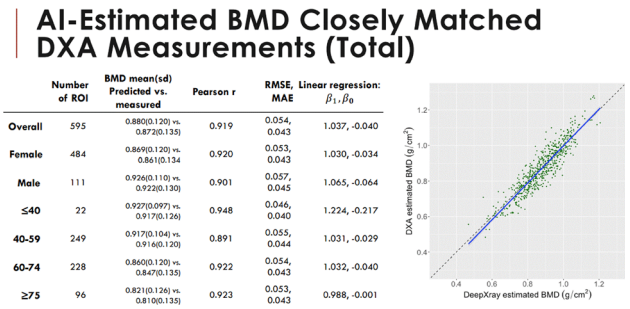
Conclusion: PPF following an incident hip fracture escalates the risk of imminent fractures and mortality within a year. Employing AOM post-hip fracture may effectively mitigate the risk of PPF.

P498
FROM PIXELS TO PREVENTION: AI-POWERED DIGITAL RADIOGRAMMETRY DEMOCRATIZES OSTEOPOROSIS DIAGNOSIS

F. Shau-Huai[1], L. Cheng Wei[2], L. Chia-Hung[2], J. Yu-Ming[2], T. Qingzong[2], L. Yen-Jun[3]

[1]Dept. of Orthopedics, National Taiwan Univ. Hospital Yun-Lin Branch, Douliu, [2]Alpha Intelligence Manifolds, Taipei, [3]Radiology Dept., Far-Eastern Memorial Hospital, New Taipei City, Taiwan

Objective: BMD, assessed through DXA, is the gold standard for diagnosing osteoporosis. However, the availability of DXA remains a challenge, especially in rural areas. This study investigates the estimation of BMD from standard pelvic radiographs as an alternative.
Methods: The study employed deidentified data from Far Eastern Memorial Hospital and three primary care clinics in Taiwan, including 2235 patients with 2321 paired pelvic radiograph-DXA samples. The BMD values obtained from standard DXA scan within $\pm$ 6 months of the Xray imaging time were used as the ground truth value for AI model training. A hip landmark model was developed to extract radiogrammetric parameters, such as Cortical Thickness Index and Femoral Neck Width. Test-time intensity augmentation and ablation studies were performed to assess feature contributions. An AI-augmented radiogrammetric BMD estimation model was developed based on the RegNet neural network architecture while incorporating radiogrammetric features. The model was trained with paired Xray-DXA data from 85% of the patients. The remaining 15% of patient data was reserved for model performance testing. Pearson correlation and RMSE between model-predicted and DXA-measured BMD were evaluated. Binary classification performance of the model for osteoporosis was also assessed.
Results: In the test set of 595 hip x-ray-DXA BMD pairs (81.3% female, mean age 61.4 y), the prevalence of osteoporosis was 24.7%. The Pearson correlation between predicted total hip BMD and measured BMD was 0.919. Subgroup analysis for female and male showed correlations of 0.920 and 0.901, respectively. Correlations remained strong across age groups. Predicted femoral neck BMD and measured BMD correlated at 0.868. Using a T-score ≤ -2.5 as the cutoff, the positive predictive value was 0.903, the negative predictive value was 0.907, and the ROC AUC was 0.950.



Conclusion: The AI model estimates BMD by radiogrammetry rather than absorptiometry, providing a robust and accurate BMD estimate that is highly correlated with DXA-measured BMD. This correlation allows rapid classification of osteoporosis according to established criteria. In addition, the implementation of an opportunistic screening strategy can expand diagnostic coverage, particularly benefiting rural areas.

P499
REAL WORLD CLINICAL OUTCOMES WHEN DISCONTINUED DENOSUMAB OR BISPHOSPHONATES IN SURGICALLY MANAGED PATIENTS WITH OSTEOPOROTIC VERTEBRAL COMPRESSION FRACTURE: A POPULATION-BASED COHORT STUDY

F. Shau-Huai[1], H. Chuan-Ching[2], W. Chen-Yu[3]

[1]Dept. of Orthopedics, National Taiwan Univ. Hospital Yun-Lin Branch, Douliu, [2]Dept. of Orthopedic Surgery, National Taiwan Univ. Hospital, Taipei, [3]National Center for Geriatrics and Welfare Research, National Health Research Institutes, Yunlin, Taiwan

Objective: The optimal osteoporosis treatment for patients with surgically treated osteoporotic vertebral compression fractures (OVCFs) is less investigated. This study compared the osteoporosis treatment outcomes between denosumab and bisphosphonates concerning subsequent osteoporotic fractures and mortality.
Methods: We conducted a retrospective nationwide cohort study using the National Health Insurance Research Database. Patients aged $\geq$ 50 y, admitted for surgical interventions for OVCF between 2012–2016, and subsequently received denosumab or bisphosphonates for one year were included. Patients were stratified according to their anti-osteoporosis medications and treatment adherence. A multivariable, time-varying Cox proportional hazards model was applied to evaluate the risks of osteoporotic fractures, vertebral fractures, non-vertebral fractures, and death.
Results: In this study of 2858 participants, denosumab (1123 patients) and bisphosphonates (1735 patients) were compared. Non-persistent denosumab users, persistent bisphosphonate users, and non-persistent bisphosphonate users had elevated risks of osteoporotic fractures (hazard ratios: 1.82, 1.78, 1.55). Non-vertebral fractures were significantly higher for non-persistent denosumab users, persistent bisphosphonate users, and non-persistent users (hazard ratios: 2.09, 1.86, 1.47). Only non-persistent bisphosphonate users showed an increased risk of vertebral fractures (hazard ratio: 1.72). Notably, non-persistent denosumab users had a significantly higher risk of death compared to persistent users (hazard ratio: 3.12).
Conclusion: Among patients with OVCFs requiring hospitalized and surgical intervention, those receiving ongoing denosumab treatment had less risk of developing subsequent osteoporotic fractures than those receiving bisphosphonates or non-persistent denosumab treatment. On the other hand, discontinuation of denosumab was associated with a significantly increased risk for subsequent fractures and death. Thus, adherence to the therapy is crucial for OVCF patients who initiated denosumab.

P500
RISK FACTORS ASSOCIATED WITH LOW BONE MINERAL DENSITY IN AXIAL SPONDYLOARTHRITIS

F. Z. Y. Heddi[1], K. Khelif[1], W. Zahdour[1], A. Benammar[1], Z. Lamri[1]

[1]Faculty of Medicine, Univ. of Oran 1, Rheumatology Dept., Oran Univ. Hospital, Oran, Algeria

Objective: To determine BMD and risk factors of low BMD in patients with spondyloarthritis.
Methods: This retrospective, single-centre study included 171 patients diagnosed with axial spondyloarthritis. BMD measurements of the lumbar spine (L1-L4) and femoral neck by DXA were used and WHO criteria were used for the diagnosis of osteopenia and osteoporosis. Univariable and multivariable linear regression analysis was performed to explore factors associated with low BMD.
Results: Of the 171 patients, 63 (41 males, 22 females) had BMDs, the mean age was 39.7 $\pm$ 14.8 y. The mean age at the diagnosis was 34.8 $\pm$ 12.9 y and the mean disease duration was 12.1 $\pm$ 9.5 y. HLAB27 was positive in 38.5% and smoking was reported by 22.2%. The mean BMI was 26.6 $\pm$ 6.8 kg/m^2 and 22 patients (34.9%) had coxitis. 72.4% had elevated erythrocyte sedimentation rate and 83% had elevated C-reactive protein levels. The mean ASDAS-CRP was 3.7 $\pm$ 1.1 and the mean BASDAI was 4.4 $\pm$ 2.3. Osteopenia and osteoporosis occurred in 23.8% and 17.5% of patients, respectively. Low BMD scores occurred in the lumbar spine in 57.7% of measurements and the femoral neck in 61.5% of measurements. Univariable linear regression showed that older age ($p = 0.004$), longer disease duration ($p = 0.02$), longer delay to diagnosis ($p = 0.006$), smoking ($p = 0.003$), obesity ($p = 0.05$), early-onset arthritis ($p = 0.04$) and the presence of biological inflammatory syndrome ($p = 0.04$) were associated with a low BMD. In multivariable linear regression analysis, only longer diagnostic delay and smoking were associated with low BMD.
Conclusion: 41.3% of patients with axial spondyloarthritis had low BMD. This decrease in BMD seems to be related to smoking and a longer diagnostic delay.

P501
IMPACT OF PERIPHERAL MANIFESTATIONS IN SPONDYLOARTHRITIS

F. Z. Y. Heddi[1], Z. Lamri[1], K. Khelif[1]

[1]Faculty of Medicine, Univ. of Oran 1, Rheumatology Dept., Oran Univ. Hospital, Oran, Algeria

Objective: To investigate the frequency of peripheral manifestations in patients with spondyloarthritis (SpA) and to evaluate their impact on treatment and patient-reported outcomes.
Methods: This observational, single-centre study included 192 patients diagnosed with SpA. Data collected were: demographics, disease characteristics, Peripheral manifestations (peripheral arthritis, peripheral enthesitis, or dactylitis), treatment, and patient-reported outcomes.
Results: 120 patients (62.5%) reported at least 1 peripheral manifestation during their disease course, 98 patients (51.0%) also had axial involvement. Among these, 13 (13.3%) showed at least 1 peripheral manifestation before axial symptoms, 59 (60.2%) concomitantly, and 26 (26.5%) after axial involvement. 57.8%, 40.6%, and 9.9% reported peripheral arthritis, peripheral enthesitis, and dactylitis, respectively. Among the whole population with peripheral joint disease, 23.4%, 37.9% and 38.7% of patients showed monoarticular, oligoarticular and polyarticular involvement, respectively. Peripheral manifestations were associated with older age ($p = 0.005$), longer disease duration ($p = 0.02$), longer delay to diagnosis ($p = 0.03$), psoriasis ($p = 0.002$), higher level of ESR ($p = 0.02$), HLA B27 negativity ($p = 0.05$), and absence of sacroiliitis on X-ray or MRI ($p = 0.03$). No significant differences were observed regarding the degree of disease activity as measured either by ASDAS or BASDAI and the function as measured by the BASFI between patients with and without peripheral involvement. Concerning treatment, 79.1% of patients with peripheral manifestation received csDMARDs, 41.6% bDMARDs and 28.7% had received glucocorticoids.
Conclusion: Peripheral manifestations appear in 62.5% of patients with SpA. Longer delay to diagnosis, psoriasis, and the absence of HLA B27 and radiographic sacroiliitis are associated with the development of peripheral symptoms.

P502
OSTEOPOROSIS AND FRAGILITY FRACTURE IN A PATIENT WITH B THALASSEMIA MAJOR: A CASE REPORT

F. Z. Y. Heddi[1], Z. Lamri[1], K. Khelif[1]

[1]Faculty of Medicine, Univ. of Oran 1, Rheumatology Dept., Oran Univ. Hospital, Oran, Algeria

Osteoporosis is a prominent cause of morbidity in β thalassemia major because of the increased risk for vertebral and long bone fractures. The aim of this case report was to raise awareness of thalassemia-induced osteoporosis, which is multifactorial, and whose management is very difficult. We present a case about a thalassemic young male with osteoporosis and multiple spine fractures.
Casereport: A 20-year-old male patient with β thalassemia major was referred to our Rheumatology Dept. for invalidating back pain with no history of trauma. The thoraco-lumbar X-ray showed a 6-level severe compression vertebral fractures of T5, T10, T11, L1, L3 and L4. Blood testing showed reduced values of hemoglobin, MCV, MCH, and vitamin D, hepatic cytolysis, and high levels of ferritine and serum alkaline phosphatase with normal calcium and phosphorus. The BMD measured by DXA was 0.324 g/cm^2 with a Z-score of − 4.5 standard deviation at the femoral neck and the total body bone density was 0.766 g/cm^2. The diagnosis of severe osteoporosis with multiple vertebral fractures was established. The patient suffered from β thalassemia major requiring transfusion once a month since childhood and iron chelating therapy with desferoxamine and he has a history of hypothyroidism, hypogonadism and splenectomy. His medications consisted of levothyroxine and testosterone undecanoate. He was treated with intravenous zoledronic acid 4 mg/y with calcium and vitamin D supplementation. The patient showed a decrease in spinal pain soon after initiation of therapy and the DXA showed a 6% increase in BMD at the femoral neck compared to the initial evaluation after one year of treatment. No further fractures were identified by VFA and thoraco-lumbar X-ray.
Conclusion: The development of osteoporosis in β thalassemia major patients is multifactorial, the factors included in this case were anemia, bone marrow expansion, Iron overload, hypogonadism, hypothyroidism and vitamin D deficiency. Zoledronic acid plus calcium, vitamin D supplementation improved the BMD.

P503
SEVERE OSTEOMALACIA SECONDARY TO UNDIAGNOSED CELIAC DISEASE: A CASE REPORT

F. Z. Y. Heddi[1], K. Khelif[1], Z. Lamri[1]

[1]Faculty of Medicine, Univ. of Oran 1, Rheumatology Dept., Oran Univ. Hospital, Oran, Algeria

Objective is to highlight the importance of considering asymptomatic celiac disease (CD) as a possible cause of osteomalacia. We describe a case report of a patient with severe osteomalacia and hyperparathyroidism.
Casereport: A 31-year-old woman, with an unremarkable medical history, was admitted to our department of rheumatology because of diffuse bone pain and proximal muscular weakness, which have progressed gradually over the last year. There was no trauma or fall. She denied any gastrointestinal symptoms. She appeared pale, and she had a waddling gait without limitation of the hips. Laboratory tests showed microcytic hypochromic anemia, hypocalcemia, hypophosphatemia, low 24-h urinary calcium and 25-hydroxy vitamin D levels, and a normal PTH level. Erythrocyte sedimentation rate, creatine phosphokinase, liver enzymes and renal function were normal. Skeletal radiographs showed Looser-Milkman fractures of the two pubic rami and costal fractures. Bone scintigraphy revealed a multifocal tracer uptake of Tc-99m. DXA scan showed a Z-score of –1.2 at lumbar spine and –2 at femoral neck. The diagnosis of osteomalacia was then confirmed. Upper gastrointestinal endoscopy with duodenal biopsy revealed diffuse villous atrophy consistent with the diagnosis of CD. Treatment with a gluten-free diet, supplemental calcium, vitamin D and iron was initiated, with a complete resolution of symptoms and normalization of biochemical parameters. At 6 months follow-up, assessment of bone and mineral metabolism revealed high calcemia, phosphaturia, 24-h urinary calcium, and PTH levels with normal phosphatemia and 25-hydroxyvitamin D levels. The findings of Sestamibi parathyroid scintigraphy were consistent with a single parathyroid adenoma, which was surgically removed. The postoperative biological assessment showed normal calcemia and PTH levels.
Conclusion: CD diagnosis should be suspected in any patient with osteomalacia. A gluten-free diet and supplemental vitamin D may reveal, during the follow-up, hyperparathyroidism with hypercalcemia masked by an undiagnosed CD.

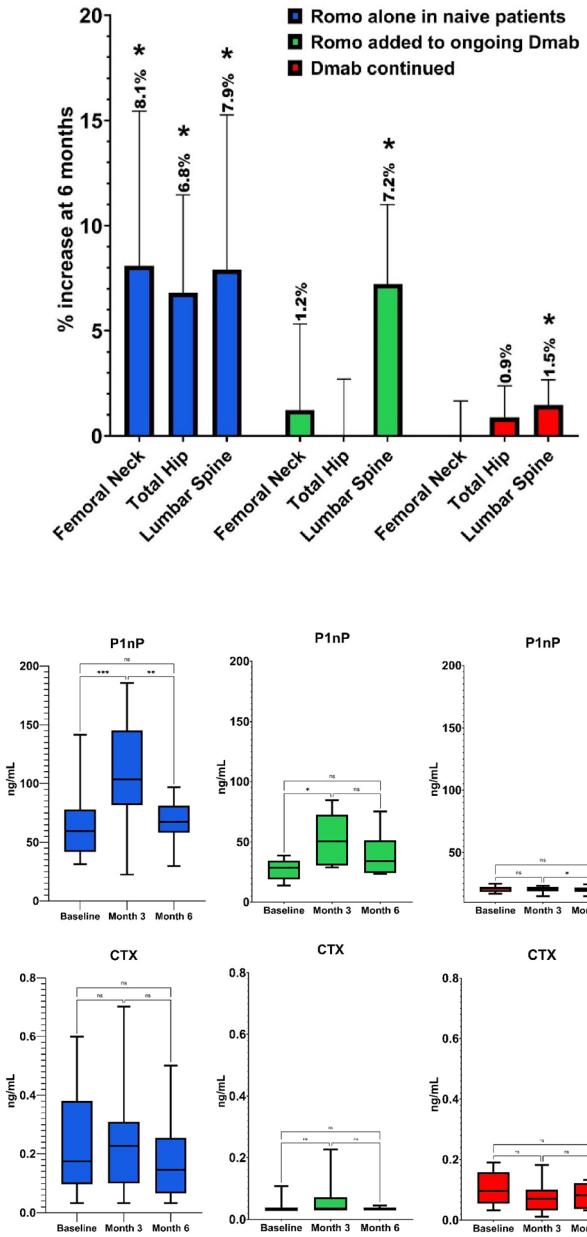
P504
ROMOSOZUMAB AND DENOSUMAB COMBINATION THERAPY IN POSTMENOPAUSAL OSTEOPOROSIS

G. Adami[1], A. Fassio[1], D. Gatti[1], O. Viapiana[1], C. Benini[1], M. Rossini[1]

[1]Univ. of Verona, Rheumatology Unit, Verona, Italy

Objective: Optimization of sequential and combination treatment is crucial in shaping long-term management of postmenopausal osteoporosis (OP). We aimed to investigate the effectiveness of the combination of romosozumab to ongoing denosumab treatment.
Methods: We conducted a 6-month prospective observational study on postmenopausal women with severe OP receiving treatment with romosozumab either alone (in patients naïve to treatment) or in combination with ongoing long-term denosumab (> 2 y). We also included a group of patients with ongoing denosumab (> 2 y) as a control group to isolate the specific effects attributable to romosozumab, especially on bone turnover markers (BTMs) and calcium metabolism. We collected serum samples for BTMs, bone modulators and calcium phosphate metabolism at baseline, month 3 and month 6. BMD was assessed at baseline and after 6 months.
Results: 52 postmenopausal women (73 ± 9.6 y) with OP were included in the study. Nineteen received romosozumab alone, 11 received romosozumab combined to ongoing denosumab and 22 continued denosumab alone. Baseline characteristics did not differ significantly between groups at baseline (including FRAXplus adjusted for recency of the fracture, 10y% fracture risk 37 ± 14 vs. 47 ± 16 vs. 33 ± 13, p NS). BMD increased significantly at all sites at 6 months of follow-up in the romosozumab alone group (femoral neck + 8.1%, total hip + 6.8% and lumbar spine + 7.9%). In contrast, BMD increased significantly only at lumbar spine in the combination group (+ 7.2%) and in the denosumab group (+ 1.5%) (Fig. 1). P1NP increased significantly in romosozumab groups at month 3 (+ 70.4% SD ± 64.5, p 0.0002 in romosozumab alone group; + 99.1% SD ± 100.5, p 0.027 in combination group). CTX decreased (not significantly) in the romosozumab alone group, whereas was suppressed (< 0.033) at all time points in combination group and denosumab alone group (Fig. 2). We found a small decline in calcium concentration at month 3 in the romosozumab alone group (− 2.8% SD ± 3.8, p 0.037), which settled back to normal concentrations at month 6 (-0.06% SD ± 4.1, p ns). Calcium did not change in the combination and denosumab alone groups. Sclerostin levels increased steeply in both romosozumab groups and Dkk1 did not change. After accounting for multiplicity using false discovery rate (Q value 5% of FDR), we found a significant positive association

between baseline sclerostin levels and delta femoral neck BMD between baseline and month 6 in patients receiving romosozumab alone (r2 0.408, p 0.047).



Conclusion: Romosozumab added to ongoing denosumab resulted in an increase in P1NP and lumbar spine BMD, but not in femoral neck BMD. For patients on denosumab, using romosozumab as an additional treatment appeared to be useful in terms of bone formation markers and spine BMD vs. denosumab alone.

P505

VALIDATION OF A NEW POINT-OF-CARE CALCANEAL ULTRASOUND DENSITOMETER (BEETLE)

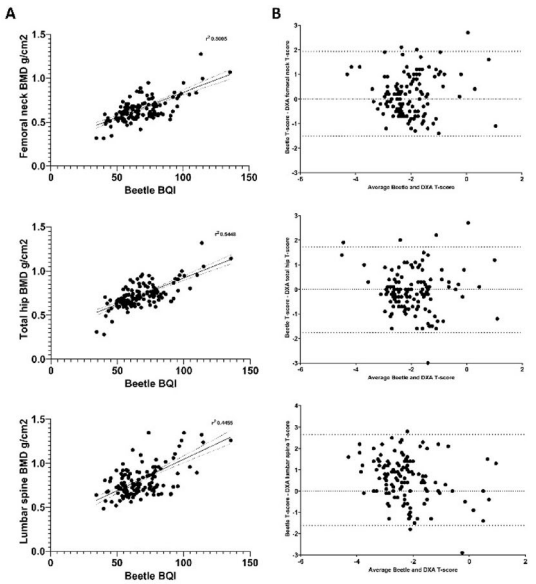
G. Adami[1], D. Gatti[1], O. Viapiana[1], C. Benini[1], A. Fassio[1], M. Rossini[1]

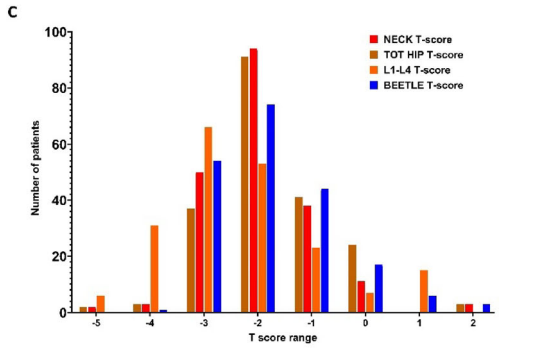
[1]Univesity of Verona, Rheumatology Unit, Verona, Italy

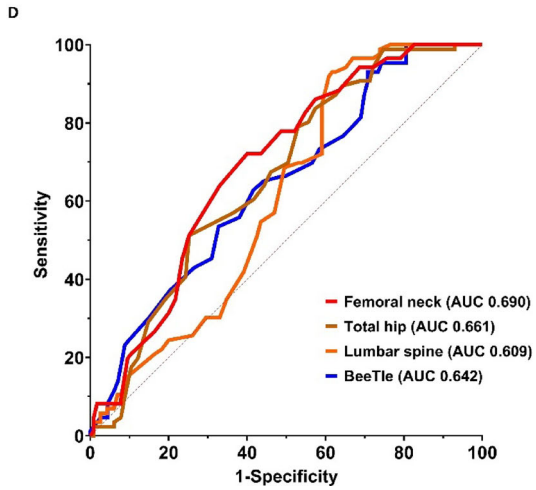
Objective: DXA represents the gold standard for measuring BMD. However, its size and bulkiness limit its use in mass screening. Portable and easily accessible instruments are more suitable for this purpose. We aimed to assess and validate a novel point-of-care ultrasound densitometer.

Methods: We conducted a study to assess the repeatability, sensitivity, accuracy, and validation of a new ultrasound densitometer for the calcaneus (BeeTLe) compared to standard DXA. BMD (g/cm^2) was measured at the femoral and lumbar spine levels using DXA (iLunar General Electric), and the Bone Quality Index (BQI, a dimensionless measure of bone quality) was measured with BeeTLe in patients attending the osteoporosis clinic at two bone specialist centers. The Bland-Altman test and simple linear regression were used to evaluate the association between values measured with the two instruments. Additionally, the ability of the T-score calculated with BeeTLe to identify patients with previous osteoporotic fractures was tested using ROC curves.

Results: A total of 201 patients (94.5% females) with a mean age of 62.1 ± 10.2 were included in the study. The BeeTLe instrument showed a coefficient of variation (CV, in 23 repeated measurements) of 1.22%, which was not statistically different from the CV of DXA (1.20%). Figure 1A shows the regression curves between BQI and BMD at the femoral neck (r2 0.500, $p < 0.0001$), total femur (r2 0.545, $p < 0.0001$), and lumbar spine (r2 0.455, $p < 0.0001$). Figure 1B displays the Bland-Altman plot for T-score differences at various sites. Figure 1C shows the distribution of T-scores with DXA and Beetle. Figure 1D presents the ROC curves describing the ability of BeeTLe and DXA at different sites to classify patients with fractures vs. non-fractured (AUC not significantly different).







Conclusion: In this preliminary study, BeeTLe, a new point-of-care ultrasound densitometer, demonstrated good repeatability and performance similar to DXA. Therefore, its use can be proposed in screening for osteoporosis.

P506
MACHINE LEARNING TO CHARACTERIZE BONE BIOMARKERS PROFILE IN RHEUMATOID ARTHRITIS

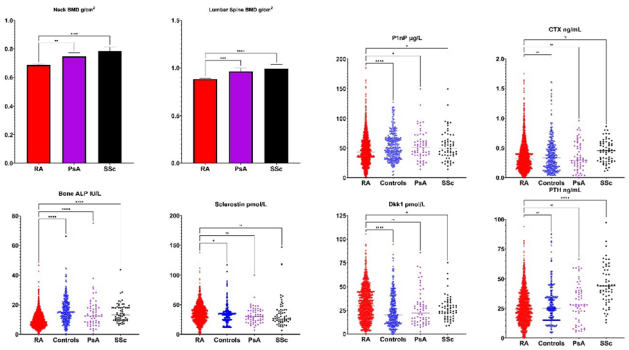
G. Adami[1], D. Gatti[1], C. Benini[1], O. Viapiana[1], A. Fassio[1], M. Rossini[1]

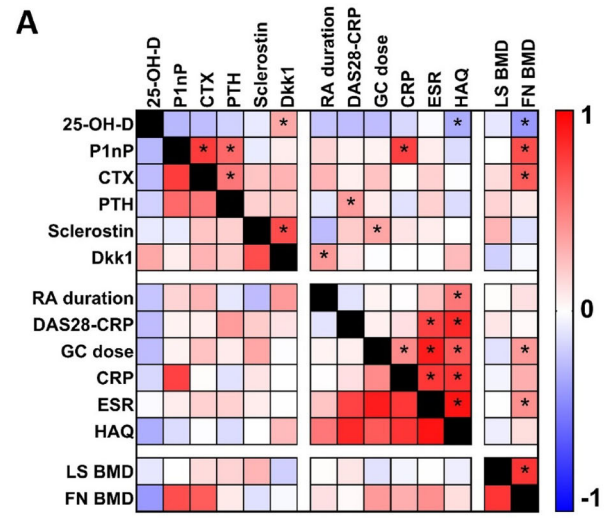
[1]Univesity of Verona, Rheumatology Unit, Verona, Italy

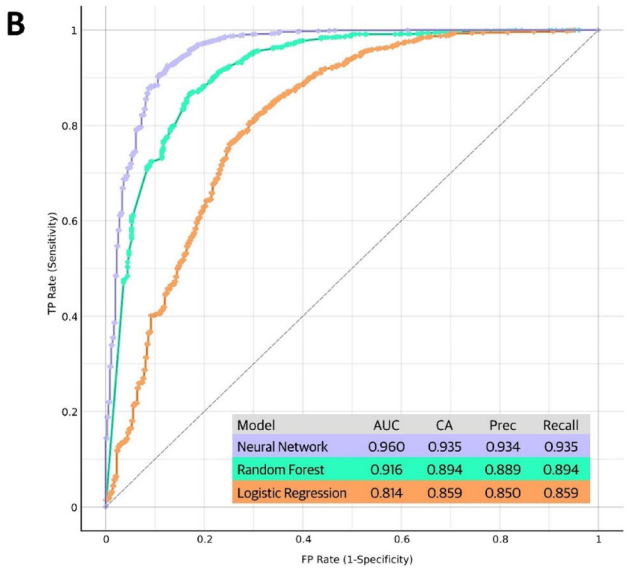
Objective: Bone metabolism is disrupted in rheumatoid arthritis (RA); however, the bone metabolic signature of RA is poorly known. The objective of the study is to further characterize the bone metabolic profile of RA and compare it to psoriatic arthritis (PsA), systemic sclerosis (SSc) and healthy controls.

Methods: We did a cross-sectional case-control study on consecutively enrolled patients and age-matched controls. We collected clinical characteristics, serum biomarkers related to bone metabolism and BMD. A multiple correlation analysis using Spearman's rank correlation coefficient was conducted within the RA patient group to investigate associations between biomarker levels and clinical variables. Machine learning (ML) models and principal component analysis (PCA) was performed to evaluate the ability of bone biomarker profiles to differentiate RA patients from controls. We ran three different ML models (random forest, neural network, logistic regression) considering the following features in addition to all serum biomarkers tested: cumulative glucocorticoid intake, age, gender, CRP levels, csDMARD and b/tsDMARD use. To assess the performance of these machine learning models, we employed standard evaluation metrics, including classification accuracy (CA), precision, recall, and receiver operating characteristic (ROC) curves with area under the curve (AUC) analysis. We implemented cross-validation (10 folds, stratified) to ensure the robustness of our models and mitigate overfitting.

Results: A total of 1883 participants were included in the analysis, comprising 1462 RA patients, 60 PsA patients, 62 SSc patients, and 359 age-matched healthy controls. We found significantly lower BMD in RA patients compared to PsA, and SSc groups. RA patients exhibited higher Dkk1, sclerostin and lower P1nP and B-ALP levels compared to controls. No significant differences in CTX levels were noted. Figure 1 shows the relevant markers. Correlation analysis revealed associations between bone biomarkers and clinical variables (Fig. 2A). PCA and ML highlighted distinct biomarker patterns in RA which can effectively discriminated bone biomarkers profile in RA from controls (Fig. 2B).







Conclusion: Our study helped uncover the distinct bone profile in RA, including changes in bone density and unique biomarker patterns. These findings enhance our comprehension of the intricate links between inflammation, bone dynamics, and RA activity, offering potential insights for diagnostic and therapeutic advancements in managing bone involvement in this challenging condition.

P507

LONG-TERM EFFECTS OF WEIGHT RESTORATION ON BONE MINERAL DENSITY (BMD) IN PATIENTS WITH ANOREXIA NERVOSA

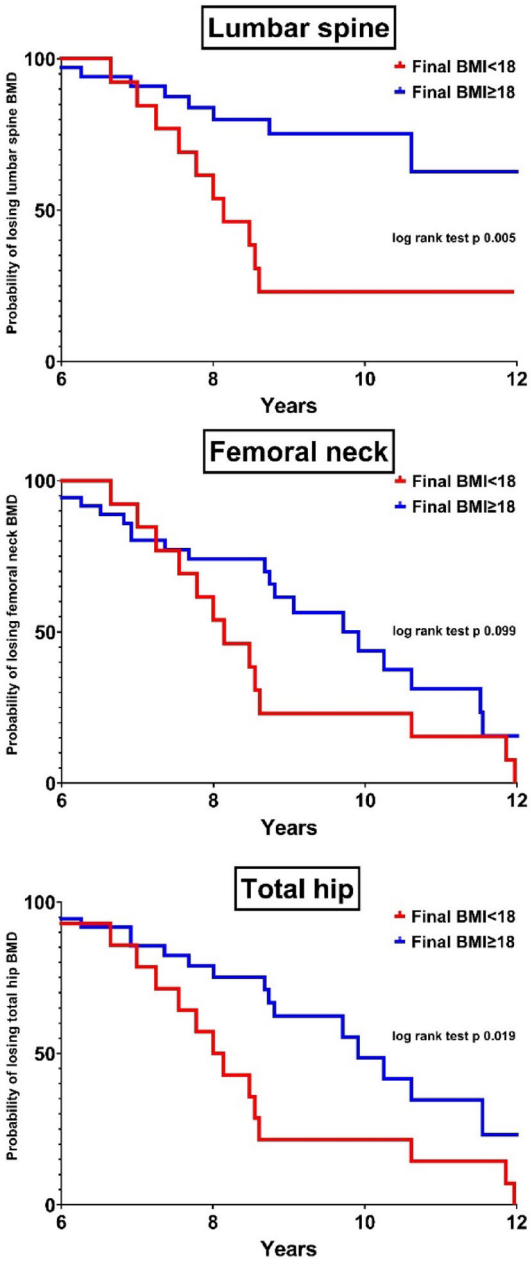
G. Adami[1], O. Viapiana[1], S. Calugi[2], M. Molgora[2], M. Chimini[2], B. Segattini[2], A. Dalle Grave[2], D. Gatti[1], R. Dalle Grave[2]

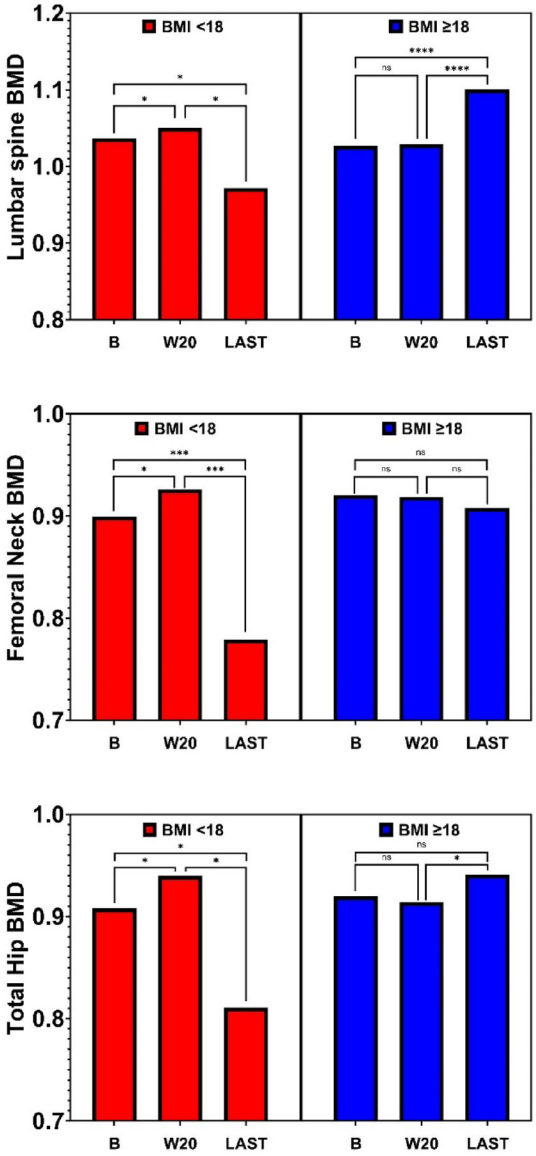
[1]Univesity of Verona, Rheumatology Unit, [2]Casa di Cura Villa Garda, Verona, Italy

Objective: Anorexia nervosa is an eating disorder characterized by extremely low BMI with consequent low BMD and higher risk of fractures. We aimed to investigate the long-term effects of body weight restoration on BMD in patients with anorexia nervosa.

Methods: We conducted a prospective observational study of patients with anorexia nervosa admitted to an eating disorder clinic for intensive weight restoration program, inpatient (20-week program) followed by an outpatient long-term follow-up. Clinical, demographic, body composition and BMD data were collected at baseline (admission), at week 20 (W20) and after > 5 y.

Results: 53 women were enrolled in the study. Mean age at baseline was 32 ± 9.2 y and the median follow-up was 8.0 y (IQR 9.1–7.0). Mean BMI at baseline was 15.8 ± 1.7. Lumbar spine BMD Z-score at baseline was -0.72 ± 1.14, femoral neck Z-score at baseline was -0.37 ± 0.97 and total hip Z-score at baseline was -0.40 ± 1.06. All patients had normal (> 20 ng/mL) 25-OH-vitamin D levels throughout the study. All subjects achieved BMI ≥ 18 at W20 and in aggregate BMD increased at all sites at W20. However, after a median follow-up of 8.1 years (IQR 7.3–8.6), 14 patients had BMI < 18 (weight loss after discharge—in red in the Figures), whereas 39 subjects kept BMI ≥ 18 over a median follow-up of 8.0 y (IQR 6.9–9.2), in blue in the Figures. Figure 1 shows the cumulative probability of losing BMD at various sites stratified by maintenance of BMI above or below the threshold of 18. Figure 2 shows the trend in BMD levels at the femur and lumbar spine in patients that maintained BMI ≥ 18 or < 18.





Conclusion: In aggregate, short-term weight restoration was associated with a significant increase in BMD at all sites. Keeping BMI $\geq$ 18 in the long term was associated with a positive non-plateau effect on lumbar spine BMD. In contrast, weight loss after discharge was associated with a significant bone loss at all sites.

P508

3D MODELING OF HIP DUAL-ENERGY X-RAY ABSORPTIOMETRY (DXA) IN POSTMENOPAUSAL WOMEN TREATED WITH ROMOSOZUMAB

G. Adami[1], O. Viapiana[1], D. Gatti[1], A. Fassio[1], C. Benini[1], M. Rossini[1]

[1]Univesity of Verona, Rheumatology Unit, Verona, Italy

Objective: Romosozumab, a sclerostin inhibitor, can increase BMD faster and to a higher extent than any other anti-osteoporotic drugs available. However, the precise effects on cortical and trabecular bone are not fully clarified. We aimed to investigate the effect of

romosozumab on three-dimensional QTC-like parameters of cortical and trabecular compartments of the proximal femur.

Methods: We conducted a 6-monhts prospective observational study on postmenopausal women treated with romosozumab. Image files of the hip DXA scans at baseline and after 6 months of romosozumab were transferred for DXA-based 3D modeling (3D-SHAPER v2.10.1, Galgo Medical, Spain). In brief, the software built a QCT-like 3D proximal femur model for each DXA image, based on a database of QCT scans from a reference population. Integral, cortical and trabecular vBMD (mg/cm^3) were extracted. Other 3D-DXA measurements included: Cortical surface sBMD (mg/cm^2), cortical BMC (g), cortical and trabecular volume (cm^3), cortical thickness (mm), cross-sectional area (CSA, cm^2) and cross-sectional moment of inertia (CSMI, cm^4).

Results: 19 postmenopausal women were included in the study. The increase in aBMD were paralleled by a significant increase in most trabecular parameters but not cortical parameters. Figure shows the 6-month % increase in 3D-DXA parameters and p-values adjusted with Holm–Šídák method. In synthesis (list not complete—see Table for absolute variations and Figure for % variations in X-axis the % increase in the parameter and in Y-axis the − log10 of the p value, the higher the more significant change): Trabecular vBMD Total (mg/cm^3) increased from 74.82 to 83.56 (SE of difference 3,43, p 0.02), integral vBMD Total (mg/cm^3) increased from 194.7 to 204.4 (SE of difference 3.79, p 0.02), CSA InterTroch (cm^2) increased from 0.97 to 1.03 (SE of difference 0,02, p 0.01) and CSMI InterTroch (cm^4) increased from 3.46 to 3.68 (SE of difference 0.09, p 0.02).

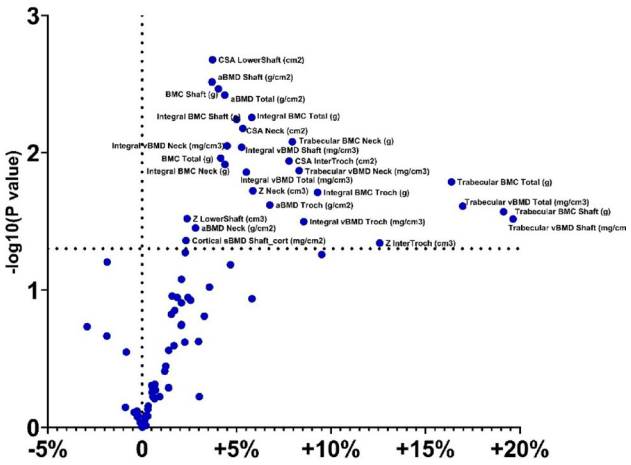
Cortical sBMD Neck (mg/cm2)	0,125	101,6	98,76	2,840	1,765



Conclusion: Romosozumab increased most trabecular 3D-DXA parameters in 6 months. Cortical parameters did not change over time.

P509
RADIOFREQUENCY ECHOGRAPHIC MULTI SPECTROMETRY (REMS) FOR NON-IONIZING ASSESSMENT OF BMD IN THE PEDIATRIC POPULATION

G. Adami[1], C. Caffarelli[2], S. Casciaro[3], A. Colucci[4], F. Conversano[3], A. Fassio[1], D. Gatti[1], S. Gonnelli[2], F. A. Lombardi[3], G. Luceri[4], P. Pisani[3], M. Rossini[1]

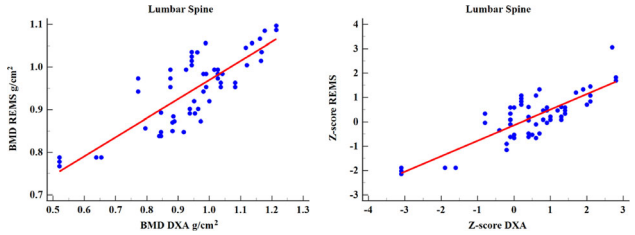
[1]Univ. of Verona, Policlinico GBRossi, Rheumatology Unit, Verona, [2]Dept. of Medicine, Surgery and Neuroscience, Univ. of Siena, Policlinico Le Scotte, Siena, [3]Institute of Clinical Physiology, National Research Council, Lecce, [4]R&D Dept., Echolight S.p.a., Lecce, Italy

*Equal contributors listed in alphabetic order

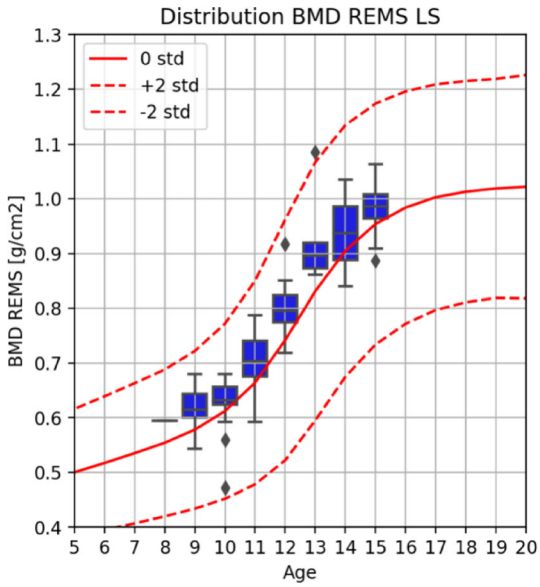
Objective: Starting from pediatric age, monitoring bone growth is important both in healthy subjects to prevent bone pathologies, and in pathological patients to timely identify any growth alteration. Since the use of X-ray is strongly restricted in pediatrics, REMS can represent a particularly suitable alternative to DXA on this patient categories thanks to its non-ionizing nature. REMS technology is already used for the assessment of bone health status and fracture prediction on the reference axial sites in adult subjects. The aim of this work is to evaluate bone health status in pediatric patients by a dedicated REMS algorithm.

Methods: In this preliminary study a cohort of 81 pediatric patients of both genders were unrolled (age < 15 y). All patients underwent REMS and DXA scan on lumbar spine (LS). Starting from REMS adults models, a new REMS-based algorithm has been developed to evaluate BMD and Z-SCORE in pediatric populations. The diagnostic agreement between REMS and DXA (BMD and Z-score parameters) was assessed by Pearson correlation coefficient.

Results: Significant correlation was found between REMS-BMD and DXA-BMD ($r = 0.81$; $p < 0.0001$), and between REMS-Z-score and DXA-Z-score ($r = 0.82$; $p < 0.0001$):



Although the number of considered patients was relatively low, for each considered age the REMS-based BMD distribution was in good agreement with the DXA-based reference curves, as shown in the Figure below.



Conclusion: The obtained results showed the REMS capability to assess the bone health status at the lumbar spine also in pediatric subjects. Therefore, REMS can represent an accurate non-ionizing technology to assess pediatric subjects, avoiding the use of X-ray on this fragile patient categories.

P510
PARTICULATED COSTAL HYALINE CARTILAGE ALLOGRAFT WITH SUBCHONDRAL DRILLING IMPROVES JOINT SPACE WIDTH AND SECOND-LOOK MACROSCOPIC ARTICULAR CARTILAGE SCORES COMPARED WITH SUBCHONDRAL DRILLING ALONE IN MEDIAL OPEN-WEDGE HIGH TIBIAL OSTEOTOMY

G. B. Kim[1], J. Y. Jung[2]

[1]Yeungnam Univ. College of Medicine, Daegu, [2]Gumi CHA Univ. Medical Center, Gumi, South Korea

Objective: To compare the articular cartilage regeneration based on second-look arthroscopy in patients who underwent medial open-wedge high tibial osteotomy (MOWHTO) combined with particulate costal hyaline cartilage allograft (PCHCA) implantation with those who underwent MOWHTO and subchondral drilling (SD). Moreover, we compared the clinical and radiographic outcomes between the groups.

Methods: From January 2014 to November 2020, patients with full-thickness cartilage defect on the medial femoral condyle who

underwent MOWHTO combined with PCHCA (group A) or SD (group B) were reviewed. Fifty-one knees were matched after propensity score matching. The status of regenerated cartilage was classified according to the International Cartilage Repair Society-Cartilage Repair Assessment (ICRS-CRA) grading system and Koshino staging system, based on second-look arthroscopic findings. Clinically, the Knee Injury and Osteoarthritis Outcome Score, the Western Ontario and McMaster Universities Osteoarthritis Index, and range of motion were compared. Radiographically, we compared the differences in the minimum joint space width (JSW) and change in JSW.

Results: The average age was 55.5 y (range, 42–64 y), and the average follow-up period was 27.1 months (range, 24–48 months). Group A showed a significantly better cartilage status than group B based on the ICRS-CRA grading system and Koshino staging system ($P < .001$ and $< .001$, respectively). There were no significant differences in clinical and radiographic outcomes between groups. In group A, the minimum JSW at the last follow-up was significantly increased than that before surgery ($P = .013$), and a significantly greater increase in JSW was observed in group A ($P = .025$).

Conclusion: When performed with MOWHTO, the combination of SD and PCHCA was associated with superior articular cartilage regeneration on the ICRS-CRA grading and Koshino staging on second-look arthroscopy performed at a minimum of 2 y follow-up than SD alone. However, there was no difference in clinical outcomes.

P511
ASSOCIATION BETWEEN SOCIAL SUPPORT AND MUSCULOSKELETAL HEALTH IN COMMUNITY-DWELLING OLDER ADULTS: FINDINGS FROM THE HERTFORDSHIRE COHORT STUDY

G. Bevilacqua[1], S. D'Angelo[1], F. Laskou[1], E. Zaballa[1], E. M. Dennison[1]

[1]MRC Lifecourse Epidemiology Centre, Univ. of Southampton, Southampton, UK

Objective: Poor physical functioning and low BMD are common in later life and are associated with increased mortality and risk of fracture. Previous studies have suggested that social support, a measure of the emotional and practical assistance within an individual's social environment, are associated with physical capability and musculoskeletal health. Here we consider how different dimensions of social support relate to grip strength, physical capability tests, and BMD among community-dwelling older adults.

Methods: Participants were recruited from the Hertfordshire Cohort Study. Confiding/emotional, practical, and negative support (indicating that a participant would have liked to confide more with someone or talking to them made things worst) were assessed using the Close Persons Questionnaire. Muscle strength was measured by grip strength dynamometry. Physical capability was assessed by timed up-and-go, chair rises, and walking speed tests. BMD was assessed using DXA (Hologic QDR 4500). Outcomes were transformed into z-scores. Linear regression was used, and estimates were adjusted for age, sex, BMI, alcohol, smoking, physical activity, social class, and diet.

Results: 1842 men and women (mean [SD] age 65.7 [2.8] y) participated. Low emotional support (vs. high) was associated with weaker grip strength and poorer physical capability tests, although estimates were not robust to adjustment. Participants who received low practical levels of support completed the timed up-and-go (β − 0.171, 95% CI − 0.319, − 0.024) and walking speed (β − 0.157, 95% CI − 0.306, − 0.007) tests in shorter times. Negative aspects of social support were associated with lower grip strength (β − 0.145, 95% CI − 0.223, − 0.067), and slower walking speeds (β 0.159, 95% CI 0.004, 0.314). No social support exposures were associated with BMD.

Conclusion: Different types of social support are differentially associated with different measures of musculoskeletal health in older adults. Not unexpectedly, a limited requirement for practical support was associated with better physical capability. However, high negative aspects of social support were also associated with poorer physical capability outcomes. In contrast to physical performance measures, no measure of social support was associated with BMD. Further work is required to better understand these relationships to develop interventions to support older adults.

P512
RELATIONSHIPS BETWEEN SELF-PERCEIVED FRACTURE RISK AND FAMILY HISTORY IN THE HERTFORDSHIRE INTERGENERATIONAL STUDY: THE SAME OR DIFFERENT TO PERCEPTIONS REGARDING HEART DISEASE RISK?

G. Bevilacqua[1], L. D. Westbury[1], C. Cooper[1], E. M. Dennison[1]

[1]MRC Lifecourse Epidemiology Centre, Univ. of Southampton, Southampton, UK

Objective: Self-perceived fracture risk (SPR) has been associated with fracture independent of FRAX objectively calculated risk, and links to osteoporosis medication uptake. A family history of fracture is an important predictor of personal fracture risk. We examined correlates of SPR among UK community-dwelling individuals, aged 21–70 y. We also compared the relationship between SPR and family history of hip fracture with the relationship between self-perceived risk of heart disease and family history of myocardial infarction.

Methods: We studied 303 participants from the Hertfordshire Intergenerational Study. Participants indicated whether they thought that their risk of breaking a bone was 'much lower', 'a little lower', 'about the same', 'a little higher' or 'much higher' compared to others of the same sex. Potential correlates examined included sociodemographic and lifestyle factors, comorbidity level (assessed by number of systems medicated) and family history of hip fracture. Associations between these exposures and SPR were explored using ordinal logistic regression with adjustment for sex and age. Statistically significant correlates ($p < 0.05$) were then included in a mutually-adjusted model along with sex and age. Relationships were compared with those between self-perceived risk of heart disease and family history of myocardial infarction.

Results: Median (lower quartile, upper quartile) age of participants was 56 (43, 61) y. The only factors related to SPR in all analyses were personal fracture history and number of systems medicated. Relationships between SPR and family history of hip fracture were much weaker than relationships between perceived heart disease risk and family history of myocardial infarction ($p = 0.37$ vs. $p < 0.001$).

Conclusion: This analysis highlights differences in perception of risk of clinical outcomes among individuals with a family history of hip fracture vs. myocardial infarction. It suggests that better education around how a family history of hip fracture impacts individual risk might be beneficial to empower individuals to make positive lifestyle and healthcare choices at a point in the lifecourse when such change might have substantial benefit.

P513
BODY COMPOSITION, BONE DENSITY AND BONE GEOMETRY IN URBAN AND RURAL INDIAN ADULTS

G. Bhat[1], A. Ireland[2], N. Shah[1], K. Gondhalekar[1], A. Khadilkar[1]

[1]Hirabai Cowasji Jehangir Medical Research Institute, Jehangir Hospital Pune, Pune, India, [2]Manchester Metropolitan Univ., Manchester, UK

Objective: Osteoporosis is a growing public health concern in India due to its large, rapidly-ageing population, whilst large-scale rural-urban migration is associated with changes in exposures such as physical activity and diet relevant to osteoporosis. We aimed to characterize differences in body composition, bone density and geometry in urban and rural Indians and study associated factors.
Methods: Sociodemography, 24 h diet recall, physical activity, tobacco consumption, sunlight exposure, anthropometry were assessed in 744 healthy urban (359) and rural (385) adults (men-346, women-398, mean age 53.3 ± 7.7 y) from Pune, India. Body composition, lumbar spine and femur BMD DXA and bone geometry at 4%/66% proximal-distal radius length (pQCT) were assessed.
Results: Rural participants had lower lean mass, fat mass, BMD and calcium intake ($p < 0.05$). Prevalence of osteoporosis was higher ($p < 0.05$) in rural men (10.7%) & women (42.6%) than urban men (6.2%) and women (18.1%). Regression analysis showed that BMD (spine/femur) was negatively associated with lower lean and fat mass indexes, increasing age, rural residence, and menopause in women. Trabecular density was positively associated with LMI in both sexes ($p < 0.05$) and calcium intake ($B = 0.024$, $p = 0.011$) in women. Periosteal circumference was higher in rural participants and was associated with LMI ($p < 0.05$). Endosteal circumference in women, was negatively associated with older age and urban residence and positively with tobacco consumption ($p < 0.05$). Stress-strain index was significantly higher in rural men and women and was positively associated with LMI ($p < 0.05$).
Conclusion: We found significant differences in body composition, bone density/geometry between urban and rural participants. While bone density (DXA) of rural participants was lower, higher bone cross-sectional area, periosteal circumference and SSIp in rural participants indicated a larger bone size with better bone strength. This could be explained by differences in genetic, environmental and lifestyle factors including mechanical loading via heavy physical activity, and greater sun exposure in rural participants. Greater endosteal circumference in rural participants indicated more age-related loss in bone mass.
Acknowledgement: Funding from Hirabai Cowasji Jehangir Medical Research Institute, Jehangir Hospital, Pune, India.

P514
OUTCOME OF ZOLEDRONIC ACID ON THE VERTEBRAL BODY BONE MINERAL DENSITY AFTER INSTRUMENTED INTERVERTEBRAL FUSION IN OSTEOPOROTIC POSTMENOPAUSAL WOMEN OF INDIA

G. C. Kakadiya[1]

[1]Topiwala National Medical College & BYL Nair Hospital, Mumbai, India

Objective: To evaluate the effect of zoledronic acid, an anti-osteoporosis treatment, during the perioperative period on vertebral body BMD after spinal fusion surgery in postmenopausal women with osteoporosis.
Methods: A Retrospective cohort study. The postmenopausal patients from India with osteoporosis who underwent instrumented intervertebral fusion for lumbar degenerative spine disease between July 2017 and May 2020 were included in this study. Patients with high comorbidities or conditions which might affect bone metabolism were excluded from this study. 92 patients did not receive any anti-osteoporosis treatment before surgery and during the postoperative follow-up (untreated group). Another 92 patients were treated with zoledronic acid perioperatively and were matched for age and BMI to patients in the untreated group. Preoperative and postoperative DXA records and lumbar BMD values of the involved spinal segments and of the cephalad levels, as well as of the femoral neck were recorded.
Results: The mean age in the treated group was 67.33 ± 10.14 and 67.17 ± 10.30 in the untreated group. a mean follow-up period of 8.89 ± 1.8 months. A significant decrease in cephalad vertebral BMD values was observed in the untreated group (− 11.46%, $P < 0.001$), with a slight decrease in the femoral neck (− 1.27%, $P > 0.05$). Zoledronic acid prevented rapid bone loss after instrumented intervertebral fusion surgery, with a bone loss in the cephalad levels of − 0.76 ± 4.73% compared to – 11.46 ± 16.45% in the untreated group ($P < 0.001$). while the change in BMD of the femoral neck in the treated group was 1.52 ± 5.89% compared to − 1.27 ± 6.57% in the untreated group ($P = 0.036$).
Conclusion: Perioperative zoledronic acid treatment may offer protection against a significant decrease in BMD of cephalad vertebrae after spinal fusion surgery among postmenopausal women with osteoporosis.

P515
ROLE OF TERIPARATIDE ON SUBSEQUENT VERTEBRAL FRACTURES AFTER SPINE FIXATION SURGERY FOR OSTEOPOROTIC VERTEBRAL COMPRESSION FRACTURES

G. C. Kakadiya[1]

[1]Topiwala National Medical College & BYL Nair Hospital, Mumbai, India

Objective: To assess the incidence and effect of teriparatide on subsequent vertebral fractures following a long-instrumented fusion surgery for osteoporotic vertebral compression fractures (OVCFs).
Methods: A retrospective study. A total of 94 patients who underwent long-instrumented fusion surgery (≥ 3 levels) for OVCFs with neurological deficits between 2016–2020 were enrolled in this study. Teriparatide was used in 38 patients (TP group). The mean age of the subjects was 75.6 y. The average of fused vertebrae was 4.9. The incidence of subsequent vertebral fractures was estimated with Kaplan–Meier analyses and compared between both groups using the log-rank test. Risk factors were evaluated using a Cox proportional hazards model.
Results: A total of 38% (36/94 cases) of the subjects were identified with subsequent vertebral fractures. There were no significant differences in the age, sex, fused levels, presence of prevalent fractures, and correction loss of the two groups. The occurrence of subsequent vertebral fractures was lower in the TP group than in the non-TP group (16 vs. 54%, $p = 0.014$). The log-rank test revealed that the TP treatment significantly reduced the risk of subsequent vertebral fractures ($p = 0.048$). A Cox proportional hazards model revealed that preoperative teriparatide treatment is only a protective factor of subsequent vertebral fractures after instrumented fusion surgery for OVFs (hazard ratio, 0.281; $p = 0.047$).
Conclusion: In this retrospective study, pre-and postoperative teriparatide treatment significantly reduced the incidence of subsequent vertebral fractures after instrumented fusion surgery for OVFs. A prospective randomized study is warranted to determine the efficacy of teriparatide treatments.

P516
POOR BONE QUALITY IN APPARENTLY HEALTHY MALES OFTEN NEGLECTED CLINICAL ENTITY

G. C. Kakadiya[1]

[1]Topiwala National Medical College & BYL Nair Hospital, Mumbai, India

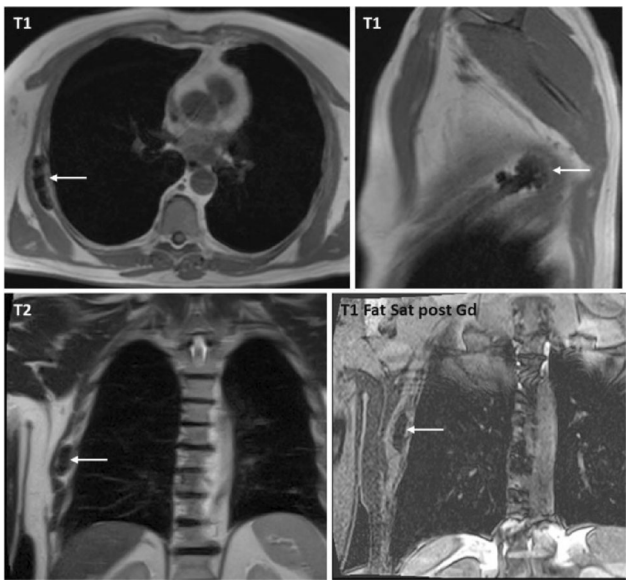
Objective: Current guidelines recommend BMD measurement in asymptomatic men above age 70 y and vertebral fracture assessment above 80 years with T-score < -1.0 with risk factors. We studied the prevalence of osteoporosis and morphometric vertebral fracture in asymptomatic males aged 60 y and above in India.
Methods: Free-living community-dwelling men (n = 482, age: mean ± standard deviation 68.0 ± 6.2 y) underwent a detailed history, physical examination, biochemical evaluation, and BMD measurements at three different sites: lumbar spine, total hip (TH), and femoral neck (FN). Morphometric vertebral fractures were assessed by instant vertebral assessment using Genant's semiquantitative method.
Results: We observed osteoporosis, osteopenia, and normal BMD in 19%, 56%, and 25% of subjects, respectively. The decade-wise prevalence of osteoporosis in the age groups 60–70 y, 71–80 y, and > 80 y was 16.9%, 17%, and 50%, respectively. Mean serum vitamin D3 levels were 17.2 ± 10.3 ng/mL. Vitamin D deficiency (65 ng/mL) was present in 68.8% and 45.4%, respectively. A vertebral fracture was present in 29.6% of subjects (grade I: 58%, grade II: 32.4%, and grade III: 8.8%). Age and serum PTH had a significant negative correlation with BMD at FN and TH. Serum 25-OHD had no correlation with BMD at any site. The prevalence of VF was positively associated with age (p = 0.018) and negatively associated with BMD at FN (p = 0.002) and TH (p = 0.013).
Conclusion: Osteoporosis and vertebral fractures are common in asymptomatic Indian males aged 60 years and above. Screening for osteoporosis and instant vertebral assessment may be recommended earlier than currently existing guidelines.

P517
A RARE BONE DISORDER: MELORHEOSTEOSIS-FLUOROSIS CONUNDRUM IN HYPOPARATHYROIDISM PATIENT

G. C. Kakadiya[1], P. Gedam[1]

[1]Topiwala National Medical College & BYL Nair Hospital, Mumbai, India

Osteosclerosis is a condition characterized by high BMD associated with disorders such as hypoparathyroidism, renal osteodystrophy, fluorosis and osteopetrosis. Hypoparathyroidism and fluorosis are two of the most common diseases causing sclerotic bone disease. Fluorosis also causes secondary hyperparathyroidism and has been implicated in renal dysfunction. The co-occurrence of these disorders is both rare and confusing.
Casereport: A 41-year-old male, previously diagnosed case of hypoparathyroidism presented with, fixed flexion deformity of the spine and limbs, episode of seizure, recurrent carpopedal spasms and low back ache. On examination, there were positive Chvostek's and trousseau signs, proximal muscle weakness and restriction of movement at both hip and spine, dental examination revealed mottling without any discernable pitting. On investigation, serum calcium was low (5.92 mg/dl), and serum phosphorus was high (7.82 mg/dl). Serum PTH and vitamin D levels were 2.9 pg/ml and 26.8 ng/ml respectively. X-ray was suggestive of osteopetrosis, DXA scan—left neck femur: + 3.8, lumbar spine: + 5.9. On further workup, the patient's drinking water fluoride content was measured and was found to be 12 ppm over 10 times the recommended WHO limit. The candle wax appearance especially in the tibia also posed melorheosteosis as a potential differential diagnosis but the fact that the patient hailed from the fluoride belt of Rajasthan and other features along with raised fluoride led us to the diagnosis of hypoparathyroidism with fluorosis and the patient was managed on oral calcium and calcitriol.



Conclusion: Hypoparathyroidism together with fluorosis is a rare entity and timely diagnosis can prevent morbidity and improve the quality of life.

P518
DOES BONE MINERAL APPARENT DENSITY FACILITATE ACCURATE IDENTIFICATION OF OSTEOPOROSIS IN SHORT POSTMENOPAUSAL WOMEN?

G. C. Kakadiya[1]

[1]Topiwala National Medical College & BYL Nair Hospital, Mumbai, India

Objective: Height is one of the most important aspects affecting the areal BMD. There are several height adjustments in children but none in widespread use for adults. This is specifically a problem in ethnic groups where mean height is substantially lower. We hypothesized that height adjustment of areal BMD would reduce the misclassification in short individuals.
Methods: This is a retrospective study involving 373 postmenopausal women. Their records were reviewed and bone mineral apparent density (BMAD) was calculated. Areal BMD T-scores and BMAD T-scores were then compared.
Results: The mean height of the cohort was 154.4 cm. There were 47 women who were defined as short ($\leq$ 147 cm). In short women, BMAD neither showed improvement nor decrement in T-scores, and BMAD T-scores predicted more osteoporosis than BMD T-scores. When divided into height ranges, taller women (> 160 cm) showed worsening of BMAD T-scores as compared to BMD T-scores (chi-square test for trend $P < 0.001$). Hence, BMAD might actually be "correct" for larger bones and not shorter bones.
Conclusion: BMAD was not found to be a suitable alternative in short postmenopausal women to accurately determine whether the low bone density in them is because of DXA artefact or whether they truly have a low density.

P519
PSEUDO-SEPTIC HIP ARTHRITIS AS THE PRESENTING FEATURE OF JUVENILE ANKYLOSING SPONDYLITIS: A CASE REPORT

G. C. Kakadiya[1]

[1]Topiwala National Medical College & BYL Nair Hospital, Mumbai, India

Juvenile onset AS differs from the adult form of the illness in that peripheral joint (like hip) arthritis is much more common and can precede, by many years, the onset of inflammatory back disease.
Casereport: A young male patient of 15 years started having hip pain (right > left) associated with limping. Initially, he was diagnosed as a case of right side TB hip but anti-tubercular therapy failed to improve his symptoms. After about 3 y he was again diagnosed with bacterial septic arthritis, this time of the left hip and managed for that. Finally, the diagnosis of juvenile onset ankylosing spondylitis (AS) was made based on modified New York criteria. Intervention: Emphasis was placed on the importance of a long-term home exercise program. Outcome: At a 2-month follow-up visit, the patient gained significantly in his ease of performing activities of daily living. Also, he was referred for surgical spinal osteotomy for kyphosis correction and/or bilateral total hip replacement.
Conclusion: Pseudo-septic hip arthritis as the presenting features of AS has been quite rare but may be expected in the juvenile onset variant.

P520
EFFECT OF INTRA-KNEE INJECTION OF AUTOLOGOUS ADIPOSE STEM CELLS OR MESENCHYMAL VASCULAR COMPONENTS ON SHORT-TERM OUTCOMES IN PATIENTS WITH KNEE OSTEOARTHRITIS

G. C. Kakadiya[1]

[1]Topiwala National Medical College & BYL Nair Hospital, Mumbai, India

Objective: Osteoarthritis (OA) of the knee is a prevalent degenerative joint disease that affects a staggering 350 million people worldwide. The study objectives were to assess the efficacy of single and multiple intra-articular injections of autologous adipose-derived stem cells (ASCs) and adipose-derived stromal vascular fraction (ADSVF) for the treatment of knee OA.
Methods: We conducted a thorough and systematic search of several databases, including PubMed, Embase, Web of Science, Cochrane Library, and ClinicalTrials.gov, to identify relevant studies. The included studies were randomized controlled trials (RCTs) that involved single or multiple intra-articular injections of autologous ASCs or ADSVF for the treatment of patients with knee osteoarthritis, without any additional treatment, and compared to either placebo or hyaluronic acid.
Results: A total of 7 RCTs were analyzed in this study. The results of the meta-analysis show that compared to the control group, both single and multiple intra-articular injections of ASCs or ADSVF demonstrated superior pain relief in the short term ($Z = 3.10$; $P < 0.0001$ and $Z = 4.66$; $P < 0.00001$) and significantly improved function ($Z = 2.61$; $P < 0.009$ and $Z = 2.80$; $P = 0.005$). Furthermore, MRI assessment showed a significant improvement in cartilage condition compared to the control group. ($Z = 8.14$; $P < 0.000001$ and $Z = 5.58$; $P < 0.00001$).
Conclusion: In OA of the knee, single or multiple intra-articular injections of autologous ASCs or ADSVF have shown significant pain improvement and safety in the short term in the absence of adjuvant therapy. Significant improvements in cartilage status were also shown. A larger sample size of randomized controlled trials is needed for a direct comparison of the difference in effect between single and multiple injections.

P521
NOVEL LOW-COST MODALITY TO AUGMENT PEDICLE SCREWS IN OSTEOPOROTIC SPINE: MERSILENE TAPE

G. C. Kakadiya[1], K. C. Chaudhary[2]

[1]Topiwala National Medical College & BYL Nair Hospital, [2]P D Hinduja Hospital & Research Centre, Mumbai, India

Objective: Gradually kyphosis and collapse are a natural history of osteoporotic vertebral compression fractures (OVCF). The principle of OVCF is fixing instability, providing anterior support, and decompression. The osteoporotic spine has weak and rarified trabeculae in the cancellous bone and pedicles, which offer little resistance against screw pull-out. The sublaminar implant relies on the lamina for holds which is the strongest part of vertebrae. The study purpose was to assess the safety and efficacy of sublaminar mersilene tape-augmented pedicle screws fixation as a novel and low-cost modality for OVCFs instrumentation fixation.
Methods: A retrospective study of 40 consecutive patients of the OVCFs. All patients were operated with open decompression, pedicle screw fixation, and sublaminar mersilene tape augmentation. Preoperative and postoperative clinical (visual analogue scale [VAS], modified Oswestry disability index [M-ODI], neurologic deficit, revision surgeries, and infection) and radiological (axial collapse, fracture union, implant failure/back out,) parameters were compared to describe the utility of sublaminar mersilene tape augmented pedicle screws for OVCFs treatment.
Results: Compete neurological improvement was noted in 38 patients and two patients had Frankel Garde D neurology. The mean VAS was significantly improved from preoperative 8.98 ± 0.60 to 2.76 ± 0.54, final follow-up and M-ODI from 80.10 ± 6.90 to 15.30 ± 6.90. The mean local kyphosis angle was improved from $23.20 \pm 5.90°$ preoperative to $5.30 \pm 3.9°$ postoperatively and $3.30 \pm 2.50°$loss of correction at final follow-up. There was no pseudoarthrosis and implant failure noted. No iatrogenic dural or nerve injury.
Conclusion: Sublaminar mersilene tape augmentation relies on the lamina for its hold, which is the strongest part of an osteoporotic vertebra. Sublaminar mersilene tape augmented pedicle screws fixation is a novel and low-cost modality for OVCFs. It provides significant improvement in clinical and radiological outcomes. This technique is an easy learning curve, is user-friendly and safe, which makes this a viable alternative option for OVCFs fixation.

P522
VERTEBROPLASTY WITH SHORT SEGMENT FIXATION VERSUS LONG FIXATION FOR OSTEOPOROTIC VERTEBRAL FRACTURE: A RETROSPECTIVE COMPARATIVE STUDY

G. C. Kakadiya[1]

[1]Topiwala National Medical College & BYL Nair Hospital, Mumbai, India

Objective: The thoracolumbar region is susceptible to injury because of its location between the stiff thoracic kyphotic and mobile lumbar lordotic. The osteoporotic vertebral compression fractures (OVCFs) can lead to delayed union or non-union and lead to progressive collapse that can result in kyphosis with the possibility of neurological deficit. There is controversy regarding the ideal treatment for OVCFs. The study purpose was to compare the safety and efficacy of

vertebroplasty with short-segmented cement-augmented pedicle screws fixation and long-segment fixation for OVCF in elderly patients.

Methods: A retrospective study of 182 single-level OVCF. 88 patients were treated by vertebroplasty and short-segment PMMA cement augmented pedicle screws fixation, and 94 patients were operated with long-segment posterior fixation. Local kyphosis angle, vertebral height, VAS, ODI and neurological state were compared and analysed.

Results: 48.35% of patients had short segment and 51.65% had long segment Spine fixation. Significant improvement was noted in VAS, ODI and neurological status in both groups. The mean kyphosis angle was corrected significantly from 19.08 ± 4.9° preoperative to 6.49 ± 2.59° immediately post-operative, and 8.62 ± 2.60° at one-year follow-up in the short segment group In the long segment group mean kyphosis was also corrected significantly from 23.20 ± 5.90° to 5.30 ± 3.9°immediate postop, and 8.60 ± 4.60° at one-year follow-up. Anterior vertebral height was restored from 56.10 ± 8.9 to 85.9 ± 11.2% postoperative in the short segment group. In the long segment, it was restored from 55.80 ± 11.9 to 87.6 ± 13.1. Four cases of cement leakage in the short-segment group. In the short-segment group, one patient had proximal junction failure, two had implant failure and it was four and six in the long-segment group respectively.

Conclusion: Both short-segment and long-segment fixation can restore local kyphosis for osteoporotic vertebral fracture with lower complication and faster pain relief. A short-segment stabilization has faster relief of pain, lesser tissue destruction, minimised blood loss, and shorter surgical duration with less stress risers at the junctional area.

P523
A COMPREHENSIVE ANALYSIS OF FACTORS INFLUENCING 1-YEAR MORTALITY IN ELDERLY WITH FRAGILITY HIP FRACTURES: INSIGHTS FROM THE FRAGILITY FRACTURE NETWORK TREATMENT—A PRELIMINARY REPORT

G. Chinvattanachot[1]

[1]Ramathibodi Hospital, Mahidol Univ., Bangkok, Thailand

Objective: To evaluate the factors affecting adverse outcomes of elderly fragility hip fractures (EFHF). In addition to commonly studied factors such as demographic data and surgical considerations, we also incorporated biological markers to study the predictive value of each factor, contributing to the development of a future prognostic scoring system.

Methods: A retrospective review was conducted on EFHF patients between 2020–2021. All patients received standard care following the Fragility Fracture Network treatment protocol. Predictive factors, including demographic data and laboratory results, were collected, while outcomes were assessed in terms of complications, 30-d, and 1-y mortality. Multivariate logistic regression analysis was carried out to identify independent risk factors. The predictive value of the model was calculated through ROC analysis.

Results: 88 patients were included, with mean age of 81.4 y and mean time from admission to surgery of 44.5 h. The 1-y mortality rate was 15.9%. Factors significantly associated with mortality included frailty, Charlson's comorbidity index, total lymphocyte count (TLC), monocyte to lymphocyte ratio, neutrophil to lymphocyte ratio, pre-operative hemoglobin, albumin, and the number of units of blood transfusion ($p < 0.1$). After multivariate analysis was performed, only frailty and TLC remained statistically significant, with a hazard ratio of 7.798 ($p = 0.002$, 95% CI 2.14–29.72) and 0.998 ($p = 0.025$, 95% CI 0.997–0.999), respectively, with area under the curve of 0.82 (95% CI 0.72–0.89).

Conclusion: Among all considered factors, frailty emerged as the most impactful determinant influencing 1-year mortality in elderly individuals with fragility hip fractures. The combination of frailty and TLC could provide good predictive value of 1-y mortality in EFHF.

P524
INTEGRATING OSTEOPOROSIS IN PRIMARY CARE: THE OSTEOPOROSIS RISK AND MANAGEMENT (ORMA) PROJECT

S. Vogrin[1], D. Navarro-Perez[1], A. Beauchamp[2], M. Grossman[3], P. Hamblin[1], J. Zanker[4], G. Duque[5]

[1]Australian Institute for Musculoskeletal Science (AIMSS), St. Albans, Australia, [2]School of Rural Health, Monash Univ., Melbourne, Australia, [3]Dept. of Medicine Austin Health, Melbourne Medical School, Univ. of Melbourne, Melbourne, Australia, [4]Australian Institute for Musculoskeletal Science (AIMSS), St. Albans, Canada, [5]Bone, Muscle & Geroscience Group. Research Institute of the McGill Univ. Health Centre, Montreal, Canada

Objective: Despite the availability of accurate diagnostic methods and very effective pharmacotherapy, osteoporosis remains significantly underdiagnosed and undertreated, particularly in primary care settings. The objective of the ORMA Project was to facilitate identifying and treating osteoporosis in primary care practices using innovative technology without demanding additional effort by health professionals.

Methods: The ORMA Project was a randomized stepped wedge study from September 2020 to January 2022. We implemented and evaluated a novel osteoporosis e-technology (Clinical Audit Tool (CAT)-Osteoporosis) which, after being integrated into medical software supports: 1. detection and management of osteoporosis and associated risk factors; 2. education for general practitioners (GPs) on osteoporosis; and, 3. assistance for GPs in the development of care plans. Sixteen primary care practices (125 GPs) were randomly assigned in a 1:1 ratio to the CAT-Osteoporosis + education (2-h teaching sessions) vs. education alone. Identification of risk factors, densitometries requests and treatment initiation data were collected from the software.

Results: A total of 11,326 participants were recruited. Participants' median age was 71 y (IQR 65, 78), 61% female and, on average, having 16 consultations within the last 24 months (IQR 4, 31). The rate of risk factor identification increased (at month 1 IRR 1.05 [1.02, 1.08], $p = 0.0009$ and at month 4 IRR 1.17 [1.13, 1.20], $p < 0.0001$) in the CAT-Osteoporosis group. At baseline, 13% had a record of BMD performed, 56% had vitamin D tested, and only 10% had both tests performed. Over the study period, the testing rate for BMD + vitamin D had an increase of up to 5% in the CAT-Osteoporosis group ($p = 0.045$). Treatment (medication + vitamin D) was received by 37% of participants with osteoporosis. The highest proportion of treatment was noted in a subgroup that had a formal diagnosis of osteoporosis and a record of minimal trauma fracture (around 50%, 203/477). In comparison, participants with a minimal trauma fracture and no history of osteoporosis had the smallest rate of treatment (~ 10%, 40/386). The study intervention showed no effect on treatment rates in either subgroup of participants.

Conclusion: Although the effectiveness of our intervention could have been affected by the COVID-19 pandemic, our e-technology effectively increased the identification of osteoporosis and the use of bone densitometries by primary care physicians. The reason for the lack of increase in osteoporosis treatment remains unknown and will be identified in future studies.

P525
IN-VIVO PRECISION OF TRABECULAR BONE SCORE VERSION 4.0 (TBS INSIGHT®) ACROSS MULTIPLE DXA DEVICES

G. Gatineau[1], K. Hind[2], D. Krueger[3], N. Binkley[3], B. Dawson-Hughes[4], E. Shevroja[1], D. Hans[1]

[1]Center of Bone Diseases, Rheumatology Unit, Bone and Joint Dept., Lausanne Univ. Hospital, & Univ. of Lausanne, Lausanne, Switzerland, [2]Medimaps group SA, Plan-Les-Ouates, Switzerland, [3]Osteoporosis Clinical Research Program, Univ. of Wisconsin-Madison, Madison, USA, [4]Bone Metabolism Laboratory, Jean Mayer USDA Human Nutrition Research Center on Aging, Tufts Univ., Boston, USA

Objective: TBS iNsight version 4.0 (v4) is the latest advancement in TBS software, assessing bone quality via DXA. It incorporates a soft tissue correction based on DXA-measured abdominal soft tissue thickness, diverging from the previous version (v3) which relied on BMI. This study evaluated the in vivo precision of TBS v4 across multiple DXA devices.

Methods: This study involved in vivo lumbar spine DXA scans derived from four different devices: GE Lunar Prodigy, GE Lunar iDXA, Hologic Discovery and Hologic Horizon, with 30 participants per device and 42 for Hologic Horizon. Participants received two consecutive scans with repositioning, and analysis was conducted using TBS iNsight v4.0. Precision was calculated as the root mean square coefficient of variation (RMS-CV%), least significant change (LSC) at 95% and root mean square standard deviation (RMS-SD). The minimum acceptable precision for TBS v4.0 was calculated from the upper 90 percentile RMS-CV%, based on the 2005 International Society for Clinical Densitometry official positions on minimum precision standards for DXA.

Results: Participant characteristics varied slightly across devices, with mean ages ranging from 60.7 (SD 8.9) to 72.2 (SD 9.6) y and BMI from 25.9 (SD 4.5) to 26.8 (SD 5.2). Measurement precision varied across devices: LSC was lowest for Hologic Discovery (3.64%) and highest for GE Prodigy (5.16%). TBS v4 average precision was 1.55% (LSC = 4.29%), and the minimum acceptable precision was 1.76% (LSC = 4.87%).

Table 1 Precision assessment of TBS v4 and abdominal soft tissue thickness across four different DXA devices.

	RMS CV%		LSC (95%)		RMS-SD
	TBS v4	Tissue Thickness	TBS v4	Tissue Thickness	TBS v4
GE Lunar Prodigy	1.86	1.35	5.16	3.75	0.025
GE Lunar iDXA	1.52	1.06	4.21	2.95	0.020
Hologic Discovery	1.31	0.87	3.64	2.42	0.017
Hologic Horizon	1.50	0.98	4.15	2.73	0.019
Average	1.55	1.06	4.29	2.96	0.020
Upper 90 percentile	1.76	1.26	-	-	-

Conclusion: This study confirms the reliability of TBS v4.0 across various DXA devices, with noted precision variations between devices. The global LSC derived from the upper 90 percentile of RMS CV% provides a conservative benchmark for clinicians and researchers interpreting TBS measurements, particularly for monitoring and follow-up of individuals.

P526
EFFECTIVENESS OF *LIMOSILACTOBACILLUS REUTERI* IN THE PREVENTION OF EARLY POSTMENOPAUSAL BONE LOSS: A RANDOMIZED PLACEBO-CONTROLLED SINGLE-CENTER CLINICAL TRIAL

G. Gregori[1], A. Pivodic[2], P. Magnusson[3], L. Johansson[4], U. Hjertonsson[1], E. Brättemark[1], M. Lorentzon[1]

[1]Univ. of Gothenburg, Dept. of Internal Medicine and Clinical Nutrition, Sahlgrenska Osteoporosis Centre, Gothenburg, [2]APNC, Gothenburg, [3]Univ. of Linköping, Dept. of Clinical Chemistry, Biomedical and Clinical Science, Linköping, [4]Sahlgrenska Univ. Hospital The Västra Götland Region, Dept. of Orthopedics, Mölndal, Sweden

Objective: Daily supplementation with *Limosilactobacillus reuteri* ATCC PTA 6475 (L.Reuteri) vs. placebo has previously been demonstrated to reduce bone loss in an estrogen deficiency mice model and older women, although the magnitude of the effect was small. We hypothesized that long-term treatment with L.Reuteri could result in clinically relevant skeletal benefits in postmenopausal osteoporosis. We aimed to evaluate if daily supplementation with L.Reuteri vs. placebo could reduce early postmenopausal bone loss and if the effects remained or increased over time during two years of treatment.

Methods: The study is a double-blind randomized placebo-controlled single centre clinical trial performed in Gothenburg, Southwestern Sweden. Participants: Recruited by online advertisements and letters which were sent to 10,062 women 50-60 years old. Women who responded (n = 752) underwent a first telephone screening process, resulting in 292 women who were invited to a screening visit. Of those screened, 239 women met all inclusion criteria and had no exclusion criteria. Interventions: Capsules with L.reuteri in two different doses, 5×10^8 or 5×10^9 colony-forming units (CFU), taken twice daily, or placebo. All capsules also included 200 IU of cholecalciferol. Main outcome measures: The primary outcome was the relative change in tibia total volumetric BMD (vBMD) over 2 y. Secondary outcomes included relative change in areal BMD of the spine and hip, bone turnover markers CTX and P1NP, as well as tibia trabecular bone volume fraction and cortical BMD.

Results: Tibia vBMD, hip and spine BMD and tibia cortical area and BMD declined significantly in all groups with no group-to-group differences. There were no significant treatment effects on any other predefined outcomes. A pre-specified sensitivity analysis found a significant interaction between BMI and treatment effect (Fig. 1).

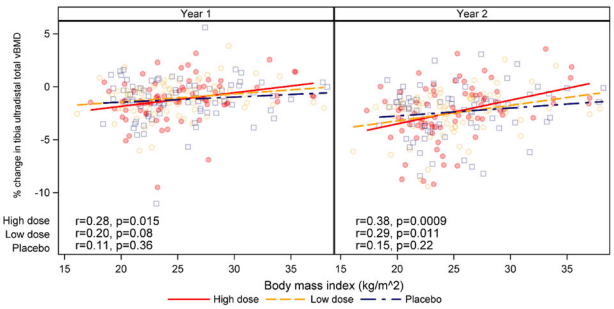


Figure 1. Pearson correlation between BMI and% change in tibia total vMBD by treatment group over time (ITT population).

Conclusion: Supplementation of L.Reuteri RCT did not affect bone loss or bone turnover in early postmenopausal women over two years. The observed interaction between BMI and treatment effect warrants further investigation.

P527
SINGLE-CELL TRANSCRIPTOMICS REVEALS THE HETEROGENEITY IN OSTEO-IMMUNE FUNCTIONS OF OSTEOPOROSIS

G. H. Kim[1], B. R. Keum[2], H. J. Kim[3], J. H. Shin[2], H. K. Chang[4], D. G. CHANG[3]

[1]Korea Basic Science Institute, Cheongju, [2]School of Medicine, Chungnam National Univ., Daejeon, [3]Inje Univ. Sanggye Paik Hospital, Seoul, [4]Korea Univ. Ansan Hospital, Seoul, South Korea

Objective: Although bisphosphonates (BPs) are frequently prescribed as an antiresorptive agents for osteoporosis, BP treatment failure rate can be high as 40%. The objective of this study was to describe the heterogeneity of immune system in osteoporosis patients with different BP-responses.

Methods: Three groups of postmenopausal women were recruited under the strict exclusion criteria: nonosteoporotic, osteoporosis that improved after BP treatment, and osteoporosis that did not improve after BP treatment. Peripheral immune cells were collected from the cohort, then single-cell RNA sequencing was performed. Proportions of immune cell subtypes, enriched cellular pathways, differentially expressed genes (DEGs), cell-cell networks were analyzed between cohorts.

Results: The populations and gene expression profiles of monocytes, T cells, NK cells, and B cells were different in patients with and without osteoporosis, and in patients for whom BP succeeded or failed. Osteoporotic condition retains an increased proportion of monocytes-to-lymphoid cells. Particularly, T-cell-receptor-expressing macrophages were enriched in osteoporosis patients. The NK cell population was expanded in the BP-failure group; this cell type is closely associated with stimulation of osteoclastogenesis. Moreover, subtypes of monocytes, lymphoid cells, and B cells showed differently enriched cellular pathways and DEGs which distinguishes three conditions. Cell-cell interaction analysis revealed the heterogeneity in outgoing and incoming signaling patterns in immune cell subtypes.

Conclusion: This study provides a microscopic atlas of postmenopausal osteoporosis, which will help us to better understand the role of immune heterogeneity in BP-failure. Moreover, this study can be useful source of information to develop potential diagnostic and therapeutic targets for preventing BP treatment failure.

P528
CENTRAL SENSITIZATION DURING OSTEOARTHRITIS AND ITS IMPACT ON PATIENT'S LIFE'S QUALITY IN A TUNISIAN POPULATION

G. H. Nahdi[1], F. Arfaoui[2], H. Ajlani[2]

[1]Faculty of Medicine of Tunis, Tunis, [2]Regional Hospital of Ben Arous, Ben Arous, Tunisia

Objective: Osteoarthritis is the most prevalent disease in the world, leading to disability and so economic burden. This is due to its chronic pain, generally recognized as nociceptive in origin because of the local pathology. However different studies and trials have shown that pain experience in OA is not stable and its quality is important to consider. The purpose of our study is to identify the type of pain among patients with osteoarthritis, thus we can improve pain management and reduce the resulting disability.

Methods: This is a descriptive cross-sectional study carried out over a period of 2 months (September–October 2023) in a rheumatology unit. 101 patients followed for osteoarthritis were included. Patients' data was obtained through a pre-established questionnaire associated with an exhaustive examination and a radiological assessment. Central sensitization inventory (CSI), Visual analog scale and DN4 were completed to type the pain experience. The SF-12 was also calculated to evaluate to life quality.

Results: There were 101 patients with mean age 57 y (24-88) and 85% were women. The most prevalent comorbidities were hypertension (32.7%) and diabetes (24.8%). The average duration of progression of osteoarthritis was 3.8 y. The different joints affected with osteoarthritis were lumbar spinal, cervical spinal and knee with respectively 62.4%, 49.5% and 40.6%.The half of the studied population had more than one joint affected. The totality of our patients was under medication: Nonsteroidal anti-inflammatory and paracetamol, physical rehabilitation was prescribed to 48.5%. Two patients only had corticoid infiltration. The VAS mean was 6.09 ($\pm$ 1.42SD). Central sensitization inventory was between 24–66 with mean a of 45.65 ($\pm$ 7.8SD). The SF12 mean score was 33 which is 70% of optimal. Patients with lumbar spinal osteoarthritis had the lowest SF12 scores. 79% had a CSI score $\geq$ 40, which means the presence of central sensitization. Among them, 20 patients were followed for lumbar spinal osteoarthritis, 15 for cervical spinal osteoarthritis and 9 for knee osteoarthritis. Thirty patients with CSI score $\geq$ 40 had 2 or more joints affected. The DN4 score was $\geq$ 4 in only 9 patients; testifying neuropathic pain. The interaction between CSI score and the VAS was significant, high VAS had central sensitization. Moreover we have found that the CSI score was significantly associated with the duration of progression of osteoarthritis (p-value = 0.001); patients with the longest duration had the highest CSI score. It was also associated with the number of joints affected (p-value = 0.001). The quality of life was associated with the central sensitization; patients having nociplastic pain had the lowest SF12 scores. However, there was no interaction between the CSI score and the osteoarthritis treatment.

Conclusion: In persons with osteoarthritis affecting different joints, any type of pain may exist. The central sensitization; indicator of nociplastic pain is not uncommon. It is associated with the number of joints affected, and the duration of osteoarthritis' progression. Our management of the OA must considerate these characteristics in order to relieve the patient's pain, improve his quality of life and prevent disability.

P529
OSTEOARTHRITIS AMONG HYPERTENSIVE PATIENTS IN A TUNISIAN POPULATION

G. H. Nahdi[1], F. Arfaoui[2], H. Ajlani[2]

[1]Faculty of Medicine of Tunis, Tunis, [2]Regional Hospital of Ben Arous, Ben Arous, Tunisia

High blood pressure may interfere with the pathogenesis of osteoarthritis (OA) since the final pathway of OA is perfusion abnormality of the synovium, articular cartilage and subchondral bone. That presupposes that high blood pressure as a vascular disease can change the OA course. This study was undertaken to assess the clinical and functional characteristics of osteoarthritis in hypertensive patients consulting in a rheumatology unit in Tunisia.

A total of 101 patients with osteoarthritis were included. Thirty-three (28 females, 5 males) had high blood pressure (HBP), 68 had not and were taken as controls. All participants had completed preliminary questionnaires, clinical examination and an X-ray exam. Scores were used for pain (visual analog scale VAS, central sensitization index CSI) and for the quality of life (SF-12).

The mean age of participants was 57.56 y [$\pm$ 13 SD]. The frequency of diabetes was 57.7% in HBP compared with 9% in controls. Forty-five percent (45%) of the HBP group and 55% of controls were workers. Hypertensive patients had higher VAS scores (VAS average = 6.7 $\pm$ 2.14) than the controls (VAS average = 4.8 $\pm$ 3.3). The prevalence of knee OA was higher in hypertensive patients than in

controls with 54.5% and 30% respectively. The central sensitization was found in 75% of both groups' patients. The hypertensive patients with OA had lower work ability index with poor work ability in 15% and moderate work ability 45% than controls with poor work ability in 10%. The quality of life was bad in HBP patients. All patients were under medication. There were significant associations of high blood pressure and knee osteoarthritis, VAS score, SF-12 ($p = 0.026$, $p = 0.004$ and $p = 0.016$ respectively).

High blood pressure is prevalent in patients with OA, especially knee OA and associated with worse pain, work ability score and impaired quality of life. Patients attending rheumatology unit for OA should have their BP taken, and those with known high blood pressure should have the co morbidity under control and well treated.

P530
SAFETY OF ANTI-OSTEOARTHRITIS MEDICATIONS: PRELIMINARY FINDINGS FROM A SYSTEMATIC REVIEW OF POST-MARKETING SAFETY SURVEILLANCE STUDIES

G. Honvo[1], L. Lengelé[2], J.-Y. Reginster[1,3,4], O. Bruyère[1,3]

[1]Division of Public Health, Epidemiology and Health Economics, Univ. of Liège, Liège, Belgium, [2]Metabolism and Nutrition Research Group, Louvain Drug Research Institute, UCLouvain, Université Catholique de Louvain, Sint-Lambrechts-Woluwe, Belgium, [3]World Health Organization (WHO) Collaborating Center for Epidemiology of Musculoskeletal Health and Ageing, Univ. of Liège, Liège, Belgium, [4]King Saud University (KSU), College of Science, Riyadh, Saudi Arabia

Objective: In 2019, we published a series of meta-analyses reassessing the safety of antiosteoarthritis (OA) drugs, using mainly data from full safety reports. The current systematic review (SR) intends to provide complementary insights on the safety of anti-OA medications, now using evidence from post-marketing safety surveillance studies.
Methods: This study followed the Cochrane methodology for SRs of interventions. Four bibliographic databases were comprehensively searched: Medline, CENTRAL, Scopus and TOXLINE. The outcomes of this review were any adverse events (AEs), or any safety issues reported in the included studies.
Results: Fifty-three (53) studies were retrieved, which assessed various anti-OA medications including non-steroidal anti-inflammatory drugs (NSAIDs, 22 studies), intra-articular hyaluronic acid (IAHA, 16 studies), symptomatic slow-acting drugs for osteoarthritis (SYSADOAs, 5 studies), Opioids (4 studies), Corticosteroid injections (4 studies), Nutritional supplements and herbal mixtures (2 studies). Most of these studies were cohort studies or case reports. The most common AEs reported by drugs were: Meloxicam (Gastrointestinal [GI] AEs), Celecoxib (Cardiovascular AEs), Nimesulide (GI, nervous system AEs), and Flurbiprofen (small increase in serum creatinine); other studies (1 per drug) reported mainly GI AEs with Piroxicam, Naproxen, Indoprofen, Sulindac, Etodolac, Fenbufen, Imidazole salicylate, Flavocoxid, and multiple NSAIDs; there was a case report of specific AEs with Etoricoxib (toxic epidermal necrolysis), Ibuprofen (delayed blood clotting with concomitant use of warfarin) and Diclofenac (spontaneous thigh hematoma). Other drugs and AEs were: IAHA (injection site pain); Diacerein (GI AEs and reddish urine); ASU-Piascledine (GI AEs—1 study); Combinations of non-pharmaceutical grade Glucosamine and Chondroitin (allergic reactions, musculoskeletal and GI disorders—2 studies); Opioids (hip fracture associated with long-term tramadol use among older adults and a case of anaphylaxis complicated by loss of consciousness; a case of topical erythematous reaction with a buprenorphine transdermal patch; and various GI and nervous system disorders with hydrocodone); Corticosteroid injections (increased risk of OA progression; a case of rare vision disturbances and of a septic arthritis); Nutritional supplements and herbal mixtures (GI AEs).
Conclusion: This very first SR of post-marketing surveillance studies in OA confirms previous evidence from SRs of phase 3 clinical trials. Real-life safety surveillance of anti-OA medications should be strengthened with large cohort studies and complementary data from adverse drug reaction report registries.

P531
THE FIT-FRAILTY APP FOR ASSESSMENTS OF FRAILTY IN OLDER ADULTS: RELIABILITY IN A GERIATRIC CLINIC

G. Ioannidis[1], A. Relan[2], C. C. Kennedy[1], S. Park[1], P. Fisher[3], S. Vinson[3], J. D. Adachi[1], K. Rockwood[4], B. Egbujie[5], A. Papaioannou[1]

[1]McMaster Univ./Dept. of Medicine, Hamilton, [2]McMaster Univ./Dept. of Health Research Methodology, Hamilton, [3]St. Peter's Hospital, Hamilton, [4]Dalhousie Univ./Dept. of Medicine, Halifax, [5]Univ. of Waterloo/School of Public Health Sciences, Waterloo, Canada

Objective: Frailty has been described as the most problematic expression of population aging. Assessing frailty with existing tools may be too time-consuming and require additional equipment and staff-time. The Fit-Frailty App is a comprehensive measure of frailty utilizing fully guided, interactive smartphone/tablet technology. It was designed to be easily completed with older adults in clinical/research settings in $\sim$ 15 min. Scoring is based on the well-validated Rockwood Frailty Index method and considers disease-related, physical, cognitive, mood, psychosocial, nutritional, and functional aspects. The full assessment includes interactive cognitive screening and physical performance measures. The primary aim is to conduct a reliability study of the Fit-Frailty App in older adults attending a geriatric clinic.
Methods: A convenience sample of 75 patients over the age of 65 y attending a geriatric clinic in Hamilton, ON were recruited. A clinic nurse administered the App with the patient during their clinic appointment and phone Fit-Frailty assessments were administered by a trainee 7 (follow-up 1) and 14 d (follow-up 2) after. The Fit-Frailty scores were categorized into severe frailty (> 0.4), frail (0.25–0.40), and not frail (< 0.25). Intraclass correlation coefficient (ICC) and 95% CI was calculated.
Results: The sample was 53% female, mean age 79.2 y (SD = 7.03) and SMMSE 23.8 (SD = 5.52). A total of 33% of participants were severely frail (25/75), 40% were frail (30/75), and 27% were not frail (20/75). The mean fit-frailty score was 0.33 (SD = 0.13) at in-person assessment, 0.30 (SD = 0.13) at phone follow-up 1 and 0.30 (SD = 0.11) at phone follow-up 2. The mean time to complete the virtual assessment was 13.7 min (SD = 8.4). The ICC between in-person and phone follow-up 1 was 0.840 (95% CI 0.830–0.853). The ICC between phone follow-up 1 and follow-up 2 was 0.911 (95% CI 0.911–0.912).
Conclusion: The Fit-Frailty App demonstrated excellent reliability when compared to in-person App assessment in measuring frailty in older adults attending a geriatric outpatient clinic. The Fit-Frailty App can assess home bound older adults, assist with triaging, and monitor changes over time.

P532
IMPORTANCE OF CALCIUM USE IN THE TREATMENT OF POSTMENOPAUSAL OSTEOPOROSIS

G. Kavaja[1], B. Kavaja[2], S. Tonuzi[1]

[1]Durres Regional Hospital, Durres, [2]Faculty of Medicine, Tirane, Albania

Objective: Osteoporosis is a progressive, systemic skeletal disorder characterized by reduced bone density. Patients with osteoporosis are at increased risk of fracture, although the condition remains asymptomatic until a fracture occurs. Oral bisphosphonates are generally considered the first-line treatment for patients with osteoporosis. It is important to ensure that patients with osteoporosis have adequate calcium and vitamin D levels for better results. We aimed to study the importance of using calcium as a supplement in bisphosphonate therapy in postmenopausal women with osteoporosis.
Methods: The study included 250 menopausal women diagnosed with osteoporosis. The diagnosis was made during the rheumatology visit and DXA examination. The first group included 150 female patients in menopause who were treated with oral bisphosphonate once a week and oral calcium 500 mg/d. The second group included 100 female patients in menopause who were treated with oral bisphosphonate once a week. In this group, the use of calcium was irregular due to the patients' compliance with it. The patients were followed for a period of 2 y by measuring the bone density every year.
Results: In the group of women in menopause treated with bisphosphonate and calcium, the prevention of bone loss was more significant compared to the second group where calcium intake was rare ($p < 0.05$). Mean changes in bone density were [± SE], for the spine $0.56 \pm 0.94\%$ vs. $-1.06 \pm 0.88\%$ and for the femoral neck $1.04 \pm 0.82\%$ vs. $-1.94 \pm 0.77\%$.
Conclusion: Treatment with bisphosphonate and calcium was more effective than treatment with bisphosphonate alone. The use of calcium slowed the bone loss in the femoral neck and spine in women in menopause.

P533
OBSERVATIONAL STUDY ON BONE QUALITY BY EVALUATION OF "BONE STRAIN INDEX" IN MALE AND FEMALE PATIENTS AFFECTED BY OSTEOGENESIS IMPERFECTA

G. Marcucci[1], F. Miglietta[1], C. Signorini[1], M. L. Brandi[2], L. Masi[3]

[1]Dept. of Experimental and Clinical Biomedical Sciences, Univ. of Florence, [2]FIRMO Foundation Onlus, Italian Foundation for Research on Bone Diseases, [3]Bone Unit, Univ. Hospital of Florence, CTO-Careggi, Florence, Italy

Objective: Osteogenesis Imperfecta (OI) is a group of connective tissue disorders with a broad range of phenotypes characterized primarily by bone fragility. Recently, a new densitometric index of "Bone Strength" has been introduced, which provides information on skeletal resistance to loads, called "Bone Strain Index" (BSI). The aim of the study was to evaluate the BSI in patients affected by OI and to correlate this index to BMD, T- and Z-score, measured by DXA, in male and female patients.
Methods: An observational, retrospective, single-center study was conducted on patients with OI. The statistical analyzes used include: descriptive statistical analyses, Pearson correlation coefficient, and t-test.
Results: 46 patients affected by OI were enrolled (females: 29/46; males: 17/46) with an average age of 37.7 ± 20.4 years. The lumbar BSI (L1–L4) was ≥ 2.4 (reduced Bone Strength) in 41.3% of patients (n: 19/46), > 1.68– < 2.4 (partially reduced) in 45.6% (n:21/46), and ≤ 1.68 (normal) in 13% (n: 6/46). Femoral neck BSI was ≥ 2.4 in 16.6% of patients (n: 6/36), > 1.68– < 2.4 in 50% (n: 18/36), and ≤ 1.68 in 33.3% (n:12/36). L1–L4 BSI negatively correlates with L1-L4 BMD (r: -0.63, $p < 0.001$), Z-score (r: -0.52, p:0.003), and T-score (r: -0.91, $p < 0.0001$). Femoral neck BSI negatively correlates with femoral neck BMD (r: -0.51, p: 0.001), and T-score (r: -0.90, $p < 0.001$). In females, lumbar BSI was ≥ 2.4 in 10.34% (3/29), > 1.68 to < 2.4 in 51.72% (15/29), and ≤ 1.68 in 37.93% (11/29). In males, lumbar BSI was ≥ 2.4 in 23.5% (4/17), > 1.68 to < 2.4 in 35.29% (6/17), and ≤ 1.68 in 41.17% (7/17). In females, femoral neck BSI was ≥ 2.4 in 25% (n: 6/24), > 1.68 to < 2.4 in 54.16% (n:13/24), and ≤ 1.68 in 20.83% (n:5/ 24). In males, femoral neck BSI was ≥ 2.4 in 40% of patients (n: 6/15), > 1.68 to < 2.4 in 46.66% (n:7/15), and ≤ 1.68 in 13.33% (n:2/ 15).
Conclusion: In the majority of patients, the BSI index was reduced or partially reduced and negatively correlated significantly with the BMD, T- and/or T-score. These preliminary results are essential for further studies on BSI in patients affected by OI, and correlations with clinical data, fractures, other bone quality parameters and response to therapies.
Acknowledgment: ENDO-BOND-ERN.

P534
OBSERVATIONAL STUDY ON BONE MINERAL DENSITY, TRABECULAR BONE SCORE AND BIOIMPEDANCE IN PATIENTS AFFECTED BY ANOREXIA NERVOSA

G. Marcucci[1], C. Dani[2], L. Cianferotti[1], C. Signorini[1], E. Rossi[2], E. Cassioli[2], A. I. Altomare[2], E. Borri[2], A. De Martino[2], F. Cioppi[3], L. Vannucci[3], G. Castellini[2], V. Ricca[2], L. Masi[3]

[1]Dept. of Experimental and Clinical Biomedical Sciences, Univ. of Florence, [2]Psychiatry Unit, Dept. of Health Sciences, Univ. of Florence, [3]Bone Unit, Univ. Hospital of Florence, CTO-Careggi, Florence, Italy

Objective: Anorexia nervosa (AN) is often associated with reduced BMD and increased fracture risk. The aim of the study was the evaluation and correlation between BMD, TBS and bioelectrical impedance analysis (BIA).
Methods: An observational, retrospective, single-center study was conducted on patients with AN. Evaluation of risk factors for bone fragility, laboratory exams of bone metabolism, BMD and TBS measured by DXA, and bioimpedance analysis were performed. Statistical analyzes used included: Pearson correlation coefficient, age-corrected correlations, and ANOVA (Bonferroni post hoc test).
Results: 85 female patients (mean age: 25.39 ± 10.19 y) with AN, and mean BMI of 15.47 ± 1.38 kg/m^2 were enrolled. The mean disease duration was 8.7 ± 11.3 y. The mean BMD L1–L4 values were 0.870 ± 0.13 g/cm^2 with Z-score -1.46 ± 1.21, neck femur BMD 0.750 ± 1.44 g/cm^2 with Z-score -1 ± 1.16, and total femur BMD 0.820 ± 0.91 g/cm^2 with Z-score -1.4 ± 0.8. The Z-score was < -2 in 34.6% of patients at the lumbar level and in 18.6% at the femoral neck. Mineral metabolism tests showed normal parameters, with the exception of mean 25(OH)D_3 levels slightly below the normal range (29.6 ± 10.9 ng/ml). In a subgroup of 35 patients, TBS and bioimpedance measurement were performed. The study showed a significant correlation between free fat mass (FFM) and lumbar BMD (r: + 0.33, p: 0.04), femoral neck BMD (r: + 0.38, p:0.017), femoral neck Z-score (r: + 0.41, p:0.011). Mean value of TBS was 1313 ± 1197 (min: 1197; max: 1469). The 62.85% of patients (22/35) had TBS partially degraded, and the remainder were normal. The TBS score correlated positively with lumbar and femoral BMD and Z-scores measured with DXA and FFM in a statistically significant manner.

Conclusion: The significant positive correlation between FFM, TBS and DXA described represent important results for further correlation studies between these parameters, measured with widely used methods, in order to evaluate FFM as a predictive risk factor for reduction of low bone mass and altered bone quality in affected patients from AN.

P535
UNVEILING CHALLENGES: HIGH MORTALITY AND DISABILITY IN OSTEOPOROTIC PATIENTS WITH HIP FRACTURE IN A BRAZILIAN TERTIARY SETTING: A 1-YEAR FOLLOW-UP STUDY

G. Pacífico Seabra Nunes[1], H. Neneve Prohmann[1], J. Alícia Silveira Lopes[1], L. Vicentini Godoy de Lucca[1], B. Fernandes Boaventura[1], P. De Oliveira Barbalho Junior[1], E. De Azevedo[1]

[1]IAMSPE, São Paulo, Brazil

Objective: To evaluate the profile of patients who had a hip fracture in the period of 2021 and 2022, and one-year follow-up to assess the degree of mortality, disability and treatment of osteoporosis.
Methods: Retrospective study based on medical records and phone inquiry of one year follow up regarding mortality and morbidity of patients who experienced hip fracture in 2021 and 2022 in a tertiary hospital of São Paulo.
Results: 138 patients were hospitalized due to hip fracture in the period. The median age was 83 y (range, 50–101 y), most of them were female (71.7%). All the patients underwent surgical treatment, except one that died before treatment. 45 (32.6%) patients died within one year after fracture. Fourteen patients died during the hospitalization, 9 caused by infections and 5 by pulmonary embolism. 63% of the remaining alive patients had some sort of disability after one year of fracture; 36 (38.7%) had to use walking stick, 18 (19.3%) were in a wheelchair and 5 (5.3%) were bedridden. 57 (61.3%) patients claimed that they were not informed that they had the diagnosis of osteoporosis. From the total patients, only 31 (22.4%) patients were referred for osteoporosis treatment. Bisphosphonates were the main treatment used in this population.
Conclusion: In the study population we can identify that the median population age and mortality is higher than the other studies. These differences may be interrelated. As expected, the degree of disability at the end of the first post-fracture year was also high (approximately 65% of the patients). High mortality, high disability rates and little knowledge about the disease highlight the great burden of osteoporosis.

P536
BREAKING THE SILENCE ON OSTEOPOROSIS TREATMENT: A DEEP DIVE INTO A SÃO PAULO'S TERTIARY HOSPITAL EXTREME ELDERLY POPULATION

B. Fernandes Boaventura[1], G. Pacífico Seabra Nunes[1], P. De Oliveira Barbalho Junior[1], E. De Azevedo[1]

[1]IAMSPE, São Paulo, Brazil

Objective: To outline the clinical and treatment profile of osteoporosis in individuals above 85 years old in a tertiary hospital in São Paulo.
Methods: Data collection and retrospective analysis of electronic medical records from a sample of 100 patients above 85 years old, under follow-up in a specialized rheumatology outpatient clinic of a tertiary service in São Paulo in 2022–2023.
Results: Among the evaluated patients, 89% were women. Regarding the clinical profile, only 2% had one comorbidity; 49% had two to four, and 49% had five or more. These values correlate with polypharmacy, with only 3% of patients using up to 3 medications; 49% using four to eight, and 52% using nine or more continuous medications. A history of osteoporotic fracture was present in 76%, ranging from one to six affected sites, with 29% having a fracture at a single site, 39% at two sites, and 8% at three sites. The majority used bisphosphonates as first-line treatment (90%). Of these, 80% had an indication for sequential therapy. Denosumab was indicated in 41%, mainly due to prolonged use of bisphosphonates and renal dysfunction. Replacement with Teriparatide occurred in 40.28% and was also motivated by duration of use or therapeutic failure. After the anabolic cycle, the transition to denosumab was observed in 44% and to bisphosphonates in 13%.
Conclusion: Osteoporosis in the extremely elderly poses a significant challenge, given the increasing incidence of osteoporotic fractures with age, impacting morbidity and mortality. Understanding and Treating osteoporosis in this population is crucial given the high risks, and the beneficial impact that the therapy causes.

Objective: Very few is still known about RET role in the pathophysiology of the marfanoid habitus affecting MEN2B patients. Aim of this study is evaluating the presence of RET in a cell model of human growth plate, to investigate RET role in MEN2B marfanoid habitus.
Methods: A biopsy of growth plate has been collected and treated to establish a primary cell line of hypertrophic chondrocytes. Specific cellular and molecular biology analyses were performed to confirm the phenotype of hypertrophic chondrocytes before studying the possible effects of RET ligand (i.e., GDNFRa1 and GDNFRa2) treatment, at several concentrations (i.e., 100 nM, 50 nM, 25 nM and 10 nM), on cell proliferation, and on osteogenic and chondrogenic differentiation. GDNFra1 and GDNFRa2 effects have been evaluated by using immunohistochemical assays, fluorometric assay and Taq-Man technology.
Results: We have established a primary cell line of human hypertrophic chondrocytes, marked as GP-1. GP-1 line expressed all the hypertrophic cartilage marker genes, had the capacity to differentiate in osteoblasts or chondrocytes, under specific differentiation conditions, maintaining the expression of RET mRNA and protein, respect to a primary cell line of differentiated articular cartilaginous cell line. Regarding the effects of GDNF ligands on osteogenic differentiation we showed not only an increase of alkaline phosphatase activity and of hydroxyapatite deposition, but also an increment of chondrogenic differentiation potential under treatment with GDFRa1 and GDFRa2, respectively. It has been noticed that both these treatments positive regulate expression levels of osteogenic and chondrogenic marker genes during both differentiation processes. Finally, we reported an increase of the proliferation rate for both GDNF ligand treatments.

Conclusion: Our research established a human hypertrophic chondrocyte cell line characterized by the presence of RET protein, setting up the first in vitro human model to study RET pathway in the cartilage. Our data suggested that GDNF ligands and RET are significantly associated with the functionality of hypertrophic chondrocytes, opening the possibility that RET is directly involved in the clinical manifestation of the marfanoid habitus in MEN2B patients.

P538
PREVALENCE AND POPULATION ATTRIBUTABLE FRACTION OF ASSOCIATED RISK FACTORS ON SARCOPENIA: IRANIAN MULTICENTER OSTEOPOROSIS STUDY (IMOS-2021)

A. Ghazbani[1], G. Shafiee[1], A. Aghakhani[2], N. Fahimfar[3], A. Ostovar[3], R. Heshmat[1]

[1]Chronic Diseases Research Center, Endocrinology and Metabolism Population Sciences Institute, Tehran Univ. of Medical Sciences, [2]Endocrinology and Metabolism Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran Univ. of Medical Sciences, [3]Osteoporosis Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran Univ. of Medical Sciences, Tehran, Iran

Objective: As an important musculoskeletal disease, sarcopenia is characterized by the degeneration of both muscle mass and functionality. Recognizing the growing importance of musculoskeletal disorders within the Iranian population, the current investigation was undertaken to address a knowledge gap in the existing literature by measuring the prevalence and population-attributable fraction (PAF) of established risk factors for sarcopenia in Iran using data from the Iranian Multicenter Osteoporosis Study (IMOS-2021).
Methods: IMOS was a population-based, cross-sectional survey that was conducted in Iran to estimate the prevalence of osteoporosis, osteopenia, and sarcopenia and their possible related risk factors among people over 50 y of age in Iran. Sarcopenia was defined by the presence of low muscle mass with low muscle strength, and severe sarcopenia was considered when low muscle strength, low muscle mass, and low physical performance were all detected. The survey set analysis was carried out using the STATA statistical software, to determine the weighted prevalence of sarcopenia among adults in Iran. Using modified Poisson regression analysis, an adjusted prevalence ratio (PR) with 95% CI was used to show the measure of associations in the final model. To calculate the PAF of established risk factors for sarcopenia, the complex survey design was taken into consideration, along with the incorporation of sampling weights.
Results: In the present study, 716 participants $\geq$ 60 y were included. The mean subjects' age was 66.8 $\pm$ 6.1 y and 51.4% of those were women. The weighted prevalence of sarcopenia (including sarcopenia and severe sarcopenia) was estimated to be 13.8% (11.1–17.0%). There was a significant increasing trend in the prevalence of sarcopenia with advancing age (p for trend = 0.001). The results of the Poisson regression analysis revealed that high-fat mass was positively associated with sarcopenia (PR: 2.09, 95% CI 1.33–3.28). Age $\geq$ 75 y had a positive association with sarcopenia (PR: 1.72, 95% CI 1.10–2.70). Subsequently, low physical activity emerged as another significant factor, with a prevalence ratio of 1.64 (95% CI 1.04–2.60). In addition, the direct associations were detected with low BMI (PR: 6.69, 95% CI 2.78–16.12) and low protein intake (PR: 1.66, 95% CI 1.01–2.75) and having sarcopenia. The attributable risks of advancing age (> 75 y), low BMI (BMI, 25 kg/m^2), low protein intake, low physical activity, and high-fat mass were as follows: 17.3%, 19.7%, 23.8%, 28.8% and 40.7% for sarcopenia. However, most of the PAF was due to high-fat mass, the combination of the PAF of these risk factors accounted for 78.6% of sarcopenic subjects.
Conclusion: Our finding demonstrated a high prevalence for sarcopenia suggesting a high disease burden in a rapidly aging country. Also, these data confirm that high fat mass, low physical activity, and low protein intake are major risk factors for sarcopenia. Therefore, implementing effective prevention programs that specifically target these factors has the potential to significantly reduce the occurrence of sarcopenia in Iran.

P539
RELATIONSHIP BETWEEN DYSMOBILITY SYNDROME AND MALNUTRITION WITH THE RISK OF MORTALITY IN OLDER PEOPLE: THE BUSHEHR ELDERLY HEALTH (BEH) PROGRAM

G. Shafiee[1], F. Abbasloo[2], H. R. Aghaei Meybodi[3], N. Fahimfar[4], A. Ostovar[4], S. Maleki Birjandi[1], I. Nabipour[5], R. Heshmat[1]

[1]Chronic Diseases Research Center, Endocrinology and Metabolism Population Sciences Institute, Tehran Univ. of Medical Sciences, Tehran, [2]Endocrinology and Metabolism Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran Univ. of Medical Sciences, Tehran, [3]Evidence-Based Medicine Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran Univ. of Medical Sciences, Tehran, [4]Osteoporosis Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran Univ. of Medical Sciences, Tehran[5]The Persian Gulf Tropical Medicine Research Center, Bushehr Univ. of Medical Sciences, Bushehr, Iran

Objective: Dysmobility syndrome and malnutrition are highly prevalent in older adults and are associated with adverse outcomes. This study aimed to evaluate the role of a combination of dysmobility syndrome and malnutrition on the mortality rate in a cohort of older adults in Iran.
Methods: The BEH program is a prospective population-based cohort study, which aims to investigate the incidence of non-communicable diseases and their risk factors among people over 60 years old in Bushehr, Iran. Dysmobility was defined as three or more of the following: high body fat, osteoporosis, low muscle mass, low muscle strength, slow gait speed, or falling history. Body composition was assessed with DXA. Gait speed was measured via a timed walk, muscle strength via hand grip strength, and fall risk via self-reported balance problems in the past year. Nutritional status was determined with a). The participants were divided into six groups: No dysmobility/normal nutrition, No dysmobility/malnutrition risk, No dysmobility/malnutrition, dysmobility/normal nutrition, dysmobility/malnutrition risk, and dysmobility/malnutrition. Hazards ratios (HR) for mortality were calculated with Cox proportional hazards models.
Results: The study included 2123 participants: 660 had no dysmobility/normal nutrition, 932 had dysmobility/normal nutrition, 263 had dysmobility/malnutrition risk, and 151 had dysmobility/malnutrition. Over 7 y of follow-up, there were 355(14.6%) deaths, and the Kaplan-Meier curves showed that dysmobility/malnutrition had a higher risk of mortality. The incidence rates of mortality were 11.62, 16.06, 9.00, 20.88, 32.40, and 36.55 per 100 person-years among patients with no dysmobility/normal nutrition, no dysmobility/malnutrition risk, no dysmobility/malnutrition, dysmobility/normal nutrition, dysmobility/malnutrition risk, and dysmobility/malnutrition, respectively. In the survival analysis, the group with dysmobility and malnutrition showed a higher HR of 2.90 (95% CI 185-4.55) for mortality when compared to a group with no dysmobility/normal nutrition in all models.
Conclusion: Older adults with dysmobility and malnutrition combined showed higher mortality risk. These findings highlight the

importance of diagnosing and treating malnutrition and dysmobility in older people for both can increase mortality rate.

P540
ASSOCIATION OF VITAMIN B6 AND KYNURENINE PATHWAY WITH SARCOPENIA, METABOLOMIC APPROACH: RESULTS OF BUSHEHR ELDERLY HEALTH (BEH) PROGRAM

G. Shafiee[1], N. Zargar Balajam[1], H. A. Mardani-Fard[2], N. Fahimfar[3], F. Razi[4], A. Etemadi[5], A. Kasaeian[5], F. Bandarian[4], A. Ostovar[3], R. Heshmat[1]

[1]Chronic Diseases Research Center, Endocrinology and Metabolism Population Sciences Institute, Tehran Univ. of Medical Sciences, Tehran, [2]Dept. of Mathematics, Yasouj Univ., Yasouj, [3]Osteoporosis Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran Univ. of Medical Sciences, Tehran, [4]Metabolomics and Genomics Research Center, Endocrinology and Metabolism Molecular-Cellular Sciences Institute, Tehran Univ. of Medical Sciences, Tehran, [5]Endocrinology and Metabolism Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran Univ. of Medical Sciences, Tehran, Iran

Objective: Sarcopenia, the age-related decline in muscle mass and function, poses a significant health challenge. The intricate molecular mechanisms underlying age-related muscle mass decline are not yet fully understood. The present study aimed to investigate the impact of tryptophan (Trp), downstream kynurenine metabolites, and Vitamin B_6 as a coenzyme in this pathway on sarcopenia in older people.
Methods: Data was randomly extracted from 2426 elderly people $\geq$ 60 y participating in the second stage of the BEH program, a population-based prospective cohort study in Bushehr, Iran. Anthropometric measurements, performance and muscle strength tests, blood pressure, and body composition measurements were performed, and venous blood was taken from participants after 12 h of fasting. Frozen plasma samples measured kynurenine- tryptophan metabolites and vitamin B6- metabolomics. Metabolites were analyzed using tandem mass spectrometry. Data processing included replacing zero values with half the minimum value and missing values with mode. We conducted the lasso regression analysis to detect the strongest metabolites associated with sarcopenia and also logistic regression models were used to calculate crude and adjusted odds ratios (ORs).
Results: A total of 400 participants were included in this study. We adjusted the analysis for possible confounders including; sex, age, BMI, diabetes, smoking, physical activity, and vitamin B group intake. The Lasso model showed effective metabolites on the occurrence of sarcopenia. 3-hydroxykynurenine, anthranilic acid, xanthurenic acid, pyridoxal 5-phosphate (the active form of vitamin B6), nicotinamide, and 3-hydroxyanthranilic acid had the most relationship with sarcopenia and its parameters, respectively. Our results showed that in the full model, Xanthurenic acid, and anthranilic acid were positively associated with sarcopenia, and pyridoxal 5-phosphate and Picolinic acid were inversely associated with sarcopenia ($P < 0.05$).
Conclusion: Our investigation reveals compelling associations between the Trp and vitamin B6 metabolites with sarcopenia. These findings may pave the way for innovative approaches to prevent or treat this disease**,** ultimately enhancing the quality of life for the elderly. Further research in this area is warranted to elucidate the underlying mechanisms and develop targeted interventions.

P541
CLINICAL PRACTICE GUIDELINES FOR SARCOPENIA PREVENTION, DIAGNOSIS AND MANAGEMENT IN IRAN

G. Shafiee[1], N. Zargar Balajam[2], F. Abbaspour[1], S. Maleki Birjandi[1], R. Heshmat[1]

[1]Chronic Diseases Research Center, Endocrinology and Metabolism Population Sciences Institute, Tehran Univ. of Medical Sciences, [2]Endocrinology and Metabolism Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran Univ. of Medical Sciences, Tehran, Iran

Objective: Sarcopenia, as an age-related progressive loss of muscle mass and muscle strength, is one of the most important topics of elderly medicine that occurs in approximately 37% of hospitalized older adults aged > 65 y. Therefore, the existence of a comprehensive guideline for the prevention, diagnosis, or possible treatment of this disease is vital and practical. There is no comprehensive guideline about this disease in Iran, so the purpose of this article is to provide the most effective evidence-based clinical practice guidelines (CPGs) for screening, diagnosis, management of sarcopenia, and formulation of monitoring policies in the elderly.
Methods: This guideline for sarcopenia in Iran was developed based on various existing guidelines from different societies, such as the Foundation for the National Institutes of Health (FNIH), International Clinical Practice Guidelines for Sarcopenia (ICFSR), European Working Group on Sarcopenia in Older People (EWGSOP/ EWGSOP2), Asian Working Group for Sarcopenia (AWGS) as well as two the Australian and New Zealand society for sarcopenia and frailty research (ANZSSFR) expert working group. All studies in national and international journals by Iranian authors in the field of sarcopenia from the inception until the start of 2024 were included in this comprehensive study. Databases including MEDLINE (PubMed), Web of Science, and SCOPUS were used as sources of information.
Results: The final guideline of sarcopenia in Iran was made by answering questions about screening, diagnosis, prevention, and treatment of this disease. These questions were answered according to the existing guidelines, a model called the Sarcopenia Screening Assessment Model (SarSA Mod) designed in Iran, and the available clinical evidence directly from the patients, which included the following: (I) Who should be screened for sarcopenia? (II) How to find people at risk of sarcopenia? (III) How to diagnose the possibility of sarcopenia? (IV) What is the definitive diagnosis of sarcopenia? (V) What is the basis of the prevention and treatment of sarcopenia? (VI) What is the role of nutrition in the prevention and treatment of sarcopenia? (VII) What is the role of drug interventions in the prevention and treatment of sarcopenia?
Conclusion: Here we present the sarcopenia guideline for the Iranian community, emphasizing the need for improved clinical trial quality. Although these guidelines are based on available studies and articles as well as data obtained from patients to make better decisions about sarcopenia, their applicability may vary across different settings and patient populations. By incorporating additional parameters and removing restrictions, more comprehensive models can be developed and implemented to address this condition effectively.

P542
ALTERATIONS IN BONE HEALTH IN TRANSGENDER ADOLESCENTS AND ADULTS RECEIVING GENDER AFFIRMATION HORMONAL THERAPY AND/OR SEX REASSIGNMENT SURGERY: SCOPING REVIEW

G.-A. Cruz-Priego[1], A. Gonzalez-Miranda[1], M.-A. Guagnelli[1], J.-L. Neyro[2], P. Clark[1]

[1]Clinical Epidemiology Research Unit, Hospital Infantil de Mexico Federico Gomez, Mexico City, Mexico, [2]Servicio de Ginecología y Obstetricia, Hospital Universitario Cruces. International Master on Climacteric. Univ. of Madrid (UDIMA), Bilbao, Spain

Objective: This scoping review aims to consolidate current evidence on bone health alterations in transgender adolescents and adults receiving gender-affirming hormonal treatments (GAHT).
Methods: A comprehensive literature review was conducted across various digital libraries, encompassing all cultures, geographies, races, and genders. This review was unrestricted by language or publication year and focused on transgender adolescents and adults who received aGnRH therapy, gender affirmation therapy, or sex reassignment surgery. The primary focus was on alterations in bone metabolism, specifically BMD and bone marker changes. The review included secondary and tertiary evidence, such as systematic reviews, overviews, umbrella reviews, and international guidelines.
Results: From 991 studies identified, 38 were included: 4 systematic reviews, 1 randomized controlled trial (RCT), 1 quasi-experimental study, 7 longitudinal studies, 9 cross-sectional, and 16 narrative reviews. Systematic reviews revealed inconsistent findings on bone density in male-to-female (MtF) and female-to-male (FtM) transgender patients undergoing long-term hormone therapy. While some studies reported BMD comparable or higher than controls, others noted reduced BMD in MtF patients, with no similar reduction in FtM patients. The limited number and quality of RCTs and quasi-experimental studies impede conclusive evidence. Longitudinal studies displayed variable, sometimes contradictory results, particularly in adult bone density measurements and turnover markers. Adolescent studies also showed varied outcomes, underscoring the need for long-term research. Cross-sectional studies, limited by design, provided baseline data with similar trends in adults and adolescents.

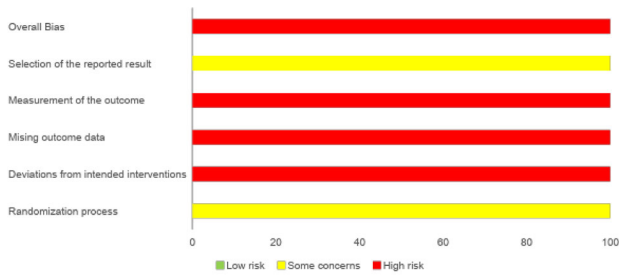

Figure 1. Risk of bias from randomized clinical trials.

Conclusion: Current research is insufficient for a comprehensive understanding of GAHT's bone effects in transgender individuals. High-quality, long-duration prospective studies are necessary for reliable conclusions. There is a critical need for more robust data to inform health professionals in decision-making regarding gender affirmation treatments.

P543
PREDICTIVE CAPACITY OF FRACTURE RISK ASSESSMENT TOOLS: OVERVIEW OF SYSTEMATIC REVIEWS

G.-A. Cruz-Priego[1], B. Araiza-Nava[1], L. Mendez-Sánchez[1], P. Clark[1]

[1]Clinical Epidemiology Research Unit, Hospital Infantil de Mexico Federico Gomez, Mexico City, Mexico

Objective: To conduct an overview of systematic reviews of the current fracture risk prediction tools in use.
Methods: We included systematic reviews (SRs) that assessed the predictive ability of any tool, score, algorithm, or other instrument for fracture risk. The primary outcome measure was the area under the curve (AUC) representing predicted fracture risk within a specified timeframe obtained from receiver operating characteristic (ROC) analysis. We included SRs that studied both men and women with fractures in the general adult population.
Results: The review identified 26 different tools currently in use to predict fracture risk. Within these tools a total, 21,717 different prediction variables were found. Among the different tools, a different number of factors were used ranging from the BWC model that used a single predictor variable to the GSOS tool that incorporated 21,717 predictor variables in its model (including many individual SNPs). Regarding the performance of the tools, AUC ranging from 0.60–0.89. None of the models had a prediction capacity $> 90\%$. Most of the models are within the range of 0.7–0.75, but it cannot be said that any specific one stands out over the others. Rather, a fluctuating behavior is observed in all models within the different studies. The discrimination of the two most frequently validated models, including FRAX with and without BMD, varied among the studies with AUC/C index ranging from 0.55–0.90, respectively. Other commonly validated model, including the Garvan Model showed AUC between 0.57–0.84.
Conclusion: The vast majority of the models performance is within the range of 0.7–0.75. To compare the performance of different tools when predicting fracture, it is very important to consider the differences between prediction tools, the number of risk factors considered, as well as the nature of the variables as they will have an important impact on the feasibility of its use in clinical practice. Likewise, differences in the prediction results may depend on sex, age, types of fractures, as well as the temporal intervals of the prediction and could affect the use of the tools in the daily clinical routine.

P544
TENOFOVIR-INDUCED PHOSPHOPENIC OSTEOMALACIA: A CLINICAL CASE REPORT

H. Bagirova[1], P. Khandaeva[1], E. Przhiayalkovskaya[1], Z. Belaya[1]

[1]Endocrinology Research Centre, Moscow, Russia

HIV infection is a known cause of secondary osteoporosis and bone fragility. However the exact mechanism of bone complications in these patients remains the subject of research. Long-term use of tenofovir, a HIV nucleoside reverse transcriptase inhibitor, may cause osteomalacia in HIV patients.

Case report: a 49-year-old woman was referred to our clinic with a 10-month history of progressive, immobilizing pain involving the back, hips and ankles. The pain was exacerbated by physical activity and she needed a cane for walking. She had been diagnosed with a HIV 7 years previously and had been taking a combination of antiretroviral drugs including tenofovir, lamivudine and dolutegravir. The laboratory revealed severely impaired renal function and proteinuria (0.25 g/L). Serum phosphate was low (0.66 mmol/L) and alkaline phosphatase was high (340 U/L), while 25-OH vitamin D

(68.4 ng/mL) and PTH were normal. Tubular reabsorption of phosphate was 93%. Lateral radiographs of the thoracic and lumbar spine confirmed vertebral fractures at L2–3 (27–29% vertebral body height loss) and vertebral deformities at Th6-8,12. DXA showed severe BMD loss at the femoral neck (− 3.6 SD) and at the lumbar spine (− 2.6 SD) and 33% radius (− 3.4 SD). We diagnosed phosphopenic osteomalacia due to tenofovir use. Tenofovir was replaced by abacavir, treatment with alfacalcidol was initiated, and there was a rapid improvement in symptoms. The bone pain disappeared within a few weeks. The patient was able to walk unaided after 3 months. After stopping tenofovir, serum phosphate and alkaline phosphatase normalized and renal function improved.

Conclusion: Tenofovir treatment may add significantly to the musculoskeletal complications of HIV patients due to the development of phosphopenic osteomalacia. HIV treatment should be reanalysed in case of detected bone fragility or physical performance deterioration.

P545
ASSESSMENT OF OSTEOPOROSIS AWARENESS AMONG TUNISIAN WOMEN

H. Ben Ayed[1], H. Bettaieb[1], M. Boudokhane[1], R. Bourguiba[1], W. Helali[1], M. H. Dougui[1], S. Belakhal[1]

[1]Dept. of Internal Medicine, Internal Security Forces Hospital, La Marsa, Tunisia

Objective: Osteoporosis (OP) ranks as the second most significant healthcare challenge globally, after cardiovascular disease (1). We aimed to assess the level of knowledge of Tunisian women on osteoporosis.

Methods: We conducted a cross-sectional descriptive study among Tunisian women. Participants were invited to answer an anonymous web-based questionnaire composed of 22 questions. Female healthcare workers were excluded from the study. The data were analyzed with descriptive statistics using the SPSS statistical package.

Results: A total of 53 women, with a mean age of 54.4 ± 13.1 y, responded to the questionnaire. 32 (60%) participants pursued higher education at college. 36 (67.9%) of them were postmenopausal. Overall, 72% of them (n = 38) regarded their knowledge level of osteoporosis as good. Their information sources were as follows: social circle (n = 34), family doctor (n = 13) and media (n = 7). Only 20% (n = 11) of participants have had a DXA scan at least once in their lifetime. The test was recommended by a doctor in ten patients, mainly a rheumatologist (n = 6). Regarding the definition of OP, 47% (n = 25) and 23% (n = 13) of participants wrongly identified this disease as a lack of calcium in bone and as bone inflammation disease, respectively. Participants correctly identified these risk factors of OP: dietary calcium deficiency (n = 34), long-term corticosteroids therapy (n = 21) and positive family history of OP (n = 15). Overall, 40% (n = 21) of women were aware that OP leads to an increased risk of bone fracture. In regards to the management of OP, only 13.2% (n = 7) of women recognized that bisphosphonates are effective treatments for this disease, while 62.2% (n = 33) believed that vitamin D supplementation alone is sufficient. According to the participants, the factors that can prevent osteoporosis are as follows: calcium and vitamin D supplementation (n = 43), regular sunlight exposure (n = 34) and physical activity (n = 27).

Conclusion: Our study revealed that while most Tunisian women reported having some awareness of OP, their level of knowledge was average, especially regarding treatment options. Hence, OP education programs are highly recommended among Tunisian women.

P546
EVALUATION OF THE KNOWLEDGE OF TUNISIAN ORTHOPEDIC SURGEONS IN PERIOPERATIVE METHOTREXATE MANAGEMENT

H. Bettaieb[1], H. Ben Ayed[1], M. Ben Romdhane[2], M. Boudokhane[1], W. Helali[1], R. Bourguiba[3], M. H. Dougui[3], S. Belakhal[3]

[1]Dept. of Internal Medicine, Internal Security Forces Hospital, [2]Dept. of Orthopaedic Surgery, Internal Security Forces Hospital, [3]Dept. of Internal Medicine, Internal Security Forces Hospital, La Marsa, Tunisia

Objective: To assess the knowledge and attitudes of Tunisian orthopedic surgeons regarding the perioperative Methotrexate (MTX) management in patients with chronic inflammatory rheumatism (CIR).

Methods: A cross-sectional descriptive study, an anonymous questionnaire composed of 16 questions, designed with the Google-Forms software, was sent to Tunisian orthopedic surgeons. The data were analyzed with descriptive statistics using the SPSS statistical package.

Results: A total of 50 surgeons responded to the questionnaire (46 men and 4 women). The mean age was 38.1 ± 10.7 [26-66] y. Participants were as follows: 40% residents (n = 20), 31% orthopedic surgeons in the public sector and 29% orthopedic surgeons in the private sector. Forty-two percent (n = 21) of them have been practicing for more than 10 years. About 70% (n = 35) of them think that arthroplasty in patients taking MTX is a surgery with septic risk. Forty-four surgeons (88%) agreed that MTX should be discontinued temporarily prior to surgery. During the pre-operative preparation, 82% (n = 41) of orthopedics seek the advice of rheumatologist (82%), 10% of them (n = 5) ask for the anesthetists' opinion and 8% of them (n = 4) rely on the High Authority of Health (HAS) recommendations. According to them, the continuation of MTX could be the cause of an increased perioperative infection risk (57.1% of responses) or a delayed wound healing (22.4% of responses). After orthopedic surgery, only 11 (22%) of participants believed that MTX can be resumed once the wound has healed. Thirteen (26.5%) of them were uncertain about the timing for restarting. Overall, 92% (n = 46) of orthopedic surgeons considered their academic training about the perioperative management of MTX inadequate and poor.

Conclusion: We identified a low to average level of knowledge among orthopedic surgeons regarding the perioperative use of MTX in patients with CIR. Training courses for these physicians on this frequent clinic situation is needed.

P547
JOURNEY OF POLYMYALGIA RHEUMATICA PATIENTS IN TUNISIA: FROM SYMPTOMS TO TREATMENT

H. Ben Ayed[1], H. Bettaieb[1], Y. Makhlouf[2], S. Miladi[2], A. Fazaa[2], H. Boussaa[2], M. Boudokhane[1], L. Souabni[2], K. Ouenniche[2], S. Kassab[2], S. Chekili[2], K. Ben Abdelghani[2], A. Laatar[2]

[1]Dept. of Internal Medicine, Internal Security Forces Hospital, [2]Dept. of Rheumatology, Mongi Slim Hospital, La Marsa, Tunisia

Objective: Polymyalgia rheumatica (PR) is a chronic inflammatory disease characterized by arthralgia and myalgia of the shoulder and hip girdles that occurs in individuals over the age of 50 y (1). This condition is always long under-recognized and therefore underdiagnosed. We aimed to assess the different delays of PR patients' journey from disease onset to treatment initiation and to identify possible influencing factors.

Methods: We conducted a retrospective study including patients with PR (ACR/EULAR 2012 criteria). Demographic and disease characteristics were collected from medical files. Different intervals were

defined from symptom onset until the initiation of treatment. The significance threshold (p-value) was set at 0.05.
Results: 25 patients were enrolled with a mean age of 75.8 ± 12.4 years old. The male-to-female ratio was 0.16. Mean age at PR onset was 68.6 ± 10.5 y. The onset of symptoms was progressive in 68% of cases. Median delays from onset of symptoms until the first consultation and PR diagnosis were 5 ± 10 [0–48] and 33.4 ± 19.6 [0–75] months, respectively. Median delay from PR diagnosis until treatment initiation was 1 ± 1.4 [0-6] months. A significant association was found between the diagnosis delay and the following parameters: progressive symptoms onset ($p = 0.04$), absence of fatigue ($p = 0.035$) and absence of fever ($p = 0.018$). Diagnosis delay was negatively correlated with C-reactive protein level ($r = -0.55$, $p = 0.01$) and anemia ($r = -0.46$, $p = 0.016$) respectively. However, no correlation was noted between diagnosis delay and the following parameters: age ($p = 0.4$), presence of morning stiffness ($p = 0.1$) and shoulder/ pelvic girdle stiffness ($p = 0.5$).
Conclusion: Our study findings indicate that patients with PR encounter a considerable delay in both diagnosis and treatment initiation. These delays primarily stem from the absence of alarming clinical or biological indicators at the onset of the disease.

CLINICAL AND THERAPEUTIC FEATURES OF POLYMYALGIA RHEUMATICA IN TUNISIA

H. Bettaieb[1], H. Ben Ayed[1], Y. Makhlouf[2], S. Miladi[2], A. Fazaa[2], H. Boussaa[2], M. Boudokhane[1], L. Souabni[2], K. Ouenniche[2], S. Kassab[2], S. Chekili[2], K. Ben Abdelghani[2], A. Laatar[2]

[1]Dept. of Internal Medicine, Internal Security Forces Hospital, [2]Dept. of Rheumatology, Mongi Slim Hospital, La Marsa, Tunisia

Objective: To describe the clinical and therapeutic features of polymyalgia rheumatica (PR) in Tunisia.
Methods: We conducted a retrospective study including patients with PR (ACR/EULAR 2012 criteria). Demographic and disease characteristics were collected from medical files. The significance threshold (p-value) was set at 0.05.
Results: Overall, 25 patients (21 women and 4 men) were enrolled with a mean age of 75.8 ± 12.4 years old. Mean age at PR onset was 68.6 ± 10.5 y. The onset of symptoms was progressive in 68% of cases. Shoulder and pelvic girdle stiffness were reported by 100% and 36% (n = 9) of patients respectively. Morning stiffness was found in 68% (n = 17) of cases. Giant cell arteritis symptoms were reported by 48% of patients: headache (n = 16), jaw claudication (n = 3), scalp hyperesthesia (n = 3), and B symptoms signs (n = 3). At physical examination, shoulder girdle limitation was found in 84% (n = 21) of cases with bilateral involvement in 20 patients. Pelvic girdle limitation and peripheral arthritis were noted in 12% (n = 3) and 16% (n = 4) cases respectively. Blood inflammatory markers were raised in 96% of cases. Mean erythrocyte sedimentation rate and C-reactive protein were 74.8 ± 30.5 [30–125] mm and 34 ± 43.1 [5–136] mg/l respectively. Shoulder ultrasound was necessary to confirm the diagnosis in four patients and revealed subacromial-subdeltoid bursitis (n = 3) and tenosynovitis of the long head of the biceps (n = 2). Median diagnosis and therapeutic delays were 33.4 ± 19.6 months and 34.5 ± 21.4 months. All patients underwent corticosteroid therapy at an initial mean dose of 23.5 ± 9.1 [10–40] mg/d. Treatment with methotrexate was necessary in 4% of cases. The evolution was as follows: healing (64%), relapse (16%), Giant cell arteritis (12%) and corticosteroid dependence (8%). A significant association was found between diagnosis delay (> 3 months) and unfavourable outcomes ($p = 0.04$).
Conclusion: Our study emphasises the heterogeneous presentations of PR in Tunisia. Early diagnosis and treatment are paramount for a better prognosis.

P549
EVALUATION OF HEALTHCARE PROFESSIONALS' KNOWLEDGE ON OSTEOPOROSIS

H. Ben Ayed[1], H. Bettaieb[1], M. Titey[2], M. Boudokhane[1], W. Helali[1], R. Bourguiba[3], M. H. Dougui[3], S. Belakhal[3]

[1]Dept. of Internal Medicine, Internal Security Forces Hospital, [2]Dept. of Occupational Medicine, Internal Security Forces Hospital, [3]Dept. of Internal Medicine, Internal Security Forces Hospital, La Marsa, Tunisia

Objective: Osteoporosis (OP) is a significant health concern globally, characterized by low bone mass and deterioration of bone tissue (1). The role of healthcare professionals in lowering the burden of osteoporosis via patients and public education is critical. We aimed to assess the level of knowledge of healthcare professionals on OP.
Methods: We conducted a cross-sectional descriptive study among Tunisian healthcare workers (doctors excluded). Participants were invited to answer an anonymous web-based questionnaire composed of 20 questions. The data were analyzed with descriptive statistics using the SPSS statistical package.
Results: A total of 37 healthcare workers (29 women and 8 men), with a mean age of 35.3 ± 16.1 y, responded to the questionnaire. 26 participants (70.3%) were nurses and 70% of them have been practicing for > 5 y. Among the participants, 35% (n = 13) worked in a rheumatology department. Overall, 46% of them (n = 17) regarded their knowledge level of osteoporosis as good. However, only 29.7% (n = 11) of them had participated in OP training courses after their graduation. Regarding the definition of OP, 32.4% (n = 12) of participants wrongly identified this disease as a lack of calcium in bone and as bone inflammation disease. 29 participants (78.4%) knew that OP can occur in both genders. Most of the healthcare professionals (79.5%) recognized that the diagnosis is based on the DXA scan test. Only 48.6% of responders understood the difference between osteopenia and OP. Participants correctly identified these risk factors of OP: positive family history of OP (n = 27), early menopause (n = 24) and long-term corticosteroids therapy (n = 22). Overall, 62% (n = 23) of women were aware that OP leads to an increased risk of bone fracture. Only 37.8% (n = 14) of healthcare workers acknowledged bisphosphonates as effective treatments, while 65% (n = 25) believed that vitamin D supplementation alone is sufficient.
Conclusion: Healthcare workers have a moderate level of knowledge and attitude towards OP. Thus, implementing practical and motivational training methods seems essential to improve the understanding and engagement of healthcare professionals.

P550
ARE BLOOD CELLS-DERIVED INDEXES INDICATORS OF LOW BONE MINERAL DENSITY IN RHEUMATOID ARTHRITIS?

H. Ben Ayed[1], Y. Makhlouf[1], H. Boussaa[1], A. Fazaa[1], S. Miladi[1], L. Souabni[1], K. Ouenniche[1], S. Kassab[1], S. Chekili[1], K. Ben Abdelghani[1], A. Laatar[1]

[1]Dept. of Rheumatology, Mongi Slim Hospital, La Marsa, Tunisia

Objective: To investigate the association between different blood-cell-based indexes (BCI) and BMD in rheumatoid arthritis (RA) patients.

Methods: We conducted a retrospective study including patients with RA (ACR/EULAR 2010 criteria). BMD testing was performed using DXA. The following indexes were derived from the absolute neutrophil (N), lymphocyte (L), and platelet (P) counts: the neutrophil to lymphocyte ratio (NLR) = N/L; the platelet to lymphocyte ratio (PLR) = P/L; the product of platelet count and neutrophil count (PPN) and the systemic immune-inflammation index (SII) = P × (N/L).The significance threshold was set at a p value < 0.05.
Results: 48 patients with a male-to-female ratio of 0.17 were included. The mean age was 59.5 (11) [31–83] y. The mean 28 disease-activity-score (DAS28) ESR was 4.07 (1.4) [1.6–6.9]. The mean BMD at the lumbar spine (LS) and femoral neck (FN) sites were 0.916 (0.196) [0.531–1.48] and 0.784 (0.2) [0.263–1.434]. A BMD decrease was noted in 79% of the patients: osteopenia (21%) and osteoporosis (58%). The mean NLR, PLR, PPN and SII were 2.3 ± 1.2, 1.41 ± .55, 151 ± 82.8 and 703.3 ± 474.8, respectively. A positive significant correlation was noted between the DAS28ESR and the PLR (r = 0.3, p = 0.02) and the SII (r = 0.28, p = 0.047). The FN BMD was negatively associated with the PLR (r = − 0.432, p = 0.017) and the SII (r = − 0.288, p = 0.038). No significant correlation was noted between LS BMD and the different BCI ($p > 0.05$). Multiple linear regression analysis showed that NLR (β = − 0.25, p = 0.7), PLR (β = − 0.24, p = 0.07), PPN (β = − 0.82, p = 0.3), and SII (β = − 0.9, p = 0.3) were not independent predictors for BMD decrease.
Conclusion: PLR and SII are significantly associated with a lower FN BMD in RA patients, as they are strongly correlated to disease activity, which suggest that osteoporosis in RA patients results from the systemic immune and inflammatory status of the human body rather than from the direct effect of immune cells on bone cells.

P551
EPIGENETIC REGULATION OF IL-4 PROMOTER TARGETING P300 ATTENUATING INTERVERTEBRAL DISC DEGENERATION AND PAIN BY INHIBITING IL-1B

H. Cui[1], Z. Zheng[2]

[1]Sichuan Academy of Medical Sciences·Sichuan Provincial People's Hospital, Chengdu, [2]The First Affiliated Hospital of Sun Yat-sen Univ., Guangzhou, China

Objective: To investigate the role of p300/IL-4 in intervertebral disc degeneration (IVDD) and pain and elucidate the underlying molecular mechanism.
Methods: Human intervertebral disc samples were collected and graded based on the Pfirrmann grading scheme. A rat model of IVDD was established through posterior disc puncture, and various treatments were administered. The mechanical and thermal hyperalgesia were assessed using von Frey hair tests and the plantar test, respectively. Chromatin immunoprecipitation (ChIP) and ChIP-qPCR were performed, and lentivirus transduction was used for p300 knockdown.
Results: We investigated the role of CBP/p300 in IVDD. Degenerated nucleus pulposus (NP) tissues from IVDD patients exhibited a significant downregulation of p300 at both nucleic acid and protein levels, while CBP levels remained unchanged. Manipulating p300 expression in NPCs regulated matrix production, with p300 overexpression enhancing aggrecan and collagen II expression and knockdown leading to increased matrix-degrading proteins. In a rat IVDD model, activating p300 function with CTPB alleviated IVDD and pain, while inhibiting p300 with C646 exacerbated IVDD and pain. Transcriptome analysis implicated IL-4 as a downstream effector of p300, and IL-4 demonstrated protective effects against IVDD and pain. Mechanistically, p300 was found to acetylate H3K27 at the IL-4 promoter, promoting its expression.

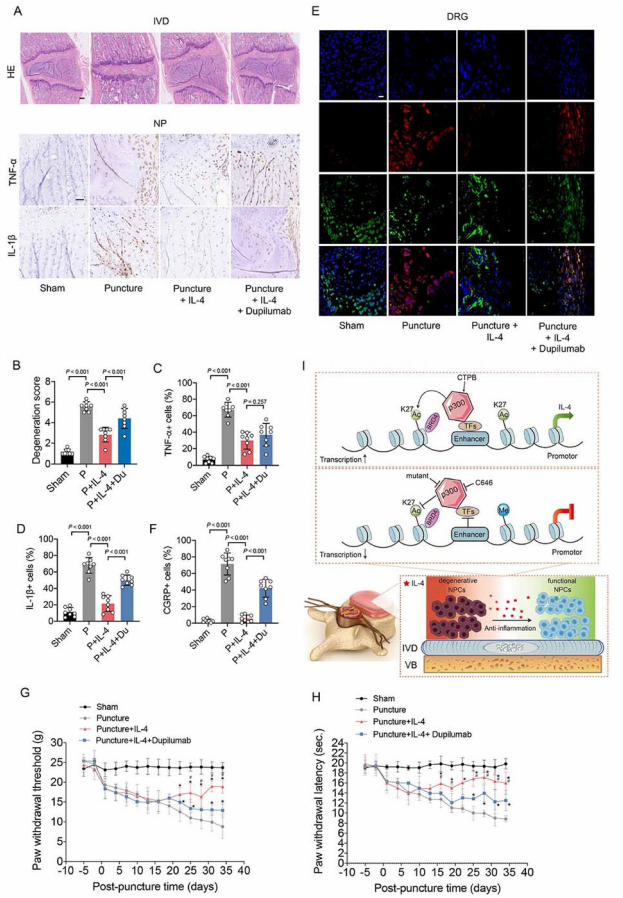

Figure. IL-4 has a therapeutic effect on IVDD and pain behavior. (A-B) Morphological staining and quantitative analysis of the effect of IL-4 and dupilumab on disc degeneration in vivo. IHC staining of TNF-α and IL-1β positive cells in sham, puncture, puncture + IL-4 and puncture + IL-4 + dupilumab group. Scale bar: 100 μm. n=8 per group. (C-D) Quantitative analysis of TNF-α and IL-1β positive cells in (A). (E-F) IHC staining and quantitative analysis of CGRP in DRGs. Scale bar: 100 μm. n=8 per group. (G-H) The 50% withdrawal threshold and thermal withdrawal threshold in puncture model of sham, puncture, puncture + IL-4 and puncture + IL-4 + dupilumab group. (I) Schematic diagram illustrating p300/IL-4 alleviate IVDD and pain by inhibiting the inflammatory microenvironment.

Conclusion: The novel findings of this study suggest that the p300/IL-4/IL-1β axis may represent a promising therapeutic target for IVDD and LBP. These results propose a hypothesis that early in the inflammatory phase, NPCs may initiate a self-protective mechanism through p300, aiding itself in preserving a favorable metabolic microenvironment. This mechanism is primarily mediated by the expression of IL-4, which has the capacity to counteract IL-1β, rather than TNFα.

A SURROGATE FRAX MODEL FOR MONGOLIA

H. Johansson[1], M. Jaalkhorol[2], A. Dashtseren[3], S. Avirmed[4], O. Bruyere[5], M. Schini[6], E. Liu[1], M. Lorentzon[7], L. Vandenput[1], N. Harvey[8], E. McCloskey[9], J. Kanis[10]

[1]Mary McKillop Institute for Health Research, Australian Catholic Univ., Melbourne, Australia, [2]Dept. for Student Development and Management, Mongolian National Univ. of Medical Sciences, Ulaanbaatar, Mongolia, [3]Dept. of Preventive Medicine, School of Public Health, Mongolian National Univ. of Medical Sciences, Ulaanbaatar, Mongolia, [4]Graduate School, Mongolian National Univ. of Medical Sciences, Ulaanbaatar, Mongolia, [5]Division of Public

Health, Epidemiology and Health Economics, Univ. of Liege, Liege, Belgium, [6]Dept. of Oncology and Metabolism, Univ. of Sheffield, Sheffield, UK, [7]Sahlgrenska Osteoporosis Centre, Institute of Medicine, Univ. of Gothenburg, Gothenburg, Sweden, [8]MRC Lifecourse Epidemiology Centre, Univ. of Southampton, Southampton, UK, [9]Centre for Metabolic Bone Diseases, Univ. of Sheffield, Sheffield, UK, [10]Mary McKillop Institute for Health Research, Australian Catholic Univ., Melbourne, Australia

Objective: FRAX models are frequently requested for countries with little or no data on the incidence of hip fracture. In such circumstances, the International Society for Clinical Densitometry and International Osteoporosis Foundation have recommended the development of a surrogate FRAX model, based on country-specific mortality data but using fracture data from another country, usually within the region, where fracture rates are considered to be representative of the index country. This abstract describes the development and characteristics of a surrogate FRAX model for Mongolia.

Methods: The FRAX model used the ethnic-specific incidence of hip fracture in men and women living in China, combined with the death risk for Mongolia (United Nations (UN), 2015–2019). The 10-y probability of a major osteoporotic fracture (MOF) was used when comparing the surrogate model and the FRAX model for China. Examples are given for a woman with no clinical risk factors and BMI 25 kg/m^2, where the BMD was not known. The hip fracture incidence and UN population data were used to calculate estimated number of fractures 2020 and 2050.

Results: The surrogate model gave similar 10-y fracture probabilities for men and women compared to the model for China. There were very close correlations (r = 0.99) in fracture probabilities between the surrogate and authentic models, so that the use of the Mongolia model had little impact on the rank order of risk. When the fracture incidence from Chinas was used to the population of Mongolia, it was estimated that 530 hip fractures arose in 2020 in individuals over the age of 50 y, with a predicted increase by approximately 3.6 times to 1896 in 2050.

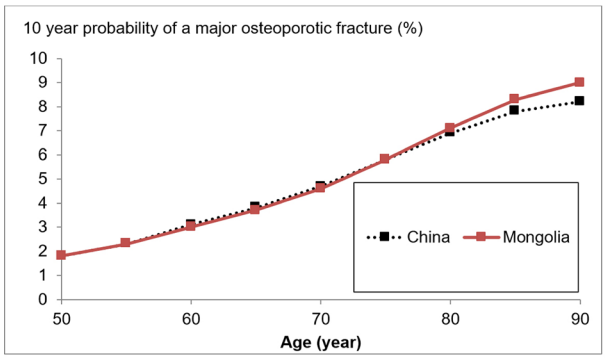

Figure The 10-year probability of a major osteoporotic fracture (%) for a woman with no clinical risk factors, BMI 25 kg/m^2 where the BMD was not known.

Conclusion: The surrogate FRAX model for Mongolia provides an opportunity to determine fracture probability within the Mongolia population and help guide decisions about treatment.

EPIDEMIOLOGY OF HIP FRACTURE IN EGYPT AND DEVELOPMENT OF A COUNTRY-SPECIFIC FRAX MODEL

H. Johansson[1], Y. El Miedany[2], M. El Gaafary[3], N. Gadallah[4], S. Mahran[5], M. Abu-Zaid[6], W. Hassan[7], W. Elwakil[8], N. Harvey[9], M. Schini[10], E. Liu[1], L. Vandenput[1], M. Lorentzon[11], E. McCloskey[12], J. Kanis[13]

[1]Mary McKillop Institute for Health Research, Australian Catholic Univ., Melbourne, Australia, [2]Canterbury Christ Church Univ., England, UK, [3]Community and Public Health, Ain Shams Univ., Cairo, Egypt, [4]Rheumatology and Rehabilitation, Ain Shams Univ., Cairo, Egypt, [5]Physical Medicine, Rheumatology and Rehabilitation, Assiut Univ., Assiut, Egypt, [6]Rheumatology and Rehabilitation, Tanta Univ., Tanta, Egypt, [7]Rheumatology and Rehabilitation, Benha Univ., Benha, Egypt, [8]Physical Medicine, Rheumatology and Rehabilitation, Alexandria Univ., Alexandria, Egypt, [9]MRC Lifecourse Epidemiology Centre, Univ. of Southampton, Southampton, UK, [10]Dept. of Oncology and Metabolism, Univ. of Sheffield, Sheffield, UK, [11]Sahlgrenska Osteoporosis Centre, Institute of Medicine, Univ. of Gothenburg, Gothenburg, Sweden, [12]Centre for Metabolic Bone Diseases, Univ. of Sheffield, Sheffield, UK, [13]Mary McKillop Institute for Health Research, Australian Catholic Univ., Melbourne, Australia

Objective: To develop a country-specific fracture prediction FRAX® tool for Egypt based on the epidemiology of osteoporotic fractures in the State of Egypt.

Methods: Hip fracture data (ICD 10: S72.0, S72.1, S72.2) were sourced from Fracture Liaison Service centres in Alexandria and Assiut University Hospitals covering the northern and southern parts of Egypt during the period from February 2022 to February 2023 [El Miedany et al., Arch Osteoporos 2023;18:115]. The derived age- and sex-specific incidence of hip fracture were combined with national mortality rates (United Nations (UN), 2015–2019) to create a FRAX model for Egypt. Fracture probabilities were compared with those from neighboring countries having FRAX models. The hip fracture incidence and UN population data were used to calculate the estimated number of fractures in 2020 and 2050.

Results: Age-specific fracture rates were higher in women than in men except for the age intervals 45–49 y. Hip fracture rates were lower than estimates from Israel, Malta, and Greece, particularly at older ages. Therefore, probabilities of a major osteoporotic fracture or hip fracture were also lower in Egypt than in the comparison countries. When the fracture incidence from Egypt was applied to the population of Egypt, it was estimated that 27,016 hip fractures arose in 2020 in individuals over the age of 50 y, with a predicted increase of approximately 2.8 times to 77,345 in 2050.

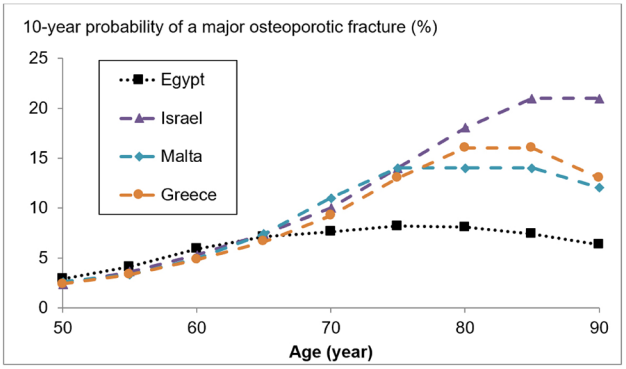

Figure The 10-year probability of a major osteoporotic fracture (%) for a woman with no clinical risk factors, BMI 25 kg/m^2, and BMD not included.

Conclusion: The FRAX model should enhance the accuracy of determining fracture probability among the Egypt population and help guide treatment decisions.

P554
EPIDEMIOLOGY OF HIP FRACTURE IN COSTA RICA AND DEVELOPMENT OF A COUNTRY-SPECIFIC FRAX MODEL

P. Clark[1], H. Johansson[2], S. Cerdas Perez[3], A. Ortiz[4], G. Cruz Pliego[1], N. Harvey[5], M. Schini[6], E. Liu[2], L. Vandenput[2], M. Lorentzon[7], E. McCloskey[8], J. Kanis[9]

[1]Clinical Epidemiology Unit, Children's Hospital of Mexico, Federico Gomez-Faculty of Medicine, National Autonomous Univ. of Mexico (UNAM), Mexico City, Mexico, [2]Mary McKillop Institute for Health Research, Australian Catholic Univ., Melbourne, Australia, [3]Dept. of Endocrinology, Hospital Cima San José, Universidad de Costa Rica, San José, Costa Rica, [4]School of Public Health, Faculty of Medicine, Univ. of Costa Rica, San José, Costa Rica, [5]MRC Lifecourse Epidemiology Centre, Univ. of Southampton, Southampton, UK, [6]Dept. of Oncology and Metabolism, Univ. of Sheffield, Sheffield, UK, [7]Sahlgrenska Osteoporosis Centre, Institute of Medicine, Univ. of Gothenburg, Gothenburg, Sweden, [8]Centre for Metabolic Bone Diseases, Univ. of Sheffield, Sheffield, UK, [9]Mary McKillop Institute for Health Research, Australian Catholic Univ., Melbourne, Australia

Objective: To describe the epidemiology of osteoporotic fractures in the State of Costa Rica and develop a corresponding country-specific FRAX® tool.

Methods: Hip fracture data (ICD 10: S72.0, S72.1, S72.2) were retrieved from the discharge database for the years 2015–2019 from Caja Costaricense de Seguro Social (CCSS), the principal public health care provider in the state of Costa Rica. The CCSS covers almost 91%, and is representative, of the country's population. These data were used to derive age- and sex-specific incidence of hip fracture in Costa Rica residents and, combined with national mortality rates (United Nations (UN), 2015–2019), were used to create a FRAX model for Costa Rica. Fracture probabilities were compared with those from neighboring countries having FRAX models. The hip fracture incidence and UN population data were used to calculate the estimated number of fractures nationally in 2020 and 2050.

Results: Age-specific fracture rates were higher in women than in men except for ages 50-59 y. Hip fracture rates were somewhat higher than estimates from Ecuador, Venezuela, Colombia, and Mexico. Therefore, probabilities of a major osteoporotic fracture or hip fracture were also higher in Costa Rica than in the neighboring countries (Figure). Using these incidence rates, it was estimated that 3176 hip fractures occurred in 2020 amongst individuals over the age of 50 years, with a predicted increase by approximately 3.1 times to 9946 in 2050.

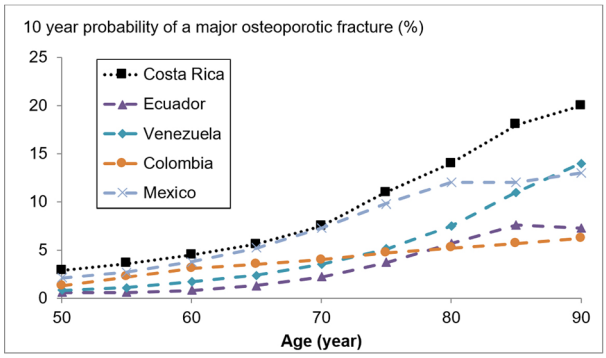

Figure The 10-year probability of a major osteoporotic fracture (%) for a woman with no clinical risk factors, BMI 25 kg/m^2, and where BMD was not known.

Conclusion: The FRAX model should enhance the accuracy of determining fracture probability among the Costa Rica population and help guide treatment decisions.

A SURROGATE FRAX MODEL FOR BRUNEI

H. Johansson[1], Y. Kwang[2], M. Chandran[3], M. Schini[4], M. Lorentzon[5], L. Vandenput[1], N. Harvey[6], E. McCloskey[7], J. Kanis[8], E. Liu[1]

[1]Mary McKillop Institute for Health Research, Australian Catholic Univ., Melbourne, Australia, [2]Endocrine Centre, Raja Isteri Pengiran Anak Saleha Hospital, Brunei Darussalam, Darussalam, Brunei, [3]Osteoporosis and Bone Metabolism Unit, Dept. of Endocrinology, Singapore General Hospital, Singapore, Singapore, [4]Dept. of Oncology and Metabolism, Univ. of Sheffield, Sheffield, UK, [5]Sahlgrenska Osteoporosis Centre, Institute of Medicine, Univ. of Gothenburg, Gothenburg, Sweden, [6]MRC Lifecourse Epidemiology Centre, Univ. of Southampton, Southampton, UK, [7]Centre for Metabolic Bone Diseases, Univ. of Sheffield, Sheffield, UK, [8]Mary McKillop Institute for Health Research, Australian Catholic Univ., Melbourne, Australia

Objective: FRAX® models are frequently requested for countries with little or no data on the incidence of hip fracture. In such circumstances, the International Society for Clinical Densitometry and International Osteoporosis Foundation have recommended the development of a surrogate FRAX model, based on country-specific mortality data but using fracture data from another country, usually within the region, where fracture rates are considered to be representative of the index country. This abstract describes the development and characteristics of a surrogate FRAX model for Brunei.

Methods: The FRAX model used the ethnic-specific incidence of hip fracture in men and women living in Singapore with Malay ethnicity (Source: Singapore Ministry of Health), combined with the death risk for Brunei (United Nations (UN), 2019). The 10-y probability of a major osteoporotic fracture (MOF) was used when comparing the surrogate model and the FRAX model for Singapore Malays. Examples are given for a woman with no clinical risk factors, BMI 25 kg/m^2, and BMD unknown. The hip fracture incidence and UN population data were used to calculate estimated number of fractures in 2020 and 2050.

Results: The surrogate model gave similar 10-y fracture probabilities for men and women up to the age of 75 y compared to the model for Singapore Malays. For older ages the probabilities were lower for the surrogate model due to higher death risk in Brunei. There were very close correlations (r = 0.99) in fracture probabilities between the surrogate and authentic models, so that the use of the Brunei model had little impact on the rank order of risk. When the fracture incidence from Singapore Malays was used to the population of Brunei, it was estimated that 117.7 hip fractures arose in 2020 in individuals over the age of 50 years, with a predicted increase by approximately 5.6 times to 663.9 in 2050.

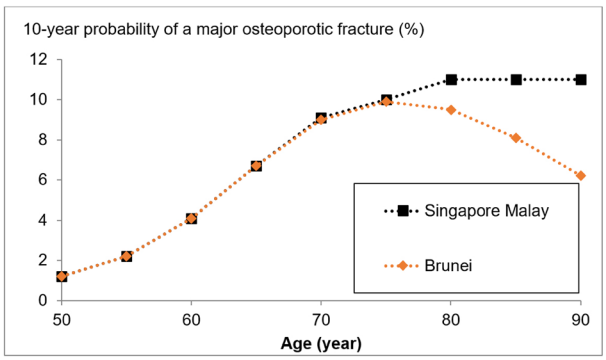

Figure The 10-year probability of a major osteoporotic fracture (%) for a woman with no clinical risk factors, BMI 25 kg/m^2, and BMD unknown.

Conclusion: The surrogate FRAX model for Brunei provides an opportunity to determine fracture probability within the Brunei population and help guide decisions about treatment.

EFFECTS OF TST002 (BLOSOZUMAB) IN CHINESE SUBJECTS WITH REDUCED BONE MINERAL DENSITY: A SINGLE ASCENDING DOSE TRIAL

J. Li[1], D. Chen[2], P. Feng[2], L. Li[3], X. Zhu[1], B. Cao[1], Q. Wang[2], C. Li[3], X. Qian[4], C. Germa[4], C. Qi[4], J. Wang[4], Z. Yao[4], X. Lin[4], Y. Liu[4], X. Zhu[4], H. Lin[1]

[1]Metabolic Bone Disease Prevention and Treatment Research Center, Nanjing Drum Tower Hospital, Nanjing, [2]Dept. of Endocrinology and Metabolism, West China Hospital, Chendu, [3]Endocrine Dept., The First Affiliated Hospital of Henan Univ. of Science and Technology, Luoyang, [4]Clinical Research & Development, Suzhou Transcenta Therapeutics Co., Ltd, Suzhou, China

Objective: TST002 (blosozumab) is a humanized monoclonal antibody targeting sclerostin. The study was aimed to evaluate the safety, tolerability, pharmacokinetics, pharmacodynamics of TST002 in Chinese population.

Methods: In the randomized, double-blind, placebo-controlled, ascending, single-dose study, eligible subjects received TST002 (200, 400, 800 or 1200 mg) or placebo intravenously in a ratio of 3:1 and were monitored for 85 d after dosing.

Results: 30 postmenopausal women and 2 elder men with reduced BMD were enrolled. The mean lumbar spine, total hip and femoral neck BMD T value at baseline were − 1.50, − 1.42, − 1.70. The single dose administration of TST002 200–1200 mg demonstrated a generally good tolerability and safe profile. Most TEAEs were of grade 1 or 2 (CTCAE v5.0). The TEAEs reported by ≥ 3 subjects included hypocalcemia, fecal occult blood positive, blood triglyceride increased, upper respiratory tract infection, COVID-19, blood low density lipoprotein increased, and blood alkaline phosphatase increased. The incidence was almost balanced between TST002 and placebo cohort and without dose correlation. No DLT, SAE, or death event was reported. The exposure (C_{max}, AUC) showed a positive correlation with TST002 dosage. The half-life ranged from 4.38–8.06 d. Furthermore, a dose dependent increase in lumbar spine bone BMD was observed at D85, ranging from 3.52–6.20%, which was higher than 0.30% in placebo cohort. The percentage change at D85 from baseline in total hip and femoral neck BMD also exhibited a positive correlation with the dosage, ranging from 1.30–1.74% and − 0.01% to 1.85% respectively, which were higher than 0.51% and -0.73% in placebo cohort. The P1NP level experienced a rapid increase with dose correlation while the β-CTX displayed a quick decrease without dose correlation after TST002 administration.
Conclusion: The single dose administration of TST002 up to 1200 mg was found to be well tolerated without cardiac signal. Encouraging increase in BMD was observed, consistent with that in pervious blosozumab SAD studies in Caucasian and Japanese population. These findings suggest the potential efficacy of TST002 as a therapeutic option for the patients with osteoporosis and other bone diseases. Multiple dose studies with less frequent dosing intervals are warranted.

P558
BASELINE BONE HEALTH ASSESSMENTS IN PATIENTS WITH ADVANCED MELANOMA RECEIVING HIGH-DOSE SYSTEMIC GLUCOCORTICOIDS FOR IMMUNE CHECKPOINT INHIBITOR INDUCED TOXICITY

H. N. Katifi[1], N. Coupe[1], H. E. Turner[2], M. Bhattacharyya[3], M. K. Javaid[4]

[1]Dept. of Oncology, Oxford Univ. Hospitals NHS Foundation Trust, Oxford, [2]Dept. of Endocrinology, Oxford Centre for Diabetes, Endocrinology and Metabolism, Univ. of Oxford, Oxford, [3]Berkshire Cancer Centre, Royal Berkshire Hospital, Reading, [4]Nuffield Dept. of Orthopaedics, Rheumatology and Musculoskeletal Sciences, Univ. of Oxford, Oxford, UK

Objective: Immune checkpoint inhibitors (ICIs) have transformed oncology therapeutics yet can cause severe immune-related adverse events (irAEs) that require high-dose systemic glucocorticoids. We evaluate whether bone health assessments and anti-osteoporotic interventions are implemented by oncologists at glucocorticoid initiation for ICI-induced irAEs.
Methods: Between December 2016 and April 2023, 233 adults with advanced melanoma received combination ipilimumab and nivolumab at a UK tertiary cancer centre. 141 (60.5%) were exposed to high-dose glucocorticoids, equivalent to ≥ 5 mg/d prednisolone over 3 months. A consecutive series by NHS number were audited to collect: (i) FRAX® clinical risk factors; (ii) features of vertebral compression fractures (VCFs) including ≥ 4 cm height loss, kyphosis, and back pain; (iii) calcium intake; (iv) 25-hydroxyvitamin D (25-OHD) level; (v) DXA; and (vi) pharmacologic measures to prevent glucocorticoid-induced osteoporosis.
Results: 20 patients were sampled with a median age of 63.5 y. 8/20 patients were female and 75% postmenopausal. 65% received ≥ 2 glucocorticoid courses for irAEs. No patients were considered for anti-osteoporosis medication at baseline glucocorticoid exposure. 4 patients underwent DXA scans, and 2 were subsequently commenced on bisphosphates, both following an osteopenia diagnosis. 6/9 tested for 25-OHD were deficient (< 50 nmol/L). 3/9 patients with back pain had radiographic evidence of VCFs. Smoking and alcohol history were determined in 75% of patients. No patients were evaluated for: calcium intake, ≥ 4 cm height loss, thoracic kyphosis, nor parental history of hip fracture.
Conclusion: Baseline bone health assessments are sub-optimally performed by oncologists for patients with advanced melanoma receiving high-dose systemic glucocorticoids for ICI-induced irAEs. Vitamin D deficiency and VCFs were common, confirming the importance of integrating bone health as part of the management of oncology patients receiving ICIs.

P559
REAL-WORLD DATA OF OSTEOPOROTIC TREATMENT WITH ANABOLIC AGENTS

H. T. Lee[1], Y. L. Teng[2], T. Y. Chen[3]

[1]Lee General Hospital, [2]Osteoporosis Prevention Center, Taichung Veterans General Hospital, [3]Dept. of Neurosurgery, Neurological Institute, Taichung Veterans General Hospital, Taichung, Taiwan

Objective: Osteoporosis is a major health issue in most aging society. As the fourth common health issue in the elderly population in Taiwan, the prevalence of osteoporosis is around 25.9% and 38.3% in man and woman over 50. The condition has brought about substantial morbidity and mortality once left unattended. Teriparatide is an anabolic agent which not only increases BMD, and reduces the risk of vertebral fracture and hip fracture. Romosozumab is another anabolic agent that has been widely used as new tools against osteoporosis with established efficacy, tolerability and preferable treatment interval. The aim of this study is to retrospectively analyze the real-world data of these two agents in terms of improvements in BMD.
Methods: We reviewed the medical records of the patients who received teriparatide or romosozumab in a tertiary medical center in the past 5 y. Those who did not complete the treatment course (12 months of teriparatide or 12 doses of romosozumab) were excluded. The BMD data before and after the treatment was analyzed.
Results: A total of 195 patients were enrolled for analysis; 152 patients received teriparatide and 43 receive romosozumab. The median BMD of lumbar spine before and after treatment with teriparatide was 0.754 and 0.823. BMD of lumbar spine before and after treatment with romosozumab was 0.780 and 0.892. Both groups have statistically significant increase in the BMD. The mean difference in the teriparatide group is 0.053 and the romosozumab 0.101.
Conclusion: We presented real-world data of patients treated with anabolic agents for osteoporosis. Both agents showed notable increase in the BMD but the difference is more prominent in those who treated with romosozumab. Future studies need to focus on subgroup analysis and try to developed personalized, tailored therapy for osteoporotic patients.

P560
NUTRITIONAL AND METABOLIC STATUS AFFECT MUSCLE AND BONE MASS IN ELDERLY JAPANESE TYPE2 DIABETES PATIENTS

H. Todoroki[1], T. Takayanagi[1], K. Kamimura[2], S. Asai[3], A. Harada[4], A. Ito[4], K. Iwai[1], H. Sumioki[1], M. Hatsuno[1], H. Koide[1], Y. Nakajima-Hasegawa[1], K. Yamaguchi[1], H. Shigeyasu[1], K. Nishida[1], S. Kanie[1], S. Fuse[1], R. Morikawa[1], Y. Asada[1], S. Kumon[1], S. Ueno[1], K. Okamoto[1], Y. Matsuo[1], Y. Yoshino[1], I. Hiratsuka[1], S. Sekiguchi-Ueda[1], A. Kakita[5], M. Shibata[1], Y. Seino[1], N. Hayakawa[6], A. Suzuki[1]

[1]Dept. of Endocrinology, Diabetes and Metabolism, Fujita Health Univ., Toyoake, [2]Nursing Dept., Fujita Health Univ. Hospital, Toyoake, [3]Food and Nutrition Services Dept., Fujita Health Univ. Hospital, Toyoake, [4]Food and Nutrition Services Dept., Fujita Health Univ. Hospital, Toyoake, [5]Dept. of Joint Research Laboratory of Clinical Medicine, Fujita Health Univ., Okazaki Medical Center, Okazaki, [6]Clinical Pharmacotherapeutics I, Faculty of Pharmacy, Meijo Univ., Nagoya, Japan

Objective: To evaluate the relationship between nutritional and metabolic status with muscle and bone mass in elderly patients with type 2 diabetes (T2DM).
Methods: A cross-sectional study was conducted in elderly Japanese T2DM patients equal to or above 75 years old in single diabetes center. Nutrient intake and physical activity were estimated by questionnaires. Fasting blood and serum samples were collected. Skeletal muscle index (SMI) by bioelectrical impedance analysis (BIA), handgrip strength, and gait speed were measured. BMD was measured by DXA, and their image at the hip region were analyzed by using 3D-SHAPER^{TM} software.
Results: A total of 46 independent elderly T2DM patients were enrolled from August 2021 to November 2022, with 19 males (81.1 $\pm$ 3.9 y) and 27 females (79.6 $\pm$ 3.4 y). BMI was 22.8 $\pm$ 4.8 kg/m^2 for male, and 21.8 $\pm$ 2.8 kg/m^2 for female. Mean Barthel ADL index was 94.1 $\pm$ 8.7. HbA1c and FBG levels were 8.0 $\pm$ 1.5% and 141.0 $\pm$ 34.0 mg/dL, respectively. According to AWGS2019, 21 participants were diagnosed as sarcopenia. There were 18 participants with osteoporosis, a half of which had both sarcopenia and osteoporosis. SMI had positive correlation with total amino acids, essential amino acids, branched-chain amino acids and C-peptide. Femoral neck BMD showed positive association with serum C-peptide. Although the correlation between exercise amount and SMI was not statistically significant, a tendency toward a positive correlation was observed.
Conclusion: Branched-chain amino acids, which are components of skeletal muscle proteins and have been shown to promote skeletal muscle synthesis and suppress degradation, act to maintain the formation and maintenance of skeletal muscle also in elderly people with type 2 diabetes and suggests that insulin secretion is involved in maintaining skeletal muscle mass and femoral neck BMD.

P561
AGE- AND SEX-SPECIFIC INCIDENCE RATES AND FUTURE PROJECTIONS FOR HIP FRACTURES IN ZIMBABWE

H. Wilson[1], T. Manyanga[2], A. Burton[1], N. Mafirakureva[1], P. Mushayavanhu[3], M. Ndekwere[3], J. Chipanga[2], S. Graham[4], J. Masters[4], M. Costa[4], R. Ferrand[2], C. Gregson[1]

[1]Musculoskeletal Research Unit, Bristol Medical School, Univ. of Bristol, Bristol, UK, Bristol, UK, [2]The Health Research Unit (THRU) Zimbabwe, Biomedical Research and Training Institute, Harare, Zimbabwe, Harare, Zimbabwe, [3]Dept. of surgery, Sally Mugabe Central Hospital, Zimbabwe, Harare, Zimbabwe, [4]Oxford Trauma and Emergency Care, Nuffield Dept. of Orthopaedics, Rheumatology and Musculoskeletal Science, UK, Oxford, UK

Objective: In southern Africa, rapidly ageing populations are increasing demands on healthcare services, hence we estimated current and future hip fracture incidence in Zimbabwe.
Methods: Cumulative hip fracture incidence was determined over 2 y (Oct 2021–Oct 2023) in all adults aged $\geq$ 40 y, resident in Harare, presenting to any of the 7 hospitals in Harare. Sex-specific incidence hip fracture rates per 100,000 were calculated for 5-y age bands using United Nations (UN) population estimates for the city in 2021. National UN estimates were then used to calculate age-standardised hip fracture incidence rates in adults age $\geq$ 40 y across Zimbabwe, and predict future hip fracture numbers up to 2051.
Results: In 2021 there were an estimated 212,830 women and 208,607 men aged $\geq$ 40 y living in Harare, equating to 16.2% of the city's population. Over 2 y we identified 243 hip fracture cases (133 [54.7%] female), mean (SD) age 71.2 (15.9) y, most presented to public hospitals (202[83.1%]), with a fragility fracture (210 [86.8%]). High-impact trauma, e.g., traffic accidents, was most common in younger men. In women, crude incidence per 100,000 person-years rose exponentially with age, reaching a rate of 1261.9 in those aged $\geq$ 80 y. By contrast, between 40-49 y, incidence was higher in men than women (11.3 vs. 1.2), the rate in men fell to match women at age 50-59, and then rose steadily with age to reach 900.6 in those age $\geq$ 80 y. From 2021 to 2051, the overall projected sex-specific age-standardised hip fracture incidence rate (per 100,000 adults age $\geq$ 40 in Zimbabwe) is estimated to increase for women (from 17.8 to 31.2) and men (from 11.3 to 26.4) (Fig. 1). The greatest increase is expected in women and men aged $\geq$ 80 y, with rates increasing from 20.8 to 33.9 for women and from 8.1 to 13.7 in men. Across Zimbabwe, the total number of hip fractures in adults aged $\geq$ 40 y is projected to increase from 813 in 2021 to 2172 by 2051.

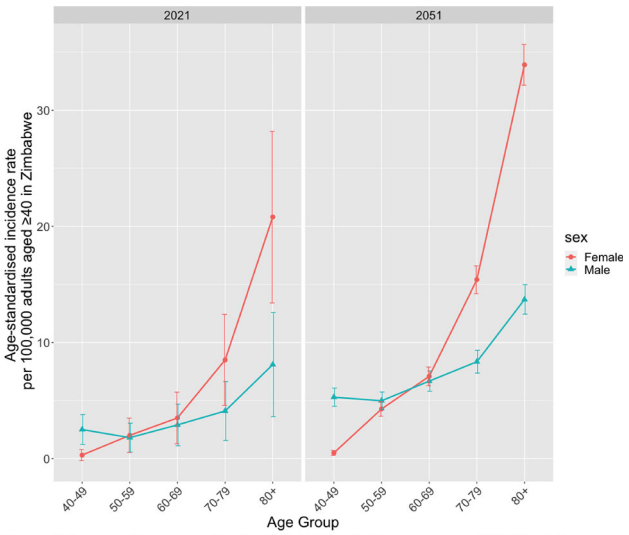

Figure 1. Sex-specific age-standardised hip fracture incidence rate per 100,000 adults age ≥40 y in Zimbabwe in 2021, with predicted rates in 2051.

Conclusion: Hip fracture incidence rates in Zimbabwe are similar to those previously reported in Black South Africans. The majority are fragility fractures, reflecting population ageing. Demands on an already over challenged healthcare system will increase; fracture services will need to respond.

P562
DISCORDANCE BETWEEN SPINE-HIP AND AFFECTED-UNAFFECTED HIP DXA AFTER STROKE: A MULTICENTER STUDY

H. Y. Lee[1], S. D. Yoo[2], J. Y. Lee[3], J. E. Son[4], S. A. Lee[4], T. W. Kim[1]

[1]Seoul National Univ. Hospital, Dept. of Rehabilitation Medicine, National Traffic Injury Rehabilitation Hospital, Dept. of Rehabilitation Medicine, Seoul, [2]Kyung Hee Univ. Hospital at Gangdong, Dept. of Physical Medicine and Rehabilitation, Kyung Hee Univ., Dept. of Medicine (AgeTech-Service Convergence Major), Seoul, [3]National Traffic Injury Rehabilitation Hospital, National Traffic Injury Rehabilitation Research Institute, Yangpyeong, [4]Kyung Hee Univ. Hospital at Gangdong, Dept. of Physical Medicine and Rehabilitation, Seoul, South Korea

Objective: Discordance between the lumbar spine (LS) and hip T-scores is sometimes observed based on the WHO T-score criteria, which can inhibit timely osteoporosis treatment. Bone loss, particularly in the paretic hip, can occur following stroke. Herein, we investigated the prevalence and risk factors of T-score discordance between the spine and hip as well as between the affected and unaffected hips in hemiplegic stroke patients.
Methods: This study was a multicenter retrospective analysis of 579 patients admitted for stroke rehabilitation between 2014–2022, who underwent DXA of LS and bilateral hips.
Results: The prevalence rates of concordance, low LS discordance, and low hip discordance between the hip and LS were 54.9%, 11.9%, and 33.2%, respectively. The discordance rate was 17.8% between the bilateral hips, and was all minor discordance. DXA scans of both hips and LS identified a minor discordance of 0.3% and major discordance of 0.9–1.2% between the spine and the hip that would have been missed owing to underestimation on LS and single-hip DXA scans. Hemiplegic stroke patients showed a higher prevalence of hip low discordance between the LS and hip than the general population. The analysis indicated that a duration of > 6 months after stroke was a significant risk factor for low hip discordance.
Conclusion: As stroke survivors are at high risk for hip fractures, more sensitive measures for identifying osteoporosis with DXA scans of both the hips and LS should be included in the standard management of post-stroke osteoporosis.

P563
UTILIZING DEEP LEARNING ALGORITHMS FOR THE DETECTION AND VISUALIZATION OF VERTEBRAL FRACTURES IN PLAIN RADIOGRAPHS

H.-Y. Chen[1], C. Soong[2], T.-H. Yang[3], R.-S. Yang[4]

[1]Dept. of Orthopedic Surgery, National Taiwan Univ. College of Medicine and National Taiwan Univ. Hospital, Taipei, [2]Institute of Biomedical Engineering, College of Medicine and College of Engineering, National Taiwan Univ., Taipei, [3]Dept. of Orthopedic Surgery, National Taiwan Univ. Hsin-Chu Hospital, Hsinchu, [4]Dept. of Orthopedics, National Taiwan Univ. College of Medicine and National Taiwan Univ. Hospital, Taipei, Taiwan

Objective: Detecting vertebral fractures (VFs) is crucial for effective secondary fracture prevention, as they are linked to higher risks of future fractures. Thoracolumbar Spinal Radiographs are routinely used for various clinical purposes and offer an excellent opportunity for the opportunistic identification of VFs. In this study, we employ a deep convolutional neural network (DCNN) to assess the potential of screening, detecting, and locating VFs using PARs.
Methods: DCNN was initially pretrained using the ImageNet dataset and then further retrained with 1000 thoracolumbar spinal radiographs images with 500 images in anterior-posterior view and 500 images in lateral view database, acquired between August 2015 and December 2018. Five pretrained CNN networks were used as feature extractors. To assess the model's performance, we evaluated its accuracy, sensitivity, specificity, and the area under the receiver operating characteristic curve (AUC). For model interpretation, we utilized the gradient-weighted class activation mapping (Grad-CAM) visualization algorithm.
Results: By employing various deep learning techniques and combining them with the ensemble method, the accuracy of identifying vertebral fractures significantly improved. The best performing ensemble strategy, which included all models, achieved high scores in evaluation metrics such as AUC, accuracy, recall, precision, and F1-score (AUC = 0.87, accuracy = 0.87, recall = 0.88, precision = 0.87, and F1-score = 0.87).
Conclusion: This study demonstrated the effectiveness of deep learning models in enhancing the accuracy of automatic vertebral fracture identification. Continued investigation and development of new model for detecting and diagnosing vertebral fractures are crucial as they have the potential to greatly impact public health and enhance the quality of life for patients.

P564
RISK FACTORS FOR MORTALITY, FRACTURES AND FALLS AMONG PATIENTS PARTICIPATING IN A FRACTURE LIAISON SERVICE PROGRAM: A MACHINE LEARNING APPROACH

R.-S. Yang[1], C. Soong[2], T.-H. Yang[3], H.-Y. Chen[4]

[1]Dept. of Orthopedics, National Taiwan Univ. College of Medicine and National Taiwan Univ. Hospital, Taipei, [2]Institute of Biomedical Engineering, College of Medicine and College of Engineering, National Taiwan Univ., Taipei, [3]Dept. of Orthopedic Surgery, National Taiwan Univ. Hsin-Chu Hospital, Hsinchu, [4]Dept. of Orthopedic Surgery, National Taiwan Univ. College of Medicine and National Taiwan Univ. Hospital, Taipei, Taiwan

Objective: The use of big data for disease prediction has been widely accepted in the fields of public health and healthcare services. This study employs computer learning models to identify the attributable risk factors associated with mortality, fractures and falls among patients participating in a fracture liaison service program.
Methods: Patient data for 600 cases with 112 characteristic fields were analyzed for prediction of "2-year dead," "2-year fracture," and "2-year fall". Model training and validation are conducted using k-fold cross-validation. Feature importance analysis using Recursive Feature Elimination with Cross-Validation (RFECV) selects the most influential features. Performance evaluation metrics such as accuracy, precision, sensitivity, specificity, F1-score, and AUC are utilized to assess the model's predictive abilities in disease diagnosis and classification.
Results: For "2-year dead," the Balanced Random Forest model is superior to the Random Forest model for handling imbalanced data, with better sensitivity, precision and F1-scores. Top 33 features were identified using RFECV as contributive to the classification target. For "2-year fracture," random undersampling performed better at improving the performance of the Balanced Random Forest model in handling extreme imbalanced data, compared to Synthetic Minority Oversampling Technique (SMOTE) and random oversampling. Top 31 contributory features were identified. For "2-year fall", the Balanced Random Forest model achieved better sensitivity and F1-score than the Random Forest model. 64 features were identified as significant predictors to whether a subject will experience a fall within 2 years.

Conclusion: The report demonstrates the importance of machine learning models, preprocessing techniques, and feature selection in disease classification. Addressing sample imbalance and utilizing appropriate evaluation metrics are crucial for accurate predictions. Future research should focus on improving the handling of imbalanced data and optimizing model performance.

P565
EPIDEMIOLOGICAL CHARACTERISTICS OF PATIENTS WITH POTENTIAL DECREASE OF MINERAL DENSITY BONE USING CLASSIC EVALUATION AND MUSCULAR ASSESSMENT

I. Abdula[1], L.-E. Stanciu[2], D. Iliescu[3], A.-D. Nedelcu[1], T. E. Iliescu[3], M.-G. Iliescu[4]

[1]Ovidius Univ. Faculty of Medicine Doctoral School. Hospital Rehabilitation Unit, Balneal Sanatorium of Techirghiol, [2]Hospital Rehabilitation Unit, Balneal Sanatorium of Techirghiol. Dept. of Medical Rehabilitation, Faculty of Medicine, Ovidius Univ. of Constanta, [3]Ovidius Univ. Faculty of Medicine, [4]Ovidius Univ. Faculty of Medicine Doctoral School. Hospital Rehabilitation Unit, Balneal Sanatorium of Techirghiol. Dept. of Medical Rehabilitation, Faculty of Medicine, Ovidius Univ. of Constanta, Constanta, Romania

Objective: Our epidemiological study was conducted to demonstrate the importance of performing bone densitometry regardless of age, background, muscular status and the presence or absence of menopause.
Methods: We made an observational study, carried out by analyzing 100 patients from South-Est area of Romania, who visited the diagnostic center between November and December 2023, who were undergoing their first DXA analysis. Using the Primus Osteosys device, both bone density and body composition were assessed, determining also the risk of sarcopenia by evaluating the physiopathological muscular status.
Results: Following DXA analysis, of the 100 patients included in the study, 48% had osteopenia, 28% osteoporosis, 24% bone density within normal limits and 8% sarcopenia. Female patients predominated, despite the fact that these diagnoses may also be present in male patients. The patient population included 5% patients aged 50–60 y, 27% aged 50–60 y, 40% aged 60–70 y and 26% aged 70–80 y. Most importantly, 7% of patients were not menopausal and resulted in 5% with osteopenia and 1% with osteoporosis. Of the menopausal patients, 43% were diagnosed with osteopenia and 26% with osteoporosis. Also, the majority of the patients belonged to the urban environment, 72% and 28% to the rural environment.
Conclusion: This study could act as a framework for the design and the implementation of osteoporosis prevention interventions, making a real portrait of the patient in this area, with real impact in clinical practice.

P566
WHEN FEMURS LOSE THEIR HEADS

I. Almeida[1], L. Saraiva[1], I. Santos[1], M. Couto[1]

[1]Unidade Local de Saúde Viseu Dão-Lafões, Rheumatology Dept., Viseu, Portugal

Avascular necrosis (AVN) of the femoral head occurs due to the interruption of the vascular supply to the proximal femur, leading to bone ischemia. It can result from traumatic or non-traumatic systemic conditions and, if left untreated, ultimately leads to femoral head collapse and secondary hip osteoarthritis. Glucocorticoids (GC) and chronic alcohol abuse are the most frequently reported nontraumatic causes. Smoking is considered to be correlated with AVN. A non-operative management is recommended for patients in early precollapse stages, while advanced stages require surgical treatment.

Case report: A 55-year-old man, with undifferentiated spondylarthritis for 10 y, taking prednisolone 5 mg/d, calcium 1500 mg/d, vitamin D 880 U/d and acemetacin 90 mg on demand, had been complaining of hip pain for 3 months. The pain radiated to the groin and was briefly relieved with analgesics and nonsteroidal anti-inflammatory drugs. The patient also had a history of alcohol abuse and a smoking history of 40 pack-years. The pelvic X-ray showed severe irregularities in the femoral heads with sclerosis and collapse of the articular surface, corresponding to avascular necrosis at stage IV of the ARCO staging system (Fig. 1). The dose of GC was reduced and the patient underwent total hip arthroplasty.

Figure 1. AP pelvic radiography showing bilateral femoral head avascular necrosis

Discussion: AVN resulting from GC therapy manifests in up to 38% of patients and exhibits a dose-dependent relationship. There are few case reports related to low dose of GC ($\leq$ 5 mg prednisone equivalent per day). In this case, the long-term therapy, the history of alcohol abuse and smoking might have increased the risk, ultimately contributing to the occurrence of AVN.
Conclusion: In a patient undergoing GC therapy, even at a low dose, hip pain of recent onset should raise the suspicion of AVN. If feasible, GC administration should be discontinued; alternatively, the dosage should be reduced. Evaluation by an orthopaedic surgeon is essential to assess the need for surgical intervention.

P567
OSTEOMALACIA MISDIAGNOSED AS OSTEOPOROSIS: A CASE REPORT

I. Almeida[1], L. Saraiva[1], M. Couto[1]

[1]Unidade Local de Saúde Viseu Dão-Lafões, Rheumatology Dept., Viseu, Portugal

Osteomalacia is a metabolic bone disease characterized by deficient mineralization of the bone matrix. Crohn's disease (CD) can impair nutrient absorption, either by inflammation of the intestinal mucosa or by the reception of segments of the small intestine. This can lead to deficits in phosphate (P), calcium (Ca) and vitamin D (vit D) that predispose to metabolic bone disease.
Casereport: A 56-year-old man, diagnosed with CD since the age of 15, with a history of 3 ileocecal resections, high cumulative dose of glucocorticoids and multiple intravenous therapies with ferric carboxymaltose, presented with nonspecific complaints of musculoskeletal pain. Bone scintigraphy revealed multiple foci of dispersed hyperuptake, suggestive of multiple fragility fractures of cervical and dorsal vertebrae, costal arches and lesser trochanter, confirmed by CT. Bone densitometry showed a femoral neck T-score of -2.7, and bisphosphonates were started. Due to worsening

musculoskeletal pain and muscle weakness, he was referred to our rheumatology department. Clinical analyses revealed P 1.0 mg/dL (2.3–3.7), Ca 9.2 mg/dL (8.7–10.4), alkaline phosphatase (ALP) 251 IU/L (25–100), PTH 193.7 pg/mL (18.50–88.00), vit D 18.9 ng/mL (30.0–95.0) and tubular P reabsorption rate 59% (78–98%). Ultrasound showed no nodular formations in the parathyroid glands. He started phosphate and calcitriol supplementation and stopped bisphosphonates. After 4 months of therapy, there was clinical and analytical improvement: P 1.4 mg/dl; ALP 210 IU/L; PTH 204 pg/mL; vit D 28.6 ng/mL. The supplementation dosage was adjusted.

Discussion: In this case, hypophosphataemia resulted from several factors: poor intestinal absorption; ferric carboxymaltose therapy causing increased FGF23 and subsequent renal P wasting; vit D deficiency with secondary hyperparathyroidism amplifying renal P excretion.

Conclusion: Fragility fractures in a patient with low BMD do not equate to osteoporosis. A complete bone metabolism study for accurate diagnosis and appropriate treatment is essential, especially in the presence of pathologies that compromise nutrient absorption.

P568
EFFECT OF THE CONSUMPTION OF BIOACTIVE COMPOUNDS (VITAMIN C, D3, CA, POLYPHENOLS) ON BONE METABOLISM INDICES IN POSTMENOPAUSAL WOMEN WITH OSTEOPOROSIS' RISK: A PROSPECTIVE STUDY

M. Konstantinidi[1], I. Anastasiou[2], Stavroula Stoupi[3], NikolaosVlachos[4], George Tsakotos[5], Antonios Koutelidakis[1]*

[1]Laboratory of Nutrition and Public Health, Unit Of Human Nutrition, Department of Food Science and Nutrition, University of the Aegean, 81400, Myrina, Lemnos, Greece, [2]Orthopedic Clinic, Agiou Georgiou 51 Korydallos, Greece, [3]Department of Dietetics, School of Health, Metropolitan College, 74 Sorou st., Marousi, [4]Orthopedic Clinic, Athens Medical Group, Antersen 1 Psychic, Greece, [5]Orthopedic Clinic, Kyprou 1, Tripoli Arcadias, Greece

Objective: The evaluation of possible changes in biomarkers of bone metabolism and in bone density in postmenopausal women, with high risk of osteoporosis, followed by a nutritional intervention program.

Methods: It was a prospective randomized controlled trial with 115 postmenopausal women with decreased bone density, aged 45-75 y. The women randomized into four interventional groups: (I) group (n = 40) received daily 1000 mg vitamin C, 500 mg vitamin D_3, 500 mg calcium (Ca) and 300 mg magnesium (Mg), (II) group (n = 42) received daily 500 mg vitamin D_3, 500 mg Ca and 300 mg (Mg), (III) group (n = 18) received daily 150 mg bisphosphonates, 500 mg vitamin D_3, 500 mg Ca and 300 mg (Mg) and (IV) group (n = 15) received daily 364 mg polyphenols via an innovative functional food (50 g olive paste enriched with mountain tea extract) along with 500 mg vitamin D_3, 500 mg Ca and 300 mg Mg. Groups I-III received supplementation for one year whereas group IV for 5 months. Changes in calciregulatory PTH were evaluated at the beginning of the study as well as at 5 and 12 months intervals. Blood levels of vitamin D, vitamin C, Ca, Mg and the lipid profile were assessed at the beginning and at the end of the study. Bone density were evaluated with DXA at the beginning and at the end of the study. Statistical analysis was performed with IBM-SPSS Statistics 21 with level of statistical significance at $p < 0.05$.

Results: Vitamin D levels were improved, in groups II, III and IV, while PTH levels were increased for groups I and IV at the end of the intervention period. Significant positive changes recorded in bone density, in all four study groups. Significant beneficial changes on total cholesterol was observed in group IV and on HDL-Cholesterol in group I.

Conclusion: More clinical and epidemiological studies are needed for further investigation of the role of specific bioactive compounds on bone metabolism.

P569
EFFECT OF TYPE OF FAT DISTRIBUTION ON SEVERITY OF OSTEOARTHRITIS OF KNEE JOINTS

I. Bashkova[1], I. Madyanov[2]

[1]Chuvash State Univ. named after I.N. Ulyanov; Federal Center for Traumatology, Orthopedics and Arthroplasty (Cheboksary), [2]Chuvash State Univ. named after I.N. Ulyanov; Institute for the Improvement of Doctors, Cheboksary, Russia

Objective: To evaluate the association of fat distribution patterns with the course of primary knee osteoarthritis (OA).

Methods: We examined 91 patients (22 men) with a reliable diagnosis of primary knee OA (the clinical group) according to ACR criteria. The average age of patients was 54 [50; 58] y, duration of OA—7 [4; 12] y. Anthropometric examination, assessment of joint pain by VAS, Lequesne index, WOMAC, radiographic and arthrosonographic examination of knee joints were performed. The type of fat distribution—abdominal (AO) or gluteofemoral (GFO) obesity—was judged by waist circumference and waist to hip circumference ratio index. The control group was formed from 114 practically healthy individuals and was representative of the age and sex composition of the clinical group.

Results. The mean value of BMI in OA patients was 28.6 ± 5.8 kg/m^2 and was not significantly higher than in the control group—27.6 ± 4.5 kg/m^2. BMI increase was directly related to the increase in the size of osteophytes ($r = 0.434$, $p = 0.003$) and inversely correlated with the width of the X-ray articular gap ($r = -0.373$, $p = 0.014$). It appeared that it is not obesity itself, but the nature of its distribution that is of greater importance for OA. If in AO pronounced radiologic changes (III, IV stages according to Kellgren) were found in every 4th patient (26.4%), in GFO—in none of the cases ($p\chi^2 = 0.037$). Synovitis was significantly more frequent in AO than in GFO (43.4 vs. 7.1%, $p\chi^2 = 0.028$), morning stiffness was longer (24.5 ± 9.1 vs. 18.1 ± 0.3 min, $p < 0.05$), C-reactive protein level was higher (10.4 ± 1.5 vs. 6.9 ± 1.4 mg/L, $p < 0.01$). In patients with abdominal type, the severity of joint pain on loading was 33.3% higher than in patients with GFO type ($p < 0.001$), total Lequesne and WOMAC indices were 27.2% ($p < 0.05$) and 20.1% ($p < 0.05$) higher, respectively. The articular cartilage thickness of the medial tibial condyle was less in patients with AO (1.48 ± 0.48 vs. 1.91 ± 0.35 mm, $p < 0.05$). The probable negative impact of abdominal fat redistribution on the course of OA may be indicated by the positive association of waist circumference with VAS pain severity ($r = 0.238$, $p = 0.024$), Lequesne index ($r = 0.443$, $p = 0.027$), radiologic stage of OA ($r = 0.467$, $p = 0.019$) and osteophyte size ($r = 0.364$, $p = 0.012$).

Conclusion: Abdominal obesity is associated with a more severe course of OA than GFO obesity. Visceral obesity is characterized by more pronounced inflammatory, arthrosonographic and radiological changes in the joints, which is important to consider in the treatment of this category of patients.

P570
ASSESSMENT OF INDIVIDUAL RISK OF BONE FRACTURES IN PATIENTS WITH CLINICALLY MANIFEST PAGET'S DISEASE

I. Bashkova[1], N. Bezludnaya[2]

[1]Chuvash State Univ. named after I.N. Ulyanov; Federal Center for Traumatology, Orthopedics and Arthroplasty (Cheboksary), [2]Federal Center for Traumatology, Orthopedics and Arthroplasty (Cheboksary), Cheboksary, Russia

Objective: To assess individual 5-y bone fracture risk, risk of recurrent fracture, and estimated "skeletal age" in patients with clinically manifest Paget's disease (PD).
Methods: The study included 26 patients (14 of them were men) with clinically manifest form of PD. The median age of the patients was 59.5 [54; 73] y. The diagnosis of PD was established on the basis of characteristic radiologic picture and increased activity of alkaline phosphatase (ALP) in blood serum. BMD of axial skeletal sections was determined using a Lunar DPX X-ray osteodensitometer. When analyzing the densitograms, the BMD values of vertebrae or femoral neck were excluded if zones of bone tissue remodeling were detected in them. The individual 5-y risk of bone fractures, risk of recurrent fractures, and estimated skeletal age were estimated using the BONEcheck® digital tool, and the 10-y probability of low-energy fractures was estimated using the Russian model of the FRAX® calculator.
Results: The median age of clinical manifestation of PD was 53 [41; 63] y. In 76.9% of cases there was a late diagnosis of the disease—on average 7 [3; 10] y after the appearance of the first clinical symptoms. Only 6 patients (23.1%) were diagnosed in the first 2 y of the disease. At the time of diagnosis verification, the polyosseous form of the disease was diagnosed in 84.6% of patients, whereas the monosseous form was diagnosed in only 15.4% of cases, which may be related not only to the peculiarities of the course of the disease, but also to its late diagnosis. Peripheral skeletal bones were affected in 18 patients (69.2%), axial skeletal bones in 5 patients (19.2%), simultaneous lesions of the axial skeleton and pelvic girdle bones in 3 patients (11.6%). In serum of all patients with PD at the time of diagnosis, an increase in alkaline phosphorus activity was detected, exceeding the upper limit of the reference interval on average 3 times. The average values of alkaline phosphate activity amounted to 475 [296; 1211] U/L. The average content of total calcium in blood in PD patients was 2.40 [2.24; 2.45] mmol/l. According to osteodensitometry, the mean T-criteria values in the lumbar spine (LBP) were − 2.8 [− 4.1; − 0.8] CO and in the neck of femur were − 2.0 [− 3.6; − 1.2] CO. Osteopenic syndrome was detected in 79% of PD patients: osteoporosis (58%), osteopenia (10.5%), and decreased BMD below age normal in men under 50 y of age (10.5%). The 10-y probability of major osteoporotic fractures and fractures of femoral neck calculated with the FRAX® calculator in PD patients was 9.2 [5.5; 20]% and 1.9 [0.7; 11]%, respectively. While the 5-y risk of any fracture and hip fracture determined in patients aged 50 y and older using the BONEcheck® tool was higher at 14 [6; 42.5]% and 3.5 [1; 24.5]%, respectively. The mean rates of predicted risk of subsequent fractures in PD patients were found to be 14.5 [8.5; 22]%. The mean estimated "skeletal age" was 70.5 [60.2; 78.0] y and was 8.8% higher than the chronologic age (64.5 [55; 74] y) of patients in whom the BONEcheck® calculation tool was used. Almost every 2nd patient with PD (46.2%) had a history of pathologic fractures. Compression fractures of vertebral bodies were detected in 7 patients, fractures of the proximal femur in 4 patients, pelvic bones in 2 patients, surgical neck of the humerus in 1 patient. In 8 out of 12 patients with a history of low-energy fractures, the latter were multiple or there was an indication of repeated fractures of one bone. A single infusion of zoledronic acid in the dose of 5 mg not only promotes normalization of alkaline phosphorus level, but also leads to a significant increase in BMD according to the densitometry data performed in a year. However, a single parenteral administration of zoledronic acid may not be sufficient to prevent primary and recurrent fractures in PD patients. Since PD patients, even in the absence of a history of fracture, have a mean 5-year risk of primary fractures of 6 [3; 27]%, and with effective pathogenetic treatment, the risks are probably not eliminated in all patients—2 [0; 14.5]%.
Conclusion: Osteopenic syndrome is a frequent complication of clinically manifest PD (detected in 79% of cases). The predicted 5-y risk of bone fractures in PD patients was high and amounted to 14 [6; 42.5]%. Almost every 2nd patient had a history of pathologic fractures. The calculated risks of recurrent fractures were also quite high (14.5 [8.5; 22]%). Due to the high individual risks of bone fractures, life expectancy in a number of PD patients may be on average 6 years shorter due to bone fractures or exposure to risk factors that increase the likelihood of fracture.

P571
EVALUATION OF THE SAFETY SKILLS OF PATIENTS WITH BIOLOGICAL DMARDS AFTER A THERAPEUTIC PATIENT EDUCATION PROGRAM

I. Bencharif[1], D. Bendjenna[2], Y. Kitouni[1], A. Ladjouze-Rezig[3]

[1]Univ. of Constantine, Constantine, [2]Hospital Benbadis of Constantine, Constantine, [3]Univ. of Algiers, Algiers, Algeria

Objective: Biological DMARDs (bDMARDs) are well known cause a number of specific complications, including infectious ones. Patients receiving bDMARDs must know them and acquire self-care and safety skills in order to take charge of themselves in risky situations. This is only possible thanks to therapeutic patient education (TPE) programs in chronic Inflammatory arthritis such as rheumatoid arthritis (RA), spondyloarthritis (SpA) and psoriatic arthritis (PsA). We aimed to evaluate the impact of the therapeutic patient education program "EST-RIC" on the safety skills in patients treated with bDMARDs and on clinical parameters (Disease activity scores, compliance, number of infectious events, number of treatment stops, vaccination rate).
Methods: Nonrandomized clinical trial comparing the knowledge and safety skills between two cohorts of patients with RA, SpA or PsA receiving bDMARDs for at least three months in the day hospital center of CHU of Constantine: group TPE (patients joined the "EST-RIC" therapeutic education program) vs. group TPE-naive (patients who did not wish to participate).The primary outcome was the acquisition of safety skills at 3 and 6 months measured by the Biosecure questionnaire (0–100 scale), a 55 item validated questionnaire assessing competences to deal with fever, infections, vaccination, and other daily life situations [1]. The secondary outcomes were disease activity scores (DAS 28 for RA and BASDAI for SpA) at 6 months, compliance (Morisky score), number of infectious events, number of treatment stops, vaccination rate at 12 months.
Results: 450 patients were included, with mean age 41.6 ± 12.1 years old; 235 (52.2%) women; 192 (42.7%) had RA; mean disease duration 9.9 ± 6.6 y, 269 (60%) received subcutaneous bDMARDs. 240 patients in group TPE vs. 210 patients in group TPE-naive. The median Biosecure score was significantly higher in the group TPE than in the group TPE-naive (75.7/100 vs. 57.9/100; $p < 0.001$) at 6 months. There was a significant difference in disease activity scores: DAS28 and BASDAI, in rates of vaccination and discontinuation of treatment by forgetfulness. Regarding the observance to treatment or incidence of infectious events, there was no significant difference between the groups TPE and TPE-naive.
Conclusion: Safety is an important issue in the management of inflammatory arthritis treated with bDMARDs. In this trial,

therapeutic patient education improves knowledge and safety skills of arthritis patient receiving bDMARDs, and disease activity scores.

P572
BISPHOSPHONATES IN (MONA) SPECTRUM DISORDER

I. Bencharif[1], D. Bendjenna[2], Y. Kitouni[1]

[1]Univ. of Constantine, [2]Hospital Benbadis of Constantine, Constantine, Algeria

Objective: Multicentric osteolysis, nodulosis and arthropathy (MONA) spectrum disorder is a rare inherited progressive skeletal disorder caused by mutations in the matrix metalloproteinase 2 (MMP2) gene. It characterized by multiple peripheral osteolysis, wide metacarpals, osteoporosis, progressive joint contractures, short stature, subcutaneous nodules as well as a coarse face, skin lesions/ hirsutism and ocular and cardiac manifestations. The diagnosis is based on the typical clinical features together with normal laboratory findings, which allow this disease to be distinguished from other syndromes, including fibrotic, rheumatic and lysosomal diseases. Treatment options are limited. Bisphosphonates in (MONA) spectrum disorder may be an alternative therapeutic approach.
Methods: We present successful bisphosphonate therapy in two affected sisters, A.N, 10-year-old and A.I, 7-year-old, presented with history of fractures of their long bones after trivial traumas with progressive painful deformities in hands and feet with limitation motion. They were treated with bisphosphonates (intravenous zoledronate every 6 months). The following outcome variables were assessed: skeletal pain, range of motion, internal medical problems as well as neurocognitive function.
Results: Skeletal pain was reduced soon after initiation of therapy. Range of motion did not significantly improve. Neurocognitive development was normal. No further low-impact fractures occurred after starting bisphosphonate therapy. Although the nature of the disease is progressive, they are still able to walk and use their hands for writing.
Conclusion: Bisphosphonate therapy was effective especially in controlling skeletal pain and reducing fractures in MONA spectrum disorder. Early initiation of treatment seems to be particularly important in order to achieve the best possible outcome.

P573
MANAGEMENT OF A PATIENT WITH RHEUMATOID ARTHRITIS ASSOCIATED WITH SICKLE CELL DISEASE AND HEPATITIS C

I. Bencharif[1], D. Bendjenna[2], Y. Kitouni[1]

[1]Univ. of Constantine, [2]Hospital Benbadis of Constantine, Constantine, Algeria

The occurrence of rheumatoid arthritis in patient with sickle cell disease (hereditary genetic disease affecting red blood cells called hemoglobinosis s) has diagnostic, therapeutic and prognostic consequences. We aimed to show the complexity of the management of rheumatoid arthritis associated with sickle cell disease and hepatitis c when most drugs are contraindicated.

We report a case observed in a 32-year-old woman with a history of hepatitis c, who presents with deforming rheumatoid arthritis at the stage of bilateral fusing carpitis. The terrain and the different repercussions of the two conditions made the patient management complex. Indeed, corticosteroid therapy is contraindicated in the event of a flare-up of rheumatoid arthritis since it risks triggering a vaso-occlusive crisis of sickle cell disease which can be fatal. Hepatitis C contraindicates the use of disease-modifying treatments for rheumatoid arthritis. Consultation between hematologist, hepatologist, rheumatologist and infectious disease specialist was necessary to choose the appropriate treatment and achieve remission.

P574
DENSITOMETRIC PROFILE OF PATIENTS WITH OSTEOPOROTIC RISK FACTORS

I. Bencharif[1], T. Khaled[2]

[1]Univ. of Constantine, [2]Private rheumatology practice, Constantine, Algeria

Objective: Bone densitometry (DXA) measurement currently constitutes the most accurate diagnostic approach to osteoporosis. The precise indications for DXA are still debated. Indeed, the distribution of DXA values observed in fractured subjects and that observed in matched controls largely overlap, which shows that factors other than BMD play a role in determining osteoporotic fractures. This is the reason why the indications for bone densitometry are based on the existence of osteoporosis risk factors. We aimed to identify the densitometric profile of patients with osteoporotic risk factors.
Methods: This is a descriptive study of the results of bone densitometry carried out following requests from the rheumatology, orthopedics, endocrinology, oncology and internal medicine departments. Patients who underwent DXA with at least one osteoporosis risk factor were included.
Results: Of 250 patients seen, 123 presented with osteoporosis. 90.1% were women. The average age was 62.1 y; that at menopause was 47.2 y. The average BMI was 27.8 kg/m^2. 75% of patients had more than 2 major risk factors for osteoporosis: Personal or family history of fracture (38.5%), corticosteroid therapy (22.3%), anti-aromatase treatment (15.1%) and 30% had suffered at least one fall. 28.7% of patients presented at least one vertebral fracture, and 16.8% peripheral fractures: femoral neck fractures (8), wrist fractures (24), ankle fractures (7), rib fractures (3). 19.5% of patients had a delay of more than 10 years between their fracture and the performance of DXA. 60.2% of osteoporotic patients had a T-score < -2.5 at at least one site and 39.8% had a T-score < -3. 47.2% of patients were referred by rheumatologists, followed by oncologists (17.5%).
Conclusion: Risk factors for falls and osteoporosis must be sought in elderly people. Low-energy fractures can occur in non-osteoporotic patients.

P575
EPIDEMIOLOGICAL PROFILE AND CHARACTERISTICS OF GONARTHROSIS IN EASTERN ALGERIA

I. Bencharif[1], T. Khaled[2]

[1]Univ. of Constantine, [2]Private rheumatology practice, Constantine, Algeria

Objective: Gonarthrosis is one of the preferred sites of degenerative cartilage disease, which is particularly common in the elderly and can lead to incapacity and disability. It represents a public health problem. The Algerian population is increasingly exposed to symptomatic forms of gonarthrosis due to the growing ageing of the population. We present the epidemiological profile and characteristics of gonarthrosis in eastern Algeria.
Methods: A descriptive cross-sectional study was carried out over a 2-y period (January 2021-January 2023), including patients with gonarthrosis defined according to ACR criteria, seen in rheumatology (private and public). Data on the epidemiological profile and

characteristics of the patients were collected. We excluded patients who had received surgical treatment for their gonarthrosis.
Results: 582 patients were included. The mean age was 64.2 ± 9.2 y, with a sex ratio of 3.5 F/H. The mean duration of the disease was 8.6 ± 5.6 y. The duration of the disease varied, ranging from 1–45 y, with an average of 14.1 ± 14.8 y. In terms of medical history, the main chronic diseases reported and monitored were, in descending order of frequency, arterial hypertension (47.4%), followed by diabetes (34.1%), hypothyroidism (10.2%) and ischaemic heart disease (7.8%). Apart from the knee, 78.4% of patients had a secondary location: lumbar spine, cervical spine and hands. There was only one case of osteoarthritis of the hip and one case of omarthrosis. The average BMI was 29.9 ± 3.8 kg/m^2. Kellgren–Lawrence radiographic grade 3 was the most common (41.4%), and the mean total WOMAC score was 73.3 ± 11.8. With regard to previous treatments, 99.1% of patients reported having taken painkillers, 97.4% had taken non-steroidal anti-inflammatory drugs and 3.8% had taken a corticosteroid. Regarding slow-acting anti-arthrosic treatments, 37.9% had already received them. Finally, 24.4% had corticosteroid infiltration in the knees and 34.7% viscosupplementation.
Conclusion: In eastern Algeria, gonarthrosis is predominantly female, rather advanced and rarely isolated. Hip and shoulder involvement is almost nonexistent. Few patients benefit from local treatments or anti-arthrosic agents.

P576
EVALUATION OF MEDICAL PARAMEDICS' KNOWLEDGE OF BIOLOGICS: A REVIEW OF THE SITUATION IN EASTERN ALGERIA

I. Bencharif[1], D. Bendjenna[2]

[1]Univ. of Constantine, [2]Hospital Benbadis of Constantine, Constantine, Algeria

Objective: Biologics are now an essential part of the management of systemic diseases, whether autoimmune or auto-inflammatory. It is essential that paramedical staff have adequate knowledge of these molecules (indications and contraindications, elements of the pre-therapeutic assessment, monitoring elements and adverse effects) in order to facilitate the management of patients with biologics.
Methods: We conducted a cross-sectional, descriptive study to assess the skills of nurses working in day hospitals where biologics are prescribed using a validated questionnaire aimed at assessing knowledge of biologics.
Results: 73 nurses responded to the questionnaire, 39 women (53.4%) and 34 men (46.6%), the average age was 32 y (22–52 y) with a length of practice of 12.7 y, they worked in the departments of internal medicine (42.4%), rheumatology (26.5%), gastroenterology (18.6%) and dermatology (12.5%). The median score was 75.7/100 (IQR: 70.9–78.7). By analysing the different skills, i.e., the 55 items making up the dimensions of the questionnaire, all the paramedical staff questioned had answered correctly the question relating to premedication, the route and method of administration of the biotherapy and the storage methods for the different biotherapies. The skill dimensions which it is desirable to know about, but which should be emphasised, are in particular the skills relating to the management of fever and wounds. Skills relating to communication, symptoms requiring consultation and vaccination were well mastered. The skills least well mastered were contraception on biologics, dental care and planning surgery. 49.5% felt they had insufficient training in biologics. Most wanted to join a continuing professional development programme.
Conclusion: Assessment of paramedics' knowledge of biologics is far from optimal. It is crucial to take concrete action to improve this situation through regular continuing professional development sessions, while ensuring that initial programmes include theoretical and practical training based on current recommendations.

P577
CHARACTERISTICS OF PATIENTS TREATED WITH DENOSUMAB IN DAY HOSPITALS

I. Bencharif[1], D. Bendjenna[2]

[1]Univ. of Constantine, [2]Hospital Benbadis of Constantine, Constantine, Algeria

Objective: Denosumab (Dmab) is a human monoclonal antibody (IgG2) that targets RANKL and is the 1st biologic against osteoporosis. It was introduced in Algeria in 2015. According to the updated SFR/GRIO 2016 recos, the use of parenteral drugs (zoledronic acid, denosumab: reimbursed in 2nd line after bisphosphonates) can be preferred in the following situations fractures of the upper end of the femur (FESF), very low initial BMD, presence of comorbidities and in particular memory disorders, lack of observance and polypharmacy, the characteristics of the population taking Dmab, the place of Dmab in the therapeutic arsenal for osteoporosis
Methods: Retrospective study on records conducted in 2 centers: CHU Constantine, CHU Batna. Were included all patients who received Dmab from Jan 2017 to Jan 2018, the characteristics of the population were collected: age, sex, profession, BMI, duration of osteoporosis, associated pathologies, risk factors for osteoporosis, fall, calcium and vitamin D diet, initial BMD, phosphocalcic balance, initial vit D and PTH, previous anti-osteoporotic treatments, tolerance to denosumab, treatment discontinuations, occurrence of new fractures
Results: The characteristics of the population (24 patients): Sex (F/M) (23 M/1), mean age (y) = 67.04 ± 9.85 (36/87), diagnosis date (y) = 3.83 ± 4, 56 (0/10), BMI (kg/cm^2) 25.43 ± 6.15 (16/38) Initial biological assessment: serum calcium: 92 ± 5.54 mg/l (86–108), PAL: 98.78 ± 44.01 (43–170), PTH: 68.33 ± 51.34 (12–167), 10 patients who had no prior treatment had a history of fracture (N = 17), 5 of these patients had several fractures.
Conclusion: Osteoporosis is underdiagnosed, untreated. Dmab is prescribed in severe fractured osteoporosis, often as first-line treatment. The very low BMD < -3 conditions the start of the Dmab. Osteoporosis should be sought in asthmatics and priority should be given to dietary calcium intake and physical activity. Dmab has a good tolerance profile.

P578
OPINION OF HOSPITAL AND PRIVATE PRACTICE RHEUMATOLOGISTS REGARDING BIOSIMILARS

I. Bencharif[1], D. Bendjenna[2]

[1]Univ. of Constantine, [2]Hospital Benbadis of Constantine, Constantine, Algeria

Objective: bDMARDs are widely used in rheumatoid arthritis, and their cost is high. The expiration of patents for the first bDMARDs and development of (bs)DMARDs that arrived on the Algerian, 2 y ago. We assessed the opinion of rheumatologists in hospitals and private practice regarding biosimilars.
Methods: We conducted a survey of rheumatologists in hospitals and private practice regarding biosimilars using a self-administered electronic questionnaire distributed by e-mail.
Results: We showed a need for rheumatologists to have more knowledge and experience of bsDMARDs: More than half of rheumatologists know. Although rheumatologists' knowledge of bsDMARDs may vary from "a little" to "well", the survey enabled

them to gain a better understanding of the fears and questions that remain in the field, concerning substitution, tolerance, iatrogenicity and extrapolation.
Conclusion: Rheumatologists are convinced that savings can be made. A strategy for using and monitoring the first biosimilars to arrive in Algeria needs to be considered.

P579
PREVALENCE OF NEUROPATHIC PAIN IN GONARTHROSIS

I. Bencharif[1], F. Touati[1]

[1]Univ. of Constantine, Constantine, Algeria

Objective: Pain is a ubiquitous symptom in gonarthrosis and is generally considered to be nociceptive in nature. However, pain in osteoarthritis is a specific pathology with a complex pathophysiology including peripheral and central neuropathic abnormalities and local inflammation affecting all joint structures. Receptors involved in neuropathic pain have recently been observed in the joints. The aim of our study was to determine the prevalence of neuropathic pain in patients suffering from gonarthrosis and to evaluate its association with the clinical and radiological profile of the patients.
Methods: This was an observational, cross-sectional study of patients presenting to a rheumatology consultation with gonarthrosis diagnosed according to the gonarthrosis classification criteria of EULAR. Patients with a neurological pathology that could alter the assessment of the neuropathic component were excluded. Neuropathic pain was defined as a DN4 score ≥ 4.
Results: Of 120 patients (77% female) included, 90 had bilateral involvement. The mean age was 57 ± 10.8 y, the mean BMI was 29.3 ± 4.7, and the duration of gonarthrosis was 6.8 ± 5.7 y. Neuropathic pain was found in 33.5% of the arthrosic patients assessed. These patients had more intense pain (high VAS) and greater structural damage (more advanced Kellgren-Lawrence radiographic grade).
Conclusion: Osteoarthritis patients with a probable component of peripheral neuropathy, as determined with the DN4 questionnaire, may represent a specific phenotype of osteoarthritis and should benefit from specific treatment.

P580
SCREENING FOR FIBROMYALGIA IN SPONDYLOARTHRITIS

I. Bencharif[1], F. Touati[1]

[1]Univ. of Constantine, Constantine, Algeria

Objective: Fibromyalgia is a common chronic pain syndrome combining chronic diffuse musculoskeletal pain (for more than 3 months), fatigue and sleep disorders. It is associated with a variety of other functional symptoms, including cognitive problems and a feeling of waking up without rest. This syndrome is due to altered processing of nociceptive impulses in the nervous system. The prevalence of fibromyalgia appears to be higher in chronic inflammatory rheumatic diseases, particularly spondyloarthritis. The aim of this study was to estimate the prevalence of fibromyalgia in spondyloarthritis.
Methods: A cross-sectional, descriptive study including patients with spondyloarthritis diagnosed according to the ASAS (Assessment of SpondyloArthritis international Society) criteria and who had completed the FiRST (Fibromyalgia Rapid Screening Tool) questionnaire. This consisted of 6 questions graded 0 or 1. A fibromyalgia was considered for any score ≥ 5. I
Results: 60 patients were included, 8 women and 52 men (86.7%), mean age 43.8 ± 9.7 y, HLA B27 positive in 29 patients (48.3%), mean duration of spondyloarthritis 16.2 ± 9.4 y, disease activity assessed by BASDAI score 4.5 ± 2.5. Anti-TNFα therapy was prescribed in 34 patients (56.7%). A score ≥ 5 indicating fibromyalgia was found in 19 patients (31.6%).
Conclusion: In agreement with the data in the literature, this study confirms the coexistence of fibromyalgia and spondyloarthritis, which could make it more difficult to assess disease activity. In practice, screening for fibromyalgia should be systematic in order to ensure appropriate therapeutic management

P581
CONTENT, STRUCTURE, AND DELIVERY CHARACTERISTICS OF EFFECTIVE YOGA INTERVENTIONS FOR MANAGING OSTEOARTHRITIS SYMPTOMS: A SYSTEMATIC REVIEW AND META-ANALYSIS

I. Biswas[1], G. Nalbant[1], S. Lewis[1], K. Chattopadhyay[1]

[1]Univ. of Nottingham, Nottingham, UK

Objective: To synthesise content, structure, and delivery characteristics of effective yoga interventions for managing osteoarthritis symptoms.
Methods: JBI systematic review methodology was followed. 17 databases were searched for randomised controlled trials (RCTs) that assessed yoga's effectiveness in osteoarthritis (i.e., on pain or function). Meta-analyses and a narrative synthesis were conducted to address the objective.
Results: 18 and 16 articles (representing 16 and 14 RCTs) were included in the systematic review and meta-analysis, respectively. Overall, the included studies had low methodological quality scores. 10 of 14 interventions were effective in reducing pain (SMD -0.70; 95% CI -1.08, -0.32) and/or improving function (-0.40; -0.75, -0.04). 6 effective interventions had centre-based (supervised, group) sessions with additional home-based (unsupervised, individual) sessions. Effective interventions included 34 different yogic poses (10 standing, 12 sitting, 4 prone, 8 supine), 8 breathing practices, and 3 meditation and relaxation practices, and all three major yoga components were included in 3 interventions. To address participants' needs (e.g., physical limitations), yogic poses were adapted in 4 interventions. The median duration of centre-based sessions was 8 weeks (IQR 8–11 weeks) and each session was around 53 min (IQR 45–60 min), mostly delivered once a week. The median duration of home-based sessions was 10 weeks (IQR 8–12 weeks) and each session was 30 min (IQR 29–30 min), mostly delivered 4 times a week. Strategies were used to monitor and improve adherence to home practice e.g., self-recorded diaries and videos, telephone calls, and email reminders.
Conclusion: Given previous studies' limitations, a high-quality RCT should be conducted using synthesised content, structure, and delivery characteristics of previous effective yoga interventions for osteoarthritis.

P582
IRISIN, TROLOX AND RESVERATROL: A POTENTIAL ANTI-SENESCENCE COCKTAIL TO REPRODUCE THE EFFECTS OF A HEALTHY LIFESTYLE AND COUNTERACT THE PROGRESSION OF OSTEOPOROSIS

I. Cariati[1], R. Bonanni[2], A. Falvino[2], B. Gasperini[2], A. Chiavoghilefu[3], R. Iundusi[3], E. Gasbarra[3], V. Tancredi[1], U. Tarantino[4]

[1]Dept. of Systems Medicine, "Tor Vergata" Univ. of Rome, [2]Dept. of Biomedicine and Prevention, "Tor Vergata" Univ. of Rome, [3]Dept. of Orthopaedics and Traumatology, "Policlinico Tor Vergata" Foundation, [4]Dept. of Clinical Sciences and Translational Medicine, "Tor Vergata" Univ. of Rome, Rome, Italy

Objective: To evaluate the effects of administering a cocktail of recombinant irisin (r-irisin), resveratrol and trolox in osteoblasts isolated from sedentary osteoporotic patients to (i) counteract the cellular senescence that characterizes age-related musculoskeletal diseases such as osteoporosis, and (ii) identify a potential strategy that can mimic the effects of a healthy lifestyle based on regular exercise and adequate diet.
Methods: Primary cultures of human osteoblasts were set up from bone biopsies taken from 10 patients undergoing hip arthroplasty for fragility fracture. After treatment with the anti-senescence cocktail for 6 days, quantitative assays were performed to assess cell viability and the presence of intracellular reactive oxygen species (ROS). B-galactosidase activity was assessed by quantitative and colorimetric assay, while immunocytochemistry and western blot analyses were performed to detect the Sirt1 and NOX4 expressions.
Results: The treatment significantly reduced the amount of intracellular ROS and β-galactosidase activity, while cell viability was significantly improved. Interestingly, a modulation of SIRT1 expression was observed in association with reduced NOX4 expression.
Conclusion: The administration of r-irisin, trolox and resveratrol exerts powerful beneficial effects on osteoblasts, suggesting that strategies that mimic the effects of a healthy, balanced lifestyle can counteract cellular senescence in osteoporosis.

P583
ASSESSMENT OF GAIT STEREOTYPE FUNCTION IN PATIENTS WITH TRAUMATIC AND COMPRESSION-ISCHEMIC NEUROPATHIES

I. Chapko[1], A. Filipovich[1], J. Ovsjanik[1]

[1]National Science and Practice Centre of Medical Assessment and Rehabilitation, Yukhnovka, Belarus

Objective: 36 patients with traumatic and compression-ischemic neuropathies using quantitative criteria were examined.
Methods: Assessment of stato-dynamic violations using codes ICF.
Results: The following data were obtained in the course of the study: b770.0. No impairment (0–4%). Patients complained of slight walking impairment (uneven surface, 131 accelerated steps). b770.1: Mild impairment (5–24%). Visual limping on the paretic leg is noted. Increase in the number of steps when walking 100 m to 150–160, increase in the duration of a double step to 1.5–1.7 s, decrease in the walking pace to 64–70 steps/min, decrease in the walking rhythm factor to 0.85–0.90, decrease in walking speed to 3.0 km/h. b770.3.1: Severe impairment (50–75%). Paretic gait. Increase in the number of steps when walking 100 m to 204–226, increase in double step duration to 2.6–3.6 s, decrease in walking pace to 29–46 steps/min, decrease in walking rhythm coefficient to 0.52–0.58. b770.3.2: Severe impairment (76–95%). Gait is grossly impaired with significantly delayed movement. b770.4: Absolute impairment (96–100%). Patient cannot move independently.
Conclusion: A clinical and functional analysis of the gait stereotype function was carried out in 36 patients with traumatic and compression-ischemic neuropathies using quantitative criteria for the purpose of medical examination and rehabilitation diagnostics.

P584
ASSESSMENT OF THE RISK OF DISABILITY FORMATION IN PATIENTS WITH TRAUMATIC AND COMPRESSION-ISCHEMIC NEUROPATHIES

I. Chapko[1], A. Filipovich[1], J. Ovsjanik[1]

[1]National Science and Practice Centre of Medical Assessment and Rehabilitation, Yukhnovka, Belarus

Objective: A clinical and functional study of 42 patients was carried out.
Methods: Assessment of stato-dynamic violations using codes ICF.
Results: First of all, such factors as the presence and high functional class ($FC > 1$) of the severity of the main (deficit) neurological syndrome, low dynamics of restoration of impaired functions during treatment and rehabilitation had a high significance in the development of disability in the late recovery period; inability to perform professional work in their previous profession. In the course of the study, it was found that the significance of individual factors in different periods of the disease is unequal, if in the acute and recovery period of the disease the significance of medical factors is higher, then in the long-term period the role of social (professional) factors is higher. In a number of cases, patients had difficulties in implementing an individual rehabilitation program in terms of fulfilling labor recommendations, which was especially true for individuals. employed in labor with a high role of physical labor, forced position of the body, prescribed pace of work. The psychological characteristics of patients played a certain role in reducing the rehabilitation potential and prolonging disability. In cases of psychopathological disorders caused by situational influence (injury as a result of a traffic accident, occupational disease) with FC1 and above, as the pathological process stabilized due to damage to nerve structures, the pain process gradually became chronic, the role of psychopathological and psychovegetative disorders in the formation of disability increased. due to the presence of social compensation syndrome.
Conclusion: The factors determining the reduction of the rehabilitation potential and the formation of disability in patients with traumatic and compression ischemic neuropathies at different periods of the disease are established.

P585
IN VITRO CHARACTERIZATION OF SATELLITE CELLS ISOLATED FROM A HUMAN SKELETAL MUSCLE BIOPSY AND ROLE OF THE ENDOCANNABINOID SYSTEM

I. Falsetti[1], G. Palmini[2], S. Donati[1], C. Aurilia[1], L. Margheriti[3], G. Galli[1], R. Zonefrati[2], C. Romagnoli[1], G. Picchioni[3], T. Iantomasi[1], M. L. Brandi[2]

[1]Dept. of Experimental and Clinical Biomedical Sciences, Univ. of Florence[2]Fondazione Italiana Ricerca sulle Malattie dell'Osso (F.I.R.M.O Onlus), [3]Stabilimento Chimico Farmaceutico Militare (SCFM)_Agenzia Industrie Difesa (AID), Florence, Italy

Objective: Satellite cells are mitotically quiescent in healthy skeletal muscle but following damage they become activated and transform into myoblasts to regenerate muscle tissue. In recent years, studies

have shown that the endocannabinoid system (ES) is involved in numerous physiological muscle processes, such as muscle cell growth and muscle regeneration. Therefore, the aim of this work is to evaluate the presence and role of the ES in an in vitro model of human skeletal muscle satellite cells.

Methods: The human muscle biopsy sample was treated with 0.3 mg/ml collagenase to establish a primary satellite cell line, marked as SC-1. Initially, SC-1 was characterized by molecular and cellular biology analysis. On the established cell line, the expression levels of myogenic differentiation genes were assessed with TaqMan technology. In addition, the expression of the different ES components was assessed by qualitative PCR analysis.

Results: From the muscle biopsy, the primary satellite cell line was set up and the stem phenotype has been confirmed through the osteogenic and the adipogenic assays. Myogenic differentiation was confirmed by positively evaluating the expression of myogenic differentiation marker genes (*Desmin* and *Miosin Heavy Chain*), myogenic regulatory factors (*Myf5, MyoD, Myogenin* and *MRF4*), hormone receptors (*VDR, TRα, TRβ, GCR* and *IGF*) and *Irisin*. Then the gene expression analysis of ES components (*CB1, CB2, TRPV1, NAPE, FAAH,* and *DAGLα*) revealed not only their presence in the satellite cell line, but also that these genes are modulated during myogenic differentiation.

Conclusion: A primary satellite cell line was set up and characterized from a muscle tissue biopsy. In this study, for the first time, not only the presence of ES but also its modulation during the differentiation and maturation process of satellite cells was demonstrated. Since ES has been shown to be involved in muscle regeneration, these preliminary data can help identify new therapeutic targets in diseases where there is muscle tissue impairment.

Acknowledgments: Supported by Fondazione Ente Cassa di Risparmio di Firenze and by F.I.R.M.O Onlus.

C. Ercolani[1], F. B. Fabbri[1], C. G. Casacci[1], F. M. Ferracci[1], B. V. Boccardi[1], P. M. Mecocci[1], B. M. Baroni[1], R. C. Ruggiero[1]

[1]Orthogeriatric Service, Geriatric Unit, Institute of Gerontology and Geriatrics, Dept. of Medicine, Univ. of Perugia, Perugia, Italy

Objective: Telemedicine is increasingly widespread to overcome monitoring barriers associated with monitoring of chronic diseases, including those at high risk for fragility fractures, albeit supported by little evidence so far. We investigated the feasibility and effectiveness of telemedicine in managing patients at high risk for fragility fractures during the lockdown period for COVID-19 and then we evaluated the satisfaction of telemedicine service among patients and caregivers and bone specialists.

Methods: From January 2021 to June 2021 we conducted a prospective observational study in older adults with ongoing drug treatments for secondary prevention of fragility fractures by using tele-health service. Patients with ongoing treatments with denosumab or teriparatide require 6 or 12 months assessment for safety and adherence and according with patients' schedule, a nurse made telephone calls with patients, after explanation of the opportunity to attend the virtual service, booked an agreement about day and time of the visits in a dedicated agenda. The televisits are performed by a dedicated platform ad generated a report with updated medical prescriptions and healthy lifestyle recommendations, that the patients downloaded to forward to their GPs.

Results: 407 subjects were contacted and 352 older patients accepted the virtual approach. The majority of patients (59.88%) are women, aged 81.4 ± 8.8 years old, 90.9% leaves in the same healthcare district of the outpatient clinic. All patients are community dwellings with high level of independence in basic daily activities (49.6% with more than 5 ADL independence and mean ADL 4.27 ± 1.6) and instrumental daily activities (37.8% with more than 6 for all sample and mean IADL equal to 4.21 ± 2.8). The majority of patients (343; 8%) experiences major fragility fractures and less than half of the sample also minor fragility fractures (42.5%; n 173). The most prevalent ongoing antifracture drugs include denosumab (79.6%) followed by teriparatide (12%) and about 80.6% of patients on antifracture drugs were also taking both calcium and vitamin D supplements and 50.6% plus vitamin D supplements alone. A satisfaction questionnaire about telemedicine has been proposed to patients and bone specialists.

Conclusion: The telemedicine service may be a great alternative at visit in presence.

P587
TIMING OF SURGERY FOR HIP FRAGILITY FRACTURES: DOES IT MATTER?

I. Genrinho[1], C. Machado[2], A. Humenyuk[3], S. P. Silva[4], S. F. Azevedo[2], C. Oliveira[4], A. Barcelos[4]

[1]Rheumatology Dept., Centro Hospitalar Tondela Viseu, Viseu, [2]Orthopaedic Dept., Centro Hospitalar Baixo Vouga, Aveiro, [3]Dept. of Mathematics, Univ. of Aveiro, Aveiro, [4]Rheumatology Dept., Centro Hospitalar Baixo Vouga, Aveiro, Portugal

Objective: To evaluate the impact of surgical timing on clinical outcomes, complications, and mortality rates associated with hip fragility fractures.

Methods: A retrospective study was conducted involving patients aged ≥ 50 years old with fragility hip fractures admitted to our Fracture Liaison Service between 2019-2023. Lifestyle behaviours, demographic data, comorbidities, preoperative wait times, hospital stay, postoperative complications, re-hospitalization at 1 and 3 months, and the need for re-operation, were assessed. The impact of surgical timing on one-year mortality was analysed. Data was analysed using RStudio.

Results: 359 hip fracture patients were screened, with a mean age of 81.0 y (± 9.2); the majority were women (85%). Patients were divided into two groups: Group 1 underwent surgical intervention within the first 48 h (63%), while Group 2 experienced delayed surgical intervention (37%). The mean hospital stay was 6.8 d (± 4.1) for Group 1 and 11.2 (± 5.9) for Group 2. 49% of the patients had an ASA score of III, followed by II (26%), I (21%), and IV (4.2%). Postoperative complications were observed in 31 patients with respiratory tract infections being the most reported (3.6%), followed by urinary (2.5%) and wound infections (2.5%). 25 patients required re-operation, while re-hospitalization was necessary for 7 and 3 patients at 1 and 3 months, respectively. The mortality rates were 3.4% and 5.3% at 6 and 12 months. Significant differences were noted between patients regarding hospital stay and ASA score ($p < 0.005$). However,

no differences were observed between the two groups concerning postoperative complications and mortality rates.

Conclusion: While early surgical intervention within the first 48 h is commonly advocated, delayed surgery remains a significant approach for many patients. No differences in postoperative complications and mortality rates between the early and delayed intervention groups were found. These findings highlight the need for further exploration into the factors influencing clinical outcomes beyond the temporal aspect of surgical timing.

P588
GLUCOSAMINE AND/OR CHONDROITIN VERSUS STRUCTURAL MODULATION OF GUT MICROBIOTA: FRIEND OR FOE?

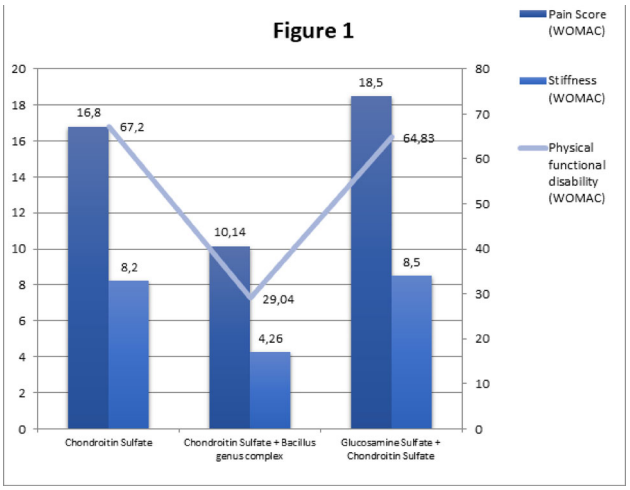
D. Rekalov[1], I. Golovach[2], T. Mefford[3], T. Tarasenko[1], I. Bryner[1], I. Daniuk[4], S. Dotsenko[4]

[1]Professor Rekalov Clinic of Rheumatology, Dnipro, [2]Feofaniya Clinical Hospital, Kyiv, Ukraine, [3]Medical Center "Consilium Medical", Kyiv, [4]Zaporizhzhia State Medical and Pharmaceutical Univ., Zaporizhzhia, Ukraine

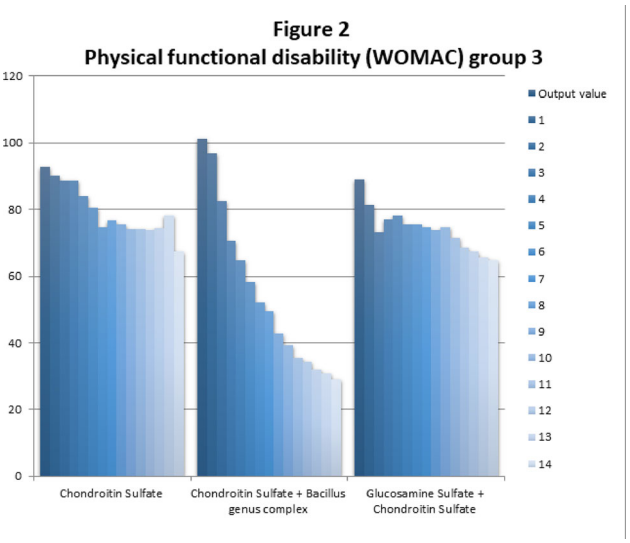
Objective: Despite multiple clinical trials of the use of glucosamine (GS) and chondroitin sulfate (CS) in osteoarthritis (OA), controversy regarding the efficacy of these drugs. Among the most debatable issues is combining GS with CS because of probable interference with GS absorption. According to the collected data, inflammation in OA is characterized as an innate immune response. Gut microbiota (GM) is a collection of microbial populations, responsible for immunological functions. Targeting the (GM) may represent a new therapeutic strategy for chronic pain management of OA. The aim of the study was to assess the efficacy and safety of combination therapy of Bacillus genus composition (BGC) with CS compared to GS and/or CS treatment in patients with OA.

Methods: Our study was performed in 30 patients with Kellgren–Lawrence radiographic grade I–II knee OA and moderate-to-severe pain (mean ± SD global pain score 64.2 ± 12.1 mm on a 100-mm visual analog scale [VAS]). Patients were randomized to receive either CS in a monotherapy (Fish, group 1, n = 10) or combined therapy with BGC plus CS (Fish, group 2, n = 10) or treatment with CS (Bovine, 1500 mg) plus GS (1200 mg) (group 3, n = 10) for 28 d. The main outcomes included the mean change in the investigator's global assessment of disease activity, total WOMAC, pain, stiffness and function subscale scores on the WOMAC.

Results: Patients of the group 3 (BGC + CS), according to the WOMAC score, have shown a statistically significant reduction in pain intensity, stiffness improvement in physical function.



After 14 d, the intensity of pain was lower by 47.83% ($p < 0.05$), and on the 28th day of treatment by 63.59% ($p < 0.05$) smaller relative to the baseline. As well as joint stiffness. On the day 14 the reduction was 50.43% ($p < 0.05$), by the day 28—63.59% ($p < 0.05$). Improving of physical function on the day 14 was achieved—51.18% ($p < 0.05$) and 51.34% at the end of treatment ($p < 0.05$).

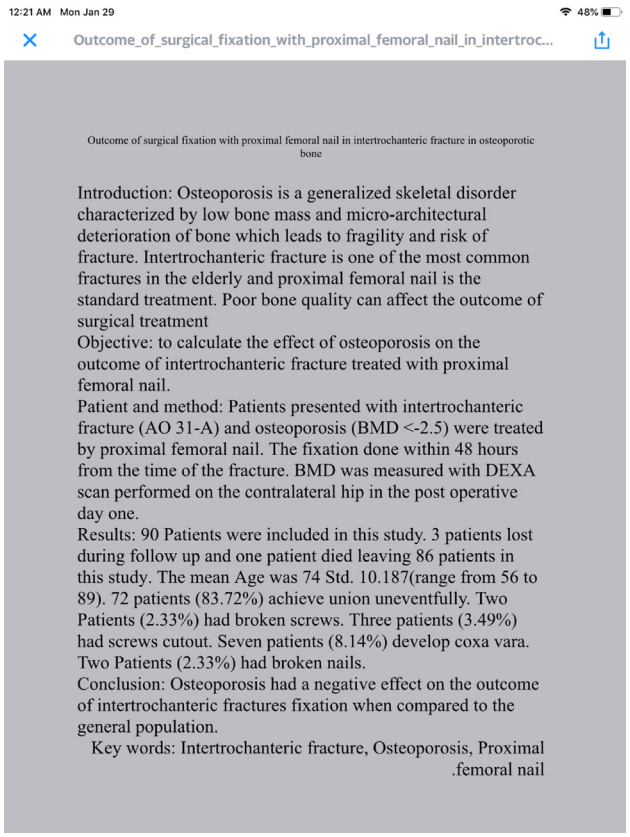


Conclusion: The results of our trial demonstrates a superiority of combination therapy of CS plus BGC over the traditional approaches including GS and/or CS treatment in terms of reducing joint pain, stiffness and functional impairment in patients with symptomatic knee OA for 28 d.

P589
OUTCOME OF SURGICAL FIXATION WITH PROXIMAL FEMORAL NAIL IN INTER TROCHANTERIC FRACTURES IN OSTEOPOROTIC BONE

I. H. Qasim[1]

[1]Alwasity Teaching Hospital, Baghdad, Iraq



12:21 AM Mon Jan 29 48%

Outcome_of_surgical_fixation_with_proximal_femoral_nail_in_intertroc...

Outcome of surgical fixation with proximal femoral nail in intertrochanteric fracture in osteoporotic bone

Introduction: Osteoporosis is a generalized skeletal disorder characterized by low bone mass and micro-architectural deterioration of bone which leads to fragility and risk of fracture. Intertrochanteric fracture is one of the most common fractures in the elderly and proximal femoral nail is the standard treatment. Poor bone quality can affect the outcome of surgical treatment

Objective: to calculate the effect of osteoporosis on the outcome of intertrochanteric fracture treated with proximal femoral nail.

Patient and method: Patients presented with intertrochanteric fracture (AO 31-A) and osteoporosis (BMD <-2.5) were treated by proximal femoral nail. The fixation done within 48 hours from the time of the fracture. BMD was measured with DEXA scan performed on the contralateral hip in the post operative day one.

Results: 90 Patients were included in this study. 3 patients lost during follow up and one patient died leaving 86 patients in this study. The mean Age was 74 Std. 10.187(range from 56 to 89). 72 patients (83.72%) achieve union uneventfully. Two Patients (2.33%) had broken screws. Three patients (3.49%) had screws cutout. Seven patients (8.14%) develop coxa vara. Two Patients (2.33%) had broken nails.

Conclusion: Osteoporosis had a negative effect on the outcome of intertrochanteric fractures fixation when compared to the general population.

Key words: Intertrochanteric fracture, Osteoporosis, Proximal femoral nail.

P590
ANTEROLATERAL BIKINI TOTAL HIP REPLACEMENT

I. H. Qasim[1]

[1]Alwasity Teaching Hospital, Baghdad, Iraq

Short term outcome of anterolateral bikini total hip arthroplasty

Introduction: Bikini incision was first propose for direct anterior approach hip arthroplasty as it follow anatomic skin creases and result in a more acceptable scar. Direct anterior hip approach has risk of lateral femoral cutaneous nerve injury. In this study the bikini incision was used in the anterolateral approach instead of the classical Watson-Jones incision.

Objectives: Outcome assessment regarding intraoperative trochanteric fracture and stem perforation, and post operative dislocation and lateral femoral cutaneous nerve injury in anterolateral bikini skin incision.

Methods: This is a prospective study of 394 Patients had undergone primary total hip arthroplasty via anterolateral bikini approach. All performed by single primary surgeon. Intraoperative trochanteric fracture, stem perforation and lateral femoral cutaneous nerve injury were assessed. Patients were followed for minimum of six months for dislocation.

Results: Statistical analysis showed that 1% of patients had trochanteric avulsion during reaming manipulation. 0.8% had stem perforation. Non develop hip dislocation or cutaneous nerve injury.

Conclusion: Anterolateral bikini total hip arthroplasty provide safe alternative to traditional incision with stable hip replacement with minimal or no risk of dislocation, stem perforation, trochanteric avulsion or lateral femoral cutaneous nerve injury.

Keyword: Anterolateral hip approach, hip arthroplasty, bikini incision.

Conflict of interests: The authors declare that there is no competing interests and nothing to disclose.

MUSCULOSKELETAL DISORDERS IN MOTHERS OF CHILDREN WITH CEREBRAL PALSY

I. Haddada[1], S. El Arem[1], A. Haj Salah[1], A. Ameur[1], M. H. Zaafrane[2], T. Sayhi[2], A. Fekih[3], M. Sghir[1], W. Kessomtini[1]

[1]Physical Medicine and Rehabilitation Dept. Taher Sfar Univ. Hospital, Mahdia, [2]Dept. of Family Medicine, Univ. of Monastir, Monastir, [3]Orthopaedic Dept. Fattouma Bourguiba Univ. Hospital, Monastir, Tunisia

Objective: Children with cerebral palsy (CP) need assistance for their self activities which expose the caregivers to different risk factors of musculoskeletal disorders (MSDs). The aim of the present study was to identify prevalence of MSDs among mothers of children with CP and to determine the associated factors.

Methods: Mothers of children with established diagnosis of CP were recruited at the period from July to December 2021. MSDs were evaluated by the standardized Nordic Musculoskeletal Questionnaire (NMQ). The functional statuses of the children were graded according to the Gross Motor Function Classification System (GMFCS) scale.

Results: The study included 71 mothers, with mean age 38.77 $\pm$ 7.27 y [23-55 y]. The mean age of the children with CP was 7.7 $\pm$ 2.75 y [2–12 y]. The most common clinical subtype of CP was spastic quadriplegia (47.9%). 38 children had the lowest level of functional status GMFCS (IV 18.3% and V 35.2%). 7 children (9.9%) had high grade BMI. A total of 61 mothers (85.9%) reported having experienced an MSD for a minimum of six weeks at the evaluation. Basing

on the NMQ questionnaire, the common MSD identified were low back pain (77.5%), neck pain (29.6%) and shoulder pain (30.9%). Pain was mild to moderate in 83.1% of cases with a mean visual analogue scale (VAS) 4.21 ± 2.23 mm [1-8]. The average duration of pain was 3.26 ± 2.78 y [1-9 y]. In our study, Significant association was observed between musculoskeletal pain and functional level of the child (GMFCS) ($p = 0.023$). The variables clinical subtype of CP, BMI and age of the child had no significant association with musculoskeletal pain among mothers.

Conclusion: It can be concluded that the primary caregivers for children with CP have shown a significant prevalence of MSDs. Thus, clinicians who treat children with physical disability should screen the caregivers for musculoskeletal discomfort.

P592
CHRONIC LOW BACK PAIN: PAIN INTENSITY, DISABILITY AND QUALITY OF LIFE AMONG CAREGIVERS OF STROKE PATIENTS

I. Haddada[1], A. Ameur[1], S. El Arem[1], A. Haj Salah[1], A. Fekih[2], M. Sghir[1], W. Kessomtini[1]

[1]Physical Medicine and Rehabilitation Dept. Taher Sfar Univ. Hospital, Mahdia, [2]Orthopaedic Dept. Fattouma Bourguiba Univ. Hospital, Monastir, Tunisia

Objective: Owing to limitations in daily movements, stroke patients need assistance for their self activities which expose the caregivers to different risk factors of musculoskeletal disorders such as chronic low back pain (CLBP). Moreover, musculoskeletal discomfort might worsen caregivers' depressive symptoms and quality of life (QOL). The aims of the study were to assess perceived pain and disability among stroke caregivers and to determine the impact of CLBP on QOL.

Methods: Caregivers of stroke patients were recruited during the period from December 2021 to November 2022. Back pain intensity was assessed by the visual analog scale (VAS). We used the Oswestry low back pain disability questionnaire and the Dallas Pain Questionnaire to assess LBP-related functional disability. For each caregiver, the QOL was evaluated according to the Short Form Health Survey (SF-36).

Results: The study included 59 wife-caregivers, with a mean age of 55 ± 9 y [34–82 y]. The mean age of impairment patients was 60.64 ± 10 y [40–85 y]. In our study, 68.3% of wife-caregivers reported CLBP. The mean VAS for pain was 6.45 ± 1.23 mm [3–9]. Pain was severe (VAS > 7) in 54.2% of cases. The average duration of CLBP was 3.5 ± 5.78 y [2-10]. The average score of Oswestry was 33.42% ± 19.83 [22–78]. Nineteen caregivers (32.2%) were severely disabled (Oswestry score > 41%). Concerning the mean Dallas score, the segmental results were as follows: 63.1% of impact on daily activities, 35.7% of impact on work/leisure ratio, 45.2% of impact on anxiety/depression ratio and 38.5% of impact on sociability. Concerning the QOL: the mean SF-36 scale was 41.18 ± 20.88 and a poor QOL (SF-36 < 66.7) was noted in 83.05% of cases. A significant association was observed between functional limitation (Oswestry) ($p = 0.043$), pain intensity ($p = 0.002$) and pain duration ($p < 0.001$) with poor QOL among caregivers.

Conclusion: CLBP was present to a higher degree in caregivers and had a negative impact on their QOL.

P593
CHRONIC LOW BACK PAIN IN MOTHERS OF CHILDREN WITH CEREBRAL PALSY

I. Haddada[1], S. El Arem[1], A. Haj Salah[1], A. Ameur[1], M. H. Zaafrane[2], T. Sayhi[2], A. Fekih[3], M. Sghir[1], W. Kessomtini[1]

[1]Physical Medicine and Rehabilitation Dept. Taher Sfar Univ. Hospital, Mahdia, [2]Dept. of Family Medicine, Univ. of Monastir, Monastir, [3]Orthopaedic Dept. Fattouma Bourguiba Univ. Hospital, Monastir, Tunisia

Objective: Cerebral palsy (CP) is the most common cause of physical disability in childhood. Owing to limitations in daily movements, disabled children need assistance for their self activities which expose the caregivers to different risk factors of musculoskeletal disorders. The aims of the study were to investigate how low back pain (LBP) affects functional limitations in mothers of children with CP and to determine the associated factors.

Methods: Mothers of children with established diagnosis of CP were recruited at the period from July to December 2021. The functional statuses of disabled children were graded according to the Gross Motor Function Classification System (GMFCS) scale. Back pain intensity was assessed by the visual analog scale (VAS). We used the Oswestry low back pain disability questionnaire and the Dallas Pain Questionnaire to assess LBP-related functional disability.

Results: The study included 71 mothers, with mean age 38.77 ± 7.27 y [23–55 y]. The mean age of the children with CP was 7.7 ± 2.75 y [2–12]. 38 children had the lowest level of functional status GMFCS (IV 18.3% and V 35.2%). 7 children (9.9%) had high grade BMI. In our study, 77.5% of mothers reported LBP. The mean VAS for pain was 4.21 ± 2.23 mm [1–8]. Pain was mild to moderate in 83.1% of cases. The average duration of LBP was 3.26 ± 2.78 y [1–9]. The average score of Oswestry was 33.42% ± 19.83 [22–78]. 19 mothers (26.8%) were severely disabled (Oswestry score > 41%). Concerning the mean Dallas score, the segmental results were as follows: 53.1% of impact on daily activities, 30.7% of impact on work/leisure ratio, 55.2% of impact on anxiety/depression ratio and 40.5% of impact on sociability. In our study, Significant association was observed between functional limitations in mothers (Oswestry) and pain intensity ($p = 0.023$), age of the mother ($p = 0.001$), functional level of the child (GMFCS) ($p = 0.043$) and overweight in children ($p = 0.043$).

Conclusion: A significant prevalence of low back pain and discomfort in caregivers of children with CP.

P594
FREQUENCY OF MUSCULOSKELETAL DISORDERS IN CAREGIVERS OF STROKE PATIENTS

I. Haddada[1], A. Ameur[1], S. El Arem[1], A. Haj Salah[1], A. Fekih[2], M. Sghir[1], W. Kessomtini[1]

[1]Physical Medicine and Rehabilitation Dept. Taher Sfar Univ. Hospital, Mahdia, [2]Orthopaedic Dept. Fattouma Bourguiba Univ. Hospital, Monastir, Tunisia

Objective: Taking care of a patient with a motor disability can significantly impact both the physical and psychological statuses of caregivers. Musculoskeletal disorders (MSDs) such as pain in the back, shoulder, knee, etc. are common in full-time caregivers. However, the prevalence of MSDs in caregivers remains unknown. The aim of the present study was to identify prevalence of MSDs among family caregivers of stroke patients and to determine the associated factors.

Methods: Caregivers of stroke patients were recruited during the period from December 2021 to November 2022. The functional

statuses of patients with disability were determined using the Functional Independence Measure (FIM). MSDs were evaluated by the standardized Nordic Musculoskeletal Questionnaire (NMQ). Pain was evaluated according to the visual analog scale (VAS).
Results: The study included 59 wife-caregivers, with a mean age of 55 ± 9 y [34–82 y]. The mean age of impairment patients was 60.64 ± 10 y [40–85 y]. Nineteen motor-impaired patients (13.76%) had high-grade BMI. The average score of FIM was 99.3 [8–126]. The mean duration of a caregiver's role was 5.58 y [1–35 y]. The average number of weekly hours spent in caregiving was 35 h/week. A total of 49 (83%) wife-caregivers reported having experienced an MSD for a minimum of 6 weeks at the evaluation. Based on the NMQ questionnaire, the common MSD identified were low back pain (54.34%), neck pain (19.56%), and shoulder pain (27.53%). The pain was severe (VAS > 7) in 39.4% of cases with a mean VAS of 4.33 ± [1–10]. The average duration of pain was 4.23 ± 4 y [1-8 y]. A significant association was observed between pain and age of impaired patients ($p < 0.001$), obesity ($p = 0.002$), the number of weekly hours spent in caregiving ($p < 0.001$) and the duration of the caregiver's role ($p = 0.001$). However, no significant association was found between musculoskeletal pain and functional status (FIM) ($p = 0.073$).
Conclusion: The results indicated a significant prevalence of pain and musculoskeletal discomfort in caregivers of stroke patients; we recommend routine training in safe transferring, lifting and carrying techniques to all parents and caregivers.

P595
SYSTEMATIC EVALUATION OF ABDOMINAL AORTIC CALCIFICATION IN PATIENTS WITH A RECENT CLINICAL FRACTURE VISITING THE FRACTURE LIAISON SERVICE

I. J. A. De Bruin[1], C. E. Wyers[1], L. Vranken[1], J. T. Schousboe[2], R. Y. van der Velde[1], H. M. J. Janzing[3], F. O. Lambers Heerspink[4], P. P. M. Geusens[5], J. P. W. van den Bergh[1]

[1]Dept. of Internal Medicine, VieCuri Medical Centre, Venlo, Netherlands, [2]Park Nicollet Clinic and HealthPartners Institute, HealthPartners Inc., Minneapolis, USA, [3]Dept. of Surgery, VieCuri Medical Centre, Venlo, Netherlands, [4]Dept. of Orthopaedic Surgery, VieCuri Medical Centre, Venlo, Netherlands, [5]Dept. of Internal Medicine, Subdivision Rheumatology, CAPHRI, Maastricht Univ. Medical Centre + (MUMC+), Maastricht, Netherlands

Objective: Abdominal aortic calcification (AAC) is associated with an increased risk of cardiovascular disease (CVD), osteoporosis and fractures. We analyzed the prevalence and severity of AAC in patients with a recent clinical fracture who attended the Fracture Liaison Service (FLS).
Methods: Cross-sectional cohort study of patients with a recent clinical fracture (aged 50–90 y) attending the FLS. Patients received an evaluation of risk factors for fracture, verified medical history, BMD measurements, and lateral spine imaging using DXA. AAC prevalence was assessed using the AAC-24 score and categorized as none, moderate (AAC-24 1-4) and severe (AAC-24 ≥ 5). Multivariate logistic regression analyses were performed to study the association between risk factors for AAC and the presence and severity of AAC.
Results: AAC was present in 478 (27.6%) of 1731 patients of which 207 (43.3%) had moderate and 271 (56.7%) severe AAC. Most patients with AAC (318, 66.5%) did not have a medical history of CVD. The presence of AAC was associated with age (OR: 1.09, 95% CI 1.07–1.11), BMI (OR: 0.94, 95% CI 0.91–0.97), smoking (OR: 2.00, 95% CI 1.50–2.66), history of CVD (OR: 1.96, 95% CI 1.46–2.63), and prevalent grade 2/3 vertebral fractures (VFs) (OR: 1.37, 95% CI 1.01–1.88). The presence of severe AAC was associated with age (OR: 1.11, 95% CI 1.09–1.13), BMI (OR: 0.93, 95% CI 0.90–0.97), and history of CVD (OR: 2.31, 95% CI 1.63–3.27). In the subgroup without myocardial infarction or cardiovascular accidents, AAC was associated with age, BMI, and smoking.
Conclusion: The prevalence of AAC was 27.6% in patients with a recent clinical fracture, who attended the FLS. Besides association with classical risk factors (age, CVD history) and BMI, the presence or severity of AAC was not associated with BMD (categorical). The presence of AAC, but not the severity of AAC, was associated with a prevalent grade 2 or 3 VF and smoking.

P596
SKELETOMUSCULAR ROBUSTNESS AND BONE STRUCTURAL PARAMETERS IN ELITE YOUTH ATHLETES

I. Kalabiska[1], A. Zsákai[2], D. Annár[1], Z. Borbás[1], N. Bondarchuk[3], H. P. Bhattoa[4]

[1]Hungarian Univ. of Sport Science, Research Center for Sport Physiology, Budapest, Hungary, [2]Eotvos Lorand Univ., Dept. of Biological Anthropology, Budapest, Hungary, [3]Uzhhorod National Univ., Dept. of Physical Education, Uzhhorod, Ukraine, [4]Univ. of Debrecen, Dept. of Laboratory Medicine, Debrecen, Hungary

Objective: In DXA analytical practice, it is important to use athlete references to estimate bone development in athlete children and adolescents. In 2020, our research team introduced new bone mineral reference values about young athletes. Our aim of the study was to construct BMD and bone mineral content (BMC) references of athletes by the type of sports.
Methods: DXA was used in 1793 elite athletes aged between 11-20 y. The bone structural parameters of each athlete were converted to z-scores relative to age- and sex-specific reference values specified by the DXA software. Z-profile analysis and principal component analysis were used to identify body structural components in young athletes and to evaluate the associations between the identified component and the type of sport.
Results: The total BMD of male athletes is considerably higher than the age-specific references for males ($p < 0.001$ in each age-group). An outstanding skeleto-muscular robusticity of male wrestlers, pentathletes and cyclers could be observed in the studied sports: wrestlers had significantly more developed skeletomuscular robusticity and BMD than the age-group average among elite athletes, while pentathletes and cyclers had worse bone structural parameters than the reference level for their age-group among elite athletes. The corresponding trends in the BMC of female athletes are significantly higher than the references ($p < 0.001$ in every age-group, with the exception of 13 y, $p = 0.04$). In case of female athletes, the rhythmic gymnasts' and pentathletes' bone structural parameters differed significantly from the players' average parameters of the studied elite athletes: their average skeletal robusticity both in the trunk and the extremities lagged behind the age-group mean values for elite athletes.
Conclusion: Compared to reference values for the general population, BMD and BMC of the youth athletes were better developed. The skeletal development of cyclers, pentathletes and rhythmic gymnasts should be monitored more frequently, since their bone development lags behind not only their age-peer elite athletes' bone development but also the population-based reference values.

P597
METABOLISM OF VITAMIN D DURING NORMAL PREGNANCY

I. Katsobashvili[1], E. Pigarova[1], L. Dzeranova[1], S. Vorotnikova[1], E. Bibik[1], M. Evloeva[1]

[1]Endocrinology Research Centre, Moscow, Russia

Objective: To study of vitamin D metabolism peculiarities in normal pregnancy in comparison with a control group of healthy female patients.
Methods: Two groups of patients participated in the study: group 1-pregnant patients (n = 20) from 18–45 y of age with gestational age from week 9 to 13; group 2—healthy female patients (n = 19) who underwent blood sampling for vitamin D metabolites to determine total 25(OH)D by immunochemiluminescence assay and 25(OH)D3, 3-epi-25(OH)D3, 24,25(OH)2D3, 1,25(OH)2D3 by high-performance liquid chromatography with mass spectrometric detection (HPLC-MS/MS).
Results: In group 1, the following results were obtained: total 25(OH)D, 26.1 ng/mL [17.4; 37.3], 25(OH)D3, 25.6 ng/ml [17.4; 37.3], 3-epi-25(OH)D3, 1.8 ng/mL [1.1; 3.2], 1,25(OH)D3, 33.4 pg/mL [16.1; 46.0], 24,25(OH)D3, 0.8 ng/mL [0.4; 1.5]. In group 2: total 25(OH)D—16.7 ng/mL [13.5; 27.2], 25(OH)D3—19.5 ng/mL [14.0; 27.0], 3-epi-25(OH)D3—1.1 ng/mL [0.75; 1.47], 1,25(OH)D3—38.8 pg/mL [34.0; 46.4], 24,25(OH)D3—1.5 ng/mL [0.82; 2.69]. For the above parameters, statistically significantly higher levels in the pregnancy group were obtained for total 25(OH)D ($p = 0.02$) and 3-epi-25(OH)D3 ($p = 0.002$). The ratio of 1,25(OH)D3/25(OH)D3 metabolites, reflecting 1-α-hydroxylase activity, was 0.00132 ng/mL [0.00067; 0.00206] vs. 0.0021 ng/mL [0.00153; 0.00264] ($p = 0.02$); the 25(OH)D3/24,25(OH)D3 ratio reflecting 24-hydroxylase activity was 24.1 ng/mL [18.6; 60.7] vs. 11.6 ng/mL [10.9; 17.6], $p = 0.003$, and the 3-epi-25(OH)D3/25(OH)D3 ratio reflecting 3-epimerase activity, 0.08 ng/mL [0.07; 0.10] vs. 0.05 ng/mL [0.05; 0.6], $p = 0.0004$, for group 1 and group 2, respectively.
Conclusion: The data obtained indicate that in the first trimester of pregnancy the epimerization of vitamin D increases, which raises the levels of this metabolite in the blood. A decrease in activation and increase in deactivation of vitamin D in pregnant women was also observed, which reflects the ratios of metabolites that characterize these processes.

P598
TRANSVERSE MYELITIS AND COVID-19 DISEASE LEADING TO SARCOPENIA

I. Kostoglou-Athanassiou[1], L. Athanassiou[2], A. Pastroudis[3], D. Begkas[3], P. Athanassiou[4], Y. Shoenfeld.[5]

[1]Dept. of Endocrinology, Diabetes and Metabolism, Asclepeion Hospital, Voula, Athens, Greece, [2]Dept. of Rheumatology, Asclepeion Hospital, Voula, Athens, Greece, [3]6th Dept. of Orthopedics, Asclepeion Hospital, Voula, Athens, Greece, [4]Dept. of Rheumatology, St. Paul's Hospital, Thessaloniki, Greece, [5]Zabludowicz Center for Autoimmune Diseases, Sheba Medical Center, Reichman Univ., Herzelia, Israel

The SARS-CoV-2 virus has caused the recent pandemic. In some patients the SARS-CoV-2 infection was characterized by neurological manifestations. One of these is transverse myelitis thought to be caused either by the virus itself as the SARS-CoV-2 virus may be neuroinvasive or by an autoimmune reaction due to molecular mimicry between the viral and host proteins. Transverse myelitis may lead to sarcopenia. The aim was to describe the case of a male patient with Hashimoto's thyroiditis who developed transverse myelitis leading to sarcopenia in the course of COVID-19 illness.
Casereport: The case of a 52 year-old male patient is described who developed transverse myelitis after COVID-19 infection. The patient presented with Hashitoxicosis approximately 15 y ago at the age of 37 y. TSH was 0.01 μIU/ml, anti-Tg and anti-TPO antibodies were positive, while a thyroid ultrasonogram revealed loss of homogeneity of the thyroid parenchyma. Unimazole was administered. During the course of the disease the patient developed hypothyroidism and thyroxine was administered. Approximately a year ago he presented with COVID-19 disease and a rather severe illness. The patient was admitted to a COVID-19 department. During hospitalization he started to feel numbness in the lower extremities and subsequently the lower extremities were paralyzed. Transverse myelitis was diagnosed and prednisolone was administered. Over the course of two months prednisolone was tapered and the patient improved. During the course of a year the patient improved substantially and is now in a program of rehabilitation. The patient developed sarcopenia in the course of time.
Conclusion: Transverse myelitis in the course of COVID-19 disease has been described. The disease may be due to the virus itself, as it may be neuroinvasive or to an autoimmune reaction due to molecular mimicry, i.e. due to the homology of amino acid sequences of the viral proteins to human amino acid sequences. Transverse myelitis may cause sarcopenia.

P599
MANAGEMENT OF OSTEOPOROSIS IN BREAST CANCER PATIENTS

I. Kostoglou-Athanassiou[1], L. Athanassiou[2], G. Georgiadis[3], A. Pastroudis[4], E. Manta[4], P. Athanassiou[5]

[1]Dept. of Endocrinology, Diabetes and Metabolism, Asclepeion Hospital, Voula, Athens, [2]Dept. of Rheumatology, Asclepeion Hospital, Voula, Athens, [3]4th Dept. of Orthopedics, Asclepeion Hospital, Voula, Athens, [4]6th Dept. of Orthopedics, Asclepeion Hospital, Voula, Athens, [5]Dept. of Rheumatology, St. Paul's Hospital, Thessaloniki, Greece

Breast cancer patients after surgery may get treatment with aromatase inhibitors. Aromatase inhibitors may induce osteoporosis and diffuse skeletal pain. Patients with breast cancer, who are treated with aromatase inhibitors should be followed up for the development of osteoporosis and should get specific treatment for the prevention and treatment of osteoporosis. The aim was to present a cohort of patients with breast cancer who were administered aromatase inhibitors and were treated with bisphosphonates.

A group of 10 female patients, aged 45–62 y, presented with breast cancer. Following surgery they were offered treatment with aromatase inhibitors. During follow-up BMD was measured.

Within the group of the patients with breast cancer, 6 were found to have osteopenia, T-score range − 1.6 to − 2.3 and 4 were found to have osteoporosis, T-score range − 2.5 to − 3.0. All patients were administered supplementation with calcium and vitamin D. Patients with osteoporosis were given alendronate in the effervescent form. BMD improved in the group with osteoporosis.

Breast cancer is a major health issue in the female population. Nowadays treatment with aromatase inhibitors significantly decreases endogenous estrogen levels and decreases the risk of recurrence or metastatic disease. However, aromatase inhibitors may induce osteoporosis. Bisphosphonates, in particular alendronate improves bone mass and is known to significantly decrease the risk of metastatic disease and death in breast cancer patients. In conclusion, we suggest that treatment with bisphosphonates, in particular alendronate in the effervescent form, may be a useful addition in the treatment of

patients with breast cancer, as it improves bone mass, decreases fracture risk and may improve the prognosis of the neoplasm, as it decreases the risk of recurrence and death.

P600
PREGNANCY AND LACTATION-ASSOCIATED OSTEOPOROSIS: UNANSWERED ISSUES

I. Lomtadze[1], T. Khutsishvili[2], N. Dvalishvili[3], N. Tonia[4], N. Eloshvili[5], M. Baratashvili[6]

[1]Aversi Clinic, [2]Todua Clinic, [3]Vakhtang Bochorishvili Clinic, [4]MediClubGeorgia, [5]New Hospitals, [6]Healthycore, Tbilisi, Georgia

Objective: Illustration of clinical features and treatment effectiveness of pregnancy and lactation-associated osteoporosis (PLO).
Methods: Laboratory tests, radiological scan and follow-up outcomes were analyzed.
Results: We report the 27-year-old woman, who presented to our hospital 3 months after her delivery. She complained about severe low back pain, which had started from third trimester of her pregnancy. The patient underwent DXA densitometry scan, which showed Z-score − 4.1 (at AP Spine). Lumbar MRI revealed vertebral compressive fractures at Th6, Th8, Th9, L1, L2. The patient had no history of trauma. The causes of secondary osteoporosis have also been excluded. Accordingly, the patient was diagnosed with PLO. Laboratory examination revealed vitamin D deficiency at 8.0 ng/ml. Other serum tests were within the normal ranges (PTH, ionized Ca, RF, ALP, P, TSH). Her BMI was 22.4 kg/m^2. The patient was advised to cease breastfeeding. Although zoledronic acid has been prescribed, first year the patient took only calcium and vitamin D supplementation. After one year follow-up visit DXA densitometry showed BMD improvement by 11.9% at the lumbar spine, 0.6% at total femur, and decreasing in BMD at femoral neck by − 3.3%. Patient took zoledronate (5 mg/100 ml) infusion. One year after zoledronate infusion the gain in BMD at AP Spine was 6.8, 5.4% at total femur and 6.3% at femoral neck. Although MBD was remarkably improved, at the 12th month of zoledronate infusion the patient felt low back pain radiated to sacroiliac joint. The patient underwent MRI scan, where sacral lateral mass fracture was detected.
Conclusion: Our case showed annual gain in lumbar spine BMD by 11.9% on calcium and vitamin D treatment only (and breastfeeding cessation as well), and new fracture development after bisphosphonate infusion. Many issues remain unanswered in terms of PLO management, further research on this condition is required.

P601
EFFECT OF MUSCLE POWER AND FUNCTIONAL PERFORMANCE ON QUALITY OF LIFE IN KNEE OSTEOARTHRITIS PATIENTS

I. M. Borda[1], L. Irsay[1], V. Ciortea[1], A. Ciubean[2], R. Ungur[1]

[1]Univ. of Medicine and Pharmacy Iuliu Hatieganu, Rehabilitation Dept., Rehabilitation Hospital, [2]Univ. of Medicine and Pharmacy Iuliu Hatieganu, Rehabilitation Dept., Cluj-Napoca, Romania

Objective: To evaluate muscle power and functional performance in knee osteoarthritis patients and to correlate them with quality of life.
Methods: 57 patients (62.5 ± 3.6 y, 29 men and 28 women) diagnosed with knee osteoarthritis according to ACR criteria were included in this cross-sectional study. Knee extensor power was measured by the isokinetical method at the angular velocity of 120°/s, using a Gymnex Iso 2 Dynamometer. Functional performance was assessed by the timed up-and-go (TUG) test, chair rising test (CRT) and 6-min walk (6 MW) test. Quality of life was assessed by SF-36 questionnaire (Romanian version). Analyses of the relationship between power and functional performance parameters and quality of life scores were done.
Results: TUG score negatively correlated with knee extensor power ($r = -0.276$, $p < 0.05$) and SF-36 score ($r = -0.592$, $p < 0.05$). Positive correlation was found between the CRT and the knee extensor power ($r = 0.422$, $p < 0.05$), as well as between the CRT and SF-36 score ($r = 0.511$, $p < 0.05$). 6 MW test positively correlated with the knee extensor power ($r = 0.395$, $p < 0.05$) and the SF-36 score ($r = 0.578$, $p < 0.05$). SF-36 score positively correlated with knee extensor power ($r = 0.396$, $p < 0.05$).
Conclusion: Muscle power and functional performance significantly influenced the quality of life in the knee osteoarthritis patients. Therefore, they should be included in rehabilitation programs focused on muscle training and functional improvement, leading to a consequently better quality of life.

P602
RELEVANCE OF SEGMENTAL BODY COMPOSITION IN FRAGILITY FRACTURE PATIENTS AMONG COMMUNITY DWELLING ELDERLY

I. M. Imaoka[1], T. F. Tazaki[1], H. M. Hida[1], I. W. Ichinose[1], T. S. Takamatsu[1], S. K. Sakai[1], N. M. Nakamura[1]

[1]Osaka Kawasaki Rehabilitation Univ., Osaka, Japan

Objective: This study investigated the characteristics of individuals with reduced BMD and a history of fractures after the age of 60 y. This study considered previously reported associations, segmental anthropometric measurements, and information communication technology tool use.
Methods: The study included 242 community-dwelling elderly individuals (mean age 74.4 ± 6.6 years) in Japan. Participants were excluded if they were unable to undergo motor function assessment or had pacemakers that prevented body composition analysis. The study collected data on various parameters, including BMD, walking speed, grip strength, two-step time, skeletal muscle mass index (SMI), segmental muscle mass and fat mass, number of medications, number of online tools used, Geriatric Depression Scale score, Addenbrooke's Cognitive Examination score, Trail Making Test parts A and B, and other basic attributes. For the statistical analysis, participants with BMD below 90% and a history of fracture after the age of 60 y were divided into two groups: the fragility fracture group and the non-fragility fracture group. Univariate analysis was conducted between the two groups to identify factors characteristic of the fragility fracture group.
Results: The fragility fracture group comprised 22 patients (9.1%), while the non-fragility fracture group comprised 220 patients (90.9%). A comparison between the two groups revealed significant differences in several parameters, excluding bone density. SMI was lower in the fragility fracture group (5.5 ± 0.8 kg/m^2) compared to the non-fragility fracture group (6.0 ± 1.0 kg/m^2). Similarly, right lower limb muscle mass was lower in the fragility fracture group (5.0 ± 0.1 kg/m^2) compared to the non-fragility fracture group (5.7 ± 1.4 kg/m^2). Left lower limb muscle mass also significantly differed between the groups, with 5.0 ± 1.1 kg/m^2 in the fragility fracture group, and 5.7 ± 1.1 kg/m^2 in the non-fragility fracture group. No other study parameters showed significant differences between the two groups.
Conclusion: Patients with fragility fractures demonstrate significantly lower SMI and lower limb muscle mass compared to those without fragility fractures. These findings suggest that quantitative assessment of segmental muscle mass, fall risk assessment, and BMD enhancement may be crucial for improving the effectiveness of secondary fracture prevention strategies.

P603
INFLUENCE OF LUMBAR SYNDROME ON THE ABILITY TO PERFORM ACTIVITIES OF DAILY LIFE

A. Kosic[1], J. Zvekic-Svorcan[2], K. Boskovic[2], I. Minakovic[3], T. Jankovic[2], R. Krasnik[4]

[1]Univ. of Novi Sad, Faculty of Medicine Novi Sad, [2]Univ. of Novi Sad, Faculty of Medicine Novi Sad. Special Hospital for Rheumatic Diseases, [3]Univ. of Novi Sad, Faculty of Medicine Novi Sad. Health Center "Novi Sad", [4]Univ. of Novi Sad, Faculty of Medicine Novi Sad. Institute of Child and Youth Health Care of Vojvodina, Novi Sad, Serbia

Objective: To examine the limitations in various activities of daily life in patients with lumbar syndrome.
Methods: With the approval of the Ethics Committee (14/32-1/1-22) of the Special Hospital for Rheumatic Diseases in Novi Sad, Serbia, a prospective cross-sectional study involving 100 subjects of both sexes, aged 40–65 y, diagnosed with lumbar syndrome was conducted. All patients signed an informed consent prior to administering a general questionnaire constructed by the examiner and the Oswestry disability index (ODI) assessing the impact of back pain on their ability to manage everyday life. Statistical processing and analysis were performed in SPSS ver.24.
Results: Majority (68%) of respondents were women, 63% of the participants were obese and 70% were married, while 58% completed secondary vocational education. In 66% of the cases, pain in the lumbar spine occurred when resting and working, and 69% of respondents experienced it ≥ 3 times per year, leading to work absences in 21% of the cases. While the mean ODI value for the sample was 28.13, a statistically significant difference in daily functioning was noted among respondents of different marital status ($F = 3.201$, $p < 0.05$). Divorced ($M = 40.90$) and married ($M = 26.17$) individuals reported the highest and the lowest degree of restriction, respectively. Those who live alone showed a higher degree of limitation ($M = 35.89$) than those living with family members ($M = 26.43$, $F = 6.225$, $p < 0.05$). The greatest limitation in daily functioning was noted in individuals experiencing back pain at rest and while working ($M = 32.20$), while being the lowest in subjects in whom back pain occurs only during work ($M = 19.78$, $F = 8.315$, $p < 0.001$). As expected, greater limitation in functioning was noted in subjects frequently absent from work ($M = 42.50$) compared to those with occasional absences ($M = 23.44$, $F = 4.795$, $p < 0.01$). A greater limitation in functioning was also associated with back pain frequency (≥ 3 times per year: $M = 30.91$ vs. < 3 times per year: $M = 22.60$, $F = 4.115$, $p < 0.05$).
Conclusion: The greatest degree of limitation in daily functioning is experienced by individuals who are divorced, live alone, in whom lower back pain occurs during rest and work, it emerges ≥ 3 times per year, and leads to frequent work absences.

P604
DETERMINANTS OF FREQUENT SICK LEAVE IN PATIENTS WITH CHRONIC LOW BACK PAIN

I. Minaković[1], J. Zvekić-Svorcan[2], D. Živanović[3], M. Vojnović[4], A. Miljković[5], K. Bošković[6]

[1]Faculty of Medicine, Univ. of Novi Sad, Novi Sad, Serbia; Health Center "Novi Sad", Novi Sad, [2]Faculty of Medicine, Univ. of Novi Sad, Novi Sad; Special Hospital for Rheumatic Diseases Novi Sad, Novi Sad, [3]Faculty of Medicine, Univ. of Novi Sad, Novi Sad; Dept. of Psychology, College of Social Work, Belgrade, [4]Faculty of Medicine, Univ. of Novi Sad, Novi Sad, [5]Faculty of Medicine, Univ. of Novi Sad, Health Center "Novi Sad", Novi Sad, [6]Faculty of Medicine, Univ. of Novi Sad,; Special Hospital for Rheumatic Diseases Novi Sad, Novi Sad, Serbia

Objective: An estimated 2–3% of the population in developed nations grapple with chronic back pain, which is defined as persisting for a duration of three months or longer. This condition places a considerable burden on society due to the substantial costs associated with its treatment, extended sick leaves, and reduced work productivity. The aim of this study was to identify the factors that increase the likelihood of more frequent sick leave in individuals suffering from chronic low back pain.
Methods: This retrospective cross-sectional study comprised 100 individuals of both genders aged between 40–65 y who reported lumbosacral spine pain of at least 5 on the Numerical Pain Rating Scale (NPRS). The study encompassed patients who received treatment at the Special Hospital for Rheumatic Diseases in Novi Sad from April 2022 to August 2022. Data concerning body weight, height, sociodemographic information, and the outcomes of the Pain Catastrophizing Scale (PCS) and NPRS questionnaires were extracted from the patients' medical records.
Results: Significant predictors of sick leave in patients suffering from lower back pain included a higher level of pain catastrophizing ($OR = 1.045$, $p = 0.016$), engagement in physically demanding occupations, and the presence of pain radiating down the leg ($OR = 4.524$, $p = 0.013$). Individuals who engage in extensive walking during their work duties ($OR = 5.400$, $p = 0.009$) and those involved in physically demanding tasks ($OR = 5.85$, $p = 0.011$) are five times more likely to experience work absenteeism compared to respondents whose work primarily involves sitting. Nevertheless, the sole factor predicting more frequent sick leave (≥ 3 times within a single year) was the occurrence of radiating leg pain ($OR = 7.111$, $p = 0.047$).
Conclusion: Prominent statistical indicators for sick leave among patients with lower back pain involve an elevated degree of pain catastrophizing and involvement in physically demanding professions. Furthermore, the occurrence of pain radiating to the lower extremities serves as a statistically significant predictor for both sick leave and its frequency.

P605
CORRELATION BETWEEN METABOLIC SYNDROME AND EXTENT OF STRUCTURAL AND FUNCTIONAL IMPAIRMENT IN KNEE OSTEOARTHRITIS

I. Minaković[1], J. Zvekić-Svorcan[2], L. J. Dražić[3], M. Smuđa[4], J. Javorac[5], T. Janković[6]

[1]Faculty of Medicine, Univ. of Novi Sad, Health Center "Novi Sad", Novi Sad, [2]Faculty of Medicine, Univ. of Novi Sad, Special Hospital for Rheumatic Diseases Novi Sad, Novi Sad, [3]Special Hospital for Rheumatic Diseases Novi Sad, Novi Sad, [4]Faculty of Medicine, Univ. of Novi Sad, Novi Sad, The Academy of Applied Studies Belgrade, Dept. of Higher Medical School, Belgrade, [5]Faculty of Medicine, Univ. of Novi Sad, Novi Sad, Institute for Pulmonary Diseases of Vojvodina, Sremska Kamenica, [6]Faculty of Medicine, Univ. of Novi Sad, Special Hospital for Rheumatic Diseases Novi Sad, Novi Sad, Serbia

Objective: Lately, numerous studies have investigated the link between metabolic syndrome (MetS) and osteoarthritis (OA). Nonetheless, the exact nature of the association between these two conditions remains controversial. The aim of this study was to investigate the connection between MetS and the extent of structural and functional knee impairment in postmenopausal women with knee OA.
Methods: This retrospective cross-sectional study comprised 90 female participants aged between 60–75 y. These individuals received

treatment for knee OA at the Special Hospital for Rheumatic Diseases Novi Sad, Serbia, from February 2022 to October 2022. Data were extracted from their medical records, including anthropometric measurements, blood pressure, biochemical blood findings, the presence of comorbid conditions, and standard knee radiographs. Participants were categorized into three groups according to the extent of knee damage determined through assessment using the Kellgren-Lawrence (KL) scale. Additionally, the study incorporated responses from the Lower Extremity Functional Scale (LEFS) questionnaire, previously completed by the participants.

Results: In the sample, 43.3% of the participants had grade KL2 knee damage (Group I), 34.4% had grade KL3 (Group II), and 22.2% were classified as grade KL4 (Group III). The mean age of the respondents was 67.25 (standard deviation = 4.21), and there were no statistically significant differences between the groups ($p = 0.081$). MetS was highly prevalent in the subjects belonging to the III group, with a rate of 95.0%, while 83.9% of individuals in class II and 69.2% of individuals in class I had this syndrome. The study revealed that MetS is a statistically significant predictor of structural knee damage ($p = 0.019$). On the other hand, in a univariate linear regression analysis, it was determined that the presence of MetS does not have statistical significance as a predictor for the knee's functional state ($p = 0.131$).

Conclusion: MetS is a statistically significant predictor of structural knee impairment but not functional knee impairment in patients with knee OA.

P606
SHOUD WE THINK ABOUT OSTEOPOROSIS IN PSORIATIC ARTHRITIS?

L. J. Bozic Majstorovic[1], I. Ovcina[1], J. Mrdja[1], D. Popovic[1], G. Vrhovac[1], N. Spiric[1]

[1]Univ. Clinical Centre of the Republic of Srpska, Banjaluka, Bosnia & Herzegovina

Objective: To detect correlation between clinical features and occurrence of osteoporosis in psoriatic arthritis (PsA) and to compare bone densitometry results between patients with PsA and healthy controls.

Methods: The 20 patients diagnosed with PsA were included in the study. The demographics, laboratory parameters, nail involvement, psoriasis area and severity index (PASI) score were collected. Patients underwent bone densitometry using DXA (Hologic) and the 10-y fracture risk was calculated with FRAX score. To compare bone densitometry parameters we included 14 healthy patients. Statistical significance was set at $p < 0.05$.

Results: The mean age was 58 ± 9.1 y and there were 55% male patients. Positive rheumatoid factor (RF) had 30% of the patients, nail lesions 60% and the mean PASI score were 10.37 ± 10.13 and the mean CRP 15.54 ± 10.08. The 35% patients received corticosteroids, 20% were smokers and the mean BMI 26.35 ± 3.83. The 30% of the patients had osteoporosis and 40% had increased fracture risk. There were significant relationship between RF and osteoporosis ($p = 0.002$) and the presence of nail lesion and high fracture risk ($p = 0.005$). There weren´t other significant relationships. The mean age of control group was 55.9 ± 7.4 and there were 50% male patients. There were difference between BMD and FRAX score in patients and control group but without statistical significance (Table 1).

Table 1. BMD and fracture risk in patients and controls

	Patients	Controls
L1-L4 BMD	0.94±0.22	1.03±0.22
T-score	-1.64±1.26	-1.42±0.8
LF BMD	0.90±0.17	0.89±0.93
T-score	-1.28±1.2	-1.24±0.64
RF BMD	0.89±0.14	0.91±0.06
T-score	-1.32±1.1	-1.08±0.54
FRAX major fracture	10.85±8.05	8.38±3.49
FRAX hip	3.71±3.24	2.48±1.3

Conclusion: There was a correlation between presence of positive RF in patients with PsA and PsA patients with nail lesions and high fracture risk. Therefore, in patients with PsA who are not on corticosteroid therapy but have positive RF and nail lesions, we must think about osteoporosis and high fracture risk in order to prevent fragility fracture. We need larger studies to definitively prove this relationship

P607
DIFFERENCES OF BMD BETWEEN HIP FRACTURED ELDERLY PATIENTS WITH AND WITHOUT DIABETES MELLITUS TYPE 2

I. P. Papaioannou[1], G. P. Pantazidou[2], Z. K. Kokkalis[3], N. G. Georgopoulos[4], E. J. Jelastopulu[5], A. B. Baikousis[6]

[1]Orthopedic Dept., General Hospital of Patras, [2]Univ. of Patras, Public Health Postgraduate Program, [3]Orthopedic Dept., Medical School, Univ. of Patras, [4]Endocrinology Dept., Univ. Hospital of Patras, [5]Dept. of Public Health, Univ. of Patras, [6]Orthopedic Dept. of General Hospital of Patras, Patras, Greece

Objective: To evaluate the differences of BMD measurements between hip fractured elderly patients with and without diabetes mellitus type 2 (T2DM)

Methods: We retrospectively studied 114 elderly patients (> 65 years old) with osteoporotic hip fractures, which were treated between January 2021 and January 2022. The non-diabetes group was consisted of 49 patients, while the diabetes group included 65 patients. 11 patients were newly diagnosed with impaired hemoglobin A1C (HbA1C) and switched to the diabetic group. 4 out of 11 patients were diagnosed with T2DM and 7/11 had prediabetes. We measured the values of BMD with DXA and/or quantitative ultrasound (QUS) of calcaneus

Results: Normal BMD values were not found in any patient of both groups. In non-diabetic group 73.5% (36/49) of patients were found with T-score lower than -2.5 and were diagnosed with osteoporosis. In contrary osteoporosis in diabetic group was diagnosed in 66.2% (43/65). Osteopenia (T-score between -1 and -2.5 was found in 26.5% (13/49) of non-diabetic patients and in 33.8% (22/65) of diabetic patients. Despite the differences of BMD between the two groups the statistical analysis (SPSS v 28.0) based on chi-square or χ^2 test did not reveal statistical significance ($p = 0.402$)

Conclusion: Our study, despite the small number of patients confirmed the fact that patients with T2DM are associated with higher BMD, although they are at increased risk for fracture. This paradox, which is strongly supported by the current literature should be taken into consideration by physicians for fracture prevention. TBS and revised FRAX-score are paramount of importance to achieve this goal. Bone fragility should be recognized as a new complication of T2DM, especially in elderly patients. The elderly patients are even more vulnerable to T2DM-induced bone fragility due to additional factors, such as senile osteoporosis, severe VD deficiency,

comorbidities, insulin usage, diabetes-related complications and especially diabetic neuropathy and retinopathy, predisposing to falls. Undiagnosed T2DM should be investigated to eliminate an additional risk factor for poor bone quality and all the well-known complications of T2DM

P608
IS HYPOALBUMINEMIA CORRELATED WITH HYPOVITAMINOSIS D IN ELDERLY WITH HIP FRACTURE WITH AND WITHOUT DIABETES MELLITUS TYPE2?

I. P. Papaioannou[1], G. P. Pantazidou[2], Z. K. Kokkalis[3], N. G. Georgopoulos[4], E. J. Jelastopulu[5], A. B. Baikousis[6]

[1]Orthopedic Dept., General Hospital of Patras, [2]Univ. of Patras, Public Health Postgraduate Program, [3]Orthopedic Dept., Medical School, Univ. of Patras, [4]Endocrinology Dept., Univ. Hospital of Patras, [5]Dept. of Public Health, Univ. of Patras, [6]Orthopedic Dept. of General Hospital of Patras, Patras, Greece

Objective: To identify if there is any correlation between hypoalbuminemia and hypovitaminosis d in diabetic and non-diabetic elderly with hip fracture
Methods: We retrospectively studied 114 elderly patients (> 65 years old) with low energy hip fractures, with and without history of diabetes mellitus type 2, which were treated in our department during the last 2 years between January 2021 and January 2023. We measured the values of albumin (alb) and 25 OH vitamin D (VD). The diabetic group was consisted of 65 patients and their counterparts were 49.
Results: The non-diabetic patients had mean value of albumin 2.94 ± 0.56 g/dL, while the diabetic group had 2.94 ± 0.53 g/dL. The results for VD were 10.03 ± 5.43 g/dL and 10.01 ± 5.09 g/dL respectively. In non-diabetic group we found 12 individuals with normal albumin levels (3.4–5.4 g/dL) with mean value of VD 10.24 ± 5.93 g/dL and 37 patients with hypoalbuminemia (< 3.4 g/dL) accompanied with mean value of VD 9.96 ± 5.34 g/dL. So, non-diabetic patients with hypoalbuminemia have lower levels of VD, although the statistical analysis didn't reveal any significance as the p-value was 0.743. The diabetic patients with sufficient albumin levels were 16 out of 65 with mean value of VD 12.30 ± 5.45 g/dL, while their counterparts with hypoalbuminemia had mean value of VD 9.26 ± 4.80 g/dL. In this group the difference of VD levels was statistically significant as the p-value was 0.038
Conclusion: Hypoalbuminemia was found to be prevalent among elderly patients with hip fracture, while VD deficiency and abnormal glycemic status were identified as risk factors for even lower levels of albumin. Decreased albumin should alert physicians for possible malnutrition and subsequence lower VD levels. VD deficiency, hypoalbuminemia and impaired glycemic status consist elements of a circle, which requires a holistic management of an elderly patient with low energy hip fracture

P609
PHOSPHORUS LEVELS IN DIABETIC PATIENTS WITH LOW ENERGY HIP FRACTURE

I. P. Papaioannou[1], G. P. Pantazidou[2], Z. K. Kokkalis[3], N. G. Georgopoulos[4], E. J. Jelastopulu[5], A. B. Baikousis[6]

[1]Orthopedic Dept., General Hospital of Patras, [2]Univ. of Patras, Public Health Postgraduate Program, [3]Orthopedic Dept., Medical School, Univ. of Patras, [4]Endocrinology Dept., Univ. Hospital of Patras, [5]Dept. of Public Health, Univ. of Patras, [6]Orthopedic Dept. of General Hospital of Patras, Patras, Greece

Objective: To identify if there is any difference of phosphorus levels between diabetic and non-diabetic elderly patients with hip fracture
Methods: We retrospectively studied 114 elderly patients (> 65 years old) with low energy hip fractures, with and without history of diabetes mellitus type 2, which were treated in our department during the last 2 years between January 2021 and January 2023. We measured the values of serum phosphorus (Ph), serum calcium (ca) and glomerular filtration rate (eGFR). The diabetic group was consisted of 65 patients and their counterparts were 49. Patients with chronic kidney disease (CKD) grades 4 and 5 were excluded from the study, because severe renal failure results in reduced synthesis of calcitriol and secondary hyperparathyroidism
Results: Serum calcium levels had no significant difference (p = 0.272) between non-diabetic and their counterparts (9.08 ± 0.5 vs. 9.19 ± 0.52 mg/dL respectively). GFR values differ between the two groups despite the exclusion of diabetic patients with CKD grades 4 and 5. The eGFR values were 72.14 ± 24.81 and 66.55 ± 21.43 for non-diabetic and diabetic patients respectively. Non-diabetic patients were found to have decreased e-GFR values, although the difference wasn't statistically significant (p = 0.178). Diabetic patients were found to have increased levels of Ph (3.22 ± 0.72 mg/dL) in comparison with their counterparts (2.91 ± 0.72 mg/dL). The difference was statistically significant p = 0.026
Conclusion: The diabetic group had increased levels of Ph compared with their counterparts, although the values of Ph were in normal limits. Diabetic patients of our studied had lower eGFR levels but not to that extent to result in hyperphosphatemia and increased PTH. Clinicians should be aware that hyperphosphatemia in severe CKD patients can lead to an increased risk of vascular calcification that increases the risk of cardiovascular events. It's worth noting that increased Ph contributes to vascular and metabolic disturbances in elderly patients with type 2 diabetes mellitus and further renal impairment

PARATHORMONE FLUCTUATIONS IN DIABETIC AND NON-DIABETIC ELDERLY PATIENTS WITH LOW ENERGY HIP FRACTURE

I. P. Papaioannou[1], G. P. Pantazidou[2], Z. K. Kokkalis[3], N. G. Georgopoulos[4], E. J. Jelastopulu[5], A. B. Baikousis[6]

[1]Orthopedic Dept., General Hospital of Patras, [2]Univ. of Patras, Public Health Postgraduate Program, [3]Orthopedic Dept., Medical School, Univ. of Patras, [4]Endocrinology Dept., Univ. Hospital of Patras, [5]Dept. of Public Health, Univ. of Patras, [6]Orthopedic Dept. of General Hospital of Patras, Patras, Greece

Objective: To identify if there is any difference of PTH levels between diabetic and non-diabetic elderly patients with hip fracture
Methods: We retrospectively studied 114 elderly patients (> 65 years old) with low energy hip fractures, with and without history of diabetes mellitus type 2, which were treated in our department during the last 2 years between January 2021 and January 2023. We measured the values of 25 OH vitamin D (VD), PTH and glomerular filtration rate (eGFR). The diabetic group was consisted of 65 patients and their counterparts were 49. Patients with chronic kidney disease (CKD) grades 4 and 5 were excluded from the study, because severe renal failure results in reduced synthesis of calcitriol and secondary hyperparathyroidism
Results: VD levels were similar in both groups (10.03 ± 5.43 g/dL non-diabetic vs. 10.01 ± 5.09 g/dL diabetic) without any statistically significant difference (p = 0.986). PTH levels differ significantly between the two groups (p = 0.018). PTH levels in non-diabetic patients were 79.71 ± 57.6 pg/mL, while in diabetic patients the

values were 56.42 ± 45.57 pg/mL. The eGFR values were 72.14 ± 24.81 and 66.55 ± 21.43 for non-diabetic and diabetic patients respectively. Non-diabetic patients were found to have increased e GFR values, although the difference wasn't statistically significant (p = 0.178)

Conclusion: Secondary hyperparathyroidism (SHPT) is common among elderly due to two main causes: VD deficiency and renal failure. SHPT is often associated with disturbances of bone turnover, as well as visceral and vascular calcifications, which are responsible for cardiovascular morbidity and mortality. PTH acts as a stimulus for increased osteoclast activity, which results in calcium and phosphorus resorption from the bone. As GFR levels do not differ dramatically, a possible explanation of the difference between PTH levels is the dysfunction of parathyroid gland due to diabetic microangiopathy and the fact that only severe VD deficiency is correlated with increased levels of PTH. In our study severe hypovitaminosis d (< 10 g/dL) was prominent in non-diabetic group (59.2 vs. 56.9%)

CLINICAL PATTERNS, DIAGNOSTIC ASSESSMENT AND MANAGEMENT OF ASYMPTOMATIC PRIMARY HYPERPARATHYROIDISM (APHPT) IN RIGA EAST CLINICAL UNIVERSITY HOSPITAL (RECUH) IN TERTIARY CARE HOSPITAL IN LATVIA: A 3-YEAR RETROSPECTIVE BASED STUDY

D. Stūrīte[1], I. Rasa[2]

[1]Rīga Stradiņš Univ. (RSU), Latvian Osteoporosis and Bone Metabolic Diseases Association (LOKMSA), [2]Latvian Osteoporosis and Bone Metabolic Diseases Association (LOKMSA), Riga East Clinical Univ. Hospital (RECUH), Riga, Latvia

Objective: Primary hyperparathyroidism and APHPT rank as the third most common endocrine disorder, displaying varying clinical presentation. The study aimed to evaluate clinical patterns and patients (pts) management with APHPT

Methods: Data from 168 pts with APHPT at RECUH between January 2021 and November 2023 were analysed, including medical records, lab findings, imaging, surgical protocols, and histopathology. We used IBM SPSS 29.0 for statistical analysis

Results: 168 pts (mean age: 63.7 ± 11.8 y), 86.3% (n = 145) were females, 13.7% (n = 23) males. The mean preoperative maximal calcium level was 2.9 ± 0.3 mmol/L, iPTH level 247.6 ± 224.9 pg/mL, minimal phosphorus 1.3 ± 6.7 mmol/L and 25-OH vitamin D level 28.3 ± 14.7 ng/mL. 5.3% (n = 9) had normocalcaemic APHPT. Parathyroid adenoma sizes ranged from 0.3 × 0.4 cm to 5.3 × 3.7 cm. Calcium levels positively correlated with adenoma cross-sectional area (ρ = 0.187, p = 0.029) and maximal dimension (ρ = 0.215, p = 0.011). Ultrasonography verified parathyroid adenomas in 63.9% (107/168), SPECT/CT 68.4% (52/76), 99mTc-sestamibi scintigraphy 65.6% (61/93), 3D-CT 70.6% (24/34), contrast-enhanced ultrasonography (CEUS) 84% (21/25) and MRI in 40% (2/5) cases. 12.5% (n = 21) of pts had unlocated parathyroid adenoma. 22.0% (n = 37) of pts had kidney stones, 17.3% (n = 29) gallstones, 34.5% (n = 58) osteoporosis, 12.5% (n = 21) osteoporotic fractures and 47.6% (n = 80) osteopenia. The mean preoperative eGFR was 90.6 ± 28.2 ml/min/1.73 m^2, creatinine—72.5 ± 23.9 μmol/L. 17.9% (n = 30) of pts received oral bisphosphonates, 4.0% (n = 7) intravenous bisphosphonates, 8.0% (n = 14) denosumab, and 1.1% (n = 2) had medication holidays. 80.4% (n = 135) of patients had thyroid nodules, 48.2% (n = 81) had nontoxic goiter, and 24.4% (n = 31) had autoimmune thyroiditis. 18.5% (n = 31) of pts were found to have a diagnosis of malignancy. 61.9% (n = 104) of pts underwent parathyroidectomy. Histopathology and radiologic imaging revealed a single parathyroid adenoma in 95.2% (n = 99), double parathyroid adenomas in 1.9% (n = 2), parathyroid hyperplasia in 2.9% (n = 3) and parathyroid carcinoma in 1.9% (n = 2) pts. The mean maximal postoperative calcium level (n = 103) was 2.4 ± 0.1 mmol/L, iPTH (n = 101) 63.5 ± 27.7 pg/mL, 25-OH vitamin D 41.5 ± 13.3 ng/mL, and mean minimal phosphorus (n = 56) 1.1 ± 0.2 mmol/L. Three pts developed hungry bone syndrome following parathyroidectomy. Three required reoperation

Conclusion: APHPT is common, often exhibiting bone manifestations. The sensitivity of diagnostic modalities and the prevalence of osteoporosis differed from what has been reported in Western Europe and the USA, with osteoporosis occurring more frequently. It's crucial to consider the diverse clinical manifestations in pts with APHPT

P612
EVALUATION OF THE EFFECTIVENESS OF LOCAL THERAPY OF EROSIVE OSTEOARTHRITIS OF SMALL WRIST JOINTS

B. S. Bekmurzoda[1], I. S. Kniazev[1]

[1]Avicenna Tajik State Medical Univ., Dushanbe, Tajikistan

Objective: Erosive osteoarthritis (OA) of the wrist joints more often affects the proximal interphalangeal joints and is radiologically characterized by subchondral erosions, which can progress to the bone and cartilage destruction, significant instability and bone ankylosis. Usually, the erosive form of OA has a sudden onset, severe pain syndrome and functional disorders, inflammatory symptoms (stiffness, soft tissue edema, erythema, paresthesia), moderately elevated C-reactive protein (CRP) levels and a worse outcome in comparison with non-erosive OA

Methods: We observed 115 patients with erosive osteoarthritis of small joints of the wrists. 83 patients had type 2 diabetes mellitus. The average age of the patients was 61 ± 3.4 y. All patients received therapy with chondroitin sulfate, ointments containing nonsteroidal anti-inflammatory drugs. Before the providing of local therapy with the use of the biopolymer microheterogenic collagen-containing implant the estimated value of pain according to VAS was 65 ± 12.3, the value of stiffness according to WOMAC was 9.4, the value of functionality according to WOMAC was 90 ± 1.4, the value of the HAQ index was 1.2 ± 0.3. Three procedures with the 2 weeks intervals between them of peri-tendon injections of the biopolymer microheterogenic collagen-containing implant to the tendons of the extensors of the fingers of the wrists in the projection of the Heberden nodules were provided by ultrasound navigation control

Results: We estimated the effectivity of peri-tendon injections of biopolymer microheterogenic collagen-containing implant after 4 weeks from the third procedure. WOMAC pain index was reduced on 52%, the WOMAC functionality index was reduced from 90 to 42 (on 47%), and the VAS pain index from 65 to 35 (on 54%). HAQ was reduced till 0.6

Conclusion: The local peri-tendon injections of biopolymer microheterogenic collagen-containing implant were effective in pain control and improvement of the wrist function in the patients with the erosive OA of the wrist joints

P613
UNILATERAL FEMORAL HEAD POST-COVID19 ASEPTIC NECROSIS: PERSPECTIVES OF LOCAL THERAPY

B. S. Bekmurzoda[1], I. S. Kniazev[1]

[1]Avicenna Tajik State Medical Univ., Dushanbe, Tajikistan

Objective: The COVID-19 pandemic was marked by an increased number of cases of aseptic necrosis of bone tissue of various

localization. The undisputed leader in frequency of occurrence is aseptic necrosis of the femoral head (ANFH), approximately 39% of patients infected with SARS-CoV-2 developed femoral head necrosis a few months after infection

Methods: 63 patients with ASNFH (age 49.5 ± 3.8 y (36 women and 27 men)) were observed in the period from 2022–2023. All patients received therapy using NSAIDs, calcium containing drugs and bisphosphonates. The duration of the period from the transferred COVID19 to the moment of the appearance of clinical signs of hip joint damage was 125 ± 18 d. In 57 patients, II degree and 6 patients with the IIIA degree of ASNFH occurred according to MRI classification. From these cohorts, patients with the II degree of ANFH got 4 intrajointal injections (once in 3 months) under ultrasound control of the biopolymer microheterogenic collagen-containing implant with the size of microparticles of the crosslinked collagen fraction not exceeding 100–200 microns. Patient with the IIIA degree of ASNFH got 3 intrajointal injections (once in 4 months) of the biopolymer microheterogenic collagen-containing implant with the size of microparticles of the crosslinked collagen fraction not exceeding 250–300 microns

Results: At the end of the course of local therapy (4 weeks after last intrajointal procedure), patients in both groups showed a decrease in the WOMAC pain index from 9.8 to 5, a decrease in the WOMAC functionality index from 70 to 42, and a decrease in the VAS pain index from 80 to 30. In addition, none of the patients from the observed cohorts underwent total hip replacement

Conclusion: the results of the observation demonstrate the effectiveness of local therapy of post-COVID19 aseptic femoral necrosis using a biopolymer microheterogenic collagen-containing implant in terms of improved joint function and provided the possibility of preventing joint replacement in this category of patients
