Objective: Pelvic radiotherapy is a known cause of insufficiency fractures and avascular necrosis. Postmenopausal women with osteoporosis constitute the highest risk population

Methods: Based on clinical observation of a patient with pelvic radionecrosis

Results: A 69-year-old overweight female seeks the Emergency Department for left inguinal pain lasting 2 weeks, with sudden onset after bending forwards to take off her shoes. Her medical history includes early menopause at 42, uterine carcinoma treated with radiotherapy 26 years ago, a left Colles' fracture and a dropped foot due to iatrogenic injury of the right superficial and deep peroneal nerves. On physical examination, she presents painful flexion of the left hip above 90°. Pelvic X-ray reveals a left ischiopubic ramus fracture and she initiates weekly alendronate 70 mg. Lumbosacral MRI identifies a fracture of L5 and heterogeneous hypersignal on the left side of the sacrum. Despite analgesic therapy adjustments and rehabilitation program, she maintains pain complains. Bone scintigraphy shows suspicious changes compatible with secondary lesions in the left ischiopubic ramus, sacroiliac joints, L5 and L5–S1. Additional studies do not identify other lesions suggestive of primary or secondary neoplasms. Pelvic MRI presents extensive signal alterations in both sacral wings, predominantly on the left with extension to soft tissues (Fig. 1). A bone biopsy concludes remodeling radionecrosis. Bone densitometry reveals a T-score of − 3.9 for the lumbar spine and − 2.3 for the femoral neck. She is referred to rheumatology consultation for therapeutic adjustment with semi-annual denosumab 60 mg, monthly calcifediol 0.266 mg and daily calcium carbonate + cholecalciferol 1500 mg + 400 IU

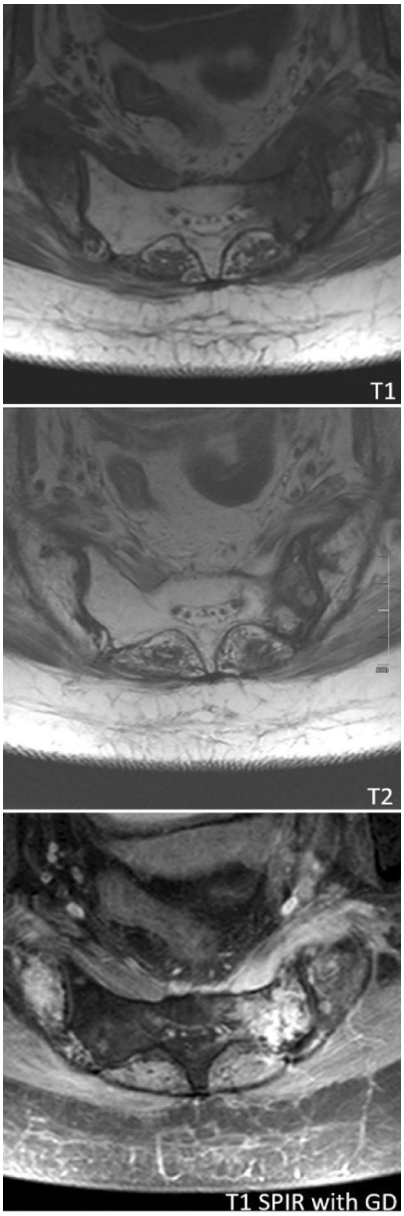

Figure 1: Pelvic MRI

Conclusion: In patients with a history of malignancy, the differential diagnosis between insufficiency fracture and metastatic bone disease is extremely relevant, given the therapeutic and prognostic implications

P615
FEMORAL NECK FRACTURE AT THE 9TH KM MARK OF A TRAIL RUN

I. Santos[1], R. Evangelista[2], I. Almeida[1], N. Martins[1], P. Monteiro[1], I. Inácio[3], V. Ermida[2], J. Caldas[2]

[1]Rheumatology Unit, Centro Hospitalar Tondela-Viseu[2]Dept. of Physical Medicine and Rehabilitation, Centro Hospitalar Tondela-Viseu, [3]USF Coração da Beira, ACES Dão Lafões, Viseu, Portugal

Objective: Femoral neck fragility fractures (FNF) are uncommon in athletes. Women with eating disorders, amenorrhea, decreased BMD and a sudden increase in training volume constitute the highest risk population

Methods: Based on clinical observation of a patient with FNF

Results: A 38-year-old female athlete experienced a "pop" in her right hip with immediate functional impairment at the 9th kilometer of a trail run. In the Emergency Department, she presented with right inguinal pain and was unable to bear weight on the limb. Right hip radiography revealed FNF (Fig. 1). She underwent closed reduction and stabilization with three cannulated screws. A rehabilitation program was initiated at 12 weeks, focusing on joint range of motion, peri-articular muscle strengthening and gait training. She also underwent aquatic treadmill sessions with good progress. The patient had chronic urticaria and irritable bowel syndrome, managed with ketotifen and clidinium bromide. She was a former smoker with a BMI of 17.1 kg/m^2. No history of eating disorders, or gynecological or obstetric conditions was reported. She had resumed sports activity one year before the current episode, after a two-year hiatus following the birth of her only child. She had showed sporadic right inguinal discomfort during training for the previous 6 months. Bone densitometry revealed a Z-score of − 2.8 for the lumbar spine and + 0.3 for the contralateral femoral neck. Alendronate, calcium and vitamin D supplementation were initiated. She was referred to Rheumatology consultation for secondary osteoporosis exclusion. Analytically, she had a vitamin D deficiency (13 ng/mL) and hyperhomocysteinemia 15.4 µmol/L (normal range: 3.7–13.9), with no other significant abnormalities. No dorsolumbar fractures were observed

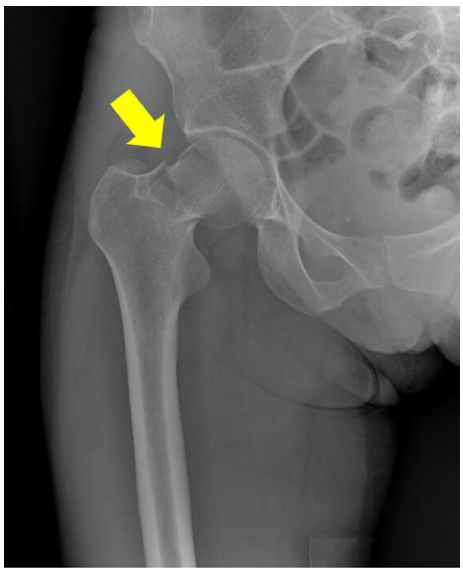

Figure 1: Right hip radiography with femoral neck fracture (arrow)

Conclusion: The inappropriate progression in training volume combined with the patient's low BMD and BMI resulted in FNF. The optimization of risk factors in a multidisciplinary team and the implementation of an individualized rehabilitation program allowed the improvement of functional outcomes and a safe return to sports activity

P616
CHRONIC KIDNEY DISEASE—MINERAL AND BONE DISORDER: DEMOGRAPHIC AND CLINICAL DIFFERENCES IN A COHORT WITH PROXIMAL FEMUR FRAGILITY FRACTURE

I. Santos[1], G. Terroso[2], C. Marques-Gomes[2], M. Diz-Lopes[2], L. Costa[2]

[1]Rheumatology Unit, Centro Hospitalar Tondela-Viseu, Viseu, [2]Rheumatology Dept., Centro Hospitalar Universitário São João, Porto, Portugal

Objective: To identify demographic or clinical differences in patients with and without chronic kidney disease (CKD) who had experienced a proximal femur (PF) fragility fracture (FF).

Methods: Retrospective single-center study including patients aged 50 years or older who were referred to a Fracture Liaison Service during their hospitalization in an Orthopedics department due to PFFF, registered in Reuma.pt FF protocol. Individuals were grouped based on their glomerular filtration rate according to 2021 CKD-Epidemiology Collaboration equation either as CKD (< 60 mL/min/1.73 m^2) or non-CKD patients (≥ 60 mL/min/1.73 m^2). Demographic and clinical data were collected and compared between groups

Results: A total of 230 patients were included. 64 patients presented CKD (27.8%), of which 84.4% stage 3 (n = 54), 12.5% stage 4 (n = 8) and 3.1% stage 5 (n = 2), these latter on hemodialysis. Osteoporosis (OP) was diagnosed in 93.9% (n = 216). In the remaining, adynamic bone disease was weighed, with 4.8% having presumed diagnosis (n = 11) and 1.3% currently being considered for bone biopsy (n = 3). Most patients were females (n = 199, 86.5%), all postmenopausal. CKD patients were considerably older than non-CKD (84.0 ± 7.3 vs. 79.3 ± 7.8 y, p = < 0.001). No significant differences were found regarding other health conditions or drugs that induce OP, although CKD patients tended to have higher rates of early menopause [n = 11 (23.4%) vs. n = 14 (11.8%), p = 0.059] and furosemide use [n = 3 (4.7%) vs. n = 1 (0.6%), p = 0.066]. CKD patients had higher phosphate (mean 3.6 ± 0.5 vs. 3.4 ± 0.5 mg/dL, p = 0.014) and PTH levels [median 65.9 (52.8) vs. 44.6 (28.3) pg/mL, p = < 0.001]. With no group differences, 50.4% (n = 116) had at least one previous FF (p = 0.250) and 7.7% (n = 17) had a history of parental PFFF (p = 1.000). Overall, median femoral neck T-score was − 2.7 (1.4) (p = 0.583) and 14.3% of the patients (n = 33) had received prior anti-OP drugs (p = 0.360)

Conclusion: CKD patients were older and tended to have greater rates of early menopause and furosemide use, as well as higher phosphate and PTH levels. However, CKD did not impact the existence of prior FF, history of parental PFFF, femoral neck T-score, or previous use of anti-OP drugs

P617
CHRONIC KIDNEY DISEASE—MINERAL AND BONE DISORDER: THERAPEUTIC DIFFERENCES IN A COHORT WITH PROXIMAL FEMUR FRAGILITY FRACTURE

I. Santos[1], G. Terroso[2], M. Diz-Lopes[2], C. Marques-Gomes[2], L. Costa[2]

[1]Rheumatology Unit, Centro Hospitalar Tondela-Viseu, Viseu, [2]Rheumatology Dept., Centro Hospitalar Universitário São João, Porto, Portugal

Objective: To identify therapeutic differences in patients with and without chronic kidney disease (CKD) who had experienced a proximal femur (PF) fragility fracture (FF)
Methods: Retrospective single-center study including patients aged 50 years or older who were referred to a Fracture Liaison Service during their hospitalization in an Orthopedics department due to PFFF, registered in Reuma.pt FF protocol. Individuals were grouped based on their glomerular filtration rate according to 2021 CKD-Epidemiology Collaboration equation either as CKD (< 60 mL/min/1.73 m^2) or non-CKD patients (≥ 60 mL/min/1.73 m^2). Diagnostic and therapeutic data were compared between groups
Results: A total of 230 patients were included. 64 patients presented CKD (27.8%), of which 84.4% stage 3 (n = 54), 12.5% stage 4 (n = 8) and 3.1% stage 5 (n = 2), these latter on hemodialysis. Osteoporosis (OP) was diagnosed in 93.9% (n = 216). In the remaining, adynamic bone disease (ABD) was weighed, with 4.8% having presumed diagnosis (n = 11) and 1.3% currently being considered for bone biopsy (n = 3). No significant differences were found regarding previous use of anti-OP drugs (p = 0.360). Overall, alendronate was the most frequent first prior drug (n = 24, 72.7%). On the other hand, current treatment significantly differed between groups ($p < 0.001$). Alendronate and zoledronate were more frequently used in non-CKD patients than in CKD patients [respectively, n = 22 (13.3%) vs. n = 0 (0.0%), p = 0.002 and n = 61 (36.7%) vs. n = 12 (18.8%), p = 0.009]. Denosumab was more commonly employed in the CKD group [n = 37 (57.8%) vs. n = 61 (36.7%), p = 0.004], with CKD patients having 2.4 times the odd of non-CKD patients to receive denosumab (OR = 2.4, 95% CI 1.3–4.2, p = 0.004). None of the 11 patients with presumed ABD were receiving anti-OP therapy, as well as 2 of the 3 patients being considered for bone biopsy (66.7%). The other patient (33.3%) was maintaining denosumab while awaiting the decision of bone biopsy
Conclusion: Alendronate and zoledronate were preferred in non-CKD patients and denosumab in CKD patients, the latter probably due to safety concerns. Antiresorptive agents are discouraged in ABD to avoid further suppression of bone turnover. Anabolic agents may be beneficial but have not yet been approved for its treatment. Therefore, most patients with suspected ABD were not under any therapy

P618
SYSTEMIC INFLAMMATION MARKERS AND LEAN MASS IN IBD YOUNG PATIENTS

I. Soare[1], A. Sirbu[1], M. Diculescu[1], B. Mateescu[1], C. Tieranu[1], L. Cima[1], S. Fica[1]

[1]Univ. of Medicine and Pharmacy Carol Davila Bucharest, Bucharest, Romania

Objective: Inflammatory bowel disease (IBD), comprising Crohn's disease (CD) and ulcerative colitis (UC) represents a chronic gastrointestinal disease. Chronic inflammatory state has been reported to be associated with low muscle mass. We aimed to study the impact of systemic inflammation (SII) scores on muscle mass in IBD patients
Methods: Anthropometric data were collected, and all patients underwent blood tests measurements. ASMI (appendicular muscle skeletal index) was determined using DXA whole body was measured using albumin levels, prognostic nutritional index (PNI), neutrophil–lymphocyte ratio (NLR), and platelet-lymphocyte ratio (PLR). Low lean mass represented an ASMI Z-score < -1SD for age and gender, using NHANES scales
Results: A multicentric cross-sectional study was conducted on 56 young IBD patients (36 with CD, 20 with UC), 36 women, median age 33 (IQR18) y, mean duration of disease 6 (IQR6) y, BMI 22.2 ± 4.7 kg/m^2. Low lean mass was present in half of the patients evaluated. ASMI correlated negatively with PLR ($r = -0.402$, $p = 0.003$) and positively with PNI ($r = 0.429$, $p = 0.003$). The best parameter to differentiate between normal or low lean mass is PNI (ROC AUC = 0.735, p = 0.005)
Conclusion: Low muscle mass is a frequent complication, even in young IBD patients. PNI could represent an important parameter to assess the risk of low muscle mass in these patients

P619
MAXILLARY INTERRADICULAR ALVEOLAR BONE STRUCTURE AFTER IMPLANTATION OF CERAMIC HYDROXYLAPATITE OK-015 INTO THE TIBIA

A. Pilavov[1], I. Solovyova[1], V. Ryabkov[1], M. Trufanova[1]

[1]FSBEI HI St. Luka LSMU of MOH of Russia, Lugansk, Russia

Objective: To analyze changes in structure of maxillary interradicular alveolar bone after implantation of ceramic hydroxyapatite OK-015 into the tibia
Methods: 90 male rats with body weight of 190–225 g were used. Animals were distributed into three groups. Group 1 consisted of the intact animals. Group 2 consisted of the animals with tibia fracture modeled as 2-mm round openings in both tibiae. In animals of the group 3 the same openings were filled with hydroxyapatite material OK-015. Hematoxylin–eosin stained sections of the maxillary interradicular septum (MSI) behind the first molar tooth (M1) were photographed under the light microscope and images were used for histomorphometry. Bone volume fraction (BV), trabecular thickness (TrT), and intertrabecular spaces (ISp) were calculated using standard methods. Measurements were performed at the MSI next to the first molar. The data obtained were analyzed with the use of variation statistics methods
Results: In the group 2 BV at the MSI of M1 was lower than that of the group 1 by 5.86%, 7.43%, 6.97%, and 4.95% in the period from the 15th to the 90th day after surgery, and TrT—by 4.48%, 8.33%, 7.75%, 7.52%, and 5.38% in the period from the 7th to the 90th day after surgery. ISp in the period from the 7th to the 90th day widened in comparison with those of the group 1 by 5.57%, 6.81%, 7.07%, 9.58%, and 5.93%. In the group 3, BV values at the MSI of M1 decreased in comparison with the group 2 by 6.22% on the 15th day and TrT decreased by 5.25% and 6.19% by the 7th and the 15th day. ISp in the same period increased by 5.28% and 5.47%. By the 60th and 90th day BV values exceeded those of the group 2 by 7.49% and 5.69% and TrT by the 60th day—by 5.02%. ISp on the 90th day decreased by 5.13% in comparison with the group 2
Conclusion: Implantation of OK-015 into the tibia reduces adverse effects of intervention on MSI structure beginning from the 60th day after intervention

P620
FREQUENCY OF VITAMIN D DEFICIENCY AND HYPOCALCEMIA IN PREGNANCY

R. Alimanovic-Alagic[1], I. Surkovic[2], A. Bazdarevic-Rasidagic[3], N. Kulenovic-Kokorovic[4], S. Saric[5]

[1]Clinica for Nuclear Medicine and Endocrinology, [2]Clinic for Nuclear medicine and Endocrinology, [3]Public Medical Care Sarajevo, [4]Institute for the Protection of Women and Maternity, [5]Public Medical Care Institution, Sarajevo, Bosnia & Herzegovina

Objective: Vitamin D is a nutrient that helps our body for good health. It helps our body absorb calcium, one of the main building blocks for strong bones. Vitamin D also has a role in our nervous, muscle, and immune systems. People can get vitamin D in three ways: through from skin, from diet, and from supplements
Methods: As a part of the investigational project 254 pregnant woman were examined at the Clinic for Nuclear medicine and Endocrinology of the University Clinical Center of Sarajevo, age 20–40 during 12 months. The study was designed as prospective. For each patient we did personal history, BMI, which is pregnancy in order, trimester of pregnancy. We established presence of risk factors (of, smoking), poor nutrition, chronic diseases, physical activity
Results: In investigated group of 254 patients three factors leading for vitamin D deficiency and hypocalcemia development are: poor nutrition (45%), no physical activity (26%) and endocrine presence frequently vitamin D deficiency and hypocalcemia (23%)
Conclusion: Vitamin D deficiency is thought to be common among pregnant women in some populations, and has been found to be associated with an increased risk of pre-eclampsia, gestational diabetes mellitus, preterm birth, and other tissue-specific conditions. The signs and symptoms of hypocalcemia are dependent on the severity, rapidity of development, the rate of decline of serum calcium, and duration of the hypocalcemia varying from an asymptomatic biochemical abnormality to a life-threatening disorder. Pregnant women should be encouraged to receive adequate nutrition, which is best achieved through consumption of a healthy balanced diet. The daily upper limits for vitamin D include intakes at pregnant and breast-feeding teens and women 100 mcg (4000 IU)

P621
REFERENCE INTERVALS FOR SERUM CONCENTRATIONS OF BONE ALKALINE PHOSPHATASE FOR GREEK ADULT MEN AND WOMEN

I. Trifonidi[1], P. Loukas[2], S. Tournis[3], E. Cavalier[4], E. Chronopoulos[3], K. Makris[5]

[1]KAT General Hospital/Clinical Biochemistry Dept,. Kifissia, Greece, [2]Clinical biochemistry Dept., KAT General Hospital, Liege, Belgium, [3]Laboratory of Research of Musculoskeletal System "Th. Garofalidis", KAT General Hospital, Medical School, Univ. of Athens, Athens, Greece, [4]Dept. of Clinical Chemistry, Univ. of Liege, CHU de Liege, CIRM, Liege, Belgium, [5]Clinical biochemistry Dept., KAT General Hospital, Kifissia, Greece

Objective: Bone turnover markers (BTMs) reflect the metabolic activity of bone tissue and can be used to monitor osteoporosis therapy. To adequately interpret BTMs, method-specific and population specific reference intervals are needed. We aimed to determine reference intervals for serum concentrations of bone specific alkaline phosphatase (bALP).
Methods: We collected samples from 431 apparently healthy Greeks (140 men, 150 pre- and 139 postmenopausal women), who volunteered to participate in our study. Data on sociodemographic characteristics, medical histories and medications were collected and subjects with conditions or receiving medications that affecting bone metabolism were excluded. DXA used to measure BMD in all participants. All blood collections were performed in the morning after overnight fast. Serum bALP concentrations were measured by an automated immunoassay on the ISYS analyzer (Immunodiagnostic Systems, Boldon, UK). The reference interval was defined as the central 95% range. We determined reference intervals according to CLSI guide C28-A3 and using the MedCalc Software.
Results: The mean age of men, pre- and post-menopausal women were 50.7, 40.7 and 58.4 years respectively. DXA results revealed that 348 participants had normal BMD, 74 were osteopenic and 9 had osteoporosis who excluded from analysis. Since our data were not normally distributed (Shapiro–Wilk test) in any group and after the exclusion of outliers (Tukey test), we used the non-parametric method suggested by the CLSI guide in order to determine the reference intervals. We found out that subjects with osteopenia exhibited significantly higher values for bALP compared to those with normal BMD [median (25,75 percentiles)] 12.8 μg/mL (10.07–16.35) vs. 16.13 μg/mL (12.61–20.10). No significant differences were observed between men and women. The majority of subjects with osteopenia (94.59%) were over 50 years old. Subsequent analysis according to age revealed that subjects over the age of 50 had significantly higher bALP values compared to younger individuals. For subjects > 50 y the reference intervals were calculated as 7.80–28.40 μg/mL, and for subjects < 50 years 3.73–20.52 μg/mL.
Conclusion: We provide reference intervals for bALP concentrations in serum for the Greek adult population using an automated immunoassay. Our data may aid to interpret bone turnover in the Greek adult population.

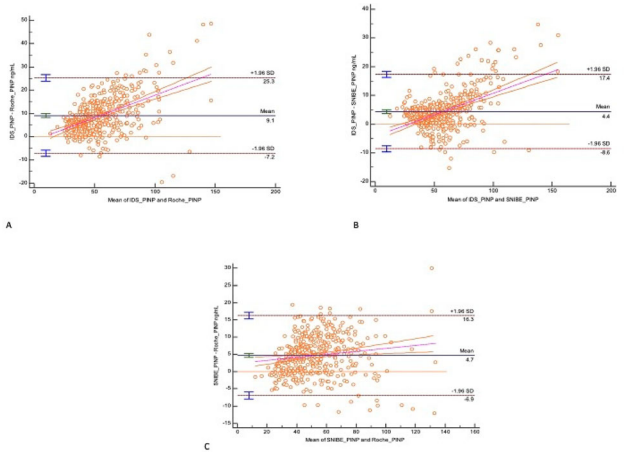
P622
EVALUATION OF HARMONIZATION STATUS OF N-TERMINAL PROPEPTIDE OF TYPE I PROCOLLAGEN (P1NP)

I. Trifonidi[1], P. Loukas[2], S. Tournis[3], E. Cavalier[2], E. Chronopoulos[3], K. Makris[4]

[1]KAT General Hospital/Clinical Biochemistry Dept., Kifissia, Greece, [2]Dept. of Clinical Chemistry, Univ. of Liege, CHU de Liege, CIRM, Liege, Belgium, [3]Laboratory of Research of Musculoskeletal System "Th. Garofalidis", KAT General Hospital, Medical School, Univ. of Athens, Athens, Greece, [4]Clinical biochemistry Dept., KAT General Hospital, Kifissia, Greece

Objective: Biochemical bone turnover markers (BTM) are useful tools to assess bone remodelling at the cellular level. P1NP has been recommended as a reference marker for bone formation in research studies. However, the absence of standardization may hinder results interpretation due to discrepancies between different commercial assays. This study aims to evaluate the current status of harmonization of three commercial assays measuring P1NP
Methods: Serum samples from 431 subjects (348 healthy donors, 74 osteopenic and 9 osteoporotic patients) were collected in Athens, Greece and were tested in Athens and Liege, Belgium with three automated commercial assays (IDS on ISYS, Roche on Cobas e-411 and SNIBE on Maglumi-X3). All measurements were performed according to manufacturers instructions. Passing-Bablok regressions, Bland–Altman plots, and the concordance correlation coefficient (CCC) between methods were used to determine the agreement between results
Results: Three paired comparisons were performed (IDSvsRoche, SNIBEvsRoche and IDSvsSNIBE). Bland–Altman analysis (figure) and Passing-Bablok regression revealed small but significant proportional and systematic bias between the three methods. In all paired comparisons intercept's 95% CI did not include 0 [1.57 (0.05, 3.19),

2.15 (0.52, 3.77) and 1.54 (0.11, 2.99) respectively] and slopes did not include 1 [0.82(0.79, 0.85), 1.09 (1.06, 1.14) and 0.90 (0.88, 0.93) respectively]. Calculation of CCC revealed a moderate agreement between the three methods (0.94 0.93 and 0.94 respectively)



Conclusion: Harmonization of P1NP assays is necessary in order to use results from all commercial assays interchangeably. Production and use of certified reference materials to calibrate assays will help to achieve this goal

P623
BONE METABOLISM IN PATIENTS WITH NORMOCALCEMIC PRIMARY HYPERPARATHYROIDISM

I. Yankova[1], A. Shinkov[1], R. Kovatcheva[1]

[1]Dept. of Endocrinology, Medical Univ. of Sofia, Sofia, Bulgaria

Objective: Normocalcemic primary hyperparathyroidism (nPHPT) is a condition characterized by persistently high levels of PTH and normal serum calcium levels in the absence of other causes for secondary hyperparathyroidism. The aim of the present study was to assess the biochemical characteristics, the markers of bone metabolism and the BMD in patients with nPHPT and to compare them with those in patients with hypercalcemic PHPT (hPHPT) and in healthy control group

Methods: The study included 352 patients (310 women and 42 men, average age 59.1 ± 11.9) diagnosed with PHPT. A control group of 74 age- and sex-matched subjects without bone disorders was defined. Total serum calcium, inorganic phosphates (PO_4), PTH, urinary Ca (uCa), albumin, creatinine, 25(OH)D and bone markers (b-CTX and ALP) were examined in all participants. BMD of the lumbar spine (LS), distal third of the radius (DR), femoral neck (FN) and total proximal femur (TF) were measured by a DXA. The PHPT patients were divided into two groups according to albumin-corrected calcium (Ca) level – with hPHPT (Ca > 2.62 mmol/L) and with nPHPT (Ca 2.12–2.62 mmol/l), without other causes for secondary hyperparathyroidism

Results: The frequency of nPHPT was 16.5%. Normocalcemic patients had lower levels of PTH, higher PO_4 and 25(OH)D, and smaller parathyroid adenomas. No significant difference in the bone markers, prevalence of osteoporosis and low-energy fractures was found between nPHPT and hPHPT. There was no difference in BMD between the two groups. The patients with nPHPT had lower BMD LS and DR and higher prevalence of osteoporosis compared to the control group

Conclusion: The patients with nPHPT show a more favorable biochemical profile compared to those with hPHPT. Nevertheless, clinical manifestations and complications are similar, with no significant difference in the BMD, the prevalence of osteoporosis and low-energy fractures

P624
ASSESSMENT OF RISK OF OSTEOPOROSIS AND OSTEOPOROIC FRACTURES IN MALE PATIENTS WITH CORONARY HEART DISEASE

Y. Popenko[1], T. Shaldybin[2], N. Shadchneva[1], E. Dolya[1], A. Zayaeva[1], I. Yatskov[1], V. Kaliberdenko[1], E. Kuliyeva[1]

[1]V.I. Vernadsky Crimean Federal Univ., [2]Medaira Clinic, Simferopol, Russia

Objective: An impact on common risk factors for coronary heart disease (CHD) and osteoporosis (OP) will prevent severe complications of both diseases. The purpose of this work was to study risk factors for AP and osteoporotic fractures in male patients with coronary artery disease

Methods: The risk factors for AP and osteoporotic fractures were studied in 102 men aged 51–75 years old (median age 61 y) with coronary artery disease verified by coronary angiography. Based on the result of dual-energy absorptiometry according to the T-score of the lumbar spine and femoral neck, BMD was assessed in all patients as follows: normal BMD (T-score ≥ − 1), osteopenia (T-score from − 1 to − 2.5) and OP (T-criterion ≤ − 2.5). The FRAX calculator was used to estimate the risk of major osteoporotic and proximal femoral fractures over the next 10 y

Results: According to BMI, the patients were distributed as follows: normal BMI was noted in 21.6%, elevated—in 56.9%, obesity (BMI ≥ 30 kg/m^2)—in 21.6% of patients. No body weight deficiency (BMI < 18.5 kg/m^2) was detected in patients. Of all the patients examined, 61.7% of men smoked. Previous fractures were recorded in 21.6% of cases, and a history of a hip fracture in parents was recorded in 6.9%. According to the BMD status, the majority of patients (79.4%) had osteopenic syndrome (OPS), in the structure of which osteopenia occurred in 47.0% of patients, and AP in 32.4%. A high risk of major fractures according to FRAX was detected in 10.8%, a high risk of hip fractures in 3.9% of patients. Correlation analysis showed a significant negative correlation between BMI and the risk of hip fracture according to the FRAX scale (r = 0.23; p = 0.020)

Conclusion: The significant prevalence of APS demonstrates a high proportion of the combination of the atherosclerotic process with low BMD among men with coronary artery disease aged 51–75 y. An increased risk of hip fracture according to the FRAX score is associated with a decrease in BMI in men with coronary artery disease over 50 years of age

P625
A CASE OF MAFFUCCI SYNDROME IN A 17-YEAR-OLD FEMALE WITH MULTIPLE ENCHONDROMAS, OSTEOCHONDROMA AND CAVERNOUS HEMANGIOMAS

I.-S. Chirică[1], F.-I. Ionete[1], O. Vutcanu[1], M. Bojincă[1]

[1]"Dr. Ion Cantacuzino" Clinical Hospital, Bucharest, Romania

This case report aims to comprehensively present the clinical manifestations, diagnostic investigations, and histopathological findings of a 17-year-old female with Maffucci syndrome, a rare disorder characterized by the coexistence of multiple enchondromas, osteochondroma, and cavernous hemangiomas.

Casereport: The patient's medical history, clinical examinations, and a series of diagnostic investigations were systematically reviewed. Previous surgical interventions, radiological studies, and ultrasound evaluations were considered, along with the current admission findings. Surgical excision of formations in the right armpit was performed, and the specimens were sent for histopathological evaluation. The patient's history revealed a diagnosis of enchondromatosis at the age of 5, with subsequent surgical interventions for osteochondromas in the left femoral neck and proximal tibia. Radiological studies indicated skeletal asymmetry, dysplastic changes in the left forearm, and the presence of enchondromas. Soft tissue ultrasounds identified formations in the right axilla, prompting further investigation. Clinical examination at the current admission revealed subcutaneous formations in the right armpit, and targeted imaging studies suggested calcifications associated with a hemangioma. Surgical excision of these formations confirmed cavernous hemangiomas through histopathological evaluation, revealing dilated blood vessels with microcalcifications.
Conclusion: This case highlights the complexity of Maffucci syndrome, characterized by the coexistence of multiple enchondromas, osteochondroma, and cavernous hemangiomas. The varied clinical manifestations, diagnostic challenges, and the importance of multidisciplinary collaboration are emphasized. Surgical intervention and histopathological evaluation played a crucial role in confirming the diagnosis and providing insights into the patient's condition.

P626
BONE DENSITOMETRY BY RADIOFREQUENCY ECHOGRAPHIC MULTI-SPECTOMETRY (REMS) IN KIDNEY TRANSPLANT RECIPIENTS

J. A. Fernández[1], M. Reina[1], D. Andrade[1], A. Medina[1]

[1]Fundación Universitaria de Ciencias de la Salud (FUCS), Bogotá, Colombia

Objective: Characterize BMD in kidney transplant recipients (KTR) and determine the presence of post-renal transplant mineral bone disease (post-RTx-MBD) by REMS considering the limitations of DXA in special population.
Methods: Exploratory cross-sectional study was performed including 26 KTR in whom REMS-BMD was characterized by T-score in > 50 y; and Z-score in < 50 y. Fracture risk was measured using the REMS Fragility Score (FS). The clinical, biochemical profile and imaging (vertebral morphometry by X-ray of the thoracic or lumbar spine) were obtained and the results were recorded in a database. Data were analyzed using descriptive statistics and the nonparametric test (Mann–Whitney U test).
Results: We document a median age of 56.5 y and median time since transplantation of 81.5 months IQR (25.7–116.8). Some alteration in BMD in lumbar spine (LS), femoral neck (FN) and total hip (TH) was observed in 53.8% (n = 14) of which 34.6% (n = 9) had osteopenia and 19.2% (n = 5) osteoporosis, none with fragility fractures. In those under 50 y, they didn't have low bone mass according to the Z-score. In the osteoporotic population we found a median concentration of iPTH in 95 pg/mL IQR (55.9–171) and 25-hydroxyvitamin D levels in 22.5 ng/ml IQR (18.8–28.6). It wasn't alterations in serum level of calcium and phosphate.
Conclusion: An overall decrease in skeletal remodeling and bone turnover has been described after transplantation, with a cumulative dose of steroids directly related to slower bone turnover and mineralization. Regarding the differences between patients with normal BMD and patients with osteoporosis or osteopenia, statistical significance ($p < 0.05$) was found in diabetes mellitus ($p = 0.02$), high FS in LS ($p < 0.001$), and in TH ($p < 0.001$). REMS seems to detect a higher percentage of patients with osteoporosis although the sample size is low. Post-RTx-MBD and osteoporosis are common disorders in KTR, therefore, an effective diagnostic method helps avoid adverse outcomes such as fragility fractures. The REMS densitometry is effective in detecting patients with post-transplant osteoporosis, and FS estimates the risk of fragility fracture at 5 y.

P627
FOLLOW-UP IN TREATMENT, REFRACTURES, MORTALITY, AND DISABILITY BY A SECONDARY FRACTURE PREVENTION PROGRAM

A. Medina[1], S. Tabares[1], J. A. Fernández[1], M. A. Rueda[1], N. Camargo[1], A. L. Ely[1]

[1]Fundación Universitaria de Ciencias de la Salud (FUCS), Bogotá, Colombia

Objective: Supervise treatment and monitor falls, refractures, disability and mortality during a one-year follow-up in patients admitted to the Secondary Fracture Prevention Program of the San José Hospital in Bogotá Colombia since 2022.
Methods: A one-year telephonic follow-up study was carried out in patients with fragility fractures admitted to the Fracture Liaison Service (FLS) named Secondary Fracture Prevention Program at the Hospital San José in Bogota-Colombia between January 2022 and August 2023. Variables were analyzed at 3, 6 and 12 months after the fracture occurred according to Key Performance Indicator (KPI) established by the International Osteoporosis Foundation (IOF).
Results: A final sample of 118 patients with one year follow-up was obtained, 74.6% (n = 88) were women, and the median of age was 79 y. Regarding the fracture site: 66%, 13%, 8.4% and 7.6% were located in hip, vertebrae, radius and humerus, respectively. During the hospitalization, patients underwent laboratory tests, radiographs of the dorsolumbar spine and densitometry with REMS technology. During telephone follow-up, only 13% (n = 15) didn't respond to calls.
Conclusion: FLS are intended to prevent refracture through timely treatment and prevention of falls, but refractures follow-up are poorly studied. According to the KPIs used to assess the FLS performance, it was found that 87% (n = 103) of patients received indications to start osteoporotic management prior to hospital discharge of which 58% (n = 46) started the treatment in the first 4 months; 42% and 39% were under treatment at 6 and 12 months pos-fracture respectively. A fall was present in 2.5% and a new fracture in 1.7% of patients, 12% dead and disability was present in 45% during one-year follow up. The fracture follow-up is really difficult to carry out, because the patients treated at the hospital do not return to the controls but are directed by the health-system to other centers. This is a warning to health entities to become aware of the presence of refractures and death, which can be avoided with timely treatment for osteoporosis.

P628
CORTICAL BONE PARAMETERS DERIVED FROM PERIPHERAL QUANTITATIVE COMPUTED TOMOGRAPHY ARE LOWER IN PERIMENOPAUSAL COMPARED TO PREMENOPAUSAL WOMEN

K. L. Holloway-Kew[1], A. G. Morse[1], K. B. Anderson[1], J. W. Harland[1], M. A. Kotowicz[1], J. A. Pasco[1]

[1]Deakin Univ., Geelong, Australia

Objective: Postmenopausal BMD loss has been well described. There are fewer studies examining changes in other bone measures following the onset of menopause. This study aimed to examine differences between pre- and perimenopausal women using pQCT.

Methods: Women (n = 66) participating in the most recent follow-up phase of the Geelong Osteoporosis Study were included. Menopause data were self-reported. A pQCT instrument (XCT 2000, Stratec Medizintechnik, Pforzheim, Germany) was used to obtain standard transverse scans at 4% and 66% of radial and tibial length. BMD was measured using a GE-Prodigy densitometer. TBS iNsight software (Version 2.2) was used to obtain TBS values. Percentage differences comparing the perimenopausal (1–5 y since last menstrual period, n = 28) to the premenopausal group (n = 38) were calculated.
Results: Compared to the premenopausal group (median age 45.3 y, IQR 40.0–47.4 y), women in the perimenopausal (median age 53.5 y, IQR 50.0–57.7 y) group had lower femoral neck (− 5.8% 95% CI − 13.0%, − 0.3%), lumbar spine (− 11.0% 95% CI − 20.1%, − 4.9%) and ultra-distal forearm (− 10.9% 95% CI − 15.0%, − 2.5%) BMD, as well as TBS (− 8.5% 95% CI − 12.1%, − 1.9%). Cortical bone density was lower for the perimenopausal group compared to the premenopausal group at both the radius (4% site: − 11.0% 95% CI − 18.0%, − 5.9%; 66% site: − 2.8% 95% CI − 4.4%, − 1.5%) and tibia (4% site: − 3.6% 95% CI − 10.2%, − 1.1%; 66% site: − 2.3% 95% CI − 3.6%, − 0.3%). Total density was also lower at the radius (4% site: − 11.0% 95% CI − 17.5%, − 4.8%; 66% site: − 7.5% 95% CI − 10.7%, − 0.9%). Cortical area at the 66% tibial site (− 7.0% 95% CI − 12.0%, − 0.3%) and bone mineral content at the radial 4% site (− 10.0% 95% CI − 14.4%, − 2.2%) were also lower for perimenopausal women.
Conclusion: Differences in bone parameters, particularly reduced cortical bone, were observed between pre- and perimenopausal women.

P629
ALLOSTATIC LOAD AND TRABECULAR BONE SCORE IN MEN: DATA FROM THE GEELONG OSTEOPOROSIS STUDY

J. A. Pasco[1], K. B. Anderson[1], L. J. Williams[1], M. A. Kotowicz[1], B. Agustini[1], K. L. Holloway-Kew[1]

[1]Deakin Univ., Geelong, Australia

Objective: Allostatic load (AL) refers to 'wear and tear' on the body which accumulates following exposure to repeated or chronic stress. Research suggests that some mediators of AL also affect bone homeostasis. By utilising markers for cardiovascular, metabolic and inflammatory disturbances, we aimed to evaluate the association between AL and TBS in men.
Methods: Blood samples and anthropometry for 1007 men (median age 63 y, IQR 48–75) from the Geelong Osteoporosis Study were used to calculate the AL score whereby a value in the high-risk quartile of each of nine variables contributed one point to the overall score: resting systolic blood pressure and diastolic blood pressure, BMI, and fasting levels of serum glycosylated haemoglobin, C-reactive protein, IL-6, triglycerides, high-density lipoprotein and albumin. At follow-up, 571 men also provided TBS values at the lumbar spine (L1–4) using iNsight software (v2.2) 5 y later and were included in analyses. Linear regression models were used to evaluate the association between high AL (scores ≥ 4) and TBS, before and after adjusting for age.
Results: The proportion of men with high AL increased with age up to age-group 70–79 y: 20–29 y n = 0 (0%), 30–39 y n = 4 (6.9%), 40–49 y n = 8 (9.6%), 50–59 y n = 20 (18.4%), 60–69 y n = 20 (18.4%), 70–79 y n = 48 (41.0%) and 80 + y n = 15 (27.8%); $p < 0.001$. Mean (± SD) TBS was lower for 115/571 (20.1%) men with high AL (1.138 ± 0.143 v 1.222 ± 0.154; $p < 0.001$) which remained significant after adjusting for age (β − 0.04274, p = 0.005). Age was identified as an effect modifier; high AL was associated with low TBS for ages < 80y, with differences in TBS between those with and without high AL diminishing with advancing age.
Conclusion: High AL was associated with lower TBS at follow-up, at least in men < 80y. Further research is needed to determine if AL impacts the trajectory of deteriorating bone microarchitecture observed with fragility fractures.

P630
IMPORTANCE OF MEASURING STRENGTH AND WALKING TESTS IN ASSESSMENT IN RISK OF FALLING AND FRACTURES IN ELDERLY WOMEN

J. Aleksic[1], J. Zvekic-Svorcan[2]

[1]Railway Healthcare Institute, Belgrade, [2]Univ. of Novi Sad, Medical Faculty of Novi Sad, Special Hospital for Rheumatic Diseases, Novi Sad, Serbia

Objective: Osteoporosis is associated with falls and fractures. Due to muscle weakness, spine kyphosis, decreased postural control and low physical activity, women with osteoporosis have higher risk of falls[1]. We aimed to observe the differences in walking abilities and muscle strength among groups of fallers and non-fallers in elderly women.
Methods: In this cross-sectional study, data were collected related to the fracture. Strength and walking abilities were measured using time up and go (TUG) test. An older adult who cannot perform test within 14 s is at increased risk of falling.
Results: In this study, 440 women were included with 119 (24.8%) being over 64 years old. A far greater percentage of falls in the same level was registered among older participants (74.8 vs. 39.1%). In the group over 64 years old, 40.3% of them experienced a fracture due to minor trauma, while the percentage in the younger group is 15.5% ($\chi^2 = 36.218$; df = 1; p = 0.000). The TUG test can be performed by 81% of subjects. A statistically significant difference was found in the ability to perform the TUG test in relation to age ($\chi^2 = 72.44$; df = 1; p = 0.000). Women younger than 65 are able to perform this test in 94% of cases, while 64% of older participants. Among the women without fracture, 89.2% of them could perform this test, while in the subgroup with a fracture only 66.4% ($\chi^2 = 34.9$; df = 1; p = 0.000). Also, a smaller percentage of subjects with vertebral (35.6 vs. 64.4%), non-vertebral (16.5 vs. 83.5%) and both types of fractures at the same time (45.7 vs. 54.3%) are able to perform this test in the allotted time, in relation to test subjects who do not have these fractures ($\chi^2 = 24.6$; df = 2; p = 0.001). Subjects with a previous fracture of the forearm, upper arm and other fractures can perform this test in a fairly high percentage (76.8%, 64% and 70.9%), unlike subjects who had a hip fracture (41.9%)
Conclusion: Impaired walking abilities and muscle strength is associated with risk of fall among elderly women

P631
INFLUENCE OF AGE ON SLEEP QUALITY OF PHYSIOTHERAPISTS: PILOT STUDY

M. Stanic[1], R. Krasnik[1], A. Mikov[1], J. Aleksic[2], J. Zvekic-Svorcan[3]

[1]Univ. of Novi Sad, Faculty of Medicine Novi Sad. Institute of Child and Youth Health Care of Vojvodina, Novi Sad, [2]Railway Healthcare Institute. Dept. of Physical Medicine and Rehabilitation, Belgrade, [3]Univ. of Novi Sad, Faculty of Medicine Novi Sad. Special Hospital for Rheumatic Diseases, Novi Sad, Serbia

Objective: To assess the effect of age on the quality of sleep of physiotherapists.

Methods: Prospective cross-section study encompassed 21 physiotherapists of both sexes, working at the Clinic for Physical Medicine and Rehabilitation of the Institute for Health Care of Children and Youth of Vojvodina, Novi Sad, Serbia. The study was approved by the Ethics Committee of the Institute (part. No.: 17/14-2023) and all subjects have signed the informative consent form. Data from a sociodemographic questionnaire (created by the examiner) and data from a sleep quality assessment questionnaire (Pittsburgh Sleep Quality Index-PSQI, validated for Serbian population) were used. This questionnaire consists of two parts: 19 self-assessed questions and 5 questions assessed by a bed partner. Questions are scored from 0 = no difficulty to 3 = severe difficulty. Scores range from 0 to 21 (a higher score indicates poorer sleep quality), and a score > 5 is considered a significant sleep disorder. Statistical processing and data analysis were done using SPSS v.23 software.
Results: In this research participated 21 respondents of both sexes, with an average age of 38.43 ± 11.28 y. Average body height was 170.24 ± 9.13 cm, and body weight was 74 ± 10.51 kg. The PSQI score values on average were 5.86 ± 2.61. Pearson's correlation coefficient determined that there is a statistically significant positive correlation between age and sleep quality of physiotherapists ($r = 0.474$, $p < 0.05$). The group of older respondents (over 40 y) had worse sleep quality, compared to the younger group of respondents (up to 40 y) (6.89 ± 2.57 vs. 5.08 ± 2.47), although this difference isn't statistically significant ($t = -1.629$, $p > 0.05$).
Conclusion: Sleep difficulties are associated with an increased incidence of cognitive and psychomotor function disorders and workplace injuries, which is significant for all individuals (especially healthcare workers), and the risk of these disorders increases with age. It's necessary to conduct further research on a larger sample to assess how other factors such as body height, body weight, gender, years of work experience have an impact on the quality of sleep, in order to find out how it can be improved.

P632
PREVALENCE OF OSTEOPOROTIC FRACTURES OF THE DISTAL FOREARM IN PEOPLE OF OLDER AGE GROUP

J. Averkieva[1], M. Koroleva[1], M. Letaeva[1], O. Malyshenko[1], T. Raskina[1]

[1]Kemerovo State Medical Univ., Kemerovo, Russia

Objective: To study the prevalence of osteoporotic fractures of the distal forearm in people of the older age group.
Methods: The prevalence of osteoporotic fractures of the distal forearm was assessed by the attendance of patients aged 50 years and older to trauma centers in Kemerovo. 446 fractures were recorded. Among women, fractures of this location occurred in 89.01% of cases (397 people), among men in 10.99% of cases (49 people) ($p < 0.0001$).
Results: The frequency of fractures of the distal forearm according to appeal was 286.75/100,000 of the population aged 50 years and older for both sexes: for men—84.62/100,000, for women—406.6/100,000 of the population. The analysis showed that the highest incidence of fractures of the distal forearm in women was registered at the age of 80 years and older and amounted to 680.6/100,000 person/y, the smallest number of fractures was noted at the age of 50–54 y: 94.7/100,000 person/y. years ($p < 0.05$). In the age group of 55–59 y, a statistically significant trend towards an increase in the number of fractures was revealed: 347.3/100,000 ($p < 0.01$). It was found that in women aged 60 years and older, no statistically significant differences between age groups were obtained ($p > 0.05$). In men, the majority of fractures of the distal forearm were registered in the age groups 70–74 y, 80 y and older: 234.1/100,000 and 278.7/100,000 person/y, respectively, the smallest number of fractures occurred in the age groups 50–54 y and was 17.2/100,000 person/y ($p < 0.05$). Starting from the age of 55–59 y, there was a statistically significant increase in the number of fractures in men: 79.3/100,000 person/y ($p < 0.05$).
Conclusion: It was found that in women the incidence of fractures of the distal forearm was statistically significantly higher than in men. The highest incidence of fractures was recorded at the age of 80 y and older in people of both sexes.

P633
X-LINKED HYPOPHOSPHATEMIA'S BURDEN OF MUSCULOSKELETAL ISSUES: A CROSS-SECTIONAL STUDY

H. Parente[1], T. Gill[2], M. Dudley[2], R. Keen[2], J. Bubbear[2]

[1]Rheumatology Dept., Unidade Local de Saúde do Alto Minho, Ponte de Lima, Portugal, [2]Metabolic Bone Disease Unit, Royal National Orthopedic hospital, London, UK

Objective: X-linked hypophosphatemia (XLH) is a rare condition presenting in childhood through rickets, bone deformities and dental issues. It progresses to adulthood, compounding many musculoskeletal complications. We aimed to investigate the burden of musculoskeletal features and orthopedic surgeries, in an XLH cohort at the Metabolic Bone Diseases of the Royal National Orthopedic Hospital.
Methods: Cross-sectional study among adult XLH patients (diagnosed through clinical and biochemical tests, or PHEX mutation). Data was retrospectively collected from electronic clinical records: age, sex, symptomatic osteoarthritis, enthesopathy, fractures, tertiary hyperparathyroidism, number and type of orthopedic procedures, and XLH medications. SPSS Statistics v29 was used for a descriptive analysis.
Results: Our sample had 52 patients (16 males), with a mean current age of 47.6 ($\pm$ 15.7) years old. All patients had at least one surgery or musculoskeletal diagnosis related to XLH; 76.9% of patients had at least 2 musculoskeletal complications. Soft tissue conditions were observed in 38.4%, most commonly rotator cuff tendinopathy/calcifications/bursitis and spine calcifications; enthesopathy was reported in 15.4%, most frequently at the trochanteric site; symptomatic osteoarthritis was present in 53.9%, mostly in the lower limbs. 51.9% of patients had at least one fracture, with a total of 66 fractures reported. Tertiary hyperparathyroidism was identified in 9.6%, implicating parathyroid surgery in 4 cases. 86.5% underwent at least one arthroscopy or surgery, compounding a total of 157 orthopedic surgeries, mostly femoral and tibial osteotomies. Steroid injections were used in 17.3%.
Conclusion: Soft tissue disorders, enthesopathies, osteoarthritis, and fractures manifest at a higher rate and progress more rapidly than in the general population, demanding earlier and more frequent need for orthopedic surgeries.

P634
EFFICACY OF HIGH INTENSITY LASER THERAPY VERSUS SHAM LASER IN SYMPTOMATIC KNEE OSTEOARTHRITIS: A DOUBLE-BLIND RANDOMIZED CONTROLLED TRIAL

J. Champaiboon[1], C. Laotammateep[2], T. Surarangsit[2], W. Likhitpithak[2], J. Boonhong[1]

[1]Dept. of Rehabilitation Medicine, Faculty of Medicine, Chulalongkorn Univ., [2]Dept. of Rehabilitation Medicine, King Chulalongkorn Memorial Hospital, Bangkok, Thailand

Objective: Osteoarthritis (OA) of the knee is a prevalent musculoskeletal condition associated with pain and functional impairment.

High intensity laser therapy (HILT) has been proposed as a potential intervention to alleviate symptoms in OA patients. This study aims to investigate the efficacy of a specific HILT protocol in reducing pain and improving function in individuals with mild to moderate symptomatic OA knee.

Methods: This study was a randomized, double-blinded controlled trial including 40 patients with mild to moderate symptomatic OA knee. The HILP group (n = 20) underwent HILT twice weekly for three weeks. The initial two sessions utilized the analgesic mode, administering a total energy of 600 J at the medial and lateral joint lines, followed by the subsequent 4 sessions using the biostimulation mode at the medial joint line with a total energy of 3000 J. The sham group (n = 20) received an identical protocol of sham laser therapy sessions. Both groups participated in a supervised home exercise program. Pain levels were assessed using the visual analog scale (VAS), and functional outcomes were measured using WOMAC and the timed up and go test (TUG). Evaluations were conducted before treatment and at 3 and 6 weeks after the initial treatment.

Results: Both groups demonstrated significant improvements in VAS and WOMAC. However, there were no significant differences in any of the measured outcomes between the two groups. Additionally, neither the HILT group nor the sham group demonstrated significant improvement in TUG.

Conclusion: Within the context of treating mild to moderate OA knee, the incorporation of a regimen involving twice weekly sessions of HILT—encompassing 2 sessions of analgesic and 4 sessions of biostimulation mode—alongside an exercise program did not demonstrate superior efficacy when compared to exercise alone.

P635
PRIOR ANTICOAGULATION IS NOT ASSOCIATED WITH WORSE OUTCOMES IN PATIENTS UNDERGOING SURGICAL MANAGEMENT OF HIP FRACTURES

A. M. López[1], J. D. Bernate[2], J. Rojas Lievano[2], C. M. Olarte[2], R. Pesantez[2], A. Patiño[1], V. Sanint[1], J. Salavarrieta[2], D. Morales[1]

[1]Geriatrics, [2]Orthopaedics, Hospital Universitario Fundación Santa Fe de Bogotá, Bogotá, Colombia

Objective: To evaluate the influence of preoperative anticoagulant therapy on postoperative outcomes, specifically transfusion requirement, ICU admission, and mortality rates in elderly patients undergoing hip fracture surgery.

Methods: A retrospective cohort of 638 hip fracture patients at our Orthogeriatric Clinical Care Center was analyzed. We used multivariate logistic regressions controlled for age, sex, BMI, Charlson Comorbidity Index, Barthel Index, and preoperative hemoglobin levels to assess the outcomes associated with preoperative anticoagulant use.

Results: Preoperative anticoagulation was not a significant predictor of postoperative transfusion, ICU admission, 30-d, or 1-y mortality (OR = 1.07, p = 0.758). The average time to surgery for patients who were not previously anticoagulated was 27.4 h vs. 42.5 h in the previously anticoagulated. The models accounted for a comprehensive set of clinical and demographic factors, ensuring robust adjustment for potential confounders.

Conclusion: The results demonstrate that despite the use of anticoagulant therapy prior to surgery in elderly patients treated for hip fractures, there was no increase in the risk of adverse postoperative outcomes and these demonstrate that in the clinical practice of preoperative anticoagulant management in this patient population it is possible to undergo timely surgery within the first 48 h after admission.

P636
DEPENDENCE OF FRAILTY ON NUMBER OF FALLS AND GAIT SPEED AMONG ELDERLY

J. Danilova[1], V. Ginevičienė[1], J. Kilaitė[1], R. Dadelienė[1], I. E. Jamontaitė[1], A. Mastavičiūtė[1], E. Pranckevičienė[1], I. I. Ahmetov[1], V. Alekna[1]

[1]Vilnius Univ., Vilnius, Lithuania

Objective: The highest frequency of falls among elderly is observed among those who are less active and have a slow walking speed. Walking speed is a reliable and sensitive measure of functional abilities, closely associated with the well-being, healthy aging, frailty, and mortality of older adults. Therefore, the aim of the study was to determine the dependency between falls and walking speed in relation to the frailty among elderly.

Methods: The study included 55 community dwelling older adults (mean age 77.98 ± 7.62 y): 12 (21.42%) men and 43 (78.58%) women. Measures included self-reported history of falls during one-year period, sociodemographic characteristics. Frailty was defined according to five Fried's criteria: weakness, low gait speed, low physical activity, weight loss, and exhaustion. Participants were categorized as robust, pre-frail, and frail if they scored 0, 1–2, and 3 points, respectively.

Results: According to frailty status 13 (23.6%) participants were evaluated as being robust, 25 (45.5%) having pre-frailty and 17 (30.9%) were frail. Falls were reported in 34 (61.8%) participants. Frailty and falls were found in 16 (29.1%) participants: 5 (31.25%) men and 11 (68.75%) women. Low gait speed were reported in 35 (63.6%) participants, frailty and low gait speed were found in 17 (30.9%) participants 5 (29.4%) men and 12 (70.6%) women. Among elderly individuals, the median of walking speed is 0.625 m/s, the results significantly ($p < 0.001$) differ from the median norms of older adults living in the community, as assessed by the Irish longitudinal study on aging (TILDA) to be 1.17–1.27 m/s. Correlation analysis showed a significant negative relationship between frailty and gait speed (m/s) ($r = -0.541$; $p < 0.001$) and significant positive correlation between frailty and falls ($r = 0.58$; $p < 0.001$). Logistic regression revealed that an increased risk of frailty was associated with falls and increased gait speed (OR: 1.21 (38.36–0.04) and OR: 0.24 (7.49–0.01)).

Conclusion: Our study showed that frailty depends on the number of falls experienced per year and the average walking speed.

P637
SHORT VERSUS LONG-TERM PREDICTION MODELS IN THE SELECTION FOR TREATMENT OF PATIENTS AT HIGH RISK OF FRACTURE: DATA FROM THE BELGIAN FRISBEE COHORT

J. De Filette[1], L. Iconaru[1], A. Charles[2], A. Bellanger[2], F. Baleanu[1], M. Moreau[3], M. Surquin[4], F. Benoit[4], J. J. Body[1], P. Bergmann[5]

[1]Dept. of Endocrinology, CHU Brugmann, Université Libre de Bruxelles, [2]Laboratoire de Recherche Translationnelle, CHU Brugmann, Université Libre de Bruxelles, [3]Data Centre, Inst. J. Bordet, Université Libre de Bruxelles, [4]Dept. of Internal Medicine, CHU Brugmann, Université Libre de Bruxelles, [5]Dept. of Nuclear Medicine, CHU Brugmann, Université Libre de Bruxelles, Brussels, Belgium

Objective: To analyze how patients with a recent fracture would be selected for pharmacological treatment using long-term (FRAX®

uncorrected or corrected for recency) vs. short-term prediction models (FRISBEE imminent model for MOFs).
Methods: We identified subjects in the FRISBEE cohort who sustained an incident MOF after inclusion (mean age 76.5 ± 6.8 y). We calculated their estimated 10-y fracture risk with FRAX before and after adjustment for recency and the 2-y fracture risk with the FRISBEE MOFs model.
Results: After 6.8 y of follow-up, we validated 480 incident and 54 imminent MOFs. 94.0% of the subjects who had an imminent fracture had a fracture risk estimated > 20% by FRAX before correction for recency and 98.1% after adjustment, with a specificity of 20.2% and 5.9%, respectively. The sensitivity and specificity of the FRISBEE imminent model were 72.2% and 55.4%, respectively, for a threshold of 10%. For these thresholds, 47.3% of patients were identified as high risk in both models before correction and 17.2% of them had an imminent MOF. The adjustment for recency did not change this selection. Before the correction, 34.2% of patients were selected for treatment by FRAX only and 18.8% would have had an imminent MOF. This percentage increased to 47% after the adjustment for recency, but only 6% of these would suffer a MOF within 2 y.
Conclusion: In the FRISBEE cohort, the imminent model was less sensitive but more selective in the selection of subjects in whom an imminent fracture should be prevented, resulting in a lower NNT, which could lower treatment costs. Correction for recency in this elderly population further decreased the selectivity of FRAX. Our result demonstrate the benefits of using the prediction model for imminent fractures in the selection of subjects at very high fracture risk, who are most in need of immediate treatment with high potency and rapid effect on fracture risk reduction, but are more expensive and require rigorous patient selection.

P638
CORRECTION FOR RECENCY OF 5-YEAR FRACTURE RISK ESTIMATED BY FRAX® IN THE FRISBEE COHORT

J. De Filette[1], L. Iconaru[1], A. Charles[2], A. Bellanger[2], F. Baleanu[1], M. Moreau[3], M. Surquin[4], F. Benoit[4], J. J. Body[1], P. Bergmann[5]

[1]Dept. of Endocrinology, CHU Brugmann, Université Libre de Bruxelles, [2]Laboratoire de Recherche Translationnelle, CHU Brugmann, Université Libre de Bruxelles, [3]Data Centre, Inst. J. Bordet, Université Libre de Bruxelles, [4]Dept. of Internal Medicine, CHU Brugmann, Université Libre de Bruxelles, [5]Dept. of Nuclear Medicine, CHU Brugmann, Université Libre de Bruxelles, Brussels, Belgium

Objective: Prediction models, especially FRAX, are widely used to estimate fracture risk at 10 y, but the current algorithm does not account yet for time elapsed after a fracture. Kanis et al. recently proposed correction factors to adjust the FRAX score for fracture recency. The objective of this work was to analyze the effect of fracture recency in the FRISBEE cohort and to compare to FRAX estimations.
Methods: We identified subjects in the FRISBEE cohort who sustained a validated fracture during the first 5 y after an incident MOF. We calculated their estimated 5-y fracture risk with FRAX, either uncorrected or corrected for recency and further adjusted for the MOF/hip ratios calibration factors previously derived for the Belgian FRAX. We compared the fracture risk estimated by FRAX before and after these corrections with the observed incidence of validated fractures in our cohort.
Results: In our cohort, 376 subjects had a first non-traumatic incident validated MOF after inclusion; 81 of them had a secondary fracture during the 5-y period after this index fracture. The FRAX score significantly under-evaluated the observed incidence of fractures in our cohort by 54.7% (fracture rate of 9.7%; 95% CI 6.8–12.9%) if uncorrected ($p < 0.001$) and by 32.6% after correction for recency (14.5%; 95% CI 11.1–18.2%) ($p = 0.01$). Calibration for MOF/hip ratios also improved the prediction (17.5%; 95% CI 13.7–21.4%) ($p = 0.2$). However, after adjustment for recency and calibration, the predicted value was over-estimated by 22% (fracture rate of 26.1%; 95% CI 21.6–30.5%) but this over-estimation was not significant ($p = 0.1$).
Conclusion: Our data indicate that the correction of the FRAX score for fracture recency improves fracture prediction. However, correction for recency and calibration for MOF/hip ratios tends to overestimate fracture risk in our population of elderly women.

P639
ONE-YEAR MORTALITY RATE AFTER PROXIMAL FEMUR FRACTURE IN A BRAZILIAN QUATERNARY UNIVERSITY HOSPITAL INSTITUTE

J. Dias[1], F. F. Sanches[1], K. A. A. Medeiros[1], M. M. Arouca[1], K. E. Kojima[1], M. C. Leonhardt[1], J. S. Silva[1], O. P. Camargo[1], M. U. Rezende[1]

[1]Departamento de Ortopedia e Traumatologia do Hospital das Clínicas da Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil

Objective: To document mortality in the first year of patients hospitalized at IOT/HCFMUSP, due to osteoporotic fracture of the proximal femur and evaluate whether personal characteristics influence this mortality.
Methods: Retrospective observational study, with patients admitted to the IOT due to osteoporotic proximal femur fracture, between 07/01/2020 and 06/30/2021, correlating with personal data of age, gender, laterality, previous diagnosis of osteoporosis, type of proximal femur fracture, American Society of Anesthesiology (ASA) score and Charlson Comorbidity Index (CCI).
Results: Of the 156 hospitalized patients, 64 (43%) had mortality within 1 y. Age, ASA score and CCI influenced patients' mortality in the first year ($p < 0.05$), however, after adjusting the variables, only the ASA score and CCI influenced the patients' outcome independently of the other characteristics ($p = 0.024$ and $p = 0.002$ respectively). For every 1° increase in the ASA score, there is a 139% increase in the chance of mortality in the 1st year. Mortality with ASA III score was 52.1% and ASA IV was 100%. For every 1-point increase in the CCI there is a 36% increase in the chance of mortality in the 1st year. The area under the ROC curve was 0.749. The average CCI for patients who survived was 4.5 ± 2.2 and of those who died in the first year was 6.6 ± 2.3. The best CCI cutoff point of 5.5 was established to discriminate mortality within 1 year, with sensitivity of 65.6% and specificity of 72.9%.
Conclusion: The mortality of patients with osteoporotic proximal femoral fractures at this quaternary institute was higher than that described in the literature (43%), with the ASA score and CCI influencing mortality. Mortality at ASA IV score was 100%. There is a greater probability of death in the first year in patients with CCI ≥ 6.

P640
GENICULAR NERVES ABLATION BOTH BY PULSATED RADIOFREQUENCY AND PHENOL IMPROVE SEVERE KNEE OSTEOARTHRITIS SYMPTOMS AND FUNCTION AT ONE-YEAR

J. Dias[1], M. Freitas[1], M. M. Arouca[1], G. P. Ocampos[1], M. U. Rezende[1], O. P. Camargo[1]

[1]Departamento de Ortopedia e Traumatologia do Hospital das Clínicas da Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil

Objective: To document the effects of genicular nerves ablation in patients with severe knee osteoarthritis (KOA).
Methods: Prospective, randomized, controlled trial comparing 35 patients with grade IV Kelgren & Lawrence (Alhback grade III and IV) submitted to ablation of genicular nerves with pulsed radiofrequency (RF) or phenol. Clinical outcomes were evaluated at baseline, 1, 3, 6 and 12 months VAS and KOOS, 30 s sit to stand test (30STS) and timed up and go (TUG).
Results: Groups were similar at inclusion (Table 1). Both groups improved similarly in all moments up to a year ($p < 0.001$, Table 2). VAS decreased on average 30% from baseline to all subsequent evaluations ($p < 0.05$). TUG decreased only between baseline and one month post-procedure ($p = 0.001$) and 30STS increased on average from baseline to one, three and 12 months ($p < 0.05$).

Table 1 – Baseline characteristics and evaluations.

THE EFFECT OF ROMOSOZUMAB ON BONE MINERAL DENSITY DEPENDING ON PRIOR TREATMENT: A PROSPECTIVE, MULTICENTRE COHORT STUDY IN SWITZERLAND

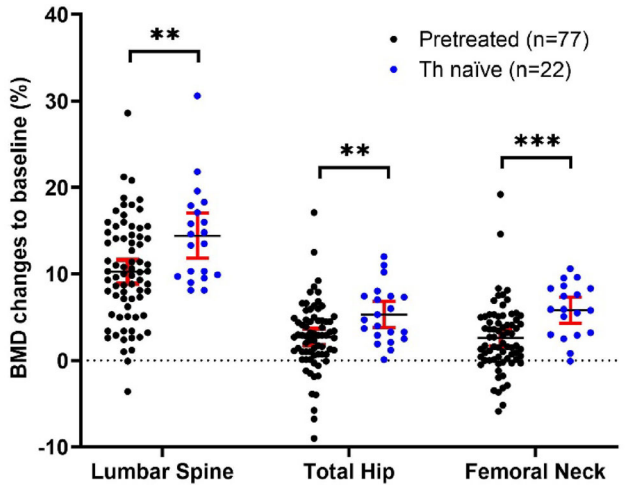
J. Everts-Graber[1], M. Wenger[2], S. Oser[2], U. Studer[3], C. Steiner[3], R. Ziswiler[3], K. Sromek[4], G. Schmid[4], B. Gahl[5], S. Reichenbach[1], T. Lehmann[3]

[1]Univ. Hospital of Bern, Dept. of Rheumatology and Immunology, Bern, [2]Zentrum für Rheuma- und Knochenerkrankungen, Klinik Im Park, Hirslanden Zürich, Zürich, [3]OsteoRheuma Bern, Bern, [4]Dept. of Rheumatology, Lucerne Regional Hospital, Lucerne, [5]Surgical Outcome Research Center, Dept. of Clinical Research, Univ. Hospital Basel and Univ. of Basel, Basel, Switzerland

Objective: In Switzerland, romosozumab is administered to high-risk osteoporosis patients. Our study aimed to assess the effect of romosozumab on BMD, considering prior therapies.
Methods: This multicentre, prospective cohort study measured the effect of romosozumab for 12 months in patients in a nationwide

Swiss osteoporosis registry. BMD and bone turnover marker (P1NP and CTX) changes were measured and compared between patients with prior antiresorptive therapy vs. treatment-naïve patients.

Results: 99 patients (92 women and 7 men, median age 71 y [65, 76]) were enrolled from January 2021 to December 2023. Among them, 22 had no prior treatment before romosozumab, while 77 had previous therapy (including 23 with a history of prior teriparatide therapy), accumulating 6 y [4, 11] of cumulative antiresorptive treatment. Over 12 months, romosozumab led to BMD changes of 10.3% [7.5, 15.5] at the lumbar spine, 3.1% [1.1, 5.8] at the total hip, and 3.1% [0.5, 5.4] at the femoral neck, exhibiting notable variability. Significantly lower BMD responses were observed in pre-treated patients, with the duration of prior antiresorptive therapy inversely associated with BMD increases at the lumbar spine and hip. Other predictors of BMD changes at the total hip included baseline lumbar spine and total hip T-scores, BMI and baseline CTX level, while the BMD response at the lumbar spine was associated with age, baseline lumbar spine T-score and baseline CTX level, but not P1NP levels.



Conclusion: Prior antiresorptive therapy blunted the BMD response to romosozumab, with the duration correlating with changes at both the lumbar spine and total hip.

P642
FRACTURE DISTRIBUTION IN PATIENTS WITH OR WITHOUT RHEUMATOID ARTHRITIS OR USE OF GLUCOCORTICOIDS: ANY INDICATIONS OF METHOTREXATE OSTEOPATHY?

E. Bührer[1], A. Popp[2], U. Studer[3], R. Ziswiler[3], C. Steiner[3], G. Schmid[4], S. Reichenbach[1], T. Lehmann[3], J. Everts-Graber[1]

[1]Univ. Hospital of Bern, Dept. of Rheumatology and Immunology, Bern, [2]Inselspital Univ. Hospital Bern, Dept. of Diabetes, Endocrinology, Nutritional Medicine and Metabolism, Bern, [3]OsteoRheuma Bern, Bern, Switzerland, [4]Dept. of Rheumatology, Lucerne Regional Hospital, Lucerne, Switzerland

Objective: Case series have suggested a potential association between the use of low-dose methotrexate and an elevated risk of stress fractures in the lower leg and foot. This study aimed to analyse the distribution and frequency of fractures in individuals with a potential history of methotrexate use in comparison to those without such history.

Methods: The distribution and frequency of non-vertebral fractures were investigated in patients with a documented history of rheumatoid arthritis and/or the use of glucocorticoids, encompassing those undergoing low-dose methotrexate therapy. This analysis was conducted using data from a nationwide osteoporosis registry of rheumatologists in Switzerland.

Results: Out of the 23,802 registered patients enrolled between January 2015 and December 2023, 2117 were identified with a history of rheumatoid arthritis and/or glucocorticoid use. Within this cohort, 812 non-vertebral fractures were documented, with 224 (28%) involving the lower leg or foot (tibia, fibula, ankle, calcaneus, tarsus, or metatarsalia). In comparison, the total osteoporosis population documented 2958 lower leg or foot fractures (27%), with no statistically significant difference observed (p = 0.97). The incidence of multiple lower leg and foot fractures did not significantly differ between patients with rheumatoid arthritis/use of glucocorticoids (n = 76, 34%) and the entire osteoporosis population in the registry (n = 954, 32%, p = 0.60).

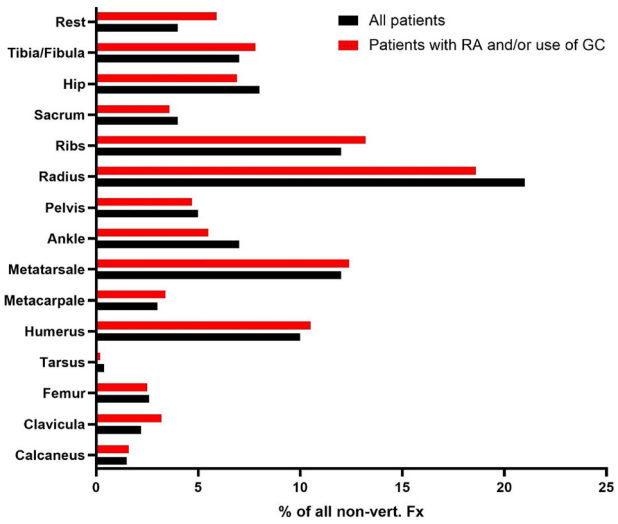


Figure 1. Percentage of non-vertebral fractures in patients with RA and/or use of glucocorticoids (GC) (red, n=2'117) vs. all patients in the osteoporosis registry (black, n=23'802).

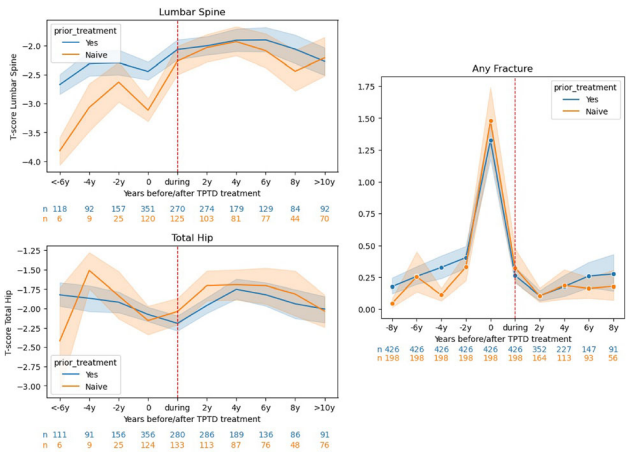
Conclusion: Single and multiple stress fractures of the lower leg and foot were observed in equal proportions in patients, regardless of whether they were using methotrexate or not. These findings suggest that there is no specific association between the occurrence of these fractures and the use of methotrexate.

P643
LONG-TERM IMPACT OF TERIPARATIDE ON BONE MINERAL DENSITY, TRABECULAR BONE SCORE AND FRACTURE INCIDENCE OVER A DECADE: INSIGHTS FROM A REGISTRY-BASED COHORT STUDY

J. Everts-Graber[1], O. Lehmann[2], M. Wenger[3], S. Oser[3], L. Guyer[4], U. Studer[5], C. Steiner[5], R. Ziswiler[5], G. Schmid[6], S. Reichenbach[1], T. Lehmann[5]

[1]Univ. Hospital of Bern, Dept. of Rheumatology and Immunology, Bern, [2]ETH Zürich, Dept. of Information Technology and Electrical Engineering, Zürich, [3]Zentrum für Rheuma- und Knochenerkrankungen, Klinik Im Park, Hirslanden Zürich, Zürich, [4]Faculty of Medicine, Univ. of Bern, Bern, [5]OsteoRheuma Bern, Bern, [6]Dept. of Rheumatology, Lucerne Regional Hospital, Lucerne, Switzerland

Objective: The fracture reduction efficacy of teriparatide followed by subsequent antiresorptive therapy has been observed for up to 2 y. However, the critical question remains whether the sequential administration of anabolic agents followed by antiresorptives can lead to a sustained increase in BMD and TBS levels, ultimately resulting in a consistently low fracture risk.
Methods: In this multicentre cohort study, the effect of teriparatide administration for 18–24 months, followed by antiresorptive therapy, was assessed among patients enrolled in a nationwide Swiss osteoporosis registry. BMD and TBS measurements, along with fracture incidence, were documented up to 10 y before the initiation of teriparatide and up to 10 y after. Subgroup analysis was conducted to compare outcomes between patients receiving first-line and second-line teriparatide.
Results: A total of 624 patients (87% female, age 67 ± 13 years) were enrolled from May 2004 to December 2023. Among them, 198 (32%) had no prior treatment before teriparatide, while 426 had received previous antiresorptive therapies (mean duration of 5.9 y [2.2, 8.0]). All patients underwent subsequent antiresorptive therapy, mainly bisphosphonates and denosumab. The incidence of vertebral, hip, and any fractures was 0.96, 0.11, and 1.37, respectively, 2 y or less before teriparatide initiation, and these rates rapidly declined during the treatment period. After transitioning from teriparatide to antiresorptive regimens, fracture incidences remained low and never returned to pre-teriparatide levels. Consequently, BMD was significantly higher up to 5 y after teriparatide compared to the pre-treatment period (T-score + 0.876 for lumbar spine, $p < 0.001$, and + 0.112 for total hip, $p < 0.005$), and TBS increased by 0.047 ($p < 0.001$). Overall, significant improvement was observed in patients who received teriparatide as either a first-line or second-line treatment.



Conclusion: Teriparatide, whether used as a first-line or second-line therapy, resulted in sustained lower incidences of vertebral, hip, and any fractures up to 10 y after transitioning to antiresorptive agents. Additionally, BMD and TBS levels were significantly higher than those observed before teriparatide treatment.

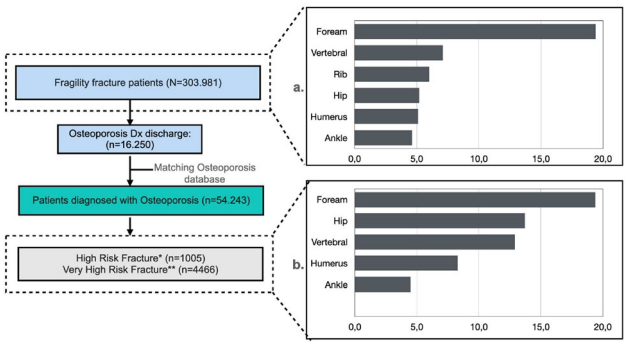
P644
OSTEOPOROSIS CARE GAPS IN COLOMBIA: HIGH RISK AND REFRACTURE RATES

J. F. Betancur[1], L. E. Perez[1], J. E. Bolaños[1], V. Bernal[1]

[1]Unidad de Investigacion SURA, Medellin, Colombia

Objective: To examine the prevalence of osteoporosis and refracture rates as imminent risks among high- and very high-risk patients in Colombia, highlighting the inadequacies in current healthcare management.

Methods: This nationwide retrospective cohort study analyzed medical records of individuals over 50 who sustained fragility fractures between 2003–2022. Clinical and demographic characteristics at the time of the initial fracture were analyzed, as well as the subsequent imminent risk (refracture rate) and the diagnosis and treatment gap.
Results: Over nearly two decades, 303,982 fragility fractures have occurred, and only 5.3% of patients were diagnosed with osteoporosis upon discharge. The most prevalent index fractures were forearm, vertebral, rib, and hip. Only 17.8% of the cohort had a matched osteoporosis diagnosis, indicating a low healthcare capture (Figure). Among the diagnosed patients, 10.08% were classified as high- and very high-risk of fracture, predominantly women with a mean age of 73 y. Comorbidities included diabetes, Sjögren's syndrome, and heart failure. The prevalence of osteoporosis has increased significantly from 2004 to 2022, possibly due to improved detection methods, an aging population, or a combination of both. Despite this increase, treatment delay was evident. Refractures affected 70.5% of the patients, with forearm, hip, humerus, and vertebral fractures being the most common, with a mean time of refracture of 7 months.



Conclusion: This study underscores significant gaps in the timely management of osteoporosis in Colombia, with most fragility fracture patients needing more prompt diagnosis and treatment. These findings suggest an urgent need for improved healthcare protocols and national policies to enhance osteoporosis care and reduce the incidence of subsequent fractures.

P645 Characterization of the role of IL-6 and IL-8 in osteoblasts with normal or low bone density in vitro

J. F. Bousch[1], C. Beyersdorf[1], K. Schultz[1], J. Windolf[1], C. V. Suschek[1], U. Maus[1]

[1]Univ. Hospital of Düsseldorf, Düsseldorf, Germany

Objective: In this study, we characterized the role of the proinflammatory cytokines IL-6 and IL-8 by evaluating their impact on the osteogenic differentiation potential of osteoblasts from patients with normal bone density and osteoporosis and by analyzing the expression patterns of IL-6 and IL-8 during differentiation in vitro.
Methods: Primary osteoblasts were isolated from the femoral heads of patients undergoing hip arthroplasty due to osteoarthritis and fracture. Based on DXA, the cells were classified as normal bone density (OB; $T > -1.0$) or osteoporotic (oOB; $T < -2.5$). In cell culture, the cells were differentiated in osteogenesis induction medium (OIM) for 35 days and in the presence and absence of IL-6 and IL-8 for 21 d. Protein expression was analyzed by ELISA and mineralization was quantified by alizarin red S staining.
Results: For IL-8, we observed a lower secretion in oOB than in OB. The secretion started at day 14 of differentiation and reached its maximum at day 35 in OB (1947 pg/ml) and at day 28 in oOB (1360 pg/ml). IL-6 was already secreted in undifferentiated cells with no

difference between OB and oOB. Interestingly, however, both cytokines had a more increasing effect on mineralization in oOB with an even significant difference in response to IL-6 compared to OB. Observing the mineralization over time, the process was similar for oOB and OB over 28 d of differentiation, but significantly decreased for oOB at day 35.

Conclusion: Since in vivo IL-8 correlates with low bone density, the lower IL-8 secretion in oOB shown in this study may be an adaptive response to the inflammatory milieu in osteoporotic patients. However, the increased mineralization in response to IL-8 and IL-6, which was even greater in oOB than in OB, may be a compensatory response. Further work should address the effect of inflammation on the activity of primary human osteoclasts and their interaction with osteoblasts.

P646
2-YEAR OUTCOMES OF A FRACTURE LIAISON SERVICE: ASSESSMENT OF MORTALITY, REFRACTURE RATE AND READMISSION RATE

D. Augusto[1], S. P. Dinis[1], F. Cunha-Santos[1], A. S. Pinto[1], N. Madeira[1], L. Matos[1], I. Campos[1], P. Rocha[1], G. Monteiro[1], I. Neves[1], C. Pontinha[1], A. R. Batista[1], S. Venâncio[1], G. Cunha[1], S. C. Anunciação[1], E. Pires Alves[1], C. Vaz[1], J. F. Ferreira[1]

[1]Serviço de Reumatologia da Unidade Local de Saúde da Guarda, Guarda, Portugal

Objective: To assess the 2-y refracture, readmission and mortality outcomes and prevalence of treatment modalities of patients followed in our Fracture Liaison Service (FLS) after a fragility hip fracture (FHF).

Methods: We registered sociodemographic, types of FHF, treatment type, refractures, readmissions and deaths data that happened until the 2-y follow up mark. Descriptive and comparative analysis was made using the means, T-tests, chi-square and Mann-Whitney U tests. Logistic regression was performed to assess predictors of refracture.

Results: Of the 147 patients referred, 126 went to the first appointment, of which 84.1% were female. The mean age was 77.27 $\pm$ 8.6 y. 46.8%, 34.9% and 5.6% of the patients had respectively femoral neck, intertrochanteric and subtrochanteric fracture. 12.7% of fractures were atypical. Regarding treatment type, 69.9%, 26.0% and 1.6% of patients were treated with denosumab, a bisphosphonate or teriparatide, respectively. 2.4% were not medicated. 2.4% of patients died (n = 3), 5.6% were readmitted to a hospital ward (n = 7) and 11.9% of patients had a refracture (n = 15). Patients with previous fragility fractures (PFF) had more refractures than the group without previous fractures (p = 0.047). When testing in logistic regression, PFF were predictors of refractures: p = 0.044; R^2 = 0.033. Odds ratio for PFF was 3.125 (95% CI 1.033–9.452). No differences were found in refracture rate between treatment modalities (p = 0.244).

Conclusion: Our population had a 2.4% mortality rate, performing better than the mortality seen overall. Patients with PFF were 3.125 times more likely to have a refracture. This work shows previous fragility fractures may be a predictor of refracture in patients with FHF, hence the importance of preventing them from happening in the first place. All treatments appeared similar in refracture risk.

P647
MAPPING TREATMENT PATHS: A DECISION TREE ANALYSIS OF FACTORS INFLUENCING OSTEOPOROSIS TREATMENT PRESCRIPTIONS

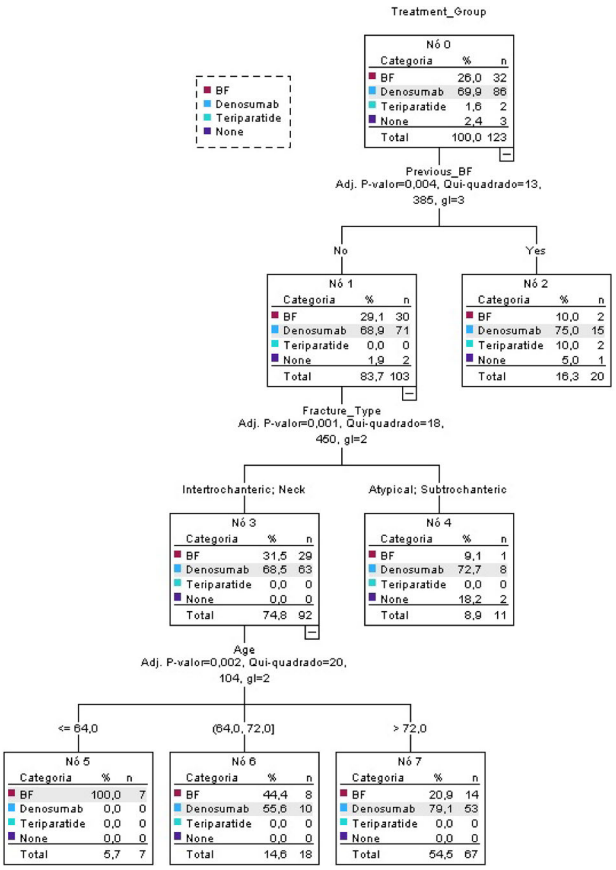
D. Augusto[1], S. P. Dinis[1], F. Cunha-Santos[1], A. S. Pinto[1], N. Madeira[1], L. Matos[1], I. Campos[1], P. Rocha[1], G. Monteiro[1], I. Neves[1], C. Pontinha[1], A. R. Batista[1], S. Venâncio[1], G. Cunha[1], S. C. Anunciação[1], E. Pires Alves[1], C. Vaz[1], J. F. Ferreira[1]

[1]Serviço de Reumatologia da Unidade Local de Saúde da Guarda, Guarda, Portugal

Objective: To analyze determinants impacting osteoporosis treatment decisions in patients from our Fracture Liaison Service (FLS) following fragility hip fractures (FHF).

Methods: Retrospective analysis using the decision tree algorithm in SPSS®, examining sociodemographic and clinical data.

Results: 69.9%, 26.0% and 1.6% of patients were treated with denosumab (Dmab), a bisphosphonate (BF) and teriparatide (TPTD), respectively. 2.4% were not medicated. The first major split was determined by the presence or absence of prior BF treatment. Patients were further stratified based on the type of fracture and age categories, forming the decision hierarchy of the decision tree. For patients without prior BF treatment (83.7% of the cohort), Dmab (68.9%) and BF (29.1%) prescription was common and TPTD was never used. In those with prior BF treatment, Dmab (75.0%) prescription was followed by TPTD (10.0%), with a frank reduction in the prescription of BF (10.0%). In the subgroup without prior BF treatment, patients with intertrochanteric and femur neck fractures, 68.5% were treated with Dmab and 31.5% with BF. Further stratification by age within this subgroup showed that among those aged < 64, 100% received BF. In the 64–72 age group 55.6% received Dmab and 44.4% received BF. In the > 72 age group, the majority (79.1%) were treated with Dmab. For atypical and subtrochanteric fractures within the no previous BF treatment subgroup, Dmab was the prevalent choice (72.7%), while a smaller proportion received BF (9.1%). 18.2% of these patients in this subgroup were not treated with any osteoporosis treatment.



Conclusion: Dmab prescription followed international guidelines, favored in older patients with higher risk of fracture. Younger patients universally received BF. A conservative approach was observed for some atypical fractures.

P648
OBSTACLES IN COMMENCING OSTEOPOROSIS TREATMENT AMONG FRAGILITY FRACTURE PATIENTS AT A TERTIARY HOSPITAL IN MALAYSIA

J. F. Leong[1], N. A. Shohor[1], S. Jeyakumar[1], S. A. Mokhtar[1]

[1]Fracture Liaison Service, Orthopaedic and Traumatology Dept., Hospital Canselor Tuanku Muhriz, Kuala Lumpur, Malaysia

Objective: Osteoporosis is a skeletal disease that severely affects the mechanical properties of bones. It increases the porosity of cancellous bone and reduces the resistance to fractures. Osteoporotic fracture remains a significant health and economic burden in Malaysia. Several treatments for osteoporosis, including bisphosphonates (alendronate, ibandronate, risedronate, and zoledronic acid) and non-bisphosphonates (denosumab, raloxifene, teriparatide, and romosozumab), have been approved in Malaysia. Despite the availability of multiple treatment options, the clinical management of osteoporosis has remained challenging throughout the years.
Methods: This is a prospective study throughout the year 2022. Patients > 55 years old with fragility fractures were identified and reviewed in a university teaching hospital by Fracture Liaison Service (FLS) coordinators. A total of 282 osteoporotic patients with fragility fractures were identified. The patients were counselled about anti-osteoporotic medications.
Results: Among the 282 patients, 76% were keen on anti-osteoporotic medications after being counselled by FLS coordinators. A total of 67 (24%) patients with fragility fractures did not initiate anti-osteoporosis medication. The primary reasons for not initiating osteoporosis medication were financial issues (59%), patient's decisions (29%), physician's decisions (8%), concern of side effects (2%), and those with too many medications (2%).
Conclusion: Among those who are diagnosed with osteoporosis and refuse anti-osteoporosis therapy, financial issues are the most common reason for not initiating therapy. Awareness and too many medications due to old age also played an important role in negligence towards osteoporosis. The likelihood and type of side effects were also ranked as important factors in making the decision to use the recommended medications. The results of this study show that barriers to osteoporosis therapy include medication cost, undertreatment of osteoporosis, and the concern of side effects. The percentage of elderly patients willing to take anti-osteoporotic medications has increased significantly compared to the last two years after they were being counselled by FLS coordinators. More commitment is needed to introduce the FLS not only in tertiary hospitals but also in primary care centres to raise awareness about osteoporosis and its treatment.

P649
ADHERENCE TO ANTI-OSTEOPOROSIS MEDICATION, CALCIUM, AND VITAMIN D SUPPLEMENTATION AT THE 6-MONTH AND 1-YEAR MARKS

J. F. Leong[1], S. Jeyakumar[1], N. A. Shohor[1], M. K. Yin[2], S. A. Mokhtar[1]

[1]Fracture Liaison Service, Orthopaedic and Traumatology Dept., [2]Pharmacological Dept., Hospital Canselor Tuanku Muhriz, Kuala Lumpur, Malaysia

Objective: Osteoporosis is a condition characterised by excessive bone loss and significant public health issues in elderly men and women. Adherence to medication for osteoporosis patients has become a challenge since those medications are required for the long term. Similar to other chronic diseases such as hypertension and diabetes, osteoporosis has struggled with suboptimal medication adherence, resulting in more fractures and all-cause mortality in elderly people.
Methods: From January 2021 to June 2021, patients initiating osteoporosis treatment were systematically monitored by the Fracture Liaison Service (FLS) over a 1-y period. Compliance with medication was evaluated after 6 months and 1 y post-treatment initiation.
Conclusion: A cohort of 76 patients was identified and managed by the FLS. Initially, 76% of patients exhibited compliance with anti-osteoporotic medication at the 6-month mark, which decreased to 68% after 1 y. Notably, individuals receiving denosumab (85%) demonstrated superior compliance compared to those prescribed bisphosphonates (74%) at the 1-y follow-up. Various factors contributing to reduced compliance were identified, including financial constraints, transportation challenges, and instances where patients discontinued treatment for reasons unknown. Enhancing compliance with anti-osteoporosis regimens necessitates the implementation of effective pharmacological management strategies. Collaborative efforts among healthcare professionals and interdisciplinary teams can significantly benefit osteoporosis patients. The integration of FLS emerges as a crucial initiative for facilitating early intervention and ensuring treatment adherence among osteoporosis patients.

P650
A CASE REPORT OF ATYPICAL FEMUR FRACTURES SECONDARY TO NON-TYPICAL ETIOLOGIES IN A MALAYSIAN TERTIARY HOSPITAL

J. F. Leong[1], N. A. Shohor[1], S. Jeyakumar[1], S. A. Mokhtar[1]

[1]Fracture Liaison Service, Orthopaedic and Traumatology Dept., Hospital Canselor Tuanku Muhriz, Kuala Lumpur, Malaysia

Atypical femur fractures (AFFs) typically result from prolonged bisphosphonate therapy and are characterised by distinct radiographic features. However, AFFs can also occur due to other underlying conditions or factors, presenting diagnostic dilemmas for clinicians. We present a case of AFFs with atypical aetiologies encountered at a Malaysian tertiary hospital, shedding light on the diagnostic approach and management strategies in such scenarios.
Case report: A 72-year-old male presented to our hospital with complaints of Left hip pain following a fall. Radiographic evaluation revealed fractures consistent with AFFs in the left proximal femur prompting further investigation into potential causative factors. Prior to the fall, the patient relied on a walking frame for mobility. He complained of persistent throbbing pain in the left proximal thigh that had persisted for 2 weeks. Notably, he had been on Omeprazole for few years and had been using MDI Beclomethasone since 2013 for his bronchial asthma. Subsequently, the patient underwent left proximal femur nailing with good post-operative outcome.

Figure shows atypical fracture of proximal left femur

Discussion: This case challenges the conventional understanding of AFFs solely linked to bisphosphonate therapy and underscores the necessity of a comprehensive diagnostic workup to elucidate alternative etiologies. Use of Proton Pump Inhibitor may decrease bone strength and increase the incidence of insufficiency fractures by inhibiting proton pumps in osteoclasts and decreasing bone turnover, impairing calcium absorption, and altering homocysteine levels through impairment of folate and vitamin B12 absorption. Prolonged use of glucocorticoid can increase bone resorption and reduce bone formation. Combination of these 2 medications can increase risk of AFF.
Conclusion: This case report highlights the importance of considering non-typical aetiologies in the diagnosis and management of atypical femur fractures. Clinicians should maintain a high index of suspicion for alternative causative factors, especially in regions with unique patient demographics and healthcare paradigms. Further research is warranted to elucidate the spectrum of etiologies contributing to AFFs and optimise treatment approaches for affected individuals.

P651
ENHANCEMENT IN BONE MINERAL DENSITY FOLLOWING TWO YEARS OF ADHERENCE TO ANTI-OSTEOPOROSIS MEDICATION, CALCIUM, AND VITAMIN D SUPPLEMENTATION

J. F. Leong[1], N. A. Shohor[1], S. Jeyakumar[1], S. A. Mokhtar[1]

[1]Fracture Liaison Service, Orthopaedic and Traumatology Dept., Hospital Canselor Tuanku Muhriz, Kuala Lumpur, Malaysia

Objective: The initial assessment of BMD serves as a pivotal step in diagnosing osteoporosis and determining the necessity of treatment. Subsequent monitoring of BMD is essential for patients undergoing treatment or transitioning from medication. This study aims to elucidate the efficacy of BMD monitoring in individuals receiving anti-osteoporotic therapy.
Methods: Seventy-one patients aged 55 years and older, admitted to the orthopaedic wards at Hospital Universiti Kebangsaan Malaysia due to osteoporotic or low-trauma fractures, were identified by the Fracture Liaison Service (FLS) for inclusion. Exclusion criteria included patients with malignancies, while those admitted for other reasons must have lacked a history of osteoporotic or low-trauma fractures. Patient demographics, including age, gender, race, comorbidities, and medication history, were documented.
Results: Prior to compliance with anti-osteoporotic medications, responders exhibited a significant increase in BMD. After two years of anti-osteoporotic therapy, both lumbar and hip BMD showed significant improvement. Specifically, the study demonstrated a 4% to 6% increase in spinal bone density and a 3% to 5% increase in hip bone density.
Conclusion: The majority of patients demonstrate a notable increase in BMD with treatment. Clinical trials indicate that less than 2% of treated patients experience a significant decrease in BMD. Non-compliance with medication, particularly within the first 6 months of therapy, is the primary cause of decreased BMD among patients. The FLS plays a crucial role in assisting multidisciplinary teams in identifying, diagnosing, and treating elderly patients at high risk of osteoporosis.

P652
PERIOPERATIVE FACTORS INFLUENCING FUNCTIONAL OUTCOMES 1-YEAR AFTER FRAGILITY HIP FRACTURE SURGERY

S. Dinis[1], A. S. Pinto[1], F. Cunha Santos[1], D. Augusto[1], H. Ferreira-Cardoso[2], L. Matos[3], I. Campos[3], P. Rocha[4], G. Monteiro[4], I. Neves[4], C. Pontinha[4], A. R. Batista[4], S. Venâncio[4], G. Cunha[4], E. Alves[4], N. Madeira[1], C. Vaz[1], J. Ferreira[1]

[1]Rheumatology Dept., Unidade Local de Saúde da Guarda, Guarda, [2]Dept. of Physical Medicine and Rehabilitation, Centro Hospitalar Universitário de São João, Porto, [3]Nutrition Dept., Unidade Local de Saúde da Guarda, Guarda, [4]Dept. of Orthopedics and Rehabilitation, Unidade Local de Saúde da Guarda, Guarda, Portugal

Objective: To determine the factors that influence functional outcomes of patients surgically treated for fragility hip fractures.
Methods: Retrospective study, including fragility hip fracture patients postoperatively followed-up at our Fracture Liaison Service between September 2019 and January 2023. Demographic and clinical characteristics were evaluated. Functional outcome was assessed using Barthel Index (BI) and 30-s chair to stand test (30CST) at discharge and at 12 months postoperatively. Inferential analysis was divided in 2 approaches: the first, measuring the difference between "at 12-month" and "at discharge" for both BI and 30CST, to evaluate functional recovery. The second approach divided the patients in 2 groups at 12-months postoperatively: those who had achieved a full recovery (maximum BI = 100) and those who had not (BI < 100). Mann Whitney and Chi-Square tests were used, and Pearson correlation coefficient was calculated. The significance level was < 0.05.
Results: A total of 78 patients were enrolled (69 female), with a median [interquartile range (IQR)] age of 78 [11] y. The median [IQR] "at discharge" BI score was 60 [7.5]. In the first analysis, we found no statistically significant differences in postoperatively functional recovery according to gender, BMI, previous fractures, fracture type, surgical technique, time until surgery, BMD and serum vitamin D. In the second approach, when considering the patients who had achieved a maximum BI score of 100 (76.9%) and those who had not (23.1%), a significant age difference was found ($p = 0.003$). In fact, the group that achieved a BI = 100 (75,23 y, CI95% [73,29–77,18]) was significantly younger than the group that did not (81,22 y, CI95% [77,49–84,96]). No other significant differences were observed.
Conclusion: Our results revealed that increased age negatively influenced autonomy recovery in fragility hip fractures. All patients improved their autonomy to perform activities of daily living, with 76.9% achieving a maximum BI score at 12-month follow-up. Some limitations of our study are the small sample size and the inability to evaluate the pre-fracture functional status, one of the best-known determinant factors of functional outcomes.

P653
THE BURDEN OF DIABETES IN AN FLS

F. Falcão[1], D. Augusto[2], S. Paiva Dinis[2], A. Amorim[1], F. Cunha Santos[2], A. S. Pinto[2], N. Madeira[2], L. Matos[3], I. Campos[3], P. Rocha[4], G. Monteiro[4], I. Neves[4], C. Pontinha[4], A. R. Batista[4], S. Venâncio[4], G. Cunha[4], E. Pires Alves[2], C. Vaz[5], J. Fonseca Ferreira[5]

[1]Faculty of Health Science, Univ. of Beira Interior, Covilhã, [2]Rheumatology Dept., Local Health Unity of Guarda, Guarda, [3]Nutrition Dept., Local Health Unit of Guarda, Guarda, [4]Rehabilitation Nurse Team, Orthopedics Dept., Local Health Unit of Guarda, Guarda, [5]Rheumatology Dept., Local Health Unity of Guarda and Faculty of Health Sciences at the Univ. of Beira Interior, Guarda, Portugal

Objective: To Determine, in a real word FLS (Fracture Liaison Service), the prevalence of type 1 and type 2 diabetes mellitus, and the number of antidiabetic drugs taken by patients with hip osteoporotic fractures, since a consensus established that the presence of diabetes mellitus is associated with a greater risk of developing osteoporosis.
Methods: All patients enrolled in our FLS after a fragility hip fracture, from October 2019 until October 2023, were systematically questioned about sociodemographic, clinical, densitometric, clinical and pharmacologic data. We establish two groups, one with diabetes and the other without diabetes. Descriptive and comparative analysis used the means, T-tests, chi-square, and Mann–Whitney U tests. p-value $< 0,05$ was considered significant.
Results: Out of the 147 patients who were referred, 126 o attended at least one appointment. Among them, 84.1% were female. The mean age of the patients was 77.3 ± 8.6 y. Type 2 diabetes was present in 21.7% of the patients, while there was no case of type 1 diabetes in this group. In the FLS 18% were taking oral antidiabetic drugs (14.3% metformin, 7.1% DPP-4 inhibitors, 3.9% SGLT2 inhibitors, 1.6% Sulfonylurea, and 0.8% were taking both GLP-1 analogs and thiazolidinediones), and 7% were treated with insulin. We found a significant association between diabetes and hypertension in our cohort (p 0.020), but no other association was significant.
Conclusion: This study is unique as it assesses the occurrence of diabetes in an FLS whereas most studies focus on the prevalence of osteoporosis in patients with diabetes. Our findings revealed that roughly 20% of patients with hip fractures had diabetes mellitus, and we observed a correlation with other cardiovascular factors, such as hypertension. This highlights the importance of preventing cardiovascular risk factors in FLS.

P654
DO WE REALLY NEED CALCIUM AND VITAMIN D TABLETS?

C. Amorim[1], D. Augusto[2], S. Paiva Dinis[2], F. Falcão[1], F. Cunha Santos[2], A. S. Pinto[2], L. Matos[3], I. Campos[3], P. Rocha[4], G. Monteiro[4], N. Madeira[2], I. Neves[4], C. Pontinha[4], A. R. Batista[4], S. Venâncio[4], G. Cunha[4], E. Pires Alves[2], C. Vaz[5], J. Fonseca Ferreira[5]

[1]Faculty of Health Science, Univ. of Beira Interior, Covilhã, [2]Rheumatology Dept., Local Health Unity of Guarda, Guarda, [3]Nutrition Dept., Local Health Unit of Guarda, Guarda, [4]Rehabilitation Nurse Team, Orthopedics Dept., Local Health Unit of Guarda, Guarda, [5]Rheumatology Dept., Local Health Unity of Guarda and Faculty of Health Sciences at the Univ. of Beira Interior, Guarda, Portugal

Objective: To compare the effects of calcium and vitamin D supplements on analytical and functional outcomes in a prospective FLS cohort.
Methods: Data was collected from October 2019 to October 2023 on consecutive patients who were enrolled in our FLS program following a hip fracture. We recorded various data including sociodemographic, clinical, densitometric, and pharmacologic details at baseline and after 12 months. Additionally, we recorded the timed-up-and-go test, sit-to-stand test, and 0-m walk test at baseline, 6 months, and 12 months. Patients were divided into 2 groups: group 1 received either calcium and vitamin D supplements or only vitamin D supplements, while group 2 did not receive any supplements. We used descriptive and comparative analysis, including means, T-tests, Mann–Whitney U, and chi-square tests as appropriate. A p-value < 0.05 was considered significant.
Results: Out of 147 referred patients, 126 attended at least one appointment. Among them, 84.1% were female, and the mean age was 77.3 ± 8.6 y. We found that 73.3% of patients had a prescription for calcium and/or vitamin D, while 26.8% did not take any supplements. We compared the outcomes of both groups and found no significant differences in analytical or functional results without calcium and vitamin D supplementation.
Conclusion: Our research findings imply that the intake of calcium and vitamin D supplements did not have a significant effect on functional or analytical responses in this study. However, it is important to note that we did not monitor dietary calcium uptake, such as the completion of daily calcium requirements, the reasons for declining supplements, or the reasons for not being prescribed, which could have influenced the results. Additionally, we did not investigate refracture rates, which could have been impacted by the use of calcium and vitamin supplementation. Therefore, although it seems that consuming calcium and vitamin D tablets may not be necessary, further research is required to fully understand this topic.

P655
RISK FACTORS FOR SUBSEQUENT FRACTURES AFTER DISTAL RADIUS FRACTURE

J. H. Ahn[1], E. J. Lim[2], S. H. Lee[1], J. K. Kim[1], H. J. Kim[1], Y. H. Shin[1]

[1]Dept. of Orthopedic Surgery, Asan Medical Center, Univ. of Ulsan College of Medicine, Seoul, [2]Dept. of Orthopaedic Surgery, Chungbuk National Univ. Hospital, Chungbuk National Univ. College of Medicine, Cheongju, South Korea

Objective: To evaluate the risk factors for subsequent fractures after distal radius fracture (DRF).
Methods: We retrospectively reviewed 705 patients with DRF who performed DXA within 6 months before or after the DRF and followed for more than 12 months. We identified patients with subsequent fractures and multivariate logistic regression analyses were conducted with demographic information, underlying disease status, and bone fragility parameters at the time of DRF to evaluate the risk factors for subsequent fractures.
Results: Subsequent fractures occurred in 56 patients (7.9% of 705 patients) with 65 fractures at a mean time of 33.5 months after DRF. In multivariate logistic regression analysis, older age (OR 1.032; 95%CI, 1.001–1.064, p = 0.044), diabetes mellitus (DM) (OR 2.663; 95%CI, 1.429–4.963, p = 0.002) and previous fracture history (OR 1.917; 95%CI, 1.019–3.607, p = 0.043), and low total hip BMD (OR 1.410; 95%CI, 1.083–1.836, p = 0.011) were significant risk factors for the occurrence of subsequent fractures.
Conclusion: This study demonstrated that older age, DM, previous fracture history, and low hip BMD are the risk factors for subsequent fractures after DRF. Active glycemic control would have a role in patients with DM and a more aggressive treat-to-target approach may be necessary for patients with low BMDs to prevent subsequent fractures after DRF.

P656
PATIENT-REPORTED OUTCOMES AFTER OPEN REDUCTION INTERNAL FIXATION FOR DISTAL RADIUS FRACTURE IN MEN

J. H. Ahn[1], J. K. Kim[1], B. H. Oh[1], Y. H. Shin[1]

[1]Dept. of Orthopedic Surgery, Asan Medical Center, Univ. of Ulsan College of Medicine, Seoul, South Korea

Objective: Most of the previous clinical studies on distal radius fractures (DRF) have primarily focused on women, particularly those beyond peri-menopausal ages, due to the demographic characteristics of DRF patients. This study aims to assess patient-reported outcomes

following open reduction and internal fixation (ORIF) for DRF in men, as well as the factors influencing these outcomes.
Methods: We conducted a retrospective review of the medical records and radiographs of 109 men who underwent ORIF for DRF from September 2016 to January 2022, with a follow-up period exceeding 2 y. The assessment included the visual analogue scale for pain, grip strength, range of motion of both wrists, Disabilities of the Arm, Shoulder, and Hand (DASH), and Patient-Rated Wrist Evaluation (PRWE) questionnaires at postoperative 3 months, 1 y, and annually thereafter.
Results: In a multivariate linear regression model estimating postoperative 1-y DASH scores, older age (B 0.201; 95%CI 0.042 to 0.361; p = 0.014) and worker's compensation (B 13.348; 95%CI 4.530 to 22.165; p = 0.003) were significantly associated with higher DASH scores. The same analysis for postoperative 1-y PRWE scores showed that only worker's compensation (B 5.417; 95%CI 2.646 to 24.122; p = 0.015) was significantly associated with higher PRWE scores. In a multivariate linear regression model estimating final follow-up PRWE scores, only AO/OTA type C (B 7.201; 95%CI 0.396 to 14.007; p = 0.038) was significantly associated.
Conclusion: Older age and worker's compensation are significantly associated with poor patient-reported outcomes after ORIF for DRF in men up to the postoperative 1-y. Careful evaluation of these patients is essential to determine whether this poor outcome is related to secondary gain from worker's compensation and age-related normal functional decline. After more than 2 y post-operation, only the initial fracture severity was significantly associated with poor patient-reported outcomes.

P657
WHAT FACTORS DETERMINE MEN'S SELF-PERCEIVED RISK OF OSTEOPOROSIS? FINDINGS FROM THE HERTFORDSHIRE INTERGENERATIONAL STUDY

J. Hammond[1], K. Mcgill[1], I. Bloom[1], E. Dennison[1]

[1]MRC Lifecourse Epidemiology Centre, Southampton, UK

Objective: While awareness of osteoporosis might be considered reasonable in women, far fewer research studies consider male osteoporosis and few educational materials target men. Despite this, demographic changes mean that osteoporotic fractures are likely to become much more common in both sexes. The primary aim of this qualitative study was to explore men's understanding of factors associated with risk of osteoporosis.
Methods: Nine male participants aged 55–68 y were recruited from the Hertfordshire Cohort intergenerational study. Men were interviewed by Teams or phone using semi structured interviews, recordings were transcribed and thematically analysed. Self-completed questionnaires regarding past medical history and lifestyle were available, to guide discussion.
Results: Several key themes were identified including personal and family history of fracture, participants reported seeing the consequence of a parental hip fracture in later life, and recognized age as important. Participants spoke commonly about the importance of physical activity and maintenance of a healthy body weight for good health generally, rather than in relation to bone health. Diet was often mentioned, and several participants spoke about the importance of dairy products, calcium tablets and vitamin D supplementation. In some cases, this reflected awareness that their wife took supplements for bone health. Four respondents discussed the relevance of cigarette smoking and heavy alcohol consumption to bone health, and medical history (specifically use of steroids) was recognized as important by several respondents. Several participants reported that they thought fractures were always related to high trauma and so 'being careful' would protect them.
Conclusion: Overall, it appeared that many men who participated had some knowledge of bone health and spoke frequently of their desire to make lifestyle change to improve their health generally. However, some men reported no awareness, and described it as 'a women's disease'. Although our sample likely reflected a healthy cohort effect, with greater health awareness than might be present in the wider population, heavy alcohol consumption and cigarette smoking as risk factors were named as important by a minority of respondents, suggesting that this may be an area to target when considering educational materials aimed at men.

P658
IMPACT OF PROTON PUMP INHIBITORS ON FEMORAL NECK OSTEOPOROSIS

J. Hankollari[1], V. Duraj[2]

[1]Albanian Univ., [2]Univ. Hospital Center "Mother Teresa", Tiranë, Albania

Objective: Proton pump inhibitors (PPIs) are used to treat several clinical conditions like: esophagitis, gastritis, duodenitis, symptomatic GERD, gastric and duodenal ulcers, Zollinger-Ellison syndrome, etc. Many studies have shown that proton pump inhibitors have a negative impact on femoral neck osteoporosis. We aim to study this hypothesis in our population.
Methods: We opted to conduct a retrospective study, in which 120 patients were enrolled. We compared the change in T-score values in the femoral part between patients who received PPIs treatment for a duration exceeding one year and those who did not receive this treatment. We selected female patients, postmenopausal, who did not take other medications and did not have other accompanying diseases or only pathologies where the use of PPIs is indicated.
Results: After analyzing the data, it was observed that patients who were treated with PPIs, about 59% of the cases, had a smaller improvement in T-score values compared to patients who did not receive such treatment, with a p-value of < 0.05, which is statistically significant.
Conclusion: PPIs have a negative impact on femoral neck osteoporosis.

P659
ROLE OF SUMOYLATED SIRT1 IN THE PATHOLOGICAL DEVELOPMENT OF INTERVERTEBRAL DISC DEGENERATION BY REGULATING NUCLEUS PULPOSUS CELL SENESCENCE

T. Y. Teng[1], J. J. M. Jianjun[1]

[1]Zhejiang Univ., Hangzhou, China

Objective: Low back pain is a prevalent clinical symptom of musculoskeletal degenerative disease. The primary cause of low back pain is intervertebral disc degeneration (IDD). However, the regulatory mechanism of post-translational modification (PTM) of silent mating type information regulation 2 homolog 1 (SIRT1) during IDD remains unclear. Our study reveals that SUMO modification of SIRT1 plays a crucial role in the process of IDD.
Methods: SiRNA and lentiviral plasmid were used to knock down and overexpress SIRT1 in nucleus pulposus cells (NPCs), respectively. Subsequently, we detected the expression levels of synthetic and catabolic factors to verify the function of SIRT1 in NPCs. Professional websites were utilized to predict potential SUMO modification sites in SIRT1, which were further confirmed through

point mutations experiments. Immunoprecipitation and co-immunoprecipitation techniques were used to validate the effect of nicotinamide adenine dinucleotide (NAD +)-dependent deacetylase activity on p53 acetylation after SUMO modification by SIRT1. Additionally, we studied the impact of SIRT1 on IDD using both SIRT1 knockout mice and acupuncture modeling.

Results: Our findings demonstrate that there is a significant decrease in SIRT1 expression within degraded intervertebral disc tissues; however, overexpression can increase extracellular matrix production while reducing decomposition factors. Similar results were observed in gene knockout mice models as well. Mechanistically, our research indicates that SUMO modification can occur at K113, K132, K439 residues within SIRT1 protein sequence leading to improved stability for this protein variant. Consequently, enhanced stability promotes deacetylation process targeting p53 protein resulting in its accelerated degradation along with inhibition cell senescence.

Results: Our findings demonstrate a significant decrease in SIRT1 expression within degraded intervertebral disc tissues. However, we observed that overexpression of SIRT1 led to an increase in extracellular matrix production and a decrease in decomposition factors. These results were further validated through gene knockout experiments conducted on mice. Mechanistically, we identified SUMO modification sites at K113, K132, and K439 of SIRT1 which enhanced its stability. This modification facilitated the deacetylation of p53 protein, resulting in accelerated degradation of p53 and inhibition of cell senescence.

Conclusion: Our study highlights the role of SUMO modification in regulating the stability of SIRT1 and influencing nucleus pulposus cell senescence via modulation of the p53 signaling pathway. These findings provide novel targets and experimental evidence for potential therapeutic interventions against intervertebral disc degeneration (IDD).

P660
VERTEBRAL FRACTURES BY DXA: IS THE CURRENT DEFINITION ADEQUATE?

J. L. A. Morales Torres[1], J. Romero Ibarra[1], J. Morales Vargas[2]

[1]Hospital Aranda de la Parra, [2]Morales Vargas Centro de Investigacion, Leon, Mexico

Objective: Osteoporotic vertebral fractures (VF) indicate reduced bone strength and predict new fractures. Their identification in patients with suspected osteoporosis (OP) by DXA-based Vertebral Fracture Assessment (VFA) improves current definition of OP[1]. We aimed to describe the frequency of VF in patients referred to an osteodensitometry (ODM) center using the commonly accepted definition.

Methods: We included patients referred for an ODM study, who underwent a VFA as they met criteria for it[2]. VFA studies were performed on a GE-Lunar, iDXA device. We report the frequency of VF defined as a loss of vertebral body height of $\geq$ 20% in one or more segments[1]. The characteristics of those with and without VF are compared by Student's t-test.

Results: We included 1226 patients (91.9% women) with a mean age of 74 ($\pm$ 8.5) y, seen since the end of 2021. Of these, 807 (65.8%) had at least one VF and 419 (34.2%) had none. Their characteristics are summarized in Table 1. Mean BMD is significantly lower in the VF population.

Table 1. Characteristics of the patients included

	No fracture (n=419)	With fracture (n=807)	P
Mean age	73.2 (±8.28)	74.82 (±8.71)	0.0017
Mean height	154.1(±10.41)	152.1(±8.39)	0.0003
Mean Weight	64.67(±13.56)	62.84(±11.91)	0.0136
Spine BMD (± SD)	1.028 (±0.207)	0.982 (±0.214)	0.0003
Spine BMD (± SD)	0.854 (±0.164)	0.777 (±0.152)	0.0001

Conclusion: Prevalence of VF in the community is 19.2 for women and 9.8 for men in Mexico[3]. Findings of this report exceed that. Population referred to ODM is more likely to have OP but, is the 20% limit adequate to define the presence of a fracture? Current paradigm prompts to consider all patients with a VF as having OP and requiring pharmacological therapy[1]. We found a high frequency of VF by VFA. According to the current definition, all such patients should be considered candidates for OP treatment.

SARCOPENIA CLINIC: THREE-YEAR EXPERIENCE OF A PRAGMATIC APPROACH

J. Morales Vargas[1], J. L. A. Morales Torres[2], A. Guadian Moreno[1], P. Ramirez Muñoz[1]

[1]Morales Vargas Centro de Investigacion, [2]Hospital Aranda de la Parra, Leon, Mexico

Objective: The level of knowledge about frequency and impact of sarcopenia (SARC) is limited among the general population and health professionals. We have proposed a Sarcopenia Clinic (SC) with a pragmatic and comprehensive approach to manage SARC according to proposals of the European Working Group (EWGOSP) in real life, in Mexico[1]. We aimed to describe the findings of implementing a stepwise approach for identification and treatment of SARC.

Methods: Patients with suspected or screened positive for SARC are referred by their physicians and are evaluated following the algorithm proposed by the EWGSOP adapted to the center's resources. Malnourished patients or at risk of developing malnutrition receive nutritional assessment. Treating physicians obtain a report including strength, muscle mass, physical performance, nutritional risk and serum levels of 25OHvitamin D, with a Vivifrail[2] classification and a proposed management plan.

Results: From June 2021 to October, 2023, 135 patients referred from diverse services, have been evaluated. Their mean age was 66.8 $\pm$ 9.56 y and 72.6% were women. Tests included were completed in about 30 min. Table 1 summarizes the findings of patients evaluated. Among subjects not classified as SARC with the EWGSOP definition, we found low physical performance (16%), low strength (24%) and low muscle mass (60%).

Table 1. Findings in 135 patients at the Sarcopenia Clinic

Evaluation:	Interpretation	Frequency *
Nutritional Screening	Normal	51.1%
	Risk of malnutrition	36.6%
	Malnutrition	13.3%
Grip Strength	Normal	60.0%
	Low	37.8%
Get up and Go test	Normal Strength	73.3%
	Low strength	17.8%
	Unable	2.2%
	Not done	4.4%
Appendicular Muscle Mass Index	Normal	70.5%
	Low	29.5%
Physical Performance	Normal	77%
	Low	23%
Diagnostic conclusion	Normal	40.7%
	Probable SARC	22.2%
	SARC	10.4%
	Severe SARC	6.7%

*Some of the sums do not reach 100% due to the impossibility of completing an evaluation.

Conclusion: The methodology implemented in the SC allows the identification of subjects with SARC and peri-sarcopenic conditions and may orient their treating physicians to implement early preventive and therapeutic approaches.

ASSOCIATION BETWEEN BONE MINERAL DENSITY AND BODY COMPOSITION AMONG MONGOLIAN ADULT WOMEN

J. N. Jargalsaikhan[1], A. G. Ajnai[1], S. S. Surenkhorloo[1]

[1]Fourth Hospital, Ulaanbaatar, Mongolia

Objective: Maintaining bone health is an important public health issue and challenge (concern) in women for preventing a determinant of the risk of developing osteoporosis later in life. The aim of the present study is to investigate the relationship between BMD, and body composition in a female population in Mongolia.

Methods: A sample of 309 women aged between 20–39 y who performed scans between January and December 2022 by DXA in Fourth Hospital. The correlation between BMD and total fat mass, total lean mass, and total bone mass was analyzed by Pearson correlation and multiple linear regression analysis.

Results: According to the DXA results, 76.4% of women had normal BMD, and 20.1% and 3.6% of women were diagnosed with osteopenia and osteoporosis, respectively. Multiple linear regression analysis indicated BMD was positively associated with total fat mass (β: 0.042, $p < 0.001$), total lean mass (β: 0.083, $p < 0.001$), and bone mass (β: 0.857, $p < 0.001$). The positive correlation of BMD and lean and bone mass was significant in younger women aged < 30 y, whereas women aged over 30 were positively associated with lean mass and fat mass. There were no significant relationships between BMD and body weight, percentage of body fat, and android/gynoid ratio parameters.

Conclusion: Women younger than 30 were associated with BMD, lean, and bone mass. Emphasizing lean mass and bone mass in young Mongolian women may be valuable for improving bone health.

P663
ULTRASOUND-GUIDED RADIOFREQUENCY ABLATION OF GENICULAR NERVES IN THE TREATMENT OF CHRONIC KNEE PAIN: A SINGLE-CENTER RETROSPECTIVE STUDY

J. Nurković[1]

[1]Center for Regeneration and Rehabilitation, Novi Pazar, Serbia

Objective: Radiofrequency (RF) treatment of the genicular nerves shows promise for managing chronic osteoarthritic and persistent postsurgical knee pain (PPSP) that doesn't respond to conventional medical management.

Methods: The retrospective single-center cohort study of patients treated with ultrasound-guided conventional RF of the genicular nerves for chronic knee pain was conducted in the Center for Regeneration and Rehabilitation Novi Pazar, Serbia, from October 2022 to November 2023. Subgroup analysis based on the etiology of pain (PPSP and degenerative knee pain) was performed in addition to the total study population analysis. Outcome parameters were global perceived effect (GPE), Numeric Rating Scale for pain, consumption of potent opioids, and treatment safety at six weeks and cross-sectionally at a variable time point. Treatment success was defined as GPE $\geq$ 50%.

Results: Results showed that out of 48 cases screened, 45 were included in the study, with 13 diagnosed with PPSP and 32 with degenerative knee pain. The study found that treatment success was achieved in 40 out of 45 interventions (88.9%) at six weeks, with similar results in both groups. Follow-up assessments showed that in 95% of patients with significantly reduced pain, this effect was maintained over 6 months and in 72% of patients over 9 months, with the mean duration of the impact of the RF treatment being 8.9 months. Additionally, the safety analysis conducted at six weeks and at the second time point showed a good safety profile of the treatment.

Conclusion: Conventional RF of the genicular nerves has shown promising results in the study population, with a success rate of over 88% for those refractories to conventional medical management. Additionally, the treatment was well-tolerated and had a mean duration of effect of 8.9 months.

P664
IS A KNEE X-RAY BETTER STANDING OR SITTING?

J. Nurković[1]

[1]Center for Regeneration and Rehabilitation, Novi Pazar, Serbia

Objective: To compare the joint space width between standing and sitting radiographs to diagnose the knee's primary osteoarthritis (OA).

Methods: Digital radiographs of 120 medial osteoarthritic knees in 60 patients were performed. The patients underwent standing and sitting anteroposterior (AP) views. The severity of the osteoarthritis was evaluated using the joint space width and Kellgren-Lawrence (KL) radiographic classification. The t-test was used for statistical analysis.

Results: The mean medial joint space width found in the standing and sitting view was measured at 1.5 mm and 2.3 mm, respectively ($p < 0.001$, 95%CI 0.45 to 0.67). 59%, 45.4%, and 21.4% of the knees diagnosed with a KL grade of I, II, and III in the standing views were changed to KL grade II, III, and IV in the sitting views, respectively. No changes for KL IV osteoarthritis diagnoses have been found between standing and sitting views.

Conclusion: Standing radiographs better represent joint space width than sitting radiographs. 59% of standing radiographs have changed the KL grading to a more severe grade than that in the sitting radiographs. It is recommended to use a standing knee X-ray for OA diagnostics.

P665
RADIOFREQUENCY ABLATION TO TREAT OSTEOARTHRITIS OF THE KNEE

J. Nurković[1]

[1]Center for Regeneration and Rehabilitation, Novi Pazar, Serbia

Objective: Recent evidence suggests a benefit in radiofrequency (RF) treatment of genicular nerves for the knee in managing moderate to severe osteoarthritis (OA). There is a reported reduction in pain and improved function. However, there is very little level-one literature available that supports this practice and conclusively proves a benefit. There are only several randomized control trials conducted in North America that are proving their efficacy.
This study aimed to determine if RF treatment of genicular nerves administered in patients with knee OA over three to twelve months demonstrated any benefit.
Methods: The WOMAC tool was used before RF treatments and one year after the RF treatments in 45 patients. RF ablation was performed on all three branches of the n. genicular in all patients. The outcomes observed were pain, stiffness, and physical function, and the total WOMAC score was calculated.
Results: RF ablation of genicular nerves reduced total WOMAC score, pain, stiffness, and physical function by 79.3%, 86.37%, 61.12%, and 58.03%, respectively, 3 months after the interventions. What is very important is that these effects were maintained a year after the treatments.
Conclusion: Results showed a trend of reduction in the WOMAC score. However, further studies are needed to explore whether the grade of OA and patients' weight significantly impact the results and when it is time to repeat interventions.

P666
PRECISION NAIL PRESERVATION: A MINIMALLY DAMAGING TECHNIQUE FOR TREATMENT OF AN ELUSIVE SOFT TISSUE BENIGN NEOPLASM

J. P. Pereira[1], A. V. Vilela[1], J. A. Azevedo[1], D. F. Ferreira[1], L. F. R. Rodrigues[1], P. V. Varanda[1]

[1]Hospital de Braga, Braga, Portugal

In the realm of soft tissue neoplasms, digital fibromyxoma (DF) stands as a rare and benign entity, frequently targeting the digits, especially the nail apparatus. Its clinical manifestation involves a gradual development of a mass, accompanied by xanthonychia, nail thickening, and proximal paronychia. This often leads to diagnostic challenges, with frequent misidentification as a fungal infection. The primary approach to address DF is through en-bloc resection, despite a notable recurrence risk.
Case report: This case revolves around a 48-year-old female presenting a 2-y history of discoloration and thickening of the right third fingernail. Initial treatment with anti-fungal agents was unsuccessful. As such, surgical treatment was decided upon, which consisted on longitudinal partial proximal plate nail avulsion. This procedure unveiled a consistent, gelatinous, and well-demarcated flesh-colored lesion. Histopathological examination validated the diagnosis of DF, showcasing CD34 positivity and pS-100 immunomarker negativity. Over the subsequent 12 months of follow-up, the patient remained completely asymptomatic, free from any signs of lesion recurrence or nail dystrophy.
Conclusion: Emphasizing the importance of preserving the nail matrix and achieving optimal clinical outcomes, this case report advocates for the adoption of minimally damaging techniques when approaching soft tissue tumors around the nail apparatus. Recognizing this rare entity and understanding its characteristic presentation holds the utmost significance for ensuring precise diagnosis and timely surgical management.

P667
BONE MINERAL DENSITY T-SCORES COMPARISON BETWEEN OBESE AND NON-OBESE INDIVIDUALS INCLUDED IN A FRACTURE LIAISON SERVICE FOLLOWING A RECENT FRAGILITY FRACTURE

G. Marchasson[1], B. Cortet[1], C. Philippoteaux[1], I. Legroux-Gérot[1], J. Paccou[1], H. Béhal[1]

[1]Lille Univ. Hospital, Lille, France

Objective: To compare the mean T-scores of obese and non-obese patients after recent fragility fractures.
Methods: Over a period of 5.5 y, from January 2016 to May 2021, patients from a fracture liaison service were identified and their demographic characteristics, osteoporosis risk factors, BMD T-scores, and fracture sites were compared between obese (BMI $\geq$ 30 kg/m^2) and non-obese (19 kg/m^2 $<$ BMI $<$ 30 kg/m^2) patients.
Results: A total of 712 patients were included (80.1% women; mean age 73.8 $\pm$ 11.3 y). 16% had type 2 diabetes mellitus and 80% had a major osteoporotic fracture (MOF). 135 patients were obese and 577 non-obese, with obese patients younger ($p < 0.001$) and more frequently female ($p = 0.03$). Obese patients presented with fewer hip fractures (10 vs. 21%, $p = 0.003$) and more proximal humerus fractures (16 vs. 7%, $p < 0.001$) than non-obese patients. After adjusting for age, sex, and diabetes mellitus, BMD T-score values were significantly higher at all measurement sites (lumbar spine, total hip, and femoral neck) in obese patients than in non-obese patients for all types of fractures, with a mean difference of 1 standard deviation ($p < 0.001$ for all comparisons). The same results were observed in the population limited to MOF.

	Obese patients	Non-obese patients	T-score differences	P-value
	All fractures (n=712)			
	n=135	n=577		
BMD T-score; lumbar spine[1]	-0.7 [-1.0; -0.4]	-1.6 [-1.8; -1.5]	-0.9 [-1.3; -0.5]	<0.001
BMD T-score; total hip[2]	-0.7 [-0.9; -0.5]	-1.8 [-1.9; -1.6]	-1.0 [-1.3; -0.8]	<0.001
BMD T-score; femoral neck[3]	-1.5 [-1.7; -1.3]	-2.1 [-2.3; -2.0]	-0.6 [-0.9; -0.4]	<0.001
	Major osteoporotic fractures (MOF) (n=569)			
	n=98	n=471		
BMD T-score; lumbar spine[4]	-0.8 [-1.2; -0.4]	-1.6 [-1.8; -1.4]	-0.9 [-1.3; -0.4]	<0.001
BMD T-score; total hip[5]	-0.8 [-1.0; -0.5]	-1.8 [-1.9; -1.6]	-1.0 [-1.3; -0.7]	<0.001
BMD T-score; femoral neck[6]	-1.5 [-1.8; -1.2]	-2.1 [-2.3; -2.0]	-0.6 [-0.9; -0.4]	<0.001

Conclusion: Given the crucial role of BMD T-score in determining the need for anti-osteoporotic medication following fragility fractures, it is reasonable to question the existing T-score thresholds in obese patients.

P668
BONE TURNOVER IN PATIENTS WITH DIFFERENTIATED THYROID CANCER UNDER THYROXINE SUPPRESSIVE THERAPY

J. S. Hwang[1], J. F. Chen[2]

[1]Chang Gung Memorial Hospital, Taoyuan, [2]Chang Gung Memorial Hospital, Kaohsiung, Taiwan

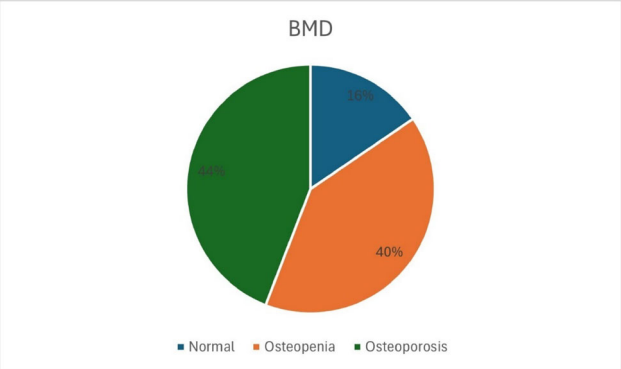
Objective: Differentiated thyroid carcinoma is the most common endocrine neoplasia, after thyroidectomy with/without radioiodine treatment, patients required levothyroxine therapy to suppress thyrotropin-stimulating hormone to reduces tumor recurrence rates. Endogenous hyperthyroidism has been shown may reduce bone density due to accelerates bone turnover and shortens the normal bone remodeling cycle. Furthermore, in the FRAX model, common risk factors and BMD were also estimated the fracture risk in untreated long-standing hyperthyroidism patients. Although, many studies have investigated bone turnover markers have useful in fracture risk assessment and monitoring treatment efficacy in postmenopausal osteoporosis. The aim of this study is to evaluate the bone turnover and fracture risk in postmenopausal osteoporosis women with thyroid cancer under thyroxine suppressive therapy.
Methods: This cross-sectional study investigated patients who were postmenopausal osteoporosis women with differentiated thyroid cancer follow-up at endocrine clinic. In this study, country-specific fracture risk for 10-y probability of a hip or major osteoporotic fracture, were calculated by the WHO Collaborating Center, using the FRAX algorithm. The FRAX algorithm includes femoral neck BMD, age, sex, BMI, previous history of fracture, parental history of hip fracture, current smoking, recent use of corticosteroids, presence of rheumatoid arthritis, secondary osteoporosis cause and at least 3 alcoholic beverages per day. A single, fasting blood sample to assess bone markers, and other biochemical tests were performed in the study visit. Patients were measure the bone specific alkaline phosphatase for formation markers, and β-CrossLaps (β-CTX) for resorption markers were analyzed the bone turnover rate.
Results: In this cross-sectional study, we investigated 64 Taiwanese postmenopausal women, with 34 thyroid cancer subject diagnosed 2–6 y and 30 non- thyroid cancer postmenopausal osteoporosis women at osteoporosis clinic, aged between 50–62 y, found both bone formation and resorption markers were elevated in thyroid cancer patients under thyroxine suppressive therapy.
Conclusion: Postmenopausal osteoporosis women with differentiated thyroid cancer under thyroxine suppressive therapy for 3 y have high bone turnover markers, but no significant difference risk for 10-y major or hip fracture probability by FRAX than non- thyroid cancer osteoporosis women.

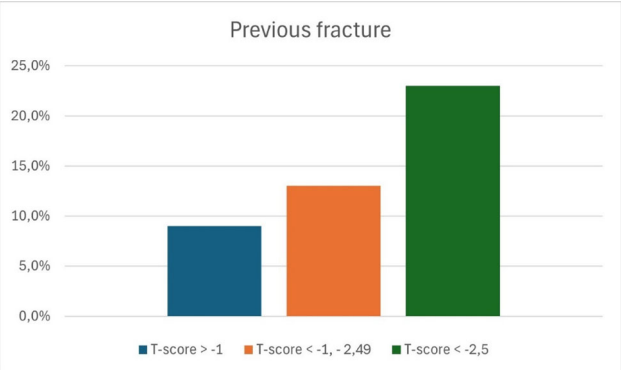
P669
BONE DENSITOMETRY AND FRAGILITY FRACTURE RISK

J. Sacramento[1], N. Montesino[1], N. Padrón[1], M. J. Montesa[1], B. González[1]

[1]Hospital Universitario Nuestra Señora de Candelaria, Santa Cruz de Tenerife, Spain

Objective: To evaluate BMD outcomes in patients who have suffered a vertebral fragility fracture during the previous year.
Methods: Observational, descriptive, cross-sectional, single-center study. Consecutively included patients ≥ 50 y seen from January 2017 to December 2023 in patients referred to a Fracture Liaison Service (FLS) for recent fragility vertebral fracture (during the last year).
Results: 225 patients were included and DXA was performed on 136. The reasons for not carrying it out were absence or because its result was not going to modify therapy decision. 85.29% were women with a mean age of 71.4 (± 8.55) y. At the time of the fracture, only 44.12% had a T-score < -2.5 SD, while more than half had osteopenia (40.44%, T-score between—1.0 and—2.5) or normal BMD (15.44%, T-score -1.0 or greater) (Fig. 1). Furthermore, 33.09% had a previous history of fragility fracture, and 10% of them had normal BMD (Fig. 2).





Conclusion: In our cohort, less than half of the patients with vertebral fragility fracture had densitometric osteoporosis and even 16% had normal densitometric values. The normality of the DXA does not exempt the presence of bone fragility in this patient profile.

P670
THE EXPERIENCE OF FEELING OLD AFTER A FRAGILITY FRACTURE

J. Sale[1], L. Frankel[1], E. Bogoch[1], G. Carlin-Coleman[1], S. Hui[1], J. Saini[1], J. Mckinlay[1], L. Meadows[2]

[1]Unity Health Toronto, Toronto, [2]Univ. of Calgary, Calgary, Canada

Objective: There has been little exploration of the effect of fragility fractures on patient perceptions of their age. The common assumption is that fractures "happen to old people". In individuals with a fragility fracture, our objective was to explore the experience of feeling old after sustaining a fragility fracture.
Methods: A secondary analysis of data from 145 community-dwelling women and men participating in six qualitative primary studies was conducted relying on a phenomenological approach. Participants were English-speaking, 45 years and older, who had

sustained a recent fragility fracture or reported a history of previous fragility fractures. Data for the analysis included direct statements about feeling old as well any discussions relevant to age post-fracture.
Results: We highlight two interpretations based on how individuals with a history of fragility fracture talked about age: 1) Participants described feeling old post-fracture. Several participants made explicit statements about being "old". However, the majority of participants discussed experiences post-fracture that implied that they felt old and had resigned themselves to being old. This appeared to entail a shift in thinking and perception of self that was permanent and had become a part of their identity; and 2) Perceptions of increasing age after sustaining a fracture were reinforced by health care providers, family, and friends.
Conclusion: Our findings challenge the notion that fractures "happen to old people" and suggest that fractures can make people feel, and embody, feeling old.

P671
THE NEED FOR FRACTURE LIAISON SERVICES IN A REHABILITATION HOSPITAL SETTING

J. Sale[1], T. Inrig[1], E. Bogoch[1], A. Verduyn[1], S. Journeay[1], V. Elliot-Gibson[1], L. Ly[1]

[1]Unity Health Toronto, Toronto, Canada

Objective: Fracture prevention has not been a priority in rehabilitation settings yet 40% of hip fracture patients are admitted to a rehabilitation hospital in Ontario, Canada, and fractures account for 30% of inpatients in Canadian rehabilitation hospitals. Our aim was to adapt the Fracture Liaison Service (FLS) model of care to a rehabilitation hospital in Ontario in order to address the unique fracture prevention needs of patients in this setting.
Methods: We reviewed 736 fracture admissions to a rehabilitation hospital without an FLS over an 18-month period (pre-COVID). Fractures of the hip and spine were automatically considered high risk for future fracture and indicated for pharmacological intervention based on the Canadian guidelines. According to the guidelines, patients with non-hip and non-spine fractures should be recommended a BMD test to assess fracture risk status. We examined the electronic discharge pharmacy medication list in patients' charts for bone health recommendations.
Results: Length of stay for inpatients with a fragility fracture (mean age of 80 y; approximately 70% female) was two weeks or greater. Of 736 fracture patients, 474 (64%) were automatically considered high risk. Of the high risk patients, 22% were discharged with a bone active medication. Of the remaining patients (assumed to be not high risk), 6% received a BMD test recommendation at discharge.
Conclusion: We identified a 78% treatment gap in patients deemed high risk for future fracture. The rehabilitation setting is an ideal location to identify patients who need immediate bone health treatment.

P672
CORRELATION BETWEEN CALCIUM INTAKE AND BONE MINERAL DENSITY IN A SOUTH AMERICAN COHORT

J. Sanabria[1], S. A. Blanco[1], L. A. Dulcey[1], J. A. Gomez[1], E. Y. Gutierrez[1], A. P. Lizcano[1]

[1]Autonomous Univ. of Bucaramanga, Bucaramanga, Colombia

Objective: To determine the influence of calcium intake on BMD values in the adult female population at a South American hospital, seeking to assess calcium consumption through 24-h dietary recalls and nutritional status for analysis of the relationship between intake of this mineral and found BMD values, also comparing said intake with ideal recommendations, in order to generate useful information on dietary habits and osteoporosis prevention in this population.
Methods: A cross-sectional analytical observational study was conducted in 100 female patients over 35 years old who attended the Bone Densitometry and Nutrition Services at a South American hospital over 4 months. The 24-h calcium intake recall method was used; weight in kg and height were recorded with a Harpenden stadiometer, then calculating BMI; an X-ray bone densitometry was performed at the femoral neck and entire hip level. Finally, the reported calcium intake was related to the obtained BMD values to determine the possible influence between these variables.
Results: The majority presented overweight (40%) or obesity (21%) with an average calcium intake lower than recommended by age. 78% of patients had an inadequate intake of the mineral, regardless of nutritional status. The diagnosis of osteoporosis (79%) predominated, associated with low calcium intake. A positive correlation was found between the intake of this mineral and BMD values in hip regions.
Conclusion: Calcium intake influenced BMD values in the analyzed adult female population. The majority of patients presented overweight and obesity, as well as a calcium intake below the recommendations for their age. It is concluded that inadequate calcium intake influenced low bone mineralization and the development of osteoporosis in the studied population, highlighting the importance of an adequate intake of this mineral for bone health.

P673
TRENDS OF SERUM 25(OH)D LEVELS IN PATIENTS HOSPITALIZED DURING YEARS 2018–2020

J. Smaha[1], M. Kužma[1], P. Jackuliak[1], J. Hrtánková[1], J. Payer[1]

[1]5th Dept. of Internal Medicine, Comenius Univ. Faculty of Medicine, Univ. Hospital Bratislava, Bratislava, Slovakia

Objective: Recently, an increased research interest in vitamin D and its nonclassical effects, such as its influence on the immune system or the course and prognosis of acute respiratory diseases, was seen. How this transformed the vitamin D status of patients in actual clinical practice is unclear.
Methods: A retrospective analysis of the health records of all patients admitted to the general internal ward of University Hospital Bratislava, Slovak Republic, between 2018–2020 was performed. Our primary outcome was to compare yearly average 25- hydroxyvitamin D (25(OH)D) levels and to compare the proportion of patients who had their blood tested for 25(OH)D upon admission.
Results: In total, 10,175 patients' admission forms, of which 3258 patients had a serum 25(OH)D level assessed upon admission, were reviewed. A significantly higher percentage of patients with blood tested for 25(OH)D concentration during the monitoring period was. observed. 23%, 34 and 42% of patients (between-group differences with $p < 0.001$) were tested during 2018, 2019, and 2020, respectively. There was a significant difference in average mean 25(OH)D serum levels between three years (2018–20) ($p = 0.005$). The mean value of 25(OH)D in 2018 (15.08 ng/mL $\pm$ 9.22) was significantly lower than in 2019 (15.98 ng/mL $\pm$ 9.35; $p = 0.031$) and in 2020 (16.76 ng/mL $\pm$ 9.92; $p = 0.001$). Mean serum 25(OH)D concentration increased by 1.68 ng/mL in the recorded period.
Conclusion: The proportion of vitamin D-tested patients and serum 25(OH)D concentration increased during the observed period. Our data suggest increasing awareness about vitamin D status in clinical practice.

P674
TREATMENT WITH LORECIVIVINT LEADS TO IMPROVED LONG-TERM PATIENT ACCEPTABLE SYMPTOM STATE (PASS) COMPARED TO PLACEBO: DATA FROM PHASE 3 EXTENSION TRIAL.

C. Swearingen[1], Y. Yazici[1], J. Tambiah[1], P. Conaghan[2]

[1]Biosplice Therapeutics, Inc, San Diego, USA, [2]Univ. of Leeds School of Medicine, Leeds, UK

Objective: Lorecivivint (LOR) has demonstrated beneficial effects on clinical outcomes in knee OA trials. A "patient acceptable symptom state" (PASS) also provides a clinically relevant assessment (Roos 2019). Year 1 results from a Phase 3 extension study, OA-07 (NCT04520607), with LOR 0.07 mg clinical outcomes including WOMAC Pain [0–100] and Function [0–100], were evaluated for PASS.
Methods: Severe knee OA patients (medial JSW 1.5–4.0 mm) who completed the parent trial were enrolled into the OA-07 extension. A repeat injection according to original parent randomization (LOR/-placebo (PBO)) was given at OA-07 Year 1 start to blinded patients irrespective of symptom state. PASS is assessed with a 'yes/no' response to the question "Taking into account all the activities you have during your daily life, your level of pain, and also your functional impairment, do you consider that your current state is satisfactory?" at parent study baseline and end of OA-07 Year 1. PASS response and odds ratios (OR; 95%CI) between treatment groups were calculated using baseline-adjusted logistic regression. Differences between treatment groups were explored for patients with a positive PASS.
Results: 276 patients (mean age 61.0 ± 8.2 y, BMI 31.8 ± 4.9 kg/m^2, female 62.7%, Kellgren-Lawrence [KL] 3 45.3%, medial JSW 2.63 ± 0.69 mm) were enrolled. Adverse event data showed LOR appeared safe. Following the repeat injection, compared to PBO at end of Year 1: LOR treatment significantly increased odds of a 'yes' PASS response (LOR 103/121 (85.1%) vs. PBO 93/129 (72.1%), OR 2.45 [1.25, 4.78], P = 0.009) (Figure); patients with a 'yes' PASS response also reported improvements in WOMAC Pain (LOR -6.8 (± 2.0) vs. PBO -1.0 (± 2.1), t-test P = 0.049) and Function (LOR -7.0 (± 1.9) vs. PBO -2.4 (± 1.9), t-test P = 0.090).

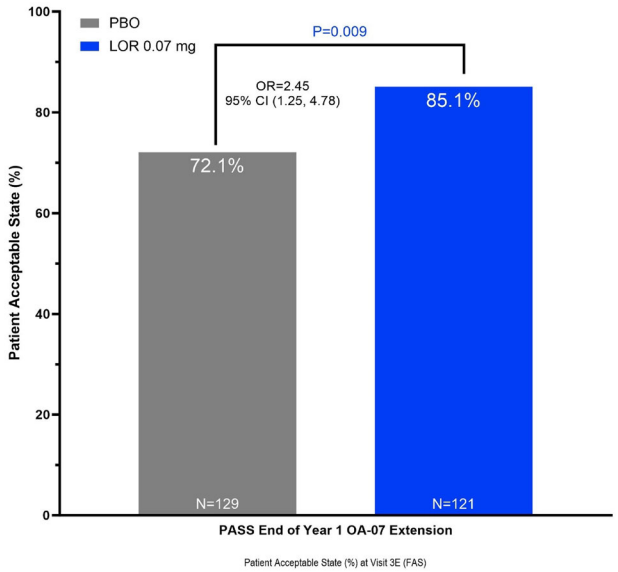


Figure. Patient Acceptable Symptom State between LOR and PBO at End of Year 1 Extension

Conclusion: Compared to PBO, LOR-treated Knee OA patients were significantly more likely to achieve a positive PASS 1 year after a second injection. Pain and function outcomes showed greater improvements for subjects reporting a positive PASS. These data suggest that LOR may provide long-term benefits for knee OA symptoms.

GAUDI STUDY: EFFECTIVENESS OF SPECIALIZED PRO-RESOLVING MEDIATORS SUPPLEMENTATION IN KNEE OSTEOARTHRITIS PATIENTS

J. Vergés[1], I. Möller[2], G. Rodas[3], J. M. Villalón[4], J. A. Rodas[5], F. Angulo[6], N. Martinez[1]

[1]Osteoarthritis Foundation International (OAFI), Barcelona, [2]Institut Poal de Reumatología, Barcelona, [3]FC Barcelona, Barcelona, [4]FC Atlético de Madrid, Madrid, [5]Asturias Football Federation, Avilés, [6]Athletic FC, Bilbao, Spain

Objective: To assess the effectiveness and safety of Specialized Pro-resolving Mediators (SPM) supplementation in reducing knee pain in patients with symptomatic knee osteoarthritis (KOA).
Methods: A randomized, double-blind, pilot study, was conducted on 5 Spanish centers and included adults aged 18–68, both current and former football players diagnosed with KOA at grades 2–4 on the K-L radiological scale. For 12 weeks, the treatment group received SPM-enriched oil supplementation, while the control group received olive oil supplementation. Patients were evaluated using various measures, including the VAS and OMERACT-OARSI score for pain intensity and type, WOMAC index for stiffness and function, EUROQoL-5 for health-related quality of life, and monitoring of concomitant, rescue, and anti-inflammatory medication use.
Results: A total of 51 participants participated in the study. In the treatment group (n = 23), where the mean age was 61.2 y with 52.17% being female, while the control group (n = 28) had a mean age of 57.3 y, with 53.57% females. Most patients had KOA at grade 2 on the K-L scale (73.91% and 67.86% respectively). The SPM group experienced a notable reduction in pain on the VAS after 8 (p = 0.039) and 12 (p = 0.031) weeks compared to the placebo group. Intermittent pain significantly reduced after 12 weeks (p = 0.019) in the SPM group compared to placebo (p = 0.091). Functional status did not change significantly after SPM or placebo consumption. Remarkably, the SPM group showed enhancements in all five aspects of the EUROQoL-5, including a significant improvement in the dimension of usual activities. None of the participants required rescue medication, and no adverse events were reported.
Conclusion: These findings suggest that sustained SPM consumption reduces pain in KOA patients, improving their quality of life, and support the safety and tolerability profile of SPM supplementation.

P676
DEVELOPMENT AND VALIDATION OF PREDICTIVE MODELS FOR HIP OSTEOPOROSIS IN WOMEN USING ELECTRONIC HEALTH RECORDS

J. W. L. Jin[1], S. Z. F. Sheng[1]

[1]Health Management Center, Second Xiangya Hospital of Central South Univ., Changsha, China

Objective: Hip fractures are associated with reduced mobility, morbidity, mortality and high healthcare costs, and approximately 90% of hip fractures in the elderly are associated with osteoporosis, making it particularly important to screen the population for hip osteoporosis and intervene early. DXA) has limited accessibility, so predictive

models for hip osteoporosis that do not use BMD data are essential. We aimed to develop and validate gender-specific hip osteoporosis prediction models using electronic health records (EHRs) without BMD data.

Methods: In this retrospective cross-sectional study, anonymous medical electronic records aged $\geq$ 50 y were exported from the Health Management Center of the Second Xiangya Hospital from September 2013 to November 2023. A total of 8039 women were included in the derivation cohort. The cohort was randomized into a 75% training dataset and a 25% internal test dataset. Using 50 potential predictors (demographic, examination and laboratory data from electronic records), the variables that would ultimately enter the model were selected after parameter selection, and the model was trained using six machine learning (ML) algorithms: logistic regression (LR), decision trees, random forests, xgboost, support vector machines and neural networks, and the model was tuned using five-fold cross-validation. The best model was determined by comparing the performance of the test set.

Results: 8 variables were entered into the model and the xgboost model had the highest AUC 0.8064 (95%CI: 0.7805–0.8322), which was superior to OSTA 0.65 (95%CI: 0.6206–0.6784).

Conclusion: The xgboost model can be integrated into routine clinical workflows to help identify people at high risk of osteoporosis in the hip who require a DXA scan.

P677
ANALYSIS OF RISK FACTORS FOR COMPRESSION RATE PROGRESSION IN OSTEOPOROTIC VERTEBRAL COMPRESSION FRACTURES

J. W. Soh[1], T. J. Jeong[1]

[1]Sahmyook Seoul Medical Center/Orthopaedic Surgery, Seoul, South Korea

Objective: In osteoporotic vertebral compression fractures(OVCF), vertebral body compression often progressed. We analyzed whether there were any factors affecting the progression of the compression rate and also investigated the period when the compression rate progressed the most.

Methods: A retrospective study. Among 76 patients visited with OVCF, excluding 15 patients, 61 patients who could be followed up for more than 6 months were included in this study. The associations between age, gender, fractured level, BMD, BMI, previous osteoporosis medication, initial compression rate, pelvic incidence, and the compression rate progressed by more than 30% at the final follow-up compared to the initial compression were analyzed. In addition, compression rates were measured at the initial, 1st month, 2nd month, and 3rd month, and the time period affecting the compression rate progression was analyzed. Statistical univariate analysis was performed with the Chi-square test and multivariate logistic regression analysis was done by using SPSS 25 ($p < 0.05$).

Results: In univariate analysis, other factors were not associated, but an increase in compression rate was significantly high in cases when the initial compression rate was 30% or more ($p = 0.001$). In multivariate logistic regression analysis, it was analyzed as significant when the initial compression rate was 30% or more ($p = 0.003$, odds ratio = 5.932). Also, with respect to the time period affecting compression rate progression, in univariate analysis, the compression rate at the initial ($p = 0.001$) and 1st month ($p = 0.010$) was significant, and in multivariate logistic regression analysis, the compression rate at 1st month was significant($p = 0.020$, odds ratio = 9.226).

Conclusion: If the initial compression rate was 30% or more, there was a high probability that the compression rate progressed. Also, it was analyzed that the period up to 1st month after the fracture had the most influence on the compression rate progression. When performing conservative treatment of patients with osteoporotic compression fractures, it is considered that these points should be taken into account.

P678
COMMUNITY FRACTURE CAPTURE: A NOVEL ONLINE LEARNING TOOL

A. Elsayed[1], C. Chiang[2], R. Audehm[3], A. Gorelik[4], S. Chang[5], C. Yates[2], S. Snow[6], R. Barmanray[2], S. Price[7], L. Collins[8], J. Wark[9]

[1]Univ. of Melbourne, Dept. of Medicine (Royal Melbourne Hospital), Melbourne, [2]Melbourne Health, Dept. of Diabetes and Endocrinology, Parkville, [3]Univ. of Melbourne, Dept. of General Practice and Primary Care, Melbourne, [4]Monash Univ., School of Public Health and Preventive Medicine, Melbourne, [5]Univ. of Melbourne, School of Computing and Information Systems, Melbourne, [6]Praxhub, Melbourne, [7]Royal Womens Hospital, Obstetric Medicine, Melbourne, [8]Royal Childrens Hospital, Dept. of Endocrinology, Melbourne, [9]Univ. of Melbourne, Dept. of Medicine (Royal Melbourne Hospital), Parkville, Australia

Objective: Osteoporosis treatment initiation post-fragility fracture is a challenging treatment gap. An interactive online Community Fracture Capture (CFC) learning hub is potentially attractive to address it. We aim to further develop a CFC Learning Hub with primary care physicians (PCP) to improve their knowledge and confidence in this topic.

Methods: The CFC Learning Hub is a secure online community site with flexible scheduling, comprising an online discussion forum with case studies contributed by participants and a knowledge repository. The platform allows participants to post questions and comments, receiving guidance from bone specialists and senior PCP facilitators to fulfill each module's learning objectives. It also permits online surveys and utilizes backend analytics to evaluate knowledge, level of activity and engagement, and progress.

Results: Four 6-week small-group cycles involved 55 PCPs [median (IQR) years in practice 22 (16–34) y, over 80% metropolitan-based]. Topic modules covered osteoporosis, treatment, monitoring, and challenging conditions; higher PCP activity was in clinically-applicable themes. In program evaluation (n = 35/55): 91% reported joining the course either to learn from the expert or to improve patient management; 82% were satisfied with the content and the most popular aspects of the learning were small group learning (37%) and live webinars (26%) followed by interactive learning (20%) and on-demand videos (17%); 57% found the platform easy to use. The most popular access times were evening (66%) or weekends (29%). At completion, 89% were likely to recommend the training. Most participants were either entirely (73%) or partly (23%) satisfied that their training needs had been met.

Conclusion: The CFC program was created by bone specialists, PCPs, software engineers, and information technology specialists. This collaboration produced a user-friendly, case-based, interactive, and time-flexible program bridging investigation and management gaps in osteoporosis. It is customized to address challenges faced by PCPs, and also is relevant in diverse health-related and other fields.

COMPARATIVE ANALYSIS OF TERIPARATIDE AND ROMOSOZUMAB IN PREVENTING SYMPTOMATIC SUBSEQUENT VERTEBRAL COMPRESSION FRACTURE AFTER CEMENTING

W.-H. Kao[1], Y.-H. Chiang[1], W.-C. Lo[1], M.-H. Wu[1], J.- H. Jiann-Her[1]

[1]Taipei Medical Univ. Hospital, Taipei, Taiwan

Objective: Subsequent vertebral compression fracture (SVCF) is a common and impactful complication. Because it usually occurs in the subacute phase (< 6 months after cementing of the primary VCF), the timing of prevention is critical. Teriparatide (TP) reduces fracture risk after 6 months but it did not show its effects in the subacute phase. Romosozumab (RM) with a quick onset time has the potential to prevent SVCF in the subacute phase. Our study compares their effectiveness in preventing symptomatic SVCF requiring another operation.
Methods: This retrospective observational study at TMUH includes 226 patients treated with either TP or RM after vertebroplasty or kyphoplasty due to OVCF from January 1, 2021, to June 27, 2023. The characteristics of the patients were reviewed. The primary outcome was a symptomatic SVCF requiring another operation. The secondary outcome was adjacent or non-adjacent fracture.
Results: This study included 118 and 99 patients in TP and RM groups, respectively. Between both groups, we find no significant difference in terms of age, gender, BMI, BMD, and underlying condition including HTN, DM, dyslipidemia, CKD, CAD, autoimmune disease, cancer, COPD, and OVCF at thoracolumbar junction. The rate of SVCF was 4.0% (4/99) in RM group compared to 14.4% (17/118) in TP group with statistically significant difference ($p = 0.01$). The subsequent adjacent fracture rate was 2.0% (2/99) in RM group vs. 11.9% (14/118) in TP group, showing a significant difference ($p = 0.005$). In contrast, no significant difference was observed in the rate of non-adjacent fracture ($p = 0.76$).
Conclusion: RM was associated with reduced symptomatic SVCF compared to TP especially in the subacute phase, highlighting RM's potential advantage in preventing SVCFs on adjacent levels.

P680
A NATURAL LANGUAGE PROCESSING TOOL TO PROMOTE ADHERENCE TO HOME REHABILITATION AFTER TOTAL KNEE ARTHROPLASTY

J.-M. Blasco[1], B. Díaz-Díaz[1], D. Hernández-Guillén[1], J. Pérez-Maletzki[1], S. Roig-Casasús[1], A. Silvestre[2], I. Martínez-Garrido[3]

[1]Universitat de València, [2]Hospital Clinic i Universitari Valencia, [3]Hospital Universitari i Politècnic La Fe de València, Valencia, Spain

Objective: To evaluate the effectiveness of a natural language processing tool (NLPT) in promoting adherence to home rehabilitation after total knee arthroplasty.
Methods: Randomized clinical trial with two groups and participants from two Hospitals in Valencia, Spain (2020–2023) undergoing total knee replacement (TKR). The participants received standard postoperative rehabilitation; the use of an NLPT to assist with home exercises underpinned the difference between the groups. The day before the treatment participants were instructed via chatbot in a personal smartphone on aspects such as length and phases of the treatment. Then, messages were automated and sent every training day with recommendations, videos, and GIFs to instruct participants on how to exercise. Compliance with rehabilitation and clinical measures of function (WOMAC), pain (VAS), and levels of physical activity (IPAQ-E) were compared with CI set at 95%. All participants signed consent to participate. Ethics approval (no.2020/350 and no.2021–001-1) and prospective publication of methods [1].
Results: Overall, 91 participants were randomized and 65 completed the intervention (aged 70 yo.). Adherence was higher in the experimental group [89 vs. 74%; OR95% = 4.1 (1.2 to 14.9)]. Participants in the experimental group presented benefits on self-reported functionality (WOMAC) and increased levels of physical activity (IPAQ-E) with $p < 0.001$ over standard care. However, pain levels were similar among groups after the interventions.
Conclusion: A strategy to promote adherence to rehabilitation based on an automated chatbot was useful to increase adherence with early postoperative home rehabilitation in patients undergoing TKR over standard care. This translated into a better functional performance of participants, although similar benefits on pain to standard care.

P681
CONFRONTING GLUCOCORTICOID-INDUCED OSTEOPOROSIS AND FRACTURES IN PATIENTS WITH RHEUMATOID ARTHRITIS: EXPLORING THE IMPACT OF TEGOPRAZAN AND PROTON PUMP INHIBITORS

J.-Y. Jung[1], J.-W. Kim[1], H.-A. Kim[1], C.-H. Suh[1], Y. J. Choi[2]

[1]Dept. of Rheumatology, Ajou Univ. School of Medicine, Suwon-si, Gyeonggi-do, [2]Dept. of Endocrinology and Metabolism, Ajou Univ. School of Medicine, Suwon-si, Gyeonggi-do, South Korea

Objective: Rheumatoid arthritis (RA) patients commonly use proton pump inhibitors (PPIs) due to long-term glucocorticoid or NSAID use, leading to acid-related gastroesophageal conditions. Recently, tegoprazan, a potassium-competitive acid blocker approved for acid-related diseases, emerged as a commercial alternative to PPIs with a faster onset. However, its impact on bone density and limited research comparing effects to PPIs remain unclear. This retrospective study aims to explore the impact of tegoprazan or PPIs in RA patients at risk of glucocorticoid-induced osteoporosis or fractures.
Methods: We retrospectively collected records of RA patients on current glucocorticoid treatment with a history of tegoprazan or PPI use for at least 3 months. Bone quality was assessed using BMD and TBS through DXA, with osteoporotic fractures confirmed via spinal radiographs.
Results: The study involved 87 patients in the tegoprazan group and 92 in the PPI group. No significant differences in baseline demographics, comorbidities, RA duration, or medication history were observed. Cumulative glucocorticoid doses were similar (tegoprazan 4,049 mg vs. PPI 4,124 mg, $p = 0.918$). Mean 25-(OH)-vitamin D concentrations showed no significant difference (tegoprazan 22.2 ng/ml vs. PPI 19.9 ng/ml, $p = 0.093$). In the evaluation of bone quality, no significant differences were found in baseline TBS (tegoprazan 1.37 vs. PPI 1.365, $p = 0.275$) or BMD at femoral neck ($p = 0.053$) and total hip ($p = 0.077$). No annual percentage changes were observed in TBS, femoral neck BMD, or total hip BMD during follow-up. Baseline L-spine BMD significantly differed between groups ($p < 0.001$), with no annual percentage change. the occurrence of osteoporotic fractures did not differ significantly between the two groups, with rates of 2.6% for tegoprazan and 3.3% for PPIs.
Conclusion: Our study found no significant differences in bone quality or osteoporotic fractures between tegoprazan and PPIs in RA patients at risk of glucocorticoid-induced osteoporosis. Considering

its faster onset and longer duration, tegoprazan could be considered a PPI substitute for acid-related gastroesophageal disease in RA patients.

P682
ASSESSMENT OF MUSCLE MASS AND FUNCTION OF PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

J.-W. Kim[1], J.-Y. Jung[1], C.-H. Suh[1], H.-A. Kim[1]

[1]Dept. of Rheumatology, Ajou Univ. School of Medicine, Suwon, South Korea

Objective: Decreased muscle mass and muscular dysfunction mainly occurs in elderly, relating to various disorders and causing problems. Even most patients with systemic lupus erythematosus (SLE) are young age, chronic inflammation and long-term use of glucocorticoids are known to affect impairment of muscular skeletal structure and function.
Methods: Several muscle mass indexes were measured with a body composition analyzer, physical performance was measured and SARC-F, a screening questionnaire, was investigated from all participants.
Results: There's no difference in age, height, weight, and BMI between 58 SLE patients and 44 HCs, and mean age were 43.3 ± 12.2 and 43.4 ± 11.0 y. Total muscle mass and appendicular lean mass index (aLM) didn't differ between SLE patients with HCs, but aLM/weight levels were significantly lower in SLE patients compared to those in HCs (0.32 ± 0.02 vs. 0.87 ± 0.15 kg/kg, $p < 0.001$). Moreover, grip strength levels significantly were lower in SLE patients compared to those in HCs (24.4 ± 10.2 vs. 28.0 ± 7.3 kg, $p = 0.005$), while walk speed levels were faster in SLE patients compared to those in HCs (4.1 ± 0.5 vs. 3.9 ± 0.5 m/s, $p = 0.01$). 7 (12.1%) patients with SLE were sarcopenia by EWGS, and 2 (3.4%) patients with SLE were sarcopenia by AWGS, and 2 (3.4%) patients reported sarcopenia by SARC-F questionnaire.
Conclusion: Decreased muscle mass and minimal muscular dysfunction were observed in patients with SLE.

P683
EFFICACY AND SAFETY OF CT-P41, A PROPOSED DENOSUMAB BIOSIMILAR, COMPARED TO REFERENCE DENOSUMAB (PROLIA) IN POSTMENOPAUSAL WOMEN WITH OSTEOPOROSIS

J.-Y. Reginster[1], E. Czerwinski[2], A. Strzelecka[3], K. Szymanowski[4], S. Postol[5], A. Poder[6], J. Supronik[7], K. Wilk[2], P. Borowy[2], T. Budlewski[8], M. Janowska-Maus[3], J. Kwiatek[4], S. H. Kim[9], J. H. Suh[9], N. R. Han[9], N. H. Kim[9], S. H. Bae[9], S. L. Silverman[10]

Komandytowa—Lodz, Lódz, Poland, [4]Centrum Medyczne Poznan—PRATIA, Skórzewo, Poland, [5]Medical Center of Medbud—Clinic LLC, Kyiv, Ukraine, [6]Clinical Research Centre Ltd, Tartu, Estonia, [7]Osteo Medic SC Artur Racewicz Jerzy Supronik, Bialystok, Poland, [8]Dept. of Rheumatology, Medical Univ. of Lodz, Lodz, Poland, [9]Celltrion, Inc., Incheon, South Korea, [10]OMC Clinical Research Center and Cedars Sinai Medical Center, Beverly Hills, USA

Objective: To demonstrate similar efficacy, safety, and immunogenicity of CT-P41 and Prolia in postmenopausal women with osteoporosis (PMO).
Methods: This was a double-blind, active-controlled, Phase 3 study (NCT04757376) in PMO with lumbar spine BMD (LS-BMD) T-score of ≤ − 2.5 to ≥ − 4.0. A total of 479 patients were randomized (1:1) to receive 60 mg of CT-P41 or Prolia every 6 months. The primary efficacy endpoint was the percent change from baseline (%CFB) in LS-BMD at Week 52. The secondary efficacy endpoints were the %CFB in LS-BMD and in BMD at total hip (TH) and femoral neck (FN) and fracture incidence. Safety and immunogenicity were monitored during the study. Here, the results up to Week 52 in the CT-P41 and Prolia groups are presented.
Results: The therapeutic equivalence was demonstrated between the CT-P41 and Prolia groups in the mean %CFB in LS-BMD at Week 52 with 95%CIs for the treatment difference which was entirely within the predefined equivalence margins (± 1.503%) (Table 1). The mean %CFB in BMD for LS, TH, and FN increased after each dosing and were comparable between groups. A new vertebral fracture was reported for 1 patient each at Week 26 in both groups. There was no hip fracture reported and the incidence of nonvertebral fracture was similar between groups (CT-P41: 0.8%; Prolia: 1.7%). The incidence of adverse events (AEs) (CT-P41: 75.7%; Prolia: 70.2%) and serious AEs (CT-P41: 2.9%; Prolia: 4.2%) were similar between groups. Most AEs were Grade 1 or 2 and were not related to study drugs. Most patients had at least one anti-drug antibody (ADA) positive result due to the sensitive assay but most of the ADA titer values were low. There was no patient with a positive neutralizing antibody result.

Table 1. Percent Change from Baseline in BMD for Lumbar Spine by DXA at Week 52 (ANCOVA)

Analysis Set Group	n / N	LS Mean (SE)	LS Mean Difference	95% CI of LS Mean Difference	Mean difference and 95% CI (CT-P41 – Prolia)
Full Analysis Set					
CT-P41	222 / 239[1]	4.9317 (0.31508)	-0.139	(-0.826, 0.548)	-0.826, 0.548
Prolia	212 / 238[1]	5.0706 (0.32714)			
Per-protocol Set					-0.973, 0.414
CT-P41	215 / 215[2]	5.0330 (0.31640)	-0.280	(-0.973, 0.414)	
Prolia	202 / 202[2]	5.3125 (0.33505)			-1.503% 0 +1.503%

Abbreviation: ANCOVA, analysis of covariate; BMD, bone mineral density; CI, confidence interval; DXA, dual-energy X-ray absorptiometry; LS, least square; SE, standard error.
1. The number of patients who had a BMD assessment result for lumbar spine by DXA at Week 52 / The number of patients in full analysis set.
2. The number of patients who had a BMD assessment result for lumbar spine by DXA at Week 52 / The number of patients in per-protocol set.

Conclusion: The therapeutic equivalence of efficacy was demonstrated between the CT-P41 and Prolia in PMO. The secondary efficacy, safety, and immunogenicity results supported the similarity of CT-P41 and Prolia. CT-P41 was well tolerated with a safety profile comparable to that of Prolia.
Disclosures:

Incheon, South Korea, [10]OMC Clinical Research Center and Cedars Sinai Medical Center, Beverly Hills, USA

Objective: To demonstrate similar pharmacokinetics (PK) and pharmacodynamics (PD) of CT-P41 compared with Prolia in post-menopausal women with osteoporosis (PMO).
Methods: This was a double-blind, active-controlled, Phase 3 study (NCT04757376) in PMO with lumbar spine BMD (LS-BMD) T-score of ≤ -2.5 to ≥ -4.0. A total of 479 patients were randomized (1:1) to receive 60 mg of CT-P41 or Prolia every 6 months. The primary PD endpoint was the area under the effect curve (AUEC) of serum C-terminal cross-linking telopeptide of type I collagen (s-CTX) over the first 6 months. The secondary PD endpoints were the AUEC of procollagen type I N-terminal propeptide (P1NP) over the initial 6 months and the percent change from baseline (%CFB) of s-CTX and P1NP at Weeks 26, 52, and 78. The secondary PK endpoints included PK parameters over the first 6 months, trough serum concentration (C_{trough}), and serum concentration of denosumab up to Week 78. Here, the results up to Week 52 in the CT-P41 and Prolia groups are presented.
Results: The PD similarity was demonstrated between the CT-P41 and Prolia groups in the AUEC of s-CTX over the first 6 months with 95%CIs for the ratio of the geometric least square mean which was entirely within the predefined equivalence margins (80% to 125%) (Table 1). The mean AUEC of P1NP and the median %CFB for serum concentration of s-CTX and P1NP were also similar between groups. The PK parameters including maximum serum concentration (C_{max}), truncated area under the concentration–time curve from time zero to Week 26 ($AUC_{0\text{-}t}$), time of observed maximum serum concentration (T_{max}), volume of distribution (V_d), and terminal elimination half-life ($T_{1/2}$) over 26 weeks after the first dosing, C_{trough}, and serum concentration of denosumab were comparable between groups.

Table 1. Area Under the Effect Curve of s-CTX (day*%) over the Initial 6 Months (ANCOVA): Full Analysis Set

Group	n / N[1]	Geometric LS Mean	Geometric LS Mean Ratio	95% CI of Geometric LS Mean Ratio	Mean Ratio and 95% CI (CT-P41 / Prolia)
CT-P41	227 / 239	13835.3915	94.94	(90.75, 99.32)	0.9075 0.9932
Prolia	221 / 238	14572.6010			0.8 1 1.25

Abbreviation: ANCOVA, analysis of covariance; AUEC of s-CTX, area under the effect curve of serum carboxy-terminal cross-linking telopeptide of type I collagen over the initial 6 months (from Day 1 predose to Week 26 predose); CI, confidence interval; LS, least squares.
1. The number of patients who had the result of AUEC of s-CTX / The number of patients in full analysis set.

Conclusion: The equivalence of PD was demonstrated and the comparable PD results for the secondary PD endpoints supported the similarity of CT-P41 and Prolia. The PK profiles of CT-P41 were comparable to those of Prolia in PMO.

P685
DEVELOPMENT OF PREDICTION MODEL FOR 1-YEAR MORTALITY AFTER HIP FRACTURE SURGERY

K. Alexiou[1], A. Koutalos[1], S. Varitimidis[1], T. Karachalios[1], K. Malizos[1]

[1]Univ. General Hospital of Larissa, Larissa, Greece

Objective: Hip fractures in the older persons have been associated with a lower quality of the patient's life, increased morbidity and mortality. The primary aim of this study is to identify risk factors of mortality at twelve months after surgery for hip fracture and construct a prognostic index serve at the decision making pre-operatively. Secondary outcomes include the evaluation of functional outcomes and quality of life after at one year after surgery for hip fractures.
Methods: This was a cohort retrospective study with prospectively collected data. The data have been prospectively collected in a tertiary care National Health System academic hospital and in a remote secondary care public hospital. Informed consent was obtained from all individual participants included in the study. From August 2013 to August 2016, 669 patients with hip fractures were treated in the tertiary hospital and another 169 patients were treated in the secondary hospital. 72 patients in the tertiary hospital and 22 in the secondary hospital did not show-up at the follow-up or could not be traced by telephone. So, the data from 597 patients of the tertiary hospital and 147 patients of the secondary hospital were available for analysis. Patient's demographics, functional and cognitive pre-fracture status, together with quality of life assessment and the peri-operative data were retrieved from the hospitals' medical records for retrospective analysis. Inclusion criteria included all patients above 65 years of age, that were admitted to hospital with a fragility or geriatric hip fracture. Pathological and high energy fractures were excluded. All surgeries were performed from or under the supervision of 14 trauma surgeons. The perioperative data were collected from medical charts and interviews. Functional Assessment Measure score, Short Form-12 and mortality were recorded at 12 months. Patients and surgery variables that were associated with increased mortality were used to develop a mortality index.
Results: In-hospital mortality was 2.4%. Mortality for the whole cohort was 19.4% at one year. In the tertiary hospital mortality was 18.3% while in the secondary it was 23.0%. Functional outcome at one year was similar to preoperative status, even though their level of physical function dropped after the hip surgery and slowly recovered. From the variables tested BMI < 25, age > 80, CCI > 6, time to surgery > 48 h, ASA ≥ 3, use of anti-coagulants and male sex was associated with increased mortality. Regression coefficients were used to construct a hip fracture mortality index with minimum value of 0 and a maximum value of 13. The higher points in the mortality index were attributed to the ASA score and CCI index (four and three respectively). A patient with a value of 8 to 10 is considered average risk (20–30% probability of death at one year). ROC curve was constructed for the prediction model. AUC was calculated at 0.814 (CI 95%, 0.769–0.859, $p < 0.001$) which is considered as excellent discrimination.
Conclusion: The mortality prediction model that was developed in this study calculates the risk of death at one year for patients with hip fractures. It is simple and could be implemented in everyday clinical practice. This index, however, cannot affect or modify the treatment management of hip fractures which is based on early surgery. Nonetheless, it could possibly detect high risk patients so appropriate management is initiated early. Furthermore, it is a useful tool for advising patients and caregivers.

P686
PREVALENCE OF GERIATRIC SYNDROMES IN PATIENTS 60 YEARS AND OLDER WITH VERTEBRAL FRACTURE

K. Belova[1], K. Gordzheladze[2], L. Shubin[1]

[1]Yaroslavl State Medical Univ., [2]Yaroslavl Regional Emergency Care Hospital n.a. N.V. Solovyev, Yaroslavl, Russia

Objective: To study the prevalence of geriatric syndromes (GS) in patients 60 years and older with clinical vertebral fracture.
Methods: We investigated all patients (n = 42) with a vertebral fracture aged 60 years and older who were admitted to Yaroslavl Regional Emergency Care Hospital n.a. N.V. Solovyev from 1.04.2021 to 1.09.2021. To assess the prevalence of major GS, we used the following scales: Barthel activities daily living index,

Lawton instrumental activities of daily living scale, National validated questionnaire for identification of frailty "Age is not a hindrance", Morse Fall Scale, SARC-F questionnaire, Mini-Cog test, Mini Nutritional assessment, visual analogue scale (VAS), Overactive Bladder Questionnaire Short Form, Geriatric depression scale, Insomnia Severity Index.
Results: The mean age of the patients was 69,7 ± 5,28 y. Using Barthel scale, we recognized that 36 (85,7%) patients were independent on assistance, 2 (4,76%) were mildly and 4 (9,52%) – moderately dependent. For complex activities (Lawton scale), 36 (85,7%) were independent on assistance. Frailty was detected in 2 (4,7%) patients, 8 (19,0%). patients had pre-frail condition. Probable sarcopenia was revealed in 10 (23,8%) patients. Malnutrition was detected in 1 (2,4%) patient. A high risk of falls was noted in 23 (54,8%) patients. Depression was detected in 13 (31,0%) respondents. Chronic pain syndrome disturbed 17 (40,5%) patients. Nicturia was detected in 27 (64,3%) patients, stress urinary incontinence in 1 (2,4%), combined urinary disorders in 2 (4,8%). Mild sleep disturbances were revealed in 10 (23,8%) patients, moderate and severe – in 2 (4,8%) in both cases. 16 (38,1%) patients had visual impairments, 11 (26,2%) had hearing problems. Generally, among all the hospitalized patients with vertebral fractures only 2 (4,8%) didn't have any GS, 22 (52,4%) had 1–2 GS, 7 (16,7%) had 3–4 GS, and 11 (26,2%) patients had ≥ 5 GS.
Conclusion: The results of this study confirm the high prevalence of GS in elderly patients with vertebral fracture.

P687
CORRELATION BETWEEN POLYPHARMACY AND GERIATRIC SYNDROMES IN PATIENTS 60 YEARS AND OLDER WITH HIP FRACTURE

K. Belova[1], K. Gordzheladze[2], M. Belov[3], L. Shubin[1]

[1]Yaroslavl State Medical Univ., [2]Yaroslavl Regional Emergency Care Hospital n.a. N.V. Solovyev, [3]Yaroslavl State Medical Univ., Yaroslavl Regional Emergency Care Hospital n.a. N.V. Solovyev, Yaroslavl, Russia

Objective: To assess polypharmacy in patients 60 years and older with a hip fracture and its correlation with the presence and severity of geriatric syndromes (GS).
Methods: We assessed all the patients (n = 140) with a hip fracture aged ≥ 60 y admitted to Yaroslavl Regional Emergency Care Hospital n.a. N.V. Solovyev from 1.04.2021 to 1.07.2021. To reveal major GS we used: Barthel activities daily living index, Lawton instrumental activities of daily living scale, National validated questionnaire for frailty "Age is not a hindrance", Morse Fall Scale, SARC-F questionnaire, Mini-Cog test, Mini Nutritional assessment, visual analogue scale (VAS), Overactive Bladder Questionnaire Short Form, Geriatric depression scale, Insomnia Severity Index. Statistical analysis was performed using Spearman's rank correlation coefficient.
Results: The mean age of patients was 81.3 ± 7.67 y (in women 82.5 ± 6.54 y, in men 75.86 ± 10.81 y). 22 (15,7%) patients were not interviewed due to severe dementia. Polypharmacy (taking 5 or more drugs before the hospitalization) was detected in 26 (21.3%) respondents. There was a strong correlation between polypharmacy and the presence of chronic pain (0.94), sarcopenia (0.87), urinary dysfunction (0.86), high risk of falls (0.83), malnutrition (0.79), depression (0.74), pre-frailty/frailty (0.72), insomnia (0.72), cognitive impairment (0.72), and an average correlation with high risk of falls (0.69). There was a strong correlation between polypharmacy and the severity of chronic pain (0.72), a moderate correlation with the severity or intensity (considering the number of points according to the questionnaires) of sarcopenia (0.62), frailty (0.59), malnutrition (0.58), insomnia (0.58), depression (0.56), cognitive impairment (0.51), risk of falls (0.66).
Conclusion: A moderate or strong correlation was found between polypharmacy and the presence, as well as the severity of most GS in patients with a hip fracture 60 years and older.

P688
CLINICAL OUTCOME OF PHYSICAL THERAPY FOR PATIENTS WITH PARTIAL ROTATOR CUFF TEAR

D. Simić-Panić[1], K. Bošković[2], S. Pantelinac[1], A. Knežević[1], D. Popović[1], S. Tomašević-Todorović[1]

[1]Faculty of Medicine, Univ. of Novi Sad, Medical Rehabilitation Clinic, Clinical Centre of Vojvodina, [2]Faculty of Medicine, Univ. of Novi Sad, Special Hospital for Rheumatic Diseases, Novi Sad, Serbia

Objective: To determine the effectiveness of therapeutic exercises and physical modalities (low-level laser therapy and transcutaneous electrical nerve stimulation) on the recovery of patients with symptomatic partial rotator cuff tears.
Methods: A prospective observational cohort study was conducted in an outpatient setting in Medical Rehabilitation Clinic, Clinical Centre of Vojvodina, Novi Sad, Serbia from June 1, 2022, to December 31, 2022. A total of 30 patients with clinically and radiologically diagnosed partial rotator cuff were included in the study. Patients were blindly randomized into two groups. The first group received TENS and therapeutic exercises while the second group received low-level laser therapy and therapeutic exercises. Outcome measures were patients' visual analog scale pain score, Western Ontario Rotator Cuff Index score, and the Shoulder Pain and Disability Index score at the baseline and after 6 weeks of treatment.
Results: Statistical analysis indicated a significant reduction in visual analog pain score (6.9 ± 1.04 vs. 3.6 ± 1.02), and improvement in Western Ontario Rotator Cuff Index score (63.8 ± 3.36 vs. 72.6 ± 2.64), and the Shoulder Pain and Disability Index score (75.1 ± 6.85 vs. 63.7 ± 0.64) (P value < 0.001) after the rehabilitation treatment. A comparison of the two treatment methods between groups did not reveal any significant differences (P value > 0.05). Low-level laser therapy combined with therapeutic exercises was associated with a greater improvement in pain intensity and TENS combined with therapeutic exercise with a greater improvement in functionality.
Conclusion: Using low-level laser therapy and TENS in addition to therapeutic exercise for the treatment of partial rotator cuff tears appears to be equally effective in terms of pain relief and functional improvement.

P689
EVALUATION OF BONE MINERAL DENSITY OF TRANSGENDER WOMEN IN SOUTHERN BRAZIL

K. Chrisostomo[1], N. Sandrim[2], T. Skare[3], R. Nisihara[3]

[1]Federal Univ. of Paraná, [2]Catholic Univ. of Paraná, [3]Mackenzie Evangelical College of Paraná, Curitiba, Brazil

Objective: To evaluate BMD and body composition of Brazilian transwomen (TW) undergoing cross-sex hormone therapy (CSHT) for 3 y or more, comparing with control groups of cisgender women and cisgender men.
Methods:

- Cross-sectional observational study, through the collection of sociodemographic, epidemiological and clinical data

- Performing bone mineral densitometry and total body bone densitometry exams with the LUNAR PRODIGY ADVANCE DXA SYSTEM – Encore version 14.10, Radiation Corporation, Madison, WI. GE Healthcare dual beam system
- The study was carried out in the city of Curitiba, Paraná, Brazil from August 2018 to August 2019
- After recruitment and application of the inclusion and exclusion criteria, 31 TW treated at the Center for Research and Assistance for Transvestites and Transsexuals (CPATT) and at the Regional Specialties Center (CRE) of the Health Department of the state of Paraná agreed to participate in the study and signed the free and informed consent form
- Two control groups matched by age, BMI and lifestyle habits, with 31 cisgender women and 31 cisgender men, totaling 93 participants
- Data analyzed using the GraphPad Prism 6 program, San Diego, CA

Results:

- The BMD of TW is lower than that of matched groups; 12.9% of TW had low bone mass (Z score $\leq$ 2), this percentage was 3.2% for cisgender women and 3.3% for cisgender men
- TW had a lower Z-score, both for the spine (0.26 $\pm$ 1.42 vs. 0.50 $\pm$ 1.19) and the femur (-0.41 $\pm$ 0.95 vs. 0.29 $\pm$ 1.04) than cisgender women
- When compared to cisgender men, TW had a lower total femur Z-score (-0.41 $\pm$ 0.95 vs. 0.20 $\pm$ 0.83)
- Higher values of lean mass were positively correlated with total femoral BMD (p = 0.40; 95%CI = 0.009–0.68; p = 0.04) and femoral neck BMD (p = 0.48; 95%CI = 0.11–0.74; p = 0.01)
- Neither the type of therapy received nor its duration of use had any impact on bone mass

Conclusion: Low BMD is frequently found in TW and that this is related to lean body mass, which corroborates the need for more studies on the effects of hormonal therapy on the bones and muscles of TW.

P690
STUDY OF PEAK BONE MASS IN YOUNG HEALTHY ADULTS

K. E. Akhiiarova[1], R. I. Khusainova[2], A. V. Tyurin[1]

[1]Bashkir State Medical Univ., Internal Medicine Dept., [2]Bashkir State Medical Univ., Medical Genetics Dept., The National Endocrinology Research Centre, Laboratory of Genomic Medicine, Ufa, Moscow, Russia

Objective: Peak bone mass (PBM) is the amount of bone tissue that has been formed by the time of stable skeletal condition at a young age. The assessment of BMD in young people is of interest, since the reference values of BMD (aBMD), as well as their "normal" maximum (peak) values, are practically not described in the literature. PBM is an important predictor of the occurrence of primary osteoporosis. The purpose of this study was to analyze the values of aBMD in young people.
Methods: A single-stage noninvasive descriptive study was conducted among young healthy people (N = 84, male N = 10) without diseases and risk factors affecting bone metabolism. The mean age was 26.04 $\pm$ 1.34 y. aBMD was assessed in various parts of the body by X-ray absorptiometry with determination of absolute values (g/cm^2).
Results: At the first stage, gender groups were formed. The mean values of aBMD in men exceeded the values of women, since men tend to have a more massive skeleton. The greatest differences in aBMD in the groups of men and women were found for trunk aBMD (0.80 $\pm$ 0.01 vs. 1.09 $\pm$ 0.06) and lower extremities (1.04 $\pm$ 0.03 vs. 1.21 $\pm$ 0.04), but no statistical significance was achieved (Fig. 1). Further, aBMD was evaluated on the general sample. The analysis of aBMD in the general sample showed that the highest values were observed in the lower extremities (1.15 $\pm$ 0.02) and pelvis (1.08 $\pm$ 0.02), the lowest values in the upper extremities (0.86 $\pm$ 0.01), and the total aBMD in absolute values was 1.16 $\pm$ 0.01 g/cm^2. The value of the total aBMD for young men and women may correspond to PBM.

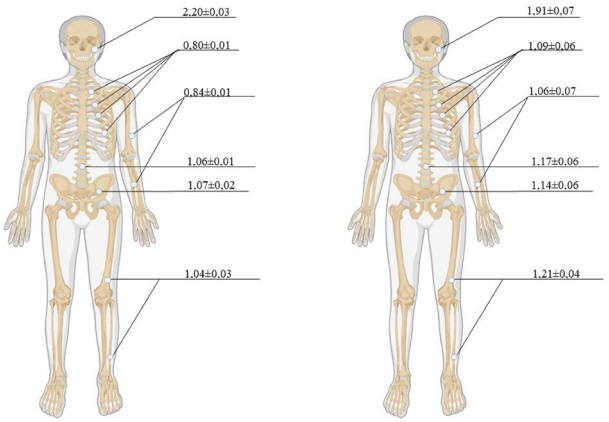

Figure 1. Distribution of aBMD values in men (right) and women (left) relative to body parts (g/cm^2)

Conclusion: The total aBMD in absolute values was 1.16 $\pm$ 0.01 g/cm^2, male – 1.30 $\pm$ 0.03, female –1.15 $\pm$ 0.01. The obtained values of total aBMD for young healthy men and women may correspond to peak values of bone mass.

P691
SIGNIFICANCE OF RECENT FRACTURE LOCATION FOR IMMINENT RISK OF HIP AND VERTEBRAL FRACTURES: A NATIONWIDE COHORT STUDY ON OLDER ADULTS IN SWEDEN

K. F. Axelsson[1], H. Litsne[2], M. Lorentzon[2]

[1]Geriatric Medicine, Institute of Medicine, Sahlgrenska Academy, Gothenburg Univ., Skövde, [2]Geriatric Medicine, Institute of Medicine, Sahlgrenska Academy, Gothenburg Univ., Mölndal, Sweden

Objective: Hip and vertebral fractures are the most serious in terms of associated morbidity, mortality, and societal costs. There is limited evidence as to which recent fracture sites are associated with the highest risk for subsequent hip and vertebral fractures. This study aimed to determine which recent index fracture sites are most strongly associated with imminent risk of hip and vertebral fracture.
Methods: Conducted as a nationwide retrospective cohort study, we utilized Swedish national registers to assess the risk of hip and vertebral fractures based on the site of the recent ($\leq$ 2 y) index fracture, and an old (> 2 y) prevalent fracture. This risk was compared to that observed in individuals without any prevalent fractures. This study encompassed all Swedes aged 50 years and older between 2007–2010, included in a previously collected cohort, used to investigate the association between recent fracture and risk of any fracture and major osteoporotic fracture (Axelsson et al. JBMR 2023). Patients with a recent fracture were categorized into specific groups based on the type of their previous fracture and were followed until December 2017, with censoring for death and migration. The study

assessed the risk of hip and vertebral fractures during the follow-up period.

Results: The study included a total of 3,423,320 individuals, comprising 145,780 with a recent fracture, 293,051 with an old fracture, and 2,984,489 without a previous fracture. The median follow-up times for the three groups were 7.6 y (IQR 4.0–9.1), 7.9 y (5.8–9.2), and 8.5 y (7.4–9.7), respectively. Patients with a recent fracture at all sites exhibited a significantly increased risk of vertebral fracture, whilst most (32 out of 36) index fracture sites were associated with an increased risk of hip fracture compared to controls (Figure).

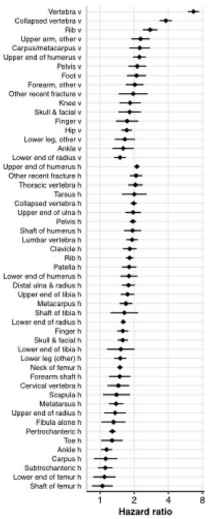

Figure. Risk of incident vertebral (top third) and hip (lower thirds) fracture. Adjusted hazard ratios per site of recent fracture (≤2 y), categorized in subgroups compared to patients with no previous fracture. The Cox model is adjusted for age, sex, inclusion year, osteoporosis medication, multiple recent fractures, and Charlson comorbidity index.

Conclusion: With a few exceptions, patients with recent fractures had an increased risk of subsequent hip and vertebral fractures independent of the index fracture site. These results strengthen the notion that all patients with a recent fracture, regardless of fracture site, should be included in secondary prevention programs, to improve the prevention of the clinically most serious fractures.

P692
GENDER DIFFERENCES FOR SARCOPENIA IN PATIENTS UNDERGOING TOTAL KNEE ARTHROPLASTY FOR ADVANCED KNEE OSTEOARTHRITIS

K. G. B. Kim[1], J. J. Y. Jung[2]

[1]Yeungnam Univ. College of Medicine, Daegu, [2]Gumi CHA Univ. Medical Center, Gumi, South Korea

Objective: To compare gender differences in the incidence of sarcopenia, demographic characteristics, and preoperative sarcopenic parameters in patients undergoing TKA for advanced knee osteoarthritis (OA). Moreover, we sought to compare patient-reported outcome measures (PROMs) and the predisposing factors after TKA in patients with sarcopenia by gender through subgroup analysis.

Methods: From May 2020 to September 2022, a total of 892 patients were enrolled in whom body composition, strength, and physical performance could be measured prior to primary TKA. Sarcopenia was defined according to the Asian Working Group for Sarcopenia 2019 criteria. Patients were assessed according to the presence or absence of sarcopenia. After a two-to-one matched pair analysis for subgroup analysis, 21 knees in male were matched with a corresponding number of knees in female (42), resulting in a total of 63 knees. PROMs were investigated using the Knee Injury and Osteoarthritis Outcome Score, Western Ontario and McMaster Universities Osteoarthritis Index, and the Short Form-12 physical and mental component summary scores. Moreover, postoperative complications and predisposing factors for male sarcopenia were investigated.

Results: The prevalence of sarcopenia was 10.9%, and the prevalence was higher in men (19.6%) than in women (9.7%). In subgroup analyses, male patients had significantly inferior PROMs up to 12 months after index surgery. Moreover, there was no significant difference in systemic complications between the two groups. Multivariate binary logistic regression analysis indicated that alcohol, smoking, and higher modified Charlson Comorbidity Index (mCCI) were predisposing factors for male patients with sarcopenia.

Conclusion: The prevalence of sarcopenia was higher in male patients undergoing primary TKA. When compared with the propensity-matched female group, male patients had inferior PROMs up to 12 months postoperatively. Alcohol, current smoker, and higher mCCI were predisposing factors for sarcopenia in male patients with advanced knee OA.

P693
SCREENING FOR SARCOPENIA AND SARCOPENIC OBESITY IN THE ORTHOPEDIC SURGERY CLINICAL SETTING: A PILOT STUDY

K. Godziuk[1], I. Hollyer[2], G. Loughran[2], N. Giori[2]

[1]Univ. of Alberta, Edmonton, Canada, [2]Stanford Univ., Palo Alto, USA

Objective: Sarcopenia [low strength with low muscle mass] and sarcopenic obesity (SO) [low strength, low muscle and higher fat mass] may increase surgical complications and impact recovery, function and quality of life after total joint arthroplasty (TJA). New consensus approaches for sarcopenia and SO identification are available. We assessed the feasibility of screening and identifying these conditions in orthopedic practice using published consensus criteria.

Methods: Individuals age > 40 y attending a lower extremity arthroplasty clinic were screened for sarcopenia using the EWGSOP2 criteria, or SO using the European Society for Clinical Nutrition and Metabolism and European Association for the Study of Obesity (ESPEN/EASO) criteria when BMI was ≥ 30 kg/m^2. Low strength + low muscle were required for identification of sarcopenia and SO. Strength screening involved maximal handgrip in one hand (HGS) and number of chair sit-to-stands in 30 s (CSTS). Low HGS [< 20 kg in females (F) or < 30 kg in males (M)] or low CSTS [< 10] defined low strength. Low strength patients were referred for same-day DXA assessment of appendicular lean soft tissue (ALST). Low muscle was confirmed by low ALST/height^2 [< 5.45 m^2 F, < 7.26 m^2 M] for sarcopenia or low ALST/weight [$< 19.4\%$ F, $< 25.7\%$ M] for SO.

Results: N = 101 patients (93% male, mean age 69.6 ± 8.9 y, BMI 31.7 ± 7.9 kg/m^2) were screened Dec2022-Feb2023. HGS was completed in 99% of patients (1 had cervical compression impacting grip). 44.5% completed CSTS (non-completion due to joint pain = 36, inability to stand without hands = 6, imbalance = 7, vertigo/hypotension = 3, stiffness = 1, other = 3). 39 patients had low strength (low HGS = 30, CSTS = 17, both HGS + CSTS = 8) and were recommended for DXA; 17 agreed (completed = 16, DXA unavailable = 1) and 22 declined (unable to stay = 15, uninterested = 7). In 16 patients with complete screening, 3 had sarcopenia and 5 had SO.

Conclusion: Low strength assessment was feasible using HGS but not CSTS, supporting that alternatives for low strength assessment are

needed in orthopedic patients. DXA completion was limited by same-day appointments, impacting screening uptake. In patients with complete screening, 50% had sarcopenia or sarcopenic obesity. Future work should identify the cost-effectiveness of screening and whether interventions for sarcopenia or sarcopenic obesity can improve TJA outcomes.

P694
FEASIBILITY, ACCEPTABILITY, AND EFFECTIVENESS OF THE POMELO [PREVENTION OF MUSCLE LOSS IN OSTEOARTHRITIS] PROGRAM FOR INDIVIDUALS WITH OBESITY

K. Godziuk[1], F. Vieira[1], J. Mota[2], J. Werle[3], M. Forhan[4], C. Prado[1]

[1]Univ. of Alberta, Edmonton, Canada, [2]Federal Univ. of Goias, Goias, Brazil, [3]Univ. of Calgary, Calgary, Canada, [4]Univ. of Toronto, Toronto, Canada

Objective: Improving physical function and body composition [i.e., preserving muscle while reducing fat mass] should be prioritized in adults with osteoarthritis (OA) and obesity to prevent functional decline. We examined the feasibility, acceptability, and effectiveness of a multimodal weight-neutral behavioural intervention to improve these factors in a pilot trial of adults aged $\geq$ 40 with advanced knee OA and BMI $\geq$ 35 kg/m^2.
Methods: Prevention Of MusclE Loss in Osteoarthritis [POMELO] is a two-arm pilot randomized trial conducted September 2021-July 2023 (clinical trials.gov identifier NCT05026385). Participants were randomized 1:1 to receive usual care (UC), following clinical care standards, or POMELO intervention. POMELO was a 3-month personalized program of supervised progressive whole-body resistance exercise (3x/week), a nutrition consultation, and 12-weekly group education sessions on nutrition and arthritis self-management, followed by 6-months of unsupervised maintenance. Assessments included DXA [fat mass, appendicular lean soft tissue (ALST)], strength and physical function [maximal handgrip (HGS), 6-min walk (6MWT), 30-s chair-sit-to-stand (CSTS)], and health-related quality of life [EQ-5D VAS] at baseline and 9-months. Feasibility was determined by intervention completion $\geq$ 80% and adherence $\geq$ 60% (i.e., attendance at 12-sessions, exercise 3x/week). Acceptability was assessed with a 4-point Likert-scale satisfaction survey.
Results: 32 individuals completed the study (16/group), 69% female, mean age of 64.9 $\pm$ 1.2 y, and BMI 42.1 $\pm$ 1.0 kg/m^2. POMELO completion was 80% with 70% adherence and no adverse events. Higher satisfaction rates in POMELO vs. UC (3.4 vs. 2.2, $p < 0.001$) indicated acceptability. POMELO was more effective in improving 6MWT, CSTS, and HGS compared to UC ($p = 0.05, < 0.001, 0.02$, respectively), and shows promise to improve ALST and quality of life ($p = 0.19, 0.15$, respectively).
Conclusion: The personalized multimodal POMELO intervention may confer greater positive impacts on patients' mobility and health compared to usual care for advanced knee OA. A larger study is needed to confirm findings.

P695
USING ADDITIONAL STABILIZATION METHODS OF MEDIAL MENISCUS EXTRUSION CAUSED BY MEDIAL MENISCUS ROOT TEAR

O. Buryanov[1], K. Honchar[2]

[1]Bogomolets National Medical Univ., Dept. of traumatology and orthopedics, [2]Bogomolets National Medical Univ., Kyiv, Ukraine

Objective: Extrusion of the medial meniscus is a common problem in arthroscopic operations for medial meniscal root tears. Numerous surgical techniques permit the restoration of the anatomical position of the medial meniscus root, however, without supplementary fixation of the meniscus, they do not permit the reduction of extrusion. The aim of the study is to evaluate the results of treatment for patients with medial meniscus root and extrusion using additional methods of meniscus stabilization.
Methods: 20 patients with medial meniscal root tears were included. The diagnosis was confirmed by an MRI. Patients were divided into 2 groups. The main group included patients with suture of the medial meniscus root with using additional stabilization suture under arthroscopic control (n = 10), and the comparison group—suture of medial meniscus root without using additional stabilization methods (n = 10). Meniscal extrusion was assessed by MRI before the operation and 6 months after surgery.
Results: The extrusion of the medial meniscus in the main group and the comparison group was evaluated by preoperative MRI. The average value of extrusion distance before surgery was obtained 4.4 $\pm$ 0.6 mm ($p < 0,05$) for main and comparison groups. Patients in the main group underwent meniscal root repair surgery with an anatomic transtibial tunnel pullout technique with peripheral stabilization suture through an additional transtibial tunnel at the apex of the posterior horn under arthroscopic control. Patients in the control group were performed meniscal root repair surgery with an anatomic transtibial tunnel pullout technique under arthroscopic control. 6 months after surgery, the extrusion distance of the main group was 2.6 $\pm$ 0.4 mm and 3.5 $\pm$ 0.4 mm ($p < 0.05$) of the comparison group.
Conclusion: The additional stabilization methods for medial meniscal extrusion associated with medial meniscus root tear improved the results of treat extrusion distance of medial meniscus. This method may help prevent additional extrusion of the meniscal tissue outside the joint.

P696
ENHANCED ANALGESIC EFFICACY OF PREEMPTIVE LOW-DOSE KETOROLAC VERSUS PARECOXIB FOLLOWING TOTAL KNEE ARTHROPLASTY: A RETROSPECTIVE PROPENSITY SCORE MATCHING STUDY

K. Iamthanaporn[1], N. Rojjanasirisawat[1], V. Yuenyongviwat[1]

[1]Dept. of Orthopedics, Faculty of Medicine, Prince of Songkla Univ., Songkhla, Thailand

Objective: Total knee arthroplasty (TKA) commonly induces substantial postoperative pain necessitating effective management for optimal recovery. NSAIDs are frequently employed, but the choice of NSAID and dosing regimen significantly influences outcomes.

Methods: This retrospective cohort study, conducted from January 2016 to December 2020, scrutinized TKA patients segregated into two groups: those administered preemptive low-dose ketorolac (15 mg, followed by 15 mg every 6 h for 48 h) and those given parecoxib (40 mg every 12 h for 48 h). Pain scores, opioid consumption, and adverse events were evaluated.
Results: Ketorolac exhibited superiority over parecoxib, with markedly lower Visual Numeric Rating Scale (VNRS) scores reported at 8 and 20 h post-surgery. Linear mixed models affirmed this advantage ($p = 0.0084$). Ketorolac also correlated with diminished opioid usage in the initial 24 h. Importantly, adverse event rates were comparable.
Conclusion: Preemptive low-dose ketorolac emerges as a promising strategy for augmenting pain control within the initial 24 h post-TKA, potentially mitigating opioid requirements. Further investigations are warranted to comprehensively assess its sustained analgesic effects and safety profiles across diverse surgical scenarios, offering crucial insights for refining pain management strategies.

P697
MICRORNA ANALYSIS TO DERIVE FACTORS ASSOCIATED WITH BISOPHOSPHONATE FAILURE AMONG STROKE PATIENTS

K. J. M. Kim[1], P. K. Y. Park[2], H. R. K. Kim[2]

[1]Seoul National Univ. Hospital, [2]Chung-Ang Univ. Hospital, Seoul, South Korea

Objective: Bisphosphonate is one of the most common therapeutics for osteoporosis. We tried to find out prognostic factors related with treatment outcome among the stroke patients with osteoporosis by analyzing microRNA signature from venous blood.
Methods: Acute cerebral infarction patients with osteoporosis was eligible to be included between December 2020 and March 2023. We obtained 5 mL of venous blood after informed consent for the microRNA analysis. All the patients received intravenous zoledronate and treatment response was followed after 12 months by DXA. Demographic and laboratory data were compared between the patients with and without BMD improvement. Next generation small RNA sequencing will be performed to derive a set of microRNA which can predict treatment response.
Results: A total of 20 stroke patients were included, with mean age of 78.1 ± 7.4 y and 14 female patients. Combined medical condition included hypertension in 13 patients, atrial fibrillation in 4 patients and diabetes mellitus in 2 patients. While seven patients were lost to follow up, 7 patients showed improvement, but 6 patients were deteriorated according to the followed BMD 12 months after zoledronate treatment. Osteoporotic fracture event was not detected during follow up period, but two patients experienced recurrent stroke. The expression signature of microRNAs will be presented in the conference.
Conclusion: This study can help to derive molecular signature to predict bisphosphonate treatment among stroke patients.

P698
PEOPLE WITH DISABILITIES ARE AT RISK OF OSTEOPOROTIC FRACTURE: A POPULATION-BASED STUDY IN SOUTH KOREA

C. Hyunjeong[1], K. So Young[2], P. Jong Eun[2], P. Jong-Hyock[3], K. Ji Hyoun[1]

[1]Dept. of Internal medicine, Chungbuk National Univ. Hospital, [2]Dept. of Public Health and Preventive Medicine, Chungbuk National Univ. Hospital, [3]Institute of Health & Science Convergence, Chungbuk National Univ., Cheongju-si, South Korea

Objective: This study aims to examine of the incidence and type for osteoporotic fractures compared to individuals without disabilities.
Methods: Using national disability registration data and National Health Insurance claims data, we analyze incidence of osteoporotic fracture from 2008–2017. The types of osteoporotic fractures in disabled and non-disabled individuals were also investigated.
Results: The age-standard incident rate (ASIR) of osteoporotic fractures was higher in disabled individuals compared to those without disabilities over a period of 10 y. Although vertebral fractures had the highest incidence, the distribution rate of non-vertebral fractures was also higher in disabled individuals compared to non-disabled ones. In a multivariate logistic regression analysis, the highest odds ratios (OR) for males were observed for epilepsy (OR: 3.80, 95%CI 2.40–5.99), respiratory disease (OR 2.38), and intellectual disability (OR 1.95). For females, the highest ORs were found for epilepsy (OR 3.19), liver disease (OR 1.64), and respiratory disease (OR 1.49).

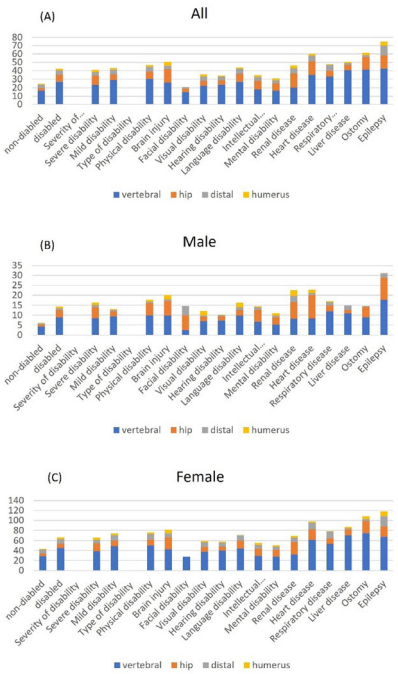

Figure. Distribution of fracture type depending on type of disabilities and sex by age-standardized incidence rate (ASIR) per 10,000 persons. The blue bar represents a vertebral fracture, the orange bar represents a hip fracture, the gray bar represents a distal fracture, and the yellow bar represents a humerus fracture.

Conclusion: The incidence of osteoporotic fracture in people with disabilities is higher than in people without disabilities. The rate of non-vertebral fractures in disabled people was higher compared to non-disabled people. The risk of osteoporotic fracture is highest in individuals with epilepsy.

P699
INCIDENCE RATE AND CHARACTERISTICS OF FALLS IN IRANIAN OLDER ADULTS: THE PROSPECTIVE FOLLOW-UP OF THE PARTICIPANTS IN THE IRANIAN MULTICENTER OSTEOPOROSIS STUDY (IMOS), 2021–2022

V. Mohseni[1], K. Khalagi[2], M. Ahmadi[1], N. Fahimfar[1], M. Sanjari[1], M. J. Mansourzadeh[1], F. Hajivalizadeh[3], S. Hajivalizadeh[1], E. Hesari[1], A. Ostovar[4]

[1]Osteoporosis Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran Univ. of Medical Sciences, [2]Obesity and Eating Habits Research Center, Endocrinology and Metabolism Molecular -Cellular Sciences Institute, Tehran Univ. of Medical Sciences, [3]Center for Non-Communicable Disease Control & Prevention, Deputy of Public Health, Ministry of Health and Medical Education, [4]Endocrinology and Metabolism Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran Univ. of Medical Sciences, Tehran, Iran

Objective: Falling is the primary cause of osteoporotic fractures in older adults. Understanding the incidence rate and consequences of falls among this demographic is essential for comprehensive healthcare planning. This study aimed to estimate the incidence rate and characteristics of falls among older adults aged $\geq$ 50 in Iran.
Methods: The study included 1416 participants from the 4th national IMOS survey, who were followed up for a median duration of 1.8 y. Comprehensive data on falls were collected, including frequency of falls, post-fall medical consultations, outpatient and inpatient visits, causes of falls categorized by age-related and environmental factors, fall sites, and the presence of post-fall fear. Post-fall complications were also assessed.
Results: The mean (SD) age of the participants was 61.25 (7.88) y, with 773 (54.6%) being women. Over the follow-up period, 261 falls were recorded, with 95 individuals (35.85%) seeking medical attention. The incidence rate (95%CI) of falling in the whole population, women, men, those $<$ 65 years old, and those $\geq$ 65 y were estimated as 14.08% (95%CI: 12.47–15.90), 16.90% (95%CI: 14.53–19.65), 10.78% (95%CI: 8.79–13.23), 14.5% (95%CI: 12.56–16.74), and 13.13% (95%CI: 10.45–16.49), respectively. Additionally, 23 falls (8.7%) resulted in hospitalization. Age-related causes, including gait disorders, vertigo, weakness, and low blood pressure, contributed to 144 (54.3%) falls. Environmental factors, such as slippery floors, improper home arrangements, and city infrastructure issues, were linked to 86 (32.4%) falls. The combination of both factors led to 33 (12.4%) falls. Furthermore, 46.79% of falls occurred inside the house, with yards being the most common location, followed by the kitchen and stairs. Outside the house, streets were the primary fall sites, along with parks and other covered areas. Notably, 153 individuals (57.7%) developed a fear of falling after their initial incidence, and 199 (75.1%) patients experienced post-fall complications, including bruising, scratches, ligament strains, and fractures.
Conclusion: Addressing both age-related and environmental factors is crucial for effective fall prevention strategies, considering the associated healthcare utilization, the development of post-fall fear, and the occurrence of post-fall complications. These findings underscore the importance of tailored interventions and public health initiatives to mitigate the impact of falls in the aging population.

P700
DEVELOPMENT OF SIMPLE ASSESSMENT TOOL FOR FRACTURE ESTIMATION IN KOREAN ELDERLY WOMEN (SAFE) TO PREDICT IMMINENT RISK OF FRACTURES IN KOREAN ELDERLY WOMEN

S. Y. Park[1], S. Sujin[2], K. J. Kim[3], S. H. Ahn[4], K. M. Kim[2]

[1]Division of Endocrinology and Metabolism, Dept. of Internal Medicine, Kyung Hee Univ. College of Medicine, Seoul, [2]Dept. of Endocrinology, Yongin Severance Hospital, Yonsei Univ. College of Medicine, Yongin, [3]Division of Endocrinology and Metabolism, Dept. of Internal Medicine, Korea Univ. College of Medicine, Seoul, [4]Division of Endocrinology and Metabolism, Dept. of Internal Medicine, Inha Univ. School of Medicine, Incheon, South Korea

Objective: Previously developed fracture risk prediction models have limitations in applying them to clinical practice. In this study, we developed more simplified and convenient fracture risk prediction model in Korean elderly women.
Methods: A total of 1,440,988 women who underwent 66-year-old life changing national examination in 2011–2017 were included and followed for 3 y. Incidence of major osteoporotic fracture (MOF) and hip fracture in 1 y or 3 y were analyzed. Clinical risk factors such as age, BMI, BMD, history of fall within 6 months, past fracture within 3 y, recent fracture within 1 y, and recurrent fracture were collected. Multivariate logistic regression analysis was used to calculate the odds ratio (OR) of each risk factor for osteoporotic fracture. A new fracture prediction score for MOF and hip fracture was developed; Simple Assessment tool for Fracture Estimation, SAFE.
Results: Scores were calculated using the OR of each risk factor for osteoporotic fracture According to the sum of the scores, it was classified into 6 groups; 0–3, 4–6, 7–9, 10–12, 13–15, and 16–18 score. The higher the score, the higher the risk of 1-y and 3-y MOF and hip fracture. The 3-y MOF and hip fracture was 5% and 0.2% (0–3 score), 5% and 0.2% (4–6 score), 9% and 0.4% in 7–9 score, 17% and 0.8% in 10–12 score, 30% and 0.8% in 13–15 score, 35% and 2.2% in 16–18 score. The 1-y MOF and hip fracture was 2% and 0% (0–3 score), 2% and 0.1% (4–6 score), 4% and 0.2% in 7–9 score, 8% and 0.3% in 10–12 score, 13% and 0.4% in 13–15 score, 16% and 0.8% in 16–18 score.
Conclusion: SAFE can predict well the imminent fracture risks, which could happen within 1 or 3 y.

P701
USE OF COMBINATION OF TERIPARATIDE AND DENOSUMAB IN THE TREATMENT OF OSTEOPOROSIS: EXPERIENCE FROM AN IRISH SPECIALIST BONE HEALTH CLINIC

L. A. Ali[1], K. M. Mccarroll[1], R. L. Lannon[1], N. M. Maher[1], N. F. Fallon[2], J. C. Carraher[1], D. F. Fitzpatrick[1]

[1]Mercer's Institute for Research and Ageing, St James's Hospital, Dublin, Ireland

Objective: The combination of denosumab and teriparatide has been demonstrated to increase BMD of both the hip and spine more than either drug alone, though data on antifracture efficacy is lacking. Combination therapy is not common practice and there is a lack of

clear guidance on its use. In this study, we explore our experience with combination therapy at our bone health clinic.

Methods: This was a retrospective review of patients attending our bone health clinic over the last six years who were commenced on dual therapy with denosumab and teriparatide, either simultaneously, or else were being treated with denosumab and teriparatide was subsequently added. We evaluated the characteristics of these patients including their fracture history and bone densitometry (DXA).

Results: There were 33 patients with a mean age of 76 ± 8 y and 32 were female. Teriparatide and denosumab were commenced simultaneously in 52% (n = 17) while in the remainder, teriparatide was added in patients already established on denosumab (median duration of 55 (IQR 15–87) months). For those started on simultaneous combination therapy, 94% had a previous vertebral fracture, 71% a T-score < -3.0 at the hip or neck of femur and one a hip fracture. In patients were teriparatide was added, 75% (12/16) had vertebral fracture(s) when on denosumab and 25% (5/16) a deterioration in lumbar spine BMD on therapy. Patients started on simultaneous combination therapy vs. those where teriparatide was added in were more likely to have lower T-scores in the spine (P = 0.040) and total hip (P = 0.02).

Conclusion: Patients started on denosumab and teriparatide simultaneously at our clinic had severe osteoporosis of the spine and generally hip T-scores < -3.0. Vertebral fractures on denosumab therapy was the main reason for adding in teriparatide. Current guidelines do not yet provide recommendations on the use of combination therapy, though in patients at high risk of both hip and vertebral fractures, it may be a good option. For patients on denosumab with no improvement in bone density or recurrent vertebral fractures, the addition of teriparatide also may be beneficial though studies are needed to investigate this.

P702
ORAL HEALTH QUALITY OF LIFE IN PATIENTS UNDER BISPHOSPHONATES TREATMENT FOR OSTEOPOROSIS

W. Lahmar[1], K. Maatallah[1], H. Ferjani[1], F. Majdoub[1], L. Kharrat[1], D. Ben Nessib[1], D. Kaffel[1], W. Hamdi[1]

[1]Kassab's Institute of Orthopedics, Manouba, Tunisia

Objective: Bisphosphonates (BPs) stand as the most widely prescribed antiresorptive drugs for the treatment of osteoporosis. There is consensus among guidelines that a thorough oral evaluation is recommended prior to initiating bisphosphonate therapy, and treating any existing dental health problems before starting the BPs. The aim of the study was to investigate the oral health impact on quality of life for those patients who underwent dental therapy before starting the BP for osteoporosis.

Methods: A monocentric cross-sectional study including osteoporosis patients treated with BP. Sociodemographic and clinical characteristics were collected. The dentistry treatment was assessed. The impact that oral health problems can have on an individual's life was measured using the Oral Health Impact Profile-14 (OHIP-14). The answers were recorded on a Likert scale with values ranging from 0 to 4 coded as 0 "never" to 4 "very often". The OHIP-14 sum score can range from 0 to 56 with a higher score indicating poorer quality of life [25]. The 14 items can be grouped into 7 subdomains: 1) functional limitation (items 1 and 2), 2) handicap (3 and 10), 3) psychological disability (4 and 11), 4) psychological discomfort (5 and 14), 5) physical disability (6 and 12), 6) physical pain (7 and 13), and 7) social disability (8 and 9).

Results: We enrolled 100 patients, predominantly women (87%), with a mean age of 66 y ± 7.7 [42–85]. Of these, 29% had a rheumatic disease, and 17 were on regular steroid intake. The mean BMI was 28.3 kg/m^2. Twenty-nine patients had major osteoporotic fractures. The mean BMD in the vertebral site was 0.781 g/cm^2 ± 0.09 [0.563–0.922] and in the femoral site 0.580 g/cm^2 ± 0.8 [0.016–1.150]. The prescribed bisphosphonates were alendronate (46 cases), risedronate (43 cases), and zoledronate (11 cases), with 89 cases involving oral administration. Most patients were prescribed bisphosphonates for postmenopausal osteoporosis (n = 89). Following the initial dental evaluation, 88 patients received dental care, including extractions in 46 cases (6 resulting in edentulism), root canal treatment in 7 cases, dental fillings in 4 cases, dental cleaning in 45 cases, and prosthodontic treatment in 9 cases, including 4 with implants. The OHIP-14 scores were assessed, with a total mean score of 33.06 ± 14.55 [14–54]. Mean subdomain scores were as follows: functional limitations:3 [2–9], handicap 5 [2–10], social disability:5.11 ± 3.19 [2–17], physical pain: 4.83 ± 2.61 [2–9], physical disability: 4.83 ± 2.61 [2–10], and psychological disability: 4.9 ± 2.16 [2–10]. The age of disease onset showed a negative correlation with the overall OHIP-14 score (r: -0.302, p = 0.010), as well as with social disability (r: -0.318, p = 0.004), and psychological disability (r = -0.364, p = 0.001). Serum creatinine levels demonstrated a positive correlation with the overall OHIP-14 score (r: 0.253, p = 0.044), as well as with social disability (r: 0.310, p = 0.009), physical pain (r: 0.254, p = 0.032), and physical disability (r: 0.275, p = 0.020) subdomains. Patients who experienced major osteoporotic fractures and those with rheumatic diseases had higher mean scores in both the total OHIP-14 ($p < 10^{-3}$) and the functional limitations subdomain ($p < 10^{-3}$).

Conclusion: Our study highlights the impact of oral health on the quality of life in osteoporosis patients undergoing BP therapy. The negative correlation of disease onset age with oral health-related quality of life emphasizes the importance of early intervention. Additionally, the positive association between serum creatinine levels, severe osteoporosis, a rheumatic disease, and dental implications suggests the necessity for more evaluations in the management of osteoporosis.

P703
DELAY IN BISPHOSPHONATE TREATMENT INITIATION: INFLUENCE OF INITIAL DENTAL INTERVENTIONS IN OSTEOPOROSIS PATIENTS

K. Maatallah[1], W. Lahmar[1], H. Ferjani[1], F. Majdoub[1], D. Ben Nessib[1], L. Kharrat[1], D. Kaffel[1], W. Hamdi[1]

[1]Kassab's Institute of Orthopedics, Manouba, Tunisia

Objective: Osteoporosis has emerged as a major health problem for middle-aged and older individuals, with bisphosphonates (BP) being the primary antiresorptive drugs prescribed for its treatment. Consensus guidelines emphasize the importance of a thorough oral assessment before initiating BP therapy, recommending the resolution of any dental issues beforehand. However, the potential delay in bisphosphonate initiation resulting from this evaluation and dental treatment raises a critical question in clinical practice. We aimed to assess the delay in bisphosphonate (BP) treatment initiation and determine whether such delays are attributable to underlying dental issues.

Methods: A retrospective study involving patients diagnosed with osteoporosis and prescribed BP. Relevant demographic and clinical data, and baseline BMD) using DXA, were extracted. The BP delay was defined as the time interval between diagnosis and treatment decision and initiation of BP treatment. Dental interventions preceding bisphosphonate therapy were assessed, and the delay of dental treatment was calculated.

Results: We enrolled 100 patients with a sex ratio (F/M) of 8.09 and a mean age of 66 y ± 7.7 [42–85]. The reasons for BP prescription

were postmenopausal osteoporosis in 89 cases and senile osteoporosis in 11. The mean BMI was 28.3 kg/m^2. 29 patients had major osteoporotic fractures. Mean BMD in the vertebral site was 0.781 g/cm^2 ± 0.09 [0.563–0.922], and in the femoral site 0.580 g/cm^2 ± 0.8 [0.016–1.150]. The prescribed bisphosphonates were alendronate (46 cases), risedronate (43 cases), and zoledronate (11 cases). In 89 cases, the BP was taken orally. Mean delay in BP initiation was 10.30 ± 14.5 [0–96] months. Following the initial assessment before starting BP therapy, 88 patients underwent dental interventions. These included 46 cases of extractions (resulting in edentulism in 6 cases), 7 cases of root canal treatment, 4 cases of dental fillings, 45 cases of dental cleaning, and 9 cases of prosthodontic treatment, including 4 with implants. The mean duration of dental treatment was 7.01 ± 4.27 months [1–24 months]. A positive correlation between BP delay and the duration of dental treatment (r: 0.743, $p < 10^{-3}$) was found.

Conclusion: While consensus guidelines recommend an oral assessment before initiating BP therapy, our study highlights a long treatment delay resulting from the preceding dental treatment. We emphasize the need for a balanced approach in clinical decision-making, ensuring timely osteoporosis management without compromising oral health considerations.

P704
PATIENT AWARENESS OF THERAPEUTIC AND ADVERSE EFFECTS OF BISPHOSPHONATES

K. Maatallah[1], S. Loukil[1], H. Ferjani[1], F. Majdoub[1], D. Ben Nessib[1], L. Kharrat[1], D. Kaffel[1], W. Hamdi[1]

[1]Rheumatology Dept. of Mohamed Kassab Institute, Tunis, Tunisia

Objective: To assess the level of awareness and understanding among osteoporosis patients regarding therapeutic benefits and potential adverse effects associated with bisphosphonates.

Methods: We conducted a cross-sectional survey involving patients receiving bisphosphonates(BP), recruited from the rheumatology department of Mohamed Kassab Institute. Sociodemographic data and disease-related characteristics were transcribed (educational background, treatment modalities, duration of the therapy, and treatment compliance). Patients were queried about their knowledge of the therapeutic impact of BP, as well as their awareness of the common and rare possible adverse effects.

Results: The study included 100 patients undergoing bisphosphonate therapy, with a female predominance (sex ratio M/F = 0.15). The mean age was 66 ± 7.7y. Socioeconomic status was classified as good for 13 patients, average for 63, and poor for 22. Regarding education qualification, the distribution was as follows: College degree or above 5%, high school diploma 15%, less than high school 41% and illiteracy 39%. The most frequent reason justifying BP prescription was postmenopausal osteoporosis (87%). The mean disease duration was 10 ± 6 years. A total of 89 patients were using oral BP and 11 received intravenous (IV) BP. Oral alendronate was the most commonly used BP (N = 46), followed by oral risedronate (N = 43). The mean duration of treatment was 29 ± 19 months. The majority of patients reported good compliance with their treatment (83%). Among the surveyed participants, 40% reported a good awareness regarding the therapeutic benefits of BP in reducing fracture risk and improving BMD. Regarding adverse effects, 69% of the participants lacked sufficient knowledge about common adverse effects such as gastrointestinal symptoms, and only 36% were familiar with rare adverse reactions associated with BP, such as osteonecrosis of the jaw or ulcers (3.5%). Several factors influencing awareness levels were identified, including educational level (P = 0.019), socioeconomic level (P = 0.02), and disease duration (P = 0.046). Treatment adherence was significantly associated with poor awareness levels regarding the adverse effects of BP(P = 0.027).

Conclusion: Our study revealed a significant gap in patient knowledge about the therapeutic and adverse effects of their medication with bisphosphonates. Healthcare providers should prioritize comprehensive discussions with patients to enhance understanding of treatment benefits, and promote better awareness about potential side effects.

P705
BISPHOSPHONATE ROTATION PATTERNS AND DISCONTINUATION CAUSES IN OSTEOPOROSIS MANAGEMENT

W. Lahmar[1], K. Maatallah[1], H. Ferjani[1], F. Majdoub[1], D. Ben Nessib[1], L. Kharrat[1], D. Kaffel[1], W. Hamdi[1]

[1]Kassab's Institute of Orthopedics, Manouba, Tunisia

Objective: Given the chronic nature of osteoporosis and the aging population, prolonged treatment of osteoporosis may be necessary, involving the successive use of various anti-osteoporotic treatments. We aimed to determine the rotation of bisphosphonates (BP) patterns in osteoporosis patients and the causes of BP treatment discontinuation.

Methods: It's a retrospective study involving patients diagnosed with osteoporosis and prescribed BP. Relevant demographic, clinical data and baseline BMD, using DXA, were extracted. Chosen molecules of BPs, doses, treatment duration, and causes of discontinuation were collected.

Results: We included 100 patients with a female-to-male sex ratio of 8.09 and an average age of 66 y ± 7.7 [42–85]. BP were prescribed for postmenopausal osteoporosis in 89 cases and senile osteoporosis in 11 cases. The mean BMI was 28.3 kg/m^2. Among them, 29 patients had major osteoporotic fractures. The mean BMD in the vertebral site was 0.781 g/cm^2 ± 0.09 [0.563–0.922], and in the femoral site, it was 0.580 g/cm^2 ± 0.8 [0.016–1.150]. The initially prescribed BP were alendronate (46 cases) at 70 mg/week, risedronate at 35 mg/week orally (43 cases), and zoledronic acid infusions of 5 mg/y (11 cases). The mean duration of bisphosphonate treatment was 28.81 months ± 19.23 [1–60] in the first sequence. 17 patients experienced a rotation of BPs after the first treatment sequence, with zoledronic acid being the most common (65% vs. 35% alendronate or risedronate, p = 0.046). The initial choice of BP was not associated with a specific rotation or second choice (p = 0.191). The second sequence of BP treatment had a mean duration of 14.93 months ± 10.10 [5–48]. The increase in BMD after BP rotation showed no significant difference between oral and intravenous (IV) BP in the lumbar site (oralBP: 0.807 g/cm^2 vs. IV.BP: 0.789,p = 0.070), and in the femoral site (oralBP:0.679 g/cm^2 vs. IV.BP: 0.770 g/cm^2,p = 0.809). Causes of discontinuation of the first sequence included adverse effects in 4 cases, treatment failure (vertebral fracture in 5 cases, peripheral fracture in 1 case), and patient-decided inefficacy in 1 case.

Conclusion: Our study revealed a notable occurrence of BP rotation in osteoporosis patients, zoledronic acid being the prevalent second choice. The duration of initial treatment and the specific BP chosen initially did not predict subsequent rotation patterns. Discontinuation reasons varied and were essentially failure of the first sequence.

P706
IMPACT OF BISPHOSPHONATE MOLECULES ON BONE DENSITY

K. Maatallah[1], M. Gdaiem[1], H. Ferjani[1], F. Majdoub[1], D. Ben Nessib[1], L. Kharrat[1], D. Kaffel[1], W. Hamdi[1]

[1]Dept. of Rheumatology, Mannouba, Tunisia

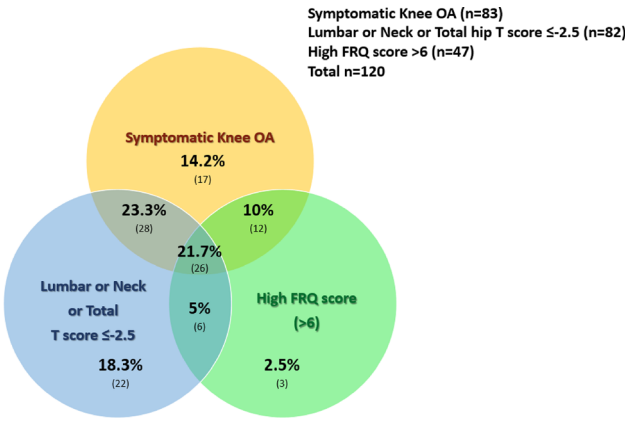
Objective: To determine the impact of bisphosphonate molecules on bone density.
Methods: A cross-sectional comparative study was conducted on patients with osteoporosis. Based on the type of bisphosphonate prescribed, we categorized the study population into three groups. DXA was used to assess BMD at the lumbar spine (L2–L4) and femoral site. The vertebral fracture incidence was assessed.
Results: A total of 100 patients (sex ratio = 0.15) were included. The average age was 66 y ± 7.7. Patients were stratified into 3 groups: risedronate (35 mg/week) (n = 43), alendronate (70 mg/week) (n = 46), and zoledronate (5 mg/y) (n = 11). The mean initial BMD value for the risedronate group at the vertebral site was 0.819 ± 0.593 g/cm^2, and at the femoral site was 0.735 ± 0.215 g/cm^2. The average risedronate intake was 32.87 ± 20.42 months. In the post treatment assessment, the mean BMD at the vertebral site was 0.890 ± 0.96 g/cm^2, with a corresponding femoral site BMD of 0.801 ± 0.22 g/cm^2 (p = 0,07). No new fractures were observed in this group. In the alendronate group, the mean initial values were 0.782 ± 0.862 g/cm^2 at the vertebral site and 0.581 ± 0.902 g/cm^2 at the femoral site. The average duration of alendronate intake was 28.38 ± 18.28 months. In the post treatment assessment, the mean BMD was 0.788 ± 0.93 g/cm^2 at the vertebral site and 0.659 ± 0.154 g/cm^2 at the femoral site (p = 0,2) One patient experienced new vertebral fractures (treatment duration of 10 months). In the zoledronate group, the initial BMD values were 0.623 ± 0.584 g/cm^2 at the vertebral site and 0.623 ± 0.584 g/cm^2 at the femoral site. The average duration of zoledronate intake was 15.36 ± 11.9 months. In the post-treatment assessment, BMD was 0.635 ± 0.01 g/cm^2 at the vertebral site and 0.601 ± 0.215 g/cm^2 at the femoral site (-0.022 g/cm^2) (p = 0.03). New vertebral fractures occurred in 3 patients (treatment duration of 8 ± 1,2 months).
Conclusion: Only zoledronate was associated with bone loss. However, further investigations are crucial in assessing the long-term effects of each specific bisphosphonate.

P707
EVALUATING OSTEOARTHRITIS AND BONE MINERAL DENSITY IN ELDERLY HIP FRACTURE PATIENTS

K. Mekariya[1], N. Adulkasem[1], E. Vanitcharoenkul[1], P. Chotiyarnwong[1], A. Unnanuntana[1]

[1]Dept. of Orthopaedic Surgery, Faculty of Medicine Siriraj Hospital, Mahidol Univ., Bangkok, Thailand

Objective: Osteoarthritis (OA) of the knee and osteoporosis are common yet manageable degenerative conditions that significantly impact patient mobility and balance, increasing the risk of falls and subsequent fragility fractures. However, the specific prevalence of knee OA and the BMD of the contralateral hip or lumbar spine in patients with fragility hip fractures (FHFs) is currently unknown. This study aimed to establish the prevalence of symptomatic knee osteoarthritis (SKOA) and its impact on BMD in the lumbar spine and contralateral hip among elderly FHF patients.
Methods: A cross-sectional analysis was performed on FHF patients treated surgically between January 2020 and May 2023. Diagnosis of knee OA followed the American College of Rheumatology criteria, with severity assessed via the Kellgren–Lawrence (KL) classification. SKOA was defined as FHF patients exhibiting knee OA of KL grade II or higher with substantial knee pain (visual analogue scale pain score of > 2/10 for more than 2 months) or gross instability. BMD at the lumbar spine and contralateral hip was measured using DXA scans. Fall risks were quantified using a self-rated questionnaire.
Results: Among 162 FHF patients (mean age 79.9 ± 8.1 y, 80.2% female), 66% had SKOA, correlating with increased multiple fall rates (p = 0.013) and fall risk (p = 0.020). Notably, 26.5% of SKOA patients were in end-stage knee OA (KL IV). Of 120 patients with BMD data, 68% exhibited low BMD (T-score < -2.5) at either the contralateral hip (16.7%), lumbar spine (15.8%), or both (23.2%). Half of the FHF patients had concurrent SKOA and low BMD, while approximately 20% presented with SKOA, low BMD, and high fall risk (self-rated questionnaire scores ≥ 4).



Conclusion: This study highlights a significant occurrence of both SKOA and low BMD among FHF patients. Given the manageability of both knee OA and osteoporosis, comprehensive evaluation and treatment are crucial. This includes considering surgical intervention for knee OA, particularly for those with osteoporosis at the spine or contralateral hip who are at the highest risk of subsequent fractures. Such a proactive approach could significantly mitigate the risk of further fragility fractures in this vulnerable population.

P708
GREATER VARIATION OF BONE TURNOVER MARKERS WITH DENOSUMAB THAN WITH ZOLEDRONATE IN OSTEOPOROTIC POSTMENOPAUSAL WOMEN WITH PRIMARY HYPERPARATHYROIDISM

K. Mlekus Kozamernik[1], L. Lezaić[2], M. Hočevar[3], T. Kocjan[1]

[1]UMC Ljubljana/Dept. of Endocrinology and Faculty of medicine, Univ. of Ljubljana, [2]UMC Ljubljana, Dept. of Nuclear Medicine and Faculty of Medicine, Univ. of Ljubljana, [3]Institute of Oncology, Dept. of Surgical Oncology and Faculty of Medicine, Univ. of Ljubljana, Ljubljana, Slovenia

Objective: Primary hyperparathyroidism (PHPT) is a state of increased bone turnover. We compared the antiresorptive effect of zoledronate and denosumab on bone-related biochemical parameters in PHPT.
Methods: We analyzed data from our ongoing trial comparing the effects of treatment with either annual zoledronate 5 mg iv or with biannual denosumab 60 mg sc in osteoporotic postmenopausal women with PHPT (ClinicalTrials.gov NCT04085419). Here, we compared the serum calcium levels (S-Ca), intact PTH (iPTH), and bone turnover markers (CTX, P1NP, bone-specific alkaline

phosphatase (BALP)) at baseline, 3 months (3 M), and 6 months (6 M) after the start of the treatment.

Results: We enrolled 40 osteoporotic females with PHPT (aged 73.0 (7.8 SD) y, 22.6 (10.0) years from menopause, BMI 27.77 (5.1) kg/m^2). After randomization, 20 women received zoledronate (ZOL group) and 20 denosumab (DMAB group). Within-group analysis showed a significant decrease in serum calcium (S-Ca) (DMAB Δ S-Ca 3 M -0.07 (0.15); p = 0.05, ZOL Δ S-Ca 3 M -0.09 (0.09); p < 0.001 mmol/L), an increase in iPTH level (DMAB Δ iPTH 3 M 61.91 (126.9); p = 0.042, ZOL Δ iPTH 3 M 30.24 (56.84); p = 0.002 ng/L) and a reduction in bone turnover markers from baseline to 3 months in each group. At 6 months, S-Ca remained low, and iPTH stayed high in both groups. The between-group comparison revealed a significantly greater decline of CTX and BALP in the DMAB group from baseline to (DMAB Δ CTX 3 M -0.952 (0.639) vs. ZOL Δ CTX 3 M -0.556 (0.439) μg/L; p = 0.03 and DMAB Δ BALP 3 M -19.92 (8.51) vs. ZOL Δ BALP 3 M -12.99 (9.3) μg/L; p = 0.03). The decline in P1NP was not statistically significant (DMAB Δ P1NP 3 M -75.45 (33.87) vs. ZOL Δ P1NP 3 M -55.12 (32.52) μg/L; p = 0.06). The increase in CTX from 3 to 6 M was significantly greater in the DMAB group (DMAB Δ CTX 6 M-3 M 0.223 (0.371) vs. ZOL Δ CTX 6 M-3 M 0.019 (0.085) μg/L; p = 0.03).

Conclusion: In postmenopausal women with PHPT, denosumab caused a greater decrease in CTX and BALP from baseline to 3 months and a greater increase in CTX from 3 to 6 months than zoledronate.

P709
PYCNODYSOSTOSIS

K. Nassar[1], S. Zaher[1], A. Ajerouassi[1], S. Janani[1]

[1]Dept. of Rheumatology, Ibn Rochd Univ. Hospital Center, Hassan II Univ., Faculty of Medicine and Pharmacy, Casablanca, Morocco

Pycnodysostosis, or Toulouse-Lautrec syndrome, is a rare autosomal recessive skeletal dysplasia, due to a defect in the gene encoding cathepsin K. Its prevalence is 1/100,000. It is characterized by short-limbed, short stature, typical facial appearance; convex nasal ridge and small jaw with obtuse mandibular angle, osteosclerosis with increased bone fragility, acro-osteolysis of the distal phalanges, delayed closure of the cranial sutures, and dysplasia of the clavicle. The diagnosis is usually based on the clinic and bone x-rays, or better by the study of the gene abnormally located on the cathepsin K gene (1q21). We present two isolated and separate cases, with typical clinical-radiological criteria, who were admitted for the assessment of bone status.

Case reports: We present two isolated and separate cases of pycnodysostosis with the context of consanguinity and past history of fractures. It is about 32-year-old women and 19-year-old man. The clinical examen found short stature, brachydactyly, dystrophic nails, facial dysmorphia with frontal bossing, bilateral ocular proptosis, micrognathia, open fontanels, prominent nose and abnormal teeth. Radiography showed acro-osteolysis of the distal phalanges, diffuse osteosclerosis, brachydactyly and wide cranial sutures. Both patients presented normal levels of vitamin D, phosphatase alkaline, TSH, free T4, blood and urinary calcium and phosphate levels. They are followed at bone disease unit in rheumatology department without any complications.

Conclusion: Pycnodysostosis is a rare inherited disorder of the bone, autosomal recessive. The diagnosis is essentially based on radio-clinical criteria. The bone pathological fractures occur due to sclerosis. skull bones appear thickened with generalized osteosclerosis. It can be revealed by fractures or exceptionally neurological complications that require specific treatment. The main differential diagnosis is osteopetrosis, of which there is a close and complex link. The treatment is based on that of complications. The prognosis is generally not involved.

P710
ASSESSMENT OF THE ASSOCIATION BETWEEN RHEUMATOID ARTHRITIS ACTIVITY AND BODY COMPOSITION

K. Nassar[1], A. Ajerouassi[1], S. Zaher[1], S. Janani[1]

[1]Dept. of Rheumatology, Ibn Rochd Univ. Hospital Center, Hassan II Univ., Faculty of Medicine and Pharmacy, Casablanca, Morocco

Objective: Rheumatoid arthritis (RA) is associated with altered body composition, which can result in rheumatoid cachexia caused by the inflammatory factors. RA patients often present with low muscle mass and decreased strength with high fat mass. The muscle changes may occur in the early stages of RA and persist throughout the disease duration like the excess of fat mass. The purpose of the study is to assess the link between the activity of the RA and the change of the fat and lean body mass.

Methods: Transversal and descriptive monocentric study conducted in 26 RA patients followed in the rheumatology department at the University Hospital Ibn Rochd. The study include 13 patients with active RA and 13 control group with remission disease. Demographic characteristics were noted in all patients as well as disease activity and treatment characteristics. All patients underwent a DXA with evaluation of the body mass precisely the lean and the fat mass. Finally the data of the 2 groups were compared to assess the relationship between disease activity and disturbances in body mass.

Results: 26 patients were included. The mean age was 52 ± 10.3, predominantly female (92.3%. The mean BMI was 26.2 ± 6.4. 7.6% are diabetic, 3.8% are smoking 53.8% are postmenopausal. Mean duration of RA 12 ± 7.4 y. Mean sedimentation rate was at 57.4 ± 31 mm/1e h and CRP at 26.6 ± 24.1 mg/l. The DAS 28 m crp was at 3.59 ± 1.35. The DXA found T-score m at the lumbar spine at (-2,1 ± 1,39), femoral neck at (-1,33 ± 1,32) and the total hip at (-1,13 ± 1,30). Concerning the evaluation of body mass, we found the following results: Total Leg average fat mass (g) at 3731 ± 2390, total leg mean lean mass (g) at 9267 ± 2619, total leg BMC (g) at 446 ± 159. The whole Body average Fat (g) at 17,715 ± 13,322, the

average lean whole body (g) at 46,883 ± 5802 and the BMC whole body (g) at 2201 ± 346 (table).

Table. Population characteristics and the assessment of the link between active RA and body mass

	Remission RA	Active RA PR	p-value
	Number=13	Number 13	
Demographic characteristics			
Mean age	58± 7,5	45,9±9,2

Disease characteristics			
Mean duration	12,19± 8,2	11,9± 6,6	0,37
Mean age	45± 12	34,4±10,5	0,04
Mean sedimentation rate	59,4± 36,8	62,1±22,4	0,08
Mean C-reactive protein	21,4± 19,9	31,4±26,5	0,008
Mean DAS 28 CRP	2,48± 0,48	4,7±0,9	
Mean BMD (T-SCORE)			
Lumbar spine	0,887 ±0,174 (-2,1±1,27)	0,915 ±0,185 (-2,06±1,44)	0,08
Femoral neck	0,729 ±0,126 (-1,68±0,90)	0,835 ±0,185 (-1±1,55)	0,16
Total hip			0,04
Whole Body	0,753 ±0,133 (-1,65±1,03)	0,923 ±0,153 (-0,6±1,33)	
Mean total Leg fat mass (g)	3286± 2107	4177±2567	0,21
Mean total leg lean mass (g)	9074±3387	9461±1474	0,28
Total leg BMC (g)	410±195	482±100	0,11
Mean whole body fat (g)	15022±12819	20408±13271	0,2
Mean whole body lean mass (g)	43871±4700	49895±5205	0,001
Whole body BMC (g)	2059±333	2342±298	0,02

Conclusion: The assessment of fat and lean mass is important in patients followed for chronic inflammatory rheumatism such as RA. Inflammation induces an increase in fat mass and a decrease in lean mass with the risk of osteoporosis and fall, especially in patients with active rheumatism and obesity. Our study showed an increase in fat content in patients with active RA but without statistically significant difference with the control group. Regarding the lean mass, the expected results were not found in our study. This can be explained by the low number of patients and the few associated comorbidities. The changes in body composition during RA are linked to a cascade of metabolic abnormalities with inflammatory factors. There are multiple, complex interactions which remain largely unknown.

P711
SARCOPENIA IN POSTMENOPAUSAL WOMEN

K. Nassar[1], A. Ajerouassi[1], S. Zaher[1], S. Janani[1]

[1]Dept. of Rheumatology, Ibn Rochd Univ. Hospital Center, Hassan II Univ., Faculty of Medicine and Pharmacy, Casablanca, Morocco

Objective: From the age of 50 onwards a progressive loss of muscle mass may be observed, it often leads to real sarcopenia. Age, sedentary lifestyle, hormonal factors, unbalanced feeding habits represent major risk factors. The decrease in muscle tone leads to a loss of function, an altered quality of life, and the increase of fracture risk. Sarcopenia has a high prevalence in postmenopausal women. The purpose of the study is to evaluate the presence or absence of sarcopenia in menopausal women by calculating the skeletal muscle index.

Methods: Transversal and descriptive monocentric study conducted in 20 postmenopausal women homogeneous regarding demographic and risk factors. Demographic characteristics were noted. All women underwent a DXA, in rheumatology department at Ibn Rochd University Hospital, with evaluation of the body mass precisely the lean and the fat mass. We calculated the skeletal muscle index to assess the presence or absence of sarcopenia. The sarcopenia is retained when the skeletal muscle index is less than 5,45 kg/m^2 in woman.

Results: 20 postmenopausal women was including. The mean age was at 63,5 ± 7,2. The mean BMI was at 27,9 ± 4,7. There were no past medical history apart fracture in 30%. The mean age of menopause was at 48,2 ± 6. The mean T-score at the lumbar spine was at -2,82 ± 0,97 (BMD = 0,802 ± 0,138), femoral neck at -1,76 ± 0,6 (0,725 ± 0,08) and total hip at -1,5 ± 0,87 (0,792 ± 0,110. The evaluation of the whole body found: the mean total leg fat mass at 4337 ± 1460 g, the mean feat total leg mass at 8272 ± 1313 g, and the bone mineral content at 364 ± 60 g. The mean whole fat mass was at 20,013 ± 7705 g, the mean feat whole mass at 44,576 ± 6010 g, the whole bone mineral content at 2061 ± 219 g. The total feat mass (kg)/ taille^2 (m) was at 18,99 ± 2,66 kg/m^2. Finally, the skeletal muscle index was at 4,24 ± 0,76 kg/m^2, correlated with sarcopenia.

Conclusion: Sarcopenia has a high prevalence in postmenopausal women, what joins the results of our study. It affects at least 20% of the population from the age of 70 and also obese subjects, posing multiple diagnostic problems (obesity-sarcopenia syndrome). It is predominant in the lower limbs with a loss of muscle mass of around 15%, compared to 10% for the upper limbs. Sarcopenia is the consequence of multiple intertwined factors, which participate in its genesis, but also in its progression: neuronal, hormonal factors, lifestyle, vitamin D deficiency. The evaluation and prevention of sarcopenia are important in the management of postmenopausal women by acting on risk factors, muscle strengthening and prevention of falls and fractures.

P712
MANAGEMENT OF POSTMENOPAUSAL OSTEOPOROSIS ABOUT 113 CASES

K. Nassar[1], S. Zaher[1], A. Ajerouassi[1], S. Janani[1]

[1]Dept. of Rheumatology, Ibn Rochd Univ. Hospital Center, Hassan II Univ., Faculty of Medicine and Pharmacy, Casablanca, Morocco

Objective: Osteoporosis is the most common benign osteopathy. Reduced bone strength places patients at increased risk of fracture. The objective of this study is to describe the clinical, paraclinical and therapeutic profile of patients followed exclusively for postmenopausal osteoporosis at the consultation for osteopathies in the rheumatology department in a hospital structure, in order to evaluate and improve the management of patients.
Methods: This is a single-center descriptive study carried out in the rheumatology department of a university hospital center in the osteopathy center, over a period of nine years. The inclusion criteria were patients who had densitometric osteoporosis (according to the WHO classification), a severe fracture or a FRAX score above the threshold for therapeutic intervention. Those with osteopathy of malignant, metabolic or secondary origin were excluded.
Results: We identified 113 patients. The average age was 66.37 ± 9.29. The average BMI was 29.53 kg/m^2 ± 4.42 and BMI < 19 was found in 2.38%. Menopause before age 40 was found in 11% of cases. The history of peripheral fracture was noted in 33.63% of cases and axial fracture in 5.30% of cases. The average T-Score at the lumbar spine, femoral neck and total hip was -2.96 ± 1.02, -1.94 ± 0.94 and -1.7 ± 0.93 respectively. The vertebral fracture was found on standard radiography in 28.07% of cases. Hypo-vitamin D was noted in 75.22% of patients, 13.27% of patients had no indication for treatment and they were placed under surveillance, while the indication for treatment in the other cases was asked in case of severe fracture, T-Score < -3, FRAX score above the threshold for therapeutic intervention and on a case-by-case basis when the T-score was between -2.5 and -3.The most prescribed anti-osteoporotic treatment was oral bisphosphonates in 45.13%, followed by zoledronic acid in 8% of cases. The treatment was well tolerated. Digestive intolerance was noted in 5.31% of patients and the majority of cases had a densitometric gain during monitoring.
Conclusion: Postmenopausal osteoporosis is a common pathology that progresses silently. Its diagnosis is based on DXA and the search for clinical risk factors for fractures. Its treatment has benefited from the development of an effective and generally well-tolerated therapeutic arsenal. Our study is consistent with the results of the literature due to its frequency, diagnosis and therapeutic management as well as the association with clear vitamin D insufficiency.

P713
VITAMIN D STATUS IN 113 PATIENTS FOLLOWED FOR POSTMENOPAUSAL OSTEOPOROSIS

K. Nassar[1], A. Ajerouassi[1], S. Zaher[1], S. Janani[1]

[1]Dept. of Rheumatology, Ibn Rochd Univ. Hospital Center, Hassan II Univ., Faculty of Medicine and Pharmacy, Casablanca, Morocco

Objective: Osteoporosis is the most common benign osteopathy. Reduced bone strength places patients at increased risk of fracture. Menopause represents a period at risk of osteoporosis and a drop in vitamin D, given the hormonal upheaval caused. Knowing the protective role of vitamin D on bone tissue, its supplementation should systematically be evaluated. The objective of this study is to evaluate the vitamin D status in patients followed for postmenopausal osteoporosis, through 113 cases.
Methods: This is a single-center descriptive study carried out in the rheumatology department of a university hospital center, over a period of 9 y. The inclusion criteria were patients who had densitometric osteoporosis (according to the WHO classification), and who had received vitamin D testing. Those with osteopathy of malignant, metabolic or secondary origin were excluded. and patients who do not have a vitamin D dosage.
Results: We identified 113 patients. The average age was 66.37 ± 9.29. The average BMI was 29.53 kg/m^2 ± 4.42 and BMI < 19 was found in 2.38%. Menopause before age 40 was found in 11% of cases. The history of peripheral fracture was noted in 33.63% of cases and axial fracture in 5.30% of cases. The average T-Score at the lumbar spine, femoral neck and total hip was -2.96 ± 1.02, -1.94 ± 0.94 and -1.7 ± 0.93 respectively. On a biological level, the drop in vitamin D was found in 75.22% of patients, 64.60% of whom were insufficient and 10.62% deficient. While knowing that 35% of patients have already received or were on vitamin D supplementation at inclusion. They received correction protocols according to the schemes proposed by the recommendations of learned societies in addition to bone-targeted treatment for those who were eligible for anti-osteoporotic treatment.
Conclusion: Postmenopausal osteoporosis is a common pathology that progresses silently. Vitamin D reduction is often associated with it. Our study is consistent with the results of the literature regarding the clear association of vitamin D insufficiency and postmenopausal osteoporosis. Assessment of vitamin D status before and during patient follow-up is essential for better therapeutic care.

P714
ULTRASOUND-BASED FRACTURE RISK DISCRIMINATION IN PATIENTS WITH DIABETES MELLITUS

E. Wiebe[1], C. Dehnen[1], A. Galindo[2], M. Lukas[3], H. Paula[1], H. Aghamiry[2], Z. Liu[2], N. Lepetre[1], O. Palmer[4], K. Raum[2]

[1]Charité – Universitätsmedizin Berlin, Medizinische Klinik m.S. Rheumatologie und Klinische Immunologie, [2]Charité – Universitätsmedizin Berlin, Center for Biomedicine—Imaging-Simulation & Stimulation, [3]Charité – Universitätsmedizin Berlin, Medizinische Klinik für Endokrinologie, [4]Aemedes Gruppe, Endokrinologikum Berlin, Berlin, Germany

Objective: Diabetes mellitus (DM) is a common chronic metabolic disease that increases the risk of fragility fractures, with DXA-based BMD often underestimating fracture risk in these patients. Cortical backscatter (CortBS) ultrasound, a radiation-free technique, examines cortical viscoelastic material and microstructural properties. This study aims to assess CortBS's discrimination performance in DM patients compared to the gold standard (DXA).
Methods: The study (DRKS00029331, EA4/140/22) included 48 women and 38 men with DM (Type I = 38, Type II = 46, Type other = 2), aged > 49 y, along with 77 matched individuals without DM. DXA measured bone density in the lumbar spine and both femoral sites. CortBS measurements were taken in the anteromedial tibia using a SonixTOUCH with custom software. Multivariate analysis of variance assessed the impact of DM type on CortBS and DXA. Partial least squares discriminant analyses with cross-validation were used to compare the discrimination performance for vertebral, non-vertebral, and any fragility fractures, considering gender, age, and anthropometric information (AP: weight, height, BMI).
Results: The DXA T-score was influenced by AP factors and age and was significantly higher in DM patients than in those without DM (Type I: + 0.73 SD, Type II: + 1.36 SD), but not significantly different between patients with and without fractures. The CortBS risk score was independent of AP factors, gender, and DM, and was

significantly larger in patients with non-vertebral fractures. CortBS outperformed DXA for all fracture types, the difference was significant for vertebral and non-vertebral fractures (AUCDXA $\leq$ 0.58, AUCCortBS $\leq$ 0.64, Fig. 1).

Conclusion: Irrespective of DM status, patients with fractures exhibited an elevated fracture risk in the ultrasound score, but not a decreased DXA T-score (Fig. 1).

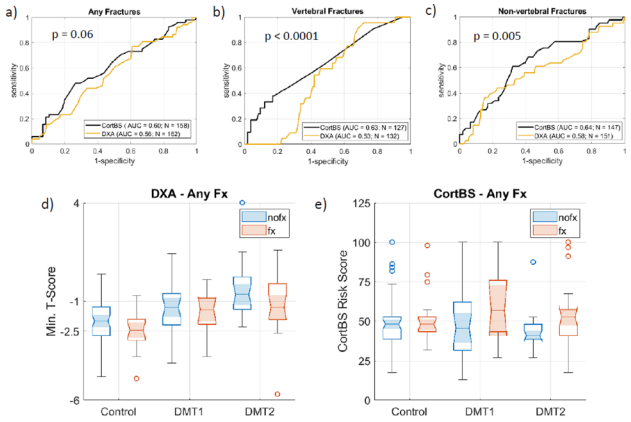

Fig. 1 ROC-AUC with 5-fold cross-validation for a) any, b) vertebral and c) non-vertebral fragility fractures for all study participants (independent of DM disease). DXA T-scores (d) show the well-known "overestimation" in patients with DM. The CortBS risk score (e) is particularly elevated in patients with DM type I and fractures.

P715
CORTICAL ULTRASOUND SPECTROSCOPY DISCRIMINATES FRAGILITY FRACTURES IN WOMEN AND MEN BETTER THAN BONE MINERAL DENSITY

G. Armbrecht[1], A. Galindo[2], H. Aghamiry[2], Z. Liu[2], N. Lepetre[3], K. Raum[2], E. Wiebe[3]

[1]Charité—Universitätemedizin Berlin, Klinik für Radiologie, [2]Charité – Universitätsmedizin Berlin, Center for Biomedicine—Imaging- Simulation & Stimulation, [3]Charité – Universitätsmedizin Berlin, Medizinische Klinik m.S. Rheumatologie und Klinische Immunologie, Berlin, Germany

Objective: Cortical ultrasound spectroscopy (CortBS) is a novel non-ionizing imaging technique that measures viscoelastic material properties and intracortical pore size distribution in the tibia. A preliminary study in postmenopausal women with low BMD confirmed better fracture discrimination of CortBS over the gold standard (DXA). This research aims to evaluate the discrimination performance of CortBS in male and female patients and young healthy volunteers and compare it with DXA.

Methods: The study (DRKS00025849, EA4/068/19) contained 144 women (including 55 postmenopausal women from a previous study [1]) and 33 men (age: 30–86 y, DXA: > 56 y). DXA bone density was taken at the lumbar spine and both femoral sites. CortBS measurements were performed in the anteromedial region of the tibia using a SonixTOUCH with custom software. Multivariate analysis of variance investigated the influence of gender, age and anthropometric (AP) information (height, weight, BMI) on CortBS and DXA. Partial least squares (PLS) discriminant analyses with cross-validation were used to compare the discrimination performance for vertebral, non-vertebral and any fragility fractures with and without gender, age and AP information.

Results: The DXA T-score was affected by weight and BMI and was significantly lower in patients with non-vertebral fractures ($p < 0.05$). CortBS fracture risk score was significantly increasing with age ($p < 0.01$) and significantly higher in patients with fractures ($p < 0.005$). CortBS outperformed DXA's discrimination ability for all fracture types ($AUC_{DXA} \leq 0.60$, $AUC_{CortBS} \leq 0.72$, Fig. 1). Regardless of gender, patients with fractures showed an increased fracture risk in the ultrasound score, but not in the DXA T-score (Fig. 1).

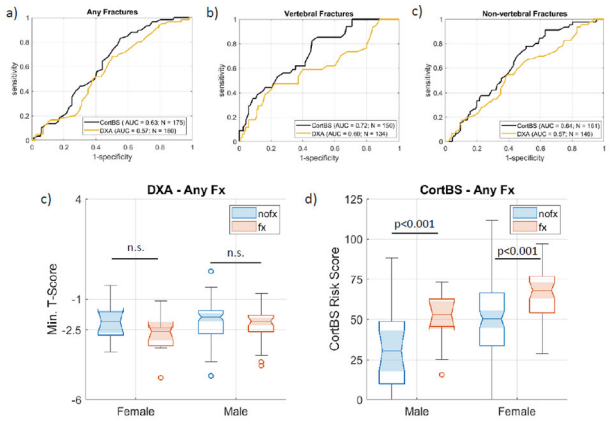

Fig. 1 ROC-AUC with 5-fold cross-validation for (a) any, (b) vertebral and (c) non-vertebral fragility fractures. DXA T-scores (c) and CortBS-risk scores (d) for any fractures. For patients with fractures the CortBS score is significantly higher, which is independent of the gender.

Conclusion: CortBS exhibits the general age- and gender-associated fracture risk and has a significantly better discrimination performance than DXA.

P716
USE OF INTRAVENOUS IRON FOR ANAEMIA IN ELDERLY HIP FRACTURE PATIENTS DURING PERI-OPERATIVE PERIOD: A SYSTEMATIC REVIEW AND META-ANALYSIS

K. S. Lai[1]

[1]Dept. of Medicine and Geriatrics / Tai Po Hospital / Hospital Authority / HKSAR, Tai Po, Hong Kong SAR China

Objective: Newer generations of intravenous iron preparations have been developed in recent decades and their use have been increasing since then as alternatives or adjuvants to conventional blood transfusion in anaemia management among elderly patients during their peri-operative periods, for example, hip fracture repair surgeries. The aim of this study is to review whether the use of intravenous iron would give comparable or even more favourable clinical and administrative outcomes, when compared with conventional treatment group, among elderly hip fracture patients.

Methods: A systematic review of randomized controlled trials on the topic done between 2000–2022 is conducted. A meta-analysis on the data extracted is performed to compare various clinical (occurrence and amount of blood transfusion, side effects, mortality and morbidities) and administrative (hospitalization length of stay (LOS)) outcomes.

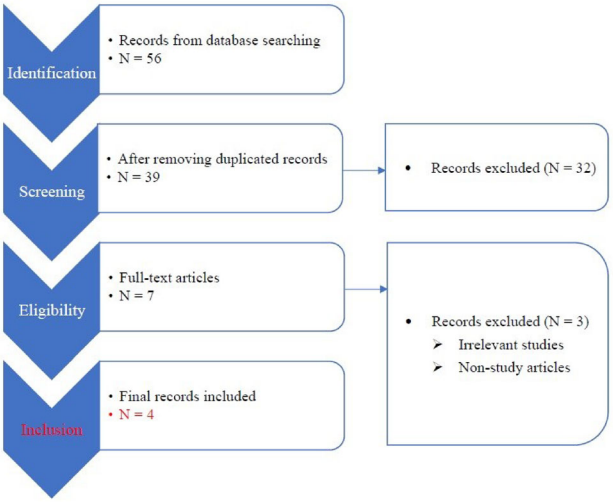

Figure 1 – Preferred Reporting Items for Systematic Reviews and Meta-analysis (PRISMA)

Results: Four trials conformed to inclusion criteria. The pooled data consisted of 732 subjects (intervention group: 367, control group: 365) with average age 84.6 years old. Meta-analysis showed that intravenous iron reduced hospitalization LOS which was not statistically significant. Furthermore, there were no significant differences between the two groups in terms of blood transfusion rate and 30-d mortality.

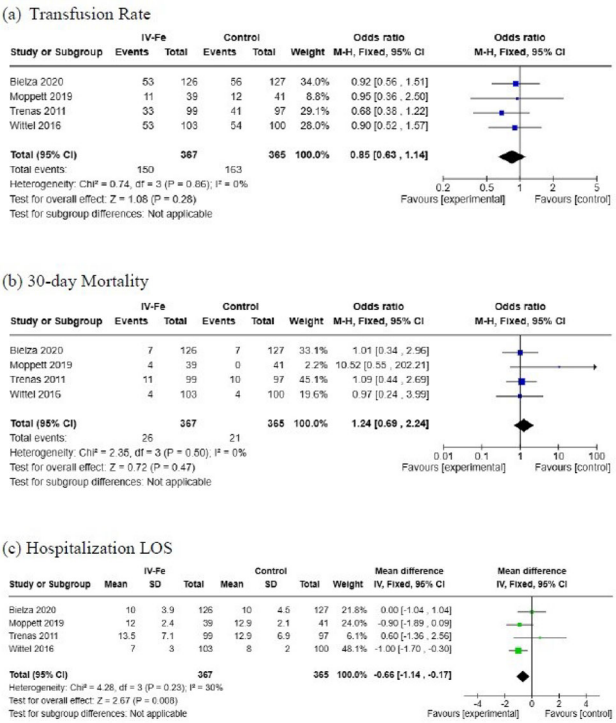

Figure 2 – Forest plots for outcomes

Conclusion: This review shows comparable clinical and administrative outcomes in terms of blood transfusion requirement, 30-d mortality and hospitalization LOS between intravenous iron and conventional treatment groups of elderly hip fracture patients during their peri-operative periods. Further studies are warranted in assessing the long-term effects of intravenous iron, as well as the use of the newest fourth-generation intravenous iron preparation.

P717
ACUTE DROP IN HAEMOGLOBIN LEVEL AFTER HIP FRACTURE SURGERY

K. S. Lai[1]

[1]Dept. of Medicine and Geriatrics / Tai Po Hospital / Hospital Authority / HKSAR, Tai Po, Hong Kong SAR China

Objective: Haemoglobin drop after hip fracture surgery in elderly patients is common. While this is usually a result of the fracture itself or as a consequence after surgery-related blood loss, other causes of major active bleeding should also be considered. To date, data for the exact extent of such haemoglobin drop is lacking. This study is to review the incidence and extent of acute haemoglobin drop after hip surgery in elderly patients suffering from a hip fracture, and the possible contributing factors or correlation.
Methods: Patients $\geq$ 60 years old admitted due to hip fracture with surgery were reviewed for basic demographics, hip fracture types and surgery types, and serum haemoglobin levels before and after surgery. Those with blood transfusion before and during operation were excluded. The post-operative haemoglobin drop was compared among different subgroups (fracture types, surgery types, use of anti-platelets or anti-coagulants).
Results: 333 patients were eligible for this study. Their overall mean post-operative haemoglobin drop was 2.73 g/dl. Patients with extra-capsular fractures and patients receiving arthroplasty surgery had greater post-operative haemoglobin drop than those with intracapsular fractures and receiving internal fixation surgery, respectively, though the differences were not statistically significant. Only 14 patients had documented major active bleeding or a subsequent gastro-intestinal endoscopy performed.

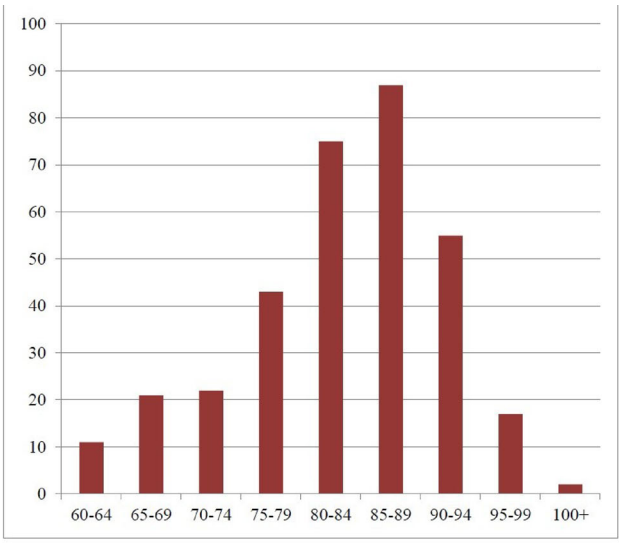

Figure 1: Age Distribution of All Hip Fracture Patients with Surgery

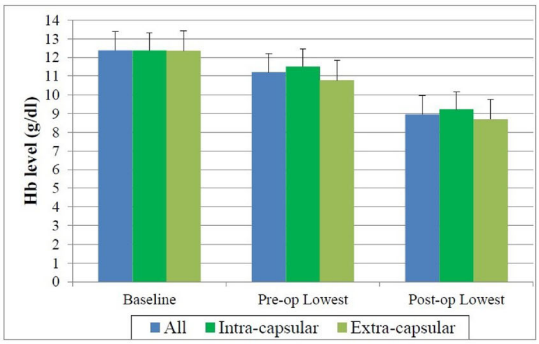

Figure 2: Haemoglobin Level Trends among Different Fracture Types

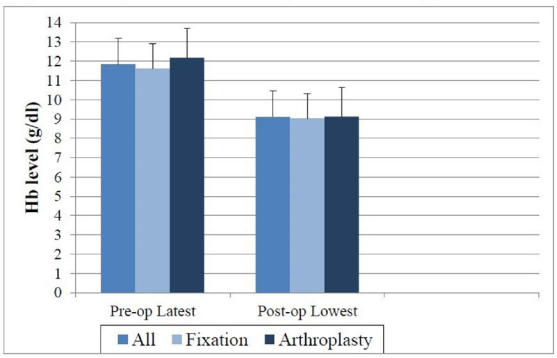

Figure 3: Haemoglobin Level Trends among Different Surgery Types

Conclusion: The type of fracture and the type of surgery were possible associated factors for acute haemoglobin drop in elderly patients after hip fracture surgery.

P718
RISK FACTORS AND FREQUENCY OF VERTEBRAL FRACTURES IN PATIENTS WITH REDUCED BONE DENSITY

K. S. Marković[1], R. Filipov[1], M. Bačević[2], M. M. Bačević[2]

[1]Institution of Rheumatology "Niška Banja", [2]Faculty of Medicine, Niš, Serbia

Objective: Osteoporosis is a generalized metabolic process that reduces bone density and increases susceptibility to fractures. Osteoporotic vertebral fractures are a leading cause of disability and morbidity, particularly in the elderly and are usually unrecognized. We aimed to study frequency of osteoporotic vertebral fractures and their association with the most common risk factors.
Methods: The retrospective analysis included 11,836 patients. BMD was measured at: lumbar spine and hip by DXA apparatus Hologic Discovery. Patients whose hip or lumbar spine T-score was greater than -1 SD were excluded from the analyses, so 4971 patients were analyzed. The fracture was diagnosed radiologically.
Results: Of the 4971 patients, 93.31% (4638) were women and 6.69% (333) were men. The age of the respondents was 60–80 y (average 68.55 y). Of the 4971 subjects, 140 (2.82%) had a vertebral fracture, 101 women (72.15%) and 39 men (27.85%) and 96 (68.56%) had osteoporosis. 54 (1.09%) had one vertebral fracture, 21 (0.42%) had 2 vertebral fractures, 12 (0.24%) had 3 vertebral fractures and 9 (0.18%) had 4 fractures. In the zone of osteopenia, the percentage of vertebral fractures was: 89 (1.81%) subjects had one vertebral fracture, 37 (0.75%) had 2 vertebral fractures, 17 (0.35%) had 3 vertebral fractures and 13 (0.27%) had 4 fractures. The most common risk factor in patients with vertebral fractures was low BMI (< 18.5 g/cm^2), 122 patients (87.78%), followed by previous fractures 87 (62.44%), smoking in 42 patients (29.82%), early menopause 38 (27.16%) subjects, glucocorticoid intake 30 (21.84%), autoimmune diseases 25 (17.92%), fractures in the family 13 (9.52%) and alcohol consumption 4 patients (2.94%).
Conclusion: Osteoporosis complicated by vertebral fractures is more common in women, with reduced bone density (on the level of osteopenia) and low BMI. Based on this retrospective study, we believe that it is necessary to pay more attention to the early recognition of predisposing risk factors for vertebral fractures.

P719
ACUPUNCTURE FOR TREATING TEMPOROMANDIBULAR JOINT DISORDERS: A SYSTEMATIC REVIEW

C. Jae-Heung[1], K. Se-Yun[1], Y. You-Suk[2]

[1]Kyung-Hee Univ. Medical Center, Seoul, [2]Chamjalham Hospital of Korean Medicine, Gyeonggi-do, South Korea

Objective: To assess the clinical evidence for or against acupuncture and acupuncture-like therapies as treatments for temporomandibular joint disorder (TMD).
Methods: Nine electronic databases were searched from their inception to September 2023; PubMed, Cochrane Library, Embase, CNKI, KISS, ScienceOn, RISS, OASIS, KMBASE. Only randomized controlled trials were included in this review. All RCTs of

acupuncture for TMD were searched without language restrictions. The primary outcome was visual analogue scale (VAS) for pain. The secondary outcomes included mouth opening, muscle tenderness and adverse events. Continuous outcome data were presented as mean differences with 95%CIs.

Results: Nine RCTs involving 423 participants were included in this systematic review and meta-analysis. Results revealed that acupuncture improved VAS for pain vs. all controls (MD = -1.04, 95%CI:-2.00 $\sim$ -0.09, Z = 2.14, p = 0.03, I^2 = 94%), vs. sham laser (MD = -0.62, 95%CI:-1.22 $\sim$ -0.02, Z = 2.04, p = 0.04, I^2 = 0%). Muscle tenderness were significantly improved in the acupuncture compared to controls (MD = -1.17, 95%CI:-2.15 $\sim$ -0.19, Z = 2.35, p = 0.02, I^2 = 56%). No significant difference was observed in mouth opening between acupuncture and controls (MD = 0.15, 95%CI:-0.27 $\sim$ 0.57, Z = 0.68, p = 0.49, I^2 = 41%). Adverse events were reported in only one study.

Conclusion: Our systematic review and meta-analysis demonstrate that the evidence for acupuncture as a symptomatic treatment of TMD is limited. Further rigorous and large randomized controlled trials are required to confirm and clarify our result, and to establish beyond doubt whether acupuncture has therapeutic value for this indication.

P720
EFFECTS OF VITAMIN K2 AND D3 ON MINERALIZTION BEHAVIOUR OF HUMAN OSTEOPOROTIC OSTEOBLASTS ON A ROUGHENED TITANIUM SURFACE IN VITRO

K. Tscheu[1], K. Schultz[1], C. Suschek[1], J. Windolf[1], U. Maus[1]

[1]Dept. of Orthopaedics and Trauma Surgery at Düsseldorf Univ. Hospital, Düsseldorf, Germany

Objective: This project investigates the effects of a roughened surface structure of titanium preparations on the osteogenic behavior of human healthy osteoporotic osteoblasts (hopOB) under the application of vitamin K2 (VK2) and D3 (VD3).

Methods: Cell cultures hopOB were isolated from femoral head specimens (hopOB with T < -2.5 in DXA measurement). The titanium plates (Peter Brehm GmbH; diameter 11.7 mm; thickness: 2.0 mm) have a conventional roughened surface structure. Cells in plastic wells were used as control. Calcein and fluorescein diacetate visualized the extracellular matrix (ECM). Alizarin Red S staining quantified the degree of calcification and alkaline phosphatase (ALP) enzyme activity indicated the differentiation.

Results: The ECM could be visualized clearly on both surfaces. A crosslinking was particularly evident on the titanium surface. After 24 h of mineralization, this was also more pronounced on the rough titanium surface than in the respective control cells. After 7 and 14 days, the degree of mineralization of the hopOBs on the rough titanium surface under the influence of VK2 was significantly ($p < 0.05$) higher than the degree of mineralization without the vitamin (on average lower by a factor of 1.6). The degree of differentiation of the hopOBs was initially more pronounced on the titanium preparations than on the plastic surface. After 21 d, there was a significantly higher ALP activity of the hopOBs under VD3 on the rough titanium surface compared to the ALP activity with VK2 and without vitamins.

Conclusion: Under the influence of the vitamins, mineralization and differentiation in interaction with the titanium surface proceeds better than without the addition of vitamins. In principle, the rough titanium surface promotes the formation of the ECM and differentiation. Initially, VK2 has a positive effect, especially on mineralization. In the long term, VD3 positively supports the process of differentiation.

P721
IMPACT OF VITAMIN K2 ON MINERALISATION BEHAVIOUR OF HUMAN ADIPOSE STEM CELLS ON A MODIFIED TITANIUM SURFACE IN VITRO

K. Tscheu[1], K. Schultz[1], C. Suschek[1], J. Windolf[1], U. Maus[1]

[1]Dept. of Orthopaedics and Trauma Surgery at Düsseldorf Univ. Hospital, Düsseldorf, Germany

Objective: This work investigates the behaviour of human adipose stem cells (ASCs) on a roughened titanium surface under the influence and absence of vitamin K2 (VK2) to implement an in vitro model.

Methods: Cell cultures ASCs were isolated from subcutaneous adipose tissue. The titanium plates (Peter Brehm GmbH; diameter 14.7 mm; thickness: 2.0 mm) show a conventional roughened and a smooth surface structure. Cells in plastic wells were used as control. Calcein visualized the extracellular matrix (ECM) and Bisbenzimide showed the cell nucleus. The degree of calcification of the ECM is measured by using Alizarin Red S staining and the activity of alkaline phosphatase (ALP) indicated the degree of differentiation.

Results: The ECM was clearly visible on both sides of the plates. Under VK2, a qualitatively higher cross-linking between the cells was observed after 7 d. After 7 d, the mineralisation of the ECM on the rough surface structure was significantly ($p < 0.05$) more extensive than that of the respective control cells, both with and without VK2. With VK2 treatment, the ECM was significantly more developed on the rough titanium surface structure after 14 d than on the rough surface without VK2 treatment. ALP activity was significantly higher after 21 d on the rough side with and without VK2 than on the respective control cells. Furthermore, the degree of differentiation on the rough surface of the plates with VK2 was significantly higher after 21 d than without VK2 on the rough surface structure.

Conclusion: Basically, the rough surface structure ensures faster and more extensive mineralisation and differentiation. This effect is supported by VK2, whereby the mineralisation is initially positively reinforced by VK2 and the degree of differentiation increases in the long term.

P722
OSTEOPOROSIS SCREENING USING X-RAY ASSESSMENT AND OSTEOPOROSIS SELF-ASSESSMENT TOOL FOR ASIANS IN PATIENTS UNDERGOING HIP SURGERY

K. Uemura[1], R. Higuchi[1], K. Takashima[1], H. Mae[1], H. Abe[2], T. Imagama[3], T. Sakai[3], S. Okada[1], H. Hamada[1]

[1]Osaka Univ., Suita, [2]Hoshigaoka Medical Center, Hirakata, [3]Yamaguchi Univ., Ube, Japan

Objective: Osteoporosis plays an important role in the initial fixation and postoperative period after hip surgery. However, it is difficult to screen using DXA. Therefore, the present study aimed to develop a simple method to efficiently screen for osteoporosis using a combination of anteroposterior hip X-ray assessment and the Osteoporosis

Self-Assessment Tool for Asians (OSTA), which is calculated as (body weight—age) × 0.2.
Methods: One hundred Japanese women (age: 73 ± 11 y, body weight: 54.4 ± 11.1 kg) who underwent hip surgery, anteroposterior hip X-ray, and DXA at two institutions were included. Based on the DXA results of the total proximal femur, 35 cases were diagnosed with osteoporosis. 15 orthopaedic surgeons visually inspected the hip X-ray images and scored the suspicion of osteoporosis on a scale of 1–4 (1: very unlikely, 4: very suspicious), which is referred to as "pred-score." In addition, OSTA was calculated as a continuous variable (OSTA score). Osteoporosis was screened using the pred-score and OSTA score, and both scores were analyzed using the receiver operating characteristic curves.
Results: The area under the curves (AUCs) of the pred-score and OSTA score were 0.626–0.875 and 0.817 across surgeons, respectively. When both scores were used, the AUC for screening osteoporosis ranged from 0.821–0.915 across surgeons. Significant improvement from AUCs calculated with the pred-score or OSTA score was found in 11 surgeons (73.3%).
Conclusion: The combination of X-ray assessment and OSTA can be used to screen for osteoporosis. By combining the pred-score and OSTA score, an AUC > 0.82 was maintained across surgeons for predicting osteoporosis. The results demonstrate the potential of combining visual assessment with OSTA, which may be used as a new simple screening tool for osteoporosis in daily clinical practice.
Acknowledgments: This study was supported by the Japanese Orthopaedic Association (JOA-Subsidized Science Project Research: 2023–2), Grant-in-Aid for Science Research from the Japanese Society for Replacement Arthroplasty Foundation (2023-RP05), and the Japan Society for the Promotion of Science Grants-in-Aid for Scientific Research (KAKENHI) Number 21K16655.

P723
ASSOCIATION BETWEEN SARCOPENIA AND OBESITY IN WOMEN WITH RHEUMATOID ARTHRITIS

K. Zouaoui[1], S. Mhamdi[1], R. Ben Othmane[2], M. Abbes[1], S. Rahmouni[1], S. Boussaid[1], S. Rekik[1], H. Sahli[1], M. Elleuch[1]

[1]Rheumatology Dept., La Rabta Hospital, [2]National Institute of Nutrition, Tunis, Tunisia

Objective: To determine whether there is an association between obesity and sarcopenia in women with rheumatoid arthritis (RA).
Methods: A single-center cross-sectional study including female patients with RA meeting the ACR/EULAR 2010 criteria was conducted. Demographic, clinical and paraclinical data were collected. The participants underwent a hand grip test using a dynamometer to evaluate muscle strength. The assessment of muscle mass was conducted using a bioelectrical impedance analysis (BIA) and DXA. The appendicular skeletal muscle mass index (ASMI) was calculated by dividing appendicular lean mass by squared height. Sarcopenia was defined by a hand grip test < 16 kg and an ASMI ≤ 5.5 kg/m^2. Obesity was defined by a BMI ≥ 30 kg/m^2.
Results: 55 female patients were included with an average age of 58 ± 8 y [40–76]. Among our participants, 34.5% (n = 19) had diabetes, 23.6% (n = 13) had dyslipidemia, and 5.5% (n = 3) had hypothyroidism. The average weight and height were 71 ± 15 [42–103] kg and 156 ± 7 [143–170] cm, respectively. The mean BMI was 29 ± 6 [17–44] kg/m^2. The mean duration of RA was 9 ± 6 y [1–30]. RA was immunopositive in 90.9% of the cases and erosive in 90.9% of the cases. The mean (DAS28-CRP) was 4 ± 1.8 [1.2–6.5]. The average hand grip test result was 9.5 ± 6 kg [1.8–25.6]. The mean ASMI was 7.4 ± 1.2 kg/m^2 [5.4–11] using BIA and 6.47 ± 1.1 kg/m^2 [4.19–8.84] using DXA. Sarcopenia was present in 85.5% of the patients (n = 47), while obesity was noted in 43.6% of the patients (n = 24). There was no observed significant correlation between these two parameters (p = 0.508).
Conclusion: Sarcopenia and obesity were common in our female RA patients. However, no association has been found between these two parameters.

P724
IS SARCOPENIA ASSOCIATED WITH OSTEOPOROSIS IN FEMALE PATIENTS WITH RHEUMATOID ARTHRITIS?

K. Zouaoui[1], S. Mhamdi[1], R. Ben Othmane[2], S. Rahmouni[1], M. Abbes[1], S. Boussaid[1], S. Rekik[1], H. Sahli[1], M. Elleuch[1]

[1]Rheumatology Dept., La Rabta Hospital, [2]National Institute of Nutrition, Tunis, Tunisia

Objective: To determine if there is an association between sarcopenia and osteoporosis in female patients with rheumatoid arthritis (RA).
Methods: A single-center cross-sectional study was conducted on female patients with RA meeting the ACR/EULAR 2010 criteria. Demographic, clinical, paraclinical and therapeutic data of participants were collected. Muscle mass was assessed using bioelectrical impedance analysis (BIA) and DXA. The appendicular skeletal muscle index (ASMI) was calculated as the appendicular muscle mass divided by squared height. Muscle strength was evaluated by the hand grip test using a dynamometer. A patient was considered sarcopenic if her ASMI was ≤ 5.5 kg/m^2 AND her hand grip test was < 16 kg. Bone densitometry was performed to identify osteoporosis, defined by a T-score ≤ -2.5 standard deviations at the lumbar spine and/or femoral neck.
Results: Our study englobed 55 female patients with an average age of 58.22 ± 7.9 y [40–76]. 65.5% lived in urban areas and 81.8% were unemployed. The mean duration of RA was 9.2 ± 6.4 y [1–30]. RA was immunopositive in 90.9% of the cases and erosive in 90.9% of the cases. The mean DAS28-CRP was 4 ± 1.8 [1.2–6.5]. Active disease with a DAS28-CRP ≥ 5.1 was noted in 89.1% of the patients (n = 49). The average Health Assessment Questionnaire (HAQ) was 1.08 ± 0.6 [0.1–2.5]. Corticosteroids were used in 98.2% patients (n = 54), with an average dose of 6 ± 1.9 mg of prednisone. At least one conventional synthetic disease-modifying antirheumatic drug (cs-DMARD) was prescribed. 41.8% patients (n = 23) were treated with a biologic. The mean hand grip test was 9.5 ± 5.7 kg [1.8–25.6]. The mean ASMI was 7.4 ± 1.2 [5.4–11] kg/m^2 by BIA and 6.5 ± 1.1 [4.2–8.8] kg/m^2 by DXA. Sarcopenia was present in 85.5% (n = 49) of patients and osteoporosis was present in 37.3% of the patients (n = 19). There was a significant association between sarcopenia and osteoporosis (p = 0.021).
Conclusion: According to our study, sarcopenia seems to be associated with osteoporosis in female RA patients.

P725
IMPACT OF DIABETES ON OSTEOPOROSIS IN PATIENTS WITH RHEUMATOID ARTHRITIS

K. Zouaoui[1], R. Ben Othmane[2], S. Rahmouni[1], I. Trabelsi[2], M. Abbes[1], S. Boussaid[1], S. Rekik[1], H. Sahli[1], M. Elleuch[1]

[1]Rheumatology Dept., La Rabta Hospital, [2]Dept. of Nutrition, National Institute of Nutrition, Tunis, Tunisia

Objective: Rheumatoid arthritis (RA) is a common chronic inflammatory disease often associated with osteoporosis. Diabetes represents a frequently encountered comorbidity in RA. Through this work, we studied the effect of diabetes on osteoporosis in RA patients.

Methods: A 3-month cross-sectional study was carried out in a rheumatology department. Patients followed for RA according to the ACR/EULAR 2010 criteria were included in the work. Demographic, clinical and biological data were collected. We retained the significance threshold of 0.05 to study the correlation between diabetes and osteoporosis.
Results: We recruited 52 RA patients. The average age was 56.1 ± 12.1 y [22–85] with a clear female predominance (84.6%). RA evolved on average for 13 ± 8.32 y [2–30]. It was immunopositive in 88.5% of cases and erosive in 94.2% of cases. The mean number of painful joints was 9.1 ± 7.7 [0–28] and the mean number of swollen joints was 4.8 ± 4.7 [0–20]. The mean DAS28 was 4.47 ± 1.48 [1.28–8.19] and 32.7% of the population had highly active disease. Among the patients, 19.2% had diabetes and 32.7% had osteoporosis. We did not note a significant correlation between diabetes and osteoporosis in our patients (p = 0.264).
Conclusion: Diabetes is not associated with osteoporosis risk in RA patients.

P726
IS C-REACTIVE PROTEIN CORRELATED WITH SARCOPENIA IN RHEUMATOID ARTHRITIS?

K. Zouaoui[1], R. Ben Othmane[2], M. Abbes[1], S. Rahmouni[1], I. Trabelsi[2], S. Boussaid[1], S. Rekik[1], H. Sahli[1], M. Elleuch[1]

[1]Rheumatology Dept., La Rabta Hospital, [2]Dept. of Nutrition, National Institute of Nutrition, Tunis, Tunisia

Objective: It is currently admitted that sarcopenia is common in rheumatoid arthritis (RA). Actually, there is no biological marker for sarcopenia. The objective of our study was to investigate the link between C-reactive protein (CRP) and sarcopenia during RA.
Methods: It was a 3-month cross-sectional study including patients followed for RA meeting the ACR/EULAR 2010 criteria. Demographic and clinical data of our patients were collected. The CRP level was noted. We used the hand grip test to assess the muscular strength of our patients. Sarcopenia was defined by muscle strength < 27 kg in men and 16 kg in women. The significance threshold p was set at 0.05.
Results: In total, 52 patients were included with a sex ratio M/F = 0.18. The mean age was 56.1 ± 12.1 y [22–85]. The average duration of disease was 13 ± 8.32 y [2–30]. RA was immunopositive in 88.5% of cases and erosive in 94.2% of cases. Half of the patients were obese with a mean BMI of 28 ± 3.46 kg/m^2 [24–30]. The DAS28 averaged 4.47 ± 1.48 [1.28–8.19] and 32.7% of the population had highly active disease. CRP level averaged 14.04 ± 9.35 mg/l [0–68.2]. Muscle strength was 13.1 ± 11.05 kg [3–40.6]. Sarcopenia was noted in 22.4% of participants. There was no significant association between the CRP level and the existence of sarcopenia (p = 0.93).
Conclusion: The CRP level has no impact on sarcopenia during RA.

P727
EVALUATION OF ADHERENCE TO THE MEDITERRANEAN DIET IN PATIENTS WITH RHEUMATOID ARTHRITIS

K. Zouaoui[1], R. Ben Othmane[2], S. Rahmouni[1], M. Abbes[1], I. Trabelsi[2], S. Boussaid[1], S. Rekik[1], H. Sahli[1], M. Elleuch[1]

[1]Rheumatology Dept., La Rabta Hospital, [2]Dept. of Nutrition, National Institute of Nutrition, Tunis, Tunisia

Objective: Dietary measures are currently integrated into the non-pharmacological management of chronic inflammatory joint diseases particularly rheumatoid arthritis (RA). The objective of our study was to evaluate the adherence of RA patients to the Mediterranean diet and to assess its impact on disease activity.
Methods: A cross-sectional study was carried out over 3 months including patients followed for RA according to the ACR/EULAR 2010 criteria. The socio-demographic, clinical and biological data of these participants were collected. RA activity was judged by the DAS28 score. We used a questionnaire from the PREDIMED study, composed of 14 items, to study our population's adherence to the Mediterranean diet [1].
Results: The study included 52 patients followed for RA with a sex ratio M/F = 0.18 and a mean age of 56.1 ± 12.1 y [22–85]. The mean disease duration was 13 ± 8.32 y [2–30]. RA was immunopositive in 88.5% of cases and erosive in 94.2% of cases. 50% of patients were obese with a mean BMI of 28 ± 3.46 kg/m^2 [24–30]. The number of painful joints averaged 9.1 ± 7.7 [0–28] and the number of swollen joints averaged 4.8 ± 4.7 [0–20]. The DAS28 averaged 4.47 ± 1.48 [1.28–8.19]. The average score for adherence to the Mediterranean diet was 7.23 ± 1.85 [3–11]. This diet had no significant impact on the DAS28 score (p = 0.88). It also had no impact on the number of painful joints (p = 0.231) nor on the number of swollen joints (p = 0.409).
Conclusion: The Mediterranean diet does not seem to have any influence on RA activity.

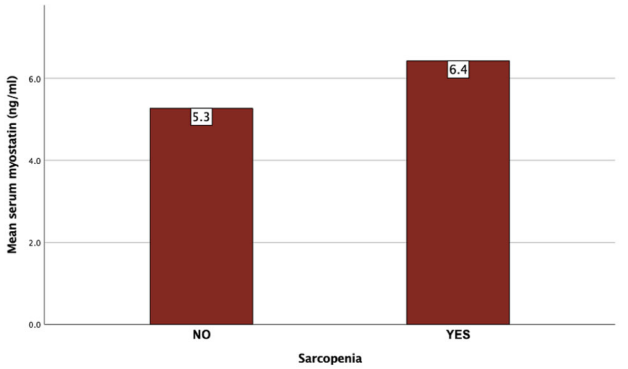
P728
LONG-LASTING AGGRESSIVE RHEUMATOID ARTHRITIS CAUSES SARCOPENIA THROUGH AN INCREASE IN THE SKELETAL MUSCLE ENZYME MYOSTATIN

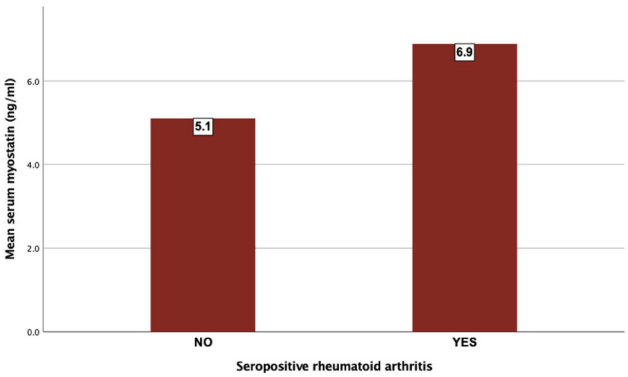
K. Zoupidou[1], M. Krikelis[2], D. Moschou[2], S. Tournis[3], K. Makris[4], S. Gazi[2], D. Boumpas[1], E. Chronopoulos[3], I. Dontas[3]

[1]Rheumatology and Clinical Immunology Unit, 4th Univ. Clinic of Internal Medicine, Attikon Univ. Hospital, [2]Rheumatology Dept., KAT General Hospital, [3]Laboratory of Research of the Musculoskeletal System, National and Kapodistrian Univ. of Athens, [4]Laboratory of Biochemistry, KAT General Hospital, Athens, Greece

Objective: Myostatin is a skeletal-muscle molecule with a negative influence in myogenesis. Chronic inflammation of rheumatoid arthritis (RA) has been associated with increased levels of serum myostatin (1). The aim of this study is to assess serum myostatin levels in RA patients and associate them with disease characteristics and sarcopenia parameters.
Methods: A case series study of 97 postmenopausal women with RA under treatment (1987 ACR criteria). Patient demographics and disease characteristics were recorded. Serum myostatin was calculated using the ELISA method. Patients underwent whole-body DXA to calculate lean skeletal muscle mass (ASMI). Handgrip strength was measured with a Jamar-type hand dynamometer. Physical performance was calculated with the Short Physical Performance Battery (SPPB) test. Sarcopenia was defined according to the revised EWGSOP criteria of 2019. Severe sarcopenia was recognised when all three defining parameters (ASMI, SPPB and handgrip strength) were low.
Results: Mean age was 65 ± 10 y and mean BMI was 29 ± 5 kg/m^2. Mean disease duration was 7 ± 3 y and 40% of the patients had seropositive disease. Mean DAS28 (ESR) was 3.8 ± 1.7 and mean HAQ-DI was 0.8 0.6. One-third of the patients (35%) suffered from sarcopenia, whereas 18% had severe sarcopenia. Mean serum myostatin levels were 5.9 ± 2.1 ng/ml. Increased serum myostatin levels were associated with the existence of sarcopenia (6.4 vs. 5.3 ng/ml, p = 0.012) and with seropositive disease (6.9 vs. 5.1 ng/ml,

$p < 0.001$). Patient functionality assessed with the HAQ-DI index was inversely associated with serum myostatin levels (-0.237, $p = 0.026$).





Conclusion: In this representative RA cohort, higher serum myostatin levels were associated with the presence of sarcopenia, an aggressive disease profile and lower patient functionality scores. These findings suggest that long-lasting aggressive rheumatoid arthritis might to sarcopenia through the upregulation of myostatin.

P729
LOW-DOSE METHOTREXATE TREATMENT INCREASED RISK IN DEVELOPING OSTEOPOROSIS IN SKIN DISEASES: A POPULATION-BASED COHORT STUDY

K.-K. Tung[1], Y.-T. Wen[2], L.-L. Hseuh[3], C.-H. Lin[4], C.-H. Lee[1], S.-Y. Lin[5], K.-K. Chen[6], C.-S. Chiu[7]

[1]Dept. of Orthopedics, Taichung Veterans General Hospital, [2]Dept. of Education, Taichung Veterans General Hospital, [3]Dept. of orthopedics, Taichung Veterans General Hospital, [4]Taichung Veterans General Hospital, [5]Center for Geriatrics and Gerontology, Dept. of Internal Medicine, Taichung Veterans General Hospital, [6]Dept. of Orthopedics, Taichung Veterans General Hospital, [7]Dept. of Dermatology, Taichung Veterans General Hospital, Taichung, Taiwan

Objective: To determine the association between low-dose methotrexate (LD-MTX) treatment and the risk of osteoporosis and fragility fractures, particularly focusing on dermatological conditions. The study sought to elucidate the potential risks and benefits of LD-MTX therapy, especially concerning bone health and its influence on patients diagnosed with dermatological disorders.

Methods: The Osteoporosis Prevention Center (OPC) database from Taichung Veterans General Hospital was the primary data source. Patient records from December 1999 through August 2023 were meticulously reviewed. The study population was bifurcated based on LD-MTX administration. Eligibility was limited to subjects initiating LD-MTX treatment after a confirmed dermatological diagnosis. Patient characteristics and variables were statistically analyzed using ANOVA, chi-square tests, or Fisher's exact test. Both age and gender-stratified analyses were conducted.

Results: Out of 58,299 individuals, 2,342 were under LD-MTX treatment. A significant association between LD-MTX usage and elevated fragility fracture risk was found, especially in individuals aged 40–65 and in females. Chronic urticaria patients predominantly used LD-MTX. After adjustments, LD-MTX correlated with an adjusted HR of 2.59 for osteoporosis risk. Age-stratified analysis showed a significant association in both age brackets, while gender-stratified analysis revealed a pronounced association only in the female cohort.

Conclusion: There is a significant relationship between LD-MTX treatment and increased fragility fracture risk, predominantly in mid-aged individuals and females, especially those diagnosed with chronic urticaria. While the findings offer valuable insights, further comprehensive investigations are necessary to understand the underlying mechanisms and validate the results.

P730
ASSOCIATION BETWEEN OSTEOPOROSIS AND ALL-CAUSE MORTALITY IN HIP FRACTURE PATIENTS: A COMPREHENSIVE ANALYSIS

K.-K. Tung[1], K.-H. Chen[2], S.-Y. Lin[3], Y.-L. Deng[4], C.-E. Hsu[2]

[1]Dept. of Orthopedics, Taichung Veterans General Hospital, [2]Dept. of Orthopedics, Taichung Veterans General Hospital, [3]Center for Geriatrics and Gerontology, Dept. of Internal Medicine, Taichung Veterans General Hospital, [4]Dept. of Nursing, Taichung Veterans General Hospital, Taichung, Taiwan

Objective: To investigate the associations between osteoporosis and cause-specific mortality in a specific cohort of hip fracture patients within the general Asian population, using a comprehensive longitudinal database from Taiwan.

Methods: Participants were recruited exclusively from Taichung Veterans General Hospital's Osteoporosis Prevention Center, focusing on high-risk individuals who had DXA for BMD screening between 2011–2021. Mortality data were matched with death certificates using a probabilistic record linkage method. Cox proportional hazards models calculated hazard ratios (HR) and 95%CI for mortality risk.

Results: Among 2230 hip fracture patients, 1422 were alive, and 808 deceased during follow-up. Notable findings include significantly increased all-cause mortality risk for hip fracture patients with osteoporosis in femur (HR = 1.41, 95%CI: 1.13–1.77), spine (HR = 1.22, 95%CI: 1.02–1.43), overall BMD (HR = 1.28, 95%CI: 1.10–1.48), and TBS-spine (HR = 1.64, 95%CI: 1.01–2.67). Osteoporosis was significantly associated with higher cause-specific mortality, including cancer (TBS-spine, HR = 3.02, 95%CI: 1.12–8.12), cardiovascular disease (TBS-spine, HR = 3.10, 95%CI: 1.11–8.67), and diabetes (Femur aBMD, HR = 3.09, 95%CI: 1.53–6.27). Pulmonary-related mortality was significantly associated with osteoporosis, particularly in femur aBMD (HR = 1.81, 95%CI: 1.05–3.13).

Conclusion: Osteoporosis is significantly linked to an elevated risk of all-cause and specific-cause mortality, including cancer, cardiovascular disease, diabetes, and pulmonary issues, in a specific cohort of hip fracture patients within the general Asian population. These

findings emphasize early osteoporosis detection and management's importance in hip fracture patients, significantly impacting their long-term survival and specific cause-related mortality. Furthermore, this study sheds light on the persistent excess mortality associated with hip fractures, with substantial implications for public health and healthcare systems. Osteoporotic hip fractures pose significant health challenges due to increased mortality rates, lasting functional impairment in many patients, and substantial economic burdens on the National Health System. As life expectancy continues to rise, addressing the multifaceted consequences of hip fractures, including their long-term mortality trends, becomes increasingly imperative in healthcare planning and intervention strategies.

P731
EFFECTIVENESS OF VIRTUAL REALITY TECHNOLOGIES AND ROBOTIC MECHANOTHERAPY TRAINING IN IMPROVING THE FUNCTION OF MOVEMENT IN PATIENTS WITH COXARTHROSIS AND OSTEOPOROSIS AFTER HIP REPLACEMENT SURGERY

E. N. Ryabkov[1], L. A. Marchenkova[1]

[1]National Medical Research Center for Rehabilitation and Balneology, Moscow, Russia

Objective: To evaluate the impact of the training with virtual reality technologies and robotic training with biofeedback on the function of movement and the biomechanics of gate of patients with coxarthrosis and concomitant osteoporosis who underwent hip replacement surgery.
Methods: The study sample consisted of 80 men and women aged 60–85 y in the period from 5–30 weeks after hip replacement surgery due to coxarthrosis, with a T-score in the spine or collateral femur $\leq$ -2.5 according to DXA. Patients of the main group (n = 40) received a new rehabilitation complex, including training in virtual reality, robotic training with biofeedback and a special complex of strength and resistance exercises. The rehabilitation course for the control group (n = 40) included only complex of strength and resistance exercises. The examinations included assessment of pain intensity using a visual analogue scale (VAS), assessment of biomechanics and walking speed on a touch treadmill—C-Mill ergometer and functional tests.
Results: After completion of rehabilitation in the main group there were a decrease in pain level according to VAS was detected by 41.7% (p = 0.023 compared to the initial level, p = 0.047 compared to the control group), increase in walking speed (by 20.5%, p = 0.028) and a decrease in step width (by 8.2%, p = 0.048), which indicates the restoration of the physiological walking pattern. Also, in patients of the main group, a decrease in the time to complete the "Up and go" test was revealed from 15.6 [10.1; 16.4] to 13.2 [8.8; 13.0] sec (p = 0.043) and an increase in walking speed according to the 10-m test from 0.71 [0.5; 1.0] to 0.88 [0.8; 1.3] m/sec (p = 0.039), which indicates a significant improvement in functionality and mobility in patients. There were no significant changes in the pain intensity, speed and biomechanics of walking in the control group ($p > 0.05$).
Conclusion: A new rehabilitation complex, including methods of mechanotherapy with biofeedback and virtual reality, can be recommended for the rapid restoration of motor function and walking biomechanics after hip replacement in patients with coxarthrosis and concomitant osteoporosis.

P732
GATE AND BALANCE DISORDERS IN PATIENTS WITH TYPE 2 DIABETES MELLITUS: IMPACT OF DISTAL POLYNEUROPATHY

L. A. Marchenkova[1], V. A. Vasileva[1], G. G. Kuzminov[1]

[1]National Medical Research Center for Rehabilitation and Balneology, Moscow, Russia

Objective: To investigate the degree of impairment of gate and balance function in patients with type 2 diabetes mellitus (T2DM) and distal diabetic polyneuropathy (DPN).
Methods: The study included 120 patients with T2DM and distal DPN, age 57.0 [49.0; 61.0] years. A group of 60 practically healthy volunteers without DM was formed as a healthy control by gender and age. The complex of research methods included a study of the severity of DPN symptoms using the NSS neuropathy symptom scale and the NDS neurological dysfunctional score scale, assessment of gait biomechanics on a sensory track with C-Mill biofeedback, and functional tests for ambulation and balance assessment.
Results: In patients with DPN compared with persons without DM the time to complete the Up and go test was increased by 28.6% (9.0 [7.5; 10.5] vs. 7.0 [5.5; 8.5] sec, respectively, p = 0.032) and walking speed was reduced by 11.8% (1.5 [1.2; 1.7] vs. 1.7 [1.1; 2.1] m/sec, respectively, p = 0.023). According to the One leg standing test in patients with DPN compared with healthy volunteers there was a decrease in the time of maintaining balance on the left leg with eyes open by 43.8% (4.5 [2.0; 8.0] vs. 8. 0 [6.0; 12.0] sec, respectively, p = 0.035) and with eyes closed by 64.3% (1.0 [0; 3.0] vs. 2.8 [1.0; 3.5] sec, respectively, p = 0.040) and on the right leg with eyes closed – by 37.5% (2.5 [0; 3.0] vs. 4.0 [3.0; 5.5] sec, respectively, p = 0.012). Patients with DPN compared with healthy volunteers showed a decrease in walking speed by 16.0% (79.0 [68.0; 91.0] vs. 94.0 [77. 0; 100.0] steps/min, respectively, p = 0.028) and an increase in step width by 11.5% (184.0 [138.0; 235.0] mm vs. 165.0 [10.2; 186.0] mm, respectively, p = 0.041) according to on C-mill treadmill testing. The time to complete the up and go test correlated with the values of the NSS scale (r = 0.28, p = 0.033), the speed of covering a distance of 10 m depended on the severity of DPN symptoms on the NSS scale (r = -0.24, p = 0.04) and NDS scale (r = -0.28, p = 0.036).
Conclusion: A significant decreased walking speed, deterioration of gait biomechanics and static balance function were revealed in patients with DPN.

P733
VARUS DEFORMITY IS A FACTOR IN THE PROGRESSION OF KNEE OSTEOARTHRITIS

N. Kashevarova[1], L. Alekseeva[1], E. Strebkova[1], E. Taskina[1]

[1] V.A.Nasonova Research Institute of Rheumatology, Moscow, Russia

Objective: To study the relationship of varus deformity of the knee with the risk of progression of knee osteoarthritis (OA) in a 5-y prospective follow-up.
Methods: The study involved 52 women with primary knee OA (ACR criteria), with a disease duration of up to 5 y (average age 59.11 $\pm$ 8.95 y, average disease duration of 3.46 $\pm$ 1.32 y). The patients were examined twice with an interval of 5 y, the data were entered into a specially designed map, including anamnestic, anthropometric and clinical data, assessment of knee pain according to VAS, X-ray, ultrasound and MRI of the knee.
Results: After 5 y of follow-up, the progression of knee OA (an increase in the X-ray stage) was noted in 14 patients, in 38 the OA stage did not change. Patients in both groups were comparable in age

and duration of the disease. However, patients in the group with OA progression had more intense pain 60.36 ± 18.33 vs. 48.71 ± 17.81, p = 0.043 (mm), a higher BMI of 34.45 ± 4.60 vs. 28.92 ± 4.92, p = 0.001 (kg/m^2) and varus deformity of the knee was more often detected 28.6% vs. 5.3%, p = 0.02. Using discriminant analysis, the main risk factors for the progression of knee OA were identified: varus deformity of the knee, synovitis, osteitis, and taking combination therapy of chondroitin sulfate (HC) and glucosamine (G) for more than 6 months a year for 5 y was identified as a factor reducing the risk of disease progression. Based on the identified factors and their coefficients, a model was created that allows predicting the course of the disease in a particular patient with high accuracy (the area under the ROC curve was—0.93). The sensitivity of the model is 78.6%, the specificity is 84.2%.

Conclusion: Varus deformity of the knee, synovitis, and osteitis are the main risk factors contributing to the progression of knee OA in patients with a disease duration of up to 5 y. Long-term use of a combination of HC and G had a positive effect on the risk of X-ray progression.

P734
RELATIONSHIP OF VITAMIN D AND OSTEOARTHRITIS: COMPARATIVE CLINICAL CHARACTERISTICS

N. Kashevarova[1], L. Alekseeva[1], E. Taskina[1], E. Strebkova[1], E. Sharapova[1], N. Savushkina[1], K. Mikhailov[1], S. Glukhova[1], N. Demin[1]

[1] V.A.Nasonova Research Institute of Rheumatology, Moscow, Russia

Objective: To evaluate the relationship of vitamin D with clinical parameters in knee osteoarthritis (OA) in a single-stage study.

Methods: The study included 171 patients aged 40–75 y, with knee OA (ACR) of X-ray stage I-III (Kellgren–Lawrence). The average age was 53.5 ± 9.94 y, BMI was 29.8 ± 6.4 kg/m^2, and the duration of the disease was 3 [1; 7] y. An individual card was filled out for each patient, including anthropometric indicators, anamnesis and clinical examination data, assessment of knee pain according to VAS, WOMAC, and the patient's general health status (GSH). All patients underwent X-ray, ultrasound, MRI of the knee joints (WORMS) and laboratory examination.

Results: Normal vitamin D values (more than or equal to 30 ng/ml) were detected in 62 patients (36.3%) in group 1, decreased (< 30 ng/ml) in 109 patients (63.7%), while insufficiency (< 30 ng/ml, but > 20 ng/ml) was registered in 66 patients (38.6%) in group 2, and deficiency (< 20 ng/ml) in 43 (25.1%) in group 3. The patients of the three groups were comparable in age and duration of the disease, but significantly differed in weight and BMI (with a predominance in groups with reduced vitamin D values, $p < 0.05$). Also, these patients had significantly ($p < 0.05$) higher pain indicators for VAS, total WOMAC and its components (pain, stiffness and FN), GSH, and worse ($p < 0.05$) data on the KOOS index. More patients of groups 2 and 3 ($p < 0.05$) had hip OA, hand OA, synovitis, flat feet and quadriceps hypotrophy. Fewer patients ($p < 0.05$) engaged in physical therapy (exercise therapy) and took calcium and vitamin D, they more often had concomitant diseases: coronary heart disease (CHD), hypertriglyceridemia, arterial hypertension (AH).

Conclusion: Vitamin D deficiency is associated with a more severe course of knee OA. These patients had a higher BMI, higher pain values according to VAS, the WOMAC index (total and its components), worse indicators of KOOS, GSH. They were more likely to have X-ray stages 2 and 3 of knee OA, other localizations of OA, synovitis, quadriceps hypotrophy, flat feet and concomitant diseases: CHD, hypertriglyceridemia, AH.

P735
RELATIONSHIP OF VITAMIN D AND OSTEOARTHRITIS: COMPARATIVE LABORATORY AND INSTRUMENTAL CHARACTERISTICS

N. Kashevarova[1], L. Alekseeva[1], E. Strebkova[1], E. Taskina[1], E. Sharapova[1], N. Savushkina[1], K. Mikhailov[1], S. Glukhova[1], O. Alekseeva[1], D. Kudinsky[1], N. Demin[1], E. Samarkina[1]

[1]V.A.Nasonova Research Institute of Rheumatology, Moscow, Russia

Objective. To evaluate the relationship of vitamin D with laboratory and instrumental parameters in knee osteoarthritis (OA) in a single-stage study.

Methods: The study included 171 patients aged 40–75 y, with knee OA (ACR) of X-ray stage I-III (Kellgren–Lawrence). The average age was 53.5 ± 9.94 y, BMI was 29.8 ± 6.4 kg/m^2, and the duration of the disease was 3 [1; 7] y.

Results: Normal vitamin D (≥ 30 ng/ml) were detected in 62 patients (36.3%) group 1, decreased (< 30 ng/ml) in 109 patients (63.7%), while deficiency vitamin D (< 30 ng/ml, but > 20 ng/ml) was registered in 66 patients (38.6%) in group 2, and severe deficiency (< 20 ng/ml) in 43 (25.1%) in group 3. The patients of the groups were comparable in age and duration of the disease. Patients with vitamin D deficiency (groups 2 and 3) had higher concentrations of CRP, leptin, glycated hemoglobin, glucose, and alkaline phosphatase were more often recorded ($p < 0.05$ for all values). Ultrasound examination of patients in group 1 more often ($p < 0.05$) revealed large sizes of cartilage tissue both on the anteromedial and anterolateral surfaces of the knee; MRI (WORMS) less often ($p < 0.05$) revealed osteitis in the medial condyles of the femur and tibia (Table 1).

Table 1. The incidence of osteitis in patients with different vitamin D levels

Parameter	Normal vitamin D (n=62) (Group 1)	Vitamin D deficiency (n=66) (Group 2)	Vitamin D severe deficiency (n=43) (Group 3)	P
Osteitis in the medial condyles of the femur,%	5,72	20,0	33,3	*0,01
Osteitis in the medial condyles of the tibia,%	8,57	15	22,2	* 0,03

p* - significance between groups 1 and 2,3

Conclusion: Vitamin D deficiency is associated with a more severe course of knee OA. These patients were significantly more likely to have elevated values of CRP, alkaline phosphatase, leptin, smaller cartilage in the medial parts of the knee (ultrasound), they were significantly more likely to have osteitis (MRI) in the medial parts of femur and tibia.

P736
EFFICACY OF BIOACTIVE CONCENTRATE OF SMALL MARINE FISH IN PATIENTS WITH HAND OSTEOARTHRITIS

L. Alekseeva[1], E. Taskina[1], E. Strebkova[1], N. Kashevarova[1], A. Lila[1]

[1]V.A.Nasonova Research Institute of Rheumatology, Moscow, Russia

Objective: To evaluate the efficacy of SYSADOA (bioactive concentrate of small marine fish (BCSMF) containing chondroitin sulfate, amino acids, peptides, sodium, potassium, calcium, magnesium, iron, copper and zinc ions) in patients with hands osteoarthritis (OA) in a multicenter observational study.

Methods: The study included 2776 patients with hands OA according to the criteria of the ACR. The median age was 63 (56–70) y.o., BMI was 27.7 (25–31.2) kg/m^2, and VAS pain was 60 (41–70) mm. The duration of the study is from 20–31 d, the number of visits is 2: visit 1 (V1) – the beginning of therapy, visit 2 (V2) – within 10 d after the

completion of the 1st course of treatment. BCSMF was prescribed 1 ml intramuscular daily No. 20 or 2 ml intramuscular every other day No. 10.

Results: Against the background of one course of the drug, there was a significant decrease in pain (V1 – 52 [33; 70] and V2 – 14 [2; 30] mm, $p < 0.05$, Fig. 1), an improvement in the quality of life (EQ-5D), $p < 0.05$ and general health status (GHS), $p < 0.05$. The median reduction in pain (VAS) was 62.3%. Against the background of therapy, the need for NSAIDs also decreased: at the beginning of therapy, 53.6% of patients received these drugs, at the end of treatment 49.8% ($p = 0.01$). Good response to therapy (pain reduction by 50% or more) it was detected in 73.5%; pain reduction of < 40 mm in 87.6% of patients. Older age, more severe X-ray manifestations of OA, high pain intensity and worse indicators of GHS, low quality of life and concomitant pathology were associated ($p < 0.05$) with a lower effect of therapy in hand OA (pain reduction by < 50%).

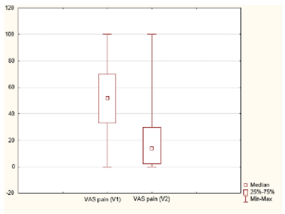

Fig. 1 – Dynamics of pain (VAS) in hand OA against the background of drug treatment

Conclusion: The results of the use of BCSMF in hand OA indicate the expediency of its widespread use in real clinical practice. Taking into account and correcting factors associated with a less pronounced analgesic effect of the drug will improve the efficacy of OA therapy.

P737
COMPARATIVE CLINICAL CHARACTERISTICS OF METABOLIC AND OSTEOPOROTIC PHENOTYPES OF KNEE OSTEOARTHRITIS

L. Alekseeva[1], E. Strebkova[1], N. Kashevarova[1], E. Taskina[1], N. Savushkina[1], E. Sharapova[1], K. Mikhailov[1], A. Khalmetova[1], A. Lila[1]

[1]V.A.Nasonova Research Institute of Rheumatology, Moscow, Russia

Objective: A comparative analysis of clinical indicators of metabolic (MetOA) and osteoporotic (OP) phenotypes of osteoarthritis (OA) of the knee joints (KJ).

Methods: The study included 195 patients with MetOA (metabolic syndrome and/or type 2 diabetes mellitus) and 176 with OP (with reduced BMD: the presence of osteoporosis or osteopenia in the axial skeleton), with a reliable diagnosis of knee OA (criteria of the ACR) of stage I-III (Kellgren-Lawrence).

Results: Patients of both groups did not differ in age ($p = 0.36$) and duration of the disease ($p = 0.26$), however, patients with MetOA compared with OP had statistically significantly a heavier course of OA: movement restriction was more often determined in KJ (RR = 1.811, 95%CI 1.388–2.363, $p = 0.001$), quadriceps hypotrophy (RR = 1.556, 95%CI 1.193–2.029, $p = 0.005$), higher pain values for VAS, total WOMAC and its components (pain, stiffness and FN), worse the values of KOOS and general state health (GSH) (Table 1). In patients with OP, the first radiological stage of OA was more often determined (RR = 0.257, 95%CI 0.131–0.507, $p < 0.001$) compared with MetOA, in whom more advanced radiological stages were more often verified (RR = 1.633, 95%CI 1.249–2.136, $p = 0.04$). With OP, flat feet and scoliosis of the spine were more often detected. These results demonstrate a more severe course of patients with MetOA.

Table 1. Comparative clinical characteristics of patients with metabolic and osteoporotic phenotypes of OA

Parameter	Patients with MetOA (n=195)	Patients with OP (n=176)	p
The pain is VAS, mm, Me	40 [25; 52]	20 [2,5; 30]	<0,001
Pain WOMAC, mm, Me	170 [118; 250]	112 [42; 157]	<0,001
Total WOMAC, mm, Me	880 [595; 1215]	457 [205; 820]	<0,001
KOOS, points, Me	48 [37; 58]	57 [49; 77]	0,002
Flat feet,%	69,4%	83,9%	0,01
Scoliosis of the spine,%	45,6%	72,4%	0,001

Conclusion: The results of our work demonstrate a more severe clinical course of knee MetOA. In this regard, therapeutic measures should include both nonpharmacological and pharmacological interventions aimed not only at OA, but also at all components of metabolic syndrome, which will help slow the progression of the disease.

P738
KNEE OSTEOARTHRITIS IN PATIENTS WITH OBESITY AND NORMAL BODY WEIGHT: COMPARATIVE CHARACTERISTICS OF CLINICAL AND LABORATORY PARAMETERS

L. Alekseeva[1], E. Strebkova[1], E. Taskina[1], N. Kashevarova[1], N. Savushkina[1], E. Sharapova[1], K. Mikhailov[1], A. Khalmetova[1], A. Lila[1], T. Raskina[2], J. Averkieva[2], E. Usova[2], I. Vinogradova[3], O. Salnikova[3], A. Markelova[3]

[1]V.A.Nasonova Research Institute of Rheumatology, Moscow, [2]Kemerovo State Medical Univ., Kemerovo, [3]Ulyanovsk Regional Clinical Hospital No. 1, Ulyanovsk, Russia

Objective: To evaluate the effect of high BMI on the clinical course of knee osteoarthritis (OA) in a multicenter program.

Methods: The study included 495 patients aged 40–75 y with a reliable diagnosis of knee OA (ACR) of stage I-III (Kellgren-Lawrence) who signed an informed consent. The average age of the patients was 60.5 ± 8.33 y (from 40–75), the duration of the disease was 7 (3–14) y.

Results: Obesity (BMI > 30 kg/m^2) was detected in 244 individuals (49.3%). According to the presence or absence of a high BMI, patients were divided into 2 groups. Obese patients were older and had a longer duration of OA. Statistically significant differences were revealed when evaluating the clinical manifestations of OA. In patients with high BMI, a more pronounced intensity of knee pain (VAS), worse pain indicators and all the constituent parameters of the WOMAC and KOOS ($p < 0.05$). Obese patients had more often detected ($p < 0.05$): synovitis, knee flexion restriction, hypotrophy quadriceps, knee varus deformity, flat feet and the generalized form of OA. In a laboratory study, higher concentrations of CRP, leptin and IL-6 were determined in obese patients ($p < 0.05$ for all values). Spearman correlation analysis ($p < 0.05$) confirmed the relationship between high BMI and duration of OA ($r = 0.24$), radiological stages ($r = 0.31$), generalized form of OA ($r = 0.13$), pain according to VAS ($r = 0.21$) and WOMAC ($r = 0.27$), KOOS ($r = 0.25$). Significant positive associations were also noted with the following laboratory parameters: CRP ($r = 0.41$), leptin ($r = 0.66$) and IL-6 ($r = 0.31$).

Conclusion: The results obtained demonstrate the important role of obesity as predictors of severe OA. Obese patients have high pain values according to VAS, according to the WOMAC and KOOS index, higher concentrations of inflammatory mediators (CRP), adipokines (leptin) and cytokines (IL-6). Given the growth rate of the obesity pandemic in the world, it is necessary to optimize the treatment algorithms for patients with obesity and knee OA.

P739
DYNAMIC PARAMETERS OF PROXIMAL FEMORAL DYSPLASIA IN INNATE DISLOCATION IN CHILDHOOD AND ADOLESCENCE

L. Ametova[1], A. Useinova[1], V. Kaliberdenko[1], E. Kulieva[1]

[1]V.I. Vernadsky Crimean Federal Univ., Simferopol, Russia

Objective: The study of the features of hip dysplasia in different age groups gives an idea of the choice of conservative or surgical methods of intervention in children with congenital dislocation.
Methods: 990 radiographs of 178 joints of children with congenital hip dislocation aged from 1–14 y were studied. Radiometry of linear and angular values of the hip joint was performed, as well as a study of the bioelectric activity of the muscles surrounding the hip joint.
Results: As a result of the study, it was determined that the cervical-diaphyseal angle is mainly increased in preschool children (150,1° ± 15,8–148,8° ± 15,6), and it normalizes or slightly elevated at an older age (up to 136.2 ± 3.21°). The magnitude of the Shenton line gap was also determined. In the age group from 1–3 y, it was 20.3 ± 1.22 mm, and tends to increase with the age of patients. Thus, in the group from 11–14 years old, the gap of the Shenton line was 39.0 ± 8.13 mm. This indicates a shortening and an increase in the tone of the pelviotrochanter muscles, which was confirmed by an electromyogram. There is also the horizontal size of the ossification nucleus increases with the age of the patient: 1–3 y -12.5 ± 0.91 mm, 4–5 y—18.7 ± 0.63 mm, 6–7—25.3 ± 1.48 mm, 8–10—32.0 ± 3.11 mm, 11–14 y—31.7 ± 3.32 mm. The antetorsion of the proximal end of the femur reaches its maximum in children aged 5 y and is 65.3 ± 1.65°, and in subsequent age groups it decreases to 54.2 ± 4.2°.
Conclusion: This study confirms the importance of early diagnosis of congenital hip dislocation, since when this pathology is detected at the age of 1 y, it remains possible to perform closed hip reduction, which is quite effective.

P740
PROGNOSIS OF DEVELOPMENT OF INNATE FEMORAL DYSPLASIA BY X-RAY MARKER

L. Ametova[1], A. Useinova[1], V. Kaliberdenko[1], E. Kulieva[1]

[1]V.I. Vernadsky Crimean Federal Univ., Simferopol, Russia

Objective: The frequency of diagnosis of congenital hip dysplasia occurs in up to 6.5% of all newborns and there is a need to predict the course of pathology in order to choose the right tactics in each individual case.
Methods: 608 radiographs of 152 joints of children with congenital hip dislocation aged 1–5 y were studied.
Results: The analysis of the main parameters of femoral joint was determined: the lumbosacral synchondrosis (LSS), the acetabular index (AI), the thickness of the iliac bone and the bottom of the acetabulum, the cervical-diaphyseal angle (CDA).The significance of the correlation matrix data was verified using the Kolmogorov–Smirnov criterion (n = 100, a = 0.05). It turned out that the size of the LSS has a significant correlation with the indicators of the dysplastic joint: the larger the size of the LSS, the smaller the thickness of the iliac bone body, the bottom of the acetabulum, and the size of the femoral head. The correlation of radiographic parameters in the age groups 1–2 and 3–5 y was studied. The data obtained indicate the high informativeness of the linear values of the LSS. However, this value correlated differently depending on the age group. So, in the first age group (n = 50), using the example of the thickness of the acetabulum bottom, there is a direct moderate (0.3) correlation, and in the second—a weak reverse (-0.19).
Conclusion: Surgical interventions for congenital hip dislocation in children, such as acetabuloplasty or osteotomy, are very traumatic methods of correcting this pathology and should be justified. Therefore, the conducted study allows the orthopedist to reliably predict the possibility of independent hip joint development in children when choosing the optimal treatment tactics based on the indicator of linear values of LSS.

P741
PATHOGENESIS OF GLUCOCORTICOIDS OSTEOPOROSIS

E. Kuliyeva[1], V. Kaliberdenko[1], L. Ametova[1]

[1] V.I. Vernadsky Crimean Federal Univ., Simferopol, Russia

Objective: Glucocorticoids are steroid hormones synthesized by the adrenal cortex. The glucocorticoids are used in medicine as anti-inflammatory, immunosuppressive, anti-allergic and anti-shock drugs. However, prolonged using of these hormones can cause of structural and functional changes of bones or osteoporosis that develops in 30–50% of cases.
Methods: The analysis of research and scientific and literary materials of foreign authors working on the study of glucocorticoids and their depiction on bone density.
Results: The Pathogenesis of glucocorticoid osteoporosis begins from the first weeks of therapy with glucocorticosteroids, as the result the absorption of calcium in the intestine decreases while in the renal tubules the reabsorption of the same element is decrease. In addition, there is a hyperparathyroidism, which occurs in most patients at the stage of hormone therapy, contributes to the leaching of calcium from bones. The glucocorticoids also decrease the functional activity and differentiation of osteoblasts. Hormones inhibit the synthesis of type I procollagen, which makes up to 90% of the organic bone matrix. Together with the suppression of bone formation, the drugs stimulate the activity of osteoclasts, which enhance bone resorption. This process realizes by expression of nuclear factor RANKL and macrophage colony stimulating factor. In the pathogenesis of glucocorticoid osteoporosis, an important role is played by the disorders of metabolism of the sex hormones that increases bone resorption.
Conclusion: In spite of the fact that glucocorticoids are included in the arsenal of modern therapy of the different diseases, it is necessary not to forget about the risk of possible complications, one of which is glucocorticoid induced osteoporosis.

P742
ROMOSOZUMAB AS A SCLEROSTIN INHIBITOR IN OSTEOPOROSIS TREATMENT

E. Kuliyeva[1], V. Kaliberdenko[1], L. Ametova[1]

[1]V.I. Vernadsky Crimean Federal Univ., Simferopol, Russia

Objective: Osteoporosis is a multifactorial disease, with predominant damage and destruction of bone tissue by the type of "leaky bone", characterized by a violation of the mechanical and biophysical properties of bone, due to which bone tissue loses its elasticity and strength. Maintaining the health of the bone system is primarily associated with the use of pharmacological therapy for this purpose in 2019, romosozumab that approved by the US Food and Drug Administration as an inhibitor of sclerostin.
Methods: The analysis of research and scientific literary materials of foreign authors working on the study of osteoporosis and treatment.
Results: Romosozumab is a human monoclonal antibody (IgG2) formed in a mammalian cell line, more precisely in the ovary of a Chinese hamster using recombinant DNA technology. By inhibiting

the sclerostin, it enhances the anabolic processes of bone tissue and reduces its resorption. In comparison with other osteoanabolic drugs, romosozumab has a large anabolic window and has a greater effect on increasing BMD. According to the Cochrane meta-analysis, 6137 patients who took romosozumab for a year at a dose of 210 mg once a month subcutaneously showed a decrease in the frequency of vertebral fractures, fractures of other localization and the risk of falls after 24 months. BMD in the lumbar spine, as well as the entire hip and hip neck, compared with the baseline level, increased by 12.5 ± 2.4% and 5.5 ± 0.7% after 12 months, respectively. According to Langhdal B et al. (2022), taking romosozumab at the same dose for 12 months reduced the risk of vertebral and clinical fractures. The study shows that in the phase IIIb, the drug significantly increased BMD after 12 months of using. At the same time, the clinical effect persisted for 12–24 months.
Conclusion: Using of romosozumab in the treatment of osteoporosis is highly effective that confirmed by a number of large-scale studies.

P743
IMPACT OF OBESITY ON BONE RESORPTION

E. Kuliyeva[1], V. Kaliberdenko[1], L. Ametova[1]

[1] V.I. Vernadsky Crimean Federal Univ., Simferopol, Russia

Objective: Obesity is the result of the formation of excess body fat and, as a rule, accompanied by metabolic syndrome, the main criterion of which is abdominal obesity, characterized by a waist circumference of more than 80 cm in women and more than 94 cm in men. There is evidence that obesity can affect bone resorption.
Methods: The analysis of research and scientific literary materials of foreign authors working on the study of obesity, osteoporosis and bound between them.
Results: According to research, changes in body weight better reflect the dynamics of BMD compared to BMI. Obesity may be associated not only with nutritional errors, but also with increased levels of PTH, which also increases bone formation by protecting osteoblasts from apoptosis in rodent models. The positive effect of obesity on skeletal growth and bone density in children was revealed, i.e., with an increase in the base body fat mass, bone mass and area increased. During the studying, the frequency of fractures in people with excess fat mass founded that excess fat mass protected against both total fractures and osteoporotic fractures. Probably these processes are associated with hyperinsulinemia, both insulin, as well as amylin secrete together and strongly inhibit bone resorption. Glucose-dependent insulinotropic polypeptide (GIP), which enhances postprandial insulin secretion, is also associated with this process. Despite the fact that GIP does not directly affect bone resorption, he stimulates the proliferation of osteoblasts, and therefore reduces bone loss. In patients with hyperinsulinemia, the free concentration of sex hormones in the blood increases, which affects osteoclast and osteoblast activity. According to the data, the risk of vertebral fractures is reduced by 50% in people with insulin resistance.
Conclusion: Despite the fact that obesity reduces the number of fractures and injuries by affecting bone resorption by inhibiting it, should not forget that obesity itself serves as a predictor of many diseases.

P744
CRITERIA FOR ASSESSING RISK OF THROMBOEMBOLIC COMPLICATIONS IN LIMB FRACTURES

A. Useinova[1], V. Kaliberdenko[1], L. Ametova[1], E. Kuliyeva[1]

[1]V.I. Vernadsky Crimean Federal Univ., Simferopol, Russia

Objective: Developing of the criteria for the prognosis of venous thromboembolic complications (VTEC) in case of limb fractures.
Methods: 74 patients aged 18–44 y with fractures of the lower extremities were studied. Group 1—44 patients with common fractures, Group 2—30 patients with VTEC. The control group consisted of 100 healthy men and women. Patients with concomitant diseases and women during menstruation and menopause were excluded. Clinical, laboratory and instrumental parameters were studied. The examination was carried out within 10 d after surgery using the IBM SPSS Statistics Version 25.0 program for statistical processing of the results.
Results: Based on the results of binary logistic regression, the most informative indicators were included in the equation: lymphocyte-platelet adhesion (LTA), international normalized ratio (INR) and D-dimer, and their significance was determined. The developed prognostic model has a sensitivity of 0.97, specificity of 1.0, $p < 0.001$. Based on these data, a computer program was created to determine the risk of developing VTEC in fractures. The user enters the LTA, INR and D-dimer concentrations in the user window, the program shows the result: a red window for high risk and a green window for low risk. It helps determine the risk of VTEC in fractures and improve patient treatment tactics.
Conclusion: Determining the LTA index, INR and D-dimer concentration in patients with fractures of long bones of the extremities and carrying out calculations using the proposed computer program can allow timely determination of the risk stratification of an unfavorable outcome and implementation of timely preventive measures.

P745
PREDICTORS AND RISK FACTORS FOR LOW-ENERGY FRACTURES IN NON-INSULIN-DEPENDENT DIABETES MELLITUS

A. Useinova[1], L. Ametova[1], V. Kaliberdenko[1], E. Kuliyeva[1]

[1] V.I. Vernadsky Crimean Federal Univ., Simferopol, Russia

Objective: Evaluation of risk factors for low-energy fractures (FFE) in postmenopausal patients with type 2 diabetes mellitus (T2DM).
Methods: Among 81 patients with type 2 diabetes, two groups were divided: 35 people with low-energy fractures and 46 people without fractures. Exclusion criteria included diseases causing osteoporosis and taking medications that affect bone density. Patients were examined on a variety of parameters, including plasma concentrations of various substances (total alkaline phosphatase, creatinine, etc.), analysis of bone metabolism and assessment of chronic diseases.
Results: The 35 patients in group 1 had 55 fractures, for an average of 1 fracture per person. The most common fracture sites were the radius (32.72%) and tibia (25.45%). Patients with neuropathy had significantly higher postmenopausal duration, blood phosphorus levels, and duration of insulin therapy. According to ROC analysis, in postmenopausal patients with T2DM, the likelihood of developing NEP

increased with a postmenopausal duration of > 15 y, a phosphorus level above 1.48 mmol/l, and a duration of insulin therapy of > 3 y. Literary data also indicate a risk of falls due to an increase in the frequency of hypoglycemia with insulin therapy and deterioration in bone quality, which increases the risk of fractures in patients with decompensated type 2 diabetes. There was no relationship between complications of type 2 diabetes, classes of glucose-lowering therapy, duration of the disease, BMI, values HbA1c, sclerostin, cathepsin K, CIRS and the presence of NES in the examined patients.
Conclusion: The most significant risk factors for the development of NEP in postmenopausal patients with type 2 diabetes mellitus were the duration of postmenopause, the duration of insulin therapy for > 3 y and an increase in blood phosphorus.

P746
DEVELOPMENT OF RHEUMATOID ARTHRITIS, AN AUTOIMMUNE MUSCULOSKELETAL DISEASE, AFTER SARS-COV-2 INFECTION

L. Athanassiou[1], P. Tsakiridis[2], P. Athanassiou[2], I. Kostoglou-Athanassiou[3], Y. Shoenfeld[4]

[1]Dept. of Rheumatology, Asclepeion Hospital, Voula, Athens, Greece, [2]Dept. of Rheumatology, St. Paul's Hospital, Thessaloniki, Greece, [3]Dept. of Endocrinology, Diabetes and Metabolism, Asclepeion Hospital, Voula, Athens, Greece, [4]Zabludowicz Center for Autoimmune Diseases, Sheba Medical Center, Reichman Univ., Herzelia, Israel

Objective: The SARS-CoV-2 virus has been related to the development of autoimmunity. Mechanisms possibly involved are molecular mimicry and the development of extracellular neutrophil traps. The aim was to describe two cases of patients who developed seropositive rheumatoid arthritis (RA) shortly after infection with the SARS-CoV-2 virus.
Methods: The cases of two female patients are described who developed late onset RA after COVID-19 infection.
Results: The first patient, aged 79, presented with arthralgias of the large joints and morning stiffness 2 months after COVID-19 infection. On clinical examination arthritis of the right shoulder and the left 3rd metacarpophalangeal joint was observed along with limited mobility of both knee joints. Laboratory examinations revealed ESR 75 mm, CRP 1.48 mg/dl (normal values < 5 mg/dl), RF 256.6 U/ml (< 30 U/ml), anti-CCP 584 U/ml (< 5 U/ml). Late onset seropositive RA was diagnosed. Prezolon 7.5 mg/d and hydroxychloroquine 200 mg/d were administered with significant improvement. The second patient, aged 74, developed diffuse arthralgias and morning stiffness 7 months after COVID-19 infection. She had symmetric polyarthritis with tender and swollen carpal, metacarpophalangeal and proximal interphalangeal joints in both hands. Laboratory evaluation revealed ESR 44 mm, CRP 1,16 mg/dl (< 0,5 mg/dl), RF 23,8 U/ml (< 30 U/ml), anti-CCP > 200 U/ml (< 5 U/ml), ANA 1/1280. Low dose corticosteroids and methotrexate 12.5 mg/week were administered with improvement.
Conclusion: The development of seropositive RA after clinical COVID-19 infection is described. The SARS-CoV-2 virus may be related to the development of clinical autoimmune disease.

P747
SEVERE OSTEOPOROSIS LEADING TO MULTIPLE FRACTURES IN THE CONTEXT OF MULTIPLE SCLEROSIS

L. Athanassiou[1], P. Athanassiou[2], D. Begkas[3], G. Georgiadis[4], A. Pastroudis[3], E. Manta[3], I. Kostoglou-Athanassiou[5]

[1]Dept. of Rheumatology, Asclepeion Hospital, Voula, Athens, [2]Dept. of Rheumatology, St. Paul's Hospital, Thessaloniki, [3]6th Dept. of Orthopedics, Asclepeion Hospital, Voula, Athens, [4]4th Dept. of Orthopedics, Asclepeion Hospital, Voula, Athens, [5]Dept. of Endocrinology, Diabetes and Metabolism, Asclepeion Hospital, Voula, Athens, Greece

Multiple sclerosis is an autoimmune demyelinating disease which may affect patient mobility. The disease is characterized by autoimmune etiology. The aim was to present the case of a patient with multiple sclerosis who developed severe osteoporosis with multiple fractures.
Case report: A patient, female, aged 52 y, presented with multiple sclerosis. She was treated with corticosteroids and interferon beta-1a. Approximately 10 y later she presented with a fracture of the right hip. She was treated surgically and recovered. Her mobility improved. Subsequently, approximately 2 y later she presented with a fracture of the left hip. She was treated surgically. BMD measurement was performed. T-score was -3.8. The patient was given effervescent alendronate 70 mg once weekly, calcium and vitamin D supplements and alphacalcidol 1 μg daily. A year later BMD measurement was performed and T-score was -3.4. The patient's mobility is compromised, as after the bilateral surgical procedures her right foot is a little shorter than the left. Physiotherapy was prescribed.
Conclusion: The case of a female patient with severe osteoporosis and multiple sclerosis is presented. Multiple sclerosis is known to be associated with severe osteoporosis. Osteoporosis in the context of multiple sclerosis is thought to be due to mobility limitations as well as to the immune modulating treatment for the autoimmune process. The presence of depression may also be related to osteoporosis in the context of multiple sclerosis. However, recent findings implicate the inflammatory nature of the disease as well as cardiovascular autonomic nervous dysfunction which affects bone homeostasis via neuronal, systemic and local mediators.

P748
TUMOUR-INDUCED OSTEOMALACIA MIMICKING SEVERE OSTEOPOROSIS WITH MULTIPLE FRACTURES

L. Brunerova[1], J. Ferda[2], J. Hrudka[3], S. Batek[4], R. Pichova[4], M. Chovanec[5]

[1]Faculty Hospital Kralovske Vinohrady and 3rd Faculty of Medicine, Dept. of Medicine, Prague, [2]Dept. of Radiology, Faculty Hospital and Faculty of Medicine Plzen, Plzen, [3]Dept. of Pathology, Faculty Hospital Kralovske Vinohrady and 3rd Faculty of Medicine, Prague, [4]Dept. of Radiology and Nuclear Medicine, Third Faculty of Medicine, Charles Univ. in Prague and Faculty Hospital Kralovské Vinohrady, Prague, [5]Dept. of Otorhinolaryngology, Charles Univ., 3rd Faculty of Medicine and Univ. Hospital Kralovske Vinohrady, Prague, Czech Republic

Tumour-induced osteomalacia (TIO) is a rare paraneoplastic syndrome characterized by bone pain, fractures and muscle weakness,

caused by overproduction of FGF23 in usually small benign mesenchymal tumour, location of which is challenging but crucial since complete removal is curative.

Case report: A 75-year old man has been suffering from gradually progressive pain of ribs and long bones since 2019. In June 2023, CT revealed multiple rib fractures and multiple osteolytic lesions in vertebras suspicious of either from hematologic malignancy or prostate cancer. Nonetheless, both of them were excluded. Due to BMD femoral neck (T-score -3.0) he was referred as osteoporosis with multiple fractures. At the examination, he was sarcopenic with decreased muscle strength, practically immobile (moving on the wheel chair) with thoracic brace. Laboratory examination revealed normal serum calcium but very low serum phosphate (0.4 mmol/l), increased urinary phosphate (40 mmol/l), normal parathormone and vitamin D. FGF-23 was 324 (normal range up to 95,4 ng/L) confirming the diagnosis of TIO. Treatment with 1,25-dihydroxycholecalciferol (1.5 mg daily) together with phosphate solution had, however, minimal effect on serum phosphate level. DOTATOC PET CT revealed the picture of Milkman´s syndrome with two suspicious lesions in right maxilla and near sphenoid bone. MRI described the latter one as meningioma. At otorhinolaryngology, subtotal maxillectomy was performed leading to immediate normalization of FGF23 levels. Histology confirmed phosphaturic mesenchymal tumour expressing FGF23.

Conclusion: The case represents a rare condition of TIO caused by phosphaturic mesenchymal tumour of maxilla, which was curatively removed, and thus emphasizes the urgency for proper differential diagnosis of low BMD with multiple fractures.

P749
EXPLORING PATIENT AND CLINICIAN UNDERSTANDING OF BONE DENSITY (DXA) SCAN RESULTS: A QUALITATIVE STUDY

C. Kettle[1], J. Butterworth[2], J. Griffin[3], B. Henderson[4], C. Jinks[1], K. Knapp[5], F. Manning[5], L. Bullock[1], Z. Paskins[1]

[1]School of Medicine, Keele Univ., Newcastle-under-Lyme, [2]Exeter Collaboration for Academic Primary Care (APEx), Univ. of Exeter Medical School, Exeter, [3]Healthy Bones Service, Derriford Hospital, Univ. Hospitals Plymouth NHS Trust, Plymouth, [4]Keele Univ. Research User Group, Keele Univ., Newcastle-under-Lyme, [5]Faculty of Health and Life Sciences, Exeter Univ., Exeter, UK

Objective: Patient and clinician understanding of DXA scans and results is integral to support clinical decision-making and adherence to osteoporosis medicines. The INDEX (understandINg bone DEnsity [dXa] scans) study aims to explore patient and clinician understanding of DXA scans and results.

Methods: Semi-structured think-aloud interviews with patients and clinicians about views of DXA scans and results. Patients attending DXA scans across 3 NHS sites are invited to interview. Clinicians are recruited via existing clinical networks and the Clinical Research Network. Framework analysis, informed by the common-sense model of illness self-regulation, facilitates understanding of people's perceptions of, and responses to, DXA results.

Results: 24 patient and 12 clinician (11 primary care; 1 secondary care) interviews. Recruitment and analysis are ongoing. Many patients reported having uncertainties about clinical terminology and numeric scores within clinical reports (e.g., T-scores and fracture risk). Varying patient preferences were discussed in relation to receiving numeric results. Clinicians often preferred not to discuss numerical results because they (1) lacked clinical knowledge to interpret and communicate results and/or (2) believed that patients would not understand them. To address this, clinicians suggested development of accessible guidance to support knowledge and visual support tools to help communicate results. Some patients discussed uncertainty relating to (1) what the scan entailed, (2) how/when they would receive their DXA results (3) treatment options and/or how to take medication (4) if and/or when a follow-up DXA scan was needed. Patients wanted further resource around this to establish clear next steps. Likewise, clinicians expressed uncertainty regarding patient treatment management, particularly long-term bisphosphonate use and intolerances to first-line treatment.

Conclusion: Patients and clinicians have uncertainties about DXA scans and results, highlighting opportunities to enhance understanding; these results will inform co-production of resources to support DXA understanding.

NHS Foundation Trust, Manchester, [8]Dept. of Health Sciences, Univ. of York, York, [9]Centre for Musculoskeletal Health Research, School of Medicine, Keele Univ. & Haywood Academic Rheumatology Centre, Haywood Hospital, Midlands Partnership Univ. NHS Foundation Trust, Stoke-on-Trent, [10]Univ. of Exeter Medical School, Exeter, [11]School of Nursing and Midwifery, Keele Univ. & Haywood Academic Rheumatology Centre, Haywood Hospital, Midlands Partnership Univ. NHS Foundation Trust, Stoke-on-Trent, [12]Centre for Behavioural Medicine, UCL School of Pharmacy, Univ. College London, London, UK

Objective: The iFraP (improving uptake of fracture prevention drug treatments) study developed an osteoporosis decision aid (DA) to improve shared decision-making (SDM) and medicine adherence in Fracture Liaison Services (FLSs). This abstract details the multi-method development of the prototype iFraP intervention.

Methods: Four substudies guided intervention development: 1) review of the quality of existing osteoporosis Das; 2) review of osteoporosis patient information; 3) Delphi survey to gain consensus on intervention content, informed by relevant clinical guidelines and behavioural theories; and 4) focus groups and supplementary interviews with patients and clinicians to explore current practice, and barriers and facilitators to change. Expert stakeholders and public contributors informed the design and output of each substudy.

Results: Studies 1 and 2 found existing osteoporosis DAs and patient information to have poor readability and variable quality. Study 3 identified essential consultation components. Findings from studies 1–3 informed iFraP DA content e.g. inclusion of understandable explanations of osteoporosis medicines. Study 4 identified the need for complementary resources, training, and potential barriers to DA use. Patients and clinicians expressed the need for a patient-friendly individualised consultation summary to facilitate understandable and consistent information. This finding informed development of an individualised, easy-read print-out of the iFraP DA. Training needs included communicating risk and involving patients in decisions. Clinicians were concerned that SDM may undermine their goal to facilitate medicine adherence. These findings informed training content and delivery, with consideration of theoretically informed behaviour change techniques.
Conclusion: The iFraP study demonstrates the use of multiple methods to develop an evidence-based and theoretically informed intervention to facilitate SDM in FLSs, in preparation for testing.

P751
OSTEOPOROSIS: COMORBIDITY IN ANKYLOSING SPONDYLITIS

L. Chişlari[1], L. Groppa[1], E. Russu[1], A. Nistor[1], L. Gonţa[2]

[1]"Nicolae Testemitanu" State Medical and Pharmaceutical Univ., [2]Republican Diagnostic Center, Chisinau, Moldova

Objective: Osteoporosis (OP) is the frequent complication of ankylosing spondylitis (AS). It has been shown that patients with AS in the early stages of the disease experience a significant decrease in bone mass, but the prevalence of OP, as well as the mechanism of its development in AS, are poorly studied. We evaluated BMD according to the degree of activity, form, radiological stage and duration of ankylosing spondylitis.
Methods: 72 patients with AS from the rheumatology department of the republican hospital (Chişinau) were examined (66 men and 6 women) aged between 20–60 y; men under 48 y predominated (80%), the average age was 42.2 ± 8.9 y. Diagnostic verification was performed according to the ASAS criteria.
Results: AS patients with low BMD were significantly older, had longer disease duration, and more severe functional impairment—the BASFI score being higher than in patients with normal bone density (5.5 ± 1.1 vs. 4,2 ± 0.6, $p < 0.01$) and a high degree of SA activity, which was manifested by significantly higher ASDAS-CRP indices, (3.9 ± 0.7 vs. 3.2 ± 0.9, $p < 0.01$), BASDAI (5.0 ± 0.9 vs. 3.6 ± 0.4, $p < 0.01$) and a large number of inflamed joints (IJ), mainly hip, knee and shoulder (3.4 ± 3.1 vs. 1.8 ± 1.9, $p = 0.012$). Patients with low BMD had significantly more pronounced radiographic changes in the spine than those with normal BMD.
Conclusion: More than half (57%) of patients with AS presented a decrease in BMD: 20% met the criteria for osteoporosis, 37% for osteopenia. The reason for osteoporosis in patients with AS is considered to be the high activity of the disease, as well as the disturbance of metabolism by increasing bone resorption and decreasing bone formation.

P752
EXPERIENCE OF NHS LOWER LIMB JOINT ARTHROPLASTY AMONG PARTICIPANTS IN THE HERTFORDSHIRE COHORT STUDY

L. D. Westbury[1], F. Kirkham-Wilson[1], C. Pearse[1], N. R. Fuggle[1], E. Zaballa[1], F. Laskou[1], G. Bevilacqua[1], K. A. Ward[1], C. Cooper[1], E. M. Dennison[1]

[1]MRC Lifecourse Epidemiology Centre, Univ. of Southampton, Southampton, UK

Objective: Joint arthroplasty is a commonly performed elective surgery for severe osteoarthritis (OA), recommended for conditions that cannot be managed conservatively. The Hertfordshire Cohort Study, a cohort of community-dwelling older adults (n = 2997) was established in 1998; participants were then followed up for around 20 y. Here we report prevalence and correlates of NHS-funded lower limb joint arthroplasty.
Methods: Participants completed baseline questionnaires which detailed difficulties walking and use of aids. Of the initial cohort, 987 underwent baseline knee radiographs, which were graded according to Kellgren & Lawrence (K&L). DXA of the hip was contextually performed for 992 participants during the same visit. Participants were followed up from baseline (1998–2004) until December 2018 using Hospital Episode Statistics, reporting clinical outcomes using ICD-10 and OPCS-4 coding. Baseline characteristics in relation to risk of joint arthroplasty during follow-up were examined using sex-adjusted logistic regression.
Results: Mean (SD) age at baseline was 66.2 (2.8) y. Prevalence of radiographic OA (K&L ≥ 2) at baseline was 42% and 38% among men and women respectively. 14% of men and 18% of women had a lower limb joint arthroplasty (hip or knee) during follow-up; 8% of men and 10% of women underwent knee arthroplasty. Compared to their counterparts with no reported difficulties walking at baseline, those experiencing difficulties (reported problems, used walking aids, required help from others or were unable to walk) were more likely to undergo a knee arthroplasty over follow-up (odds ratio (95%CI): 3.33(2.54,4.37), $p < 0.001$); effect size was lower for hip arthroplasty (1.73(1.27,2.36)). Likewise, there was a graded association between baseline K&L score and lower limb arthroplasty (2.01(1.64,2.47) per unit increase in score, $p < 0.001$). As reported elsewhere, we observed positive relationships between femoral neck BMD t-score and knee arthroplasty (1.30(1.07,1.58) per unit increase, $p < 0.01$).
Conclusion: Our results highlight the high prevalence of joint arthroplasty in an unselected UK population and likely represent an underestimate, as we excluded privately funded joint arthroplasty. Given the personal and financial burden of joint arthroplasty surgery, our data highlight the value of interventions that target modifiable

factors which might slow OA progression and reduce this need in future generations.

P753
SOCIOECONOMIC POSITION, HEALTH BEHAVIOURS AND INCIDENT FRACTURE RISK: FINDINGS FROM THE HERTFORDSHIRE COHORT STUDY

L. D. Westbury[1], G. Bevilacqua[1], C. Cooper[1], E. M. Dennison[1]

[1]MRC Lifecourse Epidemiology Centre, Univ. of Southampton, Southampton, UK

Objective: Several studies have highlighted a link between socioeconomic position and fracture, but relevant lifestyle information that is available is typically restricted to smoking, alcohol and physical activity. We examined relationships between socioeconomic position and health behaviours that included dietary behaviour, and examined socioeconomic position in relation to incident fracture risk among participants of the UK Hertfordshire Cohort Study, a community-dwelling cohort of older adults.
Methods: Data from 2997 individuals, aged 59–73 y at baseline (1998–2004), were analysed. Clinician-administered questionnaires were used to ascertain the following characteristics: age at leaving full-time education, occupational social class, housing tenure, smoking status, alcohol consumption, diet quality, and physical activity. Incident fractures were identified using ICD-10 codes from Hospital Episode Statistics data, available from baseline until December 2018. Markers of socioeconomic position in relation to health behaviours were examined using linear and logistic regression; socioeconomic markers in relation to fracture risk were examined using time-to-first event Cox regression. Analyses were adjusted for age and stratified by sex; $p < 0.05$ was regarded as statistically significant.
Results: Overall, 9% of men and 22% of women had a fracture during follow-up. Leaving education before age 15 was related to poorer diet quality; manual social class was related to current smoking, reduced likelihood of high alcohol consumption (women only) and poorer diet quality; and not owning one's home was related to current smoking, poorer diet quality and lower physical activity. Among women, not owning one's home was related to increased risk of incident fracture (hazard ratio (95%CI): 1.33 (1.03, 1.72), $p = 0.028$); this association was similar but slightly weaker among men (1.41 (0.96, 2.07), $p = 0.079$).
Conclusion: Associations between socioeconomic position and health behaviours were similar among men and women. Our findings were in accord with previous studies but extended these by including diet quality, an important health behaviour and established risk factor for fracture.

P754
ANXIETY AND DEPRESSION ARE ASSOCIATED WITH POOR HEALTH BEHAVIOURS AND INCIDENT FRACTURE AMONG WOMEN: FINDINGS FROM THE HERTFORDSHIRE COHORT STUDY

L. D. Westbury[1], G. Bevilacqua[1], C. Cooper[1], E. M. Dennison[1]

[1]MRC Lifecourse Epidemiology Centre, Univ. of Southampton, Southampton, UK

Objective: A recent systematic review has highlighted possible links between depression and fracture risk, but no information regarding possible explanatory health behaviours was available. In this study we used a well phenotyped community-dwelling cohort of older adults (the Hertfordshire Cohort Study) to consider these associations further.
Methods: Data from 2997 men and women, aged 59–73 y at baseline, were analysed. At baseline, mental health characteristics and health behaviours were ascertained through clinician-administered questionnaires. Anxiety and depression (mild or worse) were identified by scores of > 7 on the corresponding Hospital Anxiety and Depression Scale. Health behaviours included current smoking, alcohol consumption, diet quality and physical activity (Dallosso questionnaire). Incident fractures were identified using ICD-10 codes from Hospital Episode Statistics data, available from baseline (1998–2004) until December 2018. Health behaviours in relation to anxiety and depression were examined using logistic regression; anxiety and depression in relation to incident fracture were examined using Cox regression. All analyses were sex-stratified and adjusted for age; $p < 0.05$ was regarded as statistically significant.
Results: Prevalence of anxiety was 15% among men and 25% among women; prevalence of depression was 5% among men and 6% among women. Overall, 9% of men and 22% of women had a fracture during follow-up. Among men and women, poorer diet quality and lower physical activity were associated with depression; these health behaviours were also associated with anxiety among men. Current smoking was associated with anxiety and depression among women. Among women, anxiety (hazard ratio (95%CI): 1.34 (1.05, 1.72), $p = 0.019$) and depression (1.76 (1.18, 2.64), $p = 0.006$) were related to increased risk of incident fracture; among men, associations for anxiety ($p = 0.198$) and depression ($p = 0.265$) in relation to fracture were weaker.
Conclusion: Anxiety and depression were associated with increased risk of incident fracture among women, possibly due to their association with poor health behaviours, which are established risk factors for fracture. Preventive strategies are required to address poor health behaviours and mental health among older adults.

P755
A COMPREHENSIVE ANALYSIS CONCERNING THE IMPACT OF MUSCLE STRENGTH AND BONE QUALITY ON OSTEOPOROTIC FRACTURES IN ELDERLY WOMEN

L. Donggyu[1], L. Eun Chae[1]

[1]Yeungnam Univ. College of Medicine, Daegu, South Korea

Osteoporotic fractures are deeply correlated with both quality of life and mortality in elderly patients. Generally, the BMD is measured using DXA, which then guides the treatment of osteoporosis. However, spinal DXA measurements may be influenced by degenerative changes and calcification in tissues surrounding the spine, which can limit the accuracy of spinal BMD assessments. Therefore, TBS is employed to analyze bone quality, serving as an auxiliary marker to evaluate the likelihood of bone fractures in conjunction with BMD. Additionally, sarcopenia has been identified as a significant factor in osteoporotic fractures. This study aims to analyze factors affecting fractures in elderly patients by comprehensively examining both bony markers, such as spinal BMD and TBS, and muscular markers. We measured BMD, grip strength, and lean mass in female patients over the age of 65. Those who had undergone spinal fusion surgery, bilateral total hip replacement operations, or had been treated with osteoporosis drugs within the past year were excluded. Osteoporosis and lean mass measurements were conducted using DXA. We recruited a total of 52 female patients over the age of 65 (mean age 78.2 ± 5.4), 17 of whom had osteoporotic compression fractures. To investigate factors influencing fractures, a logistic regression analysis was performed considering age, spinal TBS, spinal BMD, grip strength, lean mass index, back muscle index, and grip strength

factors. The analysis revealed that only grip strength (P = 0.02) had a statistically significant impact on fractures. While BMD is known to affect osteoporotic compression fractures in studies involving all age groups, our analysis indicates that muscle strength shows a higher statistical correlation with fractures in elderly patients than BMD. Hence, evaluating and treating muscular entities is crucial in preventing osteoporotic fractures in this demographic.

P756
PERIOPERATIVE OPIOID USE AND DOSAGE TRAJECTORIES FOR GOOD VERSUS POOR PAIN OUTCOME CLASSIFICATION OF KNEE ARTHROPLASTY PATIENTS: RESULTS FROM A SECONDARY ANALYSIS OF A RANDOMIZED TRIAL

L. Dumenci[1], D. Riddle[2]

[1]Temple Univ., Philadelphia, [2]Virginia Commonwealth Univ., Richmond, USA

Objective: We determined if opioid use and dosage following knee arthroplasty (KA) varied for persons with externally validated good vs. poor pain outcome. A secondary purpose determined if bodily pain scores associated with KA outcome.
Methods: This was a secondary analysis of a prospective no-effect randomized clinical trial conducted on 384 participants scheduled for KA. Data were collected preoperatively and at 2-, 6- and 12-months following surgery. Two-piece latent class growth curve analyses applied previously validated pain outcomes to determine good vs. poor subgroup outcome trajectories for proportion of opioid users and oral morphine equivalent (OME) dosages.
Results: Substantial trajectory separation was found for opioid use and OME. Specifically, average OME dosage for the poor outcome subgroup was more than double that for the good outcome subgroup. Average preoperative opioid daily OME dosage for 170 patients reporting opioid use was 24.94 (95%CI = 20.52, 29.38). Bodily pain was consistently higher for the poor outcome subgroup compared to the good outcome subgroup.
Conclusion: Good vs. poor pain outcome subgroups in patients with pain catastrophizing demonstrated substantial differences in opioid use and dosage and were predicted by baseline body pain and changes in bodily pain over time. The poor outcome subgroup is at greater risk of opioid use and greater opioid dosages and should be targeted for preoperative interventions to reduce opioid use and potential consequences of opioid misuse.
Disclosures:
The study was supported by a grant (UM1AR062800) from the National Institute of Arthritis and Musculoskeletal and Skin Diseases (NIAMS) of the National Institutes of Health (NIH). Support was also provided by an NIH CTSA grant (UL1TR000058) from the National Center for Advancing Translational Sciences to Virginia Commonwealth University. RADIOFREQUENCY ECHOGRAPHIC MULTISPECTROMETRY (REMS) FOR THE ASSESSMENT OF BMD REDUCTION AFTER PROSTHETIC SURGERY: A CLINICAL CASE REPORT

L. Farinelli[1], F. A. Lombardi[2], P. Pisani[2], F. Conversano[2], E. Casciaro[2], C. Stomaci[3], A. P. Gigante[4], S. Casciaro[2]

[1]Clinical Orthopedics, Dept. of Clinical and Molecular Science, School of Medicine, Università Politecnica Delle Marche, Ancona, [2]Institute of Clinical Physiology, National Research Council, Lecce, [3]Dept. of Biological and environmental sciences and technologies, Univ. of Salento, Lecce, [4]Clinical Orthopedics, Dept. of Clinical and Molecular Science, School of Medicine, Università Politecnica Delle Marche, Ancona, Italy

Knee and hip arthroplasty represent common procedure in orthopaedics. However, the interaction between bone and implant need to be analysed. It has been well established that the bone around implant might be face to a decreased BMD mainly due to mechanical stress (i.e., stress shielding) of altered joint biomechanics and/or aseptic inflammatory reaction leading to periprosthetic bone resorption. For these reasons, monitoring the bone around an implant is mandatory to guarantee longevity of implant and rule out cause of pain. In recent years, the non-ionising REMS technology, through the analysis of the reference axial sites (lumbar spine and femoral neck), has been used to assess the bone health status and fracture risk prediction. However, REMS is able to analyse the bone health status even in the presence of prosthetic implants due to its capability to automatically discard artefacts. We report a clinical case of patient underwent to hip arthroplasty with the analysis of bilateral bone femoral neck through REMS technology.
Case report: A 79-year-old Caucasian man underwent to left hip arthroplasty due to osteoarthritis. Bilateral bone femoral neck was analysed through REMS technology three months after surgery. As expected, differences between the two hips have been detected: the left femoral neck (with hip arthroplasty) was characterized by osteopenia with T-score = -1.6 and BMD = 0.715 g/cm^2, while the contralateral femoral neck showed a normal bone with T-score = -1.0 and BMD = 0.794 g/cm^2. The difference in BMD values between the two femurs could be due to the presence of low systemic BMD before surgery and/or adaptative bone remodelling, and these variations seem to be solely attributable to the prosthesis design and at the location of the femoral stem's fixation on the bone.
Conclusion: This clinical case confirms the BMD reduction after prosthetic implant and consequently the importance of a timely assessment of bone health status before and after implantation. Moreover, the study demonstrates that REMS technology, is an adequate technology for the assessment of the bone health status and for improving the management of osteoporosis also in this category of patients thanks to the automatic exclusion of artefacts. For this reason, REMS represents an important step forward in the bone health status assessment.

P758
IL-17/IL-23 AXIS-RELATED CYTOKINES AND CARDIOVASCULAR RISK IN SPONDYLOARTHRITIS: A POSSIBLE LINK?

L. Kharrat[1], M. Dhifallah[1], A. Tezeghdenti[2], R. Dhahri[1], E. Ghazouani[2], M. Slouma[1], I. Gharsallah[1]

[1]Rheumatology Dept., Military Hospital of Tunis, [2]Immunology Dept., Military Hospital of Tunis, Tunis, Tunisia

Objective: Due to inflammatory cascade, patients with spondyloarthritis (SA) are exposed to a higher risk of cardiovascular (CV) events increasing their morbidity and mortality. We aimed to study the relationship between IL-17/IL-23 axis-related cytokines and CV risk factors in SA patients.
Methods: We conducted a cross-sectional study including 45 SA patients meeting the ASAS criteria. For each patient we collected the following data: age, disease activity (using BASDAI and $ASDAS_{CRP}$ scores), and CV risk factors. We also measured the following parameters: total cholesterol (TC), Low-density lipoprotein cholesterol (LDL-c), high-density lipoprotein cholesterol (HDL-c), triglycerides, and IL-17/IL-23 axis-related cytokines serum levels (IL-17, IL-23, and IL-6) as well as IL-1 level. We calculated the CV risk using the Systematic Coronary Risk Evaluation (SCORE) based on the following parameters: smoking, systolic blood pressure, and CT level. This score categorizes patients into low (SCORE risk < 1%), moderate (SCORE risk 1–4%), high (SCORE risk 5–9%), or very high (SCORE risk > 10%) 10-y risk of total CV disease mortality.
Results: We included 37 men and 8 women. The mean age was 46.1 ± 11.8 y. The mean disease duration was 9.43 ± 8.27 y. The mean BASDAI and $ASDAS_{CRP}$ were 3.69 ± 2.02 and 2.75 ± 1.23, respectively. 53% of the patients were smokers (n = 24) with a mean pack-year of 16. Comorbidities were noted in 6 patients: diabetes (n = 4), hypertension (n = 5), and dyslipidemia (n = 1). The mean BMI was 25.7 ± 5.1 kg/m^2. Almost half of the patients were overweight or obese (51.1%). The mean systolic blood pressure was 124.9 ± 12.5 mmHg. The mean levels of CT, LDL-c, HDL-c, and triglycerides were 4.6 ± 0.9, 2.9 ± 0.8, 1.1 ± 0.3, and 1,3 ± 0.5 mmol/L, respectively. The mean SCORE was 0.8%. Patients were classified as follows: 27 (60%) at low risk, 16 (35.5%) at moderate riskand 2 (4.4%) at high risk. The mean IL-1, IL-6, IL-17, and IL-23 levels were 10.9 ± 23.1, 13.9 ± 42.4, 91.8 ± 80.5, and 17.3 ± 16.9 pg/mL, respectively. IL-1 level was associated with smoking (15.27 ± 31.2 vs. 5.86 ± 2.45 pg/mL, p = 0.005). There was a negative correlation between IL-1 level and HDL-c level (r = -0.300, p = 0.045). Furthermore, patients with hypercholesterolemia had significantly higher IL-17/IL-6 ratio (47.72 vs. 18.79, p = 0.025). Moreover, IL-17 level was correlated to SCORE score (r = 0.375, p = 0.011). Patients with a SCORE > 1% have higher IL-17 (133.8 ± 110.3 vs. 63.7 ± 31.1 pg/mL, p = 0.017), IL-17/IL-1 (23.7 vs. 9.7, p = 0.041), and IL-17/IL-6 ratios (47.5 vs. 20, p = 0.015).
Conclusion: Our study showed that IL-17 level was associated with moderate to high risk of CV events over 10 y. Recently, Wang et al. showed that IL-17 level can predict the occurrence of coronary artery disease [1]. The measurement of IL-17 levels, IL-17/IL-1 ratio, and IL-17/IL-6 ratio seem to be useful in assessing CV risk in patients with SA.

P759
DOES THE PRESENCE OF ANTI-NUCLEAR ANTIBODY IMPACT THE THERAPEUTIC RESPONSE TO BIOLOGICS IN RHEUMATOID ARTHRITIS?

W. Triki[1], L. Kharrat[1], H. Ferjani[1], F. Majdoub[1], D. Ben Nessib[1], D. Kaffel[1], K. Maatallah[1], W. Hamdi[1]

[1]Rheumatology Dept., M.T Kassab of Orthopedics Institute, Ksar Saïd, Tunisia

Objective: Rheumatoid arthritis (RA) is an autoimmune disease that could be associated to antinuclear antibody (ANA) positivity [1]. The involvement of ANAs in the therapeutic response to biologics in this disease is not well studied. We aimed to study the link between ANA positivity and the therapeutic response to biological agents in RA.
Methods: We conducted a retrospective study including 93 patients followed for RA meeting the ACR/EULAR 2010 criteria. For each patient we collected the following parameters: age, gender, disease duration, tender joint count (TJC), swollen joint count (SJC), disease activity using the Disease Activity Score (DAS28), and the biological or targeted therapies received by the patients (anti-TNFα, tocilizumab, rituximab, and anti-JAK). Erythrocyte sedimentation rate (ESR), c-reactive protein (CRP) and ANAs levels were also noted.
Results: There were 83 women and 14 men. The mean age was 58.31 ± 12.19 y. The mean disease duration was 11.58 ± 8.63 y. The mean TJC and SJC were 7.69 ± 6.56 and 4.42 ± 4.72; respectively. The mean ESR and CRP levels were 41.35 ± 29.93 mm and 17.25 ± 22.64 mg/L; respectively. Mean DAS28-ESR and DAS28-CRP were 4.84 ± 1.54 and 4.35 ± 1.47; respectively. 32% of patients had positive ANAs (n = 31) with a mean titer of 1/726.52 [180/-1/3200]. Erosive RA was noted in 84% (n = 82) of cases. 43 patients were under biological agents (46%) including 13 patients with positive ANA. 27 patients were under an anti-TNFα (63%), 7 under an anti-IL6 (16%), 6 under an anti-CD20 (14%) and 3 under an anti-JAK (7%). A therapeutic switch was indicated in 13 patients (60%): 5 times for primary failure, 4 times for secondary failure, and 4 times after occurrence of adverse effects. ANA level was positively correlated with the following parameters: TJC (r = 0.910; p < 10–3), SJC (r = 0.769; p = 0.009), DAS28-ESR (r = 0.698; p = 0.037) and DAS28-CRP (r = 672; p = 0.047). Similarly, ANA level was significantly higher in case of primary failure to a biotherapy (1/1200 ± 565.68 vs. 1/322.5 ± 222.3; p = 0.044).Nevertheless, the presence of ANA was not associated with erosive RA.
Conclusion: ANA level was correlated to disease activity. Moreover, ANA level was significantly higher in case of primary failure to biological agents. These results suggest that a special attention should be paid to patients with positive ANAs and under biological or targeted agents.

FACTORS ASSOCIATED WITH LOW BONE MINERAL DENSITY IN JUVENILE IDIOPATHIC ARTHRITIS

W. Lahmar[1], L. Kharrat[1], S. Bouzid[1], H. Ferjani[1], D. Ben Nessib[1], F. Majdoub[1], D. Kaffel[1], K. Maatallah[1], W. Hamdi[1]

[1]Kassab's Institute of Orthopedics, Manouba, Tunisia

Objective: Children with juvenile idiopathic arthritis (JIA) are at higher risk of decreased BMD compared with healthy children due to genetic, inflammatory disease and medication-related causes. We

aimed to evaluate the BMD in children with JIA and the potential associations of a low bone density.
Methods: We conducted a retrospective study involving JIA patients diagnosed according to ILAR 2010 diagnosis criteria. For each patient we collected the following data: JIA subtype, age, age at the onset of the disease, disease duration, diagnosis delay, BMI, the presence of uveitis, the presence of structural damage on imagery and therapeutic management. Disease activity was assessed using the juvenile arthritis disease activity score 10 using normalized ESR (JADAS-10-ESR) for all JIA subtypes and the Juvenile Spondyloarthritis Disease Activity Index (JSpDA) for related-enthesitis arthritis (ERA) and psoriatic arthritis subtypes. Baseline BMD using a DXA of the entire body was extracted and expressed in g/cm ^{2}. A low bone density was defined as Z-score $<$ -1 [1].Patients were divided into 2 groups: G1 with Z-score $<$ -1 and G2: Z-score $>$ -1.
Results: In total 72 patients were included, comprising 37 boys and 34 girls, with a mean age of 13.73 $\pm$ 5.06 y. The mean age at the onset of the disease, the mean disease duration and diagnosis delay were 9.19 $\pm$ 4 y, 4.34 $\pm$ 3.6 y and 7.07 $\pm$ 8.53 months, respectively. The observed JIA subtypes were as follows: systemic JIA in 4 (6%) patients, oligoarthritis form in 15 (21%), polyarthritis with positive rheumatoid factor in 3 (4%), polyarthritis with negative rheumatoid factor in 5 (7%), ERA in 33 (46%) patients, psoriatic arthritis in 8 (11%) patients, and undifferentiated juvenile arthritis in 4 (6%). The mean BMD was 0.907 $\pm$ 0.11 [0.656–1.136], with a mean Z-score of -0.785 [-2.6 – 1.4]. Mean BMI was 20.02 $\pm$ 4.8 [13.75–31.20]. The mean JADAS-10-ESR and JSpDA were 9.1 $\pm$ 5.4 and 2.8 $\pm$ 1.6, respectively. Uveitis was noted in 5 patients (7%), while radiographic sacroiliitis was noted in 16 patients (22%). 17 patients had low bone density, which was associated with the presence of radiographic sacroiliitis (11 vs. 89%, p = 0.008) and conventional synthetic disease-modifying antirheumatic drugs (csDMARDs) intake (16 (66%) vs. 1(10%), p = 0.007). Mean BMD was lower in patients with juvenile spondylarthritis (ERA form and psoriasis arthritis) (0.932 vs. 0.831, p = 0.045). Mean Z-score was lower in patients with radiographic sacroiliitis. (-0.331vs -1.58, p = 0.004). Z-score correlated negatively with disease duration (r = -0.354, p = 0.037), diagnostic delay (r = -0.356, p = 0.042), and hospitalization duration (r = -0.601,p = 0.008). There was a positive correlation between Z-score and BMI (r = 0.428, p = 0.016). However, it did not show a correlation with disease activity.
Conclusion: JIA patients may be at risk of decreased BMD. The study identifies factors like the presence of sacroiliitis, longer duration of hospitalization, and csDMARDs intake which are a surrogate for a severe disease. Moreover, the juvenile spondylarthritis form was a contributor factor to low bone density. Early detection and intervention are mandatory to managing bone health in this vulnerable population.

EFFICACY OF TREATMENT WITH DENOSUMAB IN OSTEOPOROTIC GEORGIAN MALE POPULATION: NATIONAL OSTEOPOROSIS ASSOCIATION OF GEORGIA

L. K. Kilasonia[1], N. D. Dolidze[2], T. R. Rukhadze[1], M. T. Tsagareli[3], L. L. Lagvilava[4], G. A. Aladashvili[1]

[1]"Tbilisi Heart and Vascular Clinic" Ltd, [2]"MediClubGeorgia" Ltd, [3]National Institute of Endocrinology, [4]"Conslium Medulla " Ltd, Tbilisi, Georgia

Objective: Male osteoporosis cases worldwide are increasing in number, statistics of male OP have its explanatory basis. Every 3rd 50 year old or older males worldwide are suffering from femur fractures. WHO have stated that male osteoporosis cases will increase from 200 to 300 million in males at age 60 years or older, referring to phenomenon of "demographic Hurricane". Male population is less informed to have osteoporosis, therefore, prophylaxis and visits to diagnose and prevent the disease is much less, in comparison to female patients. We have decided to assess efficacy of denosumab in Georgian males.
Methods: Research involved 250 male patients in two age categories: 33–55 and 60–80. Receiving denosumab 60 mg SC 1 in every 6 months for 3 y. BMD (T-score) was measured by Lunar Prodigy.
Results: Mean BMD is less in young subgroup than in older subgroup patients. Denosumab 60 mg SC treatment showed better results in young males than in older counterparts. No side effects were observed or spotted during treatment period. Denosumab use in males diagnosed with OP, have been characterized as safe and effective.

Indications	Group 1 (age 33-55) n-92	Group 2 (age 60-80) n-100
Baseline	-3.1 +0.015	-2.9 +0.015
Post treatment	-2.6 +0.16	-2.9 +0.15
	P<0.01	P<0.05

P762
ASSESSING THE IMPACT OF HOSPITAL TRANSFER ON TIMELY SURGICAL MANAGEMENT AND POSTOPERATIVE OUTCOMES FOR HIP FRACTURE PATIENTS IN SCOTLAND: A COHORT STUDY

L. L. Lennox[1], L. F. Farrow[1], P. M. Myint[1], S. B. Baliga[2]

[1]Univ. of Aberdeen, [2]NHS Grampian, Aberdeen, UK

Objective: To determine whether indirect hospital admission via hospital transfer affects the likelihood of surgical management within 36 h for hip fracture patients. Secondary aims explored associations between transfer status and other outcomes based on the Scottish Standards of Care for Hip Fracture Patients guidelines.
Methods: A retrospective cohort study using Scottish Hip Fracture Audit data enrolled patients aged $\geq$ 50 with hip fractures between January 2019 and December 2021 in Scotland. Patients were dichotomised into two groups based on their transfer status and matched. Descriptive analysis compared patient characteristics. Regression assessed patient outcomes in the unmatched and matched cohorts. To explore the potential effects of unmeasured confounders relating to patient frailty, we performed a sensitivity analysis which replicated the main analysis but for patients aged $\geq$ 80 who were not admitted from home.
Results: The unmatched analysis included 20,190 patients, with 19,049 (94.3%) in the non-transfer group and 1141 (5.7%) in the transfer group. Transfer patients were younger (p = 0.007), more frequently admitted from home (p $<$ 0.001) and had better baseline health (p $<$ 0.001). In the matched population, 711 (63.6%) transfer patients had timely surgery, compared to 852 (75.3%) non-transfer patients. Transfer patients had 43% reduced odds of timely surgery (OR (95%CI) 0.57 (0.48 to 0.69); p $<$ 0.001); waited longer for surgery (medium (IQR) 30.1 (18.2 to 41.1) vs. 20.3 (14.5 to 35.9); p $<$ 0.001); and experienced three additional days in hospital (median (IQR) 16 (8 to 33) vs. 13 (8 to 30); p = 0.024). No significant disparities emerged between the two groups for 30-d mortality, 60-d mortality, postoperative mobilisation, and returning to residence postoperatively.
Conclusion: Hospital transfer is significantly associated with reduced odds of achieving surgical management for hip fractures within 36 h of admission, a longer time to surgery, and a greater length of stay in Scotland. Despite this, transfer patients did not experience worse postoperative outcomes. It is unclear if this is the result of residual confounding effects. Future research is required to address the limitations of this study to determine if hospital transfer is associated with worse postoperative outcomes in Scotland.

P764
SOCIETAL COSTS BEFORE AND UP TO ONE-YEAR AFTER THE FIRST FRACTURE LIAISON SERVICE VISIT IN PATIENTS REQUIRING ANTI-OSTEOPOROSIS TREATMENTS

L. Maas[1], A. Boonen[2], C. E. Wyers[3], S. Bours[4], J. van den Bergh[5], S. M. J. van Kuijk[6], S. Evers[7], M. Hiligsmann[1]

Medical Center, Maastricht, [3]Dept. of Internal Medicine, VieCuri Medical Center; Dept. of Internal Medicine, NUTRIM, Maastricht Univ. Medical Center, Maastricht and Venlo, [4]Dept. of Internal Medicine, Division of Rheumatology, Maastricht Univ. Medical Center, Maastricht, [5]Dept. of Internal Medicine, VieCuri Medical Center; Dept. of Internal Medicine, Division of Rheumatology, Maastricht Univ. Medical Center, Venlo and Maastricht, [6]Dept. of Clinical Epidemiology and Medical Technology Assessment, Maastricht Univ. Medical Center, Maastricht, [7]Dept. of Health Services Research, Care and Public Health Research Institute (CAPHRI); Center of Economic Evaluation & Machine Learning, Trimbos Institute, Netherlands Institute of Mental Health and Addiction, Maastricht and Utrecht, Netherlands

Objective: Limited literature is available on resource utilization and societal costs of patients visiting fracture liaison services (FLS). This study aimed to estimate the societal costs incurred by patients with a recent fracture requiring anti-osteoporosis medication before and one-year after the first FLS visit and to explore differences according to fracture type.
Methods: Resource utilization was collected through a self-reported questionnaire with a 4-month recall on health resource utilization and productivity losses immediately following the first FLS visit, and 4 and 12 month later. Unit costs derived from the national Dutch guideline for economic evaluations were used to compute societal and healthcare costs. Linear mixed-effects models, adjusted for confounders, were used to analyze societal and healthcare costs over time as well as effect of fracture type on societal and healthcare costs.
Results: A total of 126 patients from two Dutch FLS centers were included, of whom 41 sustained a major fracture (hip, vertebral, humerus, or radius). Societal costs in the 4 months prior to the first visit (€2911) were significantly higher compared to societal costs four months (€711, p-value = 0.009) and twelve months later (€581, p-value p = 0.001). Fracture type did not have a significant effect on total societal or healthcare costs. All costs 12 months after the initial visit were lower for major fractures compared to others.
Conclusion: Societal and healthcare costs in the year following the first FLS visit significantly decreased compared to those costs before the first visit and were independent of fracture type.
Acknowledgement: This study was funded by the ZonMw research line Rational Pharmacotherapy, grant number 848016001.

Medical Center, Maastricht, [7]Dept. of Health Services research, Care and Public Health Research Institute (CAPHRI), Maastricht Univ.; Dept. of Internal Medicine, Division of Rheumatology, Maastricht Univ. Medical Center, Maastricht, Netherlands

Objective: Shared decision making (SDM) aims to improve patients' experiences with care and treatment adherence. However, the effectiveness of SDM in patients with a recent fracture who require anti-osteoporosis medication (AOM) is unclear. The objective of this study was to assess the effectiveness of a multi-component adherence intervention (MCAI), including SDM with a patient decision aid (PDA) and motivational interviewing at fracture liaison services (FLS) on multiple outcomes, compared to usual care (UC).
Methods: This one-year pre-post superiority study included patients with a recent fracture attending FLS and requiring AOM. As primary outcome, AOM persistence (defined as a patient being in possession of AOM at 12 months, considering a refill gap of $\geq$ 4 weeks). Secondary outcomes were treatment initiation, AOM adherence (measured by medication possession rate, MPR), decision quality (SDM process (0–100; best) and decisional conflict (0–100, highest conflict), fractures, and mortality. Outcomes were tested in MCAI and UC groups at the first FLS visit and 4 and 12 months after. In addition to crude comparisons of outcomes between groups, logistic regression were used to adjust for baseline group differences. Post hoc analyses assessed the role of health literacy limitations.
Results: In total, 245 patients (MCAI: 136, UC: 109) were included (mean age: 71 y, female: 75%, health literacy limitations: 26%). AOM persistence in the MCAI group was 80.4% and 76.7% in UC (p = 0.626). AOM initiation (97.8 vs. 97.5%), MPR (90.9 vs. 88.3%), and decisional conflict (21.7 vs. 23.0) did not differ between groups. SDM process was significantly better in MCAI (60.4 vs. 55.1, p = 0.003). Results did not change after adjustment. Health literacy stratification showed a lower effect on MPR and SDM in those with health literacy limitations.
Conclusion: In FLS, MCAI has no significant effect on AOM adherence, but a significant positive effect on SDM process was found.

P766
FREQUENCY OF EXTRASKELETAL CALCIFICATION DEPENDING ON THE PTH LEVEL IN HEMODIALYSIS PATIENTS

L. Martynyuk[1], T. Malska[1], L. Martynyuk[1]

[1]Ternopil National Medical Univ., Ternopil, Ukraine

Objective: MBD-CKD which includes laboratory abnormalities, fractures and bone disorders as well as cardiovascular and intraskeletal calcification (EC) is associated with worse outcomes in CKD patients and leads to increased risk of morbidity and mortality of dialysis patients. The aim of this study was to study the prevalence of disorders of mineral metabolism to rule out factors which lead to EC in CKD dialysis patients on example of single dialysis centre.
Methods: We examined 157 adults (78 men and 79 women) CKD 5 stage on hemodialysis (mean age 48.2 ± 14.5 y) from a single dialysis centre. The laboratory investigations included evaluation of PTH, serum total and ionized calcium, serum phosphate, serum level of alkaline phosphatase concentrations. PTH level in serum was evaluated by solid phase chemiluminescent immunoassay. All patients had undergone Echocardiography examination and X-ray examination.
Results: Overall, 67 (42.7%) of patients had bicuspid, aortic valve or both valves calcification either peripheral artery calcification. Patients with EC had significantly more prominent disturbances in mineral metabolism compared to group of patients without calcification. Phosphorous concentration in group with EC showed (2.37 ± 0.09 vs. 1.97 + 0.05 mmol/l, $p < 0.01$) in group without EC. Calcium level was significantly higher in group with EC (2.32 + 0.05 vs. 2.19 + 0.02 mmol/l, $p < 0.05$). On the other hand it was not significant difference in PTH level (574.16 + 119.2 vs. 520.78 + 50.40 pg/l, $p > 0.05$). For further analysis patients were divided into groups according to KDIGO 2017 recommendations for PTH levels in order to establish the association between PTH levels and EC. In patients with low levels of PTH (less than 2 times less the lower limit) incidence of EC was significantly higher 22 (32.8% vs. group with target levels of PTH (more than 2 times more than lower limit and less than 6 times less the upper limit) – 10 (14.9%), $p < 0.05$). The same tendency was present in patients with high levels of PTH (more than 6 times over the upper limit): incidence of EC was significantly higher 35 (52.2%) compared with those with target PTH levels $p < 0.01$).
Conclusion: EC is present in 67 (42.7%) of hemodialysis patients and is associated with hypercalcemia and hyperphosphatemia. Both too low and too high levels of PTH contribute greatly in development of EC in dialysis patients compared to those with target PTH levels.

P767
INCIDENCE OF OSTEOARTHRITIS IN THE POPULATION OF EASTERN SIBERIA (RUSSIAN FEDERATION) FROM 1999–2022

L. Menshikova[1], E. Belikh[2], M. Menshikov[1]

[1]Irkutsk State Medical Academy of Postgraduate Education,
[2]Regional Clinical Diagnostic Center ("IOKKDC"), Irkutsk, Russia

Objective: Osteoarthritis is the most common joint disorder, causing pain and functional disability. We aimed to study the incidence of osteoarthritis (OA) in the population over 18 years of age in the Irkutsk region (Eastern Siberia, Russian Federation).
Methods: The analysis of the data of the official statistics of the Ministry of Health of the Irkutsk region and the Russian Federation on the morbidity of OA in the adult population (over 18 years old) for the period from 1999–2022 was carried out.
Results: The adult population of the Irkutsk region is more than 1,880,000 people. The total number of registered adult patients with OA in 1999 amounted to 1835.4 per 100 thousand, primary morbidity – 343.9 and was higher than in the Russian Federation—1263.1 and 350.8/100,000. In 2003, there was an increase in the incidence to 2385.6 and 450.8 per 100 thousand, an increase of 30.0% and 31.1%. In the Russian Federation, there is also an increase in the incidence of OA 1846.0 and 500.2/100,000 (an increase of 46.1% and 42.6%) respectively. In 2006, the incidence rates were higher than 3146.0 and 572.1/100,000 with an annual increase. In 2013, they amounted to 3959.6 and 738.0/100,000 and the growth compared to 2006 was 25.9% and 29.0%. In 2019 the highest incidence rates were noted – 4950.9 and 1570.9/100 thousand. In 2022, the morbidity decreased after COVID -19 and amounted to 4407.0 and 1066.4/100,000 of the population.
Conclusion: The general and primary incidence of OA in the adult population increased from 1999 to 2022. The increase in incidence by 2.4 and 3.1 times is due to both aging of the population and better diagnosis, including the early stage of OA using MRI (in the absence of radiological changes).

P768
FRACTURES OF THE HUMERUS IN PERSONS OVER 40 YEARS OF AGE IN EAST SIBERIA (RUSSIAN FEDERATION)

L. Menshikova[1], O. Dvoeglazova[2], M. Menshikov[1]

[1]Irkutsk State Medical Academy of Postgraduate Education, Irkutsk,
[2]MANO "Medical and Diagnostic Center", Angarsk, Russia

Objective: To study the frequency of the proximal humerus fractures in people over 40 y of age in the Irkutsk region (East Siberia, Russian Federation).
Methods: There were analyzed the medical documentations of trauma centers, trauma departments of Angarsk with a stable population, where the primary incidence was recorded. Only fractures received at a low level of injury were evaluated. A specially designed questionnaire was filled out with alphabetical verification of patients. The fracture rate was calculated based on 5-y strata and per 100,000 person-years of observation over 5 y.
Results: The average population over the age of 40 was 68.133 for women and 43.470 for men. In women, the incidence of proximal fractures ranged from 5.2/100 thousand person-years over the age of 40–49 y to 289.1/100 thousand person-years in the age group over 70 y, averaging 211.3/100 thousand person-years of follow-up. In men, the lowest incidence of humerus fractures was also found at the age of 45–49 y, 4.7/100 thousand person-years and the highest in the age group over 70 y—223.2/100 thousand person-years. The average rate of humerus fractures in men was 98.8/100 thousand. The number of man-years of follow-up was significantly lower than that of women.
Conclusion: In women, the incidence of proximal humerus fractures was higher than in men with the lowest fracture rates in the 40–49 age group and high in those over 70 y of age.

P769
PUTATIVE MEDIATORS OF DECREASED BONE MINERAL DENSITY IN HIV EXPLORED BY TARGETED PROTEOMICS

A. Mendham[1], J. Goedecke[2], I. Seipone[2], T. Olsson[3], L. Micklesfield[1]

[1]Univ. of the Witwatersrand, Johannesburg, South Africa, [2]South African Medical Research Council, Cape Town, South Africa, [3]Umea Univ., Umea, Sweden

Objective: Using a targeted proteomics approach, we aimed to explore possible mediators of lower bone mass among people living with HIV (PLWH).

Methods: This cross-sectional study includes the Middle-Aged Soweto Cohort (MASC) of Black South African men and women (n = 940; mean (SD) age: 54 (6) y) which included 185 PLWH and 755 HIV negative participants. Data was collected on age, current employment, smoking status, alcohol consumption, menopausal status, medication usage, and height and weight were measured to calculate BMI. DXA was used to measure whole body fat mass and BMD at the femoral neck, total hip, lumbar spine (L1-L4) and whole-body (minus the head). Fasting blood samples were drawn for the measurement of targeted proteomics (OLINK proximity extension assay technique). Differences in targeted proteomics between HIV groups were first explored. This highlighted target proteins to correlate with BMD and explore the mediating effects of HIV on these associations. All statistical phases adjusted for false discovery rate.
Results: Compared to HIV negative participants, PLWH were younger ($p < 0.001$) and had a lower BMI ($p < 0.001$). When adjusting for age, sex, and BMI, PLWH had a significantly lower whole-body ($p < 0.001$), lumbar spine ($p < 0.001$), femoral neck ($p = 0.001$) and total hip BMD ($p = 0.005$) compared to HIV negative participants. Of the 182 targeted proteins, 64 proteins were different between the HIV groups, of which 13 (20.3%) were associated with BMD at one or more sites. Notably, COL1A1, OPN, IGFBP2 and TIMP4 were higher in PLWH and associated with lower BMD at all sites. Using mediation analysis, we showed that these proteins partially mediated the effects of HIV on BMD (proportion of total effect mediated range: 10.4–18.9%; $p < 0.05$).
Conclusion: We have found novel protein markers that collectively represent pathways related to bone formation and resorption that may be altered in PLWH. These markers need to be explored to reveal possible mechanisms for the higher risk of osteoporosis and fractures in PLWH.

P770
COST-EFFECTIVENESS OF FRAX®-BASED INTERVENTION THRESHOLDS FOR MANAGEMENT OF OSTEOPOROSIS IN INDIAN WOMEN

L. Nagendra[1], M. Chandran[2], S. Bhattacharya[3], J.-Y. Reginster[4], M. Hiligsmann[1]

[1]Dept. of Health Economics and Health Technology Assessment, Maastricht Univ., Maastricht, Netherlands, [2]Osteoporosis and Bone Metabolism Unit, Dept. of Endocrinology. Singapore General Hospital, Singapore, Singapore, [3]Deaprtment of Endocrinology, Indraprastha Apollo Hospital, Delhi, India, [4]Dept. of Epidemiology, Public Health and Health Economics, Univ. of Liege, Liege, Belgium

Objective: FRAX-based intervention thresholds (ITs) were recently identified for osteoporosis management in India.(1) This study aimed to assess the cost-effectiveness of ITs in Indian women aged 50 y and over.
Methods: A validated Markov microsimulation model was adapted to estimate the lifetime healthcare costs (INR 2022) per quality adjusted life-years (QALY) of oral alendronate compared with no treatment. Cost-effectiveness of age-dependent FRAX major osteoporotic fracture (MOF)) ITs was estimated. In addition, cost-effectiveness of fixed thresholds of 10.5% for MOF, recommended by the Indian Society of Bone and Mineral Research (ISBMR) guidelines were assessed. Cost data was obtained from the National Health System Cost Database for India. Generic alendronate price and no long-term costs following fractures were used in base case. A cost-effectiveness threshold of INR 1,97,468 /QALY gained was used, based conservatively on one time the Indian GDP per capita.
Results: Alendronate was shown to be cost-effective at MOF ITs from the ages of 65 y under full and real-world adherence. Sensitivity analyses suggested that cost-effectiveness at MOF ITs and HF ITs was reached from the age of 60 years when including INR 10,000 monthly costs following hip fractures. When using a 10.5% IT for MOF, treatment was cost-effective from the age of 50 y assuming full adherence, and from the age of 60 y assuming real world adherence.
Conclusion: This study suggests that the treatment of Indian women with alendronate is cost-effective at age-dependant FRAX intervention thresholds at 65 y and older when assuming no long-term costs following hip fracture, and from 60 y or older when long-term costs following hip fractures were included. If fixed IT are used, cost-effectiveness could be reached from the age of 50 y in some scenarios. Offering cost-effective access to therapy for individuals with high fracture probabilities, as determined by FRAX, holds significant potential in mitigating the escalating burden of osteoporotic fractures in India.

P771
PREVALENCE OF ASYMPTOMATIC VERTEBRAL FRACTURES ON VERTEBRAL FRACTURE ASSESSMENT USING DUAL ENERGY X-RAY ABSORPTIOMETRY IN PATIENTS VISITING AN INDIAN ACADEMIC TERTIARY CENTRE AND ITS IMPACT ON THE DIAGNOSIS OF OSTEOPOROSIS

L. Nagendra[1], N. Bhavani[2], P. Pavithran[2], U. Menon[2], N. Abraham[2], V. Nair[2], M. Hiligsmann[3], H. Kumar[2]

[1]Dept. of Endocrinology, JSS Medical College, JSS Academy of Higher Education and Research, Mysuru, India, [2]Dept. of Endocrinology, Amrita Institute of Medical Sciences and Research Centre, Kochi, India, [3]Dept. of Health Economics and Health Technology Assessment, Maastricht Univ., Maastricht, Netherlands

Objective: Vertebral fracture assessment (VFA) is gaining importance as a routine part of DXA assessment. However, data on prevalence of asymptomatic vertebral fractures in the Indian setting and its impact on diagnosis osteoporosis is scarce. This study aimed to look at the prevalence of vertebral fractures by VFA in patients referred for BMD assessment and to assess its impact on the diagnosis of osteoporosis.
Methods: 100 patients aged more than 40 y who were referred to an osteoporosis clinic for BMD testing were included in the study by simple random sampling. BMD of the lumbar spine L1-L4 and the proximal femur was measured by DXA. VFA was performed by vertebral morphometry immediately after DXA. Mild fractures were excluded.
Results: The study population consisted of 93 postmenopausal women and 7 males. The mean age was 67.58 ± 9.04 y. Among the study participants, 86 fractures were detected on VFA in 44 patients of which 30 (68.1%) were asymptomatic. There was no significant correlation of fracture incidence with BMD ($p = 0.252$). There were no fractures in participants aged less than 50 y. Prevalence of vertebral fractures increased with age from 11.1% in the 50–60 y age group to 75%% in > 80 y. Addition of VFA to BMD led to a.
diagnosis of osteoporosis in an additional 16 patients who went on to receive treatment for osteoporosis.

Conclusion: There is a high prevalence of asymptomatic vertebral fractures in the Indian population and including VFA with BMD measurement substantially improves the utility of DXA in the diagnosis of osteoporosis and fracture risk assessment.

P772
PERFORMANCE COMPARISON BETWEEN HOUNSFIELD UNITS AND DXA IN PREDICTING LUMBAR INTERBODY CAGE SUBSIDENCE AFTER CIRCUMFERENTIAL LUMBAR FUSION

K. Schuler[1], L. Orosz[1], T. Yamout[2], B. Allen[1], W. Lerebo[1], R. Roy[1], T. Schuler[2], C. Good[2], C. Haines[2], J. Ehsan[2]

[1]National Spine Health Foundation, [2]Virginia Spine Institute, Reston, USA

Objective: BMD assessment is essential for spinal fusion surgical planning, but gold standard DXA is affected by degeneration often resulting in falsely elevated scores. Studies on opportunistic measurement of computed tomography Hounsfield units (CTHU) suggest lower values predict interbody cage subsidence, yet cutoff values vary and lack standardization. This study aims to determine if cutoff value CTHU < 135 is associated with lumbar interbody cage subsidence and to compare the predictive performance of subsidence between CTHU and DXA.
Methods: Circumferential lumbar fusions were retrospectively enrolled if DXA, CT, and x-rays were available, and minimum follow up was one year. Interbody fusions were analyzed for subsidence ≥ 2 mm by validated motion detection software. Lowest DXA_{any} and DXA_{spine} T-scores were categorized (normal $\geq$ -1.0, -1.0 $>$ osteopenia $>$ -2.5, osteoporosis $\leq$ -2.5) and L1 CTHUs were measured. Analysis determined the association between CTHU < 135 and subsidence. Univariate and multivariate binary logistic regression compared the predictive performance of subsidence between CTHU and DXA.
Results: The 127-patient cohort had 96.9% degenerative pathologies, 54.3% females, median age 60 y, 2.4% osteoporosis, 44.1% CTHU < 135, and 13.4% subsidence. CTHU < 135 ($p = 0.004$) and age ($p = 0.016$) were significantly associated with subsidence; DXA lowest T-score ($p = 0.550$) was not. The odds of subsidence were statistically significant if CTHU < 135 for crude and adjusted (OR = 4.0, 95%CI 1.2–13.9, $p = 0.029$) comparisons. The odds of subsidence were not significant if lowest T-score $<$ -1.0 for DXA_{any} and DXA_{spine} (OR = 1.8, 95%CI 0.6–4.9, $p = 0.284$ and OR = 1.1, 95%CI 0.3–4.1, $p = 0.920$, respectively).
Conclusion: CTHU < 135 was associated with subsidence while DXA lowest T-score was not in patients with degenerative pathologies. The odds of subsidence were 4.0 times higher for CTHU < 135 after controlling for known risks, supporting this cutoff value. This study suggests that CTHU is a more reliable predictor of subsidence than DXA when assessing degenerative spinal pathologies and is a useful tool for assessing bone quality when planning lumbar surgery.

P773
EFFICACY OF BISPHOSPHONATES IN THE TREATMENT OF SECONDARY OSTEOPOROSIS DURING PEDIATRIC RHEUMATIC DISEASES: A SYSTEMATIC REVIEW

L. Rouached[1], R. Tekaya[1], I. Mahmoud[1], O. Saidane[1], S. Bouden[1], A. Ben Tekaya[1], L. Abdelmoula[1], C. Dziri[2]

[1]Rheumatology Dept., Charles Nicolle Hospital, [2]Honoris, Tunis, Tunisia

Objective: Children with chronic rheumatic diseases are at risk for bone loss and subsequent fractures. Bisphosphonates (BSP) are prescribed with increasing frequency to children with secondary osteoporosis; however, the efficacy of these agents remains unclear. The aim of the study is to investigate, through a systematic review of the literature, the efficacy of BSP in children with osteoporosis associated with rheumatic diseases.
Methods: We searched the Medline (via PubMed), Scopus, Cochrane Library and ISI Web of Science. We systematically selected articles (randomized controlled trials, cohorts and case–control studies), published between 2000 and 2023 of BSP in children under 18 y of age, in the context of secondary osteoporosis associated with rheumatic diseases. Two reviewers independently extracted data and assessed quality.
Results: Thirteen studies (n = 285 children) discussing the efficacy of BSP in children with rheumatic disease were included. BSP examined were oral alendronate (6 studies), oral etidronate (one study) and intravenous (IV) pamidronate (three studies), alendronate IV (one study) and zoledronic acid IV (two studies). Mean duration of treatment was 1.8 y [0.5–6]. Percent change or Z-score change in lumbar spine (BMD) from baseline were consistently reported: seven studies carried out between-group analyses (study group and control group): six studies showed significant difference (using alendronate (4), zoledronic acid (1) and pamidronate (1), six other studies (case series) demonstrated a positive effect of treatment on lumbar spine BMD. Fractures were reported for only two patients under BSP vs. 12 in the control group. Bone metabolism parameters were evaluated in eight studies, they were significantly decreased under BSP except in two studies.
Conclusion: Our systematic review revealed the efficacy of BSP on bone density in secondary osteoporosis associated to pediatric rheumatic diseases. The results justify further evaluation of the effect of BSP among children with osteoporosis.

P774
DETERMINANTS OF ABSENTEEISM AMONG CHRONIC LOW BACK PAIN MALE PATIENTS

L. Rouached[1], S. Ben Dhia[1], T. Bjeoui[1], S. Bouden[1], A. Ben Tekaya[1], I. Mahmoud[1], R. Tekaya[1], O. Saidane[1], L. Abdelmoula[1]

[1]Charles Nicolle Hospital, Dept. of Rheumatology, Tunis, Tunisia

Objective: Low back pain (LBP) is a common cause of workplace absenteeism. Our study aimed to identify determinants of absenteeism in male patients with chronic LBP.

Methods: We performed a cross-sectional study over 12 months in the rheumatology department of Charles Nicolle Hospital. We included male patients with chronic LBP. Patients' characteristics and pain characteristics (intensity with visual analogic scale (VAS), duration and radicular pain) were collected. Functional limitations due to lumbar stiffness was assessed using the Lumbar Stiffness Disability Index (LSDI). Patients were screened for depression and anxiety using the Hospital Anxiety and Depression (HAD) scale. Sleep quality was assessed using the Pittsburgh Sleep Quality Index (PSQI). Patients were asked about their history of absenteeism related to LBP.
Results: 100 patients were enrolled in our study. Mean age was 52.2 ± 12.8 y and mean disease duration was 1.8 ± 0.6 y. Radicular pain was reported by 64.4% of patients. Mean VAS of pain was 62.9 ± 18.7/100. Low back pain related absenteeism was reported by 70.3% of patients. Mean LSDI was 45 ± 19. Mean HAD-Anxiety was 8.4 ± 4.9 with 21.8% of patients having possible anxiety symptoms and 30.7% having certain anxiety symptoms. Mean HAD-Depression was 7.9 ± 4.6 with 24.8% of patients having possible depression symptoms and 29.7% having certain depression symptoms. Mean PSQI was 9.2 ± 5.7. Absenteeism was associated with a higher disease duration (1.9 ± 0.3 vs. 1.3 ± 0.9 y; $p < 10^{-3}$) and VAS of pain (67.2 ± 16.6 vs. 52.1 ± 20.4; $p < 10^{-3}$). We also find a significantly higher LSDI (48 ± 17.8 vs. 38.1 ± 21.6; p = 0.027), HAD-A (9.2 ± 4.8 ± 6.2 ± 4.7; p = 0.005), HAD-D (8.6 ± 4.4 vs. 6 ± 4.3; p = 0.012), and PSQI (10.1 ± 5.2 vs. 6.9 ± 6.6; p = 0.013) in patients who reported absenteeism. Besides, patients who reported radicular pain had higher rates of absenteeism (OR = 5.7; $p < 10^{-3}$; CI [2.2–14.7]).
Conclusion: LBP related absenteeism was associated with pain intensity, duration, radicular pain, lumbar stiffness related disability, anxiety, depression, and sleep quality disturbances. This empathizes the importance of a thorough screening and management of disease impact in addition to pain management in chronic LBP patients.

P775
FACTORS ASSOCIATED WITH DISABILITY IN MALE PATIENTS WITH CHRONIC LOW BACK PAIN

L. Rouached[1], S. Ben Dhia[1], T. Bjeoui[1], S. Bouden[1], A. Ben Tekaya[1], I. Mahmoud[1], R. Tekaya[1], O. Saidane[1], L. Abdelmoula[1]

[1]Charles Nicolle Hospital, Dept. of Rheumatology, Tunis, Tunisia

Objective: Low back pain (LBP) is a common condition and one of the major causes of disability [1]. The aim of this study was to identify factors associated with disability in male patients with chronic LBP.
Methods: We conducted a cross-sectional study in the rheumatology department of Charles Nicolle Hospital. Male patients with chronic LBP were included over 12 months. Patients' characteristics and pain characteristics (intensity with visual analogic scale (VAS), neuropathic pain score Douleur Neuropathique en 4 Questions (DN4)) were collected. We assessed LBP related disability with the Oswestry Low Back Disability Questionnaire (ODI). Patients were screened for depression and anxiety using the Hospital Anxiety and Depression (HAD) scale. Sleep quality was assessed using Pittsburgh Sleep Quality Index (PSQI).
Results: We included 100 patients in our study. Mean age was 52.2 ± 12.8 y. Mean BMI was 25.5 ± 4.6 kg/m^2. Mean disease duration was 1.8 ± 0.6 y. Low back pain was associated with radicular pain in 64.4% of patients. Mean VAS of pain was 62.9 ± 18.7/100 and mean DN4 was 2 ± 2.2/10 with 21% having a positive DN4 score (≥ 4). Mean ODI was 42 ± 19. Disability was minimal (0–20%) in 19.8% of patients, moderate (21–40%) in 19.8%, severe (41–60%) in 42.6%, and 15.8% of patients were crippled (61–80%). Sedentary behaviour was reported by 46.5% of patients. Mean HAD-Anxiety, HAD-Depression, and PSQI were 8.4 ± 4.9, 7.9 ± 4.6, and 9.2 ± 5.7, respectively. Sedentary behaviour was associated with a higher ODI (46.7 ± 16.7 vs. 37.7 ± 20.3; p = 0.020). Besides, a positive correlation was found between ODI and HAD-A (r = 0.259; p = 0.010), HAD-D (r = 0.282; p = 0.005), VAS of pain (r = 0.496; $p < 10^{-3}$), DN4 score (r = 0.254; p = 0.016), and PSQI (r = 0.314; p = 0.002). No correlation was found between ODI and age, BMI, or disease duration.
Conclusion: Disability in chronic LBP male patients was associated with neuropathic pain, sedentary behaviour, anxiety, depression, and sleep disturbances. This highlights the importance of a comprehensive and multimodal approach to patient care.

INFLUENCE OF INSOLATION LEVEL ON CHANGES IN BONE METABOLISM IN POSTMENOPAUSAL WOMEN

L. S. Abboskhujaeva[1], N. M. Alikhanova[2], F. A. Takhirova[2], G. G. Akramova[1], M. M. Shakirova[1]

[1]Republican Specialized Scientific and Practical Center of Endocrinology Acad. Ya.Kh. Turakulov, [2]Institute of Health and Strategic Development, Tashkent, Uzbekistan

Objective: Osteoporosis is a major global health problem in the future, and improved methods for diagnosing and preventing this disease may be beneficial. The goal is to study the indicators of bone metabolism in postmenopausal women depending on the level of insolation.
Methods: As part of the study, a survey and examination of 155 women over 50 and under 70 years old in the city of Tashkent was conducted. To measure mineral density, DXA was performed, and anthropometric and laboratory data were also used.
Results: Indicators of calcium-phosphorus metabolism and markers of bone remodeling in postmenopausal women were within the reference values of the set. Severe vitamin D deficiency was present in 26.7% of those examined, deficiency and insufficiency in 29.7% and 20.9% of women, respectively. β-CrossLaps and PTH above the reference value occurred in 33.1% and 7.0% of women, respectively. Of the 51 women whose osteocalcin levels were determined, 13.7% had a marker above the reference range. Of 155 postmenopausal women, 72 (46.5%) women had normal BMD, 61 (39.4%) had osteopenia, and 22 (14.2%) had osteoporosis. Average values of the T- score of the femoral neck (winter: right -1.44 ± 0.89; and left -1.48 ± 0.8; summer: right -1.42 ± 0.8; and left -1.38 ± 0.8), regardless of the time of year, corresponded to osteopenia. The number of women with fractures of various locations in the groups with nBMD and osteopenia was significantly lower than in the osteoporosis group (Normal—Osteoporosis—OR 0.18; 95%CI 0.05–0.62; p = 0.01; Osteopenia—Osteoporosis—OR 0.18; 95%CI 0.05–0.65; p = 0.01).

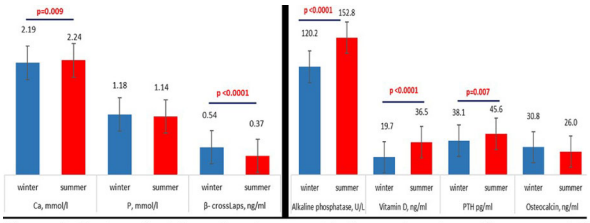

Figure. Indicators of calcium-phosphorus metabolism and markers of bone remodeling in postmenopausal women

Conclusion: Our results showed a positive effect of vitamin D during periods of high insolation in postmenopausal women; for this reason, calcium and vitamin D supplementation should be recommended as a strategic option to prevent early postmenopausal bone loss.

P777
VITAMIN D AND FGF23 LEVELS IN THE ROLE OF REGULATING MINERAL HOMEOSTASIS

N. M. Alikhanova[1], L. S. Abboskhujaeva[2], G. G. Akramova[2], F. A. Takhirova[1], C. H. B. Musakhanova[3]

[1]Institute of Health and Strategic Development, [2]Republican Specialized Scientific and Practical Center of Endocrinology Acad. Ya.Kh. Turakulov, [3]Republican Specialized Scientific and Practical Medical Center of Endocrinology named after acad. Turakulova E.H., Tashkent, Uzbekistan

Objective: FGF23 has become an important regulator of phosphate and vitamin D homeostasis. It has now been established that FGF23 regulates not only phosphate homeostasis, but also vitamin D metabolism. However, unlike PTH, FGF23 inhibits rather than stimulates the activity of 1-α-hydroxylase and calcitriol synthesis. The goal is to evaluate changes in the level of FGF23 as a regulator of phosphate and vitamin D homeostasis depending on the level of vitamin D doses taken in women over 50 y of age.
Methods: The women examined were divided into 3 groups: 1) a group with natural synthesis of vitamin D, depending on the degree of insolation; 2) a group with minimal intake of vitamin D supplements, less than 5000 IU/d; 3) a group with vitamin D supplementation, more than 10,000 IU/d.
Results: A comparative analysis showed that PTH values in the 3 compared groups increased by 1.2;1.2 times both after the summer period and after taking supplements in small doses, and in the group taking large doses (10,000 IU daily), a decrease of 1.2 times was observed, respectively. The reliability has not been revealed. The average values of PTH were 51; 44 and 40.1 ng/ml. A decrease in such an indicator as FGF23 by 3.7 times, 9.9 and 7.4 times in the compared groups also indicates a decrease in bone resorption. Thus, in all the compared groups, changes in bone mineral metabolism indicators indicate an increase in the active absorption of calcium ions in intestinal enterocytes and, as a result, a decrease in resorption and an increase in bone formation.

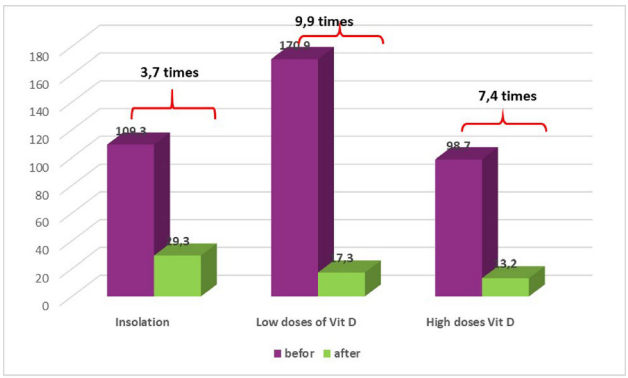

Figure. Changes in FGF23 levels in the three compared groups before and after increasing vitamin D.

Conclusion: Vitamin D levels within normal values are important for the body not only as regulators of calcium and phosphorus homeostasis, but also for reducing FGF23.

P778
VITAMIN D AND ITS POTENTIAL INTERACTION WITH PAIN

N. M. Alikhanova[1], L. S. Abboskhujaeva[2], G. G. Akramova[2], F. A. Takhirova[1], M. M. Shakirova[2], C. H. B. Musakhanova[3]

[1]Institute of Health and Strategic Development, [2]Republican Specialized Scientific and Practical Center of Endocrinology Acad. Ya.Kh. Turakulov, [3]Republican Specialized Scientific and Practical Medical Center of Endocrinology named after acad. Turakulova E.H., Tashkent, Uzbekistan

Objective: Vitamin D deficiency is common in patients with chronic pain and in healthy people, but no difference has been reported between them; thus, it remains to be confirmed whether there is a link between vitamin D deficiency and chronic pain. Osteoporosis is a common disease in chronic pain disorders. The goal is to assess the frequency of pain and fractures of various locations depending on the level of insolation.
Methods: A comparative analysis of the frequency of pain and fractures in 123 postmenopausal women, depending on the degree of insolation, was carried out: in winter, when the degree of insolation is lowest and, accordingly, vitamin synthesis in the body is naturally lowest. And in the first month of autumn, when after the spring–summer period, the accumulation of vitamin D in the body naturally reaches its maximum.
Results: 27.6% of the surveyed had severe vitamin D deficiency, 30.9% and 21.1% of women had deficiency and insufficiency, respectively. In one third (35.8%) of women, β-CrossLaps turned out to be higher than the reference index, and 8.1% had elevated PTH levels. Osteocalcin levels were above the reference range in 16.3% of women. Normal BMD was found in 46.3% of women, osteopenia in 32.5% and osteoporosis in 12.2%. When analyzing the questionnaires in the winter-summer section, it turned out that the number of women who experienced pain of various localization did not significantly increase (from 30.9% to 38.2%; OR 0.72; 95%CI 0.43–1.23; p = 0.23). The number of fractures decreased by 2 times (from 8.9% to 4.1%; OR 2.32; 95%CI 0.78–6.88; p = 0.12).

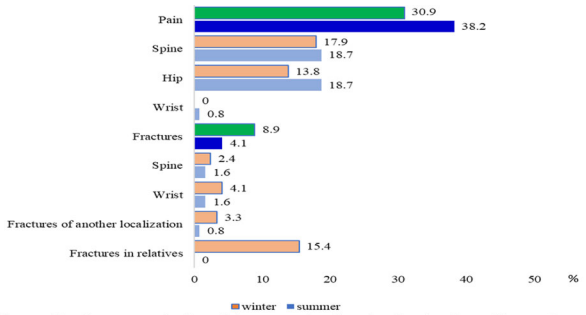

Figure. The frequency of pain and fractures of various localization depending on the season of the year.

Conclusion: The results obtained indicate a low vitamin D supply (79.7%), about half (49.6%) had a violation of mineral density. at the same time, the number of patients experiencing pain of various localization increased.

P779
BACILLUS COAGULANS AMELIORATES INFLAMMATORY BONE LOSS VIA MODULATING "BREGS-TREGS-TH17" CELL AXIS UNDER ESTROGEN DEFICIENT OSTEOPOROTIC CONDITIONS

L. Sapra[1], R. K. Srivastava[1]

[1]All India Institute of Medical Sciences, New Delhi, India

Objective: Probiotics are known to be involved in management of various-inflammatory diseases including osteoporosis. Several studies along with ours reported that probiotics showed its health promoting effects by regulating Treg-Th17 immune cell balance in host. Furthermore, various studies demonstrated that Tregs-Th17 immune cell balance can be further regulated by regulatory B cells (Bregs) in host. But no study till date had delineated the Bregs-Tregs-Th17 cell axis in case of osteoporosis i.e. "Immunoporosis". Moreover, no study investigated the immunomodulatory potential of *Bacillus coagulans* (BC) in regulating bone-health. The present study aims to examine the effect of probiotic BC on Bone Health via modulation of the host "Bregs-Tregs-Th17" cell axis in Ovx mice.
Methods: We monitored the osteoprotective effect of BC on bone health under estrogen deficient ovariectomy induced osteoporotic mice model. For the same, female C57BL/6 mice of 8–10 weeks were divided equally in three groups as Sham/control group, Ovx group and Ovx + BC group (received 10^9 cfu/ml/d BC orally) for a period of 45 days. At the end of experiment mice were sacrificed and tissues analysed for various parameters to access the role of BC administration on bone-health by using several cutting-edge technologies such as SEM, AFM, μCT, FACS and ELISA. Furthermore, we assessed the ability of BC induced Bregs in modulating osteoclastogenesis and in inducing Tregs and Th17 cell differentiation under in vitro conditions. 16S rRNA and gut integrity analysis were performed for evaluating the effect of BC administration on gut dysbiosis in Ovx mice model.
Results: Our in vivo data suggested that administration of BC attenuated bone loss in Ovx mice. Both the cortical and trabecular bone-content of Ovx + BC treated group was significantly higher than Ovx-group. Remarkably, the percentage of osteoclastogenic $CD4^+Ror\gamma t^+$ Th17 cells at distinct immunological sites such as bone marrow (BM), mesenteric lymph nodes (MLN) and Peyer's patches (PP) were significantly reduced ($p < 0.01$), whereas the percentage of anti-osteoclastogenic regulatory T cells (Tregs); $CD4^+Foxp3^+$ was significantly enhanced ($p < 0.01$) in BC treated group, thus resulting in inhibition of bone loss. Moreover, BC administration also significantly enhanced ($p < 0.01$) the population of $CD19^+CD1d^{hi}CD5^+$ Bregs in Ovx + BC group. The immunomodulatory role of BC was further supported by serum cytokine data with a significant reduction in proinflammatory cytokines (IL-6, IL-17 and TNFα) along with enhancement of anti-inflammatory cytokines (IL-10, IFNγ) in BC treated group. Furthermore, we observed that BC administration improves the bone health via improving the gut integrity and restoring the diversity of gut commensals under estrogen deficient conditions.
Conclusion: We propose for the first time that osteoprotective role of BC on bone health is mediated via its effects on the "Bregs-Treg-Th17" cell axis which further regulates osteoclastogenesis. The present study thus highlights the potential of probiotic BC as a novel osteoprotective agent in the treatment and management of bone related diseases including osteoporosis.

P780
DEVELOPMENT OF A NOVEL RESNET-BASED DEEP LEARNING MODEL FOR ACCURATE DIAGNOSIS OF OSTEOPOROSIS VIA 3D COMPUTED TOMOGRAPHY SCANS OF THE SPINE

L. Shaw[1], C.-H. Lin[2], Y.-H. Lin[3], K.-C. Tu[1], H.-T. Shih[1], Y.-H. Lin[1], Y.-P. Lai[1], K.-H. Chen[1]

[1]Dept. of Orthopedic Surgery, Taichung Veterans General Hospital, [2]Dept. of Computer Science and Engineering, National Chung Hsing Univ., [3]Dept. of Radiation Oncology, Taichung Veterans General Hospital, Taichung, Taiwan, Taichung, Taiwan

Objective: Computed tomography (CT) scans have become indispensable diagnostic tools in modern medicine, with the lumbar spine frequently being included in these examinations. In our study, we propose to develop a ResNet model that utilizes 3D CT imaging of the spine, integrating advanced AI techniques to enhance the accuracy and efficiency of osteoporosis diagnosis.
Methods: We retrospectively reviewed patients with both DXA and spinal CT scans during 2011–2022. CT scans were loaded into the deep learning model TotalSegmentator for structure annotation. After annotation, the 3D CT images of the lumbar spine were segmented using Python. The image classification model was established based on ResNet architecture. We simulated normal lumbar spine through data augmentation with random rotating and scaling the original images to avoid model overfitting. Validation dataset was performed once after each training epoch. Model with epoch 49 was chosen to perform the test dataset.
Results: Our analysis of 414 lumbar spines revealed that 45% were normal, 28% osteopenia, and 27% osteoporotic, based on DXA diagnostics. The model achieved an AUC of 0.99, 0.99, and 1.00 for normal bone quality, osteopenia, and osteoporosis, respectively. The accuracy of osteoporosis diagnosis is 91.67% with sensitivity 88.89% and specificity 94.44%. The positive predictive value of osteoporosis is 94.12%.

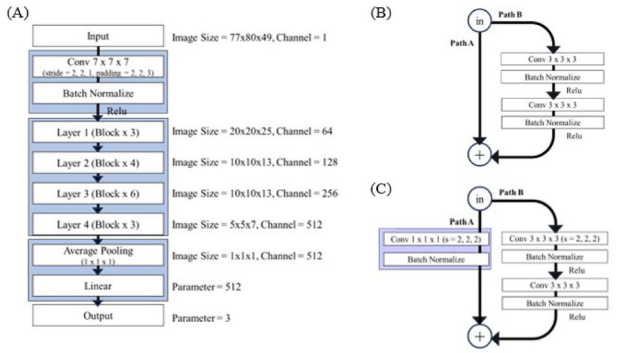

Figure 1. Figure A is our model architecture, which is generally divided into three parts: image reduction layer, residual block layers and output layer. Figure B is the residual block focused on image feature extraction. Figure C is also residual block, which shrank image while extracting image feature

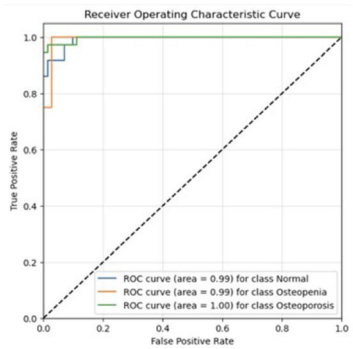

Figure 2. ROC curve for the model diagnosis accuracy. The AUCs of normal bone quality, osteopenia and osteoporosis are 0.99, 0.99 and 1.00.

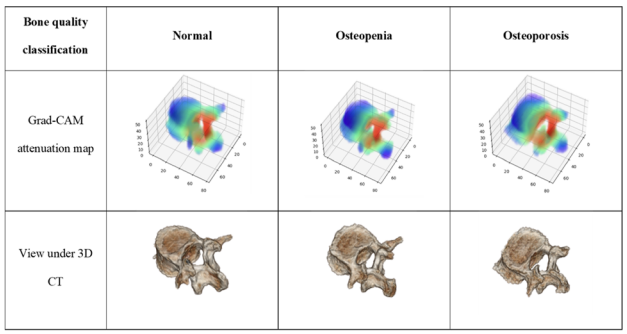

Figure 3. Grad-CAM visualization of the last convolutional layer in our ResNet model, demonstrating examples from normal bone quality, osteopenia, and osteoporosis groups. Each image below is the corresponding Grad-CAM heatmap, with bright red areas indicating regions most impactful in the model's osteoporosis screening.

Conclusion: The proposed ResNet model represents a promising and reliable auxiliary tool for the diagnosis of osteoporosis using 3D CT scans.

P781
GRAPHENE QUANTUM DOTS ERADICATE RESISTANT AND METASTATIC OSTEOSARCOMA BY ENHANCED INTERFACIAL INHIBITION

L. Shen[1], Y. Su[1], K. Ye[1], Y. Wang[1], B. Geng[2], D. Pan[2]

[1]Dept. of Orthopedic Surgery, Shanghai Sixth People's Hospital Affiliated to Shanghai Jiao Tong Univ. School of Medicine, [2]School of Environmental and Chemical Engineering, Shanghai Univ., Shanghai, China

Objective: Cancer stem cells (CSCs) with distinctive self-renewal, proliferation and differentiation capabilities, are responsible for tumor initiation, metastasis, relapse and drug resistance. However, CSCs are resistant to chemotherapy, leading to drug efflux and an inability to completely eliminate them. It is thus desirable to design intrinsically bioactive yet structurally simple nanoparticles that could target and eliminate CSCs without dependence on the use of CSC-targeted molecules or delivery systems.

Methods: We prepared graphene quantum dots (GQDs) by a microwave-assisted approach using julolidine as the precursor, ethanol and benzoic acid as the reaction media. Firstly, we examined the inhibitory effects that GQDs and representative cytotoxic agents can exert on the blockage of the metastatic process of osteosarcoma in the initial stages, migration and invasion, using transwell assay and scratch assay. Then, we established in vivo models of osteosarcoma lung metastasis to evaluate GQDs induced remote metastasis suppression. At last, we investigated whether GQDs can inhibit the proliferation of multiple cancer cells with multidrug resistance (MDR) phenotypes and further evaluated whether GQDs possessed the capability to reverse MDR for sensitization of various small-molecule drugs.

Results: As a new single drug, GQDs can block the lung metastasis of osteosarcoma regardless of high expression of drug efflux transporters. Enhanced interfacial inhibition effects on eradicating drug-resistant CSCs can be induced by self-insertion of bioactive GQDs into DNA major groove (MAG) sites in cancer cells. Since transcription factors regulate gene expression at the MAG site, MAG-targeted GQDs could exert greatly enhanced interfacial inhibition effects on downregulation of the expression of a collection of cancer stem genes such as *ALDH1*, *Notch1*, and *Bmi1*. Moreover, the nanoscale interface inhibition mechanism enables the reversal of cancer MDR by inhibition of *MDR1* gene expression by using the GQDs at non-toxic concentration (1/4 × IC_{50}) as the MDR reverser.

Conclusion: Our findings decipher the enhanced nano-bio interface inhibition effects at the MAG site on eradicating CSCs in prevention of cancer metastasis and recurrence. Given high efficacy in interfacial inhibition, CSC-mediated migration, invasion and metastasis of cancer cells can be substantially blocked by MAG-targeted GQDs, which can also be harnessed to sensitize clinical cytotoxic agents for improved efficacy in combination chemotherapy.

P782
CHRONIC PAIN SYNDROME IN PATIENTS WITH POLYARTHRITIC VARIANT OF PSORIATIC ARTHRITIS ON THE BACKGROUND OF BASELINE THERAPY

L. Shilova[1], S. Spitsina[2]

[1]Volgograd State Medical Univ., [2]Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky, Volgograd State Medical Univ., Volgograd, Russia

Objective: To evaluate the severity of chronic pain syndrome in patients with polyarthritic variant of psoriatic arthritis (PsA) on the background of baseline therapy with methotrexate.

Methods: 20 patients diagnosed with PsA according to CASPAR 2006 criteria with predominant joint involvement were examined. All patients were on basic anti-inflammatory therapy: they took methotrexate for more than 6 months. Disease activity was assessed using DAS28-CRP(4) and DAPSA indices, as well as visual analog scale (VAS) of disease activity. The severity of joint syndrome was determined by patient-rated VAS of pain, the number of swollen (VAS) and painful joints (VAS). Quality of life was assessed by BASDAI, SF-36, HAQ-DI questionnaires; the level of depression was assessed by QIDS SR-16.

Results: Among PsA patients there were 16 (80%) men, 4 (20%) women. The age of the patients was 45.8 ± 8.74 y, and the duration of the joint syndrome ranged from 6 months to 9 y. All patients were taking methotrexate as an OTC drug at a dose of 10 to 20 mg/week, as well as various NSAIDs. All patients (100%) had moderate disease activity according to DAS28-CRP(4) (4.2–5.1 points), DAPSA index (18–27.4 points). The patient-rated VAS showed 58.9 ± 6.2 mm of disease activity and the physician-rated VAS was 56.5 ± 4.3 mm. The mean number of painful and swollen joints was 14.2 ± 6.7 and 6.8 ± 0.56, respectively. The severity of pain in joint syndrome by VAS measured by the patient was 64.8 ± 5.1 mm. The obtained indices indicate the presence of PsA activity in patients, as well as a pronounced pain syndrome persisting despite the conducted baseline therapy. The presence of pain and functional limitations had a negative impact on all quality of life parameters. According to the SF-36 questionnaire, there were deviations in both physical (36.5 ± 7.9) and mental (39.2 ± 6.3) components. HAQ-DI values ranged from minimal to moderate decrease in quality of life (0.65–1.3), BASDAI index was 3.8 ± 0.46. The level of depression was assessed by the QIDS SR-16 questionnaire, which corresponded to a mild degree of depression. A negative correlation between PsA activity, pain syndrome severity, number of painful joints and indices of quality of life and depression was revealed.

Conclusion: Patients with PsA with predominantly polyarthritic variant do not achieve a low degree of disease activity or remission despite methotrexate therapy. Also, patients have a prolonged pain syndrome characterized by the severity and involvement of a sufficient number of joints in the pathological process, which negatively affects both physical and mental health indicators, including the development of a mild degree of depression. The multicomponent nature of chronic pain syndrome in PsA, the presence of a large number of factors affecting it, need further study.

P783
OSTEITIS FIBROSA CYSTICA RECOVERY FOLLOWING PARATHYROIDECTOMY FOR PRIMARY HYPERPARATHYROIDISM: A CASE SERIES AND REVIEW OF LITERATURE

Y. E. F. Eden Friedman[1], A. J. Jabarin[1], G. S. Shlomai[1], I. V. Vered[1], I. E. Eshed[2], L. T. S. Tripto-Shkolnik[1]

[1]Division of Endocrinology, Diabetes and Metabolism, [2]Dept. of Diagnostic Imaging, Sheba Medical Center, Ramat Gan, Israel

Objective: Osteitis fibrosa cystica (OFC) is an extreme manifestation of accelerated bone resorption in primary hyperparathyroidism (PHPT), rarely encountered nowadays. BMD gain following parathyroidectomy (PTx) is well documented, while little is known regarding the timeline of re-mineralization and recovery of the lytic lesions.

Methods: We present three patients with clinical, biochemical, and advanced (computer tomography or magnetic resonance) imaging post-PTx follow-up and review published similar OFC patient cases reporting serial imaging of bony lesions following PTx.

Results: The main baseline patient's characteristics are presented in Table 1. All patients received calcium, magnesium, and alfacalcidol supplementation post PTx; and serum calcium, PTH and alkaline phosphatase normalized gradually. Patients 1 and 2 demonstrated an impressive re-mineralization of pelvic lytic lesions within 6 and 12 months following PTx, respectively. Patient 3 had partial remineralization in the C4-C5 vertebrae in 6 months, which continued to progress 18 months after PTx. We summarized reports of fifty-four patients with PHPT and OFC, assessed for lytic lesion recovery after PTx with different imaging modalities. Most lesions were partially remineralized within 6–12 months. Near-complete remineralization was evident in 38 (70.3%) on the last imaging follow-up.

Table 1- main patients' characteristics

	Patient 1	Patient 2	Patient 3
Age at diagnosis	24	41	67
Gender	Female	Male	Male
PTH, x ULN	12.7	26.3	16
Albumin corrected Calcium mg/dl	13.2	13.9	13.8
25-OH-Vitamin D, ng/ml	12.5	5.7	10
Alkaline phosphatase, x ULN	4.8	10.2	2.5
Location of lytic lesions	Mandible, ilium, ischium, femoral shaft	Ilium, ischium, vertebras	Cervical vertebra, ilium, femoral neck and trochanter
Salvage orthopedic intervention	Intramedullary nailing of left femur (after PTx)	None	Corpectomy of level C4-C6 and excision of the extramedullary lesion (Before PTx)

Key: PTH- parathyroid hormone; PTx- parathyroidectomy; ULN- upper limit of normal

Conclusion: Lytic lesions of OFC undergo recovery following successful PTx; however full mineralization may take longer than a year. This timeline should be taken into account when considering the possibility of salvage orthopedic surgery. Active surveillance may be advised in most cases, excluding large lesions in weight-bearing areas, which are more prone to fracture.

P784
APPROPRIATE MECHANICAL STIMULATION INHIBITS THE SENESCENCE OF CHONDROCYTES

L. Wang[1], J. Zhao[1]

[1]Shanghai Jiaotong Univ., Shanghai, China

Objective: Osteoarthritis and related joint diseases are increasingly prevalent, significantly impacting the quality of life globally. A critical component in the progression of these diseases is the senescence of chondrocytes, the cells responsible for maintaining healthy cartilage. Recent advancements in biomechanics suggest that controlled mechanical stimulation may retard the senescence process in these cells. This study aims to elucidate the impact of varying degrees of mechanical stimulation on chondrocyte senescence, providing insights potentially transformative for therapeutic approaches in joint disease management.
Methods: We employed an advanced RNA sequencing technique to analyse the genomic expressions of chondrocytes subjected to three different levels of mechanical stimulation: none (0%), mild (10%), and moderate (20%). The mechanical stresses were applied using a custom-designed bioreactor, which allowed precise control over the duration and intensity of the stimuli. This approach enabled a comprehensive comparison of the cellular responses to different mechanical environments.
Results: Our results offer a nuanced view of the chondrocyte response to mechanical stress. In the absence of mechanical stimulation, chondrocytes showed signs consistent with typical senescence processes. Interestingly, under mild mechanical stimulation (10%), there was an upregulation of genes associated with inflammation, paradoxically coupled with a downregulation of senescence markers, suggesting a protective response against cellular senescence. However, increasing the mechanical load to 20% led to a marked increase in stress responses and degenerative markers, indicative of cell damage and accelerated senescence processes. These findings highlight a delicate balance between beneficial and detrimental mechanical forces on chondrocyte health.
Conclusion: The study underscores the critical role of mechanical forces in chondrocyte physiology and senescence. Mild mechanical stimulation appears to confer a protective effect against senescence, while excessive mechanical stress induces cellular damage and degeneration. These insights open avenues for targeted biomechanical therapies in osteoarthritis, where controlled mechanical stimuli could be harnessed to slow down or even reverse cartilage degeneration. Future research should aim to fine tune these mechanical interventions to optimize therapeutic outcomes in joint disease treatments.

P785
DURABLE IMMUNOMODULATORY HIERARCHICAL PATCH FOR ROTATOR CUFF REPAIRING

L. Wang[1], J. Zhao[1]

[1]Shanghai Jiaotong Univ., Shanghai, China

Degradable shoulder cuff patches, followed over five years, have been observed to exhibit high re-tear rates exceeding 50%, which is attributed to the inability of degradable polymers alone to restore the post-rotator cuff tear (RCT) inflammatory niche. Herein, poly(ester-ferulic acid-urethane)urea (PEFUU) was developed, featuring prolonged anti-inflammatory functionality, achieved by the integration of ferulic acid (FA) into the polyurethane repeating units. PEFUU stably releases FA in vitro, reversing the inflammatory niche produced by M1 macrophages and restoring the directed differentiation of stem cells. Utilizing PEFUU, hierarchical composite nanofiber patch (HCNP) was fabricated, simulating the natural microstructure of the tendon-to-bone interface with an oriented-random alignment. The incorporation of enzymatic hydrolysate derived from decellularized Wharton jelly tissue into the random layer could further enhance cartilage regeneration at the tendon-to-bone interface. Via rat RCT repairing model, HCNP possessing prolonged anti-inflammatory properties uniquely facilitated physiological healing at the tendon-to-bone interface's microstructure. The alignment of fibers was restored, and histologically, the characteristic tripartite distribution of collagen I – collagen II—collagen I was achieved. This study offers a universal approach to the functionalization of degradable polymers and provides a foundational reference for their future applications in promoting the in vivo regeneration of various tissues.

DISCONTINUATION AND NONPUBLICATION OF OSTEOPOROSIS CLINICAL STUDIES: A CROSS-SECTIONAL ANALYSIS

M. A. Abdelsalam[1], Y. J. Alabdallat[2], Y. R. Hussein[3], M. Sajed[4], M. Taha[5], R. M. Ibrahim[6], W. Z. Selima[7], A. H. Zabady[8]

[1]Rheumatology and Rehabilitation Dept., Faculty of Medicine, Misr Univ. for Science and Technology, Alfayyoum, Egypt, [2]Faculty of Medicine, Hashemite Univ.', Zarqa, Jordan, [3]Faculty of Medicine, Benha Univ., Benha, Egypt, [4]Faculty of Pharmacy, Al-Azhar Univ., Mansoura, Egypt, [5]Faculty of Medicine, Ain-Shams Univ., Cairo, Egypt, [6]Medical Research Group of Egypt (MRGE), Negida Academy, Arlington, MA, U.S., Port Said, Egypt, [7]Anesthesia, Intensive Care and Pain Management Dept., Ain-Shams Univ., Cairo, Egypt, [8]Dept. of Microbiology, Faculty of Science, Damanhur Univ., Cairo, Egypt

Objective: Over 200 million individuals worldwide have osteoporosis, which predisposes patients to low-impact fragility fractures and leads to a decline in their quality of life, along with increased morbidity, mortality, and disability. Clinical trials are predisposed to discontinuation and non-publication, which is considered a substantial challenge contributing significantly to research waste in clinical medicine. The aim of this study is to examine the reasons (rates) for terminated, discontinued, and unpublished osteoporosis clinical trials by reviewing their characteristics and exploring the logistical, financial, and practical reasons.
Methods: We extensively searched clinicaltrials.gov to identify all trials related to osteoporosis, including those that were published, unpublished, and discontinued. Until December 31, 2021, we excluded studies completed in the last 24 months, considering the potential for ongoing peer review processes. Then we used the NCT identifier number and other protocol information for each clinical trial to identify if it had been published. Information regarding gender, age, study type, funding source, intervention type, enrollment, and location was extracted and then analysed using multiple logistic regression to determine characteristics associated with unpublished and discontinued trials.
Results: A total of 413 registered studies were analysed, comprising 361 (87.4%) interventional studies and 52 (12.6%) observational studies. Among these, 25 (6%) were discontinued, with 40% not providing reasons. The second most common reason for discontinuation was recruitment issues (25%). Trials with a small sample size (less than 100) were more likely to be discontinued (20%) compared to those with a larger sample size. Among the completed studies, 226 (54.8%) remained unpublished. Logistic regression analysis revealed that trials involving drug or procedural intervention were more likely to be non-published among interventional studies. Studies exclusively including females and observational studies were also more likely to be nonpublished.

Conclusion: Osteoporosis clinical trials are frequently discontinued or left unpublished, exposing participants to potential harm without benefit. This not only poses challenges in recruiting for future trials but also leads to the inefficient utilization of limited time and financial resources in medical research. Enrollment size, gender, type of intervention, and type of study are the main predictors of unpublished studies.

P791
ASSOCIATIONS OF PRECLINICAL MANIFESTATIONS OF ATHEROSCLEROSIS OF THE CORONARY AND CAROTID ARTERIES WITH BONE STRENGTH INDICATORS IN WOMEN

M. A. Kolchina[1], I. A. Skripnikova[1], O. V. Kosmatova[1], O. Y. U. Isaykina[1], V. A. Vigodin[1]

[1]National Medical Research Center for Therapy and Preventive Medicine of the Ministry of Healthcare of the Russian Federation, Moscow, Russia

Objective: To study the associations between arterial stiffness, atherosclerotic plaques (AP) of carotid arteries and calcification of coronary vessels with BMD and markers of bone metabolism.
Methods: 357 female outpatients in the peri- and postmenopausal periods (aged 45–82) were enrolled into a cross-sectional study. Evaluation of the pulse wave velocity (PWV), augmentation index (AI) were carried out by applanation tonometry. The intima-media thickness (IMT), the presence and number of AP were studied using duplex scanning. Coronary vessels calcium deposits were registered by multispiral computed tomography using the Agatston calcium index. The BMD was measured using DXA. C-terminal telopeptide of type I collagen (CTX)—bone resorption marker was determined in blood serum using the β-CrossLaps method.
Results: In peri- and postmenopausal women, the severity of coronary artery calcification and carotid atherosclerosis negatively correlate with BMD in the spine and in the femoral neck. Calcification of the coronary arteries acted as an independent factor of bone mass reduction in all measured areas of the skeleton; the IMT complex and the presence of AP proved to be independent risk factors for low bone mass in the femoral neck. According to multivariate regression analysis, vascular rigidity indicators (PWV and AI) did not independently contribute to bone mass reduction. The chance of detecting age-adjusted AP with increased indicators of the marker of bone resorption of CTX significantly increases by 1.9 times. No associations were found between the Agatstone calcium index, vascular rigidity indices and the CTX.
Conclusion: A decrease in BMD and an increase in the marker of bone resorption, associated with subclinical atherosclerosis and, especially, calcification of coronary arteries, allows to think about the common mechanisms of development and progression of osteoporosis and atherosclerosis and about general preventive measures.

P792
CINACALCET IN THE CONSERVATIVE MANAGEMENT OF PRIMARY HYPERPARATHYROIDISM(PHPT): REAL-WORLD EXPERIENCE IN TWO TERTIALY CARE CENTERS

M. A. Martin Almendra[1], M. Ventosa[2], X. C. Vivas[1], M. T. Mories Alvarez[1], L. Cuellar[2], M. Gonzalez-Sagrado[3], C. Ochoa[4], A. Valverde[1], A. Herrero Ruiz[1], A. Sanchez[1], C. Muñoz[1], M. Delgado Gomez[1], C. Robles[1], H. Villanueva[1], R. A. Iglesias[1]

[1]Dept. of Endocrinology Hospital Universitario de Salamanca, Salamanca, [2]Dept. of Endocrinology Hospital Universitario Rio Hortega, Valladolid, [3]Dept. of Medical Investigation Hospital Universitario Rio Hortega, Valladolid, [4]Dept. of Medical Investigation Complejo Asistencial de Zamora, Zamora, Spain

Objective: To evaluate the role of cinacalcet(safety, efficacy and metabolic profile) in adults with hyperparathyroidism(PHPT) in whom parathyroidectomy was not an option.
Methods: A retrospective observational study in 126 subjects with PHPT included in pharmacy registries with active treatment during 2023. Clinical and metabolic variables at baseline, 1, 3 and 5 y of follow up were evaluated. A logistic binary regression analysis was run to predict fall in kidney function(KF).
Results:16 were male, 5 had MEN and 8 had previous surgery. Median age was 74 ± 12 y. At baseline: calcium 11,4 ± 0.6 mg/dl, phosphorus 2,6 ± 0,4 mg/dl, PTH 176 ± 93 pg/ml (range 50–625), eFGR 69,9 ± 17,7 ml/min (62–90), urine calcium excretion (UCa) 237 ± 142 mg/24 h (20–669), and 25OHD 27 ± 17 ng/ml (82,5% on supplementation). Mean cinacalcet dose was 38 ± 18 (15–180) at baseline and reached 52 ± 9 mg/d at 5th year. Calcium level fell to 9,9 ± 0,6 1 y, 9,8 ± 0,6 3 y and 9,8 ± 0,6 mg/dl 5 year (p0.001). UCa levels reduced from 228 ± 136 to 129 ± 84 mg/24 h, the difference was found to be statistically significant at 5th year (p0,005). UCA was higher in patients with renoureteral crisis than without at 3rd year (306 ± 191 vs. 164 ± 85 mg/24 h, p0,007). KF decreased in 43% at 1 y, 53% 3 y and 50% at 5 y. In multiple regression analysis (group of fall in KF taken as reference), UCA elevation was the only significant variable (OR 0,26 95%CI 0,71–0,84 p0.025). No other significance was found. The tolerance was excellent in 94%, 6% had digestive symptoms. 5 patients required withdrawal (3 hypocalcemia, 1 myoclonus, 1 unknown). 6 had hypercalcemic crisis before treatment and 4 during treatment. Surgery was required on 8 patients. 5 patients died (1 vascular event, 4 urinary sepsis).
Conclusion: When indicated to reduce serum calcium, cinacalcet is effective and safe along 5y in an elderly population with PHPT. Vitamin D deficit is common and requires supplementation. Cinacalcet is well tolerated and rarely needs to stop. Finally, UCA suggests to affect KF along treatment.

P793
FEMORAL NEUROPATHY SECONDARY TO ILIACUS HEMATOMA AND VASTUS MEDIALIS TEAR PRESENTING AS LEFT ANTEROMEDIAL THIGH MASS IN A PATIENT ON ANTICOAGULANT THERAPY: A CASE REPORT

G. A. Macapagal[1], M. A. Ongchuan[1]

[1]Dept. of Physical Medicine and Rehabilitation Philippine Orthopedic Center, Quezon City, Philippines

Femoral compressive neuropathy secondary to iliacus hematoma is a rare condition. This case was further complicated by a concomitant distal thigh mass due to a vastus medialis tear more visible upon change in positioning during ultrasound study.
Case report: This is a case about a 39-year-old male on warfarin therapy who noted sudden onset hip and thigh pain after kicking a concrete wall. He was diagnosed with Left iliacus muscle hematoma which was successfully drained with percutaneous pigtail catheter. After discharge, he sought consult in our clinic due to persistent inability to extend the Right leg associated with difficulty in ambulation and a mass on the Left distal anterior thigh. Ultrasound imaging revealed myotendinous tear of the vastus medialis which was visualized more clearly on standing position. Neurophysiologic evaluation revealed femoral neuropathy above the inguinal ligament. He

underwent outpatient therapy with subsequent improvement in quadriceps muscle strength and ambulation.
Conclusion: Femoral neuropathy due to iliacus hematoma, as well as the possibility of another remote lesion, should always be considered in a patient on anticoagulant therapy. Ultrasound assessment in suspected tears should be supplemented by changes in positioning or dynamic maneuvers to increase its sensitivity.

P794
RELATIONSHIP BETWEEN VITAMIN D LEVELS AND BONE MINERAL DENSITY IN TRANSGENDER POPULATION

M. A. Rueda[1], N. Camargo[1], A. Sierra[1]

[1]Fundacion Universitaria de Ciencias de la Salud. Sociedad de Cirugia de Bogotá, Hospital San José, Bogotá, Colombia

Objective: To describe the relationship between vitamin D levels and densitometric results of transgender patients (TP) prior to the start of affirmative hormone therapy (AHT) evaluated in 2 experience centers in Bogotá, Colombia.
Methods: Case series that includes 9 TP, in whom measurements of serum 25-OH vitamin D (VitD) and bone densitometry by DXA method were performed prior to the start of AHT.
Results: Six patients were transwomen (TW) and three were transmen (TM). The average age was 29.7 y. 100% of the VitD level measurements were in the range of insufficiency and deficiency, of which 5 patients had levels less than 15 ng/ml. Regarding the densitometric findings, in the lumbar spine, the average BMD value was 1.088, in 2 TW a Z-score $\leq$ -2 (22.2% of the patients), the other measurements were in normal range. In the hip, the average BMD was 0.937 (mentioned in only 6 reports), with normal Z-scores in both the femoral neck and the total hip. No patient had presented fragility fractures.
Conclusion: VitD levels and bone mineralization are influenced by AHT (1), hence the importance of knowing the state of bone health prior to its initiation. Published studies have reported that vitD deficiency has increased both in the TP and in the general population, due to nutritional and social factors and increased use of sunscreens (2,3), which is consistent with our findings. An essential factor in this population is the lesser development of their daily activities outside in relation to their dysphoric condition, with poor sun exposure and less physical activity. Regarding the densitometric findings, it is consistent with previous studies that a better state of bone mineralization is found in TM compared to TW, due to less sports activity, which also contributes to less development of muscle mass, and a lower peak bone mass. According to our experience, vitD levels and evaluation of BMD should be part of routine screening prior to starting THA.

GENDER DIFFERENCES IN DISEASE CHARACTERISTICS, COMPLIANCE, AND OUTCOMES USING TREAT-TO-TARGET APPROACH IN AXIAL SPONDYLOARTHRITIS (AXSPA)

M. A. Saeed[1], H. Ahmad[2], A. Ahmed[3], H. Ahmed[1]

[1]Central Park Medical College, Lahore, Pakistan, [2]Central Park Medical College, [3]Rashid Latif Medical College, Lahore, Pakistan

Objective: There has been wide variability in terms of gender reported from different ethnic and geographic backgrounds. In low and middle-income countries it is further complicated due to issues of access and gender discrimination. Data are scarce in general about axSpA from Pakistan and in particular about gender differences. We aimed to compare the demographic characteristics, disease activity scores at baseline, compliance, and outcome of treat to-target (T2T) approach between both genders in patients with axSpA in a real-world setting.
Methods: This is the first retrospective analysis looking at gender differences in a cohort set up with the support of the Arthritis Care Foundation enrolling patients from two academic rheumatology departments and affiliated clinics in Lahore Pakistan. All patients who were enrolled gave an informed consent. Patients were diagnosed as axSpA as per ASAS classification criteria. Data regarding demography, disease parameters, and outcome measures like Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) and Assessment of Spondyloarthritis Disease Activity Score (ASDAS)-CRP were retrieved from electronic medical records. Compliance to Treat to target strategy in both groups was assessed by adaptations to treatment as per Assessment of SpondyloArthritis International Society (ASAS) recommendations performing ASDAS-CRP scores on at least 2 visits during the minimum follow-up of 6 months. For analysis data was entered into SPSS version 26.
Results: There were a total of 270 axSpA patients enrolled from November 2019 to December 2023. Out of these, there were 218 (80.7%) men and 52 (19.3%) women. Women were found to be older than their counterparts at presentation (p = value 0.001). There was no statistically significant difference between the two genders in terms of disease duration at their first visit. However, there were more men with positive HLA-B 27 status 150 (69.4%) vs. 26 (50.0%), p = 0.000. There was no statistically significant difference In the frequency of peripheral arthritis and uveitis. Females were reported to have higher BASDAI scores at baseline (p = 0.003). Compliance to T2T by treating rheumatologists in terms of escalation of treatment was higher in male patients leading to higher use of biologic or targeted synthetic modifying rheumatic drugs (tsDMARDs) in men (46 vs. 22% p = 0.002). For a detailed comparison of outcome measures see Table 1.

Table 1. Comparison of baseline demography, disease parameters, and outcome measures between the two genders

Variable	Male	Female	P=value
Age mean±SD	31.9±10.2	37.6±12.4	0.001
HLA B27 n (%)	150 (69.4)	26 (50.0)	0.000
Peripheral Arthritis n (%)	57 (26.4)	13 (25.0)	0.838
Uveitis n (%)	20 (9.3)	8 (15.4)	0.195
Radiographic axSpA n (%)	184 (84.4)	39 (75.0)	0.108
Non-Radiographic axSpA n (%)	34 (15.6)	13 (25.0)	0.108
Follow-up duration in months mean±SD	39.2±39.1	26.7±35.7	0.036
BASDAI baseline mean±SD	3.3±1.7	4.5±1.1	0.003
BASDAI last visit mean±SD	3.0±1.6	4.0±1.9	0.001
ASDAS-CRP Baseline mean±SD	2.9±1.2	3.2±0.9	0.358
ASDAS-CRP last visit mean±SD	2.6±1.04	2.7±0.9	0.596
Adaptation to treatment as per ASAS recommendations	157 (81.3)	33 (71.7)	0.254
NSAIDs use n (%)	128 (65.6)	35 (72.9)	0.067
Use of biologics and tsDMARDs n (%)	98 (46.0)	11 (22.0)	0.002
ASDAS-CRP remission/LDA n (%)	65 (38.9)	9 (25.0)	0.115

Conclusion: This study has highlighted that the burden of disease in women is higher than in men in terms of BASDAI and comparable by

ASDAS-CRP. However, despite this, there is a disparity in terms use of biologics and tsDMARDs in females. There is an unmet need to address factors including issues of access for more vulnerable gender especially in low and middle-income countries where generally there is no coverage for outpatient rheumatic diseases.

P796
THE BURDEN OF SEPSIS IN OSTEOPOROTIC PELVIC FRACTURE PATIENTS: A NATIONWIDE COHORT STUDY IN AUSTRIA, 2010–2018

M. Behanova[1], A. Sokhan[2], J. Haschka[1], B. Reichardt[3], J. Zwerina[1], R. Kocijan[2]

[1]Ludwig Boltzmann Institute of Osteology at Hanusch Hospital of OEGK and AUVA Trauma Centre Meidling, Vienna, [2]Ludwig Boltzmann Institute of Osteology at Hanusch Hospital of OEGK and AUVA Trauma Centre Meidling, Vienna, [3]Austrian Social Health Insurance Fund, Österreichische Gesundheitskasse, Eisenstadt, Austria

Objective: Pelvic fractures (PF) are now considered osteoporotic fractures, associated with a notably high mortality rate. Elderly individuals are more susceptible to infectious diseases and display a worse prognosis attributed to the decrease in immune responses. The aim of this study was to determine the epidemiological characteristics and impact of sepsis on one-year mortality in the Austrian population of patients with PF aged $\geq$ 50 y, within the time frame 2010–2018.
Methods: We performed a retrospective nationwide register-based cohort study which included all in-hospital patients aged $\geq$ 50 with PF between 2010–2018 in Austria. We identified patients who were hospitalized with sepsis within 180 d following a PF event. Cumulative incidence of sepsis (CIF) was estimated in the context of considering mortality as a competing risk. For assessing differences in CIF by sex and age group we applied Fine and Gray risk analysis. Association between sepsis and all-cause mortality (between septic and non-septic patients), was assessed by time-varying Cox proportional hazard regression.
Results: Among 59,081 patients hospitalized with PF between 2010–2018 we identified 619 (1.05%) patients who were hospitalized with sepsis within 180 d following PF. The cumulative incidence risk of sepsis within 180 d after PF was significantly higher in males (1.4%, 95%CI 1.2%-1.5%) as compared to females (0.92%, 95%CI 0.83%-1.0%), $p < 0.001$. There were no significant differences in CIF by age group. In the cohort of patients with sepsis, the one-year mortality was 50.4%. Mortality risk was greater for patients who developed sepsis, independently of age, sex and comorbidity status (HR 3.12, 95%CI 2.83–3.44, $p < 0.001$) as compared to patients without sepsis.
Conclusion: With a very high one-year mortality risk among those who develop sepsis, our study emphasizes the substantial impact of sepsis on long term survival in fractured patients. These findings underscore the critical need for sepsis prevention and early detection and management to mitigate its detrimental effects on patient outcomes.

P797
MUSCULOSKELETAL SARCOIDOSIS WITH EXCEPTIONAL PRESENTATION

M. Slouma[1], M. Ben Messaoud[1], R. Dhahri[1], I. Gharsallah[1]

[1]Military Hospital of Tunis, Tunis, Tunisia

Sarcoidosis is a multisystem inflammatory disease that can affect various organs in the body, most commonly the lungs and lymph nodes. It is characterized by the formation of granulomas, which are clumps of inflammatory cells. The exact cause of sarcoidosis is unknown, and it can present with a wide range of symptoms. The osteoarticular involvement in sarcoidosis is rare. This report seeks to present an uncommon case of osteoarticular sarcoidosis with distinctive clinical manifestations and highlight the importance of detecting osteoarticular involvement in this disease.
Case report: A 37-year-old woman with no medical history was referred to our department with a five-year history of a painless lump affecting her left wrist, which gradually increased in size. A few months prior to our consultation, she also noticed a new mass on her right wrist and swelling of the nasal dorsum. Upon presentation, her main concerns were the recurring swelling at the base of her nose, increased size of the wrist masses, and the appearance of new lesions on the left forefoot and hindfoot (lateral retro-malleolar). She reported recent unquantified weight loss and had no other notable symptoms, such as fever, anorexia, night sweats, or history of bone/joint pain. Physical examination revealed non-tender swelling on the dorsal part of the right hand, lateral side of the left wrist, and a fusiform mass on the lateral dorsal side of the left foot. Nasal dorsal lump and palatal ulcerations evolving for one month were also noted. Joint, chest, abdomen, cardiovascular system, and skin examination showed no significant abnormalities. Routine blood tests including full blood count, inflammatory markers, bone profile, renal and liver function tests were normal despite a lymphopenia (lymphocyte level: 800/mm^3, N: 1500–4000/mm^3). Angiotensin converting enzyme assay was not performed. Rheumatoid factor and anti-cyclic citrullinated peptide antibodies (sensitive and specific diagnostic markers for rheumatoid arthritis) were negative. Antinuclear antibodies and anti-neutrophil cytoplasm antibodies were also negative. Complement (C3 and C4) was within the normal range. A tuberculin skin test was performed and revealed an anergy. The Interferon-Gamma Release Assays (IGRAs) were negative. The Treponema Pallidum Hemagglutinations Assay (TPHA) and Venereal Disease Research Laboratory (VDRL) were negative. The polymerase chain reaction (PCR) M. tuberculosis complex on both skin and synovial sheath was negative. The X-rays of hands and feet did not show any geodes or erosions. The chest radiography did not show any abnormalities. The chest CT scan revealed adenomegalia above and below the diaphragm, some of which were necrotic. There were no other scannographic signs of tuberculosis. MRI showed a mass on the dorsal surface of the right hand, centred on the tendon sheath of the 4th, 5th and 6th extensor compartments, with regular lobulated contours and local T1 hyposignal, heterogeneous T2 hyposignal with areas of hypersignal and intense enhancement after injection of Gadolinium. The mass measured 58 $\times$ 31 mm and was associated with synovitis of the 3rd, 4th and 5th metacarpophalangeal joints. It also revealed a second mass on the ulnar border of the left wrist centred on the 6th extensor compartment, with the same features as the previously described mass and with haemopigmented deposits in T2* hyposignal. It measured 53*26 mm and was associated with tenosynovitis of the 5th homolateral extensor compartment and synovitis of the distal radio-ulnar. This mass was responsible for cortical lysis opposite and extending to the ulnar styloid. The MRI findings were strongly suggestive of villonodular tenosynovitis of the extensor tendons of the hands. She had two nodules removed from the nasal dorsum, and the biopsy revealed a gigantocellular granuloma, sometimes centred on caseous necrosis, suggestive of tuberculosis. The patient had not received anti-tubercular treatment. Biopsy of the tumour of the nasal dorsum was repeated one year later when the nasal mass recurred. Histopathological examination revealed a recurrence of tuberculoid granulomatosis of the nasal dorsum, with no histological signs of malignancy. Biopsy of the synovial sheath revealed epithelioid and giganto-cellular granulomas with no obvious caseous necrosis. Accessory salivary gland biopsy showed grade 1 focal lymphocytic sialadenitis according to the classification defined

by Chisholm and Mason. There were no granulomas or amyloid deposits. She was diagnosed with pulmonary sarcoidosis based on clinical symptoms, radiological findings, and histopathological evidence of non-caseous granulomas. Long-term treatment was initiated with methotrexate 15 mg weekly. The patient received oral corticosteroids (prednisolone 0.5 mg/kg daily) and within 18 months, steroids were gradually reduced until 2.5 mg/d. There was a good response with a significant reduction of the masses on both wrists. After 2 y of follow-up, she remained stable and had no recurrence of symptoms. She is still on long-term management and monitoring to assess any potential relapses.

Conclusion: The case illustrated showcases the distinctive clinical and radiological features associated with osteoarticular sarcoidosis. Identifying osteoarticular involvement in sarcoidosis can assist clinicians in making an accurate diagnosis and initiating appropriate therapy, thereby averting potential associated morbidities.

P798
ATTITUDE OF TUNISIAN RHEUMATOLOGISTS TOWARD THE DESIRE FOR PREGNANCY IN PATIENTS WITH SPONDYLOARTHRITIS FROM CONCEPTION TO POSTPARTUM

M. Slouma[1], M. Ben Messaoud[1], R. Dhahri[1], I. Gharsallah[1]

[1]Military Hospital of Tunis, Tunis, Tunisia

Objective: Spondyloarthritis (SpA) can affect women in their reproductive years. Managing them during pregnancy can pose a significant therapeutic challenge for rheumatologists. The objective of our study was to assess the attitude of Tunisian rheumatologists toward the desire for pregnancy in patients with SpA.

Methods: A cross-sectional survey was conducted among Tunisian rheumatologists through an anonymous questionnaire distributed on social media using the Google Forms platform. The questionnaire consisted of 27 items addressing the attitudes adopted regarding the desire for pregnancy in SpA patients.

Results: In total, 40 rheumatologists (39 women and 1 man) participated in the survey within the specified timeframe. The average age was 29.8 y [26–48 y], with 90% currently in training. The average years of professional experience were 4.4 y [1–21 y]. 10% of physicians claimed to have previously attended a workshop on pregnancy in SpA. Before initiating treatment, reproductive-age patients were questioned about a potential desire for pregnancy in 35% of cases for NSAIDs and 100% of cases for disease-modifying antirheumatic drugs (DMARDs). Twenty percent of rheumatologists checked for effective contraception use before starting NSAID treatment vs. 90% for DMARDs. During disease follow-up, 30% of physicians inquire about the desire for pregnancy in patients treated with NSAIDs, as opposed to 90% for DMARDs. Effective contraception during treatment is monitored in 10% for NSAIDs and 85% for DMARDs. The majority of participants (95%) assessed the severity of the disease before allowing pregnancy. Half of the physicians permit pregnancy for at least a moderate level of disease activity. 75% of participants would schedule a preconceptional consultation. 65% of rheumatologists discuss treatment in consultation with the gynecologist. Regarding treatment, 65% of participants believe that if disease activity allows, NSAIDs should be discontinued before conception. If not, permitted NSAIDs were mainly arylcarboxylic acids (50%) and selective COX-2 inhibitors (37%). Their prescription was allowed until the second trimester of pregnancy in 67.5% of cases. Feared adverse effects were premature closure of the ductus arteriosus (90%), oligohydramnios (30%), spontaneous abortions (25%), newborn renal failure (15%), and prolonged bleeding time for mother and child (10%). The recommended DMARDs in pregnant women were mainly certolizumab (88%), etanercept (22%), and sulfasalazine (6%) for both active axial and peripheral forms. In the event of pregnancy occurring under anti-TNF, rheumatologists indicate a reassessment of the benefit/risk balance of treatment (80%), ultrasound monitoring (75%), and reporting to pharmacovigilance (60%) while reassuring the couple. Background treatments prescribed during breastfeeding were mostly certolizumab (75%), sulfasalazine (55%), and celecoxib (46%).

Conclusion: The majority of Tunisian rheumatologists follow current guidelines for the management of SpA in cases of a desire for pregnancy. The management of these patients requires more targeted training and awareness.

P799
ATTITUDE OF TUNISIAN RHEUMATOLOGISTS TOWARDS THE IMPLEMENTATION OF ARTIFICIAL INTELLIGENCE IN THE FIELD OF RHEUMATOLOGY

M. Slouma[1], M. Ben Messaoud[1], R. Dhahri[1], I. Gharsallah[1]

[1]Military Hospital of Tunis, Tunis, Tunisia

Objective: Artificial intelligence (AI) plays a crucial role in the era of the medical revolution, and the field of rheumatology is no exception. The spectrum of rheumatic diseases can be challenging to diagnose and treat due to the complexity of their symptoms. AI has the potential to enhance the accuracy of diagnosis and treatment management through automated algorithms. The objective of our study was to assess the willingness of Tunisian rheumatologists to embrace the application of AI in the field of rheumatology.

Methods: A cross-sectional survey was conducted among Tunisian rheumatologists through an anonymous questionnaire distributed on social media using the Google Forms platform. The French version consisted of 22 questions exploring the rheumatologists' perspectives towards the implementation of AI in the field of rheumatology.

Results: In total, 42 rheumatologists (40 women and 2 men) participated in the survey within the specified timeframe. The average age was 30.4 y [26–48 y], with 95% currently in training. The average years of professional experience were 3.8 y [1–21 y]. 28% of rheumatologists reported having used AI at least once in their daily practice, with a low frequency. Regarding potential applications of AI, rheumatologists believed that this technology could significantly impact patient management in the following areas: interpretation of radiological (58%) and laboratory (47%) investigations, confirmation of a positive diagnosis (32%), assessment of disease prognosis (32%), and therapeutic management (21%). Evaluation of rheumatologists' adherence to AI showed that 8% of participants had used this tool to make a positive diagnosis. The response was considered relevant in 33% of cases. None of the physicians had used AI to interpret radiological or laboratory investigations. In the research domain, 29% of rheumatologists had employed AI in scientific work, with a 56% satisfaction rate. Participants were also questioned about their perception of AI. 57% of physicians believed that AI could enhance the accuracy of medical diagnoses in the field of rheumatology. Nearly 40% of respondents were concerned that this technology might replace the patient-doctor relationship and impact equality in access to quality healthcare. In 57% of cases, rheumatologists thought that AI could harm patient wellbeing and that it might lead to biases, skill loss, and a shift of responsibility in 66% of cases. 62% of participants believed that AI would have consequences for patients' privacy. On the ethical aspect, half of the rheumatologists (52%) affirmed that AI does not undermine the fundamental values of medicine.

Conclusion: AI is a rapidly advancing field. However, its integration into the field of rheumatology in Tunisia is not yet well established.

P800
IMPACT OF FLOSSING METHOD ON THE FUNCTION OF THE JOINT IN PEOPLE AFTER KNEE INJURIES

M. Berwecka[1], B. Latała[1], A. Berwecki[2], M. Warzecha[1], A. Spannbauer[1], P. Dobosz[3]

[1]Uniwersytet Jagielloński—Collegium Medicum, Instytut Fizjoterapii, [2]Akademia Wychowania Fizycznego w Krakowie, Instytut Nauk Stosowanych, [3]Akademia Wychowania Fizycznego, Kraków, Poland

Objective: Knee injuries are common and cause extensive damage to structures surrounding the joint, such as ligaments, menisci and joint capsule. Patients require physiotherapy to improve joint function. The most common problem after an injury is the limited range of motion. One of the methods used in therapy is tissue flossing. The therapy combines compression, followed by active movement. The aim of the study was to assess the impact of the Flossing therapy on the function of the knee joint after an injury.

Methods: The study group included 40 participants (25 women and 15 men), aged 18–40, after knee injuries. The subjects completed the questionnaire that included information about circumstances of the injury. Measurements were made: range of motion using a standard Baseline 365° goniometer, muscle strength (hamstrings and quadriceps femoris) using a MicroFET2 dynamometer, functional mobility with deep squat test from the Functional Movement Screen (FMS) and pain with Numeric Rating Scale. Subsequently, participants were subjected to therapy using floss band tapes. The tape was applied around the joint bypassing the patella for 2 min with a tension of approximately 80%. Then, 3 exercises were performed with full existing range of motion: active flexion and extension in supine, deep squat and straight kneeling to sitting on heels. After removing the tape, measurements were taken again.

Results: A statistically significant increase in the range of active and passive flexion, improvement in quadriceps muscle strength and mobility, and a decrease in pain were found. A negative correlation was found between the period since the injury and the change in the range of extension in the knee joint.

Conclusion: Floss band therapy increases the range of active and passive flexion and mobility, improves the strength of the quadriceps muscle, and reduces the level of pain in people after knee joint injuries. Flossing does not affect the range of extension in the knee or the strength of the biceps femoris muscle. The effectiveness of therapy decreases as the time since the injury increases.

P801
TOPICAL DELIVERY OF ACECLOFENAC BY NOVEL NANOSTRUCTURED CARRIER FOR EFFECTIVE MANAGEMENT OF RHEUMATOID ARTHRITIS

M. Bhargava[1], S. Bhargava[2]

[1]GTB Hospital, [2]Signa College of Pharmacy, Kanpur, India

Objective: Rheumatism is any painful disorder of the supporting body bone, ligaments, tendons or muscles, i.e., not caused by infections or injury. The primary aim of treatment of rheumatic disease is reduction of pain and inflammation, maintenance of joint mobility and prevention of deformity. The aim of the study was to develop and characterize aceclofenac loaded solid lipid nanoparticles (SLN) and nanostructure lipid carriers (NLC)to study the skin permeation profile and deposition kinetics.

Methods: The SLN/NLC were prepared using glyceryl monostearate (GMS) by ultrasonication method and optimized. The in vitro characterization parameters included optical microscopy, particle size, shape, polydispersity, zeta potential and surface morphology, differential scanning calorimetry, X-ray diffraction and Entrapment efficiency. The in vivo studies included carrageenan induced paw edema method and CLSM studies.

Results: Compared to SLN, NLC showed improved drug loading capacity and a good ability to reduce the drug expulsion during storage. The data indicates prolonged and higher magnitude of edema inhibition exerted by SLN than NLC formulations. GMS based SLN or NLC hydrogel can be proposed for topical use for providing sustained effect to inflammatory disease like arthritis and ankylosing spondylits.

Conclusion: SLN or NLC based hydrogel of anti-inflammatory agent could be designed for treatment of rheumatic diseases. Permeation studies through human cadaver skin and clinical implication of data are required to develop topical drug delivery system. Nevertheless, further specialized studies are required to confirm the present hypothesis and to better investigate the role of nanoparticulate carriers for controlling and sustaining the release of the drug.

P802
DENDRITIC NANOARCHITECTURES FOR THE TREATMENT OF PSORIASIS

M. Bhargava[1], S. Bhargava[2]

[1]GTB Hospital, [2]Signa College of Pharmacy, Kanpur, India

Objective: Psoriasis is a multigenic, cutaneous inflammatory disorder, involving a variety of pathological changes in skin. The study aimed to evaluate the potential of dendrimers for safe and efficient topical delivery of antipsoriatic agent Dithranol, one of the most promising anti-psoriatic agents via topical route whose application is inconvenient and troublesome.

Methods: The polypropylene Imine dendrimers (PPID) were synthesized by divergent synthesis method. The ethylene diamine was used as core material and acrylonitrile to form branching units. Dendrimers were then characterized by IR & NMR spectroscopy and transmission electron microscopy. Dithranol loaded PPID were evaluated for in vitro drug release, haemolytic toxicity, skin irritation, tape stripping studies and drug penetration studies.

Results: Loading of dithranol was found to be pH dependent. PPID showed significantly enhanced permeation rate constant and lesser skin irritation when compared with the plain drug solution. Skin separation studies and confocal laser scanning microscope images showed that the dye-loaded dendrimers exhibits deposition of dye in pilosebaceous compartment. The entrapment of drug in dendritic system reduced skin irritation, haemolytic toxicity, enhanced permeation rate constant and penetration and accumulation in the skin. The dithranol loaded dendrimers extended drug retention time in the skin *vis-a-vis* reducing the associated disadvantages and improving the topical bioavailability of the molecules in a controlled pattern.

Conclusion: The enhanced accumulation of drug via dendrimer carrier within the skin might help optimize targeting of this drug to the epidermal and dermal sites, thus creating new opportunities for well-controlled, modern topical application of Dithranol for the treatment of psoriasis.

P803
WHAT IS THE BEST SF36 OR LUPUSQOL?

M. Bizhanova[1], E. Aseeva[2], S. Solovyev[2], S. Glukhova[2], B. Issayeva[1], S. Issayeva[1], M. Saparbayeva[1], A. Amanzholova[1]

[1]Asfendiyarov Kazakh National Medical Univ., Almaty, Kazakhstan, [2]Rheumatology, Federal State Research Institution (FSRI) named after V. A. Nasonova, Moscow, Russia

Objective: The LupusQoL is a disease-specific health-related quality of life (HRQoL) measure for patients with lupus. We conducted this study to compare the efficiency of LupusQoL with the 36-item Short-Form Health Survey (SF-36), a generic quality of life (QoL) scale, in patients with lupus. Both questionnaires were conducted for one visit to the clinic.

Methods: Disease activity was evaluated by the SLEDAI-2 K, and chronic damage by the Systemic Lupus International Collaborating Clinics Damage Index score (SDI). Associations between the LupusQoL and SF-36 domains were examined, while also examining age, disease duration, and disease activity for each questionnaire. Descriptive statistics, Spearman's correlation coefficients, and Students t-test were performed to analyze the data.

Results: A total of 400 patients with lupus (F/M 363:37, mean age 34,2 ± 11.5 y, mean disease duration 106,3 ± 91,9.0 months) were included, and 63% of these were active and 56% of these had SDI ≥ 1. The mean SLEDAI 2 K score was 9,6 ± 8,0. QOL as assessed by SF-36 and LupusQoL was low in this group of patients with SLE. The mean scores for each of the domains of the LupusQoL and SF-36 are shown in Table 1. The mean scores are < 60 in 8 domains of the SF-36 but not in social functioning (62,03 ± 27,19) and physical function (62,35 ± 28,53).

Table 1. Descriptive statistics and correlation coefficient for SF-36 and LupusQoL

LupusQoL domains	Mean (SD)	SF-36 domains	Mean (SD)	r	P
Comparable					
Physical health	66,20±23,18	PF	62,35±28,53	0,77	0,96
Emotional health	64,65±24,75	MH	50,51±8,40	0,38	0,94
Pain	70,03±24,68	BP	47,0±8,86	-0,33	0,02
Fatigue	62,7±24,73	VT	53,04±22,59	-0,70	0,83
Noncomparable					
Planning	63,90±28,46	SF	62,03±27,19		
Intimate relationships	72,92±30,93	GH	49,14±20,51		
Burden to others	50,68±27,79	RE	49,84±43,86		
Body image	65,18±27,60	RP	40,46±41,35		
		PCS	45,15±7,65		
		MCS	48,46±5,41		

The MCS and PCS scores were both < 50. Despite the fact that the mean score in LupusQoL was always higher than in SF-36 for each of the comparable domains, 3 standardized p values were not statistically significant (mean score in 400 patient visits: physical health/physical function, 66,20 ± 23,18/62,35 ± 28,53, p = 0.96; emotional health/mental health, 64,65 ± 24,75/50,51 ± 8,40, p = 0.94; and fatigue/vitality 62.70 ± 24.73/53.04 ± 22.59, p = 0.83), 1 standardized p value was statistically significant—pain/bodily pain 70.03 ± 24.68/47.00 ± 8.86, p = 0.02. The correlation of the comparable domains of LupusQoL and SF-36 was studied. There was a strong correlation between comparable domains in LupusQoL and SF-36 in 400 patient visits (physical health and physical functioning, r = 0.77; emotional health and role emotional, r = 0.38; pain and bodily pain, r = -0,33; and fatigue and vitality, r =—0.70; all p values < 0.0001). For the 4 noncomparable domains of the LupusQoL, there was a correlation between 3 domains of LupusQoL and 1 of the component scores of SF-36: body image and SF-36 MCS, r = 0.20; planning and SF-36 MCS, r = 0.13, r = 0.73; and burden to others and SF-36 MCS, r = 0.19; body image and SF-36 PCS,r = 0,38; planning and SF-36 PCS,r = 0,66; and burden to others and SF-36 PCS,r = 0,38.

Conclusion: The LupusQoL-Russian is sensitive to change in SLE patients with active SLE. LupusQoL and SF-36 were equivalent in assessing the HRQOL in the Russian SLE patients. Both LupusQoL and SF-36 are easily completed by patients and correlate very well with each other.

P804
PROGRAMMING COST ACTION 21122: IMPLICATIONS FOR THE PROMOTION OF AWARENESS ABOUT MUSCULOSKELETAL HEALTH AMONGST NON-GERIATRICIANS

M. Bonnici[1], S. Cotobal Rodeles[2], S. Duque[3], F. Kamberi[4], K. Piotrowicz[5], A. Wissendorff Ekdahl[6], G. Ogliari[7], M. Kotsani[8]

[1]Karin Grech Rehabilitation Hospital & St Vincent De Paul Residence, Pieta & Luqa, Malta, [2]Hospital Universitario Savero Ochoa Leganés, Madrid, Spain, [3]Faculty of Medicine, Univ. of Lisbon, Lisbon, Portugal, [4]Scientific Research Centre for Public Health, Faculty of Health, Univ. of Vlore "Ismail Qemali", Vlorë, Albania, [5]Jgiellonian Univ. Medical College, Kraków, Poland, [6]Dept. of Geriatric Medicine, Helsinborg Hospital and Institution of Clinical Science, Lunds Univ., Lund, Sweden, [7]Health Care for Older People (HCOP), Queen's Medical Centre, Nottingham Univ. Hospitals NHS Trust, Nottingham, UK, [8]Hellenic Society for the Study and Research of Aging, Greece, Greece

Objective: Aging entails a progressive decline in muscle mass, function and bone density, recognized as osteosarcopenia. Adverse outcomes like falls, fragility fractures, and increased mortality are associated with osteosarcopenia in older adults. Programming-CA-21122 strives to propose tailored education and training in geriatric medicine (GM) for healthcare professionals (HCP). The primary objective is to promote GM in countries where it is still emerging, acknowledging also the significance of musculoskeletal health in older adults.

Methods: Engaging 319 researchers from 43 countries, Programming-CA-21122 will last for 4 y. It utilizes online international surveys and focus groups during national events to systematically assess educational needs of medical doctors, HCP, end-year medical students and health structures managers (Working Group-WG1). A number a geriatric conditions (including frailty, falls and mobility, bone health and osteoporosis, orthogeriatrics, sarcopenia and nutritional assessment) are included in the questioning investigating the perceived level of current knowledge, relevance for the clinical practice of the responder and their interest in being trained on each of these conditions. Based on the collected data, WGs 2,3 and 4 will reach to a consensus on the recommended content and didactic methods of educational activities on basic principles of GM for non-geriatricians, spanning ambulatory, home care, acute/subacute, and long-term care settings. WG5 focuses on dissemination and impact maximization activities and on the expansion of the network.

Results: The expected results of Programming-CA-21122 are to identify a pragmatic set of possibilities for continuous professional education on basic geriatric skills, including musculoskeletal health of older adults. This initiative aspires to further instigate change at each national level, promoting the integration of GM principles into the attitudes and practices of HCP.

Conclusion: Emphasizing musculoskeletal health, it is crucial to build biological and maintain robustness throughout life and into old age. Recognizing nutrition and physical exercise as pivotal environmental factors influencing musculoskeletal health, strategies involving falls prevention methods, nutrition, and physical exercise

are essential. In regions where GM is still emerging, the introduction of an educational curriculum becomes paramount.

P805
X-LINKED FAMILY HYPOPHOSPHATEMIC RICKETS (XLH): EXPERIENCE IN ADULTS IN ARGENTINA

M. C. Balonga[1], A. C. Cantó[1], E. Giacoia[1]

[1]Centro Médico Morón, Buenos Aires, Argentina

Objective: XLH is a genetic disease characterized by rickets and osteomalacia and caused by pathogenic variants in PHEX (which encodes phosphate-regulating neutral endopeptidase PHEX)[1]. The incidence is 3.9 cases per 100,000 live births and the prevalence is 4.8 per 100,000 adults[2] and is included in the classification of "rare" diseases. Numerous genotypic variants and a great variety in phenotypic expression have been described, making it essential to control and monitor patients by doctors specializing in the disease. We aimed to describe the clinical, biochemical characteristics and complications associated with chronic disease in patients diagnosed with XLH referred to a specialized center in Argentina.
Methods: Descriptive, cross-sectional study. The medical records of 10 patients evaluated from January to December 2023 were analyzed. The clinical findings of the physical examination were evaluated and complementary studies were requested in search of the typical manifestations and complications of the disease.
Results: Tables 1 and Graph 1 summarize the findings of each patient analyzed.

Table 1

Patient	Age (y)	Gender	Job	Height (Cm)	Weight (Kg)	Family history	Treatment
1	28	F	Yes	145	69.3	Yes	Conventional*[1]
2	44	F	Yes	138	59.0	Yes	Burosumab[2]
3	24	F	Yes	133	67.2	Yes	Conventional*[1]
4	40	F	No	144	87.0	Yes	Conventional*
5	41	F	No	154	54.0	Yes	Conventional*

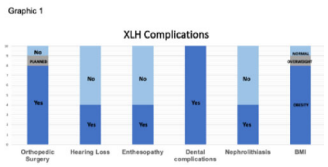
y: Years old F: Female M: Male Cm: Centimeters Kg: Kilograms

*Oral phosphate supplements + calcitriol [1]Antibody to FGF-23 [2]Start of Burosumab expected soon

Graphic 1



Conclusion: We consider that the experience acquired through follow-up consultations of patients with rare diseases such as XLH is the best tool to advance medical knowledge and thus achieve early diagnosis, access to medical treatment and multidisciplinary teamwork for orthopedic corrections with the aim of achieving a comprehensive approach, improving the quality and survival of life of patients with the disease.

P806
BENEFITS AND HARMS OF ANTIRESORPTIVE THERAPY IN MEN WITH NONMETASTATIC PROSTATE CANCER ON ANDROGEN DEPRIVATION THERAPY: A SYSTEMATIC REVIEW AND META-ANALYSIS OF RANDOMIZED CONTROLLED TRIALS

A. B. Abu El Nasr Bassatne[1], N. K. El Meski[1], R. H. Horanieh[1], F. A. Andary[1], C. R. Rhayem[1], D. Mukherji[1], E. Akl[1], G. El Hajj Fuleihan[1], M. C. Chakhtoura[1]

[1]American Univ. of Beirut, Beirut, Lebanon

Objective: Androgen deprivation therapy (ADT) is used as an adjuvant therapy in men with prostate cancer (PCa). It is associated with bone loss and increased fractures risk, due to decreased estrogen and androgen levels. We aimed to evaluate the effects of antiresorptive therapy on bone health in men with non-metastatic PCa on ADT.
Methods: We searched 4 databases until August 3, 2023 for randomized controlled trials (RCTs) conducted in men with non-metastatic PCa on ADT receiving bisphosphonates (BP), denosumab (Dmab) or placebo/control. Our outcomes included fracture risk, changes in BMD and bone turnover markers (BTM), mortality, and adverse events rates. We performed meta-analyses by outcome and comparison using RevMan5.3. We assessed the evidence certainty using the GRADE methodology. PROSPERO registration CRD42021225502.
Results: We included 26 RCTs covering parenteral BP (N = 17), oral BP (N = 5), and denosumab (N = 2). 2 RCTs compared both oral BP and Dmab. Oral BP did not reduce fracture incidence at 12 months (95%CI [0.10, 3.23]; very low certainty). Intravenous (IV) BP did not reduce morphometric vertebral fractures at 36 months (RR = 1.06; 95%CI [0.57,1.98]; very low certainty). Other fractures captured as adverse events in most IV BP trials varied by definition and number. Dmab significantly reduced the incidence of morphometric vertebral fractures at 12, 24 and 36 months (RR = 0.15–0.38), based on one trial. Treatment with antiresorptive drugs for 12 months increased BMD at the hip and the lumbar spine and decreased markers of bone formation and resorption (very low to moderate certainty). IV BP showed a non-significant increase in mortality rate (RR = 1.5, very low certainty). Gastrointestinal side effects were the most common. Acute phase reactions were common with IV BP, while jaw osteonecrosis and hypocalcemia occurred more rarely.
Conclusion: Dmab decreases risk of morphometric vertebral fractures in men with nonmetastatic PCa receiving ADT. However, data on fracture reduction with BPs is scarce. Our analyses reveal a protective role of anti-resorptive treatment on BMD and BTMs, surrogates of fractures. These findings highlight the importance of considering antiresorptives as an imperative treatment in these patients. Future well-designed and powered RCTs are needed to assess the effect of treatment on fracture risk.

P807
SEVERE SARCOPENIA AND OSTEOPOROSIS IN A CASE WITH MEDULLARY TRANSECTION

M. Cevei[1], D. Stoicanescu[2], A. Gasparik[3], A. Gherle[1], M. S. Deac[1]

[1]Univ. of Oradea, Faculty of Medicine, Oradea, Romania, Oradea, [2]Univ. of Medicine and Pharmacy "Victor Babes", Timisoara, Romania, Timisoara, [3]Univ. of Medicine and Pharmacy of Târgu Mureş, Romania

Spinal cord injuries lead to rapid and debilitating levels of bone and muscle loss, resulting in osteoporosis and sarcopenia.
Case report: We describe a 33-year-old female patient, known with T11-T12 medullary transection from 2015, who was hospitalized in the Medical Rehabilitation Clinical Hospital Baile Felix, Romania for medical rehabilitation. Physical examination revealed paraparetic motor deficit, deficit in performing ADLs. We used the modified Ashworth scale to quantify spasticity of lower limb, scoring 0—normal muscle tone, and ASIA Impairment Scale obtaining A score—neurological level T11-T12, sensory level T12. The John Health System Corporation scale established a high risk of falling, with 21 points. The patient's self-care capacity, functional independence and functional ambulatory category were assessed using the FIM, Barthel and FAC (Functional Ambulation Classification) scale, respectively. FIM scale score was 76 out of 126, 60.13%. Barthel Index score: 45 points out of 100, indicating severe dependency. FAC score of 0 indicated that the patient was a non-functional ambulatory. BMD determined by DXA from 06.09.2023 indicated: lumbar spine Z-score: -3.2; left hip Z-score:-2.0; right hip Z-score: -2.03. ALM was

0.39 revealing severe sarcopenia. Dynamometry performed with Jamar dynamometer on 10.06.2023 indicated: right handgrip strength 16 kg and left handgrip strength 14 kg. The medical rehabilitation recommendations included: daily kinetic program, comply with recommendations related to fall prevention.
Conclusion: Motor deficit due to spinal cord injuries leads to osteoporosis and sarcopenia, which impair functional and motor abilities.

P808
ENHANCING BONE DENSITY IN ELDERLY MALES AND FEMALES WITH OSTEOPOROSIS THROUGH DIETARY INTERVENTION

M. Chauhan[1]

[1]S.M.Patel College of Home Science, Sardar Patel Univ., V.V. Nagar, Gujarat, Vallabh Vidyanagar, India

Objective: As our population ages, osteoporosis becomes a major public health issue. Functional foods, known to reduce chronic diseases like osteoporosis, were investigated for bone loss prevention. The study aimed to assess the impact of consuming functional food products on individuals at risk of osteoporosis.
Methods: Sample selection of elderly males and females of the age group 40–70 y from different cities from central Gujarat was done using a combination of purposive sampling and snow-ball technique. Based on inclusion and exclusion criteria, out of the 275 subjects, 73 subjects identified as either osteopenic or osteoporotic based on BMD (T-score) were selected for the feeding study. Ultrasound bone densitometer was used to screen for BMD. The intervention involved supplementing 50 females and 23 males with two functional food products, namely khakhra and laddu. These products, enriched with functional ingredients and high calcium sources such as malted ragi (*Eleusine coracana*), defatted soybean *(Glycine max),* sesame seeds *(Sesamum indicum L.),* Amaranth seeds *(Amaranthus cruentus)* and dehydrated drumstick leaves *(Moringa Oleifera),* provided 441.74 mg calcium and 334.96 mg phosphorus per day for a 3-month period. Blood pressure, lipid profiles, serum calcium levels, urinary calcium, phosphorous, and hydroxyproline excretions were measured, along with BMD, before and after the intervention. SPSS version 23 was used for data analysis.
Results: Following the intervention, BMD improvements were observed, with values decreasing from -1.71 to -0.94 in females, -1.90 to -0.86 in males, and -1.84 to -0.89 in the total subjects ($p < 0.01$). Significant decreases ($p < 0.01$) were noted in total cholesterol and LDL cholesterol levels. Urinary hydroxyproline, calcium excretion, and phosphorus excretion also decreased significantly ($p < 0.01$). Serum calcium levels showed a slight decrease within the normal range (9.02–9.59 mg/dl), while systolic blood pressure exhibited a significant decrease ($p < 0.01$).
Conclusion: The functional components present in the developed products effectively promoted bone mineralization, highlighting the potential of functional foods in preventing osteoporosis.

P809
PREDICTIVE FACTORS OF ATLANTOAXIAL SUBLUXATIONS IN RHEUMATOID ARTHRITIS

M. Dhifallah[1], S. Rahmouni[1], M. Abbes[1], K. Zouaoui[1], S. Boussaid[1], H. Sahli[1], S. Rekik[1], M. Elleuch[1]

[1]Rheumatology Dept., La Rabta, Tunis, Tunisia

Objective: Atlantoaxial subluxation (AAS) is the most common cervical abnormality in rheumatoid arthritis (RA) [1]. Since AAS is often asymptomatic, it is important to determine its predictive factors in order to identify a group of patients at risk that need closer monitoring. We aimed to identify the predictive factor of SAA in RA patients.
Methods: We included patients with RA according to the ACR criteria. Sociodemographic data, clinical presentation, and radiological features were collected. The diagnosis of AAS was based on standard radiographs and/or on MRI. We assessed disease activity by Disease Activity Score 28 (DAS28), functional impairment by The Health Assessment Questionnaire (HAQ) and the structural damage by The modified Sharp/van der Heijde score (SHARPm).
Results: We collected data from 53 patients (7 males and 46 females). The mean age was 56 ± 11.24 y. The mean disease duration was 10.18 ± 8.14 y. 21 patients (39.6%) had joint deformities. 29 patients (54.7%) presented with extra-articular manifestations (EAM): 16 rheumatoid nodules (30%),15 ocular involvement (28%), 10 lung involvement (19%), 2 renal amyloidosis (4%), and one vasculitis (2%). Respective mean C-reactive protein (CRP) and erythrocyte sedimentation rate (ESR) were 19.95 ± 23.7 mg/l and 31.75 ± 23.38 mm/h. Mean $DAS28_{CRP}$, HAQ index and SHARPm score were: 5.37 ± 1.42, 1.63 ± 0.71, and 126 ± 94, respectively. AAS was diagnosed in 25 patients (47.1%): 20 anterior AAS (37.7%), 6 vertical AAS (11.3%), 3 lateral AAS (5.7%), 4 posterior AAS (7.5%) and 4 rotatory AAS (7.5%). Patients with AAS had longer disease duration (13.88 ± 9.3 vs. 6.89 ± 5.19 y, $p = 0.001$), higher HAQ index (1.9 ± 0.6 vs. 1.4 ± 0.72, $p = 0.009$), higher ESR (41.6 ± 26.2 vs. 23 ± 16.5 mm/h, $p = 0.003$), and higher SHARPm score (181 ± 98.2 vs. 77.3 ± 56.8, $p = 0.00$). AAS was associated with EAM (OR = 5.7, $p = 0.003$) and articular deformity (OR = 3.8, $p = 0.02$). No association was found between AAS and age ($p = 0.22$), sex ($p = 0.56$), CRP ($p = 0.083$) and $DAS28_{crp}$ ($p = 0.09$).
Conclusion: Our study showed that long disease duration, EAM, severe functional impairment, high ESR, and advanced structural damage are predictive of cervical involvement and SAA. Thus, SAA should be screened using radiographs and MRI in RA patients with such characteristics, even when asymptomatic.

P810
OSTEOARTICULAR INVOLVEMENT IN MULTIPLE MYELOMA: PREVALENCE AND RISK FACTORS

M. Dhifallah[1], A. Feki[1], S. Ben Jemaa[1], M. Ezzeddine[1], M. H. Kallel[1], H. Fourati[1], R. Akrout[1], S. Baklouti[1]

[1]Rheumatology Dept., CHU Hedi Chaker, Sfax, Tunisia

Objective: Osteoarticular (OA) involvement represents the most common extra-hematologic manifestation of multiple myeloma

(MM). This study aims to describe the OA manifestations during MM and identify its risk factors.

Methods: We conducted a retrospective study including 126 multiple myeloma cases treated in our department over a 30-y period (1993–2023). Sociodemographic, clinical, and biological data were gathered. OA involvement was assessed through radiographic and/or MRI data.

Results: The study included 126 patients with a mean age of 65.23 ± 11.63 y [36–92], comprising 65 males and 61 females. Bone pain was present in 92.1% (n = 116) with an average duration of 4 months. Mean erythrocyte sedimentation rate and C-reactive protein levels were 99.08 mm [3–190] and 27.74 mg/l [0–196], respectively. Hemoglobin was below 10 g/dl in 51.2% of cases, averaging 9.902 ± 2.22 g/dl [5–13.9]. Calcium levels exceeded 2.75 mmol/l in 20% of cases, averaging 2.49 ± 0.33 mmol/l. Mean creatinine level was 88.28 µmol/l [36–587]. Plasmocyte rates, observed in sternal puncture or bone marrow biopsy, averaged 43.93% [5–80], with 31.7% exceeding 60%. Radiological osteolysis was found in 76.2% (n = 96) of patients, with multiple lesions in 91 cases. Commonly affected bones were the skull (37.12%), pelvis (16.8%), and spine (12%). Diffuse osteosclerosis was identified in only two patients. Pathological fractures were present in 59.5% (n = 75), including 15 peripheral fractures and 70 vertebral fractures, with 43.2% affecting the lumbar region (n = 54) and 36.8% the dorsal region (n = 46). Durie and Salmon prognostic classification distributed patients as follows: stage IA (3.2%), stage IIA (4%), stage IIB (0.8%), stage IIIA (72.2%), and stage IIIB (18.3%). Plasmocyte rates in bone marrow were significantly higher in patients with multiple osteolytic lesions (36.4 vs. 52.32%, p = 0.016). Male gender was associated with higher onset of bone pain (OR = 9.643, 95%CI [1.183–78.57], p = 0.017). Stage III of the Durie and Salmon classification was associated with radiological osteolysis (χ^2 = 5.703, p = 0.05).

Conclusion: Articular involvement in multiple myeloma is polymorphic, ranging from bone pain to multiple pathological fractures. Evaluation of prognostic markers, such as plasmocyte rates and the Durie and Salmon prognostic classification, helps identify patients at risk of developing osteoarticular complications.

P811
PHYSICAL ACTIVITY AMONG MEDICAL STUDENTS: ACTIVE BODIES, HEALTHIER MINDS

M. Dhifallah[1], H. Bettaieb[1], M. Boudokhane[1], M. H. Douggui[1], S. Bellakhal[1]

[1]Dept. of internal medicine, Internal Security Forces Hospital, La Marsa, Tunis, Tunisia

Objective: Physical inactivity and sedentary behavior represent a significant health concerns, especially among young adults [1]. The aim of the study is to assess physical activity (PA) among medical students.

Methods: We conducted a cross-sectional descriptive study among preclinical and clinical students. Participants were invited to answer an anonymous web-based questionnaire. Demographic features, BMI (kg/m^2) and physical activity (PA) were assessed. Regular PA was defined as the practice of exercise routines or sports. The data were analyzed with descriptive statistics using the SPSS statistical package.

Results: A total of 278 participants (172 preclinical and 106 clinical students) responded to the questionnaire with a mean age of 23.7 ± 2.6 [18–32] y. The sex ratio (F/M) was 3.34. Mean BMI was 23 ± 3.8 [16.1–41.4] kg/m^2. Overweight and obesity were noted in 5.2% (n = 13) and 19.6% (n = 49) of cases, respectively. Mean sitting hours was 7.9 ± 2.8 [0.3–16]. Overall 47.1% (n = 131) of students had regular PA. Individual sports were reported by 16.5% of participants: Gymnastics (n = 9), combat sport (n = 7), running (n = 5), Tennis (n = 5), professional dancing (n = 5), swimming (n = 5), aerobics (n = 5), cycling (n = 4) and kayaking (n = 1). Team sports were found in 5.7% of students: basketball (n = 4), football (n = 4), volleyball (n = 4) and handball (n = 4). Physical exercise routines were respectively: weightlifting (n = 55), walking (n = 9), Pilates (n = 3) and yoga (n = 2). Predictive factors of PA were clinical studies (OR = 3.685 95Cl [2.083–6.52], p < 10–3) and male gender (OR = 2.55 95IC [1.39–4.65], p = 0.002). Moreover, students having a regular physical activity were older (25 vs. 23.4 h, p < 10–3) and had shorter sitting hours (6.8 vs. 8.3 h, p < 10–3). In contrast, no association was noted between PA and BMI (p = 0.625).

Conclusion: Less than half of the medical students are having a regular physical activity. Considering that these individuals serve as role models for their future patients, it underscores the importance of promoting awareness about physical activity in improving overall health.

P812
VITAMIN D AND DISEASE ACTIVITY IN MALE PATIENTS WITH SPONDYLOARTHRITIS: IS THERE A LINK?

S. Rahmouni[1], M. Dhifallah[1], M. Mrad[2], K. Zouaoui[1], M. Abbes[1], S. Boussaid[1], A. Bahlous[2], S. Rekik[1], H. Sahli[1]

[1]Rheumatology Dept., La Rabta, [2]Laboratory of Biochemistry and Hormonology, Institut Pasteur de Tunis, Tunis, Tunisia

Objective: To describe the vitamin (VitD) status in male patients with spondylarthritis (SA) and to determine its correlation with disease activity.

Methods: We conducted a cross-sectional study collating 56 male patients with spondylarthritis meeting the Assessment of SpondyloArthritis international Society (ASAS) criteria. We collected sociodemographic data and disease characteristics. We measured serum VitD (25(OH)D) by microparticle immunoassay with electrochemiluminescence detection (ECLIA). We referred to the Institute of Medicine (IOM) recommendations to define VitD status thresholds as follows: deficiency (< 20 ng/ml), insufficiency (20–29 ng/ml), and adequacy (30–44 ng/ml) [1].

Results: Our study included 56 male patients with a mean age of 44.96 ± 13.35 y [19–76]. The mean disease evolution was 13.45 ± 9.87 y [0–40]. The mean weight was 80.5 ± 24.73 kg. Respective mean BASDAI, ASDAS and BASFI scores were 4.21 ± 2.24, 3.13 ± 1.19 and 4.46 ± 2.39. The mean C-reactive protein (CRP) was 18.72 ± 23.62 mg/dl [1–121]. Mean VitD serum levels was 18.82 ± 1.03 ng/ml [3.31–32.6]. Only 3 patients (14.3%) had adequate VitD levels. However, deficiency and insufficiency were observed in 32 patients (57.1%) and 21 patients (11.7%), respectively. VitD levels were negatively correlated with ASDAS (r = -0.518, p = 0.014) and CRP (r = -0.348, p = 0.032). Moreover, they were positively correlated with weight (r = 0.933, p = 0.02) and disease duration (r = 0.425, p = 0.001). However, no correlation was found between VitD and age (p = 0.604), BASDAI (p = 0.926) or BASFI (p = 0.475).

Conclusion: VitD deficiency was associated with high disease activity in patient with SA, emphasizing the importance of VitD in regulating the inflammatory response. Thus, daily VitD requirements should be adequately met and its deficiency must be routinely screened when following up patients with SA to ensure disease control.

P813
CLINICAL INERTIA IN POSTMENOPAUSAL OSTEOPOROSIS: IS IT THE DOCTOR, THE PATIENT OR THE HEALTHCARE SYSTEM?

K. Zouaoui[1], M. Dhifallah[1], S. Rahmouni[1], M. A. Selmene[2], M. Abbes[1], S. Boussaid[1], S. Rekik[1], H. Sahli[1], M. Elleuch[1]

[1]Rheumatology Dept., La Rabta, [2]Orthopaedic Dept., Trauma Center Ben Arous, Tunis, Tunisia

Objective: To assess clinical inertia (CI) during postmenopausal osteoporosis (PMO) among the Tunisian rheumatologists and to identify its possible causes.
Methods: A survey, self-administered via internet and elaborated via Google Forms was carried out among rheumatologists in January 2024 assessing their practice in the management of PMO.
Results: 51 rheumatologists answered our survey (46 females and 5 males) with a mean age of 32.8 ± 8.13 y [26–60]. Physicians have been practicing on average for 6.1 ± 6.22 y [1–28]. Regarding CI, 94.1% of participants defined it as the lack of adjustment or intensification of treatment, when a patient's treatment goals are not met considering recommendations and the availability of medications. 40 participants (78.4%) thought it might constitute a hindrance to the proper care of patients. It concerned the chronic diseases for 39.2% of participants. While 4 participants (7.8%) declared that scientific papers addressing the matter practically nonexistent. Nearly 73% of rheumatologists reported receiving more than five patients with PMO weekly. 39 (76.5%) doctors admitted feeling reluctant when prescribing bisphosphonates. This situation was rare in 16 cases (31.4%), occasional in 22 cases (43.1%), and frequent in 1 case (2%). Main physician-related barriers reported by participants were medication cost (86.3%), presence of comorbidities (76.5%), dentists' recommendations (27.5%), fear of side effects (21.6%), inapplicability of recommendations in clinical practice (17.6%), fear of medication interaction (17.6%), and short life expectancy (17.6%). According to the participants, patients declined the medication for the following reasons: medication cost (84.3%), low sociocultural level (68.6%), the absence of symptoms (43.1%), fear of side effects (31.4%), lack of communication patient-doctor (23.5%), illness denial (23.5%), and psychiatric illness/addiction (15.7%). Practitioners identified the following healthcare systems barriers: absence of health insurance (92.2%), the lack of referral of patients by colleagues from other specialties (62.7%), the large number of patients (47.1%), the lack of screening for PMO (41.2%), lack of time (41.2%), and absence of regular monitoring (37.3%). To mitigate the problem of CI, 90.2% participants suggested providing ongoing education and training, 78.4% insisted on team-based care approach, 66.7% highlighted the importance of targeting patients and doctors' beliefs, 56.9% emphasized the treat-to-target approach, and 11.8% spotlighted believing in doctor's intuition when addressing CI.
Conclusion: Effective measures and strategies should be implemented to combat clinical inertia in managing PMO. Therefore, all different participating parties should be targeted to ensure the best outcomes.

P814
OPTIMAL ASSESSMENT OF COGNITIVE FUNCTION TO PREDICT RECOVERY IN ACTIVITY OF DAILY LIVING AFTER HIP FRACTURES: A SHORT-TERM PROSPECTIVE SURVEY

M. Di Monaco[1], M. Sgarbanti[1], S. Trombetta[2], L. Gullone[2], A. Bonardo[2], P. Gindri[2], C. Castiglioni[1], F. Bardesono[1], E. Milano[1], G. Massazza[3]

[1]Osteoporosis Research Center, Division of Physical and Rehabilitation Medicine, Fondazione Opera San Camillo, [2]Neuropsychology Service, Fondazione Opera San Camillo, [3]Division of Physical and Rehabilitation Medicine, Dept. of Surgical Sciences, Univ. of Turin, Turin, Italy

Objective: We studied patients with subacute hip fracture defined cognitively intact or mildly impaired on the screening evaluation performed by the Short Portable Mental Status Questionnaire (SPMSQ). We hypothesized that each of 3 further cognitive tests could independently predict activities of daily living, with optimal prediction of function obtained by performing all 3 the tests.
Methods: We focused on inpatients with subacute hip fracture consecutively admitted to our rehabilitation ward. Three cognitive tests were performed on admission to rehabilitation in the patients who made ≤ 4 errors on the SPMSQ: Montreal Cognitive Assessment (MoCA), Rey Auditory Verbal Learning Test (RAVLT, immediate and delayed recall) and Frontal Assessment Battery (FAB). We assessed activities of daily living by the Barthel index. Successful rehabilitation at the end of the rehabilitation course was defined with a Barthel index score ≥ 85.
Results: Each of the 3 cognitive tests assessed before rehabilitation significantly predicted the Barthel index scores measured at the end of the rehabilitation course in our sample of 280 inpatients. However, only the MoCA score retained its significant predictive role when the scores from the 3 tests were included together as independent variables in a multiple regression model, with adjustments for a panel of potential confounders (P = 0.007). The adjusted odds ratio to achieve successful rehabilitation for a 7-point change in MoCA score was 1.98 (CI 95% from 1.02 to 3.83; P = 0.042).
Conclusion: Contrary to our hypothesis, MoCA but not RAVLT and FAB retained the prognostic role when the scores from the 3 tests were evaluated together as potential predictors of functional ability in activities of daily living. In the presence of a normal (or mildly altered) score on the SPMSQ in subacute hip fracture, MoCA scores improve prediction of activities of daily living and should be routinely performed.

P815
FEMORAL BONE MINERAL DENSITY AT THE TIME OF HIP FRACTURE IS HIGHER IN WOMEN WITH VERSUS WITHOUT OBESITY: A CROSS-SECTIONAL STUDY

M. Di Monaco[1], C. Castiglioni[1], F. Bardesono[1], M. Freiburger[1], E. Milano[1], G. Massazza[2]

[1]Osteoporosis Research Center, Division of Physical and Rehabilitation Medicine, Fondazione Opera San Camillo, [2]Division of Physical and Rehabilitation Medicine, Dept. of Surgical Sciences, Univ. of Turin, Turin, Italy

Objective: To compare femoral BMD in hip-fracture women with vs. without obesity. We hypothesized that BMD levels could be higher in the women with obesity than in the controls and we aimed to quantify the BMD discrepancy associated with the presence of obesity.

Methods: At a median of 19 d after an original hip fracture due to fragility we measured BMD by DXA at the nonfractured femur. Obesity was defined with a BMI $\geq$ 30 kg/m^2.
Results: We studied 674 women with a subacute hip fracture. BMD was significantly higher in the 55 women with obesity than in the 619 without obesity: mean T-scores (SD) were -1.88 (0.98) and -2.67 (0.92), respectively, with a mean between-group difference of 0.79 (95%CI from 0.53 to 1.05, P $<$ 0.001). Multiple adjustments did not erase the significant association between obesity and high BMD (P $<$ 0.001). A femoral BMD T-score below the threshold of -2.5 was found in 375 of the 674 women (i.e., 56%; 95%CI from 52 to 59%). Osteoporosis prevalence was significantly higher in the absence than in the presence of obesity, with χ^2 (1, n = 674) = 15.9, P $<$ 0.001. After multiple adjustments we confirmed the significant association between the absence of obesity and the presence of osteoporosis. Compared to a woman with obesity, a woman without obesity had an adjusted odds ratio of 2.7 (95%CI: 1.4–5.2, P = 0.002) for suffering from osteoporosis.
Conclusion: Hip fractures occurred at a femoral BMD higher in the women with obesity than in the controls. Because of high BMD levels that seem not to protect against hip fractures, the fracture risk may be underestimated in the presence of obesity. To avoid miscalculations of the hip-fracture risk we suggest an adjustment based on the 0.79 BMD T-score difference between women with and without obesity, although further data from robust longitudinal studies is needed to validate the BMD-based adjustment of fracture risk assessment.

P816
DIAGNOSTIC ACCURACY OF FRAX® IN PREDIALYSIS CHRONIC KIDNEY DISEASE PATIENTS

M. Diz Lopes[1], B. Fernandes[2], C. Marques Gomes[1], T. Martins Rocha[1], R. Neto[2], J. Frazão[2], L. Costa[1]

[1]Rheumatology Dept., [2]Nephrology Dept., Centro Hospitalar Universitário de São João, Porto, Portugal

Objective: FRAX predicts 10-y fracture risk. Although it is used in chronic kidney disease (CKD) patients, it can underestimate fracture risk and some adjustments may be needed. We aimed to evaluate the fracture risk and the incidence of fractures in patients with predialysis CKD and estimate the accuracy of FRAX in this population.
Methods: Retrospective study that enrolled 54 patients (40–89 years old) followed in a predialysis clinic between 2014–2023. Relevant data and information regarding clinical evident fractures was recorded from medical registries. Radiographies of the thoracic and/or lumbar spine were evaluated to detect asymptomatic vertebral fractures. FRAX without BMD was calculated with the web-based tool (Portuguese version).
Results: Median follow-up time was 7,5 $\pm$ 3 y. Mean age at the beginning of follow-up was 65,4 $\pm$ 9,8 years old and most patients were male (79,6%). Median glomerular filtration rate was 28,5 ml/min/1.73m^2 (22–33), 20 patients progressed to dialysis and 5 died. Median FRAX was 3,2% (1,9–5,1) for major fracture and 0,9% (0,4–1,9) for hip fracture risk. When including CKD as secondary osteoporosis, median FRAX was 4,6% (2,7–7,6) for major fracture and 1,5% (0,6–3,4) for hip fracture risk. A total of 14 (25,9%) patients achieved the intervention threshold (FRAX major fracture $\geq$ 11% and/or hip fracture risk $\geq$ 3%) when including CKD as secondary osteoporosis, but only 3 patients were in the high-risk group with FRAX without adjustments. Two patients sustained clinical evident fractures. Radiographies of 51 patients were reviewed and asymptomatic vertebral fractures were identified in 3 (5,9%). High fracture risk calculated by FRAX was more prevalent in the group who sustained fractures, but this difference was only statistically significant when considering CKD as secondary osteoporosis (80 vs. 22,7%, p = 0,019). Area under the curve for FRAX without adjustments was 0,886 (CI 95% 0,781–0,992) and 0,882 (CI 95% 0,777–0,987) with CKD as secondary osteoporosis (Table 1).

Table 1 – Comparison of the accuracy of FRAX® (without BMD) with or without CKD as secondary osteoporosis in predicting fracture risk.

	FRAX® (without BMD) including CKD as secondary osteoporosis	FRAX® (without BMD)
Sensitivity	80% (95% CI 0,372-0,987)	20% (95% CI 0,013-0,628)
Specificity	77,3% (95% CI 0,639-0,879)	95 % (95% CI 0,866-0,992)
Positive Predictive Value	28,6% (95% CI 0,099-0,545)	33,3% (95% CI 0,023-0,839)
Negative Predictive Value	97,1% (95% CI 0,880-0,998)	91,3% (95% CI 0,809-0,972)
AUC for major fracture risk	0,882 (95% CI 0,777-0,987)	0,886 (95% CI 0,781-0,992)
AUC for hip fracture risk	0,820 (95% CI 0,685-0,956)	0,814 (95% CI 0,671-0,956)

Footnote: FRAX- Fracture Risk Assessment; BMD- bone mineral density; CKD – chronic kidney disease; AUC- area under the curve; 95% CI- 95% confidence interval.

Conclusion: FRAX (without BMD) showed an overall good diagnostic accuracy for predicting fractures in predialysis CKD. However, considering CKD a cause of secondary osteoporosis improved the sensitivity of FRAX in this population.

P817
BONE VOLUME VERSUS BONE MINERAL DENSITY: IMPACT ON FRACTURES IN PREDIALYSIS CHRONIC KIDNEY DISEASE

M. Diz Lopes[1], B. Fernandes[2], C. Marques Gomes[1], T. Martins Rocha[1], R. Neto[2], J. Frazão[2], L. Costa[1]

[1]Rheumatology Dept., [2]Nephrology Dept., Centro Hospitalar Universitário de São João, Porto, Portugal

Objective: Chronic kidney disease (CKD) patients develop mineral bone disorder and are at increased fracture risk. Whether the subtype of renal osteodystrophy (ROD) contributes to fracture risk is not established. We aimed to evaluate the relationship of ROD subtypes and bone volume (BV) with the occurrence of fractures in predialysis CKD patients.
Methods: Retrospective study with 54 patients followed in a predialysis clinic between 2014–2023. Bone biopsies and histomorphometric analysis were performed at the beginning of follow-up. Data from DXA scan and regarding clinical evident fractures was recorded from medical registries. Radiographies of the thoracic and/or lumbar spine were evaluated to detect asymptomatic vertebral fractures.
Results: Median follow-up time was 7,5 $\pm$ 3 y. Mean age at time of bone biopsy was 65,4 $\pm$ 9,8 years old and most patients were male (79,6%). The majority had CKD stage 4 (53,7%), 20 patients progressed to dialysis and 5 died. DXA scan was performed in 19 patients and 5 had osteoporosis. In the histomorphometric analysis, 40,7% patients had normal bone histology, 37% low bone turnover (BT) with normal mineralization and 22,3% high BT with normal mineralization. Two patients sustained clinical evident fractures and asymptomatic vertebral fractures were identified in radiographies in 3 patients. Patients who fractured had higher phosphorus levels (4,1 vs. 3,5 mg/dL, p = 0,047, Table 1). BMD, histomorphometric subtypes and circulating bone biomarkers did not correlate with the incidence of fractures. Low BV was more frequent in the fractures group (40 vs. 25,5%) but this was not significant (p = 0,579). However, BV fraction (BV/TV) was lower in the group with fractures (16,1 (11,9–17,2) vs. 19,0 (16,2–23,6)), with borderline significance (p = 0,052). Femoral neck BMD didn't correlate with BV/TV (r = 0,039, p = 0,874).

Table 1 – Characteristics of the groups with and without fractures during follow-up.
Data are reported as mean (SD) for normally distributed variables, median (IQR) for non-normally distributed variables, or percentage for categorical variables. P-values were calculated using Mann-Whitney U test for continuous variables and Chi-square with Fisher exact test for categorical variables.

	Fractures during follow-up n=5 (9,3%)	No fractures during follow-up n=49 (90,7%)	p-value
Biochemistry			
Creatinine	2,2 (1,1)	2,2 (0,5)	0,415
GFR, mL/min/1.73m2	26,5 (15,0)	30,5 (12,0)	0,157
Calcium, mg/dL	4,7 (0,0)	4,8 (0,4)	0,685
Phosphorus, mg/dL	**4,1 (0,8)**	**3,5 (0,95)**	**0,047**

Osteoporosis	0 (0,0)	5 (9,3)	0.665
Bone Histomorphometric Classification			0,833
Normal Bone Histology	3 (60,0)	19 (38,8)	
Low-turnover bone disease	1 (20,0)	19 (38,8)	
High-turnover bone disease	1 (20,0)	11 (22,4)	
Bone volume			0,579
Low (<16%)	2 (40,0)	12 (24,5)	
Normal (16-23%)	3 (60,0)	24 (49,0)	
High (>23%)	0 (0,0)	13 (26,5)	
BV/TV	**16,1 (11,9-17,2)**	**19,0 (16,2-23,6)**	**0,052**

Footnote: GFR – glomerular filtration rate; PTH- Parathyroid hormone; FGF-23- Fibroblast growth factor-23; DKK1- Dickkopf-1; sRANKL- Soluble receptor activator of nuclear factor-kappaB ligand; DXA - Dual x-ray absorptiometry; BMD- bone mineral density; BV/TV: bone volume fraction; IQR- interquartile range; PTH- Parathyroid hormone; FGF-23- Fibroblast growth factor-23; DKK1- Dickkopf-1; sRANKL- Soluble receptor activator of nuclear factor-kappaB ligand; BMD- bone mineral density; FRAX - Fracture Risk Assessment; CKD – chronic kidney disease.

Conclusion: Different ROD subtypes had no association with the incidence of fractures. When considering BV isolated (but not BMD assessed by DXA), a marginally significant association was found between low BV fraction and fractures. High phosphorus levels associated with fractures and have been previously described as a possible risk factor for fractures in CKD patients but also in general population.

P818
CONTRIBUTION OF TBS IN THE PREDICTION OF FRACTURES IN A MALE POPULATION

M. Djennane[1], M. A. Ifticene, L. Igueni[1]

[1]Medicine Dept., Tizi Ouzou, Algeria

Objective: BMD is the reference technique for assessing bone status in men, as in women. TBS is an indirect measure of bone microarchitecture independent of BMD. There are few studies on the contribution of TBS in the male population. The main objective of this work is to describe the link between BMD measurements and TBS in men. The secondary objectives are the study of TBS in patients with vertebral and/or peripheral fractures and to know if the BMD/TBS association made it possible to better predict bone fragility.
Methods: A retrospective study with descriptive and single-center analysis including men with at least one risk factor for osteoporosis. Clinical, radiographic and densitometric data were recorded with measurement of TBS.
Results: 69 patients were identified, the average age was 57 y [19—91 years], the average BMI was 23 kg/m^2. Of the 55 patients interviewed, 23% were smokers. An etiology was found in 54% of cases, these were endocrinopathy (n = 14), corticosteroid therapy (n = 15), anticonvulsants (n = 2), inflammatory rheumatism (n = 9) and 1 case of disease. chronic inflammatory bowel disease. TBS was altered in 57 patients and normal in 13 patients. TBS was weakly correlated with BMD at the spine with a correlation coefficient of 0.352 (p = 0.003), and weakly correlated with BMD at the femoral neck with a correlation coefficient of 0.356 (p = 0.003). TBS was not significantly lower in patients with at least one vertebral fracture (1,189) than in nonfractured patients (1,235), p = 0.3. 46% of patients who had a vertebral fracture had a T-score $\leq$ -2.5 and 100% had an impaired TBS. The mean TBS in patients with and without peripheral fracture was 1,199 and 1,251, respectively (P = 0.08). All those with a peripheral fracture had densitometric osteoporosis and impaired TBS.
Conclusion: Our study, despite the small number, confirms the data in the literature, on the fact that the systematic measurement of TBS is not recommended in the prediction of fracture risk. Indeed in our study we found a weak correlation between TBS and BMD and no significant difference in TBS between the groups with and without fractures (vertebral and/or peripheral).

P819
EFFECTS OF GROWTH HORMONE REPLACEMENT ON BONE MINERAL DENSITY AND BODY COMPOSITION IN PATIENTS WITH CHILDHOOD ONSET GROWTH HORMONE DEFICIENCY (COGHD) DURING TRANSITION PERIOD FROM PEDIATRIC TO ADULTHOOD ENDOCRINE CARE

[1]Neuroendocrine Department, Clinic for Endocrinology, Diabetes and Metabolic Diseases, University Clinical Center of Serbia, [2]Mother and Child Health Care Institute of Serbia "Dr Vukan Cupic", [3]University Children's Clinic Tirsova, [4]Clinic for Neurosurgery, University Clinical Center of Serbia; [5]Institute of Medical Statistics and Informatics, Belgrade, Serbia; [6]Institute for Pathology, Faculty of Medicine, University of Belgrade, Serbia, [7]Medical Faculty, University of Belgrade, Serbia

Objective: To analyze BMD and body composition (BC) in childhood-onset growth hormone deficiency (COGHD) patients on growth hormone replacement (GHr) during the transition period (TP).
Methods: In a monocentric, observational, retrospective cross-sectional study conducted from 2005–2023, 243 COGHD patients were analyzed (17–25 years old, 184 males). Median age at transfer from pediatrics to adult endocrine clinic was 18.2 $\pm$ 3.2 y. Two separate analyses were performed:(a) cross-sectional analysis of BMD and BC at first evaluation after transfer; (b) longitudinal analysis of BMD and BC changes after 3 y of GHr in TP. Body composition (% fat, fat mass—FM and lean body mass—LBM) and BMD in lumbar spine (LS) and femoral neck (FN)—(BMD g/cm^2, Z-score) were analyzed by DXA method.
Results: Patients with pituitary structural abnormalities were classified as congenital (CONG) COGHD accounting 44.5% of included patients. Subjects with a history of cranial tumor and hematological malignancies were marked as a tumoral cause (TUMC) accounting

22.7% and patients of unknown cause of COGHD were assigned to a group of idiopathic (IDOP) which included 32.8% of enrolled individuals. TUMC patients had significantly lower Z-sc LS ($P < 0.05$) and Z-sc FN ($P < 0.05$) compared to CONG and IDOP after the transfer to adult department. IDOP subjects had significantly higher LBM (47.3 ± 10.8 kg) compared to the CONG (41.4 ± 8.4 kg) and TUMC (45.8 ± 7.9 kg) groups ($P < 0.05$) and lower fat% (19.5 ± 5.9%) and FM (14.1 ± 6.4 kg) compared to TUMC (31.4 ± 6.8%; 19.3 ± 7.4 kg) and CONG (27.8 ± 8.2%; 20.4 ± 9.2 kg) groups ($P < 0.05$). We evaluated BMD and BC in 48 (32.7%) patients with persistent GHD continuing GHr in TP after 3 y. Changes in bone mass indicated significant increment of BMD LS by 7.2%. Significant improvement in BC was observed, manifesting as Fat% decrease by 5.8% and LBM increase by 10.8%.

Conclusion: Patients with COGHD caused by a cranial tumor and hematological malignancies are at greatest risk for lower BMD and unfavorable body composition. Continuation of growth hormone treatment in transition period is important for improving BMD and BC in all patients with persistent GHD.

P820
OBSERVATIONAL STUDY ON THE RELATIONSHIP BETWEEN VITAMIN D LEVELS AND VERTEBRAL FRACTURES

M. Dong[1], D. Zhang[1], Y. Ma[1], D. Wang[1], D. Xin[1]

[1]Second Affiliated Hospital of Inner Mongolia Medical Univ., Hohhot, China

Objective: The primary objective of this observational study is to evaluate the association between circulating vitamin D levels and the incidence of vertebral fractures. This study builds upon previous research that has suggested a potential protective role for vitamin D against various types of fractures.

Methods: We use an existing hospitalized dataset. The study focuses on adults aged 50 and above at a higher risk for vitamin D deficiency and vertebral fractures. Explicitly focusing on participants with measured plasma levels of 25-hydroxyvitamin D. The study design allows for analyzing the relationship between vitamin D concentration and the incidence of vertebral fractures over time. The primary outcome is the incidence of clinically diagnosed vertebral fractures. The study will also consider secondary outcomes such as BMD measurements and the occurrence of other types of fractures. The study employed Cox proportional hazards models to estimate the risk of vertebral fractures across different vitamin D levels, adjusting for potential confounders such as age, sex, BMI, lifestyle factors, calcium and vitamin D supplementation, and comorbid conditions.

Results: Higher vitamin D levels will be associated with a lower risk of vertebral fractures, and there is a threshold effect or a dose–response relationship.

Conclusion: This study's findings provide further evidence of the role of vitamin D in bone health, specifically in preventing vertebral fractures. These findings could have significant implications for public health recommendations and clinical practices regarding vitamin D supplementation, especially in populations at risk of vitamin D deficiency and osteoporosis.

P821
ROLE OF ASTRAGALUS MEMBRANACEUS IN OSTEOPOROSIS: AN ANALYSIS OF ITS POTENTIAL IN MANAGING POSTMENOPAUSAL BONE LOSS

M. E. I. Dong[1], D. D. Zhang[1]

[1]Second Affiliated Hospital of Inner Mongolia Medical Univ., Hohhot, China

With the rapid growth of the aging population, osteoporosis, an age-related skeletal disease, is becoming increasingly prevalent. In China, where over 210 million people are aged 60 and above, representing about 15.5% of the total population, osteoporosis is a significant public health concern. This abstract summarizes the potential of Astragalus membranaceus, a perennial herb in traditional Chinese medicine, in managing postmenopausal osteoporosis.

Astragalus membranaceus, found in Northeast, North, and Northwest China, and it 's variant Astragalus membranaceus var. mongholicus in Inner Mongolia, Hebei, and Shanxi, have been used in traditional Mongolian medicine primarily for qi tonification, diuresis, detoxification, and wound healing. Recent studies have highlighted its potential in myocardial protection, blood pressure regulation, immune enhancement, and overall health improvement. Its application extends to alleviating joint pain, weakness, and fatigue.

The phytoestrogen activity of Astragalus membranaceus extracts, similar to estrogen, is particularly noteworthy in postmenopausal osteoporosis. Phytoestrogens are non-steroidal compounds in many plants, fruits, and vegetables, showing both estrogenic and anti-estrogenic effects. They are categorized into isoflavones, coumestans, or lignans. Postmenopausal hormone therapy, which addresses the significant decrease in estrogen during menopause, is a known preventive measure against osteoporosis.

The pharmacological properties of Astragalus membranaceus are attributed to its diverse components, including polysaccharides, saponins, flavonoids, amino acids, and trace elements. Its polysaccharides, like Astragalus polysaccharides (APS), are known to improve BMD, structure, and formation in postmenopausal osteoporosis animal models. They may promote osteoblast proliferation and differentiation, enhancing new bone tissue formation. Additionally, APS could regulate the balance between bone resorption and formation, reducing the risk of osteoporosis. Its anti-oxidative and anti-inflammatory mechanisms could mitigate oxidative stress and inflammation damage to bone cells. Astragaloside II and IV, specific saponins in Astragalus membranaceus, stimulate osteoblast activity and bone formation, potentially offering benefits to postmenopausal women. Astragalin, a flavonoid in Astragalus membranaceus, exhibits anti-inflammatory and antioxidant potentials, suggesting its role in bone protection.

Astragalus membranaceus, with its polysaccharides, saponins, and flavonoids, demonstrates a promising potential in managing postmenopausal osteoporosis. Further research is warranted to explore how these components influence osteoclast generation and regulate the dynamic balance of the bone matrix, potentially inhibiting the expression of cathepsin K, c-Fos, NFATc1, and NFATc2, crucial in bone resorption processes.

Hospital Galway, Galway, Ireland, [4]Insight SFI Research Centre for Data Analytics, Data Science Institute, Galway, Ireland, [5]School of Management, Guangxi Minzu Univ., Nanning, China, Nanning, China, [6]Nuffield Dept. of Medicine, Univ. of Oxford, Oxford, UK, Oxford, UK, [7]Dept. of Rheumatology, Our Lady's Hospital, Manorhamilton, Ireland, [8]School of Computer Science, National Univ. of Ireland, Galway, Ireland, [9]School of Engineering, National Univ. of Ireland, Galway, Ireland

Objective: Rheumatoid arthritis (RA) patients are at greater risk of hospitalisation and death. The DXA HIP Project is studying DXA performance and musculoskeletal diseases in Ireland. We used the DXA HIP Cohort to evaluate the mortality of RA patients requiring hospitalisation in the west of Ireland, and compared them to a 'healthy' control population and an 'other' with osteoporosis, risk factors or fractures.
Methods: Data from 4 DXA machines were merged with administrative hospital data, cleaned and anonymised following I.R.B. approval, as previously described. Patients were included if they had a proximal femur DXA scan and at least 1 follow-up overnight hospital admission. We excluded those who were not white (1%) and < 20 y of age. This cohort was further sub-divided into those groups described above. Mortality risk was compared using a Kaplan – Meier analysis. A p value of < 0.05 was considered statistically significant for all analyses.
Results: 20,466 subjects met our inclusion criteria including 1,358 (6.6%) with RA, 6686 (32.7%) 'healthy' and 12,422 (60.7%) 'others'. RA patients were significantly younger and lighter than 'healthy' subjects, but had similar BMD. RA patients were also significantly younger and a lower prevalence of fracture, glucocorticoid and tobacco use than 'other' subjects but higher BMD. However, RA subjects had a significantly greater mortality than both 'healthy' and 'other' subjects, shown if the plot below, HR: 1.31, $P < 0.01$.
Conclusion: RA patients requiring hospitalisation are at significantly greater risk of death than either healthy controls or those with osteoporosis or other risk factors. Further studies are needed to evaluate better ways of managing these patients.

P823
EFFECTS OF STATINS ON BONE HEALTH

M. Payab[1], M. Ebrahimpur[2], F. Sharifi[2], Z. Shadman[2], P. Ebrahimi[3], S. Mohammadi[4], M. Gooshvar[5], M. Sarvari[6]

[1]Non-Communicable Diseases Research Center, Endocrinology and Metabolism Population Sciences Institute, Tehran Univ. of Medical Sciences, [2]Elderly Health Research Center, Endocrinology and Metabolism Population Sciences Institute, Tehran Univ. of Medical Sciences, [3]Tehran Heart Center, Tehran Univ. of Medical Sciences, [4]Endocrinology and Metabolism Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran Univ. of Medical Sciences, [5]Osteoporosis Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran Univ. of Medical Sciences, [6]Metabolomics and Genomics Research Center, Endocrinology and Metabolism Molecular-Cellular Sciences Institute, Tehran Univ. of Medical Sciences, Tehran, Iran

Objective: Osteoporosis, characterized by a decline in BMD, has become increasingly prevalent among the elderly in recent times. This systematic review and meta-analysis aim to explore the potential impact of statin medications on bone health, contributing to improved clinical management and treatment strategies for those at risk of osteoporosis and fractures.
Methods: Utilizing international databases such as PubMed, Embase, Scopus, ProQuest, and Web of Science, we identified 61 studies (45 observational and 16 randomized controlled trials) involving a total of 9,610,432 participants. In observational studies, a meta-analysis was conducted to evaluate the effects of statins on BMD, hip fractures, and other fractures.
Results: The analysis revealed that non-users had a 33.7% higher risk of hip fractures compared to statin users (odds ratio [OR] = 0.663), and the risk of other fractures was 16.2% higher in non-users than statin users (OR = 0.838). Statin users also exhibited higher BMD at the lumbar spine (standardized mean difference [SMD] = 0.082), femoral neck (SMD = 0.135), and hip (SMD = 0.101) in observational studies.
Conclusion: The most clinical trials included in this study did not find a significant association between statin consumption and bone metabolism or markers. While evidence from diverse populations suggests a positive correlation between statin medication and bone health, further research, particularly clinical trials, is essential to enhance the generalizability of these findings.

RESULTS OF LABORATORY EXAMINATION OF PATIENTS INCLUDED IN THE FRACTURE LIAISON SERVICE

M. Fominykh[1], K. Belova[2], L. Evstigneeva[3], O. Lesnyak[4], E. Gladkova[5], E. Dudinskaya[6], Y. Polyakova[7], A. Tarasova[8], L. Sivordova[7], T. Kendys[8], V. Tanaev[5], E. Bublik[9], A. Akhatov[10]

[1]Ural State Medical Univ., Ekaterinburg, [2]Yaroslavl State Medical Univ., Yaroslavl, [3]Regional Clinical Hospital No. 1, Ekaterinburg, [4]North-Western State Medical Univ. named after I.I. I.I. Mechnikov, St. Petersburg, [5]City Polyclinic No. 25 of the Nevsky District, St. Petersburg, [6]Russian National Research Medical Univ. named after N.I. Pirogov Ministry of Health of the Russian Federation, Moscow, [7]Federal State Budgetary Scientific Institution A.B. Zborovsky, Volgograd, [8]Clinical Medical and Surgical Center of the Ministry of Health of the Omsk Region, Omsk, [9]Central Clinical Hospital with a Polyclinic, Office of the President of the RF, Moskow, [10]Barsmed, Kazan, Russia

Objective: To analyze lab examination tests in patients included in the Fracture Liaison Service (FLS).
Methods: We assessed the data of the patients with fragility fractures included in the registry "Prometheus" and enrolled in 12 FLS in Russian Federation. The results of laboratory tests were assessed (hematology, biochemical parameters, bone markers and vitamin 25(OH)D).
Results: The study included 895 patients: 111 men (12.0%) and 784 women (88.0%) aged 50–95 years, the average age was 71.7 ± 9.76 years old. 25(OH) D was performed in 231 (25.8%) patients. Normal values were found in 79 (34.2%) patients, insufficiency in 72 (31.2%), deficiency in 68 (29.4%), severe deficiency in 12 (5.2%) patients. Serum calcium was examined in 641 patients, in 84 (13.1%) of them it was decreased, and in 20 (3.1%) it was increased. The serum creatinine value was higher than the normal level in 92 (12.1%) of the 762 results, 25 (3.3%) patients had low GFR (< 35 ml/min). Alkaline phosphatase was increased in 86 (14.1%) of 613 people, nobody had

decreased level. Phosphorus was examined in 572 persons, it was high in 12 (2.1%) and low in 29 (5.1%) cases. Elevated level of PTH was detected in 27 (20.6%) of 131 subjects. Thyroid-stimulating hormone was increased in 7 (5.1%), and was below normal value in 1 (1.4%) of 136 patients. The level of total protein was increased in 2 (0.7%) people, decreased in 23(8.1%) of 285 subjects.
Conclusion: Laboratory examination has an importance for patients enrolled in the FLS to identify the secondary causes of osteoporosis and contraindications for drug therapy. The detection of abnormalities in laboratory tests requires additional diagnostics and balanced approach to the selection of the antiosteoporotic medications.

P825
ANALYSIS OF MEDICAL CARE FOR HIP FRACTURES IN THE OLDER AGE GROUP IN THE SVERDLOVSK REGION FOR THE PERIOD FROM 1997–2023

M. Fominykh[1], L. Evstigneeva[2], R. Ryabov[1], D. Gavrikov[1]

[1]Ural State Medical Univ., [2]Regional Clinical Hospital No. 1, Ekaterinburg, Russia

Objective: To analyze medical care for hip fractures in older age group in the Sverdlovsk region for the period from 1997–2023.
Methods: A retrospective study was based on the medical documentation of all traumatology hospitals in Yekaterinburg (1997), all medical records of patients hospitalized in the traumatology department in Yekaterinburg (2021) and monitoring data on the provision of medical care for hip fracture in residents of the Sverdlovsk region (2023).
Results: In 1997, 540 cases of hip fractures: 126 (23.3%) in men and 414 (76.7%) in women. Only a half patients with hip fractures were hospitalized in trauma city hospitals, 272 (50.4%) were sent for outpatient treatment. In the majority of hospitalized patients were 107 (39.8%) with skeletal extension. Surgical treatment was performed in only 9.8%. Hip replacement was not performed in this study group. No one has received treatment for osteoporosis. In 2021, 549 patients were hospitalized with hip fractures, including 145 (26.4%) men and 404 (73.6%) women. Surgical treatment was performed in 437 (83.2%) patients. Surgical treatment included osteosynthesis in 285 (65.2%), hip replacement in 152 (37.8%). 39 (7.1%) people took calcium and vitamin D3 supplements after a fracture, 10 (5.5%) people took antiresorptive drugs. In 2023, hip fractures in residents of the Sverdlovsk region aged 60 y and older occurred in 2174 people, of whom 549 (25.3%) men and 1625(74.7%) women. Hip fractures were most common in the age group of 85 years and older. 1922 (88.4%) were hospitalized. Surgical treatment was performed in 1423 (74%) hospitalized patients (osteosynthesis in 1112 (71.1%), hip replacement in 311 (28.9%)). Surgical activity in patients aged 85 y and older (70.1% of patients in this age group were operated on) did not significantly differ from surgical activity in patients under 85 y of age (75.4%). The diagnosis of osteoporosis during hospitalization was established in 29.7%, calcium and vitamin D3 supplements were received by 26.6% of patients, antiresorptive drugs in 17.8%.
Conclusion: The analysis of medical care for hip fractures demonstrated an increase in surgical activity, an increase in the number of patients diagnosed with osteoporosis who receive calcium, vitamin D3 and antiresorptive drugs. However, the diagnosis of osteoporosis remains low. Increase the number of patients taking calcium supplements, vitamin D3 and antiresorptive drugs to improve the detection of osteoporosis. It is necessary to implement the Fracture Liaison Service more widely.

P826
DETERMINATION OF CARPAL INSTABILITY IN RHEUMATOID ARTHRITIS

M. Foteva[1], A. Andonovski[1]

[1]Univ. Clinic for Orthopedic Surgery- Skopje, Skopje, North Macedonia

Objective: Carpal instability is a biomechanical alteration with multiple pathogenesis which occurs when there is disruption of the normal ligamentary and bony relations that control the wrist. There are four major types of carpal instability: 1.DISI 2.VISI 3. Ulnar translocation and 4. Midcarpal instability. Instability of the rheumatoid wrist can result from incongruity of the articular and bony surfaces, capsular and ligamentary laxity and muscle–tendon imbalance. The aim of this study is by using radiographic evaluation of the wrist to answer the questions: Is there carpal instability in the rheumatoid wrist and if so, what patterns of carpal instability exist?
Methods: In 30 patients with affirmed rheumatoid arthritis we took lateral and anteroposterior radiographies in neutral position of both hands. On the anteroposterior radiographs we measured the carpal-ulnar distance. On the lateral radiographs we used the so-called axial method od Linscheid for drawing carpal axes which form angles that define the positions of the carpal bones: Scapholunate, radiolunate and capitolunate angle.
Results: From total of 60 rheumatoid hands, in 50 we determined presence of carpal instability, as follows: ulnar translocation (32 hands), VISI (14 hands), DISI (4 hands). Of these, isolated form of instability was present in 38 hands, while in large number of hands there was complex carpal instability, i.e. a combination of two patterns of instability (12 hands).
Conclusion: The method of radiographic determination of carpal instability allows detection and quantitative analysis for evaluation of carpal instability in rheumatoid arthritis.

P827
IMPACT OF ANTI-OSTEOPOROSIS MEDICATIONS ON THE RISK OF RECURRENT HIP FRACTURE

D. Shklovsky[1], I. Panksy[2], U. Yoel[3], R. Abuhasira[4], M. Fraenkel[3]

[1]Endocrine Unit, Soroka Univ. Medical Center, [2]Clinical Research Center, Soroka Univ. Medical Center, [3]Endocrine Unit, Soroka Univ. Medical Center and Faculty of Health Sciences, Ben-Gurion Univ. of the Negev, [4]Clinical Research Center, Soroka Univ. Medical Center and Faculty of Health Sciences, Ben-Gurion Univ. of the Negev, Beer-Sheav, Israel

Objective: To evaluate the impact of anti-osteoporosis medication on this risk of second OHF.
Methods: This retrospective population-based study included all patients 50 years and older, insured by Clalit Health Services (CHS) nationwide, who were operated for OHF at any of CHS hospitals between 1/2012 and 12/2021. Inclusion criteria were hospitalization with the diagnosis of OHF and surgical repair of the fracture using ICD-9 codes. Main exclusion criteria were malignancy diagnosed in the 3 years prior to the first fracture, periprosthetic, and sub-trochanteric fractures. MDClone platform was used to retrieve demographic, clinical, biochemical, and drug purchase data. Hazard ratios for second OHF were assessed by using univariable and multivariable Fine & Grey regression models, that account for the competing risk of death.
Results: Among the 9425 patients with OHF who met our study criteria, 645 (6.8%) experienced a second OHF, 5140 patients (54.5%) died without a second hip fracture, and 3640 (38.7%) were alive without a second OHF at end of follow-up. Median follow-up

was 3.4 y (IQR:1.7,5.7). Median time to a second OHF was 2.1 years (IQR:0.7,4). The average age at first fracture for patients with a second fracture was comparable to that of the entire study population (80 ± 9 vs. 80 ± 10 y, respectively). After their initial fracture, 17% of patients who later experienced a second OHF received oral bisphosphonates, compared to 12.7% of those who did not suffer a second fracture. Fifteen percent of the second-fracture group received zoledronic acid and/or denosumab compared to 20.8% of those who did not experience a second fracture. In multivariable analysis adjusted for age, sex, Charlson Comorbidity Index and socioeconomic score at first OHF, patients who received zoledronic acid and/or denosumab after their initial hip fracture, and throughout the follow-up period, showed a significantly lower risk of a second OHF, compared to those without treatment (HR: 0.65 CI 0.52–0.82). Conversely, no significant difference in risk was shown for oral bisphosphonates (HR: 1.18, CI 0.95–1.46). Similar effects were observed in patients who received these medications within 2 y of their first OHF.

Conclusion: Administration of zoledronic acid and/or denosumab after the first OHF was associated with a significant risk reduction in second OHF.

P828
USE OF ETELCALCETIDE FOR PRESERVING VITAMIN K-DEPENDENT PROTEINACTIVITYITALIAN STUDY (ETERNITY- ITA STUDY): RATIONALE AND DESIGN OF THE STUDY ON REAL WORLD EVIDENCE

M. Fusaro[1], M. Gallieni[2], G. Re Sartò[3], A. Cossettini[4], L. Cosmai[5], C. Marino[6], A. Aghi[7], G. Tripepi[6]

[1]IFC-CNR Pisa and Univ. of Padua, Padova, [2]Dept. of Biomedical and Clinical Sciences 'Luigi Sacco', Università di Milano, Milano, [3]Università degli Studi di Milano, Milano, [4]Post-Graduate School of Specialization in Nephrology, Univ. of Milano, Milano, [5]Division of Nephrology and Dialysis, Azienda Socio-Sanitaria Territoriale (ASST) Fatebenefratelli-Sacco, Fatebenefratelli Hospital, Italy, Milano, [6]National Research Council (CNR), Institute of Clinical Physiology (IFC), Reggio Calabria, [7]Independent Researcher, Padova, Italy

Vascular calcifications (VCs) are prevalent in chronic kidney disease (CKD) and mineral disorders, associated with aortic calcification and increased bone fracture risk. The complex pathogenesis involves factors like calcium overload, phosphate imbalance, and secondary hyperparathyroidism. Key inhibitors, vitamin K-dependent proteins (VKDPs) like matrix Gla protein (MGP) and osteocalcin (BGP), play pivotal roles in VC development. Traditional VC risk reduction focuses on lowering PTH, calcium and phosphorus levels. Etelcalcetide, a synthetic peptide activating the calcium-sensing receptor, demonstrates promise in clinical trials. Studies on Vitamin K Italian (VIKI) show that calcimimetic treated hemodialysis patients exhibit higher levels of total BGP and MGP, suggesting a protective effect. These findings underscore the multifactorial nature of VC in CKD, informing refined treatment strategies and targeted pathways for improved outcomes. The proposed study will investigate real world evidence of the effect of Etelcalcetide in preserving active forms of VKDPs among total MGP and total BGP with a resulting reduction of those inactive such as dephosphorylated-undercarboxylated MGP or dp-uc MGP, undercarboxylated BGP or uc-BGP, thus contributing to bone and vascular health in hemodialysis patients (Table 1).

Table 1. Inclusion and exclusion criteria.

Condition or disease	Intervention/treatment	Phase
Chronic Kidney Disease, Mineral and Bone Disorder, Renal Osteodystrophy, Vascular Calcification, Hyperparathyroidism; Secondary, Renal	Drug: Etelcalcetide	This is prospective observational study of comparative effectiveness.
Inclusion criteria:		
1. Patient has provided informed consent. 2. Patient is 18 years of age or older of both gender 3. Patients receiving maintenance HD three times per week (Kt/V ≥1.2) 4. PTH concentrations >500 ng/l at screening, or if parathyroidectomy is planned or expected, Ca >8.3 mg/dl;		
5. Will be considered patients in the exposed group: a. Patients who have started Etelcalcetide within 1-month before the study enrolment b. Patients naïve to intravenous calcimimetics use c. Patients who have suspended oral calcimimetics from at least 1-month, d. Patients who are not responder or not compliant to the treatment with calcitriol 6. In the unexposed group, patients on treatment with calcitriol or vitamin D analogs and who are age (±2 y) and sex comparable (matching) to those in the exposed group will be considered. 7. Native vitamin D can be used in both groups and should be administered to target a 25(OH)D level >30 ng/ml 8. Dialysate calcium concentration must be stable for at least 4 weeks prior to screening laboratory assessments. 9. Patient must have severe HPT as defined by two laboratory screening pre-dialysis serum PTH values >500 pg/ml, measured on two consecutive lab checks prior to entering the study. 10. Total alkaline phosphatase greater than the normal range, or even within the normal range but if greater than the tertile of the reference range for the assay. 11. Patients will be eligible only if they will show at least a /moderate Aorta VCs (16) and/or Iliac arteries VCs and at least a mild VF (17,18).		
Exclusion Criteria:		
1. Previous treatment with oral calcimimetics (cinacalcet) must have been suspended for at least 30 d. Recent start of calcimimetics (etelcalcetide) is acceptable, but patients are excluded if treatment lasts for more than 1 month. 2. Patients has received a bisphosphonate, denosumab or teriparatide during the 12 months prior to screening. 3. The patient underwent parathyroidectomy in the 6 months before the start of the study or if scheduled soon. 4. Scheduled kidney transplant during the study period or anticipated living donor evaluation within three months of recruitment 5. Patient has an unstable medical condition based on medical history, physical examination, and routine laboratory tests, or is otherwise unstable in the judgment of the Investigator. 6. Metabolic bone diseases not related to the kidney (i.e., Paget's, osteogenesis imperfecta) 7. Severe untreated hyperthyroidism		
8. Malignancy within the last 3 y (except non-melanoma skin cancers or cervical carcinoma in situ). 9. Patient is pregnant or nursing. 10. Patients with Long QT Syndrome 11. Patient likely to not be available to complete all protocol-required study visits or procedures, and/or to comply with all required study procedures to the best of the patient and Investigator's knowledge.		

This is a multicenter comparative effectiveness observational longitudinal study with no predefined interference on drug dosing on the part of the investigators. The study will enroll 160 hemodialysis patients: 80 patients considered in the exposed group (treated with Etelcalcetide) and 80 age and sex matched patients considered in the unexposed group (treated with Calcitriol or vitamin D analogs). The treating nephrologist will base their target dose of Etelcalcetide on an individual-level patient basis in order to achieve the KDIGO PTH target level. In the Etelcalcetide-treated group, the addition of

calcitriol is allowed when required by normal clinical practice (for correction of hypocalcemia) (Fig. 1).

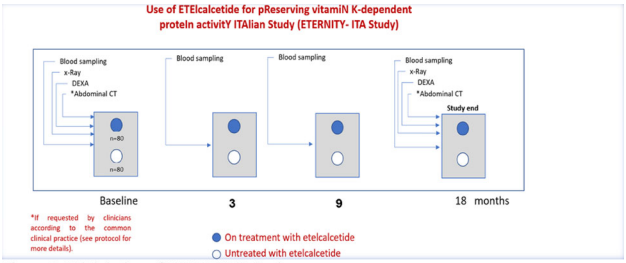

Figure 1. Trial design of ETERNITY Study.

The primary endpoint is the comparison of the levels of active and no-active forms of VKDP between patients treated with etelcalcetide and those treated with vitamin D or vitamin D analogues. The two groups will be compared for longitudinal changes in the following biomarkers, measured at baseline and after 3, 9, and 18 months of treatment: total MGP, dephosphorylated-undercarboxylated MGP, total BGP, and undercarboxylated BGP. As secondary outcomes will be evaluated bone vascular markers levels, serum calcification propensity T_{50} test, anemia markers levels, dialysis routine biomarkers, changes from baseline prevalence VCs (Aorta and Iliac arteries) and vertebral fractures by lateral dorsal lumbar spine x-Ray and BMD by DXA.

P829

CKD-MBD MANAGEMENT: RESULTS FROM A NATIONAL SURVEY ON BONE TURNOVER BIOMARKERS PRACTICE AND THERAPEUTIC STRATEGIES AMONG ITALIAN NEPHROLOGISTS

M. Fusaro[1], G. Re Sartò[2], M. Gallieni[3], S. Bianchi[4], L. De Nicola[5], M. Plebani[6], M. Zaninotto[7], A. Cossettini[8], L. Cosmai[9], C. Marino[10], A. Aghi[11], G. Tripepi[10]

[1]IFC-CNR Pisa and Univ. of Padua, Padova, [2]Università degli Studi di Milano, Milano, [3]Dept. of Biomedical and Clinical Sciences 'Luigi Sacco', Università di Milano, Milano, [4]Dept. of Internal Medicine, Nephrology and Dialysis Complex Operative Unit, Livorno, [5]Division of Nephrology, Dept. of Scienze Mediche e Chirurgiche Avanzate, Univ. of Campania, Napoli, [6]Laboratory Medicine Unit, Dept. of Medicine, Univ. of Padua, Padova, [7]Laboratory Medicine Unit, Dept. of Medicine, Univ. of Padua, Padova, [8]Post-Graduate School of Specialization in Nephrology, Univ. of Milano, Milano, [9]Division of Nephrology and Dialysis, Azienda Socio-Sanitaria Territoriale (ASST) Fatebenefratelli-Sacco, Fatebenefratelli Hospital, Milano, [10]National Research Council (CNR), Institute of Clinical Physiology (IFC), Reggio Calabria, [11]Independent Researcher, Padova, Italy

Objective: Advanced stages of chronic kidney disease (CKD) are constantly characterized by a mineral and bone disorders (MBD) syndrome concerning a complex systemic condition that includes laboratory abnormalities of bone and mineral metabolism involving calcium, phosphorus, PTH, or vitamin D; abnormalities in bone turnover, mineralization, volume, or strength; extraskeletal calcifications, such as vascular or other soft tissue. CKD-MBD syndrome determines relevant consequences in terms of fragility fractures, cardiovascular events and higher mortality. The nephrologist's awareness of CKD-MBD diagnostic and management tools and therapeutic strategies is key to improving CKD patients' prognosis and outcomes.

Methods: A new national survey (composed of 17 online questions) was conducted among Italian nephrologists to investigate the reference laboratory availability of bone turnover markers (BTMs), the clinical attitude on secondary hyperparathyroidism (sHPT) management, and the CKD-MBD therapeutic approach in different stages of CKD and dialysis patients.

Results: 89 Italian nephrologists participated in the survey. The reference laboratories largely fulfill the biomarkers request of ionized calcium (97.7%), phosphorus (100%), PTH (100%), alkaline phosphatase (ALP) (100%), magnesium (100%), 25-OH and 1,25-OH vitamin D levels (92.1%; 53.9%); while most of the hospital laboratories do not regularly support the availability of specific BTMs, both for diagnosis and monitoring the bone resorption and formation (Fig. 1), such as bone ALP (75.3%), calcifediol (37.1%), calcitriol (40.5%), FGF23 (intact 9% and C-terminal 4.5%), vitamin K (33.7%), Klotho (6.75%, soluble 4.5%), osteocalcin (38.2%), matrix gla protein (10.1%), TRAP-5b (6.75%), CTX (32.6%) and P1NP (10.1%). The nephrologist's attitude to start management and treatment of sHPT is revealed to be mainly led by KDOQI (n = 42, 47%) and KDIGO (n = 39, 44%) guidelines considering their PTH cut-off values; in 53.9% of clinicians the measure of PTH levels is then performed every 3 months according to KDOQI guidelines. In relation to the definition of high turnover metabolic bone disease by BTMs, this metabolic pattern is identified in $>$ 50% and 30–40% of patients with CKD 4-5D by 31.5% and 21.4% of nephrologists, respectively. 65% of clinicians currently considered ALP of equal importance as alterations of PTH as a predictor of fracture events. Other biomarkers, such as FGF23, P1NP or TRAP-5b, emerge to not be still used in regular clinical practice. In patients diagnosed with CKD-MBD and skeletal fragility, 76.4% of nephrologists consider the AIFA (Italian Medicines Agency) note 79 to support osteoporosis treatment. The therapeutic strategies of CKD-MBD include the administration of vitamin D (e.g., cholecalciferol 27–37.1%, calcifediol 9–12.4%, calcitriol 42.7–55.1%) and its analogs (e.g., paricalcitol 23.6–52.8%) and the use of antiresorptive agents (e.g., alendronate 3.4%-23.6%, denosumab 22.5%-30.3%) with variable frequencies among different advanced CKD stages and for those patients on peritoneal or hemodialysis (Fig. 2).

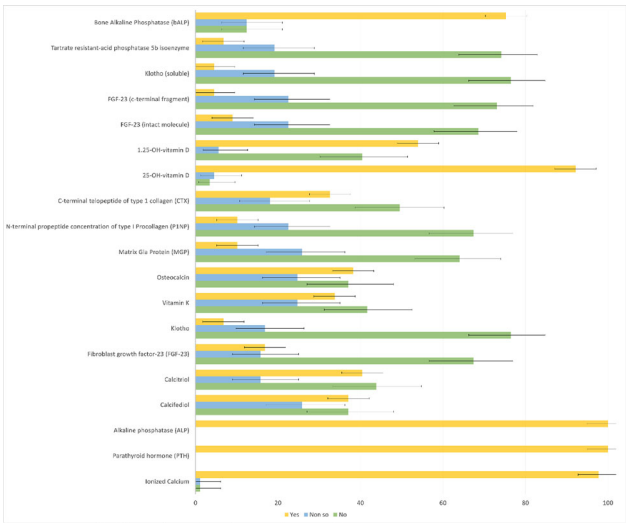

Figure 1. Availability of markers from reference laboratory.

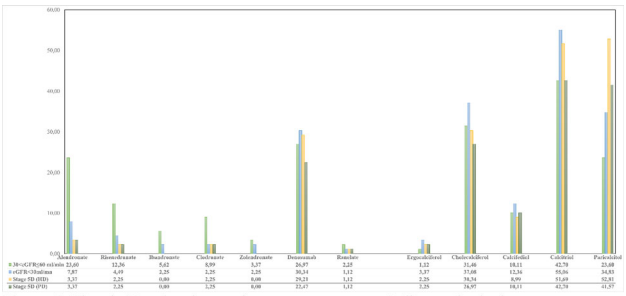

Figure 2. Vitamin D and antiresorptive agents use among Italian nephrologists.

Conclusion: Results present a suboptimal use of BTMs and a current heterogeneous therapeutic management of CKD-MBD syndrome and renal osteodystrophy in Italian clinical practice. The survey represents a starting point of work to further implement awareness of diagnostic and therapeutic issues of CKD-MBD.

P830
ROLE OF VITAMIN D AS A HUMORAL REGULATOR IN PATIENTS WITH METABOLIC SYNDROME

M. Ghasaboghlyan[1], V. Mukuchyan[2], L. Baghdasaryan[2], V. Babalyan[3], V. Vardanyan[4], A. Jaghinyan[1]

[1]Vardanants Medical Center, [2]Nairi Medical Center, Yerevan, Armenia, [3]Varta Babalyan, Osteoporosis Center, [4]Mikayelyan Univ. hospital, Yerevan, Armenia

Objective: Metabolic syndrome (MS) is a common set of metabolic risk factors, which include high blood pressure, atherogenic dyslipidemia, insulin resistance and central obesity. Metabolic syndrome is diagnosed by at least 3 of the listed criteria: abdominal obesity (BMI $>$ 30 kg/m^2), fasting glucose over 5.6 mmol/L, dyslipidemia (triglycerides $\geq$ 1.7 mmol/L, HDL for men $<$ 1 mmol/L and $<$ 1.3 mmol/L for women), high blood pressure ($\geq$ 130/80 mm Hg) or receiving an appropriate treatment for the latter. Vitamin D is a steroid hormone that has an essential effect on the mechanisms of physiological activity of the organism. In obesity, vitamin D affects insulin secretion, adipokine synthesis by adipose tissue through its direct and paracrine effects through activation of vitamin D receptors (VDR) in the pancreas. The purpose of this study is to show the connection between vitamin D insufficiency and insulin resistance.
Methods: 30 male patients (ages 23–47) with MS were enrolled in the study. All of them had hypertension (BP $\leq$ 140/90 mm Hg), dyslipidemia (triglycerides $\geq$ 1.9–3.2 mmol/L, HDL $\leq$ 35–50 mmol/L), BMI of 30–36 kg/m^2 and insulin resistance (HOMA-IR $<$ 2.7–6.0). The patients were split into two groups: the first group of patients (n = 15) received antihypertensive, antihyperlipidemic medication, Semaglutide 0.25–1.0 IU weekly by gradually increasing the dose and recommendations about healthy lifestyle and physical activity. The second group of patients (n = 15) received the same treatment and recommendations as the 1st group as well as vitamin D 50,000 IU weekly for 9 months along with that. Every 3 months blood tests were done, and BMI was measured.
Results: 9 months later significant regulation of dyslipidemia, arterial hypertension, insulin resistance and BMI were observed in group 2 patients (P = 50%).
Conclusion: Administration of vitamin D 50,000 IU weekly has a positive effect in regulation of MS, particularly in regulation of insulin resistance.

P831
TREATMENT OF SECONDARY LYMPHEDEMA FOLLOWING RADICAL PROSTATECTOMY

M. Gocevska[1], C. Gjerakaroska Savevska[1], V. Koevska[1], B. Mitrevska[1], B. Kalchovska Ivanovska[1], M. Manoleva[1], E. Nikolikj Dimitrova[1], D. Gecevska[1]

[1]Univ. Clinic of Physical Medicine and Rehabilitation; Faculty of Medicine, Ss Cyril and Methodius Univ., Skopje, North Macedonia

Lymphedema (LE) is a progressive chronic disorder frequently related to malignancies and their treatment. It markedly affects patients' quality of life, and its management is challenging, mainly based on conservative therapy such as bandages and manual lymphatic drainage, with limited results.
Case report: A 75-year-old male patient, retired, reported a one-year history of increasing volume in the leg as a whole, with leg swelling associated with a feeling of heaviness after walking. His past medical history was significant. Three years ago, he underwent transurethral resection of the prostate (histopathology- prostate adenocarcinoma, grade III), followed by hormone therapy and external radical radiation therapy. The physical examination revealed an enlarged scrotum with normal skin, unilateral edema of the lower limb, with spider and reticular veins, and pigment trophic skin changes of the pretibial region. Ultrasound scan, computerized tomography scan, and MRI of the abdomen and pelvis did not show recurrence or dissemination of previous cancer. He was treated with complex decongestive physiotherapy (CDP), which involved: skin care, lymph drainage of the affected lower extremity, low-stretch multilayered compression bandaging of the limb, and exercises. After four weeks of CDP, he reported reducing symptoms, especially in the affected lower limb, reducing swelling, and improving walking distance. LE of the scrotum remained the same as before treatment, while lymphedema of the lower limb was reduced.
Conclusion: CDP can help reduce secondary lymphedema following radical prostatectomy and improve the quality of life for these patients.

P832
RUPTURE OF THE SERRATUS ANTERIOR MUSCLE: A CASE REPORT

M. Gocevska[1], C. Gjerakaroska Savevska[1], V. Koevska[1], B. Mitrevska[1], M. Manoleva[1], B. Kalchovska Ivanovska[1], E. Nikolikj Dimitrova[1], D. Gecevska[1]

[1]Univ. Clinic of Physical Medicine and Rehabilitation; Faculty of Medicine, Ss Cyril and Methodius Univ., Skopje, North Macedonia

Trauma affecting the serratus anterior muscle (SA) typically results from injury to the long thoracic nerve, with muscle rupture being uncommon.
Case report: A 19-year-old man presented with a history of falling on his left side two months prior. Since then, he experienced persistent left shoulder pain and difficulty raising his arm above scapular level, hampering her daily activities. Physical examination from the rear revealed moderate drooping of the left shoulder and winged scapula upon arm elevation. Mild tenderness was noted when attempting to raise the arm beyond a right angle. A soft mass was palpable along the lower half of the vertebral border of the left scapula, which was non-painful and reducible upon pressure. Neurological examination findings were normal. Ultrasound and CT scan revealed a hernia of the SA along the vertebral border of the left scapula, accompanied by fatty degeneration of the muscle. A 12-week course of rehabilitative treatment aimed at pain relief, improving shoulder range of motion, and strengthening the trapezius, levator

scapulae, and rhomboids resulted in significant functional improvement.
Discussion: Diagnostic confirmation in this case was aided by ultrasound and CT scan findings indicating fatty degeneration of the muscle. Although a fall history preceded pain, disability, and local tenderness, the precise mechanism of trauma remained unclear, possibly involving abrupt contraction of the serratus anterior when the scapula was forcefully fixed against a surface.
Conclusion: Serratus anterior muscle rupture is less common than long thoracic nerve injuries. Features such as winging scapula and a palpable soft mass along the lower spinal border of the scapula are indicative of SA rupture.

P833
SUCCESSFUL TREATMENT OF GLUTEUS MEDIUS CALCIFIC TENDINOPATHY WITH RADIAL EXTRACORPOREAL SHOCK WAVE THERAPY: A CASE STUDY

M. Gocevska[1], C. Gjerakaroska Savevska[1], V. Koevska[1], B. Mitrevska[1], M. Manoleva[1], E. Nikolikj Dimitrova[1], B. Kalchovska Ivanovska[1], D. Gecevska[1]

[1]Univ. Clinic of Physical Medicine and Rehabilitation; Faculty of Medicine, Ss Cyril and Methodius Univ., Skopje, North Macedonia

Gluteus medius calcific tendinopathy is characterized by pain in the lateral aspect of the hip. Radial extracorporeal shock wave therapy (RESWT) has emerged as a potential alternative treatment for this condition. This case report aims to demonstrate the effectiveness of RESWT in managing gluteus medius calcific tendinopathy.
Case report: We present the case of a 40-year-old woman with a three-month history of clicking sensation in the right lateral hip area while walking, accompanied by moderate pain exacerbated by activity and restricted range of motion in the right hip. Despite analgesic use, the pain persisted. The patient had a medical history of postmenopausal osteoporosis. Physical examination revealed tenderness upon deep palpation over the right greater trochanter, with limited hip flexion (80°), extension (10°), external rotation (25°), and abduction (30°), all motions eliciting pain. The Numeric Rating Scale for Pain (NRSP) score was 5 (moderate pain). Plain radiography revealed calcific masses above the greater trochanter. No other significant findings or laboratory abnormalities were noted. Traditional physical modalities failed to alleviate pain and improve hip range of motion, prompting consideration of RESWT as an alternative treatment. The patient underwent four RESWT sessions, each spaced a week apart, involving the application of 2000 shockwaves at a pressure of 2.5 Bar and a frequency of 10 Hz in the painful region around the greater trochanter. Following the fourth RESWT session, hip flexion improved to 110°, with extension, external rotation, and abduction reaching 10°, 40°, and 40° respectively, and the NRSP score decreased to 0 (no pain). At the 3-month follow-up, complete resolution of calcification was observed.
Conclusion: RESWT demonstrated favorable clinical outcomes and complete resolution of radiographic findings in this case of gluteus medius calcific tendinopathy. This suggests that RESWT can serve as a safe and effective alternative treatment, potentially obviating the need for invasive interventions.

P834
SECONDARY FRACTURE IN FRAGILITY FRACTURES OF THE PELVIS

M. H. Hotta[1], K. H. Hotta[1]

[1]Amagi Central Hospital, Fukuoka, Japan

Objective: Fragility fractures of the pelvis (FFP) based on osteoporosis are on the increase. Same as vertebral fractures and proximal femur fractures, FFP have been reported to cause a variety of complications after injury. However, there are few reports of secondary fractures in patients with FFP. In this study, we examined secondary fractures in patients who could be followed for more than 1 y after FFP injury. We report here a study of secondary fractures in patients with FFP who could be followed up for at least 1 y after FFP injury.
Methods: 67 patients who sustained FFP from 2017–2019 and could be followed up for at least 1 y thereafter were included. 58 were female and 9 males, mean age 82.6 y (58–100 y). The study items were BMI, BMD (femur and lumbar spine YAM values), past history of fracture, and presence or absence of osteoporosis treatment. These above items were compared with between with secondary fractures groups and without groups.
Results: Secondary fractures occurred within 1 y of FFP injury in 11 of 67 cases. It occurred in 3 cases of proximal femur fracture, 2 cases of lumbar vertebra fracture, and 1 case each of FFP, patella fracture, distal radius fracture, proximal humerus fracture, distal humerus fracture, and distal femur fracture. Bone density for the femur YAM values was 47.2% and for the lumbar vertebrae was 69.5% in with secondary fractures group and for the femur was 53.4%, for the lumbar vertebrae was 70% in without group. There were no significant differences in any of the parameters. The total number of patients treated for osteoporosis increased from 23 of 67 to 48 of 67 after injury. After the FFP injury, 11 of 10 (91%) of the patients in the with secondary fracture group were treated for osteoporosis. The treatment consisted of bisphosphonates in 5 cases, PTH in 3 cases, and Vitamin D in 2 cases. In the no treatment group, 38 of 56 patients (68%) were treated after injury.
Conclusion: 16% of patients with FFP developed a secondary fracture within one year after injury. In this study, osteoporosis medications had no effect on secondary fracture prevention in patients with FFP. Further study is needed to increase the number of cases and to investigate what kind of medications are used after injury.

P835
REDUCED MUSCLE STRENGTH (DYNAPENIA) AND OBESITY: IMPLICATIONS FOR BONE HEALTH IN TYPE 2 DIABETES MELLITUS PATIENTS

M. Hayon-Ponce[1], B. Garcia-Fontana[2], D. Blanquez-Martinez[3], M. D. Avilés-Perez[2], M. Muñoz-Torres[2]

[1]Universitary Hospital Virgen de las Nieves, Bone Metabolic Unit, Endocrinology and Nutrition Division. Universitary Hospital Clínico San Cecilio, Granada, [2]Bone Metabolic Unit, Endocrinology and Nutrition Division. Universitary Hospital Clínico San Cecilio, Granada, [3]Pharmacy Hospitality Division. Universitary Hospital Ceuta, Ceuta, Spain

Objective: To examine bone health parameters [by DXA and TBS] and muscle strength (by hand grip) in T2DM patients.

Methods: Cross-sectional observational study. 60 T2DM patients (60% males and 40% postmenopausal women) aged 49–85 y. Anthropometric and metabolic parameters were determined. BMD of the lumbar spine (LS), femoral neck (FN) and total hip (TH) and TBS were assessed using DXA and TBS iNsight Software. Hand grip strength (kg/cm^2) was measured with a jamar® hydraulic hand dynamometer (5030j1; jackson, MI). Handgrip strength < 30 kg (male) or < 20 kg (female) was defined as low muscle strength. Data were analysed using SPSS 25.0.
Results: 60 patients with T2DM were studied. Mean age of T2DM patients was 66.3 ± 8.31 years. Mean HbA1C was $7.7 \pm 1.1\%$. 73.3% had poorly glycemic control (HbA1c $> 7.5\%$). 95.8% of female and 91.7% of male had low muscle strength. Hand-grip strength was positively correlated with TBS ($R = 0.321$, $p < 0.01$) and with TH- BMD ($R = 0.268$, $p < 0.05$).
Conclusion: The reduction of muscle strength was significantly associated with decreased bone mass and deteriorated bone microarchitecture in T2DM patients.

P836
RELATIONSHIP BETWEEN BONE PARAMETERS AND SEX HORMONE BINDING GLOBULIN IN TYPE 2 DIABETES MELLITUS PATIENTS

M. Hayon-Ponce[1], B. Garcia-Fontana[2], D. Blanquez-Martinez[3], M. D. Avilés-Perez[2], M. Muñoz-Torres[2]

[1]Universitary Hospital Virgen de las Nieves, Bone Metabolic Unit, Endocrinology and Nutrition Division. Universitary Hospital Clínico San Cecilio, Granada, [2]Bone Metabolic Unit, Endocrinology and Nutrition Division. Universitary Hospital Clínico San Cecilio, Granada, [3]Pharmacy Hospitality Division. Universitary Hospital Ceuta, Ceuta, Spain

Objective: The effects of SHBG in diabetic bone fragility are complex and incompletely known. Our aims was to examine bone health parameters [by DXA and TBS] and sex hormone binding globulin (SHBG) in T2DM patients.
Methods: Cross-sectional observational study in 137 T2DM patients (49–85 y). BMD of the lumbar spine (LS), femoral neck (FN) and total hip (TH) and TBS were assessed using DXA and TBS iNsight Software. Serum SHBG were determined by electrochemiluminescence immunoassay analyser (ECLIA) (Roche Elecsys 1010/2010).
Results: 137 T2DM patients, mean age 65.2 ± 7.5 y (58% male and 42% postmenopausal women). SHBG was negatively correlated with LS-BMD in females ($r = -0.282$; $p = 0.032$), while showed a positive association between serum SHBG and TBS in males ($r = 0.299$;$p = 0.013$) and females ($r = 0.376$; $p = 0.005$).Significantly higher values of TBS were observed in patients with SHBG values above the median in both men ($p = 0.022$) and women ($P = 0.004$).BMD at LS, FN and TH was lower in women with above-median SHBG levels, although the relation was not statistically significant. In men, the same trend was observed except for LS-BMD. The SHBG values showed a progressive increase according to the BMD categories "normal bone mass, osteopenia and osteoporosis" with the highest SHBG levels in women with osteoporosis. The prevalence of low bone mass (T-score < -1) in postmenopausal women showed an increased trend with the increase in SHBG quartiles. No clear trend was found in SHBG values in terms of DXA classification nor in the proportion of low bone mass according to SHBG quartiles in men.
Conclusion: Low SHBG could be a risk factor of degraded TBS. Our findings suggest that SHBG could play a role in the modulation of bone microarchitecture in T2DM patients although how SHBG is involved in diabetic bone and fractures remains unclear.

P837
PERSONALIZED ASSESSMENT OF VITAMIN D STATUS BY A NOVEL METABOLIC APPROACH

M. Herrmann[1], S. Zelzer[1], E. Cavalier[2], M. Kleber[3], C. Drexler-Helmberg[4], P. Schlenke[4], P. Curcic[1], H. Keppel[1], D. Enko[1], H. Scharnagl[1], S. Pilz[5], W. März[1]

[1]Medical Univ. of Graz, Clinical Institute of Medical and Chemical Laboratory Diagnostics, Graz, Austria, [2]Univ. of Liege, Dept. of Clinical Chemistry, Liege, Belgium, [3]Dept. of Internal Medicine 5 (Nephrology, Hypertensiology, Endocrinology, Diabetology, Rheumatology), Mannheim Medical Faculty, Univ. of Heidelberg, Mannheim, Germany, [4]Medical Univ. of Graz, Dept. for Blood Group Serology and Transfusion Medicine, Graz, Austria, [5]Medical Univ. of Graz, Dept. of Internal Medicine, Division of Endocrinology and Diabetology, Graz, Austria

Objective: Determining 25-hydroxyvitamin D (25(OH)D), 24,25-dihydroxyvitamin D ($24,25(OH)_2D$) and the vitamin D metabolite ratio (VMR) allows the identification of individuals with functional vitamin D deficiency. Here we evaluated whether or not such a functional approach provides superior diagnostic information to serum 25(OH)D alone.
Methods: 25(OH)D), $24,25(OH)_2D$ and VMR were determined in participants of the DESIRE (Desirable Vitamin D Concentrations, n = 2010) study and the LURIC (Ludwigshafen Risk and Cardiovascular Health, n = 2456) study. Functional vitamin D deficiency was defined by a $24,25(OH)_2D$ concentration < 3 nmol/L and a VMR $< 4\%$. PTH and bone turnover markers were measured in both cohorts, whereas 10-y mortality data was recorded in LURIC only.
Results: The median age in DESIRE and LURIC was 43.3 and 63.8 y, respectively. Median 25(OH)D concentrations were 68.0 nmol/L and 38.8 nmol/L, respectively. Serum 25(OH)D deficiency with < 50 nmol/L was present in 483 (24.0%) and 1701 (69.3%) participants of DESIRE and LURIC, respectively. In contrast, only 77 (3.8%) and 521 (21.2%) participants, respectively, had functional vitamin D deficiency. Regardless of the serum 25(OH)D concentration, the presence of functional vitamin D deficiency was associated with significantly higher PTH, accelerated bone metabolism and higher all-cause mortality than in the absence of functional deficiency.
Conclusion: The personalized assessment of vitamin D status using a functional approach, better identifies patients with accelerated bone metabolism and increased mortality than the use of a fixed 25(OH)D cut-off of 50 nmol/L.

P838
RISK FACTORS FOR OSTEOPOROSIS IN MONGOLIAN OUTPATIENTS: A CROSS-SECTIONAL STUDY

M. Jaalkhorol[1], D. Amarsaikhan[1], N. Khaidav[1], O. Dulamsuren[1], E. Radnaa[2], A. Khairat[1], G. Davaadorj[3], D. Munkhbayar[4], B. Baigabyl[5], O. Bold[5]

[1]Univ. of National Medical Sciences, [2]Buyant Onoshilogoo Hospital, [3]Amgalan Maternity Specialized Hospital, [4]Mongolian National Univ., [5]National Center for Communicable Diseases, Ulaanbaatar, Mongolia

Objective: Osteoporosis is a major non-communicable disease and the most common bone disease worldwide, affecting one in three women and one in five men over the age of 50. To investigate risk factors for osteopenia and osteoporosis of outpatients in central and suburban district hospitals in Ulaanbaatar.
Methods: The study was conducted using cross-sectional analysis and included 157 participants (124 females, 33 males) over age 40. Outpatients completed a questionnaire on their lifestyles, clinical

information, and measurement BMD within 30–40 min from September 2023 to November 2023. BMD of both hands was measured by DXA. The prevalence of osteoporosis was defined using WHO criteria. Multivariate logistical regression analyses were used to identify osteoporosis predictors.

Results: The study involved 157 outpatients, with an average age of 56.61 ± 11.16. Of the subjects, 59 (37.6%) had normal, 51(32.5%) had osteopenia, and 47(29.9%) had osteoporosis. Age, BMI, and height loss of more than 4 cm were significantly associated with osteoporosis in females and males. Also, comorbidity (rheumatoid arthritis, digestive tract disease) was significantly associated with osteoporosis in both genders. However regular exercise, alcohol consumption, and smoking status were not significantly associated with osteoporosis. After adjusting for age, odds ratios (OR) for osteoporosis remained significantly associated with BMI in both genders (OR, 2,80; p = 0.001; 95%CI (1,19–6,56). However, rheumatoid arthritis (OR, 0,63; p = 0.427; 95% Cl (0,21–1,92), digestive tract disease (OR, 0,50; p = 0.368; 95% Cl (0,11–2,24), and height loss of > 4 cm (OR, 0,43; p = 0.107; 95% Cl (0,16–1,19) had not a significant effect on osteoporosis in participants.

Conclusion: Osteoporosis is associated with the BMI of men and women in Mongolian outpatients. Therefore, these findings provide epidemiological evidence for the early intervention of osteoporosis in patients.

P839
HAND GRIP STRENGTH IN PATIENTS WHO DIAGNOSED WITH TYPE 2 DIABETES MELLITUS IN MONGOLIAN FAMILY HEALTH CENTER

M. Jaalkhorol[1], E. Jamsranjav[1], E. Radnaa[2], B. Bat-Orgil[3], G. Ochirdorj[1], O. Bold[4]

[1]Univ. of National Medical Sciences, [2]Buyant Onoshilogoo Hospital, [3]Singapore School, [4]National Center for Communicable Diseases, Ulaanbaatar, Mongolia

Objective: Despite the many clinical studies in Mongolia, no study has measured the hand grip strength (HGS) of citizens diagnosed with diabetes mellitus. The present study aimed to measure the HGS of people diagnosed with type 2 diabetes mellitus (T2DM) at family health centers in Ulaanbaatar city.

Methods: The study was conducted using a cross-sectional survey and included 347 participants over age 40 who had T2DM in the family health center. Hand grip strength was measured using a digital dynamometer (TKK-5101; Takei Scientific Instruments, Tokyo, Japan). HGS was measured by a handheld dynamometer with maximum effort; two attempts were made with each hand. HGS was defined according to the Asian Working Group for Sarcopenia (AWGS) criteria as low handgrip strength (< 18 kg for females). Relationships between variables were assessed by Pearson's linear correlation coefficient.

Results: We recruited 347 participants whose mean age was 59.87 ± 8.93 y. 59.9% (n = 208) of the participants were women and 40.1% (n = 139) were men. 81.3% of the participants had hypertension, 42.1% had cardiovascular disease, 36.0% had ophthalmic disease, 28.2% had kidney disease, and 26.8% had rheumatoid arthritis. By age group, the grip strength of the right hand in men was the highest in the 40–49 age group (32.23 ± 9.33 kg), while in women the highest was in the 40–49 age group (20.66 ± 5.62 kg). The median male grip strength of the participants was 30.5 kg, with a minimum value of 9 kg and a maximum value of 53 kg, while the average left-hand grip strength was 28 kg, with a minimum value of 2.5 kg and a maximum value of 50 kg. Age and diabetic variables were significantly correlated with handgrip strength in male patients (r = 0.237, p < 0.001). A strong positive correlation was found in females between handgrip strength and pregnancy diabetes (r = 0.865, p < 0.001). Also type 2 diabetes duration, occurrence of leg ulcer and rheumatoid arthritis, and handgrip strength were significantly associated.

Conclusion: The average hand grip strength of both hands significantly differed between age groups, decreasing with age. There were significant sex differences in HGS within each age group, favoring men.

P840
BARRIERS TO IMPLEMENTATION OF ARTIFICIAL INTELLIGENCE ALGORITHM INTO ROUTINE CLINICAL CARE: EXPERIENCES ACROSS 5 NHS TRUSTS IN THE UK

M. K. Javaid[1], D. D. G. Chappell[2], J. Turton[3], J. Boylan[3], J. Threlkeld[4], M. Page[4], M. Sampson[5], Y. Arlachov[6], C. Chisholm[4], R. Eckert[7], E. M. Curtis[8], K. E. S. Poole[2], O. Shalem[9], Y. Kimmel[9], M. Stone[3], R. Pinedo-Villanueva[1], S. Opinder[10]

[1]Univ. of Oxford, NDORMS, Oxford, UK, [2]Cambridge Univ. Hospitals NHS FT, Dept. of Rheumatology, Cambridge, UK, [3]Cardiff and Vale Univ. Health Board, Cardiff, UK, [4]Bradford Teaching Hospitals NHS Foundation Trust, Bradford, UK, [5]Univ. Hospitals Southampton NHS Foundation Trust, Southampton, UK, [6]Nottingham Univ. Hospitals NHS Trust, Nottingham, UK, [7]Oxford Univ. Hospitals NHS Foundation Trust, Oxford, UK, [8]MRC Lifecourse Epidemiology Centre, Univ. of Southampton, Southampton, UK, [9]Nanox AI, Neve Ilan, Israel, [10]Univ. of Nottingham, Dept. of Geriatric Medicine, Nottingham, UK

Objective: Artificial intelligence systems are being used to improve Fracture Liaison Services' identification of patients at very high fracture risk. We describe the governance steps to implement such systems in the UK public healthcare system.

Methods: Five NHS hospitals were selected for the implementation of the Nanox AI solution, which identifies vertebral fractures using existing CT images. A lead clinician in each hospital collaborated with Nanox AI and the University of Oxford to secure both information governance (IG) approval and IT support.

Results: The interval from project start to IG agreement varied from 5 to 13 months. The time from IG agreement to first patient scan analysed was 7 to 12 months with one site still in progress. Each site required a unique set of IG documents: Data Protection Impact Assessment (5/5 sites); Data Protection Agreement (2/5 sites), Digital Technology Assessment Criteria (2/5 sites) as well as other forms (Table). The content for each form varied between sites despite a single NHS template. A pre-installation IT form was sent for completion. IT delays were due to various reasons including working with 3rd party suppliers, availability of NHS IT staff and local capability to generate automatic forwarding rules.

Table. Time to approval & IG forms required by each hospital

Timelines	Hospital A	Hospital B	Hospital C	Hospital D	Hospital E
Date of collaboration agreement	03/23[1]	04/22	04/22	04/22	04/22
Date of DPIA sign off	05/23	09/22	03/23	05/23	10/22
Time from collaboration sign off to local DPIA approval (months)	13[1]	5	11	13	6
Date of first patient forwarded and analysed	12/23	09/23	12/23	TBD	11/23
Time from IG approval to first patient analysed (months)	7	12	9	>8	13

Caldicott approval form					x

DPIA- Data Protection Impact Assessment; DPA- Data Protection Agreement; DTAC- Digital Technology Assessment Criteria

[1]Hospital A did not sign the collaborative agreement until all documents were ready and so the time from the collaborative agreement to DPIA was set from April 2022.

Conclusion: Despite having a single NHS provider for England and Wales and prioritisation of AI, there is considerable variability in the types of IG forms required, IT capacity and capability that prolonged AI implementation. Consideration should be given to a single point of IG approval and central IT resources to optimise AI adoption in the NHS.

P841
REAL-WORLD PERFORMANCE OF AI ENABLED VERTEBRAL FRACTURE (VF) ALGORITHM FOR FRACTURE LIAISON STUDIES: THE ADOPT STUDY

D. D. G. Chappell[1], J. M. Brown[1], V. Sanders[1], J. M. Boylan[2], J. Turton[2], J. Threlkeld[3], M. Sampson[4], M. K. Javaid[5], E. M. Curtis[6], C. Chisholm[3], E. L. Gerety[1], R. Eckert[5], K. E. S. Poole[1], M. Stone[2], N. Harvey[6], T. Santos[4]

[1]Cambridge Univ. Hospitals NHS FT, Cambridge, [2]Cardiff and Vales Univ. Health Board, Cardiff, [3]Bradford Teaching Hospitals NHS FT, Bradford, [4]Univ. Hospitals Southampton, Southampton, [5]NDORMS, Univ. of Oxford, Oxford, [6]MRC Lifecourse Epidemiology Centre, Univ. of Southampton, Southampton General Hospital, Southampton, UK

Objective: Fewer than 30% of vertebral fragility fractures (VFs) present on routine clinical CT scans are reported. As VFs identify patients are often at very high fracture risk, improved identification would lead to a major improvement in FLS performance and clinical impact. We aimed to describe the real-world performance of the Nanox-AI model for VF detection.

Methods: 500 consecutive CT scans were retrieved by 4 sites from 2017 that included imaging of the spine. All patients were assessed for VFs from sagittal imaging by a clinician with local radiologist adjudication. For each scan, the clinician recorded if a VF was present, were VF(s) mentioned in the clinical report and did the clinical report use the term 'vertebral fracture'. These findings were compared with the outputs from the Nanox-AI model at the 'high specificity' (1 site) and 'balanced' (3 sites) settings.

Results: The scans for 2000 patients (49.7% women) were audited from 4 sites. A total 255 (12.8%) VF patients were identified by the local clinical reader. Radiology reports had a sensitivity of 51% and specificity of 100% compared with sensitivity of 79% and specificity of 81.2% in 'balanced' sites and sensitivity of 48.3% and specificity of 98.5% in 'high specificity' site. When comparing scan types, the prevalence of VFs varied from 9.7% for CT pulmonary angiogram to 42.7% for CT abdomen and pelvis. Between hospitals, the prevalence of vertebral fractures varied from 5 to 17%.

Conclusion: A clinically significant care gap remains if sites rely on radiology reporting to identify vertebral fractures. In the real-world setting, opportunistic VF reporting in CT using the Nanox-AI model identified an additional 22.5 patients per 1000 patient scans analysed with important differences by AI setting, scan type and hospital.

P842
BODY COMPOSITION, INFLAMMATION (CRP), AND VITAMIN D STATUS IN MORBIDLY OBESE PATIENTS UNDERGOING BARIATRIC SURGERY: PRELIMINARY RESULTS

M. K. P. Kardum Pejić[1], S. C. A. Cvijetić Avdagić[2], J. P. Pejić[1], M. B. Bituh[3]

[1]Univ. Hospital Dubrava, [2]Institute for Medical Research and Occupational Health, [3]Univ. of Zagreb Faculty of Food Technology and Biotechnology, Zagreb, Croatia

Objective: Obesity is one of the fast growing diseases in the modern world with far-reaching for individuals and societies. Bariatric surgery has become the method of choice for weight loss in severely obese patients. The association of body composition (BC) parameters with the level of vitamin D and C-reactive protein (CRP) as a marker of inflammation were investigated.

Methods: 12 patients (7 women and 5 men) who are being prepared for bariatric treatment were included. During the preparation for the operation, they were put on reduction diet. BC (bone, lean and adipose tissue) was determined by DXA. The measured parameters were: fat mass (FM; % of body weight), android (A) and gynoid (G) fat mass (% of FM) yielding A/G ratio, lean mass (LM; % of body weight), BMD (g/cm^2) yielding T-score. Serum vitamin D (nmol/L) and CRP (mg/L) were analysed and grip strength (lbs.) of both hands was measured. Statistical analyses were performed using nonparametric methods.

Results: The mean age of patients was 41.8 $\pm$ 13.2 y and the mean BMI (kg/m^2) was 43.3 $\pm$ 7.3. One women were in postmenopause. Seven patients (58.3%) had vitamin D deficiency (< 50 nmol/L), while five patients (41.7%) had increased CRP. Women had significantly higher T-score ($p = 0.006$), FM% ($p = 0.009$) and gynoid% ($p = 0.005$) compared to men. Men had significantly higher LM% ($p = 0.045$) and A/G ($p = 0.003$) than women. Significant positive correlation was found between FM% and CRP ($p = 0.049$). Regression analyses showed that, when controlling for age and BMI, CRP and T-score were significant positive predictors of FM% ($p < 0.001$ both). CRP was significant negative predictor of BMD, while grip strength and A/G were significant positive predictor of BMD ($p < 0.001$ both).

Conclusion: In patients treated for morbid obesity, CRP as a marker of inflammation, was significantly associated with higher FM% and lower BMD. In our group of obese patients women had higher BMD than men.

P843
LEVEL OF AWARENESS ABOUT OSTEOPOROSIS IN POSTMENOPAUSAL WOMEN

M. Koroleva[1], M. Letaeva[1], O. Malyshenko[1], J. Averkieva[1]

[1]Kemerovo State Medical Univ., Kemerovo, Russia

Objective: To assess the level and nature of awareness about osteoporosis in postmenopausal women.
Methods: A cross-sectional study was conducted using a questionnaire among postmenopausal women. 150 people took part in the study. The average age of the participants was 66.8 [57.4;73.8] y. The criteria for non-inclusion in the study were: the presence of serious illnesses that could affect the quality of filling out the questionnaires, the refusal or inability of the patient to participate in the questionnaire survey. We aimed to assess awareness of osteoporosis, a questionnaire was developed that includes anthropometric data, information about heredity, lifestyle, bad habits and other risk factors, as well as knowledge about osteoporosis and its prevention.
Results: Most of the women surveyed lead an active lifestyle and engage in physical activity at least 30 min/d (112 people—74.7%). 88.0% of women (132 people) consume milk and dairy products as a source of calcium, 50% additionally take calcium supplements (75 people). It should be noted that only 36.0% of respondents (54 people) take vitamin D supplements. The presence of bad habits, such as smoking and drinking alcohol, was noted by 26.0% and 12.7% of women, respectively. 24.0% of respondents (36 people) have a family history of osteoporosis. A decrease in height by more than 3 cm was noted as one of the symptoms of osteoporosis by 20.7% of respondents (31 people). Only 28.0% of patients (42 people) reported frequent falls, while every third woman has low-traumatic fractures in adulthood (48 people—32.0%). In general, every second woman has 2 or more risk factors for osteoporosis (52.0% of people). The majority of survey participants know what osteoporosis is (112 people—74.7%), but have no idea about the risk factors for AP (120 people—80.0%). 42.0% of women (63 people) are aware of the role of vitamin D in prevention and treatment.
Conclusion: About half of postmenopausal women have 2 or more risk factors for osteoporosis. Based on the results of the survey, a low level of awareness about risk factors and measures to prevent osteoporosis was revealed.

P844
STATE-OF-THE-ART IN HYPOPHOSPHATASIA: RECENT RECOMMENDATIONS FROM INTERNATIONAL WORKING GROUPS

M. L. Brandi[1]

[1]Fondazione FIRMO and Observatory for Fragility Fractures, Florence and Univ. San Raffaele, Milan, Florence, Italy

Hypophosphatasia (HPP) is an inborn error of metabolism caused by reduced or absent activity of the tissue non-specific alkaline phosphatase (TNSALP) enzyme, resulting from pathogenic variants in the ALPL gene. Clinical presentation of HPP is highly variable, including lethal and severe forms in neonates and infants, a benign perinatal form, mild forms manifesting in adulthood, and odonto-HPP. Diagnosis of HPP remains a challenge in adults, as signs and symptoms may be mild and non-specific. Disease presentation varies widely; there are no universal signs or symptoms, and the disease often remains underdiagnosed or misdiagnosed, particularly by clinicians who are not familiar with this rare disorder. The absence of diagnosis or a delayed diagnosis may prevent optimal management for patients with this condition.

The diagnosis of hypophosphatasia (HPP) is made on the basis of integrating clinical features, laboratory profile, radiographic features of the condition, and DNA analysis identifying the presence of a pathogenic variant of the tissue nonspecific alkaline phosphatase gene (ALPL). Often, the diagnosis of HPP is significantly delayed in both adults and children, and updated diagnostic criteria are required to keep pace with our evolving understanding regarding the relationship between ALPL genotype and associated HPP clinical features.

No formal diagnostic guidelines currently existed before for the diagnosis of this condition in children, adolescents, or adults. The International HPP Working Group is a comprised of a multidisciplinary team of experts from Europe and North America who have expertise in the diagnosis and management of patients with HPP.

Following consensus meetings, agreement was reached regarding the major and minor criteria that can assist in establishing a clinical diagnosis of HPP in adults and children.

These results will be presented and discussed at the WCO meeting.

P845
MODIFIABLE RISK FACTORS FOR OSTEOPOROSIS IN YOUNG PEOPLE

M. Letaeva[1], M. Koroleva[1], J. Averkieva[1], O. Malyshenko[1]

[1]Kemerovo State Medical Univ., Kemerovo, Russia

Objective: To evaluate modifiable risk factors for osteoporosis (OP) in young people.
Methods: A one-stage continuous study to study modifiable risk factors (RF) for OP included 543 people, of whom 147 (27.1%) were men and 396 (72.9%) women. The average age was 20.4 [19.0; 21.0] years. To assess the RF for OP, a questionnaire was developed that included questions on nutrition, lifestyle, physical activity, bad habits, history of low-energy fractures, and long-term immobilization.
Results: The survey revealed the following frequency of occurrence of RF for OP: 231 (42.5%) people had one risk factor, 172 (31.7%) people had two, 94 (17.3%) people had three, 42 (7.7%) people—four. Thus, on average, 1.8 RF were identified per respondent. In this study, the majority of respondents (440 (81.1%) people) were found to have insufficient dietary calcium intake. It was found that the average amount of calcium per day from all products was 684.97 ± 109.6 mg, which corresponds to 68.5% of the age norm.
Conclusion: The high prevalence of modifiable RF in young people, which undoubtedly indicates the need for preventive measures to prevent the development of OP and its complications in the future.

P846
ANALYSIS OF THE EFFICACY OF MINIMALLY INVASIVE INTERNAL FIXATION TO PROTECT THE PRONATOR QUADRATUS MUSCLE IN THE TREATMENT OF DISTAL RADIUS FRACTURES

M. Li[1]

[1]Dept. of Orthopaedics, the First Affiliated Hospital of Xi'an Jiaotong Univ., Xi'an, China

Objective: To investigate the curative effect of pronator quadrates protecting minimally invasive internal fixation in treating distal radius fracture.

Methods: Pronator quadrates protecting minimally invasive internal fixation was applied to treat 43 cases of distal radius fractures, and functions of wrist joints were evaluated by aid of Dienst function evaluation table; functions of wrist joints on the uninjured side and the affected side were compared to analyze the curative effect of minimally invasive internal fixation three months after the surgery.
Results: The results of recovery of wrist joint functions evaluated via the Dienst function evaluation table show that there were excellent 38 cases, 4 good cases, 1 qualified case and 0 poor case, with the rate of excellent and good cases reaching 97%. With respect to comparison in the movement of wrist joints on the uninjured side and the affected side (Dorsiflexion $70.2 \pm 1.1°$ vs. $68.2 \pm 2.1°$; palmar flexion $72.1 \pm 3.6°$ vs. $70.2 \pm 4.7°$; radial deviation $20.5 \pm 1.2°$ vs. $19.9 \pm 3.2°$; ulnar deviation $33.6 \pm 5.4°$ vs. $31.2 \pm 2.0°$; pronation $79.5 \pm 4.6°$ vs. $76.2 \pm 2.7°$; supination $78.2 \pm 6.2°$ vs. $75.2 \pm 2.0°$), there was no statistical difference ($P < 0.05$).
Conclusion: Pronator quadrates protecting minimally invasive internal fixation has a positive meaning for the treatment of distal radius fractures. In addition to shortening the operation time and reducing postoperative complications, pronator quadrates protecting minimally invasive internal fixation can also reduce the probability of fracture nonunion, retain the rotation function of patients' forearms to the largest extent, and help patients do functional exercise in the early phase.

P847
PAMIDRONATE USE FOR PAIN IN NON-MALIGNANT NORMOCALCEMIC CONDITIONS

M. Lovy[1]

[1]Desert Oasis Healthcare, Palm Springs, California, USA

Objective: To describe a cohort of patients with painful conditions affecting the bone and the role of pamidronate in their management.
Methods: A chart review of patients who had received intravenous pamidronate for pain control in an outpatient rheumatology and osteoporosis unit over a 7-y period.
Results: The conditions and number of patients receiving varying doses of intravenous pamidronate included: subacute vertebral compression fracture-324, pelvic fracture-62, post radiation pelvic fracture-3, bone marrow edema of the knee-14, bone marrow edema of the ankle-2, reflex sympathetic dystrophy-3, midfoot osteoarthritis-2, scleroderma with massively draining subcutaneous calcification-1, Erdheim-Chester disease-1, histiocytosis-1, Modic deformity-1. The response of pain to pamidronate in subacute vertebral compression fracture at two weeks identified patients who were candidates for kyphoplasty. All patients with pelvic fracture improved with pain control and mobility, although some required a second infusion. Pain relief in patients with bone marrow edema was dramatic and occurred in 2–10 d. When bone marrow edema of the knee was associated with moderate to severe osteoarthritis, patients with no response to pamidronate were referred for knee replacement. Patients with late stages of reflex sympathetic dystrophy did not respond to pamidronate. All the conditions with only 1 patient responded dramatically to pamidronate. Several patients had temporary generalized aching, a few had fever and chills associated with aching and 1 patient had an attack of pseudogout. No serious adverse events occurred.
Conclusion: Pamidronate can be useful in treating the pain and immobility associated with a variety of conditions associated with increased bone turnover or blood flow. The response to pamidronate also aided in decision making in patients with subacute vertebral compression fracture and those with bone marrow edema of the knee associated with osteoarthritis.

P848
HYPERCALCEMIA AND RENAL INSUFFICIENCY RELATED TO GRANULOMATOUS DISEASE CAUSING INCREASED LEVELS OF 1,25-DIHYDROXYVITAMIN D SUCCESSFULLY TREATED WITH LEFLUNOMIDE

M. Lovy[1]

[1]Desert Oasis Healthcare, Palm Springs, California, USA

Objective: To report the use of leflunomide for granulomatous disease causing hypercalcemia.
Methods: Chart review of 2 patients with hypercalcemia and renal insufficiency due to granulomatous disease treated with leflunomide.

Results:

Case 1: 63-year-old man presented comatose due to hypercalcemia and renal insufficiency. Malignancy, sarcoidosis, myeloma, and hyperparathyroidism were excluded. Treatment with pamidronate, ketoconazole and steroids lowered the calcium but hypercalcemia recurred necessitating several re-admissions. Rheumatology consultation noted silicone implants of the buttocks and biceps. Laboratory studies showed calcium 13.1 mg/dL, creatinine 3.3 mg/dL, PTH 10 pg/mL (normal 15–65), 25-dihydroxyvitamin D 37 ng/mL (normal 32–100), 1,25-dihydroxyvitamin D 89 pg/mL (normal 15–56). A presumptive diagnosis of silicone induced granulomatous reaction with unregulated increased conversion of 25-dihydroxyvitamin D to 1,25-dihydroxy vitamin D was made. Leflunomide was prescribed and laboratory studies normalized after discharge.

Case 2: 62-year-old man with sarcoidosis, kidney and bladder stones, renal insufficiency and hypercalcemia was referred for treatment. Serum calcium was 11.3 mg/dL, creatinine 3.1 mg/dL, 25-dihydroxyvitamin D 28 ng/mL, 1,25-dihydroxyvitamin D 75 pg/dL, and PTH 7.8 pg/dL, angiotensin converting enzyme 48 U/L (normal 9–67), and 24 h urinary calcium 359. When he did not respond to low dose prednisone, ketaconazole, and chloroquine, leflunomide was added. The calcium normalized and creatinine stabilized at 2.1 mg/dL. When the patient discontinued the leflunomide after 1 year, hypercalcemia recurred and responded to addition of leflunomide alone.
Conclusion: Leflunomide, a pyrimidine synthesis inhibitor, may be effective in controlling hypercalcemia related to granuloma induced hypercalcemia. Since leflunomide is metabolized in the liver it may be the drug of choice in patients with renal insufficiency.

P849
ROMANIAN INCIDENCE TRENDS AND RATE OF CONSERVATIVELY TREATED HIP FRACTURES 2019–2022

M. M. Bartelick[1], I. M. Pascanu[1], A. I. Gasparik[1]

[1]"George Emil Palade" Univ. of Medicine, Pharmacy, Science and Technology of Targu Mures, Targu Mures, Romania

Objective: The SCOPE 2021 scorecard reports that fragility fractures are suspected to increase by 25% annually for all fracture sites (1). In a 2017 Romanian study, 16.41% of hip fractures were managed conservatively with a significant effect on the hazard ratio for mortality (2). The aim of our study was to evaluate proximal hip fracture incidence trends and demographics in patients $\geq$ 40 years old presenting to the emergency department of the Targu Mures County Hospital, as well as the proportions of patients that refused admittance to the orthopedics department for surgical treatment.

Methods: We conducted a retrospective, single-center study using reports of patients ≥ 40 years old that presented to the emergency department between January 1, 2019 and December 31, 2022 with hip fracture (femoral neck fracture, pertrochanteric fracture, subtrochanteric fracture). Patient demographics, time spent in the emergency department and decision of admittance were recorded.
Results: We observed an annual increase in hip fracture rate between 2019–2022, totaling to a 43.8% increase. In 2019, 23.6% of patients refused admission to the orthopedics department. We observed a decrease of admission refusal rate in the following years: 15.6% (2020), 13% (2021), and 12.5% (2022). The proportion of patients that refused admission was significantly greater in those from rural environments and those with femoral neck fractures in 2019 (χ^2 p = 0.046, p = 0.03). 68% of all patients were female with a mean age of 81.5 ± 9.4 y. Males accounted for 32% of all hip fracture cases with a mean age of 76 ± 12 y. We observed that females were significantly older in all years, but no significant age difference was observed between patients of the same gender in the admission vs. refusal group.
Conclusion: Our results show an increase in hip fracture rate similar to a Romanian study conducted between 2008–2018 that evidenced a 41.5% increase nationwide (3). Although rates of conservatively treated fractures decreased between 2019 and 2022, they continue to be higher than the 3.7–6.2% reported in studies from other countries, leading to a poorer prognosis for Romanian patients (4).

P850
UNDIAGNOSED VERTEBRAL FRAGILITY FRACTURES IN PATIENTS WITH DISTAL RADIUS FRAGILITY FRACTURES: AN OPPORTUNITY FOR PREVENTION OF MORBIMORTALITY IN OSTEOPOROTIC PATIENTS IN DEVELOPING COUNTRIES

M. M. Muzzammil[1]

[1]Sindh Gov. Services Hospital Karachi, Karachi, Pakistan

Objective: To look into the frequency, location, kind, and severity of asymptomatic vertebral fractures (VF) in people who had fractures of the fragility of the distal radius. Although VF is frequently misdiagnosed, it is linked to higher mortality, morbidity, and hip fracture risk. The study also attempted to investigate the relationship between VF and certain demographic and lifestyle factors, as well as FRAX data, in this patient population.
Methods: Between 2021–2022, individuals with low-energy distal radial fractures who presented to the emergency room were the subject of a cross-sectional study. The thoracic and/or lumbar spine was imaged using radiology, and information on demographics, way of life, and FRAX was gathered. Using the Genant semiquantitative approach, an impartial and blinded orthopaedist identified VF in the images and determined their severity. SPSS version 20 was used to analyse the data.
Results: 211 (41.21%) of them were found to have radiographic VF and Only 12 (2.34%) of the 512 patients who were tested were getting osteoporotic therapy. The thoracic spine (32.7%), followed by the lumbar spine (43.12%), was the area most frequently afflicted. In 24.17% of the patients, multiple fractures of the thoracolumbar spine were found. The wedge form, followed by biconcave and crush, was the most prevalent VF type. The majority of detected VF were rated as having a 25–40% height loss, then severe (> 40%) fractures, according to the Genant grading method. Notably, there were no variations in smoking, drinking, BMI, or FRAX score between patients with and without VF that were statistically significant.
Conclusion: According to the study's findings, osteoporotic vertebral fractures occur in nearly half of individuals with distal radius fractures. The most frequently affected region is the lumbar spine, and wedge fractures are the most typical kind. Due to their high fall risk, these patients need extensive fall risk assessments and the proper treatments to increase their BMD and strength. In this patient population, identifying asymptomatic VF can help with better care and the avoidance of further problems.

P851
REVOLUTIONIZING OSTEOPOROTIC DISTAL RADIUS FRACTURE CARE IN ASIA: TERIPARATIDE'S SWIFT ACCELERATION OF HEALING IN A PIONEERING DOUBLE-BLINDED TRIAL

M. M. Muzzammil[1]

[1]Sindh Gov. Services Hospital Karachi, Karachi, Pakistan

Objective: As the Asian population experiences rapid aging, osteoporosis emerges as a prominent and costly health concern. Distal radius fractures, among the most prevalent fractures, are associated with an elevated risk of subsequent fractures. The swift attainment of union is crucial for the early resumption of daily activities and the mitigation of complications. Although teriparatide has demonstrated efficacy in accelerating fracture healing, there is a dearth of literature on its application in osteoporotic distal radius fractures among the Asian population. This study aims to evaluate the potential of teriparatide in expediting fracture healing.
Method: A double-blinded randomized controlled trial, conducted from January 2015 to June 2019, included patients with extra-articular osteoporotic distal radius fractures managed conservatively with casting. The primary objective was to compare the impact of 8 weeks of once-daily subcutaneous teriparatide (20 μg) vs. a placebo on the time to radiographic healing. Radiographic healing was defined by cortical bridging in three of four cortices, with secondary objectives including the time to healing of four cortices, assessment of anatomic deformity, and functional evaluations. Patients underwent screening on the day of the fracture, followed by randomization, an 8-week treatment period, an 8-week follow-up, and a safety extension for an additional 36 weeks.
Results: Out of 214 screened patients, 202 women were enrolled, with 12 discontinuing before or during treatment. The remaining 202 women were randomly assigned to once-daily placebo (n 107) or 20 mg teriparatide (n 107). The median time to healing was significantly shorter in the teriparatide group (95%CI 2.5 to 0.7 weeks, p.005), with no significant between-treatment differences in secondary objectives. Both groups exhibited significant improvements in pain scores, functional tests, and grip strength compared to baseline.
Conclusion: This study demonstrates that teriparatide (20 μg) accelerates the time to healing in conservatively managed distal radius osteoporotic fractures. Additionally, there were significant improvements in pain scores, functional tests, and grip strength after the 8-week treatment period. This suggests the potential for teriparatide to enhance fracture repair in this population.

P852
CLINICAL CORRELATES OF NUTRITIONAL STATUS AND PONSETI TECHNIQUE SUCCESS IN CLUBFOOT PATIENTS

M. M. Muzzammil[1]

[1]Sindh Gov. Services Hospital Karachi, Karachi, Pakistan

Objective: Malnutrition is a critical health issue, particularly prevalent in developing countries, and is a major risk factor for diseases and mortality in children. Clubfoot or congenital talipes equinovarus (CTEV) is a common form of congenital orthopedic abnormality, and the Ponseti method has become the gold standard for its treatment over the last two decades. The primary objective of this study was to determine the prevalence of malnutrition in clubfoot patients and its impact on the outcome of the Ponseti technique in patients presenting to the Orthopedic Clinic of a tertiary care hospital in Karachi, Pakistan. Additionally, we aimed to assess the correlation between clinical tests, such as CBC, serum albumin levels, serum electrolytes, and nutritional status.
Methods: We conducted a cross-sectional study from January to December 2018, including a total of 153 clubfoot patients. The WHO classification of weight-for-age index was used to assess the nutritional status of patients, and clinical tests were also conducted to evaluate the correlation between malnutrition and the outcome of the Ponseti technique. Statistical analysis was performed with a P value ≤ 0.05 deemed significant.
Results: Of the 153 patients, 121 (74.5%) were in good nutritional status, while 32 (25.5%) were malnourished. The average number of casts required per patient and the proportion of patients requiring 6 or more casts were higher in the malnourished group (45.5 vs. 21.42%). The number of Achilles tenotomy procedures performed in the malnourished group was also higher (76.4 vs. 51.8%). Clinical tests showed a direct correlation between nutritional status and outcomes of the Ponseti technique.
Conclusion: Our study reveals a significant correlation between patients' nutritional status and the outcome of the Ponseti technique. Malnutrition can lead to an increased number of casts required for treatment and a higher likelihood of relapse and failure of treatment. The study also highlights the importance of clinical tests in evaluating the nutritional status of patients and its correlation with the outcomes of the Ponseti technique.

P853
UNVEILING THE BURDEN: VERTEBRAL FRACTURE PREVALENCE AND TERIPARATIDE'S IMPACT ON POSTMENOPAUSAL PATIENTS WITH CHRONIC BACK PAIN IN A DEVELOPING NATION

M. M. Muzzammil[1]

[1]Sindh Gov. Services Hospital Karachi, Karachi, Pakistan

Objective: To investigate the incidence and consequences of vertebral fractures (VF) in postmenopausal individuals experiencing chronic, nonspecific backaches at two tertiary healthcare facilities in Karachi, Pakistan. The escalating prevalence of osteoporosis among the aging Asian population poses a significant health threat, with recurrent fractures often associated with vertebral fractures.
Methods: A cross-sectional examination involved 200 postmenopausal patients aged 45 and older, experiencing persistent, nonspecific back pain during 200 consecutive outpatient visits from June 2020 to December 2022. The study explored the link between prior vertebral fractures and the risk of future fractures in postmenopausal women. Randomly assigned to receive daily placebo or teriparatide as part of the Fracture Prevention Trial (20 g), participants were observed for an average of 24 months.
Results: Among the 200 participants (mean age 65, SD 14.14), 112 individuals (56%) exhibited radiological vertebral fractures. The wedge type was predominant, affecting the thoracic spine (45.53%) and lumbar spine (30.35%). Multiple thoracolumbar spine fractures occurred in 24.10% of cases. Genant's grading identified most fractures as mild. Teriparatide-treated participants showed no significant increase in fracture likelihood, while the placebo group exhibited a higher prevalence of vertebral fractures ($P < 0.001$) and nonvertebral fractures (9%).
Conclusion: This study underscores the heightened risk of vertebral fractures in postmenopausal women with chronic back pain. The number of prior nonvertebral fractures predicts future nonvertebral fractures, and the severity of current vertebral fractures independently forecasts future vertebral fractures. Early detection and treatment of vertebral fractures in this vulnerable population are crucial to mitigate the risk of further fractures and associated morbidity.

P854
TERIPARATIDE INTERVENTION IN STEROID-INDUCED OSTEOPOROSIS: UNVEILING THE PREVALENCE, CHARACTERISTICS, AND THERAPEUTIC IMPACT ON VERTEBRAL FRACTURES

M. M. Muzzammil[1]

[1]Sindh Gov. Services Hospital Karachi, Karachi, Pakistan

Objective: This study explores the prevalence and management of vertebral fractures (VF) resulting from steroid-induced osteoporosis, with a specific focus on the role of teriparatide. We investigate the impact of long-term glucocorticoid therapy on VF, characterize their occurrence, severity, and location, and assess the efficacy of teriparatide in managing these fractures. We aimed to determine the prevalence of asymptomatic vertebral fractures, characterize their location, type, and severity, and evaluate the role of teriparatide in managing fractures in patients on long-term glucocorticoid therapy.
Methods: This cross-sectional study involved screening 415 patients on prolonged steroid therapy for eligibility. Data collection included demographic, lifestyle, and FRAX information, along with radiological imaging of the thoracic and lumbar spine. An independent orthopedist, blinded to patient details, reviewed images for VF and utilized the Genant semiquantitative method for severity quantification. Additionally, the study explored the relationship between prior fractures and the risk of new fractures.
Results: Among the screened patients (mean age 45.3 ± 25.12 y), 65.30% exhibited radiological VF. The thoracic spine (52.02%) was the most affected location, with wedge fractures being the most prevalent type. Teriparatide significantly reduced new VF compared to the placebo group. The study also observed prior fracture healing, as evidenced by reduced pain scores and improved quality of life in the teriparatide group.
Conclusion: This study underscores a high prevalence of VF in patients on long-term glucocorticoid therapy, emphasizing an increased risk of new VF and non-VF. Teriparatide emerges as a promising treatment option, demonstrating greater increases in BMD and significantly fewer new vertebral fractures. The findings suggest teriparatide's potential effectiveness in managing vertebral fractures secondary to steroid-induced osteoporosis, particularly in developing countries.

P855
EMERGENCE OF LEUCOCYTIC EXTRACELLULAR TRAPS IN EARLY RHEUMATOID ARTHRITIS

M. Mamus[1], A. Trofimenko[1], S. Bedina[1], E. Mozgovaya[1], S. Spitsina[1]

[1]Clinical Biochemistry Lab, Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky, Volgograd, Russia

Objective: Disease mechanisms underlying induction of autoimmune response to cartilage and synovial antigens, especially their citrullinated modifications are of particular interest by entire rheumatologic community [1]. Extracellular traps of neutrophils and monocytes can be considered as their candidate source. Objective is to perform comparative analysis of extracellular traps generation by circulating monocytes and neutrophils from RA patients and healthy controls.
Methods: 15 adult patients with verified RA, disease history less than 2 years, and DAS28 score not exceeded 2.6 were included in the study. 15 healthy volunteers were included in the control group. Circulating monocytes were isolated using centrifugation of buffy coat over specific density gradient. Neutrophils were isolated with in-house one-step centrifugation procedure using double-layer density gradient. The leucocyte types were identified by light microscopy, and its activation was quantified by NBT test. The generation of monocyte and neutrophil extracellular traps (ETs) was stimulated by PMA. Morphological features of ETs were assessed using fluorescence microscopy with SYBR green. Results are expressed as percent of netting cells in smear. Central tendencies are expressed as means (95%CI).
Results: Mean age of RA patients was 56.2 y, mean disease duration was 1.4 y. Mean purity of monocyte and neutrophil fraction in RA group was 98.8% and 93.3%, respectively, cell viability in every sample was above 97.7% and 95.0%, respectively. Both monocyte and neutrophil fractions exhibiting ETs spontaneously were significantly larger in RA than in control group while ET-producing monocyte fraction was slightly larger than its neutrophil counterpart in RA (8.4 (6.6–12.0)% and 7,7 (5,9–9,5)%, respectively. Induced ET production by both cell types was also significantly higher in RA, being somewhat higher for monocytes comparing to neutrophils.
Conclusion: Substantial growth of ET generation by circulating neutrophils and monocytes has been demonstrated in our research. The obtained data suggest ETs participation in RA pathogenesis presumably through exhibition their citrulline neoepitopes.

IN VITRO CARDIOLIPIN ANTIBODY REMOVAL IN SLE-ASSOCIATED APS USING SPECIFIC MAGNETIC ADSORBENT PARTICLES

M. Mamus[1], A. Trofimenko[1], O. Emelyanova[1], S. Spitsina[1]

[1]Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky, Volgograd, Russia

Objective: Tissue damage by circulating antiphospholipid antibodies and respective immune complexes is a prominent pathogenetic factor in SLE-associated secondary APS. Due to significant risk of acute exacerbations, including catastrophic APS, development of new extracorporeal autoantibody sorption protocols can be of great practical importance. The objective is assessment of sorption efficiency of circulating anti-cardiolipin antibodies as well as concomitant blood cell damage after in vitro blood perfusion through original immobilized cardiolipin adsorbent.
Methods: Magnetic polyacrylamide beads with immobilized cardiolipin were synthesized beforehand by in-house developed technique [1] and placed in a perfusion microcolumn immediately prior to perfusion procedure. 63 adult patients with verified both SLE and APS were included in the study. Single samples of heparinized blood (50 ml) were obtained during in-hospital treatment of SLE exacerbation, split in half and immediately perfused through the packed column using peristaltic pump at 25 ml/h. Control perfusion was performed through column with activated charcoal. Concentrations of anticardiolipin antibodies were measured by ELISA before and after perfusion. Circulating immune complexes were quantified by PEG precipitation assay.
Results: Mean anti-cardiolipin antibody concentration after perfusion through magnetic polyacrylamide beads with immobilized cardiolipin was 2.77 times lower than initial ones ($p < 0.001$). Mean immune complex concentration decreased from 12.4 ± 1.2 to 4.6 ± 0.5 U ($p < 0.001$). Mean decrease of anti-cardiolipin antibody concentration after perfusion through the charcoal (1.18 times lower) as well as immune complex levels were not significant. Decrease of blood cells after perfusion through the magnetic beads was negligible unlike their counterparts after perfusion through activated charcoal.
Conclusion: Blood treatment by magnetic polyacrylamide beads with immobilized cardiolipin effectively removes highly pathogenic antiphospholipid antibodies and immune complexes from the circulation, preserving blood cells from concomitant damage. These features of the magnetic carrier are particularly significant in APS due to demand for recurrent extracorporeal therapy.

P857
ANALYTICAL PERFORMANCE OF ADVANTAGEOUS ANTI-DNASE I ELISA ASSAY FOR SLE DIAGNOSTICS

M. Mamus[1], A. Trofimenko[1], S. Bedina[1], E. Mozgovaya[1], S. Spitsina[1]

[1]Clinical Biochemistry Lab, Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky, Volgograd, Russia

Objective: Routine laboratory markers for SLE verification have insufficiently high diagnostic performance, being based primarily on classical ELISA, IIF or western blotting protocols. Another sound practical disadvantage is relatively high price of all these tests. Development of innovational immunodiagnostic tools as well as searching for new SLE biomarkers is thus of profound practical interest. Our objective is to compare analytical performance of anti-DNase I antibodies quantified by classical ELISA with anti-DNase I assay based on magnetic carrier technology.
Methods: 54 patients with verified SLE and 52 control patients with another rheumatic conditions were analyzed in the study. Common anti-DNase I ELISA protocol was made as published previously [1]. Synthesis of magnetic beads covered with DNase I and modified ELISA with these beads were made as previously described [2]. Antibody levels are indicated as optical density units.
Results: Cutoff points for the regular and upgraded ELISA were 0.061 and 0.057 units, respectively. Average anti-DNase I levels of SLE patients were significantly higher comparing to controls. There were minute differences between average anti-DNase I concentrations measured by two studied protocols in both groups. Sensitivity and specificity of the upgraded ELISA were 65% and 85%, respectively, being coincided almost perfectly with their counterparts obtained by conventional ELISA. LOQs and CVs for two assessed ELISAs were also indistinguishable. Repeatability of two analyzed protocols by means of Bland–Altman plot revealed no substantial divergence

within entire range of concentrations. Accuracy and repeatability of improved ELISA were somewhat higher than for the common approach. Usage of single reactivated magnetic carrier led to characteristics of modified ELISA similar to newly synthesized beads.
Conclusion: Analytical performance of modified anti-DNase I ELISA is virtually equivalent to common ELISA technique, having nevertheless some economic advantages.

P858
ANTI-ELASTIN ANTIBODIES AND ITS APPLICABILITY IN SLE DIAGNOSTIC SEARCH

M. Mamus[1], A. Trofimenko[1], O. Emelyanova[1], S. Spitsina[1]

[1]Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky, Volgograd, Russia

Objective: The importance of researching elastin in SLE is determined by its high prevalence as the main protein component of elastic fibers in wide variety of organs and tissues including ligaments, skin, blood vessels. Preserved function of elastic fibers exerts substantial influence on proper performance of cardiovascular and musculoskeletal system. Autoimmune inflammation mediated by specific anti-elastin antibodies is a candidate factor of damage in these tissues needed to be thoroughly studied in SLE. Objective is to analyse clinico-immunological interrelations involving serum anti-elastin antibodies.
Methods: 56 adult patients with verified SLE were included in the study during their in-hospital treatment. We assessed disease activity using ECLAM scale. 30 healthy volunteers were enrolled as controls. Synthesis of magnetic beads covered with elastin and modified ELISA with these beads were made as previously described [1]. Antibody levels are indicated as optical density units. Results were stated as means $\pm$ standard errors, differences were considered significant when $p < 0.05$.
Results: Average age of SLE patients was 42.6 ± 12.1 y. Average ECLAM score was 10.2 ± 6.7 points (from 2 to 28 points). Cutoff value for positive anti-elastin antibody results was calculated to be 0.102 units. 30 (53.3%) SLE patients were found to be anti-elastin positive whereas no positive cases were revealed in control group. Mean concentration of serum anti-elastin antibodies in SLE was 0.138 ± 0.067 units. Skin and vascular involvements are demonstrated to be associated with serum anti-elastin positivity ($p = 0.010$ and $p < 0.001$, respectively). There was positive correlation between the antibody levels and ECLAM score ($r = 0.379$, $p = 0.030$).
Conclusion: Serum anti-elastin antibodies are revealed to be common SLE feature, which depends on disease activity and some clinical manifestations. Tissues having prominent elastin abundance like skin and vessels are thought to be frequently involved in autoimmune inflammation caused by specific anti-elastin antibodies.
Reference: (1) Gontar IP, et al. An approach for removal of DNA-containing immune complexes from blood using composite sorbent. Patent RU2441674 (2010) [in Russian].

QUALITY OF LIFE IN PATIENTS WITH CALCIFYING TENDINITIS OF THE SHOULDER ROTATOR CUFF TREATED WITH EXTRACORPOREAL SHOCKWAVE THERAPY AND CONVENTIONAL PHYSICAL THERAPY

M. Manoleva[1], E. Erieta[1], V. Koevska[1], B. Mitrevska[1], C. Gjerakaroska Savevska[1], M. Gocevska[1], B. Kalcovska[1], D. Gechevska[1], L. Malinovska Nikolovska[2]

[1]Univ. Clinic For Physical Medicine And Rehabilitation, Faculty Of Medicine, Ss. Cyril And Methodius Univ., [2]Acibadem Sistina Clinical Hospital, Dept. of Pediatric Cardiac Surgery, Skopje, North Macedonia

Objective: Calcific tendinitis of the shoulder rotator cuff is a common disorder of unknown etiology. It is commonly treated with various physical treatment modalities where extracorporeal shockwave therapy (ECTUB) is emerging as an effective method. The main objective of this clinical study is to evaluate and compare the quality of life of ECTUB treatment and conventional physical therapy treatment in patients with calcific tendinitis of the shoulder rotator cuff.
Methods: The research was a prospective, monocentric clinical study that included 80 patients with calcific tendinitis of the shoulder rotator cuff who were divided into two groups: group 1 (study group), 40 patients who received ECTUB, 5 treatments were applied, once a week, with continuous frequency, pressure 3.0 Bar, frequency 12 Hz, number of strokes—3000, duration of treatment 7 min; and group 2 (control group), 40 patients who received conventional physical treatment, ultrasound therapy with an intensity of 0.5 W on an area of 1 cm^2, for 5 min, and diadynamic currents, for a duration of 3 weeks, every working day, namely 15 treatments of therapeutic ultrasound and 10 treatments of diadynamic currents. Both groups performed shoulder exercises simultaneously with the physical treatment. The efficacy of the treatment was evaluated using the Questionnaire for quality of life in patients with shoulder rotator cuff disease (RC-QOL). Clinical findings were evaluated at the same time in four time points for patients in both groups: before starting physical therapy, immediately after the end of the therapy, after the third and the sixth month after starting physical therapy.
Results: All patients after the treatment had statistically significantly better results in the both groups in the RC-QOL, but according to the obtained results, based on the scores of the RC-QOL scale, patients in the study group at the end of follow-up, i.e., 6 months after the start of treatment, had a significantly better quality of life than patients in the control group.
Conclusion: ECTUB is a safe and noninvasive treatment that improves quality of life in patients with calcifying tendinitis of the shoulder rotator cuff.

P860
ANTINUCLEAR ANTIBODY IN RHEUMATOID ARTHRITIS

M. Masko[1]

[1]Vitebsk State Medical Univ., Vitebsk, Belarus

Objective: Antinuclear antibodies (ANA) or anti-cellular (ACA) are a heterogeneous group of autoantibodies directed against various cellular antigens. ANA positivity is noted in many autoimmune diseases, and can be concern as universal test in the examination of patients with autoimmune pathology. The aim of work was to assess

by indirect immunofluorescence (IIF) the incidence and types of ANA in patients with rheumatoid arthritis (RA) and to evaluate their diagnostic value.
Methods. In the study were included 270 patients, which fulfill EULAR/ACR 2010 criteria for RA and 50 healthy controls. The mean of patients age was 52.80 y (95%CI: 51.70–54.80 y). Levels of antibodies to anti-CCP were evaluated by ELISA according to the instructions of the manufacturer (Euroimmune, Germany). Levels of rheumatoid factor (RF) were assessed by kinetic nephelometry using an automatic analyzer Beckman Coulter (USA). The presence of ANA was determined by IIF on the automated system AKLIDES (Medipan, Germany). In samples with a positive ANA result, antibodies to specific nuclear antigens (SS-A 52, SS-A 60, SS-B, ds-DNA, CENP-B, Sm, RNP/Sm) were determined on the platform AKLIDES Cytobead.
Results: Anti-CCP in patients were found 209 (77.41%) patients, RF in 192 (71.11%) patients, ANA in 99 (36.67%) patients. The incidence of anti-CCP, RF and ANA in RA was significantly higher than in healthy individuals ($p < 0.05$). Speckled pattern was the most frequent. Positive results of determination of specific autoantibodies to at least 1 nuclear antigen were found in 39.47% of ANA-positive patients. Antibodies to SS-A60 antigen (31.57% of patients) were the most common in RA, other autoantibodies were found with a lower incidence. We analyzed by ROC – analysis the possibility of ANA test to discriminate seronegative by anti-CCP and RF RA patients from healthy controls. The diagnostic sensitivity was 54.55% (95%CI: 23.5–83.1%), specificity was 100.00% (95%CI: 88.7–100.0%), area under ROC curve was 0.773; 95%CI: 0.617–0.887, $p = 0.0026$). There were no significant differences in clinical (DAS 28, CDAI, SDAI, treatment options) and laboratory characteristics (ESR, CRP, anti-CCP, RF levels) between ANA-positive and ANA-negative patients ($p > 0.05$). However, systemic manifestations were observed three times more often in ANA-positive RA (31.57 vs. 8.95%, $p = 0.0073$).
Conclusion: ANA occurs in a third of patients with RA, indicating the intensity of autoimmunity in RA. ANA may serve as additional laboratory biomarker for seronegative RA to allow to close the seronegative RA gap. Standardized evaluation of ANA by IIF allows to obtain comparable data without the influence of subjective factors, which greatly simplifies the research of ANA as a diagnostic and prognostic biomarker in RA.

P861
DOES BARIATRIC SURGERY CHANGE PHYSICAL PERFORMANCE AND FUNCTIONAL STATUS?

M. Małek[1], K. Piotrowicz[1], J. Gąsowski[1], M. Fedyk-Łukasik[1], A. Rudzińska[1], P. Major[2], B. Gryglewska[1]

[1]Dept. of Internal Medicine and Gerontology, Jagiellonian Univ. Medical College, [2]2nd Dept. of General Surgery, Jagiellonian Univ. Medical College, Kraków, Poland

Objective: To assess changes in functional status, muscle strength and physical performance in patients 6 months after bariatric surgery.
Methods: In 77 patients, before and six months after bariatric surgery, we collected basic demographic data, information on the components of the SARC-F, administered the Global Physical Activity Questionnaire (GPAQ) and performed basic anthropometric measurements. We assessed muscle strength in both the dominant and nondominant hand (HGS) and with the five times sit-to-stand test (5xSTS); physical performance was assessed with the usual gait speed (GS) test. In groups divided by sex and age (< 50 y and 50 + y), the Wilcoxon signed rank test was used for data with nonstandard distributions and the paired t-test for data with standard distributions (SPSS 9.0).
Results: Mean (SD) age was 41.0 (10.6) y, 68.8% women; median (Q1-Q3) BMI before surgery was 41.5 (39.5–46.1) kg/m^2. Significant decreases in anthropometric parameters (BMI, waist circumference, mid-arm and calf circumferences on the dominant side) were observed in all groups 6 months after surgery. A significant decrease in dominant hand HGS was observed in male [47.0 (37.0–53.5) vs. 44.0 (36.5–51.5) kg, $p = 0.046$] but not in female patients. For 5xSTS, significant improvement was observed in females [10.9 (9.4–12.4) vs. 10.0 (8.8–11.0) s, $p < 0.001$] and younger participants [10.2 (9.2–11.8) vs. 9.6 (8.5–10.9) s, $p = 0.007$]. GS improved after the surgery in all participants [females 1.2 (1.0–1.3) vs. 1.4 (1.3–1.5); males 1.1 (1.0–1.2) vs. 1.3 (1.2–1.5); younger participants 1.2 (1.0–1.3) vs. 1.4 (1.3–1.5); older participants 1.0 (0.9–1.2) vs. 1.2 (1.2–1.4) m/s; all $p < 0.001$]. Except for the walking domain of the SARC-F in younger participants, subjective performance as assessed by the SARC-F questionnaire improved in all groups.
Conclusion: Subjective improvement in functional status was reported by patients six months after bariatric surgery. All participants improved their usual walking speed. Patterns of changes in muscle strength varied, men decreased their dominant hand HGS, women and younger participants improved 5xSTS results.

P862
DOES THE PENNATION ANGLE OF THE RECTUS FEMORIS MUSCLE CHANGE AFTER BARIATRIC SURGERY?

M. Małek[1], K. Piotrowicz[1], J. Gąsowski[1], M. Fedyk-Łukasik[1], A. Rudzińska[1], S. Perkisas[2], P. Major[3], B. Gryglewska[1]

[1]Dept. of Internal Medicine and Gerontology, Jagiellonian Univ. Medical College, Kraków, Poland, [2]Univ. Center for Geriatrics, Univ. of Antwerp, Antwerp, Belgium, [3]2nd Dept. of General Surgery, Jagiellonian Univ. Medical College, Kraków, Poland

Objective: To evaluate the changes in the pennation angle (PA) of the rectus femoris muscle and its homogeneity, measured by ultrasound, 6 months after bariatric surgery.
Methods: The pennation angle of the rectus femoris muscle, defined as angle between muscle fiber and deep fascia, was measured by ultrasound before and after surgery in 59 bariatric surgery patients. Measurements were done according to the SARCUS protocol for standardising the use of ultrasound in muscle assessment. Ultrasound was performed using a Phillips Affinity 70G ultrasound machine and an L12-3 linear probe with a frequency of 3–12 MHz. Standard procedure involved three measurements in each participant and, to further assess PA heterogeneity, patients whose scores varied by > 1.5 degrees were given 3 additional measurements. The mean values were analysed. Additionally, dispersion of the pennation angle (dPA) was calculated by subtracting the minimum pennation angle result from the maximum. Changes in PA and dPA in groups divided by sex and age (< 50 y and 50 + y) were calculated using the Wilcoxon signed rank test (SPSS 9.0).
Results: We included 59 patients of the mean (SD) age of 40.1 (11.3) y, 74.6% women; the median (Q1-Q3) BMI was 41.5 (39.5–44.6) and 43.9 (39.7–49.2) kg/m^2 for women and men, respectively. Significant increase of PA was observed after the surgery in all analysed groups: for women the median value (Q1-Q3) was 9.9 (8.6–10.8)° vs. 11.3 (9.3–11.9)°, $p = 0.007$; for men 9.6 (8.6–10.5)° vs. 11.8 (10.0–14.0)°, $p < 0.001$; for participants < 50 years old 9.6 (8.5–10.4)° vs. 11.3 (9.5–12.1)°, $p < 0.001$; for participants 50 + years 10.5 (9.8–11.6)° vs. 11.7 (11.1–13.5)°, $p = 0.033$. There were no significant differences in the dPA levels found in any of the groups.
Conclusion: Although the pennation angle of the rectus femoris measured by ultrasound increased six months after bariatric surgery, we did not observe an improvement in the homogeneity of its values.

The role of the pennation angle, its homogeneity and its clinical implications as a surrogate measure of skeletal muscle quality require further investigation.

P863
BONE MINERAL DENSITY POST-TREATMENT FOLLOW-UP IN WOMEN WITH ENDOMETRIOSIS TREATED WITH RELUGOLIX COMBINATION THERAPY: SPIRIT PROGRAMME

M. McClung[1], N. Johnson[2], S. L. Ferrari[3], J. S. Perry[4], Y. Zhong[5], R. B. Wagman.[5]
[1]Oregon Osteoporosis Center, Portland, USA, [2]Robinson Research Institute, Auckland, New Zealand, [3]Univ. of Geneva, Geneva, Switzerland, [4]Sumitomo Pharma American Inc., Brisbane, USA, [5]Sumitomo Pharma America Inc., Brisbane, USA.

Objective: To evaluate BMD changes in women with endometriosis (EM)-associated pain who met prespecified bone loss criteria with relugolix combination therapy (Rel-CT: relugolix 40 mg, estradiol 1 mg and norethisterone acetate 0.5 mg) in the SPIRIT long-term extension (LTE) and underwent post-treatment follow-up (PTFU).

Methods: In the pivotal SPIRIT 1/2 studies, premenopausal women (18–50 y) with moderate-to-severe EM-associated pain were randomised 1:1:1 to receive once-daily Rel-CT, placebo or delayed Rel-CT (relugolix monotherapy/Rel-CT, 12 weeks each) for 24 weeks. Completers could enroll in the 80-week SPIRIT LTE to receive open-label Rel-CT for up to 104 weeks. BMD change was measured by DXA. Women who met protocol-specified BMD loss criteria compared with pivotal study baseline by Week104/the end of treatment were referred for PTFU DXA. BMD recovery was assessed with DXA at month (M)6 and M12 after treatment cessation. Women not meeting the recovery threshold at M6 ($\leq$ 1.5% at the lumbar spine and $\leq$ 2.5% at the total hip) were recommended for an additional scan at M12. BMD percent change from pivotal baseline to last on-treatment, M6 and M12 post-treatment, and last PTFU were summarised by anatomical location.

Results: Of 802 women who entered SPIRIT LTE, 171 (21%) women had protocol-specific BMD loss or BMD loss $>$ 3% at the lumbar spine or total hip as compared with pivotal study baseline. Of women with BMD loss and underwent M6 or M12 PTFU at lumbar spine, there was evidence of recovery ($>$ 0% change from last on-treatment DXA) to M6 or M12 PTFU DXA in 27/27 (100%) women previously treated continuously with Rel-CT, and in 21/28 (75%) women initially treated with placebo. Similar trends were observed at the total hip.

Conclusion: In women with EM-associated pain who met prespecified BMD loss criteria in the SPIRIT LTE, there was recovery or trend towards recovery after treatment cessation in all women who received continuous Rel-CT therapy for up to 2 years and in most women who transitioned from placebo to Rel-CT. The benefit/risk profile of Rel-CT remains favourable in women with EM for longer-term treatment.

P864
ANTERIOR KNEE PAIN AFTER RECONSTRUCTION OF ANTERIOR CRUCIATE LIGAMENT

M. Milankov[1], V. Krstic[2], N. Vukosav[3], M. Bjelobrk[3]
[1]Poliklinika Milankov Med, [2]Poliklinika Sport Medica, [3]Dept. of Orthopaedic Surgery and Traumatology, Clinical Center Vojvodina, Medical Faculty of Novi Sad, Novi Sad, Serbia

Objective: Anterior knee pain is one of the most common complications after anterior cruciate ligament reconstruction with bone tendon bone autograft. Anterior knee pain can disturb rehabilitation protocol and also can lead to inability to perform activities of daily living and return to sports activities. The aim of this study was to determine the influence of gender, age, side of injury, cause of injury and type of sports activity on the occurrence of anterior knee pain after reconstruction of anterior cruciate ligament, also to determine the impact of time from injury to returning to activities.

Methods: Study was designed as a retrospective study of 967 patients who underwent arthroscopic reconstruction of the anterior cruciate ligament(Table 1). It took an average of 5 months (4–12) from the knee surgery to the start of running, and 8 months to the start of training. And it took an average of 10 months (6–12) before full competitive activity.

Results: After physical activity, 34% of respondents never feel pain, 31% feel rarely, 24% feel pain sometimes, 7% of respondents feel pain often, while 4% of respondents feel pain always. There is a low but positive statistically significant association (rho Spearman coefficient) between the frequency of pain and the time from knee surgery to the start of running (rho = 0.114, p = 0.000), to the start of training (rho = 0.115, p = 0.000) and the start of full competitive activity (rho = 0.155, p = 0.000) at the $p < 0.01$ level of statistical significance.

Table 1. Demographic data

		Frequency	Percentage (%)
Gender	male	771	79,7
	female	196	20,3
Age	14-18	130	13,4
	19-25	347	35,9
	26-35	325	33,6
	36-45	142	14,7
	45-59	23	2,4
Side of injury	Right knee	524	54,2
	Left knee	413	42,7
	Both knee	30	3,1
Mode of injury	Sports activity	924	95,6
	A walk	27	2,8
	Traffic accident	16	1,7
Type of activity	Professional athlete	372	38,5
	Recreational	547	56,6
	A non-athlete	48	5
Level of sports activity	International	109	11,3
	Republican	189	19,5
	Regional	199	20,6
	Recreational	424	43,8
	A non-athlete	46	4,8

Conclusion: Anterior knee pain is not affected by sex, age, side of injury, cause of injury, type of sports activity. There is a statistically significant correlation between anterior knee pain and time from reconstruction to returning to sports activities. Anterior knee pain

occurs already in the early stages of recovery, disturbs the rehabilitation protocol and leads to a slower return to sports activities.

P865
BENIGN NEUTROPENIA IN ORTHOPEDICS: A DEVELOPING WORLD PERSPECTIVE

M. Milenkovic[1], J. Milenkovic[2]

[1]Czech Rehabilitation Hospital, [2]Cleveland Clinic, Abu Dhabi, United Arab Emirates

Infection complications in orthopedic surgery can impose significant costs and reduce quality of life. Neutropenia is a known risk factor for infection and delayed wound healing. Recent studies have revealed a high prevalence (10–20%) of neutropenia in several populations, most notably of the Middle East and African countries. This is due to a condition called benign ethnic neutropenia (BEN) which is genetically determined (also known as familial benign neutropenia) and does not increase the risk of infection or impact overall survival. This creates novel and confusing clinical situations that could negatively affect the cost and quality of patient care like delay of surgical interventions, unnecessary investigations and use of antibiotics. Hence, there is a need for timely recognition of BEN and its differentiation from neutropenia that increase risk of infections. In this paper, we review characteristics of the BEN, use of complete blood count and management steps in the diagnosis of BEN. By increasing physician awareness, addressing diagnostic challenges, and implementing administrative policies, the impact of benign neutropenia on cost and quality of care can be mitigated.

SPECIFIC CLINICAL EVALUATION OF PATIENTS WITH TYPE 2 DIABETES MELLITUS UNDERWENT REHABILITATION TREATMENT FOR DIFFERENT LOCOMOTORY DISFUNCTIONS

M. Minea[1], F. Istfan[2], L. Vlădăreanu[1], D. Oprea[3], L.-E. Stanciu[3], E.-V. Ionescu[3], C. Oprea[3], M.-G. Iliescu[4]

[1]Ovidius Univ. Faculty of Medicine Doctoral School. Hospital Rehabilitation Unit, Balneal Sanatorium of Techirghiol, [2]Hospital Rehabilitation Unit, Balneal Sanatorium of Techirghiol, [3]Hospital Rehabilitation Unit, Balneal Sanatorium of Techirghiol, Dept. of Medical Rehabilitation, Faculty of Medicine, Ovidius Univ. of Constanta., [4]Ovidius Univ. Faculty of Medicine Doctoral School. Hospital Rehabilitation Unit, Balneal Sanatorium of Techirghiol, Dept. of Medical Rehabilitation, Faculty of Medicine, Ovidius Univ. of Constanta, Constanta, Romania

Objective: We evaluated the patients with type 2 diabetes mellitus (DM) admitted in the Balneal and Rehabilitation Sanatorium Techirghiol Romania (BRST), for different main pathologies, observing clinical and paraclinical features, cardiovascular risk factors and their response to the functional therapy.
Methods: Our descriptive retrospective study, included 483 patients with DM (from a total of 5881), admitted in the hospital unit rehabilitation department in 2023, for specific treatments. Anamnestic, clinical and paraclinical data, the BMI, functional independence measure (FIM) and pain level by visual analogue scale (VAS) were collected from the medical records. Student t-test was used for one sample and two independent samples and determined the Pearson correlation coefficient (- r).
Results: The patients were aged between 27 and 86, 226 women and 257 men. 420 were admitted for osteoarthritis (OA), followed by neurological diseases (18), post herniated disc surgery (23), secondary to an orthopedic condition (13) and inflammatory rheumatological illnesses (9). 62 had inherited history of DM. 45 subjects required only diet for the glycemic control, 402 oral antidiabetic medication (OAD), 62 insulin and 23 semaglutide. 55 patients were smokers, 63 alcohol consumers, 396 had hypertension, 32 ischaemic heart disease and heart failure 16. Major cardiovascular events (stroke, acute myocardial infarction) was noted for 17, DM neuropathy in 23 cases and 234 presented obesity. The average VAS was 6.83 at admission and 3.98 at discharge. We noticed moderate inverse correlation between delta VAS and glycosylated haemoglobin value (r =—0.4). The group without cardiovascular risk factors had a better improvement of the pain relief, compared with the one who associated 4 risk factors. Kineto-therapy was applied for 247 patients and the pain relief (VAS values) was statistically significant (p = 0,01) higher in that group compared with the one who didn't perform exercises.
Conclusion: For the majority DM was controlled by OAD and diet, up to half of them presenting different levels of obesity. The pain relief after treatment is better for the patients with an efficient controlled disease, for the ones with less cardiovascular risk factors and in the group that followed kineto-therapy.

P867
OSTEOPOROSIS AND RELATED FACTORS IN KENYA: A RETROSPECTIVE COHORT STUDY

M. Mohammed[1], T. Hassan[1], S. Ndirangu[2]

[1]Rayhaan Healthcare, Nairobi, [2]Moi Teaching and Referral Hospital, Eldoret, Kenya

Objective: The WHO defines osteoporosis as bone mass density 2.5 standard deviation or more below the average value for young and healthy population. Osteoporosis is estimated to affect 200 million individuals globally with associated 5 million disability adjusted life years[1]. There are an estimated > 8.9 million osteoporotic fractures occurring globally annually[2]. There are limited number of studies and data in Africa on the prevalence of osteoporosis. A review of 3 studies in Africa showed 39.5% (22.3–59.7%) as the highest prevalence of osteoporosis[3]. In Kenya a study in Kiambu among 254 postmenopausal women aged 50–95 y showed a prevalence of 26.4% of osteoporosis[4]. Also a review of patients attending the Nairobi Rheumatology clinic between January 2002 and January 2013 found 56 patients with osteoporosis among a retrospective evaluation of 9975 patients. Among the osteoporosis risk factors, postmenopausal women are at a greater risk of osteoporosis than men of the same age. Most of the routine DXA scan osteoporosis screening tests are targeted to postmenopausal women[5]. We aimed to investigate factors associated with occurrence of osteoporosis in patients who underwent a DXA Scan in Nairobi County.
Methods: The retrospective cohort study was carried out using a cross-sectional study design. Purposive sampling was used to recruit all subjects whose had undergone a DXA scan at Rayhaan Health care for various bone related symptoms with documented T-scores of the lumbar spine or femoral neck. Data was collected from the DXA scan machine as collected during the time of examination. Data was analyzed using MS Excel and SPSS.
Results: There were 224 subjects in the study who had undergone a DXA scan for bone related symptoms over a 2-y, 7-month period in Rayhaan Healthcare, Nairobi, Kenya. Majority were females (76.8%, n = 172), those aged 61–75 (39.3%) and Asian ethnic background (n = 121; 54%). Age of subjects ranged from 26–96 y. Subjects with BMI 25–29.9 were the majority (36.2%). The risk factors for osteoporosis evaluated in this study included alcohol intake more than three units per day, current smoking, history of previous fracture, and parental hip fracture. Other evaluated risk factors include use of glucocorticoids, rheumatoid arthritis, and secondary osteoporosis.

Among these risk factors, history of previous fracture was in majority of subjects (n = 67: 29.9%). Based on the T-score findings, the incidence of osteoporosis was 30.8% (n = 69) with majority of subjects having osteopenia (43.8%; n = 98). Among subjects with osteoporosis, highest incidence of osteoporosis in females was among those aged 61–75 (45.6%, n = 26) and among males aged over 75 y (41.7%; n = 5). Bivariate analysis revealed that age > 65 (RRR 2.287, $p < 0.001$), current smoking (RRR 35.942, $p < 0.001$), alcohol intake (RRR 6.739, $p < 0.001$), history of previous fracture (RRR 2.314, $p < 0.001$), parental hip fracture (RRR 4.493, p = 0.003), use of glucocorticoids (RRR 2.995, p = 0.037), and normal BMI (RRR 1.579, p = 0.038) conferred increased risk for osteoporosis as compared to other groups.

Conclusion: Osteoporosis presents a huge public health burden considering the aging global population and is associated with significant morbidity and mortality requiring key emphasis on targeted screening, and diagnosis of osteoporosis in Kenya. There is need for further studies to investigate factors associated with osteoporosis and to develop guidelines for screening, diagnosis, and management of osteoporosis.

DRUG-VIRUS INTERACTION: COLCHICINE AND COVID-19

M. Ozaybi[1]

[1]Pharmaceutical Care Dept., King Fahad Central Hospital, Jazan Health Affairs, Ministry of Health, Jazan, Saudi Arabia

Objective: To focus on the interaction between COVID-19 and colchicine.

Methods: We performed a review of articles describing COVID-19 and drug-disease interactions. The searches were conducted on the PubMed date of 9/30/2023. Information about colchicine comes from product information on the FDA and the last updated COVID-19 from the WHO webpage.

Results: Pharmacists and physicians often pay so much attention to drug-drug interactions, but drug-virus interactions are not considered. Lack of knowledge: despite significant progress in the field of virology, there is still much that scientists do not know about how viruses work, how they spread, and how they can be effectively treated. WHO does not recommend the use of colchicine with COVID-19. Based on data from 598 participants in 5 randomized controlled studies. Drug-virus interactions occur when a virus changes the body's response to a drug, causing an unwanted reaction. The chance of a COVID-19 patient having drug-virus interactions compared to a non-COVID-19 patient is much higher. CYP3A4 is the most important metabolizing enzyme for possible drug-virus interactions. CYP3A4 suppression is extremely sensitive to IL-6 elevation and gets downregulated even with a minor increase in IL-6 as quickly as within 24 h. Because IL-6 and other cytokines have potent inhibitory effects on this isoform, clinicians should pay particular attention to the substrates of CYP3A4. For COVID-19 experimental medications (such as colchicine) and drugs for comorbidities, measurement of plasma drug levels at specific intervals is required to determine the therapeutic window in infected persons. This will make therapeutic medication monitoring easier and can reduce negative drug effects as well as liver damage caused by high drug concentrations in COVID- 19 patients. These interactions can be classified into three categories based on severity and relevance: Class I, no predicted interaction; Class II, predicted interaction but unknown relevance; and Class III, clinically relevant interaction, which should be avoided.

Conclusion: Colchicine may increase the risk of adverse effects leading to drug discontinuation (Class III).

P869
DRUG-VIRUS INTERACTION: BARICITINIB AND COVID-19

M. Ozaybi[1]

[1]King Fahd Central Hospital, Jazan, Saudi Arabia

Objective: To focus on the interaction between COVID-19 and baricitinib.

Methods: We performed a review of articles describing COVID-19 and drug-disease interactions. The searches were conducted on the PubMed date of 9/30/2023. Information about baricitinib comes from product information on the FDA and the last updated COVID-19 from the WHO webpage.

Results: Pharmacists and physicians often pay so much attention to drug-drug interactions, but drug-virus interactions are not considered. Lack of knowledge: despite significant progress in the field of virology, there is still much that scientists do not know about how viruses work, how they spread, and how they can be effectively treated. Baricitinib is a Janus kinase (JAK) pathway inhibitor. JAK consists of a group of intracellular tyrosine kinases that transmit signals from cytokine or growth factor-receptor interactions on the cellular membrane to influence cellular processes of hematopoiesis and immune cell function. Drug-virus interactions occur when a virus changes the body's response to a drug, causing an unwanted reaction. CYP3A4 is the most important metabolizing enzyme for possible drug-virus interactions. CYP3A4 suppression is extremely sensitive to IL-6 elevation and gets downregulated even with a minor increase in IL-6 as quickly as within 24 h. Because IL-6 and other cytokines have potent inhibitory effects on this isoform, clinicians should pay particular attention to the substrates of CYP3A4. Based on data from 2309 participants in 4 randomized controlled studies, for COVID-19 experimental medications (such as baricitinib) and drugs for comorbidities, measurement of plasma drug levels at specific intervals is required to determine the therapeutic window in infected persons. This will make therapeutic medication monitoring easier and can reduce negative drug effects as well as liver damage caused by high drug concentrations in COVID-19 patients. These interactions can be classified into three categories based on severity and relevance: Class I, no predicted interaction; Class II, predicted interaction but unknown relevance; and Class III, clinically relevant interaction, which should be avoided.

Conclusion: With baricitinib, there is probably little to no difference in adverse effects leading to discontinuation (Class II).

P870
UNAPPROVED/UNLICENSED USE OF MEDICATION: STRATEGIES FOR ENHANCING THE QUALITY OF PATIENT SAFETY AND REDUCING HEALTH CARE COSTS

M. Ozaybi[1]

[1]Pharmaceutical Care Dept., King Fahad Central Hospital, Jazan Health Affairs, Ministry of Health, Jazan, Saudi Arabia

Objective: To explore methods and strategies to improve patient safety and reduce health care costs.

Methods: We performed a review of articles that described (Raising the quality of patient safety and reducing health care costs), (off-label drugs), and (drug-drug interaction) on PubMed on Tue, Aug. 22, 2023, 14:06:35, and Wed, Aug. 30, 2023, 22:32:17.
Results: Patient safety refers to the measures and practices taken to prevent harm or injury to patients during their healthcare experience. It involves creating a safe environment, minimizing medical errors, and ensuring quality care delivery. Patient safety initiatives may include protocols, guidelines, technology, and education aimed at reducing risks, improving communication, and enhancing the overall safety of healthcare processes. It is a critical aspect of healthcare that prioritizes the well-being and protection of patients. Quick story about hydroxychloroquine with a COVID-19 lesson on drug safety and regulations: Hydroxychloroquine is a drug that was originally used to treat malaria and autoimmune disorders such as lupus and rheumatoid arthritis. It gained widespread attention during the COVID-19 pandemic, when some studies suggested it may have the potential to treat or prevent the virus. However, subsequent studies showed conflicting results, and the drug was not shown to be effective for COVID-19 treatment.
Conclusion: The following strategies will help our healthcare system raise the quality of patient safety and reduce health care costs:
1. Reducing health care costs by using AI.
2. Rationalizing and regulating responsible consumption of drugs and preventing irresponsible use.
3. Ensure that patients have full rights.
4. Monitoring adverse effects.
5. Educate health care providers.
6. Reporting adverse events.
7. Evidence-based practice: the best available evidence of the safety and efficacy of off-label drugs must be provided for intended use.
8. Documentation of the use of off-label drugs.
9. Encourages collaboration between health care providers, including pharmacists, doctors, and other members of the health care team, to ensure the appropriate use of off-label drugs.
10. Provide ongoing education and training to health care providers on the appropriate use of off-label drugs to ensure that they are up to date with the latest evidence and best practices.

P871
DRUG-VIRUS INTERACTION: TOCILIZUMAB AND COVID-19

M. Ozaybi[1]

[1]Pharmaceutical Care Dept., King Fahad Central Hospital, Jazan Health Affairs, Ministry of Health, Jazan, Saudi Arabia

Objective: To focus on the interaction between COVID-19 and tocilizumab.
Methods: We performed a review of articles describing COVID-19 and drug-disease interactions. The searches were conducted on the PUBMED date of 9/30/2023. Information about tocilizumab comes from product information on the FDA and the last updated COVID-19 from the WHO webpage.
Results: Pharmacists and physicians often pay so much attention to drug-drug interactions, but drug-virus interactions are not considered. Lack of knowledge: despite significant progress in the field of virology, there is still much that scientists do not know about how viruses work, how they spread, and how they can be effectively treated. Tocilizumab is an IL-6 receptor antagonist. IL-6 is a pleiotropic proinflammatory cytokine produced by a variety of cell types, including T- and B-cells, lymphocytes, monocytes, and fibroblasts. IL-6 has been shown to be involved in diverse physiological processes such as T-cell activation, induction of immunoglobulin secretion, initiation of hepatic acute phase protein synthesis, and stimulation of hematopoietic precursor cell proliferation and differentiation. IL-6 is also produced by synovial and endothelial cells, leading to local production of IL-6 in joints affected by inflammatory processes. Drug-virus interactions occur when a virus changes the body's response to a drug, causing an unwanted reaction. CYP3A4 is the most important metabolizing enzyme for possible drug-virus interactions. CYP3A4 suppression is extremely sensitive to IL-6 elevation and gets downregulated even with a minor increase in IL-6 as quickly as within 24 h. Because IL-6 and other cytokines have potent inhibitory effects on this isoform, clinicians should pay particular attention to the substrates of CYP3A4. Based on data from 815 participants in 2 randomized controlled studies for COVID-19, experimental medications such as tocilizumab. These interactions can be classified into three categories based on severity and relevance: Class I, no predicted interaction; Class II, predicted interaction but unknown relevance; and Class III, clinically relevant interaction, which should be avoided.
Conclusion: The effect of tocilizumab on adverse events leading to discontinuation is uncertain (Class II).

P872
DRUG-VIRUS INTERACTION: IVERMECTIN AND COVID-19

M. Ozaybi[1]

[1]Pharmaceutical Care Dept., King Fahad Central Hospital, Jazan Health Affairs, Ministry of Health, Jazan, Saudi Arabia

Objective: To focus on the interaction between COVID-19 and ivermectin.
Methods: We performed a review of articles describing COVID-19 and drug-disease interactions. The searches were conducted on the PubMed date of 9/30/2023. Information about ivermectin comes from product information on the FDA and the last updated COVID-19 from the WHO webpage.
Results: Pharmacists and physicians often pay so much attention to drug-drug interactions, but drug-virus interactions are not considered. Lack of knowledge: despite significant progress in the field of virology, there is still much that scientists do not know about how viruses work, how they spread, and how they can be effectively treated. Ivermectin is a medication used to treat parasitic infections. The antiviral activity of Ivermectin has been shown against a wide range of RNA and DNA viruses, for example, dengue, Zika, yellow fever, and others. The FDA has not approved ivermectin for use in treating or preventing COVID-19 infection in humans. The WHO recommends not using ivermectin in patients with COVID-19 to reduce viral replication, except in clinical trials. Based on data from 584 participants in 3 randomized controlled studies. Drug-virus interactions occur when a virus changes the body's response to a drug, causing an unwanted reaction. CYP3A4 is the most important metabolizing enzyme for possible drug-virus interactions. CYP3A4 suppression is extremely sensitive to IL-6 elevation and gets downregulated even with a minor increase in IL-6 as quickly as within 24 h. Because IL-6 and other cytokines have potent inhibitory effects on this isoform, clinicians should pay particular attention to the substrates of CYP3A4. These interactions can be classified into three categories based on severity and relevance: Class I, no predicted interaction; Class II, predicted interaction but unknown relevance; and Class III, clinically relevant interaction, which should be avoided.
Conclusion: Ivermectin may increase the risk of serious adverse events leading to drug discontinuation (Class III).

P873
DRUG-VIRUS INTERACTION: LOPINAVIR + RITONAVIR AND COVID-19

M. Ozaybi[1]

[1]Pharmaceutical Care Dept., King Fahad Central Hospital, Jazan Health Affairs, Ministry of Health, Jazan, Saudi Arabia

Objective: To focus on the interaction between lopinavir, ritonavir, and COVID-19.
Methods: We performed a review of articles describing COVID-19 and drug-disease interactions. The searches were conducted on the PubMed date of 9/30/2023. Information about lopinavir + ritonavir comes from product information on the FDA and the last updated COVID-19 from the WHO webpage.
Results: Pharmacists and physicians often pay so much attention to drug-drug interactions, but drug-virus interactions are not considered. Lack of knowledge: despite significant progress in the field of virology, there is still much that scientists do not know about how viruses work, how they spread, and how they can be effectively treated. Lopinavir and ritonavir are a combination of antiviral medications used to treat HIV. Common side effects of lopinavir and ritonavir may include nausea, vomiting, diarrhea, or high cholesterol or triglycerides. WHO does not recommend the use of lopinavir and ritonavir with COVID-19. Based on data from 259 participants in 2 randomized controlled studies, the outcome was acute kidney injury. Based on data from 370 participants in 4 randomized controlled studies, the outcome was diarrhea. Based on data from 370 participants in 4 randomized controlled studies, the outcome was nausea or vomiting. Drug-virus interactions occur when a virus changes the body's response to a drug, causing an CYP3A4 suppression that is extremely sensitive to IL-6 elevation and gets downregulated even with a minor increase in IL-6 as quickly as 24 h. Because IL-6 and other cytokines have potent inhibitory effects on this isoform, clinicians should pay particular attention to the substrates of CYP3A4. These interactions can be classified into three categories based on severity and relevance: Class I, no predicted interaction; Class II, predicted interaction but unknown relevance; and Class III, clinically relevant interaction, which should be avoided.
Conclusion: Lopinavir + ritonavir and COVID-19 were examples of this interaction in Class III.

P874
MALIK'S DRUG-VIRUS INTERACTION: A NEW STRATEGY FOR ENHANCING QUALITY OF PATIENT SAFETY AND REDUCING HEALTH CARE COSTS

M. Ozaybi[1]

[1]Pharmaceutical Care Dept., King Fahad Central Hospital, Jazan Health Affairs, Ministry of Health, Jazan, Saudi Arabia

Objective: To focus on the interaction between drugs and viruses.
Methods: We performed a review of articles describing COVID-19 and drug-disease interactions. The searches were conducted on the PubMed sent on Friday, September 29, 22:12:34, 2023. A two-step approach was performed to detect clinically relevant drug interactions between drugs and viruses. First, understanding COVID-19 from basic mechanisms to clinical perspectives. Second, information about drugs comes from FDA and the last updated COVID-19 from the WHO webpage.
Results: Pharmacists and physicians often pay so much attention to drug-drug interactions, but drug-virus interactions are not considered. Based on data from 2309 participants for baricitinib, based on data from 15,243 participants for convalescent plasma, based on data from 15,406 participants for casirivimab and imdevimab, based on data from 598 participants for colchicine, and based on data from 6118 participants for hydroxychloroquine, the outcome was cardiac toxicity, diarrhea, nausea or vomiting, and delirium. Based on data from 815 participants for IL-6 receptor blockers (tocilizumab or sarilumab), based on data from 584 participants for ivermectin, based on data from 629 participants for lopinavir and ritonavir, based on data from 4796 participants for molnupiravir, based on data from 2246 participants for nirmatrelvir and ritonavir, based on data from 956 participants for ruxolitinib, based on data from 1379 participants for remdesivir, based on data from 14,013 participants for systemic corticosteroids, based on data from 1044 participants for sotrovimab, based on data from 284 participants for tofacitinib. Drug-virus interactions occur when a virus changes the body's response to a drug, causing an unwanted reaction. These reactions may range from no predicted interaction to clinically relevant interactions that require the avoidance of concomitant administration. CYP3A4 is the most important metabolizing enzyme for possible drug-virus interactions. Because IL-6 and other cytokines have potent inhibitory effects on this isoform, clinicians should pay particular attention to the substrates of CYP3A4.
Conclusion: Drug-virus interaction can be classified into three categories based on severity and relevance: class I, no predicted interaction; class II, predicted interaction but unknown relevance; and class III, clinically relevant interaction, which should be avoided.

P875
MALIK'S DRUG-VIRUS INTERACTION: HYDROXYCHLOROQUINE AND COVID-19

M. Ozaybi[1]

[1]Pharmaceutical Care Dept., King Fahad Central Hospital, Jazan Health Affairs, Ministry of Health, Jazan, Saudi Arabia

Objective: To focus on the interaction between hydroxychloroquine and COVID-19.
Methods: We performed a review of articles describing COVID-19 and drug-disease interactions. The searches were conducted on the PubMed sent on Friday, September 29, 22:12:34, 2023. From 18, we took three that met our objective. A two-step approach was performed to detect clinically relevant drug interactions between hydroxychloroquine and COVID-19. First, understanding COVID-19 from basic mechanisms to clinical perspectives. Second, information about hydroxychloroquine comes from FDA-approved labeling information and the last updated COVID-19 from the WHO webpage.
Results: Pharmacists and physicians often pay so much attention to drug-drug interactions, but drug-virus interactions are not considered. Lack of knowledge: despite significant progress in the field of virology, there is still much that scientists do not know about how viruses work, how they spread, and how they can be effectively treated. WHO does not recommend the use of hydroxychloroquine with COVID-19. Based on data from 3287 participants in 7 randomized controlled studies, the outcome was cardiac toxicity. Based on data from 979 participants in 6 randomized controlled studies, the outcome was diarrhea. Based on data from 1429 participants in 7 randomized controlled studies, the outcome was nausea or vomiting. Based on data from 423 participants in one randomized controlled study, the outcome was delirium. Drug-virus interactions occur when a virus changes the body's response to a drug, causing an unwanted reaction. These reactions may range from no predicted interaction to clinically relevant interactions that require the avoidance of concomitant administration. CYP3A4 is the most important metabolizing enzyme for possible drug-virus interactions. Because IL-6 and other cytokines have potent inhibitory effects on this isoform, clinicians should pay particular attention to the substrates of CYP3A4. Two major mechanisms of interaction between hydroxychloroquine and

COVID-19 are pharmacokinetics and pharmacodynamics. These interactions can be classified into three categories based on severity and relevance: Class I, no predicted interaction; Class II, predicted interaction but unknown relevance; and Class III, clinically relevant interaction, which should be avoided.
Conclusion: Hydroxychloroquine and COVID-19 were examples of this interaction in Class III.

P876
MALIK'S DRUG-VIRUS INTERACTION: MECHANISMS OF INTERACTIONS

M. Ozaybi[1]

[1]Pharmaceutical Care Dept., King Fahad Central Hospital, Jazan Health Affairs, Ministry of Health, Jazan, Saudi Arabia

Objective: To focus on the mechanisms of interaction between drugs and viruses.
Methods: We performed a review of articles describing COVID-19 and drug-disease interactions. The searches were conducted on the PubMed sent on Friday, September 29, 22:12:34, 2023. A two-step approach was performed to detect clinically relevant drug interactions between drugs and COVID-19. First, understanding COVID-19 from basic mechanisms to clinical perspectives. Second, information about drugs comes from FDA-approved labeling information and the last updated COVID-19 from the WHO webpage.
Results: Pharmacists and physicians often pay so much attention to drug-drug interactions, but drug-virus interactions are not considered. Lack of knowledge: despite significant progress in the field of virology, there is still much that scientists do not know about how viruses work, how they spread, and how they can be effectively treated. Drug-virus interactions occur when a virus changes the body's response to a drug, causing an unwanted reaction. CYP3A4 is the most important metabolizing enzyme for possible drug-virus interactions. WHO does not recommend the use of hydroxychloroquine with COVID-19. Two major mechanisms of interaction between hydroxychloroquine and COVID-19 are pharmacokinetics and pharmacodynamics. Pharmacokinetic interactions occur when viruses affect the way a drug is absorbed, distributed, metabolized, or eliminated in the body. Pharmacodynamic interactions occur when the virus and the drug have similar or opposing effects, leading to additive, synergistic, or antagonistic effects. Combined toxicity happens when a virus causes a toxic effect on the body or a drug, causing a toxic effect that would not occur on its own. Displacement interactions occur when the virus displaces the drug from its binding site, resulting in increased levels of the drug in the body. Enzyme induction or inhibition occurs when the virus affects the activity of the enzymes responsible for drug metabolism, leading to changes in its effectiveness or the potential for side effects.
Conclusion: Hydroxychloroquine and COVID-19 were examples of these mechanisms of interaction.

P877
MALIK'S DRUG-VIRUS INTERACTION: COVID-19 AS MAJOR CYTOCHROME P450 ENZYMES INHIBITOR

M. Ozaybi[1]

[1]Pharmaceutical Care Dept., King Fahad Central Hospital, Jazan Health Affairs, Ministry of Health, Jazan, Saudi Arabia

Objective: To focus on exploring how COVID-19 may act as an inhibitor of the major CYP450.
Methods: We performed a review of articles describing (off-label drug) and (drug disease interaction) on Wednesday, August 30, 2023, at 22:32:17, and articles describing (COVID-19 and drug-disease interactions) on Friday, September 29, 2023, at 22:12:34, both on PubMed. A two-step approach was performed to detect clinically relevant drug interactions between drugs and viruses. First, understanding COVID-19 from basic mechanisms to clinical perspectives. Second, the last updated COVID-19 is from the WHO webpage.
Results: Pharmacists and physicians often pay so much attention to drug-drug interactions, but drug-virus interactions are not considered. Lack of knowledge: despite significant progress in the field of virology, there is still much that scientists do not know about how viruses work, how they spread, and how they can be effectively treated. WHO does not recommend the use of hydroxychloroquine with COVID-19. Based on data from 3287 participants in 7 randomized controlled studies, the outcome was cardiac toxicity. Based on data from 979 participants in 6 randomized controlled studies, the outcome was diarrhea. Based on data from 1429 participants in 7 randomized controlled studies, the outcome was nausea or vomiting. Based on data from 423 participants in one randomized controlled study, the outcome was delirium. Drug-virus interactions occur when a virus changes the body's response to a drug, causing an unwanted reaction. These reactions may range from no predicted interaction to clinically relevant interactions that require the avoidance of concomitant administration. The chance of a COVID-19 patient having a virus-drug interaction compared to a non-COVID-19 patient is much higher. COVID-19 patients will experience acute suppressive effects on CYP expression, reduced drug metabolism, decreased drug elimination, and eventually local and systemic drug toxicity as early as 48–72 h after active infection. CYP3A4, CYP2B6, and CYP2C9 are the most important metabolizing enzymes for drug-virus interactions. Because IL-6 and other cytokines have potent inhibitory effects on this isoform, clinicians should pay particular attention to these enzymes.
Conclusion: Hydroxychloroquine and COVID-19 were examples of this interaction.

P878
MALIK'S DRUG-VIRUS INTERACTION: COLCHICINE AND COVID-19

M. Ozaybi[1]

[1]Pharmaceutical Care Dept., King Fahad Central Hospital, Jazan Health Affairs, Ministry of Health, Jazan, Saudi Arabia

Objective: To focus on the interaction between COVID-19 and colchicine.
Methods: We performed a review of articles describing COVID-19 and drug-disease interactions. The searches were conducted on PubMed Friday, September 29, 2023, at 22:12:34. Information about colchicine comes from FDA-approved labeling information and the last updated COVID-19 from the WHO webpage.
Results: Pharmacists and physicians often pay so much attention to drug-drug interactions, but drug-virus interactions are not considered. Lack of knowledge: despite significant progress in the field of virology, there is still much that scientists do not know about how viruses work, how they spread, and how they can be effectively treated. WHO does not recommend the use of colchicine with COVID-19. Based on data from 598 participants in 5 randomized controlled studies. Drug-virus interactions occur when a virus changes the body's response to a drug, causing an unwanted reaction. The chance of a COVID-19 patient having drug-virus interactions compared to a non-COVID-19 patient is much higher. CYP3A4 is the most important metabolizing enzyme for possible drug-virus interactions. CYP3A4 suppression is extremely sensitive to IL-6 elevation and gets downregulated even with a minor increase in IL-6 as quickly as within 24 h. Because IL-6 and other cytokines have potent

inhibitory effects on this isoform, clinicians should pay particular attention to the substrates of CYP3A4. For COVID-19 experimental medications (such as colchicine) and drugs for comorbidities, measurement of plasma drug levels at specific intervals is required to determine the therapeutic window in infected persons. This will make therapeutic medication monitoring easier and can reduce negative drug effects as well as liver damage caused by high drug concentrations in COVID-19 patients. These interactions can be classified into three categories based on severity and relevance: Class I, no predicted interaction; Class II, predicted interaction but unknown relevance; and Class III, clinically relevant interaction, which should be avoided.
Conclusion: Colchicine may increase the risk of adverse effects leading to drug discontinuation (Class III).

P879
MALIK'S DRUG-VIRUS INTERACTION: BARICITINIB AND COVID-19

M. Ozaybi[1]

[1]Pharmaceutical Care Dept., King Fahad Central Hospital, Jazan Health Affairs, Ministry of Health, Jazan, Saudi Arabia

Objective: To focus on the interaction between COVID-19 and baricitinib.
Methods: We performed a review of articles describing COVID-19 and drug-disease interactions. The searches were conducted on PubMed Friday, September 29, 2023, at 22:12:34. Information about baricitinib comes from FDA-approved labeling information and the last updated COVID-19 from the WHO webpage.
Results: Pharmacists and physicians often pay so much attention to drug-drug interactions, but drug-virus interactions are not considered. Lack of knowledge: despite significant progress in the field of virology, there is still much that scientists do not know about how viruses work, how they spread, and how they can be effectively treated. Baricitinib is a Janus kinase (JAK) pathway inhibitor. JAK comprises a group of intracellular tyrosine kinases that transmit signals from cytokines or development factor receptors intelligent on the cellular layer to impact cellular forms of hematopoiesis and immune cell function. Drug-virus interactions occur when a virus changes the body's response to a drug, causing an unwanted reaction. CYP3A4 is the most important metabolizing enzyme for possible drug-virus interactions. CYP3A4 suppression is extremely sensitive to IL-6 elevation and gets downregulated even with a minor increase in IL-6 as quickly as within 24 h. Because IL-6 and other cytokines have potent inhibitory effects on this isoform, clinicians should pay particular attention to the substrates of CYP3A4. Based on data from 2309 participants in 4 randomized controlled studies, for COVID-19 experimental medications (such as baricitinib) and drugs for comorbidities, measurement of plasma drug levels at specific intervals is required to determine the therapeutic window in infected persons. This will make therapeutic medication monitoring easier and can reduce negative drug effects as well as liver damage caused by high drug concentrations in COVID-19 patients. These interactions can be classified into three categories based on severity and relevance: Class I, no predicted interaction; Class II, predicted interaction but unknown relevance; and Class III, clinically relevant interaction, which should be avoided.
Conclusion: With baricitinib, there is probably little to no difference in adverse effects leading to discontinuation (Class II).

P880
MALIK'S DRUG-VIRUS INTERACTION: TOCILIZUMAB AND COVID-19

M. Ozaybi[1]

[1]Pharmaceutical Care Dept., King Fahad Central Hospital, Jazan Health Affairs, Ministry of Health, Jazan, Saudi Arabia

Objective: To focus on the interaction between COVID-19 and tocilizumab.
Methods: We performed a review of articles describing COVID-19 and drug-disease interactions. The searches were conducted on PubMed Friday, September 29, 2023, at 22:12:34. Information about tocilizumab comes from FDA-approved labeling information and the last updated COVID-19 from the WHO webpage.
Results: Pharmacists and physicians often pay so much attention to drug-drug interactions, but drug-virus interactions are not considered. Tocilizumab is an IL-6 receptor antagonist. Tocilizumab, being a monoclonal antibody, is metabolized differently from small-molecule drugs. It does not undergo the same type of metabolism as chemicals or biologically active small molecules that are often processed by liver enzymes. Instead, tocilizumab is broken down into smaller peptides and amino acids through catabolic pathways that are widely distributed throughout the body. These processes occur at the cellular level, mainly through the action of proteolytic enzymes. Since it is a protein, tocilizumab isn't subject to liver enzyme cytochrome P450-mediated metabolism, and it doesn't have the same types of drug-drug interactions that small-molecule drugs might have. However, the pharmacokinetics of tocilizumab or any biological drug can be complex, and individual factors such as immune function can affect how the drug is metabolized and cleared from the body. Drug-virus interactions occur when a virus changes the body's response to a drug, causing an unwanted reaction. CYP3A4 suppression is extremely sensitive to IL-6 elevation and gets downregulated even with a minor increase in IL-6 as quickly as within 24 h. Based on data from 815 participants in 2 randomized controlled studies for COVID-19, the experimental medication was tocilizumab. These interactions can be classified into three categories based on severity and relevance: Class I, no predicted interaction; Class II, predicted interaction but unknown relevance; and Class III, clinically relevant interaction, which should be avoided.
Conclusion: The effect of tocilizumab on adverse events leading to discontinuation is uncertain (Class II).

P881
MALIK'S DRUG-VIRUS INTERACTION: IVERMECTIN AND COVID-19

M. Ozaybi[1]

[1]Pharmaceutical Care Dept., King Fahad Central Hospital, Jazan Health Affairs, Ministry of Health, Jazan, Saudi Arabia

Objective: To focus on the interaction between COVID-19 and ivermectin.
Methods: We performed a review of articles describing COVID-19 and drug-disease interactions. The searches were conducted on PubMed Friday, September 29, 2023, at 22:12:34. Information about ivermectin comes from FDA-approved labeling information and the last updated COVID-19 from the WHO webpage.
Results: Pharmacists and physicians often pay so much attention to drug-drug interactions, but drug-virus interactions are not considered. Lack of knowledge: despite significant progress in the field of virology, there is still much that scientists do not know about how viruses work, how they spread, and how they can be effectively treated. Ivermectin is an anti-parasitic medication widely used to treat

infections caused by various parasites, including those that lead to conditions such as onchocerciasis (river blindness), strongyloidiasis, and scabies. It works by binding to the invertebrate muscle and nerve cells of parasites, causing paralysis and the death of the parasites. The WHO recommends not using ivermectin in patients with COVID-19 to reduce viral replication, except in clinical trials. Based on data from 584 participants in 3 randomized controlled studies. Drug-virus interactions occur when a virus changes the body's response to a drug, causing an unwanted reaction. CYP3A4 is the most important metabolizing enzyme for possible drug-virus interactions. CYP3A4 suppression is extremely sensitive to IL-6 elevation and gets downregulated even with a minor increase in IL-6 as quickly as within 24 h. Because IL-6 and other cytokines have potent inhibitory effects on this isoform, clinicians should pay particular attention to the substrates of CYP3A4. These interactions can be classified into three categories based on severity and relevance: Class I, no predicted interaction; Class II, predicted interaction but unknown relevance; and Class III, clinically relevant interaction, which should be avoided.
Conclusion: Ivermectin may increase the risk of serious adverse events leading to drug discontinuation (Class III).

P882
MALIK'S DRUG-VIRUS INTERACTION: LOPINAVIR, RITONAVIR, AND COVID-19

M. Ozaybi[1]

[1]Pharmaceutical Care Dept., King Fahad Central Hospital, Jazan Health Affairs, Ministry of Health, Jazan, Saudi Arabia.

Objective: To focus on the interaction between lopinavir, ritonavir, and COVID-19.
Methods: We performed a review of articles describing COVID-19 and drug-disease interactions. The searches were conducted on PubMed Friday, September 29, 2023, at 22:12:34. Information about lopinavir and ritonavir comes from FDA-approved labeling information and the last updated COVID-19 from the WHO webpage.
Results: Pharmacists and physicians often pay so much attention to drug-drug interactions, but drug-virus interactions are not considered. Lack of knowledge: despite significant progress in the field of virology, there is still much that scientists do not know about how viruses work, how they spread, and how they can be effectively treated. Lopinavir and ritonavir are a combination of antiviral medications used to treat HIV. Common side effects of lopinavir and ritonavir may include nausea, vomiting, diarrhea, or high cholesterol or triglycerides. WHO does not recommend the use of lopinavir and ritonavir with COVID-19. Based on data from 259 participants in 2 randomized controlled studies, the outcome was acute kidney injury. Based on data from 370 participants in 4 randomized controlled studies, the outcome was diarrhea. Based on data from 370 participants in 4 randomized controlled studies, the outcome was nausea or vomiting. Drug-virus interactions occur when a virus changes the body's response to a drug, causing an CYP3A4 suppression that is extremely sensitive to IL-6 elevation and gets downregulated even with a minor increase in IL-6 as quickly as 24 h. Because IL-6 and other cytokines have potent inhibitory effects on this isoform, clinicians should pay particular attention to the substrates of CYP3A4. These interactions can be classified into three categories based on severity and relevance: Class I, no predicted interaction; Class II, predicted interaction but unknown relevance; and Class III, clinically relevant interaction, which should be avoided.
Conclusion: Lopinavir, ritonavir, and COVID-19 were examples of this interaction in Class III.

P883
MALIK'S DRUG-VIRUS INTERACTION: NIRMATRELVIR, RITONAVIR, AND COVID-19

M. Ozaybi[1]

[1]Pharmaceutical Care Dept., King Fahad Central Hospital, Jazan Health Affairs, Ministry of Health, Jazan, Saudi Arabia

Objective: To focus on the interaction between nirmatrelvir, ritonavir, and COVID-19.
Methods: We performed a review of articles describing COVID-19 and drug-disease interactions. The searches were conducted on PubMed Friday, September 29, 2023, at 22:12:34. Information about nirmatrelvir and ritonavir comes from FDA-approved labeling information and the last updated COVID-19 from the WHO webpage.
Results: Pharmacists and physicians often pay so much attention to drug-drug interactions, but drug-virus interactions are not considered. Lack of knowledge: despite significant progress in the field of virology, there is still much that scientists do not know about how viruses work, how they spread, and how they can be effectively treated. Nirmatrelvir and ritonavir are a combination of antiviral medications used to treat SARS-CoV-2. Nirmatrelvir is a peptidomimetic inhibitor. It is boosted with low dose ritonavir to decrease metabolism of nirmatrelvir by inhibiting CYP3A4. Based on data from 2246 participants in one randomized controlled study, nirmatrelvir-ritonavir has little or no risk of adverse effects leading to drug discontinuation. Drug-virus interactions occur when a virus changes the body's response to a drug, causing CYP3A4 suppression that is extremely sensitive to IL-6 elevation and gets downregulated even with a minor increase in IL-6 as quickly as 24 h. Because IL-6 and other cytokines have potent inhibitory effects on this isoform, clinicians should pay particular attention to the substrates of CYP3A4. These interactions can be classified into three categories based on severity and relevance: Class I, no predicted interaction; Class II, predicted interaction but unknown relevance; and Class III, clinically relevant interaction, which should be avoided.
Conclusion: Nirmatrelvir, ritonavir, and COVID-19 were examples of this interaction in Class II.

P884
MALIK'S DRUG-VIRUS INTERACTION: MOLNUPIRAVIR AND COVID-19

M. Ozaybi[1]

[1]Pharmaceutical Care Dept., King Fahad Central Hospital, Jazan Health Affairs, Ministry of Health, Jazan, Saudi Arabia

Objective: To focus on the interaction between molnupiravir and COVID-19.
Methods: We performed a review of articles describing COVID-19 and drug-disease interactions. The searches were conducted on PubMed Friday, September 29, 2023, at 22:12:34. Information about molnupiravir comes from FDA-approved labeling information and the last updated COVID-19 from the WHO webpage.
Results: Pharmacists and physicians often pay so much attention to drug-drug interactions, but drug-virus interactions are not considered. Lack of knowledge: despite significant progress in the field of virology, there is still much that scientists do not know about how viruses work, how they spread, and how they can be effectively treated. Molnupiravir is a prodrug of nucleoside analogue beta-D-N4-hydroxycytidine (NHC). Molnupiravir is metabolized primarily in the liver to the active form β-D-N4-hydroxycytidine-5'-triphosphate (NHC-TP), through a series of phosphorylation steps. Possible side effects of molnupiravir include diarrhea, nausea, dizziness, hypersensitivity, anaphylaxis, angioedema, erythema, rash, and urticaria.

Based on data from 4796 participants in 6 randomized controlled studies, molnupiravir has little or no risk of adverse effects leading to drug discontinuation. Drug-virus interactions occur when a virus changes the body's response to a drug, causing an unwanted reaction. The chance of a COVID-19 patient having a virus-drug interaction compared to a non-COVID-19 patient is much higher. Symptoms of COVID-19 start after the 4th day of infection, and immune response-based inflammation is a hallmark of the disease. Patients can experience a cytokine storm in severe cases, where there is an overproduction of immune cells and their signaling molecules. This can lead to changes in multiple metabolic pathways and contribute to organ dysfunction. These interactions can be classified into three categories based on severity and relevance: Class I, no predicted interaction; Class II, predicted interaction but unknown relevance; and Class III, clinically relevant interaction, which should be avoided.
Conclusion: Molnupiravir and COVID-19 were examples of this interaction in Class II.

P885
MALIK'S DRUG-VIRUS INTERACTION: SYSTEMIC CORTICOSTEROIDS AND COVID-19

M. Ozaybi[1]

[1]Pharmaceutical Care Dept., King Fahad Central Hospital, Jazan Health Affairs, Ministry of Health, Jazan, Saudi Arabia

Objective: To focus on the interaction between systemic corticosteroids and COVID-19.
Methods: We performed a review of articles describing COVID-19 and drug-disease interactions. The searches were conducted on PubMed Friday, September 29, 2023, at 22:12:34. Information about systemic corticosteroids comes from FDA-approved labeling information and the last updated COVID-19 from the WHO webpage.
Results: Pharmacists and physicians often pay so much attention to drug-drug interactions, but drug-virus interactions are not considered. Despite significant progress in the field of virology, there is still much that scientists do not know about how viruses work, how they spread, and how they can be effectively treated. Systemic corticosteroids are a class of medications that are widely used for their potent anti-inflammatory and immunosuppressive effects. These medications are used to treat a variety of conditions, including asthma, autoimmune diseases, allergic reactions, and inflammation. Common systemic corticosteroids include prednisone, methylprednisolone, and dexamethasone. Systemic corticosteroids can have significant side effects, especially with long-term use, such as increased risk of infections, osteoporosis, adrenal suppression, weight gain, diabetes, and others. Due to these potential effects, their use is generally carefully monitored for drug-virus interaction by healthcare providers. Based on data from 8938 participants in 24 studies, the outcome was hyperglycemia. Based on data from 5015 participants in 6 studies, the outcome was hypernatremia. Drug-virus interactions occur when a virus changes the body's response to a drug, causing an unwanted reaction. COVID-19 patients will experience acute suppressive effects on CYP expression, reduced drug metabolism, decreased drug elimination, and eventually local and systemic drug toxicity as early as 48–72 h after active infection. CYP3A4, CYP2B6, and CYP2C9 are the most important metabolizing enzymes for drug-virus interactions. Because IL-6 and other cytokines have potent inhibitory effects on this isoform, clinicians should pay particular attention to these enzymes. These interactions can be classified into three categories based on severity and relevance: Class I, no predicted interaction; Class II, predicted interaction but unknown relevance; and Class III, clinically relevant interaction, which should be avoided.
Conclusion: Systemic corticosteroids and COVID-19 were examples of this interaction in Class III.

P886
PHARMACOVIROLOGY SCIENCE: A NEW SCIENCE FOR ENHANCING QUALITY OF PATIENT SAFETY AND REDUCING HEALTH CARE COSTS

M. Ozaybi[1]

[1]Pharmaceutical Care Dept., King Fahad Central Hospital, Jazan Health Affairs, Ministry of Health, Jazan, Saudi Arabia

Objective: To the establishment or discussion of a scientific field that combines pharmacology and virology.
Methods: We performed a review of articles that described (raising the quality of patient safety and reducing health care costs), (off-label drugs), (drug-drug interaction), and (COVID-19 and drug-disease interactions) on PubMed Tue, Aug. 22, 2023, 14:06:35, Wed, Aug. 30, 2023, 22:32:17, on Friday, September 29, 2023, at 22:12:34.
Results: Pharmacists and physicians often pay so much attention to drug-drug interactions, but drug-virus interactions and virus-disease interactions are not considered. Lack of knowledge: despite significant progress in the field of virology, there is still much that scientists do not know about how viruses work, how they spread, and how they can be effectively treated. WHO does not recommend the use of hydroxychloroquine with COVID-19. Based on data from 3287 participants in 7 randomized controlled studies, the outcome was cardiac toxicity. Based on data from 979 participants in 6 randomized controlled studies, the outcome was diarrhea. Based on data from 1429 participants in 7 randomized controlled studies, the outcome was nausea or vomiting. Based on data from 423 participants in one randomized controlled study, the outcome was delirium. There is a high prevalence of pre-existing CVD among patients with COVID-19, such as myocardial injury, arrhythmias, acute coronary syndrome, and venous thromboembolism. Patients with certain conditions (e.g., hypertension, diabetes, hyperlipidemia) are more susceptible to the infection than the general population. Poorly controlled blood glucose levels can increase the risk of infections in general and may also lead to worse outcomes in COVID-19.
Conclusion: Pharmacovirology science is a field that studies the interaction of drugs and diseases with viruses. This can involve looking at how viruses work, how they spread, and how they can be effectively treated. Pharmacovirology is a specialized field within pharmacology and virology.

ADVANCING OSTEOARTHRITIS RESEARCH THROUGH PATIENT-SPECIFIC ORGAN-ON-A-CHIP MODELING

M. Pasztorek[1], J. Fischer[1], A. Otahal[2], A. De Luna[2], S. Nehrer[2], J. Rosser[1]

[1]Pregenerate, Vienna, Austria, [2]Univ. for Continuing Education, Krems, Austria

Authors:
Markus Pasztorek[1], Johanna Fischer[1], Alexander Otahal[2], Andrea de Luna[2], Stefan Nehrer[2], Julie Rosser[1]
[1]Pregenerate GmbH, Vienna, Austria
[2]Center for Regenerative Medicine, Dept. for Health Sciences, Medicine and Research, University for Continuing Education Krems, Krems an der Donau, Austria

Objective: This study introduces a novel in-vitro model utilizing Organ-on-a-Chip (OoC) technology to investigate patient-specific responses of osteoarthritic chondrocytes to various medications. The objective is to gain insights into the complex interplay between cellular behavior, molecular responses, and potential therapeutic interventions for osteoarthritis (OA).

Methods: Chondrocytes were isolated from cartilage biopsies from arthroplasties of thirteen osteoarthritic patients (male and female, aged 42–80) and cultured in the microfluidic chip Optimate OA^{TM} to mimic the joint microenvironment. The cells were subjected to a 10-d experiment involving treatment with medications commonly used for OA management (hyaluronic acid, triamcinolone, diclofenac, PDGF-BB). Fluorescence microscopy, RNA extraction, and RT-PCR were employed to assess cell morphology, viability, and gene expression patterns.
Results: The 3D-cultivated chondrocytes exhibited a rounded morphology, reminiscent of their natural state, with a survival rate exceeding 80%. Gene expression analysis revealed distinct responses to medications, particularly in degenerative and regenerative markers. Triamcinolone demonstrated inhibitory effects on matrix metalloproteinases and IL-6. Patient-specific variations in treatment responses were observed.
Conclusion: This study provides a comprehensive understanding of chondrocyte responses within an OoC environment, offering insights into the potential therapeutic effects of commonly used OA medications. The results underscore the importance of individualized approaches and highlight the suitability of OoC systems for studying OA pathogenesis and treatment strategies.
Acknowledgments: Gratitude to Syed Faheem Ali, MSc., for his support throughout the study.
Disclosures:
M Pasztorek and J Fischer are employees of PreGenerate GmbH; J Rosser owns the patent of Optimate OA technology and received a consultation honorarium as CEO from PreGenerate GmbH.

SARCOPENIA IS A STRONG PREDICTOR OF ALL-CAUSE MORTALITY IN THE ELDERLY

M. Ebrahimpur[1], M. Payab[2], F. Sharifi[3], P. Ebrahimi[4], A. Ayati[5], Z. Shadman[3]

[1]Endocrinology and Metabolism Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran Univ. of Medical Sciences, [2]Non-Communicable Diseases Research Center, Endocrinology and Metabolism Population Sciences Institute, Tehran Univ. of Medical Sciences, [3]Elderly Health Research Center, Endocrinology and Metabolism Population Sciences Institute, Tehran Univ. of Medical Sciences, [4]Tehran Heart Center, Tehran Univ. of Medical Sciences, [5]Osteoporosis Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran Univ. of Medical Sciences, Tehran, Iran

Objective: The prevalence of sarcopenia is increasing in the world. This study was designed to investigate the association between all-Cause Mortality and sarcopenia.
Methods: The results of this study were come from Birjand Longitudinal Aging study (BLAS). The subjects were volunteers aged > 60 y who were participants in an aging cohort study on a community dwelling older adults that started in 2018. The death occurrence was registered by telephone interview with the family of the participants during September 2018 to end of 2023. Sarcopenia was defined according to EWGSOP2. Hand grip was measured six times (three times in each hand) the maximum values were considered as value of hand grip. Muscle mass was measured using body adiposity index (BAI) that corrected by BMI. Gait speed was measured over six meters three times and the maximum of last two measurements was used for more calculations. Univariate and multiple Logistic regression models adjusted for age, gender, number of morbidities, and BMI were used for assessing association between sarcopenia and all-Cause Mortality.
Results: Mean age of the 1354 participants was 69.77 $\pm$ 7.55 y and 703 subjects of the participants were female. In final model after adjustment for age, sex, number of morbidities and BMI, probable sarcopenia and severe sarcopenia were associated with death (odds ratio of probable sarcopenia 1.65; CI 95% 1.04–2.60, 1.43; sarcopenia CI 95% 0.56–3.62, and severe sarcopenia 3.02 CI 95% 1.43–6.39).
Conclusion: Sarcopenia is a strong predictor of the all-cause mortality in elderly. There is a serious attention to screen for frailty in general population and carry out appropriate multidisciplinary intervention strategies to prevent poor outcomes and reduce the rate of mortality among elderly.

P889
CLINICAL CASE OF A PATIENT WITH FORESTIER'S DISEASE IN A PATIENT WITH ACROMEGALY

M. Perepelova[1], E. Przhiyalkovskaya[1], L. Dzeranova[1], N. Tarbaeva[1], L. Kovalevich[1], V. Ankina[1], S. Chechelnitskaya[1], E. Gavrilova[1], E. Pigarova[1]

[1]Endocrinology Research Centre, Moscow, Russia

Long-term exposure to elevated levels of growth hormone can cause numerous pathological changes in the spine, including degenerative joint disease, axial arthropathy, spinal stenosis, vertebral fracture, and diffuse skeletal hyperostosis. Forestier's disease is a rare non-inflammatory disease of the musculoskeletal system associated with calcification of ligaments and tendons, which gradually leads to ankylosis and limitation of the patient's mobility. Forestier's disease still remains one of those pathologies whose etiology is unknown, and specific treatment has not been developed. We present a clinical case of a patient with Forestier disease and acromegaly.
Case report: Patient D., aged 62 y, with acromegaly after transnasal adenomectomy in 2018 and on therapy with somatostatin analogues, was hospitalized in 2023 in the endocrinology hospital for treatment correction. I have been experiencing joint pain since I was 37 years old; acromegaly was diagnosed at 48 years old. During hospitalization, the absence of remission of the underlying disease was confirmed—the IGF-1 level was 346 ng/ml (16–245). One of the patient's main complaints was back pain when trying to straighten up, limited mobility in large joints (shoulder, knee, hip). According to the results of a multislice computed tomography of the thoracic spine: signs of subtotal calcification of the longitudinal and interspinous ligaments (corresponding to Forestier's disease). Rheumatoid arthritis was excluded. Consulted with a rehabilitation specialist, muscle tone is diffusely reduced; deformations of skeletal bones of the acromegaloid type; range of motion in large joints is reduced; posture (computer optical topography): full straightening of the back is impossible due to spasms of the iliac muscles; feet on both sides—the initial stages of the hollow foot. Several physical therapy sessions were conducted, after which the patient felt a significant improvement, and it was recommended to continue rehabilitation activities on an outpatient basis.
Conclusion: It is important that patients with acromegaly be screened for degenerative spinal disease at diagnosis, as failure to promptly treat the disease process, including rehabilitation, can lead to irreversible damage.

P890
ADHERENCE TO MEDITERRANEAN DIET AND ITS ASSOCIATIONS WITH RHEUMATOID ARTHRITIS

M. Rachdi[1], A. Feki[1], S. Ben Jemaa[1], Z. Gassara[1], M. Ezzedine[1], M. H. Kallel[1], H. Fourati[1], R. Akrout[1], S. Baklouti[1]

[1]Dept. of Rheumatology, Hedi Chaker Hospital, Sfax, Tunisia

Objective: Healthy diet and lifestyle have been associated with a better disease control in rheumatoid arthritis (RA) patients. We aim to evaluate the impact of adherence to mediterranean diet (MD) which is worldwide sponsored as a healthy diet on disease activity and quality of life among Tunisian RA patients.
Methods: It's a cross-sectional study including patients with RA who fulfilled the 2010 ACR/ EULAR criteria. Sociodemographic data and disease characteristics were collected. Adherence to MD was assessed via the Mediterranean Diet Score (MDS): a validated index, including 9 components and ranging from 0 (no adherence) to 9 (complete adherence) points. The quality of life was assessed using the Rheumatoid Arthritis Impact of disease score (RAID): a patient-reported outcome measure to evaluate the impact RA on a patient's quality of life. It includes domains of pain, function, fatigue, sleep disturbance, emotional and physical wellbeing, and coping. RAID < 2 was defined as a patient acceptable state. P values < 0.05 were considered significant.
Results: 53 patients with RA were included: 36 women (67.9%) and 17 (32%) men with a mean age of 44.7 y [22–64]. The median disease duration was 87.1 months [9–277]. Mean BMI was 23.1 kg/m^2 [16.4–32.1]. The median DAS28ESR was 2.24 [1.32–3.76]. Main tender joint count (TJC28), Swollen joint count (SJC28), Patient global assessment (PGA) and visual analogue scale (VAS) were:3[0–7], 1[0–4], 3[0–6],4 [0–7] respectively. The mean morning stiffness duration was 33 min [0–60]. The mean HAQ value was 0.34 [0–1]. Mean RAID score was 3.12 [0.86–4.8]. The mean MDS score was 5.9 [1–9]. Patient's levels of adherence were distributed as follows: low adherence (MDS [0–3]), medium adherence (MDS [4–6]) and high adherence (MDS [7–9]) in 31.6%, 46.2% and 21.2% respectively. A significant association between MDS and morning stiffness (p = 0.04), PGA (p = 0.02) and HAQ (P = 0.05) was found. However, no statistically significant association was found between MD adherence and DAS28 ESR (p = 0.341). RAID total score had a statistically significant negative correlation with MDS p = 0.03).
Conclusion: Diet is a major modifiable determinant of chronic diseases. Although a modest impact of MD was described on objective parameters, an important effect on the more subjective aspects of the disease was highlighted in our study.

P891
CHALLENGE OF IDENTIFYING FIBROMYALGIA IN TUNISIAN GERIATRIC POPULATION

M. Boudokhane[1], M. Rachdi[1], H. Bettaieb[1], R. Bourguiba[1], W. Helali[1], M. Ayari[1], I. Abdelaali[1], H. Douggui[1], T. Jomni[1], S. Bellakhal[1]

[1]Dept. of Internal Medicine, Internal Security Forces Hospital., Marsa, Tunisia

Objective: The peak incidence of fibromyalgia (FM) is reported to be between 30–50 y. Yet, many older adults experience chronic pain which should not be accepted as a feature of aging. We aim to assess the prevalence and characteristics of FM among older patients.
Methods: We conducted a study including patients aged > 65 y. Epidemio-clinic data was gathered. FM was diagnosed according to the modified ACR diagnosis criteria for FM 2016. The results were statistically significant if the p-value was < 0.05.
Results: 34 patients: 20 women (64.5%) and 11 male (35.4%) with a mean age of 71 y [65–78] were enrolled. Six patients (19%) were smokers with a mean cumulative exposure to tobacco smoke estimated to 25 packyear [20–46]. The mean number of co-morbidities was 2.4 [0–4] distributed as follows diabetes(n = 14), high blood pressure(n = 12), cardiac disease (n = 9), osteoporosis (n = 9), osteoarthritis (n = 28), rheumatoid arthritis(n = 3) and inflammatory bowel disease(n = 3) corresponding to 41%, 35.2%, 26.4%, 26.4%, 82.3%, 8.82%,8.82 respectively. The mean BMI was 22.6 kg/m^2 [15.4–31.1]. Twenty-eight patients (82.3%) reported having experienced generalized pain for at least 3 months. Among them 22 patients (64.7%) met the ACR 2016 modified criteria for FM diagnosis. The mean number of tender points was 13 ± 2. The mean SSS was 5 ± 3. The mean visual analogue scale (VAS) was 5.13 [3–9]. Intensity of pain was reported to increase with mobilization in 12 patients (35.2%) and bad mood in 29 patients (85.2%). Factors alleviating the pain were: Rest(n = 9, 26.4%), distraction(n = 11, 32%), sleep(n = 14, 41.1%), alternative therapies (n = 10, 29.4%). The overall prevalence of FM was significantly related to female gender (p = 0.05) and the high number of comorbidities (p = 0.03). The increased number of tender points was significantly observed in women (p = 0.03). BMI > 25 was statistically significant to the presence of tenderness (p = 0.04), and waking-up unrefreshed (p = 0.012).
Conclusion: Identifying FM via a careful anamnesis and physical examination, in the vulnerable population of older patients is crucial in order to offer them the appropriate management.

P892
SHEDDING LIGHT ON SEXUAL DYSFUNCTION IN PATIENTS WITH CHRONIC LOW BACK PAIN

M. Boudokhane[1], M. Rachdi[1], H. Bettaieb[1], R. Bourguiba[1], W. Helali[1], M. Ayari[1], I. Abdelaali[1], H. Douggui[1], T. Jomni[1], S. Bellakhal[1]

[1]Dept. of Internal Medicine, Internal Security Forces Hospital., Marsa, Tunisia

Objective: To determine the prevalence of sexual dysfunction in patients suffering from CLBP.
Methods: It's a cross-sectional study including patients diagnosed with CLBP. Sociodemographic data and disease characteristics were collected. Patients having diseases or taking treatments interfering with sexual function were excluded. The sexual function was assessed in male and female patients with the international index of erectile function (IIEF-5) and the female sexual function index (FSFI) respectively. The IIEF is a validated multidimensional, self-administrated, 5-question questionnaire. A score of 0–5 is awarded to each of the 5 questions. The lower the score the more severe the sexual dysfunction. The FSFI is a 19-item self-report measure of female sexual function that provides scores on overall levels of sexual function in women. The 19 items of the FSFI use a 5-point Likert scale ranging from 1–5 with higher scores indicating greater levels of sexual functioning. The results were statistically significant if the p-value was < 0.05.
Results: 52 patients (38 men and 14 women) were included. The main age was 41 y [29–58]. 10 patients had primary level (19.2%), 8 (15,3%) had secondary level and 34 (65,3%) had a bachelor's level. The mean BMI was 23.2 kg/m^2 [19.6–31.1]. 18 patients (34.6%) were obese (BMI $\geq$ 30 kg/m^2). The mean waist circumference was 96 cm [84–110] and 87 [82–98] in men and women respectively. The mean disease duration was 48 months [6–108]. The mean visual analogue scale (VAS) was 50 cm [0–80]. 23 patients (44.2%) had severe pain (VAS $\geq$ 70). The functional impact was assessed with the Oswestry low back pain disability questionnaire and the mean score was 34 [0–57]. The main IIEF5 score in male patients was 14 [10–25]. Five

patients (13.1%) did not have an erectile dysfunction (IIEF-5 range 22–25), 22 patients (55.2%) had mild erectile dysfunction (IIEF-5 range 17–21), 10 patients (26.3%) had mild to moderate erectile dysfunction (IIEF range 12–16) and 2 patients (5.2%) had moderate erectile dysfunction (IIEF range 8–11). The main global FSFI score in female patients was 24 ± 6,4. According to the FSFI, nine patients (64.2%) had sexual dysfunction. In univariate analysis, sexual dysfunction was related to age (p = 0.032), disease duration (p = 0,050) and pain (p = 0,018) in men. A significant association was found between sexual impairment and age (p = 0.019), educational level (P = 0,031), pain (0,02) and functional impairment (p = 0,04) in women.

Conclusion: Multidisciplinary programs seem to be indicated to treat the various aspects of chronic low back pain including sexual dysfunction in order to improve patient's care and quality of life.

P893
A CASE REPORT HIGHLIGHTING THE ENTRAPMENT OF THE MUSCULOCUTANEOUS NERVE: AN EASILY BUT INFREQUENTLY RECOGNIZED TUNNEL SYNDROME

M. Rachdi[1], C. Rahmani[1], R. Beji[1], B. Kallel[1], W. Elleuch[1], A. Yahya[1], S. Ghroubi[1], M. H. Elleuch[1]

[1]Physical Medicine and Rehabilitation Dept., Habib Bourguiba Hospital, Sfax, Tunisia

The musculocutaneous nerve (MCN) emerges from the lateral cord of the brachial plexus, containing fibers from the C5, C6 and C7 spinal nerve roots. It innervates the three anterior muscles of the upper arm. We report a case of an isolated MCN entrapment after heavy physical activity to highlight the clinical presentation and diagnostic criteria in order to allow early diagnosis and intervention in this condition.

Case report: We present the case of a healthy 32-year-old construction man who presented with painless left upper arm weakness after heavy manual work. Over the following days, his elbow flexion strength deteriorated. These symptoms were accompanied with dysesthesia and numbness on the radial aspect of the left forearm radiating from the elbow crease to the base of the thumb. He had no history of previous neck pain or upper limb injuries. On clinical examination, there was a visible atrophy of the left biceps with no visible contractions (Fig. 1).

Figure 1. Normal right biceps bulk, obvious left biceps atrophy

Right upper and bilateral lower extremities were scored 5/5 according to the medical research council grading (MRC). However, the power grading of the left biceps, brachioradialis and brachialis were 2/5, 3/5 and 3/5 respectively. The left biceps reflex was absent. Sensory examination revealed a narrow zone of reduced light touch, pin and temperature appreciation in the lateral aspect of the left forearm. To confirm these findings, an electromyography (EMG) and nerve conduction studies (NCS) were performed and did indeed demonstrate a severe injury to sensory and motor components of the MCN. Acute denervation in the left biceps muscle was diagnosed with a marked decrease in the number of motor units activated. Thus, MCN tunnel syndrome was diagnosed. The patient underwent a MCN neurolysis. Post operatively, the patient had immediate return of biceps firing and improvement in numbness and dysesthesia. Elbow flexion force and arm circumference continued to improve. One year after the surgery, he had complete return of shoulder and elbow function.

Conclusion: The diagnosis of isolated MCN entrapment should be borne in mind in patients with loss of forearm flexion strength and bulk of the biceps muscle after heavy manual work.

P894
ASSESSING TREATMENT SATISFACTION IN PATIENTS WITH CHRONIC RHEUMATIC DISEASES RECEIVING BIOLOGIC THERAPIES

M. Rachdi[1], A. Feki[1], S. Ben Jemaa[1], Z. Gassara[1], M. Ezzedine[1], H. Fourati[1], M. H. Kallel[1], R. Akrout[1], S. Baklouti[1]

[1]Dept. of Rheumatology, Hedi Chaker Hospital, Sfax, Tunisia

Objective: To assess the treatment satisfaction and the underlying related factors affecting it in patients with rheumatoid arthritis (RA) and spondyloarthritis (SpA) treated with biological disease modifying antirheumatic drugs (bDMARDs).

Methods: It's a cross-sectional study including patients fulfilling the 2010 RA classification criteria and patients fulfilling the ASAS 2009 criteria for SpA diagnosis. Sociodemographic data and disease characteristics were gathered. Treatment satisfaction was evaluated via treatment satisfaction questionnaire for medication (TSQM) designed to assess patient treatment satisfaction in chronic diseases. It comprises 14 items focusing on effectiveness, side effects, convenience, and global satisfaction of the medication. A score ≥ 80 was defined as satisfied.

Results: 62 patients were enrolled: RA (n = 42; 67%), SpA (n = 20; 32.2%). 43 of them were women (88.2% of RA, 49% of SpA). Mean age was 50.4 y ⌈21–67⌉. The mean duration of education was 8.5 y. The mean of BMI was 28.1 kg/m^2 ± 2.55 and of disease duration was 10.4 y ⌈1–26⌉. 46 patients (74.1%) suffered from other physical diseases, while 9 patients had mental disease (19.5%). Mean of DAS28-ESR was 2.8 ⌈1.8–5.3⌉, of ASDAS-CRP was 1.6 ⌈1–3.5⌉ and of BASDAI was 1.4 ⌈0–5⌉. The disease's functional impact was assessed via HAQ in RA patients and via BASFI in SpA patients with a median score of 0.8 ± 0.5 and 1.5 ± 1 respectively. 38 patients (61.2%) were on intravenous biologic. Mean of TSQM summary scores were distributed as follows: treatment effectiveness 80.3 (78.5 vs. 96), side effects 41 (34.5 vs. 45), convenience of administration 70.8 (67.9 vs. 72.7), and global satisfaction 82.6 (88.3 vs. 79.4). There were statistically significant correlations between TSQM and age (p = 0.04), educational level (p = 0.031), the lower number of comorbidities (p = 0.04), DAS28-ESR (p = 0.01) and BASDAI (p = 0.012). Patients having TSQM scores ≥ 80 (n = 38, 61.2%) had a higher educational level, lower patient and physician global assessment and more remission or low activity disease rates compared to 80 or less group.

Conclusion: Treatment satisfaction was significantly associated with educational level, disease activity and the number of comorbidities in chronic rheumatic disease patients.

P895
IMPACT OF THE NUTRITIONAL STATUS ON BONE HEALTH IN RHEUMATOID ARTHRITIS PATIENTS

M. Rachdi[1], Y. Makhlouf[1], S. Miladi[1], H. Boussaa[1], A. Fazaa[1], L. Souebni[1], K. Ouenniche[1], S. Kassab[1], S. Chekili[1], K. Ben Abdelghani[1], A. Laatar[1]

[1]Dept. of Rheumatology, Mongi Slim Hospital, La Marsa, Tunisia

Objective: Well balanced nutrition, although usually overlooked in clinical practice, is required to improve both bone health and disease management, particularly in rheumatoid arthritis (RA) patients. We aimed to assess the nutritional status and determine its association with bone health in RA patients.
Methods: We conducted a cross-sectional study, including RA patients fulfilling the 2010 ACR/EULAR classification criteria. Sociodemographic data and disease related characteristics were gathered. Functional status was measured via the health assessment questionnaire (HAQ). Nutritional status was assessed via the nutrition risk screening 2002 (NRS). It is a validated tool composed of a pre-screening evaluation including 4 questions and a final screening evaluating risk of malnutrition based on: BMI, disease severity and age. A NRS score ≥ 3 indicates risk of malnutrition. DXA was used to measure the BMD of the lumbar spine and the femoral neck. Results were statistically significant if the p-value was < 0.05.
Results: 45 patients were enrolled. The mean age was 59.5 y [31–83]. There was a female predominance with a sex-ratio of 0.14 (females: 85.4%). The median disease duration was 124.7 months [6–366]. The mean DAS28-ESR was 4.07 [0.97–6.90]. The mean HAQ was 0.95 [0–3]. The mean BMI was 25.7 kg/m^2 [13.5–35.8]. Low BMD was found in 56.3% of cases (osteoporosis: 29.4% and osteopenia: 26.9%). Risk of malnutrition according to the NRS was found in 27 patients (56.3%). In the 'at risk of mal nutrition' group, there were significantly more osteoporotic patients (22 vs. 5; p = 0.04). There was a statistically significant association between an impaired nutritional status and a lower BMD expressed in T-score and g/cm^2 at the femoral neck (-2.47 $\pm$ 1.29 SD vs. -1.68 $\pm$ 1.19; p = 0.036) and the lumbar spine (0.717 g/cm^2 $\pm$ 0.193 vs. 0.870 g/cm^2 p = 0.046) respectively. Similarly, an altered nutritional status was associated with advanced age (p = 0.05), and lower BMI (p = 0.061) without reaching a statistically significant threshold. In contrast, lower NRS scores were associated with a longer disease duration(p = 0.006). BMI (OR = 1.10, p = 0.04), and disease duration (OR = 3.02, p = 0.004) were the independent determinants of low bone density in RA patients. While both advanced age (OR = 1.2, p = 0.005) and disease duration (OR = 1.9, p = 0.02) were the independent determinants of nutritional impairment.
Conclusion: Almost half of RA patients had an altered nutritional status. Predictive factors of an altered nutrition and low bone density were mainly advanced age and longer disease duration.

P896
IS THERE AN ASSOCIATION BETWEEN BREAST SIZE AND FUNCTIONAL DISABILITY IN CHRONIC LOW BACK PAIN?

Y. Makhlouf[1], M. Rachdi[2], L. Souebni[1], S. Miladi[1], A. Fazaa[1], H. Boussaa[1], K. Ouenniche[1], S. Kassab[1], S. Chekili[1], K. Ben Abdelghani[1], A. Laatar[1]

[1]Dept. of Rheumatology, Mongi Slim Hospital, La Marsa, [2]Dept. of Rheumatology, Hedi Chaker Hospital, Sfax, Tunisia

Objective: Breast hypertrophy can cause several musculoskeletal symptoms, with spinal pain being the most prevalent one [1]. We aimed to assess the association between breast size and functional disability in CLBP.
Methods: We conducted a cross-sectional study including women with CLBP. Sociodemographic and clinical data were collected. Breast size was assessed with the Sacchini index (SI) [2]. Three breast size groups were defined as follows: Hypomastia (SI < 9 cm), normal breast size (NB) (SI [9-11 cm]), and hypertrophic breast (HB) (SI > 11 cm). The severity of CLBP and the functional disability were measured via the visual analogue scale (VAS) and the Oswestry disability index (ODI) respectively. Lumbosacral spine X-rays were performed in refractory CLBP women and lumbar spinal static parameters were calculated. Statistically significant threshold was fixed for a p-value < 0.05.
Results: 56 women with a mean age of 52.4 y [23–66] were enrolled. The occupational work was distributed as follows: office work (25%) and physical labor (19.6%). The mean duration of CLBP was 8.7 y [1–24] with a mean attack frequency of 2.78 [1–7]. 38 patients were overweight while 17.8% were obese. 39 patients (69,6%) were classified as having HB while 30.3% had a NB. The mean VAS pain was 4.30 [1–7]. ODI was distributed as follows: minimal (26.7%), moderate (60.7%) and severe (12.5%). The mean measures of sacral slope, pelvic tilt, and lumbar lordotic Cobb's angles were: 50.9° [29–74], 50° [23–71] and 41.8° [22–68] respectively. Impaired postural balance was found in 32 patients. There was no significant association between HBS and lumbar lordosis (p = 0.091), pelvic tilt (0.156), sacral slope (p = 0.128), and abnormal spinal posture (p = 0.304). Similarly, HB was more frequent in patients with higher VAS and ODI scores, without reaching a statistical significance (p = 0.055 and P = 0.069) respectively. Moreover, HB and NB groups were comparable in terms of age (p = 0.113), attack frequency (p = 0.320), and disease duration (p = 0.246), although the mean BMI was higher among the HB group (29.2 vs. 24.6 kg/m^2, p = 0.002).
Conclusion: Increased breast size had a positive, yet not statistically significant impact on pain intensity and functional ability in women with CLBP. Further studies with larger sample sizes are needed to identify better the impact of breast size on this common condition.

P897
APPLICABILITY OF OPPORTUNISTIC CT FOR BONE AND MUSCLE ASSESSMENT IN ADULT POPULATION WITH SPINAL MUSCULAR ATROPHY

M. Rakusa[1], Z. Snoj[2], L. Leonardis[3], B. Koritnik[3]

[1]Dept. of Endocrinology, Diabetes and Metabolic Disease, Univ. Medical Centre Ljubljana, [2]Radiology Institute, Univ. Medical Centre Ljubljana, [3]Institute of Clinical Neurophysiology, Univ. Medical Centre Ljubljana, Ljubljana, Slovenia.

Objective: Spinal muscular atrophy (SMA) is hereditary, degenerative, neuromuscular disease, that leads to muscle weakness and atrophy. Number of survival motor neuron 2 (SMN2) gene copies affect severity of disease. Osteoporosis and fractures are common in SMA. Nusinersen, which is administrated intrathecally, is approved therapy for SMA. Computed tomography (CT) is often needed for planning of lumbar puncture. The aim of our study is to evaluate incidence of osteoporosis, vertebral fractures and muscle characteristics using opportunistic CT in SMA population.
Methods: We retrospectively analysed CT scans. We measured bone and muscle density in Hounsfield units (HU) and bilateral area of erector spinae muscles on L1 level. We assessed vertebral fracture according to Genant semiquantitative score. We compared measured parameters to ambulatory status and SMN2 gene copies.

Results: 17 patients with SMA type 2 and 3 patients (10 females (59%)), of median age 40 (IQR 20.5) y, had CT prior to start of nusinersen treatment. Six (35%) were ambulatory. Only 1 (6%) patient had vertebral fracture (grade 2). Median bone density was 85 (IQR 134) HU, muscle density 70 (IQR 42) HU, bilateral muscle area 26.5 (25.5) cm^2. There were overall 9 (53%) patients with low bone density, 5 (29%) with normal bone density and 3 (18%) in intermediate range. Patients with normal or intermediate bone density had 4 or 5 and patients with low bone density had 2 or 3 SMN2 copies. All patients with low bone density were non-ambulatory. Ambulatory and non-ambulatory groups were significantly different in bone density, muscle density and bilateral muscle area ($p < 0.001$, $p < 0.001$ and $p = 0.020$). Bone density and muscle density correlated with SMN2 copies (Spearman's rho 0.694, $p = 0.002$ and 0.654, $p = 0.004$, respectively).
Conclusion: CT a is useful method for assessment of bone density in SMA population. Ambulatory status and SMN2 copies are important risk factors for low bone and muscle density. Vertebral fracture incidence in our population was low. Further studies on SMA population are needed.

P898
EFFICACY OF ULTRASOUND GUIDED CAUDAL EPIDURAL STEROID INJECTION WITH OR WITHOUT OZONE IN PATIENTS WITH LUMBOSACRAL CANAL STENOSIS; A RANDOMIZED CLINICAL CONTROLLED TRIAL

M. Rayegani[1], V. Soltani[1], S. Raeissadat[1]

[1]Physical Medicine and Rehabilitation Research Center, Shohada Tajrish Medical Center, Shahid Beheshti Univ. of Medical Sciences, Tehran, Iran

Objective: Lumbosacral canal stenosis is known as the most common cause of back surgery with several complications. Selecting a minimally invasive treatment with high efficacy in such patients is necessary. This study was designed to evaluate the effectiveness of ozone therapy in combination with caudal epidural steroid in patients with lumbar spinal stenosis.
Methods: A double-blind randomized clinical trial was conducted on 50 patients with lumbar spinal stenosis allocated into two study groups. Under ultrasound guidance, the first group received 80 mg of triamcinolone hexavalent with 4 mL of Marcaine 0.5% and 6 mL of distilled water to the caudal epidural space. The second group received an injection similar to the first group, combined with 10 mL of ozone (O2-O3) gas at a concentration of 10 μg/cc. The patients were followed at baseline, one, and six months after injection with clinical outcomes measures using visual analog scale (VAS), walking distance (WD) and Oswestry disability index (ODI).
Results: The mean age of subjects, 30 males (60%) and 20 females (40%), was reported as 64.51 ± 7.19 years old. Reduction of pain intensity based on VAS score was statistically significant in both groups at follow-up periods ($P < 0.001$). The VAS changes in the first month and sixth months showed no significant difference between the two groups ($P = 0.28$ and $P = 0.33$, respectively). The improvement in disability index (ODI) in both types of treatment during follow-up was significant ($P < 0.0001$), and there was no difference between the two treatment groups in 1 month and 6 months ($P = 0.48$ and $P = 0.88$, respectively). As for walking distance, the improvement process with both types of treatment during follow-up periods was significant ($P < 0.001$). However, after 1 and 6 months of treatment, the rate of improvement in patients' walking distance in the caudal epidural steroid injection plus ozone group was significantly higher than in the epidural steroid group ($p = 0.026$ and $p = 0.017$, respectively).
Conclusion: The results of VAS and ODI outcomes showed that caudal epidural steroid injection combined with ozone has no advantage over caudal epidural steroid injection alone.

P899
BIOFEEDBACK TRAINING EFFICIENCY IN RHEUMATOID ARTHRITIS PATIENTS

R. Grekhov[1], A. Aleksandrov[1], M. Raza[2], V. Aleksandrov[1]

[1]Zborovsky' Research Institute for Clinical and Experimental Rheumatology, Volgograd State Medical Univ., Volgograd, Russia, [2]Riga Stradins Univ., Faculty of Medicine, Riga, Latvia

Objective: To increase the efficiency of complex therapy of patients with rheumatoid arthritis (RA) using biofeedback training (BFB).
Methods: We observed 90 patients with diagnosis of RA: 65 women (72,2%) and 25 men (27,8%) aging from 18–66 y. According to the objectives, RA patients were divided randomly into two groups, similar according to gender, age and duration of disease: main (n = 60) and control (n = 30). RA patients of the main and control groups received similar medicament and physiotherapeutic treatment. Besides, patients of main group received in addition 14 daily sessions of biofeedback training using Reacor—rehabilitation psycho-physiological computer device.
Results: Analysis of the dynamics of mandatory clinical and laboratory parameters of effectiveness of the therapy and their comparison in patients of the main and control groups was carried out. Score of treatment efficacy was assessed by ACR criteria (Table 1).

Table 1. Evaluating the effectiveness of treatment of RA patients with ACR criteria

Estimated parameter	Main group (n=60)	Control group (n=30)	Reliability (χ^2; p)
ACR 20	39 (65%)	13 (43,3%)	χ^2=4,12; p=0,04
ACR 50	12 (20%)	5 (16,6%)	χ^2=0,09; p=0,76
ACR 70	–	–	–

Evaluating the effectiveness of therapy by ACR 20 criteria in the main group was significantly higher than in control ($p = 0,04$). At the same time, DAS 28 authentically changed in patients of both groups (at $p < 0,001$), but these changes corresponded to 1,6 points in the main group, and 1,2 in the control that corresponds to moderate effect of anti-rheumatic therapy. When using BFB training there was a decrease of intensity of pain eventually bringing to relief and a decrease in exudative phenomena in the joints, increased joint mobility, and improved overall well-being of patients. BFB training gives the patient the opportunity to receive positive reinforcement through feedback, informing them about the development of skills of self-regulation, the patient brings a sense of satisfaction associated with the completion of self-voluntary efforts, and the awareness of the possibility of improvement. Sense of hopelessness and helplessness is replaced by feeling of the prospect, new possibilities that promotes the reduction of pain syndrome and a decrease in depression and frustration.
Conclusion: Application of biofeedback therapy enhances the effectiveness of complex therapy of RA patients by reducing pain and joint syndrome, promotes active and conscious participation of the subject in the course of therapy on the basis of self-regulation and self-control, and therefore mobilized will potential and increased self-esteem of patients. The method of BFB training is an affordable and safe treatment that can be recommended for widespread use in rheumatology practice.

P900
PSYCHOLOGICAL FORMS OF AGGRESSIVITY IN RHEUMATOID ARTHRITIS PATIENTS

R. Grekhov[1], A. Aleksandrov[1], M. Raza[2], V. Aleksandrov[1]

[1]Zborovsky' Research Institute for Clinical and Experimental Rheumatology, Volgograd State Medical Univ., Volgograd, Russia, [2]Riga Stradins Univ., Faculty of Medicine, Riga, Latvia

Objective: Rheumatoid arthritis (RA) refers to diseases with an insufficiently known pathogenesis. It remains actual to study not only immunobiological, but also psychosomatic prerequisites for its development, in particular, the study of indicators and forms of aggressiveness in RA patients, which was the purpose of this study.
Methods: 37 patients with RA in average age 44.01 ± 12.23 y were examined. The study was conducted using the Buss-Durkee Hostility Inventory (BDHI) to measure of the various aspects of hostility and guilt.
Results: It was revealed that the aggressiveness index in 56,75% of the subjects was below the norm, in 40,55% the norm of aggressiveness was revealed, and only 2,7% of patients demonstrated high levels of aggressiveness. The hostility index in 59,45% of the subjects was within the normal range, high hostility was detected in 32,43%, and hostility was low in 8,1% of patients. The data indicate that RA patients are quite hostile, but not aggressive outwardly, and hostile tendencies remain unreacted. Further, an analysis of individual forms of aggressiveness was carried out. The most characteristic form of aggression for patients is a feeling of guilt (on average 76,1 ± 21,12 points). The indicators of indirect aggression were also high (on average 59,7 ± 22,81 points). The average value in terms of resentment was 55,2 ± 22,81 points. The feeling of resentment does not contribute to the constructive response of aggressive impulses, but rather leads to their suppression and accumulation, which can also be a prerequisite for the development of psychosomatic diseases. The indicators of verbal aggression and irritation were less pronounced – on average 49,3 ± 22,35 and 47,2 ± 21,12 points, respectively. Patients are least prone to manifestations of suspicion (on average 44,9 ± 27,97 points), physical aggression (41,6 ± 25,02 points) and negativism (34 ± 23,97 points).
Conclusion: Patients with RA have a certain specificity of aggressive manifestations, which can be characterized as autoaggressive. They tend to project aggression onto their own personality, feel guilty or accumulate anger in the form of resentment, but do not actively show aggressive impulses to the outside in the form of physical aggression, etc. Patients are quite hostile to the world, they feel a threat to their own safety, but these feelings remain unreacted. Our findings indicate the need to provide RA patients not only with medication, but also with psychological help that should be aimed at overcoming self-destructive tendencies, feelings of guilt and resentment, reducing hostility, as well as developing skills for constructive response to aggressive impulses.

P901
SEVERE SARCOPENIA IN A MAN WITH INCOMPLETE SPINAL CORD INJURY

M. S. Deac[1], A. Gherle[1], D. Stoicanescu[2], M. Cevei[1], I. R. Cevei[2], A. C. Zamfir[2]

[1]Univ. of Oradea, Faculty of Medicine, Oradea, [2]Univ. of Medicine and Pharmacy "Victor Babes", Timisoara, Romania

Different factors may contribute to the loss of muscle strength and mass, leading to sarcopenia.
Case report: We describe a 58-year-old male patient with a history of an accident by falling from a 3-m height in 2020 resulting in dorsolumbar spinal cord injury. The D12-L1 fracture was operated with a posterior metal rahisynthesis. He was admitted to the Medical Rehabilitation Clinical Hospital Baile Felix, Romania for tetraparetic motor deficit. The clinical examination revealed: ASIA C score—L4 motor level. The John Health System Corporation scale established a high risk of falling, with 16 points. Functional Independence Measure scale revealed 63 points out of 126, 50%. Barthel Index for Activities of Daily Living assessing functional independence revealed 50 points out of 100 indicating severe dependence. Functional Ambulation Classification score was 2 indicating ambulation dependent on physical assistance. BMD determination using DXA from 02.09.2023 indicated osteopenia: lumbar spine Z-score:—1.5; left hip Z-score: -2.0; right hip Z-score: -1.8. ALM value was 0.5 indicating sarcopenia. Jamar hand-held dynamometer used to measure handgrip strength indicated 24 kg for the right hand and 20 kg for the left hand. Medical rehabilitation included daily kinetic program; back toning exercises; limiting weight lifting; toning exercises: weight training three times a week; postural exercises: WKO combined with tilting of the pelvis and extension of the back. Patient's compliance with all measures related to fall prevention is very important.
Conclusion: Although the spinal cord injury was at the dorsolumbar level, the muscle strength and the functionality of the upper limbs were also impaired.

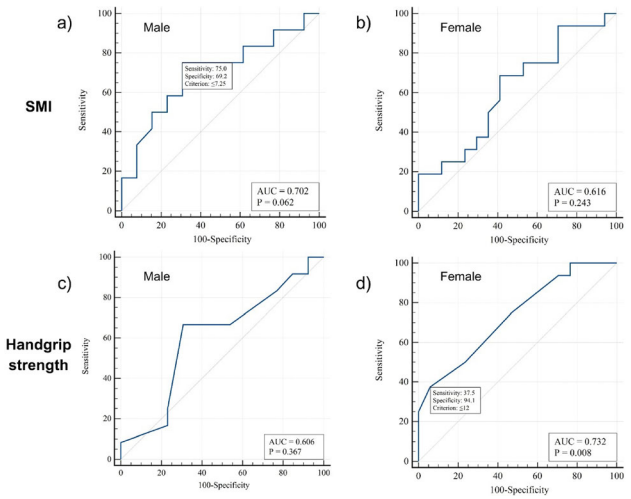
P902
PREDICTION OF LOW BONE MINERAL DENSITY BY CUT-OFF MUSCLE MASS AND STRENGTH VALUES IN ADULTS WITH JUVENILE IDIOPATHIC ARTHRITIS

M. S. Kulyk[1], A. L. Novytska[2], R. A. Potomka[2], O. I. Ivashkivsky[2], T. A. Karasevska[3], H. V. Mostbauer[3], R. L. Lories[4], K. D. V. De Vlam[4], M. B. Dzhus[5]

[1]Internal Medicine Dept. No2, Bogomolets National Medical Univ., Kyiv, Ukraine; KU Leuven, Skeletal Biology and Engineering Research Center, Leuven, Belgium, [2]Rheumatology Dept. of Communal Non-commercial Institution "Oleksandrivska Clinical Hospital", Kyiv, Ukraine, [3]Internal Medicine Dept. No2, Bogomolets National Medical Univ., Kyiv, Ukraine, [4]KU Leuven, Skeletal Biology and Engineering Research Center, Leuven, Belgium, [5]Internal Medicine Dept. No2, Bogomolets National Medical Univ.,; Rheumatology Dept. of Communal Non-commercial Institution "Oleksandrivska Clinical Hospital", Kyiv, Ukraine

Objective: To predict low BMD by cut-off muscle mass and strength values in adults with juvenile idiopathic arthritis (JIA).
Methods: This cross-sectional study in a single center, approved by the local research and ethics committees, included 58 young patients who applied to the rheumatology department. Skeletal muscle mass and BMD were determined using DXA. The skeletal muscle mass index (SMI) was defined by appendicular skeletal mass/height^2 (kg/m^2) with such thresholds for men: < 7.23 kg/m^2 and women: < 5.67 kg/m^2. Handgrip strength (HGS) was assessed using a hand dynamometer (JAMAR) with the following thresholds: < 27 kg for men and < 16 kg for women. The median value of BMD was determined for males and females to predict the decrease of BMD depending on the low muscle mass and strength. The area under the receiver operating characteristic curve (AUROC) was calculated to determine the ability of HGS and SMI to predict low BMD.
Results: For males, a decrease in BMD was defined as less than the median value (< 1.092 g/cm^2), and for females—less than the median value (< 1.028 g/cm^2). The connection between the risk of a decrease in BMD and low SMI for males was not found; AUC does not differ from 0.5 but has such a tendency ($p = 0.062$) (Fig. 1a). The connection between the risk of BMD reduction and SMI for females was not found; AUC curve does not differ from 0.5 ($p = 0.243$) (Fig. 1b).

The connection between the low BMD and decreased HGS for males was not found; AUC does not differ from 0.5 (p = 0.367) (Fig. 1c). The connection between the low BMD depending on HGS for females was found, AUC = 0.73 (95%CI 0.56—0.90) (p = 0.008) (Fig. 1d). A decrease in the risk of low BMD for females was found with increasing HGS for each unit, OR = 0.67 (95%CI 0.47–0.97).



Conclusion: The connection between low HGS and low BMD was found in female patients with JIA, which can mean the cut-off value of HGS less than 16 kg can be a helpful tool for predicting low BMD.

P903
FACTORS ASSOCIATED WITH SARCOPENIA IN YOUNG ADULTS WITH JUVENILE IDIOPATHIC ARTHRITIS

M. S. Kulyk[1], A. L. Novytska[2], R. A. Potomka[2], O. I. Ivashkivsky[2], T. A. Karasevska[3], H. V. Mostbauer[3], R. L. Lories[4], K. D. V. De Vlam[4], M. B. Dzhus[5]

[1]Internal Medicine Dept. No2, Bogomolets National Medical Univ., Kyiv, Ukraine; KU Leuven, Skeletal Biology and Engineering Research Center, Leuven, Belgium, [2]Rheumatology Dept. of Communal Non-commercial Institution "Oleksandrivska Clinical Hospital", Kyiv, Ukraine, [3]Internal Medicine Dept. No2, Bogomolets National Medical Univ., Kyiv, Ukraine, [4]KU Leuven, Skeletal Biology and Engineering Research Center, Leuven, Belgium, [5]Internal Medicine Dept. No2, Bogomolets National Medical Univ.,; Rheumatology Dept. of Communal Non-commercial Institution "Oleksandrivska Clinical Hospital", Kyiv, Ukraine

Objective: To determine the prevalence of sarcopenia and its associated factors in young adults with juvenile idiopathic arthritis (JIA).
Methods: This cross-sectional study in a single center, approved by the local research and ethics committees, included fifty-eight patients who applied to the rheumatology department. Inclusion criteria: patients with JIA, 18–44 years old. Exclusion criteria: patients with joint replacement, diabetes mellitus, obesity. Sarcopenia was defined as a decrease in muscle mass and strength. Skeletal muscle mass and BMD were determined using DXA. The skeletal muscle mass index (SMI) was defined by appendicular skeletal mass/height^2 (kg/m^2) with such thresholds for men: < 7.23 kg/m^2 and for women: < 5.67 kg/m^2. Muscle strength was assessed using a hand dynamometer (JAMAR) with the following thresholds: < 27 kg for men and < 16 kg for women. Anthropometric, clinical, and laboratory data were determined for all patients, including BMI, disease activity by Disease Activity Score (DAS28), Juvenile Arthritis Disease Activity Score (JADAS27), and functional capacity according to the Health Assessment Questionnaire (HAQ).
Results. The mean age of the patients was 24.2 ± 2.3 y. The prevalence of sarcopenia was 35/58 among patients of both sexes, 11/25 among men and 24/33 among women, respectively. The following factors associated with sarcopenia in a univariate logistic regression model were identified: male sex (odds ratio (OR) 0.29, confidence interval (CI) 0.10–0.89; p = 0.03), BMI (OR 0.73, CI 0.60–0.89; p = 0.002), DAS28 and JADAS27 indices (OR 2.44, CI 1.39–4.27; p = 0.002; OR 1.15, CI 1.04–1.27; p = 0.007, respectively), HAQ (OR 4.14, CI 1.38–12.5; p = 0.01) and femoral neck BMD (OR 0.005, CI 0.0002–0.17; p = 0.003).
Conclusion: Sarcopenia was noted in 60% of young patients with JIA. Loss of muscle mass and strength in young patients with JIA is associated with disease activity, BMI, and HAQ.

P904
MODERN TREATMENT OF OSTEOPOROSIS—DENOSUMAB: CASE REPORT

M. S. Marinkovic[1]

[1]General Hospital Uzice, Uzice, Serbia

Case report: Patient JC, 61 years old, noticed a slight flexion of the shoulder and pain in both shoulder joints. He suffers from diabetes, type—a II, on OAD therapy. The menstrual cycle stopped at the age of 45. She had a fracture of her right forearm in January 2020. The level of vitamin D was determined, which was 29.3 nmol/l, calcium level 2.56, phosphorus 1.00, PTH: 99.0, ALP: 56. In June 2020, a diagnosis of osteoporosis was made by osteodensitometry, which shows a significantly reduced bone density in terms of osteoporosis in both the hip and the spine. Prescribed therapy Prolia amp. A 60 mg, once in 6 months and vitamin D a 1000 ij, 1 tablet a day. The patient comes for the first control examination after a year, by then she received 2 Prolia ampoules, when we do the DXA examination again, in order to determine the effectiveness of the given therapy. At the first control DXA examination, it was determined that there was still a decrease in bone density both at the level of the spine and at the level of the hip, in terms of osteoporosis, but with an improvement in bone density at the level of the spine by 4.9% and 2.8% at the level of the hip. We continue the current therapy and schedule the next control examination in a year. A second follow-up with a new DXA scan shows improved bone densities at both the spine and hip levels. Bone density at the level of the spine enters the region of osteopenia (T score -2.4), which indicates an improvement in bone density compared to the first examination by 12%. On the hip, the bone density improved by 6.8% compared to the first examination, but the bone density on the hip still remains at the level of osteoporosis (T-score -2.8). Laboratory tests including a calcium level of 2.48 and a significantly improved vitamin D level of 56 nmo/l. The patient felt much better, the pain in her shoulder joints disappeared, she was in a better mood and she herself noticed that she straightened up. We continued the same therapy (Prolia amp and vitamin D), which gave a positive clinical effect, as well as an improvement in bone density on examination with an osteodensitometer. We scheduled a control examination with laboratory analyzes and a new DXA examination in 2 y.
Conclusion: In our case, the therapy with Prolia ampoules and denosumab proved to be very effective, because it improved the clinical and psychological condition of our patient, and the examination with an osteodensitometer showed a significant improvement in bone density.

P905
METABOLIC SYNDROME: A GOOD RESPONDER TO PRP INJECTION FOR KNEE OSTEOARTHRITIS TREATMENT, PROSPECTIVE COHORT STUDY

M. S. Metadilogkul[1], V. N. Virasathienpornkul[1], W. S. Wanitchakorn[1]

[1]Institute of Orthopedics, Lerdsin Hospital, Dept. of Thailand Medical Services., Bangkok, Thailand

Objective: Platelet-rich plasma (PRP) intra-articular injections have gained popularity and are suggested to be more effective and longer lasting than corticosteroid or viscosupplementation therapy. There is an increasing number of studies have found correlation between metabolic syndrome (MetS) and knee osteoarthritis. To study how metabolic syndrome state effects to an efficacy of PRP injection in the patients with KOA.
Methods: 84 patients with radiologically confirmed mild-to-moderate knee osteoarthritis who received single intra-articular PRP injections were included in a study. Parameters of MetS according to International Diabetes Federation (IDF) criteria were collected. Patient reported outcomes was measured using WOMAC)and the visual analogue scale (VAS) before the treatment, at 6 month and 12 months follow up.
Results: Significant improvements in the majority of WOMAC and VAS were found throughout the entire 12-month follow-up, following the PRP injections in both KOA with MetS and non-MetS groups. Mean difference in WOMAC total at 12 months was 48.4% and 40.7% in MetS and non-MetS groups, respectively ($p < 0.001$). Mean reduction in VAS at 12 months was 4.8 and 3.6 in MetS and non-MetS groups, respectively ($p < 0.05$).
Conclusion: Intra-articular injection of PRP alleviates symptoms and pain and improves functionality in patients with KOA. Patients with MetS have a better clinical response to PRP application. To assess metabolic syndrome state in the patients with KOA might be a benefit as prognostic factor to identify which patient will have more efficacy from this treatment intervention.

P906
CLINICAL-ANALYTICAL AND DENSITOMETRIC CHARACTERISTICS OF A COHORT OF PATIENTS WITH SEVERE OSTEOPOROSIS TREATED WITH ROMOSOZUMAB

M. S. Moreno Garcia[1], Y. Uson Rodriguez[1], E. Meriño Ibarra[2], E. Giner Serret[3], M. Arce Benavente[1], J. C. Cobeta García[4], M. D. Fábregas Canales[5], J. Ulier Bellmunt[1], G. Boselli Oporto[1], F. J. Manero Ruíz[1]

[1]Hospital Universitario Miguel Servet, Zaragoza, [2]Hospital San Jorge, Huesca, [3]Hospital Royo Villanova, Zaragoza, [4]Hospital Ernest Lluch, Calatayud, Zaragoza, [5]HOspital Barbastro, Barbastro, Huesca, Spain

Objective: Romosozumab (ROMO) is an antisclerostin antibody used in treatment of severe osteoporosis (OP). In 2022, ROMO was approved for use in Spain for the treatment of severe OP in clinical practice. In our country, there are several restrictions for its financing: women with severe OP with BMD < -3, previously treated with bisphosphonates, previous major fragility fracture in the previous 24 months, with no history of heart attack, stroke or coronary artery disease, and with low/moderate cardiovascular risk according to REGICOR (< 10%). We describe a clinical, analytical, densitometric characteristics, and cardiovascular risk factors in patients treated with ROMO.
Methods: A multicenter prospective observational descriptive study developed in rheumatology clinics in Aragon, Spain, that included patients with OP in whom ROMO treatment was initiated from 2022–2023. The following information was collected: baseline characteristics (age, sex), cardiovascular risk factors, such as: history of high blood pressure (HBP), dyslipemia (DLP), diabetes mellitus (DM) and smoking habits, the estimation of cardiovascular risk by REGICOR calculator, glomerular filtration rate, previous therapies (antiresorptives) and results of BMD pre-ROMO therapy.
Results: A total of 46 patients were included, all women with severe OP. The average age was 69.8 y. A total of 80.4% of the patients had suffered a vertebral fracture. Regarding the cardiovascular risk factors, we found: 37% high blood pressure, 37% dyslipidemia, 10.9% active smoking. Cardiovascular risk was estimated by REGICOR calculator, 2,82% patients were at low-moderate risk. It should be noted that this tool does not allow us to assess the risk in people over the age of 74 years old. All patients had good renal function (GFR 83 ml/min ± 12.2). Only in 12 patients CTX was determined with a mean of 436 pg/ml (SD 307) prior to ROMO treatment. (more data see Table 1). Previous treatment was done in 89,1% of patients, 34,8% were treated with one drug, 34% two drugs and 19,6% three drugs (bisphosphonates, denosumab and teriparatide). Concomitant treatment with calcium and D vitamin was received in 67.4% of patients. More than 50% of patients were treated with PPI. With regard to baseline BMD, the mean T-Score in the lumbar spine was -3.49 and -2.67 in femoral neck.

Table 1. Baseline characteristics of studied cohort, before treatment with romosozumab.

Variable		N=46
Age(y), mean±DE		69,8±6,49
CVRF, n (%)	HBP	17 (37%)
	DM	-
	DLP	17 (37%)
	REGICORE, mean±DE	2,82±0,85
Active smoker, n (%)		5 (10,9%)
Early menopause, n (%)		11 (23.9%)
Parental hip fracture, n (%)		8 (17,8%)
Fracture before treatment, n (%)	Vertebral	37 (80,4%)
	Vertebral Fx number, mean±DE	2,7±2,24
	Hip	3 (6,5%)
	Other fractures	13 (28,3%)
	None	4 (8,7%)
Previous treatment with corticosteroids, n (%)		5 (10,9%)
Previous treatment with SSRIs, n (%)		17 (37%)
Previous PPI treatment, n (%)		26 (56,5%)
BMD, mean±DE	T-Score L1-L4	-3,49±0,66
	T-Score femoral neck	-2,67±0.86
FRAX (%), mean±DE	Major Fx Risk	18,1±8,63
	Hip Fx risk.	8,44±7,65
Treatment before romosozumab, n (%)	Bisphosphonates	29 (63%)
	Denosumab	26 (56,5%)
	Teriparatide	20 (43,5%)
Treatment with calcium and D vitamin, n (%)		31 (67,4%)

CVFR: Cardiovascular risk factors

Conclusion: Preliminary characteristics of the cohort of patients to follow-up are described at two years (after ROMO one year and subsequent antiresorptive and densitometry at 2 years—2025).Our cohort of women treated with ROMO is characterised by severe osteoporosis with vertebral fractures, high prevalence of cardiovascular risk factors and in most cases had received previous treatment.

P907
EFFECTS OF THE COVID-19 PANDEMIC ON DIAGNOSIS AND TREATMENT OF OSTEOPOROSIS

S. Hajivalizadeh[1], M. Sanjari[1], K. Khalagi[1], M. Effatpanah[2], Z. Shahali[3], F. Hajivalizadeh[4], N. Fahimfar[1], M. Mohammadian[5], P. Montazerlotf[6], E. Hesari[1], M. J. Mansourzadeh[1], A. Ostovar[1]

[1]Osteoporosis Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran Univ. of Medical Sciences, [2]Pediatric Dept., School of Medicine, Imam Khomeini hospital, Tehran Univ. of Medical Sciences, [3]National Center for Health Insurance Research, [4]Center for Non-Communicable Disease Control & Prevention, Deputy of Public Health, Ministry of Health and Medical Education, [5]Dept. of Epidemiology, School of Public Health and Safety, Shahid Beheshti Univ. of Medical Sciences, [6]Endocrinology and Metabolism Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran Univ. of Medical Sciences, Tehran, Iran

Objective: The emersion of the COVID-19 pandemic has substantially affected the management of non-communicable diseases, including osteoporosis. In this study, we investigated the impact of COVID-19 on the diagnosis and treatment of osteoporosis.
Methods: This cross-sectional study was conducted on health insurance data, which covered all 31 provinces of Iran from 2019–2021. Since COVID-19 emerged in Iran in February 2020, the number of prescribed osteoporosis-related diagnostic tests and medications were assessed before and during the pandemic. The evaluated prescriptions of tests included serum vitamin D levels, serum calcium levels, and BMD. The number of FRAX tests done with Iranian internet protocol addresses (IP addresses) between 2019–2021 were received from Sheffield University and assessed in this study. The evaluated medications were prescribed alendronates. The Mann–Whitney test and Interrupted time series analysis were used by STATA statistical software version 15. β coefficient of interrupted time series analysis was estimated as the change in the number of prescribed tests and medications before and during the COVID-19 pandemic. The research ethics committee of the Endocrinology and Metabolism Research Institute of Tehran University of Medical Sciences approved this study.
Results: Regarding osteoporosis-related prescribed tests and medications, 2,862,871 vitamin D serum levels prescriptions, 1,952,600 calcium serum levels prescriptions, 62,718 BMD prescriptions, and 388,519 alendronate prescriptions were assessed. The results of the statistical analysis are shown in Table 1. The results of interrupted time series for changing levels of prescribed diagnostic tests, medications, and FRAX after the initiation of the pandemic compared to before the pandemic (β coefficient) are demonstrated. According to them, 71,579 prescribed vitamin D serum levels and 814 prescribed calcium serum levels were added to their number before the pandemic. Unlike them, 2682 prescribed BMDs, 11,579 prescribed alendronates, and 411 FRAX decreased after the onset of the pandemic. All of the changing levels were statistically significant except for the increase in the prescription of calcium serum levels. However, the increase in the prescription of this test was statistically significant based on the Mann–Whitney test.

Table 1. Comparison of the prescription of medications and tests before and during the COVID-19 pandemic

	Bivariate analysis					Interrupted time series analysis	
	Before pandemic		During pandemic		P-value*	β coefficient	P-value
	Median	IQR	Median	IQR			
Vitamin D serum levels	741.5	359	98133	69698	<0.001	71579	0.042
Calcium serum levels	305.5	121	65296	49527	<0.001	814	0.601
BMD	2128	209	840	1224	0.047	-2682	<0.001
Alendronate	20471	1523	4578	7656	<0.001	-11579	0.002
FRAX	708	186	960	596	0.005	-411	<0.001

* Mann-Whitney test

Conclusion: The prescription of serum levels of vitamin D increased after the pandemic initiation due to the effect of vitamin D in the management of COVID-19. This study demonstrated that the emersion of the COVID-19 pandemic disrupted the diagnosis and management of osteoporosis in Iran.

P908
FRACTURE MANAGEMENT CONSIDERING OSTEOPOROSIS IN OLDER ADULTS BY PHYSICIANS: A QUALITATIVE STUDY

S. Salehi[1], M. Sanjari[2], P. Zarepour[1], F. Z. Dehestani[1], N. Fahimfar[2], A. Ostovar[3]

[1]Dept. of Epidemiology and Biostatistics, school of public health, Tehran Univ. of medical sciences, [2]Osteoporosis Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran Univ. of Medical Sciences, [3]Endocrinology and Metabolism Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran Univ. of Medical Sciences, Tehran, Iran

Objective: To explain the approach of physicians in the diagnosis, treatment, and follow-up of fractures considering osteoporosis in the elderly population.
Methods: This study was a qualitative content analysis, using the conventional method. The participants were selected based on their expertise in purposive sampling methods. The semi-structured interviews were conducted with eight physicians (two general practitioners, three orthopedists, two emergency physicians, and one rheumatologist) in inpatient and outpatient clinical settings. The transcript was read line by line and coded. These codes were converted into primary and also main categories by comparing approaches. Data analysis and coding were performed simultaneously with the interviews and transcripts. Informed consent was obtained from all participants. Ethics code: IR.TUMS.EMRI.REC.1402.042.
Results: The mean age of participants was 31.75. Three of them were male and five of them were female. Data analysis led to 101 codes, 20 subcategories, and six main categories. The main category "forgotten osteoporosis in the face of the fracture" showed that physicians pay less attention to the diagnosis of osteoporosis in the initial encounter with the fracture. One of our main categories was "Treatment of fracture beforehand osteoporosis disease" which revealed that the treatment of osteoporosis is the second priority in comparison to the treatment of fracture. The main category "osteoporosis treatment during fracture treatment" explains that physicians considered osteoporosis as an effective factor during treatment and follow-up of

the fracture outcomes. "Specific characteristics of osteoporosis" is another main category that elucidates, the specialists more than general physicians, deliberate specific considerations in risk evaluation and diagnosis of osteoporosis. The osteoporosis knowledge is not adequate in the medical school curriculum and the task of osteoporosis treatment is mostly moved to specialists; these findings guide to another main category "shortage of osteoporosis in the medical curriculum". Also, the deficiency of patient education and empowerment about osteoporosis, falls, and refractures leads to the main category "Ignoring the patient with osteoporosis".
Conclusion: The study highlights the emphasis on the implementation of guidelines and pathways in clinical settings and addressing adequate education on osteoporosis in the medical curriculum.

P909
MISCONCEPTIONS ABOUT OSTEOPOROSIS IN YOUNG ADULTS: A QUALITATIVE STUDY

M. Ramezanzade[1], M. Sanjari[2], S. Fahimifar[1], N. Fahimfar[2], A. Ostovar[3]

[1]Dept. of Knowledge and Information Science, Faculty of Management, Univ. of Tehran, [2]Osteoporosis Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran Univ. of Medical Sciences, [3]Endocrinology and Metabolism Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran Univ. of Medical Sciences, Tehran, Iran

Objective: Osteoporosis is a common metabolic disease that causes bone loss and fractures. One of the most important factors that can prevent osteoporosis is the elimination of common misconceptions in society and the general public. The purpose of this qualitative research is to illustrate the false beliefs in healthy young adults.
Methods: This study is a qualitative content analysis in which data was collected through semi-structured interviews. The 11 participants including young people aged 20–40 were selected through convenience and purposive sampling methods. The average interview time is 30 min. The interviews were recorded and transcribed verbatim. To familiarize with the interviews, their text was studied several times and finally analyzed by conventional content analysis. The transcript was read line by line and coded. These codes were converted into subcategories and also main categories by comparing approaches. Ethics code: IR.TUMS.EMRI.REC.1402.001.
Results: Qualitative data analysis led to a total of 291 codes, 17 subcategories, and 7 main categories. The main category "Osteoporosis in the frame of ignorance and disbelief" includes the beliefs that the disease is not serious and individuals' ignorance of osteoporosis. The main category of "misunderstanding of risk factors", includes false opinions about the effect of inappropriate personal and environmental conditions, genetics, and obesity on the catch the disease. The untrue beliefs regarding the prohibition of dairy product consumption in patients with kidney and digestive diseases as well as the benefit of consumption of meat and bone-containing foods because they strengthen bones, leads to another main category "Improper usage of food". The main category of "Amateurish bone protection with traditional medicine" includes uninformed use of traditional medicine and herbal medicine to prevent osteoporosis and treatment of minor fractures. "Living in the dark shadow of osteoporosis", as the main category, includes unreal fears and concerns about the consequences of osteoporosis, such as the underlying cause of other diseases, and disrupting the normal life process of the affected person. Also, the incorrect views include failure of the bone healing after fracture and unavoidable disability after fracture leads to another main category "Detachment of life after fracture". The last main category "health literacy is the missing linkage", which includes obtaining incorrect health information from invalid cyberspace and platforms.
Conclusion: Accordingly, to prevent osteoporosis, it is necessary to identify existing false beliefs and provide awareness programs such as campaigns to reduce the rate of these misconceptions and replace them with proper and valid health information and behaviors.

P910
OSTEOPOROSIS MANAGEMENT VIRTUAL COURSE: A QUASI-EXPERIMENTAL STUDY ON THE PRINCIPLES OF OSTEOPOROSIS MANAGEMENT

E. Hesari[1], M. Sanjari[1], N. Fahimfar[1], F. Hajivalizadeh[2], M. Aalaa[3], M. Amini[1], M. J. Mansourzadeh[1], M. Darman[2], H. Ghajari[4], S. Hajivalizadeh[1], A. Ostovar[5], K. Khalagi[6], B. Larijani[7]

[1]Osteoporosis Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran Univ. of Medical Sciences, [2]Center for Non-Communicable Disease Control & Prevention, Deputy of Public Health, Ministry of Health and Medical Education, [3]Dept. of e-learning in Medical Education, School of Medicine, Tehran Univ. of Medical Sciences, [4]Dept. of Epidemiology, School of Public Health and Safety, Shahid Beheshti Univ. of Medical Sciences, [5]Dept. of Epidemiology and Biostatistics, School of Public Health, Tehran Univ. of Medical Sciences, [6]Obesity and Eating Habits Research Center, Endocrinology and Metabolism Molecular -Cellular Sciences Institute, Tehran Univ. of Medical Sciences, [7]Endocrinology and Metabolism Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran Univ. of Medical Sciences, Tehran, Iran

Objective: Osteoporosis leads to fractures, and disability and imposes a large economic burden on health systems. Therefore, it is necessary to retrain and empower the healthcare providers to prevent and manage Osteoporosis and complications. In this study, the effect of virtual training on the principles of osteoporosis management was investigated.
Methods: The semi-experimental study was conducted on general practitioners who participated in the osteoporosis management virtual course. The sampling method was convenient. The subjects of this study were general practitioners and family physicians from various regions of the country. During this training course, general practitioners had access to the 5 main modules and 22 submodules and received and studied the educational materials offline within one month. The pre-test and post-test were provided to the participants. At the end of the course, the questionnaires "Evaluation of attitude, perception and perceived Barriers" and "Evaluation of electronic modules quality" were provided to the participants. Descriptive data were reported with frequency and percentage. SPSS and Excel software were used for data analysis. Ethics code: IR.TUMS.EMRI.REC.1401.125.
Results: In general, 498 physicians participated in the virtual training program on the principles of osteoporosis management. The average age of the participants was 35 y and $> 70\%$ of the participants were women. The average scores of the participants in all 5 modules increased from 38 to about 83 and more than doubled ($P < 0.001$) (Table 1). In total, more than half of the participants agreed and fully agreed that the virtual course system of the principles of osteoporosis management has good quality, information and services. The mean and standard deviation of the perceived readiness score among the participants was reported as 11.9 ± 2.4. Also, about 40% of physicians had the necessary preparation, computer skills, and technical support to participate in virtual training courses. The mean and standard deviation of the total score of perceived obstacles among the participants was reported as 19.3 ± 4.6.

Table 1. The effectiveness of virtual training on the principles of osteoporosis management for physicians

P value	Mean (SD) post-test scores	Mean (SD) pre-test scores	Module type
<0.001	84.9(10)	40.0(21.9)	Module 1: Bone measurement and fracture risk assessment
<0.001	83.3(9.5)	39.4(11.5)	Module 2: Diagnosis of osteoporosis
<0.001	82.1(9.6)	38.3(10.9)	Module 3: Clinical management
<0.001	81.7(8.9)	35.5(10.6)	Module 4: Monitoring and follow-up
<0.001	82.2(9.2)	36.8(11)	Module 5: Sarcopenia

Conclusion: The virtual course on the principles of osteoporosis management held for general practitioners had a significant impact on increasing the awareness and positive attitude of the participants. In general, the virtual course system of the principles of osteoporosis management was of good quality.

P911
OSTEOPOROSIS DIAGNOSIS AND TREATMENT GAP IN IRANIAN OLDER ADULTS: PROSPECTIVE FOLLOW-UP OF PARTICIPANTS IN THE IRANIAN MULTICENTER OSTEOPOROSIS STUDY (IMOS), 2021–2022

M. J. Mansourzadeh[1], M. Sanjari[1], M. Ahmadi[1], N. Fahimfar[1], V. Mohseni[1], K. Khalagi[2], S. Hajivalizadeh[1], F. Hajivalizadeh[3], E. Hesari[1], A. Ostovar[4]

[1]Osteoporosis Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran Univ. of Medical Sciences, [2]Obesity and Eating Habits Research Center, Endocrinology and Metabolism Molecular-Cellular Sciences Institute, Tehran Univ. of Medical Sciences, [3]Center for Non-Communicable Disease Control & Prevention, Deputy of Public Health, Ministry of Health and Medical Education, [4]Endocrinology and Metabolism Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran Univ. of Medical Sciences, Tehran, Iran

Objective: Osteoporosis poses a significant health challenge for aging populations worldwide. This study aimed to assess the diagnosis and treatment gap in Iranian older adults aged $\geq$ 50, shedding light on factors influencing awareness and adherence to osteoporosis management.

Methods: The study included 1416 participants from the 2021 IMOS national survey, who were followed up for a median duration of 1.8 y. BMD assessments were conducted in the baseline phase. The diagnosis gap, defined as the proportion of individuals with osteoporosis symptoms who have not been diagnosed before, and the treatment gap, defined as the proportion of eligible patients not receiving prescribed medication, were evaluated. Factors contributing to these gaps were explored, including patient awareness and adherence patterns to osteoporosis treatment.

Results: The mean (SD) age of the participants was 61.25 (7.88) y, with 643 (45.41%) being men. Among these participants, 908 (64.86%) visited a doctor to discuss their BMD results. Of the 908 individuals consulting a doctor, 404 (44.49%) were diagnosed with osteoporosis (299 (74.01%) women and 105(25.99%) men). Notably, only 74 of these individuals were aware of their condition before the study. So, the diagnosis gap was calculated as approximately 81.68%. Of the diagnosed individuals, 239 were prescribed osteoporosis medications, making the treatment gap identified as 40.85%. Examining medication adherence among those prescribed, merely 72 out of 239 maintained regular drug intake, resulting in an adherence rate of 30.13%.

Conclusion: These results underscore the challenges in the osteoporosis management continuum, with a substantial number of individuals experiencing a gap in both diagnosis and treatment. The results emphasize the need for targeted interventions to enhance awareness, facilitate timely diagnosis, and improve adherence to prescribed medications, addressing the overall osteoporosis care gap in the Iranian older adult population.

P912
IMPACT OF EXCESSIVE GESTATIONAL WEIGHT GAIN ON BONE REMODELING AND SUBCLINICAL ATHEROSCLEROSIS

M. Shargorodsky[1], M. M. Mashavi[2]

[1]Assuta Hospital, Ramat Hachayal, [2]Wolfson Medical Center, Holon, Israel

Objective: Gestational weight gain (GWG) has been related to altering future weight gain curve and increased risks of obesity later in life. Obesity may adversely impact bone health and vascular atherosclerotic changes, and as a result, may promote two major disorders: osteoporosis and cardiovascular disease. Noninvasive arterial testing such as ultrasonographic measurement of carotid IMT is considered a surrogate for systemic atherosclerotic disease burden and is predictive of cardiovascular events. Osteoprotegerin (OPG), a member of the TNF superfamily, exerts osteoprotective effects by inhibiting osteoclast differentiation and activation and is involved in both pathological processes: bone remodeling and vascular inflammation. Currently there is no consistent evidence regarding vascular and bone influence of excessive GWG. The present study was designed to investigate the impact of gestational weight gain on bone remodeling using OPG and P1NP and early atherosclerotic changes using IMT.

Methods: The study group consisted of 59 pregnant women who has been divided into two groups: Group 1 included 32 women with pregnancy weight gain within recommended range; Group 2 included 27 women with excessive weight gain during pregnancy. Blood sampling for bone markers, including osteoprotegerin and P1NP, was performed. The IMT was measured from non-diseased intimal and medial wall layers of the carotid artery on both sides (Apogee CX Color, ATL).

Results: In subjects with excessive compared to recommended pregnancy weight, circulating OPG was significantly lower (203.2 ± 155.1 vs. $90.0 = /-23.3$, $p < 0.001$) and IMT level was significantly higher (0.6 ± 0.1 vs. 0.7 ± 0.1, $p = 0.028$). P1NP was marginally lower in excessive GWG compared to Group 1 ($p = 0.057$). In multiple linear regression analysis, significant by-group differences in terms of these parameters persisted even after adjustment. Additionally, excessive GWG was associated with a higher rate of placental lesions related to fetal vascular malperfusion as well as rate of neonatal complications.

Conclusion: Excessive weight gain during pregnancy is associated with an adverse effect on subclinical atherosclerosis and bone health as well as placental vascular circulation. The precise mechanism for these vascular and bone remodeling changes, as well as the overall clinical impact of weight control during pregnancy deserves further investigation.

P913
DELINEATING THE OSTEOGENIC POTENTIAL OF BIFIDOBACTERIUM LONGUM DERIVED EXTRACELLULAR VESICLES IN PREVENTING GLUCOCORTICOID INDUCED OSTEOPOROSIS EX VIVO

M. Sharma[1], R. K. Srivastava[1]

[1]All India Institute of Medical Sciences, Delhi, India

Objective: Glucocorticoids are anti-inflammatory steroid medications widely used for the treatment of various inflammatory conditions like

RA, SLE, colitis, cancer, COVID-19, etc. Prolonged glucocorticoids usage is known to increase the risk of osteoporosis. Glucocorticoid induced osteoporosis (GIOP) is the most common cause of secondary osteoporosis & iatrogenic osteoporosis. The role of probiotics in modulating bone health has already been established by our group. But to date, the role of probiotics in ameliorating GIOP is relatively unexplored. One of the mechanisms by which probiotics regulate bone health is via the release of extracellular vesicles. We aimed to investigate the potential of probiotic *Bifidobacterium longum* derived extracellular vesicles (BL-EVs) in enhancing osteoblastogenesis in dexamethasone (DEX) treated MC3T3-E1 cell line and murine bone marrow mesenchymal stem cells (BMSCs).

Methods: Extracellular vesicles were isolated from *B. longum* culture medium by ultracentrifugation and characterized by nanoparticle tracking analysis (NTA) and transmission electron microscopy (TEM). Effect of DEX & BL-EVs on the cell viability of MC3T3-E1 and murine BMSCs was evaluated via MTT assay. For osteoblastogenesis, MC3T3-E1 cells and murine BMSCs were cultured in osteoblastogenic medium and treated with DEX; DEX + BL-EVs. ALP, ARS staining & qRT-PCR were performed to evaluate osteoblastogenesis.

Results: DEX treatment significantly decreased the cell viability of MC3T3-E1 and BMSCs in a dose dependent manner while no significant change in cell viability was observed in BL-EVs treated cells. Moreover, Osteoblastogenesis was significantly decreased in DEX treated MC3T3-E1 cells and BMSCs. Interestingly, in the presence of BL-EVs, osteoblastogenesis was significantly increased in DEX treated MC3T3-E1 and BMSCs as indicated by ALP and ARS staining of osteoblast cells and qRT-PCR of osteoblastogenic genes: Runx2, ALP and bglap.

Conclusion: Taken together, our results for the first time establish the osteoprotective potential of probiotic BL-EVs in preventing GIOP via modulating the effects of DEX on bone forming (osteoblasts) cells ex vivo. Our results thereby propose probiotic EVs as a viable therapy for the management and treatment of GIOP.

P914
VITAMIN D DEFICIENCY IN MIDDLE-AGED JAPANESE WOMEN

M. Shibata[1], S. Kanie[1], H. Todoroki[1], A. Kakita[2], T. Takayanagi[1], T. Konagaya[3], A. Suzuki[1]

[1]Dept. of Endocrinology, Diabetes and Metabolism, Fujita Health Univ., Toyoake, [2]Dept. of Joint Research Laboratory of Clinical Medicine, Fujita Health Univ. Okazaki Medical Center, Okazaki, [3]Marine Clinic, Nagoya, Japan

Objective: For primary prevention of osteoporosis, it should be effective to assess bone fragility from younger age. However, the rate of screening test for osteoporosis in relatively young populations around menopause is lower than other lifestyle-related diseases.

Methods: The study included women aged 40 and older but less than 70, who underwent bone check-ups from January 2021, to October 2022. BMD at the distal 1/3 of the radius was measured using DXA, and serum levels of Ca, P, creatinine, bone-specific alkaline phosphatase (BAP), 25-hydroxyvitamin D [25(OH)D], as well as urinary Ca, P, and creatinine, were measured. Morphological vertebral fractures were evaluated using plain X-rays.

Results: A total of 211 subjects (mean age: 54.8 ± 5.6 y) were enrolled in this study. Morphological changes of vertebral bodies were found in 9 individuals without past history of clinical vertebral fracture. Mean BMD at distal radius was 0.601 ± 0.088 g/cm^2. According to the diagnostic criteria in Japan, 11 subjects were diagnosed as osteoporosis. Serum 25(OH)D levels were < 10 ng/mL in 34 cases, 10 ng/mL or more but < 15 ng/mL in 81 cases, 15 ng/mL or more but < 20 ng/mL in 65 cases, and 20 ng/mL or more in 31 cases. There was no correlation between serum 25(OH)D and BAP. BAP had a positive correlation with age and showed a negative association with BMD.

Conclusion: Vitamin D deficiency is observed throughout the year in middle-aged Japanese women. Although 25(OH)D levels did not directly correlate with BAP, nutritional guidance for bone health should be initiated from younger age.

P915
MUSCLE STRENGTH IN MEN WITH ANDROGEN DEPRIVATION THERAPY

M. Siderova[1], S. Radev[1]

[1]Univ. Hospital St. Marina, Dept. of Endocrinology, Varna, Bulgaria

Objective: In recent years, prostate cancer has been the most commonly diagnosed type of cancer among the male population. Androgen deprivation therapy (ADT) is an increasingly used therapeutic regimen, not only for metastatic but also for localized prostate cancer. Side effects of ADT include different clinical outcomes, including reduced muscle mass and physical strength. Furthermore, a plenty of recent studies show a strong relationship between sarcopenia and osteoporosis, since they share common risk factors and both increase fracture risk. The aim of this study was to analyze handgrip strength value as a screening tool for sarcopenia and testosterone levels in prostate cancer patients treated with ADT and age-matched healthy men.

Methods: We included 20 male patients with prostate cancer treated with ADT (age 67,7 ± 7,5 y) and 14 healthy men (age 64,4 ± 7,1 y). All subjects performed a handgrip dynamometer test (HGD) as a test for muscular strength. Each individual performed 3 trials of the HGD test, after which the average value of both hands was recorded. Testosterone levels were measured in the morning of the day of the handgrip test for all participants.

Results: The mean testosterone level was 0,69 ± 0,1 nmol/l in the patients' group and 14,30 ± 4,38 nmo/l (CI 11,92–16,68 nmol/l) for the control group, respectively. The mean handgrip strength was significantly lower among the prostate cancer patients with ADT (31,53 ± 6,58 kg) compared to the control group (39,28 ± 4,88 kg) (p-value < 0,05). Furthermore, we found strong positive linear correlation between the testosterone value and handgrip strength measurement (p-value < 0,05, R = 0,766).

Conclusion: Our results emphasize that low handgrip strength, as a simple diagnostic tool for muscle strength and a screening tool for sarcopenia, could be associated with a low levels of testosterone. This may contribute to increased tendency to falls, frailty and fracture risk among men.

P916
SPECIFICITIES OF INFECTIOUS SPONDYLODISCITIS IN DIABETIC PATIENTS

M. Slouma[1], M. Dhifallah[1], R. Dhahri[1], L. Metoui[1], R. Battikh[2], I. Gharsallah[1]

[1]Rheumatology Dept., [2]Infectious Disease Dept., Military Hospital of Tunis, Tunis, Tunisia

Objective: Diabetes mellitus represents an immune-compromised condition, leading to a significant prevalence of this comorbidity in patients with infectious spondylodiscitis (ISD). The objective of our study was to determine the characteristics of ISD in diabetic patients.

Methods: We conducted a retrospective study in a rheumatology department over 7 y [2016–2023] with infectious spondylodiscitis

diagnosed based on clinical, bacteriological, and imaging features. Patients were divided into 2 groups: diabetic (G1) and non-diabetic patients (G2). We compared the epidemiological, clinical, biological, and radiological features between the 2 groups.

Results: Our study comprised 23 diabetic patients diagnosed with ISD, including 12 men and 11 women with a mean age of 61.83 ± 9.75 y [23–43]. The average duration of symptom evolution was 3 ± 3.17 months, characterized by back pain (n = 20), alteration of the general state (n = 8), and fever (n = 8). MRI identified disc and adjacent endplate signal abnormalities in all patients, canal abscess (n = 8), paravertebral soft tissues abscess (n = 15), epiduritis (n = 13), and spinal cord compression (n = 5). Elevated inflammatory markers were present in 76% (n = 16). The mean C-reactive protein (CRP) was 83.05 ± 93.09 mg/l, and the mean erythrocyte sedimentation rate (ESR) was 67.65 ± 29.43 mm/h. The implicated pathogens were distributed as follows: Mycobacterium tuberculosis (n = 10), common bacteria (3 Staphylococcus, 2 Streptococcus, 2 Enterococcus, 1 Escherichia coli), Candida albicans (n = 1) and Brucella (n = 1). No pathogen was identified in 3 patients. The age of diagnosis was significantly higher in diabetic patients (61.83 vs. 55.37, p = 0.042). However, no significant difference was found regarding the diagnostic delay (p = 0.697), CRP levels (p = 0.817) or ESR levels (p = 0.588). Diabetes was not associated with a higher prevalence of fever (p = 0.461) or back pain (p = 0.353).

Conclusion: Diabetes mellitus is one of the recognized risk factors for infectious spondylodiscitis. However, this comorbidity doesn't seem to affect clinical presentation or biological findings of this disease.

P917
PRO-INFLAMMATORY CYTOKINES AND MATRIX METALLOPROTEINASE-3 IN RADIOGRAPHIC AXIAL SPONDYLOARTHRITIS: AN ASSOCIATION WITH STRUCTURAL DAMAGE AND FUNCTIONAL IMPAIRMENT

M. Slouma[1], S. Bouzid[1], L. Kharrat[2], A. Tezeghdenti[3], R. Dhahri[1], E. Ghazouani[3], I. Gharsallah[1]

[1]Rheumatology Dept., Principal Military Hospital of Instruction, Tunis, [2]Rheumatology Dept., M.T Kassab of Orthopedics Institute, Ksar Saïd, [3]Immunology Dept., Principal Military Hospital of Instruction, Tunis, Tunisia

Objective: Pro-inflammatory cytokines play a crucial role in the pathophysiology of spondyloarthritis (SpA) via the IL-17/IL-23 axis. Some studies also suggested the role of matrix metalloproteinase-3 (MMP-3) in SpA [1,2]. We aimed to assess the associations between serum levels of pro-inflammatory cytokines, MMP-3, and disease assessment tools in radiographic axial SpA.

Methods: A cross-sectional study was conducted, including patients followed for radiographic axial SpA meeting the ASAS 2009 criteria. The Bath Ankylosing Spondylitis Radiology Index (BASRI) was used to assess structural damage, while the Bath Ankylosing Spondylitis Metrology Index (BASMI) was used to evaluate axial mobility. The Bath Ankylosing Spondylitis Functional Index (BASFI) was calculated to assess functional impairment. Erythrocyte sedimentation rate (ESR) and C-reactive protein level were measured. Serum levels of interleukins IL-1, IL-6, IL-8, IL-17, IL-23, TNFα, and MMP-3 were also measured.

Results: We included 32 patients with a mean age of 44.84 ± 11.21 y. The mean disease duration was 8.94 ± 7.49 y. The mean ESR and CRP level were 35 ± 26.83 mm and 10.99 ± 22.89 mg/L, respectively. The mean IL-1, IL-6, IL-8, and TNFα levels were 11.88 ± 27.36, 11.88 ± 49.79, 15.97 ± 23.24, and 19.19 ± 27.36 pg/mL, respectively. The mean IL-17 and IL-23 levels were 88.94 ± 79.40 and 14.89 ± 25.19 pg/mL respectively. The mean MMP-3 level was 23.48 ± 29.65 ng/mL. IL-6 was significantly correlated to IL-1 (r = 0.788, p = 0.001), ESR (r = 0.408; p = 0.023), BASFI (r = 0.410; p = 0.024), and BASMI (r = 0.390; p = 0.028). Furthermore, IL-1 was associated with more severe structural damage, as evidenced by a BASRI score > 3 (OR = 1.625, IC95% [1.057–2.497], p = 0.006). However, no correlations were noted between MMP-3 level and pro-inflammatory cytokines levels.

Conclusion: IL-6 level was associated with functional impairment and limitation of axial mobility in SpA. Moreover, IL-1 level was associated with structural damage. These results suggest the usefulness of these biomarkers in predicting SpA prognosis.

P918
ROLE OF PRO-INFLAMMATORY CYTOKINES IN PSORIATIC ARTHRITIS

M. Slouma[1], M. Dhifallah[1], L. Kharrat[2], A. Tezeghdenti[3], R. Dhahri[1], E. Ghazouani[3], I. Gharsallah[1]

[1]Rheumatology Dept., Principal Military Hospital of Instruction, Tunis, [2]Rheumatology Dept., M.T Kassab of Orthopedics Institute, Ksar Saïd, [3]Immunology Dept., Principal Military Hospital of Instruction, Tunis, Tunisia

Objective: Psoriatic arthritis (PsA) is a chronic immune-related inflammation that affects joints, enthesis, skin, and nails. Its pathophysiology is complex and implicates several cytokines [1]. We aimed to determine the pro-inflammatory cytokines serum levels in psoriatic arthritis and their relationship to the disease activity.

Methods: We conducted a cross-sectional study that compared patients diagnosed with psoriatic arthritis (G1) meeting the Assessment of SpondyloArthritis international society (ASAS) 2009 criteria with healthy controls (G0). Sociodemographic parameters were collected. Disease activity was assessed using the Ankylosing Spondylitis Disease Activity Score (ASDAS) and the Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) for axial involvement, and the Disease Activity Score in 44 joints (DAS44) for peripheral articular involvement. We measured serum levels of the following cytokines: interleukin IL-17, IL-23, IL-22, IL-1, IL-6, and TNFα as well as C-reactive protein (CRP) level.

Results: A total of 62 subjects were included. Each group included 31 patients. G1 included 21 men and 10 women and G0 included 24 men and 7 women. The mean age was 47.29 ± 15.55 y in G1 and 43.193 ± 9.31 y in G0 (p = 0.124). In G1, the mean BASDAI and ASDAS-$_{CRP}$ were 3.72 ± 1.96 and 2.91 ± 1.41, respectively. The mean DAS44-$_{CRP}$ was 3.81 ± 1.4. The following cytokines were significantly higher in patients with PsA patients compared to controls: IL-1 (G1 = 5.75 vs. G0 = 4 pg/mL, p = 0.028), IL-17 (G1 = 116.74 vs. G0 = 1.08 pg/mL, p < 0.001), IL-22 (G1 = 47.12 vs. G0 = 10.63 pg/mL, p = 0.001), and IL-23 (G1 = 27.27 vs. G0 = 1.59 pg/mL, p < 0.001). We noted that IL-6 level was correlated to CRP level (r = 0.386, p = 0.032), DAS44-CRP (r = 0.554, p = 0.009), and ASDAS-CRP (r = 0.469, p = 0.037), Furthermore, TNFα level was correlated to BASDAI (r = 0.543, p = 0.016). ASDAS$_{CRP}$ was also correlated to IL-1 (r = 0.448, p = 0.048), IL-17 (r = 0.451, p = 0.046), and IL-22 (r = 0.464, p = 0.039) serum levels.

Conclusion: IL-17/IL-23 axis-related pro-inflammatory cytokines were significantly higher in PsA patients compared to controls.

Interestingly, these cytokines levels were correlated to disease activity suggesting their potential as therapeutic targets.

P919
WORKPLACE FOOTWEAR HABITS AMONG MEDICAL RESIDENTS: A NATIONAL SURVEY

W. Lahmar[1], M. Slouma[1], R. Dhahri[1], I. Gharsallah[1]

[1]Military Hospital of Tunis, Tunis, Tunisia

Objective: Shoes play a crucial role in maintaining stability and comfort for healthcare practitioners throughout their work. Physicians, in particular, often spend long hours on their feet and may be at risk of musculoskeletal complaints, such as foot pain. Despite their significance, few studies have explored this issue. The aim of our work was to understand the footwear habits of healthcare professionals and their impact on health and safety at work.
Methods: A cross-sectional study conducted through an online self-administered questionnaire distributed to medical residents working in various Tunisian hospitals. Data collected included sociodemographic factors, work characteristics, and footwear habits during regular work hours and on duty. The questionnaire was distributed to participants online via Google Forms, ensuring anonymous and confidential responses.
Results: 282 residents responded, with a mean age of 27.98 $\pm$ 2.10 y [24–41] and a gender ratio (F/M) of 3.5. The average BMI was 23.24 $\pm$ 3.76 kg/m^2 [15.24–42.9]. Two respondents (0.7%) had diabetes, and 4 (1.4%) had chronic inflammatory rheumatism. 204 (86.9%) experienced foot pain in the workplace. 41 (14.5%) residents were in a surgical specialty, and 87 (30.9%) were in an intensive medical specialty. They worked, on average, < 40 h/week in 40.8% of cases, and 57 residents (20.2%) worked > 48 h/week. 155 participants (55%) worked 3–6 night shifts/month. During regular work hours, they wore running shoes, commercial shoes, commercial clogs, and orthopedic clogs in 46 (16.3%), 108 (38.3%), 19 (6.7%), and 16 (5.7%) cases, respectively. On duty, they wore running shoes, commercial shoes, commercial clogs, and orthopedic clogs in 39 (13.8%), 31 (11%), 101 (35.8%), and 65 (23%) cases, respectively. Residents wearing commercial clogs were found to have less foot pain ($p = 0.061$).
Conclusion: Foot pain is common among medical residents in the workplace. These results emphasize the importance of considering the choice of work shoes for healthcare professionals to minimize foot pain and promote their comfort and safety at work.

P920
MAPPING FOOT AND ANKLE PAIN AMONG MEDICAL RESIDENTS

W. Lahmar[1], M. Slouma[1], R. Dhahri[1], I. Gharsallah[1]

[1]Military Hospital of Tunis, Tunis, Tunisia

Objective: Foot and ankle pain is a common issue among healthcare professionals who spend long hours standing during shifts, daily rounds, or in the operating room. These pains can be indicative of underlying and more severe problems. Therefore, it is crucial to understand the location of the pain and propose preventive measures and effective treatments. This study aimed to describe the location of foot and ankle pain among Tunisian medical residents.
Methods: A cross-sectional study was conducted using an online self-administered questionnaire distributed to medical residents working in various Tunisian hospitals. Collected data included sociodemographic factors, work characteristics, the presence of foot and/or ankle pain, and the pain location specified using a foot diagram dividing the feet and ankles into 26 zones. Participants with foot pain were asked to choose the corresponding number for the painful area. The questionnaire was distributed online, allowing for anonymous and confidential responses.
Results: Our study included 282 residents: 62 males and 220 females. The mean age was 27.98 $\pm$ 2.10 y [24–41]. The mean BMI was 23.24 $\pm$ 3.76 kg/m^2 [15.24–42.9]. 205 reported foot pain at work. Among them, 41 (14.5%) residents were in surgery, and 87 (30.9%) were in intensive medical specialties. The reported painful regions are summarized in Table 1.

Table 1. Pain region frequency on the foot and ankle

Foot region		Right foot	Left foot
Forefoot	Big toe (n(%)	7 (2.5)	10 (3.5)
	Second toe (n(%)	8 (2.8)	5 (1.8)
	3rd,4th and 5thtoe (n(%)	11(3.9)	12 (4.3)
	1st metatarsal head (n(%)	8 (2.8)	4 (1.4)
	2nd metatarsal head (n(%)	0	0
	3,4 and 5th metatarsal head (n(%)	5 (1.8)	4 (1.4)
Midfoot	Medial midfoot (n(%)	8 (2.8)	4 (1.4)
	Lateral midfoot (n(%)	3 (1.1)	5 (1.8)
Hindfoot	Inferior talar region (n(%)	15 (5.3)	12 (4.3)
	Posterior talar region (n(%)	4 (1.4)	3 (1.1)
Ankle (n(%)		17 (6)	15 (5.3)

Conclusion: More than three-quarters of medical residents reported foot pain at work, with the most frequent painful regions being the big toe and the lower heel region. This aligns with epidemiological studies in the general population, which suggest that hallux valgus and plantar fasciitis are the most common causes of foot pain.

P921
AGING AND HEPATIC FIBROSIS: A RISK ALLIANCE IN PATIENTS WITH RHEUMATOID ARTHRITIS

W. Lahmar[1], M. Slouma[1], R. Dhahri[1], I. Gharsallah[1]

[1]Military Hospital of Tunis, Tunis, Tunisia

Objective: Hepatic fibrosis results from scar tissue accumulation in the liver, leading to impaired liver function and, ultimately, cirrhosis. Age is a known risk factor for fibrosis progression in patients with chronic viral liver disease. We aimed to evaluate hepatic fibrosis using non-invasive methods in rheumatoid arthritis (RA) patients and assess the age effect on the liver in rheumatic patients.
Methods: A single-center cross-sectional study included RA patients diagnosed according to the ACR-EULAR 2010 criteria. Demographic, clinical, and disease characteristics (duration/disease activity using DAS28CRP) were collected. Noninvasive hepatic fibrosis assessment included FIB-4 score [(age (y) $\times$ AST (U/L)/platelets (PLT) (10^9/L) $\times \sqrt{}$ALT (U/L)], with FIB-4 < 1.3 indicating a negative predictive value for hepatic fibrosis, and FIB-4 > 2.67 suggesting severe fibrosis. Liver elasticity was evaluated by fibroscan, with > 6 kPa indicating early fibrosis.
Results: Out of 73 patients (52 women, 21 men) with a mean age of 51 [22–83] y, mean disease duration was 8.5 y [0.25–31]. Disease was erosive in 70% (n = 51), with positive immunological status in 86% of the cases (n = 63). Mean DAS28CRP was 3.93 $\pm$ 1.4 [0.93–6.94], and 53 patients (72%) had active disease. Mean FIB-4 score was 0.97 $\pm$ 0.54 [0.2–2.79]; it was < 1.3 in 68% (n = 50), and > 2.67 in one patient. Mean liver elasticity was 4.5 kPa $\pm$ 1.52[2.6–12]; 12% (n = 9) had fibrosis using fibroscan. Univariate analysis showed a strong positive correlation between age and FIB-4 ($r = 0.634$, $p < 0.001$) and age and liver elasticity ($r = 0.234$, $p = 0.046$). In multivariate analysis, age > 60 y was an independent factor associated with fibrosis detected by fibroscan (OR: 22.703; 95%CI

[1.238–416.487]; p = 0.035). No association was found with prolonged disease duration.
Conclusion: The study highlights age as a factor influencing hepatic fibrosis development in RA patients. Those aged over 60 have an increased risk, regardless of rheumatic disease duration, emphasizing the need for careful liver function monitoring.

P922
MANAGING GLUCOCORTICOID-INDUCED OSTEOPOROSIS

F. L. Popa[1], R. P. Ristea[2], M. Stanciu[3]

[1]Lucian Blaga Univ. of Sibiu, Dept. of Physical Medicine and Rehabilitation, [2]County Clinical Emergency Hospital of Sibiu, Dept. of Endocrinology, [3]Lucian Blaga Univ. of Sibiu, Dept. of Endocrinology, Sibiu, Romania

Objective: To assess the management of severe secondary osteoporosis in systemic lupus erythematosus patients on chronic glucocorticoid therapy. This is a case report. A complete bone status assessment was performed.
Case report: A 56-year-old female on methylprednisolone since 2005 for lupus with Sjögren's syndrome and primary biliary cirrhosis overlap, presented in 2018 with a left femoral neck fracture and vertebral compression fractures (T8, T10, T12, L1). DXA revealed lumbar T-score -2.4, BMD = 0.892, Z-score = -1.6; left femoral neck T-score -3.3, BMD = 0.640, Z-score = -2. Bone marker tests revealed osteocalcin at 5.6 ng/mL and beta CrossLaps at 0.19 ng/ml. The patient received oral risedronic acid(2018–2021), but the treatment was discontinued due to a superior digestive hemorrhage. Teriparatide was then administered for 15 months and discontinued voluntarily due to thoracic pain and muscle cramps. Denosumab was initiated in 2023, resulting in a favorable clinical response-no new fractures, and increased DXA-measured body mass density.
Conclusion: Management of severe secondary osteoporosis in the context of autoimmune disorders and chronic glucocorticoid therapy is complex. Early initiation of bone protective therapy is important, especially in individuals at heightened fracture risk. The introduction of denosumab in 2023 aligns with current guidelines, considering both efficacy and tolerability.

P923
EFFICACY OF TERIPARATIDE THERAPY IN OSTEOPOROTIC VERTEBRAL FRACTURES

R. P. Ristea[1], F. L. Popa[2], M. Stanciu[3]

[1]County Clinical Emergency Hospital of Sibiu, Dept. of Endocrinology, [2]Lucian Blaga Univ. of Sibiu, Dept. of Physical Medicine and Rehabilitation, [3]Lucian Blaga Univ. of Sibiu, Dept. of Endocrinology, Sibiu, Romania

Objective: To assess the occurrence of vertebral fractures in teriparatide-treated women with postmenopausal osteoporosis.
Methods: This retrospective study included 48 female patients (mean age ≈72.32) with postmenopausal osteoporosis, who had prior bisphosphonate treatment. Inclusion criteria: age, back pain intensity, and a minimum of 24 months of teriparatide treatment. BMD was measured annually using DXA via a Hologic instrument. Vertebral compression fractures were evaluated in all patients.
Results: Among the 48 patients, 28 (58.3%) experienced multiple vertebral compression fractures, while 7 (14.6%) had a single vertebral compression fracture. The remaining 13 participants (27.1%) showed no vertebral fractures. T12 was the most affected vertebra. Six patients (12.5%) underwent vertebroplasty for fracture management. Distal radial epiphysis fractures occurred in 9 participants (18.8%), and 3 (6.3%) experienced hip fractures. Pain complaints varied, with lumbar and dorsal back pain being the most common (56.2%), along with hip pain. No new fractures were reported during teriparatide treatment, and pain intensity significantly improved.
Conclusion: Osteoporosis and associated pain contribute to emotional and social challenges. A 24-month teriparatide treatment in patients with severe osteoporosis demonstrated protective potential against new fractures, increased BMD, and provided substantial pain relief.

P924
MANAGEMENT OF POSTMENOPAUSAL OSTEOPOROSIS ASSOCIATED WITH PARKINSON'S DISEASE AND CHRONIC AUTOIMMUNE THYROIDITIS

R. Pipernea[1], G. Ielciu[1], R. P. Ristea[2], F. L. Popa[3], A. Brescan[4], S. Brescan[4], M. Stanciu[5]

[1]Emergency Clinical County Hospital of Sibiu, Dept. of Rehabilitation, Sibiu, Romania, [2]County Clinical Emergency Hospital of Sibiu, Dept. of Endocrinology, Sibiu, Romania, [3]Lucian Blaga Univ. of Sibiu, Dept. of Physical Medicine and Rehabilitation, Sibiu, Romania, [4]Anregiomed Klinikum Ansbach, Ansbach, Germany, [5]Lucian Blaga Univ. of Sibiu, Dept. of Endocrinology, Sibiu, Romania

Objective: To evaluate and manage postmenopausal osteoporosis associated with Parkinson's disease and chronic autoimmune thyroiditis, disorders that may increase fracture risk.
Case report: We present the case of a 62-year-old patient diagnosed with severe osteoporosis at 43 after early menopause, who underwent bisphosphonate treatment for 20 y, and currently receiving teriparatide. Diagnosed 6 years ago with Parkinson's disease, neurological treatment was initiated. The patient is known with a non-toxic multinodular goiter with euthyroidism, and chronic autoimmune thyroiditis which is considered a contributing factor to osteoporosis. Over the last 18 months, the patient suffered multiple falls, leading to various fractures, including a neglected L3 vertebral fracture requiring L2-L4 rachisynthesis for spine stabilization, a right forearm, and radiocarpal region fractures, treated with osteosynthesis. A few months before admission to our rehabilitation clinic, surgery was performed for an open right forearm fracture. During hospitalization, the patient received anti-Parkinson's drugs, teriparatide, cholecalciferol, and calcium. Following an individualized rehabilitation program, the evolution was slightly favorable with functional improvement and partial walking rehabilitation achieved.
Conclusion: Degenerative neurological conditions and autoimmune thyroid disease are important factors that contribute to postmenopausal osteoporosis. A correct interdisciplinary management of these conditions can favorably influence the evolution in these cases. References 1. P925
USING DATA TO INFORM THERAPY: REAL-WORLD UTILIZATION PATTERN OF ROMOSOZUMAB AMONG POSTMENOPAUSAL WOMEN

M. Toth[1], M. Elgaafary[2], Y. El Miedany[3]

[1]King's college London, London, UK, [2]Ain Shams Univ., Cairo, Egypt, [3]Canterbury Christ Church Univ., Canterbury, UK

Objective: Romosozumab is a NICE-approved humanized monoclonal antibody sclerostin inhibitor used to treat osteoporosis in postmenopausal women at high risk of fracture, including patients with a history of osteoporotic fracture, multiple risk factors, or that have failed or are intolerant to other available osteoporosis. Aims:
1. To assess the possibility of involving the patients in the decision making of prescribing romosozumab
2. To evaluate the safety of romosozumab in treating postmenopausal women with osteoporosis
3. To assess adherence to romosozumab therapy during consequent follow ups
Methods: This was an audit which included women who met the NICE guidelines and West Kent and Medway Osteoporosis Group recommendations for romosozumab therapy. All the patients who newly started romosozumab therapy in Kent, England were identified as candidates for inclusion in this work. Validated management algorithm started with a pre-Romosozumab therapy screen. This was carried out using a self-reported patient questionnaire to check for any possible contraindication to romosozumab therapy. Patients with Paget's disease, metastatic cancer or the diagnosis of cancer at the same time of considering the therapy were excluded from the work. All the patients who completed at least 6 months of romosozumab therapy were included in this work. Patient education: All the patients received patients' friendly information leaflets that gives full details of the pros and possible side effects of romosozumab therapy. Training on how to administer the injections was carried out using a demo. Study outcomes: I. adherence to romosozumab therapy, defined as the proportion of the days covered [PDC]; using the equation: PDC (%) = number of days covered by medication/ number of days in period $\times$ 100; II. 12-months interruption rate defined as the proportion of the patients who did not have their medication renewed within 30 days after exhaustion of the previous dispensed romosozumab injections.
Results: 22-patients were identified to meet the national and regional criteria for romosozumab therapy. Mean age was 80.54 $\pm$ 4.18. All the patients received previous osteoporosis therapy. All the patients had past history of fragility fractures. Mean 10-y probability of major osteoporosis fracture was 31.08 $\pm$ 13.47 whereas for hip fractures it was 16.82 $\pm$ 15.25. Using the pre-therapy screening questionnaire, 6 patients had past history of cardiovascular incidents, whereas 1 patient refused to start the treatment as she was concerned about the side effects. Another patient stopped the romosozumab therapy 1 month after starting the treatment because of her concern about the medication safety as she has positive family history of cardiac problems. 14 patients completed 10 months or more of romosozumab therapy. High adherence was reported among romosozumab users (mean PDC was 93.3%) at both 6 months and 12 months. Interruption rate was 6.7% among romosozumab cohort at both 6 months and none at 12 months. None of the patients sustained a new fragility fracture during the monitoring period. None of the patients sustained any major adverse cardiovascular event.
Conclusion: High adherence and few interruptions among romosozumab therapy patients was noted in this work. The high scores of baseline hip fracture probability show the gap in osteoporosis care which needed to be filled in the management of patients at high risk of sustaining hip fractures. The pre-therapy screening questionnaire was helpful to identify the patients who had contraindications to

romosozumab therapy. Patient education and involving the patients in the decision making has helped to ensure better adherence to therapy.

CREATING AND PILOTING AN ONLINE OSTEOPOROSIS COURSE THROUGH A MULTIDISCIPLINARY MULTI-INSTITUTE APPROACH: A CROSS-SECTIONAL QUALITATIVE STUDY

L. Jafri[1], M. U. N. Effendi[1], H. Majid[1], A. H. Khan[1], S. Ahmed[1], M. Zaman[2], Q. Riaz[3], S. Fatima[4], A. Ejaz[5], F. Aslam[6]

[1]Dept. of Pathology and Laboratory Medicine, The Aga Khan Univ., Karachi, [2]Dept. of Radiology, The Aga Khan Univ., Karachi, [3]Dept. of Education, The Aga Khan Univ., Karachi, [4]Dept. of Biological and Biomedical Sciences, The Aga Khan Univ., Karachi, [5]Mohi Uddin Islamic Medical College, Mirpur Azad Jammu and Kashmir, [6]Quaid e Azam Medical College, Bahawalpur, Pakistan

Objective: Postgraduate trainees (PGs) trained via a multidisciplinary model receive collaborative learning opportunities from a wide range of experts. There is a dearth of such approaches in the current post-graduate medical education (PGME) curriculum in Pakistan. Taking the example of osteoporosis, a multidisciplinary online course on osteoporosis was designed to gauge the impact of a novel educational tool on the teaching and learning capabilities of PGs and course facilitators.
Methods: A multi-institute multidisciplinary team was formulated to deliver a course on osteoporosis on a virtual learning environment (VLE) platform. PGs (n = 9) from various disciplines and institutes were nominated by their respective faculty and enrolled after obtaining informed consent. The modular component consisted of recorded micro-lectures, flashcards, videos, case challenges, and mini-interviews with the experts. Educational impact was measured by pre-, and post-module tests and perception of the process was taken on a Likert scale of 1–5.
Results: A pre-test was attempted by 66% (n = 6) of PGs with a mean score of 43.8%. After taking the VLE module, all PGs (n = 9) cleared the end of the module test with an average score of 96%. All the PGs (n = 9) believed that VLE was a great platform for online courses and were satisfied with this teaching strategy. They (n = 8), 88.9%, stated that they could easily navigate the course and were comfortable using VLE. The majority (n = 8), 88.9%, agreed that course learning was implementable in clinical practice, whereas 66.7% (n = 6) were extremely satisfied with learning objectives and the content uploaded. The process also led to the capacity building of facilitators to become acquainted with VLE.
Conclusion: An institute with adequate facilities for faculty training can develop online multidisciplinary modules to benefit institutes in resource-limited settings.

P927
UNRAVELING THE GENETIC LANDSCAPE OF HYPOPHOSPHATEMIA: A RARE CASE ANALYSIS REVEALING A NOVEL DMP1 MUTATION

A. H. Khan[1], M. U. N. Effendi[1], H. Majid[1], M. Bilal[1], S. Kirmani[2]

[1]Dept. of Pathology and Laboratory Medicine, The Aga Khan Univ., [2]Dept. of Paediatrics and Child Health, The Aga Khan Univ., Karachi, Pakistan

Autosomal recessive hypophosphatemia arises from homozygous inactivating mutations in dentin matrix protein 1 (DMP1), a gene responsible for encoding a noncollagenous bone matrix protein expressed in osteoblasts and osteocytes**.** The objective of this case report is to present and analyze a rare case of hypophosphatemia, highlighting its clinical manifestations and diagnostic approach to contribute valuable insights to the medical community. This case report outlines the evaluation of a patient in a Metabolic Bone Disease Clinic at The Aga Khan University Hospital, Karachi, Pakistan. Through detailed patient history, laboratory investigations, and imaging studies, we characterized the etiology and clinical course of a rare case of hypophosphatemia. Ethical considerations were adhered to, with informed consent obtained for both clinical assessment and genetic testing.
Case report: A 46-year-old lady, having been diagnosed and managed as a case of vitamin D-dependent rickets during childhood developed stiffness and limited range of motion at various joints with increasing age. Biochemistries were consistent with hypophosphatemia owing to renal phosphate wasting with the ratio of the renal tubular maximum reabsorption rate of phosphate to glomerular filtration rate (TmP/GFR) being 1.8 mg/dl and fractional excretion of phosphate ($FePO_4$) 16.2%. Radiographs showed generalized diffuse osteosclerosis, diffuse hyperostosis frontalis in the skull, ossification of the sacrospinous and paravertebral ligaments, and some enthesopathy along the proximal aspect of bilateral tibia and fibula. A comprehensive skeletal disorder panel consisting of 358 genes was employed to investigate the genetic basis of the patient's condition and it revealed a novel homozygous splice site mutation in Intron 5 (c.184-7A > G) of the DMP1 gene.
Conclusion: The findings provide crucial insights into the molecular basis of hypophosphatemia-related skeletal complications in this patient.

P928
SELECTIVE EMBOLIZATION OF GENICULAR ARTERIES MAY BE A SOLUTION TO TREAT SYNOVITIS, STIFFNESS, AND PAIN AFTER TOTAL KNEE ARTHROPLASTY

M. U. Rezende[1], L. G. M. Valle[2], A. M. André[3], G. P. Ocampos[1], F. L. Galastri[2], B. B. Affonso[2], F. C. Carnevalle[4], F. Nasser[2]

[1]Departamento de Ortopedia e Traumatologia do Hospital das Clínicas da Faculdade de Medicina da Universidade de São Paulo, [2]Hospital Israelita Albert Einstein, [3]Insituto de Radiologia do Hospital das Clínicas da Faculdade de Medicina da Universidade de São Paulo, [4]Instituto de Radiologia do Hospital das Vlínicas da Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil

Objective: To document the effects of embolization of branches of genicular arteries in patients with pain and synovitis after total knee arthroplasty due to osteoarthritis (OA).
Methods: Prospective case series of 8 patients (9 knees) with persistent pain, effusion, stiffness, and synovitis after knee arthroplasty submitted to transcatheter arterial embolization since August 2021. Clinical outcomes were evaluated at baseline, one and two years with EQ5D, WOMAC (0–96) and KOOS. All patients had their knees aspirated at the operating room to ascertain lack of infection.
Results: Abnormal neovessels were identified in all cases. One patient remained with cutaneous color changes even after 2 years of the procedure in both knees. No tissue necrosis, dermal ulcers, or peripheral ulcers. Three patients required to do the procedure more than once (twice in two and thrice in one). EQ5D improved from an average of 0.9063 ± 0.05 to $0{,}9562 \pm 0.04$ (one year), and 0.9828 ± 0.02 at 2 years. WOMAC pain improved from 1.83 ± 2 to 1.33 ± 1(one year) and 0 at 2 years (only three patients, i.e., four knees performed the procedure only once and reached de 2-year follow-up mark). Stiffness improved from 1 ± 1.5 to 0.5 ± 1.2(one year) and 0 (2-year). Baseline WOMAC function was 9.5 ± 6.2 improving to 3.1 ± 2.3 (one year) and 1.75 ± 0.96 at two years.

WOMAC total (0–96) WOMAC total reduced from average of 12.3 to ± 7.4 to 4.7 ± 2.9(one year) and 1.75 ± 0.96 (two years). KOOS pain improved from 85 ± 14.2 to 89.5 ± 6.6(one year) and 94.5 ± 3.8 at 2 years. KOOS activities of daily living improved from 72.3 ± 35.2 to 94.3 ± 3.2(one year), and 95.2 ± 1.5(2-year). KOOS sports improved from 39.2 ± 27.3 to 55.8 ± 30(one year) and 79.5 ± 27.8. KOOS quality of life improved from 59.3 ± 12.4 to 72.2 ± 14.8 at one year and to 73.75 ± 16.7 (2-year). KOOS general improved from 75.8 ± 11.3 to 84 ± 4.3 at one year and to 88 ± 3.4 at two years. All patients improved in all parameters continuously.
Conclusion: Embolization of branches of genicular arteries in patients with persistent pain, stiffness, effusion, and synovitis, after total knee arthroplasty, due to OA, may provide long lasting improvements in pain, function, and quality of life.

P929
TWO-YEAR RESULTS OF EMBOLIZATION OF PATHOLOGICAL BRANCHES OF GENICULAR ARTERIES IN KNEE OA WITH SYNOVITIS AND STIFFNESS

M. U. Rezende[1], L. G. M. Valle[2], A. M. Assis[3], F. L. Galastri[2], G. P. Ocampos[1], B. B. Affonso[2], F. C. Carnevalle[4], F. Nasser[2]

[1]Departamento de Ortopedia e Traumatologia do Hospital das Clínicas da Faculdade de Medicina da Universidade de São Paulo, [2]Hospital Israelita Albert Einstein, [3]Insituto de Radiologia do Hospital das Clínicas da Faculdade de Medicina da Universidade de São Paulo, [4]Instituto de Radiologia do Hospital das Vlínicas da Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil

Objective: To document the effects of embolization of branches of genicular arteries in patients with knee osteoarthritis (OA) with pain, stiffness, and synovitis.
Methods: Prospective case series included 27 patients (29 knees) with OA Kellgren-Lawrence (KL) grades 2–4 and synovitis with persistent moderate to severe pain resistant to conservative management submitted to transcatheter arterial embolization since August 2021. Clinical outcomes were evaluated at baseline, one and two years with EQ5D, WOMAC and KOOS.
Results: Abnormal neovessels were identified in all cases. Four patients (all women) remained with cutaneous color changes even after two years (of these, three had skin necrosis that either healed spontaneously (two), or that necessitated debridement (one). Five patients (all Ahlback 5) had their total knee replacement between six months and two years due to increased pain e decreased function. Of the remaining patients EQ5D improved from an average of 0.7798(± 0.18) to 0.8914(± 0.1) at 1 year and 0.9118(± 0,18). WOMAC total (0–96) improved from 29.2 (± 17) to 12.9(± 10.7) and 11 at two years. WOMAC stiffness improved in all patients from an average of 2.35 ± 2 to 0.6 ± 1(one year) and 0.4 ± 1.2 at two years. KOOS pain improved from 59.4 ± 18.7 to 80.8 ± 13.3 at one year and 85 ± 23 at two years. KOOS activities of daily living improved from 68 ± 22.1 to 82.8 ± 20.9 (one year) and 81.7 ± 33.3 at two years. KOOS sports improved from 28.8 ± 23.5 to 53.2 ± 28.4 (one year) and 65.5 ± 34.7 at two years. KOOS Quality of life improved from 37.8 ± 14.8 to 56.2 ± 16.6(one year) and 67.5 (two years). KOOS general improved from 52.2 ± 15.7 to 78.2 ± 16.3 (one year) and 82.3 at two years. Patients with grade IV K&L OA and Ahlback V with painful periarticular cysts did not improve with the technique. Pain and function results for grade V (Ahlback) declined after 6 months to one year leading to total knee arthroplasty. Pain, stiffness, function, and quality of life remained steady in patients with K&L grades 2 and 3 up to two years.
Conclusion: Selective embolization of pathological branches of genicular arteries can provide long lasting improvements in pain, function, and quality of life of patients with K&L grades 2 and 3.

P930
LOW VITAMIN D LEVELS IN PATIENTS WITH RHEUMATOID ARTHRITIS HAVE AN IMPACT ON THE EFFECTIVENESS OF REHABILITATION INTERVENTIONS

M. V. Nikitin[1], N. V. Aleksandrova[2], V. A. Aleksandrov[3], R. A. Grekhov[3], A. V. Aleksandrov[3]

[1]"Sanatorium-resort complex "Vulan"—Branch Federal State Budget Institution "National Medical Research Center for Rehabilitation and Balneology" of the Ministry of Health of the Russian Federation, Gelendjik, [2]Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky, Volgograd, [3]Volgograd State Medical Univ., Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky, Volgograd, Russia

Objective: Vitamin D deficiency may be associated with the development of autoimmune diseases such as rheumatoid arthritis (RA). The immunoregulatory role of vitamin D in the prevention and treatment of RA is discussed nowadays. We aimed to evaluate the effect of vitamin D deficiency on the effectiveness of posthospital rehabilitation of patients with RA.
Methods: We examined 48 women (mean age 52.2 ± 11.4 years old, disease duration 8.3[3.8;14.5] y) with a reliable diagnosis of RA who underwent posthospital rehabilitation (sanatorium treatment for 21 d). Disease activity was evaluated by DAS28, pain intensity (when walking) by visual analog scale (VAS Huskisson), fatigue severity by BRAF-NRSv2 scale. The level of serum 25(OH)D was determined by enzyme immunoassay (test system "25-OH-Vitamin D Total", DRG, Germany).
Results: Vitamin D deficiency (< 10 ng/mL) was determined in 12.5%, insufficient levels (values in the range of 10–29 ng/mL) were determined in 79.2%, and sufficient levels (values in the range of 30–100 ng/mL) were determined in 8.3% of RA patients. Lower vitamin D content ($p = 0.033$) was observed in patients who came for treatment from regions with low solar insolation (group I, n = 22). In addition, patients from group I had higher DAS28 disease activity ($p < 0.001$) and VAS score ($p = 0.012$) than RA patients from regions with high levels of solar insolation (group II, n = 26). No intergroup differences in fatigue scores on the BRAF-NRSv2 scale were found ($p > 0.05$). The 3-week stay and treatment in the sanatorium (high level of solar insolation) demonstrated reduction of pain intensity according to VAS ($p = 0,017$) and fatigue according to BRAF-NRS questionnaire scales: severity ($p = 0,041$) and NRS-effect ($p = 0,029$) only in patients from group II. No significant changes in these indices were found in group I. Disease activity according to DAS28 also did not change neither in group I, nor in group II ($p > 0,05$) during the treatment.
Conclusion: Vitamin D deficiency in patients with RA is associated with the level of insolation in the region of residence, depends on disease activity and is associated with increased VAS and fatigue. The proven potential of vitamin D to regulate the immune response can be used at the stage of medical rehabilitation of patients with RA to control the disease and its manifestations.

P931
DO WE PAY ENOUGH ATTENTION TO SKELETAL HEALTH IN PATIENTS TREATED WITH CINACALCET FOR PRIMARY HYPERPARATHYROIDISM?

M. Ventosa[1], M. A. Martín-Almendra[2], J. M. Palacio[3], C. Crespo[3], F. García-Urruzola[3], L. Cuéllar[3], M. T. Mories[4], M. González-Sagrado[5], D. Peñalver[3], M. Peralta[3], A. González-González[3], A. Manso[3], F. Núñez[1]

[1]Dept. of Endocrinology. Hospital Universitario Río Hortega., Valladolid, [2]Dept. of Endocrinology. Hospital Universitario de Salamanca, Salamanca, [3]Dept. of Endocrinology. Hospital Universitario Río Hortega, Valladolid, [4]Dept. of Endocrinology. Hospital Universitario Salamanca, Salamanca, [5]Dept.of Medical Investigation. Hospital Universitario Río Hortega, Valladolid, Spain

Objective: To investigate fracture (Fx) incidence, BMD monitoring and osteoporosis (OP) management in patients on cinacalcet therapy with primary hyperparathyroidism (PHP).
Methods: Retrospective observational study of 126 patients with PHP treated with cinacalcet in 2023, from 2 hospitals in Castilla y León. Clinical, laboratory and densitometric data were analyzed from the beginning of treatment until 5 y later.
Results: 16/110 male/female were included. Age 74.1 ± 12 y (16–93); total calcium 11.4 ± 0.6 mg/dl. 78.6% had a DXA before cinacalcet. Lumbar spine T-score -2.13 ± 1.3, femoral neck T-score -2.01 ± 0.9. OP in 47.9% (spine 40.4%, femoral neck 32%) and 40.7% at 5 y. DXA available at 1 y in 35.1%; 43.4% at 3 y and 50.9% at 5 y. 17.5% experienced at least 1 previous clinical Fx. 4.3% had a new Fx in the 1st year; 9.3% in 3 y; 15% in 5 y. Previous Fx were more prevalent if lumbar OP was present: 32.5 vs. 10.2% ($p < 0.01$). Patients with previous Fx experienced a new Fx more frequently than non-fractured: 47.1 vs. 6.1% ($p < 0.001$). In a logistic regression model, after adjustment for age > 80 y and vit D < 10 ng/ml, the risk of new Fx was associated with sex(male) (OR 22.1; p 0.03) previous Fx (OR 22.1; p 0.01) and femoral OP (OR 12.8; p 0,03). Total calcium was 9.8 ± 0.6 mg/dl at 5 y ($p < 0,001$). 58.3% achieved vit D levels > 30 ng/ml after 5 y (88.9% under vit D supplementation). Initially 23.8% were on bisphosphonate treatment, 4% on denosumab and 0.8% on strontium ranelate. During follow-up 29.4% on bisphosphonates, 6.3% on denosumab and 0.8% on raloxifene.42.9% of the patients who experienced a new Fx were treated with bisphosphonates, 7.1% with denosumab.
Conclusion: PHP patients had a high incidence of clinical fractures before and through 5 y of treatment with cinacalcet. Conservative treatment with cinacalcet and vit D was effective to improve calcium and vit D levels. BMD monitoring and OP treatment are mandatory in this population.

P932
INCREASING THE DIFFERENTIATION POTENTIAL OF ADIPOSE DERIVED STEM CELL INTO OSTEOCYTE AND CHONDROCYTE BY PLANT DERIVED EXOSOMES: A POSSIBLE THERAPEUTIC STRATEGY FOR CARTILAGE DEFECTS

M. Y. C. Yıldırım Canpolat[1], N. Ünsal[1], B. K. Kabataş[1], O. E. Eren[1], F. Şahin[1]

[1]Yeditepe Univ., Biotechnology, İstanbul, Turkey

The treatment of articular cartilage defects is a particularly pressing issue, in large part because the available therapeutic alternatives are insufficiently effective. Even very slight injury may continue and cause joint deterioration, which can eventually lead to osteoarthritis due to the avascular cartilage's limited potential for self-repair. Cell- and exosome-based therapies show promise as potential treatments for repairing injured cartilage, despite the fact that a variety of therapy approaches have been explored. Plant extracts have been used for many decades, and research into the impact that these extracts have on the regeneration of cartilage has been conducted. Exosome-like vesicles, which are released by all live cells, have a role in both the communication between cells and the maintenance of the homeostasis of individual cells. In this study, human adipose-derived mesenchymal stem cells (hASCs) were differentiated into chondrocytes to explore the differentiation potential of exosome-like vesicles obtained from *R. raphanistrum*, *S. lycopersicum* and *C. limon*, which are known to have anti-inflammatory and antioxidant activities. An aqueous two-phase system was carried out in order to create radished-derived exosome like vesicles (RELVs), tomato-derived exosome-like vesicles (TELVs) and lemon-derived exosome-like vesicles (LELVs). Using methods such as the Zetasizer, NTA FAME analysis, and scanning electron microscopy, we were able to characterize the separated vesicles according to their size and form. According to these findings, RELVs, TELVs and LELVs both boosted the vitality of the cells and did not have any harmful effects on the stem cells tested. While RELVs and TELVs promoted chondrocyte development, LELVs had the opposite effect and inhibited it. Following treatment with RELV, there was an uptick in the level of expression of chondrocyte markers such as ACAN, SOX9, and COMP. Additionally, protein expression of the two most significant proteins present in cartilage's extracellular matrix, COL2 and COLXI, increased. Both of these proteins are located in cartilage. These results point to the possibility that RELVs may be used for cartilage regeneration, which would make them an innovative and potentially fruitful therapy for osteoarthritis.

BIOINFORMATIC ANALYSES TO IDENTIFY OSTEOGENIC ROBUSTNESS IN TISSUE-SPECIFIC HUMAN MESENCHYMAL STEM CELLS (MSCS) AND 3D IN VITRO PLATFORMS FOR RAPID FUNCTIONAL VALIDATION

M. Yen[1], L. Wang[1], J. Hung[1], H. Wang[2], B. Yen[2]

[1]National Taiwan Univ., College of Medicine, Dept. of Ob/Gyn, Taipei, [2]Institute of Cellular & System Medicine, National Health Research Institutes, Zhunan, Taiwan

Objective: Progress in precision medicine has dramatically improved outcomes for oncology and related cell therapies, but allogeneic mesenchymal stem cell (MSC) therapy, which holds the most promise for regeneration of bone, is complex with its many available tissue sources, lags in establishing molecular and high-resolution criteria to predict and improve therapeutic outcomes. In addition, while in vivo validation is the gold standard for osteogenesis, the long time period required (4–8 weeks) and the need for immunocompromised mice when testing human cellular products make use of this assay difficult and costly for clinical application.

Methods: We assess the use of whole transcriptomic information followed by rapid functional validation in a 3D in vitro platform to identify robust osteogenic capacity between commonly used sources of human MSCs.
Results: Transcriptomic analysis revealed similar enrichment for osteogenic-related pathways adult bone marrow (BM) MSCs compared to fetal placental MSCs (PMSCs). Interestingly, mitochondrial-related pathways were significantly more enriched in PMSCs than BMMSCs. Functional assessment of mitochondrial membrane potential and respiration validated the transcriptomic findings. Functional osteogenic differentiation in 3D in vitro culture demonstrated more robust osteogenesis with PMSCs compared to BMMSCs. Moreover, 3D culture further enhanced the mitochondrial functions of PMSCs in a significant fashion, which was not consistently seen with BMMSCs. Inhibiting mitochondrial function in 3D-cultured PMSCs resulted in a significant decrease in osteogenesis at both transcriptomic and functional levels, demonstrating the importance of mitochondrial health in MSC osteogenesis.
Conclusion: Bioinformatics analyses of whole transcriptomes is therapeutically useful for identification of functional osteogenic capacity between difference sources of human MSCs. Moreover, the state of mitochondrial health is strongly aligned with MSC osteogenic capacity and can be modulated by 2D vs. 3D in vitro culture. Our data implicates additional therapeutically relevant strategies to improve regeneration of bone, an organ which undergo age-related as well as pathologic decline, through modulating mitochondrial health and 3D in vitro culture systems.

ZINC: AN ANONYMOUS FOE OR AN EVIDENT COMRADE FOR OSTEOARTHRITIS? A COMPREHENSIVE LITERATURE REVIEW

I. Tekeoğlu[1], M. Z. Şahin[2]

[1]Sakarya Univ. Faculty of Medicine, Dept. of Rheumatology,,
[2]Sakarya Univ. Faculty of Medicine, Dept. of Physical Medicine and Rehabilitation, Sakarya Univ. Training and Research Hospital, Sakarya, Turkey

Objective: Osteoarthritis (OA) is a chronic debilitating disease that mainly affects the articular cartilage throughout the human body. Higher prevalence is seen in the elderly population and the risk increases with comorbid diseases or obesity. Owing to zinc being the second most abundant trace element found in the body after iron, it holds great significance for the human body. It exerts substantial influence in intracellular signaling pathways on account of it being a cofactor for more than 300 enzymes and 3000 metalloproteins. Thus, it is not a surprise that modern studies show plenty of pathological pathways incorporating zinc in osteoarthritis (OA) pathogenesis. Numerous recent studies indicate that zinc has a preventative effect against Monosodium Iodoacetate (MIA)-stimulated osteoarthritic cartilage. Intraarticular MIA injection is used worldwide to induce joint pathology mimicking OA. However, the clear effect of zinc on human OA remains undisclosed. We aimed to elucidate the impact of zinc on bone health and osteoarthritic cartilage and determine the concentrations associated with these effects.
Methods: We thoroughly searched PubMed, Wiley, and Cochrane Library databases using the keywords 'Osteoarthritis', 'Zinc', 'Enzymes', 'Immunity', and 'Pathophysiology' for relevant articles and conducted an exhaustive review of the literature to ensure a comprehensive understanding of the topic relying mainly on articles published in the years following 2000.
Results: Overall, 131 articles were analyzed. We observed that low zinc concentrations result in decreased bone mass and growth, reduced antibody production, lower TH1/TH2 ratio, hypothalamic–pituitary–adrenal axis activation, and increased apoptosis rates of cells. On the other hand, high zinc concentrations lead to disrupted homeostasis of other trace elements, alter cytokine production, and act as a cofactor of many catalytic enzymes.
Conclusion: Owing to the countless positive effects of zinc on bone health and immunity, zinc is commonly considered to have favorable impacts on patients with OA. It is evident that zinc prevents the progression of MIA-induced OA. However, plenty of studies indicate detrimental outcomes of zinc on OA as well. Therefore, the management of patients with OA with zinc supplementation might resemble a double-edged sword.

P935
INCREASED BONE MARROW ADIPOSITY IS RELATED TO HIGHER FRACTURE RISK AND LOWER BONE MINERAL DENSITY IN OLDER SWEDISH WOMEN

M. Zoulakis[1], K. F. Axelsson[1], H. Litsne[1], L. Johansson[1], M. Lorentzon[1]

[1]Univ. of Gothenburg, Dept. of Internal Medicine and Clinical Nutrition, Sahlgrenska Osteoporosis Centre, Gothenburg, Sweden

Objective: Recent research suggests that bone marrow adiposity (BMAT) is associated with osteoporosis and increased fracture risk. However, quantifying BMAT can be challenging mostly because the golden standard for assessment is by MRI, a method limited by low availability and high costs. We recently developed a method to quantify BMAT from HR-pQCT) images.[1] This method was able to explain up to 76% of the variation in the MRI-derived bone marrow fat fraction (BMFF) at the ultradistal tibia. This study aimed to investigate if BMAT, derived from HR-pQCT images, was associated with incident fractures and osteoporosis prevalence in older women
Methods: In total, 2984 women aged 75–80 y, from the SUPERB cohort, participated in a population-based study between March 2013 to May 2016 and underwent a comprehensive assessment of bone characteristics including bone densitometry (DXA), and HR-pQCT measurements of the ultradistal tibia at baseline. The BMFF was measured as previously described[1] using HR-pQCT images at the ultradistal tibia. Follow-up of x-ray verified incident fractures data was completed in March 2023. Associations between BMFF, anthropometrics, and BMD, were investigated using correlations, linear and logistic regression. Cox regression was used to study the association between BMFF and incident fractures.
Results: BMFF was inversely associated with BMI ($r = -0.22$, $p < 0.001$) and with total hip BMD ($r = -0.50$, $p < 0.001$; $\beta = -0.43$, $p = 0.001$, after adjustment for age and BMI). During a median follow-up time of 7.3 (4.4, 8,4) y, 797 major osteoporotic fractures (MOF), 1069 any fractures, and 235 hip fractures occurred. Increasing BMFF (per SD) was associated with increased risk of MOF (hazard ratio [HR] = 1.28, 95%CI 1.19–1.38), any fracture (HR = 1.23, 95%CI 1.16–1.31), and hip fracture HR = 1.34, 95%CI 1.17–1.53), All associations, except for hip fracture, remained significant after adjustments for clinical risk factors (CRFs) and femoral neck BMD (Figure).

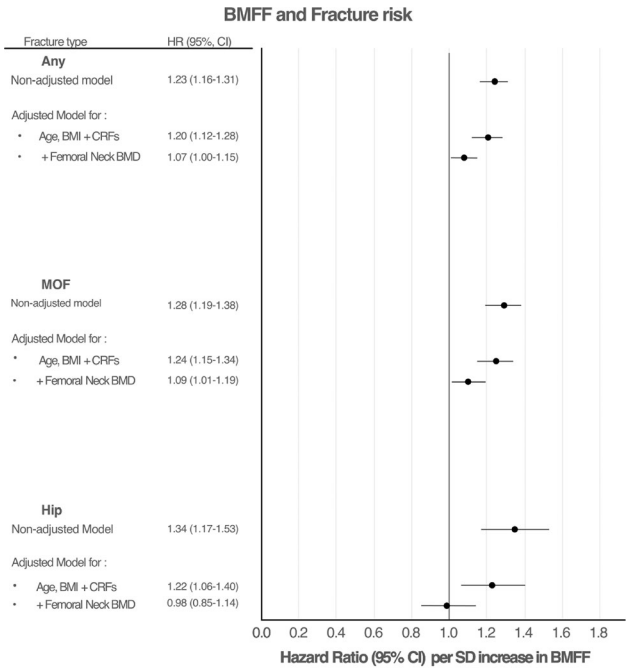

Figure. Forest plot of adjusted and non-adjusted Hazard Ratio (HR) and 95% Confidence Interval (95% CI) per SD increase in bone marrow fat fraction (BMFF) for : Any fracture, Major Osteoporotic Fracture (MOF) and Hip Fracture

Conclusion: Increasing BMFF was associated with lower BMD and with greater fracture risk in older Swedish women.

P936
THE LUNG IN RHEUMATOID ARTHRITIS: FOCUS ON DIFFUSING CAPACITY OF THE LUNGS FOR CARBON MONOXIDE (DLCO), THE MOST SENSITIVE INDEPENDENT PREDICTOR

M.-L. Anton[1], A. Cardoneanu[1], E. Rezuş[1]

[1]Clinical Rehabilitation Hospital, Rheumatology, Iasi Romania, Iasi, Romania

Objective: DLCO represents the most sensitive independent factor of the growing burden era of rheumatoid arthritis with interstitial lung disease (RA-ILD). This study aimed to highlight the importance of DLCO as a predictor of ILD progression in RA, beside the pattern on high-resolution chest CT (HRCT) and the double seropositivity of disease.

Methods: This prospective cohort study, carried out between August 2022 and March 2024, included 60 RA patients with ILD, fulfilling the 1987 ACR or 2010 ACR/EULAR classification criteria. Important attention was paid to respiratory functional tests abnormalities, immunological changes, and specific lung pattern on HRCT. Patients with current malignancies, active infections or overlap syndrome were excluded from our study.

Results: 60 RA patients, mostly women with a mean age of 65.54 ± 10.58 years old and the mean age of onset of RA 52.58 ± 11.36 years old. The proportion of patients with decreased DLCO was 70% at the side of RA seropositivity in 60% cases. By statistical tests we found significant correlations between DLCO and age, double seropositivity and specific pattern on HRCT.

Conclusion: ILD, an underrecognized disease, may be considered one of the most serious of all extra-articular manifestations in RA, the risk of mortality being triple in these cases. Our results were significant for the coexistence of decreased DLCO, HRCT pattern and double seropositivity of disease.

HEALTH RELATED QUALITY OF LIFE (HRQOL) AMONG PATIENTS WITH OSTEOPOROTIC VERTEBRAL FRACTURES

N. A. Shohor[1], J. F. Leong[2], S. L. Panduragan[1], S. A. Mokhtar[3]

[1]Faculty of Medicine, Universiti Kebangsaan Malaysia, [2]Dept. of Orthopedics and Traumatology, Hospital Canselor Tuanku Muhriz, [3]Dept. of Orthopedics and Traumatology, Hospital Canselor Tuanku Muhriz, Kuala Lumpur, Malaysia

Objective: To assess the impact of osteoporotic vertebral fractures (OVF) on health-related quality of life (HRQOL) among patients with osteoporosis.

Methods: A total of 45 Malaysian women aged 55 years and older were enrolled in this cross-sectional study using the Short-Form 36 (SF-36) questionnaire. The collected data were analysed using the Statistical Package for Social Sciences (SPSS).

Results: HRQOL has 10 domains, whereas the locations of fracture were lumbar vertebrae and thoracic vertebrae. The mean bodily pain (44.48 ± 7.93 vs. 38.37 ± 7.28) and social functioning (49.32 ± 10.34 vs. 41.43 ± 13.58) scores were found to be significantly higher in the lumbar region than the thoracic vertebrae ($p < 0.05$). The mean physical component summary (PCS) score was also found to be significantly higher in the lumbar vertebrae (38.81 ± 6.60) than in the thoracic vertebrae (34.35 ± 7.51) ($p < 0.05$).

Conclusion: The researcher concluded that the lumbar location of the fracture has a higher or better HRQOL compared to the thoracic fracture location. This could probably be due to the fact that the rigidity of the lumbar spine is less than that of the thoracic spine, which is more rigid by nature. Proper management of OVF indirectly provides better PCS scores in patients with lumbar fractures than thoracic when the nature of the spine is taken into consideration. Looking at the increasing trend of HRQOL as an indicator of a patient's overall health, increasing awareness and understanding o how OVF affects the patient's quality of life are crucial to be carried out.

P938
ASSOCIATION BETWEEN PAIN AND DISABILITY AMONG PATIENTS WITH OSTEOPOROTIC VERTEBRAL FRACTURES (OVF)

N. A. Shohor[1], J. F. Leong[2], S. L. Panduragan[1], S. A. Mokhtar[2]

[1]Faculty of Medicine, Universiti Kebangsaan Malaysia, [2]Dept. of Orthopedics and Traumatology, Hospital Canselor Tuanku Muhriz, Kuala Lumpur, Malaysia

Objective: To determine the association between pain and disability among patients with OVFs.

Methods: A total of 45 Malaysian women aged 55 years and older were enrolled in this cross-sectional study using a questionnaire consisting of the Oswestry disability index (ODI) and the visual analogue scale for pain (VAS). The collected data were analysed using the Statistical Package for Social Sciences (SPSS).

Results: 86.7% of the subjects with an average age of 72.78 (SD = 7.30) years old had other medical problems, and the mean BMI of the respondents was 26.21 (SD = 4.05) kg/m^2 with 42.4% of them had normal BMI. The mean ODI percentage was 37.82% (SD = 16.92) with the majority (51.1%) having moderate disability, with a mean

VAS score of 5.23 (SD = 1.37). Almost 69% of the respondents had a moderate VAS score. The result revealed that there was a significantly strong association between the ODI and the VAS score ($p < 0.001$) among patients with osteoporotic vertebral fractures.
Conclusion: The management of osteoporosis needs to be implemented effectively and efficiently among doctors, nurses, and other health care professionals because the major complication of osteoporosis is the increase in fragility fractures leading to morbidity, mortality, and decreased quality of life, referring to the strong association between the ODI and the VAS score in this study. Furthermore, early detection and early treatment will directly and significantly improve their quality of life and enable them to embrace the ageing process with manageable, minimal medical complications.

P939
PREVALENCE AND PREDICTING FACTOR OF LOW BACK PAIN (LBP) IN JOB PERFORMANCE AMONG NURSES IN UNIVERSITY HOSPITAL

N. A. Shohor[1], J. F. Leong[2], S. L. Panduragan[1], S. A. Mokhtar[2]

[1]Faculty of Medicine, Universiti Kebangsaan Malaysia, [2]Dept. of Orthopedics and Traumatology, Hospital Canselor Tuanku Muhriz, Kuala Lumpur, Malaysia

Objective: To determine the prevalence and predicting factor of low back pain in job performance among nurses in tertiary university hospitals.
Methods: A quantitative cross-sectional study with a self-administered questionnaire was used to collect data among 132 nurses in the Clinical Training Centre (CTC) of a university hospital. The collected data were analysed using the Statistical Package for Social Sciences (SPSS).
Results: The prevalence of nurses who suffer from LBP was 112 (84.8%) in the previous 12 months. The highest risk for LBP among nurses was carrying patients to bed with 106 nurses (94.7%), moving or supporting patients to bed with 108 nurses (96.4%), pushing wheel chairs or patient beds with 109 nurses (97.3%), and pushing heavy objects with 96 nurses (85.7%). This study shows that there was no significant association between LBP among nurses and socio-demographic variables such as gender, age, and BMI. However, this study also revealed that the predicting factor for LBP among nurses that affects their job performance is the last episode of LBP taken medication ($R = 0.076$, $F = 10.717$, p value < 0.003), support or move patients to bed ($R = 0.122$, $F = 9.000$, $p < 0.014$) and pushing heavy objects ($R = 0.149$. $F = 7.467$, $p < 0.048$).
Conclusion: The highest prevalence of low back pain and work-related back injuries reported among nurses compared to other occupational groups and a higher risk of functional disability may affect the standard and quality of patient care as nurses are the frontline workers who provide direct care to the patients. The result of this study may be used to plan future actions focusing on eliminating or reducing the risks of low back pain. Different strategies, guidelines, and activities that authorise individuals and provide knowledge to manage and prevent low back pain among nurses need to be implemented.

P940
COMPARISON OF PROTEIN INTAKE ASSESSED FROM 24-H URINE SAMPLES, FOOD DIARIES AND WEIGHED PROTEIN POWDERS IN COMMUNITY-DWELLING ADULTS WITH SARCOPENIA: RESULTS FROM THE ENHANCE STUDY

N. Amini[1], A. Devriendt[1], L. Lapauw[1], J. Dupont[1], K. Verbeke[1], L. Vercauteren[1], S. Verschueren[1], J. Tournoy[1], E. Gielen[1]

[1]KU Leuven, Leuven, Belgium

Objective:
1. To determine total protein intake by nitrogen-excretion in 24-h urine samples (dietary + supplemental protein/placebo)
2. To compare total protein intake estimated from a combination of 4-d food diaries (dietary protein) and weighed protein powders (supplemental protein/placebo) against total protein intake estimated from 24-h urine samples (dietary + supplemental protein/placebo).
Methods: Longitudinal data of the ongoing Exercise and Nutrition for Healthy AgeiNg (ENHANce) study were used. ENHANce is a 5-armed triple blinded RCT in older adults ($\geq$ 65 y) with EWGSOP2-defined sarcopenia. This RCT aims to assess the effect of combined anabolic interventions (protein supplement, omega-3 supplement and physical exercise) vs. placebo or no intervention on physical performance (12-week intervention). The amount of protein/placebo supplement was individualized to achieve a mean total intake of 1.5 g/kg BW/d. Total protein intake in participants was determined by a combination of weighed protein powders and 4-d food diaries and by nitrogen-excretion in 24-h urine samples at 8 different measurement moments in the intervention period. Mean differences and Lin's concordance correlation coefficients were used to assess agreement between the two methods.
Results: After 12 weeks, nitrogen analysis showed that the mean total protein intake was 1.31 g/kg BW in the protein powder group ($n = 33$) and 0.86 g/kg BW in the placebo group ($n = 17$). Mean protein intake according to the combination of food diaries and weighed powders (87.0 g/d) was overestimated by 7.7 g/d compared to the method using 24-h urine samples (79.3 g/d). Throughout the whole intervention period, correlation coefficients between protein intake derived from the combined method and 24-h urine samples varied between 244–0.565 and 0.382–0.641 in the placebo group and protein group, respectively.
Conclusion: Protein supplementation increased protein intake to meet the daily recommended amount of protein intake for older adults (1.0–1.2 g/kg BW), but not that for sarcopenic older adults (1.5 g/kg BW). Protein intake in sarcopenic older adults can be estimated with fair to moderate accuracy by the combination of food diaries and weighed powders.

P941
SERUM 25-HYDROXYVITAMIN D UP TO 60 NG/ML IS NOT ASSOCIATED WITH FALLS IN POSTMENOPAUSAL WOMEN

N. Binkley[1], C. Sempos[2], G. Borchardt[1], J. Lappe[3]

[1]Univ. of Wisconsin-Madison, Madison, [2]Vitamin D Standardization Program, Havre de Grace, [3]Creighton Univ. School of Nursing, Omaha, USA

Objective: Falls are common and cause fractures. High circulating 25(OH)D may increase falls risk; thus, recent guidance recommends 25(OH)D not exceed 50 ng/mL. Prior falls studies have not reported standardized 25(OH)D (s25D) data. The purpose of this planned secondary analysis of a 4-y calcium/vitamin D supplementation trial was to evaluate the association of s25D with falls.
Methods: This study recruited 2,303 postmenopausal women. The analytic dataset consisted of pooled concatenated data from years 2–4 ($N_{Total} = 5{,}732$). Serum 25(OH)D was measured annually and subsequently retrospectively standardized using Vitamin D Standardization Program methods. Falls were recorded by diary. Incidence for $\geq$ 1 fall and $\geq$ 2 falls was assessed by s25D group

($\leq$ 20, 20- $<$ 30, 30- $<$ 40, 40- $<$ 50, 50- $<$ 60 and $\geq$ 60 ng/mL) using multivariable logistic regression.
Results: Mean (SD) baseline s25D was 32.6 ng/mL (8.3) with no difference between supplement and placebo groups. s25D increased to 41.3 ng/mL at year 2 in the supplement group then remained stable. By s25D group, incidence for $\geq$ 1 fall varied from 22–32% (p = 0.19). For $\geq$ 2 falls incidence varied (p = 0.03) from 6% ($<$ 20 ng/mL) to 17% ($\geq$ 60 g/mL.) There was no significant association between s25D and $\geq$ 1 fall. Those with s25D $\geq$ 60 ng/mL had a higher adjusted odds of $\geq$ 2 falls (OR = 1.99 $\pm$ 1.2–3.3) compared to women with s25D of 30- $<$ 40 ng/mL.
Conclusion: s25D up to 60 ng/mL was not associated with greater risk for $\geq$ 1 or $\geq$ 2 falls. Women with a s25D $\geq$ 60 ng/mL were at higher odds for $\geq$ 2 falls.

P942
RHEUMATOLOGIST'S POINT OF VIEW REGARDING THE FUTURE OF HIS SPECIALTY

N. Bouhedja[1], L. Poulain[1], X. Grapton[2], P. Lemesle[3]

[1]Private practice, La Garenne Colombes, [2]Hopital Suisse de Paris, Issy Les Moulineaux, [3]Hopital Rives de Seine Courbevoie, Courbevoie, France

Objective: Evaluate the outcome of rheumatology by the 51 rheumatologists (Rh) from the CREER group.
Methods: Average age 58, 40% M/W, $>$ 58, 4 M/W, practice: M = W + 12y, private practice (PP) 30%, mixed 50%, salaried (S) 20%. M teleconsults 16% / 48%, W (twice as much if $<$ 58yo).
Results: Patients referred:
- infiltration (If): general practitioner (Gp) M 41/W 27%, orthopedist (0r) 10% M = W;
- osteoporosis (OP): Gp 23/20%, gynecologist (Gy) 12/8%, Or 4% M = W;
- osteoarthritis (OA) Gp 39/33%, physiotherapist (Ph) 6/10%, Or 11/4%;
- inflammatory rheumatisms (IR): Gp 56/26, others 17/8%.

Rh comes in second rank after Ph and osteopaths 67%, Or 52%, Acupuncturist 9%. Rh is consulted (except for Gp) in 2nd 55%, 3rd 32%, 4th 8%, 1st in 4%. Feeling of a downgrade perceived by Rh: M $<$ 58 yo yes 80% S = PP, $>$ 58 yo yes 72% PP $>$ S, W $<$ 58 yo no 55% PP $>$ L, $>$ 58 yes 80% S = PP. Factors influencing our patients: Gp 52%, Net 22%, Surroundings 15%, associations, experts cited last. Rh consulting their internet profile: M no 58% but yes for M $<$ 58 in 87%, $>$ 58 no 87%, W no 64%, $<$ 58 yo 60%, $>$ 58 70%. Transfer of tasks, Rh opinion: Against M 61/W 52%, $>$ 58 75/54%. Substitution by pharmacist no 70%. Advanced practice nurse (APN): Infiltration no 94%, 80% yes for therapeutic education, 52% yes for screening yes. Task transfer is necessary: M 70% no, W 60% yes, consistent yes 60/66%, secure no 88/50%. Who is responsible: Rh 50%, performer 50%, Shared responsibility 50% M = W. Vision of the future of rheumatology specialty: Regression 83/70%, If towards internist conceivable 75/65%, not desirable 77/95. OA to Or possible 33/41%, not desirable 95/100%, OP to Gp conceivable 33/5%, not desirable 83/98%. Out of 17 solutions for safeguarding rheumatology, the 4 most frequent: internships at private practice, increasing the doctors' fees for the consultation, raising patients' awareness of the need for rheumatology via the media and medical associations, vigilance and concern about task transfers.
Conclusion: Patients are referred primarily by Gp. RH perceive a downgrade of their specialty W = M, except W $<$ 58 yo and S $>$ PP. Should remain dedicated to Rh patients: screening and, above all, therapeutic. Education could be transferred to APN, which seems necessary for W but not for M. What about individual responsibility?

P943
ASSESSMENT OF MENTAL STATUS OF PEOPLE LIVING WITH KNEE OSTEOARTHRITIS: A SYSTEMATIC REVIEW

N. C. Ojielo[1], N. R. Njeze[1]

[1]Univ. of Nigeria Teaching Hospital, Enugu, Nigeria

Objective: Knee osteoarthritis (KOA) is a prevalent chronic joint condition that significantly affects the well-being of individuals as well as the quality of life, and currently available treatments exhibit limited effectiveness. While there is no definitive cure for knee osteoarthritis, individuals typically contend with the condition for an extended period, lasting approximately 30 years. Existing research predominantly focuses on assessing the prevalence, risk factors, and conventional medical interventions, often overlooking the potential influence of this enduring ailment on their mental health. This systematic review aims to investigate the mental health implications for individuals living with knee osteoarthritis, directing healthcare providers' attention to this co-occurrence.
Methods: The search spanned electronic databases such as MEDLINE, PubMed, Cochrane Library, Google Scholar, and Embase, adhering to evidence-based guidelines from inception until October 2023. Inclusion criteria encompassed studies presenting data on depressive symptoms and anxiety in individuals with osteoarthritis. Out of 948 articles reviewed based on titles and abstracts, 108 underwent a full-text assessment, and data were extracted according to pre-specified criteria for 74 articles, along with 24 identified through bibliographic review (n = 98).
Results: 24 studies fulfilled the inclusion criteria, involving 14,900 patients with knee osteoarthritis. Anxiety and depression emerged as consistently reported mental health issues, delineated by diverse screening criteria and thresholds. The pooled prevalence of depressive symptoms in osteoarthritis was 19.9% (95%CI: 14.8–23.5%, n = 9,811), while the corresponding prevalence for anxiety symptoms was 20.8% (95%CI: 15.1–27.9%; n = 1,142). P-value is 0.043. Relative risk analysis indicated a depression risk of 1.14 (95%CI 0.58–1.52, three studies, n = 902) among individuals with osteoarthritis compared to those without. The relative risk for anxiety was 1.21 (95%CI: 0.54–3.48; three studies, n = 718) compared to individuals without osteoarthritis.
Conclusion: Approximately one in five individuals with osteoarthritis experiences symptoms indicative of depression and anxiety. However, while statistically significant, there is no direct evidence supporting a definitive increase in anxiety and depression among those with osteoarthritis. We advocate for more robust, methodologically rigorous, large-scale randomized controlled trials to address this research question. Furthermore, healthcare providers are encouraged to heighten their awareness of depressive symptoms in patients with osteoarthritis.

P944
RELATIONSHIP OF LUMBO-SACRAL ANGLE TO DEGREE OF LOW BACK PAIN AMONG NIGERIAN ADULTS ORLU IMO STATE

C. Udeagu[1], N. C. Ojielo[2], N. R. Njeze[2]

[1]Dept. of Radiology, Imo State Univ. Teaching Hospital Orlu, Imo, [2]Univ. of Nigeria Teaching Hospital, Enugu, Nigeria.

Objective: Low back pain (LBP) refers to pain and muscle stiffness experienced in the back region below the rib cage and above the buttocks. Lumbo-sacral angle (LSA) is the angle formed with a line drawn along the top of the first sacral vertebra and intersecting with another line parallel to the horizontal. This study aims at determining the relationship between LSA and severity of low back pain in Nigerian adults.
Methods: Patients referred to Radiology Department of Imo State University Teaching Hospital Orlu, for lumbo-sacral radiographs on account of low back pain were recruited in this study from 1 April 2019 to 29 November 2019. Data were collected and analyzed using statistical package for social sciences (SPSS) version 20.0.window software.
Results: There were four hundred respondents in this study. Their age ranged from 18–109 years with mean age of 63.5 y. Age group from 50–60 y recorded the highest frequency while age group from 30–40 y yielded the lowest frequency. Male to female ratio was 1:1.4. Mean age at onset of chronic LBP is 49 $\pm$ 16. 7 y and mean age at onset of acute low back pain is 48 $\pm$ 17.7 y. The normal LSA is 4^{o} and LSA for mild LBP is 43 $\pm$ 6.3°, LSA for moderate LBP is 40 $\pm$ 8.5° and LSA for severe LBP is 38 $\pm$ $9.1^{o.}$
Conclusion: Increased severity of low back pain among adult Nigerians is correlated with decreased lumbo-sacral angle. LBP is more prevalent in female gender and age group 50 y and above.

P945
DETERMINATION OF THE EFFECT OF OVERWEIGHT ON LOW BACK PAIN (LBP) IN NIGERIAN ADULTS IN ORLU IMO STATE.

C. Udeagu[1], N. C. Ojielo[2], N. R. Njeze[2]

[1]Dept. of Radiology, Imo State Univ. Teaching Hospital Orlu, Imo, Nigeria, [2]Univ. of Nigeria Teaching Hospital, Enugu, Nigeria

Objective: LBP is the most prevalent musculoskeletal condition and one of the most common causes of disability in the world. On any given day, an estimated 6.5 million people in the USA are bedridden because of back pain and approximately 1.5 million new cases of back pain are seen by physicians each month. More than 85% of LBP has no specific cause. The objective is to determine the effect of overweight on LBP in Nigerian adults in IMSUTH Orlu.
Methods: 400 LBP patients were used in this study in IMSUTH Orlu between the 1 April to 29 November 2019. The weight of these patients was measured by asking them to remove any materials that could alter the patient's weight. This sparsely clothed patient was then asked to climb the scale; and stand without support, the weight observed was recorded in kilograms using a Camry weighing scale, made in China model BR9011 2008. Patients' heights were measured in meters by asking the patients to remove their footwear and stand erect on a height scale. A ruler was placed on top of the patient's head; the corresponding reading was taken as the patient's height in meters. BMI of these patients were used to classify them into normal BMI of 18.5–24.5, overweight BMI $>$ 24.5 and underweight BMI $<$ 18.5. Data collected was analyzed using SPSS version 20.0.window software.
Results: This study shows that a higher population of LBP respondents are overweight (64%). It was then shown that overweight was a major risk factor for LBP. The confidence level of this study is 95%.
Conclusion: Being overweight was a major risk factor for LBP in Nigerian adults in IMSUTH Orlu Imo State. Thus, weight loss is highly recommended.

P946
USING BONE MINERAL DENSITY AND TRABECULAR BONE SCORE FOR PREDICTION OF LOW-ENERGY VERTEBRAL FRACTURES

N. Dimic[1], B. Stamenkovic[1], S. Stojanovic[1], J. Nedovic[1], A. Dimic[2], J. Jocic[1], J. Cvetkovic[1]

[1]Institute for treatment and rehabilitation "Niska Banja", Nis, [2]Polyclinc Natus, Aleksinac, Serbia.

Objective: TBS assesses bone microarchitecture and can be used to predict the risk of osteoporotic fractures alone or in addition to BMD. In retrospective case–control study (13 years of monitoring), we compared ability of TBS and lumbar spine BMD (BMD L1-L4) to predict low-energy vertebral fractures. Inclusion criteria were female gender, aged 45–85 years of age in postmenopausal period with clinical risk factors for osteoporosis. Subjects with secondary osteoporosis are not included in the research.
Methods: Both diagnostic tests (BMD L1-L4 and TBS) were evaluated to predict probability of low-energy vertebral fractures using the Bayesian "OR rule" (diagnosis is negative if both diagnostic test are negative/diagnosis is positive if only one diagnostic test is positive) or using the "AND rule" (the diagnosis is positive if both tests are positive/diagnosis is negative if one of tests is negative). 9 out of a total of 101 women had a documented low-energy vertebral fracture (diagnosed by MRI, CT scan or conventional radiography).
Results: TBS and BMD L1-L4 showed similar ability to predict low-energy vertebral fractures, with a positive predictive value (PPV) of 15.2% and 16.1%. The negative predictive values (NPV) were 93.4% and 92.9%. If we compare individually each diagnostic tool: "OR-rule" significantly increased the NPV to 94.58%; "AND-rule"—there were no statistically significant differences.
Conclusion: Using LS-BMD and TBS together may improve the predictive value in diagnosing low-energy vertebral fractures. Also, there is a significant nonexistence of low-energy fractures in women with both negative diagnostic tests.

P947
CHANGE IN BONE MINERAL DENSITY IN PATIENTS WITH SYSTEMIC SCLEROSIS: ONE YEAR FOLLOW-UP

J. Jocić[1], B. Stamenković[2], J. Nedović[1], S. Stojanović[2], N. Dimić[1], J. Cvetković[1]

[1]Institute for Treatment and Rehabilitation "Niška Banja", [2]Institute for Treatment and Rehabilitation "Niška Banja" Faculty of Medicine, Univ. of Niš, Niš, Serbia

Objective: Patients with systemic sclerosis (SSc) may be at increased risk for reduced bone density due to chronic inflammation, malabsorption or malnutrition, corticosteroid use, and the risk of

osteoporosis is related to the severity and duration of the disease.
Methods: the cross-sectional study included 44 patients who met the ACR criteria for SSc, with an average age of 63.52 ± 8.55 y and a mean duration of the disease of 12.02 ± 6.87 y. Out of the total number, 20 (45.45%) patients had diffuse (dSSc) while 24 (54.55%) had a limited form of the disease (lSSc). BMD was measured on the lumbar spine and neck of the femur, using DXA on the Hologic Discovery device, in the period from January 2020 to December 2023 at the Institute for Treatment and Rehabilitation in Niška Banja. BMD is expressed in absolute values (g/cm^2) and in the form of T-score. All patients underwent a clinical examination, standard and specific laboratory tests—anticentromeric antibodies (ACA), antibodies to topoisomerase-I (ATA) and total antinuclear antibodies (ANA). Based on the therapeutic modality, we divided the patients into two groups: patients who were previously treated with cyclophosphamide and patients treated with other disease-modifying drugs (azathioprine, chloroquine and methotrexate)—who never had cyclophosphamide in their therapy. Also, we divided all patients into those with and without glucocorticoids, and then we divided the group with GK into two subgroups in relation to the therapeutic dose (up to 10 mg and over 10 mg/d). The groups were comparable in relation to other proven risk factors for osteoporosis (smoking, menopause, age, etc.). The data were processed with descriptive and analytical statistical methods using statistical software SPSS Statistics 22.0.
Results: Out of the total number of respondents, 25/44 (56.82%) had positive ACA, while 19/44 (43.18%) had positive ATA. By comparing the bone density on the spine and hip in patients with ACA and ATA before and after the application of the basic drug, a decrease in BMD was observed over time in both groups; a greater decrease in bone density was observed in ACA-positive patients (deterioration at the hip 21.8 vs. 13.5%; at the spine—24.1 vs. 6.4%, $p < 0.001$). In the group of subjects treated with cyclophosphamide—8/44 (18.18%), comparing bone density before and after therapy, we found a decrease in bone density at the neck of the femur by 26.6% ($p = 0.002$), while this decrease was smaller in female patients on therapy with other disease-modifying drugs—14.3%, indicating a statistically significant intergroup difference ($p < 0.0001$). A total of 34/44 (77.27%) were also on GC therapy. In relation to the GK dose, the patients were divided into two subgroups: 18 (52.94%) patients had a GK dose of up to 10 mg—an average of 8.06 mg/d. (average cumulative dose 8760 g) and 16 (47.06%) patients with GK dose over 10 mg/d—average 22.5 mg (average cumulative dose 10.950 g). The group of patients with a higher dose of GK had a significant decrease in bone density both at the spine and at the hip at the time of surgery (hip 18.6 vs. 13.5%; spine—15.2 vs. 11.6%, $p < 0.001$). Out of the total number, 16/44 (36.36%) patients with SSc had normal BMD before therapy, 20/44 (45.45%) had osteopenia, and 8/44 (18.19%) had osteoporosis. At the time of surgery, after therapy, 13/44 (29.55%) had normal BMD findings, 20/44 (45.45%) new osteopenia findings, while 11/44 (25%) patients had osteoporosis. The summary results in relation to the therapeutic approach indicate that the greatest decrease in bone density was recorded in patients treated with cyclophosphamide and GK in a dose of more than 10 mg/d.
Conclusion: Our results indicated a higher number of patients diagnosed with osteoporosis after one year of follow-up. Patients with + ACA, treated with CYP and GK in a dose higher than 10 mg/d are at special risk.

P948
OSTEOMALACIA FROM RENAL TUBULE ACIDOSIS

N. Elias[1], M. Curria[1], L. Caldas[1], M. Perez Abdala[2]

[1]Hospital Britanico de Buenos Aires, Buenos Aires, [2]Hospital regional Dr Ramon Carrillo, Santiago del Estero, Argentina

Renal tubular acidosis (RTA)'s prevalence is around 0.46/10,000 inhabitants. It presents with metabolic acidosis with normal anion GAP and is caused by an altered mechanism of renal tubules that facilitate the reabsorption of HCO3 and the secretion of hydrogen ions of both. Osteomalacia is a disease characterized by altered mineralization. Patients with this condition present bone pain, weakness and pseudofractures. The aim of this clinical is to describe the bone impact that RTA can generate.
Case report: 30-year-old male, referred from orthopedic surgeon for spontaneous bilateral hip fracture of 6 years' duration. In the anamnesis he reported pain in the lower back and both hips. Laboratory: calcium (Ca): 9.9 mg/dl (VR: 8.8–10 mg/dl), phosphorus (P): 2.4 mg/dl (VR: 2.5–5.6 mg/dl), alkaline phosphatase (ALP): 1551 mg/dl (VR: < 270 mg/dl), PTH: 22 pg/ml (VR: 10–55 pg/ml), 25(OH)VitD: 18 ng/ml (VR: 25–80 ng/ml), TSH: 2.97 mIU/L (VR: 0.37–4.7 mIU/L), urinary phosphorus: 630 mg/d (VR: 300–800 mg/d), urine creatinine: 1484 mg/d (VR: 500–2000 mg/d), urine sodium: 290 mEq/d d (VR: 40–220 mEq/d), urinary potassium: 48 mEq/d (25–125 mEq/d), calcium-creatinine ratio: 0.23 mg/mg (VR: ± 0.2 mg/d). Bilateral renal ultrasound: not lithiasis. A decrease in sodium was indicated, vitamin D and hydrochlorothiazide was prescribed. New fractures were found in both femoral shafts. New laboratory was requested: Ca: 9 mg/d, P: 2.3 mg/dl, FAL: 503 mg/dl and an acid–base state, pH: 7.31 (7.35–7.45), bicarbonate (HCO3-): 20 mmol/l (VR: 22–26 mmol/l), renal tubular acidosis was diagnosed.
Conclusion: RTA is an important factor in the cause of osteomalacia due to vitamin D deficiency. It should be considered in case of no or partial response to the treatments performed. Both clinical entities, if not treated promptly, could lead to organic complications and life limitations.

P949
SOCIOECONOMIC INEQUALITY IN OSTEOPOROSIS AMONG OLDER ADULTS IN IRAN: INSIGHTS FROM THE BUSHEHR ELDERLY HEALTH (BEH) PROGRAM

K. Khalagi[1], N. Fahimfar[1], M. Sanjari[1], M. J. Mansourzadeh[1], S. Hajivalizadeh[1], E. Hesari[1], I. Nabipour[2], B. Larijani[3], A. Ostovar[1]

Objective: To investigate the socioeconomic inequality of osteoporosis and low BMD among individuals aged 60 y and above in Iran, building on prior research indicating a higher risk of osteoporosis and related fractures among those with lower socioeconomic status (SES).

Methods: The analysis utilized baseline data from the BEH program, encompassing 2266 participants. BMD was assessed using DXA, with osteoporosis defined as T-score $\leq$ -2.5 at the total hip, spine, or neck of the femur, and low BMD as T-score $<$ -1. Participants' SES was determined by constructing indices using principle component analysis of their assets, income, education level, and employment status, followed by their categorization into 5 SES quintiles. The Concentration Index and Lorenz curve were employed to depict the levels of inequality for osteoporosis and low BMD.

Results: The participants' mean (SD) age was 69 (6.3) y, with women comprising 52% of the cohort. The prevalence of osteoporosis and low BMD decreased with higher SES levels (Table 1). The Concentration Index (95%CI) for osteoporosis and low BMD was estimated as -0.11 (-0.14, -0.07), p-value $<$ 0.001 and -0.05 (-0.06, -0.03), p-value $<$ 0.001, respectively. Figures 1 and 2 illustrate the Lorenz curve of SES inequality for osteoporosis and low BMD, respectively.

Conclusion: The findings indicate a concentration of osteoporosis and low BMD among older adults with lower SES levels, emphasizing the need for targeted interventions to address these inequalities.

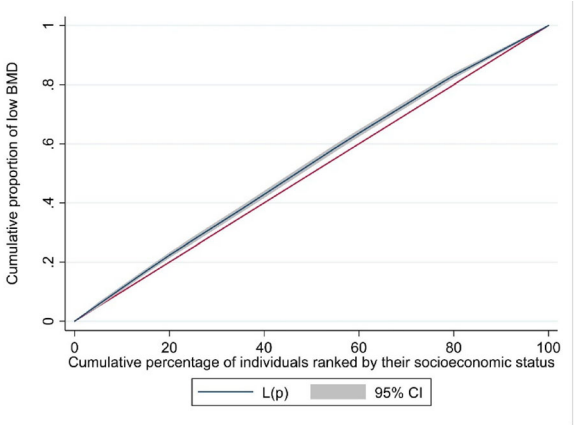

Figure 2. Lorenz curve illustrating SES inequality in low BMD

Table 1. Prevalence of osteoporosis and low BMD across SES quintiles

SES quintiles	Osteoporosis		Low BMD	
	No. (%)	P-value	No. (%)	P-value
1	173 (41.1)	<0.001	351 (83.4)	<0.001
2	132 (33.2)		301 (75.6)	
3	155 (32.6)		370 (77.7)	
4	125 (26.3)		346 (72.7)	
5	115 (23.2)		312 (63)

ASSOCIATION BETWEEN POOR SLEEP QUALITY AND OSTEOPOROSIS IN THE ELDERLY POPULATION: RESULTS OF THE POCOSTEO STUDY

S. Hajivalizadeh[1], N. Fahimfar[1], V. Mohseni[1], S. Akbarpour[2], A. Najafi[2], K. Khalagi[1], M. J. Mansourzadeh[1], M. Sanjari[1], G. Shafiee[3], I. Nabipour[4], E. Hesari[1], P. Khashayar[5], B. Larijani[6], A. Ostovar[1]

[1]Osteoporosis Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran Univ. of Medical Sciences, Tehran, Iran, [2]Occupational Sleep Research Center, Baharloo Hospital, Tehran Univ. of Medical Sciences, Tehran, Iran, [3]Chronic Diseases Research Center, Endocrinology and Metabolism Population Sciences Institute, Tehran Univ. of Medical Sciences, Tehran, Iran, [4]The Persian Gulf Marine Biotechnology Research Center, the Persian Gulf Biomedical Sciences Research Institute, Bushehr Univ. of Medical Sciences, Bushehr, Iran, [5]Center for Microsystem Technology, Imec and Ghent Univ., Gent, Belgium, [6]Endocrinology and Metabolism Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran Univ. of Medical Sciences, Tehran, Iran

Objective: Poor sleep quality can be associated with a variety of disorders, including osteoporosis, particularly in the elderly population. This study aimed to investigate the association between poor sleep quality and osteoporosis in the Iranian elderly population.
Methods: This was a cross-sectional study on the data of the PoCOsteo prospective cohort study. This cohort was a population-based study conducted on males and females aged 50 years and older to investigate musculoskeletal disorders. Demographic characteristics of the subjects, including age, gender, and years of education, were evaluated using questionnaires. Bone mineral densitometry was evaluated with DXA using the Hologic device to assess the Osteoporosis status. Osteoporosis was defined as a T-score < -2.5 in each site of the femoral neck, total hip, and spine. Sleep quality was measured using the Pittsburgh Sleep Quality Index (PSQI). Poor sleep quality was defined as a score > 5 according to the PSQI guideline. The chi-square test was used for statistical analysis.
Results: In total, 1926 (1087 women) individuals with a mean age of 62.2 ($\pm$ 8.1) y were included; of them, 530 (27.5%, 95%CI: 25.7–29.7) individuals were diagnosed with osteoporosis. Poor sleep quality was detected in 909 (47.2%) participants. The mean sleep quality score was significantly higher in osteoporotic (5.7) compared to non-osteoporotic individuals (4.9) (P-value < 0.001). In general, poor sleep quality was reported in 52.6% and 44.6% of participants with and without osteoporosis, respectively (P-value < 0.001).
Conclusion: Poor sleep quality is more prevalent in osteoporotic patients. Hence, investigations into this association and conducting interventions for increasing sleep quality in the elderly population are necessary.

P951
INCIDENCE RATE OF OSTEOPOROTIC FRACTURE IN IRANIAN POPULATION AGED 50 YEARS AND OLDER: IRANIAN MULTICENTER OSTEOPOROSIS STUDY (IMOS)

M. Ahmadi[1], N. Fahimfar[1], M. J. Mansourzadeh[1], V. Mohseni[1], K. Khalagi[1], M. Sanjari[1], S. Hajivalizadeh[1], F. Hajivalizadeh[2], E. Hesari[1], A. Ostovar[3]

[1]Osteoporosis Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran Univ. of Medical Sciences, [2]Center for Non-Communicable Disease Control & Prevention, Deputy of Public Health, Ministry of Health and Medical Education, [3]Endocrinology and Metabolism Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran Univ. of Medical Sciences, Tehran, Iran

Objective: Osteoporotic fractures pose a significant health burden among older adults. This study aimed to investigate the incidence rate and risk factors of osteoporotic fractures among a nationally representative sample of the Iranian people aged $\geq$ 50 years old.
Methods: Totally, 1450 men and women aged 50 y or older were selected through a multistage, cluster random sampling and participated in the 4th round of IMOS-2021. BMD was measured using the DXA method with calibrated Hologic devices. All participants were contacted by a trained staff to inquire about occurring osteoporotic fracture at least one year after the baseline measurements. Incidence rates of minor trauma osteoporosis fracture were estimated using Kaplan–Meier method. Multivariable Cox proportional hazard models were used to estimate hazard ratios (HR) for potential risk factors.
Results: Follow-up data was gathered for 1416 (97.7%) individuals participated at the baseline. During a total of 1815 person-years of follow-up, 50 fractures were reported. Notably, 40 fractures were attributed to minor trauma, resulted in an incidence rate of 22.0 (95%CI: 16.1–29.9) per 1000 person-year. The incidence rate was significantly higher in women (28.2, 95%CI:19.5–40.9), compared to the rate in men (14.4, 95%CI: 8.2–25.4). In the univariable analysis, male sex [HR:0.47, 95%CI (0.22–1.004)], diabetes [HR:1.95, 95%CI (0.97–3.91)], serum calcium [HR:2.06, 95%CI (0.88–2.85)], and vitamin D [HR: 1.01,95%CI (1.36–3.13)] were associated with a higher risk of mild trauma fractures. However, only diabetes [HR:2.61, 95%CI: (1.21–5.63)] emerged as a significant risk factor for osteoporotic fractures.
Conclusion: The observed incidence rate of osteoporotic fracture is relatively high in individuals $\geq$ 50 years old particularly among women in Iran. Preventive measures for those with higher fracture risks are necessary to reduce serious outcomes.

P952
BONE MINERAL DENSITY AND HAND GRIP STRENGTH IN POSTMENOPAUSAL WOMEN WITH FOREARM FRACTURES

I. Stets[1], A. Iniushyna[1], D. Kurylo[1], A. Musiienko[1], N. Grygorieva[1]

[1]D. F. Chebotarev Institute of Gerontology, NAMS of Ukraine, Kyiv, Ukraine

Objective: Forearm fractures (FF) are one of the important osteoporotic fractures that increase the risk of other osteoporotic fractures in the future and lead to temporary or even permanent decrease in a patient's functional capabilities. The study aimed to assess BMD and hand grip strength in postmenopausal women depending on previous FF.
Methods. 150 postmenopausal women (average age 66.9 $\pm$ 8.5 y) were examined and divided into 2 groups. Group I consisted of 75 persons without any previous fractures and Group II included 75 females with previous FF (age at the time of the fracture 57.1 $\pm$ 10.1 y, duration of the period after a fracture—10.0 [2.0–16.0] y). BMD, T, and Z-scores of the lumbar spine, hip, femoral neck, and radius were measured using DXA (Hologic Discovery WI, USA, 2016). Muscle strength was assessed by handgrip strength of both hands using a spring hand dynamometer.
Results: The women of both groups did not differ significantly by age and height; however subjects with FF had a significantly lower body mass (67.4 $\pm$ 11.7 and 79.8 $\pm$ 14.9 kg, respectively), BMI (25.8 $\pm$ 4.0 and 30.1 $\pm$ 5.4 kg/m^2), age of menopause (48.1 $\pm$ 4.5 and 50.3 $\pm$ 3.4 years, for all parameters $p < 0.001$) and higher duration of postmenopausal period (19.2 $\pm$ 9.4 and 16.1 $\pm$ 8.5 y, $p < 0.05$). BMDs of the lumbar spine, hip, femoral neck, and radius of females with FF were significantly lower than the parameters of subjects without fractures.
Despite the absence of the BMD differences at broken and unbroken forearm (0.535 $\pm$ 0.089 and 0.538 $\pm$ 0.090 g/cm^2, respectively, 0.622 $\pm$ 0.060 g/cm^2 for Group I), significantly lower muscle strength was established at the side of broken forearm (16.0 [12.0–20.0] kg) compared to other hand (18.0 [15.0–23.0] kg, $p < 0.001$).
Conclusion: Women with previous FF had lower mass, BMI, and age of menopause and worse BMD parameters compared to females without previous fractures. Despite the absence of the BMD differences at the broken and unbroken forearm, hand grip strength was worse at the side of the broken forearm, which confirms the negative FF consequences for a long time after the fracture.

UKRAINIAN GUIDELINE FOR DIAGNOSTIC, PREVENTION AND TREATMENT OF POSTMENOPAUSAL OSTEOPOROSIS

N. Grygorieva[1], V. Kovalenko[2], M. Korzh[3], T. Tatarchuk[4], N. Dedukh[1], S. Strafun[5], Z. Dubossarska[6], G. Protsenko[2], A. Kalashnikov[5], A. Musiienko[1], S. Regeda[7], O. Efimenko[7], E. Chaykivska[8]

[1]D.F. Chebotarev Institute of Gerontology of the National Academy of Medical Sciences of Ukraine, Kyiv, [2]National Scientific Center "The M.D. Strazhesko Institute of Cardiology, Clinical and Regenerative Medicine of the National Academy of Medical Sciences of Ukraine", Kyiv, [3]Sytenko Institute of Spine and Joint Pathology of the National Academy of Medical Sciences of Ukraine, Kharkiv, [4]Institute of Pediatrics, Obstetrics and Gynecology named after Academician O.M. Lukyanova of the National Academy of Sciences of Ukraine, Kyiv, [5]Institute of Traumatology and Orthopedics of the National Academy of Medical Sciences of Ukraine, Kyiv, [6]Dnipro State Medical Univ., Dnipro, Ukraine, [7]Center of Innovative Medical Technologies of the National Academy of Sciences of Ukraine, Kyiv, Danylo Halytsky Lviv National Medical Univ., Lviv, Ukraine

Objective: Postmenopausal osteoporosis (PMO), the most frequent type of systemic osteoporosis is a great challenge worldwide; however, its full value management is insufficient in Ukraine, especially during the war. The latest calculation by the Ukrainian Center of Osteoporosis demonstrated that almost 2 million Ukrainian women have PMO. The first Ukrainian guideline devoted to the management of PMO was published in 2009, so new data and results of high quality research in this field require its revision. However, not all modern strategies for antiosteoporotic treatment are available in Ukraine which became the background for the re-assessment of accessible ones and the creation of this guide. The aim was to develop the guideline on the diagnosis, prevention, and treatment of PMO to improve its management in Ukraine.

Methods: A panel of 13 leading Ukrainian scientists and physicians of various specialties was assembled. A rigorous review of current literature devoted to this topic conducted from January 2013 to June 2023 was performed. The assessment of the level of evidence was used by the GRADE system. An assessment guideline recommendations quality was carried out using the AGREE II tool. Two rounds of voting for the guideline recommendations were held in the summer of 2023.

Results: The 15 key recommendations were formulated and voted on successfully. They included the Expert position related to the diagnosis and differential diagnosis of PMO, the evaluation of osteoporotic fracture risk, the role of bone turnover markers in PMO management, common and alternative methods of diagnosing osteoporosis and fracture risk, and available strategies for the treatment of PMO in Ukraine.

Conclusion: The Ukrainian guideline for the management of PMO, featuring 15 main recommendations, developed through thorough critical analysis and synthesis of modern literature is an important tool for the management of PMO in Ukraine and is recommended by the Ukrainian Association of Osteoporosis for medical community use.

UKRAINIAN CONSENSUS OF DIAGNOSIS, PREVENTION, AND TREATMENT OF VITAMIN D DEFICIENCY IN ADULTS

N. Grygorieva[1], M. Tronko[2], V. Kovalenko[3], S. Komisarenko S[4], T. Tatarchuk[5], N. Dedukh[1], M. Veliky[4], S. Strafun[6], Y. Komisarenko[7], A. Kalashnikov[6], V. Orlenko[2], V. Pankiv[8], O. Shvets[9], I. Gogunska[10], S. Regeda[11]

[1]D.F. Chebotarev Institute of Gerontology of the National Academy of Medical Sciences of Ukraine, Kyiv, [2] V.P. Komisarenko Institute of Endocrinology and Metabolism of the National Academy of Medical Sciences of Ukraine, Kyiv, [3]National Scientific Center "The M.D. Strazhesko Institute of Cardiology, Clinical and Regenerative Medicine of the National Academy of Medical Sciences of Ukraine", Kyiv, [4]Palladin Institute of Biochemistry of the National Academy of Sciences of Ukraine, Kyiv, [5]Institute of Pediatrics, Obstetrics and Gynecology named after Academician O.M. Lukyanova of the National Academy of Sciences of Ukraine, Kyiv, [6]Institute of Traumatology and Orthopedics of the National Academy of Medical Sciences of Ukraine, Kyiv, [7]O.O. Bogomolets National Medical Univ., Kyiv, [8]Ukrainian Scientific and Practical Centre for Endocrine Surgery, Transplantation of Endocrine Organs and Tissues, Health Ministry of Ukraine, Kyiv, [9]National Univ. of Life and Environmental Sciences of Ukraine, Kyiv, [10]O.S. Kolomiychenko Institute of Otolaryngology of the National Academy of Medical Sciences of Ukraine, Kyiv, [11]Center of Innovative Medical Technologies of the National Academy of Sciences of Ukraine, Kyiv, Ukraine

Objective: Vitamin D deficiency (VDD) is a widespread global concern with varying prevalence among different populations. Recent studies in Ukraine confirmed a decreased share of VDD in the general population, but even now this problem remains relevant. Some modern strategies for diminishing VDD in Ukraine are absent and to date, the Ukrainian medical community has lacked national recommendations for diagnosing, preventing, and treating VDD in adults which became the background for its creation. The aim was to develop the consensus recommendations on the diagnosis, prevention, and treatment of VDD to improve its management in Ukraine.

Methods: A consensus was achieved using the Delphi method, utilizing the SurveyMonkey® platform for voting. After approval of the composition of the Consensus Group consisting of 15 leading Ukrainian scientists and physicians of various specialties, establishing the Consensus formation process and structure, creating and correcting the key statements, and conducting two rounds of voting the final 14 Consensus statements were created in the spring of 2023.

Results: Despite a recent reduction in VDD frequency in Ukraine, Experts recommended raising awareness among the medical community and the general population regarding the issue and its solutions, and various positive effects of vitamin D. The screening of the total serum level of 25-hydroxyvitamin D (25(OH)D) was recommended in at-risk groups to achieve target concentrations of 30–50 ng/ml (75–125 nmol/l). To achieve this target, Experts recommended the individual selection of a prophylactic dose of cholecalciferol (800–2000 IU/d for young healthy subjects and 3000–5000 IU/d for patients with diseases and conditions affecting vitamin D metabolism). For VDD treatment, Experts recommended short-term use of higher doses of cholecalciferol (4000–10,000 IU/d) with control of the 25(OH)D level after 4–12 weeks of the treatment and subsequent

use of maintenance, prophylactic doses. Additionally, it was recommended to assess serum 25(OH)D level before the initiation of antiosteoporotic therapy in patients with osteoporosis and its complications to enhance treatment effectiveness and safety.
Conclusion: The Ukrainian Consensus for the management of VDD, consisting of 14 main statements, developed through thorough critical analysis and synthesis of modern literature is an important tool for the management of VDD in Ukraine and is recommended by the Ukrainian Association of Osteoporosis for medical community use.

P955
COMPARISON OF TWO APPROACHES OF BONE BIOLOGICAL MODELING USING MACHINE LEARNING

N. Grygorieva[1], A. Pisaruk[1], V. Gurianov[2], A. Musiienko[1], V. Shatylo[3]

[1]D.F. Chebotarev Institute of Gerontology of the National Academy of Medical Sciences of Ukraine, [2]O.O. Bogomolets National Medical Univ., [3]National Technical Univ. "Ihor Sikorskyi Kyiv Polytechnic Institute", Kyiv, Ukraine

Objective: Numerous studies now confirm the increased risk of osteoporosis in the elderly population. To optimize diagnostic strategies, a combination of various methods is employed, and the calculation of biological bone age (BA) may be important in predicting the disease consequences. Recently, new methodological approaches using mathematical methods have emerged, however, in Ukraine, research employing advanced techniques, particularly neural networks (NN) in BA modeling, remains limited. This study aimed to develop the BA models and compare their accuracy using stepwise multiple regression (MLR) and NN analysis methods.
Methods: In a single-center cohort study, we retrospectively analyzed data from 3071 healthy women aged 40–90 y. The analysis included anthropometric parameters, DXA, and parameters of the 10-y probability of major osteoporotic fractures (FRAX). For developing the BA models, MLR methods were used, and the NN model was constructed using a multilayer perceptron model.
Results: The MLR formula for calculating bone BA was derived, taking into account BMD of the lumbar spine and radius, minimal femoral and hip BMD, TBS, and FRAX. The MLR equation allowed for the calculation of BA with an error of less than 4.9 years for both the study and control groups and demonstrated a strong correlation between calculated and chronological ages ($R = 0.77$; $p < 0.00001$). The use of NN analysis yielded the best results with 6 input variables and 1 internal layer of 7 neurons. The assessment of the connection between BA and chronological age revealed a high correlation coefficient ($R = 0.88$; $p < 0.000001$) with an average age calculation error of less than 3.7 y for both the study and control groups.
Conclusion: A comparison of the accuracy of both models of BA showed a significant advantage of the deep learning NN method. However, it should be noted that the use of a trained NN model requires specialized software, whereas the MLR formula can be employed without additional costs.

P956
DOES SARCOPENIA INFLUENCE THE COURSE OF OSTEOARTHRITIS IN POSTMENOPAUSAL WOMEN?

N. Zaverukha[1], A. Musiienko[1], N. Grygorieva[1]

[1]D.F. Chebotarev Institute of Gerontology of the National Academy of Medical Sciences of Ukraine, Kyiv, Ukraine

Objective: To detect the peculiarity of pain, physical activity, quality of life, and muscle strength in females with knee osteoarthritis (OA) depending on the risk of sarcopenia (SP).
Methods: We have examined 95 postmenopausal women (mean age 65.4 ± 8.0 y) with knee OA (grade 2–3 according to Kellgren & Lawrence classification) and divided them into 2 groups. Group I –33 females without high risk of sarcopenia, Group II – 62 women with high risk of SP detected by Questionnaire to Rapidly Diagnose Sarcopenia (SARC-F ≥ 4 points). All patients have undergone Knee injury and Osteoarthritis Outcome Score-12 (KOOS-12) questionnaire (subscales: pain, function daily living, and quality of life) and a "stand up from a chair" test.
Results: Women of the two groups did not differ in height (162.7 ± 5.3 vs. 160.7 ± 5.7 cm, $p > 0.05$) and body weight (79.8 ± 20.0 vs. 80.9 ± 10.9 kg, $p > 0.05$). According to the KOOS-12 questionnaire, the result of the pain subscale was significantly higher in patients with OA and a high risk of SP (43.7 [31.3–62.5] points), compared to females without the high risk of SP (68.8 [50.0–93.8] points, $Z = 3.6$, $p < 0.05$). The subscale of function and daily living also showed significantly higher (i.e., worse) result in Group II (43.8 [31.3–68.8] points) compared to Group I (75.0 [56.3–100.0] points, $Z = 4.1$, $p < 0.05$), as well as the quality of life—43.8 [37.5–62.8] vs. 75.0 [43.8–87.5] points in Group II and I respectively ($Z = 3.0$, $p < 0.05$). Patients with OA without the high risk of SP performed significantly quickly "stand up from a chair" test (14.0 [10.0–16.0] sec compared to women with OA and high risk of SP (18.0 [11.0–23.0] sec, $Z = 2.4$, $p < 0.05$).
Conclusion: The combination of OA and high risk of SP was associated with more pronounced knee pain, lower function, daily living, and quality of life and should be taken into account in the women of the older age groups.

P957
TRABECULAR BONE SCORE IN PATIENTS WITH PRIMARY HYPERPARATHYROIDISM

M. Tsagareli[1], E. Giorgadze[1], T. Sulikashvili[1], T. Zerekidze[1], N. Jeiranashvili[1]

[1]National Institute of Endocrinology, Tbilisi, Georgia

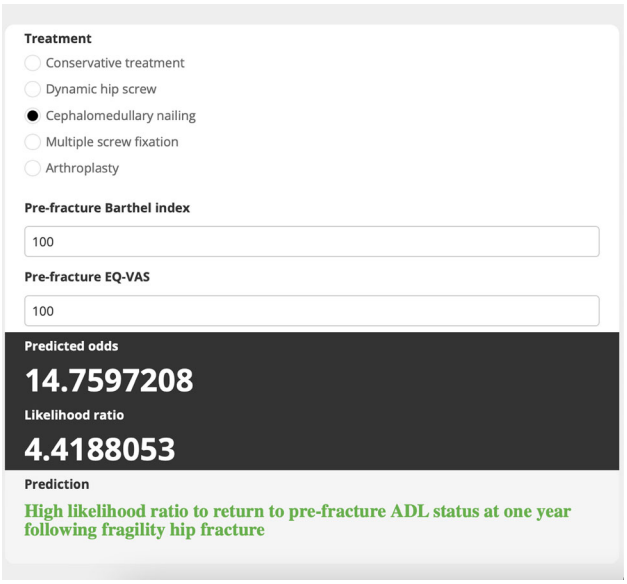
Objective: Primary hyperparathyroidism (PHPT) is associated with increased risk of fractures. The aim of our study was to assess whether PHPT is related to impaired BMD and TBS.
Methods: 38 women with PHPT were enrolled in the study. lumbar spine (LS), total hip and radius 33% BMD values were obtained using DXA, TBS was calculated using TBS iNsight software.
Results: BMD was lower in patients with PHPT compared to control group. Mean LS BMD T-score was ($-2,4 \pm 0,12$ SD), FN BMD T-score—($-2,0 \pm 0,14$ SD), radius 33% BMD T-score—($-2,5 \pm 0,1$ SD). 37% of patients had degraded TBS $< 1,2$.
Conclusion: PHPT is associated with cortical BMD and Trabecular microarchitecture deteriorations. TBS can be a useful measurement for the assessment of fracture risk in patients with PHPT.

P958
DEVELOPMENT OF CLINICAL PREDICTION RULES FOR PREDICTING PATIENTS' ABILITY TO RETURN TO PRE-FRACTURE ACTIVITIES OF DAILY LIVING STATUS AT ONE YEAR FOLLOWING FRAGILITY HIP FRACTURE

N. Kitcharanant[1], P. Atthakomol[1], J. Khorana[1], P. Phinyo[1], A. Unnanuntana[1]

[1]Chiang Mai Univ., Chiang Mai, Thailand

Objective: To develop the multivariable clinical prediction rules to predict patients' ability to return to pre-fracture activities of daily living status at one year following fragility hip fracture.
Methods: The clinical prediction rule was developed and internally validated using a retrospective data from patients who admitted with fragility hip fracture at Siriraj hospital (a university affiliated tertiary care center) during February, 2017 and April, 2019. Multivariable fractional polynomial algorithm was used to fit multiple continuous predictors into a binary logistic regression model.
Results: A total of 421 patients were included. Of these, 324 patients (77%) were able to return to their pre-fracture activities of daily living (ADL) levels one year after fragility hip fractures. Pre-fracture Barthel index, EQ-VAS scores and type of treatment were significant predictors for differentiation of patients with the ability to recover pre-fracture ADL and were incorporated into the prediction model. The model showed excellent discriminative ability [AuROC of 0.86 (95%CI 0.82 to 0.91)] and good calibration.
Conclusion: The prediction model allows the clinicians to predict the patients' ability to recover after one year of fragility hip fracture individually. In addition, it can guide counseling and decision making for aggressive strategies to improve rate of functional recovery after fragility hip fractures during post-treatment period. The web application (Fig. 1) is available at www.calconic.com/calculator-widgets/hip-fracture-functional-recovery-prediction-tool/64903a84b4cd1f001eb92003?layouts=true.



P959
PROGNOSTIC FACTORS FOR FUNCTIONAL RECOVERY AT ONE YEAR FOLLOWING FRAGILITY HIP FRACTURES

N. Kitcharanant[1], P. Atthakomol[1], J. Khorana[1], P. Phinyo[1], A. Unnanuntana[1]

[1]Chiang Mai Univ., Chiang Mai, Thailand

Objective: The main objective of treating fragility hip fractures is to maximize the patients' ability to return to their basic activities of daily living (ADL) levels. This study explored prognostic factors associated with the ability to recover pre-fracture ADL levels one year after fragility hip fractures.
Methods: We retrospectively recruited patients admitted with fragility hip fractures between July 2016 and September 2018. Details of the following were extracted from electronic medical records: age, sex, BMI; pre-fracture Charlson Comorbidity Index (CCI), Barthel index, and EuroQol-Visual Analog Scale (EQ-VAS) scores; pre-fracture ambulatory status; and fracture type and treatment. The primary endpoint was the ability to return to pre-fracture ADL status at one year. Multivariable logistic regression analysis assessed the prognostic ability of predictors.
Results: Of 405 patients, 284 (70.1%) managed to return to their pre-fracture ADL status. Multivariable logistic regression analysis demonstrated that the predictor with the most apparent effect size was pre-fracture EQ-VAS scores ≥ 65 (multivariable odds ratio [mOR] = 12.90; P = 0.03). Other influential predictors were CCI scores < 5 (mOR = 1.96; P = 0.01) and surgical treatment for the hip fracture.
Conclusion: Three prognostic factors can predict a hip fracture patient's ability to return to the pre-fracture ambulatory status at one year. They are the patient's CCI score, operative treatment for the hip fracture, and the pre-fracture EQ-VAS score. This information could be used to develop a clinical prediction model based on the prognostic factors.

COLLATERAL EFFECTS OF THE COVID-19 PANDEMIC ON ENDOCRINE TREATMENTS FOR BREAST AND PROSTATE CANCER IN THE UK: IMPLICATIONS FOR BONE HEALTH

N. L. Barclay[1], M. Català[2], A. M. Jödicke[1], D. Prieto-Alhambra[1], D. Newby[1], A. Delmestri[1], W. Y. Man[1], A. Roselló Serrano[3], M. Pineda Moncusí[1], O. C. Optima Consortium[4]

[1]Nuffield Dept. of Orthopaedics, Rheumatology and Musculoskeletal Sciences (NDORMS), Univ. of Oxford, Oxford, UK, [2]Nuffield Dept. of Orthopaedics, Rheumatology and Musculoskeletal Sciences (NDORMS), Univ. of Oxford, Oxford, UK, [3]Institut Català d'Oncologia, Hospital Universitari Dr Josep Trueta, Girona, Spain, [4]Univ. of Aberdeen, Aberdeen, UK

Objective: The COVID-19 pandemic affected cancer screening, diagnosis and treatment pathways. This study examined the impact of the pandemic on incidence and trends of endocrine treatments in patients with breast or prostate cancer; and endocrine treatment-related side effects including osteopenia, osteoporosis and bisphosphonate prescriptions.
Methods: Population-based cohort study using UK primary care Clinical Practice Research Datalink GOLD database. There were 13,701 newly diagnosed breast cancer patients and 12,221 prostate cancer patients with $\geq$ 1-y data availability since diagnosis between January 2017-June 2022. Incidence rates (IR) and incidence rate ratios (IRR) were calculated across multiple time periods before and

after lockdown to examine the impact of changing social restrictions on endocrine treatments and treatment-related outcomes.
Results: In breast cancer patients, aromatase inhibitor prescriptions increased during lockdown vs. pre-pandemic (IRR: 1.22 [95%CI: 1.11–1.34]), followed by a decrease post-first lockdown (IRR: 0.79 [95%CI: 0.69–0.89]). In prostate cancer patients, first-generation antiandrogen prescriptions increased vs. pre-pandemic (IRR: 1.23 [95%CI: 1.08–1.4]). For breast cancer patients on aromatase inhibitors, diagnoses of osteopenia, osteoporosis and bisphosphonate prescriptions were reduced across all lockdown periods vs. pre-pandemic (IRR range: 0.31–0.62).
Conclusion: During the first 2 y of the pandemic, newly diagnosed breast and prostate cancer patients were prescribed more endocrine treatments compared to pre-pandemic, due to restrictions on hospital procedures replacing surgeries with bridging therapies. But breast cancer patients had fewer diagnoses of osteopenia and osteoporosis, and bisphosphonate prescriptions. These patients should be followed up in the coming years for signs of bone thinning. Evidence of poorer management of treatment-related side-effects will help assess resource allocation for patients at high risk for bone-related complications.

P961
AUTONOMIC DYSREFLEXIA EXACERBATES BONE LOSS AFTER SPINAL CORD INJURY IN RATS

N. L. Nan[1], G. C. Guoqing[2], H. X. Huayi[1]

[1]Dept. of Rehabilitation Medicine, Peking Univ. Third Hospital, [2]Dept. of Rehabilitation Medicine, Peking Univ. Third Hospital, Beijing, China

Objective: Rapid and extensive bone loss was found after spinal cord injury (SCI). Various mechanisms are involved in the progress of abnormal bone metabolism after spinal cord injury, including changes in mechanical stress, lack of sunshine exposure, etc. The possible influence of the changed sympathetic activity on bone structure after spinal cord injury still remains uncertain. This study aims to investigate the effect of autonomic dysreflexia (AD) on the bone metabolism after spinal cord injury.
Methods: 34 adult male Sprague Dawley rats were randomized to receive (A) SHAM surgery (T3 laminectomy), (B) SCI (T3 transection), or (C) SCI + AD (T3 transection + AD induction). systolic blood pressure (SBP) and heart rate were recorded every week. μCT analysis, TRAP staining and detection of NE, OCN, CTX-I, RANKL/OPG were performed at 6 weeks.
Results: At 6 weeks post injury, SBP and NE expression were significantly increased in SCI + AD group compared with SHAM group and SCI group. μCT scanning showed that the volume of cancellous bone and the thickness of trabecular bone in fourth lumbar vertebral body and proximal femur of SCI + AD rats significantly decreased compared to SCI group. HE staining showed that bone mass significantly decreased in SCI + AD group compared with SCI group. TRAP staining showed increased number of osteoclasts ($p = 0.0035$), CTX-I activity in peripheral blood was significantly increased in the SCI + AD group ($p = 0.0046$), while RANKL expression was found significantly increased in distal femur and lumbar vertebrae after SCI, and further increase in SCI + AD group at distal femur.
Conclusion: Abnormal sympathetic activity plays an important role in bone remodeling after SCI. Increased sympathetic activity related to autonomic dysreflexia may exacerbate bone resorption, leading to extensive bone loss and development of osteoporosis.

P962
ASSOCIATION BETWEEN SINGLE-POINT INSULIN SENSITIVITY ESTIMATOR AND LOW BONE MINERAL DENSITY IN ARAB ADULTS

N. M. Al-Daghri[1], K. Wani[1], M. N. K. Khattak[1], A. M. Alnaami[1], Y. Al-Saleh[2], S. Sabico[1]

[1]King Saud Univ., [2]Dr Mohammad Alfagih Hospital, Riyadh, Saudi Arabia

Objective: The present observational study investigated the association between BMD and insulin sensitivity in a total of 1270 Arab adults (mean age 56.7 ± 8.1 y) with one or more risks associated with bone loss.
Methods: Lumbar BMD scan was performed using DXA. T-Scores and an index for insulin sensitivity called Single Point Insulin Sensitivity Estimator (SPISE) were calculated.
Results: The average SPISE values were significantly higher among those with low BMD (T-Score < -1.0) (4.6 ± 1.3 vs. 4.3 ± 1.2, $p < 0.001$) and a significant inverse correlation ($r = -0.21$, $p < 0.001$) was found between SPISE index and T-score. A multivariate linear regression analysis revealed that this inverse association was significant only in participants having hyperglycemia (> 7 mmol/l) alone (adjusted $\beta = -0.29$, $p < 0.001$) and ones with hyperglycemia and low BMD (adjusted $\beta = -0.11$, $p = 0.03$) suggesting that this association is largely influenced by hyperglycemia status.
Conclusion: The findings maybe clinically useful in assessing the bone health of T2DM patients in areas where healthcare resources are scarce (e.g., no DXA) since SPISE is inversely associated with BMD independent of age and status of menopause and that it can be calculated in the absence of known glycemic parameters.

P963
POSITIVE ASSOCIATION BETWEEN SERUM ALKALINE PHOSPHATASE AND HBA1C IN SAUDI CHILDREN

N. M. Al-Daghri[1], S. D. Hussain[1], S. Yakout[1], N. Aljohani[2], S. Sabico[1]

[1]King Saud Univ., [2]King Fahad Medical City, Riyadh, Saudi Arabia

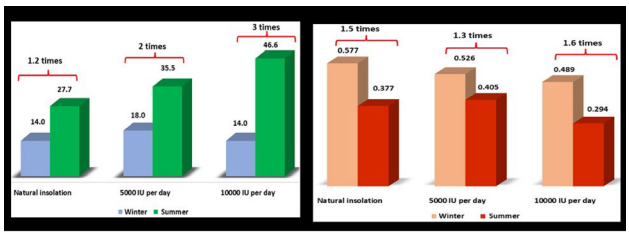
Objective: Previous studies have linked serum alkaline phosphatase levels and the risk of diabetes, but reported controversial results in adult population. It has also been reported that serum alkaline phosphatase has increased activity in growing children. Therefore, this study aims to observe association between serum alkaline phosphatase and HbA1c.
Methods: This cross-sectional study was performed between September 2019 and March 2021. Adolescents aged 12–17 y from 60 different secondary and preparatory year schools in Riyadh, Saudi Arabia were included.
Results: A total of 2666 adolescents participated in this study with mean age of 14.9 ± 1.7. There were 1601 girls and 1065 boys. The overall prevalence of diabetes was 4.6% (n = 122/2666) and was higher in boys than girls but no significance was observed (5.3 vs. 4.1%, p = 0.169). Preliminary analysis showed that there is a significant positive association between alkaline phosphatase (ALP) and HbA1c in adolescent with correlation coefficient of 0.10 ($P < 0.001$). Furthermore, similar positive association was also observed with bone specific alkaline phosphatase (BLP) and HbA1c with correlation coefficient of 0.12 (P = 0.020). Furthermore, median ALP concentration, i.e., 78.2 (55.0 – 108.5) was higher in in diabetic children as compared to non-diabetic children with median ALP concentration of 63.0 (42.6–93.0) ($p < 0.001$).
Conclusion: There is a positive association between ALP and HbA1c in children aged 12–17 y. Poor blood glucose control can cause a negative impact on bone mass acquisition at an early age, as these children and adolescents are developing height, along with the progression of diabetes. Diabetes during pubertal growth will foster a deficiency in bone mass gain, thus achieving a bone mass peak smaller than that of healthy individuals.

P964
INDICATORS OF MINERAL BONE METABOLISM DEPENDING ON THE DOSE OF VITAMIN D IN WOMEN OVER 50 YEARS OF AGE

L. S. Abboskhujaeva[1], N. M. Alikhanova[2]

[1]Republican Specialized Scientific and Practical Center of Endocrinology acad. Ya.Kh. Turakulov, [2]Institute of Health and Strategic Development, Tashkent, Uzbekistan

Objective: The problem of vitamin D deficiency in women persists even during periods of maximum insolation, which makes it necessary to specifically study various markers in order to develop preventive and treatment programs in this direction. The aim of this study was to estimate the level of markers of mineral bone metabolism during the period of maximum insolation and the dose of vitamin D.
Methods: 123 women were divided into 3 groups: 1) group with natural synthesis of vitamin D, depending on the degree of insolation (n = 73); 2) group with minimal vitamin D supplementation, < 5000 IU/d (n = 37); 3) group with vitamin D supplementation, > 10,000 IU/d (n = 13).
Results: A comparative analysis showed that vitamin D levels in the 3 compared groups both after the summer period and after taking supplements in two modes increased significantly ($p < 0.05$). The average vitamin D values were 27.7; 35.6 and 46.6 ng/ml. As the level of vitamin D increased, alkaline phosphatase levels also increased significantly ($p < 0.05$) in the 3 compared groups by 1.2, 1.3 and 1.5 times. At the same time, PTH levels had a multidirectional trend, but within the reference range, and the changes in values were not significant. Indicators reflecting bone tissue resorption (β-CrossLaps) in all groups decreased by 1.5, 1.3 and 1.6 times, respectively, indicating a decrease in bone resorption.



Vitamin D levels (a) and β-Cross Laps (b) in the three compared groups.

Conclusion: Changes in mineral bone metabolism indicators indicate a decrease in resorption and an increase in bone tissue formation. Changes in indicators in one direction or another in all groups occurred within the reference values, and a period of low insolation cannot provoke any pathological changes in the body. And perhaps taking large doses of vitamin D supplements does not make sense and does not provide additional benefits to the body. Although such conclusions require longer and more in-depth studies.

P965
EFFECTS OF QUERCITIN ON STRENGTH FEATURES OF THE HUMERUS IN RATS OF DIFFERENT AGES AFTER SURGICAL PERFORATION OF THE TIBIA

N. Mosyagina[1], V. Luzin[1], O. Bugakova[1], D. Lebed[1]

[1]FSBEI HI St. Luka LSMU of MOH of Russia, Lugansk, Russia

Objective: To test strength of the humerus in rats of different ages after fracture (FR) of the tibia.
Methods: Rats (n = 252) were distributed into 3 groups. Group 1 – intact animals. In the 2nd group, animals with through defect of both tibiae at the border of the proximal metaphysis and diaphysis with a diameter of 2 mm. Group 3 received quercetin daily via oral gavage in dosage of 3 g per kg of body weight. Observation terms were 7, 15, 30, and 90 d. The humerus was tested in bending at a loading rate of 0.25 mm/min until destruction. Fracture energy, breaking point, elasticity modulus, and specific sag were calculated.
Results: In animals of the group 2 with fracture of the tibia resulted in decrease in the strength of the humerus. Specific sag on the 7th day decreased by 18.26% as compared to the group 1, and on the 15th and 30th days it was 8.07% and 16.03% higher. Minimum fracture energy values during all observation periods were 18.84%, 19.46%, 16.64% and 8.65% lower than those of the intact animals. In rats of the group 3 intragastric administration of quercetin reduced negative effects of the experimental conditions. Minimum fracture energy was 12.31%, 10.18% and 11.20% less than the first group from 7 to 30 d. Breaking point changed more significantly: it varied from the 7th to the 30th day by 12.23%, 13.33% and 9.19% below the values of the first group. Elasticity modulus by the 30th day of the experiment was 10.04% less than that of the first group.
Conclusion: Use of Quercetin in animals can significantly reduce negative changes of the strength of the humerus evidenced by decreased amplitude of deviations of the studied parameters and reduced alterations.

P966
BONE GROWTH AND FORMATION IN RATS BORN FROM RATS TREATED WITH INSULIN

O. Skriabina[1], N. Mosyagina[2], L. Sankova[3]

[1]Lugansk State Medical Univ., Rivne, [2]Lugansk State Medical Univ., Lugansk, [3]Kyiv Medical Univ., Kyiv, Ukraine

Objective: To test bone growth and formation in rats born from rats treated with insulin.
Methods: Female rats (n = 60) were separated into two groups. Group 1 comprised intact animals which were injected subcutaneously with water equal to insulin volume. Group 2 was injected with insulin-long subcutaneously at a dose of 3 IU/kg. 30 d after the beginning of insulin administration, males were temporarily placed to females' cages. Mating was performed in the presence of estrus signs in vaginal smears, for 4 h in the morning. Newborn rats were euthanized immediately after delivery, their bodies were fixed and further sectioned using conventional technique. Sections were stained with alizarin to determine ossification points for area measurements.
Results: In 2nd group length of the ossification nuclei of the tibial, radial, humerus and pubic bones increased by 3.66%, 3.65%, 4.17%, and 3.36% respectively, as compared with the control values. During the examination of the area of ossification nuclei in the primordia of both tubular and spongy bones, it was found that their values were lower than those of controls: in the tibia by 4.75%, in the femur by 0.49%, in the radius by 0.36%, in the ulna by 1.69%, in the humerus by 3.69%, in the pubic bone by 7.38%, in the scapula by 0.60% and in the clavicle by 1.07%.
Conclusion: An increase of the ossification nuclei length and a decrease in their width in rats born from animals that received exogenous insulin may be the result of the fact that this hormone mainly plays the role of growth hormone in utero.

P967
ASSOCIATION OF DIETARY AND URINARY SODIUM WITH BONE MINERAL DENSITY AND THE RISK FOR OSTEOPOROSIS: A SYSTEMATIC REVIEW AND META-ANALYSIS

N. Namazi[1], L. Azadbakht[2], S. Fatahi[3]

[1]Endocrinology and Metabolism Research Institute, Tehran Univ. of Medical Sciences, [2]Tehran Univ. of Medical Sciences, [3]Beheshti Univ. of Medical Sciences, Tehran, Iran

Objective: Despite previous research on the link between dietary/urinary sodium and BMD, bone mass content (BMC), and the risk of osteoporosis (OS), there is still conflicting evidence. The purpose of the present study was to examine the associations between dietary/urinary sodium and BMD, BMC, and the risk of OS as a systematic review and meta-analysis.
Methods: A systematic search was conducted in PubMed/MEDLINE, SCOPUS, and Web of Science to identify relevant studies. Articles that included cross-sectional and cohort designs and reported odds ratios (ORs), correlations (r), or β coefficients for the association between dietary/urinary sodium and OS, BMD, or BMC were included. In the present study all eligible articles written in English language was considered.
Results: By pooling 11 effect sizes from a total of 39,065 individuals, it was found that higher sodium consumption significantly increased the risk of OS (OR = 1.20; 95%CI, 1.02–1.41; p = 0.026), although there was high heterogeneity among the studies (I2 = 68.0%; p = 0.001). Subgroup analyses revealed a significantly higher risk of OS in premenopausal women (OR = 1.31; 95%CI, 1.01–1.69; p = 0.036), participants with a mean age older than 50 y (OR = 1.15; 95%CI, 1.04–1.28; p = 0.005), the dietary sodium intake subgroup (OR = 1.45; 95%CI, 1.19–1.77; $p < 0.001$), and individuals with adjustment for energy (OR = 1.77; 95%CI, 1.38–2.27; $p < 0.001$). However, there was no significant association between urinary sodium and BMD, as indicated by the correlation coefficients (r = -0.46; 95%CI, -0.74 to -0.18; p = 0.02).
Conclusion: This study found a positive association between sodium intake and the risk of OS, while no significant association was observed with urinary sodium. Additionally, there was no significant correlation between sodium intake and BMD. Given the high heterogeneity, further studies are recommended in this regard.

P968
TREATMENT OF PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS WITHOUT GLUCOCORTICOIDS

N. Nikishina[1], A. Mesnyankina[1], E. Aseeva[1]

[1]V.A.Nasonova Research Institute of Rheumatology, Moscow, Russia

Objective: Achieving stable remission in patients with SLE. Cancellation of oral GC or the use of therapy without GC in patients with SLE.
Methods: 3 clinical cases. Two patients (N1, N2) had a combination of SLE with Sjogren's syndrome with predominantly musculoskeletal syndrome. In these patients, severe organ lesions (lupus nephritis, vasculitis, central nervous system damage) were excluded. SLEDAI-2 K in these patients was 9 and 8 points. Both patients had a decrease in C3, C4 complement component, ANA positivity, arthritis, hematological disorders. In N2, an increase in at to ds-DNA was determined. Therapy with oral GC, immunosuppressive drugs was not carried out in them. Patient N3 with lupus nephritis (hematuria, leukocyturia), exudative pleurisy, polyarthritis, high immunological activity (SLEDAI-2 K—16 points) was prescribed GC at a dose of 2 tab per day. Creatinine and urea were within normal limits. The patient had high immunological activity: low C3, C4 complement, at to dsDNA 200 IU/ml, ANA positivity (1:1280). Due to the presence of lupus nephritis, the patient received mycophenolate mofetil 1500 mg/d. All patients received double anti-B-cell therapy with the sequential use of rituximab (RTX) 1000 mg intravenously in patients N1 and N2, and N3 at a dose of 2000 mg/d with premedication of 6-methylprednisolone at a dose of 250–500 mg intravenously. After 1–3 months, belimumab infusions were started at a dose of 10 mg/kg/month. The observation period is 1 y.
Results: Anti-B-cell therapy allowed patients to be treated without oral GC. A patient with LN (N3) was prescribed low doses of GC at the time of initiation of therapy with RTX, however, they were subsequently completely canceled by the 6th month of therapy. Clinical remission of the disease was achieved in all three patients. Clinical manifestations of the disease were stopped. SLEDAI-2 k was 0–2 points due to minor hypocomplementemia. No new irreversible organ damage and relapse of the disease were registered. Patients continued to receive monthly infusions of BLM, there were no repeated courses of RTM. The patient with kidney damage continued to take MM.
Conclusion: Consistent therapy of RTX and BLM allowed to achieve not only a high clinical and immunological effect, but also the possibility of reducing and even abandoning the oral dose of GC, which is consistent with the concept of "Treat to target" in SLE. In addition, all patients were closely monitored by a rheumatologist once a month, which was partly achieved thanks to monthly infusions of BLM, which were carried out in the clinic.
1. The abolition of GC in patients with SLE is a very real and achievable goal of therapy, as well as treatment without GC.

2. Discussion and application of only GIBP therapy without the use of GC is possible with certain subtypes of SLE without damage to vital organs.

3. The decision to reduce the dose of GC to the minimum with the subsequent cancellation or complete rejection of the use of GC therapy should be made by an experienced rheumatologist.

P969
LONG-TERM DATA ON RITUXIMAB AND BELIMUMAB THERAPY IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

N. Nikishina[1], A. Mesnyankina[1], E. Aseeva[1]

[1]V.A.Nasonova Research Institute of Rheumatology, Moscow, Russia

Objective: To evaluate the effectiveness of combination therapy with rituximab (RTM) and belimumab (BLM) in patients with SLE with long-term follow-up.

Methods: 12 patients with SLE (1 M/11F) of high and moderate disease activity, 9 of them with skin-joint manifestations, others had kidney damage, peripheral nervous system, vasculitis. Patients received RTM at a dose of 500–2000 mg with premedication of 6-methylprednisolone, and then BLM was prescribed according to the standard scheme of 10 mg/kg once a month. The patients were divided into two groups depending on the time of evaluation of long-term results. In the first group, data were analyzed 7–9 y after the initiation of RTM (4 people). In the second group of 8 patients after 2–4 y. The efficacy and tolerability of therapy, the activity of SLE, as well as the dose of oral glucocorticoids (GK) were evaluated.

Results: Against the background of combination therapy, a clinical and immunological response was obtained in 11 out of 12 patients one year later (initially, the Me of SLEDAI-2 K was 10 [9.5;14.5] points, 6 and 12 months after the initiation of BLM, Me was 4 [2;6] points, $p < 0.008$). Patients who started receiving RTM + BLM within 0–2 y from the moment of the debut of SLE responded better to therapy, and a more significant improvement in clinical and laboratory parameters was achieved. Subsequently, BLM therapy was limited, on average, to two years with the achievement of stable remission. This therapy allowed the use of medium and low doses of GK as an initiating therapy for exacerbation of SLE, followed by their decrease in dynamics. Clinical remission was achieved and persists in 7 patients, in three exacerbations were observed at different times after the withdrawal of BLM, the effect eluded in one patient, and another had no effect on combination therapy.

Conclusion: the achievement of the most pronounced positive result can be assumed in patients for whom RTM + BLM therapy is initiated as early as possible from the moment of diagnosis (0–2 y). BLM infusions should preferably be carried out according to the recommendations once a month, without long breaks between injections for at least 2 y, and, if possible, continue for a long time until a lasting effect is achieved. The use of low doses of GK and their elimination is a very real and achievable goal, however, careful monitoring of patients is required in order to identify early symptoms of exacerbation.

P970
ROLE OF REPEAT KIDNEY BIOPSY IN LUPUS NEPHRITIS

N. Nikishina[1], A. Mesnyankina[1], E. Aseeva[1]

[1]V.A.Nasonova Research Institute of Rheumatology, Moscow, Russia

Objective: To demonstrate the clinical value of kidney biopsy for patients with lupus nephritis in order to select personalized therapy.

Methods: Patient K., 30 years old, has been observed at to the clinic with a definite diagnosis of SLE (according to SLICC ACR 2012 criteria) since 2012, the onset of the disease began with articular, skin syndrome, and leukopenia. The examination revealed immunological disorders: anti-DNA, ANF, antibodies to Sm, treatment was carried out with hydroxychloroquine 400 mg/d – 200 mg/d, glucocorticosteroids (GCS) at a dose of 16 mg/d, with a decrease to 4 mg/d and complete cancellation in 2019 due to clinical and laboratory remission of the disease. Deterioration of the condition on 12.2020—arthritis of the joints of the hands and feet, development of lupus nephritis. 02.2021—hospitalization at the clinic, during the examination an increase in AT to dsDNA, ANF, RNP-70, aCL, aBeta-2-GP-1, a decrease in C3, C4, a decrease in leukocytes, leukocyturia, erythrocyturia, daily proteinuria 0.8 g/d was noticed. A kidney biopsy with immunofluorescence revealed diffuse proliferative glomerulonephritis with 11% segmental fibrocellular crescents. Activity index-5. Chronicity index-1. Taking into account the young age, high activity of the disease (SLADAI 2 K = 20b.), rapid progression of the disease, the development of the patient's life-threatening condition caused by kidney damage (class IV lupus nephritis), during hospitalization pulse therapy was performed by 6 methylprednisolone (total dose 4 g) therapy was initiated by rituximab and mycophenolate mofetil 2000 mg/d, the dose of oral corticosteroids was increased to 25 mg/d, hydroxychloroquine was increased to 400 mg/d, anticoagulant therapy was initiated. The patient received an infusion of Rituximab every 6 months (total dose of 4000 mg), the dose of oral corticosteroids was reduced to 5 mg/d, and the intake of mycophenolate mofetil and hydroxychloroquine was extended. As a result of the therapy, it was possible to stop the manifestations of lupus nephritis and the immunological activity of the disease, and remission was achieved (SLEDAI 2 K-0). After 24 months, to resolve the issue of the need to continue immunosuppressive therapy, a repeat nephrobiopsy was performed (without complications), as a result, mesangioproliferative glomerulonephritis (class II) was detected. Activity index-0. chronicity index-0. Due to the morphologically confirmed absence of active VL, a decision was made to discontinue the pharmacological therapy and reduce mycophenolate mofetil and corticosteroids.

Results: Since there are no markers that reliably reflect the histopathology of the kidneys in SLE, a repeat kidney biopsy makes it possible to assess the activity of LN, the initial phase of immunosuppressive therapy, and to make decisions about its further correction.

Conclusion: Kidney biopsy remains the gold standard for establishing the diagnosis of LN and guiding clinical management. It allows for differential diagnosis in clinically complex cases, selecting adequate therapy based on the morphological form of kidney damage and avoiding the unreasonable prescription of glucocorticosteroids and cytostatics.

DETERMINANTS OF QUALITY OF LIFE IN THE ELDERLY WITH OSTEOPOROSIS: BUSHEHR ELDERLY HEALTH PROGRAM (BEHP)

N. Panahi[1], N. Fahimfar[2], A. Sedokani[1], M. Hosseinpour[2], Y. Zarinfar[1], K. Khalagi[2], M. Sanjari[2], M. J. Mansourzadeh[2], M. R. Mohajer Tehrani[3], I. Nabipour[4], B. Larijani[3], A. Ostovar[2]

[1]Metabolic Disorders Research Center, Endocrinology and Metabolism Molecular-Cellular Sciences Institute, Tehran Univ. of Medical Sciences, Tehran, [2]Osteoporosis Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran Univ. of Medical Sciences, Tehran, [3]Endocrinology and Metabolism Research Center, Endocrinology and Metabolism Clinical Sciences

Institute, Tehran Univ. of Medical Sciences, Tehran, [4]The Persian Gulf Marine Biotechnology Research Center, The Persian Gulf Biomedical Sciences Research Institute, Bushehr Univ. of Medical Sciences, Bushehr, Iran

Objective: To evaluate the determinants of quality of life (QOL) in elderly individuals with osteoporosis, given the growing aging population and the increased prevalence of this condition.
Methods: The study was conducted using the cross-sectional data of the BEH program, phase 2. QOL was assessed using the SF-12 Questionnaire. Individuals with osteoporosis based on the WHO diagnostic criteria were enrolled. The physical (PCS) and mental (MCS) component summaries of QOL were estimated. Statistical analysis was conducted via univariable linear regression model.
Results: A total of 997 individuals (73% female) with osteoporosis were enrolled in the study. Men exhibited higher PCS and MCS scores compared to women, with mean differences of 6.2 (95%CI: 5–7.4) and 3.6 (2.1–5.1) respectively. Various factors such as depression, fear of falling, recent falling, and cognitive impairment were significantly associated with lower PCS scores in both men and women with beta coefficients ranging from -2 to -10. On the other hand, physical activity was positively linked to PCS (β F:3, M:4). Diabetes, hypertension, glucocorticoid use in women, and fracture history in men were significantly associated with lower PCS scores. Depression and fear of falling in both sexes; cognitive impairment, rheumatoid arthritis, glucocorticoid use, and recent falling in women; and smoking in men were associated with lower MCS scores. (β F:-14, M:-11 for depression; and -2 to -6 for other variables).
Conclusion: Elderly women with osteoporosis had lower QOL scores compared to men. Depression and fear of falling were identified as crucial factors contributing to reduced PCS and MCS scores in both sexes, while physical activity was associated with higher PCS scores in both men and women.

P972
ASSOCIATION BETWEEN OSTEOPOROSIS AND QUALITY OF LIFE IN THE ELDERLY: BUSHEHR ELDERLY HEALTH PROGRAM (BEHP)

N. PANAHI[1], N. Fahimfar[2], M. Hosseinpour[2], A. Sedokani[1], M. Sanjari[2], K. Khalagi[2], M. J. Mansourzadeh[2], A. Farhadi[3], M. R. Mohajer Tehrani[4], I. Nabipour[5], B. Larijani[4], A. Ostovar[2]

[1]Metabolic Disorders Research Center, Endocrinology and Metabolism Molecular-Cellular Sciences Institute, Tehran Univ. of Medical Sciences, Tehran, [2]Osteoporosis Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran Univ. of Medical Sciences, Tehran, [3]The Persian Gulf Tropical Medicine Research Center, The Persian Gulf Biomedical Sciences Research Institute, Bushehr Univ. of Medical Sciences, Bushehr, [4]Endocrinology and Metabolism Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran Univ. of Medical Sciences, Tehran, [5]The Persian Gulf Marine Biotechnology Research Center, The Persian Gulf Biomedical Sciences Research Institute, Bushehr Univ. of Medical Sciences, Bushehr, Iran

Objective: Considering the ageing of the population and the increased prevalence of osteoporosis, this study aimed to evaluate the association between QOL and osteoporosis and the determining factors in the elderly population.
Methods: This study was conducted using the cross-sectional data of the second phase of the BEH program, a population based cohort. QoL was assessed using the SF-12 Questionnaire. Patients were classified as osteoporosis and non-osteoporosis based on the WHO diagnostic criteria. The physical (PCS) and mental (MCS) component summaries of QoL were estimated. Statistical analysis was conducted via univariable and multivariable linear regression models.
Results: Overall 2399 participants > 60 y including 997 individuals with osteoporosis (73% women), and 1402 without osteoporosis (37% women) were enrolled. QoL was lower in osteoporosis compared to non-osteoporosis individuals in both men and women. In multivariable regression analysis, stratified by sex, osteoporosis was significantly associated with PCS in women [β: -0.90 (-1.83, -0.02)] but not men. Other factors contributing significantly with PCS include age [β F: -0.22; M: -0.21], BMI [-0.25; -0.09)], depression [-6.11; -8.67], physical activity [1.63; 2.20], glucocorticoid use [-0.61; -1.31], and fear of falling [-3.06; -3.41] in women and men; diabetes [-1.04] in women; smoking [0.91], fracture history [-1.05], and recent falling [-2.32] in men. Depression (-13.44) and fear of falling (-2.5) were associated with lower MCS scores in both sexes.
Conclusion: Although, QoL scores were lower in elderly individuals with osteoporosis compared to those without, after adjusting for possible confounders the association was significant only for PCS in women. Age, BMI, depression, physical activity, and fear of falling are among identifying factors associated with QoL in the elderly.

P973
BRIEF, LOW-IMPACT, HIGH-INTENSITY OSTEOGENIC LOADING TRAINING WITH OSTEOSTRONG DEVICES WITH ONCE-A-WEEK, 10-MIN EXERCISES FOR AT LEAST 12 MONTHS, IMPROVES BONE MINERAL DENSITY AND TRABECULAR BONE SCORE IN WOMEN WITH OSTEOPOROSIS OF THE LUMBAR SPINE

N. Papadopoulou-Marketou[1], A. Papageorgiou[2], G. Vavetsis[2], P. Tsiamyrtzis[3], N. Marketos[4], G. Chrousos[2]

[1]Neuroendocrine Tumor Unit, ENETS Centre of Excellence, 1st Dept. of Propaedeutic and Internal Medicine, Laiko General Hospital, National and Kapodistrian Univ. of Athens, Athens, Greece, [2]Univ. Research Institute of Maternal and Child Health and Precision Medicine, National and Kapodistrian Univ. of Athens, Athens, Greece, [3]Dept. of Mechanical Engineering, Politecnico di Milano, Milan, Italy, [4]Dept. of Physiology, Medical School, National and Kapodistrian Univ. of Athens, Athens, Greece, Athens, Greece

Objective: Osteoporosis is a chronic condition characterized by decreased bone density (BMD) and disrupted microarchitecture (TBS), associated with increased bone-fracture risk. Women with menopausal osteoporosis are usually treated with antiresorptive medication. "Osteostrong" is a bone-strengthening system that uses brief (10 min), weekly, low-impact, high-intensity osteogenic loading. We aimed to investigate the effectiveness of Osteostrong in women with osteoporosis of the lumbar spine.
Methods: 154 postmenopausal women with osteoporosis of the lumbar spine, followed at the Unit on Clinical and Translational Research in Endocrinology, University of Athens, Greece, were enrolled. They were divided into 2 groups. Group A included 75 women treated with Osteostrong (mean age: 58.8y, 95%CI 56.6–60.9); Group A was subdivided in GA1 that included women, who had no parallel antiresorptive treatment, and GA2, that included women who were treated in parallel with such medication. Group B included 79 women who had no Osteostrong intervention (mean age 61.5y, 95%CI 59.2–63.7). Group B was subdivided in GB1, that included women who received no anti-resorptive treatment, and GB2, that included women who were treated with such medication. All the participants had a complete physical examination, an assessment for exclusion of secondary osteoporosis, and a DXA examination [Horizon W(S/N 300472 M)], twice, at the time of inclusion in the trial and 12 months after. Statistical analysis performed using

freeware R(4.2.2) and examined during the period of study for significant mean differences in the recorded response variables.
Results: Paired Student t-test of BMD and TBS of the lumbar spine before and after Osteostrong intervention showed a significant improvement in both patients not receiving bone antiresorptive medication, and synergistically in those receiving such treatment in parallel. In patients receiving neither Osteostrong nor antiresorptive treatment there was a deterioration of BMD and TBS, while in those receiving medication there was a mild BMD and TBS improvement.
Conclusion: The study showed a significant improvement of BMD and TBS in the lumbar spine of women with osteoporosis treated with Osteostrong, regardless of parallel anti-resorptive treatment. Osteogenic loading has a synergistic effect with anti-osteoporotic medication, further improving bone strength and quality, leading to reduced bone fracture risk.

COMPARATIVE STUDY OF SUBCHONDRAL BONE AND ARTICULAR CARTILAGE CHANGES IN MONOSODIUM IODOACETATE-INDUCED OSTEOARTHRITIS IN RAT AND RABBIT MODELS USING MICROCOMPUTED TOMOGRAPHY AND HISTOLOGY

N. S. Umran[1], S. Lau[1], N. Mohd[1], I. Madzuki[2], R. Yahya[3], M. Ajat[1]

[1]Universiti Putra Malaysia, Selangor, [2]Universiti Malaysia Perlis, Perlis, [3]Malaysia Nuclear Agency, Selangor, Malaysia

Osteoarthritis (OA), a degenerative joint disease, profoundly impacts the quality of life and imposes significant socioeconomic burdens. Animal models serve as valuable platforms for assessing the efficacy of drugs and nutraceuticals in clinical development. This study aims to evaluate and compare the progression and pathogenesis of OA in rat and rabbit models using the MIA-induced OA model. MIA-induced OA was induced in rat and rabbit models by intraarticular injection of 3 mg and 8 mg, respectively, at the right knee joint. At week 12, the subchondral cartilage and bone were harvested and evaluated through macroscopic observation, μCT imaging, and architectural, and histology analysis. The results of macroscopic observation, micro-architecture parameters, and histology showed that OA was more severe in the rat compared to the rabbit model. The rat exhibited progression to the bone remodeling stage, indicated by increased bone volume, trabecular thickening, and increased trabecular separation and porosity. The extensive and rapid pathological changes observed in the osteoarthritic joints of the rat model may limit the investigation of OA severity. This study demonstrates both similarities and differences between the two animal models, providing insights into individualized therapeutic approaches and the monitoring of disease progression and treatment strategies.

EFFECTIVENESS OF DOUBLE BOILED EDIBLE BIRD NEST EXTRACT IN ALLEVIATING OSTEOARTHRITIS IN A RABBIT MODEL

N. S. Umran[1], S. Lau[1], N. Mohd[1], M. Ajat[1], I. Madzuki[2], S. Sulaiman[1]

[1]Universiti Putra Malaysia, Selangor, [2]Universiti Malaysia Perlis, Perlis, Malaysia

Osteoarthritis (OA) is associated with a high economic burden due to the effects of disability and the expense of treatment. To date there is no known cure for OA, the treatments include exercises, a weight loss program, support devices, pain relief medications, and surgical treatment. Generally, NSAIDs and analgesics are prescribed to OA patients to alleviate pain. These treatments have been proven effective in reducing symptomatic OA but the adverse effects of these current prescriptions have raised concern among consumers. Therefore, there is an urgent need in finding alternative nutripharmaceutical supplements for preventing OA. Edible bird's nest (EBN) is the salivary secretion originating from specific swiftlets, e.g., *Aerodramus fuciphagus* and *Aerodramus maximus* that have anti-catabolic, anti-inflammatory, and pro-anabolic activity on human osteoarthritic chondrocytes. 45 adult male New Zealand White Rabbits were divided into five groups; Group I: Sham (n = 9), Group II: Negative control, OA (n = 9), Group III: Positive control, OA + Diclofenac 3 mg/kg daily orally (n = 9), Group IV: OA + Double-boiled EBN Extract 75 mg/kg daily orally (n = 9), Group V: OA + Double-boiled EBN Extract 150 mg/kg daily orally (n = 9). Chemically induced OA was performed on all rabbits (n = 36) except the sham group by using 8 mg/knee joint of monosodium iodoacetate (MIA). 3 rabbits from each group were sacrificed at week 4, week 8, and week 12. Macroscopic, μCT, histology, and proteomic results showed that DBEBNE treatment has a chondroprotective effect in ameliorating OA. This study suggests that DBEBNE may have bone improvement, chondroprotective, antioxidant, and anti-inflammatory properties in ameliorating OA, based on results at the morphological as well as molecular level.

P976
RELATIONSHIP OF T2 RELAXATION TIME OF VARIOUS CARTILAGE LAYERS WITH THE LEVEL OF ADIPOKINES IN EARLY OSTEOARTHRITIS OF THE KNEE JOINTS

N. Savushkina[1], E. Taskina[1], N. Kashevarova[1], E. Strebkova[1], E. Sharapova[1], A. Khalmetova[1], D. Kudinskij[1], L. Alekseeva[1], A. Lila[1]

[1] V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia

Objective: To determine the relationship of T2 relaxation time according to MRI with the level of adipokines in early osteoarthritis (OA) of the knee joints (KJ).
Methods: A prospective study included 82 women who met the ESKOA criteria being developed and currently being tested, with KJ OA and X-ray stage 0-II (Kellgren-Lawrence), who signed the informed consent. The average age of patients was 49.0 ± 10.2 y, the duration of the disease was 1 [0.5; 1] y. The average BMI values corresponded to overweight (26.6 ± 5.4 kg/m^2). The level of blood adipokines (visfatin, resistin, leptin) was studied in patients, and MRI with color mapping of cartilage tissue of targeted KJ was performed with calculation of T2 relaxation time. Statistical processing of the material was carried out using Statistica 10.0 software.
Results: The average level of visfatin was 33.8 ± 12.7 ng/ml, resistin—9.0 ± 3.1 ng/ml, leptin—24.8 ± 3.1 ng/ml; an increase in leptin levels was noted in 59.8% of cases, and visfatin levels—in absolutely all patients. The total MR T2 relaxation time of the cartilage of the targeted KJ was 36.0 [32.0;39.5] ms, the deep layer—36.4 [33.7;39.1] ms, the surface layer—37.0 [34.1;41.1] ms. The Spearman correlation analysis (Table 1) confirmed statistically significant positive relationships ($p < 0.05$) between the values of T2 relaxation time of cartilage in its individual layers and age, BMI, weight, cholesterol and leptin levels.

Table 1. Correlation coefficients between MR T2 cartilage relaxation time and various anthropometric and laboratory parameters

Parameter	MR T2 relaxation time of cartilage of the targeted knee joint	p
Total cartilage layer		
Age, years	0,44	<0,05
Weight, kg	0,41	<0,05
Leptin, ng/ml	0,40	<0,05
Cholesterol, mmol/l	0,44	<0,05
Deep layer		
Age, g	0,37	<0,05
BMI, kg/m^2	0,53	<0,05
Weight, kg	0,53	<0,05
Waist size, cm	0,49	<0,05
Hip volume, cm	0,43	<0,05
Leptin, ng/ml	0,50	<0,05
Cholesterol, mmol/l	0,45	<0,05
The surface layer		
Age, g	0,40	<0,05
Leptin, ng/ml	0,41	<0,05
Cholesterol, mmol/l	0,38	<0,05

Conclusion: Leptin, an increase in which occurs in most patients with early OA, is a promising diagnostic marker of the disease, since its increase significantly correlates with T2 relaxation time in all layers of cartilage.

P977
RELATIONSHIP OF PAIN LEVELS WITH LABORATORY PARAMETERS IN EARLY OSTEOARTHRITIS OF KNEE JOINTS

N. Savushkina[1], E. Taskina[1], N. Kashevarova[1], E. Strebkova[1], E. Sharapova[1], A. Khalmetova[1], L. Alekseeva[1], A. Lila[1]

[1]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia

Objective: To determine the relationship of pain levels with laboratory parameters in early osteoarthritis (OA) of the knee joints.
Methods: A prospective study for the period 2022–2023 included 82 women who met the ESKOA criteria being developed and currently being tested, with knee joint OA and X-ray stage 0-II (Kellgren-Lawrence), who signed the informed consent. The average age of patients was 49.0 ± 10.2 y (from 35–73), the duration of the disease was 1 [0.5; 1] y. An individual card was filled out for each patient, including anthropometric parameters, WOMAC indicators, concomitant diseases and therapy during the follow-up period. Statistical processing of the material was carried out using Statistica 10.0 software.
Results: Knee joint pain according to WOMAC reached 60 [20; 140] mm, stiffness—30 [10; 70] mm, functional insufficiency (FN)—145 [40; 390] mm, the total index of WOMAC—250 [80; 630] mm. The median markers associated with OA, inflammation, metabolic syndrome, and cartilage destruction were as follows: cholesterol—5.4 [4.83; 5.85] mmol/L, IL-1β—3.29 [1.15; 2.84] ng/ml, IL-10—0.02 [0.001; 32.5] ng/ml, IL-34—0,01 [0,001; 13,2] ng/ml, CTX-I—0.007 [0.002; 0.079] ng/ml. The Spearman correlation analysis (Table 1) revealed statistically significant positive relationships ($p < 0.05$) between various components of WOMAC and CTX-I levels, and negative ones with MMP3, IL-10 and IL-34. It was also demonstrated that an increase in MS components and hypercholesterolemia had significant negative correlations with the level of the anti-inflammatory cytokine IL-10, as well as the level of IL-34.

Table 1. Correlation coefficients between the components of WOMAC and metabolic syndrome and laboratory parameters in early knee OA

Parameter		p
Pain-WOMAC	IL-10	<0,05
	IL-34	<0,05
FN-WOMAC	CTX-I	<0,05
Stiffness-WOMAC	IL-10	<0,05
	IL-34	<0,05
Total WOMAC	CTX-I	<0,05
	IL-10	<0,05
The number of components of the metabolic syndrome	IL-10	<0,05
	IL-34	<0,05
Hypercholesterolemia	IL-34	<0,05

Conclusion: The CTX-1 subchondral bone remodeling marker increases as knee joint pain increases in early OA, which makes it possible to consider it as a possible marker of disease progression. Negative correlations between the level of pain and anti-inflammatory cytokines indicate a weakening of anabolic processes during the development of OA, which requires further study.

P978
OSTEOPOROSIS AND CEREBROVASCULAR EVENTS: A RETROSPECTIVE COHORT BONE DENSITY STUDY

N. Theerapakanunt[1], S. Jannoo[1], N. Kietsiriroje[1], P. Limumpornpetch[1], T. Ingviya[1], R. Leelawattana[1]

[1]Prince of Songkla Univ., Hatyai, Thailand

Objective: There is a link between low bone density and atherosclerosis, yet the impact of low bone mass on cardiovascular disease remains to be investigated. This study aims to explore the relationship between osteoporosis and major adverse cardiovascular events (MACE).
Methods: This retrospective cohort included participants aged 60–75 y during their initial BMD measurement from January 1, 2005 to December 31, 2021. Osteoporosis was defined by BMD T-scores at the lumbar spine or femoral neck ≤ -2.5 or when fragility fracture was evident. MACE included the composite of cardiovascular death, nonfatal myocardial infarction, or nonfatal stroke (3P-MACE) collected after the date of BMD to November 15, 2023. The Cox-proportional hazard model was employed to assess the hazard ratios (HR) of MACE, adjusted for potential confounders, with the osteoporotic status as a fixed factor. $P < 0.05$ was used to determine statistical significance.
Results: In total, 348 patients were included, with 329 (94.5%) being female, mean age 67.4 ± 4.2 y, and mean BMI 24.4 ± 4.8 kg/m^2. A total of 167/348 (48.0%) patients were diagnosed with osteoporosis at entry. The primary endpoint, 3P-MACE, occurred in 68/348 (27.4%) in both groups with HR 1.43 [95%CI: 0.89–2.32], p = 0.14 in the osteoporosis group. The rate of nonfatal stroke events was significantly higher in the osteoporosis group, 25/167 (25.0%) vs. 10/181 (5.5%) (HR 2.69 [95%CI: 1.29–5.61], p = 0.008) whereas nonfatal myocardial infarction events similarly occurred between the two groups 15/167 (9.0%) vs. 19/181 (10.5%) (p = 0.58). After adjusting for age, sex, and other risk factors, the risk of nonfatal stroke remains significantly higher (adjusted HR 3.09 [95%CI: 1.37–6.93], p = 0.006).

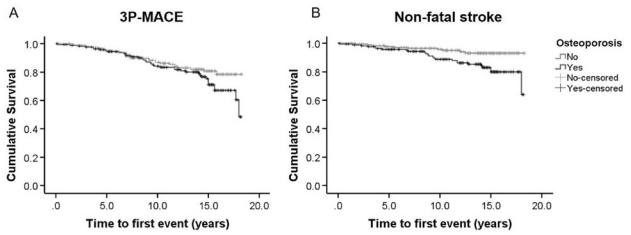

Figure 1 Time-to-First-Event Analysis for A) primary cardiovascular composite endpoint (death from cardiovascular causes, nonfatal myocardial infarction, or nonfatal stroke; 3P-MACE) and B) non-fatal stroke. The *black line* refers to the osteoporosis group (n=167) and the *grey line* refers to the non-osteoporosis group (n=181).

Conclusion: This study demonstrates the increased risk of nonfatal stroke in patients with osteoporosis. Yet, the relationship between osteoporosis and major cardiovascular events is inconclusive. A larger prospective study is warranted to further elucidate this link.

P979
IMPACT OF GLP-1 RECEPTOR AGONISTS AND SGLT-2 INHIBITORS ON BONE METABOLISM IN PATIENTS WITH TYPE 2 DIABETES MELLITUS

N. Timkina[1], A. Simanenkova[1], M. Mart'Yanova[1], L. Karonova[1]

[1]Almazov National Medical Research Centre, St. Petersburg, Russia

Objective: Bone fracture risk increases in diabetes mellitus type 2 (DM2). The impact of certain glucose-lowering drugs on bone remodeling is not fully understood. This study aims to investigate bone metabolism in patients with DM2 undergoing treatment with SGLT-2i and GLP-1 RAs.

Methods: 94 DM2 patients (36 men, aged 45–75 y, with glycated hemoglobin (HbA1c) level 1–2.5% higher than the target) were receiving SGLT-2i (empagliflosin, dapagliflosin or canagliflosin, n = 55) or GLP-1 RAs (semaglutide, liraglutide, dulaglutide, n = 39) in addition to metformin for 12 months. Level of phosphorus (P, mmol/l), calcium (Ca, mmol/l), 25(OH)D, ng/ml, PTH (pg/ml), osteocalcin (OC, ng/ml), osteoprotegerin (OPG, pmol/l), RANKL (pmol/l), FGF23 (pmol/l) were measured at the start of treatment and after 12 months. 56 patient underwent DXA.

Results: The median age was 58 y (50.8; 58), and the median HbA1c was 7% (6.4; 8). Three patients (excluded from the study) had osteoporosis according to BMD measurements. 13 (24%) patients had osteopenia. 27 (50.9%) and 6 (11.3%) patients were diagnosed with degraded and partly degraded microarchitecture of bone tissue, respectively, according to the TBS. After 12 months, patients receiving SGLT-2 inhibitors showed an increase in FGF23 levels (from 1.05 (0.85; 1.31) to 1.23 (1.09; 1.41), p = 0.059), a decrease in hip BMD (from 1.14 g/cm^3 (1.04; 1.2) to 1.07 (1.01; 1.12), p = 0.035), and a decrease in neck hip BMD (from 1.02 g/cm^3 (0.94; 1.13) to 0.97 (0.9; 1), p = 0.042). In the GLP-1 RAs group, BMD, TBS, and bone markers remained stable. FGF23 correlated with HbA1c (ρ = 0.359, p = 0.001). RANKL correlated with age (ρ = -0.27, p = 0.02) and TBS (ρ = -0.35, p = 0.027). OC correlated with HbA1c (ρ = -0.26, p = 0.02), Ca (ρ = 0.344, p = 0.09), BMD L1-L4 (ρ = -0.374, p = 0.01), and BMD hip (ρ = -0.328, p = 0.06).

Conclusion: GLP-1 RAs have a neutral effect on bone metabolism. SGLT-2 inhibitors can impair BMD by increasing FGF23 and subsequently triggering the Ca-PTH axis.

P980
BONE MICROARCHITECTURE IN POSTMENOPAUSAL WOMEN WITH RHEUMATOID ARTHRITIS

M. Kozyreva[1], O. Dobrovolskaya[1], N. Demin[1], O. Nikitinskaya[1], N. Toroptsova[1]

[1]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia

Objective: To compare the microarchitecture of bone using TBS in postmenopausal women with rheumatoid arthritis (RA) and without rheumatic diseases.

Methods: 242 postmenopausal women were included: 198 patients with confirmed RA (mean age 58 $\pm$ 12.1 y) and 44 without rheumatic diseases (mean age 61.3 $\pm$ 8.4 y, p = 0.09). Clinical examination and DXA of the lumbar spine (L1-L4) and the proximal femur were conducted. Based on the measurement of BMD L1-L4 TBS was calculated using the TBS Insight software, version 3.0. The microarchitecture of bone tissue was ranked according to TBS: degraded—TBS $\leq$ 1.23, partially degraded—TBS > 1.23—< 1.31, normal bone microarchitecture—TBS $\geq$ 1.31.

Results: The determination of TBS values in women with RA revealed that 98 (49.5%) had a normal microarchitecture, 40 (20.2%) partially degraded, and 60 (30.3%) degraded microarchitecture. In the control group there were 22 (50%) women with normal TBS, 17 (38.6%) with moderate values of TBS and 5 (11.4%) with low TBS. Normal TBS levels were significantly more common in patients without RA (p = 0.009). Osteoporosis (OP) was found in 62 (31.3%) patients with RA and in 7 (15.9%) women of the control group, p < 0.05. OP was significantly more often diagnosed in L1–L4 compared with the proximal femur in both groups (p < 0.05). Among RA patients with OP in L1-L4, degraded bone microarchitecture was revealed in 28 (62.2%), partially degraded in 10 (22.2%), normal microarchitecture in 7 (15.6%) women, while in patients of the control group with OP in L1-L4—3 (42,9%), 2 (28,6%) and 2 (28.6%) persons, respectively, (p > 0.05). In RA patients with OP in femoral neck (FN) and/or total hip (TH), the degraded bone microarchitecture was determined in 9 (53%), partially degraded in 5 (29.4%), normal in 3 (17.6%) patients. In the control group—0 (0%), 1 (50%) and 1 (50%) person, respectively (p > 0.05).

Conclusion: The degraded microarchitecture of bone tissue by TBS was detected in 30.3% of postmenopausal women with RA and 11.4% of persons without rheumatic diseases. In individuals with OP, the frequency of low TBS did not differ between two groups.

P981
TRABECULAR BONE SCORE AND IMMUNOLOGICAL MARKERS IN RHEUMATOID ARTHRITIS PATIENTS

M. Kozyreva[1], O. Nikitinskaya[1], E. Samarkina[1], N. Toroptsova[1]

[1]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia

Objective: To determine the association between TBS and immunological markers in postmenopausal women with rheumatoid arthritis (RA).

Methods: 198 postmenopausal women with a confirmed diagnosis of RA according ACR/EULAR 2010 were included. All patients were surveyed using a specially designed questionnaire, X-ray osteodensitometry of the lumbar spine (L1-L4) was performed to assess BMD and TBS. The immunological study included the determination of rheumatoid factor (RF), antibodies to cyclic citrullated peptide

(ACCP), C-reactive protein (CRP) by nephelometric method on the Atellica® NEPH 630 system analyzer (Siemens Healthineers, Erlangen, Germany).
Results: The median age of the examined individuals was 58 ± 12.1 y, the postmenopausal period was 13.0 [5.0; 18.0] y and the duration of RA was 9.0 [3.0; 16.0] y. Low TBS was detected in 60 (30.3%), moderate in 40 (20.2%), and normal in 90 (39.5%) patients. RF seropositive were 149 (75.3%) women (median RF level 55.9 [10.6; 199.0] IU/ml). ACCP was determined in 188 patients, with 135 (68.2%) persons being positive (median level 58.15 [6.0; 228.6] IU/ml). Median CRP was 6.0 [1.6; 15.9] mg/l. Spearman's correlation analysis did not reveal a link between TBS and RF, ACCP, and CRP. When comparing patients with low and normal TBS, no significant differences were found: RF—55.9 [11.7; 259.0] IU/ml vs. 45.7 [10.0; 141.0] IU/ml, respectively; ACCP—59.5 [5.6; 263.6] IU/ml vs. 47.4 [5.8; 200.0] IU/ml, respectively; CRP—5.4 [1.4; 16.1] mg/l vs. 7.5 [1.7; 14.5] mg/l, respectively, $p > 0.05$.
Conclusion: Low TBS was detected in 30.3% of women with RA. No significant differences in the level of RF, ACCP and CRP were revealed between patients with degraded and normal bone microarchitecture.

P982
TRABECULAR BONE SCORE AND BIOCHEMICAL BLOOD PARAMETERS IN POSTMENOPAUSAL WOMEN WITH RHEUMATOID ARTHRITIS

M. Kozyreva[1], O. Dobrovolskaya[1], N. Demin[1], O. Nikitinskaya[1], N. Toroptsova[1]

[1]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia

Objective: To find out association between TBS and blood biochemical parameters in postmenopausal women with rheumatoid arthritis (RA).
Methods: 198 postmenopausal women with a confirmed diagnosis of RA were included (mean age 58 ± 12.1 y). The laboratory examination included a clinical blood test and a biochemical analysis (level of glucose, total cholesterol, uric acid, creatinine, total protein, albumin, alkaline phosphatase, calcium and phosphorus). Creatinine clearance was calculated using the Cockcroft-Gault formula. DXA of the lumbar spine (L1-L4) and the proximal femur was performed (Lunar Prodigy Advance, GE, USA). The L1-L4 TBS was determined using the TBS insight software, version 3.0. A correlation analysis using the Spearman method was performed.
Results: Median value of TBS was 1.31 [1.21; 1.38], while degraded bone microarchitecture (TBS ≤ 1.23) was detected in 60 (30.3%) people, partially degraded (TBS > 1.23—< 1.31) in 40 (20.2%), and normal (TBS ≥ 1.31) in 98 (49.5%) of persons. In individuals with degraded microarchitecture mean erythrocyte sedimentation rate (ESR) was 31.8 ± 22.3 mm/h and in patients with normal bone microarchitecture—16.9 ± 11.6 mm/h, $p < 0.001$. No differences were found in hemoglobin level, leukocyte formula, platelet count. There were also differences in glucose level (5.6 ± 1.3 vs. 5.2 ± 0.5 mmol/l, respectively, $p < 0.05$), uric acid (294.7 ± 69.0 vs. 236.2 ± 66.4 mmol/l, respectively, $p < 0.001$), total cholesterol (5.6 ± 0.8 vs. 5.0 ± 1.0 m/mol/l, respectively, $p = 0.01$), alkaline phosphatase (96.9 ± 42.9 vs. 76.7 ± 22.0 u/l, respectively, $p < 0.001$). Albumin level was significantly lower in patients with low TBS compared with those with normal TBS (38.7 ± 7.8 vs. 46.6 ± 3.8 g/l, respectively, $p < 0.05$). Patients with partially degraded bone microarchitecture did not differ from the other two groups in terms of clinical and biochemical blood parameters. Negative correlations have been established between TBS and uric acid ($r = -0.301$, $p < 0.05$), total cholesterol ($r = -0.235$, $p < 0.05$), alkaline phosphatase ($r = -0.247$, $p < 0.05$), phosphorus ($r = -0.307$, $p < 0.05$), as well as a positive with creatinine clearance ($r = 0.162$, $p < 0.05$).
Conclusion: 30.3% of patients with RA had degraded trabecular bone microarchitecture. TBS negatively correlated with the level of uric acid, total cholesterol, alkaline phosphatase and phosphorus, and positively with creatinine clearance.

P983
SARCOPENIA, OSTEOSARCOPENIA AND RISK OF FALLS AND FRACTURES IN PATIENTS WITH RHEUMATOID ARTHRITIS

O. Dobrovolskaya[1], N. Demin[1], A. Feklistov[1], N. Toroptsova[1]

[1]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia

Objective: To assess the risk of falls and fractures in women with rheumatoid arthritis (RA) with sarcopenia (SP) and osteosarcopenia (OSP).
Methods: The study included 102 women (mean age 58.1 ± 9.2 y), with RA (ACR/EULAR criteria, 2010), median disease duration was 8.0 [4.0; 15.0] y. The study was approved by the local ethics committee. The 10-y probability of a major osteoporotic fracture was assessed using the FRAX tool. DXA was performed to evaluate body composition and BMD of lumbar spine, femoral neck, total hip. Falls and low-energy fractures were registered during a 3-y prospective study. Univariant logistic regression was used to identify risk of falls and fractures.
Results:10 (9.8%) patients had SP and 13 (12.7%) OSP. According to FRAX, 42.9% of patients with SP and 92.3% with OSP had a high risk of fractures vs. 34.0% of women with normal body composition (NBC) had a high risk of fractures ($p < 0.001$). The frequency of falls during the year before the study in patients with SP was 40.0%, with OSP—61.5% and in women with NBC—22.4% ($p < 0.05$), during the prospective follow-up, the frequency of falls was 50.0%, 53.8% and 10.3%, respectively ($p < 0.001$). During the follow-up, 1 (1.0%) vertebral fracture and 4 (3.9%) peripheral fractures were registered. The frequency of fractures did not differ between the groups. Univariate logistic regression showed that SP and OSP increased the risk of falls compared with women with NBC (OR 9.3 (2.53–40.99), $p = 0.001$ and OR 13.25 (2.81–64.48), $p = 0.001$, respectively).
Conclusion: 22.5% of women with RA had SP or OSP, among them 52.2% had a high 10-y probability of fractures according to FRAX. OSP increased the risk of falls by 13 times; SP by 9 times in women with RA. We did not found relationship between the presence of SP/OSP and fractures. Further research is needed involving more people with SP/OSP.

P984
FACTORS ASSOCIATED WITH SARCOPENIA IN POSTMENOPAUSAL WOMEN WITH RHEUMATOID ARTHRITIS

N. Toroptsova[1], O. Dobrovolskaya[1], N. Demin[1], O. Nikitinskaya[1]

[1] V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia

Objective: To evaluate the frequency of sarcopenia (SP) and factors associated with it in postmenopausal women with rheumatoid arthritis (RA).
Methods: 104 postmenopausal women (age 60.5 [51.1; 66.0] y) with confirmed RA (ACR/EULAR, 2010) were enrolled. Nutritional status was assessed using a MNA (Mini Nutricial Assessment)

questionnaire. All patients underwent handgrip strength by mechanical dynamometer for muscle strength determined. A laboratory examination and DXA were conducted. Osteoporosis (OP) was diagnosed according to WHO criteria, and SP was diagnosed according to the criteria EWGSOP2.

Results. SP was diagnosed in 33 (31.7%) women with RA. Persons with and without SP (SP + and SP- respectively) did not differ in age and RA duration ($p > 0.05$). Normal BMI was found in 72.7% SP + patients and in 28.2% SP- ($p < 0.001$). Women SP + had BMD lower than those SP- at any region. OP was diagnosed in 18 (54.5%) patients SP + and in 17 (23.9%) women SP- ($p = 0.002$). AMM correlated with BMI ($r = 0.61$, $p < 0.001$), BMD in the lumbar spine ($r = 0.32$, $p < 0.001$), BMD in the femur neck ($r = 0.53$, $p < 0.001$) and BMD in the total hip ($r = 0.44$, $p < 0.001$). Negative correlations were found with C-reactive protein ($r = -0.18$, $p = 0.036$). AMM was not correlated with age. In univariate logistic regression analyses SP was associated with BMI < 25 kg/m^2 (OR 8.13; 95%CI (3.30–20.01), $p < 0.001$), OP (OR 4.01; 95%CI 1.78–9.03, $p < 0.001$), and nutritional status by MNA < 24 points (OR 2.82; 95%CI (1.16–6.83), $p = 0.022$).

Conclusion: 1/3 of postmenopausal women with RA had confirmed SP. Factors associated with SP were BMI < 25 kg/m^2, presence of OP and reduce nutritional status.

P985
SARCOPENIC PHENOTYPE AND PHYSICAL PERFORMANCE IN RHEUMATOID ARTHRITIS PATIENTS WITH BIOLOGICAL THERAPY

O. Dobrovolskaya[1], N. Demin[1], A. Feklistov[1], M. Kozyreva[1], N. Toroptsova[1]

[1]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia

Objective: To evaluate appendicular lean mass, muscle strength and physical performance in rheumatoid arthritis (RA) women with biological therapy (BT).

Methods. The study included 63 women (mean age 60.3 ± 8.9 y) with confirmed RA treated with BT (BT +) and control group (117 age-matched RA patients who had never previously treated with BT). Clinical and laboratory examination, evaluation of body composition using DXA and tests to assess muscle strength and physical performance were carried out. The sarcopenic phenotype was diagnosed with an appendicular lean mass of < 15 kg or an appendicular lean mass index of < 5.5 kg/m^2.

Results: The frequency of sarcopenic phenotype among RA patients was 23.3%: in group BT + – 27.0%, in the control – 21.4% ($p > 0.05$). There were no differences among the groups based on the results of muscle strength assessment tests, however, patients BT + performed significantly better the short physical performance battery (SPPB) and had a higher gait speed ($p = 0.016$ and $p = 0.002$, respectively). Univariate linear regression analysis confirmed the relationship of the BT presence with the physical performance according to the results of SPPB ($b^* = 0.24$; $p = 0.018$) and gait speed ($b^* = 0.28$; $p = 0.006$).

Conclusion: The frequency of sarcopenic phenotype among patients with RA was 23.3% and was comparable in those who received BT and without it. There were no differences in muscle strength depending on the presence of BT, but the physical performance was significantly better in women BT + .

P986
BONE MINERAL DENSITY AND URIC ACID ASSOCIATION IN POSTMENOPAUSAL WOMEN

N. Toroptsova[1], O. Dobrovolskaya[1], N. Demin[1], E. Samarkina[1]

[1]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia

Objective: To assess the frequency of hyperuricemia (HU) and its association with MD) in postmenopausal women.

Methods. 263 postmenopausal women (median age 62 [56; 67] y) enrolled in the study. DXA to measure BMD of lumbar spine (LS), femoral neck (FN) and total hip (TH) was performed. All patients underwent laboratory examination to assess the level of uric acid (UA) in the blood serum (spectrophotometry; Cobas C311 analyzer). The level of MK > 360 μmol/l was taken as HU. The study was approved by the local ethics committee.

Results: Median UA level was 273.9 [220.0; 326.0] μmol/l, 33 (12.5%) women had HU. A cut-off point (200 mmol/l) was found using ROC analysis. In women with UA < 200 μmol/l BMD at any region was significantly less and the frequency of the osteoporosis was more than in those with UA > 200 μmol/l. We found correlation between BMD of LS and TH with UA ($p = 0.001$ and $p = 0.004$ respectively). In subgroup analyses according to age in women < 60 years old association among BMD of LS and UA was found ($p = 0.005$), in persons 60–70 years old BMD of FN and TH positively correlated with UA ($p = 0.004$ and $p = 0.002$ respectively). There were no significant correlations between BMD and UA in women > 70 years old. In the univariate linear regression associations between BMD and UA were confirmed. We didn't find any association between TBS, 10-y probability of fracture according to FRAX, frequency of previous low-energy fractures and UA.

Conclusion: The UA level < 200 μmol/l can be used as an additional risk factor of osteoporosis. Postmenopausal women with UA < 200 μmol/l. Postmenopausal women with UA < 200 μmol/l need to carry out DXA.

P987
ASSOCIATION OF BONE MINERAL DENSITY AND BIOCHEMICAL AND IMMUNOLOGICAL MARKERS IN WOMEN WITH RHEUMATOID ARTHRITIS

O. Dobrovolskaya[1], N. Demin[1], M. Kozyreva[1], E. Samarkina[1], M. Cherkasova[1], M. Diatroptov[1], N. Toroptsova[1]

[1]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia

Objective: To study the associations of BMD with biochemical and immunological markers of blood serum in postmenopausal women with rheumatoid arthritis (RA).

Methods: 173 women with RA were examined (age 61.0 [56.0; 66.0] y). BMD was measured in all patients at lumbar spine (LS), femur neck (FN) and total hip (TH) by DXA. C-reactive protein (CRP), rheumatoid factor, anti-citrullinated protein antibodies (ACPA), PTH, IL-6, adiponectin and leptin were determined.

Results: The linear regression analysis revealed a significant association, independent of age, BMI and postmenopause duration, between BMD at any site and PTH ($\beta = -0.22$, $\beta = -0.35$ and $\beta = -0.30$, for LS, FN and TH, respectively), CRP ($\beta = -0.18$, $\beta = -0.23$ and $\beta = -0.22$, for LS, FN and TH, respectively) and leptin ($\beta = 0.35$, $\beta = 0.32$ and $\beta = 0.42$, for LS, FN and TH, respectively). Significant associations were also found between adiponectin and BMD in LS and TH ($\beta = -0.36$ and $\beta = -0.28$, respectively), ACPA and BMD in FN and TH ($\beta = -0.21$, $\beta = -0.24$, respectively) and IL6 and BMD in FN ($\beta = 0.37$).

Conclusion: CRP, ACPA, PTH, IL6, adiponectin and leptin were associated with BMD independently of age, BMI and duration of post menopause in women with RA.

P988
EFFECT OF PHYSICAL ACTIVITY ON FATIGUE IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

N. V. Aleksandrova[1], V. A. Aleksandrov[1], I. Y. Alekhina[2], R. A. Grekhov[3], A. V. Aleksandrov[3]

[1]Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky, Volgograd, [2]Stavropol State Medical Univ., the Dept. of Hospital Therapy, Stavropol, [3]Volgograd State Medical Univ., Volgograd, Russia

Objective: Severe fatigue is an important obstacle to physical activity in patients with systemic lupus erythematosus (SLE). We aimed to evaluate the effect of additional physical activity on reducing fatigue in outpatients with SLE.
Methods: 54 patients with SLE participated in the study. Fatigue was assessed using visual analog scale (VAS) and FACIT scale. The program of additional physical activity (during 4 weeks) included dosed walking (daily, duration of 30–60 min) taking into tolerability to physical activity according to the 6MWD-test. The level (total score) of kinesiophobia was determined by the Tampa Scale for Kinesiophobia (TSK) questionnaire.
Results: The mean level of fatigue on the VAS screening scale was 58.3 [24;73] points, and the mean level of kinesiophobia on the TSK was 34.8 $\pm$ 9.49 points. A positive correlation was noted between TSK and FACIT, FACIT and VAS scores. At the final stage of the study, according to the results of questionnaire processing, SLE patients were divided into two groups: I—dosed walking $>$ 5.5–6 thousand steps/d ($n = 31$), II—dosed walking $<$ 5.5 thousand steps/d ($n = 23$). Group I showed a decrease in walking time in the 50-m test ($p = 0.019$) and a decrease in fatigue according to VAS ($p = 0.026$) and FACIT ($p = 0.01$). In group II, there was an increase in kinesiophobia ($p = 0.025$) and an increase in FACIT fatigue ($p = 0.043$).
Conclusion: The severity of fatigue in patients with SLE depends on physical activity and the level of kinesiophobia. Motivating patients to overcome irrational fear of active movement may help to increase endurance and reduce the risk of depression.

P989
TOTAL JOINT ARTHROPLASTY AND ANTIRHEUMATIC MEDICATIONS IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS AND RHEUMATOID ARTHRITIS

N. V. Seredavkina[1], E. Y. Polischuk[1], V. N. Amirdjanova[1], M. A. Makarov[1], T. M. Reshetnyak[1]

[1]V.A. Nasonova Scientific Research Rheumatology Institute, Moscow, Russia

Objective: To evaluate the incidence of thrombohaemorrhagic and infectious complications of antirheumatic medications in patients with systemic lupus erythematosus (SLE) and rheumatoid arthritis (RA) undergoing total joint arthroplasty.
Methods: 34 patients (4 SLE and 30 RA) who underwent primary hip (11(32%)) and knee (23(68%)) arthroplasty were included. To prevent venous thromboembolic complications anticoagulants (ACs) were prescribed to all the patients 12 h after arthroplasty: nadroparin 0.3 ml/d for 7 d, then DOAC. Coagulogram and thrombodynamics tests were performed at 3 points: before arthroplasty, after arthroplasty before ACs and 7 d later the arthroplasty.
Results: Methylprednisolone and hydroxychloroquine were given to all SLE patients without cancellation. Methylprednisolone was given to 23(76%) RA patients and was cancelled preoperatively in 8(27%) patients. RA patients received the following antirheumatic medications (AMs): 21(70%) methotrexate, 4(13%) leflunomide, 1(3%) sulfasalazine and 3(10%) hydroxychloroquine. AMs were not cancelled in the perioperative period. 6(20%) RA patients were treated with biologics: 3 abatacept, 1 etanercept, 1 golimumab and 1 rituximab. In 1 patient, the abatacept administration coincided with arthroplasty and was delayed until the postoperative wound healed. None of the patients had early infections of the prosthetic joints. 2 RA patients developed vascular complications: 1 minor bleeding and 1 deep vein thrombosis. Before arthroplasty, thrombodynamics demonstrated normocoagulation in 58% patients and hypercoagulability in 42% patients. After arthroplasty, the frequency of hypercoagulability increased to 90%, and a state of thrombotic readiness was diagnosed in 8(33%) patients. Normocoagulation in all patients was achieved after use of nadroparin.
Conclusion: The use of antirheumatic medications and biologics in patients with SLE and RA did not increase the risk of prosthetic joint infection. Anticoagulant therapy in total joint arthroplasty in patients with SLE and RA was safe and effective in prevention of thromboembolic complications. Thrombodynamics allowed timely detection of the state of thrombotic readiness in patients with prosthetic joints.

P990
LRP5 MUTATION WITHOUT PSEUDOGLIOMA IN A YOUNG MAN WITH FRAGILITY FRACTURES

N. Vaghasia[1], A. Mithal[1], A. Dutta[1]

[1]Institute of Endocrinology and Diabetes, Max Healthcare, Saket, Delhi, New Delhi, India

Osteoporosis in children and young adults is relatively rare. Hereditary causes are often overlooked in the absence of a positive family history. We report a rare case of a 29-year-old male presenting with recurrent fragility fractures since the age of 6 y.
Case report: A 29-year-old male presented with an atraumatic painful spinal wedge compression. He reported a history of multiple childhood fractures (right humerus fracture at the age of 6 years, right fibula fracture at the age of 10 years and compression fracture of D12 at the age of 16 y). Secondary causes such as celiac disease, inflammatory disorders, hypogonadism etc. were ruled out. Family history was negative for any bone disease. Exome sequencing using Massively Parallel Sequencing (Next Generation Sequencing) was performed, which revealed two novel mutations in LRP gene—intron 5 c.1015 + 1G $>$ A and Exon 5 c.892C $>$ T. Although the former mutation has been described as a cause of osteoporosis in the homozygous state, it manifested as osteoporosis in our patient, in the heterozygous state, in presence of a second mutation on the LRP gene. Eye involvement, which is classically seen in "Osteoporosis-Pseudoglioma syndrome" homozygotes was absent in our patient. Genetic analysis of parents revealed that the father was a carrier of intron 5 c.1015 + 1G $>$ A and mother a carrier of Exon 5 c.892C $>$ T mutation. However, none of them had history of fractures or low bone density. The patient was subsequently treated with intravenous zoledronic acid (planned to be administered annually) and showed a significant improvement in bone density at spine and left femur with no further fractures over one year of follow up.
Conclusion: We report a novel presentation of a LRP5 mutation in a young male, which highlights the importance of genetic testing for primary osteoporosis in children and young adults.

P991
SARCOPENIC OBESITY AND HEALTH OUTCOMES: AN UMBRELLA REVIEW OF SYSTEMATIC REVIEWS WITH META-ANALYSIS

N. Veronese[1], F. S. Ragusa[1], F. Pegreffi[2], L. Dominguez[2], M. Barbagallo[1], M. Zanetti[3], E. Cereda[4]

[1]Univ. of Palermo, Palermo, [2]Univ. of Enna Kore, Enna, [3]Univ. of Trieste, Trieste, [4]IRCCS San Matteo, Pavia, Italy

Objective: Many studies supported that sarcopenic obesity (SO) could be considered as a potential risk factor for negative health outcomes. However, these results have been inconsistent and no umbrella reviews exist regarding this topic.
Methods: Several databases until November 2023 were searched for systematic reviews with meta-analysis of observational studies (cross-sectional, case–control and prospective). For each association, random-effects summary effect sizes, with correspondent 95%CIs were evaluated using the GRADE tool.
Results: Among 213 papers initially screened, nine systematic reviews with meta-analysis were included with a total of 384,710 participants. In any population addressed in cross-sectional and case–control studies, compared to non-SO, SO increased the prevalence of cognitive impairment (high certainty of evidence), coronary artery disease and dyslipidaemia (both moderate certainty of evidence). However, when compared to sarcopenia or obesity, the results were conflicting. In prospective studies, the association between SO—compared to non-SO—and other negative outcomes was supported by low/very low certainty of evidence and limited to a few conditions and no comparison with sarcopenia or obesity was provided. Finally, only few studies have used muscle function/physical performance in the diagnostic workup.
Conclusion: SO could be considered as risk factor only for a few conditions with a literature mainly based on cross-sectional and case–control studies. Future studies with clear definitions of SO are needed for quantifying the importance of SO—particularly when compared to the presence of only sarcopenia or obesity – and the weight of muscle function/physical performance in its definition.

P992
IMPACT OF LIFELONG EXERCISE ON CARDIOMETABOLIC HEALTH: A SYSTEMATIC REVIEW AND META-ANALYSIS

N. Veronese[1], M. I. Burgio[1], C. Mandalà[1], L. Dominguez[2], M. Barbagallo[1], L. Smith[3], L. Fontana[4], K. Prokipidis[5]

[1]Univ. of Palermo, Palermo, Italy, [2]Univ. of Enna Kore, Enna, Italy, [3]Anglia Ruskin Univ., Cambridge, UK, [4]Univ. of Syndey, Sydney, Australia, [5]Univ. of Liverpool, Liverpool, UK

Objective: The impact of lifelong exercise on cardiometabolic risk is a crucial aspect of public health. However, limited knowledge exists regarding differences in cardiometabolic parameters between older athletes, older controls, and sedentary/active young controls.
Methods: A comprehensive search in major databases until October 2023 was conducted for studies comparing older athletes with older controls or with both sedentary and active younger individuals. Mean differences (MDs) with 95%CIs were used for data reporting.
Results: From 25,910 screened studies, 61 studies including 75 cohorts were deemed of good quality, encompassing 1393 older athletes, 1369 older controls, 402 young sedentary controls, and 283 young active individuals. In comparison to older controls, older athletes exhibited significantly improved vascular parameters (systolic [MD = -5.04 mmHg] and diastolic [MD = -2.03 mmHg] blood pressure), cardiac (heart rate frequency [MD = -10.41 bpm]), and metabolic parameters (serum cholesterol profile). Conversely, when compared to young sedentary controls, older athletes displayed a less favorable blood pressure and metabolic (cholesterol, glucose) profile. Similar trends were observed when comparing older athletes to young active controls. Sensitivity and meta-regression analyses suggested that exercise lasting over 30 y might offer partial benefits for several markers of cholesterol and VO2max.
Conclusion: Lifelong exercise plays a crucial role in enhancing cardiometabolic parameters, although it may not fully replicate the metabolic and cardiovascular health observed in younger individuals.

P993
DEFERIPRONE ATTENUATES ESTROGEN DEFICIENCY-INDUCED OSTEOPOROSIS THROUGH PROMOTING COUPLING OF OSTEOGENESIS AND ANGIOGENESIS VIA INHIBITING FERROPTOSIS

N. Wang[1], F. Wang[1]

[1]Zhejiang Academy of Traditional Chinese Medicine, Hangzhou, China

Objective: Defective coupling of osteogenesis and angiogenesis is an important characteristic of postmenopausal osteoporosis. Increasing evidences and our previous work have proved that ferroptosis pathway was significantly activated in the development of postmenopausal osteoporosis[1]. Deferiprone (DFP) has been clinically used in treating transfusional iron overload in thalassemia patients. However, the effects and underlying mechanism of DFP on osteogenesis and angiogenesis coupling remain unclear. The present work aimed to test the hypothesis that DFP promotes coupling of osteogenesis and angiogenesis by suppressing ferroptosis, and exerts anti-osteoporosis effect under estrogen-deficient conditions.
Methods: The osteoporosis mouse model was established by bilateral ovariectomy (OVX) operation. We cultured iron overload-induced bone marrow mesenchymal stem cells (BMSCs) and endothelial cell (ECs) cell models.
Results: Estrogen deficiency led to a significant decrease of BMD and $CD31^{hi}endomucin^{hi}$ vessels in femurs in OVX-induced mice. Based on our data from BMSCs and ECs co-culture experiments, iron overload resulted in accumulated mitochondrial reactive oxygen species, furtherly increased lipid peroxidation deposition, ultimately led to ferroptosis. Iron overload also suppressed the secretion of slit guidance ligand 3 and vascular endothelial growth factor A, which are important factors in coupling of osteogenesis and angiogenesis. Importantly, DFP could reverse the lipid peroxidation, inhibit ferroptosis, improve osteogenesis and angiogenesis in the OVX-induced mice. In vitro results demonstrated that DFP suppressed ferroptosis in iron-overload-induced BMSCs and ECs models, and subsequently improved osteogenesis differentiation of BMSCs and tube formation ability of ECs.
Conclusion: Ferroptosis is one of key mechanisms of defective coupling of osteogenesis and angiogenesis in postmenopausal osteoporosis. We reveal that DFP promotes osteogenesis and angiogenesis coupling by inhibiting estrogen-deficiency-induced ferroptosis.

IMPROVING FRAGILITY FRACTURE CARE IN A NEW ZEALAND RURAL SETTING

N. Ward[1], E. Venecourt-Jackson[1], T. Wilson[1], D. Lee[1]

[1]Fracture Liaison Service Team, Whakatane Hospital, Hauora a Toi Bay of Plenty, Tauranga, New Zealand

Objective: Improving hip fracture bone protection medication use in a small rural hospital.
Methods: The Australian New Zealand Hip Fracture Registry (ANZHFR)[1] collects data on bone protection medication outcomes after hip fracture. Data for Whakatane hospital, a small rural hospital in the Eastern Bay of Plenty (EBOP) with a population of 56, 000 covering a large geographical area, with a significant proportion of our patients living in rural settings combined with a large Māori population (40%)[2], showed < 10% of patients were treated post hip fracture from 2017–2020. An orthogeriatric service started in August 2019 and a full complement of a Fracture Liaison Service (FLS) commenced in July 2021. We wanted to assess the impact of this service on the use of bone protection medication for hip fracture patients in the EBOP population.
Results: Prior to 2020, Whakatane hospital was achieving < 10% bone protection medication for hip fracture patients. Providing a geriatrician and FLS nurse one day per week and pharmacist half a day, the ANZHFR data for bone protection medication at 120 d shows Whakatane Hospital ranked No: 1 in New Zealand for both 2021 and 2022, with over 80% of their patients given bone protection medication.
Conclusion: Given the rural setting, both treatment and review in the community is a challenge due to accessibility and cost. The introduction of a hospital orthogeriatric service and FLS working together with dedicated follow up has significantly improved bone protection medication use for hip fracture patients and now has the ANZHFR bone protection medication at 120-day outcome as the best in New Zealand.

INTEGRATING A FRAGILITY FRACTURE REGISTRY WITH AN FLS PATIENT MANAGEMENT SYSTEM: THE NEW ZEALAND EXPERIENCE

N. Ward[1], D. Mackenzie[2], F. Anderson[3], R. Harris[3], C. Gill[2], P. Mitchell[2], S. Stewart[4], D. Kim[5], K. Kim[2], A. Roddick[2]

[1]New Zealand arm of Australian and New Zealand Fragility Fracture Registry, Wellington, New Zealand, Tauranga, New Zealand, [2]Osteoporosis New Zealand, Wellington, Auckland, New Zealand, [3]New Zealand arm of Australian and New Zealand Fragility Fracture Registry, Wellington, New Zealand, [4]OperaIT Data Services, Logan, Queensland, Brisbane, Australia, [5]Diabetes and Endocrinology Services, North Shore Hospital, Te Whatu Ora Waitematā, Auckland, New Zealand

Objective: Implementing the nationwide rollout of the newly developed Australia & New Zealand Fragility Fracture Registry (ANZFFR) in New Zealand, which serves as both a data collection tool for measuring against clinical standards and a tailored Patient Management System (PMS) for Fracture Liaison Services (FLS).
Methods: The ANZFFR, designed as a PMS, integrates National Clinical Standards as Key Performance Indicators into a software application, encompassing patient information, diary management, and treatment guidance. FLS teams, including administrative staff, received training for day-to-day registry management upon securing ethics approval at each site. The continuously updated registry dashboards allow teams to assess their performance against national KPIs effortlessly. Substantial funding for FLS expansion was secured through negotiations between Osteoporosis New Zealand (ONZ) and the Accident Compensation Corporation of New Zealand (ACC), with the aim of enhancing national compliance with care standards. Extensive piloting with FLS teams refined functionality, leading to the registry going live in May 2022 after receiving national ethics approval in December 2021.
Results: By November 2023, 21 out of 22 FLS teams in New Zealand, covering 95% of the population, have adopted the ANZFFR as their PMS. Feedback from FLSs is overwhelmingly positive, with many regarding the PMS as a valuable labour-saving tool. As of 10 January 2024, 19,785 patients counts and 20,837 fragility fractures recorded.
Conclusion: The successful nationwide rollout of the ANZFR represents a significant achievement in advancing FLS in New Zealand. This success is indicative of the team's acknowledgment of the registry as an efficient patient management system, offering time savings, valuable real time service data, with a responsive and effective support system. With the first annual report released March 2024 (for July 2022-June 2023 data for 11,600 patients).

TRENDS IN PREVALENCE OF HYPOVITAMINOSIS D OVER A 10-YEAR PERIOD IN JAPAN: RESEARCH ON OSTEOARTHRITIS/OSTEOPOROSIS AGAINST DISABILITY (ROAD) STUDY

N. Yoshimura[1], T. Iidaka[1], G. Tanegashima[1], S. Muraki[1], H. Oka[2], K. Nakamura[3], S. Tanaka[4]

[1]Dept. of Prev. Med. for Locomotive Organ Disorders, The Univ. of Tokyo, [2]Division of Musculoskeletal AI System Development, Faculty of Medicine, The Univ. of Tokyo, [3]Towa Hospital, [4]Dept. of Orthopaedic Surgery, Sensory and Motor System Medicine, Graduate School of Medicine, The Univ. of Tokyo, Tokyo, Japan

Objective: To clarify the trends in the prevalence of vitamin D insufficiency and deficiency among general inhabitants using population-based cohort data from the baseline and a survey conducted 10 y later.
Methods: The baseline survey of the Research on Osteoarthritis/Osteoporosis Against Disability (ROAD) study was conducted from 2005–2007. Blood examination was performed to measure serum 25-hydroxyvitamin D (25D) and intact PTH levels in 1683 participants (595 men, 1088 women). Participants completed an interviewer-administered questionnaire, underwent measurements of BMD, and had X-ray examinations. The fourth survey was conducted from 2015–2016; 1902 individuals (636 men, 1,266 women) completed assessments identical to those in the baseline survey. Vitamin D deficiency and insufficiency were defined by serum 25D levels < 20 ng/mL and ≥ 20 ng/mL but < 30 ng/mL, respectively.
Results: The mean levels of serum vitamin D were 23.3 ng/mL at baseline and 25.1 ng/mL in the fourth survey, respectively, which

increased significantly (baseline vs. 4th, $p < 0.0001$). The prevalence of vitamin D insufficiency at baseline and the 4th survey was 52.9% and 54.8%, respectively, and those of deficiency was 29.5% and 21.6%, respectively. The proportion of hypovitaminosis D decreased significantly over 10 years (baseline 82.5% vs. 4th 76.5%, $p < 0.001$). **Conclusion:** In the population-based survey with a 10-y interval, the prevalence of hypovitaminosis D decreased significantly. This favorable change could contribute to the decrease in the occurrence of osteoporosis and osteoporotic fractures in the future.

EFFECT OF RADISH (*RAPHANUS SATIVUS*) DERIVED EXOSOMES ON OSTEOARTHRITIS

N. Ünsal[1], M. Y. C. Yıldırım Canpolat[1], O. E. Eren[1], B. K. Kabataş[1], F. Şahin[1]

[1]Yeditepe Univ., Biotechnology, İstanbul, Turkey

Osteoarthritis (OA), characterized by articular cartilage loss, is a well-established cause of impairment. Given the underlying pathology of OA, it is clear that injured cartilage has a low ability for regeneration. This means the proposed action is essential. Deterioration of articular cartilage, alterations in subchondral bone, and synovitis are hallmarks of this complex illness. Current OA treatments focus mostly on alleviating symptoms like pain and inflammation rather than stopping the disease itself from progressing. There is a significant knowledge gap when it comes to the mechanism that contribute to the OA development. Articular cartilage's extracellular matrix homeostasis is kept in check by a delicate balancing act between anabolic and catabolic pathways; abnormalities in this equilibrium are linked to OA. Chondrocytes are the special cells that make up cartilage in joints. Collagens, proteoglycans, and non-collagen proteins are all synthesized by these cells to form the extracellular matrix. Chondrocyte responses to molecular cues vary between areas and stages of illness, suggesting that mechanical stress and biochemical variables play major roles in disease development. In this regard, the utilization of plant-based products in the treatment of medical disorders is gradually becoming a preferred option due to the fewer negative effects associated with these items. In this respect, objective of this study to examine potential effects of *Raphanus sativus* derived exosomes on OA treatment by defining proliferative, anti-inflammation potential and upregulating cartilage specific activities on protein and gene expression levels for osteoarthritis. Our results demonstrated that, *Raphanus sativus* derived exosomes has anti-inflammation effect on OA while decreasing expression of IL-1β and IL-6 levels and inducing TGFβ. Also, these exosomes has proliferative effect on OA chondrocyte cells while promoting main extracellular matrix components. Based on these findings, *Raphanus sativus* derived exosomes appear as a potential therapeutic for OA treatment.

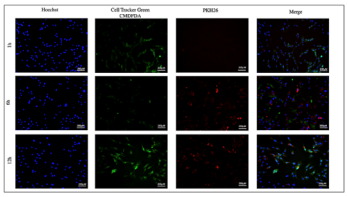

Figure 4. 3. Uptake images HC-OA cells with 100 µg/mL of *R. sativus* exosomes for 1st, 6th and 12th hour (20X magnification)

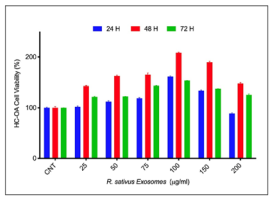

Figure 4. 2. Different doses of *R.sativus* exosomes between 25-200 µg/mL effects on HC-OA cells for 3 days and proliferation percentages compared to control group. The results are the mean standard deviation of three separate experiments.

EFFECT OF ANTIHYPERTENSIVE MEDICATIONS ON BONE MINERAL DENSITY IN ADULTS AGED 18 YEARS AND ABOVE AT A TERTIARY CARE HOSPITAL IN TAIWAN

N.-C. Shih[1,2]

[1]Dept. of Family Medicine, Taichung Veterans General Hospital, [2]Institute of Medicine, Chung Shan Medical Univ., Taichung, Taiwan

Objective: To investigate the effect of classic antihypertensive drugs on BMD and risk of osteoporosis among adult hypertensive patients.
Methods: In this cross-sectional study, adults (≥ 18 y) diagnosed with hypertension were consecutively enrolled at a single medical center from January 2000 to December 2021. Individuals who had been taking antihypertensive medications for more than 3 months after the diagnosis of hypertension and had undergone DXA examination were further selected for the study. We evaluated differences in femoral neck and lumbar spine BMD and estimated the odds ratios (ORs) of osteoporosis between adults groups with different antihypertensive use.
Results: A total of 1255 patients (584 males and 671 females) with mean age of 69.7 ± 12.5 y were included. Among them, 574 individuals were diagnosed with osteoporosis, 504 with osteopenia, and 177 with normal bone density. Regardless of femoral neck BMD, lumbar spine BMD, T-score (spine), or T-score (femur), there were significant differences among individuals taking different antihypertensive drug (angiotensin-converting enzyme [ACE] inhibitors/angiotensin receptor blockers [ARBs], calcium channel blockers [CCBs], combined users) ($P < 0.01$). Patients using ACE inhibitors/ARBs (OR = 0.66; 95%CI 0.51, 0.86; p = 0.002), β-blockers (OR = 0.54; 95%CI 0.40, 0.74; $p < 0.001$) showed a lower risk of osteoporosis compared to those on CCBs as the reference group.
Conclusion: Compared to patients with hypertension who take CCBs, those treated with ACE inhibitors, ARBs, or β-blockers demonstrated a greater reduction in the risk of osteoporosis.
Acknowledgments: Thanks to Chiann-Yi Hsu and Biostatistics Team at Taichung Veterans General Hospital, Taichung, Taiwan.

EXPERIMENTAL CORRECTION OF THYROID STATUS IN PATIENTS WITH RHEUMATOID ARTHRITIS

O. A. Rusanova[1], O. I. Emelianova[1], S. S. Spitsina[1], A. S. Trofimenko[1], S. A. Bedina[1]

[1]Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky, Volgograd, Russia

Системные аутоиммунные заболевания, развивающиеся вследствие недостатков иммунной регуляции, приводят к неконтролируемой гиперпродукции антител к компонентам собственных тканей человека и развитию аутоиммунного воспаления, в которое вов, лекается, в том числе, и щитовидная железа. Для устранения антител из крови мы используем метод гемосорбции с использованием иммобилизованных гранулированных препаратов с магнитными свойствами — модификацию, предложенную Гонтаром и др. в 2007 году.
Цель. Изучить in vitro изменения продукции антител к гормонам щитовидной железы (трийодтиронину и тироксину) на экспериментальной модели гемосорбции у больных ревматоидным артритом.
Методы. Под наблюдением находились семьдесят пять больных ревматоидным артритом; из них у 25 человек было сопутствующее заболевание щитовидной железы. Вторую группу составили 65 больных с диагнозом системная красная волчанка; из них у 33 человек были заболевания щитовидной железы. В третьей группе из 42 больных системной склеродермией у 9 человек имелось заболевание щитовидной железы. Группу сравнения составили 30 практически здоровых лиц. Антитела к трийодтиронину и тироксину определяли методом твердофазного иммуноферментного анализа с использованием иммобилизованных гранулированных препаратов этих гормонов. Элиминацию антител достигали пропусканием крови через полиакриламидный носитель с магнитными свойствами (как сорбент) с ковалентно иммобилизованными тиреоидными гормонами с помощью перистальтического насоса. Гормоны вводили в гранулированный препарат методом эмульсионной полимеризации с последующей фиксацией глутаровым альдегидом. Антитела измеряли до и после сорбции.
Полученные результаты. В контрольной группе антитела к трийодтиронину измеряли 0,033 ± 0,022 единицы поглощения, а антитела к тироксину—0,045 ± 0,018 единиц поглощения. У больных ревматоидным артритом до сорбции уровень антител к трийодтиронину составлял 0,132 ± 0,027 единиц оптической плотности, а антител к тироксину—0,156 ± 0,06 единиц оптической плотности. После сорбции уровень антител к трийодтиронину составил 0,037 ± 0,007 единиц оптической плотности, а антител к тироксину—0,039 ± 0,009 единиц оптической плотности. Во второй группе больных системной красной волчанкой исходные значения составили 1,127 ± 0,064 ед. оптической плотности и 0,135 ± 0,077 ед. После процедуры значения составили 0,82 ± 0,008 единиц оптической плотности и 0,062 ± 0,007 единиц оптической плотности. В третьей группе больных системной склеродермией до сорбции уровень антител к трийодтиронину находился в пределах 0,129 ± 0,056 единиц поглощения, антител к тироксину—0,146 ± 0,026 единиц поглощения; после процедуры значения составили 0,057 ± 0,009 единиц оптической плотности и 0,048 ± 0,008 единиц оптической плотности соответственно.
Заключение. Экспериментальная модель гемосорбции с использованием сорбентов на основе гормонов щитовидной железы для элиминации антител из крови больных ревматоидным артритом показала достоверное снижение антител к трийодтиронину и тироксину по сравнению с исходными значениями. Уровень этих антител стал соответствовать уровню антител в контрольной группе, что позволило улучшить состояние щитовидной железы у пациентов с системными нарушениями и нормализовать функцию щитовидной железы.

P1000
AUTOIMMUNE MARKERS OF NERVOUS SYSTEM LESION IN PATIENTS WITH RHEUMATOID ARTHRITIS

O. A. Rusanova[1], O. I. Emelianova[1], S. S. Spitsina[1], A. S. Trofimenko[1], S. A. Bedina[1]

[1]Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky, Volgograd, Russia

Широкий спектр патологических неврологических признаков у больных аутоиммунными системными заболеваниями позволяет рассматривать их как модельные системы для изучения патогенетического механизма развития поражений центральной и периферической нервной системы. Потенциальными мишенями аутоиммунной агрессии могут быть различные биополимеры нервной ткани, в том числе миелин, его основной белок и белок S-100.

ЦЕЛЬ. Определение диагностической значимости аутоантител к основному белку миелина (ОБМ) и белку S-100 для прогнозирования неврологических нарушений центральной и периферической нервной системы у больных ревматоидным артритом.

МАТЕРИАЛЫ И МЕТОДЫ. В исследование вошли 94 пац, иента, госпитализированных в 25 городских больниц с диагнозом ревматоидный артрит. Антитела к ОБМ и белку-100 определяли в сыворотке крови методом непрямого иммуноферментного анализа (ИФА) с использованием магнитных сорбентов, магнитные сорбенты синтезировали методом эмульсионной полимеризации в токе газообразного азота.
ПОЛУЧЕННЫЕ РЕЗУЛЬТАТЫ. В сыворотке крови здоровых лиц уровень антител к ОБМ составлял 0,03 ± 0,01 ЕД, антител к белку S-100—0,02 ± 0,01 ЕД. Повышенные антитела к ОБМ выявлены у 37 (39,4%) больных ревматоидным артритом, пов, ышенные антитела к S-100 выявлены у 30 (32,4%) больных ревматоидным артритом. Высокий уровень антител к BMP и белку S-100 при ревматоидном артрите связан с поражением централ, ьной и периферической нервной системы. При ревматоидном артрите максимальные значения антител к ОБМ выявлены у больных с периферическим поражением периферической нервной системы (мононевропатия и невралгия тройничного нерва) и ЦНС (нарушения сна, фиксационная амнезия, забывание давно минувших событий, дизартрия, поражение лобных долей и эпилептиформные припадки, вертебробазилярная недостаточность).
ВЫВОДЫ. Выявленные закономерности поражения периферической и центральной нервной системы у больных ревматоидным артритом с повышенным уровнем антител к ОБМ позволяют прогнозировать клиническое течение заболевания и обеспечить раннее лечение начинающегося заболевания.

BONE MINERAL DENSITY CURVE FROM A QATARI POPULATION: DATA FROM QATAR BIOBANK

O. Alsaed[1], F. Alam[1], N. Abdulla[1], I. Abdulmomen[1], A. Lutf[1], S. Alemadi[1]

[1]Hamad Medical Corporation, Dept. of Medicine, Rheumatology Division, Doha, Qatar

Objective: Based on the available hip fracture data from the gulf cooperation council (GCC) countries, the incidence rate of fragility fracture is much lower to that of European and North American populations which makes populations from GCC to have a lower probability of fracture risk when these fracture data are used to formulate each nation fracture risk assessment (FRAX®) tool. In light of this, we hypothesized that the BMD of Arab population is also different from North America and European countries. We aimed to generate a reference BMD curve of neck of femur (NOF) and total hip (TH) from Qatari healthy individuals and compare it with age-sex matched individuals from US NHANES (National Health and Nutrition Examination Survey) population (Z score).
Methods: BMD readings of Qatari individuals aged between 20–69 years old were obtained from Qatar Biobank i-DXA (Lunar®) database. The exclusion criteria were: history of major osteoporotic fracture, renal impairment (eGFR < 60 ml/min), primary hypo/hyper parathyroid diseases, uncontrolled hyperthyroidism, hyperadrenalism, hypogonadism, active malignancy or history of malignancy, chronic liver diseases, inflammatory bowel disease, uncontrolled diabetes mellitus type II (HbA1c > 6.5), diabetes mellitus type I, early oophorectomy or early menopause (below age of 45), severe deficiency of 25 hydroxyvitamin D < 20 ng/ml (50 nmol/L), any autoimmune rheumatic diseases, history of using anti-osteoporosis drugs, chronic use of systemic glucocorticoid, sex hormone deprivation therapy, anticonvulsants and heparin, BMI < 18 or > 35 kg/m^2 and participants with short stature < 150 cm. The study population was divided into five 10-y age groups: 20–29, 30–39, 40–49, 50–59, and 60–69. Conventionally, the sample size of 30 is sufficient for normative measures.
Results: 523 subjects were captured. Female to male ratio for each age group 20–29, 30–39, 40–49, 50–59, and 60–69 was 62:51, 74:80, 40:48, 40:40 and 41:47, respectively. Males had higher BMD in all age groups in both NOF and TH. BMD peaked at age of 20 s in males and at age of 30 s in females (Fig. 1). The lowest Z-score (-0.957) was observed at females age group 20–29 (Table 1).

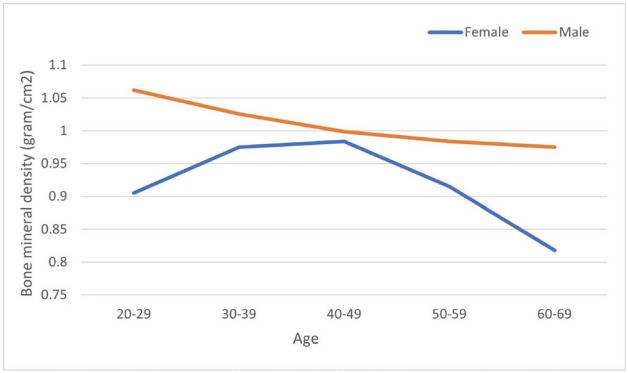

Figure 1. Comparison between males and females' neck of femur BMD at different age groups.

Table 1. Mean BMD (standard deviation) of neck of femur and total hip at different age groups with the corresponding mean Z-score.

	Female				Male			
Age	No.	Total hip (SD)	NOF (SD)	NOF Z-score	No.	Total hip (SD)	NOF (SD)	NOF Z-score
20-29	62	0.929 (0.102)	0.905 (0.109)	-0.957	51	1.073 (0.136)	1.062 (0.133)	-0.181
30-39	74	1.009 (0.124)	0.975 (0.123)	-0.189	80	1.057 (0.140)	1.026 (0.144)	-0.190
40-49	40	1.022 (0.130)	0.984 (0.153)	0.202	48	1.067 (0.127)	0.999 (0.129)	-0.107
50-59	40	0.973 (0.132)	0.915 (0.126)	0.060	40	1.074 (0.114)	0.984 (0.111)	0.094
60-69	41	0.910 (0.107)	0.818 (0.115)	-0.208	47	1.077 (0.134)	0.975 (0.130)	0.305
No, number; NOF, neck of femur; SD, standard deviation								

Conclusion: The NOF Z-score of the healthy Qatari individuals is within 0.3 standard deviation except for females at age of 20 s, it is close to 1.

P1002
CLINICAL CHARACTERISTICS AND MAJOR ADVERSE CARDIOVASCULAR EVENTS IN PATIENTS USING ROMOSOZUMAB

O. Alsaed[1], I. Abdulmomen[1], S. Alemadi[1]

[1]Hamad Medical Corporation, Dept. of Medicine, Rheumatology Division, Doha, Qatar

Objective: Usually, patients with osteoporosis are elderly and have multiple cardiovascular disease comorbidities. Romosozumab is a novel anabolic agent that is approved for postmenopausal women with very high-risk profile for fragility fractures. The USA of Food and Drug Administration has labeled romosozumab use as a potential risk for myocardial infarction, stroke, and cardiovascular death. Which hinders physicians in prescribing this agent. We aimed to elaborate the number of major adverse cardiovascular events (MACE) and ischemic stroke associated with romosozumab use in Qatar population from Jan 2020 to Dec 2023.
Methods: All prescriptions of romosozumab were captured electronically from the database of the pharmacy of Hamad Medical Corporation (HMC) from Jan 2020 to Dec 2023. Patients with nondispensed prescriptions were excluded from the analysis. Electronic medical records (EMR) of these patients were reviewed retrospectively to identify the demographic and clinical characteristics, baseline atherosclerotic cardiovascular disease (ASCVD) score, starting and stopping dates of romosozumab, MACE and ischemic stroke during romosozumab use.

Results: 31 romosozumab prescriptions were identified from the database of the pharmacy of HMC during the study period. Data of three subjects were excluded from the analysis as their prescriptions were not dispensed. The total number of patients who received romosozumab during the study period was 28 subjects with mean (± SD) age 67.6 (± 11.5) y. Females were 26 (92%) subjects. The baseline ASCVD score was as the following: low risk 8 (28%), borderline 2 (7.1%), intermediate 6 (21.4%), and high 7 (25%). ASCVD score was not assessable in 5 subjects due to missing variables from EMR. 15 (53.6%) subjects had at least one fragility fracture. The mean (± SD) T-score of the cohort received romosozumab was -3.3(± 0.8). Anti-osteoporosis medications naïve subjects were 16 (57.1%). The number of subjects who received zoledronic acid, alendronate, denosumab or teriparatide before romosozumab was 5(17.9%), 3(10.7%), 5(17.9%) 5(17.9%), respectively. The mean (± SD) duration of romosozumab therapy was 10.6 (± 4.7) months. Two subjects stopped romosozumab before completing the 12 months therapy for nonmedical reasons. One subject received romosozumab for two years. No reports of MACE or ischemic stroke from this cohort during the study period.
Conclusion: There were no MACE or ischemic stroke reports during receiving romosozumab in patients with high risk ASCVD score. This finding needs to be confirmed in a larger population with comparator arm.

P1004
GENDER DISPARITIES IN AXIAL SPONDYLOARTHRITIS: UNRAVELING CLINICAL CHARACTERISTICS AND DISEASE DYNAMICS

O. Boudriga[1], H. Ferjani[1], D. Ben Nessib[1], K. Maatallah[1], D. Kaffel[1], W. Hamdi[1]

[1]Kassab Institute of Orthopedics, Rheumatology, Tunis, Tunisia

Objective: Axial spondyloarthritis (AxSpA) is a chronic inflammatory rheumatic disorder subdivided into radiographic AxSpA (r-AxSpA) and non-radiographic AxSpA (nr-AxSpA). Historically, SpA was predominantly considered a male disease. However, increased disease awareness has altered this perspective, leading to a greater inclusion of women. This study aims to examine the clinical presentation, disease onset characteristics, metrology, HLA frequency, and clinical features of male and female AxSpA patients.
Methods: A retrospective study was conducted, including 115 patients meeting the Assessment of SpondyloArthritis International Society (ASAS) classification criteria for AxSpA published in 2009. We compared features between genders and utilized SPSS 26.0 for statistical analysis.
Results: The study comprised 40 (34.8%) females and 75 (65.2%) males. Statistically significant differences in ASAS classification were observed; nr-AxSpA was more prevalent among females (67.5%) than males (17.3%), P = 0.01. HLA-B27 frequency was comparable between men and women (45.9 vs. 40%, P = 0.594). Symptom distribution at disease onset was similar in both genders. Enthesopathy was more prevalent among women than men (57.5 vs. 37.3%, P = 0.038). Coxitis was significantly predominant in males than females (52.5 vs. 16.7%, P < 0.0001). No differences were noted in extra-articular manifestations (uveitis, psoriasis, and inflammatory bowel disease). In males, disease onset was more acute (47.5 vs. 16.7%, P < 0.001). The age at the beginning of the disease was 39.95 ± 11.05 y for females and 28.45 ± 10.47 y for males (P < 0.001). The time to diagnosis (in months) was 34 [11.5–132] for females and 14 [3–60] for males (P < 0.001). Both men and women had comparable functional impairment measured by BASFI (50 vs. 44.1%, p = 0.570) and disease activity measured by ASDAS CRP (44.4 vs. 38.9%, p = 0.931).
Conclusion: Nr-AxSpA is more frequent in women than in men, although radiographic disease is more prominent in men. The prevalence of HLA-B27 is comparable in both genders with AxSpA. Males are older at the onset of the disease and were diagnosed sooner than females. Females had similar disease activity and functional impairment as males.

P1005
ASSESSMENT OF CLINICAL, RADIOLOGICAL, AND BIOLOGICAL CHARACTERISTICS IN AXIAL SPONDYLOARTHRITIS WITH COXITIS

O. Boudriga[1], H. Ferjani[1], D. Ben Nessib[1], K. Maatallah[1], D. Kaffel[1], W. Hamdi[1]

[1]Kassab Institute of Orthopedics, Rheumatology, Tunis, Tunisia

Objective: Axial spondyloarthritis (axSpA) stands out as the most prevalent chronic inflammatory rheumatic disease involving the hips, representing a significant indicator of disease severity due to its considerable impact on functionality. This study seeks to elucidate the clinical, biological, and radiological features of axSpA with coxitis, as well as to identify factors associated with its occurrence.
Methods: A retrospective and analytical study was undertaken, encompassing patients diagnosed with axSpA. Data on demographics, clinical aspects, biological markers, radiological findings, and activity scores were collected. The significance threshold was set at $p < 0.05$.
Results: The study involved 115 axSpA patients, with 65.2% being men. The mean age was 40.6 ± 11.05 y, and the mean age at onset was 33.02 ± 10.72. Smoking prevalence was 11.3%. HLA-B27 was positive in 44.35%, and uveitis occurred in 7.83% of patients. Coxitis was present in 39.13% of patients, initiating in 11.11% and being bilateral in 66.89% of cases. Coxitis was more prevalent in men, with males constituting 75.55% in axSpA with coxitis compared to 58.57% without coxitis ($p < 0.001$). The mean age of SpA onset was lower in patients with coxitis (29.24 ± 11.5 vs. 36.61 ± 11.51 y; p = 0.003). Pure axial form and low back and buttock pain were more common in patients with coxitis (17.78 vs. 13.33%, p = 0.034, 31.11 vs. 22.22%, p = 0.023, respectively). Enthesopathy was more frequent in SpA without coxitis (53.33 vs. 31.11%, $p < 0.001$). Inflammatory markers (CRP and ESR) were significantly higher in patients with coxitis (19.16 ± 23.21 vs. 8.58 ± 14.6, p = 0.008, and 44.82 ± 25.57 vs. 24.88 ± 17.42, $p < 0.001$ respectively). No significant differences were observed between the two groups for disease activity measured by ASDAS-CRP and BASDAI (p = 0.95; p = 0.38, respectively). The frequency of a family history of SpA, smoking, HLAB27, uveitis, and the presence of radiographic sacroiliitis remained unchanged, regardless of the presence or absence of coxitis. In multivariate analysis, coxitis was associated with male gender, early age of onset, and pure axial form.
Conclusion: Our study reveals an association between the presence of coxitis and male gender, early disease onset, the pure axial form of axSpA, and biological inflammatory syndrome.

P1006
DETERMINANTS OF HIP INVOLVEMENT IN AXIAL SPONDYLOARTHRITIS

H. Ferjani[1], O. Boudriga[1], D. Ben Nessib[1], K. Maatallah[1], D. Kaffel[1], W. Hamdi[1]

[1]Kassab Institute of Orthopedics, Rheumatology, Tunis, Tunisia

Objective: Hip involvement in axial spondyloarthritis (axSpA) significantly contributes to the functional prognosis and adversely impacts the patient's quality of life (1). Recognizing these factors has

the potential to shape our management strategy through the formulation of targeted therapeutic protocols. This study aims to ascertain the factors associated with hip involvement in spondyloarthritis.

Methods: This single-center prospective observational study was conducted between June 2021 and June 2023. AxSpA patients meeting ASAS criteria were included, and comprehensive clinical, biological, and imaging data were collected on a patient-by-patient basis.

Results: A total of 115 axSpA patients were evaluated, with 39.13% (45 patients) exhibiting hip involvement. Among these, there were 34 men and 11 women (gender ratio = 3.09), with an average age of 40.6 ± 11.05 y. The biological inflammatory syndrome was observed in 68.89% of cases, and HLA B27 was found in 35.56% of patients. Anatomio-radiological forms included the destructive form (37.78%), condensant constructive form (22.22%), initial form (24.44%), and synostotic form (15.56%). TNFα treatment was initiated in 68.89% of cases, with a third of patients undergoing total hip arthroplasty. Factors associated with hip involvement included functional impotence assessed by BASFI ($p = 0.002$), limitation of spinal and joint mobility by BASMI ($p < 0.001$), structural damage by total BASRI ($p < 0.001$), and initiation of anti-TNFα treatment ($p = 0.003$). Conversely, the age of hip involvement, gender, bilateral involvement, high scores of the BASDAI and ASDAS indices, and the presence of biological inflammatory syndrome did not appear to be implicated.

Conclusion: Hip involvement in axSpA appears to be prevalent in our country, serving as a significant predictor of poor prognosis and indicating a severe form of the disease.

P1007
ASSESSING DISEASE ACTIVITY AND FUNCTION IN PATIENTS WITH NONRADIOGRAPHIC AXIAL SPONDYLOARTHRITIS: A COMPARISON BETWEEN CLINICAL AND IMAGING ARMS

O. Boudriga[1], H. Ferjani[1], D. Ben Nessib[1], K. Maatallah[1], D. Kaffel[1], W. Hamdi[1]

[1]Kassab Institute of Orthopedics, Rheumatology, Tunis, Tunisia

Objective: The concept of axial spondyloarthritis (axSpA) and nonradiographic axSpA (nr-axSpA), a subgroup of axSpA, has recently emerged. There are several studies proving the similar levels in disease activity and quality of life in patients with or without structural damage in spondyloarthritis. The aim of this study is to compare disease activity, functional status and quality of life in patients from the clinical and imaging arm of nonradiographic axial spondyloarthritis.

Methods: A cross-sectional survey was conducted in 40 patients with nr-axSpA meeting the Assessment of SpondyloArthritis International Society (ASAS) classification criteria published in 2009. Demographics and clinical data were collected. Disease activity (BASDAI) and functional status (BASFI) were compared between the patients with or without MRI data for sacroiliitis. The level of significance was set to 0.05.

Results: A total of 34 patients from the imaging arm of nonradiographic arm and 12 patients from the clinical arm of nr-axSpA patients were included in this analysis. A higher proportion of patients from the imaging arm were female patients (68.9 vs. 32.1%). The mean age was 39.8 ± 11.08 in the imaging arm and 39.67 ± 11.57 in the clinical arm ($p = 0.865$), with mean symptoms duration in both groups respectively 3.76 ± 3.46 and 2.75 ± 1.48 y ($p = 0.345$). The mean value of C-reactive protein was predominant in the imaging arm (15.81 ± 15.59 and 7.05 ± 10.04, $p = 0.028$). The disease activity determined using BASDAI was 5.3 ± 2.01 vs. 4.8 ± 2.18 ($p = 0.594$) and using ASDAS-CRP 2.31 ± 0.87 vs. 2.05 ± 0.52 ($p = 0.835$) in the imaging and clinical arm. The evaluation of the function BASFI was 4.96 ± 1.22 vs. 4.48 ± 1.14, $p = 0.865$ in both groups of patients with nr-axSpA.

Conclusion: Patients in the both imaging and clinical arms of nr-axSpA exhibit similar clinical features, with a notable predominance of biological inflammatory syndrome in the imaging arm. The functional status of the disease remains comparable among the investigated subgroups of nr-axSpA patients.

P1008
DETERMINANTS OF CERVICAL PROGRESSION IN INDIVIDUALS WITH AXIAL SPONDYLOARTHRITIS

H. Ferjani[1], O. Boudriga[1], D. Ben Nessib[1], K. Maatallah[1], D. Kaffel[1], W. Hamdi[1]

[1]Kassab Institute of Orthopedics, Rheumatology, Tunis, Tunisia

Objective: The assessment of cervical, lumbar spinal structures, and hip joints holds significant importance, as reflected in variables within scoring systems for patients with axial spondyloarthritis (axSpA). This study aimed to investigate the factors contributing to cervical spinal progression in patients with axSpA.

Methods: Patients diagnosed with axSpA, whose cervical modified Stoke Ankylosing Spondylitis Spinal Score (mSASS) was evaluated through cervical X-rays, were included in the study. Demographic, clinical, and laboratory characteristics were recorded. The relationship between the presence of cervical structural damage and other factors was assessed through both univariate and multivariate analyses.

Results: Among the 115 patients in the study, 65.22% were male, and the median age at diagnosis (IQR) was 33 (14). Additionally, 65.22% of the patients had radiographic axSpA. Demographic, clinical, and laboratory characteristics were comparable in the study groups. Cervical involvement was identified in 21 patients (18.26%). The presence of cervical structural damage was associated with symptom duration ($p = 0.004$), age at symptom onset ($p = 0.011$), age at diagnosis ($p < 0.001$), the presence of total ankylosis in sacroiliac joint X-ray ($p < 0.001$), cervical mSASS score ($p < 0.001$), the presence of cervical syndesmophyte ($p < 0.001$), and baseline lumbar mSASS score ($p < 0.001$). Cervical progression did not show associations with HLA-B27, smoking, the presence of either extramusculoskeletal or peripheral involvement, nor with disease activity scores (BASDAI, ASDAS-CRP). In multivariate analysis, age at diagnosis ($p < 0.001$), the presence of cervical syndesmophyte ($p = 0.014$), and sacroiliac joint score ($p = 0.004$) were identified as factors associated with cervical progression.

Conclusion: It is essential to consider age at diagnosis, the presence of spinal involvement, and sacroiliac joint score as potential predictors of cervical spinal progression during the follow-up of axSpA patients.

P1009
COST-EFFECTIVENESS ANALYSIS OF PHARMACEUTICAL-GRADE CHONDROITIN SULFATE IN THE TREATMENT OF KNEE OSTEOARTHRITIS: A POST HOC ASSESSMENT DERIVED FROM INDIVIDUAL PATIENT DATA FROM A RANDOMISED CLINICAL TRIAL

O. Bruyère[1], J.-Y. Reginster[1]

[1]1 WHO Collaborating Center for Epidemiologic Aspects of Musculo-skeletal Health and Ageing, Division of Public Health, Epidemiology and Health Economics, Univ. of Liège, Belgium, Liège, Belgium

Objective: In a previously published randomised, placebo-controlled trial, 800 mg/d of pharmaceutical-grade chondroitin sulfate (CS) was shown to be superior to placebo in reducing pain and improving function over 6 months in patients with symptomatic knee osteoarthritis (OA) (Reginster J-Y, et al. Ann Rheum Dis 2017;76:1537). The aim of the current post hoc analyses is to evaluate the cost-effectiveness of CS compared to placebo in a European perspective using individual patient data from this clinical trial.
Methods: Patients with knee OA randomised to CS or placebo were followed up at 1, 3 and 6 months. The algo-functional Lequesne index was used to derive the EQ-5D-5L score based on a validated formula. The EQ-5D-5L scores at each time point were used to calculate the changes in quality-adjusted life years (QALYs) with the area-under-the-curve (AUC) method. Costs were assessed using the average price of CS in the countries where (1) the original study took place and (2) CS is currently marketed. The costs of CS in 3 countries were then used (i.e., Czech Republic, Italy and Switzerland). The incremental cost-effectiveness ratio (ICER) threshold for CS to be considered cost-effective was set at 91,8705 EUR per QALY (equivalent to the usually recommended threshold of US $100,000). The study used an intention-to-treat (ITT) population, i.e., patients who received one dose of the study drug, and imputed missing values using the basal observation carried forward method.
Results: No significant differences in baseline characteristics were observed between the CS group (N = 199) and the placebo group (N = 205). The mean cost of CS for 6 months of treatment was 179 EUR. After 6 months of treatment, CS showed a mean ICER of 31,415 EUR per QALY gained, indicating cost-effectiveness compared to placebo.
Conclusion: These results highlight the role of CS as a cost-effective therapeutic option in the management of OA. However, further studies taking into account the use of other health care resources are warranted for a more complete understanding.

P1010
MAPPING THE LEQUESNE FUNCTIONAL INDEX INTO THE EQ-5D-5L UTILITY INDEX IN PATIENTS WITH KNEE OSTEOARTHRITIS

N. Dardenne[1], A.-F. Donneau[1], O. Bruyère[2]

[1]Biostatistics Center (B-STAT), Univ. Hospital and Univ. of Liège, Belgium, Liège, Belgium, [2] WHO Collaborating Center for Epidemiologic Aspects of Musculo-skeletal Health and Ageing, Division of Public Health, Epidemiology and Health Economics, Liège, Belgium

Objective: To map the Lequesne Index onto the EuroQol 5 Dimension (EQ-5D-5L) utility index in patients with knee osteoarthritis (OA).
Methods: The baseline data from a previously published randomized controlled trial were used to develop mapping functions. All patients diagnosed with knee osteoarthritis (OA) completed both the EQ-5D-5L and Lequesne questionnaires. Out of all patients included at baseline, 461 were used for the mapping development phase and 230 for the validation phase. For the development phase, various modelling techniques, including general linear models (GLM), Tobit and beta regression models, were employed to derive several mappings functions. Factors such as age, sex, and BMI were also taken into account. The selection of preferred models was based on the Akaike information criteria (AIC), the Bayesian information criteria (BIC), the adjusted R^2, the mean absolute error (MAE), and root mean squared error (RMSE). For the validation phase, the pre-selected derived functions were assessed through MAE, RMSE, and the intraclass correlation coefficient (ICC). This study follows the MApping onto Preference-based measures reporting Standards (MAPS) statement.
Results: Five models were developed by means GLM, Tobit and Beta regressions. Two models including the effect of age, sex and/or BMI and the Lequesne Index as explanatory variables presented the best goodness-of-fit indexes whatever the type of regression. For the validation phase, the predictive performance of these models was similar for the three types of regression. They also showed similar MAE and RMSE values., although the ranges obtained using the Beta regression models were wider and closer to those of the validation dataset. ICC values were also better for the Beta regression models. At last, both models tented to overpredict for lower EQ-5D-5L values while they tended to underpredict for better health status, whatever the type of regression.
Conclusion: To the best of our knowledge, these mapping functions represent the very first attempts to translate the Lequesne Index to EQ-5D-5L values in patients with knee OA. These functions demonstrated a satisfactory fit and precision, offering valuable tools for clinicians and researchers, particularly in situations where cost-effectiveness studies are required, and generic preference-based health-related quality of life instruments for utility derivation are not accessible.

Research Grant from IBSA.

P1011
COMPARISON OF REGENERATIVE METHODS IN TREATMENT OF OSTEOCHONDRAL LESIONS: EVALUATION IN AN ANIMAL MODEL

O. Burianov[1], T. Omelchenko[1], Y. E. Levytskiy[1], L. Khimion[2]

[1]Bogomolets National Medical Univ., Traumatology and Orthopedics Dept., [2]Shupyk National Healthcare Univ. of Ukraine, Internal Diseases, Family Medicine, Hematology and Transfusiology Dept., Kyiv, Ukraine

Objective: To evaluate by morphologic studies and compare results of treatment of the osteochondral lesions with use of different regenerative methods (filling with collagen-fibrin matrix, BMDCT, PRP) in experimental study on 32 rabbits.
Methods: The study included 4 series of experimental animals which were given different regenerative treatment and no treatment after artificial surgical standard osteochondral defects (SOD) had been performed. SOD was reproduced in the medial part of the femur of a critical size with a diameter of 3 mm in a depth of 5 mm. The defect was not filled (1st series, control group), filled with collagen-fibrin matrix (2nd series), collagen-fibrin matrix with PRP (3rd series) or with BMDCT (4th series). On 41st day after damage we performed histologic evaluation of the regenerate's tissue (integration into the surrounding tissues, structure, content of cellular structures,

noncellular elements, which formed in the defect) was using scale recommended by the Committee of the International Cartilage Regeneration Union (SCRS) with our modifications.
Results: Analysis of the results of treatment using a modified histological evaluation scale showed that hyaline cartilage was present only in the samples from experimental animals of series No. 3 and No. 4 and they did not show significant stratification of the surface of the cartilage. In regenerates samples from group No. 3, the formation of hyaline cartilaginous tissue with chondroblast, chondrocytes and fibrochondrocytes, which densely filled the bone and cartilage defects, was found in the area of the bone and cartilage defect. In the experimental group of animals No. 4, defects located in the articular cartilage were filled with a dense, well developed hyaline cartilaginous tissue with a high degree of integration with the edges of the defect. The comparison of the regenerates histology in the control animals (1st series) and experimental groups was performed and significant difference was found in all parameters between controls and samples from PRP and BMDCT groups, the latter demonstrated better quality of the regenerate tissue and its cellular composition.
Conclusion: Use of the regenerative techniques in treatment of the osteochondral artificial defects in experiment demonstrates better outcomes then natural healing, with the most promising results proved by morphology study in case of BMDCT application.

P1012
ASSESSMENT OF MENISCAL EXTRUSION IN PATIENTS WITH DEGENERATIVE MEDIAL MENISCUS ROOT TEAR FOLLOWING SURGICAL TREATMENT

O. Burianov[1], V. Lykhodii[1], M. Zadnichenko[1], T. Pshenychnyi[2], V. Lianskorunskyi[1]

[1]Bogomolets National Medical Univ., Dept. of Traumatology and Orthopedics, [2]SI "The Institute of Traumatology and Orthopedics" by NAMS of Ukraine, Kyiv, Ukraine

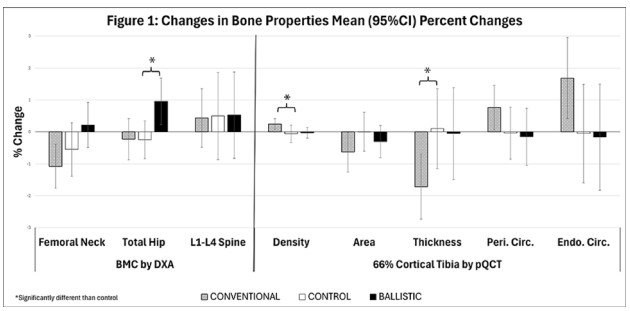
Objective: Compare of medial meniscal extrusion (MME) in patients with degenerative medial meniscal root tear (MMRT) after partial meniscectomy and transtibial medial meniscal root repair (without additional augmentation).
Methods: Observed pre- and postoperative (12 months) MRI scans of 55 patients with symptomatic degenerative medial meniscus root tear who underwent arthroscopic surgery. MME was evaluated as the distance between a vertical line passing by the outer edge of medial tibial plateaus and another vertical line tangential to the outer margin of the medial meniscus. Patients were divided into two groups. In the main group (n_m = 18) the repair of medial meniscus root tear was performed under arthroscopic control using transtibial fixation. In the comparison group (n_c = 37), a partial meniscectomy was performed, which consisted of the removal of the damaged posterior horn and part of the body of the medial meniscus under arthroscopic control.
Results: The mean age in patients of the main group was 53.61 ± 4.92 y, comparison group – 54.16 ± 4.4 y (p = 0.67). BMI in the main group was 32.1 ± 1.85, comparison group – 31.8 ± 1.92 (p = 0.68). In the main group were 14(77.8%) females and 4(22.2%) males and in the comparison group were 26 (70.3%) females and 11 (29.7%) males (p = 0.56). Before surgery, the MME in patients of the main group (n_m = 18) was 3.9 ± 1.2 mm, in the comparison group (n_c = 37)—3.2 ± 1.7 mm (p = 0.1). In the main group (n_m = 18) MME before surgery was 3.9 ± 1.2 mm and 12 months after surgery – 3.0 ± 1.8 mm (p = 0.1). In the comparison group (n_c = 37) MME before surgery was 3.2 ± 1.7 mm and 12 months after surgery – 4.0 ± 1.2 mm (p = 0.02). 12 months after surgery, on MRI in patients of the main group (n_m = 18) MME was 3.0 ± 1.8 mm, in the comparison group (n_c = 37)—4.0 ± 1.2 mm (p = 0.01).
Conclusion: Increasing of medial meniscal extrusion in patients with MMRT who underwent partial meniscectomy indicates progression of OA and worsening of MRI symptoms in short follow-up period. Medial meniscus root repair prevents further progression of the medial meniscal extrusion, and potentially it could decrease rapid progression of the knee OA, but it doesn't complete restore normal position of the medial meniscus.

P1013
EFFECT OF EIGHT MONTHS OF BALLISTIC AND CONVENTIONAL RESISTANCE EXERCISE TRAINING ON BONE STRENGTH IN POSTMENOPAUSAL WOMEN: THE REPROOF STUDY

O. Caliskan[1], E. A. Marques[1], J. P. Folland[1], K. Brooke-Wavell[1]

[1]Loughborough Univ., Loughborough, UK

Objective: High-load, progressive resistance training (RT) is recommended for osteoporosis (OP) prevention. Fast ballistic RT involves moving as explosively as possible with a light/moderate load, attempting to launch the load, if possible, to maximize power production throughout the whole movement, but effects on BMD are unknown. We aimed to investigate the influence of ballistic and conventional RT, relative to control, on BMC and BMD in postmenopausal women.
Methods: The resistance exercise programme on risk of osteoporosis and osteoarthritis in females (REPROOF) was an 8-month RCT involving healthy, postmenopausal (> 4 y) women (50–70 y), randomised to ballistic (BRT), conventional (CRT) resistance training and control (CON) groups. Both RT groups attended similar sessions twice a week with hack squats and unilateral calf raises. One repetition maximum (1RM) was measured monthly and used to determine undulating periodized loads between 20–50% 1RM in BRT and 60–80% 1RM in CRT. Both hips and lumbar spine were measured by DXA (GE iDXA), and the tibia was measured by pQCT (Stratec XCT-2000L). Group comparisons were made by regression adjusting for baseline.
Results: 109 women were randomised. 82 completed the study; 63.1 ± 3.7 y; 24.5 ± 3.5 kgm^{-2}. Femoral neck T-score -1.0. DXA scans were available in 28 BRT, 29 CRT and 25 CON and pQCT in 27 BRT, 26 CRT and 23 CON. Mean adherence was ~ 98% in RT groups. BRT showed significant improvements; total hip BMC by mean (95%CI) 0.33 (0.07, 0.59) g (p = 0.02) and BMD by 0.008 (0.001, 0.014) gcm^{-2} (p = 0.02) compared to CON. CRT increased cortical density by 3.18 (0.05,6.31) gcm^{-2} (p = 0.05) but reduced cortical thickness by -0.07 (-0.13,-0.01) mm (p = 0.03) relative to CON in (Fig. 1).



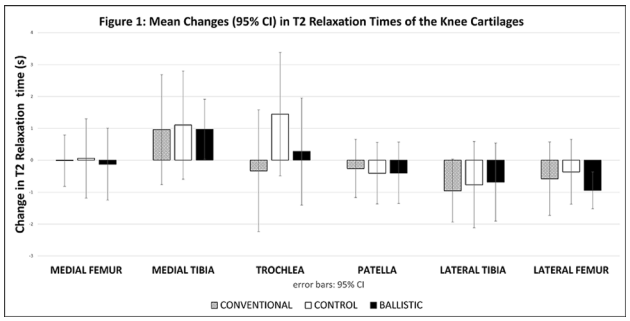
Conclusion: Ballistic RT increased total hip BMC and BMD. This contrasts with previous findings that high-load RT is necessary for bone adaptation. Ballistic RT was feasible in healthy postmenopausal women and may have a role in OP prevention.

P1014
CHANGES IN T2 RELAXATION TIMES OF THE KNEE JOINT FOLLOWING A BALLISTIC AND CONVENTIONAL RESISTANCE TRAINING PROGRAMME IN POSTMENOPAUSAL WOMEN: THE REPROOF STUDY

O. Caliskan[1], E. A. Marques[1], W. J. Rennie[2], J. P. Folland[1], K. Brooke-Wavell[1]

[1]Loughborough Univ., Loughborough, [2]Univ. Hospitals of Leicester NHS Trust, Leicester, UK

Objective: Resistance training (RT) is recommended for osteoarthritis management, but its role in prevention is less clear. T2 relaxation depends on cartilage water and collagen content, with higher values being predictive of osteoarthritis, but the effects of RT are unknown. Ballistic RT involves light to moderate loads at very high velocities, attempting to launch the load, whereas conventional RT involves higher loads at lower velocities. We aimed to investigate the change in T2 relaxation times after ballistic and conventional RT relative to controls in postmenopausal women.
Methods: The resistance exercise programme on the risk of osteoporosis and osteoarthritis in females (REPROOF) was 8-month RCT. Healthy, postmenopausal (> 4 y) women (50–70 y) were randomly allocated to ballistic (BRT), conventional (CRT), or control (CON) groups. Both RT groups attended similar twice-weekly sessions focused on hack squats and calf raises. Monthly measured one repetition maximum (1RM) used to calculate undulating periodized loads between 20–50% 1RM in BRT and 60–80% 1RM in CRT. 3D scans of the left knee were acquired by a 3 T MRI scanner (GE Discovery MR750w). Medial, trochlear, lateral femur, medial and lateral tibia, and patella T2 relaxation times were measured from sagittal T2 sequences. RM-ANOVA was used.
Results: 66 of 109 randomised participants (25BRT, 21CRT and 20CON; 63.1 ± 3.5 y; 24.7 ± 3.5 kgm^{-2}) had valid pre and post-scans. Adherence was 98% in both RT groups. Intratester CV in mapping was between 0.7 and 2.6% in all ROIs. T2 relaxation times decreased by 0.93 sn (CI: -1.51, -0.36, p = 0.003) in lateral femoral cartilage in the BRT with no difference between the RT groups and CON [group*ROI (p = 0.572) and group (p = 0.835)].



Conclusion: No significant differences were found between groups, indicating that neither type of RT had a detrimental effect on cartilage composition. BRT is feasible in this population with no adverse effects on knee cartilage despite greater impact.

P1015
DETERMINATION OF ANTIBODIES TO GLUTATHIONE PEROXIDASE IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS USING MAGNETIC-CONTROLLED IMMUNOSORBENTS

O. Emelyanova[1], O. Rusanova[1], A. Trofimenko[1], S. Spitsina[2]

[1]Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky, [2]Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky, Volgograd State Medical Univ., Volgograd, Russia

Objective: Research in recent years has shown that free radical and peroxidation reactions also take part in the damage to the connective tissue structures of various organs and systems during the development and progression of the lupus process, the products of which can change the antigenic structures of tissue. Two antioxidant defense systems prevent the intensification of free radical oxidation—non-enzymatic (vitamins A and K, tocopherols, glutathione, etc.) and enzymatic, which includes superoxide dismutase (SOD), glutathione peroxidase (GP), glutathione reductase (GR), catalase (CAT), etc. GP has a powerful antiperoxide effect and plays an important role in the processes of oxidation-antioxidation. Since in systemic lupus erythematosus (SLE) there is an increase in reactive oxygen species, one would obviously expect a compensatory increase in the synthesis of components of the body's antioxidant system, in particular GP, which led to the inhibition of free radicals. But with SLE, on the contrary, the accumulation of secondary toxic products of free radical reactions occurs. Research shows that one of the reasons for the weakening of individual components of the enzyme antioxidant defense in rheumatic diseases is the formation of antibodies to antioxidant enzymes, including GP. We studied the development of additional criteria for laboratory immunodiagnosis of SLE using magnetically controlled immunosorbents based on glutathione peroxidase.
Methods: The serum of 30 donors, 40 with SLE was studied. SLE patients: 9 patients (22.2%) had a low degree of activity, 22 (55%) had a moderate degree and 9 patients (22.2%) had the maximum degree of activity of the pathological process. Antibodies to HP were determined using the enzyme immunoassay method when fixing the antigen in magnetically controlled sorbents using the Gontar method. The results were expressed in optical density units.
Results: In a study of blood serum from healthy individuals, the level of antibodies to GP was 0.196 ± 0.117 optical density units. Elevated levels of antibodies to GP were detected in 24 (60%) patients with SLE. In SLE patients, the level of antibodies to GP significantly depended on the pathological process ($p < 0.05$) and kidney damage ($p < 0.05$). Anti-GP antibodies were more often detected in patients with active SLE (ECLAM > 2). A positive correlation was found between the level of antibodies to GP and the values of the ECLAM activity index (r = 0.376, p = 0.04). As a result of immunosuppressive therapy, there was a tendency to reduce the level of antibodies to GP to 34.2%.
Conclusion: The determination of antibodies to GP in patients with SLE using magnetosorbents is diagnostically informative and can be used as an additional method for the immunodiagnosis of SLE. Detection of antibodies to GP may serve as an indication for active therapy with the inclusion of synthetic antioxidants.

P1016
DIAGNOSTIC VALUE OF CERULOPLASMIN INDICATORS IN PATIENTS WITH RHEUMATOID ARTHRITIS

O. Emelyanova[1], O. Rusanova[1], A. Trofimenko[1], S. Spitsina[2]

[1]Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky, [2]Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky, Volgograd State Medical Univ., Volgograd, Russia

Objective: Antibody formation to ceruloplasmin (CP) in rheumatoid arthritis (RA) is a poorly understood problem. The choice of this copper-containing alpha 2—blood plasma glycoprotein, which has multienzyme properties, as an object of study was not accidental. CP is one of the main extracellular antioxidant enzymes; it plays an important role in the pathogenesis of rheumatic diseases, including RA. We aimed to improve the immunological diagnosis of RA by parallel determination of antibodies to CP, as well as its quantity and enzymatic activity.
Methods: The serum of 30 healthy individuals and 102 patients with RA was studied. Antibodies to CP were determined by ELISA using immobilized granular antigen preparations (IGAP) (modification of I.P. Gontar et al., 2002). Determination of the amount of CP was carried out using the enzyme immunoassay method according to I.S. Kuzmina et al. (1991) using a commercial enzyme-linked immunosorbent diagnostic kit produced by the Research Institute of Vaccines and Serums named after Mechnikov.
Results: According to ELISA data, the average level of antibodies to CP in donor serum was 0.020 ± 0.006 e.o.p. The level of normal indicators of specific antibodies, defined as $M \pm 2$ s, includes extinction values in the range from 0–0.086. The average value of oxidase activity and the amount of CP in healthy individuals was 716 ± 26.3 ng/ml and 921 ± 32 mg/ml, respectively. During the research, a significant increase in the content of antibodies to CP, activity and quantity of CP in patients with RA was revealed, in all cases, the studied parameters correlated with the degree of disease activity ($p < 0,05$), with the I degree of activity—antibodies to CP is 0.094 ± 0.012 e.o.p., CP activity is 952 ± 46.1 ng/ml, the number of CP is 1289 ± 71.4 mg/ml; at II degree activity – antibodies to CP 0.136 ± 0.007 e.o.p., CP activity—1164 ± 39.2 ng/ml, number of CP—1762 ± 67.3 mg/ml; at stage III activity—antibodies to CP—0.184 ± 0.011 e.o.p., CP activity—1369 ± 87.5 ng/ml, number of CP – 1796 ± 102.4 mg/ml. At the end of the course of inpatient treatment, compared with the initial data, there was a significant decrease in the activity and number of CP (at stage I of RA activity $p < 0,001$, and at II degree—$p < 0,01$ for both indicators, at III degree—$p < 0,05$). The decrease in antibodies to CP is characterized by slow dynamics, especially in patients with pronounced activity of the pathological process, which reflects serious disorders in the immune system that are not completely relieved by a 30-day course of hospital treatment.
Conclusion: Determining CP indicators allows us to expand the existing understanding of the pathogenesis of RA, and the determination of antibodies to CP can be used to improve methods of immunological diagnosis of this disease.

P1017
OPTIMIZING ELIMINATION OF ANTI-CARDIOLIPIN ANTIBODIES IN PATIENTS WITH ANTIPHOSPHOLIPID SYNDROME AS A COMPONENT OF PATHOGENETIC THERAPY FOR PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

O. Emelyanova[1], O. Rusanova[1], A. Trofimenko[1]

[1]Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky, Volgograd, Russia

Objective: Anti-cardiolipin antibodies (ACA) determine the development of a certain subtype of systemic lupus erythematosus (SLE) with signs of antiphospholipid syndrome (APS). We studied in vitro elimination of pathogenetic anti-cardiolipin antibodies in SLE patients with APS.
Methods: Magnetic sorbent was obtained by spatially oriented fixation of antigen taking into account the hydrophobic and hydrophilic properties of cardiolipin molecule. The study was conducted in accordance with the principles of the World Medical Association's Declaration of Helsinki; the patients' informed consent was obtained in each case. The diagnosis of APS was confirmed with Hughes and Harris criteria; verification of the diagnosis was done using ACR criteria. The activity of SLE was assessed using SLEDAI score. The group of SLE patients included 63 individuals aged 15–62. The mean SLE activity was 7.3 ± 3.6 points on SLEDAI score. Immunoadsorption was performed in vitro using 20 ml of a patient's blood which was perfused using a peristaltic micropump at a rate of 25 ml/h through a glass column containing 1 ml of magnetic hemosorbent. Antibodies to IgG cardiolipin were assessed prior to and after sorption using an immunoenzyme assay. The concentration of antibodies was shown in absorbance units. The findings were shown as an arithmetical mean ($M \pm m$), a difference was considered statistically significant at $p < 0.001$.
Results: Sorption of anti-cardiolipin antibodies using magnetic sorbents yielded a pronounced decrease in antibody concentration (baseline: 0.390 ± 0.021 absorbance units, afterwards: 0.141 ± 0.006 at $p < 0.001$).
Conclusion: Selective sorption of anti-cardiolipin antibodies is an innovative technique of immunosupportive therapy; it implies extracorporeal blood circulation in a column filled with an appropriate sorbent.

P1018
ASSESSMENT OF FACTORS AFFECTING FREQUENCY OF MORTALITY IN OLDER AGE GROUPS WITH PROXIMAL FEMOR FRACTURE

Y. Popenko[1], N. Shadchneva[1], V. Kaliberdenko[1], E. Kuliyeva[1], T. Shaldybin[2], A. Zakharova[1], O. Galkina[1]

[1]V.I. Vernadsky Crimean Federal Univ., [2]Medaira Clinic, Simferopol, Russia

Objective: Fractures of the proximal femur are among the most severe complications of osteoporosis. Mortality with this fracture reaches 16.5–27.3% one year after it was received (Kates SL et al.,

2010; Kang HY et al., 2010) and 34.5–39.0% after two years (Ngobeni RS et al., 2010; Hu F et al., 2012).
Methods: A continuous prospective 2-y observational study was conducted, which included all patients with low-energy fractures of the proximal femur. 446 people were examined, of which 112 were male (25.11%) and 334 female patients (74.89%), with an average age of 76.81 ± 10.32 y. Mortality was assessed in the hospital, after 3, 6, 12 and 24 months through telephone contact with the patient or his relatives, in some cases (if it was impossible to contact the patient) through a clinic at the place of residence. Statistical analysis was performed using the StatSoft, Inc. software package. STATISTICA (data analysis software system), version 12, MedCalc Statistical Software version 15.8 (MedCalc Software). The relationship between various factors and the mortality rate was assessed by calculating the rank correlation coefficient τ-Kendall and γ).
Results: During the study, overall in-hospital mortality was 9.66%, after 3 months – 21.75%, after 6 months – 26.46%, 12 months – 29.82%, 24 months – 34.53%. The correlation analysis carried out showed a significant relationship between in-hospital mortality and age and the presence of disability in all periods of observation. In addition, after 12 and 24 months, mortality was associated with MMSE scale scores when a patient had a pronounced decline in cognitive function, after 6, 12, 24 months – with the frequency of falls, the presence of visual impairment, and after 12 months – with Parkinson's. From the indicators of physical activity of patients at all stages of observation, a connection was established with the duration of walking before the fracture and the degree of restoration of mobility during hospitalization and after discharge from the hospital.
Conclusion: The mortality of patients after a fracture turned out to be directly related to the severity of their condition upon admission and the development of complications during hospitalization (delirium, deep vein thrombosis of the legs and its treatment), with the presence of severe concomitant pathology at the time of the fracture, primarily cardiovascular diseases and decreased cognitive function. In addition, the increased risk of death was influenced by the patient's level of physical activity before and after the fracture and a number of factors that increase the risk of falls (including visual impairment, Parkinson's, repeated falls).

P1019
CASE REPORT: FEMORAL HEAD AVASCULAR NECROSIS CAUSED BY CORTISONE IN HIGH DOSES IN A YOUNG PATIENT

O. Gelaj[1], B. Bulku[2], A. Kollcaku[1], C. Todhe[1], Y. Ibrahimllari[2]

[1]Rheumatology Dept., Mother Theresa Univ. Center, [2]Radiology Dept., Salus Hospital, Tirana, Albania

The COVID-19 pandemic, widely regarded as one of the most significant global health crises of the modern era, has led to various medical complications that have yet to be fully comprehended by healthcare practitioners. Sepsis and the complications resulting from the widespread use of medications such as corticosteroids, antibiotics, etc. are among the most critical outcomes of this condition. One of the rarer complications associated with this illness is femoral head avascular necrosis, which is generally marked by intense pain and elevated inflammatory markers. It is brought on by high doses and prolonged use of corticosteroids.
Case report: This report describes a male patient, age 24, who was referred to our emergency room complaining of significant hip discomfort that persisted even at rest with restricted range of motion. He initially just mentioned that he had a severe lung infection with Sars-COVID-19 six months prior, and that he had received long-term therapy with high doses of cortisone and antibiotics. During the radiology examination, the MRI revealed alternating signals at the bilateral symphyses pubis sights and at the proximal femur sight, which were identified as necrotic areas. Additionally, a diminution in the middle region of the corpus vertebral was noted. Afterwards, based in part on the laboratory tests, we requested a thorough anamnesis, and he disclosed that he had had drepanocitosis since the age of 6. Due to a differential diagnosis, we also had to involve the hematology unit at this point. We were now faced with the dilemma of whether femoral avascular necrosis resulted from high, persistent cortisone dosages or from hematological problems.
Conclusion: The risk of femoral head avascular necrosis can be raised by both conditions, including high dosages of cortisone and drepatocitosis. Prolonged high dosages of cortisone use during the COVID-19 pandemic may have caused many complications, including avascular necrosis of the femur head. We need to proceed with vigilance when taking the anamnesis, though, as it may help us determine the best possible course of approach.

P1020
AMOUNT OF CERULOPLASMIN, ITS BIOCHEMICAL AND IMMUNOLOGIC ACTIVITY IN PATIENTS WITH RHEUMATOID ARTHRITIS

O. I. Emelianova[1], O. A. Rusanova[1], S. S. Spitsina[1], S. A. Bedina[1], A. S. Trofimenko[1]

[1]Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky, Russian Federation, Volgograd, Russia

Objective: Production of antibodies to ceruloplasmin (CP) in rheumatoid arthritis is an issue that has not been studied well enough. We investigated improving diagnosis of rheumatoid arthritis by determination of antibodies to CP as well as its amount and enzymatic activity.
Methods: We studied the serum from 30 apparently healthy individuals, and 108 rheumatoid arthritis patients. Antibodies to CP were determined by enzyme immunoassay using immobilized granulated antigen preparations (modification by Gontar et al., 2002). The amount of CP was determined by enzyme immunoassay according to the method of I.S. Kuzmina et al. (1991) using commercial diagnostic agent manufactured by Mechnikov Research Institute for Vaccines and Sera.
Results: Enzyme immunoassay showed a mean level of CP antibodies in donor sera of 0,020 ± 0,006 optical density units. The mean value of oxidase activity and the amount of CP in healthy people was 716 ± 26,3 and 921 ± 32 ng/ml, correspondingly. In the process of study we revealed a reliable increase in CP antibody count, the activity and amount of CP in patients with rheumatoid arthritis while in all cases the parameters under study correlated with the degree of disease activity ($p < 0,05$): at activity degree I CP antibodies were 0,098 ± 0,011; CP activity was 954 ± 48,1; CP amount was 1292 ± 73,4. At activity degree II CP antibodies were 0,138 ± 0,007; CP activity was 1163 ± 39,6; CP amount was 1763 ± 69,3. At activity degree III, CP antibodies were 0,182 ± 0,015; CP activity was 1368 ± 89,5; CP amount was 1794 ± 102,8. After a course of hospital treatment was completed, we noted a reliable decrease in the activity, amount of CP and antibodies in CP.
Conclusion: Determination of CP antibodies, as well as quantitative content of CP and its oxidase activity can serve as indicators of the activity of rheumatoid arthritis, as well as an accessory criterion of the effectiveness of administered therapy.

P1021
REHABILITATION MEASURES IN OSTEOSARCOPENIA

O. M. Ignatiev[1], M. I. Turchin[1], T. O. Yermolenko[1]

[1]Odessa National Medical Univ., Odessa, Ukraine

Objective: The structural and functional state of bone and skeletal muscle tissue is a biomarker of healthy aging, and the treatment and rehabilitation of osteosarcopenia (OSP) is part of antiaging strategy. This emphasizes the clinical and social significance of OSP, the need to study this condition, risk factors, search for predictors, prevention, effective treatment and rehabilitation. The purpose of the work is to evaluate the effectiveness of using modern computerized HUBER systems in restoring postural balance in osteosarcopenia.
Methods: There were 140 postmenopausal women (56.7 ± 2.3 years old) with osteosarcopies under observation. BMD was measured using DXA. Patients received standard osteotropic therapy (metabolites of vitamin D and denosumab) and two groups were randomized in rehabilitation methods: 1 (n = 90)—a complex program on the HUBER platform with the function of biological feedback; 2 (n = 50) training according to the classic complex program on the balancing platform-hemisphere "OsportBosu" without the function of biological feedback. To assess the functional state of the locomotor apparatus, a complex of registration and processing of biosignals in vertebrology "Insight TM" was used: pain sensitivity (algometry); flexible acoustics (ROM, inclinometry); surface electromyography (EMG); thermography of back muscles (Therma); heart rate variability (HRV).
Results: All patients (100%) complained of pain in the back, in the bones of the pelvis and limbs, weakness, increased fatigue and decreased ability to work. In the groups, patients were comparable in age and BMD. The T-score was (-3.52 ± 0.54) standard deviation. Evaluation of the effectiveness of treatment showed an increase ($p < 0.05$) in the time of maintaining balance in patients of group I after 6 and 12 months by 70% compared to the same in group II. As a result of treatment, there was an improvement ($p < 0.05$) in the biomechanical and neurological condition of the spine using a set of exercises proposed on the Huber apparatus. There was also a positive trend in the data on "maintaining time balance" in patients in group 1. The results on the time of maintaining balance indicate that individual and dosed implementation of complex coordination tasks on the Huber hardware complex contributes to the preservation of the patient's coordination capabilities.
Conclusion: Rehabilitation measures using hardware biofeedback are a highly effective method of medical support for patients with osteosarcopy.

P1022
EVALUATION OF SAFETY OF BIOACTIVE CONCENTRATE OF SMALL MARINE FISH IN SENILE PATIENTS WITH KNEE OSTEOARTHRITIS AND HIGH COMORBIDITY RATES

O. Malyshenko[1], M. Koroleva[1], M. Letaeva[1], J. Averkieva[1], T. Raskina[1]

[1]Kemerovo State Medical Univ., Kemerovo, Russia

Objective: To evaluate the safety of bioactive concentrate of small marine fish (BCSSF) in elderly patients with osteoarthritis of the knee joint and high comorbidity.
Methods: The study included 20 patients with knee joint OA, whose average age was 77.6 (75.8; 80.5) y. Patients received injections of BCSSF daily for 1 ml intramuscularly in courses of 20 d with a 6-month interval (in total 2 courses). The effectiveness of therapy was assessed by VAS and WOMAC index, the safety of the drug was assessed based on clinical and laboratory parameters during the entire follow-up period.
Results: In elderly patients with knee joint OA, a high level of comorbidity was revealed—5.4 + 0.8 diseases. The Charlson index was 1–2 points for 2 (10.0%) patients, 3–4 points in 14 (70.0%), ≥ 5 points in 4 (20.0%). By the end of the first course of BCSSF therapy, a statistically significant decrease in the total WOMAC index and a significant reduction in VAS pain were found. The positive dynamics persisted throughout the entire observation period. Thus, the number of patients who responded to therapy with a decrease in pain in the knee joint according to VAS by 20% or more by B1 was 13 (65.0%) patients, by B2 – 12 (60.0%). A statistically significant decrease in the total WOMAC index was revealed at all visits compared with the indicators obtained when the patient was included in the study: B0—1125 ± 135.0, B1—647 ± 229.0, B2—642 ± 224.0 ($p \leq 0.001$). No serious adverse events and clinically significant changes in laboratory parameters were detected during the entire observation period.
Conclusion: The results of the study demonstrate the effectiveness of BCSSF in patients with knee joint OA and confirm the safety of its use in elderly patients with high comorbidity, which makes it possible to consider it as a first-line drug in the complex therapy of OA.

P1023
RELATIONSHIP OF SARCOPENIA AND CAROTID ATHEROSCLEROSIS IN ELDERLY MEN WITH OSTEOARTHRITIS OF THE KNEE

O. Malyshenko[1], M. Koroleva[1], M. Letaeva[1], J. Averkieva[1], T. Raskina[1]

[1]Kemerovo State Medical Univ., Kemerovo, Russia

Objective: To evaluate the association of sarcopenia and carotid atherosclerosis in elderly male patients with osteoarthritis (OA) of the knee.
Methods: The study included 36 patients (mean age 68.9 (66; 71) y) with an established diagnosis of stage II-III knee OA according to the

Kellgren-Lawrence classification. Diagnosis of sarcopenia was based on the recommendations of EWGSOP 2010 with the determination of 3 parameters: muscle strength, muscle mass and muscle function. The severity of atherosclerotic lesions of the carotid arteries was assessed using color duplex scanning with the study of intima-media thickness (IMT), the presence of atherosclerotic plaques and the degree of arterial stenosis. A comparative analysis was carried out in 3 groups: 1st – 10 patients without sarcopenia, 2nd – 12 patients with presarcopenia, and 3rd – 14 patients with sarcopenia.

Results: IMT in the group of patients with sarcopenia was statistically significantly ($p = 0.005$) greater than the same indicator in men without sarcopenia. The majority of patients included in the study (63.9%) had atherosclerotic lesions of the carotid arteries. The most severe damage to the carotid arteries with multiple atherosclerotic plaques and stenosis of 50% or more was significantly more often determined in patients with sarcopenia—35.7% compared to the group of patients with presarcopenia (8.3%, $p = 0.015$) and without sarcopenia (10.0%, $p = 0.013$). According to the results of the correlation analysis, a significant negative relationship was established between the severity of carotid atherosclerosis and the musculoskeletal index ($r = -0.227$, $p = 0.047$).

Conclusion: The relationship between carotid atherosclerosis and body composition disorders in men with knee OA allows us to discuss atherosclerosis and sarcopenia as two conditions that have common pathogenetic mechanisms and potentially increase the risk of adverse outcomes.

P1024
EXPLORING THE IMPACT OF CONSERVATIVE TREATMENT ON QUALITY OF LIFE IN ADOLESCENTS WITH ADOLESCENT IDIOPATHIC SCOLIOSIS

O. Mohamed Fathy Kamal[1], C. Cuenca González[2], Y. Labrada Rodríguez[3], L. Garvin Ocampos[2], L. Monleón Llorente[2], M.-E. Cuadra Madrid[1]

[1]Dept. of Physical Medicine and Rehabilitation, Hospital Central de la Defensa, [2]Dept. of Physical Medicine and Rehabilitation, Hospital Clínico San Carlos, [3]Hospital de Guadarrama, Madrid, Spain

Objective: In the management of adolescent idiopathic scoliosis (AIS), the consideration of patients' quality of life (QoL) is often overlooked as a primary treatment goal. Assessing QoL presents a challenge for healthcare professionals, emphasizing the need to incorporate this parameter for optimal clinical practice. The primary objective of this investigation was to assess QoL, utilizing the SRS 22 questionnaire, in adolescents undergoing conservative treatment for AIS.

Methods: This study employed a descriptive retrospective design conducted within the Ortho-prothesis Unit, spanning from January 2019 to May 2020. Forty adolescents meeting inclusion and exclusion criteria, undergoing conservative treatment for AIS, were enrolled. Analyzed parameters included age, sex, Cobb angle, daily/night brace usage, brace type, and QoL assessed through the SRS 22 questionnaire. Telephone-based SRS 22 questionnaires were administered, while additional variables were extracted from clinical histories.

Results: Cobb angles ranged from 20–29° in 37.5% of patients and 30–39° in another 37.5%. Predominant brace types included Cheneau and Providence. Patients exhibited lower scores in self-image perception and mental health domains. The brace treatment group demonstrated poorer outcomes in self-image perception and mental health compared to the non-braced group (p 0.006 and p 0.04, respectively). Overall SRS 22 questionnaire scores were worse in patients with a greater angle of deviation (p 0.019). No statistically significant correlations were identified between QoL and variables such as sex, daily/night brace usage, and type of brace.

Conclusion: AIS adversely affects patients' quality of life, particularly in the domains of body image and mental health. The extent of this impact correlates with a greater angle of deviation and the decision to use or not use a brace.

P1025
EFFECTS OF ZOLEDRONIC ACID IN MEN WITH STEROID-INDUCED OSTEOPOROSIS AND INFLAMMATORY JOINT DISEASE

O. Mytrokhina[1]

[1]Dnipro State Medical Univ., Dnipro, Ukraine

Objective: Long-term use of glucocorticoids causes decreased bone mass and an increased risk of fractures. However, osteoporosis is more common in women than in men and is often considered as women's disease. However, in recent years the number of fractures in men has increased. Prevention and treatment of osteoporosis in men with long-term therapy with glucocorticoids remains an actual issue. The role of zoledronic acid in the treatment of steroid-induced osteoporosis in men with inflammatory joint diseases remains debatable. We aimed to evaluate the effects of zoledronic acid for steroid-induced osteoporosis in men with inflammatory joints disease.

Methods: 40 patients (mean age 58,30 ± 4,76 y) with inflammatory joints disease were enrolled. All patients were men and received glucocorticoid during > 5 y (mean duration of treatment 3,80 ± 0,67 y). Men had osteoporosis documented by either a lumbar spine T-score ≤ –2.5 or lumbar spine T-score ≤ –1.5 with 2 mild or 1 moderate prevalent vertebral fracture. 20 (50%) patients received the standard treatment and zoledronic acid 5 mg infusion once a year (1 group), while 20 (50%) (2 group) received only the standard treatment during 3 y. BMD, visual analog scale (VAS) were performed in all patients at baseline and at the end of the study.

Results: BMD and VAS did not differ significantly between the groups. After 3 y of treatment with zoledronic acid the incidence of symptoms, including arthralgia were significantly lower in the 1 group in compare with the 2 group ($P = 0.01$). The increase of BMD was greater in the 1 group than in the 2 group ($P = 0.05$). During 3 y among patients in the 2 group 35% have compression fractures in compare with the 1 group ($P = 0.01$).

Conclusion: Zoledronic acid is effective and safe for men with glucocorticoid-induced osteoporosis with inflammatory joints disease. Its use may provide benefits for the reduction of hospitalizations and mortality in its category of patients.

P1026
BONE MINERAL DENSITY, TRABECULAR BONE SCORE, SALT TRANSPORT IN PATIENTS WITH KIDNEY STONE DISEASES

O. Nishkumay[1], O. Nikitin[1], A. Korytskyi[2], I. Kordubailo[2], M. Chan[3], M. Wong[3]

[1]Bogomolets National Medical Univ., Kyiv, Ukraine, [2]Kyiv Regional Clinical Hospital, Kyiv, Ukraine, [3]European Wellness Academy, Edenkoben, Germany

Objective: Osteoporosis (OP)-decreased BMD, takes the leading place in the structure of morbidity and mortality. Among the main risk factors of OP is not adequate daily calcium intake. The global calcium map shows that many countries have low average levels of calcium intake. The fear of both patients and doctors regarding possible side effects, such as kidney stone diseases (KSD) is one of the main reasons for low calcium intake. The research aimed to conduct a

comparative assessment of the BMD and TBS, salt transport analysis in patients depending on KSD.

Methods: The study was conducted based on the Urology Department of the Bogomolets National Medical University, Department of Urology, "Kyiv Regional Clinical Hospital". To qualitatively assess crystalluria, a study of salt transport was carried out. Assessment of BMD was carried out by DXA (Hologic Discovery), using the ISCD-2019 criteria to divide the examinees into groups (osteoporosis, osteopenia, normal). The TBS iNsight method was used to assess the bone tissue quality indicator (TBS). The study included 80 patients, 15 men (18.8%) and 65 women (81.3%). Patients were divided depending on the presence of KSD. The I group included 32 participants without KSD (women—31 (96.9%), men—1 (3.1%), median age 63.2 [58.8–67.4] y). The II group included 48 patients with KSD (women—34 (70.8%)), men—14 (29.2%), average age 55.5 y [51.5–62.5]).

Results: There was no established difference amount of percentage normal, osteopenia, and osteoporosis between groups, as there was no difference between BMD indicators. However, the TBS index was significantly lower in patients with KSD ($p < 0.05$). In patients with KSD, the level of oxalate excretion exceeded both the reference norm and the dates of patients without nephrolithiasis ($p < 0.01$).

Conclusion: In patients with KSD was revealed decreased TBS and oxalaturia. Since a decrease in the TBS index even with a normal BMD is also an increased risk factor for bone fractures, it is extremely important for patients to conduct a correlational analysis of risk factors in a group of patients with nephrolithiasis.

P1027
COMPARATIVE ANALYSIS OF BONE LOSS IN PATIENTS WITH EROSIVE AND NON-EROSIVE HAND OSTEOARTHRITIS: A 5-YEAR LONGITUDINAL STUDY

O. Ruzickova[1], K. Pavelka[2], O. Sleglova[2], L. Senolt[2]

[1]Institute of Research in Rheumatology, [2]Institution of Research in Rheumatology, Prague, Czech Republic

Objective: Hand osteoarthritis (OA) and its more severe subset erosive hand OA are common causes of pain and morbidity. Some metabolic factors were suggested to be implicated in erosive disease. Few studies investigated differences in systemic bone loss between erosive and non-erosive hand OA. We aimed to compare the change of BMD between patients with erosive and non-erosive hand OA in a 5-y longitudinal study.

Methods: Consecutive patients with symptomatic HOA fulfilling the ACR criteria were included in this study. Erosive hand OA was defined by at least one erosive interphalangeal joint. All patients underwent clinical assessments of joint swelling and radiographs of both hands (Table 1). DXA examination of lumbar spine, total femur and femur neck was performed at the baseline, after 2 y and after 5 y. The data were adjusted for gender, comorbidities such as diabetes mellitus and dyslipidemia.

Table 1.

Characteristic		Non-erosive HOA (n=50)	Erosive HOA (n=62)	p-value
Age	Mean (SD)	63.7 (7.4)	66.6 (8.3)	0,057
Gender	Female (%)	45 (90.0)	57 (91.9)	0,981
BMI	Mean (SD)	26.7 (3.6)	28.2 (4.4)	0,051

Results: Altogether, 112 patients (10 male) with symptomatic nodal HOA were included in this study and followed between April 2012 and January 2018. Out of these patients, 62 had erosive disease after 5 y. The disease duration ($p < 0.01$) was significantly higher in patients with erosive compared with non-erosive disease at baseline. There was no difference in T-score (SD) and BMD (g/cm^2) between erosive and non-erosive hand OA at baseline, after two and after 5 y (Tables 2,3,4).

Table 2.

	Baseline (N=112)	24 months (N=112)	60 months (N=112)
T-score L spine			
Erosive, Mean (SD)	-0.973 (1.76)	-1.05 (1.48)	-1.12 (1.49)
Non-erosive, Mean (SD)	-0.522 (1.37)	-0.472 (1.64)	-0.613 (1.66)
Overall, Mean (SD)	-0.771 (1.60)	-0.806 (1.57)	-0.908 (1.57)
L spine bone density (g/cm^2)			
Erosive, Mean (SD)	1.05 (0.210)	1.05 (0.183)	1.04 (0.185)
Non-erosive, Mean (SD)	1.11 (0.163)	1.12 (0.206)	1.10 (0.209)
Overall, Mean (SD)	1.08 (0.192)	1.08 (0.195)	1.07 (0.197)
T-score of total femur			
Erosive, Mean (SD)	-0.671 (0.978)	-0.726 (0.978)	-0.850 (0.947)
Non-erosive, Mean (SD)	-0.362 (0.968)	-0.306 (1.11)	-0.430 (1.14)
Overall, Mean (SD)	-0.533 (0.981)	-0.550 (1.05)	-0.674 (1.05)
Total femoral bone density (g/cm^2)			
Erosive, Mean (SD)	0.918 (0.157)	0.922 (0.130)	0.901 (0.122)
Non-erosive, Mean (SD)	0.969 (0.139)	0.975 (0.148)	0.957 (0.151)
Overall, Mean (SD)	0.941 (0.151)	0.944 (0.139)	0.925 (0.137)
T-score of femoral neck			
Erosive, Mean (SD)	-1.17 (0.805)	-1.06 (0.922)	-1.10 (0.930)
Non-erosive, Mean (SD)	-0.874 (0.879)	-0.683 (0.948)	-0.760 (1.06)
Overall, Mean (SD)	-1.04 (0.848)	-0.904 (0.948)	-0.958 (0.994)
Femoral neck bone density (g/cm^2)			
Erosive, Mean (SD)	0.877 (0.110)	0.864 (0.110)	0.853 (0.115)
Non-erosive, Mean (SD)	0.919 (0.127)	0.917 (0.129)	0.898 (0.138)
Overall, Mean (SD)	0.896 (0.119)	0.887 (0.121)	0.872 (0.127)

Table 3.

DXA features	P-value
T-score L spine	0,08
L spine bone density (g/cm^2)	0,054
T-score of total femur	0,103
Total femoral bone density (g/cm^2)	0,057
T-score of femoral neck	0,083
Femoral neck bone density (g/cm^2)	0,076

ANOVA-computed p-values from linear mixed-effect models

Table 3.

DXA features	Contrast at	Difference between erosive and nonerosive	Adjusted p-value
T-score L spine	Baseline	-0,379	0,367
	2 years after	-0,461	0,22
	Five years after	-0,421	0,289
L spine bone density (g/cm^2)	Baseline	-0,05	0,261
	Two years after	-0,06	0,143
	Five years after	-0,053	0,228
T-score of total femur	Baseline	-0,247	0,229
	Two years after	-0,216	0,357
	Five years after	-0,191	0,46
Total femoral bone density (g/cm^2)	Baseline	-0,047	0,069
	Two years after	-0,032	0,348
	Five years after	-0,029	0,415
T-score of femoral neck	Baseline	-0,301	0,153
	Two years after	-0,222	0,412
	Five years after	-0,213	0,446
Femoral neck bone density (g/cm^2)	Baseline	-0,039	0,072
	Two years after	-0,027	0,34
	Five years after	-0,018	0,658

Contrasts were computed from linear mixed-effect models
Results are averaged over the levels of: gender, comorbid_diabetes_mellitus, comorbid_hypercholesterolemia
Degrees-of-freedom method: Kenward-Roger
P value adjustment: Sidak method for 3 tests

Conclusion: We found no differences in systemic bone loss between erosive and non-erosive hand OA over period of 5 y.

P1028
QUESTION THE DENSITY AS A BONE STRENGTH MEASUREMENT

A. Akhmetzyanova[1], K. Sharafutdinova[1], D. Sabirova[1], M. Baltin[1], O. Gerasimov[1], T. Baltina[1], O. Sachenkov[1]

[1]Kazan Federal Univ., Kazan, Russia

Objective: To evaluate the effect of complete spinal cord injury (cSCI) and incomplete spinal cord injury (iSCI) on the mechanical properties of bones in experimental rats: density, ultimate strength, Young's modulus of the bone tissue of the tibia and femur.

Methods: The research was conducted using the non-pedigree rats weighing 180–200 g. iSCI was introduced between Th8-Th9 levels using the modified A.R. Allen method by 2.5 g load weighing falling vertically from 5 cm height [1]. cSCI was performed by section between Th8- Th9 segments [2]. Three-point bending tests were carried out to determine the mechanical parameters [3].

Results: In the study geometric, mass and mechanical properties of the femur and tibia were measured. Both types of spinal cord injury lead to a decrease in the bone strength. cSCI results in a reduction in the rat femur strength. The Young's modulus and density of the rat femur and tibia remain unchanged in both types of spinal cord injury.

Conclusion: It is necessary to create new clinical diagnostic techniques that can accurately evaluate the strength of bone tissue in individuals with cSCI. The research also highlights the elevated risk faced by patients with iSCI, as they experience a significant decrease in bone strength that cannot be distinguished through density measurements alone.

P1029
AGE FEATURES IN CLINICAL MANIFESTATIONS OF ANKYLOSING SPONDYLITIS IN MILITARY SERVICEMEN

O. Kuryata[1], O. Sirenko[1], M. Grechanyk[1]

[1]Dnipro State Medical Univ., Dnipro, Ukraine

Objective: A substantial fraction of Ukrainian military service members with ankylosing spondylitis (AS) continued in service. However, the doubling in risk of discharge for AS is comparable to that for personnel with diabetes mellitus. The early diagnosis of AS taking into account age features can improve the efficiency of military servicemen rehabilitation. Aim of the study is to investigate the clinical manifestations, and age features of pain syndrome in Ukrainian military servicemen with AS before treatment onset.

Methods: We retrospectively studied the AS cases recorded from March 2022 to June 2023 of the rheumatology department of the largest Regional Clinical Hospital in Dnipro (Ukraine); the diagnosis was based on the ASAS-EULAR recommendations for AS. A total of 38 AS cases were diagnosed among 72 military servicemen (median age 36.7 [26.2;48.7]). The first group consisted of 15 patients aged 25–35 y, the second—23 patients aged 36–50 y.

Results: All the patients had chronic back pain. 30 (79%, 95% C.I. 77–85%) patients presented sacroiliitis of whom 21 (70%, 95% C.I. 64–76%) were bilateral. 29 military servicemen (76%, 95% C.I. 68–81%) had peripheral joint involvement. Among the patients of the first group, the peripheral joint involvement is established significantly more often – 12 (80%, 95% C.I. 72–85%) against 17 (59%, 95% C.I. 54–66%) in second group ($p < 0.05$). Four patients presented with anterior uveitis (10%, 95% C.I. 7–13%) and all were 25–35 years old. HLA-B27 antigen was found in 36 patients (95%, 95% C.I. 88–97%). Median pain intense based on VAS score was 8.8 [6.9; 9.5] in the first group, while in the second group this indicator was significantly lower 6.5 [5.7; 7.8] ($p < 0.05$). Median CRP level was 10.2 [6.2; 12.4] in the first group, in the second group—9.1 [5.8; 11.8] ($p > 0.05$).

Conclusion: Young military servicemen with ankylosing spondylitis presented significantly more frequent peripheral form and more intense pain syndrome, which must be taken into account during the rehabilitation of these patients.

P1030
FRACTURE RISK ASSESSMENT, BODY MASS INDEX AND INFLAMMATION IN PATIENTS WITH ARTERIAL HYPERTENSION AND CHRONIC PAIN IN MUSCULOSKELETAL DISEASES

O. Kuryata[1], O. Sirenko[1], M. Grechanyk[1]

[1]Dnipro State Medical Univ., Dnipro, Ukraine

Objective: The fracture risk assessment (FRAX®) algorithms are the most widely used clinical tools for the calculation of fracture risk. It is widely recognised that the calculation could be refined by more granular data about existing risk factors (e.g., glucocorticoid dose, number of prior fractures, recency of fracture etc.) or by inclusion of additional risk factors (e.g., falls, type 2 diabetes). Musculoskeletal disorders are the leading cause of disability worldwide and represent a growing problem due to the ageing population. For example, back pain, which has been reported to be the leading cause of disability in

both high-income and developing countries, results in an increased fear of pain in the elderly population. FRAX is an algorithm for fracture risk assessment useful for the primary prevention of osteoporosis, albeit it might present some limitations. Therefore, aim of our study was to evaluate the role of BMI and BP in correlation with FRAX to predict fragility fractures in patients with arterial hypertension and chronic pain in musculoskeletal diseases. We aimed to compare the relationship FRAX score, BMI and erythrocyte sedimentation rate (ESR) in patients with arterial hypertension and chronic pain in musculoskeletal diseases.

Methods: We studied 48 patients with arterial hypertension in combination with chronic pain in musculoskeletal diseases mean age 54,8 ± 5,04 (group A) and 42 patients with arterial hypertension without chronic pain in musculoskeletal diseases mean age 52,6 ± 4,7 (group B). Patients never treated with anti-osteoporotic drugs. The 10-y hip fracture risk was calculated with FRAX score and a value ≥ 2.5% signified an increased risk. Statistical significance was set at $p < 0.05$.

Results: FRAX score in a group A was higher (5,68 ± 4,1) than in group B (2,4 ± 2,1) ($p < 0,05$). The mean level of BMI: 29,3 ± 4,4 kg/m^2 in group A, 27,1 ± 2,5 kg/m^2 in a group B ($p < 0,05$). According to FRAX score, value ≥ 2.5% was found in 45 patients (93%) in a group A and in 20 patients (44%) in a group B ($p < 0,05$). There was correlation between the FRAX, weight ($r = 0,43$; $p < 0,05$), BMI ($r = -0,41$; $p < 0,05$) and ESR ($r = 0,47$; $p < 0,05$) in a group A however in a group B such connection was not observed. The mean level systolic blood pressure (BP) in a group A was higher (150,2 ± 5,8 mm Hg) than in group B (131,3 ± 4,4) ($p < 0,05$). The mean level diastolic BP changes did not significantly differ between the two groups (93,4 ± 8,4 mm Hg and 93,8 ± 6,4 mm Hg, $p = 0,54$). The level of systolic BP in a group A associated with FRAX score ($r = -0,40$; $p < 0,05$) than in group B.

Conclusion: Risk of fracture is increased in patients with arterial hypertension and chronic pain in musculoskeletal diseases. FRAX score in a group A was higher than in group B. There was correlation between FRAX score, BMI and ESR in patients with arterial hypertension and chronic pain in musculoskeletal diseases.

P1031
A BIBLIOMETRIC ANALYSIS OF SCIENTIFIC PUBLICATIONS IN THE FIELD OF THE EFFECT OF HYPOGLYCEMIC AGENTS ON BONE HEALTH

O. Tabatabaei-Malazy[1], B. Larijani[1]

[1]Endocrinology and Metabolism Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran Univ. of Medical Sciences, Tehran, Iran

Objective: Numerous studies are assessed the effect of anti-diabetic drugs on bone health. We aimed to conduct a bibliometric analysis of the scientific outputs in this field to identify the publication trend, productive country and institutions, active researchers, the journals involved, and the most popular research topics.

Methods: We carried out a bibliometric study by a comprehensive search in Scopus web database up to 4 Jan 2024. After excluding unrelated scientific papers, bibliometric metrics were extracted from the remaining papers by "analyze results", and "citation reports" tools available in Scopus, and VOSviewer 1.6.20.

Results: Within 3860 records, 532 studies were related to this topic. A time trend increasing was shown in publications with the highest number in 2022 (n = 53, 9.96%). Main type of the papers was original articles (n = 310, 8358.27%). Top three productive countries were the US (n = 151, 28.38%), China (n = 86, 16. 17%), and the UK (n = 54, 10.15%). The majority of the published papers belonged to "Osteoporos Int" (n = 20, 3.76%), "J Clin Endocrinol Metab" (n = 16, 3.01%), and "Diabetes Obes Metab" (n = 14, 2.63%). The total citation number, and H-index of 532 articles were 21,572, and 73, respectively. The highest cited paper (787) was a randomized controlled trial entitled "Pioglitazone after ischemic stroke or transient ischemic attack", published in "N Engl J Med". Top three ranked institutes in producing these documents were Steno Diabetes Center Copenhagen, Denmark (n = 17, 3.20%), followed by Universiteit Maastricht (n = 15, 2.82%) Netherlands, Aarhus Universitets hospital (n = 15, 2.82%), Denmark, and then Aalborg Universitets hospital (n = 14, 2.63%), Denmark. Top author was P Vestergaard from Denmark. Out of the 883 keywords, the top keywords included "diabetes", "osteoporosis", "metformin" and "fracture".

Conclusion: There is a large research output in the field of anti-diabetic agents and bone. We found a good position for the US as top productive country, Denmark due to its prominent authors, and institutes and "Osteoporos Int" as notable journal in dissemination of influential publications.

P1032
MAPPING OF THE SCIENTIFIC RESEARCH ON LINKS BETWEEN CVD AND BONE MASS IN OLD AGES: A SCIENTOMETRIC INVESTIGATION

O. Tabatabaei-Malazy[1], P. Khashayar[2], R. Atlasi[3], P. Khashayar[4], B. Larijani[1]

[1]Endocrinology and Metabolism Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran Univ. of Medical Sciences, Tehran, Iran, [2]School of life and Medical Sciences, Univ. of Hertfordshire, Hatfield, UK, [3]Non-Communicable Diseases Research Center, Endocrinology and Metabolism Population Sciences Institute, Tehran Univ. of Medical Sciences, Tehran, Iran, [4]Ghent Univ., Dept. of Chemistry, Ghent, Belgium.

Objective: Cardiovascular disease (CVD) ranks first among chronic non-communicable diseases worldwide. With the surge noted in the elderly population globally, the prevalence of osteoporosis is also on rise, imposing a heavy burden on the society. The relationship between bone mass and CVD in older adults has become the focus of many studies. The present research aims to map the scientific research conducted on the links between CVD and bone mass in old ages.

Methods: A bibliometric study was carried out thorough a comprehensive search strategy in the Web of Science (WOS) database up to 1 Jan 2024. From 967 records, 294 studies were included in the bibliometric analysis, conducted using the WOS database analysis software and bibliometrix R-package 4.1.1. for illustration.

Results: Most publications were produced in 2020 (n = 21, 7.14%), with original (n = 258, 87.75%) followed by review articles (n = 25, 8.50%). Most of these articles were published by "Osteoporos Int" (n = 36, 12.24%), "J Bone Miner Res" (n = 21, 7.14%) and "Calcif Tissue Int" (n = 14, 4.76%), respectively. The top three productive countries were the USA (n = 85, 28.91%), China (49) and Japan (23). The top three institutes active in the field were University of California System (n = 19, 6.46%), followed by Harvard University, and University of California San Francisco with same number of publications (n = 13, 4.42%). The total citation number of these articles was 11,723, with "Zoledronic acid and clinical fractures and mortality after hip fracture" being the highest cited paper (1332 citations). This randomized, double-blind, placebo-controlled trial was published in "N Engl J Med". The top authors were JA Cauley from University of Pittsburgh and P Szulc from University of Lyon both with 8 articles (2.72%). Most articles were in the field of "Endocrinology Metabolism" (n = 116, 39.45%) and "Cardiovascular System Cardiology" (n = 38, 12.92).

Conclusion: CVD and osteoporosis are common age-related conditions associated with significant morbidity, mortality, and disability.

This article illustrates the hot topics, valuable articles, and productive authors in this research field, helping to point out the gaps and possible future collaborations.

P1033
COMPARISON OF FUNCTIONAL OUTCOME IN CKD AND NON-CKD PATIENTS FOLLOWING FEMORAL NECK FRACTURE UNDERGOING BIPOLAR HEMIARTHROPLASTY

O.-A. Phruetthiphat[1], Y. Plumarom[1], Y. Satravaha[2], P. Pinijprapa[1]

[1]Phramongkutklao Hospital, [2]Orthodontic Dept., Mahidol Univ., Bangkok, Thailand

Objective: Chronic kidney disease (CKD) is a growing global health concern, affecting an estimated 10% of the world's population. CKD is associated with a number of adverse health outcomes, including an increased risk of hip fracture. Femoral neck fracture is a common and debilitating injury, which can lead to significant loss of function and independence. Bipolar hemiarthroplasty (BHA) is a common surgical treatment for femoral neck fracture, with generally good outcomes. However, previous research has provided less data on functional outcomes related to chronic kidney disease (CKD) in femoral neck fracture compared to the abundance of data available for osteoarthritis of the hip. Purpose of this study is going to compare the functional outcome between CKD and non-CKD underwent BHA for femoral neck fracture as well as to identify the comparison between advanced CKD and nonadvanced CKD.
Methods: 438 patients over 60 years old who sustained a femoral neck fracture from low energy trauma underwent BHA were collected. All patients were classified into 2 groups based on glomerular filtration rate (GFR): those patients without chronic kidney disease [GFR at least 60 ml/min] and those patients with CKD [GFR < 60 ml/min]. We further categorized patients into nonadvanced [GFR at least 30 ml/min] and advanced CKD [GFR < 30 ml/min]. Patients' demography and comorbidities were reviewed in both groups. Femoral bone morphology was evaluated by Dorr classification including operative parameters. Harris hip score was used for assessment the functional outcome at preinjury status, and postoperative period at 1 and 2 y.
Results: According to a comparison between CKD and non-CKD groups, there was no difference in age, gender, and BMI in both groups while the ASA class was significantly different between 2 groups ($p < 0.001$). In addition, there was no difference in Dorr type, implant design, and operative parameters in both groups. However, the preinjury status, 1 y, and 2 y HHS were significantly different between both groups ($p < 0.001$, $p = 0.002$, and $p = 0.011$, respectively). A comparison between advanced and non-advanced CKD demonstrated a significant in BMI, ASA class, time to rehabilitation, and HHS. Those patients with advanced CKD were significantly higher ASA class ($p < 0.001$), longer time to rehabilitation ($p = 0.043$), and lower preinjury HHS, one year, and 2 y HHS than the nonadvanced CKD group ($p < 0.001$, $p < 0.001$, and $p = 0.002$, respectively).
Conclusion: CKD is a significant factor influencing functional outcomes in patients with femoral neck fracture treated with bipolar hemiarthroplasty. Studies consistently demonstrate poorer underlying health status and functional outcomes in CKD patients compared to their non-CKD counterparts.

P1034
BONE HEALTH IN A UTERINE CANCER SURVIVOR WITH TSH SUPPRESSIVE THERAPY

O.-C. Sima[1], A.-M. Gheorghe[1], A.-I. Trandafir[1], A. Ghemigian[2], G. Voicu[3], E. Petrova[2]

[1]PhD Doctoral School, Carol Davila Univ. of Medicine and Pharmacy & C.I. Parhon National Institute of Endocrinology, [2]C.I. Parhon National Institute of Endocrinology & Dept. of Endocrinology, Carol Davila Univ. of Medicine and Pharmacy, [3]C.I. Parhon National Institute of Endocrinology, Bucharest, Romania

Bone resorption is stimulated by levothyroxine in TSH (thyroid stimulating hormone) suppressive therapy (TST), therefore decreasing BMD (1–10) We aim to introduce the bone status in a patient with a long history of TST in addition to a uterine cancer.
Case report: A 68-year-old female is admitted for bone assessment due to her medical history. She had surgical menopause at the age of 42 after total hysterectomy with bilateral adnexectomy for uterine leiomyoma (no hormonal replacement therapy) followed by the diagnosis of a squamous cell carcinoma of the uterine cervix, (treated with chemotherapy and radiotherapy 8 y ago). She also underwent total thyroidectomy for differentiated thyroid carcinoma 22 y prior, followed by TST. Previous DXA showed osteopenia: lumbar L1-L4 BMD = 1.005 g/cm^2, T-score = -1.5SD, Z-score = -1SD, femoral neck BMD = 0.888 g/cm^2, T-score = -1.1SD, Z-score = -0.3SD, total hip BMD = 1.048 g/cm^2, T-score = 0.3SD, Z-score = 0.7SD. She continued with 1000–2000 UI/d of cholecalciferol for 8 y. Currently, the thyroid panel confirms TST under 125 µg/d of levothyroxine and she has normal mineral metabolism assays, including 25-hydroxyvitamin D. Bone turnover markers are within normal range, except for formation marker osteocalcin = 10.73(15–46) ng/mL. No prevalent fracture is detected at profile spine X-ray. DXA-BMD is stationary: L1-L4 BMD = 0.916 g/cm^2, T-score = -2.1SD, Z-score = -1.3SD, femoral neck BMD = 0.862 g/cm^2, T-score = -1.0SD, Z-score = -0.1SD, total hip BMD = 1.059 g/cm^2, T-score = 0.5SD, Z-score = 1.1SD. TBS is normal of 1.431 (yet, she is known with pre-diabetes).
Conclusion: Despite several risk factors (early menopause, TST, and perhaps diabetes and a certain suppression of osteocalcin), a decision of not starting specific medication against osteoporosis was taken with serial DXA follow-up; this "wait and see" approach was based on DXA and FRAX-derivate risks (MOF of 7.9%, respectively, HF of 0.9%, adjusted for TBS of 6.8%, and 0.8%).

LONG-TERM THERAPY FOR BREAST CANCER AND BONE HEALTH IMPACT: A CASE-BASED STUDY

O.-C. Sima[1], A.-I. Trandafir[1], A. Dumitrascu[2], A.-M. Gheorghe[1], E. Petrova[3]

[1]PhD Doctoral School, Carol Davila Univ. of Medicine and Pharmacy & C.I. Parhon National Institute of Endocrinology, [2]C.I. Parhon National Institute of Endocrinology, [3]C.I. Parhon National Institute of

Endocrinology & Dept. of Endocrinology, Carol Davila Univ. of Medicine and Pharmacy, Bucharest, Romania

Aromatase inhibitors are listed among the therapy options for breast malignancy, especially for postmenopausal women. However, the estrogen-depriving action has a negative impact on both bone health.[1–10] We aim to introduce a patient with breast cancer and long-term treatment with anastrozole. Method: case report.

Case report: This was a 70-year-old female patient, diagnosed with breast cancer at the age of 62, for which she underwent surgery and treatment with anastrozole for 5 y. She entered spontaneous menopause at the age of 48. On the first endocrine admission, she had been following anastrozole therapy for 2 y and DXA showed osteopenia, with lumbar L1-L4 BMD = 0.983 g/cm^2, T-score = -1.6SD, Z-score = -0.7SD, femoral neck BMD = 0.825 g/cm^2, T-score = -1.5SD, Z-score = -0.6SD, total hip BMD = 0.913 g/cm^2, T-score = -0.8SD, Z-score = -0.1SD. Treatment with alendronate 70 mg/week was initiated (in addition to 2000 UI/d cholecalciferol) which she followed for almost 4 y She voluntarily stopped anti-resorptive medication for one more year (amid COVID-19 pandemic regulations). However (after her 5-y anastrozole regime was stopped) DXA remained within normal limits: L1-L4 BMD = 1.166 g/cm^2, T-score = -0.2SD, Z-score = 0.9SD, femoral neck BMD = 0.896 g/cm^2, T-score = -0.9 SD, Z-score = 0.1SD, as well as the bone turnover markers (BTM): osteocalcin = 19.92 ng/mL (normal:15–46), alkaline phosphatase = 53 U/L (normal:40–150), P1NP = 39.58 ng/mL (normal:20.25–76.31), and CrossLaps = 0.3 ng/mL (normal:0.3–0.782), respectively, the phosphorus-calcium metabolism assays, except for a mild vitamin D deficiency: 25-hydroxyvitamin D of 24.42 ng/mL (normal $>$ 30), but without secondary hyperparathyroidism: parathormone of 38.04 pg/mL (normal:15–65). She had no prevalent fragility fracture. Drug holiday was decided to continue under surveillance based on periodical DXA check-up in addition to vitamin D replacement.

Conclusion: Patients with breast malignancy and aromatase inhibitor therapy are highly predisposed to bone mass loss. However, a good DXA and BTM response at the end of this therapy, might allow a drug holiday for anti-osteoporotic medication, as well.

LOW TRABECULAR BONE SCORE IN A PATIENT WITH ADRENAL TUMOR, CHRONIC KIDNEY FAILURE, AND METABOLIC SYNDROME

O.-C. Sima[1], A.-I. Trandafir[1], A.-M. Gheorghe[1], E. Petrova[2], A. Dumitrascu[3]

[1]PhD Doctoral School, Carol Davila Univ. of Medicine and Pharmacy & C.I. Parhon National Institute of Endocrinology, [2]C.I. Parhon National Institute of Endocrinology & Dept. of Endocrinology, Carol Davila Univ. of Medicine and Pharmacy, [3]C.I. Parhon National Institute of Endocrinology, Bucharest, Romania

Bone health can be affected by a variety of conditions, including adrenal tumors-related mild/intermittent autonomous cortisol secretion (ACS) due to adrenal tumors, chronic kidney disease, and diabetes mellitus. [1–10] We aim to introduce a patient with low TBS as a tip of the iceberg for several endocrine and metabolic conditions.

Case report: This is a 79-year-old lady admitted for the evaluation of a right adrenal tumor of 2.3 cm discovered 2 years prior on an abdominal computed tomography scan (that was performed for non-specific abdominal complains). She delayed further investigations at that point due to COVID-19 pandemic circumstances. Her medical background includes high blood pressure, dyslipidemia, obesity, and cholelithiasis. On admission, baseline morning ACTH = 10.96 pg/mL(normal:3–66), and cortisol = 11.96 μg/dL (normal:4.82–19.5) were normal; post-1 mg dexamethasone test cortisol was 1.33 μg/dL (normal: $<$ 1.8), suggesting no ACS. Plasma and 24-h urinary metanephrines/normetanephrines were normal, as well as aldosterone/renin ratio, chromogranin A, and neuron specific enolase (confirming an adrenal incidentaloma). Other findings showed elevated blood glucose = 147 mg/dL (normal:83–110), glycated hemoglobinA1c = 6.2% (normal $<$ 5.9), creatinine = 1.36 mg/dL (normal:0.5–1.1), urea = 40 mg/dL (normal:22–43), and uric acid = 7.8 mg/dL (normal:2.6–6). Type 2 diabetes with renal involvement was confirmed, respectively, a mild hypovitaminosis D (25-hydroxyvitamin D of 26 ng/mL). DXA showed osteopenia: lumbar BMD = 0.923 g/cm^2, T-score = -2.4SD, Z-score = -1.7SD, femoral neck BMD = 0.793 g/cm^2, T-score = -1.6SD, Z-score = -0.5SD, total hip BMD = 0.902 g/cm^2, T-score = -0.8SD, Z-score = 0.1SD, and low TBS = 1.220. Serum bone formation markers were normal. She was recommended adequate lifestyle intervention for glucose and renal profile, uric acid and arterial hypertension lowering medication, respectively daily alphacalcidol 0.5 μg/d plus surveillance of the adrenal mass, and bone status.

Conclusion: Bone microarchitecture might be damaged in spite of a normal BMD; while solely TBS-based threshold of intervention against osteoporosis is still an open issue.

P1037
REAL-LIFE-MEDICINE- BASED SAMPLE CASE OF COMPLICATED OSTEOPOROSIS

O.-C. Sima[1], A.-I. Trandafir[1], A.-M. Gheorghe[1], E. Petrova[2], A. Dumitrascu[3]

[1]PhD Doctoral School, Carol Davila Univ. of Medicine and Pharmacy & C.I. Parhon National Institute of Endocrinology, [2]C.I. Parhon National Institute of Endocrinology & Dept. of Endocrinology, Carol Davila Univ. of Medicine and Pharmacy, [3]C.I. Parhon National Institute of Endocrinology, Bucharest, Romania

Fracture risk reduction is the focus for complicated osteoporosis, but individual response to different anti-osteoporotic drugs is the key in anti-osteoporosis management. [1–9] We aim to introduce a patient with severe osteoporosis who suffered multiple fragility fractures despite therapy.

Case report: This is a 71-year-old female who entered menopause at 50. Her medical history includes invasive lobular breast carcinoma at 66 for which she received neoadjuvant chemotherapy and tamoxifen for 2 y after mammary surgery. She was diagnosed with osteoporosis since the age of 53 and treated with bisphosphonates for 8 y, suffering multiple fragility fractures despite being compliant. Then daily teriparatide was followed for 2 y and continued with denosumab for 1 y when the patient decided the stop any medication for 1 y. At that point, the mammary malignancy was detected and treated until achieving remission. Hence, she came back for a bone assessment only after another 3 y while being in drug holiday. DXA showed osteoporosis, but better scores than before: L2-L3 BMD = 0.815 g/cm^2, T-score = -3.2SD, Z-score = -1.5SD, femoral neck BMD = 0.821 g/cm^2, T-score = -1.6SD, Z-score = 0.1SD, total hip BMD = 0.843 g/cm^2, T-score = -1.3SD, Z-score = 0.1SD. Zoledronate 5 mg was administered and vitamin D supplementation. After 1 y, DXA reveals osteopenia scores: L1-L4 BMD = 0.903 g/cm^2, T-score = -2.3SD, Z-score = -1.0SD, femoral neck BMD = 0.831 g/cm^2, T-score = -1.2SD, Z-score = 0.1SD, total hip BMD = 0.816 g/cm^2, T-score = -1.5SD, Z-score = -0.5SD, a mildly reduced TBS = 1.252, and suppressed bone turnover markers: osteocalcin = 14.32 ng/mL (normal:15–46), alkaline phosphatase = 31 U/L (normal:40–150), P1NP = 27.7 ng/mL (normal:14.28–58.92), and CrossLaps = 0.12 ng/mL (0.33–0.782). No new fracture was found at screening X-ray. She was recommended to continue with further vitamin D supplementation and periodical follow-up since redo of zoledronate might be postponed up to 36 months.

Conclusion: The particular aspects of this sample case are: multiple fractures despite adequate therapy, followed by an otherwise good response to 3-y anti-osteoporotic treatment gap having denosumab as the last drug before self-decision of drug holiday.

P1038
DECISION OF DRUG HOLIDAY FOR A PATIENT WITH PRIMARY HYPERPARATHYROIDISM-RELATED MULTIPLE FRAGILITY FRACTURES

O.-C. Sima[1], D.-E. Rentea[2], A.-I. Trandafir[1], A.-M. Gheorghe[1], E. Petrova[3]

[1]PhD Doctoral School, Carol Davila Univ. of Medicine and Pharmacy & C.I. Parhon National Institute of Endocrinology, [2]C.I. Parhon National Institute of Endocrinology, [3]C.I. Parhon National Institute of Endocrinology & Dept. of Endocrinology, Carol Davila Univ. of Medicine and Pharmacy, Bucharest, Romania

Primary hyperparathyroidism(PHP)-related osteoporosis involves different challenges during post-operatory follow-up across a large period of time amid menopause; step-by-step decision of anti-osteoporotic medication should be taken due to increasing years since menopause and aging despite blood PTH correction.[1–6] We introduce a patient who suffered multiple fragility fractures caused by PHP complicated with severe osteoporosis.

Case report: This is a 72-year-old female patient, admitted for bone status evaluation. She has a history of PHP and 5 fragility fractures that occurred before the actual diagnosis of PHP requiring 1-y apart two times parathyroidectomy due to asynchronous bilateral parathyroid tumors (without a genetic background). After surgery, lowest T-score at central DXA was at lumbar spine (-2.8); she was treated with zoledronate 5 mg IV for 3 y, followed by 1 y of ibandronate IV, at the end of which DXA improved (in addition to post-surgery PTH correction following the second intervention) lumbar L1-L4 BMD of 0.911 g/cm^2, T-score of -2.2, Z-score of -1.3; femoral neck BMD of 0.754 g/cm^2, T-score of -2, Z-score of -1; total hip BMD of 0.876 g/cm^2, T-score of -1, Z-score of -0.3; and third distal radius BMD of 0.537 g/cm^2, T-score of -2.5, Z-score of -1.4. 5 mg zoledronate IV was administered once again with 12-month DXA results showing a further improvement; hence a drug holiday was decided. After 8 y of drug holiday (under close surveillance), DXA revealed an additional increase of BMD as follows: L1-L4 BMD of 0.962 g/cm^2, T-score of -1.8, Z-score of -0.6; femoral neck BMD of 0.778 g/cm^2, T-score of -1.7, Z-score of -0.4; total hip BMD of 0.938 g/cm^2, T-score of -0.5, Z-score of 0.5; and third distal radius BMD of 0.704 g/cm^2, T-score of -2, Z-score of 0.1. Of note, a degraded microarchitecture was identified based on TBS of 1.219. Since no new clinical fracture occurred, neither an asymptomatic one was identified at screening profile spine X-ray, further drug holiday was recommended.

Conclusion: Upon correction of an endocrine cause of secondary osteoporosis, despite being already complicated with fractures, a decision of bisphosphonates holyday should be taken with caution, but some patients might prove an exceptional response and no additional exposure to anti-osteoporotic regimes is needed. TBS-based decision of therapy in subjects with corrected PHP remains challenging.

THE RIGHT SWITCH AT THE RIGHT MOMENT: IMPORTANCE OF FOLLOW-UP IN PATIENTS WITH ANTIOSTEOPOROTIC TREATMENT

O.-C. Sima[1], D.-E. Rentea[2], M. Costachescu[3], A.-I. Trandafir[1], A.-M. Gheorghe[1], E. Petrova[4]

[1]PhD Doctoral School, Carol Davila Univ. of Medicine and Pharmacy & Dept. of Endocrinology, C.I. Parhon National Institute of Endocrinology, [2]Dept. of Endocrinology, C.I. Parhon National Institute of Endocrinology, [3]Dept. of Radiology and Medical Imaging, Fundeni Clinical Institute, [4]Dept. of Endocrinology, C.I. Parhon National Institute of Endocrinology & Dept. of Endocrinology, Carol Davila Univ. of Medicine and Pharmacy, Bucharest, Romania

Osteoporosis leads to bone fragility, thus increasing the risk of low trauma fractures. Whether it is due to menopause or secondary causes, a personalized approach is mandatory, particularly when deciding the switch of anti-osteoporotic drugs.[1–5] We aim to introduce a patient with a long history of treated osteoporosis and associated pitfalls.

Case report: This is a 75-year-old patient admitted for bone assays. Her personal medical history includes total thyroidectomy performed at 69 for a left follicular adenoma. She is also known with osteoporosis since the age of 64, when DXA showed lumbar L1-L4 BMD = 0.661 g/cm^2, T-score = -4.3SD, Z-score = -3.3SD. Treatment with oral weekly risedronate was followed for 5 y (with cholecalciferol 1000–2000 UI/d); however, despite compliance and no obvious new cause of bone loss, DXA confirmed a decrease in L1-L4 BMD of 0.638 g/cm^2, T-score = -4.5SD, Z-score = -3.4SD, and L1, L2, L3 vertebral fractures were discovered on X-ray. Therefore, a switch to teriparatide 20 mg/d subcutaneously was done. After 2 y, DXA improved: L1-L4 BMD = 0.781 g/cm^2, T-score = -3.3SD, Z-score = -1.9SD without novel fractures. IV ibandronate was administered every 3 months for 1 y with poor BMD response, followed by denosumab 60 mg subcutaneously every 6 months for 4 y (during COVID-19 pandemic years, she was not reassessed by DXA). Currently, DXA reflects a BMD improvement: L1-L4 BMD = 0.857 g/cm^2, T-score = -2.9SD, Z-score = -1.5SD; femoral neck BMD = 0.798 g/cm^2, T-score = -1.5SD, Z-score = 0SD, total hip BMD = 0.848 g/cm^2, T-score = -1.3SD, Z-score = 0.1SD, with degraded microarchitecture as pointed by TBS of 1.220. Bone formation marker osteocalcin is slightly decreased (11.58 ng/mL, normal:15–46), while alkaline phosphatase and P1NP are normal; bone resorption marker CrossLaps is also suppressed (0.11 ng/mL, normal:0.33–0.782). A decision of further continuing denosumab and vitamin D was established.

Conclusion: Despite no obvious causes, the patient was not responsive to bisphosphonates, but successfully finished the 2-y teriparatide protocol and continued to have stationary BMD under denosumab, thus confirming that the type of anti-resorptive drug should be individually decided and periodical follow-up is essential.

Low BMD may be found in patients before menopause onset and these cases represent a challenge in the daily medical practice. Periodical check-up is crucial in order to find the optimal timing of treatment initiation or drug switch when results are not adequate.[1–5] We aim to introduce a patient confirmed with a childhood musculoskeletal disorder and a long history of osteoporosis associated with multiple fragility fractures.

Case report: This was a 71-year-old female admitted for DXA scan. She has congenital dysplasia of the right hip for which surgery was performed and poliomyelitis sequelae. She entered menopause at the age of 57, but she was diagnosed with osteoporosis at 51. Treatment with alendronate was recommended for a few years, followed by risedronate until the age of 57, when she suffered multiple vertebral fractures. After this, the patient started taking oral ibandronate. This was her treatment for 7 y (of note, a metatarsal fracture occurred after 1 y after initiation). At the end of this bisphosphonates sequence, DXA showed (left) total hip BMD = 0.645 g/cm^2, T-score = -3SD, Z-score = -1.5SD, femoral neck BMD = 0.59 g/cm^2, T-score = -3.3SD, Z-score = -1.5SD. A switch to teriparatide was offered to the lady; yet, early after initiation, she complained at local accuses after subcutaneous injection and refused to continue it, neither she continued with another drug against osteoporosis and did not come back for another evaluation amid COVID-19 pandemic era. During this period, she had two other fractures of the right tibial malleolus and the left calcaneus. On current admission, biochemistry panel of calcium-phosphorus metabolism showed normal levels of total serum calcium, serum phosphorus, vitamin D and parathormone, as well, as bone turnover markers while DXA-BMD was stationary. A decision of injectable bisphosphonates (5 mg/y zoledronate) was done in addition to vitamin D and continuum surveillance.

Conclusion: Fragility fractures represent the main concern in osteoporotic patients; as seen in this case, long running panel of medication over the years might impact the overall compliance in one individual.

Menopausal osteoporosis is characterized by an imbalance between bone formation and resorption, with an increase of the latter, and teriparatide represents an anabolic agent that promotes bone formation, hence reducing the risk of osteoporotic fractures, particularly at vertebral site. [1–5] Our purpose is introducing a patient that followed a full-course 24-month teriparatide protocol, preceded and followed by bisphosphonates therapy.

Case report: This is a 59-year-old female patient admitted for a DXA control. At the age of 51, DXA confirmed osteoporosis: L1-L4 BMD = 0.878 g/cm^2, T-score = -2.5SD, Z-score = -1.8SD, femoral neck BMD = 0.766 g/cm^2, T-score = -2SD, Z-score = -1SD, total hip BMD = 0.758 g/cm^2, T-score = -2SD, Z-score = -1.3SD. She started oral weekly risedronate which she followed for 3 y before suffering a single vertebra fracture. After this, teriparatide was initiated and at the end of the 2-y therapy, DXA showed increased L1-L3 BMD = 0.955 g/cm^2, T-score = -1.8SD, Z-score = -0.9SD, femoral neck BMD = 0.786 g/cm^2, T-score = -1.8SD, Z-score = -0.8SD, total hip BMD = 0.792 g/cm^2, T-score = -1.7SD, Z-score = -1SD, and the management was continued with anti-resorptive treatment. Currently, after another 3 y of intravenous ibandronate, DXA reveals no further bone loss (in addition to lack of any additional fracture) L1-L4 BMD = 0.941 g/cm^2, T-score = -2SD, Z-score = -0.8SD, femoral neck BMD = 0.772 g/cm^2, T-score = -1.7SD, Z-score = 0.6SD, total hip BMD = 0.804 g/cm^2, T-score = -1.6SD, Z-score = -0.8SD. A normal bone microarchitecture is confirmed by TBS of 1.474. Ibandronate IV in association with vitamin D supplements was further offered to the lady as well as a recommendation of lifelong skeleton health surveillance.

Conclusion: When fragility fractures occur in osteoporotic patients that already follow anti-resorptive treatment, teriparatide is useful, however, a re-introduction of post-teriparatide bisphosphonates course is highly recommended.

P1042
SEVERE TETANY OCCURANCE AFTER TOTAL TYROIDECTOMY FOR A BENIGN PARTIALLY RETROSTERNAL GOITER

M. Costachescu[1], E. Petrova[2], O.-C. Sima[3], A.-M. Gheorghe[3], A.-I. Trandafir[3], D. Ioachim[4]

[1]Dept. of Radiology and Medical Imaging, Fundeni Clinical Institute, [2]Dept. of Endocrinology, C.I. Parhon National Institute of Endocrinology & Dept. of Endocrinology, Carol Davila Univ. of Medicine and Pharmacy, [3]PhD Doctoral School, Carol Davila Univ. of Medicine and Pharmacy & Dept. of Endocrinology, C.I. Parhon National Institute of Endocrinology, [4]Dept. of Pathology, C.I. Parhon National Institute of Endocrinology, Bucharest, Romania

Surgical removal (or transitory lesion amid neck surgery) of the parathyroid glands can lead to severe effects, among which the implications at the level of neuromuscular and cardiac systems are the most important. Manifestations cover a large spectrum, from mild tingling paresthesia to life-threatening cardiac arrythmias. [1–5] We aim to introduce a patient with symptomatic postoperative hypocalcemia.

Case report: Mineral metabolism is explored based on total serum calcium, phosphorus, 25-hydroxyvitamin D (25OHD), PTH, and bone turnover markers of formation (osteocalcin), respective of resorption (CrossLaps). This is a 33-year-old patient admitted for postsurgical check-up after total thyroidectomy for a benign multinodular goiter. She accused tingling paresthesia in her fingers, toes and around the mouth, accompanied by muscle cramping, starting 2 d after the surgery. From her medical history we mention two pregnancies, 8 and 5 y ago, that were complicated with pre-eclampsia and at the end of the second, an increase of the pre-existent endemic goiter was registered. Currently, the thyroid panel showed an elevated TSH of 16.53 mUI/mL (normal: 0.35–4.94) under levothyroxine 150 μg daily, indicating an insufficient substitutive dose. Phosphor-calcium metabolism revealed hypocalcemia and a mild hyperphosphatemia, with a total serum calcium of 7.32 mg/dL (normal: 8.4–10.3) and phosphorus of 4.8 mg/dL (normal: 2.3–4.7). 25OHD, PTH and bone turnover markers were within normal range (low normal PTH). Levothyroxine was raised to 162.5 μg/d. After 10-d regime of 1 g/d intravenous calcium, oral calcium supplements (in addition to intermittent intravenous calcium if needed) associated with calcitriol 0.5 mg/d were initiated with close surveillance.

Conclusion: Post-thyroidectomy follow-up should focus not only on TSH and FT4 evaluation, but also on mineral metabolism and balance, especially in cases with more difficult surgery of partially mediastinal masses. Severe (symptomatic) tetany which is discordant with low-normal PTH is expected to be transitory, as seen in this sample case.

Parhon National Institute of Endocrinology, Bucharest, Romania

Osteoporosis may be treated either with anti-resorptive or bone forming agents, with an individual (personalized) decision in patients

with a long history. [1–4] We aim to introduce the sequential approach for a lady with complicated osteoporosis.

Case report: This was a 55-year-old female patient diagnosed with osteoporosis at the age of 48. She entered spontaneous menopause at 47. Her personal medical history included rheumatoid arthritis for which she had 1 year of glucocorticoid therapy at the age of 49. She was first admitted at 48, when DXA revealed L1-L4 lumbar BMD of 0.899 g/cm^2, T-score = -2.3SD, Z-score = -2SD, femoral neck BMD = 0.726 g/cm^2, T-score = -2.2SD, Z-score = -1.5SD, total hip BMD = 0.815 g/cm^2, T-score = -1.5SD, Z-score = -1.1SD. Due to high-dose corticoids, she was assessed as having high fracture risk; hence, she started treatment with oral weekly risedronate. After 2 y, DXA showed a BMD decrease: L1-L4 BMD = 0.807 g/cm^2, T-score = -3.1SD, Z-score = -2.8SD, femoral neck BMD = 0.728 g/cm^2, T-score = -2.2SD, Z-score = -1.5SD, total hip BMD = 0.772 g/cm^2, T-score = -1.9SD, Z-score = -1.4SD. In addition, thoracolumbar spine X-ray showed novel multiple vertebral fractures at thoracic level. Bone turnover markers remained within normal range. Therefore, it was decided to start teriparatide for 2 y with a good response, followed by denosumab under which DXA shows an improvement—lumbar L1-L4 BMD = 0.896 g/cm^2, T-score = -2.4SD, Z-score = -1.7SD, femoral neck BMD = 0.641 g/cm^2, T-score = -2.9SD, Z-score = -1.9SD, total hip BMD = 0.758 g/cm^2, T-score = -2.0SD, Z-score = -1.4SD. Bone formation marker osteocalcin is decreased (9.78 ng/mL, normal:15–46), P1NP is normal (17.12 ng/mL, normal:20.25–76.31) and bone resorption marker CrossLaps is also below the normal range (0.04 ng/mL, normal:0.33–0.782). She was recommended to continue denosumab therapy with 2000 UI/d cholecalciferol.

Conclusion: In this case, a good response to bone forming agent was synchronous with the massive reduction of glucocorticoids doses, but lifelong anti-osteoporosis therapy is required, despite her relatively young age for a complicated osteoporosis due to multiple vertebral fractures.

P1044
PITFALLS OF BISPHOSPHONATES HOLIDAY AS AN OSTEOPOROSIS APPROACH

M. Costachescu[1], E. Petrova[2], A.-I. Trandafir[3], O.-C. Sima[3], A.-M. Gheorghe[3], D. Terzea[4]

[1]Dept. of Radiology and Medical Imaging, Fundeni Clinical Institute, [2]Dept. of Endocrinology, C.I. Parhon National Institute of Endocrinology & Dept. of Endocrinology, Carol Davila Univ. of Medicine and Pharmacy, [3]PhD Doctoral School, Carol Davila Univ. of Medicine and Pharmacy & Dept. of Endocrinology, C.I. Parhon National Institute of Endocrinology, [4]Dept. of Pathology, C.I. Parhon National Institute of Endocrinology, Bucharest, Romania

One of the most challenging areas of treating primary osteoporosis is represented by the issue of bisphosphonates holiday. [1–8] We aim to introduce a patient who started drug holiday after antiresorptive treatment that led to important bone mass loss.

Case report: This was a 61-year-old female patient who was admitted for bone status planned checkup. Her medical history included gastro-esophageal reflux disease that associated pharyngolaryngitis. She was initially diagnosed with osteoporosis ten years ago and treated with alendronate for 2.5 y, after which she was offered a drug holiday. 4 y ago, DXA evaluation showed osteopenia and it was decided to continue the bisphosphonates holiday with 1-y reassessment. Currently, DXA confirms osteoporosis with L1-L4 BMD of 0.708 g/cm^2, T-score of -3.1 SD and Z-score of -1.8 SD, total hip BMD of 0.804 g/cm^2, T-score of -1.6 SD and Z-score of -0.8 SD and femoral neck BMD of 0.657 g/cm^2, T-score of -2.3 SD and Z-score of -1.0 SD. Moreover, a de-suppression of bone formation markers osteocalcin = 32 ng/mL (normal:15–46), alkaline phosphatase = 71 U/L (normal:40–140), P1NP = 68 ng/mL (normal:20.25–76.31) and bone resorption marker CrossLaps = 0.6 ng/mL (normal:0.33–0.782) is registered. Thus, it is decided to start intravenous ibandronate every 3 months due and vitamin D supplements.

Conclusion: No incidental fracture was associated with the lowering of BMD, however BMD changes might stand alone for restarting specific medication against osteoporosis.

P1045
CONSIDERATIONS ON A TRAUMATIC FRACTURE IN A FEMALE WITH PRIMARY OSTEOPOROSIS

M. Costachescu[1], A.-M. Gheorghe[2], A.-I. Trandafir[2], O.-C. Sima[2], E. Petrova[3], D. Terzea[4]

[1]Dept. of Radiology and Medical Imaging, Fundeni Clinical Institute, [2]PhD Doctoral School, Carol Davila Univ. of Medicine and Pharmacy & Dept. of Endocrinology, C.I. Parhon National Institute of Endocrinology, [3]Dept. of Endocrinology, C.I. Parhon National Institute of Endocrinology & Dept. of Endocrinology, Carol Davila Univ. of Medicine and Pharmacy, [4]Dept. of Pathology, C.I. Parhon National Institute of Endocrinology, Bucharest, Romania

Menopause comes with significant changes in bone mass, as the decrease in estrogenic levels causes an imbalance between formation and resorption. Primary osteoporosis can lead to high risk of fractures, having a negative impact on the life of menopausal women, but additional traumatic fracture requires an adjustment of strategy in this instance. [1–8] We aim to introduce a patient with a history of a traumatic fracture and recently-diagnosed osteoporosis.

Case report: This is a 68-year-old female patient admitted for endocrine check-up. Her medical history includes a traumatic fracture in the right humerus more than a decade ago, followed by a defect in consolidation which resulted in the shortening of the left (nondominant) arm by 10 cm. She was also diagnosed with papillary thyroid carcinoma after total thyroidectomy, for which she received radioiodine therapy (160 mCi) and TSH suppression levothyroxine therapy. Currently, the thyroid panel is within normal range, with TSH = 0.35 mIU/mL (normal:0.25–4.94) and FT4 (Free levothyroxine) of 15.2 pmol/L (normal: 9–19), under levothyroxine 100 μg/d. Thyroglobulin is 2.07 ng/mL (normal: 3.5–7.7). Total serum calcium is normal, as well as phosphorus and vitamin D levels, and bone formation markers osteocalcin = 34.49 ng/mL (normal:15–46), alkaline phosphatase = 95 (40–150) UI/L, and P1NP = 68.6 ng/mL (normal: 20.25–76.31), and resorption marker CrossLaps = 0.76 ng/mL (normal: 0.33–0.782). DXA shows L1-L3 BMD = 0.942 g/cm^2, T-score = -2 SD, Z-score = -0.4 SD, femoral neck BMD = 0.833 g/cm^2, T-score = -1.2 SD, Z-score = 0.2 SD, total hip BMD = 0.898 g/cm^2, T-score = -0.8 SD, Z-score = 0.3 SD, third distal radius BMD = 0.577 g/cm^2, T-score = -3.4SD, Z-score = -1.8 SD,

confirming osteoporosis (of note, she had normal PTH and 25-hydroxyvitamin D; we used her dominant arm because of her prior lesion). A degrade microarchitecture in terms of low TBS of 1.225 was identified. Hence, a decision of initiating oral bisphosphonates was done in addition to vitamin D supplements and a second round of radioiodine treatment.

Conclusion: DXA at third distal dominant arm in cases with non-usable data for the dominant one are less useful in daily practice. However, in this case, the presence of the lowest T-score at this site in association with other fracture risks such as TSH suppressive therapy represented major clues for initiating specific therapy against osteoporosis.

BONE EFFECTS AFTER 24 MONTHS SINCE SINGLE 5-MG DOSE OF ZOLEDRONATE

M. Costachescu[1], A. Goldstein[2], O.-C. Sima[3], A.-M. Gheorghe[3], A.-I. Trandafir[3], E. Petrova[4]

[1]Dept. of Radiology and Medical Imaging, Fundeni Clinical Institute, [2]Dept. of Nuclear Medicine, C.I. Parhon National Institute of Endocrinology, [3]PhD Doctoral School, Carol Davila Univ. of Medicine and Pharmacy & Dept. of Endocrinology, C.I. Parhon National Institute of Endocrinology, [4]Dept. of Endocrinology, C.I. Parhon National Institute of Endocrinology & Dept. of Endocrinology, Carol Davila Univ. of Medicine and Pharmacy, Bucharest, Romania

After menopause, the lowering levels of estrogens lead to bone fragility and increased fracture risk, an aspect that is prolonged thought the entire life span across menopausal years, thus the importance of treatment strategies that increase the patients' adherence.[1–8] We aim to introduce the 24-month bone status assessment following single zoledronate injection against osteoporosis.

Case report: This is a 78-year-old lady with osteoporosis and previous fragility fractures at ribs and distal radius that were confirmed early after entering spontaneous menopause around the age of 50. Yet, she only started anti-osteoporotic treatment at the age of 61 (weekly alendronate) which she followed for three years, then two more years of oral ibandronate and one year of alendronate (due to protocol-based reimbursement at that time). After these 6 y, central DXA showed an improvement since initial score to L1-L4 lumbar BMD = 0.784 g/cm^2, T-score = -3.2SD, Z-score = -1.9SD, femoral neck BMD = 0.790 g/cm^2, T-score = -1.8SD, Z-score = -0.4SD, total hip BMD = 0.835 g/cm^2, T-score = -1.4SD, Z-score = -0.3SD (and no incidental fractures). She decided to stop the medication against osteoporosis (except for vitamin D supplements), but came each year for a DXA and bone markers evaluation during the following 6 y. Consecutively, DXA revealed a BMD increase in terms of L1-L4 T-score = -2.8SD. Since she already had prevalence fractures (but not novel ones), 5 mg zoledronate IV were administrated with a good 24-month effect: L1-L4 BMD = 0.883 g/cm^2, T-score = -2.5SD, Z-score = -0.8SD, femoral neck BMD = 0.760 g/cm^2, T-score = -2SD, Z-score = -0.2SD, total hip BMD = 0.842 g/cm^2, T-score = -1.3SD, Z-score = 0.3SD. Subsequently, a decision of prolonging the gap to the next administration was done; it was prolonged for three more years, when BMD decreased and the therapy was re-initiated.

Conclusion: A single 5-mg dose of zoledronate may have prolonged effects more than 12 months, thus the second and even the third year since its administration may be regarded, not as bisphosphonate holiday, but as long-term effect, thus being part of a long-standing strategy that is also meant to increase the subject's compliance.

Parhon National Institute of Endocrinology, [4]Dept. of Endocrinology, C.I. Parhon National Institute of Endocrinology & Dept. of Endocrinology, Carol Davila Univ. of Medicine and Pharmacy, Bucharest, Romania

MEN2A (multiple endocrine neoplasia type 2A) is an inherited syndrome that usually manifests through the association of medullary thyroid carcinoma, pheochromocytoma and primary hyperparathyroidism. It is diagnosed through genetic testing of the *RET* (rearranged during transfection) mutation and it is transmitted in an autosomal dominant manner. Nearly all patients develop medullary thyroid carcinoma, but the presence of pheochromocytoma and primary hyperparathyroidism varies with the specific type of mutation present. [1–10] We aim to introduce a patient with MEN2A syndrome and late-onset tetany after synchronous thyroidectomy and parathyroidectomy.

Case reports: This was a 42-year-old female patient admitted for endocrine check-up after (two times) bilateral adrenalectomy for pheochromocytoma, and synchronous total thyroidectomy for medullary thyroid carcinoma and left inferior parathyroidectomy for a parathyroid tumor. Her family medical history revealed that her mother, her sister and her first-grade cousin were also diagnosed with MEN2A, yet, she was the only family member confirmed with primary hyperparathyroidism. One of her 2 daughters harbors *RET* pathogenic variant. Following the thyroid and parathyroid surgery, low normal calcium and PTH were intermittently found. However, currently, 10 y after surgery, thyroid assessment shows slightly elevated TSH = 4.96μUI/mL (normal: 0.35–4.94), normal FT4 (free levothyroxine) = 11.69 pmol/l (normal:9–19) under levothyroxine 100 μg/d and increased calcitonin of 18.5 pg/mL (normal:1–4.8). Cervical ultrasound did not indicate any remaining thyroid tissue after total thyroidectomy. Her biochemical phosphor-calcium panel shows decreased total serum calcium of 6.54 mg/dL (normal:8.4–10.3), high levels of phosphorus = 4.67 mg/dL (normal:2.5–4.5), normal 25-OHD (25-hydroxyvitamin D) = 40 ng/mL (normal:20–100) and low PTH = 10.76 pg/mL (normal:15–65) – these being the lowest value of PTH following the neck surgery. 24-h urinary calcium was

below normal range (0.02 g/24 h, normal: 0.07–0.3). Levothyroxine dose was increased to 112.5 μg/d, calcitriol 0.5 μg/d and calcium supplements were initiated.

Conclusion: This case highlights unexpected mild hypoparathyroidism following the removal of a single parathyroid tumor a decade before. Additional mechanisms such as autoimmune might be overlapped.

DIFFICULTIES IN DECISION MAKING WITH REGARD TO MENOPAUSAL OSTEOPOROSIS COMPLICATED WITH AN ELBOW FRACTURE

M. Costachescu[1], O.-C. Sima[2], A.-M. Gheorghe[2], A.-I. Trandafir[2], E. Petrova[3]

[1]Dept. of Radiology and Medical Imaging, Fundeni Clinical Institute, [2]C.I. Parhon National Institute of Endocrinology & PhD Doctoral School, Carol Davila Univ. of Medicine and Pharmacy, [3]Dept. of Endocrinology, C.I. Parhon National Institute of Endocrinology & Dept. of Endocrinology, Carol Davila Univ. of Medicine and Pharmacy, Bucharest, Romania

Fragility fractures are associated with increased morbidity and mortality and reducing this risk is the most important aspect of anti-osteoporotic treatment. We aim to introduce a patient with osteoporosis that interrupted bisphosphonates therapy and suffered an elbow fracture. [1–10]

Case report: This is a 67-year-old female admitted for bone status investigation. She was diagnosed with osteoporosis at the age of 63, when DXA showed L1-L4 lumbar BMD = 0.829 g/cm^2, T-score = -2.8SD, Z-score = -1.6SD, femoral neck BMD = 0.796 g/cm^2, T-score = -1.7SD, Z-score = -0.5SD, total hip BMD = 0.848 g/cm^2, T-score = -1.3SD, Z-score = -0.3SD, third distal radius BMD = 0.504 g/cm^2, T-score = -2.9SD, Z-score = -1.7SD and treatment with weekly alendronate 70 mg was initiated. After 1 y, the lady stopped alendronate intake for 1 y due to COVID-19 pandemic restrictions and access difficulties to prescription; following this, she experienced a left elbow fracture. Weekly alendronate therapy was reinitiated, then a switch to oral weekly risedronate was done after 1 year due to mild gastrointestinal accuses. Currently, after 1 y of risedronate (associating a good clinical tolerance), DXA revealed an improvement L1-L4 BMD = 0.999 g/cm^2, T-score = -1.5SD, Z-score = -0.3SD, femoral neck BMD = 0.832 g/cm^2, T-score = -1.2SD, Z-score = 0.0SD, total hip BMD = 0.918 g/cm^2, T-score = -0.7SD, Z-score = 0.3SD, third distal radius BMD = 0.695 g/cm^2, T-score = -2.1SD, Z-score = -0.5SD. DXA-based TBS of 1.229 showed a degraded structure. Bone formation markers are within normal range: osteocalcin = 16.24 ng/mL (normal: 15–46), P1NP = 25.65 ng/mL (normal: 20.25–76.31) and bone resorption marker CrossLaps is slightly decreased of 0.31 ng/mL (normal: 0.33–0.782). Risedronate was further recommended in addition to adequate vitamin D intake.

Conclusion: Compliance to anti-osteoporotic treatment and periodical follow-up are mandatory in order to achieve good results, especially for patients with high risk of fragility fractures. A self-imposed drug holiday represents a challenge in the management of such patients.

P1049
SYSTEMIC SCLEROSIS WITH FRAGILITY RIB FRACTURES: WHAT OPTIONS DO YOU HAVE IN DAILY PRACTICE?

M. Costachescu[1], A.-I. Trandafir[2], A.-M. Gheorghe[2], O.-C. Sima[2], E. Petrova[3]

[1]Dept. of Radiology and Medical Imaging, Fundeni Clinical Institute, [2]C.I. Parhon National Institute of Endocrinology & PhD Doctoral School, Carol Davila Univ. of Medicine and Pharmacy, [3]Dept. of Endocrinology, C.I. Parhon National Institute of Endocrinology & Dept. of Endocrinology, Carol Davila Univ. of Medicine and Pharmacy, Bucharest, Romania

Systemic sclerosis is an autoimmune disease that progresses with the affection of multiple organs, including the skin, lung, heart, gastrointestinal tract and musculoskeletal system. Patients with this condition are particularly predisposed to osteoporosis while subcutaneous administration might not work due to the skin involvement. [1–10] We aim to introduce a patient with systemic sclerosis and multiple rib fractures under antiresorptive treatment.

Case report: This was a 55-year-old female patient with advanced systemic sclerosis manifested with Raynaud syndrome, pulmonary fibrosis, esophagitis, pangastritis and calcinosis cutis. She was diagnosed with osteoporosis 11 years ago and followed treatment with bisphosphonates for 3 years, and she suffered two rib fractures under therapy. After 3 y of antiresorptive drugs, DXA showed L1-L4 BMD = 0.011 g/cm^2, T-score = -1.4SD, Z-score = -0.5SD, femoral neck BMD = 0.736 g/cm^2, T-score = -2.2SD, Z-score = -1SD, total hip BMD = 0.843 g/cm^2, T-score = -1.3SD, Z-score = -0.4SD. Therefore, a switch to anabolic medication with subcutaneous teriparatide 20 μg daily was done. After 1 year of teriparatide, BMD did not improve, possibly due to the scleroderma that interfered with administration; hence, she was considered non-responder. She continued with IV ibandronate for 2 y and new rib fractures occurred. After this event, 5 mg single annual zoledronate injection was administered, followed by denosumab for 4 y (60 mg every 6 months). Currently, DXA confirms further bone loss: L1-L4 BMD = 0.919 g/cm^2, T-score = -2.2SD, Z-score = -0.5SD, femoral neck = 0.632 g/cm^2, T-score = -2.9SD, Z-score = -1.4SD, total hip BMD = 0.752 g/cm^2, T-score = -2SD, Z-score = -0.8SD, with DXA-based TBS of 1.286 (a partially degraded microarchitecture). Calcium-phosphorus panel was at normal levels, including low normal levels of bone turnover markers. A decision to offer her zoledronate 5 mg intravenously was further established in addition to vitamin D supplementation.

Conclusion: Due to the nature of the disease, systemic sclerosis associated with osteoporosis leads to severe fragility fractures including at rib level. The failure of antiresorptive agents to improve BMD in this case pointed towards the need for anabolic medication.

However, the range of efficient drugs is limited by the multi-systemic complications, including cutaneous.

CORRELATIONS OF BONE TURNOVER MARKERS AND BMI IN PATIENTS WITH PSORIASIS

O.-M. Niţă[1], M. J. Ţuculina[2], D. M. Albulescu[1], L. E. Stoica[1], N. M. Bugălă[1], S. A. Preda[2]

[1]Univ. of Medicine and Pharmacy, Faculty of Medicine, [2]Univ. of Medicine and Pharmacy, Faculty of Dentistry, Craiova, Romania

Objective: Study of correlations of bone turnover marker values in relation to BMI in patients with psoriasis.[1–16].

Methods: The study was conducted between 2018–2020, included 58 patients with psoriasis (27 women and 38 men) aged between 23–74 y. BMI was calculated based on weight and height, using the classic kg/m^2 formula, with a study of the classic groups, respectively-groups based on BMI: normal weight (NW), with BMI between 18.5–24.9 kg/ m^2—15 cases, overweight (OW) group with BMI between 25–29.9 kg/m^2—18 cases, and obesity (first grade) group including patients with a BMI of 30–34,9 kg/m^2—25 cases The diagnosis of psoriasis was established based on the histopathological examination. The assessments include venous blood bone turnover markers as following: osteocalcin (electrochemiluminescence method) and bone resorption marker CrossLaps (electrochemiluminescence assay).

Results:

Group	Number of patients	OS (ng/mL)	CL (ng/mL)
NW	15	28.39±10.22	0.54±0.17
OW	18	25.39±12.73	0.50±0.24
I grade	25	22.32±11.79	0.43±0.22

Conclusion: Based on present study, the biochemical bone turnover markers are not distinctive between the groups of different BMI. Large intra-individual variations do not allow a predictive.

PSORIASIS, SEX HORMONES AND ERECTILE DYSFUNCTION

O.-M. Niţă[1], M. J. Ţuculina[2], D. M. Albulescu[1], L. E. Stoica[1], N. M. Bugălă[1], S. A. Preda[2]

Objective: Psoriasis is a chronic, relapsing skin disease that presents a wide variety of lesions, of different shapes and sizes, but the primary lesion is papulo-erythematous, covered by a shiny scale. Sex hormones play an essential role in the pathogenesis of psoriasis through their biological and immunological effects on the skin. Psoriasis, by its very nature, has a significant impact on the sexual function of patients and, therefore, on their quality of life. The role of this study was to establish correlations between serum sex hormones and erectile function in male patients with psoriasis. The study was compared with a group of healthy controls, we correlated these findings with various parameters of the dermatological disease. [1–16].

Methods: Total testosterone and serum estradiol were measured by an ELISA technique in 136 men with psoriasis and 47 healthy controls. Erectile function evaluation of all subjects included in the study was estimated by the international index of erectile function version-5.

Results: The group of patients with psoriasis showed a significantly lower serum level of total testosterone, a higher level of estradiol. The group of patients with psoriasis showed impaired erectile function compared to the group of healthy patients.

Conclusion: Hormonal values measured in the group of men with psoriasis prove a cause of the associated erectile dysfunction.

P1053
CORRELATIONS BETWEEN THYROID HORMONES AND PSORIASIS

O.-M. Niţă[1], M. J. Ţuculina[2], D. M. Albulescu[1], L. E. Stoica[1], N. M. Bugălă[1], S. A. Preda[2]

[1]Univ. of Medicine and Pharmacy, Faculty of Medicine, [2]Univ. of Medicine and Pharmacy, Faculty of Dentistry, Craiova, Romania

Objective: To evaluate the prevalence of thyroid diseases in patients confirmed with psoriasis compared to the group of healthy patients. [1–16].
Methods: The study was conducted in two groups. One group included patients with histopathologically confirmed psoriasis (59 patients—27 women—aged between 31–72 y and 32 men aged between 28–69 y) and a group of healthy patients (73 patients—44 female patients aged between 22–71 y—30 male patients aged between 23–62 y). Both groups of patients had thyroid evaluation in the form of measurement of TSH, free thyroxine (FT4), anti-thyroid peroxidase antibody (TPO Ab) and anti-thyroglobulin antibody (Tg Ab). Thyroid ultrasound examination was performed looking for volume, hypoechogenicity, pseudo-nodularity and increased vascularity. Psoriasis severity assessment was performed using the PASI (Psoriasis Area and Severity Index) score.
Results: In the group of patients with psoriasis, a significantly higher prevalence of TPO Ab, Tg Ab, hypo-echogenicity, pseudo-nodularity and vascularization was found. The prevalence in psoriasis vs. the healthy patient group was for TPO Ab (24.82 vs. 8.2%, $p = 0.022$), Tg Ab (29.94 vs. 10.12%, $p = 0.012$), hypoechogenicity (31.42 vs. 8.99%, $p = 0.023$), pseudonodularity (16.1 vs. 0%, $p = 0.002$) and increased vascularity (34.73 vs. 5.68%, $p = 0.002$). Psoriasis patients with age of onset at diagnosis $\geq$ 23 y No significant differences were reported in the prevalence of hypothyroidism and subclinical hypothyroidism between the two study groups. In patients with psoriasis, psoriasis types, severity, duration, age, sex, personal and family history of autoimmune diseases did not correlate with thyroid autoimmunity.
Conclusion: This study demonstrates a significant correlation between psoriasis and thyroid damage. Therefore, thyroid evaluation by anti-thyroid antibodies and ultrasound should be included in the diagnosis of patients with psoriasis.

NEUROLOGICAL, PSYCHIC AND BONE MANIFESTATIONS IN THYROID INSUFFICIENCY

O.-M. Niţă[1], M. J. Ţuculina[2], D. M. Albulescu[1], L. E. Stoica[1], N. M. Bugălă[1], S. A. Preda[2]

[1]Univ. of Medicine and Pharmacy, Faculty of Medicine, [2]Univ. of Medicine and Pharmacy, Faculty of Dentistry, Craiova, Romania

Objective: Identification of cases with thyroid insufficiency, clinical and biological objectification of the etiological diagnosis of hypothyroidism, evaluation of nervous and mental clinical manifestations, quantification of BMD by osteodensitometry (DXA).[1–16].
Methods: 36 cases (14 men and 22 women) were included in the study, whose ages were between 26–49 y, of which 13 developed hypothyroidism after surgical thyroidectomy, and 23 through an autoimmune mechanism. The following paraclinical investigations were performed: FT4 dosage, TSH, ATPO titer, thyroid ultrasound, and indirectly the thyroid function was evaluated through the existing changes in metabolism: lipidic, carbohydrate, enzymatic. Osteodensitometry (DXA) was assessed only in 5 cases with premature ovarian failure.
Results: Neuropsychic disorders are constantly severe and characteristic. It presents a slowing down (bradypsychia) of all the elements that make up the higher nervous activity. It shows permanent drowsiness, especially during the day, and the attention is deficient, with a lack of interest especially in personal and social events. Sensory and neurological disorders are constant but variable in intensity. In the 5 cases investigated by DXA, the T-score values were between -2.9 and -4,1 D.S. All cases presented high TSH values and the ATPO titer was increased in cases with autoimmune hypothyroidism.
Conclusion: Neuropsychic disorders are constant, characteristic and severe in hypothyroidism. Osteo-articular disorders are found especially in cases with severe hypothyroidism (myxedema).

THERAPEUTIC MANAGEMENT IN HYPOGONADIC OSTEOPOROSIS

O.-M. Niţă[1], M. J. Ţuculina[2], D. M. Albulescu[1], L. E. Stoica[1], N. M. Bugălă[1], S. A. Preda[2]

[1]Univ. of Medicine and Pharmacy, Faculty of Medicine, [2]Univ. of Medicine and Pharmacy, Faculty of Dentistry, Craiova, Romania

Objective: Hypogonadal osteoporosis can set in early, it is asymptomatic for a long time and the etiological diagnosis is sometimes laborious. The early diagnosis of gonadal insufficiency requires the adoption of some measures to prevent bone changes from the prepubertal, pubertal or postpubertal stage in order to ensure a maximum bone mass corresponding to sex and age.[1–16].
Methods: The case study is represented by 67 patients, of which with: late puberty (36 cases) and premature ovarian failure (31 cases). Clinical and paraclinical criteria were used to elucidate the etiological diagnosis.
Conclusion: The paper suggests two major objectives in the therapeutic strategy of hypogonadal osteoporosis: early diagnosis of gonadal insufficiency, in order to adopt some prophylactic measures of bone changes; estrogen-progestational/androgenic substitution associated with antiresorptive or proforming medication.

The neuropeptide Y system (NPY) is one of the frequently expressed neuropeptides in neuronal tissues, being found in both central and peripheral nervous systems. In the brain, NPY has a complex distribution, with marked expression in a number of regions, with the highest levels of expression occurring within the hypothalamus. Specifically, hypothalamic NPY-ergic neurons are most prominently distributed in the arcuate nucleus. In peripheral nervous tissue, NPY is found in the sympathetic nervous system, co-stored and co-released with noradrenaline during nerve stimulation. While NPY expression was initially discovered in neural tissue, it is increasingly present in peripheral tissues. It is important to know that NPY is expressed in osteoblastic cells. In addition to NPY, there are two other ligands of the NPY family; peptide YY (PYY) and pancreatic polypeptide (PP).[1–16].

ESTROGEN AND BONE HEALTH IN MEN AND WOMEN

O.-M. Niţă[1], M. J. Ţuculina[2], D. M. Albulescu[1], L. E. Stoica[1], N. M. Bugălă[1], S. A. Preda.[2]
[1]Univ. of Medicine and Pharmacy, Faculty of Medicine, [2]Univ. of Medicine and Pharmacy, Faculty of Dentistry, Craiova, Romania.

Estrogen is the key regulator of bone metabolism in both men and women. Estrogens actively suppress bone turnover and maintain a balanced rate of bone formation and resorption. At the cellular level, estrogens affect the generation, lifespan, and functional activity of osteoclasts and osteoblasts. They decrease osteoclast formation and activity, while increasing osteoclast apoptosis. At the molecular level, estrogens decrease the production of cytokines, inhibiting osteoclast apoptosis, such as IL-1, IL-6, TNFα, M-CSF, and decrease the expression of the activated NfkB gene, a suppressor of apoptosis. In contrast, estrogens favor the expression of TGFβ, a direct inhibitor of osteoclast activity and an activator of osteoclastic apoptosis. Estradiol level also predicts fractures. Similar associations were found in men. Despite lower BMD and higher fracture risk in men with hypogonadism, there is little association between circulating testosterone, fracture, and bone loss. However, the combination of any low sex steroid hormone and 25-hydroxyvitamin D was associated with an increased risk of fracture. Menopausal hormone therapy has been shown to reduce fracture rates Clinical trials of testosterone therapy in older men yield tantalizing but inconclusive results. The results suggest that testosterone treatment probably improves BMD, but the results are less conclusive in older men than in younger men.[1–16].

P1058
THE IMPORTANCE OF MODERN INVESTIGATIONS IN ORTHODONTICS

O.-M. Niţă[1], F. I. Mărăşescu[2], P. Mărăşescu[2]

[1]Univ. of Medicine and Pharmacy, Faculty of Medicine, [2]Univ. of Medicine and Pharmacy, Faculty of Dentistry, Craiova, Romania

In the correct diagnosis of dento-maxillary abnormalities, the knowledge of their complex etiopathogenesis associated with the application of modern investigative techniques facilitates the application of a personalized treatment to the clinical case. At present, nutritional disorders play an essential role in the occurrence of these anomalies. A diet poor in vitamin A can cause the appearance of dental hypoplasia or a reduced calcification of the alveolar processes with the appearance of dento-alveolar disharmony with dental crowding. Vitamin D deficiency at young ages (up to 1 year) leads to the appearance of serious diseases (rickets), with repercussions in the development of the dento-maxillary apparatus and implicitly malocclusions. At older ages, it can cause the appearance of dental caries and tooth fractures with the appearance of dental malpositions. Hypo or hypersecretion of the endocrine glands along with factors also play a substantial role in the occurrence of malocclusions. Current orthodontic treatment techniques, also bring about undesirable changes in the enamel surface. This creates favorable conditions for the appearance of dental caries. The OCT (optical coherence tomography) helps us to identify the cracks that appear in the enamel structure following orthodontic treatment. The in vivo applicability of OCT will lead to an increase in the performance of orthodontic treatment techniques. CBCT (cone beam computed tomography), MRI, MEF are other modern investigative techniques that allow us to detect deficiencies in orthodontic treatment techniques. Thus, we can emphasize the accuracy and efficiency of these modern investigative techniques in orthodontics. Their role is to help us establish a quick and accurate diagnosis of dento-maxillary abnormalities. The purpose of these investigations is also to identify the etiological factors of these anomalies and subsequently correct them as much as possible. These investigations are also useful for improving the quality of orthodontic treatment materials and techniques.[1–16].

P1059
MEDICATION RELATED OSTEONECROSIS OF THE JAWS: A RETROSPECTIVE STUDY

O.-M. Niţă[1], G. A. Ciobanu[2], A. Camen[2], M. Ionescu[2], R. Mercuţ[1], S. M. Popescu[2]

[1]Univ. of Medicine and Pharmacy, Faculty of Medicine, [2]Univ. of Medicine and Pharmacy, Faculty of Dentistry, Craiova, Romania

Medication related osteonecrosis of the jaws (MRONJ) is a severe complication among patients treated with different types of medication, like bisphosphonates, usually for osteoporosis or for the prevention or treatment of bone metastases from various forms of cancer [1–4]. Frequently, bisphosphonate osteonecrosis is diagnosed in an advanced stage when it became clinically evident, as in case of the exposure of a bone area in the oral cavity [5,6]. MRONJ has a multifactorial aetiology, being implicated systemic factors such as hypertension [7], as well as local factors, such as dental extractions, periodontal disease and periapical infections [8–10]. The aim of the retrospective study was to determine the frequency of osteonecrosis cases in Oltenia region in the period 2012–2022. Material and method: The data extracted from the file charts and used in this study were: age, sex, environment, condition treated with bisphosphonate, MRONJ location and stage. The statistical analysis was performed with Microsoft Excel and SPSS for Windows. Results: The study included 126 patients, of which 51 men and 75 women, with an average age of 65.4 ± 9.5. The age groups most affected by MRONJ were between 70–79 and 60–69 years, with a disease frequency of 55%, respectively 32% of the group. MRONJ was predominant in women aged between 50–69 years, while for men the most affected age group was 70–79 years ($p < 0.05$). MRONJ was encountered especially in women with breast or ovarian cancer (31.94%), and in men with prostate cancer (18.06%). From MRONJ patients only 5.55% had osteoporosis, especially women. The main bisphosphonate implicated in MRONJ was IV zoledronic acid in cancer cases. Ibandronic acid, alendronic acid and risedronate sodium have been implicated in MRONJ in osteoporosis cases. From the studied group, 31.94% were diagnosed with osteonecrosis of the jaw and 68.06% with osteonecrosis of the mandible, achieving a ratio of 1:2.13 ($p < 0.005$). Patients presented to the hospital with an advanced stage of MRONJ, for mandibular MRONJ being stage II in 81% of cases and for maxillary MRONJ being stage III in 72% of cases ($p < 0.05$). **Conclusion:** MRONJ was encountered especially in patients with breast, ovarian or prostate neoplasm, with bone metastases, who received intravenous zoledronic acid, being especially present in the mandible, in advanced stages. Medication related osteonecrosis of the jaw in patients with osteoporosis was less common compared to osteonecrosis in patients with cancer.

IS THERE A CONNECTION BETWEEN BRUXISM AND VITAMIN D LEVELS?

O.-M. Niţă[1], A. M. Popescu[2], D. E. Vlăduţu[2], V. Mercuş[2], S. M. Popescu[2], M. J. Ţuculina[2]

[1]Univ. of Medicine and Pharmacy, Faculty of Medicine, [2]Univ. of Medicine and Pharmacy, Faculty of Dentistry, Craiova, Romania

Bruxism is a contraction disorder of the masticatory muscles [1–3] characterized by grinding and clenching of the teeth and/or thrusting and bracing of the mandible [4–8]. The prevalence of bruxism is 3.5-40.6% in children, 31.6% in adolescents (students) [9] and 21.5% in adults, with 5% for awake bruxism and 16.5% for sleep bruxism [10]. Vitamin D, or its active form 1,25-dihydroxyvitamin D3 [1,25(OH)2D3] influences masticatory muscles improving thickness and tonicity [11]. For this review, potential role of vitamin D in the etiology of bruxism was inquired in order to establish whether the current knowledge supports 25-hidroxyvitamin D (25-OHD) supplementation in bruxism associated with insufficient levels of vitamin D. Methods. A literature research was performed in Google Scholar, PubMed, Science Direct, Wiley and Scopus databases, and a total of 9 articles were included for analysis. Results. Among the studies published to date, investigating the role for vitamin D in the bruxism aetiology, there are 4 of them suggesting a connection between bruxism and vitamin D serum levels. As a result, bruxism suffering patients with deficient levels of vitamin D (< 30 ng/mL) could benefit from supplementation. Supplementation with vitamin D especially in winter could be a simple way to reduce the intensity and frequency of bruxism episodes. In order to introduce this approach in current practice, more randomized and placebo-controlled trials are needed.

Chromium, in the form of trivalent chromium, is a trace element naturally present in many foods and available as a dietary supplement. Chromium may play a role in carbohydrate, lipid, and protein metabolism by potentiating the action of insulin. Although the precise mechanism for this activity has not been identified, scientists suggest that chromium binds to an oligopeptide to form cromodulin, a low molecular weight substance that binds to chromium and activates the insulin receptor to stimulate insulin action. Chromium may also have antioxidant effects. Chromium may have beneficial effects on impaired glucose tolerance and diabetes mellitus, metabolic syndrome, polycystic ovary syndrome, dyslipidemia, and obesity. We aim to measure the impact of chromium supplementation on anthropometric indices. Concomitant use of chromium with insulin may increase the risk of hypoglycemia. Since some studies have shown that chromium supplementation may lower blood sugar levels, metformin or other diabetes medications taken with chromium may increase the risk of hypoglycemia.[1–16].

PERIODONTAL TREATMENT WITH LASER ER:YAG IN THE CASE OF PERIODONTITIS WITH RAPID EVOLUTION IN PATIENTS WITH DIABETES AND ENDOCRINE DISEASES

O.-M. Niţă[1], D. M. Albulescu[1], L. E. Stoica[1], O. A. Diaconu[2], A. Nicola[2], M. Bătăiosu[2], C. Dăguci[2], A. Camen[2]

[1]Univ. of Medicine and Pharmacy, Faculty of Medicine, [2]Univ. of Medicine and Pharmacy, Faculty of Dentistry, Craiova, Romania

Traditional periodontal treatment usually involves the use of metal and rotary instruments to remove plaque and tartar. This can be a painful and invasive procedure that can cause bleeding and discomfort for the patient.[1–16] The LiteTouch laser is an innovative technology that can provide a more effective and comfortable alternative for periodontal treatment. LiteTouch emits a high-energy light beam that can be used to remove plaque and tartar without causing pain or discomfort to the patient. Among the advantages of using the LiteTouch laser for periodontal treatment we mention:

- Minimal pain: LiteTouch laser procedures are non-invasive, requiring no anesthesia.

This means that the patient will experience minimal or no pain during the treatment.

- Minimal Bleeding: The LiteTouch Laser is a precise tool that can be used to remove plaque and tartar without damaging healthy tissue. This means that the patient will experience minimal or no bleeding during treatment.

- Faster healing: The LiteTouch laser helps stimulate tissue healing, leading to faster gum healing.

- Better results: The LiteTouch laser helps achieve better results in periodontal treatment compared to traditional treatment.

In addition to these advantages, the LiteTouch laser also offers the following benefit for dentists: efficiency: The LiteTouch laser can be used to remove plaque and tartar faster and more efficiently than traditional tools. This can lead to a reduction in treatment time and labor costs.

PROMOTION OF DENTAL IMPLANT THERAPY IN PATIENTS WITH OSTEOPOROSIS

O.-M. Niţă[1], N. M. Bugălă[1], S. A. Preda[2], O. A. Diaconu[2], L. E. Stoica[1], A. Camen[2], M. J. Ţuculina[2]

[1]Univ. of Medicine and Pharmacy, Faculty of Medicine, [2]Univ. of Medicine and Pharmacy, Faculty of Dentistry, Craiova, Romania

Osteoporosis changes the density of the bones in the oral cavity, but does not influence the possibility of replacing missing teeth with dental implants. Depending on the bone with which the patient presents to the dentist, whether soft or hard, the specialist surgeon determines together with him which technique is the most adapted and which materials are beneficial depending on the density of the bone. When patients find out that they are diagnosed with osteoporosis, and the treating doctor has to prescribe a treatment with bisphosphonates, it is very important that before taking the drugs they come to the dentist, to solve all their dental problems.[1–16] During a single surgical intervention, the team of specialists will insert the dental implants. As a rule, 6 implants are recommended for the upper part of the maxillary arch and 4 implants for the lower part. In addition to dental implants, other procedures can be performed. For example, if you do not have enough bone, the doctor can perform a bone addition before inserting the implants.

THE ROLE OF VITAMIN K2 IN THE TREATMENT OF OSTEOPOROSIS

O.-M. Niţă[1], D. M. Albulescu[1], S. A. Preda[2], L. E. Stoica[1], O. A. Diaconu[2], A. Nicola[2], A. Camen[2], M. J. Ţuculina[2]

[1]Univ. of Medicine and Pharmacy, Faculty of Medicine, [2]Univ. of Medicine and Pharmacy, Faculty of Dentistry, Craiova, Romania

A coenzyme of glutamate γ-carboxylase, vitamin K2 can carboxylate glutamate residues of vitamin K-dependent osteocalcin proteins and γ-carboxylate glutamate residues. Several studies have shown that vitamin K2 can provide major benefits for bone health. Osteocalcin would thus favor bone formation. However, if we think about fat-soluble vitamin K2, it is difficult to reach its maximum concentration in the body. In addition, there is a risk of local overdose, since the vitamin is stored in the liver.[1–16] The latest studies state that their hope is to improve the bioavailability of vitamin K2, and their results are worth noting. They obtained spherical nanoparticles uniformly dispersed in the aqueous solution by optimizing the molar mixing ratio of the carrier protein and vitamin K2. Nonpharmacological management of osteoporosis includes adequate calcium and vitamin D intake, weight-bearing exercise, smoking cessation, limiting alcohol and caffeine consumption, and learning relapse prevention techniques.

COMPARATIVE ANALYSIS OF DUAL AND SINGLE CNN MODELS FOR THE CLASSIFICATION OF OSTEOPOROSIS, OSTEOPENIA, AND NORMAL BONE CONDITIONS

P. Achararit[1], S. Rathapoom[1], P. Nonthasaen[1], Y. Laphatrada[2], T. Chobpenthai[1]

[1]Princess Srisavangavadhana College of Medicine, Chulabhorn Royal Academy, [2]MUSC Expertise Faculty of Science, Mahidol Univ., Bangkok, Thailand

Objective: To critically evaluate and compare the effectiveness of dual-stage vs. single-convolutional neural network (CNN) models in classifying osteoporosis, osteopenia, and normal bone conditions,

focusing on Area Under the Curve (AUC) as the primary evaluation metric.

Methods: The study implemented two experimental setups: a single CNN model and a dual-stage CNN model. A range of architectures including VGG19, Xception, DenseNet169, InceptionResNetV2, and ResNetRS101 was trained and evaluated to identify the most effective model for each classification stage. In the dual-stage setup, the first configuration aimed to differentiate normal from abnormal conditions (osteopenia and osteoporosis), and then further classify between osteopenia and osteoporosis. The second configuration focused on separating normal/osteopenia from osteoporosis, followed by distinguishing normal from osteopenia. The performance of each model was rigorously assessed using a dataset of 658 bone density images from Chulabhorn Hospital. This dataset comprised 132 normal, 246 osteopenia, and 160 osteoporosis images for training, supplemented by 20 images per class for validation and testing.

Results: The single CNN model, using the Xception architecture, achieved an AUC of 0.74. The dual-stage model's first configuration, utilizing InceptionResNetV2 for both levels, yielded an average AUC of 0.75. The second configuration showed a more robust performance with an average AUC of 0.84, achieved by InceptionResNetV2 in the initial stage and DenseNet169 in the subsequent stage.

Conclusion: The study highlights the dual-stage model's superior classification accuracy, particularly in its second configuration, compared to the single model. This emphasizes the value of specialized CNN architectures for distinct classification stages. The findings advocate for a multi-faceted diagnostic approach, suggesting that employing different CNN models for separate tasks can significantly improve the accuracy and reliability of medical image analysis in classifying osteoporosis, osteopenia, and normal bone conditions.

Acknowledgement: This research project is funded by Chulabhorn Royal Academy.

DEVELOPMENT OF A SIMPLE PREDICTIVE MODEL WITHOUT USING CLINICAL RISKS FOR CAPTURE VERTEBRAL FRAGILITY FRACTURE AND COMPARISON WITH PREVIOUS MODELS

P. Chanplakorn[1], T. Lertudomphonwanit[1], N. Daraphongsataporn[1], C. Sritara[2], S. Jaovisidha[3], P. Sa-Ngasoongsong[1]

[1]Dept. of Orthopedics, Faculty of Medicine Ramathibodi Hospital, Mahidol Univ., [2]Dept. of Diagnostic and Therapeutic Radiology, Faculty of Medicine Ramathibodi Hospital, Mahidol Univ., [3]Dept. of Radiology, Faculty of Medicine, Ramathibodi Hospital, Mahidol Univ., Bangkok, Thailand

Objective: Early detection of vertebral fragility fracture (VFF) is crucial for maintaining patient's QOL. Many diagnosis tools have been introduced for screening the overall fracture risk but not aiming to identify the risk for VFF. The objective of this research is to study a predictive model for capture VFF and compare with previous models.

Methods: A retrospective review was conducted. Women aged $\geq$ 50 y who underwent DXA and vertebral fracture assessment (VFA) for osteoporosis screening between 2012–2019 were included. The data included age, height, weight, history of height loss (HHL) and BMD were retrieved. Sequential receiver operating characteristic (ROC) analysis, Univariate and Multivariate logistic regression was performed. A predictive model of VFF was subsequently formulated. The result of other models was calculated according to original report.

Results: A total of 617 women were included, VFF identified in 179 women. Multivariate regression analysis showed that age > 65, height loss > 1.5 cm, and femoral neck T-score < -1.7 were independent factors for risk of VFF (Fig. 1). Compared to FRAX model our model revealed comparable performance. Model without BMD included all parameters revealed highest specificity. This model revealed superior performance to FRAX, KKOS and OSTA, comparable performance to ISCD but revealed higher specificity (Fig. 2).

KKOS	-1.00	72%	46%	0.58	35%	80%	1.31	0.63	2.09
ISCD 2019 model with BMD	none	60%	68%	0.64	44%	81%	1.89	0.58	3.24

*cut off value in this model was calculated from the sum of individual risk score according to original reported for other models, AUC; area under the curve, PPV; positive predictive value, NPV; negative predictive value, LR+; positive likelihood ratio, LR-; negative likelihood ratio,

Conclusion: BMD and VFF screening should be eligible for individual women; age > 65 y and HHL > 1.5 cm regardless of BMD. VFA should be included in an individual woman with femoral neck T-score < -1.7 with HHL > 1.5 cm or age > 65 y.

P1067
CALCIUM INTAKE DEFICIT: A REALITY WE MUST FACE

P. E. Sanchez Marquez[1], A. Anacona[2]

[1]Meta, [2]EPS Sura, Medellin, Colombia

Objective: To evaluate calcium intake in a randomized population of Medellín and its metropolitan area, Colombia.

Methods: A descriptive, observational, cross-sectional cohort study was carried out with prospective data collection. The sample was obtained by convenience, from volunteers over 18 years of age in Medellín and its metropolitan area. The calcium intake questionnaire of the International Osteoporosis Foundation was completed between June-November 2022. We stratified by gender, age and socioeconomic level In those who received calcium or vitamin D supplements we evaluated if their indication was therapeutic or preventive.

Results: 452 volunteers participated. 356 women (78.7%), with an average age of 47.3 y (IQ25-70 34–61) and 42.3 (IQ25-70 31–50.2) y for men. Mean calcium intake was 835 mg/d (IQ25-75 586–982 mg/d). For women it was 812.9 mg/d (IQ25-75 567–975 mg/d), being 794.7 mg/d, 816.5 mg/d and 817.2 mg/d for women in the range of

18–30, 31–50 and older than 50 y. In men the average consumption was 918.3 mg/d (IQ25-75 717.5–1017 mg/d), being 972.6 mg/d, 911.9 mg/d and 880.6 mg/d for men in the range of 18–30, 31–50 and older than 50 y. Adequate calcium intake for age was documented in 21% of the volunteers, with an average intake of 1363 mg/d among them (IQ25-75 1123–1458 mg/d), of which 45.3% had calcium supplementation and the remaining 54.7% did not. Of the 78.9% of the volunteers who didn't have adequate intake, they had an average daily consumption of 694 mg/d (IQ25-75 520–879 mg/d). Of these, 10.9% had calcium supplementation and the remaining 89% did not. The average calcium intake in women and men from low socioeconomic stratum was 657 mg/d (IQ25-75 336–915 mg/d) and 650 mg/d (IQ25-75 452–734 mg/d) respectively, 656.8 mg/d (IQ25-75 499–717 mg/d) and 742 mg/d (IQ25-75 596–771 mg/d) in middle socioeconomic stratum and 1008.1 mg/d (IQ25-75 837–1117 mg/d) and 1040.9 mg/d (IQ25-75 878–1123 mg/d) in high socioeconomic stratum.

Conclusion: In patients who were taking calcium supplements, the main indication was prevention, 56% in women and 73% in men. The remaining 44% and 27% were indicated for treatment, mainly as part of osteoporosis treatment. Substitution is more frequent in high socioeconomic stratum (54.5%). In patients with vitamin D supplementation, the main indication was prevention, which was 70% for women and 77% for men. The remaining 30% and 23% were indicated for the treatment of low serum levels of vitamin D. Supplementation is more frequent in upper socioeconomic stratum, (62% in women and 77% in men).

P1068
HYPOPARATHYROIDISM: PROFOUND INCREASE IN BONE TURNOVER MARKERS AND HYPERCALCEMIA DURING LACTATION AFTER THE FIRST AND SECOND BIRTH

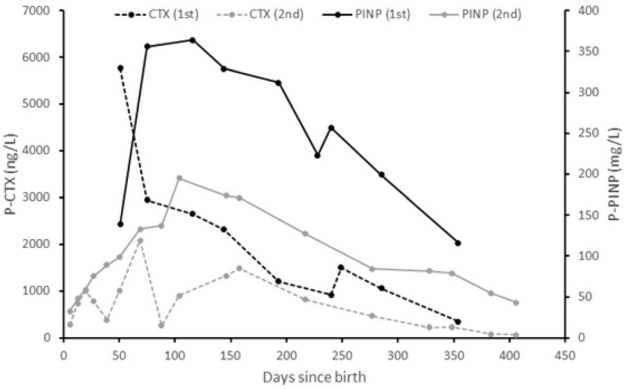
P. Eiken[1], L. Tjelum[2], R. Nolsoe[2], L. Rejnmark[3], N. R. Jørgensen[4]

[1]Dept. of endocrinology/Bispebjerg hospital, Copenhagen, [2]Endocrinology/North Zealand Hospital, Hillerød, [3]Institute of Clinical Medicine/Århus Univ. Hospital, Århus, [4]Dept. of Clinical Biochemistry, Copenhagen Univ. Hospital Rigshospitalet, Copenhagen, Denmark

Objective: Changes in bone turnover markers (BTM) and calcium levels during lactation following two pregnancies in a patient with hypoparathyroidism.

Methods: A 31-year-old woman with hypoparathyroidism following a total thyroidectomy due to thyroid cancer. She was treated with calcium supplements and activated vitamin D and became pregnant 4 y later.

Results: She gave birth twice to healthy children with three years in between. After both pregnancies, she developed (asymptomatic) hypercalcemia despite stopping calcium supplements and active vitamin D. BTM (Figure, 1st and 2nd pregnancy) showed a marked increase in CTX and P1NP after both pregnancies. CTX levels peaked 1.5–2 months after delivery and decreased thereafter, while P1NP continued to increase to a maximum of 2.5–3 months after delivery and remained high for months before gradually declining and returning to normal after cessation of lactation. The bone markers were 1000-fold higher after the first delivery compared to the second delivery. The elevation of BTM persisted for months even after plasma calcium had normalized. Active vitamin D was gradually initiated and 7–8 months after delivery, the patient was back on her full pre-pregnancy dose of active vitamin D.



Conclusion: The patient had an enormous increase in BTM after the first pregnancy, which returned to very low levels (which is normal for hypoparathyroidism) between the two pregnancies. Increased levels of BTM are probably explained by the synthesis of PTH-related peptides during pregnancy and breastfeeding. The increase in BTM after the second delivery was less pronounced and associated with less pronounced hypercalcemia. Despite closely monitoring the patient and stopping standard-of-care therapy, we were unable to prevent hypercalcemia after childbirth. Careful monitoring of calcium levels weekly is recommended for patients with hypoparathyroidism after childbirth.

P1069
RELATION BETWEEN DEFICIENCY OF VITAMIN D AND RISK OF OSTEOPOROTIC VERTEBRAL FRACTURES: A STUDY IN INDIAN FEMALE POPULATION

P. G. Kakadiya[1]

[1]Shayona Advanced Spine Care, Surat, India

Objective: To determine serum 25-hydroxyvitamin D level and its association with osteoporotic thoracolumbar junction vertebral fracture in elderly patients of India.

Methods: From June 2018 to Dec 2020, this retrospective case–control study included 267 patients with primary osteoporotic thoracolumbar junction vertebral fracture (T10–L2) and 285 elderly patients with back pain (without osteoporotic vertebral fracture) as controls. Serum vitamin D levels were measured and the association with osteoporotic vertebral fracture was analysed. Other clinical data, including BMI, comorbidities, and BMD, were also collected and compared between these two groups.

Results: It was shown that vitamin D levels were significantly lower in patients with T10–L2 vertebral fracture than in control patients. Among 267 vertebral fracture patients, 78.1% of patients showed grade 2–3 fractures. Serum 25-hydroxyvitamin D levels were significantly related to affected vertebral numbers and vertebral fracture severities. The vertebral fracture risk was 28% lower (OR = 0.72, 95%CI 0.62–0.83) per increased Standard deviation in serum 25-hydroxyvitamin D. Compared with the 1st quartile (mean 25-hydroxyvitamin D: 29.67 $\pm$ 6.18 nmol/L), the vertebral fracture risk was significantly lower in the 3rd (mean 25-hydroxyvitamin D: 60.91 $\pm$ 5.12 nmol/L) and 4th quartiles (mean 25-hydroxyvitamin D: 103.3 $\pm$ 44.21 nmol/L), but not in the 2nd quartile (mean 25-hydroxyvitamin D: 45.40 $\pm$ 3.95 nmol/L). In contrast, the vertebral fracture risk was significantly increased in the first quartile (OR = 1.87, 95%CI 1.42–2.45) compared with the 2nd–4th quartiles.

Conclusion: Vitamin D deficiency/insufficiency was associated with the risk of osteoporotic thoracolumbar junction vertebral fractures in elderly patients.

P1070
VITAMIN D DEFICIENCY AND OSTEOPOROSIS AMONG POSTMENOPAUSAL INDIAN WOMEN WITH DEGENERATIVE LUMBAR SPINE DISEASE UNDERGOING SPINE FIXATION SURGERY

P. G. Kakadiya[1]

[1]Shayona Advanced Spine Care, Surat, India

Objective: Several epidemiological studies have shown a lower prevalence of osteoporotic Spine fractures in patients with degenerative spine disease. Other studies have demonstrated elevated BMD in patients with degenerative spine disease. The prevailing view is that degenerative spine disease and osteoporosis may have an inverse relationship. The purposes of the present study were to describe a subgroup of patients with degenerative spine disease who were found to have osteoporosis and to assess the vitamin-D status and other risk factors for low bone density in degenerative spine disease subjects with and without osteoporosis.
Methods: A Retrospective study including 136 Indian postmenopausal women. The BMD of the spine, the proximal part of the femur, and the total body were measured with dual-energy x-ray absorptiometry in 136 postmenopausal white women who were scheduled to undergo spine fixation and decompression surgery for degenerative spine disease. The serum levels of 25-hydroxyvitamin D, 1,25-dihydroxyvitamin D, intact PTH, osteocalcin, and bone-specific alkaline phosphatase and the urinary level of N-telopeptide were measured. Information from validated lifestyle, dietary, and demographic questionnaires was also evaluated.
Results: 34 (25%) of the 136 women had occult osteoporosis (as indicated by a T-score of less than -2.5). 30 (22%) subjects had vitamin D deficiency, and 6 (4%) had an elevated serum PTH level. Only 4 of the 34 osteoporotic women had vitamin D deficiency. On the basis of these numbers, vitamin D status was not correlated with bone density ($p = 0.32$). Analysis of the relationship between the number of years since menopause and osteoporosis or markers of elevated bone turnover showed that osteoporosis was detected throughout the postmenopausal period.
Conclusion: 136 Indian women with degenerative spine disease had occult osteoporosis and hypovitaminosis D. Vitamin D deficiency was not restricted to the group with low bone density. These results support the need to consider the presence of both osteoporosis and vitamin D deficiency in women with degenerative spine disease.

P1071
METABOLIC MYSTERY OF OSTEOPOROTIC VERTEBRAL FRACTURE IN INDIAN PATIENTS: A HISTOMORPHOMETRIC AND BIOCHEMICAL CORRELATION

P. G. Kakadiya[1]

[1]Shayona Advanced Spine Care, Surat, India

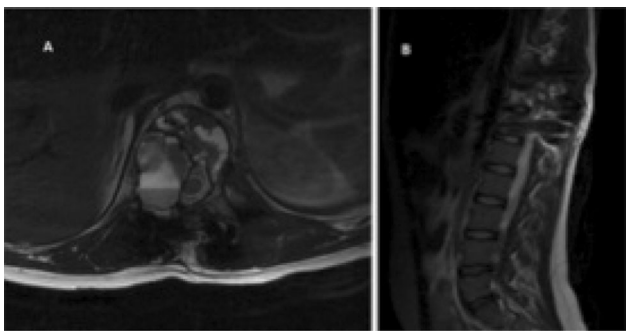
Objective: A high prevalence of hypovitaminosis D is being reported in Indian patients with osteoporotic vertebral fractures. The gold standard to diagnose osteoporosis and osteomalacia is bone histomorphometry. There is no study evaluating histopathological histomorphometry in Indian Osteoporotic vertebral fracture patients. The purpose of the study was to evaluate osteoporotic vertebral fracture patients for histopathological osteomalacia and osteoporosis by histomorphometry and to correlate histopathological findings with biochemical hypovitaminosis D.
Methods: A total of 110 patients with osteoporotic vertebral fractures were included in the prospective cross-sectional study. During definitive fracture fixation of these osteoporotic vertebral fractures, bone biopsy was taken from the fractured vertebral body by a novel approach for histomorphometry. Histomorphometric analysis was based on 3 indices, namely osteoid seam width, osteoblast surface, and osteoid surface. We also analysed blood-bone biochemistry and correlated it with bone histomorphometry.
Results: In osteoporotic vertebral fractures patients, the prevalence of histomorphometric osteoporosis and osteomalacia were very low (only 9.4% had osteoporosis and none had osteomalacia) however in blood bone biochemistry, we found a high prevalence (85.5%) of hypovitaminosis D. We also noted significant changes when correlated bone histomorphometry with different blood bone biochemistry.
Conclusion: Patients with osteoporotic vertebral fractures were found to have a high prevalence of biochemical hypovitaminosis D but unlike Western literature, there was a low prevalence of histomorphometric osteoporosis with no evidence of histomorphometric osteomalacia. Correct knowledge about the metabolic status of osteoporotic vertebral fractures is required to improve outcomes, decrease complications and optimise the cost of the treatment.

P1072
ANEURYSMAL BONE CYST WITH SCOLIOSIS: UNUSUAL PRESENTATION

P. G. Kakadiya[1]

[1]Shayona Advanced Spine Care, Surat, India

Aneurysmal bone cysts are benign bone tumours that not uncommonly involve the spine. However, this involvement can cause scoliosis rarely. This case report focuses on the importance of proper management for complete tumour resection to prevent recurrence and spinal deformity.
Case report: A 13-year-old Indian boy, with a history of T11 aneurysmal bone cyst resection and bone grafting carried out at another hospital, presented with a spine deformity of four months' duration. The deformity was not associated with pain or neurological deficit. A whole-spine MRI with contrast confirmed the recurrence of the aneurysmal bone cyst. Posterior spinal instrumentation with corpectomy of T11 was then performed and confirmed with histopathology the recurrence of aneurysmal bone cyst. Two years post-corpectomy, deformity correction was done from T5–L4.



Conclusion: Management of aneurysmal bone cysts requires meticulous planning and full excision to prevent a recurrence, especially in the growing spine. If neglected, it can cause major spinal deformities and cord compression, which places a medical burden on the patient and family. To avoid such complications, treating aneurysmal bone cysts along with scoliosis correction can prevent deformity progression.

P1073
A RARE GENETIC DISORDER: GONADAL DYSGENESIS WITH MAYER ROKITANSKY KÜSTER HAUSER SYNDROME

P. G. Kakadiya[1]

[1]Shayona Advanced Spine Care, Surat, India

46,XX gonadal dysgenesis is a rare genetically heterogeneous disorder characterized by underdeveloped ovaries with consequent impuberism, primary amenorrhea, and hypergonadotropichypogonadism. Mullerian agenesis or Mayer-Rokitansky-Kuster-Hauser (MRKH) syndrome is characterized by congenital aplasia of the uterus and the upper part (2/3) of the vagina in a woman with normal development of secondary sexual characteristics and a normal 46,XX karyotype. An association between these two conditions is very exceptional and appears to be coincidental, independent of chromosomal anomalies. Here, we report a case of 46,XX gonadal dysgenesis and MRKH syndrome.

Case report: A 15 year 9 month old female patient presented to our hospital with complaints of primary amenorrhea and absence of secondary sexual characteristics. There was no family history of consanguinity, miscarriages, neonatal deaths, or any other family member with primary amenorrhea. Her birth, perinatal, and neonatal periods were uneventful. No history of developmental delay. No history was suggestive if systemic illness. Her height was 148.5 cm (10th centile) and her weight 38 kg with normal intelligence. Her pulse rate was 86 beats/min and her blood pressure was 100/70 mm of mercury. Scoring of pubic, axillary hair growth, and breast development were Tanner's Stage 1. External genital examination revealed normal labia majora and minora, normal clitoris. There was no facial dysmorphism, webbing of neck, or wide carrying angle. Echocardiography revealed normal chamber dimensions with no other cardiac abnormalities, and abdominal ultrasound examination revealed single horseshoe-shaped kidney at ectopic location and absence of uterus and ovaries suggestive of MRKH type B. The abdominal ultrasound findings were confirmed later by MRI of the abdomen and pelvis revealing the bladder and rectum without interposition of the uterus. Bilateral ovaries are also not seen in the adnexa. Fundus examination and pure tone audiometry were normal. Karyotyping revealed normal 46,XX complement. Her hemogram, renal and liver function tests were also normal. Endocrine evaluation revealed elevated levels of follicle-stimulating hormone (74 IU/L) and luteinizing hormone LH (45 IU/L) with low estradiol (< 5 pg/ml) levels. Her blood sugar, thyroid function tests, serum cortisol, and prolactin levels were normal. Hormonal therapy with ethinyl estradiol 10 mg/d was started for the development of secondary sexual characteristics and to prevent osteoporosis. There remains the unsolved problem of infertility.

Discussion: The paramesonephric ducts develop lateral to the gonads and play an essential role in the development of uterine tubes, the uterus, the superior part of the vagina and broad ligaments. Estrogens may influence the development of the paramesonephric system. The absence of Mullerian-inhibiting substance is also essential for its development. Mutations of the gene encoding the anti-Mullerian hormone receptor and the lack of estrogen receptors during embryonic development have been hypothesized to cause MRKH syndrome. An undifferentiated gonad may produce anti-Mullerian hormone in an earlier embryologic period. But this hypothesis cannot be valuable without the presence of the chromosome Y. Occurrence of these two conditions compromises fertility both in the mechanic and hormonal way.

P1074
A COMPARISON OF DIFFERENT SCREENING TOOLS FOR PREDICTING OSTEOPOROSIS IN COMMUNITY-DWELLING POSTMENOPAUSAL WOMEN IN INDIA

P. G. Kakadiya[1]

[1]Shayona Advanced Spine Care, Surat, India

Objective: DXA is the gold standard in diagnosing osteoporosis. However, screening all postmenopausal women (PMW) for osteoporosis is not feasible in clinical practice. Questionnaire-based screening tools have still not been validated in Indian settings. This cross-sectional study aimed to assess the performance of various osteoporosis screening tools (OSTA, ORAI, SCORE, ABONE, BW, OSIRIS) in the prediction of osteoporosis in PMW.

Results: We enrolled 190 healthy middle-class community-dwelling postmenopausal women (mean age 61.09 $\pm$ 6.5 y, range 50–86 y). The mean age of menopause was at 46.21 $\pm$ 4.9 y. The mean BMI was 27.92 $\pm$ 4.72 kg/m^2. Self-reported fracture was present in 26.8% of patients. BMD parameters showed osteoporosis in 63 (38.7%); osteopenia in 54 (33.1%) and normal in 46 patients (28.2%). Vitamin D deficiency (serum 25OHD < 20 ng/ml) was present in the majority (48.7%) of subjects. Clinically applicable screening tools for osteoporosis status were ABONE (AUC: 0.628) followed by the ORAI (AUC: 0.608, specificity 41%, Sensitivity- 97%).

Conclusion: ABONE and ORAI clinical risk instruments demonstrate high sensitivity for predicting osteoporosis in PMW. These can help us identify individuals at high risk for osteoporosis and prioritize them for DXA scanning.

P1075
EFFICACY OF A PILOT SCREENING PROGRAM FOR FRACTURE RISK EVALUATION IN POSTMENOPAUSAL WOMEN IN TWO CENTERS IN POLAND

K. Turzanska[1], T. Blicharski[1], A. Mozdzen[1], A. Nowakowska-Plaza[2], E. Zielinska[2], J. Tomasiuk[2], M. Stasiek[2], T. Sadura-Sieklucka[2], P. Gluszko[2]

[1]Dept. of Rehabilitation and Orthopaedics, Medical Univ. of Lublin, Lublin, [2]Dept. of Rheumatology, National Institute of Geriatrics, Rheumatology and Rehabilitation, Warsaw, Poland

Objective: Current epidemiological data from the Polish National Health Fund indicate that over 80% of patients remain undiagnosed with osteoporosis, and over 90% do not receive appropriate pharmacological treatment. To strengthen collaboration between primary health care units, hospitals, and specialist centers focused on the diagnosis and treatment of osteoporosis, the first Operational Program Coordination for the Prevention of Osteoporotic Fractures (POWER) was implemented in Poland in the years 2019 -2023. In this study, we present a preliminary analysis of the results of simple screening tests used in this program to detect women at risk for fractures or who already have fractures.

Methods: The POWER program was carried out by four centers in four macroregions of Poland, screening by June 2023, 9309 women aged 50–70 y who had never previously been diagnosed with osteoporosis. Simple screening tests for the assessment of risk factors for fractures like BMI measurement, risk calculation with FRAX PL, and an interview regarding falls and bone fractures were carried out in primary health care units and orthopedic departments, and women with low-energy fractures or with medium or higher risk assessed by FRAX were referred to specialist centers for further diagnostics including DXA and X-ray examination. In the National Institute of Geriatrics, Rheumatology, and Rehabilitation in Warsaw, the center

selected for this study, cooperating with 44 primary care units, 3819 women were screened. In the Independent Public Hospital No. 4 in Lublin, working in conjunction with 47 primary care clinics, a similar analysis of the screening results of 2051 women was performed.
Results: In the Warsaw center and cooperating units in central Poland, the FRAX PL calculator revealed a medium or high probability of fractures in 19.9% (762 women). Subsequent DXA densitometric examinations confirmed osteoporosis in 30.8% of these patients, while 43.3% were diagnosed with osteopenia. Furthermore, low-energy fractures were identified in 237 women. Lublin Center (eastern Poland): Out of the participants, 55% (1128 women) progressed to the second stage of the study based on a medium or high probability of fractures in FRAX. Ultimately, 1051 patients (52%) underwent evaluation at the specialist medical center. Within this group, DXA examination disclosed osteoporosis in 34% of the women assessed, and osteopenia was identified in 32%. Additionally, 138 women were diagnosed with previously unknown low-energy fractures.
Conclusion: The observations currently analyzed in two program centers only confirm the results reported in comparable international studies. Our data support recommendations for highly effective, simple, and low-cost screening procedures aimed at identifying people at risk of osteoporotic fractures and, notably, in a relatively younger group of women. Further research on screening errors, false positive or negative diagnoses, and methods of improving cooperation with primary care units and orthopedic hospitals are being conducted.

P1076
CONOTOXINS FROM SEA SNAILS VENOM AS BONE REMODELING DISRUPTORS

B. Iduarte-Frías[1], P. Fournier[1], A. Licea[1], P. Juarez[1]

[1]Centro de Investigación Científica y de Educación Superior de Ensenada, Ensenada, Mexico

Objective: Disruption of bone remodeling results in an imbalance between bone formation and resorption, leading to osteoporosis. New molecules that can effectively modulate bone remodeling are needed. Conotoxins, small peptides from the venom sea snails, exhibit high affinity and selectivity for ion channels that are also present in bone cells. Thus, we aimed to characterize the effects of two synthetic conotoxins on osteoclasts, osteoblasts, and osteocytes in vitro and ex vivo.
Methods: Transcriptomic analysis of osteoblast treated with conotoxin revealed a significant downregulation of multiple genes associated with ossification, skeletal development, bone development, bone mineralization, and osteoblast differentiation. Then, we tested the effects of conotoxins in OB and OC in vitro.
Results: We found conotoxins were able to decrease the mineralization of mice osteoblasts ($p < 0.001$) while increasing the differentiation of mouse bone marrow cells into osteoclasts when stimulated with RANKL and M-CSF ($p = 0.001$). Also, treatment with conotoxin significantly increased osteoclast resorption activity ($p = 0.001$). Our data also indicated that this pro-osteoclastic effect was RANKL-dependent. Real-time qPCR (RT-qPCR) revealed that conotoxins downregulated the expression of osteoblastic genes Runx2 ($p = 0.027$), Alpl ($p = 0.006$), and Col1a1 ($p = 0.001$) while upregulating osteoclastic genes such as Nfatc1 ($p = 0.015$) and RANK ($p = 0.048$). Additionally, conotoxins modulated the expression of nAChR ($p = 0.015$) on bone cells. We tested the effect of conotoxins on an ex vivo calvaria culture model; histological analysis indicated a significant decrease in bone area ($p = 0.005$) and an increase in the number of osteoclasts ($p = 0.001$) in conotoxin treated calvaria. Lastly, we evaluated the effect of conotoxins on gene expression in osteocyte-enriched bone, and RT-qPCR indicated an upregulation of the expression of Dmp1 ($p = 0.0015$), Sost ($p = 0.002$), Rankl ($p = 0.002$).
Conclusion: The evaluated conotoxins disrupt bone remodeling, affecting bone cell differentiation and activity in vitro and ex vivo. These results suggest using conotoxins as a combined therapy to modulate resorptive therapies.

P1077
LONG-TERM FOLLOW-UP OF PATIENTS WITH RHEUMATOID ARTHRITIS: EMPHASIS ON BONE MINERAL DENSITY

P. Kovalenko[1], I. Dydykina[1], A. Smirnov[1], S. Glukhova[1]

[1] V. A. Nasonova Research Institute of Rheumatology, Moscow, Russia

Objective: To assess the dynamics of BMD with long-term observation of patients with rheumatoid arthritis.
Methods: 107 women with rheumatoid arthritis (RA) (ACR 1987, EULAR/ACR 2010) were included in an open-label, prospective, cohort study, the average age was 63.7 ± 8.3 y, RA duration at baseline 14.3 ± 9.8, who underwent an outpatient or inpatient examination in 2010–2014 (follow-up duration was 9.5 ± 1.9 y). A generally accepted clinical examination was performed, X-ray densitometry with measurement of MD in the lumbar spine (L1-L4), femoral neck (FN), proximal hip (PH) was performed at baseline and in dynamics, thoracic and lumbar spine X-rays were performed in lateral projection with assessment of vertebral deformations by Genant method (a decrease in the height of the vertebra by 20% or more was considered as a fracture and is described below as vertebral body index < 0.8).
Results: In general, during the period the L1-L4 did not change significantly: 0.896 ± 0.155 vs. 0.894 ± 0.158 g/cm^2. Significant ($p < 0,05$) negative dynamics of BMD in HN and PH in the whole group was established: 0.683 ± 0.119 and 0.632 ± 0.107 g/cm^2 (for HN) and 0.789 ± 0.139 and 0.754 ± 0.142 g/cm^2 (for PH). There was a significant ($p < 0.05$) increase in the number of patients with vertebral deformations (fractures): from 17 (16%) to 52 (48%) in the thoracic and from 7 (6%) to 13 (12%) in the lumbar region and an increase in the degree of deformation in these regions: the vertebral body index decreased from 0.77 ± 0.07 to 0.73 ± 0.1 and from 0.74 ± 0.08 to 0.7 ± 0.1, respectively. In the group of patients with lumbar deformations (n = 13), there was a trend towards an increase in BMD of L1-L4: from 0.911 ± 0.195 to 0.936 ± 0.206 g/cm^2, in contrast to the group of patients without deformations: 0.894 ± 0.149 and 0.884 ± 0.151 g/cm^2, respectively. Due to the expected association with age, patients were divided into groups by age at inclusion. In the group "baseline age $\geq$ 55 years" (n = 63), an increase in BMD of L1-L4 was detected: 0.870 ± 0.146 vs. 0.898 ± 0.164 g/cm^2 ($p = 0.02$). While the group "baseline age $<$ 55 years" (n = 44) showed a decrease in BMD L1-L4: 0.870 ± 0.146 vs. 0.898 ± 0.164 g/cm^2 ($p = 0.0003$). In patients taking glucocorticoids (at baseline or at the time of re-examination), there was a tendency for an increase in BMD in the L1-L4; in patients who did not take glucocorticoids, there was a tendency for a decrease in BMD. A significant decrease in HN and PH was recorded regardless both of glucocorticoids administration (at baseline or at the time of re-examination) and the age at inclusion (younger/older than 55 years).
Conclusion: A preliminary analysis of the results of long-term follow-up showed that regardless of the baseline age of patients and the administration of glucocorticoids, there was a significant decrease in BMD in the femoral neck and proximal hip. An increase in BMD in the L1-L4 was observed in older patients (at baseline) and seems to be associated with an increase in compression deformations of the

vertebrae of this department, in contrast to younger patients who had a decrease in BMD in the L1-L4.

P1078
LONG-TERM FOLLOW-UP OF PATIENTS WITH RHEUMATOID ARTHRITIS: EMPHASIS ON VERTEBRAL DEFORMATIONS

P. Kovalenko[1], I. Dydykina[1], A. Smirnov[1], S. Glukhova[1]

[1] V. A. Nasonova Research Institute of Rheumatology, Moscow, Russia

Objective: To assess the dynamics of vertebral deformations in patients with rheumatoid arthritis with long-term observation.
Methods: 107 women with rheumatoid arthritis (RA) (ACR 1987, EULAR/ACR 2010) were included in an open-label, prospective, cohort study, the average age was 63.7 ± 8.3 y, RA duration at baseline 14.3 ± 9.8, who underwent an outpatient or inpatient examination in 2010–2014 (follow-up duration was 9.5 ± 1.9 y). A generally accepted clinical examination was performed, at baseline and in dynamics thoracic and lumbar spine X-rays were performed in lateral projection with assessment of vertebral deformations by Genant method (a decrease in the height of the vertebra by 20% or more was considered as a fracture and is described below as vertebral body index < 0.8).
Results: During the observation period, 35 (33%) patients experienced the occurrence of vertebral deformation (fracture) or increase in the existing baseline deformation. There was a significant ($p < 0.05$) increase in the number of patients with vertebral deformations (fractures): from 17 (16%) to 52 (48%) in the thoracic and from 7 (6%) to 13 (12%) in the lumbar site and an increase in the degree of deformation in these regions: the vertebral body index decreased from 0.77 ± 0.07 to 0.73 ± 0.1 and from 0.74 ± 0.08 to 0.7 ± 0.1, respectively. Due to the expected association between patients' age and the presence/severity of deformations, patients were divided into groups by age at the time of inclusion. According to the average daily, cumulative dose of glucocorticoids at baseline/over time, the duration of glucocorticoids administration—groups did not differ. Only in the group "baseline age ≥ 55 years" (n = 63) there was a significant ($p < 0.05$) increase in deformations of the thoracic and lumbar sites: vertebral body index decreased from 0.76 ± 0.09 to 0.73 ± 0.1 in the thoracic and from 0.73 ± 0.08 to 0.68 ± 0.12 in the lumbar regions. Whereas in the group "baseline age < 55 years" (n = 44), significant ($p < 0.05$) increase in deformations was noted only in the thoracic site: 0.79 ± 0.02 to 0.74 ± 0.1. In both groups, there was a significant increase in the number of patients with deformations in both departments. Due to the small number of subgroups when separating patients with deformities depending on glucocorticoid intake, no reliable statistical data were obtained, the data are not provided.
Conclusion: A preliminary analysis of the results of long-term follow-up showed a significant increase in the number of patients with vertebral deformations (fractures) in both sites regardless of the baseline age of patients. Baseline age at inclusion influenced the severity of the deformations. In older patients (baseline), there was a negative change in the degree of deformity in both parts of the spine, while in younger patients (baseline)—only in the thoracic site. A larger sample is needed to assess the impact of glucocorticoids.

P1079
EROSION COUNT DYNAMICS IN PATIENTS WITH RHEUMATOID ARTHRITIS WITH LONG-TERM FOLLOW-UP

P. Kovalenko[1], I. Dydykina[1], A. Smirnov[1], M. Diatroptov[1], S. Glukhova[1]

[1] V. A. Nasonova Research Institute of Rheumatology, Moscow, Russia

Objective: To assess erosion count dynamics in patients with rheumatoid arthritis with long-term follow-up.
Methods: 107 women with rheumatoid arthritis (RA) (ACR 1987, EULAR/ACR 2010) were included in an open-label, prospective, cohort study, the average age was 63.7 ± 8.3 y, RA duration at baseline 14.3 ± 9.8, who underwent an outpatient or inpatient examination in 2010–2014 (follow-up duration was 9.5 ± 1.9 y). At baseline and in dynamics there were performed a generally accepted clinical examination, X-ray of hands and feet in direct projection (with Sharp/Van der Heide assessment), immunological analysis of ACCP (cyclic citrullinated peptide antibodies), RF (rheumatoid factor), CRP (C-reactive protein), IL-6, MMP-3 (matrix metalloproteinase-3) as well as osteoimmunological markers (osteocalcin, osteoprotegerin, RANKL, CTX-1, BAP (bone alkaline phosphatase)) were determined.
Results: In general, during the period the group showed a significant ($p < 0.0001$) increase in erosion count: 16.0 [3.0; 44,0] vs. 16,0 [5,0; 64.0] Me [25%; 75%]. An increase in erosion count was observed in 54 patients, while stabilization of this indicator was observed in 48 people. When comparing these groups of patients (with increase (group 1) or stabilization of erosion count (group 2) over the study period), it was found that in group 1 there were initially younger patients: 52.9 ± 9.9 vs. 56.3 ± 7.1 y ($p = 0.02$). In group 1 (increased erosion count), patients were significantly more often were positive for the RF and ACCP: 44 (81.5%) vs. 24 (50%) ($p = 0.0007$) and 42 (77.8%) vs. 28 (58.3%) ($p = 0.03$), respectively. At baseline, patients in group 1 had higher levels of MMP-3 and IL-6 than in group 2: 55.5 [19.5; 119,5] vs. 23,8 [14; 68] ng/mL ($p = 0.02$)—for MMP-3 and 7.5 [2.9; 21,8] vs. 5,9 [0,3; 9.6] pg/mL ($p = 0.01$)—for IL-6. Correlation analysis also revealed a valid association between erosion count at baseline and baseline level of MMP-3, IL-6. In dynamics the examination revealed a direct relationship between erosion count and MMP-3 level.
Conclusion: A preliminary analysis of the results of long-term observation of patients with RA, younger age, positivity in the RF and ACCP showed that higher baseline MMP-3 and IL-6 levels are associated with an increase in erosion count.

P1080
PATIENT'S FEELINGS REGARDING THE FUTURE OF RHEUMATOLOGY

P. Lemesle[1], X. Grapton[2], L. Poulain[3], N. Bouhedja[3]

[1]Hopital Rives de Seine Courbevoie, Courbevoie, [2]Hopital Suisse de Paris, Issy Les Moulineaux, [3]Private practice, La Garenne Colombes, France

Objective: Evaluate the evolution and outcome of rheumatology from the patients' perception.
Methods: 51 Rheumatologists (Rh) of CREER group (Ile de France) have interrogated their patients about their appreciation of

rheumatology private practice in 2023. 261 patients, Men(M) 20% / Women (W). 4 groups A: 10% < 39 yo; B 26% < 40–59 > ; C 49% < 60–79 > ; D 15% > 79.

Results: Media, social network, and close circle influence is quoted on 3 levels. Access to information:—Media: moderate influence for all ages, -Social networks: Null for 50%, except A,—Social networks: Null for 50%, except A, -Social networks: Null for 50%, except A,-Close circle Important for all ages. Decision to accept the treatment: -Media: heterogenous for all ages, -Social network: Null for 50% except A, -Close circle: Important for all ages and mostly A. Internet search before Rh consultation by their symptoms: no 62%—Direct access to Rh: 35%. Referred by general physician: 54%—Teleconsultation: No 88%, M = W. Internet interrogation about the Rh, diagnosis (Dg) and treatment: No respectively 71%, 64%, 72%, M = W, except for RH and Dg. Previous treatment before RH: general physician, 27%, physical therapist 66%, osteopath 75%. Complete and sufficient Information given by Rh > 90%—Rh preferred for infiltration (no tomography and no X-rays) 81%—Osteoporosis (OP) is the Rh matter 80%, gynecologist 13%, M = W—Infiltrations by nurses (No: 80%), by pharmacist (No 85%), M = W—Generic substitution: No 57%

Conclusion: Patients are poorly influenced by media when it comes to medical decisions and even less by social networks including for the youngest. Close circle influence remains essential for all ages. Despite a complete information, the Rh comes in third position for a consultation. Rh is still the medical reference for OP and infiltrations which the transfer to nurses or pharmacists is unconceivable.

P1081
ABSENCE OF REBOUND INCREASE IN BONE TURNOVER MARKERS IN NON-OSTEOPOROTIC PATIENTS TREATED WITH HIGH DENOSUMAB DOSES FOR 6 MONTHS: A 30-MONTH PROSPECTIVE STUDY

P. Makras[1], A. Anastasilakis[2], M. Yavropoulou[3], A. Papatheodorou[1], S. Papapoulos[4]

[1]251 Hellenic Air Force & VA General Hospital, Athens, Greece, [2]424 General Military Hospital, Thessaloniki, Greece, [3]National and Kapodistrian Univ. of Athens, Athens, Greece, [4]Leiden Univ. Medical Center, Leiden, Netherlands.

Objective: The importance of length of treatment for the consequences of the overshoot of bone turnover markers following discontinuation of denosumab (Dmab) has been clearly shown in prospective studies of patients with osteoporosis. The contribution, however, of the total dose of administered drug to this response is currently unknown due to the lack of information of long-term changes of bone turnover after stopping Dmab given at doses higher than those used in the treatment of osteoporosis.

Methods: We addressed this question in a prospective, single-arm, open-label, multicenter, Phase 2b clinical trial of 10 non-osteoporotic adult patients with Langerhans Cell Histiocytosis (LCH; 8 with bone lesions) treated with Dmab 120 mg every 2 months for 6 months (4 injections / total dose 480 mg) and followed for 2 y after the last injection. During a total observation period of 30 months, we measured bone turnover markers at regular intervals and BMD annually.

Results: As recently reported, treatment was clinically very effective (80% regression of lesions, 10% stable disease, 10% development of a new lesion[1]). Following Dmab, bone turnover markers were reduced up to 90% from baseline values at 6 months. Thereafter, they started increasing at 6 months after the last injection, reached peak values at 12 months and decreased thereafter; a pattern very similar to that after the last injection of Dmab 60 mg for osteoporosis followed by uncompensated discontinuation. The peak values of serum CTX (0.522 ± 0.016 ng/ml) and P1NP (72.2 ± 11.4 ng/ml) were not significantly different from baseline values (p = 0.1109 and 0.6534, respectively). LS-BMD increased significantly by 3.93% during the first year and returned to baseline at the end of the study.

Conclusion: The highly efficacious treatment of adult LCH patients with Dmab was not followed by an overshoot of bone turnover markers or bone loss despite the administration within 6 months of a total dose equal to that given to patients with osteoporosis for 3.5 years. These results suggest that the total Dmab dose is not an important determinant of the "rebound" of bone turnover.

P1082
ASSOCIATION OF GENETIC MARKERS WITH CLINICAL CHARACTERISTICS IN PATIENTS WITH RHEUMATOID ARTHRITIS

P. Marozik[1], E. Rudenka[2], A. Rudenka[2], K. Kobets[1], V. Samokhovets[3]

[1]Institute of Genetics and Cytology NAS Belarus, [2]Belarusian State Medical Univ., [3]31st Minsk City Clinical Hospital, Minsk, Belarus

Rheumatoid arthritis (RA) is a multifactorial disease caused by environmental and hereditary factors. RA contributes to an increased risk of developing osteopenia and osteoporosis (OP), especially due to the use of certain antirheumatic drugs. Identification of individual genetic predictors of an increased risk of RA complications will allow timely adjustment of treatment and avoidance of adverse effects.

Objective: To identify the most significant polymorphic variants in genes associated with clinical and biochemical parameters in patients with RA.

Methods: The study included 262 people (128 controls and 176 patients with RA). Individuals included in the study underwent an outpatient examination at the 1st Minsk City Hospital (Belarus); all participants signed informed consent. Clinical examination of patients included collecting a history of the disease, measuring body length and mass, assessing the clinical picture of the disease, including the presence of systemic manifestations, filling out patient cards with counting the number of swollen (SJ) and painful joints (PJ). The BMD was evaluated using DXA. Genetic studies were carried out using real-time PCR of the following polymorphic variants of the genes *IL19* rs587776843, *ATIC* rs4673993 and rs2372536, *ABCB1* rs1128503 and rs1045642, *ABCG2* rs2231142, *AMPD1* rs17602729, *ITPA* rs1127354, *ADORA2A* rs 5,760,410 and rs2236624, *TLR4* rs4986790, *HLA-E* rs1264457, *NR3C1* rs258751, *ATP5F1E* rs1059150, *KLRD1* rs2302489, *GLCCI1* rs37973, *CRHR1* rs1876828, *ESR1* rs1801132, *PRL* rs7739889, IL6 rs1800795, CALCR rs1801197.

Results: Based on genotyping results, we found that in carriers of the C/C genotype for rs1801132 of the *ESR1* gene, the level of BMD of the femoral neck was statistically significantly lower in the group of patients (0.76 ± 0.01) compared to the control (1.02 ± 0.01, p = 0.048). An association was also established between the A/A genotype of the rs7739889 PRL gene variant and reduced femoral neck BMD in the patient group (0.77 ± 0.02) relative to the control group (1.12 ± 0.13, p = 0.033). A similar association was revealed for the A/A genotype of the rs1801197 variant of the *CALCR* gene and the rs1800795 C/C genotype of the *IL6* gene—they are also statistically significantly associated with a decrease in BMD of the femoral neck (0.76 ± 0.01 and 0.77 ± 0.02 in patients against 1.03 ± 0.02 in the control group, p = 0.025 and p = 0.038, respectively). In addition, a statistically significant association with the

likelihood of RA was established for the TLR4 rs4986790, HLA-E rs1264457, IL19 rs587776843 loci.
Conclusion: Analysis of the results of genotyping of patients with RA allowed us to establish a significant association with the likelihood of decreased bone mass of loci *ESR1* rs1801132 C/C, *PRL* rs7739889 A/A, *CALCR* rs1801197 A/A, *IL6* rs1800795 C/C, with the likelihood of developing RA – loci *TLR4* rs4986790, *HLA-E* rs1264457, *IL19* rs587776843. Application of this approach in practice will improve the effectiveness of prevention of RA and its complications and accelerate the transition to personalized medicine.

P1083
ROLE OF FRAILTY ON REHABILITATION SUCCESS IN AN ITALIAN ORTHOGERIATRICS UNIT

G. Caggiu[1], M. Monzio Compagnoni[1], P. Floris[2], M. Passamonte[2], F. De Filippi[3], P. Mazzola[4]

[1]Università degli Studi di Milano-Bicocca, Dept. of Statistics and Quantitative Methods, Milano, [2]Ospedale di Sondrio, ASST della Valtellina e dell'Alto Lario, Sondrio, [3]Società Italiana di Geriatria Ospedale e Territorio, Roma, [4]Università degli Studi di Milano-Bicocca, School of Medicine and Surgery, Monza, Italy

Objective: To investigate the influence of frailty and delirium on rehabilitation outcomes in an Italian Orthogeriatric Unit.
Methods: All patients admitted to the Orthogeriatrics Unit at Sondrio Hospital (Italy) from 2011–2019, having $\geq$ 70 y and a femur fracture were prospectively enrolled. Among these, only patients who signed an informed consent form were included and formed the cohort study. The assessment included demographic information, functional and cognitive statuses, comorbidity, medications, and factors related to the fracture (type, timing, anesthesia, surgery). We calculated a frailty index (FI) based on 16 variables, and patients were classified in four categories according to frailty: fit ($FI < 0.15$; reference category), pre-frail ($0.15 \leq FI \leq 0.24$), mildly frail ($0.25 < FI < 0.34$) and moderate-to-severely frail ($FI \geq 0.35$). Delirium was assessed according to the DSM-5 criteria.
Results: The study population included 818 subjects (mean age 85.6 $\pm$ 5.7 y, 83.3% females). The most represented comorbid conditions were hypertension (55.8%), cardiac disorders (34.6%) and dementia (21.6%). The average time to surgery was 1.9 $\pm$ 1.1 d, and 70.2% of patients were classified as ASA 3 (severe systemic disease) or higher, reflecting an overall high operative risk. The majority of patients experienced displaced fractures (89.7%) and underwent surgery (55.1% intramedullary nail, 38.3% hemiarthroplasty) in spinal anesthesia in 77.6% of cases. In terms of rehabilitation success, i.e., Rehabilitation Efficiency Index (REI) > 0.5, it is expected that nonagenarians show the lowest rate compared to younger age groups (59.5% vs. 78.6% and 73.2% of 70–79 and 80–89 y, respectively). However, more than age per se, a frail phenotype represents a stronger risk factor for poor rehabilitation outcomes (OR 0.14, 95%CI 0.07–026 for mild frailty; OR 0.30, 95%CI 019–0.47 for moderate-to-severe frailty), with similar results among those who experienced delirium.
Conclusion: Frailty is a modifiable risk factor, thus we encourage the adoption of preventive strategies to counteract this syndrome. When caring for frail patients with hip fracture, it is advisable to direct the efforts towards early mobilization and physiotherapy, in order to make early rehabilitation as efficient as possible.

P1084
REFINING OSTEOPOROSIS RISK PREDICTION VIA ENSEMBLE FEATURE SELECTION

P1084 Refining osteoporosis risk prediction via ensemble feature selection.

[1]Princess Srisavangavadhana College of Medicine, Chulabhorn Royal Academy, Laksi, Thailand.

P. Nonthasaen[1], P. Achararit.[1]

[1]Princess Srisavangavadhana College of Medicine, Chulabhorn Royal Academy, Laksi, Thailand.

Objective: To develop a robust osteoporosis risk prediction tool by evaluating diverse feature selection techniques on a dataset of 1537 patients with 40 clinical biomarkers and bone density measurements (He, 2022). The objective was to identify a concise panel of predictive variables for accessible risk assessment and preventive treatment guidance.
Methods: We leveraged a dataset comprising 39 features and compared three feature selection methods: ANOVA, recursive feature elimination (RFE), and Lasso regression. Subsequently, Logistic regression, SVM, and random forest models were trained on the full feature set, top 10 features per method, and overlapping features between methods. Model performance was evaluated by fivefold cross-validation on metrics including accuracy, precision, recall, F1 score, and ROC-AUC.
Results: The seven overlapping features ('AS', 'Calcitonin', 'Calcitriol', 'FN', 'FNT', 'TL', 'TLT') selected by all methods showed consistent predictive power. Logistic regression with these features achieved 83% accuracy, comparable to 84% with the top 10 Lasso features, where models trained on all 39 features performed worse. Precision, recall, F1 score, and ROC-AUC were also comparable or improved using just 7 vs. 10 features across models. Similar patterns were seen for other models, with the full feature sets showing degraded performance metrics compared to the concise panel, highlighting the value of an optimized panel.
Conclusion: This study demonstrates the power of combining multiple feature selection techniques, as the ensemble panel achieved comparable or better accuracy than the full 39 feature sets. By distilling the signal from a complex dataset, the ensemble strategy offers a targeted screening tool to guide clinical decision-making. Further external validation will determine the generalizability of this targeted screening approach for routine clinical application.

ASSESSING THE IMPACT OF CHRONIC KIDNEY DISEASE (CKD) AND TYPE 2 DIABETES MELLITUS (T2DM) ON TRABECULAR BONE SCORE (TBS) IN POSTMENOPAUSAL WOMEN WITH OSTEOPOROSIS: A PRE- AND POST-TREATMENT ANALYSIS

P. Pinijprapa[1], Y. Suwansri[1], T. Songpatanasilp[1], T. Tutaworn[1], O.-A. Phruetthiphat[1]

[1]Phramongkutklao Hospital, Bangkok, Thailand

Objective: Osteoporosis is a common health problem, especially in countries with an increasing elderly population. Although BMD is

widely used, TBS has the advantage of detecting missed osteoporotic bone cases by using a pixel method in DXA lumbar spine images, along with BMD. Currently, both type 2 diabetes mellitus (T2DM) and chronic kidney disease (CKD) can affect bone strength. However, no specific study has focused on the combined effect of T2DM and CKD on TBS in osteoporotic patients. This study aims to investigate the effect of CKD and T2DM on the efficacy of osteoporotic treatment by evaluating the change in TBS before and after treatment with anti-resorptive drugs in postmenopausal women. Primary objective: To assess the significance of CKD and T2DM in terms of TBS before and after treatment with anti-resorptive drugs in postmenopausal osteoporotic women. Secondary objective: To study the importance of detecting CKD and T2DM before and after treatment with anti-resorptive drugs in postmenopausal osteoporotic women using BMD as a tool for comparison.

Methods: 253 Thai postmenopausal osteoporotic women with a mean age of 71.77 ± 8.07 years who were treated with anti-resorptive drugs. L-spine TBS and L-spine BMD were measured in all patients. TBS values before and after treatment will be calculated and compared at 1 year and 2 years, respectively. The correlation between TBS and BMD in each model will also be assessed. Using statistical analysis, CKD, T2DM and drug administration will be evaluated for correlation with TBS and BMD results.

Results: Among 253 patients, 6 models were analyzed for the results of bone density changes from baseline to 2-y follow-up. In diabetes mellitus type 2, TBS showed significant differences between the diabetic and non-diabetic groups at the L3 level at both baseline and 2-y follow-up. For CKD, baseline BMD at the L2 and L4 levels, neck, and total hip showed significant differences, as did TBS and BMD at the L4 level at 2-y follow-up. The age factor was significantly different for BMD at the neck and total hip at all follow-up times. Combining both DM and CKD, TBS at the L3 level and BMD at the L4 level showed significant differences at both baseline and 2-y follow-up. Only BMD at the L2 level was significantly different at baseline. Summation of all three factors, at baseline, TBS at the L3 level and BMD at the L2 and L4 levels were significantly different, while average TBS, TBS at the L3 and L4 levels, and BMD at the L4 level showed significant differences at 2-y follow-up. Patients with more than two risk factors were significantly more likely to have worse BMD and TBS scores compared to patients with no risk factors. In addition, a comparison between injection group and oral medication group showed that the injection group had significantly improved in BMD at the average lumbar level, neck of femur, and L1 level at baseline and in BMD at the average, L1 to L4 level at 2-y follow-up.

Conclusion: Age, chronic kidney disease, and diabetes mellitus type 2 appear to be significant factors affecting bone quality in both the lumbar spine and hip, as assessed by BMD and TBS. In patients with multiple risk factors, more pronounced differences are observed at both baseline and 2-y follow-up. The injection group may demonstrate superior outcomes compared with oral medication, and BMD more clearly reveals the progression after the treatment compared to TBS.

P1086
RADIOFREQUENCY ECHOGRAPHIC MULTI SPECTROMETRY (REMS) AS AN ULTRASOUND METHOD FOR BONE QUALITY ASSESSMENT IN PATIENTS WITH TYPE 2 DIABETES MELLITUS

P. Pisani[1], F. Conversano[1], F. A. Lombardi[1], F. R. Contaldo[2], G. Luceri[3], T. De Marco[3], E. Casciaro[1], M. Muratore[4], S. Casciaro[1]

[1]Institute of Clinical Physiology, National Research Council, [2]Dept. of Biological and Environmental Sciences and Technologies, Univ. of Salento, [3]R&D Dept., Echolight S.p.a., [4]ASL-LE, Ospedale Vito Fazzi, Lecce, Italy

Objective: Type 2 diabetes mellitus (T2DM) is a chronic, multifactorial disease characterized by persistent hyperglycaemia (high blood glucose levels) as a consequence of insulin resistance, resulting in the development of disabling health complications, such as bone fragility. Scientific literature shows both quality and quantity of bone have a strong relationship with T2DM, contributing to the increased risk of bone fragility fractures compared to nondiabetic subjects. Indeed, these patients, may fracture despite normal or even increased BMD. The bone alterations may be due to the effect of advanced glycosylation end products (AGEs) on collagen fibres and bone cells, this interaction causes a conformational alteration of the structure and of the bone strength. This study aims to use the REMS-based the Fragility Score (FS) parameter to evaluate the effect of T2DM on bone quality microarchitecture. The FS parameter is an indicator of skeletal fragility independent of BMD and ranging from 0–100 (100 indicates the maximum similarity with the fractured model, on the other hand, 0 indicates the maximum similarity with the healthy model).

Methods: A cohort of 30 Caucasian women with DMT2 were enrolled and compared with an equivalent group of healthy control women (HC) matched for age and BMI. All the patients underwent REMS scans on proximal femur and the difference of FS values between the two study groups was evaluated through t-test.

Results: The mean of age and BMI were respectively 67.9 ± 12.2 years and 24.9 ± 3.4 kg/m^2 for T2DM and 67.7 ± 12.1 y and 25.8 ± 3.7 kg/m^2 for HC. The FS values measured at the proximal femur was significantly higher in T2DM patients (46.2 ± 17.8) than those obtained by HC (41.8 ± 16.4). The mean difference between 2 group is equal to -4.37 ± 17.1.

Conclusion: As expected, an important bone quality impairment associated with T2DM has been measured. The obtained data demonstrate that REMS is a valid diagnostic tool for the monitoring of bone health status, thanks to its ability to assess bone quality, enhancing the diagnosis in T2DM patients.

P1087
USE OF TRABECULAR BONE SCORE TECHNIQUE (TBS) IN EXAMS BONE DENSITOMETRY (DXA) OF OSTEOPENIC DIABETIC PATIENTS FOR STRATIFICATION OF THE RISK OF FRAGILITY FRACTURES

P. Portinho[1]

[1]Hospital das Forças Armadas, Brasília, Brazil

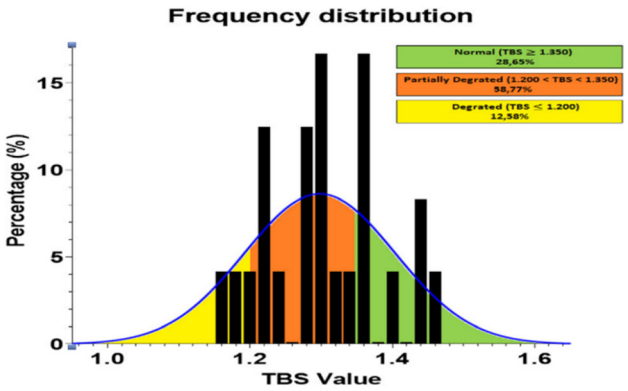
Objective: In 2015, in Brazil, there were 373 thousand fractures due to bone fragility(1). The mortality rate associated with a fragility femoral fracture in the elderly is 19.2% at 1 year (2).

The increased risk of fragility fractures is not only related to BMD, but also the quality of bone trabecular microarchitecture (3). TBS detects specific changes in bone quality related to trabecular microarchitecture, improving the diagnosis of the high risk of fragility fractures.

Diabetic patients present a deterioration in bone microstructure that is more evident in the composition of the disease (4). This study aimed to evaluate TBS in diabetic patients and stratify selected patients using TBS values in combination with BMD, in lumbar spine DXA acquisitions performed at HMAB in the period 2016 and 2020.

Methods: The sample included diabetic patients with the following inclusion criteria: men aged 70 years or over, women aged 60 or over; laboratory diagnosis of diabetes according to the criteria of the Brazilian Society of Diabetes; and DXA with osteopenia.

Results: 60 patients were evaluated; male (20%); female (80%); normal TBS 19 patients (28.65%), partially degraded 33 patients (58.775%) and degraded 08 patients (12.580%).



Conclusion: Diabetic patients develop degradation of bone microarchitecture in the lumbar spine, despite DXA showing good BMD.

ZIYUGLYCOSIDE II ATTENUATED OVX MICE BONE LOSS VIA INFLAMMATORY RESPONSES AND REGULATION OF GUT MICROBIOTA AND SCFAS

Y. Zhou[1], L. Hu[1], T. Zhou[1], Q. Dong[2], P. Sun[1]

[1]The First Affiliated Hospital of Guangdong Pharmaceutical Univ., Guangzhou, [2]Yunfu Hospital of Traditional Chinese Medicine, Yunfu, China

Objective: Osteoporosis (OP) is a frequent clinical problem for the elderly. Ziyuglycoside II (ZGS II) is a major active compound of Sanguisorba officinalis L. that has shown anti-inflammation properties. The purpose of our research is to investigate the mechanism of ZGS II in ameliorating bone loss by inflammatory responses and regulation of gut microbiota and the short chain fatty acids (SCFAs) in ovariectomized (OVX) mice.

Methods: We predicted the mode of ZGS II action on OP through network pharmacology and molecular docking, and an OVX mouse model was employed to validate its anti-OP efficacy. Then we analyzed its impact on bone micro-structure, the levels of inflammatory cytokines and pain mediators in the serum, inflammation in colon, intestinal barrier, gut microbiota structure and SCFAs in feces.

Results: Network pharmacology identified 55 intersecting targets of ZGS II related to OP. Of these, we predicted IGF1 may be the core target, which was successfully docked with ZGS II and showed excellent binding ability. Our in vivo results showed that ZGS II alleviated bone loss in OVX mice, attenuated systemic inflammation, enhanced intestinal barrier, reduced the pain threshold, modulated the abundance of gut microbiota involving norank_f_Muribaculaceae and Dubosiella, and increased the content of acetic acid and propanoic acid in SCFAs.

Conclusion: ZGS II attenuated bone loss in OVX mice by relieving inflammation and regulating gut microbiota and SCFAs.

P1090
DECODING THE MECHANISM OF ELEUTHEROSIDE E IN TREATING OSTEOPOROSIS VIA NETWORK PHARMACOLOGICAL ANALYSIS AND MOLECULAR DOCKING OF OSTEOCLAST-RELATED GENES AND GUT MICROBIOTA

T. Zhou[1], Y. Zhou[1], L. Hu[1], Q. Dong[2], P. Sun[1]

[1]The First Affiliated Hospital of Guangdong Pharmaceutical Univ., Guangzhou, [2]Yunfu Hospital of Traditional Chinese Medicine, Yunfu, China

Objective: Eleutheroside E (EE) is an anti-inflammatory natural compound derived from the edible medicinal herb Acanthopanax senticosus. This study aims to investigate the underlying mechanism of the anti-osteoporosis action of EE through network pharmacology, molecular docking and gut microbiota.

Methods: Network pharmacology was used to explore the potential core targets and main pathways mediated by EE in osteoporosis (OP) treatment. Molecular docking was exploited to investigate the interactions between the active anti-OP compounds in EE and the potential downstream targets. Following the multi-approach bioinformatics analysis, ovariectomy (OVX) model was also established to investigate the in vivo anti-OP effects of EE.

Results: The top 10 core targets in PPI network were TP53, AKT1, JUN, CTNNB1, STAT3, HIF1A, EP300, CREB1, IL1B and ESR1. Molecular docking results that the binding energy of target proteins and the active compounds was approximately between -5.0 and -7.0 kcal/mol, which EE has the lowest docking binding energy with HIF1A. Enrichment analysis of GO and KEGG pathways of target proteins indicated that EE treatment could potentially alter numerous biological processes and cellular pathways. In vivo experiments demonstrated the protective effect of EE treatment against accelerated bone loss, where reduced serum levels of TRAP, CTX, TNFα, LPS, and IL-6 and increased serum levels of P1NP were observed in EE-treated mice. In addition, changes in gut microbiota were spotted by 16S rRNA gene sequencing, showing that EE treatment increased the relative abundance of Lactobacillus and decreased the relative abundance of Clostridiaceae.

Conclusion: These findings suggested that the characteristics of multi-target and multi-pathway of EE against OP. In vivo, EE prevents the onset of OP by regulating gut microbiota and inflammatory response and is therefore a potential OP drug.

P1091
GUT MICROBIOTA AND SHORT-CHAIN FATTY ACID SIGNATURES IN POSTMENOPAUSAL OSTEOPOROSIS PATIENTS: A RETROSPECTIVE STUDY

S. Li[1], Y. Zhang[1], C. Ma[1], Q. Dong[2], P. Sun[1]

[1]The First Affiliated Hospital of Guangdong Pharmaceutical Univ., Guangzhou, [2]Yunfu Hospital of Traditional Chinese Medicine, Yunfu, China

Objective: Studies have shown that gut microbiota (GM) and its metabolites, short-chain fatty acids (SCFAs), are associated with the development of postmenopausal osteoporosis (PMO). This study

explored the clinical and laboratory evidence of the relationship of GM and SCFAs to PMO and attempted to determine the potential mechanism of action.
Methods: 18 patients (Collected from the First Affiliated Hospital of Guangdong Pharmaceutical University between January 2021 and August 2021) were included in this retrospective study, including 10 PMO women and 8 healthy young women as the healthy control (HC) group from Guangzhou, China. BMD was determined by DXA. The composition of GM and its metabolites, SCFAs, in the fecal samples were measured by 16S rRNA gene sequencing and gas chromatography/mass spectrometry (GC/MS) analysis, respectively.
Results: Compared with HC, PMO group had significantly decreased BMD in lumbar spines 1–4 (BMD_L) and femoral neck (BMD_F). 16S rRNA gene sequencing revealed that, compared with HC, PMO group had a markedly decreased abundance in Subdoligranulum, Norank_f_Muribaculaceae and Alistipes at the genus level. GC/MS analysis indicated that the concentration of propanoic acid significantly dropped in PMO group. Additionally, we found that Subdoligranulum, Norank_f_Muribaculaceae and Alistipes were positively correlated with BMD_L. Subdoligranulum and Norank_f_Muribaculaceae were also positively correlated BMD_F and propanoic acid, while Subdoligranulum is the only species that presented a strong correlation with the levels of acetic acid and butyric acid.
Conclusion: In postmenopausal women, there were evident changes in GM and SCFAs, and these changes were found correlated with patients' BMD. These correlations provide novel insights into the underlying mechanism of PMO development, representative of early diagnostic markers and therapeutic targets that may improve the bone health in postmenopausal women.

P1092
INVESTIGATING THE PROTECTIVE EFFECT OF LOGANIN IN OVARIECTOMIZED-INDUCED BONE LOSS THROUGH NETWORK PHARMACOLOGY AND MOLECULAR DOCKING

Y. Xie[1], D. Ge[1], Q. Dong[2], P. Sun[1]

[1]The First Affiliated Hospital of Guangdong Pharmaceutical Univ., Guangzhou, [2]Yunfu Hospital of Traditional Chinese Medicine, Yunfu, China

Objective: Loganin, a major iridoid glycoside derived from Cornus officinalis (CO), exerts strong anti-inflammation property. This study aims to investigate the underlying mechanism of Loganin to reduce estrogen deficiency-induced bone loss through a combination of network pharmacology, molecular docking and in vivo validation.
Methods: We first predicted the drug targets and structural interactions of Loganin with osteoclasts on postmenopausal osteoporosis (PMOP) through network pharmacology and molecular docking. An ovariectomized (OVX) mouse model was established to experimentally validate Loganin's anti-PMOP efficacy, supported by its protective effect on bone destruction and excessive inflammatory cytokines.
Results: The top 10 core targets of Loganin generated by PPI network were GAPDH, VEGFA, EGFR, ESR1, HRAS, SRC, FGF2, HSP90AA1, PTGS2 and IL-2. GO and KEGG enrichment analyses indicated that Loganin suppressed PMOP via mediating inflammation, bone formation, IL-17 signaling pathway, and NF-κB signaling pathway. Molecular docking results indicated strong binding between Loganin and core targets, in which the binding energy was approximately between -5.2 and -7.4 kcal/mol. In vivo mouse model showed that Loganin inhibited the expression of pro-osteoclastic markers, such as TRAP, CTX, TNFα and IL-6, enhanced the secretion of bone formation markers, e.g., P1NP and IL-10, and improved bone microstructure (BV/TV and Tb.N), representative of the anti-resorptive effect mediated by Loganin.
Conclusion: This study combined network pharmacology and molecular docking to predict the underlying mechanism of Loganin against PMOP, validated by the in vivo mouse model showing that Loganin attenuated OVX-induced bone loss by inhibiting inflammation.
Acknowledgment: This work was supported by grants from the Science and Technology Planning Project of Yunfu, Guangdong Province, China [No. 2020A090402].

IMPROVED GRADUATION RESULTS BY TRAINING NURSE SPECIALISTS, NURSE PRACTITIONERS AND PHYSICIAN ASSISTANTS NATIONALLY UNDER THE AUSPICES OF THEIR NATIONWIDE PROFESSIONAL GROUP

P. van den Berg[1], M. van Oostwaard[2], H. van der Heijden[3], M. van Echtelt[4], D. Bout[5], E. Appelman[6], I. Draaijer[7]

[1]Reinier de Graaf Gasthuis—Dept. of Orthopedics and Traumatology—VF&O, Delft, [2]VieCuri Medisch Centrum—Dept. of Internal Medicine, Venlo, [3]Bernhoven Ziekenhuis—Dept. of Internal Medicine—VF&O, Uden, [4]St. Antonius Ziekenhuis—Dept. of Surgery—VF&O, Utrecht, [5]Isala Ziekenhuis—Dept. of Surgery—VF&O, Zwolle, [6]Haga Medisch Centrum—Dept. of Rheumatology—VF&O, Den Haag, [7]Ommelander Ziekenhuis—Dept. of Rheumatology—VF&O, Groningen—Scheemda, Netherlands

Objective: An initiative aimed at facilitating a uniform national course for Fracture Liaison Service (FLS) health care professionals in the Netherlands, based on traditional education and discussions between experts and students.
Methods: Since 2012, Dutch FLS care nurse specialists (NS), nurse practitioners (NP), and physician assistants (PA) received their FLS education from an applied science institution. However, this arrangement did not result in a well-attended and continuous program. Therefore, in 2020, the (unpaid) board of the Dutch Nurse Professionals Association on Secondary Fracture Prevention VF&O (member of Dutch National Nursing Association V&VN) initiated a comprehensive 4-day course (two blocks of two days). This course covers all aspects of secondary fracture prevention, including medical, nursing, organizational, and quality aspects [1]. It is a self-funded initiative, with a maximum capacity to accommodate 20 students annually. The teaching materials were based on Dutch guidelines on Fractures and Falls and rephrased up to the latest version in 2022 [2]. Seventeen experts were involved in the program, which averaged 30 h per course.
Results: Although the former education program and detailed information could be found on the education institute's website, the registration by students was low, no more than 45 graduated from 2012–2020. Since its inception by VF&O in 2020, VF&O board's recruitment process involved advertising in newsletters and on VF&O and V&VN websites. From 2020 a total of 75 healthcare professionals including 52 NSs, 16 NPs, 6 PAs and 1 physician graduated supporting their careers at FLS care facilities throughout the Netherlands.
Conclusion: A high attendance and appreciation of a nationwide uniform course contributes to (inter)national goals to optimize FLS care. All these graduated trainees are currently active in secondary fracture prevention underlining the empowerment and position of this subspecialty among nurse specialists, nurse practitioners and physician assistants.
Acknowledgements: We are especially grateful to all involved medical and nursing teachers and lecturers to free up time to reach optimal course content. We are grateful to Dave Schweitzer, MD

PhD, for his textual and substantive advices and the secretarial support by V&VN.

LOW-INTENSITY PULSED ULTRASOUND PROTECTS CARTILAGE IN EXPERIMENTAL RABBIT KNEE OSTEOARTHRITIS

R. A. Ungur[1], I. M. Borda[1]

[1]Univ. of Medicine and Pharmacy Iuliu Hatieganu Cluj-Napoca, Cluj-Napoca, Romania

Objective: Many studies have shown a beneficial effects of ultrasound (US) therapy on chondrocytes apoptosis and extracellular matrix injuries in experimental osteoarthritis (OA). These effects depend on frequency, intensity and continuous or pulsed mode of US correlated with OA severity. The purpose of our study was to compare the effect of two dose of US therapy on knee articular cartilage of rabbits with knee experimental osteoarthritis (KOA).
Methods: Experimental OA was induced in 24 mature female rabbits by anterior cruciate ligament transection (ACLT). Ten weeks after ACLT, rabbits were randomized in into 4 groups: 2 control group and 2 treated groups. The treated groups (US 0.5 C and US 0.5 I) were exposed to US at a frequency of 1 MHz, 0.5 W/cm^2 intensity, in continuous (US 0.5 C), respective pulsate mode (US 0.5 I), for 5 min/d, 10 d. First control group (C1) was sacrificed immediately after the end of the period utilized for OA inducing. The second control group (C2) was exposed to sham US therapy and was sacrificed together with the treated groups, after the treatment ending. The cartilage samples were obtained from OA joints of the sacrificed rabbits and were evaluated by optical microscopy and transmission electron microscopy.
Results: In the treatment groups, we found that US therapy improved the chondrocyte viability, maintained cellular matrix structure and integrity to variable degrees. The US at 0.5 W/cm^2 intensity, in pulsate mode was more efficient in alleviating cartilage damages.
Conclusion: US can be considered a reliable option for treatment of OA patients and can act as disease modifying therapy.

P1095
DXA AND HR-PQCT EVALUATION OF BONE CHANGES IN COMPLEX REGIONAL PAIN SYNDROME

R. Abdala[1], I. Torrecilla[1], F. Jerkovich[1], F. Lustig Witis[1], M. S. Gonzalez Pernas[1], M. B. Zanchetta[1]

[1]IDIM (Instituto de Diagnóstico e Investigaciones Metabólicas), Ciudad Autónoma de Buenos Aires, Argentina

Objective: Complex regional pain syndrome (CRPS) is a neuropathic pain condition characterized by pain, sweating and trophic changes, typically manifesting as a localized limb disorder. The impact of CRPS on bone microarchitecture (BM) is not well understood. In a prior study, our group identified normal BMD differences in the hands and feet, utilizing specific regions of interest (ROIs) without noting variations in the feet BMD of healthy subjects. This study aims to elucidate changes in both BM and BMD among individuals affected by CRPS.
Methods: We recruited patients with CRPS referred to our institution for evaluation. HR-pQCT and DXA were employed to assess BM and BMD in the affected limb and its contralateral counterpart. Of the 28 enrolled patients, 15 underwent DXA, and 13 underwent HR-pQCT.
Results: DXA: All patients (n = 15) exhibited significant differences in BMD between the affected and unaffected limbs in both ROIs evaluated (-8.4% in ROIs1 and -8.9% in ROIs2). Median BMD values were 0.495 vs. 0.558 g/cm^2 in ROIs 1 ($p = 0.001$) and 0.837 vs. 1.000 g/cm^2 in ROIs2 ($p = 0.002$). HR-pQCT: Limbs affected by CRPS displayed a significantly total density (-10%), primarily attributable to the cortical component (-8.6%), in comparison with the healthy contralateral limb ($p \leq 0.05$). Although lower trabecular bone volume (-5.8%), decreased trabecular number (-7.38%), and reduced cortical thickness (-13.7%) were observed in affected limbs, these differences did not reach statistical significance.
Conclusion: We identified a significant decrease in BMD of the affected limb assessed by DXA. Additionally, a significant loss of total volumetric density, with a greater impact on the cortical component compared to the contralateral healthy limb, was observed through HR-pQCT. These findings present an alternative option for evaluating and monitoring treatment responses in patients affected by CRPS.

P1096
INFLUENCE OF WEIGHT ON URINARY AND PLASMA METABOLITES IN PATIENTS WITH KIDNEY STONES

R. Abdala[1], J. Quinchuela[2], R. Spivacow[1], M. B. Zanchetta[1]

[1]IDIM (Instituto de Diagnóstico e Investigaciones Metabólicas), Ciudad Autónoma de Buenos Aires, Argentina, [2]Fresenios Medical Care, Quito, Ecuador

Objective: Nephrolithiasis (NL) is a multisystem disease in which intrinsic factors and extrinsic factors are related. Body weight is inversely related to urinary pH, and obesity is often accompanied by conditions such as insulin resistance and metabolic syndrome that can affect the balance between kidney stone-inhibiting and promoting substances. The objective of our study was to assess the impact of body weight on the different metabolic disorders found in patients with confirmed kidney stones.
Methods: A retrospective and analytical study was carried out. A total of 1311 participants over 18 y of age with confirmed NL who consulted our institution for their metabolic study were included. Metabolite and PH were obtained in urine: UA, Ca, P, Mg, Ox, Na, K and Citrate. In blood: Ca, PTH, Vit D, Cr, AU, Urea. For the analysis, the sample was divided into men (H) and women (W) and the data were analyzed between: Normal weight (NW), Overweight (OW) and obesity (OB) with the ANOVA test. Statistical significance was considered when $p < 0.05$.
Results: 616 H and 695 M were considered for the analysis. The mean age was 49.72 ± 13.53 in M and 49.06 ± 14.17 in W. 15% of the W had a BMI > 29.9 (OB). W with OB had higher serum levels of UA mg/dL compared to OW and NW (5.1 vs. 4.5 vs. 4.1; $p < 0.001$ and lower levels in VD ng/ml (27.2 vs. 30 vs. 31.6; $p = 0.03$). In urine: W with OB presented higher levels of Cr, P, UA, Na, all these differences with a $p < 0.0001$; in addition to observing a more acidic PH $p < 0.05$. M with OB (23%) compared to OW and NW, had higher levels of AU mg/dL (6.3 vs. 5.9, vs. 5.4; $p < 0.0001$) and lower VD ng/ml (22.9 vs. 26.6, vs. 26.7; $p < 0.05$). In urine: H with OB had higher values of Cr, Ca, P, AU, Na ($p < 0.0001$) and Ox ($p < 0.05$). Furthermore, they presented more acidic urine $p < 0.0001$. The prevalence of multiple metabolic disorders (2 or more disorders) was higher among OB vs. NON-OB 76% vs. 57%; $p < 0.05$.

Conclusion: These data show the impact of obesity on the different metabolites that condition an environment suitable for the development of kidney stones. Importantly, we observed multiple metabolic disorders in this population, with increased excretion of kidney stone promoters.

P1097
IMPACT OF VITAMIN D (VD) ON CANCER

R. Amir[1]

[1]Research Group, Jeumont, France

Objective: VD is well known for its role in regulating mineral homeostasis. It has been clearly shown that VD helps the immune, muscle, and nervous system function properly. Recent epigenomic, transcriptomic, and proteomic studies have revealed novel VD-mediated biological mechanisms that regulate cancer cell self-renewal, differentiation, proliferation, transformation, and death.
Methods: Tumor micro-environmental studies have also revealed dynamic relationship between the immune system and VD's anti-neoplastic properties. In experimental studies of cancer cells and of tumors in rodents, VD has been found to have several biological activities that might slow or prevent the development of cancer, including promoting cellular differentiation, decreasing cancer cell growth, stimulating cell death (apoptosis), reducing tumor blood vessel formation (angiogenesis), and decreasing tumor progression and metastasis. VD was also found to suppress a type of immune cell that normally prevents the immune system from responding strongly to cancer. VD deficiency and racial disparities are associated with a deluge of diseases, including cancer, resulting in an escalating burden on the healthcare system. The 1,25(OH)2D effects are mediated by the VD receptor, a member of the intracellular nuclear receptor superfamily that can induce cell cycle arrest and death through post-transcriptional, post-translational and gene regulatory mechanism.
Results: The recent vital supplementation trial demonstrated that VD levels above those required for the maintenance of bone health can increase cancer patients survival, particularly in well documented regions. Novel anticancer drugs and therapeutic strategies that target the metabolic and signalling networks of VD and its metabolites are currently being researched. VD is a well known immune system process regulator that targets genes, regulatory transcription factors, and epigenetic modulators to promote anti-inflammatory responses in a variety of immune-related diseases, including cancer.
Conclusion: Given that VD sensitizes cancer immunotherapy, it may interact with these putative effector systems to sensitize tumor cell death, establishing a new paradigm in VD research and addressing racial disparities linked to VD deficiency and increased cancer incidence.

P1098
ADDUCTOR CANAL BLOCK AFTER TOTAL KNEE ARTHROPLASTY HAS COMPARABLE POSTOPERATIVE PAIN CONTROL AND QUADRICEPS MUSCLE SPARING AS ASSESSED BY SURFACE ELECTROMYOGRAPHY: A RADOMIZED CONTROL TRIAL

C. Tubtim[1], K. Sukhonthamarn[1], W. Witayakom[1], A. Wittayapairoj[2], S. Oraintara[3], K. Srungboonmee[4], R. Apinyankul[1]

[1]Dept. of Orthopaedics, Faculty of Medicine, Khon Kaen Univ., Khon Kaen, [2]Dept. of Anesthesiology, Faculty of Medicine, Khon Kaen Univ., Khon Kaen, [3]Faculty of Engineering, Mahidol Univ., Nakhon Pathom, [4]Center of Data Mining and Biomedical Informatics, Mahidol Univ., Nakhon Pathom, Thailand

Objective: To assess the impact of adductor canal block (ACB) on quadriceps muscle function after total knee arthroplasty (TKA) using surface electromyography (sEMG). The study compared outcomes, including pain control, morphine consumption, and walking capacity, between patients receiving ACB and those without ACB.
Methods: A randomized control trial comprising 25 TKA patients was conducted, with participants divided into two groups: ACB and non-ACB. Various parameters, including visual analog scale (VAS) scores, anteromedial knee sensation, morphine consumption, first-time pain control requirement, adverse events, and the median frequency of rectus femoris (RF) and vastus medialis (VM) muscles, were assessed on postoperative days (POD) 1–4. Additionally, a timed 10-m walk test was performed on POD4.

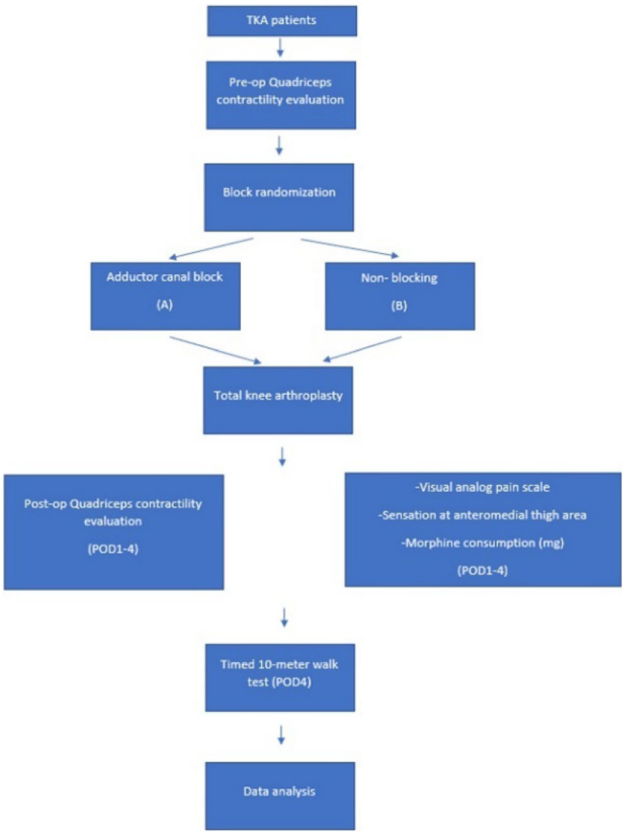

Table 1. Demographic data

	ACB (n = 12)	Non- ACB (n = 13)	p- value
Age (year) mean +/- SD	72.58 ± 4.22	67.30 ± 3.96	0.10
Height (cm) mean +/- SD	156.58 ± 5.55	153.69 ± 3.76	0.42
Weight (kg) mean +/- SD	69.73 ± 4.48	64.09 ± 4.79	0.24
BMI (kg/m2) mean +/- SD	28.44 ± 2.84	27.12 ± 1.76	0.46
Sex (female/ male)	6/6	13/0	0.002
Pre-op VAS mean +/- SD	7.5 ± 0.54	7.69 ± 0.45	0.61
Side (Left/ Right)	6/6	7/6	0.86

Results: No significant differences were observed between the two groups in terms of median frequency (MF) of RF and VM, VAS scores, morphine consumption, timed 10-m walk test results, and the occurrence of adverse events. The study findings suggest that ACB did not result in impaired postoperative Quadriceps muscle strength, as evidenced by surface EMG data. Moreover, pain relief and walking capacity were comparable between the ACB and non-ACB groups.

Figure 1: Median frequency of Rectus femoris muscle

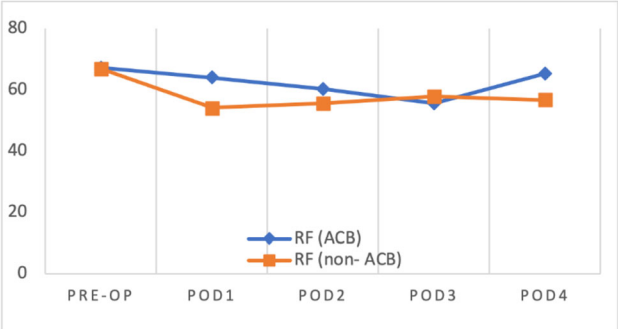

Figure 2: Median frequency of Vastus medialis muscle

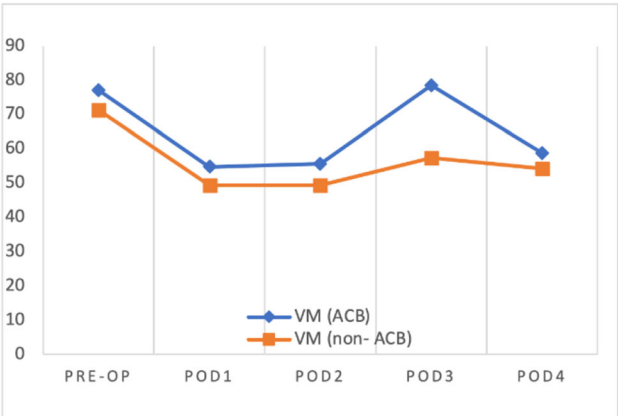

Figure 3: Postoperative VAS (Group1: ACB, Group2: Non-ACB)

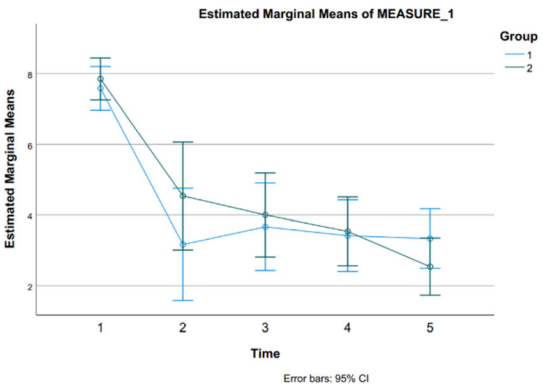


Conclusion: Based on the outcomes of this study, the administration of ACB in TKA patients did not lead to Quadriceps muscle strength impairment, as assessed by surface EMG. These findings support the safety and efficacy of ACB in providing postoperative pain relief without compromising early ambulation and functional recovery in TKA patients.

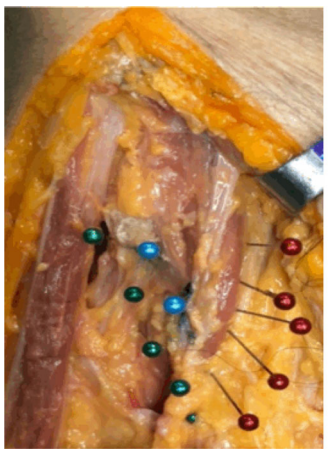
P1099

AN ANATOMIC CONSIDERATION OF THE FEMORAL NERVE DURING ANTERIOR HIP APPROACH: A CADAVERIC STUDY

W. Witayakom[1], K. Sukhonthamarn[1], W. Kosuwon[1], R. Apinyankul[1]

[1]Dept. of Orthopaedics, Faculty of Medicine, Khon Kaen Univ., Khon Kaen, Thailand

Objective: To investigate the distance and correlation between the anatomy of the anterior side of the hip joint and the femoral nerve.
Methods: Using 10 fresh-frozen cadavers, and 20 hip joints. We dissected and marked the femoral nerve in the inguinal area. Employing the direct anterior approach, we identified and marked study points, including the superior and inferior points of the anterior rim of the acetabulum, ¼ point, half point, and ¾ point along an imagined line connecting the superior and inferior point, the infero-medial and mid aspect of the femoral neck, and the soft spot. Coronal plane measurements gauged the distance between these points and the femoral nerve. The collected data were analyzed to assess distance and correlation.
Results: There was no distance between the inferior point of the anterior rim of the acetabulum and the mid aspect of the medial side of the femoral neck in the coronal plane, relative to the femoral nerve (median = 0; IQR 0–0). The mean distance between the soft spot and the femoral nerve was also 1.18 ± 0.63 cm.



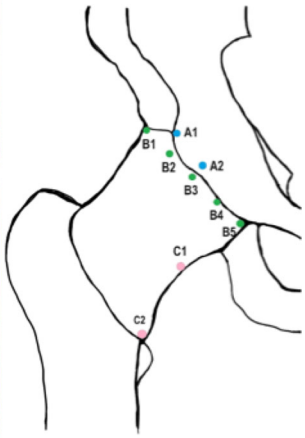


Table 1: The closest distance from the anterior aspect of the acetabular rim, neck of the femur to femoral nerve branches

Reference points	Mean ± SD or Median (IQR) (centimeter)
Superior point of the anterior acetabulum	3.02 ± 0.59
¼ point from the superior acetabulum	2.37 ± 0.63
Half point from the superior acetabulum	1.82 ± 0.53
¾ point from the superior acetabulum	0.99 ± 0.36
Inferior point of the anterior acetabulum	0 (0 – 0)
Mid aspect of the medial side neck of the femur	0 (0 - 0)
Inferomedial aspect of the medial neck of the femur	0.05 ± 0.22

SD, standard deviation; *IQR*, interquartile range

Table 2: Distance between the soft spot to the acetabulum and femoral nerve

The soft spot to femoral nerve/reference points	Mean +/- SD (centimeter)
Soft spot to femoral nerve	1.18 ± 0.63
Superior point of the soft spot to the superior point of the acetabulum	1.66 ± 0.58
Inferior point of the soft spot to the superior point of the acetabulum	2.4 ± 0.67

SD, standard deviation

Conclusion: The inferior point of the acetabulum's anterior rim and the femoral neck's mid aspect are critical caution points when approaching the hip joint via the direct anterior approach. Surgeons should insert the retractor as lateral as possible at the anterior rim of the acetabulum. The soft spot at the anterior rim of the acetabulum remains safe from direct injury when surgeons use the correct technique during insertion.

P1100
MANAGEMENT OF ACETABULAR OSTEOLYSIS WITH A RETAINED SHELL AND INJECTION OF DEMINERALIZED BONE MATRIX USING A VINYL URINARY CATHETER AND SYRINGE: A NEW TECHNIQUE AND CASE SERIES

R. Apinyankul[1], L. Silva[2], S. Goodman[3]

[1]Dept. of Orthopaedics, Faculty of Medicine, Khon Kaen Univ., Khon Kaen, Thailand, [2]Dept. of Nursing, Stanford Health Care, Stanford, CA, USA, [3]Dept. of Orthopaedic Surgery Stanford Univ. Medical Center Outpatient Center Stanford Univ. School of Medicine, Stanford, CA, USA

Objective: Management of retro-acetabular osteolysis in revision hip arthroplasty with acetabular component retention remains controversial and challenging due to limited accessibility to the area.
Methods: 14 patients with well-fixed and well-aligned acetabular components underwent revision surgery and a retained shell. A vinyl urinary catheter and syringe were used to deliver demineralized bone matrix putty to the bone defect after debridement. Clinical outcome and radiographic follow-up were scheduled at a minimum of 2 y.
Results: Significant improvement of UCLA, HHS pain, and HOOS JR scores were observed at a median 6-y follow-up. One cup failed due to an aseptic loosening cup and another from late septic loosening.

HOOS JR	47.0	82.9	34.8 (11.2,58.4)	**0.018**

Figure 2: Demineralized bone matrix putty in 10 cc. syringe (DBX® Putty) integrated with 2 inches sterile vinyl urethral catheter.

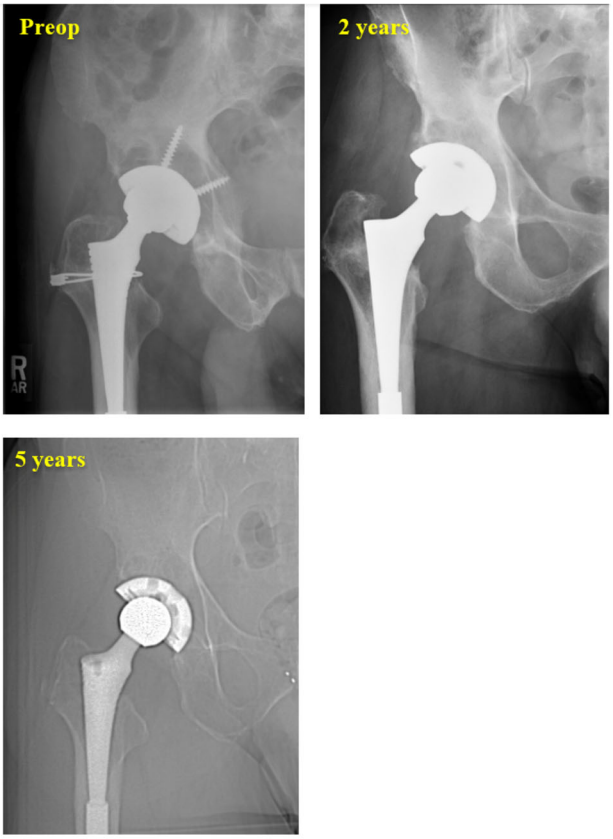

Figure 3: 74 years old man with liner and head exchange. All screws were removed for stability tests and screw hole exposure. Cup and stem were retained with liner and head

Conclusion: Management of retro-acetabular osteolysis with injected demineralized bone matrix using a syringe and vinyl urinary catheter is a reliable, easy, low-cost method with satisfactory mid-term clinical outcome improvement.

P1101
NEUROPEPTIDES, NOX4 AND S100A4: NEW IMPLICATIONS FOR THE PATHOGENESIS OF AGE-RELATED PAINFUL OSTEO-ARTICULAR DISORDERS

R. Bonanni[1], I. Cariati[2], B. Gasperini[1], A. Falvino[1], S. Gino Grillo[3], L. Tranquillo[3], R. Iundusi[3], E. Gasbarra[3], V. Tancredi[2], U. Tarantino[4]

[1]Dept. of Biomedicine and Prevention, Univ. of Rome Tor Vergata, [2]Dept. of System Medicine, Univ. of Rome Tor Vergata, [3]Dept. of Orthopedics and Traumatology, Policlinico Tor Vergata Foundation, [4]Dept. of Clinical Science and Translational Medicine, Univ. of Rome Tor Vergata, Roma, Italy

Objective: To identify a correlation between the expression of neuropeptides involved in the development and maintenance of pain, such as nerve growth factor (NGF), calcitonin gene-related peptide (CGRP), substance P (SP) and intestinal vasoactive peptide (VIP) [1], as well as the expression of NOX4 and S100A4, involved in the development and maintenance of neuropathic pain [2], with self-reported pain levels of patients with osteoporosis and osteoarthritis, in order to identify potential new markers for the management and treatment of age-related painful osteo-articular diseases.
Methods: 30 patients undergoing hip arthroplasty for osteoarthritis (OA) or fragility fracture (OP) were enrolled, and bone biopsies were collected for histological, immunohistochemistry, and western blotting analyses.
Results: The two groups showed significant differences in T-Score values and VAS score. OA patients were all characterized by chronic pain, whereas the pain of OP patients dated back to the fracture event. The bone tissue of OA patients showed better morphometric parameters and higher expression of NGF and neuropeptides than the OP group. Important, the NOX4/S100A4 ratio was significantly higher in the bone of OA patients, while abundant S100A4 expression and poor NOX4 levels were found in the bone tissue of OP patients.
Conclusion: Neuropeptide expression correlates with patients' self-reported pain levels. Of note, the increased expression of NGF in the bone tissue of OA patients could be responsible for the chronic pain of these patients. The elevated expression of NOX4 and altered NOX4/S100A4 ratio suggests the presence of a neuropathic component of pain in this cohort of OA patients. Suppression of NGF and NOX4 activity could be a potential target for the management of osteoarthritis and associated chronic pain.

TOMOGRAPHIC ANALYSIS OF METACARPALS IN MARTIAL ARTS (MUAY THAI) PRACTITIONERS AS UNPRECEDENTED EVIDENCE OF EXERCISE EFFECTS ON BONE DESIGN, INDEPENDENT OF CORTICAL TISSUE STIFFNESS

J. Bazán[1], G. Cointry[2], S. Lüscher[2], J. Ferretti[2], L. Intelangelo[1], R. Capozza[2]

[1]Unidad de Investigación Musculoesquelética, Centro Universitario de Asistencia, Docencia e Investigación – CUADI, Universidad del Gran Rosario, [2]Centro de Estudios de Metabolismo Fosfocálcico, Rosario, Argentina

Objective: This study provides original evidence for the hypothesis that physical activity improves the design over the rigidity of cortical bone tissue in human long bones, primarily mediated by the bone mechanostat. It specifically aimed to evaluate tomographic indicators from pQCT assessing mass, stiffness, and cortical tissue distribution efficiency in the 2nd and 3rd metacarpals (with fixed positions in the hand) and the 4th and 5th metacarpals (more freely pivoting over the carpus) in 15 male Muay Thai (MT) practitioners compared to 15 untrained males (Ctrl), matched for age, weight, and height.
Methods: For individuals in both groups, ten pQCT scans were performed on metacarpals 2 to 5, measuring volumetric cortical density (vCtD, indicative of tissue stiffness), cortical bone area (CtA), cortical bone content (CtC), and moments of inertia for antero-posterior (xMI) and lateral (yMI) flexion. ANOVA was used to evaluate

differences in these parameters between groups and slices, while ANCOVA assessed the correlations between bone distribution (MIs) and stiffness (vCtD).

Results: MT participants had significantly higher CtA and CtC in metacarpals 2–5 than Ctrl (ANOVA, $p < 0.05$). No significant differences were found in vCtD. MT showed higher MIs in centro-proximal cuts of metacarpals 4 and 5 ($p < 0.05$), but not in 2 and 3, contrasting with the uniformly increased mass (CtA, CtC). 'd/r' curves in proximal regions were similar for metacarpals 2 and 3, but higher in MT for metacarpals 4 and 5, indicating greater MIs for the same vCtD (ANCOVA, $p < 0.05$).

Conclusion: MT practitioners exhibited greater cortical area and mass across all metacarpals, likely due to formative stimulus from stress induced by practice. The consistency of vCtD suggests that material stiffness did not influence the results. Elevated MIs in MT, specifically in metacarpals 4 and 5, indicate enhanced resistance to A-P and lateral flexion at these sites. Differences in d/r curves for metacarpals 4 and 5 align with the biomechanics of punching, suggesting bone tissue distribution is tailored to specific stress demands. Metacarpals 2–3 show a different pattern, reflecting a mechanostat response more to compression, while metacarpals 4–5 adapt to flexural stress. This supports the hypothesis that martial arts practice fine-tunes the mechanostat's ability to adapt bone design to physical stress.

P1103
RELATIONSHIP BETWEEN PHYSIOLOGICAL CHARACTERISTICS AND CUMULATIVE INCIDENCE OF FALLS IN OVERWEIGHT OLDER WOMEN

R. Dadeliene[1], E.-I. Jamontaite[1], V. Gineviciene[1], A. Mastaviciute[1], E. Pranckeviciene[1], J. Kilaite[1], I. Ahmetov[1], V. Alekna[1]

[1]Vilnius Univ., Vilnius, Lithuania

Objective: Aging is characterized by a progressive loss of physiological integrity, leading to impaired function and increased vulnerability to death. Falls in older adults are one of the most common and serious problems. However, it is unclear which physiological factors coexist or are independent contribute to increased risk for falls in overweight older women. The aim of the study was to explore the relationship among vital lung capacity (VLC), hand grip strength (HGS), psychomotor abilities, and incidence of falls in overweight older women.

Methods: Community-dwelling older 33 women (mean age 75.79 (SD ± 6.77) y, 67% were widows and 61% of them living alone) without symptoms of sarcopenia and major disease were selected for this cross-sectional study. Socio-demographic characteristics, anthropometric measurements and data of incidence of falls during one-year period of the individuals were recorded. Participants completed a battery of tests to evaluate VLC (diagnostic spirometer Micro 1), simple and complex psychomotor reaction time (PRT), frequency of movement (device REKSAS PRO-RA-1) Handgrip hydraulic dynamometry (SAEHAN) was used as a valid, reliable measure of HGS.

Results: The average of BMI was 27.63 (SD ± 4.31) kg/m^2, indicated overweight. Was found that 21% of subjects had incidents of fall 2–4 times per year, 9%. subjects fell 5 or more times per year. VLC of the subjects was poor 2.50 ± 0.52 l. HGS of the right hand was 25.91 ± 5.63 kg, left hand—24.52 ± 6.31 kg. Simple PRT data was 355.66 ± 161.99 ml, complex PRT 530.86 ± 234.70 ml. Correlation analysis showed a significant negative relationship between simple PRT and VLC r = -0.42 ($p \leq 0{,}01$), HGS (right r = -0,388, $p \leq 0{,}05$, left r = -0,515, $p \leq 0{,}01$). Furthermore, there was determined significant correlation between the incidence of falls and single PRT r = -0,534, $p \leq 0{,}01$ and HGS (right r = -0,411, $p \leq 0{,}05$, left r = -0,377, $p \leq 0{,}05$).

Conclusion: It was determined that there is a significant relationship between vital lung capacity, psychomotor reaction time, grip strength and higher cumulative incidence of falls. The presence of this relationship may guide the planning of exercise therapy in overweight older women.

P1104
RISK OF IMPLANT FAILURE IN OPERATED UNSTABLE TROCHANTERIC FRACTURES IN PATIENTS WITH OSTEOPOROSIS

A. L. Dimitriu[1], R. Ene[1], C. Georgescu[1], E. G. Popescu[1], B. Bolos[1]

[1]Clinical Emergency Hospital / Dept. of Orthopedics, Bucharest, Romania

Objective: Fragility fractures of the trochanteric area are very common in the Emergency Departments. In these cases, because the fractures occur in the elderly population, a quick evaluation and surgical management is required, in order to quickly mobilize the patients and avoid thromboembolic complications [1]. However, some conditions need to be met, because a quite high number of these patients experience implant failure [2]. This seems to be in direct relationship to the anatomy of the fracture [3], the implant that was used [4], the surgical reduction of the fracture, the position of the lag screw in the femoral neck, the time of full weight bearing is allowed, and even, in a few numbers of cases, the tissue reaction to the implant [5].

Methods: Our study included 86 patients with unstable trochanteric fractures according to the Evans criteria, which were surgically managed between January 2022 and December 2022. In all cases intramedullary fixation was used, in 65 cases a short nail was used and in 21 cases a long nail was used, due to the diaphyseal extension of the fracture. We noted the reduction of the fracture, the position of the femoral neck screw and the time of full weight bearing.

Results: In 10 cases we experienced mechanical failure of the implant, 8 cases had cutting out of the lag screw and in two cases breakage of the nail was noticed. The surgical reduction of the fracture seems to be the most important factor that promotes healing ($p = 0.02$). Also, the correct positioning of the lag screw is also of great importance ($p = 0.05$) in order to avoid the cutting out complication. The moment of full weight bearing was not of statistical value ($p = 0.15$), maybe because in unstable fractures with loss of medial cortex we tend to be more careful and avoid full weight bearing for up to 6 weeks, and no differences between full weight bearing at 6 weeks or 8 weeks or more were found.

Conclusion: The loss of medial cortical support is of great importance in the management of trochanteric fractures, but a careful surgical reduction and correct position of the lag screw seems to be enough in order to achieve fracture healing in osteoporotic patients.

FUNCTIONAL OUTCOME AFTER NON-OPERATIVE TREATMENT OF FRAGILITY FRACTURES OF THE WRIST

C. Georgescu[1], A. L. Dimitriu[1], E. G. Popescu[1], B. Bolos[1], R. Ene[1]

[1]Clinical Emergency Hospital, Dept. of Orthopedics, Bucharest, Romania

Objective: Fragility fractures of the wrist are the most common injury in adults, notably the fracture of distal radius, accounting for approximately 17.5% of fractures [1]. No consensus has been reached to date regarding the optimal treatment for distal radius fractures, despite the fact that the rate of operative treatment has been increasing globally [2]. In many of these cases the patients are elderly, with multiple comorbidities, and it's important to carefully evaluate the individual cases and choose the right treatment for each of them, considering the expected functional outcome, risks associated [3] and possible complications of metallic implants [4] [5].
Methods: This study included 104 patients with distal radius fractures treated with closed reduction and immobilization with casts between January 2022 and December 2022. They were evaluated radiographically and clinically at 7, 14, 21 days and at 6, 12 and 24 weeks. Also at 3 and 6 months we evaluated the functional outcome using the PRWE (Patient-Rated Wrist Evaluation) score-, grip strength (measured in kg) and mobility of the wrist.
Results: 58 fractures were extraarticular (AO-A class), 19 simple intraarticular (AO-B class) and 27 complete intraarticular (AO-C class). Mean PRWE score was 18 at 3 months and 11 at 6 months. Grip strength and mobility, compared to other limb, weren't corelated with fracture class (according to AO) or age at 3 months, but slightly better mobility and grip strength was observed at 6 moths for type A and B fractures.
Conclusion: Overall, the functional outcome after non-operative treatment of wrist fractures is very good in elderly patients, with good mobility and grip strength compared to other limb at 6 months and low complication rates.

P1106
SIGNIFICANCE OF COMORBIDITY ON BONE MINERAL DENSITY IN MEN WITH HIP FRACTURE

R. F. Filipov[1], S. B. Bačević[2], D. S. Stojanović[3], I. J. V. Jovanović Vasović[1], K. M. Marković[4]

[1]Instute for Treatment and Rehabilitation Niška Banja, Niš, [2]General Hospital Prokuplje, Prokuplje, [3]Clinic for Neurology UKC Niš, Niš, [4]Instute of Rehabilitation Niška Banja, Niš, Serbia

Objective: Osteoporosis itself is a significant risk factor for fracture occurrence. Osteoporosis is characterized by a lack of pain or significant symptoms until fractures occur, earning it the nickname "silent bone thief." The aim of this study is to investigate the influence of comorbidities, visual impairment, reduced height, and hereditary predisposition on BMD in men with and without hip fractures.
Methods: The study included 100 male participants, divided into two groups: the study group (50 participants) with hip fractures and the control group (50 participants) without fractures. A detailed clinical examination was conducted for all participants. BMD was measured using a Hologic densitometer.
Results: In the hip fracture group, 34.0% had comorbidities, while the control group showed significantly fewer comorbidities (12.0%, $p = 0.007$). The most common comorbidity in both groups was high blood pressure (HOBP)—47.1% of fracture patients with comorbidities and half of the control group with comorbidities. Rheumatoid arthritis (RA) was present in 29.4% of fracture patients with comorbidities and half of the control group participants. Visual impairment was more prevalent in hip fracture patients, accounting for 28.0%, compared to 12.0% in the control group. Reduced height (> 3 cm) was observed in 54.0% of hip fracture patients and 14.0% of those without fractures, with a statistically significant difference between the groups ($p < 0.001$). Maternal hip fracture was documented in 44.0% of patients with fractures and 16.0% of the control group. A statistically significant difference in the frequency of maternal hip fractures was found between the groups ($p = 0.005$). The average values of all examined bone density parameters were significantly lower in participants with fractures compared to the control group ($p < 0.001$).
Conclusion: The presence of comorbidities represents a risk factor for reduced bone density in men.

P1107
DYNAMICS OF SUBJECTIVE CONTROL LEVEL IN SYSTEMIC SCLEROSIS PATIENTS AS A RESULT OF THE NEUROFEEDBACK TRAINING

R. Grekhov[1]

[1]Zborovsky' Research Institute for Clinical and Experimental Rheumatology, Volgograd State Medical Univ., Volgograd, Russia

Objective: To study the dynamics of the level of subjective control in patients with systemic sclerosis (SS) after the neurofeedback (NFB) training.
Methods: There were 90 patients with SS under observation, who were randomly divided into two groups: the main group ($n = 60$) and the control group ($n = 39$). The average age of the patients was 54.31 ± 12.8 y, and the average duration of the disease was 9.71 ± 7.9 y ($M \pm \sigma$). The patient groups were comparable in terms of gender, age, and duration of the disease. Patients with SS in the main and control groups received similar medical and physiotherapy treatment, but patients in the main group additionally received 14 procedures of neurofeedback (NFB) multimedia training. The technique was carried out using the psychophysiological rehabilitation complex "Reacor". Training was based on the parameters of the brain electrical activity (electroencephalogram relaxation), aimed at increasing the alpha-activity of the brain. The study of the level of subjective control was carried out using the LSC questionnaire (Bazhin EF et al., 1987).
Results: As a result of NFB training course, the indicators of the level of subjective control underwent significant changes on all scales of the questionnaire. The use of NFB contributed to an increase in the internality (increase in indicators) of SS patients on scales in the general sphere, the sphere of achievements and attitudes to health. In patients receiving traditional therapy, the dynamics of LSC was similar, but unreliable—LSC indicators also changed in the control group, but significant increase was recorded only on the scale of general internality and scale of interpersonal relations.
Conclusion: The impact of the NFB training is associated with the reorientation of the external locus of control to the internal one, which is considered as a component of personal maturity. With the help of NFB, patients acquire a sense of control over their disease, adhere to the treatment regimen more strictly, and take responsibility for taking care of their health. Perhaps it is the aspect that leads to more effective results of the therapeutic process when the patient's faith in

his ability to control the symptoms of the disease acts as more critical value than change in any physiological parameter.

P1108
DYNAMICS OF EMOTIONAL STATUS OF PATIENTS WITH SYSTEMIC SCLEROSIS UNDER THE INFLUENCE OF NEUROFEEDBACK TRAINING

R. Grekhov.[1]
[1]Zborovsky' Research Institute for Clinical and Experimental Rheumatology, Volgograd State Medical Univ., Volgograd, Russia.

Objective: To correct the emotional status of patients with systemic sclerosis (SS) using neurofeedback (NFB) training.

Methods: 99 patients with SS were selected randomly into 2 groups: the main group (n = 60) and the control group (n = 39) which were comparable in terms of gender, age, and duration of the disease. The average age of the patients was 54.31 ± 12.8 y, and the average duration of the disease was 9.71 ± 7.9 y (M ± σ). The patients of the main group additionally received 14 sessions of multimodal NFB training using the "Reacor" psychophysiological rehabilitation complex. The NFB training is based on the principle of self-regulation of body functions using external feedback systems. The method was developed within the framework of behavioral therapy and used successfully in the treatment of stress disorders and psychosomatic diseases. The analysis of the effectiveness of the BFB training was carried out by the dynamics of clinical and psychological indicators in patients of the main and control groups, including levels of personal anxiety (PA), reactive anxiety (RA) (Spielberger questionnaire) and depression (Beck questionnaire).

Results: A high level of personal (52.74 points) and reactive (53.11 points) anxiety was revealed in SS patients. The severity of reactive anxiety and the level of depression was decreased after the training course, but this dynamic was significant in patients of the main group only. The NFB training is characterized by the active and conscious participation of the subject in the treatment process. One of the likely mechanisms of the therapeutic effect of NFB training is the cognitive effect, learning self-control skills, which, according to patients, they have never had before. It is assumed that the use of NFB contributes to the correction of emotional status, reduction of reflex muscular-tonic syndromes, improvement of microcirculation, mobilization of volitional potential and self-esteem of patients.

Conclusion: The results indicate a positive effect of NFB on anxiety and depressive disorders in SS patients, which may contribute to improving the effectiveness of complex treatment of this disease, its long-term prognosis and the patients' quality of life.

P1109
ECONOMIC EVALUATION OF SARCOPENIA MANAGEMENT STRATEGIES IN IRAN: A COST-EFFECTIVENESS ANALYSIS

R. Heshmat[1], A. Darvishi[2], G. Shafiee[2], N. Zargar Balajam[3], S. Maleki Birjandi[2], M. Rezaei Hemami[4]

[1]National Center for Health Insurance Research, Tehran, Iran, [2]Chronic Diseases Research Center, Endocrinology and Metabolism Population Sciences Institute, Tehran Univ. of Medical Sciences, Tehran, Iran, [3]Endocrinology and Metabolism Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran Univ. of Medical Sciences, Tehran, Iran, [4]Perspectum Ltd, Oxford, UK

Objective: The quest for identifying the most effective sarcopenia management intervention remains a paramount concern for health systems. This study delves into the cost-effectiveness analysis of sarcopenia management strategies in Iran.

Methods: Employing a lifetime Markov model rooted in natural history, we assessed seven strategies, encompassing exercise training, nutritional supplements, whole-body vibration (WBV), and various combinations of exercise and nutritional supplements, alongside a non-intervention strategy. Parameter values were sourced from both primary data and the literature. Costs and quality-adjusted life years (QALYs) were computed for each strategy. Deterministic and probabilistic sensitivity analyses, including the expected value of perfect information (EVPI), were conducted to gauge model robustness, utilizing the 2020 version of TreeAge Pro software.

Results: All 7 strategies exhibited heightened lifetime effectiveness in terms of QALYs. The protein and Vitamin D3 (P + D) strategy emerged with the highest effectiveness values. After eliminating dominated strategies, the incremental cost-effectiveness ratio (ICER) for P + D compared to Vitamin D3 alone (D) was calculated at $131,229. Considering the cost-effectiveness threshold ($25,249), the base-case results identified the D strategy as the most cost-effective. Sensitivity analysis of model parameters underscored the robustness of results, with an estimated EVPI of $273.

Conclusion: As the pioneering economic evaluation of sarcopenia management interventions, this study reveals that, despite the superior effectiveness of D + P, the D strategy emerges as the most cost-effective. The ongoing accumulation of clinical evidence across various intervention options holds the promise of refining and enhancing the accuracy of results in the future.

P1110
EFFECT OF SARCOMEAL® ORAL SUPPLEMENTATION PLUS VITAMIN D3 ON MUSCLE PARAMETERS AND METABOLIC FACTORS IN DIABETIC SARCOPENIA PATIENTS: STUDY PROTOCOL OF A RANDOMIZED CONTROLLED CLINICAL TRIAL

R. Heshmat[1], R. Abdi Dezfouli[1], G. Shafiee[1], S. Maleki Birjandi[1]

[1]Chronic Diseases Research Center, Endocrinology and Metabolism Population Sciences Institute, Tehran Univ. of Medical Sciences, Tehran, Iran

Objective: Sarcopenia is a frequent chronic complication in diabetic patients especially in older people. The pathophysiological connection between sarcopenia and type 2 diabetes likely involves glycemic control, inflammation, oxidative stress, and adiposity. Resistance exercise is a lifestyle intervention that may improve glycemic control in older adults with T2D and sarcopenia. Since exercise is not suitable for all older people, oral supplementations may be more effective than exercise in this age range. This study aims to evaluate the efficacy of the Sarcomeal supplement, a mixture of whey protein, creatine, branch-chained amino acids (BCAA), and hydroxyl-methyl-butyrate (HMB) in diabetic sarcopenia.

Methods: This study is a randomized clinical trial, in which 60 diabetic sarcopenia patients who meet the inclusion criteria will be randomly assigned to the control or the intervention group with a 1:1 allocation. The intervention group will receive one Sarcomeal supplement sachet plus 1000 IU of vitamin D daily and the control group will be recommended to consume protein-rich food, be educated about the disease, and perform light exercises for 12 weeks. Evaluation of anthropometric parameters, body composition, muscle strength, muscle function, biochemical factors including glycemic and lipid profile, blood urea nitrogen (BUN), creatinine, high-sensitivity C-reactive protein (hs-CRP) as well as blood pressure will be done at the baseline and end of the trial. Also, medical history,

physical activity, Mini Nutritional Assessment (MNA), Activity of Daily Living (ADL) and Instrumental Activity of Daily Living (IADL), and sarcopenia-related quality of life (SarQoL) will be assessed throughout the study.
Conclusion: This study will be the first randomized clinical trial to evaluate the efficacy and safety of a mixture of whey protein, creatine, BCAA, HMB and vitamin D in diabetic sarcopenia. It is hypothesized that Sarcomeal supplement may be beneficial for the management diabetic sarcopenia by reducing inflammation and oxidative stress and glucose and lipid metabolism through various mechanisms.

P1111
ECONOMIC BURDEN OF SARCOPENIA-RELATED DISABILITY IN THE ELDERLY POPULATION: A STUDY IN IRAN

R. Heshmat[1], A. Darvishi[2], G. Shafiee[2], R. Daroudi[3], A. Nikkhah[2], S. Maleki Birjandi[2]

[1]National Center for Health Insurance Research, [2]Chronic Diseases Research Center, Endocrinology and Metabolism Population Sciences Institute, Tehran Univ. of Medical Sciences, [3]Dept. of Health Management & Economics, School of Public Health, Tehran, Iran

Objective: Sarcopenia disability, characterized by the progressive loss of skeletal muscle mass and diminished muscle function, is linked to escalating health costs, heightened risk of physical disability, diminished quality of life, increased demand for care services, and ultimately elevated mortality rates. This study aims to assess the economic impact of sarcopenia-related disability in Iran.
Methods: A prevalence-based economic burden study was conducted utilizing the population attributable risk (PAR) method, based on 2022 price indices. Prevalence data for sarcopenia, categorized by gender and disease severity, were extracted from recent comprehensive studies. The relative risk of sarcopenia disability was determined from the most robust available evidence. Subsequently, direct medical costs, direct non-medical costs, and indirect costs for each individual with sarcopenia were computed and adjusted to 2022 values to estimate disability costs. The overall economic burden of disability attributable to sarcopenia in Iran was then estimated. The cost variables were converted from the Iranian Rial (IRR) to the US dollar using the purchasing power parity (PPP) value of USD/IRR = 64,529.
Results: Taking into account the prevalence of sarcopenia and the Iranian population across various age groups, 2,192,168 adults aged $\geq$ 60 y with sarcopenia in Iran were included in the estimations. The relative risk of disability for men and women was determined to be 4.04 and 2.30, respectively. The total PAR of sarcopenia for men and women was estimated at 50% and 28%, respectively. Average direct medical costs, direct non-medical costs, and indirect costs were PPP $983, PPP $36, and PPP $156, respectively, with the total estimated cost reaching PPP $1175 for each individual with sarcopenia. The cumulative direct medical costs, direct non-medical costs, and indirect costs amounted to PPP $842 million, PPP $30 million, and PPP $134 million, respectively. Additionally, the average total economic burden of sarcopenia-related disability in the Iranian population aged $\geq$ 60 years was estimated at PPP $1006 million.
Conclusion: Sarcopenia poses a substantial economic burden on the healthcare system. Early interventions to mitigate the consequences of the disease will be pivotal in resource conservation. Expanding and augmenting scientific evidence in this regard can contribute to achieving more comprehensive and accurate results in the future.

P1112
ASSOCIATION OF RUNX2 GENE HYPOMETHYLATION WITH THE RISK OF PRIMARY OSTEOPOROSIS

B. I. Yalaev[1], R. I. Khusainova[1]

[1]Endocrinology Research Centre, Moscow, Russia

Objective: Evaluation of differential methylation of *RANKL*, *DKK1* and *RUNX2* genes in women and men with primary osteoporosis (OP).
Methods: A case–control study included 701 women (61.95 $\pm$ 7.94) and 501 men (62 $\pm$ 10.8), which included patients who underwent X-ray densitometry between 2004–2011, as well as a sex- and age-matched control group with no fractures and normal BMD levels (45% of the total sample). DNA methylation profile was analysed using bisulfite pyrosequencing (Pyromark Q24). The primer design was constructed in the GeneGlobe web platform (QIAGEN®). The Mann–Whitney test (Rstudio) was used to find significant differences in DNA methylation level in the comparison groups.
Results: Statistically significant hypomethylation of three CpG-sites in the *RUNX2* gene with the risk of OP development in men (U = 746.5, p = 0.004; U = 784, p = 0.01; U = 788.5, p = 0.01, respectively), as well as in 1 CpG-site in women (U = 537, p = 0.03) (in the position 45,387,951–45,388,050) was revealed (Fig. 1). At the same time, methylation is increased in the second and third CpG sites in women with OP both relative to the control group and relative to the average index in men (by 6%), however, the differences do not reach statistical significance ($p > 0.05$).

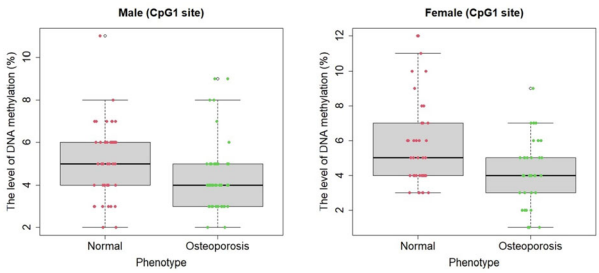

Figure 1. A boxplot of the distribution of the percentage of DNA methylation in comparison group.

Conclusion: For the first time, the level of methylation in the first CpG-site of the *RUNX2* gene was found to be reduced in women and men with primary OP from Russia. According to literature data, gene expression is increased at the early stages of differentiation of mesenchymal stem cells into osteoblast precursors; therefore, hypomethylation may lead to changes in *RUNX2* expression, resulting in impaired maturation of osteogenic cell proliferation [1–2].
Acknowledgment: This work was supported by the Ministry of Science and Higher Education of the Russian Federation (agreement No. 075–15-2022–310 from 20 April 2022).

P1113
INCIDENCE OF SUBSEQUENT FRAGILITY FRACTURES IN PATIENTS INCLUDED IN A FRACTURE LIAISON SERVICE (FLS) IN SPAIN

R. Izquierdo-Avino[1], M. Jordan-Jarque[1], D. Garcia-Aguilera[2]

[1]Fracture Liaison Service. Dept. of Trauma & Orthopaedics. Hospital Nuestra Senora de Gracia, [2]Dept. of Trauma & Orthopaedics. Hospital Royo Villanova, Zaragoza, Spain

Objective: Fragility fractures (FF) can lead to a reduction in quality of life, increased mortality and become a major risk factor of

subsequent fractures. Fracture liaison services (FLS) are designed to narrow the treatment gap emerging after these fractures. The objective of this study is to analyze the incidence of re-fracture and to identify major risk factors for re-fracture in a group of patients included in a FLS.

Methods: We conducted an observational prospective cohort study of patients aged 50 or above who sustained a FF and were included in our FLS between 2016–2022, with a follow-up of 2 y. Data on demographic characteristics, index fracture, subsequent fractures, treatment initiation and adherence were collected.

Results: A total of 2434 patients (84.4% women and 15.6% men, mean age 78.1 years old) were included in our FLS during the study period, having sustained a fragility fracture of the hip (39.1%), wrist (21.9%), vertebra (18.1%), humerus (16.6%) and other sites (4.1%). Previous fracture was present in 36.4% of patients. A total of 253 subsequent fractures were recorded (6-year cumulative incidence of 10.4%). Re-fractured patients were women in 88.8% of cases, with a mean age of 81.2 y. Most common anatomic re-fracture site was the hip (29.2%), followed by wrist (18.1%), proximal humerus (14.4%), vertebra (13.6%) and pelvic rami (7.8%). Almost 40% of patients with hip index FF sustained a subsequent hip FF. Regarding time course, 58 subsequent FF (22.9%) were sustained within the first 6 months, 42 between 6–12 months (16.6%), 72 between 12–24 months (28.4%) and 81 occurred 2 y after index FF (32%). Anti-osteoporotic drugs were initiated in 1888 patients (77.5%) and 2087 patients (85.6%) received calcium/vitamin D supplements.

Conclusion: Inclusion of patients with FF into a FLS increases the percentage of patients initiating anti-osteoporotic drugs after FF. Re-fracture was more common in women aged > 80 years, with 40% of subsequent FF sustained within the first 12 months after index FF, the hip being the most frequent anatomical re-fracture site. Patients with a hip index fracture had an increased incidence of re-fracture as compared to other fracture sites.

P1114
MORTALITY AFTER FRAGILITY FRACTURES IN PATIENTS INCLUDED IN A FRACTURE LIAISON SERVICE (FLS) IN SPAIN

R. Izquierdo-Avino[1], M. Jordan-Jarque[1], D. Garcia-Aguilera[2]

[1]Fracture Liaison Service. Dept. of Trauma & Orthopaedics. Hospital Nuestra Senora de Gracia, [2]Dept. of Trauma & Orthopaedics. Hospital Royo Villanova, Zaragoza, Spain

Objective: Fragility fractures (FF) can lead to a reduction in quality of life but have also shown to increase mortality. Fracture liaison services (FLS) are designed to narrow the treatment gap emerging after these fractures and to ensure adherence to treatment to improve clinical outcomes. The objective of this study is to analyze the incidence of mortality and to identify major risk factors for mortality after fracture in a group of patients included in a FLS.

Methods: We conducted an observational prospective cohort study of patients aged more than 50 y who sustained a fragility fracture and were included in our FLS between 2016–2022, with a minimum follow-up of 2 y. Data on demographic characteristics, index fracture, subsequent fractures, treatment initiation, adherence and mortality were collected.

Results: A total of 2434 patients (84.4% women and 15.6% men, mean age 78.1 years old) were included in our FLS during the study period, having sustained a fragility fracture of the hip (39.1%), wrist (21.9%), vertebra (18.1%), humerus (16.6%) and other sites (4.1%). Previous fracture was present in 36.4% of patients. Anti-osteoporotic drugs were initiated in 1888 patients (77.5%) and 2087 patients (85.6%) received calcium/vitamin D supplements. A total of 268 patients died during follow-up (6-y cumulative incidence 10.9%), rate being higher in male (19.7%) compared to female (9.5%); rate reached 17.4% in patients aged > 80 y. Mortality rate in re-fractured patients was 13.4% as compared with non-re-fractured patients (10.8%). Overall, mortality rate was 1.56% at 3 months and 4.52% at 1 y. Higher mortality was recorded after hip fracture (22%) followed by vertebral FF (8%).

Conclusion: Higher rates of mortality were seen in male patients aged > 80 y, patients with hip index FF, FRAX for Hip fracture > 4.5%, re-fractured patients and when vitamin D low levels were present. Nearly 40% of deaths occurred within the first year after index FF. Almost 76% of deaths were recorded in patients who had sustained an index hip FF, indicating a poor outcome after this event. High mortality rates are seen in patients with FF, which reinforces the importance of secondary fracture prevention in a FLS environment.

P1115
EFFECT OF TAI CHI AND AEROBICS EXERCISE ON COGNITION, BALANCE, CARDIOPULMONARY FITNESS AND QUALITY OF LIFE IN OLDER ADULTS

R. Joshi[1]

[1]Dr DY Patil Vidyapeeth, Pune, India

Objective: According to a WHO report, by 2030 one in six people on earth will be 60 or older. Thus, it is vital to promote autonomy to elderly, as they contribute to large portion of the population. We aimed to ascertain the effectiveness of Chen Tai Chi in comparison to aerobic exercises on cognition, balance, cardiopulmonary fitness, and quality of life in older adults.

Methods: A parallel-arm, single-blinded randomised control trial was conducted with 60 individuals between the ages of 60–75. Patients having normal cognitive function as indicated by the MOCA score, function reach test completion less than 6 inches, and a minimum 6-min walk test distance of 630 m were included in the study. Patients who had a recent serious injury, systolic blood pressure above 200 mmHg and diastolic blood pressure above 120 mmHg, major heart or lung problems, recent fractures, grade 3 or 4 OA in the knee, or a history of falling often were not included in the study. After recruitment, patients were further allocated into 3 groups: Group A Aerobics, Group B Chen Tai Chi, and Group C, the control group. Exercise sessions were 4 days per week for 4 weeks. Assessment for cognition by Montreal cognitive assessment, static balance by one leg stand test, dynamic balance by time up and go test, cardiopulmonary fitness by a 6-min walk test, and quality of life by a health-related quality of life scale taken at baseline, post-completion, and follow-up.

Results: The data revealed that aerobics, Tai-chi, and the control group showed improvement regarding cognition and static balance at post-completion and follow-up. Within group analysis, aerobics showed statistically significant improvement (cognition $p = 0.0001$, static balance $p = 0.01$). There were no statistically significant differences between the aerobics, Tai-chi, and control groups in dynamic balance, cardiopulmonary fitness, or quality of life. However, there were statistically significant improvements in these areas within the aerobics group (dynamic balance, $p = 0.0009$; cardiopulmonary fitness, $p = 0.03$; and quality of life, $p = 0.0001$).

Conclusion: Aerobics, in comparison to Chen Tai Chi and control, had greater physical and functional capacity along with quality of life, which will be helpful to prevent frailty and enhance autonomy in the elderly.

P1116
DIAGNOSTIC CRITERIA FOR ADULT HYPOPHOSPHATASIA: EXPERIENCE FROM A UK CENTRE

M. Vidal[1], J. Bubbear[1], T. Gill[1], R. Keen[1]

[1]Centre for Metabolic Bone Disease, Royal National Orthopaedic Hospital, Stanmore, London, UK

Objective: Hypophosphatasia (HPP) is a rare, genetic metabolic disorder characterized by reduced activity of serum alkaline phosphatase (ALP) and various symptoms from life-threatening, severely impaired mineralization at birth to musculoskeletal pain in adulthood. HPP is diagnosed with laboratory findings, genetic analysis of the ALPL gene, and clinical features although the diagnosis is often delayed. An International Working Group has recently published consensus diagnostic criteria to assist the clinical diagnosis of HPP[1]. This study has evaluated these criteria in adult HPP patients attending a single specialist clinic.
Methods: We reviewed the medical records of adults with a clinical diagnosis of HPP. Details of their clinical history, laboratory results and radiological imaging were compared against the proposed diagnostic criteria.
Results: In total, data was available on 18 patients (16 female, 2 male). The mean age of the patients was 39.4 y (range 19–68). The breakdown of the major and minor diagnostic criteria are shown in Table 1. It is proposed, that the diagnosis of HPP is supported by the presence of 2 major, or 1 major and 2 minor criteria. Using this classification, only 7 patients (39%) fulfilled the diagnosis of HPP.

Table 1.

	Diagnostic HPP criteria in 18 adults	Yes (%)	No (%)
Major	– Pathogenic or likely pathogenic ALPL gene variant	14 (78%)	4 (22%)
	– ↑ natural substrates[+]	11 (91%)	1 (8%)
	– Atypical femoral fractures (pseudo-fractures)	0	18 (100%)
	– Recurrent metatarsal fractures	0	18 (100%)
Minor	– Poorly healing fractures	2 (11%)	16 (89%)
	– Chronic musculoskeletal pain	16 (89%)	2 (11%)
	– Early atraumatic loss of teeth	2 (11%)	16 (89%)
	– Chondrocalcinosis	0	18 (100%)
	– Nephrocalcinosis	0	18 (100%)

[+]performed in 12 patients

Conclusion: Our data have demonstrated that the diagnosis of HPP remains challenging. Further evaluation of these criteria in different clinical cohorts will be needed and they may be adapted over time. In addition, the International HPP Registry could act as a useful resource to study the utility of these criteria.

P1117
A CASE REPORT OF SIMULTANEOUS IPSILATERAL NECK OF FEMUR FRACTURE AND ATYPICAL FEMUR FRACTURE IN A 92-YEAR-OLD WOMAN WITH PROLONGED ORAL BISPHOSPHONATE EXPOSURE

L. A. Ali[1], D. F. Fitzpatrick[1], R. L. Lannon[1], K. M. Mccarroll[1], N. F. Fallon[1], N. M. Maher[1], J. C. Carraher[1]

[1]Mercer's Institute for Research and Ageing, St James's Hospital, Dublin, Ireland

Atypical femoral fracture is a well described uncommon complication of prolonged bisphosphonate therapy. Here we describe a case of simultaneous neck of femur fracture and ipsilateral incomplete atypical femoral fracture (AFF).
Case report: The patient was a 92-year-old female with a history of osteoporosis, dyslipidaemia and uterine prolapse who had been taking alendronate for at least 10 y prior. She was admitted following a fall from standing height which resulted in a right neck of femur fracture. Further examination of her initial X-ray demonstrated a simultaneous ipsilateral sub trochanteric incomplete AFF. She had no prodromal pain. Her neck of femur fracture was treated with hemi arthroplasty which also stabilised her incomplete AFF, and alendronate was stopped. MRI excluded contralateral AFF. Densitometry performed after the fractures demonstrated a T-score of -2.5 in her lumbar spine, -2.7 at the left neck of femur and -2.0 at the left total hip. Serum cross-linked CTX measured 8 months after initial presentation was 0.261 ng/ml. She subsequently suffered an atraumatic grade 2 vertebral fracture 18 months later and teriparatide was initiated which she stopped due to the burden of daily injections.

Figure 1. AP hip radiogram from the patient on admission; showing fracture neck of femur in addition to ipsilateral undisplaced atypical femoral fracture

Figure 2. Post operative radiogram; showed hemi arthroplasty, which also stabilized the atypical femoral fracture.

Conclusion: Patients presenting with AFF may also have severe osteoporosis which presents a therapeutic challenge; there is a high

level of uncertainty in the optimal approach in these patients. Teriparatide is a potent treatment for osteoporosis and has also been shown to improve healing of surgically treated AFF. AFF has historically been underdiagnosed and this case highlights the need for vigilance for this complication in patients with prolonged antiresorptive therapies. AFFs can frequently be bilateral, and it is important to adequately image both femora.

P1118
RELATIONSHIP BETWEEN WORK INSTABILITY AND QUALITY OF LIFE AMONG PATIENTS WITH SPONDYLOARTHRITIS

R. L. Rouached[1], Z. S. Zanned[1], B. S. Bouden[1], B. A. Ben Tekaya[1], M. I. Mahmoud[1], T. R. Tekaya[1], S. O. Saidane[1], A. L. Abdelmoula[1]

[1]Rheumatology Dept., Charles Nicolle Hospital Tunis, Tunis, Tunisia

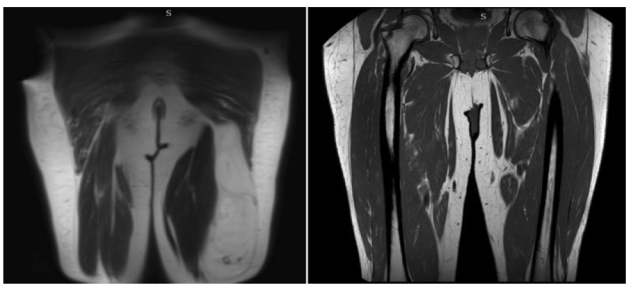
Objective: Quality of life (QoL) is a subjective measure encompassing various well-being indicators, including health, social interactions, and socioeconomic factors such as employment and economic status. Spondyloarthritis patients often face pain, stiffness, and physical limitations that can affect their professional stability. This study aims to assess the impact of work instability on the quality of life in patients with spondyloarthritis.
Methods: A prospective study was conducted on spondyloarthritis patients at a rheumatology department. Patient demographics (age, gender, educational level), disease-related parameters (disease activity, duration, treatment), comorbidities, and job characteristics were collected. The Work Instability Scale was used, it is classified into three categories: low (< 10), medium (10–17), and high (> 17) risk. Quality of life was evaluated using the Arabic Tunisian version of the SF-36 short form questionnaire.
Results: 41 patients participated with a mean age of 39.34 ± 12.58 and 73.2% were males. Educational levels were 31.8% elementary, 44% high school, and 24.4% university. Work sectors comprised 29.3% public, 34.1% private, and 36.6% independent. Job categories included agriculture (12.2%), manufacturing (14.2%), building (17%), trading (12.2%), education (4.9%), administration (4.9%), and security (7.3%). Mean working hours were 8.35 ± 1.4. Job demands included physical demands (63.4%), mental demands (26.8%), and a combination of both (9.4%). The onset age of the disease was 31.8 ± 10.68 y. Disease characteristics included disease activity measures (BASDAI = 3.08 ± 1.6 and ASDAS-CRP = 2.53 ± 1.13), with 58.5% having moderate to high disease activity. BASFI.
indicated a mean of 4.18 [0.5–8.5]. SF36 scores averaged 62 ± 17.2: Physical functioning 65.73 ± 20.23, Role physical 48.78 ± 24.55, Bodily pain 68.84 ± 18, Social functioning 67.72 ± 16.1, Mental health 61.78 ± 29.41 Role emotional 65.14 ± 14.8, Vitality 62.2 ± 19 and Global health 55.48 ± 14.35 Work instability was present in 58.8% of patients, with a mean AS_WIS of 11.17 [2–18]. Workplace adaptations were noted in 41.5% of the cases and involved: adapted furniture/tools (5%), reduced tasks/duties (2.4%), and fewer working hours (29.3%). Lower educational level was associated with lower SF36 scores, particularly in social and vitality dimensions ($p = 0.04$ and $p = 0.02$, respectively). Quality of life score SF36 was significantly negatively correlated to AS-WIS ($R = -0.63$, $p < 0{,}001$). In addition, work instability correlated to disease activity indexes BASDAI and ASDAS ($R = 0.58$; $p < 0.001$ and $R = 0.46$; $p = 0{,}004$ respectively).
Conclusion: Professional stability significantly influences quality of life in spondyloarthritis patients. Regular evaluation and intervention on associated factors are crucial to enhance and promote overall quality of life during follow-up care.

P1119
A CASE OF ATYPICAL LIPOMATOUS TUMOR

R. M. Runcheva[1], M. B. Markovski[2], K. A. Karpicharova[3]

[1]Private orthopedic practice Ortomedik, Shtip, [2]Private orthopedic practice Ortomedika, Kumanovo, [3]PHO Clinical Hospital Shtip, Shtip, North Macedonia

Atypical lipomatous tumor (ALT) is a locally aggressive but non-metastasizing adipocytic neoplasm that primarily occurs in the proximal extremities of middle-aged to older adults. Histologically, ALT is divided into adipocytic (lipoma-like), sclerosing and inflammatory subtypes. ALT can occur at any age but has a peak incidence in the fifth to seventh decades of life, with no sex predilection. It most frequently occurs in the deep soft tissue of the extremities, especially the thigh. The retroperitoneum, trunk and para testicular area are also commonly involved. Surgery is the mainstay of treatment for ALT. However, there is no consensus regarding the best surgical treatment for deep-seated ALT of the extremities.
Case report: A 57-year-old male presented with soft tumor in posterior area of left thigh, without pain, disability or neurological symptoms. He first felt the swelling in the back of his left thigh around a year ago, but within the previous 2–3 months, the alteration has become more noticeable. After set of Lab, RTG, KT and MRI investigations, an indication for operative treatment on the thigh has been set and it was carried out 6 weeks after the alteration was detected. The tumor, which weighed 1330 g and measured 21 $\times$ 17x9 cm, was surgically removed. The tumor was clearly limited in relation to surrounding structures, but due to the extensive surgical intervention, a permanent lesion of the left peroneal nerve occurred postoperatively. Due to the large cavity that was present, seroma has been created postoperatively, which was evacuated percutaneously on several occasions. After the obtained histopathological findings, an oncologist was consulted, the treatment was limited to surgical intervention only, without radiotherapy and chemotherapy due to the proven benignity of the lesion. 18 months after the surgical intervention, there are no signs of local recurrence.



Conclusion: The management of choice in atypical lipomatous tumors is resection, which is curative if complete. These tumors are not sensitive to radiotherapy or chemotherapy. Tumor prognosis and the likelihood of local recidive depend on the risk of dedifferentiation and on how amenable the location is to surgical excision. The tumors do not cause distant metastasis unless there is dedifferentiation. Patients with tumors affecting the extremities have a very good prognosis with $> 90\%$ survival after 10 y of follow-up and thus the name atypical lipomatous tumor. For selected patients with atypical lipomatous tumors of the extremities, active surveillance has been suggested as a viable option to prevent overtreatment.

P1120
PREVENTIVE EFFECT OF TRANSCUTANEOUS CO2 APPLICATION ON DISUSE OSTEOPOROSIS AND MUSCLE ATROPHY IN A RAT HINDLIMB SUSPENSION MODEL

R. Nishida[1], T. Fukui[1], K. Oe[1], Y. Kumabe[1], H. Kondo[1], Y. Yamamoto[1], K. Takase[1], R. Yoshikawa[1], T. Niikura[2], R. Kuroda[1]

[1]Univ. of Kobe, [2]Hyogo Prefectural Nishinomiya Hospital, Kobe, Japan

Objective: We previously demonstrated transcutaneous CO_2 application promotes muscle fiber-type switching, fracture healing and osteogenesis through increasing blood flow and angiogenesis. The aim of this study is to investigate the preventive effects of transcutaneous CO_2 application on disuse osteoporosis and muscle atrophy using a rat hindlimb suspension model.
Methods: 11-week-old male Sprague Dawley rats were divided into hindlimb suspension (HS), HS with transcutaneous CO_2 application ($HSCO_2$), and control groups (n = 7 per group). The HS group underwent a 30° head-down tilt to keep hindlimbs off the ground. In the $HSCO_2$ group, hindlimbs were similarly suspended and exposed to transcutaneous CO_2 application using hydrogel sealed in a polyethylene bag filled with 100% CO_2 gas, five times a week for 20 min. After 3 weeks, we harvested the gastrocnemius, femur, and tibia for assessment.
Results: The histological cross-sectional area of gastrocnemius myofiber was significantly decreased in HS compared to the control, whereas in HSCO2, it was significantly increased compared to HS. Microcomputed tomography revealed femoral trabecular and cortical atrophy in HS compared to control rats, with significant improvement observed in $HSCO_2$. Histological analysis of the proximal tibia in HS revealed more marrow adipose tissue than in the control. However, in $HSCO_2$, fewer marrow adipose tissue and osteoclasts were observed, while more osteoblasts exhibited with higher expression of PGC-1a and VEGF compared to HS. Real-time PCR showed elevated expression of myogenesis and angiogenesis markers in $HSCO_2$ gastrocnemius compared to HS, with opposite changes in atrophic markers. In the distal femur, osteogenesis and angiogenesis markers were also upregulated in $HSCO_2$ compared to HS.
Conclusion: Transcutaneous CO_2 application effectively prevents disuse osteoporosis and muscle atrophy in a rat hindlimb suspension model by activating the angiogenic pathway.

P1121
USING CATEPSIN K ACTIVITY AS A BIO-MARKER FOR OSTEOPOROSIS RESPONSE TO ALENDRONATE

R. Novac[1], I. C. Popescu[2], V. A. Cotirlet[3]

[1]Emergency Hospital Moinesti, Bacau, [2]Romanian Academy of Human Sciences, Bucharest, [3]Vasile Alecsandri Univ., Bacau, Romania

Objective: Osteoporosis has been an excruciating disease for many years now and although many treatments have been developed, our concern now needs to focus on finding better ways to precociously diagnose and monitor treatment. New biomarkers are crucial for the diagnosis or prognosis of a disease as well as elucidating the mechanism of drug action and improve decision making. Cathepsin K is a cysteine protease that cleaves collagen type I, the major type of collagen found in bone, so it is useful to measure to assess the function and number of osteoclasts. The aim of the current study was to evaluate the fluctuation of cathepsin K, phosphorus, 25 HO vitamin D, alkaline phosphatase and PTH before and after 6 and 12 months of treatment with alendronate.
Methods: We recruited samples from 28 female patients with osteoporosis and 15 healthy controls. All subjects were menopaused, non-diabetic, non-obese, all causes of secondary osteoporosis were excluded. All osteoporosis diagnosticated patients were treated with alendronate and calcium and vitamin D supplements.
Results: Serum cathepsin K activity was determined in 28 women with postmenopausal osteoporosis before and after 6 and 12 months of treatment with alendronate. Basal serum cathepsin K activity levels were also compared to postmenopausal women without osteoporosis (n = 15). We also measured phosphorus, alkaline phosphatase, PTH and 25 HO vitamin D. We observed that serum cathepsin K activity levels were higher in postmenopausal women with osteoporosis (9746.07 $\pm$ 1824 pmol/L) compared with healthy postmenopausal women (7747.33 $\pm$ 762.67 pmol/L; $p < 0.01$). Also, serum cathepsin Ka decreases gradually after alendronate treatment (5.09% at 6 months, and 7,17% at 12 months, $p < 0.05$). We also found a positive association of cathepsin K and phosphorus and PTH and a negative association with 25 HO vitamin D.
Conclusion: Serum cathepsin K activity may serve as additional marker of bone metabolism in postmenopausal women treated with alendronate and also a possible risk marker in postmenopausal women without osteoporosis.

P1122
EXPECTED LOSS OF PRODUCTIVITY FOLLOWING FRAGILITY FRACTURES IN PATIENTS OF WORKING AGE

R. Pinedo-Villanueva[1], J. Griffin[2], L. Wiggins[2], N. Nicola[3], C. Jones[2], M. K. Javaid[1]

[1]Univ. of Oxford/ NDORMS, Oxford, [2]Royal Osteoporosis Society, Bath, [3]Sheffield Teaching Hospitals NHS Foundation Trust, Sheffield, UK

Objective: The economic impact of osteoporotic fractures has been extensively studied in terms of health and social care expenditures. However, their impact on productivity losses remains underexplored.
Methods: A survey targeting Royal Osteoporosis Society members was developed to gather data on demographic variables, fractures, and changes in employment status (following Office of National Statistics (ONS) classifications) after fracture. Annual loss of earnings was estimated by apportioning the total number of fractures in England (from National Hip Fracture Database and rule of 5) in people aged 50–67 y (from Oxfordshire Fracture Prevention Service) to each ONS occupation category according to the England 2021 Census. Expected numbers of fractured people by occupation were multiplied by corresponding% of those surveyed taking early retirement or stopping their job due to the fracture, with total loss estimated by applying annualised ONS 2023 weekly earnings.
Results: The survey, conducted from 15/08/2023 for 2 weeks, received responses from 354 adults aged 50–70 y (mean 67.9, 93% women) who reported a fracture. Prior to the fracture, 42.1% were in full-time paid employment, 29.3% in part-time employment, 5.2% were volunteers, 20.1% retired, and 3.4% unemployed. The most common job categories were professional (40.5%) and administrative (17.0%). 61.4% of respondents reported a change in employment after fracture, with 29.0% ceasing work, 24.1% taking early retirement, and 46.3% modifying their job, hours, or duties. Median duration of job absence was 8 weeks (IQR 42–90 d) for those who returned to work. The direct loss of earnings from fractures from early retirement and cessation of work was estimated to be £1.01 billion per annum.
Conclusion: This study provides an estimation of productivity losses resulting from fragility fractures in UK adults aged 50 y and over. Given the aging demographic and policies promoting extended workforce participation, the potential economic benefits of effective

osteoporosis management in preserving employment and productivity warrant further exploration.

P1123
LEVEL OF MARKERS CTX-I AND CTX-II IN EXPERIMENTAL OSTEOARTHRITIS AND HYPOTHYROIDISM

D. Nosivets[1], V. Povoroznyuk[1], R. Povoroznyuk[1]

[1]D.F. Chebotarev Institute of Gerontology NAMS Ukraine, Kyiv, Ukraine

Objective: To study the changes in the level of CTX-I and CTX-II under the influence of NSAIDs and paracetamol in experimental osteoarthritis (EOA) and hypothyroidism (EH).
Methods: Experimental studies were performed on 75 white mature nonlinear rats of both sexes. On 42 day all animals divided into 14 research groups of 5 rats in each group. Group I—rats with EOA + EH without «treatment» and rats of other groups were administered the appropriate drugs. The drugs were administered daily from day 42 of the experiment for 5 days. The quantitative level of CTX-I and CTX-II in serum was performed by specific kits system Elabscience, Inc. (USA). The blood samples were obtained from the tail vein of the rats by means of puncture using a vacuum system on 42 and 47 days. The duration of administration of the drugs was 5 days and by the 47th day of the experiment all animals after the collection of biological material were removed from the study by decapitation under general anesthesia.
Results: Based on the study, it was found that the degree of influence on degenerative-dystrophic processes in bone tissue, which was assessed by the level of the marker CTX-I in the serum of rats, the studied drugs were as follows: diclofenac sodium > ibuprofen > nimesulide = meloxicam > celecoxib > paracetamol. According to the degree of influence on degenerative-dystrophic processes in cartilage tissue, which were assessed by the level of marker CTX-II in the serum of rats, the studied drugs were as follows: nimesulide > celecoxib > meloxicam > ibuprofen > diclofenac sodium > paracetamol.
Conclusion: Determination of the level of CTX I allows to evaluate of the activity of osteoclasts by the number of breakdown products of type I collagen against the background of EOA and EH. Determining the level of the marker CTX II allows to assess the severity of degenerative-dystrophic changes in cartilage tissue by the level of breakdown products of type II collagen on the background of EOA and EH and the appointment of drugs that were studied.

P1124
RECONSTRUCTION OF PECTORALIS MAJOR MUSCLE TENDON INJURY USING SUTURE ANCHORS: A RETROSPECTIVE REVIEW

R. Ratra[1], V. Shetty[1]

[1]Blackpool Victoria Teaching Hospital NHS foundation Trust, Blackpool, UK

Objective: Pectoralis major muscle rupture is one of the most infrequently occurring sports/exercise injuries. This is not commonly observed by sport surgeons around the globe. In this article, we report our experience of repairing ten cases of pectoralis major muscle complete tendon tears, which were further assessed for clinical and functional results.
Methods: In this retrospective observational study, we studied results of 10 cases with complete pectoralis major muscle tears from January 2021 to January 2023. All of them underwent repair using three suture anchors in a triangular configuration to get a better anatomical footprint at the insertion site on humerus, along with box-suture bites through the muscle-tendinous unit to provide a better bulk of muscle available for repair in chronic cases. ASES score and Bak's criteria were used for functional evaluation for the next 6 months following surgery.
Results: The ASES score improved from 46.33 ± 9.83 pre-op to 97.5 ± 2.73 post-op for acute cases (p – 0.0001), while for chronic cases it went from 52.33 ± 12.31 to 95.77 ± 3.53 (p – 0.0001). According to ASES score and Bak's criteria, patients had a good result at 3 months post-surgery which improved to excellent result with good shoulder ROM and strength and without any functional impairment at 6 months post-surgery.
Conclusion: Suture anchor fixation in a triangular configuration with box-suture bite technique provides excellent functional and cosmetic results. Suture anchor technique overall seems to be superior as compared to other techniques as it has biomechanical strength equal to transosseous and does not have various disadvantages associated with TOS technique.

P1125
BONE HEALTH FOR THE SPINE PATIENT

P. Anderson[1], R. Roy[2], D. Lee[2], T. Schuler[3]

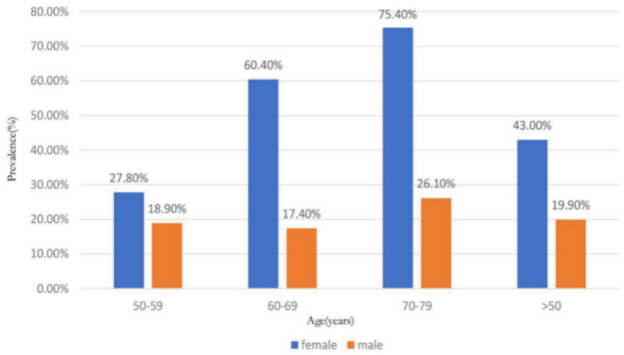
[1]Univ. of Wisconsin School of Medicine, Madison, Wisconsin, [2]National Spine Health Foundation, Reston, Virginia, [3]Virginia Spine Institute, Reston, Virginia, USA

The National Spine Health Foundation (NSHF) is the pre-eminent patient advocacy organization in spinal health care. It is the only patient-centered USA non-profit organization dedicated to helping patients overcome debilitating spinal conditions and take back their lives through patient education, award-winning research, and patient advocacy. NSHF gives patients the tools they need to make informed decisions about their spine health and navigate their own treatment journeys with confidence.

NSHF serves a critical gap in spinal health by representing the voice for patients, in connection with premiere professional societies through the Coalition for Spine Health, and fueled in partnership with industry leaders through our Spine Health Leadership Council. Our stated mission is to improve spinal health through patient education, patient advocacy, and clinical outcomes research.

We achieve much of our mission through our digital outreach efforts including our award-winning website, www.spinehealth.org. We steward a vibrant community through our Spinal Champion pro gram where patients share their successful spine health journeys to give hope and help to others seeking real answers. These Spinal Champion stories are featured on our Get Back To It podcast. Our prestigious Medical & Scientific Board volunteer their expertise to contribute to our content primarily through our premiere video edu cation offering, Spine-Talks, and through our bi-annual Spine Health Journal.

NSHF is leading a number of efforts to address key educational patient and health care professional gaps in spine care and osteoporosis, given the high prevalence of osteoporosis in patients undergoing spine surgery [PLoS One 2023; 18(5): e0286110]:



NSHF efforts to drive education and awareness regarding the connection between spine and bone health include:

1. Establishment of a *Bone Health & Your Spine* Task Force comprised of leading spine surgeons, both orthopedic and neurosurgery trained, who are committed to promoting bone health/osteoporosis prevention for spine patients through education, advocacy, and research.

2. Development of patient and professional education materials focused on comprehensive bone health assessment, pre-operative evaluation, and bone health optimization (including a health care professional survey to assess key gaps and opportunities to improve osteoporosis screening, diagnosis, and treatment in spine patients).

3. In partnership with the members of the NSHF Medical & Scientific Board, and members of the Coalition for Spine Health, a coalition dedicated to advancing spinal patient health, disseminate patient and health care professional tools in support of the release of the North American Spine Society (NASS) Diagnosis and Treatment of Osteoporotic Vertebral Compression Fractures in Adults clinical practice guideline and appropriate use criteria**.** (The members of the Coalition for Spine Health include the Cervical Spine Research Society, Lumbar Spine Research Society, North American Spine Society, and Setting Scoliosis Straight Foundation in addition to NSHF).

4. Spine-Talks expert panel videos and special edition of the NSHF Spine Health Journal focused on spine health and osteoporosis. Spine-Talks is NSHF's leading patient education platform that to date has disseminated more than 150 patient and provider videos on a variety of spine health topics produced with national clinical and patient experts (which currently includes 8 videos focused on osteoporosis).

P1126
OSTEOPOROSIS TREATMENT IN A YOUNG PATIENT WITH SECONDARY HYPERPARATHYROIDISM ON PROGRAMMED HEMODIALYSIS: CASE REPORT

R. Salimkhanov[1], E. Karaseva[1], H. Bagirova[1], A. Eremkina[1], N. Mokrysheva[1]

[1]Endocrinology Research Centre, Moscow, Russia

Osteoporosis with low-energy fractures is common in patients with advanced chronic kidney disease (CKD), including those on hemodialysis. There are various anti-osteoporotic medications, but the choice of therapy for these patients requires a complex, individualized approach.

Case report: A 37-year-old female patient, K., with secondary hyperparathyroidism (SHPT) due to end-stage CKD caused by chronic glomerulonephritis, received hemodialysis for 11 y. PTH exceeded 5000 pg/mL due to irregular monitoring and therapy. In 2021, x-ray showed L_{1-2} vertebral compression fractures (VCF) (Table 1).

Table 1. BMD at DXA (Z-score)

Date:	Lumbar Spine, SD	Femur Neck, SD	Total Hip, SD	Radius 33%, SD	Radius Total, SD
12.18	-2,0	-2,6	-	-	-
12.18	X-ray – compressions L_{1-2}				
03.22	-3,9	-2,7	-3,2	-4,1	-4,2
03.22	X-ray – compressions Th_{9-11}, L_{2-3} (6-18%)				
03.22	Total parathyroidectomy, left hemithyroidectomy (histology – parathyroid hyperplasia)				
09.22	X-ray – new compression fracture Th_8 (45%), compressions $Th_{5,9-10,12}$, L_{2-3} (4-18%)				
04.23	-0,7	-0,2	-1,3	-2,8	-2,8
04.23	X-ray – VCF progression Th_{7-9}, L_4 (20-55%), $Th_{4,10-12}$, L_{2-3} (5-15%)				

Despite medical therapy PTH remained elevated—3786 pg/mL, $Ca_{adj.}$—1.9 mmol/L (2.15–2.55), P—1.2 mmol/L (0.72–1.54) and ALP—1595 U/L (40–150). Neck US and CT showed hyperplasia of four parathyroid glands with a maximum size—3.4 × 2.4x2.0 cm. March 2022 K. underwent a total paraadenomectomy, left-sided hemithyroidectomy (Table 1). Post-surgery PTH decreased to 25 pg/mL, thus she was discharged on alfacalcidol 2 µg/d, Ca carbonate 1000 mg/d. At 6-month follow-up after surgery, the patient presented with chronic postoperative hypoparathyroidism (HypoPT): PTH—14.4 pg/mL, $Ca_{adj.}$—2.1 mmol/L, P—1.1 mmol/L and increased ALP—257 U/L. Due to multiple VCFs, persistent ALP elevation and the risk of hypocalcemia, the medical committee prescribed antiresorptive therapy with an oral bisphosphonate—alendronic acid 70 mg/week. One year after surgery, ALP level decreased to 107 U/L, x-ray confirmed new VCFs despite bisphosphonates treatment. Antiosteoporotic therapy was changed to anabolic – teriparatide 20 µg/d, in combination with alfacalcidol and Ca supplements. Continued observation.

Conclusion: Osteoporosis therapy in patients with end-stage kidney disease, requires an individualized approach that takes into account multiple factors to select the most appropriate medication.

P1127
EVALUATION OF THE RELATIONSHIP BETWEEN THORACIC KYPHOSIS AND QUADRICEPS MUSCLE THICKNESS WITH BALANCE AND FALL RISK IN WOMEN WITH POSTMENOPAUSAL OSTEOPOROSIS

E. Peker Belene[1], Z. U. Akarırmak[1], R. Terlemez[1], O. A. Kargın[2]

[1]Dept. of Physical Medicine and Rehabilitation, Istanbul Univ.-Cerrahpasa, Cerrahpasa Medical Faculty, [2]Dept. of Radiology, Istanbul Univ.-Cerrahpasa, Cerrahpasa Medical Faculty, Istanbul, Turkey

Objective: To determine the impact of thoracic hyperkyphosis, sarcopenia and quadriceps muscle thickness evaluated by ultrasonography (USG) on balance, fall risk and functional parameters in women with postmenopausal osteoporosis, to assess their interrelationships and to compare the clinical characteristics of sarcopenia and thoracic hyperkyphosis.

Methods: 103 women aged 50 or older with postmenopausal osteoporosis according to the WHO criteria and/or who had an osteoporotic vertebral fracture, were enrolled in the study. The Cobb angle of thoracic kyphosis was calculated radiographically, quadriceps muscle thickness on the anterior thigh was measured by USG and the presence of sarcopenia was determined by evaluating hand grip strength and chair stand test (CST). Patients were then divided into groups based on the presence of thoracic hyperkyphosis and sarcopenia. Balance, fall risk and physical function were assessed with tandem stance and gait test, Berg balance scale (BBS), timed up and go test (TUG) and CST.

Results: Quadriceps muscle thickness was found to be significantly lower in patients with thoracic hyperkyphosis. Linear regression analysis revealed that the presence of sarcopenia increased TUG score by 2,12 times and CST score by 4,64 times. The presence of thoracic hyperkyphosis was not an effective variable for TUG and CST. A

one-unit increase in quadriceps muscle thickness/BMI ratio decreased the TUG score by 4,17 times and increased the BBS score by 3,96 times. A one-unit increase in the Cobb angle of thoracic kyphosis reduced the BBS score by 0,04 times.
Conclusion: In our study, it was observed that balance and functional parameters were more affected by sarcopenia than thoracic hyperkyphosis. A decrease in quadriceps muscle thickness poses a risk for thoracic hyperkyphosis and deterioration in balance and physical function. Identifying the sarcopenia via evaluating quadriceps muscle thickness by USG, and considering it in the management of women with postmenopausal osteoporosis are crucial to prevent falls, to reduce morbidity and mortality.

P1128
IS THERE A LINK BETWEEN OSTEOPOROSIS AND NAIL PLATE THICKNESSES?

R. Terlemez[1], B. Ugur[1], E. Aygun[1], S. Tuzun[1]

[1]IUC Cerrahpasa School of Medicine, Istanbul, Turkey

Objective: The relatively new idea of "bone quality" appears to be able to close the gaps in our understanding of osteoporosis prediction using bone mineral densitometry. The aim of this study was to investigate the ultrasonographic nail plate thicknesses of postmenopausal women with osteoporotic fractures.
Methods: In this case–control study 15 postmenopausal women with a history of fragility fracture and 16 controls recruited from our outpatient clinic. All fingers of the patients' dominant hand were evaluated by using the ESAOTE My Lab 70 model ultrasound device, with a 6–18 MHz linear probe. The nail plate was identified by measuring the distance between the upper border of the dorsal plate and the lower border of the ventral plate. Based on the Wortsman categorization, morphological examination was performed[1]. Before enrolling the cases we conducted a preliminary evaluation to demonstrate the intra-rater reliability of ultrasonographic nail measurements.
Results: The 2nd, 3rd, 4th and 5th nail plate thicknesses of the postmenopausal women with osteoporotic fractures were significantly lower than the controls ($p < 0,05$), while there was no significant difference between the groups in terms of Wortsman morphological scores. This relationship was independent of age, BMI, and BMD values.
Conclusion: Only a small number of studies assessing nail health in individuals with osteoporosis have been reported in the literature[2]. Although most of previous investigations used spectroscopy, this study is the first to use ultrasound to assess the morphology and thickness of the nail plate in patients with osteoporosis.

P1129
ACTIVITIES OF THE OSTEOPOROSIS PATIENT SOCIETY OF TURKEY FOR THE PREVENTION OF CLINICAL AND SOCIAL BURDEN OF OSTEOPOROSIS AND FRACTURES BY 'BUILDING BETTER BONES'

U. Akarırmak[1], S. Tuzun[1], R. Terlemez[1], N. Eskiyurt[1], M. Sarıdoğan[1]

[1]İstanbul Univ.-Cerrahpaşa, İstanbul, Turkey

Objective: To share some of the work and activities the Osteoporosis Patient Society of Turkey, organized for prevention of osteoporosis and fractures in 2023. 'Building better bones' is essential, in childhood, adolescence and then still in later years.
Methods: Education about prevention of osteoporosis and fractures at all ages was provided by printed educational material, prepared by the Turkish Osteoporosis Society and Osteoporosis Patient Society of Turkey, as well as face-to-face information in the Osteoporosis Outpatient Clinics in a University Hospital in İstanbul. Educational material included osteoporosis exercises (weight-bearing and resistance, performed for 30–40 min, three to four times a week, posture and balance exercises), also regular physical activity, bone healthy nutrition, and vitamin D sources. Prevention of falls as an important issue in individuals over 65 was included.
Results: As clinically all types of fractures cause some limitation of daily function, social and economic burden on the patient, the family, the caregiver as well as the whole system due to disability, treatment costs and rehabilitation. On World Osteoporosis Day WOD2023 for awareness on a larger platform we organized an outdoor event in Bebek location at the Bosphorus/İstanbul. Posture, aerobic and balance exercises were guided by a physiotherapist and performed together with patients, MDs and healthy adults all wearing printed t-shirts with osteoporosis concept. A video of this activity, was taken by a drone from the air, including a bone shape formed by participants, and shared on many social media platforms, local TVs and local newspapers.
Conclusion: Messages on WOD2023 by the presidents of two societies, the Turkish Osteoporosis Society and Osteoporosis Patient Society of Turkey were delivered at the end of the activity concerning 'Building better bones', especially exercises, nutrition and lifestyle. Q&As of young and elderly participants were carefully addressed.

P1130
EFFECT OF INTEGRATED NEUROMUSCULAR INHIBITION TECHNIQUE ON PAIN AND DISABILITY IN UPPER TRAPEZIUS MYOFASCIAL TRIGGER POINTS IN POSTMENOPAUSAL WOMEN

R. Thakur[1], A. Kaur[1], G. Msp[1]

[1]MVPS College of Physiotherapy, Nashik, India

Objective: This study was designed to inspect the effectiveness of integrated neuromuscular inhibition technique (INIT) on pain, cervical range of motion, and disability in upper trapezius myofascial trigger points in postmenopausal women.
Methods: 30 subjects with active trigger points were selected based on the inclusion criteria received INIT three times/week for two weeks. Numeric Pain Rating Scale (NPRS), Neck Disability Index (NDI) and Active Cervical Range Of Motion (CROM) were used to evaluate subjects at two intervals (pre-treatment and post-treatment).
Results: Statistical analysis show that there is a significant change within-group for NPRS, NDI and CROM (lateral flexion) pre and post treatment with a $p < 0.0001$ for subjects with upper trapezius trigger points.
Conclusion: INIT is effective in reducing pain and disability in upper myofascial trigger points.

P1131
INVESTIGATING THE RELATIONSHIP BETWEEN FEAR OF FALLS AND UPPER EXTREMITY MUSCLE STRENGTH IN CLINICAL HOSPITAL SETTINGS

R. Thakur[1], A. Kaur[1]

[1]MVPS College of Physiotherapy, Nashik, India

Objective: Falls pose a significant clinical concern, impacting a diverse population across different settings. Around one-third of individuals residing in the community and three-quarters of those in

nursing homes aged over 60 experience yearly falls. Regrettably, some fatalities result from these incidents. Consequently, the prevention of falls becomes paramount. We aimed to investigate the relationship between fear of fall and strength of the upper extremity.
Methods: This is a cross-sectional study which included ambulatory and hospitalised patients above the age of 60 years and those who were immobile and walking with assistance, and severe neurologic disorders were excluded from the study. Participants underwent geriatric assessments, including the Mini-Mental State Examination, alongside physical evaluations like handgrip, key pinch, and the 6-m up-and-go tests.
Results: Elderly individuals experiencing fear of falling (FOF) demonstrated a markedly higher average annual falling rate compared to those without FOF, with a statistically significant difference ($p = 0.001$). Additionally, individuals with FOF exhibited significantly lower mean values in right handgrip, left handgrip, right key pinch, and left key pinch, as compared to those without FOF ($p < 0.001$ for each).
Conclusion: The assessment of upper extremity strength may serve as a predictive parameter for the fear of falls.

P1132
EFFECTIVENESS OF TELEREHABILITATION IN POSTOPERATIVE OSTEOPOROTIC HIP FRACTURES: A RANDOMIZED CONTROLLED TRIAL

R. Thongkaew[1], C. Pakpianpairoj[1]

[1]Institute of Orthopedics, Lerdsin Hospital, Dept. of Medical Services, Ministry of Public health, Bangkok, Thailand, Bangkok, Thailand

Objective: To investigate the effectiveness of telerehabilitation on mobility function, activities of daily living (ADL) and quality of life (QOL) compared to conventional rehabilitation in postoperative osteoporotic hip fractures.
Methods: This was a single center, randomized controlled trial. We recruited 90 elderly postoperative hip fracture patients and randomly assigned them to the telerehabilitation group ($n = 45$) and the conventional rehabilitation group ($n = 45$). Both groups received routine discharge instructions, and the former received remote rehabilitation based on the Internet-based protocol, while the latter received conventional rehabilitation. Time up and go test (TUG), 30-s chair stand test, Barthel index score and EQ5D5L score were used for evaluation.
Results: All outcomes measurement of the telerehabilitation group were comparable to conventional rehabilitation group but received higher overall satisfaction score and accessibility score. The timed up and go test (TUGT), 30-s chair test, Barthel index score, EQ5D5L score of both groups improved gradually with the postoperative time. At 3 months follow up the TUGT for telerehabilitation group and conventional rehabilitation group were 23.4 s and 23.7 s respectively, adjusted mean difference (-0.2, 95%CI -1.79 to 1.25, p-value 0.72).At 6 months follow up the TUGT for telerehabilitation group and conventional rehabilitation group were 14.6 s and 15 s respectively, adjusted mean difference (-0.3, 95%CI -1.45 to 0.78, p-value 0.55).
Conclusion: The internet-based postoperative hip fracture telerehabilitation protocol can improve the functional recovery of the hip joint and enhance the ability to perform activities of daily living. This could be an effective option for conducting home rehabilitation.

P1133
CHRONIC DORSAL PAIN IN SARCOPENIC FEMALES: A RANDOMIZED CLINICAL TRIAL

R. Traistaru[1], D. Kamal[2], C. Kamal[1], B. Vladutu[1]

[1]Univ. of Medicine and Pharmacy, [2]Filantropia Hospital, Craiova, Romania

Objective: Chronic dorsal pain is one of the most common symptom in sarcopenic patients leading to complex disability. Various therapeutic approaches have been proposed for chronic back pain in these patients. The aim of our study is to compare the effects of three therapeutic approaches in terms of pain, disability and self-control of the complex disorders. We take into consideration the literature data about the evidence-based primary care options for chronic back pain.
Methods: 87 patients aged between 67–82 y, diagnosed with sarcopenia were clinical (BMI), functional (time up and go—TUG, handgrip force—HG, visual analogue scale – VAS, SarQoL quality of life tool and SARC-F questionnaire) and imagistic (X-rays and sonography) evaluated. Our patients were randomized to the 3 groups in accordance to the type of treatment: group 1 (23% of patients)—only medication, group 2 (40% of patients)—medication + physiotherapy (TENS, interferential current, ultrasound), and group 3 (37% of patients) medication + aerobic and resistance training. The rehabilitation program was represented by 12 physiotherapy sessions and 18 aerobic training sessions (3 sessions/week). All assessments were performed pre-post intervention and at 6-month follow-up.
Results: All the groups showed similar decrease in pain on the third assessment and there was no significant difference between the groups. In the first and group the second there was a significant improvement in TUG values ($p < 0,05$) as well as HG ($p < 0,05$) after treatment. The third group also showed significant improvement in SarQoL value as well as TUG and HG at six month follow-up ($p < 0,01$).
Conclusion: All of the 3 therapeutic approaches were found to be effective in diminishing pain and disability in sarcopenic patients with chronic dorsal pain, but kinetic measures were found to be more effective in improving quality of life. Our results confirm the literature data—physical activity is an interesting therapy for the prevention and treatment of sarcopenia because it has no adverse side effects, it is low cost, and it confers additional benefits such as postural stability and fall prevention. Type and duration of physical training must be individualized to each patient, in accordance with severity of sarcopenia and level of disability.

P1134
ASSESSMENT AND REHABILITATION IN FRAIL OLDER PATIENTS WITH HIP FRACTURES

R. Traistaru[1], D. Kamal[2], A. M. Bumbea[1], A. Kamal[1]

[1]Univ. of Medicine and Pharmacy, [2]Filantropia Hospital, Craiova, Romania

Objective: Frail older patients have impaired physical functions. Fragility fractures in older patients trigger secondary preventive assessment, including lifestyle, non-pharmacological and pharmacological interventions. Goals of complete rehabilitation program in these patients include controlling pain, maintaining and improving the range of movement and stability of affected joints, and limiting functional impairment, for an optimal quality of life. In our

prospective study, we assessed the efficacy of rehabilitation program (TENS, laser and kinetic program, education program for regain self-esteem and optimal body image) over the global functional status. We evaluated the correlation between functional parameters (simple reaction time, walking speed), ultrasound muscle reaction in isometric contraction and quality of life (Quality of Life Questionnaire).

Methods: We studied 56 old patients (39 women, 17 men), aged between 70–81 y. All patients diagnosed with previous fragility hip fracture were clinical, functional and imagistic (X-rays, DXA and sonography) evaluated. The complex rehabilitation program (educational, dietetic, pharmacological, physical—kinetic) was performed 5 d/week, 3 weeks. All subjects were evaluated at baseline (T1) and at 2 (T2) and 3 (T3) months later.

Results: The studied parameters had improved, especially in T2 moment ($p < 0.05$). The mean values of simple reaction time, walking speed were correlated with ultrasound muscle variations in isometric contraction. Multivariate analysis showed that sonographic aspects correlated statistically with Quality of Life Questionnaire. After 3 months, improved functional status was maintained.

Conclusion: Our results reflected two aspects: 1—the favorable complex effect (clinical, functional and ultrasound) of rehabilitation performed in patients with frail older patients with fragility hip fractures; 2—ultrasound exam could orient on the muscle changes associated with sarcopenia and loss of quality of life in older patients.

P1135
POSSIBILITIES OF PROMOTING PRIMARY PREVENTION BASED ON MONITORING MATERIALS OF THE MUSCULOSKELETAL SYSTEM: FIRST EXPERIENCE

P. Novosad[1], P. Hrdý[1], R. Vrána[1]

[1]Mediekos Ambulance Ltd, Osteology Centre Zlín, Osteology Academy Zlín, o.p.s, Zlín, Czech Republic

Objective: In our view, primary prevention corresponds to the CDC definition (US centres for diseases control and prevention). It strengthens the well-being of life and thus reduces the probability of illness, disability or premature death by non-specific means. 70–75% of these diseases or death is caused by chronic diseases, which from 2022, according to the WHO, are referred to as non-communicable diseases (NCDs). They have the same causative essence, last for a long time and have a slow progression. The key risk factors for these diseases are: Physical inactivity, Unhealthy diet, Alcohol abuse, Tobacco use. Physical activity and the development of functional muscles appear to be a key element in preventing the onset and development of these diseases. It has a dominant role in the pathophysiological process of LGI (low grade inflammation). We published the principle of this problem and the verification of key data at the last four IOF congresses (2020, 2021, 2022, 2023). In the last year, we addressed the issue of how to spread these claims in the population of the Czech Republic. For the professional public, we presented our claims at a professional congress and published them in a peer-reviewed press (1). For laymen, we joined with state institutions and gave a series of lectures on this topic in public places. Since primary prevention is not a recognized work code in our country, we spent the last 6 months in intensive contacts with health insurance companies. All but one insurance company has expressed interest in cooperating with our specific program on this topic. So far, we have concluded a work contract with one of them. It is built on the financial stimulation of clients who comply with the terms of the program.

Methods: The individual elements of the program are as follows:

1. Monitoring grip strength ($M < 30$ kg, $F < 20$ kg);
2. Evaluation of habitual speed of patient according to EWGSOP ($M < 0.8$ m/s);
3. Determination of BMI;
4. Quantitative evaluation of physical body composition (determination of relative muscle index $M < 7.26$ kg/m^2; $F < 5.45$ kg/m^2);
5. Determination of activity for LGI-CRP protein high sensitivity (CRPhs < 0.4–0.6 mg/L) and IL-6 (< 7.0 ng/L). Control monitoring is offered after one year, in special cases after 6 months.
6. Recommendation of the preventive regime: This is composed of two parts:
7. Recommendation of physical activity which, according to WHO, should be 150 min/week at minimum. It is composed of two components:

- 1a Physical isometric load, i.e. exercising muscles without contraction, against weight pressure (overstimulation).
- 1b Physical longitudinal load, where the optimal span is 3–5.9 MET (Metabolic Equivalent Task). This is an optimal aerobic load.

8. Dietary regime**.** This is composed of the following parts:

- 2a Setting the basic dietary regime**.** In this context, as the basis for an individual's dietary regime, we recommend a regime very close to the Mediterranean diet.
- 2b Optimized amount of protein. The amount < 0.80 g/kg weight/a day is considered inadequate, while 0.83 g/kg weight/d is considered to be optimal (according to WHO). According to the European Society for Clinical Nutrition and Metabolism, the recommended amount for older people and a reduction dietary regime is 1.0–1.2 g/kg/weight/d. The most effective is whey protein enriched with Leucine. The optimal amount is 25–30 g of protein with one meal, enriched with 2.5–2.8 g of leucine.
- 2c Vitamin D. It is recommended to saturate the organism with vitamin D.

One of the non-communicating insurance companies, together with the representatives of general practitioners, gynaecology, and also the board of directors of the Osteological Association, came up with a program of massive primary prevention of osteoporosis using FRAX values and densitometry in these clinics. From our point of view, this solution is very problematic in terms of professional issues, but mainly in terms of cost effectiveness, as was discussed in detail at the IOF congress in 2013, at which we gave a lecture on the topic of secondary prevention (2). We continue to deal with this issue, and we are located on the Capture the Fracture world map. We wanted to verify if bone densitometry values could be used in LGI monitoring. We compared the basic values of bone densitometry and relative muscle index (kg/h^2), (marked as MI in the table). All performed on a densitometer – DXA Lunar (LS = 1.5%).

Results: Characteristics of the cohort: women n = 63, average age 73.3 (from 50–88 y).

Correlation between:

- Muscle index and age: Spearman's correlation coefficient = 0.21 p-value = 0.12
- Vertebral L-spine T-score and MI: Spearman's correlation coefficient = 0.25 p-value = 0.06
- Left hip T-score and MI: Spearman's correlation coefficient = 0.04 p-value = 0.78
- Right hip T-score and MI: Spearman's correlation coefficient = 0.39 p-value = 0.12

Conclusion: There is no correlation between relative muscle index and age, T-score of L-spine, left hip T-score and right hip T-score. Considering that we do not find any significant correlation, we must conclude that the monitoring of the relative muscle index is more effective for primary prevention as a society-wide phenomenon. The state of the muscles is the dominant entity in the development of 70–75% of chronic diseases. The muscles disability plays a significant role in the diseases development. This can sometimes be associated with osteoporosis, but osteoporosis has to be taken as one of about 40 diagnoses in terms of NCDs. Its primary prevention in the form described above is not cost effective. For osteoporosis, we would prefer secondary prevention, as we have been doing for years. From

our point of view, we have to say that the implementation of primary prevention throughout society will be much more difficult than we expected.

Acknowledgement: Very grateful to PhD. Kateřina Martinovičová for the mathematical processing of the data.

P1136 Standard X-ray images may potentially be used to quantify bone disorganization and identify patients with hypophosphatasia

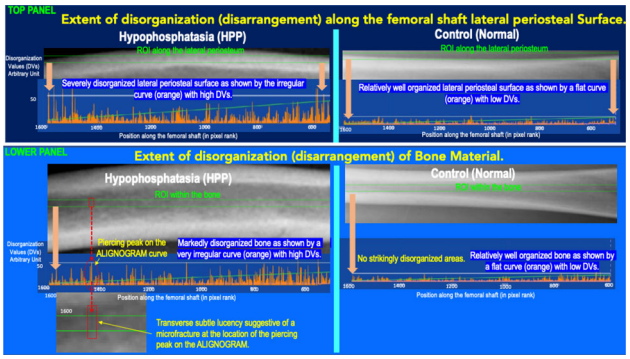
R. ZEBAZE[1], C. Shore-Lorenti[1], Z. Simon[1], K. Djopseu[2], T. Makebeh[2], F. Milat[3], R. Ebeling[1]

[1]Dept. of Medicine, School of Clinical Sciences, Monash Univ., Melbourne, Australia, [2]Zeze Co, Yaounde, Cameroon, [3]Hudson Institute of Medical Research, Melbourne, Australia

Objective: The diagnostic issue is that low BMD and structural decay (e.g., cortical or trabecular deficits) are not key features of hypophosphatasia (HPP). Hence, a critical unmet challenge is the lack of a tool to accurately identify bone fragility in patients with HPP. We proposed that the loss of function mutations in tissue non-specific alkaline phosphatase leads to an impaired ability to properly organize (arrange, align) bone. This results in disorganized, damage-prone, and fragile bone. Thus, we hypothesized that quantification of the extent of bone disorganization identifies patients with HPP.

Methods: We studied 6 adult patients with HPP and 15 age- and sex-matched controls, Mean age 48 y (IQR 23–53). The extent of disorganization and features of the most misarranged areas were assessed using a novel validated tool (ALIGNOGRAM). This tool analyses femoral X-rays using AI and novel image processing algorithms.

Results: External shape: HPP patients had markedly more disorganized contours. Their periosteal surface was threefold more disorganized than that of controls; mean disorganization values (DVs) were respectively 3.04 (IQR = 0.21–7.25) in HPP vs. 1.0 (IQR = 0.07–2.53), ($P < 0.0001$). Moreover, the pattern of disorganization of the periosteum was distinctly (threefold) more irregular (Figure, top panel). Bone material was markedly ($\sim$ threefold) more disorganized in HPP; mean DVs ($\pm$ SEM) were 3.17 1.1(IQR = 2.37–4.03) in HPP vs. 1.1(IQR = 0.83–1.14) in controls, respectively $P < 0.0001$). Noticeably, there were many random tiny areas with excessively high DVs. They allowed us to identify relatively transverse subtle bands (barely visible unless detected by the tool). These bands were either small lucent lines suggestive of micro (early-stage) fractures, or opaque lines corresponding to micro-sclerosis. No strikingly disorganized areas were detected in controls (Figure, left lower panel).



Conclusion: Abnormal bone disorganization can be quantified from readily available X-ray images as a biomarker to identify HPP patients. This may offer a path for an easy, early routine identification of HPP patients in clinical and research settings. Detection of microfractures (early stage) offers the opportunity for early intervention which may revolutionize HPP treatment. Larger studies are underway.

P1137 UREMIC TOXIN INDOXYL SULFATE INDUCES CHONDROCYTE SENESCENCE AND IRON-DEPENDENT FERROPTOSIS

S.-H. Liu[1], R.-S. Yang[1], Y.-P. Chung[1]

[1]National Taiwan Univ., Taipei, Taiwan

Objective: Indoxyl sulfate (IS) is a proteophilic urotoxic substance whose accumulation is associated with decreased renal function. Patients with kidney disease who undergo dialysis often experience symptoms, such as joint pain and osteoporosis, which may be caused by IS-induced abnormal bone metabolism and even senescence-mediated bone abnormalities. Ferroptosis is an iron-dependent cell death process, which the increased oxidative damage is believed to be closely related to senescence. Although IS may induce abnormal bone turnover or joint disease, its effects on articular chondrocytes remains unclear. Here, we investigated the effects and mechanisms of IS on human chondrocytes in vitro.

Methods: Human chondrocytes were cultured and treated with 0.1–1 mM of IS to analyze cell viability, senescence-related proteins, and senescence-associated beta-galactosidase (SA-β-gal). We also analyzed iron accumulation, antioxidant systems, and lipid peroxidation, which were key factors in ferroptosis. Deferoxamine (DFO), an iron chelator, was used to explore the role of iron or iron-dependent ferroptosis.

Results: IS at the concentrations of 0.1 and 0.3 mM, which were no apparent cytotoxicity, significantly increased the senescence-related proteins (p16, p53, and p21) and SA-β-gal activity. Furthermore, we observed an accumulation of total intracellular iron ion content, an increase in iron uptake-related proteins transferrin receptor (TFR)/divalent metal transporter-1 (DMT1), a decrease in endogenously antioxidant proteins system Xc^- (xCT)/glutathione peroxidase 4 (GPX4), and an increase in reactive oxygen species and

malondialdehyde. Finally, DFO treatment significantly reversed the key factors of ferroptosis and reduced senescence in IS-treated chondrocytes.
Conclusion: IS leads to iron-dependent cell death through TFR/DMT1 activation and subsequent iron influx in chondrocytes, as well as inhibition of the antioxidant system and induction of chondrocyte senescence. These results provide new insight and possible therapeutic direction into the effects of IS on joints.

P1138
INVESTIGATING THE CORRELATIONS BETWEEN HYPERTENSION, HYPERLIPIDEMIA, HYPERGLYCEMIA, LOW BONE DENSITY AND LOW MUSCLE MASS

K.-P. Lin[1], D.-C. Chan[1], W.-J. Huang[1], C.-J. Wen[1], T.-H. Yang[2], R.-S. Yang[3]

[1]Dept. of Geriatrics and Gerontology, National Taiwan Univ. Hospital, Taipei, [2]Dept. of Orthopedics, NTU BioMedical Park Hospital, NTUH Hsin-Chu Branch, HsinChu, [3]Dept. of Orthopedics, National Taiwan Univ. Hospital, Taipei, Taiwan

Objective: The proportion of elderly people in Taiwan reached 14% (aging society) since 2018 and is projected to 20% (super-aged society) by 2025. The most critical health issues for the elderly population include the "3 H" (hypertension, hyperlipidemia, hyperglycemia) and "2 L" (low bone density and low muscle mass). These conditions may have comorbidities or mutually influencing factors.
Methods: A total of 379 patients aged 65 and above with "3 highs", and patients aged between 20 and 64 with diabetes were enrolled. Participants will be categorized into four groups: "Robust," "Pre-sarcopenia," "Dynapenia," and "Sarcopenia". Exploratory analysis between muscle health and "3 H" as well as low bone mass were reported.
Results: The mean age for the entire cohort was 65.4 ± 14.3 y, with 49.1% female. The baseline characteristics of 4 groups were shown in the following Table.

	Robust (N=161)	Pre-sarcopenia (N=21)	Dynapenia (N=169)	Sarcopenia (N=28)	
Age	60.6±12.8	57.8±17.1	70.7±13.3	66.0±14.7	P<0.05
Weight	69.0±13.2	60.0±10.0	65.8±13.3	54.7±8.9	
Waistline	86.4±9.8	77.7±10.2	89.0±11.6	77.8±9.3	
DBP[a]	82.4±11.8	82.1±10.5	78.0±12.9	78.9±9.6	
TG[b]	126.9±70.4	102.2±59.7	128.7±59.7	111.4±69.5	
T-CHO[c]	166.2±33.1	192.5±91.8	168.8±35.5	171.7±32.9	

a. Diastolic blood pressure
b. Triglycerides
c. Total-cholesterol

Comorbidities including hypertension, cerebrovascular disease, cardiovascular diseases, kidney diseases, dyssomnia, neurodegenerative disorders, and osteoporosis showed statistically significant differences among four groups ($p < 0.05$). The BMD T-score of femoral neck and total hip were significant lower in "Dynapenia" and Sarcopenia" groups ($p < 0.05$).
Conclusion: Participants with low skeletal muscle mass were lighter and had smaller waistline and lower TG. Participants with low muscle strength or physical performance had larger waistline, lower DBP, and lower BMD.

P1139
FREQUENCY OF OSTEOPOROSIS IN A SOUTH AMERICAN MALE COHORT OF THE SIXTH DECADE

S. A. Blanco[1], J. Sanabria[1], L. A. Dulcey[1], J. A. Gomez[1], E. Y. Gutierrez[1], A. P. Lizcano[1], J. A. Garcia[1], L. C. Bacca[1], A. Suarez[1], M. S. Figueroa[1]

[1]Autonomous Univ. of Bucaramanga, Bucaramanga, Colombia

Objective: To determine the frequency of osteoporosis in men over 50 years old, as well as related risk factors found in a sample from a South American country.
Methods: An observational, cross-sectional, randomized study was conducted on 75 men over 50. During the study, it was performed medical history evaluations, physical exams, anthropometric measurements, and blood tests. Additionally, BMD of the femoral neck and lumbar spine was measured using DXA. The BMD values were expressed as mean mineral density (g/cm^2), bone mineral content (g), and percentage loss (%). Based on the T-score, it was diagnosed with osteoporosis (T-score ≤ -2.5 DS), osteopenia (T-score between -2.5 and -1.5), and normal BMD (T-score > -1.5). The FRAX tool was used to calculate the 10-y risk of osteoporotic fracture.
Results: The average age of participants was 61.15 ± 7.78 y. Based on BMD, it was found that 44% had regular BMD, 42.7% had osteopenia, and 13.3% had osteoporosis (with 60% of osteoporosis cases being lumbar). Individuals with osteopenia and osteoporosis had significantly lower weight, BMI, and waist circumference compared to those with normal BMD. The main risk factors identified were smoking, sedentary lifestyle, and alcohol consumption, with no significant differences between groups. Total testosterone and hypogonadism scores were similar between groups. As expected, BMD and T-scores of the femur and spine were lower in the osteopenia and osteoporosis groups ($p < 0.001$), and FRAX scores were higher in those groups as well ($p < 0.001$).
Conclusion: In the population under study, it was found that 13.3% of individuals had osteoporosis, and 42.7% had osteopenia. Notably, there were no significant associations observed between classic osteoporosis risk factors and the occurrence of these conditions, except for lower adiposity. Furthermore, no secondary causes were identified. These results emphasize the necessity for further research into the risk factors and underlying causes of osteoporosis in males.

P1140
DIAGNOSIS OF OSTEOPOROSIS IN A SOUTH AMERICAN COHORT IN THE POSTMENOPAUSAL PERIOD

S. A. Blanco[1], J. Sanabria[1], L. A. Dulcey[1], J. A. Gomez[1], E. Y. Gutierrez[1], A. P. Lizcano[1], J. A. Garcia[1], L. C. Bacca[1], A. Suarez[1], M. S. Figueroa[1]

[1]Autonomous Univ. of Bucaramanga, Bucaramanga, Colombia

Objective: To characterize the sample studied according to type of menopause; to evaluate BMD characteristics and prevalence of alterations; to determine dependence between age and BMD; and to identify 10-y osteoporotic fracture risk in late and surgical postmenopausal patients.
Methods: A retrospective, observational, descriptive, longitudinal study was conducted from January 2017 to December 2019. It included 1,019 postmenopausal female patients, excluding premenopausal patients, incorrectly positioned patients, whole body scans, extremity scans, and operated vertebral column scans from the original 1992 bone densitometry tests. BMD was assessed using DXA and WHO criteria. The FRAX software calculated the 10-y fracture risk. Statistical analysis contained frequencies, percentages, means,

and standard deviation. Chi-square was used for contingency tables with a significance level of 95% and $p < 0.05$.

Results: Most patients had natural menopause (86%), and the rest had post-surgical menopause (14%). Inside the natural menopause group, 8.1% had primary ovarian insufficiency, 12.4% had early menopause, 61.1% had spontaneous menopause and 4.4% had late onset. BMD was normal in 22.5%; low in 54.96%; and osteoporotic in 22.57%. In primary ovarian insufficiency, osteopenia occurred in 55.4% and osteoporosis in 19.3%; alterations peaked at ages 35–39. In early menopause, 50.8% had osteopenia, and 25.4% had osteoporosis. In spontaneous menopause, 57.1% had osteopenia, and 20.1% had osteoporosis; osteoporosis was more frequent in late menopause (31.1%) than early (25.4%) or spontaneous (20.1%) menopause. In post-surgical menopause, the high 10-year vertebral fracture risk was 60.86%, and the hip fracture risk was 6.29%; in late-onset, it was 46.66% for the vertebral column and 8.88% for the hip. A significant increase in the risk of osteoporotic fracture in the vertebral column with age was observed.

Conclusion: Low BMD is highly prevalent in postmenopausal women, especially osteopenia (54.96%). Surgical and late menopause have a 30% frequency of osteoporosis. FRAX reveals a high spine fracture risk in surgical and late menopause, eight times more common than hip fractures. Evaluation of fracture risk and BMD is recommended in menopausal women for timely prevention and treatment.

P1141
SEVERE INFLAMMATORY MYOPATHIES PATTERN

S. Abdellaoui[1], S. Lefkir-Tafiani[1]

[1]Issad Hassani Beni Messous Hospital, Algiers, Algeria

Objective: Inflammatory myopathy (IM) have experienced in recent years, in addition to adaptation of classification according to discovery of antibodies, a better physiopathological knowledge as well as a better understanding of "severe" phenotype of the disease. Objective study is to define severe myopathy pattern and thus to establish severity factors of the disease by comparing 2 populations of myositis: non-severe myositis (NSM) and severe myositis (SM).

Methods: This is a multicenter analytical descriptive study on 50 patients with myositis (20 dermatomyositis, 25 SAS, 4 NMAI and 1 IM) followed over 70 months. 2 populations of non-severe form (NSM) vs. severe form (SM) were compared prospectively according to the appearance or not of predictive signs of severity over time.

Results: Average age of SM forms was 50 y vs. 45 y NSM ($p = 0.024$) with a tendency towards a faster mode of installation in SM. Clinically, skin involvement was more frequent (machinists' hands, Raynaud's, necrosis, DM signs) in SM at 72% vs. 64% ($p = 0.12$). Muscle damage were more frequent in SM at 90 vs. 77% ($p < 0.01$). Lung involvement was found in 52 vs. 26% in NSM ($p < 0.01$) with a predominance of interstitial lung disease with basal and subpleural condensations, common pneumonia, forms of presence of a restrictive syndrome without ILD showing of a probable association of diaphragmatic damage and probably existence of HTAP. ANA was more frequently positive in SM forms 90 vs. 70% with specific antibodies MDA5 and PL7 and PL12 which dominate severe forms. During follow-up, SM forms presented 50 vs. 20% relapses ($p < 0.01$), more pleuropulmonary superinfections (35 vs. 12% $p = 0.03$), and more concomitant cancers.

Conclusion: Prospective monitoring over time of IM made it possible to identify predictive factors for severity and poorer survival: sudden onset, severity of skin/muscle and pulmonary involvement, seropositivity of myositis would be more associated with SM. This would encourage us to be more vigilant and prevent occurrence of severe phenotype further upstream.

P1142
DENSITOMETRIC GAIN UNDER ZOLEDRONATE: ILLUSION OR REALITY?

S. Abdellaoui[1], B. Bengana[1], S. Lefkir-Tafiani[1]

[1]Issad Hassani Beni Messous Hospital, Algiers, Algeria

Objective: Osteoporosis is the most common demineralizing osteopathy, its seriousness lies in increased risk of fracture which can have consequences on morbidity and mortality, particularly following cortical weakening. Several treatments have been clinical studies subject on demineralization prevention. This study is to analyze densitometric gain after treatment with zoledronate over 3 y in osteoporotic population and to identify predictive factors of better gain.

Methods: Prospective single-center study on 156 patients diagnosed with osteoporosis on BMD according to a T-score < -2.5 at the spine and/or femoral neck and treated with 3 infusions of zoledronate. A comparison of T-scores was carried out by comparing BMDs evolution (BMD1 before zoledronate initiation and BMD2 after 3 y of treatment). A rheumatological investigation including: clinical, bone densitometric, and therapeutic data (vitamin D supplementation and/or taking previous preventive treatment) was carried out. Note that no patient received another therapeutic class apart from bisphosphonates before zoledronate.

Results: We collected 156 patients (144 women vs. 12 men) with an average age of 71.33 y. BMD1 at spine found a T-score of—3.34 (0.634) and -2.21(0.567) at femoral neck vs. BMD2 found a T-score of—2.60 (0.640) at spine and -1.87(0.603) at proximal femur, i.e. a BMD gain of 2% at the spine and 1.5% at the hip. Concerning osteoporosis subgroups analyses, densitometric gain was + 3.6% at the spine vs. + 1.5% at the hip for trabecular osteoporosis, 3.8% at spine vs. + 2.1% at hip for cortical osteoporosis and + 1.8% at spine vs. + 1.2% at hip for osteoporosis at the 2 sides. Concerning of the subpopulation analyse having worsened final T-score at hip (persistence T-score low < -2.5) with a T-score at -2.9 and 0.524 mg/cm^2 of BMD at 3 y. It is made up of 27 patients (including 12, 2 and 10 trabecular, cortical and mixed osteoporosis) which increases the incidence of fractures with 22 incident fractures recorded (75% vertebral fractures). Therefore, this population should be monitored closely and either a change in therapeutic class, or addition of 3 other infusions of zoledronate or a therapeutic holiday should be proposed. Age over 65 y, female gender, history of taking alendronate, vitamin D supplementation were found to be predictive of a better densitometric gain with non-significant difference.

Conclusion: Most patients showed a gain in BMD over 3 y; vitamin D supplementation, female gender, taking previous preventive treatment and age > 65 y seemed to be predictive of a better gain. Analysis of the reduction in fracture risk would also be interesting to research in this population.

P1143
15-PROSTAGLANDIN DEHYDROGENASE EXPRESSION AND FUNCTION IN CARTILAGE TISSUE

S. Alsabri[1], M. Najar[1], M. Benderdour[2], J.-P. Pelletier[1], J. Martel-Pelletier[1], H. Fahmi[1]

[1]Osteoarthritis Research Unit Centre de Recherche du Centre Hospitalier de l'Université de Montréal (CRCHUM), [2]Orthopedics Research Laboratory, Research Center, Hôpital du Sacré-Cœur de Montréal, Université de Montréal, Montreal, Canada

Objective: Osteoarthritis (OA), is the most common form of joint disorder. It is differentiated by synovitis (synovial membrane inflammation), progressive cartilage degradation, subchondral bone remodeling, and discomfort. 15-hydroxyprostaglandin dehydrogenase (15-PGDH) is responsible for the catabolism of PGE2, which has been implicated in the regulation of inflammation and cartilage biology. The purpose of this study was to look at the expression and function of 15-PGDH in cartilage tissue.
Methods: Real-time reverse transcriptase-polymerase chain reaction (RT-PCR), immunoblotting, and immunohistochemistry were used to examine the expression of 15-PGDH mRNA and protein in cartilage. IL-1 was used to activate chondrocytes. Real-time RT-PCR and western blotting were used to assess the expression of 15-PGDH, and the impact of 15-PGDH activity in the expression of important inflammatory genes was investigated using 18-Glycyrrhetinic Acid, an inhibitor of 15-PGDH.
Results: Low levels of 15-PGDH in OA tissues show that the disease may arise as a result of decreasing amounts of the protein, which is expressed in both human and mouse cartilage. In human OA chondrocytes, IL-1β treatment downregulated the mRNA and protein expression of 15-PGDH. Additionally, we demonstrated that treatment with 18 βGA, an inhibitor of 15-PGDH activity, upregulated the expression of important inflammatory genes in cartilage, such as iNOS, COX-2, and mPGES-1, and downregulated the expression of the primary anabolic genes, type II collagen and aggrecan.
Conclusion: All of these findings point to the role of 15-PGDH in the etiology of OA. Additionally, they propose that focusing on 15-PGDH expression and/or activity might represent a unique anti-OA treatment that involves precise PGE2 level regulation.

P1144
ROLE OF EPIGENETIC REGULATION AND SP1 TRANSCRIPTION FACTOR ON DP1 RECEPTOR EXPRESSION IN OSTEOARTHRITIS

S. Alsabri[1], H. Fahmi[1]

[1]Osteoarthritis Research Unit Centre de Recherche du Centre Hospitalier de l'Université de Montréal (CRCHUM), Montreal, Canada

Objective: Osteoarthritis (OA) is the most common form of musculoskeletal disease and a major cause of long-term disability with a significant socioeconomic impact. The primary clinical signs of OA include joint pain, stiffness, and a restricted range of motion. Age, obesity, joint damage, poor knee alignment, and genetics are identified as risk factors for OA, and the main pathological characteristics of OA include the cartilage progressive degeneration, synovium inflammation, and subchondral bone sclerosis. The prostaglandin D2 receptor, D prostanoid receptor 1 (DP1), is essential for modulating inflammation and cartilage metabolism. Our previous findings demonstrated that DP1 signalling is protective against OA in mice and downregulates catabolic responses in cultured chondrocytes. Nonetheless, little is known about the DP1 transcriptional regulation mechanisms in cartilage. The aim of this study was to characterize the human DP1 promoter and investigate how DNA methylation affects DP1 expression in chondrocytes. Furthermore, we assessed the methylation state and expression level of the DP1 gene promoter in both normal and OA cartilage.
Methods: A minimal promoter region (-250/-120) containing three binding sites for specificity protein 1 (Sp1) was identified by deletion and site-directed mutagenesis analyses. Electrophoretic mobility shift assays (EMSA) and chromatin immunoprecipitation (ChIP) were used to confirm the binding of Sp1 to the DP1 promoter.
Results: Both DP1 mRNA expression and DP1 promoter activity were reduced by treatment with the Sp1 inhibitor mithramycin A. Treatment with DNA methylation inhibitor, 5-Aza-2'-deoxycytidine, upregulated DP1 expression, and the DP1 promoter activity was reduced in the in vitro methylation. There was no difference in the methylation status of the DP1 promoter or the level of DP1 expression between normal and OA cartilage.
Conclusion: Our findings suggest that DNA methylation and the transcription factor Sp1 are important determinants of DP1 transcription regulation. Furthermore, they suggest that OA cartilage does not exhibit changes in the methylation status or expression level of DP1. These results will advance our knowledge of the DP1 transcription regulatory mechanisms and could help design DP1-related intervention tactics.

P1145
ROLE OF DNA METHYLATION ON 15-LIPOXYGENASE-1 GENE EXPRESSION IN OSTEOARTHRITIS

S. Alsabri[1], H. Fahmi[1]

[1]Osteoarthritis Research Unit Centre de Recherche du Centre Hospitalier de l'Université de Montréal (CRCHUM), Montreal, Canada

Objective: Osteoarthritis (OA) is the most prevalent type of arthritis and a major contributor to physical impairment with a significant financial impact. OA. Pain, stiffness, and a restricted range of motion are the primary signs and symptoms of OA. Genetics, age, obesity, joint damage, and knee malalignment are risk factors for OA. Numerous anti-inflammatory and immunomodulatory lipid mediators are produced by 15-lipoxygenase-1 (15-LOX-1), which has been shown to have protective effects against a number of inflammatory diseases, including OA. The purpose of this study was to assess the expression of 15-LOX-1 in the cartilage of OA patients and normal donors, as well as to ascertain whether DNA methylation controls this expression.
Methods: Cartilage samples were collected from both OA-affected at the time of total knee replacement surgery, and normal knee joints during autopsy. Real-time polymerase chain reaction (PCR) was used to assess the expression of 15-LOX-1. Using 5-Aza-2'-desoxycytidine (5-Aza-dC), a DNA methyltransferase inhibitor, the significance of DNA methylation in 15-LOX-1 expression was evaluated. Using a CpG-free luciferase vector, the impact of CpG methylation on the activity of the 15-LOX-1 promoter was assessed. Pyrosequencing was used to ascertain the 15-LOX-1 promoter's DNA methylation status.
Results: Compared to healthy cartilage, OA showed increased expression of 15-LOX-1. 15-LOX-1 mRNA levels were upregulated in chondrocytes treated with 5-Aza-dc, and 15-LOX-1 promoter activity was downregulated in vitro through methylation. The methylation status of the 15-LOX-1 gene promoter did not differ between cartilage from normal and OA cartilage.
Conclusion: In OA cartilage, there was an increased expression level of 15-LOX-1, which might be related to a healing process. The methylation status of 15-LOX-1's promoter was not linked to its upregulation in OA cartilage, indicating that alternative mechanisms may be at play.

P1146
UTILITY OF EDUCATIONAL VIDEO IN IMPROVING AWARENESS OF BONE HEALTH IN PRE-SCHOOLS AND PRIMARY SCHOOL AGED CHILDREN AND EDUCATORS IN SINGAPORE

L. Gani[1], E. Chen[2], J. Pang[3], S. Kamas[4], C. Low[4], S. B. Ang[5], S. B. Chionh[6]

[1]Changi General Hospital, [2]Kandang Kerbau Women's and Children's Hospital, [3]National Univ. Hospital, [4]Health Promotion Board, [5]Kandang Kerbau Women's and Children's Hospital, [6]National Univ. Hospital, Singapore, Singapore

Objective: The foundation of skeletal health begins as early as in utero with majority of bone mass gained in childhood and adolescence. It is estimated that a 10% increase in peak bone mass would delay the onset of osteoporosis by 13 years in women 1–4. Thus, optimizing factors that would help in achieving peak bone mass would assist in the primary prevention of osteoporosis. In this study, we piloted an educational video in the preschool and primary school population to assess its effectiveness in increasing awareness of bone health and activity.
Methods: A team of doctors, dietician and physiotherapist worked together to create an educational video to increase awareness of bone health. Major theme incorporated included 1. The importance of strong bones and growth of bones in children; 2. The role of adequate calcium in healthy diet; 3. The importance of exercise in bone health. The educational video was piloted in Singapore from June to September 2022. The video was created in animated format to allow greater appeal to younger children. Teacher's activities deck along with suggestions of learning points are also shared with the various schools and pre-school institutions. The work was conducted with the collaboration of the Health Promotion Board (HPB), Singapore. Feedback on the educational video are also collected at the end of the pilot period.
Results: Over a period of 3 months, publicity was conducted in 1800 preschools and 170 primary schools. Feedbacks were received from 10 primary schools and 24 pre-school centres. The educational video was also hosted on YouTube and received over 1800 views. Over 5000 students were reached based on the feedback given by the schools. The feedback found that 88% of the users found the resources were useful with age appropriate content. There was very high level of satisfaction with 91% stating satisfaction level scale of 4–5. Majority of feedback was obtained from the kindergarten 1 and 2 and primary levels 1–4. 77% found that the resources were easy to use.
Conclusion: An animated educational health video with appealing design and simple contents is an easily administered tool and effective in increasing awareness of bone health. Hosting the video on you tube also allowed greater outreach to those beyond the schools. Further follow up is needed to ascertain the effectiveness of this educational tool in changing overall health behaviours and its long-term impact on bone health in Singapore.

SPONTANEOUS AND INDUCED MONOCYTE EXTRACELLULAR TRAPS FORMATION IN OSTEOARTHRITIS PATIENTS

S. Bedina[1], E. Mozgovaya[2], S. Spitsina[3], E. Zagorodneva[4], N. Krayushkina[4], A. Trofimenko[2], M. Mamus[2]

[1]Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky; Volgograd State Medical Univ., [2]Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky, [3]Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky; Volgograd State Medical Univ., [4]Volgograd State Medical Univ., Volgograd, Russia

Objective: Evaluation of peripheral blood monocytes' ability to generate ET spontaneously and after induction in vitro in osteoarthritis (OA).
Methods: The research was carried out in agreement with the WMA Declaration of Helsinki principles. Monocytes were purified with centrifugation procedure using originally designed iohexol density gradients [1, 2]. The cell types in the resulting fractions were identified histochemically, and the extent of cell activation was assessed using common nitro-blue tetrazolium test. Generation of ETs was stimulated by phorbol-12-myristate-13-acetate (PMA). The shape and size of ETs were assessed using fluorescence microscopy with SYBR green [3].
Results: 23 patients with verified OA (6 males and 17 females, mean age 5.4 y, mean disease duration 12.5 y). 30 healthy volunteers were enrolled as a reference group. OA patients were in clinical remission at the inclusion timepoint. Indicators of the yield of isolated cells, purity of cell fractions, viability and nonspecific activation of monocytes in the control group were comparable to those of the same name in healthy individuals. Mean contamination of the monocytic fraction both in the reference group and in the OA patients in did not exceeded 4%. Spontaneous and induced ET formation by isolated monocytes in patients with OA during exacerbation is significantly higher than in OA in remission and in the reference group ($p < 0.05$). The growth rate of spontaneous ET formation was 89.9%, induced ET formation—39.2%. The growth rate of spontaneous NET formation is 2.3 times higher than the induced ET formation.
Conclusion: We have revealed enhanced spontaneous and induced ET formation by monocytes from OA patients, suggesting that circulating monocytes may be primed to ETosis through immune inflammation.

FEATURES OF NETS FORMATION IN RHEUMATOID ARTHRITIS PATIENTS

S. Bedina[1], E. Mozgovaya[2], S. Spitsina[3], A. Trofimenko[2], I. Shushkova[4], V. Pavlovskaya[4], M. Mamus.[2]

[1]Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky; Volgograd State Medical Univ., [2]Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky, [3]Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky; Volgograd State Medical Univ., [4]Volgograd State Medical Univ., Volgograd, Russia

Methods: 39 RA patients made up the main group, 33 healthy individuals—the control group. Circulating neutrophils were isolated with one-step density gradient centrifugation using double layers of iohexol gradient [1, 2]. The cell types in the resulting fractions were identified histochemically, and the extent of cell activation was assessed using common nitro-blue tetrazolium test. NETs were induced by phorbol-12-myristate-13–acetate (PMA). NETs were visualized by fluorescence microscopy [3].
Results: RA disease activity at the inclusion timepoint shouldn't exceed 2.6 DAS28 points. In 17 RA patients, an increase in DAS28 > 3.2 points exacerbation was diagnosed during the study. The mean percentage of spontaneous and induced NETs was 3.8

(2.6–5.0) and 12.2 (9.0–15.4)% in the reference group, respectively; 5.9 (5.6–6.2) and 26 (23.9–28.1)% of inactive RA patients, 16.6 (16.1–17.1) and 38.0 (36.6- 39.4)% of active RA patients, respectively. Increase in spontaneous NETs during RA activation—181.4%, induced—46.2%. Analysis of the main components of NETs in Ra patients revealed MPO, histone H3 and citrullinated epitopes. Citrulline epitopes were found in 88% of RA patients.

Conclusion: The transition of RA from a state of remission to active inflammation is accompanied by a significant increase in NETs formation, especially spontaneous. The predominance of citrullinated epitopes in NETs demonstrates their influence on the induction and maintenance of an autoimmune response to RA-specific autoantigens.

P1149
CHONDROITIN SULFATE CONJUGATED SOLID LIPID NANOPARTICLES FOR TREATMENT OF OSTEOARTHRITIS

S. Bhargava[1], M. Bhargava[2]

[1]Signa College of pharmacy, [2]GTB Hospital, Kanpur, India

Osteoarthritis (OA) is also known as degenerative joint disease and it is characterized by degradation of joints, including articular cartilage and subchondral bone. OA commonly affects the hands, feet, spine and the large weight bearing joints such as the hips and knees.

Intra-articular drug delivery belonging to the symptom-modifying osteoarthritis drug family is compromised by the presence of a highly efficient lymphatic system that rapidly eliminates molecules from the synovial cavity, frequent dosing, adverse side effects and patient discomfort in the management of OA.

This research work reports the development and characterization of aceclofenac loaded chondroitin sulfate (CS) conjugated (CS-SLN) and unconjugated solid lipid nanoparticles (SLN) for the effective management of OA.

The SLNs were prepared using modified solvent injection method and then conjugated with CS using carbodiimide chemistry which was confirmed using IR and NMR spectroscopy. They were further characterized for surface charge, size and size distribution, zeta potential, particle shape and surface morphology by transmission and scanning electron microscopy, %entrapment efficiency and in vitro drug release profile. Anti-inflammatory activity and in vivo studies were performed which included estimation of drug in serum and various organs.

The particle size of the SLN and CS-SLN was found to be 143.4 ± 0.9 nm and 154.2 ± 1.1 nm, respectively. SLNs exhibited sustained drug release in-vitro for > 24 h. In vivo performance studies revealed the highest uptake of SLNs by the knee joint. Plain drug solution inhibited MIA-induced edema effectively upto 4 h, SLN upto 8 h and CS-SLN upto 12 h due to sustained release behavior. These results provide evidence for the site-specific targeting of the therapy to the site of inflammation.

SLNs enhanced accumulation at the knee joint due to specific interactions with CD44, annexin and leptin receptors attributed to CS coupling. CS-SLN could be potentially effective vector for the treatment or management of OA.

P1150
SOLID LIPID NANOPARTICLES FOR EFFECTIVE MANAGEMENT OF PSORIASIS

S. Bhargava[1], M. Bhargava[2]

[1]Signa College of pharmacy, [2]GTB Hospital, Kanpur, India

Psoriasis is characterized as chronic, recurring, genetically determined, immune-mediated inflammatory skin disease characterised by scaly patches due to excessive skin production. Skin rapidly accumulates at the site of onset and takes a silvery white appearance which erodes with excessive itching. To design and develop novel particulate carrier loaded with antipsoriatic drug (dithranol) for safe, efficient and constant delivery for radical cure of psoriatic plague. Solid lipid nanoparticles (SLN) have emerged as an alternative to liposomes due to various advantages such as improved physical stability, low cost compared to phospholipids and ease of scale-up and manufacturing.

Solid lipid nanoparticles are special lipid aggregates that can penetrate efficiently and retain in to the skin. The SLN were prepared by solvent injection method. Drug loaded SLN's were characterized in vitro for their shape, size, percent antigen entrapment and stability. The mean particle size was determined by photon correlation spectroscopy (PCS) using a Malvern Zetasizer. Scanning electron microscopy and transmission electron microscopy was performed.

The amount of entrapped antigen was determined after removal of unentrapped antigen. Recovered fractions were challenged with triton X-100 (0.2%, v/v) and amount of drug was determined using BCA method. In vivo studies constituted of quantitative estimation of drugs in different skin layers by Tape stripping method, Skin irritation studies by Draize patch test and fluorescence microscopy was carried out to confirm the uptake of SLNs. SLNs formed were multilamellar and were found to be stable in gastric and intestinal fluids.

Fluorescence microscopy suggested that SLNs were taken up by gut associated lymphoid tissues. Encapsulation of dithranol in SLN resulted in dramatic improvement in its stability. SLN based gel resulted in remarkably less erythematic episodes as compared to plain drug based gel. Enhanced accumulation of dithranol via SLN within the skin might help to optimize targeting of this drug to the epidermal and dermal sites.

P1151
VARIATIONS OF MUSCULOSKELETAL PAIN IN CONTEXT OF INFLAMMATORY JOINT DESEASES OR COVID-19 PATIENTS

S. Bogdanova-Petrova[1], T. Shivacheva[1], S. Dimitrov[1], R. Moraliyska[2], S. Hristova[2], G. Gerganov[2], Z. Apostolova[1], M. Markov[2], T. Georgiev[1]

[1]Medical Univ. Varna, First Dept. of internal diseases, [2]Medical Univ. Varna, Varna, Bulgaria

Objective: To assess the intensity of arthralgia and myalgia and its correlation with inflammatory biomarkers and anxiety and depressive mood disorders. The study group is a Bulgarian cohort of patients with chronic inflammatory joint diseases (IJD) or patients with COVID-19.

Methods: A single-center, observational study including two cohorts – patients with IJD (RA, AS and PsA), observed in the Rheumatology clinic, "St. Marina" UMBAL – Varna and patients with moderate or severe COVID-19 hospitalized at the COVID-19 rheumatology department. First cohort were patients with chronic, and the second

cohort were patients with acute musculoskeletal pain onset. We used visual analogue scales (VAS) to assess pain intensity for muscular and joint pain and Zung self-report scales for depression (SDS) and anxiety (SAS). Inflammatory markers were investigated in all patients. Descriptive statistics, one-sample T test, correlation and linear regression analyses were used. A significance level of $p < 0.01$ was accepted.

Results: The total participants number included in the study was 364 patients -130 with IJD and 234 with COVID-19 (35.7 vs. 64.3%). Evaluating the VAS for assessing joint and muscle pain according to gender, we found that women with COVID-19 experience more pain—both joint and muscle, but no significant differences between men and women were found in the cohort with IJD. Women scored higher on the anxiety and depression scales in both cohort patients, and the difference was again significant. Patients with COVID-19 had higher depression and anxiety rates than patients with IJD which correlated with age and gender. Depression and anxiety determine half of the variation of musculoskeletal pain in patients with COVID and far less for patients with IJD. On the other hand, inflammatory indicators (predictors) determine about 8% of the variation of the two pain indicators in patients with IJD and much less in COVID-19 population.

Conclusion: Musculoskeletal pain is one of the most common clinical presentations in large variety of diseases. The intensity of the pain correlates more with anxiety and depressive symptoms compared to inflammatory markers in this cohort of patients.

P1152
LOW BACK PAIN IN REMOTE WORK ENVIRONMENTS IN TUNISIA

S. Bouden[1], S. Mhamdi[1], S. Loukil[1], L. Rouached[1], A. Ben Tekaya[1], I. Mahmoud[1], R. Tekaya[1], O. Saidane[1], L. Abdelmoula[1]

[1]Rheumatology Dept., Charles Nicolle Hospital, Tunis, Tunisia

Objective: To estimate the prevalence of low back pain (LBP) in remote workers in Tunisia, and to identify the main contributing factors.

Methods: We conducted a cross-sectional study that included individuals who voluntarily responded to an online survey. Participants responded anonymously to a self-administered questionnaire on musculoskeletal disorders during remote working (RW).

Results: 112 individuals were included. Among them, 57 were women and 55 were men. The average age was 33.5 ± 8.8 y. The average BMI was 24.8 ± 3.3 kg/m^2. Our participants have been performing in RW for an average of 15.1 ± 5.5 months. Twenty-four percent (n = 27) received training on ergonomic measures, and 21 individuals among them applied these measures. The average daily working hours were 7.2 ± 2.4. It should be noted that 46.4% (n = 52) reported working more than 10 h/d at least once a week. The average number and duration of breaks per day were 4 ± 2 breaks and 79 ± 50 min respectively. The average stress level on a scale of 10 was 5.6 ± 2.4. 34% of participants (n = 38) had a physical activity, with an average duration of 3.8 ± 2.6 h/week. LBP was present in 56.3% (n = 63) of respondents. A positive association was observed between LBP and the age ($p = 0.02$), the number of hours of RW per day ($p = 0.02$), and the number of days of RW per week ($p = 0.019$). LBP was also significantly more frequent among workers who work more than 10 h/d at least once a week ($p < 0.001$).

Conclusion: LBP in remote workers appears to be influenced by the workload in terms of hours and days. Measures to alleviate these factors are therefore required.

P1153
MUSCULOSKELETAL DISORDERS DURING TELEWORKING

S. Bouden[1], S. Loukil[1], S. Mhamdi[1], L. Rouached[1], A. Ben Tekaya[1], I. Mahmoud[1], R. Tekaya[1], O. Saidane[1], L. Abdelmoula[1]

[1]Rheumatology Dept. Charles Nicolles Hospital, Tunis, Tunisia

Objective: To assess prevalence of musculoskeletal disorders (MSDs) in teleworking employees and to identify the factors that may contribute to the onset or aggravation of these disorders.

Methods: We conducted an online survey involving individuals engaged in teleworking, a self-administered structured questionnaire developed through Google Forms was used to gather the necessary information. The prevalence of MSDs was assessed using the Nordic Questionnaire.

Results: A total of 112 employees (57 women (51%) and 55 men (41%)) were included in the study. The mean age was 34 y [21–60]. The mean duration of employment was 7 y [1–30] within their respective companies and 15 months [1–48] during teleworking. 22% of the workers were smokers. The mean BMI was 24 kg/m^2 [19–37]. 43% were engaged in physical exercise concurrently with teleworking. The mean working hours per day was 7 h [2–12]. 72 respondents (64%) reported not receiving any basic training on telecommuting regarding ergonomics and safety measures to set up their workspace. 52% were not satisfied with the home working environment. MSDs during teleworking were distributed as follow: neck (69%), back pain (56.3%), shoulders (53%), wrists and hands (38%). Factors that were significantly associated with elevated prevalence of MSDs were: long working hours ($p = 0.04$), extended period of telecommuting ($p = 0.02$), increase in stress level ($p = 0.04$) and low levels of satisfaction with the home workspace ($p = 0.02$).

Conclusion: Our study revealed a notable increase in self-reported MSDs among teleworking employees. Recognizing the factors is essential to design a prevention, through a holistic approach that includes ergonomic education, mental health support, and the creation of comfortable and conducive home workspaces.

P1154
JUVENILE IDIOPATHIC ARTHRITIS: CORRELATION BETWEEN DISEASE ACTIVITY AND BODY MASS INDEX

S. Bouzid[1], L. Kharrat[1], W. Lahmar[1], H. Ferjani[1], F. Majdoub[1], D. Ben Nessib[1], D. Kaffel[1], K. Maatallah[1], W. Hamdi[1]

[1]Dept. of Rheumatology, Mohamed Kassab Institute of Orthopedics, La Manouba, Tunisia

Objective: Juvenile idiopathic arthritis (JIA) is the most frequent rheumatic disease in children [1]. Delayed growth and nutritional deficiency are the most reported long-term complications of JIA [2]. This study aimed to investigate the relationship between BMI and disease activity in patients with JIA.

Methods: We conducted a retrospective study, including children with JIA meeting the ILAR 2010 criteria. For each patient, we collected the following data: age, JIA subtype, disease duration, extra-articular manifestations (EAM), ESR, and CRP level. Disease activity was assessed using the JADAS-10-ESR for all JIA subtypes and the JSpDA for related-enthesitis arthritis (ERA) and psoriatic arthritis subtypes. Age- and sex-specific BMI percentiles were calculated based on WHO growth standard charts and categorized into underweight ($P < 3$), normal weight ($3 \leq P \leq 85$), overweight ($85 < P \leq 97$) and obesity ($P > 97$).

Results: In total, 46 children were included, with a mean age of 13.34 ± 4.23 y. The male-to-female ratio was 1.42 (27/19). The mean age at the disease onset was 9.54 ± 3.91 y. The mean disease

duration of JIA was 4.04 ± 3.7 y. The JIA subtypes recorded were as follows: ERA in 52% (n = 24), oligoarticular in 15% (n = 7), polyarticular in 11% (n = 5), psoriatic arthritis in 10% (n = 4), undifferentiated in 6% (n = 3), and systemic-onset in 6% (n = 3). EAM were present in 5 patients (psoriasis (n = 1), uveitis (n = 4)). The mean JADAS-10-ESR and JSpDA were 9.21 ± 5.47 and 3.26 ± 1.65, respectively. The mean ESR and CRP levels were 31.08 ± 23.42 mm/h and 21.5 ± 28.65 mg/L, respectively. The mean weight was 44.70 ± 16.66 kg [13–77]. The mean BMI was 20.02 ± 4.89 kg/m^2 [13.75–31.2]. Underweight, normal weight, overweight, and obesity were noted in 13% (n = 6), 41% (n = 19), 17% (n = 8), and 28% (n = 13), respectively. The weight was negatively correlated with JSpDA (r = -0.469, p = 0.012). The BMI was significantly correlated with both CRP (r = -0.29, p = 0.05) and JSpDA (r = -0.423, p = 0.025). Underweight patients had significantly higher levels of JSpDA compared to patients with normal weight, overweight and obesity (p = 0.021). Patients without EAM had lower BMI (20.59 ± 4.89 vs. 16.09 ± 2.94, p = 0.038).

Conclusion: Our study showed that underweight patients had more severe disease features. Authors suggested that active disease seems to affect the child's appetite leading to cachexia [3]. Other studies are needed to confirm these results.

P1155
NIGHT WORK AND RISK OF CHRONIC WIDESPREAD PAIN AMONG OLDER WORKERS IN THE UK

S. D'Angelo[1], G. Bevilacqua[1], G. Ntani[1], E. Dennison[1], K. Walker-Bone[2], N. Fuggle[1]

[1]MRC-Lifecourse Epidemiology Centre, Southampton, UK, [2]Monash Centre for Occupational and Environmental Health, Monash Univ., Melbourne, Australia

Objective: Chronic widespread pain (CWP) is prevalent and often leads to disability and incapacity for work. Night work has been linked with adverse health outcomes including CWP. The effect of night work on CWP is likely due to disrupting sleep patterns often observed among night workers, however, evidence is scarce. Therefore, we aimed to describe the association between night work and CWP and explore whether this is explained by sleep problems in a population sample of UK older workers.

Methods: We used data from the Health and Employment After Fifty (HEAF) study, a cohort of men and women recruited from GP surgeries in 2013–14, when aged 50–64. Information on health, finances, lifestyle, and employment was collected annually over 5 years. Job characteristics included whether the job involved working at night (sometimes/often vs. rarely/never) and the level of physical work demands. Sleep problems were self-reported. CWP was defined according to the American College of Rheumatology criteria and was available from follow-up 2. Associations between frequency of night work at baseline and subsequent CWP were explored with multilevel Poisson regression with robust standard error before and after adjustment for sleep problems, lifestyle, socio-economic factors, depression self-rated health, and physical work demands.

Results: In total 4822 participants (52% women) working at baseline, were included in the analyses with a mean (SD) age 57.5 (4.1) y. At baseline, 11% reported at least some night work. Prevalence of CWP at 2 y of follow-up was 10% (13% among baseline night workers) and only varied minimally over follow-up. Sometimes/often working at night was associated with increased risk of CWP (IRR = 1.36; 95%CI:1.14–1.61). The association was attenuated but remained robust after adjustment for sleep problems and other confounders (IRR = 1.20; 95%CI:1.00 to 1.44).

Conclusion: Amongst older workers, night work increased risk of CWP which was independent of sleep problems and other confounders like socio-economic status, and the physical demands of the job. Understanding the mechanism connecting night working and CWP is crucial to reducing musculoskeletal pain in the workplace and supporting prolonged working lives for older individuals.

P1156
IMPACT OF LOW MUSCLE MASS ON CALCULATED URINE CALCIUM INDICES

S. A. P. Chubb[1], S. D. Vasikaran[1]

[1]PathWest-FSH, Murdoch, Australia

Objective: Calcium excretion in fasting spot urine is reported as calculated indices that are thought to reflect metabolism and renal handling of calcium. Spot urine calcium to creatinine ratio is reported to correct for hydration status (Ca/Cr). The "calcium excretion" (CaE) is further corrected for glomerular filtration and is useful for screening for familial hypocalciuric hypercalcaemia. After noting high Ca/Cr in 4 patients with severe muscle wasting conditions and low serum creatinine results, we sought to examine the impact of muscle mass (using serum creatinine as surrogate) on urine creatinine concentration and urine Ca/Cr as well as CaE.

Methods: Urine calcium indices were calculated in a series of cases with normal renal function and severe muscle wasting and in 690 consecutive female patients over 50 y of age with estimated glomerular filtration rate > 60 mL/min/1.73m^2 after exclusion of those with PTH below normal or above twice normal. Relationships between urine Ca/Cr and CaE with quintiles of serum creatinine were studied by Kruskal–Wallis test. P-values < 0.05 were considered significant. Statistics were performed on MedCalc, version 22.017.

Results: The 4 patients with muscle wasting had low serum creatinine between 16–30 μmol/L and high Ca/Cr of 0.86–4.77 (mol/mol). Among the patients with normal muscle mass and renal function, urine and serum creatinine concentrations were significantly associated (p = 0.042). Ca/Cr ranged from 0.02–1.54. There were significant differences in Ca/Cr between quintiles of serum creatinine (p < 0.001). The median Ca/Cr in serum creatinine quintile 1 was significantly higher than that in quintiles 3,4 and 5 (p < 0.05). The range of CaE was 1.2–104 mmol/L. There were no significant differences in CaE between quintiles of serum creatinine (p = 0.057) although the test for trend across groups was significant (p = 0.014).

Conclusion: A low serum creatinine (< 61 μmol/L in our study) is associated with low urine creatinine excretion, and may lead to a significant increase in calculated Ca/Cr and to a lesser extent, in CaE. This may have contributed to the high Ca/Cr seen in our patients with muscle wasting. Calculated urine calcium indices should be treated with caution in patients with very low muscle mass.

P1157
TEMPORAL PATTERN AND RISK FACTORS FOR POST-STROKE OSTEOPOROSIS: A MULTICENTER STUDY 2014–2023

H. Y. Lee[1], S. D. Yoo[2]

[1]Seoul National Univ. Hospital, Dept. of Rehabilitation Medicine, National Traffic Injury Rehabilitation Hospital, Dept. of Rehabilitation Medicine, Seoul, [2]Kyung Hee Univ. Hospital at Gangdong, Dept. of Physical Medicine and Rehabilitation, Kyung

Hee Univ., Dept. of Medicine (AgeTech-Service Convergence Major), Seoul, South Korea

Objective: Stroke can lead to bone loss and a higher risk of fractures, which significantly impact the health and survival of stroke survivors. Hence, early screening and proactive management of bone health should be prioritized during stroke rehabilitation. The aim of this study was to identify determinants associated with the occurrence of osteoporosis in individuals with hemiplegic stroke, with particular emphasis on exploring temporal pattern and potential effects of functional impairments in the development of osteoporosis.
Methods: This retrospective study analyzed a cohort of 758 stroke patients sourced from two distinct centers and regions within Korea. To identify risk factors associated with osteoporosis, baseline demographic characteristics and clinical parameters of stroke (i.e. muscle strength and spasticity of hemiplegic lower extremity, ambulatory level, balance, cognitive function, initial NIHSS and mRS score) were systematically collected. BMD was measured at lumbar spine, femoral neck and total hip by DXA. Binary logistic regression analysis was used to assess the prognostic implications of osteoporosis according to acute, subacute, and chronic stages following stroke.
Results: Among the patients, 295 (38.9%) were identified as having osteoporosis. Significantly higher prevalence of osteoporosis was observed during the chronic stage compared to the acute and subacute stages, respectively. The binary regression analyses revealed that female sex emerged as a significant risk factor for osteoporosis during the acute stage (OR 39.05, 95%CI 5.01–304.53, $P < 0.001$). However, the association gradually weakened over time following stroke, with a still significant association during the subacute stage (OR 10.00, 95%CI 4.29–23.34, $P < 0.001$) and a further diminished but still significant association during the chronic stage (OR 4.11, 95%CI 1.39–12.18, $P < 0.05$). Risk factors associated with post-stroke disability showed significant associations exclusively during the subacute stage. Specifically, the presence of spasticity in the hemiplegic lower extremity was identified as a protective factor (OR 0.41, 95%CI 0.19–0.91, $P < 0.05$), while severe cognitive impairment (K-MMSE score < 17) (OR 3.16, 95%CI 1.27–7.84, $P < 0.05$) and moderate to severe disability of mRS > 2 (OR 3.76, 95%CI 1.44–9.62, $P < 0.05$) were primary risk factors of osteoporosis.
Conclusion: After 6 months following a stroke, there is a significant increase in the incidence of osteoporosis, making early screening and proactive intervention crucial during the acute and subacute phases of stroke. Particularly within the 1–6 month period after stroke onset, severe cognitive impairment and disability elevate the risk of osteoporosis. Therefore, proactive rehabilitation intervention for cognitive and physical impairment is necessary for the prevention of post-stroke osteoporosis.

P1158
DECREASE IN BONE MASS IN PATIENTS WITH EARLY AXIAL SPONDYLARTHRITIS

S. Dahmani[1], O. V. Sharapova[2], L. I. Gerasimova[2], N. V. Zhuravleva[3], T. L. Smirnova[3], V. N. Diomidova[3]

[1] "Rahmani" Pharmacy, Casablanca, Morocco, [2]Russian Biotechnological Univ., Moscow, Russia, [3]Chuvash State Univ. named after I. N. Ulyanov, Cheboksary, Russia

Objective: To study the mineral density of the bone tissue of the lumbar spine and the femoral neck in patients with early axial spondylitis.
Methods: Explored 53 patients (33 men and 20 women) with early axial spondylitis. Patients with a duration of inflammatory pain in the spine were taken for < 3 y: the duration of the disease—1.89 $\pm$ 13.1 months. The diagnosis is made according to the ASAS 2009 criteria for patients—29.2 $\pm$ 5.3 y, BASDAI –4.3 $\pm$ 1.75; ASDAS-CRP-2.9 $\pm$ 1.4. BASDAI > 4, ASDAS-CRP > 2.1 were considered high activity of the disease. Patients were carried out by the densitometry of the femoral neck and the lumbar spine (LII—LIV) using DXA. A decrease in the mineral density of bone tissue were considered to be T-criteria of 2.0 SD and less at least in one studied department. The decrease in the Z-criterion, defined as the ratio of bone density to the age rate, is < 2.0, indicates a decrease in the mineral density of bone tissue.
Results: For all examined patients, the Z -criteria indicators amounted to -0.9 $\pm$ 0.79 SD for the femoral neck and -0.9 $\pm$ 0.97 SD for the lumbar spine. A decrease in the mineral density of bone tissue at least in one department was detected in 11 (20.75%) patients. In 9 (16.9%) patients, a decrease in the mineral density of bone tissue was found in the lumbar spine, in 7 (13.2%) patients—in the femoral bone, a decrease in the mineral density of bone tissue in two departments was observed in 4 (7, 54%) patients. Reliable differences ($p = 0.043$) were found to reduce the mineral density of bone tissue at least in one section between two groups of patients: with a disease duration of 17.9 $\pm$ 13.3 and 28.2 $\pm$ 14.3 months. Association has not been identified between a decrease in the mineral density of bone tissue and age, the floor of patients, the high activity of the disease (BASDAI, ADSAS), acute-phase inflammation indicators (erythrocyte settlement rate, C-reactive protein).
Conclusion: The loss of bone mass with early axial spondylitis begins in the early stages of the disease and is detected in 21% of young patients. Association was found between a decrease in the mineral density of bone tissue and the duration of the disease. A decrease in the mineral density of bone tissue can be considered as a factor in an unfavorable prognosis and taken into account when choosing therapy. Patients, with the first diagnosis of early axial spondylitis, are shown densitometry.

P1159
PREGNANCY AND LACTATION ASSOCIATED OSTEOPOROSIS

S. Daly[1], A. Compton[1], K. Mccarroll[1], R. Lannon[1]

[1]Bone Health & Osteoporosis Unit, Mercer's Institute for Successful Ageing, St James's Hospital, Dublin, Ireland

Pregnancy and lactation associated osteoporosis (PLO) is a rare condition affecting pregnant and lactating women. We report a case of maternal vertebral fractures 2 months post-partum.
Case report: A 33-year-old female presented to her General Practitioner with lower back pain 2 months postpartum following lifting her son from his cot. Her pregnancy had been normal with a spontaneous vaginal delivery. She had no medical history and no regular medications. She exclusively breast fed her infant. An MRI spine was carried out showing T12, L1, L4 and L5 endplate compression fractures. A DXA scan was carried out showing a Z-score at the lumbar spine of -4.4 and at the hip of -2.6. Her vitamin D was 93 nmol/L (normal: 50–100), corrected calcium 2.33 mmol/L (normal: 2.15–2.5) and renal function was normal. Her CTX was 0.238 ng/ml, (normal: 0.016–0.573) osteocalcin 26 ng/ml (normal: 11–43) and P1NP was 66 (normal: 15.1–58.6). Her PTH was low at 8.4 pg/ml (normal: 15–65). Extended secondary screen was normal. A diagnosis of PLO with vertebral fractures was made. Treatment was cessation of breast-feeding and physiotherapy.
Conclusion: During pregnancy, there are significant changes to bone physiology. Oestrogen falls significantly post-partum resulting in increased osteoclast activity and loss of BMD. In addition, lactation contributes to loss of BMD as calcium in milk is derived from the maternal skeleton. This is mediated by PTH-related protein (PTHrP)

which also causes low PTH as seen in this case. BMD usually reduces by 2–8% postpartum. This rapidly recovers on cessation of lactation. PLO is a rare condition affecting pregnant or postpartum women and often presents as vertebral fractures in the early post-partum period. The aetiology is unclear. Possible causes are an increased level of PTHrP during lactation, undiagnosed osteopenia prior to pregnancy or a combination of both. There is likely a strong genetic component with genetic variants WNT1 and LRP5 implicated. The treatment for PLO is cessation of lactation. There is insufficient data to support the use of bisphosphonates, denosumab or teriparatide.

P1160
MICRORNAS: POSSIBLE ROLE IN THE PATHOGENESIS OF TUMORAL CALCINOSIS?

S. Donati[1], G. Palmini[2], C. Aurilia[1], I. Falsetti[1], G. Galli[1], R. Zonefrati[2], R. Di Donato[3], A. Franchi[4], G. Beltrami[5], T. Iantomasi[1], L. Masi[6], G. Picchioni[3], M. L. Brandi[2]

[1]Dept. of Experimental and Clinical Biomedical Sciences, Univ. of Florence, Florence, [2]Fondazione Italiana Ricerca sulle Malattie dell'Osso (FIRMO Onlus), Florence, [3]Stabilimento Chimico Farmaceutico Militare (SCFM)_Agenzia Industrie Difesa (AID), Florence, [4]Dept. of Translational Research and of New Technologies in Medicine and Surgery, Univ. of Pisa, Pisa, [5]Ortopedia Oncologica Pediatrica, AOU Careggi-AOU Meyer, Florence, [6]Metabolic Bone Diseases Unit, Univ. Hospital of Florence, AOU Careggi, Florence, Italy

Objective: Tumoral calcinosis (TC) is an extremely rare disease characterized by lobular calcified masses in the periarticular soft tissues. We have previously isolated a TC-stem cells (SCs) line (TC1-SC) from a primary cell line (TC1) obtained from a TC patient biopsy harboring a novel *GALNT3* mutation. In this study, we investigated the possible epigenetics mechanisms underlying TC progression, focusing on the expression of selected miRNAs and genes related to osteogenic differentiation.
Methods: After the establishment and the characterization of a SCs line, TC1-SC, from the primary established TC cell line, we analyzed the expression of selected miRNAs either predicted in silico to interact with the 3'UTR of *GALNT3* mRNA or involved in osteogenic differentiation. We also investigated the expression profile of the osteogenesis-related genes, and of those genes associated with the FGF23 signaling pathway. These analyses were carried out in TC1 and TC1-SCs lines undergoing osteogenic differentiation up to 21 days. Furthermore, alkaline phosphatase (ALP) activity and calcium-phosphate deposition were quantified by fluorometric assays during the osteogenic differentiation of TC1 (from day 0 to 35).
Results: Collectively, 8 out of 9 selected miRNAs exhibited inverse expression patterns during osteogenic differentiation between TC1 and TC1-SCs, while miR-26a was found to be downregulated in both TC lines. Our analysis revealed, for the first time, the existence of an osteogenic signature genes and miRNAs for the isolated TC1-SCs line. Interestingly, ALP activity was strongly decreased despite the higher presence of crystals of hydroxyapatite in TC1 compared to a primary healthy preosteoblastic cell line induced to differentiate into osteoblasts.
Conclusion: For the first time we have established and characterized a SCs line from a TC patient with a novel *GALNT3* mutation, revealing also a preliminary specific signature of miRNAs for the TC1-SCs line. Regarding this, we are currently evaluating the expression of other miRNAs compared to the primary TC line and studying whether the miR-26 downregulation could be responsible for the TC-associated periarticular calcium deposits by regulating the expression of *ALP*. Overall, these findings could provide a basis for further molecular mechanisms understanding of the TC pathogenesis.
Acknowledgment: Supported by FIRMO Onlus.

IN VITRO EFFECTS OF 25(OH)D3 ON OSTEOGENIC DIFFERENTIATION PROCESS AND MICRORNAS: A PRELIMINARY STUDY

S. Donati[1], G. Palmini[2], C. Aurilia[1], I. Falsetti[1], F. Marini[2], G. Galli[1], R. Zonefrati[2], T. Iantomasi[1], M. L. Brandi[2]

[1]Dept. of Experimental and Clinical Biomedical Sciences, Univ. of Florence, [2]Fondazione Italiana Ricerca sulle Malattie dell'Osso (FIRMO Onlus), Florence, Italy

Objective: It has been reported that the direct precursor of calcitriol, calcifediol ($25(OH)D_3$), can regulate the expression of several genes through vitamin D receptor (VDR) binding. Recently, the action of $1,25(OH)_2D_3$ in regulating the expression of non-coding RNAs, including microRNAs, has been recognized as a potential anticancer mechanism. Here, we investigated not only the ability of $25(OH)D_3$ to modulate the expression of specific microRNAs but also its effects on the osteogenic differentiation process of mesenchymal stem cells derived from human adipose tissue (hADMSCs).
Methods: Two hADMSCs lines were established from subcutaneous adipose tissues obtained from health donors and cultured in growth medium. Cells were exposed to different concentrations of $25(OH)D_3$ (i.e., 10 μM, 100 nM, 50 nM, and 25 nM) in osteogenic induction (OI) medium for 35 d. Alkaline phosphatase (ALP) and hydroxyapatite (HA) deposits were quantified by fluorimetric assays up to 35 d. In addition, according to the literature, we studied the expression of a preliminary panel of microRNAs for up to 21 d in osteogenic differentiated cells using TaqMan technology.
Results: Our data showed that ALP activity significantly increased in hADMSCs treated with 100 nM $25(OH)D_3$ at 14 and 35 d compared to the control. Regarding the mineralization, in the presence of 100 nM $25(OH)D_3$, the HA deposition was significantly increased at 35 d. These results were consistent with microRNAs analysis, where we reported a higher expression of those microRNAs that have been reported to positively regulate the osteogenic process (i.e., miR-27a-3p, miR-29a-3p, miR-125a-5p, and miR-196b-5p) in cells exposed to 100 nM $25(OH)D_3$ for 14 d.
Conclusion: We observed that 100 nM $25(OH)D_3$ induces osteogenesis of hADMSCs either by increasing ALP activity or by inducing extracellular matrix mineralization. Furthermore, for the first time, we found that 100 nM $25(OH)D_3$ increased the expression of pro-osteogenic differentiation microRNAs. Nowadays, we are evaluating the expression of other miRNAs and osteogenic differentiation markers genes to investigate the potential $25(OH)D_3$-related molecular mechanisms that could play a crucial role in the regulation of osteogenesis. Taken together, our findings could allow the design of novel future therapeutic applications of this molecule against metabolic bone diseases.

SCREENING PRACTICES, PREVALENCE, AND TREATMENT PATTERNS FOR OSTEOPOROSIS IN PATIENTS LIVING WITH HIV: RESULTS FROM AN IRISH HIV CLINIC

S. Donohue[1], D. Fitzpatrick[2], M. Ryan[2], K. Ryan[2], C. O'Flaherty[1], N. Stanley[2], B. Adegbemi[2], K. Mc Carroll[2], C. Bergin[1], R. Lannon[2]

[1]Dept. of Genitourinary Medicine and Infectious Diseases, St James's Hospital, [2]Mercer's Institute for Successful Aging, St James's Hospital, Dublin, Ireland

Objective: As a result of improved life expectancy, osteoporosis is becoming more common among people living with HIV (PLWH). HIV is a well described risk factor for osteoporosis[1] and in this population densitometry (DXA) is recommended in postmenopausal women and men aged ≥ 50[2]. In this study we explore the screening, prevalence and treatment patterns for osteoporosis in PLWH aged ≥ 50 y.
Methods: This was a retrospective review of PLWH ≥ 50 y attending the HIV clinic in our hospital. We examined the proportion of patients with DXA performed as well as the prevalence of osteoporosis based on the lowest T-score recorded at the lumbar spine, neck of femur or total hip. We examined the relationship between osteoporosis and age using ANOVA.
Results: Of 3156 patients attending the clinic, 978 were ≥ 50 and included. The mean age was 56.9 ± 6.0 y and 74.1% were male. 94.6% were referred for DXA, which was completed in 80.5% of the total cohort. Based on DXA, 20.0% of females and 11.3% of males had osteoporosis, while 33% of females had osteopenia compared to 40.5% of males. Of those with osteoporosis, 57.5% were on pharmacological treatment for osteoporosis. Osteoporosis was significantly associated with older age in women ($p < 0.001$), but not in men ($p = 0.751$).
Conclusion: There was a high level of screening for osteoporosis with DXA. 20% of female and 11.3% of male PLWH had osteoporosis by DXA criteria, substantially more prevalent than that reported in the general population[3]. A significant relationship with older age and osteoporosis was found in females but not males. Similar to the general population[3], there is a significant treatment gap with over a third of PLWH with osteoporosis untreated.

P1163
FACTORS INFLUENCING THE FREQUENCY OF ARTHRITIS FLARES IN PATIENTS WITH GOUT NOT RECEIVING URATE-LOWERING THERAPY: RESULTS FROM A PILOT RETROSPECTIVE STUDY

S. Eliseev[1], V. Zhelyabina[1], I. Kuzmina[1], N. Chikina[1]

[1] V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia

Objective: The severity of gout, including the frequency of arthritis flares, is associated with various factors. However, the accurate prediction of flare frequency remains challenging. Our study aims to analyze the relationship between different factors that may influence the risk of exacerbation in patients with gout who have not received urate-lowering therapy (ULT).
Methods: The study included 116 patients (6 women, 110 men) aged 25–78 with gout, who had not taken ULT. Patients were retrospectively enrolled and assessed during their first visit. Clinical characteristics of gout: arthritis progression, frequency of acute arthritis flares per year, presence of subcutaneous tophi. Analyzed factors included: alcohol consumption, smoking, BMI, presence of comorbidities, diuretic use, blood pressure readings, serum levels of glucose, creatinine, creatine phosphokinase (CPK), gamma-glutamyl transferase (GGT), alkaline phosphatase (ALP), uric acid (UA), and C-reactive protein (CRP).
Results: ≥ 4 arthritis flares per year were found in 40% of patients, subcutaneous tophi in 33.6%, and ≥ 5 affected joints in almost 70% of patients. Serum UA levels correlated with the number of subcutaneous tophi (weak link). No association was found between uricemia levels and the frequency of arthritis flares. Moderate direct correlation between serum UA and GGT levels, and weak correlations with glucose, creatinine, CPK, CRP, BMI, and patient age (at enrollment) were identified. The strongest correlation was between serum UA levels and diastolic blood pressure (DBP); weak positive correlations were found between flare frequency and the number of tophi, DBP, GGT, CPK, and CRP levels. Significant differences in UA levels were observed among patients who consumed alcohol: 543 ± 111 μmol/l and 471 ± 92 μmol/l, $p = 0.001$. Flare frequency was significantly higher in patients taking diuretics, $p < 0.001$. Statistically significant differences in the odds of developing ≥ 4 flares per year were observed: a 1.955-fold increase with a family history of gout (95%CI: 1.224–3.121, $p < 0.05$), a 1.746-fold increase with the presence of tophi (95%CI: 1.161–2.626, $p = 0.007$), a 2.656-fold increase with alcohol consumption (95%CI: 1.766–3.994, $p < 0.001$), a 1.586-fold increase with UA level ≥ 540 μmol/l (95%CI: 1.041–2.416), and a 2.111-fold increase with involvement of ≥ 5 joints over the course of the disease (95%CI: 1.291–3.452, $p = 0.003$).
Conclusion: The frequency of arthritis flares in patients with untreated gout may be associated with the number of tophi, DBP, GGT, CPK, CRP levels, and diuretic use, while serum UA levels may not play a decisive role in predicting the course of the disease.

P1164
COMPARISON OF FREQUENCY AND QUANTITY OF MEAT PRODUCT CONSUMPTION AMONG PATIENTS WITH GOUT AND ASYMPTOMATIC HYPERURICEMIA: PRELIMINARY DATA FROM A PILOT STUDY

S. Eliseev[1], V. Zhelyabina[1], I. Kuzmina[1], N. Chikina[1]

[1] V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia

Objective: To comparatively assess the frequency and quantity of meat and fish product consumption among patients with asymptomatic hyperuricemia (AHU) and gout.
Methods: The study included 112 patients with AHU or gout, aged ≥ 18 y, surveyed between January 2022 and January 2023, all with a serum uric acid (UA) level > 360 μmol/l. The diagnosis of gout was established in accordance with the ACR/EULAR 2015 classification criteria for gout. Patients not meeting the ACR/EULAR 2015 criteria were diagnosed with AHU. Initial visit assessments involved a clinical examination, including medical history collection, physical examination, anthropometric data, and standard physical assessment. Laboratory investigations included fasting serum levels of UA, creatinine, and C-reactive protein (CRP). All participants completed the Food Frequency Questionnaire (FFQ). The study was approved by the Ethical Committee of the V.A. Nasonova Research Institute of Rheumatology.
Results: The study included 57 (49.1%) patients with AHU (31 (54.4%) men and 26 (45.6%) women) and 55 (50.9%) patients with gout, predominantly men (51 (92.7%)). Notable were the higher serum UA levels (504.7 μmol/l in the gout group vs. 431 μmol/l in the AHU group), as well as higher levels of creatinine and CRP. The consumption of meat products was mostly similar between patients with gout and AHU. Interestingly, there was one patient each from the gout and AHU groups who consumed beef products 2–3 times a day and one AHU patient who consumed sausage products at the same frequency. Nearly 50 (47%) and 40 (37%) patients with AHU almost never consumed beef sandwiches and mutton products, respectively. The cohort included one AHU patient who was a vegetarian (did not consume meat or fish). Notably, approximately one-fourth of the patients did not consume fish.

Conclusion: The primary finding of our study was the comparable frequency of meat and fish consumption among patients with gout and AHU. This fact may indirectly support the theory that dietary habits do not play a primary role in the genesis of gout, although they are associated with UA levels.

P1165
COMPARISON OF COLORIMETRIC AND ELECTROCHEMICAL (EASY TOUCH GCU ANALYZER) METHODS FOR DETERMINING BLOOD URIC ACID LEVELS IN PATIENTS WITH GOUT AND HYPERURICEMIA IN CLINICAL PRACTICE: PILOT STUDY DATA

S. Eliseev[1], V. Zhelyabina[1], N. Chikina[1], I. Kuzmina[1]

[1] V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia

Objective: Hyperuricemia (HU) is a condition characterized by elevated serum uric acid (UA) levels > 360 μmol/l. Often asymptomatic, HU can manifest as episodes of peripheral arthritis (gout) under the influence of various genetic and environmental factors. Achieving normal UA levels, which can be measured by the standard colorimetric method or the less common electrochemical method in clinical self-monitoring, is essential for the remission of this disease. We aimed to compare the results of UA level measurements using the standard colorimetric method and the electrochemical self-monitoring method (Easy Touch GCU analyzer).
Methods: The study included 30 patients with gout, encompassing individuals with current/historical asymptomatic HU and patients with a confirmed diagnosis of gout according to the ACR/EULAR 2015 criteria. The study involved a general examination, medical history collection, and laboratory investigation. UA levels in venous blood serum were measured colorimetrically no later than 5 min after collection, and UA levels in fresh whole capillary blood from the fingertip were measured immediately after collection using the electrochemical method (Easy Touch GCU analyzer).
Results: The average UA level measured by the two methods differed by 13.9 μmol/l (3.9% relative to the colorimetric method). A high correlation coefficient (r = 0.86) indicates a close linear relationship between the compared results and good consistency. The method is also applicable to patients who have achieved normouricemia.
Conclusion: The electrochemical method for determining UA levels in individuals with HU and gout can be used for self-monitoring in actual clinical practice.

P1166
VITAMIN D DEFICIENCY IN PATIENTS WITH GOUT

S. Eliseev[1], V. Zhelyabina[1], I. Kuzmina[1], N. Chikina[1]

[1] V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia

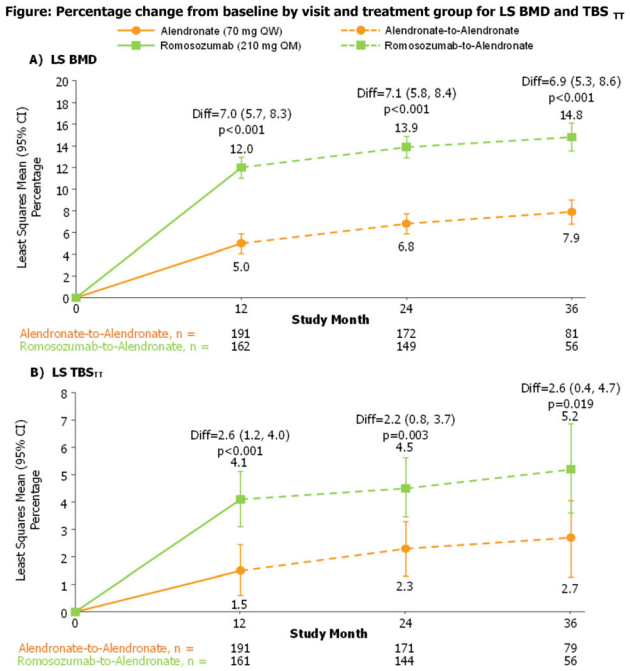
Objective: There is a limited number of studies on the mutual influence of vitamin D and uric acid (UA) levels in patients with gout. We aimed to investigate the interrelation between hyperuricemia and vitamin D levels in patients with gout.
Methods: The study included 79 patients with a confirmed diagnosis of gout. All patients were assessed for levels of uric acid, vitamin D, PTH, C-reactive protein, creatinine, ALT, AST, ALP, and estimated glomerular filtration rate (eGFR) using the CKD-EPI formula.
Results: The majority of the patients included in the analysis were men. The mean vitamin D level was below normal reference values. A vitamin D level of less than 30 ng/ml was observed in 63 patients (79.7%). A moderate correlation between vitamin D level and various factors was noted only with serum calcium levels. Uric acid levels were stratified into quartiles: < 426 μmol/l, 427–479 μmol/l, 480–540 μmol/l, and ≥ 540 μmol/l. An analysis of vitamin D levels and uric acid levels in different quartiles was conducted. Further analysis of uric acid levels, divided into quartiles, and corresponding vitamin D levels did not show statistically significant differences (p = 0.605).
Conclusion: More than 79% of participants exhibited hypovitaminosis. These data indicate a high prevalence of vitamin D hypovitaminosis among patients with gout and may suggest a need for improving prevention and treatment strategies for vitamin D deficiency in this population. The stratification of uric acid levels into quartiles did not reveal significant differences in vitamin D levels, suggesting a potential absence of a direct correlation in this population. This necessitates further research to understand the potential pathways of interaction between vitamin D and UA.

P1167
EFFECT OF ROMOSOZUMAB ON TISSUE THICKNESS-ADJUSTED TRABECULAR BONE SCORE (TBSTT) IN POSTMENOPAUSAL WOMEN WITH OSTEOPOROSIS AND DIABETES: RESULTS FROM THE ARCH STUDY

S. Ferrari[1], D. Betah[2], R. Feldman[3], B. Langdahl[4], M. Oates[2], J. Timoshanko[5], Z. Wang[2], R. Dhaliwal[6]

[1]Geneva Univ. Hospital, Geneva, Switzerland, [2]Amgen Inc., Thousand Oaks, USA, [3]MemorialCare Saddleback Medical Center, Laguna Hills, USA, [4]Aarhus Univ. Hospital, Aarhus, Denmark, [5]UCB Pharma, Slough, UK, [6]Massachusetts General Hospital, Boston, USA

Objective: Diabetes mellitus is associated with reduced bone strength and increased fracture risk.[1] TBS, a gray-level texture index derived from lumbar spine (LS) DXA scans, has been reported to be decreased in patients with diabetes and is associated with increased fracture risk, independent of BMD. In the ARCH trial (NCT01631214), romosozumab (Romo) significantly improved bone mass and bone strength, leading to superior fracture risk reduction vs. alendronate (ALN) alone.[2] We examined the effect of Romo-to-ALN vs. ALN-to-ALN on LS BMD and TBS in patients with diabetes in ARCH.
Methods: Postmenopausal women with osteoporosis and prior fracture were randomised 1:1 to Romo 210 mg monthly or ALN 70 mg weekly for 12 months (M), both followed by 24 M ALN 70 mg weekly. This post hoc analysis included participants with diabetes mellitus at baseline (BL) and LS DXA scan measurements at BL and ≥ 1 post-BL visit (Romo/ALN, n = 195; ALN/ALN, n = 165). BMD and TBS (determined by an updated TBS_{TT} algorithm; TBS iNsight^{TM} v4.0 [Medimaps][3] were assessed on LS DXA scans at BL, M12, M24, and M36.
Results: BL LS BMD was –2.63 for Romo and –2.89 for ALN; BL LS TBS_{TT} was 1.006 and 1.010, respectively. Romo led to significantly greater gains in LS BMD and TBS_{TT} at M12 vs. ALN; these were maintained after transition to ALN and persisted significantly at M24 and M36 vs. ALN alone (Figure). In the Romo/ALN group, the percentage of women with "normal" TBS values ($TBS_{TT} > 1.074$)[4] increased from 23.6% at BL to 50.0% at M36; those with "degraded" TBS values ($TBS_{TT} \leq 1.027$) decreased from 55.8% to 33.9% ($p < 0.001$). A similar trend, albeit with smaller improvement, was observed for ALN/ALN. TBS_{TT} changes were unrelated to LS BMD changes to M36 (Romo/ALN, $r^2 = 0.1493$; ALN/ALN, $r^2 = 0.0429$).



ALN: alendronate; BMD: bone mineral density; CI: confidence interval; Diff: percentage change from baseline for Romo treatment group minus percentage change from baseline for ALN treatment group; LS: lumbar spine; QM: monthly; QW: weekly; Romo: romosozumab; TBS: trabecular bone score; TBSTT: tissue thickness-adjusted trabecular bone score. LS BMD and TBSTT data were analysed based on repeated measures model adjusting for treatment, presence of severe vertebral fracture at baseline, visit, treatment-by-visit interaction, baseline BMD or TBS value as fixed effects, with machine type and baseline BMD or TBS value-by-machine type interaction as covariates, using either a compound symmetry variance covariance structure for BMD or an unstructured variance covariance structure for TBS.

Conclusion: In postmenopausal women with osteoporosis and diabetes, 12 M of Romo followed by 24 M of ALN significantly improved LS BMD and TBS as measured by TBS_{TT} (independently of BMD) to a greater extent than 36 M of ALN alone. These changes may reflect a greater improvement of bone strength by Romo vs. ALN in patients with diabetes.

PERCENTAGE OF BONE DENSITOMETRY, PRIOR TO ONCOLOGICAL TREATMENT, IN POSTMENOPAUSAL WOMEN DIAGNOSED WITH HORMONE-SENSITIVE BREAST CANCER, BETWEEN JANUARY 2016 AND AUGUST 2022 IN THE COMPLEJO HOSPITALARIO RUBER JUAN BRAVO

T. L. R. Logroño Rezola[1], I. V. Y. Vera Yuste[1], N. C. R. Cuevas Rodriguez[1], B. A. M. De Andrés Martín[1], B. M. P. Mélida Payán[1], S. G. F. Gerechter Fernandez[1]

[1]HU Ruber Juan Bravo Quiron, Madrid, Spain

Objective: Aromatase inhibitors constitute the most frequent adjuvant therapy for breast cancer, bone loss being a subsequent adverse effect. Baseline bone health in postmenopausal women is poorly characterized in prospective series of recently diagnosed breast cancer candidates to therapy with aromatase inhibitors. The objective is to describe the proportion of patients who presented bone health assessment prior to adjuvant therapy with aromatase inhibitors.

Methods: Observational, analytical descriptive, retrospective and longitudinal study. From January 2016 to August 2022, we consecutively included 83 women with a history of breast cancer treated with adjuvant aromatase inhibitors therapy, whose data from their medical records we proceeded to analyse. BMD and risk fracture were measured.

Results: Mean age was 65 y; 24,4% had their BMD assessed before receiving AI therapy. Analysis of baseline data shows half of the women had osteopenia and 40% already presented osteoporosis before therapy with aromatase inhibitors. 80% of them presented T values $\leq$ -2, being potential candidates for anti-osteoporotic treatment. Most women had their BMD assessed after initiating AI therapy, in which 50% already presented osteoporosis and 45% had osteopenia.

Conclusion: Low bone mass was highly prevalent both in the pretreatment and after initiating AI therapy. Therefore, it is crucial to assess BMD before starting therapy with aromatase inhibitors and during cancer follow-up.

P1169
PREVALENCE OF OSTEOPOROTIC FRACTURE IN WOMEN WITH BREAST CANCER TREATED WITH AROMATASE INHIBITORS AT THE HOSPITAL RUBER JUAN BRAVO BETWEEN 2020 AND 2022 WHO DO OR DO NOT RECEIVE ANTIRESORPTIVE TREATMENT

I. V. Y. Vera Yuste[1], T. L. R. Logroño Rezola[1], N. C. R. Cuevas Rodriguez[1], B. A. M. De Andrés Martín[1], B. M. P. Mélida Payán[1], S. G. F. Gerechter Fernandez[1]

[1]HU Ruber Juan Bravo Quiron, Madrid, Spain

Objective: Estrogens are hormones whose deficiency in postmenopausal women increases the risk of osteoporosis and fractures, while their excess may cause breast cancer. Aromatase inhibitors are a widely used treatment for this cancer in postmenopausal women, despite the fact that they increase the risk of fracture due to the estrogen decrease they produce. For this reason, in many cases antiresorptive drugs are used based on risk factors, densitometric and analytical results. Aim. To compare the proportion of osteoporotic fracture in women with breast cancer treated with aromatase inhibitors who did or did not receive antiresorptive treatment.

Methods: Observational, analytical, retrospective, cross-sectional, two groups studied (one received antiresorptives and the other did not). The clinical history of 83 patients were reviewed and the following variables were studied: the prevalence of osteoporotic fracture and the fact of having or not antiresorptive treatment.

Results: The patients who received antiresorptive drugs (59%) had a mean age of 66.4 y and 28.6% of them suffered a fracture, especially vertebral (4.8%) and hip (3.6%). From those who received antiresorptives, 77% received a bisphosphonate, of whom 53% had risedronate. The 52.5% of women suffered from arthralgia. The 36% of the patients were osteopenic and 54.5% had osteoporosis. In those who received antiresorptives, the means of alkaline phosphatase, NTX, and iPTH were 65, 34.3, and 51.2, respectively.

Conclusion: The prevalence of osteoporotic fracture in those receiving antiresorptive treatment is higher than the ones that didn't because they are patients with a higher risk and therefore they are correctly treated. The most frequent fractures are the vertebral and hip ones. All the fractured patients present osteopenia or osteoporosis and no patient with normal results developed fractures. The levels of bone remodeling markers are lower in the group that takes antiresorptive

treatment compared to the one that does not, demonstrating the efficacy of these drugs.

P1170
PREVALENCE OF DENSITOMETRIC OSTEOPOROSIS IN MEN OVER 40 YEARS OF AGE ATTENDING UROLOGY AND/OR RHEUMATOLOGY CONSULTATIONS AT THE RUBER JUAN BRAVO HOSPITAL IN MADRID IN THE YEAR 2022

N. C. R. Cuevas Rodriguez[1], B. M. P. Mélida Payán[1], I. V. Y. Vera Yuste[1], T. L. R. Logroño Rezola[1], B. A. M. De Andrés Martín[1], S. G. F. Gerechter Fernandez[1]

[1]HU Ruber Juan Bravo Quiron, Madrid, Spain

Objective: Osteoporosis is a bone-destroying disease that predisposes the affected population to a greater probability of fractures, thus reducing their quality of life. It has traditionally considered women disease, not taking in consideration men. However, it has been shown that men have a higher mortality rate. We aimed to determine not only the prevalence of osteoporosis in men, but the influence of medical and pharmacological records and other risk factors described in the FRAX.
Methods: Observational, descriptive, cross-sectional, retrospective study. 75 male patients with bone densitometry performed during the year 2022 were studied. The main variable was the presence or absence of osteoporosis. The data were collected by means of medical records.
Results: From 75 patients included in the study, 5 were excluded due to lack of tracking, so finally just 70 of them were studied. The result shown that 26 patients (37.1%) presented osteoporosis.
Conclusion: Statistically significant differences were found relating fragility fracture and falls with the presence of osteoporosis. Furthermore, the study shown as well that asthma and hyperparathyroidism conditions are related to the presence of osteoporosis. Osteoporosis also demonstrated statistically significant differences.

P1171
RISK OF FRACTURE IN PATIENTS WITH OSTEOPOROSIS ATTENDING THE RUBER JUAN BRAVO HOSPITAL RHEUMATOLOGY CONSULTATION IN MADRID DURING 2021 AND 2022

B. A. M. De Andrés Martín[1], N. C. R. Cuevas Rodriguez[1], I. V. Y. Vera Yuste[1], T. L. R. Logroño Rezola[1], B. M. P. Mélida Payán[1], S. G. F. Gerechter Fernandez[1]

[1]HU Ruber Juan Bravo Quiron, Madrid, Spain

Objective: Osteoporosis is a disease that causes decreased bone mass and increased risk of fragility fractures. According to the criteria of the Spanish Society for Bone Research and Mineral Metabolism (SEIOMM) updated in 2022, patients with osteoporosis can be classified according to their fracture risk as: very high risk, those with a BMD with T- score < -3.5 standard deviations (SD), at least 2 vertebral fractures or 1 hip or vertebral fracture with T-score < -3; high risk, those patients with a T-score < -2.5 SD, a fragility fracture or with major risk factors; and moderate-mild risk, those patients with a column T-score < -2.5 SD, a T-score < -2.0 SD in the femoral head, no fractures and less than 65 years of age. Different treatment regimens are recommended for each group. The hypothesis stated that, of the total number of patients with osteoporosis who attended the consultation, 20% had a very high risk of fracture, 40% high, and 30% moderate-mild. The objective was to verify if this estimate was met in the population treated in the rheumatology clinic of the Ruber Juan Bravo Hospital in Madrid during 2021 and 2022.
Methods: To do this, a database was created with information from the medical records of 104 patients with osteoporosis and analyzed using an observational and analytical study.
Results: The results obtained showed that 32.7% of the patients had a very high risk of fracture, 58.7% high, and 8.7% moderate-mild.
Conclusion: These results represent a higher percentage of patients with high and very high risk of fracture and a lower percentage with moderate-mild risk than expected. For this reason, it is important to treat patients with high and very high risk of fracture from specialized units.

P1172
INCIDENCE OF OSTEOPOROSIS IN PATIENTS WITH RHEUMATOID ARTHRITIS WITH PRE-TREATMENT RHEUMATOID ARTHRITIS TREATMENT FROM 2018–2021 IN THE HOSPITAL RUBER JUAN BRAVO

B. M. P. Mélida Payán[1], B. A. M. De Andrés Martín[1], N. C. R. Cuevas Rodriguez[1], I. V. Y. Vera Yuste[1], T. L. R. Logroño Rezola[1], S. G. F. Gerechter Fernandez[1]

[1]HU Ruber Juan Bravo Quiron, Madrid, Spain

Objective: Loss of bone mass density is observed in osteoporosis. This loss is measured through what is known as bone densitometry (DXA). Osteoporosis is considered itself a severity factor or bone fracture complication, and it is simultaneously the main complication of rheumatoid arthritis. Treatment effect on bone loss for patients that combine both pathologies is still unclear. While Methotrexate is used in rheumatoid arthritis cases, it can also be harmful for osteoporosis. It was estimated that the incidence of osteoporosis in rheumatoid arthritis patients before treatment is 5%. This percentage was reported in scientific papers on the topic.
Methods: It was an observational, descriptive, retrospective and longitudinal study, aimed at rheumatoid arthritis patients, that belonged to the Rheumatology Unit at Madrid's HJRB, aged above 18 and studied between 2018–2021. In order to calculate the sample size, the proportion estimation formula was used, along with the GRANMO calculator, and despite the result obtained was 82 individuals, finally only 56 could be included. Data was pseudonymized and assessed through a descriptive and bivariate analysis. Osteoporosis was considered the main variable and it was measured with the DXA technique.
Results: The study showed that 21,4% of the patients suffered osteoporosis before taking any rheumatoid arthritis treatment, and the resting 78,6% didn't. In this study, the number and proportion of women that had osteoporosis previous to rheumatoid arthritis treatment surpassed the number of men. DAS28 results mean was 3,22, which is considered rheumatoid arthritis moderate activity.
Conclusion: Osteoporosis incidence in individuals that suffer rheumatoid arthritis a month after diagnosis and prior to any treatment turns out to be higher than documented in other studies.

P1173
REAL-LIFE EXPERIENCE OF BUROSUMAB TREATMENT IN PATIENTS WITH TUMOR-INDUCED OSTEOMALACIA

Z. Belaya[1], S. Gronskaia[1], Y. Buklemishev[2], L. Rozhinskaya[1], S. Rodionova[2], I. Uljanova[1], G. Melnichenko[1]

[1]Endocrinology Research Centre, [2]National Medical Research Center of Traumatology and Orthopedics named after. N.N. Priorov, Moscow, Russia

Objective: To evaluate patients who required burosumab treatment among the referral population with tumor induced osteomalacia (TIO).
Methods: We evaluated patients with biochemically confirmed diagnosis of TIO referred to the Endocrinology Research Centre between July 2018 and December 2023 who required burosumab treatment. Clinical and biochemical characteristics of patients were evaluated before burosumab initiation as well as disease outcome following 6–24 months of treatment. The levels of iFGF23 were measured using ELISA Kit Biomedica BI-20700, the median values in serum of healthy individuals were 14.8 [3.8;25.0]. Phosphate levels (reference range 0.74–1.52 mmol/l), alkaline phosphatase ALP (reference range 40–150 IU/l), PTH (reference range 15–65 ng/mL) were measured by Abbott Architect c8000; tubular reabsorption of phosphate (TRP) was calculated at http://www.scymed.com/en/smnxps/pshpd274.htm. Pain measurement was done using a pain scale where 0 meant no pain and 10—extreme pain. BMD were measured prior to and 6–12 months after treatment initiation using GE iDXA machine.
Results: We included 7 patients: 2 (28.6%) were females, the mean age (± standard deviation) was 47 ± 9 y, and mean weight was 81 ± 22.2 kg. In 5 cases curative surgery were not possible (tumor localisation was in head and neck (n = 2), in calcaneus bone (n = 1), in sacrum (n = 1), in wrist bone (n = 1)), and in 2 cases no tumors were found. The starting dose of burosumab was 0.5 mg/kg which was escalated to the maximum of 2 mg/kg. Biochemical data before the treatment were: serum phosphorus 0.43 ± 0.1 mmol/L, PTH 76 ± 44.0 ng/mL, intact FGF23, 750 ± 1694 pg/ml, TRP 55 ± 17%, ALP 178 ± 70 IU/l. At the time of diagnosis, all patients had multiple pathological fractures with a decrease in height of 15 ± 8 cm. One patient could move independently, 3 patients used crutches and 3 used wheelchairs. Evaluation of 7 patients was available after 6–24 months of treatment. The increase in BMD at the total hip (TH) was 18 ± 14% and femoral neck (FN) showed highly significant increases compared to baseline 20 ± 27%. Before treatment patients suffered from severe pain (8 ± 1 in a pain scale). After treatment the mean pain score was mild 2 ± 1. Mean phosphate levels were 0.9 ± 0.3 mmol/L normalized in 6 out of 7 subjects with clinical recovery. The required burosumab dose was 1.2 ± 0.6 mg/kg every 4 weeks (50 to 150 mg/4w)). Burosumab was generally well tolerated. The one case of partial response could be explained by a large sacrum tumor of 40 mm and the highest FGF23 levels of 4588.3 pg/ml. This case may require a higher dose of burosumab.
Conclusion: Burosumab is a promising option in case of an unresectable or occult FGF23 producing tumor as it is effective at phosphate level normalization, BMD gain, new fracture prevention and pain relief. Initial FGF23 levels may affect the required burosumab dose to achieve recovery.

P1174
A RARE CASE OF HIGH DOSE TERIPARATIDE TREATMENT FOR RESISTANT POSTSURGICAL HYPOPARATHYROIDISM DEVELOPED IN A RENAL TRANSPLANT RECIPIENT

S. Gronskaia[1], E. Senjushkina[1], L. Rozhinskaya[1], E. Mamedova[1], N. Platonova[1], Z. Belaya[1]

[1]Endocrinology Research Centre, Moscow, Russia

Hypoparathyroidism (HypoPT) is a rare disease characterized by low calcium with non-adequate PTH elevation. It may manifest in chronic kidney disease (CKD) patients after total parathyroid surgery. Teriparatide, rhPTH(1–34) is a component of human PTH which may be suggested in case of severe hypoparathyroidism for an out-of-label substitutional treatment. We report a case of post-kidney transplantation male patient with severe HypoPT after total parathyroidectomy.
Case report: A 25 -year-old male renal transplant recipient presented with severe bone pain, paresthesia, and tetany. He had a medical history of CKD starting from 7 y, initiated hemodialysis at age 14, and underwent kidney transplantation at age 24. Due to end-stage renal disease he was diagnosed with tertiary hyperparathyroidism complicated by renal osteodystrophy and underwent total parathyroidectomy one year prior to transplantation. CT scan showed a reduction in vertebral bodies height > 30%, signs of fibrosis osteitis in other bones. DXA did not reveal a decrease in BMD. Laboratory evaluation showed low calcium corrected for albumin 1.3–1.55 mM/L (RR: 2.15–2.55), low Ca ionized 0.72–0.78 mM/L (RR: 1.03–1.29), high phosphate (Pi) 2.28 mM/L (RR:0.74–1.52), PTH—24.2 pg/ml within the reference range, serum creatinine (SCr) levels 148 mcmol/L, GFR 45 ml/min, and increased bone turnover markers osteocalcin 100.2 ng/ml, CTX > 6.00 ng/ml. Daily teriparatide 40 mcg, calcium 3 g, alfacalcidol 2mcg and cholecalciferol 2000 IU were initiated. After 3 d the teriparatide dose was increased to 60 mcg/d and calcium to 4 g/d, after a further 5 d the dose was increased to 80 mcg/d and after a further 2 d to 120 mcg/d with final achievement of calcium and phosphate normalisation. After 1 month of treatment with teriparatide 120 mcg/d, calcium carbonate 4 mcg, alfacalcidol 2mcg and cholecalciferol 2000 IU clinical improvement was observed with absence of pain, reduction in parestesia, normalization of Ca corrected for albumin 2.01 mmol/L, phosphate 1.28 mmol/L, SCr 149.97 mcmol/L, GFR 45 ml/min. The teriparatide dose was reduced to 80 mcg/d and after 1 month to 40 mcg/d with reduction calcium carbonate to 2 mg, alfacalcidol to 1 mcg with normal laboratory parameters after one year.
Conclusion: in this case teriparatide was an effective and safe treatment of HypoPT to overcome the post-dialysis resistance of bone to PTH and maintain treatment in a renal transplant recipient. This case add to our knowledge to the management of severe chronic HypoPT in CKD patients.

P1175
A NEW MUTATION IN THE CDKN2B-GENE ASSOCIATED WITH PRIMARY HYPERPARATHYROIDISM AND MEN-4

S. H. J. Scharla[1], U. G. Lempert[2]

[1]Practice Endocrinology and Diabetes, Bad Reichenhall and Univ. of Munich (LMU), [2]Practice Endocrinology and Diabetes, Bad Reichenhall, Germany

Up to 10% of patients with multiple endocrine neoplasia (MEN) type 1 do not have mutations of the MEN1 gene. These patients may have mutations in other genes, such as CDNK1B or CDKN2B and are described to have MEN type 4. We report the detection of a new mutation in the CDKN2B-gene (cyclin-dependent kinase inhibitor 2B) in a patient with primary hyperparathyroidism and in family members.
Case report: The female patient (age 56 y) was transferred from an orthopedic specialist for further evaluation of osteoporosis (T-score -2.9 in the DXA-measurement at the lumbar spine, and rib fractures) and increased serum calcium. Serum-calcium was slightly increased with 2.6 mM and PTH was increased with 84 ng/L. No other hormonal abnormality was detected. Renal calcium clearance was increased. 25-OH-vitamin D was in the normal range with 76 nM. Ultrasound suggested a small parathyroid adenoma at the left caudal thyroid lobe. The molecular panel diagnostics found a mutation in the CDNK2B gene (c.209_210deICG p(Ala70Glyfs*16), heterozygote (Analysis done by Dr. R. Salazar, Labor Heidrich, Hamburg). This mutation was classified as variant of unclear significance and has not

been described before. The mother of the patient was also heterozygote carrier of the same mutation and had a normal calcium (2.46 mM) and a PTH in the upper normal range (47 ng/L). The sister of the patient was also a heterozygote carrier of the mutation and exhibited a serum calcium in the upper normal range (2.45 mM) associated with a PTH at the upper normal limit (54 ng/L) and had additionally a history of multiple atraumatic fractures. The daughter of the index patient did not inherit the mutation and had a normal calcium (2,3 mM) and normal PTH (32 ng/L).
Conclusion: This novel mutation in the CDKN2B-gene appears to be related to MEN type 4. Genetic screening for suspected familial hyperparathyroidism may be recommended in order to allow early diagnosis and treatment.

P1176
UP TO 9.3-YEAR FOLLOW-UP STUDY ON DENOSUMAB FOR OSTEOPENIA AND OSTEOPOROSIS: COMPARISON BETWEEN TRABECULAR AND CORTICAL BONE MINERAL DENSITY IN SPINES MEASURED BY QUANTITATIVE COMPUTED TOMOGRAPHY

S. Harada[1], S. Fuchs[1], E. Boehm[2], M. Weigl[2], U. Mansmann[3], I. Feist-Pagenstert[2]

[1]Dept. of Orthopaedics and Trauma Surgery, Musculoskeletal Univ. Center Munich (MUM), LMU Hospital/ Institute for Medical Information Processing, Biometry and Epidemiology (IBE), Faculty of Medicine, LMU, Pettenkofer School of Public Health, [2]Dept. of Orthopaedics and Trauma Surgery, Musculoskeletal Univ. Center Munich (MUM), LMU Hospital, [3]Institute for Medical Information Processing, Biometry and Epidemiology (IBE), Faculty of Medicine, LMU Munich, Pettenkofer School of Public Health, Munich, Germany

Objective: To examine the effects of denosumab not only on vertebral trabecular but also on vertebral cortical BMD in the same vertebrae, evaluated by one or more repeated QCT over 9 y.
Methods: Men and women aged $\geq$ 49 y, with osteopenia or osteoporosis, receiving denosumab 60 mg subcutaneously every 6 to 9 months, underwent 1 or more QCTs to measure both trabecular and cortical BMDs in spine at the University of Munich Hospital. Each volumetric BMD was calculated as the mean value of the respective right and left regions in the same vertebral bodies between the 12th thoracic and 5th lumbar vertebrae, without any fractures, sclerotic lesions, or artificial devices. We assessed the associations between vertebral trabecular and cortical BMDs in the same vertebrae within patients, by adapting multiple linear regression model, 2-way repeated measurement analysis of variance test, and multivariate linear mixed-effects model.
Results: Between 8 d and 4.3 y (mean 18.7 $\pm$ 9.6 months) after starting denosumab, we performed the initial QCTs for 162 patients (female 86%, mean age 75.5 $\pm$ 7.3 y), with additional follow-up QCTs for 100 patients among them, until 9.3 y since denosumab initiation. A total of 312 QCTs were included in the analyses. Vertebral cortical BMDs were positively correlated with vertebral trabecular BMDs within patients, after adjustment for age, gender, and time from the first denosumab injection (correlation coefficient 0.32, $p < 0.0001$). Over the follow-up time, with random effects for patients and with fixed effects adjusted for age, gender, and the other part of vertebral BMDs, the vertebral cortical BMDs decreased by 2.80 [95%CI: 0.76 to 4.82] mg/cm^3 ($p = 0.008$) per year, whereas the vertebral trabecular BMDs increased by 0.88 [95%CI: 0.32 to 1.44] mg/cm^3 ($p = 0.003$) per year.
Conclusion: During our 9.3-y follow-up period after the first denosumab injection, vertebral cortical BMDs were positively correlated with vertebral trabecular BMDs. Our new findings highlighted the larger decrease in vertebral cortical BMDs over time compared to the stable vertebral trabecular BMDs over time.

P1177
INFLUENCE OF GLOMERULAR FILTRATION RATE ON BONE MINERAL DENSITY IN PATIENTS WITH COXARTHROSIS

F. Ilchenko[1], S. Hryvenko[1], I. Kaminsky[1], N. Shadchneva[1], E. Keledzhyyeva[1], V. Kaliberdenko[1], E. Kulieva[1], E. Mureyko[2]

[1] V.I. Vernadsky Crimean Federal Univ., Simferopol, [2]N.N. Petrov National Medicine Research Center of Oncology, Saint Petersburg, Russia

Objective: Currently, osteoarthritis (OA) is one of the most widespread joint diseases. With this pathology, normal or even increased BMD is often observed. However, there are often patients in whom the presence of OA is combined with reduced BMD values, i.e. with osteoporosis (OP). The presence of chronic kidney disease in patients with OA is one of the reasons for the development of secondary osteoporosis and has prognostic significance for this disease. We aimed to study the state of BMD in patients admitted for hip replacement depending on the stage of chronic kidney disease (CKD), taking into account existing risk factors.
Methods: The study involved 165 patients aged from 50–83 y (mean age 63.9 $\pm$ 3.89 y) with stage 1–3 CKD and risk factors for osteoporosis (female—80%, male—20%). All patients were divided into 3 groups, depending on the presence and stage of CKD.
Results: Normal BMD values were recorded in 29 patients (17.6%). In 136 patients, a violation of BMD was noted: of these, in 63 patients (38.2%) at the level of indicators of osteopenia, in 73 patients (44.2%) at the level of indicators of osteoporosis. Depending on the stage of CKD, the following results were obtained. In stage 1 CKD, normal BMD values were recorded in 9 patients (25.0%), BMD at the level of osteopenia in 13 patients (38.2%), BMD at the level of osteoporosis in 12 patients (36.8%). In stage 2 CKD, normal BMD values were recorded in 18 patients (19.1%), BMD at the level of osteopenia in 35 patients (38.8%), BMD at the level of osteoporosis in 38 patients (42.1%). In stage 3 CKD, normal BMD values were recorded in only 3 patients (7.6%), BMD at the level of osteopenia in 14 patients (36.7%), BMD at the level of osteoporosis in 22 patients (55.7%). From the presented data it is obvious that in CKD 3 the incidence of osteopenic syndrome significantly increases in comparison with the group of patients with normal GFR values.
Conclusion: In 82.4% of patients with chronic kidney disease admitted for hip replacement, there is a decrease in BMD. In the presence of stage 3 CKD, a decrease in BMD to the level of osteopenia and osteoporosis is significantly more often observed, which must be taken into account when performing joint replacement.

P1178
PORTRAIT OF A PATIENT WITH SYSTEMIC LUPUS ERYTHEMATOSUS FOR THE PRESCRIPTION OF THE TYPE I INTERFERON INHIBITOR ANIFROLUMAB

B. Issayeva[1], E. Aseeva[2], T. Reshetnyak[2], N. Nikishina[2], S. Issayeva[1], M. Saparbayeva[1], M. Bizhanova[1], A. Amanzholova[1]

[1]Asfendiyarov Kazakh National Medical Univ., Almaty, Kazakhstan, [2]Rheumatology, Federal State Research Institution (FSRI) named after V. A. Nasonova, Moscow, Russia

Objective: In recent years the use of monoclonal antibodies that block activity of type I interferon (IFN) or its receptors has become the new approach in the pharmacotherapy of systemic lupus

erythematosus (SLE). We aimed to characterize patients with SLE treated with the type I IFN receptor inhibitor anifrolumab (AFM, Saphnelo).
Methods: The prospective 12-month study included 21 patients with SLE who met the 2012 SLICC criteria. Standard laboratory and immunological markers for SLE were examined in all patients. The SLEDAI-2 K index was used to determine the activity of SLE and the CLASI index was used to determine the severity of the mucocutaneous syndrome. Organ damage was assessed using the SLICC/ACR Damage Index (DI). The LupusQol and FACIT-Fatigue questionnaires were used to analyze health-related quality of life (HRQoL).
Results: Female patients prevailed in the study, female/male ratio 17 (81%)/4 (19%), median age 31 [27; 46] y, disease duration 9 [6.0; 11.0] y. The majority of patients (86%) had moderate or high disease activity according to the SLEDAI-2 K index. Among the clinical manifestations of SLE, skin and mucous membranes lesions predominated (81%). Non-erosive polyarthritis of varying severity was observed in 66% of cases. Serositis showed 24% of patients (pleurisy, pericarditis), 43% had hematological abnormalities (hemolytic anemia, leukopenia, lymphopenia) and 14% urinary syndrome (daily proteinuria up to 0.5 g/l and/or urinary sediment – leukocytes/erythrocytes/cylinders up to 5 in the field of view in the absence of urinary tract infection). All patients had immunological disorders. 14% of them were diagnosed with antiphospholipid syndrome (APS) and 43% with Sjögren's syndrome. All patients received hydroxychloroquine, 95% received glucocorticoids (GC) from 5–60 mg/d, 66% received immunosuppressants (cyclophosphamide, mycophenolate mofetil, azathioprine, methotrexate). 33% of patients had anamnesis of treatment with biologic disease modifying antirheumatic drugs (rituximab, belimumab, dual anti-B-cell therapy) and Janus kinase inhibitor baricitinib. All patients experienced a significant deterioration in HRQoL.
Conclusion: The indications for prescribing AFM to 21 patients with SLE were: active SLE according to SLEDAI-2 K and/or CLASI with predominant involvement of skin, its appendages and development of polyarthritis with immunological disorders, intolerance/ineffectiveness of previous standard therapy and inability to achieve low average daily doses of oral GCs. Other clinical manifestations in some patients were: serositis, mild hematological disorders (Coombs-positive anemia, leukopenia), urinary syndrome. AFM could be prescribed for a combination of SLE with secondary APS and Sjögren's syndrome as well as for a high DI SLICC.

P1179
OVEREXPRESSION OF INOSITOL-REQUIRING ENZYME-1 (IRE-1) INHIBITS CHONDROCYTE DIFFERENTIATION

Y. S. Eom[1], S. J. Kim[1]

[1]Kongju National Univ., Dept. of Biological Sciences, Gongju, South Korea

Objective: Chondrocyte differentiation is a critical molecular process that governs the structural and functional features of cartilage and bones. In some skeletal degenerative diseases such as Osteoarthritis, Rheumatoid arthritis and lupus affect the differentiation process resulting in the degradation of differentiation markers and instigating inflammation. Our previous experiments have indicated that IRE-1 overburdens the endoplasmic reticulum with the accumulation of unfolded proteins that disturb the chondrocyte differentiation when exposed to a dedifferentiating agent. Therefore, the current study investigated the molecular effects of IRE-1 transduced inside rabbit articular chondrocyte cells.
Methods: Growth and maintenance of articular chondrocytes: A total of 30 New Zealand rabbits (2 weeks old) were used irrespective of gender having weight of about 150–200 g to extract the primary chondrocytes. Cell transfection: The siRNA (5'-GAUGUCCCA-CUUUGUGUCC-3') and cDNA (NM_001433) of IRE-1 was also purchased and transfected to evaluate the effect on chondrocyte phenotype. Immunoblotting analysis: After BCA quantification, a calibrated concentration of protein lysate was used to separate protein of interest on the gel comprised of sodium dodecyl sulfate–polyacrylamide through electrophoresis. Proteoglycan staining analysis: 0.1% alcian blue was prepared in 0.1 M of hydrochloric acid to be used as a quantifying agent to detect the proteoglycan level of treated chondrocytes.
Results: When IRE-1 was transduced at various concentrations in these cells resulted in an increase in IRE-1 gene expression which in turn decreased the type II collagen and proteoglycan levels in the chondrocytes without causing any cell death or apoptosis. Immunofluorescence data showed that type II collagen production was severely affected by IRE-1 overexpression which corroborated both phenotypic and immunoblotting data.
Conclusion: Our study discovered that IRE1 is a novel target whose inhibition can revive the production and expression of proteoglycan and differentiation markers and should be further used for drug design and development studies.

P1180
HOSPITALIZATIONS FOR HIP AND NON-HIP MAJOR OSTEOPOROTIC FRACTURES IN BELGIUM: TRENDS BETWEEN 2010–2021

S. Janssens[1], E. Gielen[1], M. R. Laurent[2], A. Sermon[3], M. Herteleer[3], M. Dejaeger[1]

[1]Dept. of Public Health and Primary Care, Division of Gerontology and Geriatrics, KU Leuven, Leuven, [2]Dept. of Geriatric Medicine, Imelda Hospital, Bonheiden, [3]Dept. of Development and Regeneration, Division of Locomotor and Neurological Disorders, KU Leuven, Leuven, Belgium

Objective: The long-term epidemiological trends of hospitalization for major osteoporotic fractures (MOF) (fractures of the hip, distal femur, pelvis, humerus, wrist, and spine) in patients aged 50 years and over in Belgium are unknown. The aim of this study was to describe the incidence and trends of hospitalizations for MOF in patients aged 50 y and over in Belgium between 2010–2021.
Methods: Population-based, retrospective study based on hospitalization data extracted from the national database NIHDI and demographical data from the Belgian Federal Bureau for Statistics. Data were combined to determine the crude and age-standardized incidence of hospitalizations for fractures of the hip, distal femur, pelvis, humerus, wrist, and vertebrae using 2010 as the reference year.
Results: A total of 445,234 hospitalizations for MOF were reported between 2010–2021 (excluding 2015). Hospitalizations for MOF increased by 5.8% between 2010–2021 ($p = 0.013$) with a higher increase in men (12.1%; $p = 0.001$) compared to women (4.1%; $p = 0.041$). The crude hospitalization incidence per 100,000 for all MOF decreased from 990 to 910 between 2010–2021 ($p = 0.572$). The age-standardized incidence for any MOF in men declined from 5.30/1,000 to 4.42/1,000 ($p = 0.010$). In women, a very similar decrease of 16.0% was observed (13.84 to 11.62; $p = 0.003$). Hospitalizations for both hip and non-hip MOF showed a decrease in both sexes.
Conclusion: Although a declining trend in the crude incidence per 100,000 and age-adjusted incidence of hospitalizations for MOF (hip, distal femur, pelvis, humerus, wrist, and spine) was observed, the absolute number of hospitalizations for MOF continued to rise due to aging of the Belgian population.

P1181
ORTHOGERIATRIC CO-MANAGEMENT FOR OLDER PATIENTS WITH A MAJOR OSTEOPOROTIC FRACTURE: AN OBSERVATIONAL PRE-POST STUDY

S. Janssens[1], A. Sermon[2], M. Deschodt[1], K. Fagard[1], M. Cerulus[3], H. Cosyns[3], J. Flamaing[1], M. Herteleer[2], M. Dejaeger[1]

[1]Dept. of Public Health and Primary Care, Division of Gerontology and Geriatrics, KU Leuven, [2]Dept. of Development and Regeneration, Division of Locomotor and Neurological Disorders, KU Leuven, [3]Dept. of Geriatric Medicine, Univ. Hospitals Leuven, Leuven, Belgium

Objective: To evaluate if nurse-led orthogeriatric co-management in patients with a major osteoporotic fracture results in better outcomes than inpatient geriatric consultation.
Methods: This single-center observational pre-post effectiveness study took place at the traumatology ward of the University Hospitals Leuven in Belgium. We evaluated 108 patients aged 75 y and older hospitalized with a major osteoporotic fracture in each cohort (usual care group with inpatient geriatric consultation vs. nurse-led orthogeriatric co-management). The intervention included proactive geriatric care, a patient's self-reported evaluation of premorbid status, a comprehensive geriatric evaluation followed by multidisciplinary interventions, and systematic follow-up. The primary outcome was the proportion of patients having one or more in-hospital complications. Additionally, a process evaluation of the intervention's core components and adherence to proactive geriatric care processes was performed.
Results: After controlling for confounding variables in a multivariable logistic regression model, the odds for any in-hospital complication in the intervention group decreased by 51% compared to the usual care group (OR = 0.49 (95%CI: 0.26–0.92), p = 0.027). Delirium incidence decreased by 13% (34 vs. 21%; p = 0.003). Furthermore, the incidence of congestive heart failure and pneumonia decreased by 3% (p = 0.269) and 5% (p = 0.119), respectively. No differences were observed in the incidence of deep venous thrombosis, pulmonary embolism, myocardial infarction, urinary tract infection, and in-hospital mortality. Adherence to the intervention's core components was as follows: completion of a self-reported questionnaire to map premorbid status (38%), multidimensional evaluation (100%), development of an individual care plan (100%), and systematic follow-up (81%). Regarding the proactive geriatric care processes, screening for dysphagia and daily food intake were introduced in clinical practice (0% vs. 70%, 0% vs. 52%), more patients received a laxative if they did not pass stool (67 vs. 94%), and more patients received calcium-vitamin D supplements (20 vs. 58%), all significant with $p < 0.001$.
Conclusion: Implementation of nurse-led orthogeriatric co-management resulted in significantly higher fidelity to proactive geriatric care processes and in a significant reduction of in-hospital delirium incidence and an overall reduction in in-hospital complication rate.

P1182
IMPROVEMENT OF BONE MINERAL DENSITY WITH HORMONE REPLACEMENT THERAPY IN PATIENT WITH DELAYED DIAGNOSIS OF PRIMARY OVARIAN FAILURE DUE TO TURNER SYNDROME MOSAICISM: CASE REPORT

S. Jovanovska Mishevska[1], I. Bitoska[1], A. Mucha[1], T. Prosheva Bajraktarova[1], B. Todorova[1], S. Markovikj[1]

[1]Univ. Clinic of Endocrinology, Diabetes and Metabolic Disorders Skopje, Skopje—Centar, North Macedonia

Patients affected with Turner Syndrome (TS) suffer low BMD and high risk of skeletal deformities, with estrogen deficiency being considered among the main contributors towards early-onset osteoporosis. We present a case of improved of BMD with hormone replacement therapy in patient with delayed diagnosis of primary ovarian failure due to Turner syndrome mosaicism.
Case report: The patient has been initially referred to our department for evaluation of short stature and primary amenorrhea at the age of 18. Determination of pituitary–gonadal and pituitary-thyroid function, growth hormone and carbohydrate metabolism indices in the peripheral blood were investigated. Patient underwent pelvic ultrasound and karyotype. Hormone replacement therapy (HRT) for TS was initiated. BMD by DXA and serum bone metabolic parameters in the peripheral blood were investigated before the initiation of HRT and at 2-year intervals afterwards. Results: Patients karyotype revealed presence of an X isochromosome with two q arms—46,X,izoX(q), leading to the diagnosis of Turner syndrome mosaicism. Hypoplastic uterine endometrium and underdeveloped gonadal structures were detected by pelvic ultrasound. Initial BMD of lumbar vertebra by DXA showed spinal osteopenia (0.832 ± 0.067 g/cm^2) with vertebral BMD Z-scores ranging from –2.4 to -1.8. Initial improvement in BMD was shown at 2 y after initiation of HRT, and the latest spinal BMD performed at the age of 26 is within age-specific reference ranges (1.100 ± 0.037 g/cm^2) with vertebral BMD Z-scores ranging from –0.5 to -0.2.
Conclusion: Inadequately treated primary ovarian insufficiency is among the risk factors for secondary osteoporosis. Early initiation of HRT and ensuring compliance with HRT are the cornerstones of osteoporosis prevention in women with Turner syndrome.

P1183
REDUCTION IN TOTAL NUMBER OF DRUGS IN THE FINAL "GERIATRIC DEPRESCRIPTION [GD]" CAN SIGNIFICANTLY REDUCE THE NUMBER OF FALLS AND POSSIBILITY OF FRAGILITY FRACTURES

S. K. B. Bajaj[1]

[1]Falls Institute of India [FII], Nagpur, India

Objective: To prove that reduction in total number of drugs an older adult [OA] is taking daily, excluding nutritional supplements, leads to significant reduction in future falls and fragility fractures.
Methods: The principle investigator [PI] studied the prescriptions of registered patients in Falls Institute of India [FII]. This is a retrospective study of 140 patients between 2015–2024. Out of 140, 82 were females and 58 were males. The age group range was from 50–99 y. The definition of number of drugs considered was: non-polypharmacy [0–4 drugs], polypharmacy [5–8 drugs], hyperpolypharmacy [9 + prescription drugs], Over-the-counter drugs. It was observed by the PI that an older adult has to consult multiple medical specialists for multiple co-morbidities. It is observed that there was no communication amongst the doctors regarding the choice of drugs to be prescribed finally. There is nobody to co-ordinate between family members and multiple doctors. Also regarding the concept of geriatric medicine in general and of deprescription in particular is in neonatal stage in India. Every patient was given at least 3–5 unnecessary drugs specially PPI, NSAID [specially aspirin], opioids like tramadol, anti-diabetic drugs, diuretics and sedatives, etc. The PI studied the prescriptions of all the 140 patients given to them in last 9 y. It was found that everyone was given polypharmacy or hyperpolypharmacy. After coming in contact for first time with FII, each patient was given final geriatric deprescription. The list of drugs to be stopped was clearly mentioned in bold letters in "STOP MEDICATIONS".

Results: This study of 140 patients between 2015–2024 clearly indicates that due to lack of knowledge regarding importance of deprescribing and communication gap amongst the Indian doctors, the older adults are exposed to fall risk increasing drugs.
Conclusion: The total number of falls, leading to fragility fractures can be significantly reduced by using various deprescribing tools like AGS's Beers Criteria, US Deprescribing Network. WHO's list of potentially inappropriate medication, etc.
References: AGS's Beers Criteria, US Deprescribing Network, Canadian Deprescribing Network.
Acknowledgment: Indian Deprescribing Network.

IMPLEMENTING IMPROVED TREATMENT FOR PATIENTS AT HIGH RISK OF FRACTURE IN PRIMARY CARE: EXPERIENCES FROM A HYBRID DIGITAL AND CLINICAL EVALUATION MODEL OF CARE

S. K. Nedungayil[1], E. V. McCloskey[2], S. Davis[3]

[1]East Lancashire Hospital NHS Trust, Blackburn, [2]Metabolic Bone Centre, Northern General Hospital, Sheffield, [3]Interface Clinical Services Limited, Leeds, UK

Objective: A large treatment gap exists in primary care osteoporosis management. We evaluated the use of a hybrid digital and clinical assessment method for risk assessment, case evaluation and management of patients in primary care.
Methods: A software algorithm analyzed electronic patient records from 551,550 people across 59 GP practices in North England to identify patients based on NICE CG 146 fracture risk assessment criteria and perform automated individual FRAX fracture risk assessment (without BMD). This was complemented by a pharmacist check on data accuracy and recommendation of appropriate management in 3 groups of high risk patients (those with a diagnosis of osteoporosis; at high-risk but not on treatment; on treatment needing medication review).
Results: 208,515 men and women over 50 were included, of whom 153,206 fulfilled the NICE criteria. A high-risk group of 27,219 individuals (13.1% of those over 50) was identified, of whom 10,361 (38.1%) had a confirmed diagnosis of osteoporosis following pharmacist evaluation. While 58.0% of the individuals with osteoporosis had a prior fracture, only 35.4% were currently on treatment (potential treatment gap 64.5%). A total of 14,076 fractures were classified as fragility fractures; a code enabling patients with such fractures to be included in the osteoporosis register for Quality Outcomes Framework reimbursement was missing in 64% (53% in over 75 s, 76% in 50 to 74-year-olds). DXA scans, recommended in high risk individuals between 50–75 y, were only coded in 32% of such cases. Overall, treatment initiation was recommended for 60% of those not on treatment, with oral bisphosphonates as the preferred choice (72%).
Conclusion: This combined approach identifies and corrects major deficiencies in osteoporosis management in primary care. Developments need to address improved digital systems for identification and risk assessment, as well as models of workforce planning to achieve maximum reductions in the primary care osteoporosis treatment gap.

P1185
COMPARATIVE EFFECTS OF VITAMIN D SUPPLEMENTATION ON SERUM CALCIOTROPIC PROFILES IN ORTHODOX NUNS WITH HYPOVITAMINOSIS D IN DIFFERENT REGIONS OF GREECE, VERSUS INTERMITTENT FASTING AND WESTERN DIET IN LAY WOMEN

S. Karras[1], N. Georgopoulos[2], M. Anemoulis[1], A. Vlastos[1], S. Pilz[3], M. Hewison[4]

[1]Thessaloniki, Aristotle Univ. Medical School, Thessaloniki, Greece, [2]Medical Univ. Patra, Patra, Greece, [3]Medical Univ. Graz, Graz, Austria, [4]Medical Univ., Birmingham, UK

Objective: Greek Orthodox monasteries due to their sartorial habits, comprise a population with high prevalence of hypovitaminosis D. Intermittent religious fasting is adopted by this population, as well as from a large part of general lay Greek population. Comparative effects of vitamin D supplementation and intermittent fasting on vitamin D equilibrium and calciotropic profiles remain scarce. We aimed to comparatively evaluate effects of vitamin D supplementation in two different forms (drops and pills at 2.500 IU daily) in Orthodox nuns from different regions of Greece, vs. Orthodox fasting and Western diet patterns in women from general population on vitamin D and calcium homeostasis.
Methods: Two groups of 25 women from two Orthodox monasteries in Northern Greece (Groups A and B) and two groups of 25 healthy women (Groups C and D) were included. During enrollment a detailed recording of demographic, dietary habits and anthropometric characteristics (via bioimpedance) was conducted. We evaluated calciotropic profiles [Calcium-Ca, Albumin, PTH, 25(OH)D] at baseline and after 12 weeks. Groups A and B received vitamin D supplementation with 2.500 international units of cholecalciferol daily (in the form of drops—Group A; and tablets—Group B). Groups C and D adopted a dietary pattern of Orthodox intermittent fasting [daily feeding window (10 am-6 pm)] (Group C) and a diet based on the recommendations of the American Heart Association (AHA) for the management of overweight and obesity in adults (Group D).
Results: All groups were comparable at baseline for calcium, PTH and 25(OH)D concentrations. All groups demonstrated significant increases of 25(OH)D [Group A (21.68 vs. 31.05 ng/ml),(Group B 25.78 vs. 38.35 ng/ml),(Group C 17.31 vs. 24.32 ng/ml), (Group D 17.62 vs. 24.12 ng/ml), with no significant between group differences. PTH concentrations decreased significantly in Group C (42.18 vs. 25.89) pg/ml and Group D (34.22 vs. 17.68) pg/ml, whereas PTH changes in groups A and B were non-significant after 12 weeks of supplementation compared to baseline, with no effects of anthropometric measures of body fat, as well as type of supplementation.
Conclusion: Intermittent fasting and AHA dietary patterns were equally effective with equal moderate doses of vitamin D supplementation in improving vitamin D status, in different groups of Greek nuns and lay women.

P1186
CLOSED STRAIGHTENING WITH MANIPULATION UNDER ANESTHESIA OF A BENDED TELESCOPING NAIL AFTER A FALL IN A CHILD WITH OSTEOGENESIS IMPERFECTA

S. Koliatzakis[1], D. Pafilas[1], C. Rossas[1], K. Vetsa[1], I. P. Papakammenos[1], L. Tsiopos[1]

[1]Orthopaedic Dept., General Hospital of Agrinio, Agrinio, Greece

Osteogenesis imperfecta is a genetic disorder characterized by reduced production of normal collagen type I, resulting in bone fragility. Telescopic intramedullary nails are usually applied in the fractured long bones of these children intended to strengthen, prevent future fractures and limit their axial deformations while allowing bone growth.

Case report: A 12-year-old child came to the emergency department due to a fall from a bicycle and an injury to the right thigh. The child was already diagnosed with osteogenesis imperfecta and had previously undergone intramedullary nailing to both his femurs (Fassier-Duval Telescopic IM System^{TM}) due to a fracture. The radiological examination revealed a fracture of the right femoral diaphysis with marked angulation and accompanying distortion of the intramedullary nail and therefore it was suggested to the parents to undergo surgery to treat the fracture with replacement of the telescopic nail. However, since the telescoping nail is not readily available in our country and the replacement surgery could only be performed after long term scheduling we proposed and the parents agreed to another feasible option. We proceeded to sedate the child with an attempt to reduce the fracture in combination with straightening as much as possible of the telescopic shaft of the nail with the help of fluoroscopy, in order to restore the axis of the femur, stabilize it with cast and give time to the parents to decide and schedule for the definitive treatment. The radiological result after closed manipulation was satisfactory and the parents decided to treat the fracture conservatively with a cast, even though they were informed that the intramedullary telescopic nail most probably would no longer work and would not offer full protection. Finally, the fracture was healed to mild angulation and did not cause functional problems to the child.

Conclusion: Closed straightening of an angulated intramedullary telescopic nail with simultaneous reduction of the fracture can be a compromise treatment option when revision surgery cannot be readily performed and as long as the radiological result is satisfactory and may not cause future problems for the child with osteogenesis imperfecta.

P1187
BASILAR THUMB ARTHRITIS: LONG-TERM RESULTS OF TRAPEZIECTOMY AND SUSPENSIOPLASTY TECHNIQUE WITH MINI TIGHTROPE

S. Koliatzakis[1], D. Pafilas[1], C. Rossas[1], K. Vetsa[1], I. P. Papakammenos[1], L. Tsiopos[1]

[1]Orthopaedic Dept., General Hospital of Agrinio, Agrinio, Greece

Objective: The thumb carpometacarpal joint (CMCJ) osteoarthritis is a common problem in middle-aged and elderly adults, especially females. It's one of the most common sites of degenerative osteoarthritis in the upper limb and due to its profound importance on hand function affects the daily activities. Many different surgical techniques have been advocated, including first metacarpal osteotomy, trapeziectomy alone or combined with ligament reconstruction and tendon interposition (LRTI) or suspensioplasty, CMCJ arthroplasty and CMCJ arthrodesis. The purpose of our study was to investigate the long-term results of a surgical method including trapeziectomy and suspensioplasty with the use of Mini TightRope (Arthrex).

Methods: In our study we recruited 12 patients (10 females and 2 males) of mean age at surgery about 62 y. All of them suffered from basilar thumb arthritis of the dominant hand (11 right and 1 left) and underwent surgical treatment with the method of trapeziectomy and suspensioplasty to stabilise first metacarpal to the second and prevent first metacarpal subsidence and narrowing of trapezial space height. For the suspensioplasty technique a newer modification was used including a synthetic implant, the Mini TightRope (Arthrex) which is made from a fibre wire and two stainless steel buttons on either side of the metacarpals. We assessed the 12 patients at regular intervals of 3 months, 6 months, 1 y and 5 y postoperatively in terms of pain, functional outcomes and radiological imaging.

Results: All of the patients reported pain relief and overall satisfaction at about 6 months after surgery according to the VAS pain scale (from mean 8 preoperatively to 0 postoperatively). There was a significant improvement of power measurement parameters in terms of hand grip, tip pinch and key pinch power. In general, patients were very satisfied after surgery and regained functional range of motion of the first CMCJ at about 1 y postoperatively. Radiologically we noted no significant change in thumb opposition, but a slight subsidence of the first metacarpal at 1 y after surgery. Moreover, in terms of complications, one patient presented with features of transient neuropraxia of the dorsal radial sensory nerve immediately after the operation which resolved 4 months later.

Conclusion: Osteoarthritis of the thumb CMCJ is very common and exist a lot of alternative surgical treatment options. A minimally invasive surgery procedure including trapeziectomy and suspensioplasty with the use of Mini TightRope gives satisfactory results and limited complications.

P1188
CALCIFICATION OF THE LINEA ASPERA: A RARE CLINICAL CASE

S. Koliatzakis[1], D. Pafilas[1], C. Rossas[1], K. Vetsa[1], I. P. Papakammenos[1], L. Tsiopos[1]

[1]Orthopaedic Dept., General Hospital of Agrinio, Agrinio, Greece

Calcification of the linea aspera of the femur is a relatively rare clinical case. If not diagnosed, it can lead to long-term suffering for the patient. The purpose of this paper is to present such an unusual clinical entity.

Case report: A 55-year-old male patient came to the emergency department of our hospital with pain on the posterior surface of the left thigh without any previous injury. Clinical examination revealed no evidence of sciatica or muscle strain and imaging was performed to rule out further pathology. A plain radiograph revealed a vaguely defined calcification at the insertion of the gluteus maximus on the posterior surface of the femur at the level of the linea aspera. Computed tomography imaging was then performed which confirmed the radiographic findings and better attributed the calcification to the gluteus maximus insertion. To further rule out pathology, an MRI and bone scan were performed with characteristic findings in the MRI. The patient was given pain-relieving treatment with anti-inflammatory and corticosteroids.

We do not have a clear record of when the patient's symptoms ameliorated. In the majority of cases, either the symptoms subside on their own or after a considerable period of time as occurs in any calcifying enthesopathy.
Conclusion: Calcification of linea aspera is a relatively rare condition that may distract the physician's attention as it may resemble a muscle contusion or sciatica.

P1189
KUMMELL'S DISEASE: A NOT SO RARE CASE THAT GOES UNNOTICED

S. Koliatzakis[1], D. Pafilas[1], C. Rossas[1], K. Vetsa[1], I. P. Papakammenos[1], L. Tsiopos[1]

[1]Orthopaedic Dept., General Hospital of Agrinio, Agrinio, Greece

The aim of this study is to present a case of osteonecrosis of the 12th vertebra body after a compression fracture.
Case report: An 88-year-old female patient presented to the emergency department due to a fall with pain in the thoracolumbar junction. Imaging revealed a T12 fracture. One month later, during a follow-up appointment, the patient was found to have osteonecrosis of the vertebra with intravertebral gas on computed tomography.

Discussion: Kummell's disease is osteonecrosis of the vertebral body after a compression fracture. The frequency of this finding is difficult to report precisely because many synonymous terms have been used to describe this pathology: posttraumatic vertebral osteonecrosis (AVN), vertebral compression fracture pseudoarthrosis (VCF nonunion), intervertebral space, cleft or gas, and delayed vertebral subsidence.
Conclusion: Kummell's disease is a potential complication in up to one third of vertebral fractures. Therefore, there is a fairly good chance that most primary care providers will at some point in their careers be involved in the treatment of a patient with Kummell's disease without perhaps knowing it.

P1190
SIGNIFICANCE OF EARLY REHABILITATION AND APPLICATION OF MYOFASCIAL MANIPULATION IN LUMBAR SYNDROME

S. Lazarevska[1], H. Lazarevska[1], O. Stojkovski[1], S. Mladenovski[2], V. Dimitrioski[3], D. Jovanovska-Jordanovski[3]

[1]Centre for Physical and Kinesitherapy—Laser Med, [2]Zan Mitrev Clinic, [3]PHI Polyclinic Jane Sandanski, Skopje, North Macedonia

Objective: Disability associated with chronic lumbar pain is one of the most common painful states of the modern human being and represents a benign condition with highest costs in the healthcare system. We aimed to detect the differences between the results from the treatment of patients with low lumbar pain, depending on the type of the applied methods of treatment: physical therapy and myofascial manipulation or medical treatment.
Methods: This study has enrolled 200 patients with low lumbar pain, treated with medical and physical therapy with myofascial manipulation that, according to the given therapy, were divided into two groups and examined before and after completion of the treatment. Oswestry Index was used for assessment of disability associated with lumbar pain.
Results: The respondents were with an average age of 53.8 y, most of who were female patients (62%) and had normal body weight, (BMI = 22.6). 34% of the respondents had a job position that mostly involves seating, whilst 48% of them had a job which does not require physical activity. T-test indicated nearly two times bigger drop of the disability index in patients who had received physical therapy with myofascial manipulation (28.8) in comparison with the drop of the disability index in patients who had received medical therapy (15.72), ($p < 0.05$).
Conclusion: The early practice of physical therapy with the application of myofascial manipulation and reduction of the longer period spent for resting bring better and quicker results for reduction of the disability associated with lumbar pain.

P1191
NOVEL SCREW-CABLE INTEGRATED SYSTEM (SCIS) FOR MINIMALLY INVASIVE TREATMENT OF PATELLA COMMINUTED FRACTURE: A FINITE ELEMENT ANALYSIS

S. Liu[1], Y. Liang[1], X. Wei[1]

[1]Orthopaedic Dept., Aerospace Center Hospital, Beijing, China

Objective: The most recommended method for treating comminuted patella fractures is modified tension band wiring (MTBW). However, the optical equipment used with MTBW remains yet to be determined. Hence, we designed a novel SCIS, which features cannulated screws and steel cables that can be freely disassembled or combined. This study aimed to compare the biomechanical characteristics of the MTBW with SCIS and cable-pin system in treating transverse patellar fracture.
Methods: A finite element (FE) model of comminuted patella fracture was created. The fracture model was fixed with either SCIS or cable-pin. Different tension force loading (400 N and 800 N), direction(0° and 45°) were set. Max contact pressure, contact area, maximum displacement of the fracture and maximum gap opening were measured by using FE analysis.

Results: Compared with cable-pin system, SCIS increased the stability of the fractured patella by reducing fragment displacement and gap opening while increasing the contact pressure and contract area. Under a 45°-400 N loading condition, the SCIS treatment method demonstrated a substantial improvement in stability metrics when compared to the Cable-pin system. The SCIS method reduced the maximum fragment displacement by approximately 23.68% (from 0.42 mm to 0.32 mm). Additionally, SCIS achieved a reduction in gap opening by approximately 30.23% (from 0.33 mm to 0.23 mm). The SCIS system exhibited a 26.06% increase in maximum contact pressure compared to the cable-pin system (from 2.70 Mpa to 3.40 Mpa). The SCIS system showed a 37.84% increased contact area compared to the cable-pin system (from 94.42 mm to 130.15 mm).
Conclusion: SCIS demonstrated improved biomechanical stability for treating comminuted patellar fractures compared to MTBW with cable-pin system. Finite element analysis showed SCIS substantially reduced fracture fragment displacement and gap opening while increasing maximum contact pressure and contact area under various loading conditions.

P1192
PREDICTIVE FACTORS FOR ASSESSING PHYSICAL PERFORMANCE AND FUNCTIONAL RECOVERY FOLLOWING FRAGILITY HIP FRACTURE SURGERY: A PROSPECTIVE COHORT STUDY

S. Luarngjindarat[1], P. Pinijprapa[2], W. Kanokwongnuwat[2], O.-A. Phruetthiphat[2]

[1]Rajavithi Hospital, [2]Phramongkutklao hospital, Bangkok, Thailand

Objective: Osteoporotic fractures are considered one of the burden issues for both patients and the health care system. Because they are often asymptomatic, osteoporotic vertebral compression fractures (OVCF) are among the most underdiagnosed fragility fractures. Hip fractures, the second most common fragility fracture, also inflict high mortality rates. In addition, the presence of OVCF alongside hip fractures worsens functional outcomes compared to those with only hip fractures. However, the incidence of combined fractures and their associated factors for short-term and mid-term functional outcomes are still unknown. The purpose of this study is to identify the associated risk factors affecting functional outcomes in both short-term and mid-term for patient with fragility hip fracture, either single or combined with OVCF.
Methods: After the Institutional Research Board approval, a prospective study was performed from April 2021 to June 2022. The inclusion criteria were patients over 60 years old diagnosed with femoral neck fracture or intertrochanteric fracture treated with either bipolar hemiarthroplasty or proximal femoral nail antirotation (PFNA) fixation, respectively. All patients were enrolled in the Fracture Liaison Service (FLS) care program. 81 patients were categorized into an isolated fragility hip fracture (isolated group) (n = 25, 30.9%) and a combined fracture with OVCF (combined group) (n = 56, 69.1%). Demographic data, including age, gender, BMI, comorbidity, the American Society of Anesthesiologists Classification (ASA class), and the Charlson comorbidity index (CCI) were collected at admission. BMD of the spine and hip were measured in all patients along with vertebral fracture assessment (VFA) for evaluating the incidence of combined OVCF. Additionally, OVCF severity was assessed using the Genant classification, and the number of OVCF levels was recorded. The physical performance was evaluated at short-term follow-up by using the timed up and go test (TUG) at 6 weeks, and the functional outcome at mid-term follow-up was assessed by the 1-y Harris Hip Score (HHS). The cutoff point of TUG was 18 s, with patients classified into good (≤ 18 s) and poor (> 18 s). Other associated risk factors were analyzed by univariate and multivariate regression methods for TUG and HHS.
Results: No significant differences in age, gender, BMI, comorbidity, ASA class, CCI, or the fracture types were observed between groups. Hip BMD and T-score of the spine were significantly lower in the combined group than in the isolated group (0.64 vs. 0.70 g/cm^2, p = 0.03; -1.68 vs. -0.84, p = 0.033, respectively). The most common OVCF occurred at the T12-L1 level and was mostly Genant grade 1 (n = 37, 45%). Female gender, advanced age (> 80 y), and intertrochanteric fracture were associated with poorer physical performance measured by the TUG test (P = 0.001, P = 0.008, and P = 0.04, respectively). Furthermore, advanced age (> 80 y) and hospital stay exceeding 7 d were significant prognostic risk factors for poor TUG test [odd ratio (OR) = 8.65, 95%CI 2.10–35.6, P = 0.003 and OR = 4.03, 95%CI 1.012–14.5, P = 0.033, respectively]. Similarly, female gender, advanced age, and combined OVCF were associated with significantly lower 1-y HHS (P = 0.047, P = 0.003, and P = 0.039, respectively). Conversely, other factors, including BMI, hip fracture pattern, and hospital stay duration, did not have a significant influence on the mid-term outcome.

Multiple logistic regression
Significant if p<0.05

Conclusion: Our study identified various factors predicting poor short-term physical performance and mid-term functional outcome in both isolated and combined fragility hip fractures with OVCF. These prognostic factors necessitate tailoring post-operative care, including focused physical therapy, appropriate osteoporotic treatment, and comprehensive fall prevention strategies, to optimize functional outcomes. An intensive rehabilitation program may be particularly beneficial for patients in the combined group to enhance recovery.

P1193
ARTHROSCOPIC TREATMENT OF SYNOVIAL CHONDROMATOSIS IN PATIENT WITH DIAGNOSED ANKYLOSING SPONDYLITIS

S. Maglevaniy[1], E. Naryshkin[1], M. Makarov[1], A. Khramov[1], A. Shumilova[1]

[1] V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia

Ankylosing spondylitis (AS) is a chronic inflammatory autoimmune disease that mainly affects spine and axial joints, causing pain and restriction of movement. Pathogenesis of AS remains unclear but immune cells and innate cytokines have been suggested to play crucial roles. Synovial chondromatosis is a rare synovial-derived metaplasia that comes from formation of cartilage nodules within the synovial connective tissue of the joint.

Case report: This presents the patient with diagnosed ankylosing spondylitis notes pain and swelling of the right knee joint. According to the patient, the injury occurred in 2021 with the following pain syndrome. MRI: pronounced synovitis and hypertrophy of the synovial tissue. Unevenly shaped level of fluid in upper parts of the knee. Consulted in the Orthopaedic Department where synovectomy was recommended and performed. Intraoperatively, a large number of small flake-like type (irregular shape), ring-shaped type (curved, ring-shaped or comma-shaped) was visualized and evacuated followed by biopsy. Synovial chondromatosis was diagnosed. The postoperative period proceeded without complications. Intake of DMARDs for ankylosing spondylitis was continued. Examination was within 3 and 6 months after operation and revealed 20 mm on VAS scale, no complaints of recurrent swelling and no restriction of movement.

Conclusion: Even with a diagnosed rheumatic disease, concomitant joint pathologies and nosologies can be identified. The combination of synovial chondromatosis and ankylosing spondylitis is extremely rare and practically does not meet in the literature. However, synovectomy, evacuation of free chondral bodies and continuation of therapy may help to prevent flares and relapses.

P1194
ANALYSIS OF FACTORS DETERMINING PROGNOSIS IN PATIENTS WITH HIP FRACTURE DURING THE COVID–19 PANDEMIC

T. Semenova[1], S. Mazurenko[1], I. Tuchin[1], O. Potanina[1]

[1]Saint Petersburg State Univ., Saint Petersburg, Russia

Objective: To analyze the prevailing risk factors that worsen the short-term prognosis in patients with low-energy hip fractures in two groups: with and without concomitant COVID-19 infection.

Methods: We examined 157 patients (116 women and 41 men) with hip fractures. The average age was 78.1 ± 26.5 y. 100 patients (69 women and 31 men; average age 78.2 ± 27.5 y) had concomitant COVID-19 infection. 57 patients with hip fractures (47 women and 10 men; average age 77.2 ± 24.5 y) were not infected. The Morse Fall scale and the physical activity scale were used to assess the risk of patients falling.

Results: In the group of patients with COVID-19 infection, surgical intervention was performed in 56 cases. 44 patients were not operated on due to the severity of COVID-19 infection, complicated by pneumonia. In this group, 25 patients died, of which 21 patients received conservative treatment and 4 patients—surgery. In the group of uninfected patients with hip fractures, 48 were operated, 9 patients received conservative treatment. In the group of uninfected patients, 3 patients died, two after surgery and one patient receiving conservative treatment. The duration of hospitalization in the two groups did not differ significantly. According to the Morse Fall scale, 94% of all patients had a high risk of falls, 6% had a low risk. The average score on the Morse scale was 96.94. Mortality in the group of infected patients was significantly higher. Timely surgical intervention improved survival in both groups. In addition, the prognosis of female patients with COVID-19 was better than that of men. In the group of uninfected patients, we found no differences in survival depending on gender. Survival in the group of infected patients depended on the severity of viral pneumonia and in both groups from physical activity before fractures.

Conclusion: During the COVID–19 pandemic, patients did not stop suffering from osteoporosis-related fractures. Low physical inactivity caused by self-isolation increased the risk of falls due to progressive sarcopenia, impaired coordination of movements. Low physical activity and COVID–19 infection worsened fracture outcomes.

P1195
ANALYSIS OF BONE MINERAL DENSITY IN PATIENTS WITH VARIOUS CAUSES OF CHRONIC KIDNEY DISEASE

S. Mazurenko[1], N. Khudyakova[1], O. Mazurenko[2], M. Shabalina[1]

[1]Saint Petersburg State Univ., [2]North-Western District Scientific and Clinical Center named after L. G. Sokolov, Federal Medical and Biological Agency, St. Petersburg, Russia

Objective: Evaluation of BMD by DXA proved its value to predict fracture risk in patient with chronic kidney disease stage 5 (CKD 5st) on dialysis and in kidney transplant recipients [1,2]. The purpose of this study was to analyze the influence of different causes of CKD on BMD.

Methods: We evaluated BMD in 609 patients (307 men and 302 women, middle age 43,9 ± 12,3) with CKD 5st. 179 patient before the start of renal replacement therapy (RRT), 337 patient on hemodialysis (HD), and 93 kidney transplant recipients. All patients

were divided on subgroups depending on the cause of CKD: diabetes mellitus (DM) types 1 and 2, arterial hypertension, chronic glomerulonephritis, polycystic kidney disease, congenital **a**nomalies of the urinary tract (CAUT)**, c**hronic tubulointerstitial nephritis, urolithiasis. The values of the Z-score were used to compare BMD in the subgroups.

Results: The performed analysis showed that in the groups of patients with CRF before the start of RRT and on HD, the lowest BMD values were noted in patients with CAUT and type 1 diabetes mellitus. The analysis of Z-scores of patients with the other renal diseases did not show a significant difference ($p > 0.05$). In the group of kidney transplant recipients, the highest BMD was found in patients with DM type 2. Statistically significant difference in BMD in subgroups with different causes of renal diseases was not revealed.

Conclusion: The most likely reason of the lowest BMD scores in subgroups of patients with CAUT and DM type 1 and patients before the start of RRT and patients on HD was the age, which in most patient did not reach the peak of bone mass at the onset of CKD.

P1196
BONE MINERAL DENSITY IN WOMEN WITH PRIMARY GLOMERULONEPHRITIS WITHOUT RENAL FAILURE

D. Monova[1], M. Stambolova[2], S. Monov[3]

[1]Medical Univ.—Sofia, Medical Institute—MIA, [2]Medical Institute—MIA, [3]Medical Univ.—Sofia, Sofia, Bulgaria

Objective: To assess BMD and to identify factors predictive of reduced BMD and occurrence of fracture in women with primary chronic glomerulonephritis (GN).

Methods: Demographic, clinical data, BMD (lumbar spine and femoral neck), functional disability and fracture-related mortality were collected. BMD was measured by using a DXA in lumbar spine (L1-L4) and femoral neck. The diagnosis of GN was confirmed by renal biopsy. Variables evaluated were duration of GN, age, serum creatinine, proteinuria, postmenopausal status, current and cumulative corticosteroid dose, use of low-molecular-weight heparin and history of fracture. Fisher's Exact and Student's t-tests were used to evaluate differences between patients with and without low BMD. Logistic regression was used for multivariate analysis.

Results: 74 women with primary GN (minimal change nephrotic syndrome in 9,46%, focal segmental GN in 21,62%, membranous GN in 22,97%, IgA GN in 21,62%, diffuse mesangial GN without IgA in 2,7%, focal mesangial GN in 6,76%, membranoproliferative GN in 14,87%) without renal failure were studied. The mean age was $37{,}32 \pm 15{,}66$ y, the mean disease duration was $7{,}12 \pm 3{,}54$ y. 42 women (56,76%) had low BMD, of those 26 (61,90%) had osteoporosis, mean BMD in lumbar spine was $-\ 2{,}92 \pm 0{,}36$ and in femoral neck was $-\ 2{,}32 \pm 0{,}24$. In correlation analysis and in multiple regression models, there were correlations between BMD and longer duration of GN ($p < 0{,}005$), age ($p < 0{,}01$), postmenopausal status ($p < 0{,}02$), low BMI ($p < 0{,}01$), presence of internal organ involvement ($p < 0{,}05$), proteinuria ($p < 0{,}05$), duration of corticosteroid (GC) treatment ($p < 0{,}005$), cumulative GC dose ($p < 0{,}002$), family history of osteoporosis ($p < 0.05$). Four women with low BMD had a fracture, compared to 1 without low BMD. No significant correlation was found between BMD and other studied parameters.

Conclusion: Our data suggest that patients with GN are at risk of low BMD, especially when and other risk factors for osteoporosis are present. A number of clinically relevant factors (longer duration of GN, proteinuria, high daily GC dose) are associated with low BMD. Using the minimally effective dose and duration of GC should be considered where possible.

P1198
CALCIUM PYROPHOSPHATE DISEASE SECONDARY TO PERSISTENT HYPOMAGNESEMIA, WITH CO-EXISTENT GOUTY ARTHRITIS AND GENERALIZED OSTEOARTHRITIS IN AN ELDERLY FILIPINO FEMALE: A CASE REPORT

S. P. Go-Soco[1], E. G. Vista[1], E. Tan[1]

[1]St Luke's Medical Center-Global City, Taguig City, Philippines

Elderly patients are predisposed to degenerative osteoarthritis. Crystal-induced inflammatory arthropathies, however, may complicate osteoarthritis. Gouty arthritis is caused by supersaturation of uric acid crystals; whereas, calcium pyrophosphate deposition disease is a crystal deposition disease. Both are associated with metabolic derangements. It is common practice to distinguish between the two inflammatory arthritides. However, these two may co-exist, as rare as it may be.

Case report: We describe the case of an elderly Filipino female, known case of degenerative osteoarthritis affecting the hips, spine, and knees. She presented with severe bilateral knee pain. On physical examination, both knees were effused, warm and erythematous. Arthrocentesis was immediately performed. Ancillaries revealed mild leukocytosis, with elevated erythrocyte sedimentation rate of 91 mm/h. Serum uric acid levels were normal. On review, she had persistent hypomagnesemia for almost a year, attributed to poor nutritional status. Synovial fluid was grossly dark yellow in color. Fluid analysis showed a cell count of 88,000 cells/uL. Gram stain and culture showed no microorganism, septic arthritis was ruled out. Polarizing microscopy revealed the presence of two crystals. Negatively-birefringent needle-shaped crystals and positively-birefringent rhomboid-shaped crystals were visualized. The former is consistent with monosodium urate crystals, and the latter with calcium pyrophosphate crystals. She was started on colchicine and febuxostat, with resolution of symptoms.

Conclusion: This case highlights that although rare, two types of crystal-associated arthropathies may co-exist in one patient. Further studies are required to probe into its association with osteoarthritis.

P1199
SURGICAL OUTCOMES OF OSTEOPOROTIC VERTEBRAL FRACTURES IN THE THORACOLUMBAR AND LUMBAR SPINE: A MONOCENTRIC RETROSPECTIVE ANALYSIS

S. P. Silva[1], D. Estrela[2], A. Barcelos[1]

[1]Rheumatology Dept., Unidade Local de Saúde Região de Aveiro, [2]Orthopedics Dept., Unidade Local de Saúde Região de Aveiro, Aveiro, Portugal

Objective: Osteoporotic vertebral fractures (OVF) are one of the most common osteoporotic fractures, and some patients require surgical intervention. The literature commonly reports the outcomes of

surgical repair of OVF at the thoracolumbar junction. We aim to evaluate surgical outcomes of lumbar OVF.
Methods: We conducted a retrospective study of patients who underwent spinal fusion surgery for OVF with a neurological deficit between November 2021 and 2023. Demographics, comorbidities, postoperative complications were compared between patients with lower lumbar fracture (L3-5) and those with thoracolumbar junction fracture (T10-L2). Nonparametric tests were used with a p-value statistically significant of < 0.05.
Results: A total of 46 patients (83.5% women with a median age of 73.50 y) were included in this study. 35 (76.6%) and 11 (23.9%) patients had thoracolumbar and lumbar OVF, respectively. Of these, 21.7% were treated with kyphoplasty, while 78.3% with vertebroplasty. All procedures were done by posterior approach, and most vertebral fixations (73.9%) were in upper and lower levels, with a minimum of 2 and a maximum of 6 fusion levels. There was a low incidence of postoperative complications, with anemia being the most common one (37.0%), with no differences between groups. We found no differences between lumbar and thoracolumbar OVF, except for previous fragility fractures, which were more prevalent in patients with lumbar OVF (14.3 vs. 54.5%, p = 0.022). More patients with thoracolumbar OVF needed rehabilitation (27.5 vs. 18.2%) and analgesics (25.7 vs. 0.0%) after surgery, but it was not statistically significant. More patients with lumbar OVF were referred to an Osteoporosis appointment (31.4 vs. 81.8%, p = 0.011). However, no differences regarding anti-osteoporotic treatment were observed (31.4 vs. 54.5%, p = 0.456).
Conclusion: Surgical intervention for OVF was effective in patients with myelopathy or radiculopathy regardless of the surgical level. Orthopedists should pay attention to intensive preoperative care to prevent various adverse events.

P1200
PARENTERIC AND SUBCUTANEOUS OSTEOPOROSIS TREATMENT ARE ASSOCIATED WITH ADHERENCE IN A PORTUGUESE FRACTURE LIAISON SERVICE

S. P. Silva[1], M. C. Portelada[1], G. Costa[1], C. Mazeda[1], P. Vilas-Boas[1], S. F. Azevedo[1], C. P. Oliveira[1], C. Vilafanha[1], P. M. Teixeira[1], G. Eugénio[1], A. Barcelos[1]

[1]Rheumatology Dept., Unidade Local de Saúde Região de Aveiro, Aveiro, Portugal

Objective: Literature describes that only 12.1% of Portuguese patients who suffered a hip fracture initiates treatment and only 3.4% were persistent in a 24-month period[1]. With that, we aimed to evaluate treatment adherence in our Fracture Liaison Service (FLS) and predictors of its persistence.
Methods: This retrospective study included patients who suffered a fragility fracture between January 2019 to December 2022. OP treatment was started according to the Portuguese recommendations and adherence to treatment were reassessed over a 1-y period. Predictors of treatment adherence were assessed using a logistic regression, and a p value ≤ 0.05 was considered statistically significant.
Results: A total of 220 patients were included, of which 176 (80%) started osteoporosis (OP) treatment: 79.3% oral bisphosphonate, 10.7% denosumab and 10.1% intravenous bisphosphonate. 34 patients lost follow-up and 7 patients died. After 12 months of follow-up, 133 (74.7%) patients maintained therapy. Patients who discontinued treatment were older (75.97 ± 10.69 vs. 79.59 ± 8.80, p = 0.050), had more respiratory diseases (3.1 vs. 13.3%, p = 0.010), had fewer previous OP treatment (24.8 vs. 8.9%, p = 0.023) and had more secondary fractures (p = 0.010). Patients that maintained OP treatment received more parenteric/subcutaneous formula (25.8 vs. 6.8%, p = 0.008). We didn't find differences in independent status, early menopause, parental hip fracture, calcium consumption, other comorbidities, smoking and alcohol habits, corticotherapy, previous fractures, vitamin D levels, institutionalization, and mortality. Patients treated with parenteric/subcutaneous OP treatment were more likely to maintain treatment, after adjusted for age and sex (OR 4.319, 95% C.I. 1.128–16.540, p = 0.033). On the other hand, patients who had respiratory chronic diseases were less likely to maintain treatment (OR 0.208, 95% C.I. 0.045–0.962, p = 0.044). Age at fracture, male gender and previous OP treatment were not significant predictors of adherence. The most common reason for treatment discontinuation was treatment complexity and self-reported adverse events.
Conclusion: In our FLS, 80% of patients started OP treatment after a fragility fracture. After 1-y, 74.7% of patients were adherent to OP. We also observed that parenteric/subcutaneous OP treatment were predictors of adherence to OP treatment. We believe that the adoption of the FLS model, could lead to better OP outcomes. Studies with longer follow-up periods are needed to confirm these findings.

P1201
COMPARATIVE ASSESSMENT OF SHORT-TERM RECOVERY AND FUNCTIONAL OUTCOMES IN ELDERLY PATIENTS UNDERGOING PFNA FIXATION FOR INTERTROCHANTERIC FRACTURES WITH AND WITHOUT CKD: A PROSPECTIVE COHORT STUDY

S. Paiboonrungroj[1], P. Pinijprapa[1], Y. Satravaha[2], O.-A. Phruetthiphat[1]

[1]Phramongkutklao hospital, [2]Orthodontic Dept., Mahidol Univ., Bangkok, Thailand

Objective: Osteoporotic hip fracture is becoming the world's major health issue as the majority of population ages. The fragility hip fracture has been shown to affect ambulatory status, quality of life, functional outcomes, mortality, resource and financial cost spent in health care system. Previous literatures demonstrated that older age, male gender, comorbidities such as liver diseases, chronic kidney disease (CKD), heart pathology and Charlson index more than 2 were associated with increased mortality. Acute kidney injury and advanced CKD in the intertrochanteric fracture were significantly associated with increased 1-y mortality, according to Kim and colleagues. In addition, Phruetthiphat et al. identified that an advanced stage CKD treated with PFNA fixation was associated with lower 1-y functional outcome and sepsis was more common in CKD stage 5. However, lack of evidence demonstrated a comparison of short-term recovery between CKD and non-CKD in elderly patients with intertrochanteric fractures treated by surgical fixation. The purpose of this study is to identify short term recover, and to compare functional outcome, complication, and mortality in both groups.
Methods: After Institutional Research Board Approval, patients over 60 years old who sustained intertrochanteric fractures with the 2018 AO/OTA type 31A1.3, 31A2.2, and 31A2.3 from low energy trauma underwent PFNA fixation were prospectively collected. All patients were categorized into 2 groups based on glomerular filtration rate (GFR): those patients without chronic kidney disease [GFR at least 60 ml/min] and those patients with CKD [GFR < 60 ml/min]. Patients' demography and comorbidities were reviewed in both groups. Koval

score was used for assessment the functional status at preoperative period, and postoperative period at 3 months, 6 months, and 1 y. 3 months, 6 months, and 1 y time up and go test (TUG) were used to identify the short term recover and physical performance. 3 months, 6 months, and 1-y functional outcome were evaluated by Harris hip score (HHS). Any complication and mortality rate were compared in both groups.

Results: This prospective study enrolled 69 participants, including 24 patients with CKD and 45 patients without CKD. There was no significant difference in length of stay, operative time and blood loss, fracture union, Koval scores, and HHS in both groups. However, the 6 months TUG in CKD group was significantly longer than the non-CKD group (41.6 vs. 32.8, p = 0.035), and almost statistical significance at 3 months (51.8 vs. 42.2, p = 0.05) between groups. In addition, the mortality rate of CKD group was significantly higher than the non-CKD group (20.8 vs. 2.2%, p = 0.017).

Koval score	13	5.38 ± 0.96	32	4.91 ± 1.42	0.273

Conclusion: Previous studies demonstrated that those patients with CKD stage 5 were associated with the highest mortality rate and lower functional outcome compared with non-CKD patients. However, they defined this comparison retrospectively while our study defined this comparison prospectively reducing possible confounding factors. In addition, this study firstly demonstrated a comparison of physical performance by TUG in both groups. Those elderly patients with intertrochanteric fracture and CKD treated with PFNA were significantly associated with longer short-term recovery, and higher mortality rate. This vulnerable group requires more attention in rehabilitation program to optimize outcome. In addition, this information is valuable for counseling their families regarding the mortality rate.

P1202
UTILIZATION OF ANABOLIC AGENTS IN VERY HIGH-RISK GROUP OF OSTEOPOROSIS IN POSTMENOPAUSAL WOMEN IN MAJOR EUROPEAN COUNTRIES

S. Palacios[1], K. Briot[2], S. Gawande[3], M. Boolell[3]

[1]Clinica Palacios C. de Antonio Acuña, Madrid, Spain, [2]Rhumatologue, Paris, France, [3]Theramex, London, UK

Objective: The study evaluated the current clinical practice in management of osteoporosis who are at very high risk (VHR) in 5 major European countries.

Methods: 1475 patient record forms (PRF) from 148 doctors from five key countries mentioned below were reached out to collect data. All physicians, specialists using anabolic, needed to have minimum of 10 VHR postmenopausal osteoporotic patients and were interviewed for 20 min to review the PRF. VHR group were postmenopausal

woman with T-score <—2.5; plus, history of more than 1 prior vertebral or non-vertebral fracture and/or recent fracture within last 2 y and/or experienced fracture whilst on treatment, and/or corticoid steroid use and/or age above 65 y.

Results: Only 30–40% of VHR patients received anabolic therapies, as opposed to the more common oral bisphosphonates (BP) or denosumab. Denosumab was utilized in 25–35% of VHR patients. Only 25–50% of patients with hip fractures received anabolic treatments instead of anti-resorptive options. Teriparatide and denosumab were used as second choice of treatment after oral BP. Patients in whom anabolic was initiated the most common fracture type was vertebral fracture (30–60%) followed by non-vertebral fracture (20–40%).

Table 1. Treatment selection varied across countries.

Parameters	Course of treatment	UK	Germany	Spain	Italy	France
Specialist*		32	31	33	26	26
% Anabolic usage in VHR osteoporosis patients assessed PRF (n).	First line#	(n-130)	(n-182)	(n-140)	(n-143)	(n-159)
	Anabolic	24%	24%	35%	32%	39%
	Denosumab	10%	17%	27%	19%	6%
	Oral BP	46%	46%	32%	42%	27%
	Second line	(n-129)	(n-93)	(n-153)	(n-91)	(n-85)
	Anabolic	38%	38%	41%	51%	41%
	Denosumab	31%	44%	44%	41%	44%
	Oral BP	3%	6%	10%	4%	4%
	Third line		(n-30)	(n-37)	(n-26)	(n-15)
	Anabolic	(n-148)	74%	79%	65%	69%
	Denosumab	67%	20%	16%	35%	12%
	Oral BP	24%	-	3%	-	-
		2%				

* Rheumatologist/Orthopaedic surgeon/Endocrinologist and trauma specialist
\# Spain, Italy, and France initiate anabolic use earlier compared to Germany and the UK.

Conclusion: Study shows notable underutilization of anabolic use for osteoporosis in VHR group and are more frequently utilized as a secondary option and beyond, underscoring the necessity for aligning treatment guidelines.

P1203
BALNEOTHERAPY AND MUSCULOSKELETAL DISEASES: EXPERIENCE OF TUNISIAN DOCTORS

S. Rahmouni[1], R. Fejji[1], K. Zouaoui[1], M. Abbes[1], S. Boussid[1], S. Rekik[1], H. Sehli.[1]

[1]Rabta Hospital, Tunisa, Tunis, Tunisia

Objective: Balneotherapy (BT) represents an interesting treatment alternative commonly used as additional intervention in the management of musculoskeletal disorders (MSD)and pain management. Our study aims to examine the perception and experience of Tunisian doctors regarding the use and the effects of BT in medicine.

Methods: An online survey comprising 17-questions was conducted in January 2024 addressed to physicians who commonly manage patients with MSD: rheumatologists (RTO), orthopedic surgeons (OS), physical therapists (PT), and general practitioners (GP).

Results: We included 129 physicians (52 RTO, 31 OS, 9 PT,37 GP), with a M/F sex ratio of 0.53. The mean age of participants was 34.28 [25–62]. Among them, three were professors, 13 were associate professors, 15 hospital-university assistants, 25 were private practice physicians, and 73 were residents. In our study, 94.6% of the doctors worked in an urban setting with an average year of practice of 7.59 ± 8.3. 75 doctors (58%) prescribed BT at least once (< 5 times a year: 77%, [5–10]:17.6% and > 10 times a year in 5.4%. the prescription was upon patient request in 81.1% of times. The cost of this therapy was covered by the national health insurance fund (NHIF) in 89.2% of cases, by private insurance in 2.7% and by the patient in 8.1%. The main indications for BT prescriptions are summarized in the following Table:

Table 1. Indications for balneotherapy prescriptions:

Medical condition	Rate (%)
Chronic inflammatory rheumatism (remission) (CIR)rm	27
Chronic inflammatory rheumatism (relapse) (CIR)rp	5.4
Low back pain/sciatica (LBP)	79.7
Cervicobrachial neuralgia and cervical pain (CBN)	23
Osteoarthritis (OA)	77
Fibromyalgia (FM)	32.4
Rotator cuff pathology (RCP)	8.1
Osteoporosis (OP)	2.7
Algodystrophy (AD)	9.5
Calcaneal spur (CS)/ Osteoporotic fracture (OF)	0

Based on the experience of the included physicians, patients reported diverse outcomes: no effect (1.4%), a sense of well-being without symptom improvement (15.1%), partial symptom improvement (58.9%), and a spectacular improvement in symptoms (24.7%). The main reasons for not prescribing BT were lack of knowledge about this therapy (58%) and the lack of social security coverage for the patients (41%). 33 physicians (25.6%) reported that patients refused BT because of lack of means (67.5%) and difficulties accessing the thermal resorts (47.5%). Based on their experience, physicians reported better outcomes of BT in the following conditions: LBP (81.4%), OA (72.9), CBN (67.4%), and CIR rm (55%). However thermal therapy was also identified effective in CIR rp (10.9), OP (7%), SC (3.9%) and OF (1.6%).

Conclusion: Although on 58% of the interviewed physicians have prescribed BT, most of them reported a beneficial effect of this therapy in musculoskeletal diseases. The main reason of not prescribing BT were the lack of knowledge about this treatment. Thus, it is crucial to raise awareness among physicians about the benefits of BT and its use.

P1204
A RARE CAUSE OF MULTILEVEL SPONDYLODISCITIS: CALCIUM PYROPHOSPHATE DEPOSITION DISEASE

S. Rahmouni[1], J. Soua[1], K. Zouaoui[1], M. Abbes[1], S. Boussaid[1], S. Rekik[1], H. Sahli[1], M. Elleuch[1]

[1]Rheumatology Dept., Rabta Hospital, Tunis, Tunisia

Calcium pyrophosphate deposition crystal disease (CPPD) is a crystalline arthropathy due to the deposition of CPP crystal in the joints. Exceptionally, CPP deposition may occur in the intervertebral discs and may cause chronic CPP crystal arthritis revealed by chronic back pain.

Case report: A 52-year-old women with no medical history was referred to the Department of Rheumatology for the assessment of inflammatory back pain, which started one year ago. She also complained of left knee pain and right shoulder. The physical examination was normal except for lumbar spine stiffness. Radiography showed multilevel discitis with linear intradiscal calcification within the nucleus pulposis (Fig. 1). Radiographs of the knees and pelvis were normal. Lumbar CT scan showed osteosclerosis of the adjacent vertebral plates of the l1-l2 disc, erosive disc disease with intradiscal calcifications and an intradiscal void. Biological assessment did not reveal any abnormality. Calcium, PTH Magnesium, ferritin and ALP levels were normal. The diagnosis of CPPD was then confirmed and the patient was prescribed colchicine (1 mg daily) with a good clinical response.

Figure 1. Lumbar X-ray showed multilevel discitis with linear intradiscal calcification within the nucleus pulposis

Conclusion: Spondylodiscitis can be due to non-infectious inflammatory spinal disorders or infectious diseases. The deposition of CPP in the spine is rare but should be considered in patients with back pain and peripheral joint symptoms.

P1205
PHYSICIANS' APPROACH TO PRESCRIBING THERMAL SPA TREATMENTS: INSIGHTS AND PRACTICES

R. Fejji[1], S. Rahmouni[1], K. Zouaoui[1], M. Abbes[1], S. Boussid[1], S. Rekik[1], H. Sehli[1]

[1]Rabta Hospital, Tunisa, Tunis, Tunisia

Objective: To assess the knowledge of physicians regarding the use of Spa therapy (ST) in musculoskeletal diseases.
Methods: In January 2024, we sent an 18-question survey via Google Forms, to physicians who commonly manage patients with MSD: rheumatologists (RTO), orthopedic surgeons (OS), physical therapists (PT), and general practitioners (GP).
Results: 129 physicians were enrolled (52 RTO, 31 OS, 9 PT, 37 GP). The average age of participants was 34.28 ± 8.86 y. Regarding the definition of ST, 33.3% considered it to be the same as crenotherapy, and 54.3% confused it with thalassotherapy and 61.2% with balneotherapy. Meanwhile, 20.2% of doctors expressed a lack of knowledge on this subject. When asked about the main indications for ST 96.1% reported rheumatic diseases, 61.2% neurological disorders, 45.7% ENT (Ear, Nose, and Throat) conditions, and 38% respiratory diseases. On the other hand, dentistry, gynecology, urology, psychiatry, and dermatology uses were reported by 3.9%, 20.2%, 20.2%,27.9%, and 28.7% of physicians, respectively. In our study, 22 doctors (17.1%) believed that a ST could be prescribed by a physiotherapist (wrong answer), 75.2% by a GP (correct answer) and 95.3% by a specialist (correct answer). The following Table summarizes the uses of ST in rheumatology.

Table 1. Indications for a ST according to the participants

Indication	Answer	Percentages
Osteoarthritis	RA	79.8
Low Back Pain	RA	88.4
Tendinopathy	RA	56.6
Inflammatory Rheumatism in Remission	RA	61.2
Fibromyalgia	RA	52.7
Osteoporosis	WA	9.3
Osteoporotic Fracture	WA	3.9
Calcaneal Spur	WA	2.9
Algodystrophy	RA	30.2
Osteomalacia	WA	4.7
Gout	WA	3.9
RA: right answer, WA: wrong answer		

Regarding the contraindications of ST, 86 patients had at least one wrong answer: pregnancy (47.3%), tendinopathy (2.3%), psoriasis (31.8%), tophaceous gout (7%), neoplasia in remission (0.8%), anticoagulant therapy (20.2%), asthma (13.2%). Regarding the average duration of a ST session, 41.1% had a good answer (18–21 d). Regarding the number of treatments per day: 21.1% of doctors believed that the maximum number of treatments allowed per day was 3, 19.5% thought it varied between 4 and 6 treatments (RA), 6.3% believed it was unlimited depending on the patient's desire, and finally, 53.1% of doctors were uncertain about the correct answer. The duration of each treatment was thought to be 1–2 h by: 8.5% of doctors, [30–60 min] by 37.2%, [10–15 min] (RA) by 4.7% and as long as the patient wants by 1.6% of doctors. While 48.1% of the participants did not know the answer.
Conclusion: Although the beneficial effect of ST on musculoskeletal diseases is well documented, our study revealed the lack of knowledge of specialist physicians RTO, OS, PT and GP regarding its use.

P1206
SPONDYLOARTHRITIS: DOES THE PROFILE OF THE PATIENT INFLUENCE VITAMIN D STATUS?

S. Rahmouni[1], R. Fejji[1], M. Mrad[2], K. Zouaoui[1], M. Abbes[1], S. Boussid[1], A. Bahlous[2], S. Rekik[1], H. Sehli[1]

[1]Rabta Hospital, Rheumatology Dept., [2]Pasteur institution, Biochemistry Dept., Tunis, Tunisia

Objective: To describe the prevalence of vitamin D deficiency in spondyloarthritis (SpA) and explore correlations between the clinical and biochemical parameters of the disease in these patients.
Methods: A cross-sectional study with prospective data collection involving 79 patients meeting ASAS criteria for SpA was conducted over a 2-y period. Sociodemographic data (age, gender, smoking), clinical information (disease duration, disease activity (BASDAI), and functional impact (BASFI)), as well as biological parameters (1–25 OH vitamin D levels, CRP), were collected. We referred to the Institute of Medicine (IOM) recommendations to define VitD status thresholds as follows: deficiency (< 20 ng/ml), insufficiency (20–29 ng/ml), and adequacy (30–44 ng/ml) [1].
Results: 79 patients, predominantly male (70.8%), were included with a M/F ratio of 2.43. The mean age was 46.3 ± 12.9. Active smoking was reported in 55.8% of cases. The mean disease duration was 12.5 ± 9.2 y. Extra-articular manifestations were present in 51 patients (60.5%), involving ocular, digestive, cutaneous, pulmonary, and bone manifestations in 13, 16, 5, 15, and 20 patients, respectively. The mean BASDAI and BASFI scores were 4.13 ± 2.11 [0.62–9.2] and 4.5 ± 2.25 [0.2–8.3], respectively. The mean CRP was 20.97 ± 24.1 mg/L. 65% of patients had vitamin D deficiency (25 (OH)D < 20 ng/ml) with an average vitamin D level of 17.7 ± 9.8 ng/ml. For the respective thresholds of 10, 20, and 30 ng/ml, the prevalence of 25(OH)D deficiency was 22.8%, 65%, and 94%, respectively. Vitamin D deficiency was significantly more common in females ($p = 0.032$) and in patients with a shorter disease duration ($p < 0.001$) and elevated CRP levels ($p = 0.021$). Additionally, no significant correlation was observed between vitamin D deficiency and BASDAI ($p = 0.472$), BASFI ($p = 0.876$), smoking ($p = 0.06$), and the presence of extra-articular manifestations.
Conclusion: Our study, consistent with existing literature, demonstrated an increased prevalence of vitamin D deficiency in SpA [2], particularly among females [3], those with a shorter disease duration [4], and those with elevated CRP levels [5].

P1207
DO PHYSICIANS WHO PRESCRIBE THERMAL SPA HAVE THE BASIC KNOWLEDGE OF REIMBURSEMENT?

S. Rahmouni[1], R. Fejji[1], K. Zouaoui[1], M. Abbes[1], S. Boussid[1], S. Rekik[1], H. Sehli[1]

[1]Rabta Hospital, Rheumatology Dept., Tunis, Tunisia

Objective: To assess the knowledge of physicians regarding the reimbursement modalities of spa therapy (ST) in musculoskeletal diseases (MSD)concerning the care modalities endorsed by the National Health Insurance Fund (NHIF) and the associated reimbursement procedures.
Methods: An online survey of 17 questions was conducted in January 2024 addressed to physicians who commonly manage patients with MSD: rheumatologists (RTO), orthopedic surgeons (OS), physical therapists (PT), and general practitioners (GP). The survey was conducted using Google Forms.
Results: We enrolled 129 doctors comprising 52 (RTO), 31 (OS), 9 (PT), and 37 (GP), resulting in a M/F sex ratio of 0.53. The average age of participants was 34.28, ranging from 25–62 y. 75 doctors (58%) recommended ST with a prescription pattern as follows: 77%: less than 5 times a year, 17.6%: [5–10] times annually, and 5.4%: more than 10 times a year. At 58%, physicians refrained from prescribing ST due to a lack of knowledge about the procedure especially regarding the modalities of coverage by social security funds in Tunisia (69.8%). Regarding the question of the number of spa treatments reimbursed by the (NHIF) that a patient can have throughout their life (without going through the medical commission), only 27.9% had a right answer (twice in a lifetime) ($p < 10^{-3}$) and 38% did not know the answer. 22% of physicians knew that a patient aged over 55 could qualify for an automatic approval for a ST without going through the NHIF commission ($p \leq 10^{-3}$), while 51.9% had no idea on this subject. Only 17.1% of physicians knew that ST was reimbursable at the rate of 85% ($p = 0.033$), while 48.4% expressed having no knowledge about this. When asked about the recognized centers eligible for reimbursement, 9% of doctors had a right answer ($p = 0.54$).
Conclusion: Although physicians prescribed commonly ST, our study highlighted their lack of knowledge about the reimbursement modalities. Improving physicians' knowledge in this area is crucial in order to increase ST prescriptions, which ultimately lead to better patient care.

P1208
IMPLICATIONS OF BISPHOSPHONATE-ASSOCIATED SIDE EFFECTS ON TREATMENT ADHERENCE AND THERAPEUTIC EFFICACY

S. Rezgui[1], K. Maatallah[1], H. Ferjani[1], F. Majdoub[1], D. Ben Nessib[1], L. Kharrat[1], D. Kaffel[1], W. Hamdi[1]

[1]Mohamed Kassab Institute of Orthopedics, Tunis, Tunisia

Objective: Bisphosphonates, commonly prescribed to improve bone density and minimize fracture risk, have proven to be effective. Nevertheless, it is crucial to acknowledge the impact of potential side effects, as they play a noteworthy role in influencing the patient's overall experience and decision-making process. This study aimed to determine the side effects caused by bisphosphonates and their impact on treatment adherence and therapeutic efficacy.
Methods: A monocentric cross-sectional study was conducted, involving osteoporosis patients treated with bisphosphonates. Sociodemographic and clinical characteristics were collected. Patients were interviewed regarding the adverse effects of bisphosphonates and the reasons for discontinuing the treatment.
Results: A total of 100 patients were enrolled, comprising 13 men and 87 women, resulting in a sex ratio of 0.15. The mean age was 66 y ± 7.7 [42–85]. Among the participants, 29% had a rheumatic disease, and 17 were on regular steroid therapy. The mean BMD at the vertebral site was 0.781 ± 0.09 [0.563–0.922] g/cm^2, while at the femoral site, it was 0.580 ± 0.8 [0.016–1.150] g/cm^2. Alendronate was prescribed for 46 patients, risedronate for 43, and zoledronate for 11. Of these, 89 patients took the bisphosphonate orally. 24 patients (26%) reported adverse effects related to bisphosphonates, distributed as follows: flu-like syndrome (patients who had zoledronate IV infusion) in 21.7%, epigastralgia in 47.8%, a sense of digestive discomfort in 21.7%, and nausea in 8.7% of cases. The occurrence of adverse effects was not significantly associated with the presence of chronic inflammatory rheumatic disease ($p = 0.87$), the treatment duration ($p = 0.057$), or the treatment administration method (IV or orally) ($p = 0.76$). The bisphosphonates' adverse effects led to the discontinuation of treatment in 4 patients, including 2 on risedronate and 2 on alendronate. This discontinuation resulted in a height loss of 2 cm in one patient.
Conclusion: Side effects may affect the quality of life for individuals on bisphosphonates, potentially influencing their decision to continue treatment and, consequently, reducing the therapeutic effect of the medication.

P1209
A VIRTUAL ASSISTANT BASED ON A CHATBOT TO PROMOTE ADHERENCE TO EARLY POSTOPERATIVE REHABILITATION AND CLINICAL OUTCOME AFTER REVERSE SHOULDER ARTHROPLASTY

J.-M. José-María[1], S. Roig-Casasús[1], M. Navarro-Bosch[2], J.-E. Aroca-Navarro[2], D. David[1], P. Pau[1]

[1]Universitat de València, [2]Hospital Universitari i Politècnic La Fe de València, Valencia, Spain

Objective: There is no clear consensus on rehabilitation guidelines after reverse shoulder arthroplasty (RSA), but it is considered essential to an optimal return to daily functional activities or more complex activities such as sports practice. However low adherence to rehabilitation is one of the main barriers. The goal was to evaluate the effectiveness of using a chatbot in promoting adherence to home rehabilitation in patients undergoing RSA.
Methods: Randomized pilot trial with patients undergoing RSA. A control group received standard home rehabilitation, while the experimental group received the same intervention, but this was supervised by a virtual assistant who communicated with patients through a personal smartphone via an instant messaging application supervised with a chatbot. The interactions included messages to inform about the intervention, motivate, and remember the days and exercises for 12 weeks. Compliance with rehabilitation and clinical measures of shoulder function, pain, and quality of life were assessed. Data were analyzed with CI set at 95%.
Results: 31 patients (17 experimental, 14 control) average aged 70.4 (3.6) completed the intervention. Higher compliance to rehabilitation was achieved in the experimental than in the control group (77 vs. 65%; OR95% = 2.4 (0.5 to 11.4)). Participants evolved in time with significant benefits regarding shoulder function and shoulder disability, pain, and quality of life ($p < 0.001$). However, there was no significant increase in shoulder strength or mobility. Statistically significant between-group differences were found in the Quick DASH and self-reported quality of life. No differences were found in the rest of the measures.

Conclusion: A strategy to promote adherence to rehabilitation based on an automated chatbot promoted adherence with early postoperative home rehabilitation in patients undergoing RSA over standard care. Future trials can be oriented to determine the long-term effectiveness of the proposal.

P1210
EFFECT OF GENDER ON ACUTE AND SUBACUTE CHANGES IN ACHILLES TENDON ECHO INTENSITY INDUCED BY TRAINING: SOCCER AND HANDBALL TEAMS MICROCYCLE FOLLOW-UP

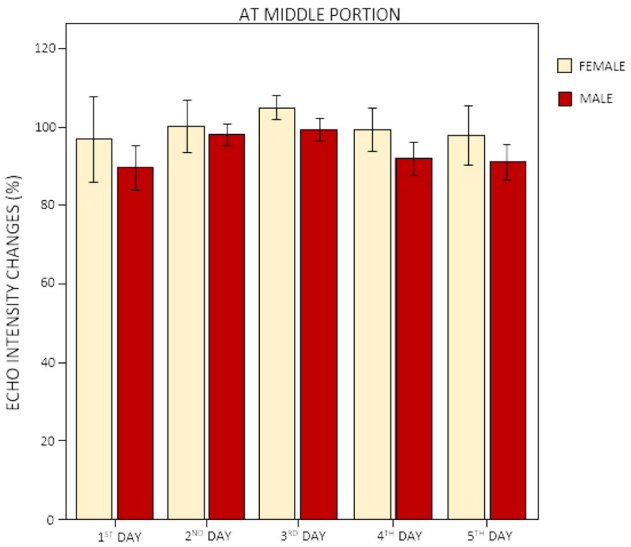
S. Salatkaite Urbone[1], D. Satkunskiene[1]

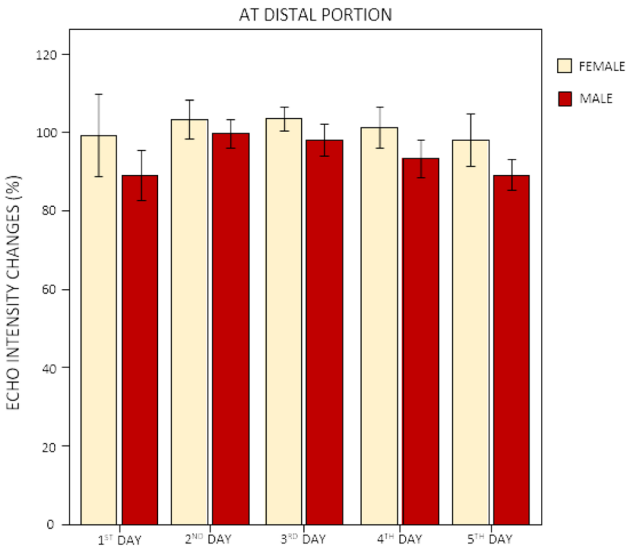
[1]Lithuanian Sports Univ., Kaunas, Lithuania

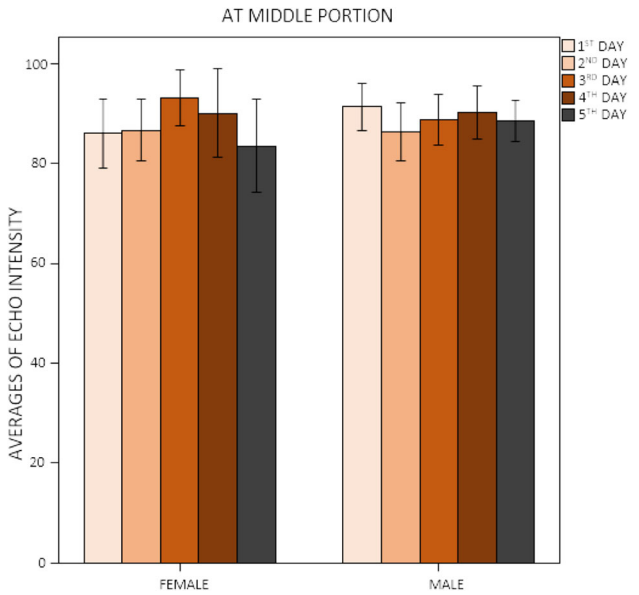
Objective: To investigate the effect of gender on Achilles tendon (AT) echo intensity (EI) acute and subacute changes induced by training during a one-week training cycle in professional soccer and handball players.

Methods: An ultrasound scanner, the Mindray Diagnostic Ultrasound System (Shenzen Mindray Bio-medical Electronics CO., LTD.), was used to collect a grayscale B-mode cross-sectional images of the AT proximal, middle, and distal portions. The study involved four professional male and female soccer and handball teams competing in the top leagues in Lithuania. Eight players from each team were tested before and after their training sessions for one week, starting on Monday and ending on Friday. All players were healthy and participated in all training sessions. The mean age, height, weight of female and male players were 23.31 ± 3.28 y, 1.68 ± 0.03 m, 61.44 ± 5.91 kg and 22.94 ± 4.27 y, 1.87 ± 0.05 m, 77.25 ± 7.72 kg respectively. This project has received funding from the Research Council of Lithuania (LMTLT), agreement No S-PD-22–27.

Results: Analysis of OMNI scale data showed that training intensity didn't change during the week ($F = 0.839$, $p = 0.503$). The acute effect had a significant impact on EI at all AT portions: proximal ($F = 18.038$, $p < 0.001$), middle ($F = 12.154$, $p = 0.002$) and distal ($F = 8.380$, $p = 0.007$). However, gender significantly interacted with acute effect only in the middle ($F = 7.052$, $p = 0.013$) and distal ($F = 9.503$, $p = 0.004$) AT portions. The subacute effect had a significant impact on the EI at the middle ($F = 3.736$, $p = 0.024$) and distal ($F = 3.929$, $p = 0.025$) AT portions, and gender significantly interacted with the subacute effect on the EI only at the middle AT portion ($F = 3.25$, $p = 0.038$). Also, the acute effect had a significant impact on the subacute effect at the proximal ($F = 4.890$, $p = 0.002$), middle ($F = 5.166$, $p = 0.005$) and distal ($F = 7.933$, $p < 0.001$) AT portions.







Conclusion: The impact of training sessions on echo intensity is significantly influenced by gender and varies depending on the portion of the Achilles tendon. For male players, echo intensity was significantly decreased at the middle and distal portions of the Achilles tendon in the acute phase. Conversely, female players experienced a greater effect on echo intensity at the middle portion of the Achilles tendon during the subacute phase.

P1211
SPECIAL FEATURES OF ANTIOXIDANT SYSTEM IN CARDIOVASCULAR MANIFESTATIONS OF SYSTEMIC SCLERODERMA

S. Spitsina[1], E. Mozgovaya[2], S. Bedina[1], A. Trofimenko[2]

[1]Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky, Volgograd State Medical Univ., [2]Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky, Volgograd, Russia

Objective: To determine the activity of glutathionereductase (GR) in patients with systemic scleroderma (SSD) with manifestations of cardiovascular system damage.
Methods: 50 patients with systemic scleroderma (48 (96%) women and 2 (4%) men) were included in the study; their mean age was 50.7 ± 9.1 y, disease duration was 10.4 ± 8.3 y. Cardiac pathology was detected in 38 patients (76%), the rest had predominantly cutaneous-articular, pulmonary symptoms. The main manifestations of cardiovascular system damage were CHD (angina pectoris, cardiosclerosis, arrhythmias) in 24 patients (63%); arterial hypertension in 32 (84%); pericarditis in 2 (5%); valve disorders in 2 (5%). GR activity was determined according to the method of Hosoda and Nakamura, and the concentration of antibodies to GR was determined by enzyme immunoassay method using magnetosorbents (I.P. Gontar et al., 2002).
Results: According to the results of the study, the enzymatic activity of GR in patients with systemic scleroderma was significantly reduced, although no statistically significant differences depending on clinical symptoms were found. Also, an increase in the content of antibodies to GR was detected in 100% of scleroderma cases. However, their highest level was determined in patients with cardiovascular lesions ($p < 0.001$). Thus, decreased GR activity and synthesis of autoantibodies to GR are associated with increased risk of cardiovascular diseases.
Conclusion: In patients with systemic scleroderma with predominant cardiovascular lesions, antibodies to GR, which inhibit its antioxidant activity and are another factor in the development of atherosclerotic process, are detected significantly more often and in a higher value.

P1212
RELATION OF PAIN SYNDROME TO THE LEVEL OF PROINFLAMMATORY CYTOKINES IN PATIENTS WITH RHEUMATOID ARTHRITIS ON BASELINE THERAPY

S. Spitsina[1]

[1]Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky, Volgograd State Medical Univ., Volgograd, Russia

Objective: To evaluate the dynamics of pain syndrome in patients with rheumatoid arthritis (RA) receiving combination therapy with methotrexate (MT) and infliximab (IF); to identify the relationship with the level of proinflammatory cytokines before and after the administration of combination therapy.
Methods: 18 patients with a diagnosis of RA verified according to ACR/EULAR 2010 qualifying criteria were included in the study. All patients received oral MT at a stable dose of 12.5–20 mg/week for 6 months or more, as well as various nonsteroidal anti-inflammatory drugs. 9 (50%) of the subjects received methylprednisolone 8 mg daily. 15 (66.7%) patients showed extra-articular manifestations in the form of mild anemia. Due to the persisting high activity of RA, patients were additionally prescribed IF (TNF-α inhibitor). The patients' condition was evaluated before IF administration (week 0) and at week 54 after combination therapy. IF was administered according to the standard regimen at a rate of 3 mg/kg body weight. RA activity was assessed using the DAS28-CRP(4) index. The patients' pain syndrome was assessed using the visual analogue scale (VAS) questionnaires for pain and disease activity assessment by the patient, HAQ and SF-36 at each of the indicated visits.
Results: The patients included in the study were female, with a mean age of 46 ± 8.4 y; with advanced and late stages of the disease. Patients had high activity of inflammatory process (DAS28-CRP(4) > 5.2); 2nd and 3rd functional class of joint failure. All patients showed a tendency of improvement of clinical manifestations by week 54 of combined MT + IF treatment: reduction of joint syndrome intensity, time of morning stiffness, pain and swelling of the affected joints, which was expressed in reduction of patient-defined VAS indices (on average, from 66.7 to 18.4 mm) and DAS28-CRP(4) (on average, from 5.5 to 3.03). Most patients showed improvement in quality of life parameters on the specialized HAQ questionnaire (from 1.4 ± 0.4 to 1.2 ± 0.21) and the general SF-36 questionnaire, especially with regard to the physical health score (from 34.3 ± 9.2 to 41.7 ± 6.5). Also, by week 54 of treatment, serum levels of measured pro-inflammatory cytokines decreased, which correlated with pain reduction. TNFα and IL-1 levels correlated directly with the VAS ($r = +0.45$ and $r = +0.23$, respectively) and HAQ ($r = +0.76$ and $r = +0.48$, respectively), inversely with the physical component of the SF-36 (r = -0.44 and r = -0.17, respectively).
Conclusion: Positive dynamics of clinical and laboratory parameters on the background of combined therapy of MT and IF was revealed: improvement of functional activity of joints, reduction of VAS of disease activity by the patient, improvement of performance of activities of daily living according to HAQ, improvement of general health according to SF-36. Correlation of the levels of

proinflammatory cytokines with the indicators characterizing the pain syndrome was noted.

P1213
ANTIBODIES TO ELASTIN AS A MARKER OF VASCULAR DAMAGE IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

S. Spitsina[1], E. Mozgovaya[2], S. Bedina[1], O. Emelyanova[2], O. Rusanova[2], A. Trofimenko[2]

[1]Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky, Volgograd State Medical Univ., [2]Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky, Volgograd, Russia

Objective: To study the concentration of antibodies to elastin in patients with systemic lupus erythematosus (SLE), to reveal the correlation with cardiovascular manifestations of the disease, as well as a possible role as a marker.
Methods: The study included 45 patients diagnosed with SLE, the mean age of whom was 40.8 ± 12.4 y. The control group consisted of 30 conditionally healthy women, comparable in age. Moderate degree of activity was in 28 people (62%), low activity in 7 (16%), high in 10 (22%). According to the course of the disease: 8 (18%) patients had an acute course, 22 (49%) had a subacute course, and 15 (33%) had a chronic course. Patients had cutaneous-articular, pulmonary, neurologic, hematologic manifestations. Myocarditis with manifestations in the form of rhythm and conduction disorders, cardialgia, were found in 11 patients (24%). Mitral and aortic valve insufficiency lesions were detected in 9 patients (20%). Raynaud's syndrome, capillaritis, and vasculitis prevailed among the symptoms of vascular lesions (in 71% of cases). Determination of the content of antibodies to elastin was performed by indirect enzyme immunoassay using immobilized granular antigenic preparations with magnetic properties. The results were reported in optical density units (o.d.u.).
Results: Antibodies to elastin were detected in 58% of cases. No significant differences depending on age were found. At the same time, the concentration of antibodies to elastin was significantly higher in patients with acute course and high activity of SLE ($p < 0.05$). Depending on the clinical variants, it was found that the group of patients with vascular lesions had a more significant increase in antibodies to elastin ($p < 0.05$), in contrast to the group with valve and myocardial lesions ($p = 0.07$).
Conclusion: Increased synthesis of autoantibodies to elastin, as a component of the vascular wall, may be the cause of the development of systemic vasculopathy and a factor in the development of atherosclerosis and, as a consequence, cardiovascular pathologies, which makes it necessary to intensify not only the therapy of SLE to reduce the activity, but also the early prevention of cardiovascular accidents.

P1214
PREDICTORS FOR EXCELLENT OUTCOME AFTER HIP REPLACEMENT FOR ELDERLY FEMORAL NECK FRACTURE

O.-A. Phruetthiphat[1], S. Tatiyaworakulwong[1], P. Pinijprapa[1], P. Woratanarat[2]

[1]Phramongkutklao Hospital, [2]Ramathibodi Hospital, Bangkok, Thailand

Objective: In elderly patients with osteoporosis, femoral neck fracture is a common and debilitating injury, leading to significant loss of function and independence. Bipolar hemiarthroplasty (BHA) is a common surgical treatment for femoral neck fracture, with generally good outcomes. A systematic review and meta-analysis of fourteen randomized clinical trial demonstrated a comparison between BHA and THA, showing THA was significantly associated with higher Harris hip score (HHS) and lower revision rate while BHA was associated with shorter operative time and lower dislocation rate (1–2). In addition, a comparison between cemented and cementless BHA for femoral neck fracture in elderly patients showed that the cementless BHA had higher HHS than the cemented BHA. In contrast, cementless BHA had significantly higher rate of periprosthetic fracture (3–4). Previous studies have focused either surgical parameters or medical factors on the outcome after hip replacement. However, there is a lack of evidence identifying both parameters prediction the outcome together. Thus, this study aims to determine the predictive factors associated with excellent outcome, as well as to develop an integrated scoring system to predict the outcome after hip replacement in elderly patients with a femoral neck fracture.
Methods: A retrospective study was conducted in our institute from January 2015 to December 2021. Elderly patients with low-energy femoral neck fractures who underwent BHA and at least a year of follow-up were included. Demographics, comorbidities including ASA class and Charlson comorbidity index (CCI), BMD, length of hospital stay (LOS), as well as surgical parameters of the patients were all evaluated. Patients were categorized based on their HHS at 1-y follow-up as having excellent or non-excellent outcomes. Regression analysis was used to identify the independent predictors for an excellent functional outcome (HHS at least 90). A new integrated scoring system (Integrate Scoring System in elderly patients with Isolated femoral neck fracture: $ISSI_{FN}$) was developed. Clinically relevant parameters and statistically significant factors were further included in the new scoring system.
Results: A total of 348 elderly patients who underwent BHA were included for regression analysis. Univariate analysis demonstrated that younger age ($p < 0.001$), lower ASA class ($p = 0.003$), higher GFR ($p = 0.002$), higher albumin ($p < 0.001$), higher hip BMD ($p = 0.007$), shorter length of hospital stay ($p = 0.002$) were significantly associated with excellent functional outcome after hip replacement. Multivariate analysis revealed that the following factors were significantly associated with an excellent outcome after BHA: age < 70 y, lower ASA class, CCI ≤ 5, GFR ≥ 60, hip BMD > -2.5, LOS ≤ 5 d, Dorr type A, cementless femoral stem, and collar type. The $ISSI_{FN}$ score ranged from 0–12 and the cut-off score of at least 6 was found to have the highest discriminatory power to determine the excellent functional outcome, achieving an area under the ROC curve of 0.757, with a sensitivity of 60% and a specificity of 75%.

Table 4 Multivariate analysis, and predictive score for excellent outcome

Factors	Adjusted OR* (95% CI)	P-value	Coefficient	Predictive Score
Age				
<70 years	4.91 (2.12-11.39)	**0.016**	1.59	**2**
≥70 years	1.00			0
ASA class				
I, II	1.34 (0.60-2.98)	0.276	0.29	**1**
III	1.00			0
CCI				
≤5	9.74 (4.00-23.71)	0.128	1.23	**2**
>5	1.00			0
Length of hospital stay				
≤5	3.43 (0.37-3.17)	0.122	1.39	**2**
>5	1.00			0
eGFR (ml/min)				
≥60	1.52 (0.48-1.33)	0.357	0.42	**1**
<60	1.00			0
Hip BMD				
> -2.5	2.08 (0.06-1.53)	0.070	0.73	**1**
≤ -2.5	1.00			0
Morphology of Proximal femur				
Dorr type A	1.72 (0.44-1.53)	0.276	0.54	**1**
Dorr type B, C	1.00			0
Type of femoral stem				
Cementless	1.94 (0.35-1.69)	0.200	0.66	**1**
Cemented	1.00			0
Collar	2.19 (1.11-2.68)	0.415	0.78	**1**
Collarless	1.00			0

ASA class: American society of anesthesiologist classification; CCI: Charlson comorbidity index; GFR: Glomerular filtration rate; BMD: Bone mineral density

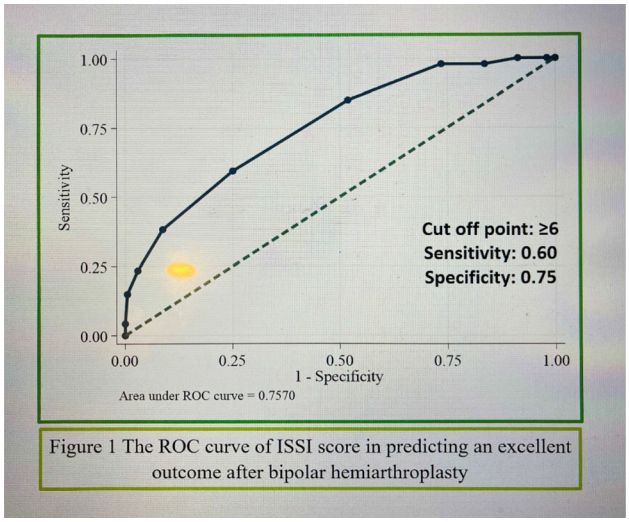


Figure 1 The ROC curve of ISSI score in predicting an excellent outcome after bipolar hemiarthroplasty

Conclusion: The $ISSI_{FN}$ score is effortless and practical for orthopedic surgeons for predicting excellent functional outcomes after hip replacement in elderly patients with an isolated femoral neck fracture. Those patients with non-excellent outcome at 2 weeks follow up in out-patient department should be required additional motivation and a more aggressive rehabilitation program for enhancing functional recovery.

A RARE CASE OF TUMOR-INDUCED OSTEOMALACIA CAUSED BY A DISTALLY LOCATED SOFT TISSUE GIANT CELL TUMOR

S. Tournis[1], M. Krikelis[2], M. Giannopoulou[2], V. Lainis[2], O. Katsouli[2], E. Mole[2], S. Gazi[2], E. Chronopoulos[1], A. Mavrogenis[3]

[1]Laboratory of Research of the Musculoskeletal System, Univ. of Athens, [2]Rheumatology Dept., KAT General Hospital, [3]First Dept. of Orthopaedics, National and Kapodistrian Univ. of Athens, School of Medicine, Athens, Greece

Tumor-induced osteomalacia (TIO) is a rare paraneoplastic syndrome of abnormal phosphate and vitamin D metabolism. It is typically associated with small mesenchymal benign tumors that secrete FGF23. This is a case report of a 54-year-old male patient diagnosed with TIO.

Case report: The patient complained of walking difficulty and muscle pains with a duration of seven months. Patient history included rib and pelvic fractures. Clinical examination revealed a Trendelenburg gait and muscle weakness mostly manifest in the pelvic girdle. No visible or palpable tumor-like lesions were found. Biochemical investigation revealed decreased phosphorus [1.3 mg/dl (2.3–4.7)], increased alkaline phosphatase [307 IU/l (50–116)], decreased 1,25 $(OH)_2$ vitamin D [< 10 pg/ml (18–80)] and a low tubular reabsorption of phosphorus (TRP) of 81%. Serum FGF23 was increased [193 kRU/l (26–110)]. The patient underwent whole-body PET/CT (68 Ga DOTATOC), which detected a round hypermetabolic lesion (SUVmax = 10) located in the soft tissues of the distal phalanx of the second left toe. After surgical excision, biopsy showed a giant cell tumor of soft tissue origin. Serum phosphorus normalized one day after excision, while five months post-excision FGF23 was normal [67 kRU/l (26–100)], along with normal phosphorus 3.8 mg/dl (2.3–4.7 mg/dl) and TRP of 91%.

Conclusion: Although typical, our TIO case is reportable because of the location and the rare histological type of the causal tumor. To our knowledge, only one similar case has been published so far.[1,2] The unusual location of our patient's causal tumor (the distal phalanx of the second left toe) underlines the importance of including the distal limbs in the PET/CT imaging.

P1216
WHAT CAN WE LEARN FROM THE WHATSAPP GROUP FOR PATIENTS WITH PREGNANCY AND LACTATION-INDUCED OSTEOPOROSIS?

S. Tuzun[1], E. Aygun[1]

[1]Dept. of Physical Medicine and Rehabilitation, Istanbul Univ.-Cerrahpasa, Cerrahpasa Medical Faculty, Istanbul, Turkey

Objective: Pregnancy and lactation-induced osteoporosis (PLO) is an uncommon type of osteoporosis that occurs early in life, resulting in mostly multiple vertebral fractures in young women. In this study, we aimed to expand the limited dataset regarding the etiology, clinical features, and risk factors by utilizing an alternative source of information via a WhatsApp group for patients.

Methods: 55 participants of a WhatsApp group called "Smile Please" diagnosed with PLO were invited to fill out a questionnaire covering four distinct sections: demographics, risk factors, diagnosis and treatment, and the impact of the patient group on their emotions related to the disease. The properties of the included subjects are

reported as mean ± SD or as the number of subjects and the percentage of responders to a particular question.
Results: 46 participants completed the survey within a 10-d period. The average age was 33.8 ± 4.8 y, with a mean BMI of 23.2. 37 women (80.4%) reported fractures, predominantly vertebral fractures (97.3%) with back pain, except for one hip fracture. Conditions most commonly reported as risk factors included smoking, physical inactivity, low weight gain during pregnancy, vitamin D deficiency, family history of osteoporosis, and the use of anticoagulants during pregnancy. 42 patients (91.3%) used vitamin D, and 29 (63%) took calcium supplements. 39.1% of patients were never treated with anti-osteoporotic medication. The distribution of anti-osteoporotic medications was as follows: teriparatide for 42.9%, oral bisphosphonates for 35.7%, denosumab for 32.1%, and parenteral bisphosphonates for 10.7%. Patients indicated that joining this group increased their knowledge about symptoms (46.3%), diagnostic methods (46.3%), treatment options (75.6%), side effects (41.5%), and prognosis (75.6%). Following membership, 50% of the patients reported a decrease in their fears related to the disease, and 41.9% expressed a reduction in concerns about treatment side effects.
Conclusion: PLO is a serious condition that leads to multiple fractures in young women. Given the rarity and obscurity of this condition, patient groups on social media platforms like WhatsApp can play a crucial role in rapidly and comprehensively collecting information about the disease's characteristics and its risk factors.

P1217
ABILITY OF FRACTURE RISK ASSESSMET TOOL (FRAX) TO IDENTIFY SUBJECTS WITH HIGHER FRACTURE RISK ASSESSED WITH RADIOFREQUENCY ECHOGRAPHIC MULTISPECTROMETRY (REMS)

S. Vladeva[1], F. Bischoff[2], E. Bischoff[3], P. Kinov[4]

[1]Trakia Univ., Medical Faculty, Stara Zagora, [2]Rheumatology practice, Stara Zagora, [3]Univ. "Prof. Dr. Assen Zlatarov"-Burgas, Medical Faculty, Burgas, [4]Univ. Hospital "Queen Giovanna", Dept. of Orthopaedics, Medical Univ. of Sofia, Sofia, Bulgaria

Objective: According to FRAX 10-y probability of a major osteoporosis-related fracture (MOF) ≥ 20% was considered as high fracture risk and is important to decide if the subject will take any medications. Cutoff value of REMS-based fragility score (FS) of 37.2 of the lumbar spine was demonstrated as REMS-based indicator for MOF at 5 y in the female population.
Methods: We assessed 72 women with mean age of 62 y with FRAX without inclusion of BMD. Age, height, weight, BMI, menopausal status, previous fractures, parental hip fractures, current smoking, use of glucocorticosteroids (CS), diagnosis of rheumatoid arthritis (RA), secondary osteoporosis and alcohol consumption were analyzed as part of FRAX questionnaire before the scan with REMS. Subsequently assessment of the fragility score of the lumbar spine with REMS was conducted by those with high fracture risk to prove the ability of FRAX to identify subjects with higher fracture risk. The data collection from the electronic health record was done with an innovative JAVA tool, developed by Kirilov et al. [1,2].
Results: The mean height of the women was 158 ± 9 cm and the mean weight was 70.5 ± 15.5 kg. The mean BMI was 28.4 ± 5.9 kg/m^2. Of 72 women, 34 women (47,2%) had 10-y probability of a MOF ≥ 20% and were assessed with REMS. Of total 34 subjects 27 subjects (79.4%) demonstrated REMS-based FS > 37.2.
Conclusion: FRAX tool showed a great ability to identify subjects with higher fracture risk assessed with REMS.

P1218
OUTCOME OF PATIENTS WITH VERTEBRAL FRAGILITY FRACTURES: A 7-YEAR EXPERIENCE OF A FRACTURE LIAISON SERVICE (FLS)

B. W. T. Yung[1], R. M. Y. Wong[2], W. W. Chau[2], S. Y. Ko[2], S. W. Law[2]

[1]Alice Ho Miu Ling Nethersole Hospital, Tai Po, [2]Chinese Univ. of Hong Kong, Shatin, Hong Kong SAR China

Objective: Hip fractures are one of the most serious forms of osteoporotic fractures. Osteosarcopenia is a growing geriatric giant that has higher risk of falls, fractures, disability and mortality. Given the importance of osteosarcopenia and treatments, the objective of this study was to determine the prevalence and risk factors of osteosarcopenia amongst Chinese hip fracture patients.
Methods: To determine the presence of osteoporosis and osteopenia, all recruited hip fracture patients underwent a DXA scan. To determine presence of sarcopenia, the Asian Working Group for Sarcopenia (AWGS) 2019 consensus update was used. Patients received a bioimpedance analysis (BIA) measurement to determine appendicular skeletal muscle mass (ASM), hand grip to determine muscle strength and 5-time chair stand test for physical performance. Patients were defined to have osteosarcopenia when there was both a presence of osteopenia/osteoporosis and sarcopenia. Patient demographics, hip fracture type, operation type were analysed as risk factors for osteosarcopenia with logistic regression.
Results: 229 hip fracture patients (N = 229) were recruited. The diagnosis of sarcopenia based on the AWGS 2019 consensus update was present in 208 hip fracture patients (90.8%). 224 hip fracture patients (97.8%) had osteopenia/osteoporosis. The combination of low BMD (osteopenia/osteoporosis) and sarcopenia was present in 203 hip fracture patients (88.6%). Age, and BMI < 23 kg/m^2 were associated with osteosarcopenia, whilst higher body weight and BMI were protective factors. Different fracture types were not associated with osteosarcopenia.
Conclusion: Our study has shown a very high prevalence of osteosarcopenia amongst hip fracture patients, and identified associated risk and protective factors. Given the potential clinical implications, we would recommend that routine sarcopenia assessment be incorporated into Fracture Liaison Services. Further research should be conducted on optimal body weight and BMI.

P1219
IMPACT OF TRANSITIONING ANTI-OSTEOPOROSIS MEDICATIONS IN TAIWAN ON THE PERSISTENCE OF OSTEOPOROSIS TREATMENT

S. Y. Lin[1], K. Kang[2], C. H. Chen[3]

[1]1Dept. of Orthopaedics, Kaohsiung Medical Univ. Hospital, Kaohsiung Medical Univ., Orthopaedic Research Center, Kaohsiung Medical Univ., Kaohsiung, [2]Dept. of Obstetrics and Gynecology, National Cheng Kung Univ. Hospital, College of Medicine, National Cheng Kung Univ., Tainan, [3]Orthopaedic research center, Kaohsiung Medical Univ., Dept. of Orthopaedics, Kaohsiung Municipal Ta-Tung Hospital, Kaohsiung Medical Univ., Kaohsiung, Taiwan

Objective: Osteoporosis treatment success hinges on long-term anti-osteoporosis medication (AOM) persistence, crucial for reducing overall fracture risk. Various AOMs are available for selection, and regimen switching is very common in real-world clinical scenarios. Previous studies have primarily focused on the persistence of AOMs

prescribed initially and considered drug switching as treatment discontinuation, overlooking the common occurrence of switching in real-world clinical practice. Current research emphasizes the impact of initial medication on switching behavior and overall persistence in osteoporosis patients, aiming to provide a comprehensive understanding.

Methods: Utilizing Taiwan's National Health Insurance claims data in an observational retrospective cohort study, we focused on patients initiating anti-osteoporosis medication (AOM) between January 1, 2013, and June 30, 2016. AOMs included alendronate, raloxifene, teriparatide, denosumab, zoledronate, and ibandronate. Persistence, defined as continuous prescription with a 45-d grace period, was assessed using a competing risk model to understand factors influencing initial AOM switching.

Results: Among 126,539 patients (mean age 75 y, 85% female), alendronate, denosumab, raloxifene, zoledronate, ibandronate, and teriparatide were initially prescribed to 43.3%, 25.6%, 14.6%, 9.3%, 5.3%, and 1.9% of patients, respectively. Over a mean 36-month follow-up, 29.6% of patients with at least two AOM claims switched medications, favoring long-dose-interval medications like denosumab and zoledronate.

Conclusion: This study recommends incorporating long-dose-interval therapy as initial treatment or during the first switch stage to enhance treatment persistence. The findings underscore the importance of considering medication switching in real-world clinical practice for a more nuanced understanding of osteoporosis treatment outcomes.

P1220
SEX DIFFERENCES IN OLDEST-OLD ADULTS WITH HIP FRACTURE SURGERY

S. Y. Lin[1], C. F. Lin[2], K. H. Chen[3]

[1]Center for Geriatrics and Gerontology, Taichung Veterans General Hospital, [2]Center for Geriatrics and Gerontology, Taichung Veterans General Hospital, [3]Dept. of Orthopedic Surgery, Taichung Veterans General Hospital, Taichung, Taiwan

Objective: As the population ages, there is a noticeable rise in the occurrence of hip fractures among the older adults. The unique challenges presented by hip fractures may provide the chance of understanding gender disparities in surgical outcomes and tailoring healthcare more effectively. This study aimed to study the distinctions in clinical presentation and post-surgery outcomes based on gender after hip fractures.

Methods: The retrospective study was conducted at a medical center in central Taiwan from January 01, 2018, to December 31, 2023. We enrolled 181 oldest-old adults, aged 85 and older, who underwent hip fracture surgery, and were followed for one year. Comprehensive documentation of sociodemographic information, clinical data, perioperative assessments, and surgical outcomes was carried out. Statistical analyses, including the Mann–Whitney U test, Kruskal–Wallis test, and the chi-square test, were utilized to evaluate gender-based group differences.

Results: In total, 81 patients were male, and 100 were female; their median age was 89.0 (interquartile range (IQR): 97.0–91.5) y. The length of stay was 8.0 (IQR: 6.0–10.0) d, and 33 patients died during the 1-y period. There was no sex difference in sociodemographic information, clinical data, perioperative assessments, and surgical outcomes, except for postoperative Harris hip score. In the postoperative assessment of the Harris hip score, sex differences were observed in limp, sitting, and absence of deformity with male patients better than female patients, but these differences did not reach statistical significance.

Conclusion: Both male and female oldest old adults with hip fractures surgery may experience declines in functional status. However, the extent of recovery and functional outcomes may vary between the sexes. Understanding these patterns is crucial for optimizing care and improving outcomes for both men and women.

P1221
IS THERE A RELATIONSHIP BETWEEN INFLAMMATORY MARKERS, BONE MINERAL METABOLISM AND CORONARY ARTERY CALCIFICATION? PRELIMINARY DATA

K. A. Nichiporuk[1], B. B. Tymkiv[1], S. Y. U. Tsarenok[1], N. A. Ilyamakova[2], V. V. Gorbunov[1], M. P. Tereshkov[2], T. A. Aksenova[1]

[1]Chita State Medical Academy, [2]Clinical Hospital Russian Railways-Medicine of the city of Chita, Chita, Russia

Objective: Ectopic calcification of the coronary arteries from the clinical and prognosis perspective determines the relevance of the study of biomarkers that reflect the process of calcification and are indicators of the main mechanisms of development of this pathological process. In recent years, a concept has been formed that characterizes coronary calcification as an active process, which is based on a systemic inflammatory reaction, disorders of bone and mineral metabolism, etc. We aimed to determine the relationship between parameters of bone-mineral metabolism and C-reactive protein (CRP) with the severity of atherosclerosis of the coronary arteries and the degree of their calcification.

Methods: A total of 16 patients with coronary heart disease were included in the study, 7 women aged from 61–73 y (mean age 66.2 ± 4.34 y), and 9 men from 59–65 y (mean age 61.3 ± 2,54 years old). Of these, 11 people had stable angina pectoris, 5 patients with post-infarction cardiosclerosis. The study included only those patients in whom coronary angiography revealed a stenosis of 50% or more in at least one vessel. The patients were examined for serum levels of phosphorus, calcium, alkaline phosphatase, 25(OH) vitamin D3, CRP, X-ray densitometry of the femoral neck and lumbar vertebrae, multislice CT (MSCT) of the coronary arteries with calculation of the coronary calcium index according to Agatston, and 24-h monitoring blood pressure with assessment of central aortic pressure and arterial stiffness parameters. Statistical analysis was carried out using the Statistica 10.0 software package. Nonparametric criteria were used: Spearman's rank correlation test and γ-correlation. Differences were considered significant at $p < 0.05$.

Results: Among the 16 patients included in the study, 75% of patients had multivessel coronary artery disease, 12.5% had two- and single-vessel disease. According to the results of MSCT, signs of coronary artery calcification were revealed in all examined individuals: in 1 patient (6255) the calcification was of moderate severity, in 15 patients (93.75%) a severe degree of coronary artery calcification was established. When conducting a correlation analysis, no significant associations were established between the levels of total calcium and phosphorus in the blood and the degree of calcification of the coronary arteries. However, the highest calcium index (2762 HU) was recorded in 1 patient with the highest total blood calcium level (4.89 mmol/l). A negative relationship was established between the level of high-density lipoproteins and the severity of coronary artery calcification ($r = -0.545$, $p < 0.05$) and there was no relationship with the level of CRP. In addition, when studying such a parameter of vascular stiffness as the augmentation index, we identified a direct relationship between this indicator and the serum concentration of alkaline phosphatase ($r = -0.605$, $p < 0.05$) and an inverse relationship with the content of 25(OH)D3 ($r = -0.696$, $p < 0.05$).

We will continue our research in this direction as we are publishing only initial preliminary data. We think that in the process of further

research we will be able to provide more complete and interesting data on this issue.

Conclusion: It has been established that patients with coronary artery disease with coronary artery stenosis of 50% or more have a severe degree of calcification. There was no association between the level of CRP, parameters of bone-mineral metabolism and the degree of coronary artery calcification. A negative relationship has been established between the level of high-density lipoproteins and the severity of coronary artery calcification. Elevated alkaline phosphatase levels and low serum 25(OH)D3 levels are associated with increased vascular wall stiffness.

P1222
DEOXYCHOLIC ACID (DCA), A SECONDARY BILE ACID MITIGATES LPS INDUCED INFLAMMATORY BONE LOSS

S. Yadav[1], R. Srivastava[1]

[1]All India Institute of Medical Sciences, Delhi, India

Objective: Osteoporosis is an inflammatory bone loss disease characterized by lower BMD, and diminished bone strength which exacerbates fragility fractures. The role of gut microbiome in modulating bone health has already been established by our group along with others. However, the role of gut-associated metabolites such as secondary bile acids on bone health has not been fully explored. DCA is one of the major secondary bile acids produced by the gut microbiota. DCA acts as a ligand for FXR and TGR5 receptors which are highly represented on both innate immune cells and bone cells. Thus, it makes DCA a potential therapeutic candidate in inflammatory bone loss. In the present study we hypothesize to unravel the role of DCA on bone remodelling in LPS induced inflammatory bone loss model in mice.

Methods: For osteoclastogenesis, murine BM cells were cultured in the presence of RANKL and M-CSF for 4 d and characterized by TRAP staining. For osteoblastogenesis, BM cells were cultured for 14 and 21 d in osteogenic media and characterized by ALP and alizarine red staining respectively. For LPS-induced inflammatory bone loss model, mice (C57/BL6, male, 12 weeks) were randomly divided into three groups (Control, LPS and LPS + DCA). The LPS and LPS + DCA groups were intraperitoneally injected with LPS (5 mg/kg). DCA dissolved in drinking water was administered orally to the LPS + DCA group (1 mg/mouse) for 10 d. At day 11, mice were sacrificed and bone (μCT, BMD), SI/LI (histology), and BM (ex vivo culture for osteoclasts and osteoblasts, qPCR) were harvested and analysed.

Results: Interestingly we observed that DCA significantly enhanced osteoblastogenesis in a dose dependent manner while simultaneously inhibiting osteoclastogenesis. Our in vivo results further confirmed that DCA enhances bone health in LPS induced inflammatory bone loss model in mice. μCT assessment of both femur and tibia bones showed loss of bone microarchitecture in LPS treated mice compared with control and DCA treated groups. DCA supplementation significantly enhanced the BMD, bone volume per tissue volume, trabecular number, trabecular thickness and decreased trabecular separation. Moreover, our ex vivo osteoclast cultures from the bone marrow of DCA treated group reflected attenuated osteoclastogenesis with respect to LPS induced mice group. Altogether, both our in vitro and in vivo data clearly establish the therapeutic potential of DCA in enhancing bone health in LPS induced inflammatory bone loss.

Conclusion: Our results for the first time establish that DCA directly affects both bone forming (osteoblasts) and bone resorbing (osteoclasts) cells and ameliorates bone loss in LPS induced inflammatory bone loss model. The findings of our study offer a new avenue in harnessing the osteoprotective potential of DCA (a secondary bile acid) in improving bone health in various inflammatory bone pathologies including RA and osteoporosis.

P1223
EPIDEMIOLOGY OF FRACTURES IN ADULTS OF AFRICAN ANCESTRY WITH TYPE 1 AND TYPE 2 DIABETES MELLITUS: A SYSTEMATIC REVIEW AND META-ANALYSIS

S. Zhang[1], T. Makebeh[2], J. Mesinovic[1], C. Martin[3], L.-Y. Lui[4], P. Cawthon[4], A. Schneider[5], J. Zmuda[6], E. Strotmeyer[6], A. Schafer[7], P. Ebeling[1], R. Zebaze.[1]

[1]Dept. of Medicine, School of Clinical Sciences, Monash Univ., Melbourne, Australia, [2]ZEZE co, Yaoundé, Cameroon, [3]School of Public Health and Preventive Medicine, Monash Univ., Melbourne, Australia, [4]Research Institute, California Pacific Medical Center, San Francisco, USA, [5]Dept. of Biostatistics, Epidemiology, and Informatics, Univ. of Pennsylvania Perelman School of Medicine, Philadelphia, USA, [6]Dept. of Epidemiology, School of Public Health, Univ. of Pittsburgh, Pittsburgh, USA, [7]Endocrine Research Unit, San Francisco Veterans Affairs Health Care System, San Francisco, USA

Objective: Although bone disease is a major complication of diabetes mellitus (DM), little is known regarding the impact of DM on fractures in Black adults. This is the first systematic review and meta-analysis to investigate the association between DM and fractures in adults of African ancestry.

Methods: Relevant literature up to November 2023 was screened from databases including MEDLINE, Scopus, CINAHL and Embase. All studies assessing the epidemiology of fractures (prevalence, incidence, or risk) in Black men and women (age $\geq$ 18 y) with type 1 and type 2 DM were included. Effect sizes for prevalence of previous fractures (%) and incident fracture risk (hazard ratio [HR]) were calculated using a random-effects model. The Hartung-Knapp-Sidik-Jonkman method was employed to estimate the variance of the pooled effect in all meta-analyses with five or less studies.

Results: Among 13 eligible studies, 12 were conducted in Black adults from the USA, while one was conducted in adults of West African ancestry from Trinidad and Tobago. We found no fracture data in Black adults with DM living in Africa. Five studies were included in a meta-analysis for incident fracture risk, reporting data from 2926 Black adults with DM and 6553 White adults with DM. There was increased risk of fractures in Black adults with DM compared with non-DM (HR = 1.65; 95%CI: 1.14, 2.39). The risk of fractures observed in White adults with DM was also elevated compared with non-DM (HR = 1.31; 95%CI: 1.06, 1.61). Five studies were included in another analysis examining fracture prevalence, of which three studies also reported fracture prevalence in White adults. There was a total of 175 previous fractures among 993 Black adults with DM and 384 previous fractures among 1,467 White adults with DM, with a pooled prevalence of 17.5% (95%CI: 15.4, 19.6) and 25.8% (95%CI: 4.8, 46.8), respectively.

Conclusion: Diabetes is associated with an increased risk of fractures in adults of African ancestry, and this risk may be higher than that observed in White populations. Urgent public health measures are needed to curtail the growing problem of diabetes-related fragility fractures, especially in Africa where the prevalence of DM is expected to increase 143% by the year 2045.

P1224
DISORGANISED BONE TISSUE AND MICROFRACTURES AS A POSSIBLE AETIOLOGY OF PERTHES' DISEASE

S. Zhang[1], K. Djopseu[2], C. Chiang[3], F. Milat[1], P. Ebeling[1], R. Zebaze[1]

[1]Dept. of Medicine, School of Clinical Sciences, Monash Univ., Melbourne, Australia, [2]ZEZE co, Yaoundé, Cameroon, [3]Dept. of Medicine, Univ. of Melbourne, Austin Health, Melbourne, Australia

Perthes' disease is characterised by idiopathic osteonecrosis of the hip with a peak incidence between 5 and 8 years of age. Its aetiology remains unknown, although mechanisms that impair blood supply to the femoral epiphysis such as repeated microtrauma may be implicated. In this case report, we discuss the potential role of bone disorganisation (poor arrangement of bone tissue) and microfractures (microcracks) as a novel cause.

Case report: Mr F is a 44-year-old Rwandan man who presented to a medical facility in Cameroon in December 2023 with severe bilateral thigh pain of more than 4 years duration. He had a previous hospital admission for gait abnormalities at the age 8 years, although no diagnosis was made. Following this, Mr. F's gait gradually deteriorated to the extent that 36 years later, he required bilateral elbow crutches for mobility. Hip X-ray revealed chronic bilateral hip osteoarthritis associated with secondary avascular necrosis of both femoral heads, suggesting bilateral Perthes' disease, a diagnosis missed earlier in life. In addition, Mr F exhibited other clinical features suggestive of a congenital disease, including tall stature, right pre-axial polydactyly, left trigger thumb and unusual bilateral palmar creases. Detailed assessment of bone quality using novel image processing software (Alignogram) revealed markedly disorganised bone tissue with disseminated microfractures, multiple foci of microsclerosis, and thick cortices with a narrow medullary cavity. Blood tests were also significant for an isolated elevation of alkaline phosphatase. Altogether, these features likely indicate a disorder of bone formation, such as an unknown form of sclerotic bone dysplasia.

Conclusion: We infer that an unknown congenital disorder has led to disorganised bone formation in this case of likely Perthes' disease. The resulting abnormal load transfer produced damage in the form of microfractures which may have disrupted blood supply at the proximal femur causing bilateral osteonecrosis at a young age. This case is unique as it proposes a novel mechanism of osteonecrosis, Perthes' disease and chronic bone pain, occurring in a patient with a likely, as yet undiagnosed, genetic disorder.

P1225
IN OTHERWISE HEALTHY YOUNG MEN, TRABECULAR BONE SCORE (TBS) IS SIGNIFICANTLY LOWER IN CASE OF INSULIN RESISTANCE: AN ANALYSIS OF THE SIBLOS STUDY

S. van Offel[1], C. Verroken[1], S. Goemaere[1], B. Lapauw[1]

[1]Ghent Univ. Hospital, Ghent, Belgium

Objective: Type 2 diabetes mellitus (T2DM) increases fracture risk, despite a preserved or even increased BMD. The DXA-derived TBS is considered to be a proxy of bone quality and is lower in people with T2DM compared to controls. Whether this is also the case in otherwise healthy, insulin resistant young men has not yet been investigated. We aimed to assess whether insulin resistance already associates with TBS in young healthy men.

Methods: 999 young healthy men were recruited in the region of Ghent and surrounding communities and were cross-sectionally assessed for multiple bone, muscle and metabolic parameters as part of the SIBLOS study. Of 459 participants, aged 35 $\pm$ 5.4 y, data on TBS, fasting glucose and insulin were available. Insulin resistance was defined by a homeostatic model assessment of insulin resistance (HOMA-IR, which is the product of fasting glucose with fasting insulin, divided by a constant) of $\geq$ 2.17. Differences in DXA-derived parameters between the insulin resistant and insulin sensitive group were assessed using t-tests.

Results: Of the 459 participants, 89 (19.4%) were insulin resistant. Mean TBS $\pm$ standard deviation in this group was 1.42 $\pm$ 0.08, which was significantly lower compared to the insulin sensitive group (1.46 $\pm$ 0.08, p = 0.002). Quantitatively, BMD was higher in the insulin resistant group in all measurement regions, but this only reached statistical significance at the femoral neck and total hip BMD (0.87 $\pm$ 0.13 vs. 0.91 $\pm$ 0.14 g/cm^2, p = 0.031; and 1.07 $\pm$ 0.13 vs. 1.11 $\pm$ 0.16 g/cm^2, p = 0.009 respectively).

Conclusion: Despite being years ahead of established T2DM, TBS is lower in insulin resistant as compared to insulin sensitive young men. However, because of the small order of magnitude, no relevant statements about bone quality on the level of the individual patient can be made based upon TBS alone.

P1226
ROLE OF PHYSICAL THERAPY IN ENDOCRINE DISORDERS

S.-D. Birsan[1]

[1]Faculty of Medicine and Pharmacy, Univ. of Oradea, Oradea, Romania

In the complex treatment of endocrine diseases, besides specific endrocrinotherapeutic means, other non-specific therapeutic factors are used. This second category of factors includes physical therapy, It is indicated in some hyper and hypofunctional endocrine disorders. Our interest is kinesiotherapy exerting favorable effects in this category of diseases, by stimulating metabolism and regulating the functions of the central and vegetative nervous system.

During the kinetotherapy sessions, free active exercises will be performed, which interest the muscle groups of the trunk and limbs. As the muscular system is trained and the adipose tissue decreases, active resistance exercises are introduced, executed at a brisk pace, alternated with breathing pauses. It is recommended to frequently change the fundamental positions in which the exercises are performed. The intensity and duration of the effort will be dosed depending on the body's capacity to physical effort and the age of the patient. It is recommended to practice in moderation sports such as: swimming, enema, tourism, rowing, tennis, volleyball, basketball.

Medical gymnastics is indicated in the complex treatment of these conditions, along with hypocaloric diet, anorexigenic hormone therapy and psychotherapy. Systematic practice of gymnastics exercises medically contributes to: stimulating metabolism and improving oxidation processes; general toning of the muscular system; improving peripheral circulation and trophic status of various systems and organs, improving pulmonary ventilation; regulation of functions of the central and vegetative nervous system.

P1227
MYO ENTEZO JOINT PAIN MANAGEMENT

S.-D. Birsan[1]

[1]Faculty of Medicine and Pharmacy, Univ. of Oradea, Oradea, Romania

Muscle injuries over time can worsen leading to a decrease in quality of life by not being able to carry out the usual daily activity. Muscle overloads can be acute or chronic, acute ones occur after a

microtrauma and chronic ones occur as a result of muscle microruptures over time.

Muscle injuries are caused by predisposing factors: endocrine and metabolic, sedentary lifestyle, joint dysfunction; precipitating factors: muscle cramps, myositis, hematomas or muscle injuries as well as non-compliance with training stages, muscle fatigue, temperature drop that predisposes to decreased muscle elasticity, dehydration; perpetuating factors; wrong moves. Symptomatology predominates with a sudden vivid pain with a burning character; presence of bruising; the existence of a painful spot on palpation and the antalgic position accompanied by partial functional impotence. The visual analogue VAS scale is used to assess pain.

Confirmation of myoentheso articular lesions is given by muscle echography confirming muscle injury; its type and severity. Treatment is medication and rehabilitation and in extreme cases surgical. In the first 48 h, the protection of the affected area is applied, segmental housekeeping, cryotherapy, local compression with elastic bandage, keeping the affected limb in a cleavage position. NSAIDs, physiotherapeutic treatment (ultrasound, laser, TENS) and massage is not recommended for a period of 14 d.

The evolution is favorable if the patient immediately goes to the doctor, the therapeutic approach will take into account the degree of bearability of the body to pain and its ability to recover.

P1228
INFLUENCE OF MECHANICAL FACTOR IN TRIGGERING DISC HERNIATION

S.-D. Birsan[1]

[1]Faculty of Medicine and Pharmacy, Univ. of Oradea, Oradea, Romania

The literature mentions the major influence that trauma has in triggering a herniated disc. In lumbar trauma, not only direct trauma is involved. Carrying weights and lifting them, jumping, wrong movements – hyperflexion associated with torsion of the trunk are traumatic factors with repercussions on the lumbar vertebral segment which, besides disc changes, can also influence the dynamics of the spine.

Clinical symptoms can sometimes occur immediately after injury or after a free interval. The trauma can be unique but violent, sometimes large and repeated, but not always the trauma is violent because in some cases the symptoms are installed after mild but repeated traumas that lead to an overwork of the sacral lumbar region and there may be professional microtrauma.

The summation of these microtraumas can cause the installation of a herniated disc which, at a time interval after degenerative changes, will determine places of disposable resistance to minimal effort such as coughing, sneezing will trigger the beginning of the clinical phase of disc herniation. Based on this fact, St.de Seze states that at the origin of sciatica, trauma is a rule, its absence an exception.

The field of rheumatic sciatica has ceded a significant territory to more frequent traumatic sciatica, therefore it must be regarded as an occupational disease in cases where it occurs in an individual whose profession requires efforts of the lumbar spine.

P1229
THERAPEUTIC ULTRASOUND TREATMENT FOR PREVENTION OF BONE DISORDER ASSOCIATED WITH CHRONIC KIDNEY DISEASE IN A MOUSE MODEL

R.-S. Yang[1], C.-Y. Lin[1], S.-H. Liu[1]

[1]National Taiwan Univ., Taipei, Taiwan

Objective: Chronic kidney disease (CKD) is a worldwide public health problem. With the decline of kidney function, increasing the risk of bone disease in CKD patients, caused so-called CKD-associated mineral and bone disorder (MBD). Uremic toxin indoxyl sulfate is considered to be one of the possible risk factors for various CKD types and also affects bone metabolism. Low-intensity pulsed ultrasound (LIPUS) has been used in many animal or clinical trials to treat neurological diseases or bone diseases. Here, we evaluated the protective potential of LIPUS on CKD-MBD using a CKD mouse model.
Methods: C57BL/6j mice (8-week-old) were used to induce CKD using unilateral renal ischemia/reperfusion injury (IRI) with nephrectomy. The left kidneys of the CKD mice were treated using LIPUS (3 MHz, 100 mW/cm^2, and 20 min/d, based on the preliminary experiments). Mice were euthanized 14 d after IRI. The blood BUN, creatinine, cystatin C, albumin, globulin, indoxyl sulfate, calcium ion, phosphate, and FGF23 levels were tested. The bone microstructure was evaluated by μCT.
Results: IRI-CKD mouse model was conducted and it was found that LIPUS stimulation had the protective effects on the increased blood renal function indicators BUN, creatinine and cystatin C and the decreased blood albumin/globulin ratio ($n = 8$, $p < 0.05$); while LIPUS had a partial alleviation effect on the decrease in body weight and kidney weight ($n = 8$, $p = 0.06$). In CKD mice, we also observed that the blood levels of indoxyl sulfate, FGF23, phosphate, and calcium ion increased significantly, which could be effectively reversed by LIPUS stimulation ($n = 8$, $p < 0.05$). Damage to bone microstructure (μCT detection) caused by CKD, including reduced BMD, BV/TV, and trabecular thickness can also be partially, but significantly, alleviated by LIPUS treatment ($n = 8$, $p < 0.05$). LIPUS (100 mW/cm^2) stimulation for 14 days had no effects on the renal function of normal mice and no other abnormalities ($n = 5$, $p > 0.05$).
Conclusion: Elevated blood indoxyl sulfate, FGF23 and phosphate levels in CKD may be related to the occurrence of subsequent bone disorder. LIPUS treatment can effectively alleviate bone disorder associated with CKD.

P1230
FACTORS AFFECTING QUALITY OF LIFE IN PATIENTS WITH OSTEOPOROTIC VERTEBRAL COMPRESSION FRACTURE AFTER TREATMENT IN TERTIRY TRAUMA CENTER IN THAILAND

T. Amphansap[1], P. Sujarekul[1], A. Therdyothin[1]

[1]Police General Hospital, Bangkok, Thailand

Objective: To identify factors affecting the quality of life in patients with osteoporotic vertebral compression fracture (OVCF) after 1 y of follow-up.
Methods: A retrospective cohort study of patients with OVCF was performed based on the hospital's electronic database of patients' information from January 1, 2015, to July 31, 2020. Further inquiry

into missing data and quality of life was done via telephone. EQ-5D-3L Questionnaire (Thai version) was employed to assess all aspects of the quality of life.
Results: 421 patients with OVCF were identified from the electronic database search. After exclusion, the remaining 336 participants were recruited (61 males, 275 females). The study revealed that gender, BMD screening, and anti-osteoporotic medication were not associated with the quality of life. However, poor quality of life was associated with age, recurrent fracture after OVCF, and admission of patients with OVCF during the initial visit. An age of over 70 y was associated with poorer quality of life (odds ratio (OR) 11.47, P-value < 0.001). Recurrent fracture after OVCF was also related to poor quality of life (OR 2.47, P-value = 0.003). Admission of patients into the hospital after diagnosis of OVCF was related to a better quality of life than those treated as outpatients.
Conclusion: This study provided information for improving assessment and treatment care in patients with OVCF in Police General Hospital. The admission of patients after OVCF at the first visit was related to improved quality of life, while older age and recurrent fracture negatively impact the outcome. Timely osteoporosis treatment is crucial to prevent future fractures after an OVCF. Fracture liaison service might offer a holistic approach to treating this group of patients with a benefit in better quality of life.

P1231
PARATHYROID CARCINOMA: CAUSE FOR SECONDARY OSTEOPOROSIS AND LOW-ENERGY FRACTURE

T. Bajraktarova Prosheva[1], A. Mucha[1], B. Todorova[1], I. Bitoska[1], S. Mishevska Jovanovska[1], A. Stevchevska[1], M. Srbinoska Bogatinoska[2], V. Limani[1], M. Ilijovska[3], S. Markovikj[1]

[1]Univ. Clinic of Endocrinology, Diabetes and metabolic disorders, Skopje, [2]Public Health Center Makedonski Brod, Makedonski Brod, [3]Newborn Clinic, Skopje, North Macedonia

Parathyroid carcinoma is a rare, malignant neoplasm of the parathyroid gland. Most of the parathyroid carcinomas are hormonally active and they secrete PTH[1]. Parathyroid carcinoma is the cause of primary hyperparathyroidism in 0.1% to 5% of cases. It is a rare condition, with an incidence of 1.25 cases per 10,000,000 people. The average age is 44–54 y, and it is equal to males and females[2]. All patients with hyperparathyroidism will get osteoporosis if the parathyroid tumor is not removed. Vertebral compression fractures are often the result of a fall, but people with osteoporosis can suffer a fracture even when doing everyday things.
Case report: A 52-year-old female patient was present for an examination due to pain in the low back. MRI scan showed compressive fracture of L3-L4 vertebrae. Laboratory findings: PTH 864.1 pg/ml, osteocalcin 250.2 ng/ml, β-CrossLaps 2.61 ng/ml, vitamin D 18.53 ng/ml, total calcium 3.8 mmol/l, calcium ionized. 1.8 mmol/l, creatinine 80 μmol/l, urea 8 mmol/L, the rest of the laboratory analyzes were normal. MIBI scan of parathyroid glands with 99mTc showed increased accumulation of the radiotracer in the lower pole of the right thyroid lobe (projection of the right lower parathyroid gland). DXA scan showed osteoporosis on the lumbar spine and on the neck of the hips. T-score: L1-L4 -3.6; left femur neck -2.9; right femur neck -3.1; Minimally invasive right parathyroidectomy and right lobectomy were performed, and histopathological findings showed changes typical for parathyroid carcinoma.
Conclusion: PTH and calcium levels are much higher in parathyroid carcinoma compared with primary hyperparathyroidism A PTH three times the upper limit of normal is suspicious for malignancy, while a PTH of 10 times higher than normal is positive predictive value of 84% for parathyroid carcinoma[3]. Early surgical approach is the best therapeutic option for that patients. The prognosis depends on the presence of invasion into adjacent structures and metastasis. In 33% of cases, the cancer is well demarcated without extension or distant metastasis, with a very good prognosis. In 33% of cases, the disease will recur and will need reoperation. In 33% of cases, there is a short and aggressive course that leads to death.

P1232
PLS3 MUTATIONS IN X-LINKED OSTEOPOROSIS: A CASE REPORT

T. Bazuhair[1], M. Almohaya[2], A. Alturkistani[3], K. Alaybaa[2]

[1]Security Forces Hospital Makkah, Makkah, [2]King Fahad Medical City-Riyadh, Riyadh, [3]King Fahad Medical City, Riyadh, Saudi Arabia

Monogenetic bone disease was linked to multiple mutations, one of them is the gene encoding the 'actin-bundling protein plastin 3(PLS3) located within chromosome band Xq23. Osteoporosis 2ry to PLS3 mutation was 1st recognized in 2013. We describe the clinical characteristics and underlying genetic mutation of a young patient with 1ry osteoporosis.
Case report: A 14-year-old boy was seen in bone clinic for concerns of recurrent fragility fractures. He is the 2nd child of healthy consanguineous parents. He presented with history of multiple fractures due to minimal trauma, his 1st fracture was at age of 18 months and his latest was 4 months prior to his presentation. Apart from mild hearing impairment, he had no significant medical history. He had no history suggestive of 2ry causes and his family history was negative for recurrent fractures or premature osteoporosis. On examination, he was proportionate with a height of 143 cm, a weight of 49 kg. Apart from the blue sclera, no other extra-skeletal features of osteogenesis imperfecta were identified. Spine examination reveals an upright spine with scoliosis. Neurological examination was normal. He had no cushingoid features and his genital exam was prepubertal. Investigations done to exclude secondary causes came back normal. DXA scan showed BMD of lumbar spine (L1-L4) 0.305 g/cm^2, BMD of dual femur neck mean 0.425 g/cm^2 and BMD of dual femur total mean 0.395 g/cm^2. Genetic testing showed mutation in PLS3 gene (Hemizygous). A family screening was done, which revealed a pathogenic variant in the PLS3 gene in his mother (heterozygous). Patient was treated with pamidronate 60 mg IV infusion started in February 2020 and received total of 3 doses then switched to zoledronic acid at a dose of 2.5 mg. A DXA scan was repeated in January 2022 for follow-up, which showed increased bone density with a significant improvement of 124.9% and 57.7% in the BMD of the lumbar spine and in both femurs, respectively. Follow-up BMD done in October 2023, showed significant increase with a 4.2% in BMD of the lumbar spine as well as 11% increase in BMD of the total femur mean.
Conclusion: This case illustrates a rare hereditary cause of early-onset osteoporosis in young male 2ry to PLS-3 mutation, this might guide clinicians to consider screening for PLS3 in such cases.

P1233
A CASE OF SIGNIFICANT HYPERCALCAEMIA SECONDARY TO TERIPARATIDE THERAPY

T. Carroll[1], D. Fitzpatrick[1], N. Fallon[1], N. Maher[1], C. O'Carroll[1], V. V. G. Steen[1], R. Lannon[1], K. Mccarroll[1]

[1]Bone Health Unit, St James Hospital, Dublin, Ireland

Transient asymptomatic hypercalcaemia (up to 16 h after teriparatide administration) is a relatively common side effect that may occur in up to 11% of patients. However, delayed hypercalcaemia (> 24 h) is rare with only few case reports to date. We describe the case of a female who developed a significant and delayed hypercalcaemia after teriparatide in the treatment of her osteoporosis.

Case report: A 72 year old female on teriparatide for treatment of severe osteoporosis was found to have hypercalcaemia (3.3 mmol/l) on routine testing three months after starting therapy. Serum calcium prior to teriparatide initiation was normal at 2.39 mmol/l. On review she reported only mild symptoms of thirst due to polyuria. Her medical history included hypertension and treated hepatitis C, and apart from calcium tablets (1000 mg /d) was on no medications that could contribute to hypercalcaemia. She was admitted to hospital for investigations which identified a serum 25(OH)D of 74 nmol/l, a low PTH of 6.0 pg/ml and normal test results for 1,25(OH)D (115 pmol/l), PTHrP (< 1.4 pmol/l), serum electrophoresis and angiotensin converting enzyme (39 IU/l). CT abdomen, pelvis and thorax revealed no evidence of malignancy and an isotope bone scan ruled out bony lytic lesions or skeletal metastases. Her hypercalcaemia normalised after 4 d, following treatment with IV fluids and cessation of teriparatide and calcium supplements. On restarting teriparatide, delayed hypercalcaemia re-occurred and her treatment was switched to denosumab.

Conclusion: Delayed and nonmild hypercalcaemia (> 3.0 mmol/l) due to teriparatide is rare but may result in therapy withdrawal. The underlying predisposing risk factors remain unclear and support the routine assessment of a serum calcium level on treatment. Stopping or reducing calcium supplements and/or the frequency of teriparatide injections may be considered. Given the extent of hypercalcaemia and its reoccurrence in our patient, teriparatide was stopped and her therapy was switched to denosumab.

P1234
A CASE OF OSTEONECROSIS OF THE EXTERNAL AUDITORY CANAL ASSOCIATED WITH BISPHOSPHONATE THERAPY

T. Carroll[1], D. Fitzpatrick[1], N. Fallon[1], G. Steen[1], N. Maher[1], R. Lannon[1], K. Mc Carroll[1]

[1]Bone Health Unit, St James Hospital, Dublin, Ireland

Osteonecrosis of the auditory canal associated with bisphosphonate use is very rare. It was first reported in 2006 with only 19 cases described in the literature. In most patients, it occurs during the treatment of osteoporosis with oral bisphosphonates. Some cases have been bilateral and occurred spontaneously but the pathogenesis is unclear with similar risk factors for MRONJ proposed. We report the case of a patient on oral bisphosphonates who developed this rare condition.

Case report: A 60-year-old lady attending an otolaryngology clinic for routine follow up was noted to have an area of de-epithelialisation in her left auditory canal with underlying bone necrosis and exposure of her temporomandibular joint capsule. Six months previously she had aural microsuctioning to treat otitis externa but had been asymptomatic since with no otalgia, otorrhea or hearing loss. Her medical history included osteoporosis, treated with risedronate for the previous four years. She also a history of breast cancer (treated with local surgical excision and adjuvant chemotherapy), hypertension and ischaemic heart disease. Temporal bone CT confirmed osteonecrosis with an area of demineralisation in the left external auditory canal but with no middle ear abnormalities. A biopsy showed necrotic tissue potentially consistent with a cholesteatoma, however given the location in the external auditory canal this was excluded as a cause. As she was deemed to have a low fracture risk, her risedronate was stopped and she was managed conservatively. There was gradual healing of the area with complete re-epithelisation noted at an outpatient review three years later. She has remained off bisphosphonates and BMD has been stable.

Conclusion: Osteonecrosis of the external auditory canal is a very rare potential adverse effect of bisphosphonate therapy. Given their widespread use, it's important to be aware of this possible diagnosis in patients on bisphosphonates who have ear infections, pain or discharge and who may warrant more careful aural examination. In our patient, predisposing factors may have been possible trauma from aural microsuctioning and prior chemotherapy. The decision to stop bisphosphonates in these cases needs to be carefully balanced against the risk of future fracture.

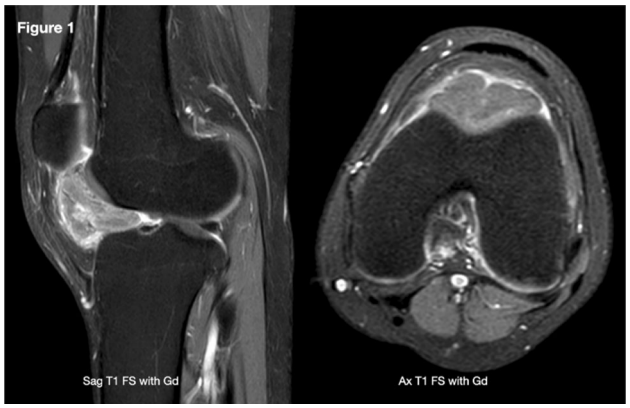
P1235
SYNOVIAL HEMANGIOMA PRESENTED WITH CHRONIC PAINFUL INFRAPATELLAR MASS: A CASE REPORT

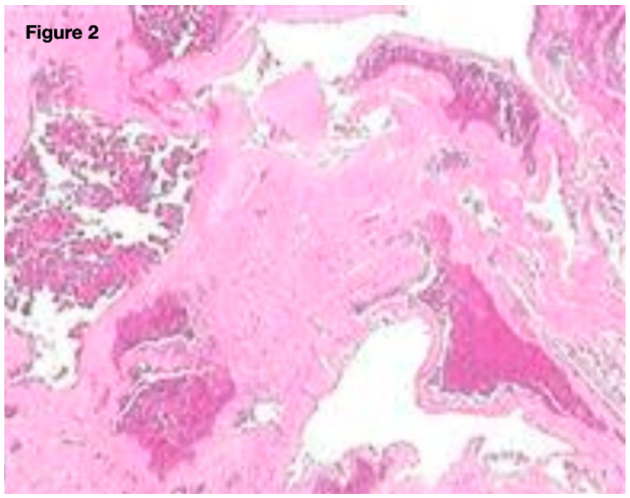
T. Chobpenthai[1], W. Suphakitchanusan[2], N. Wongboonkuakul[1], K. Trakulsujaritchok[1], C. Decha-Umphai[1]

[1]Princess Srisavangavadhana College of Medicine, Chulabhorn Royal Academy, [2]Chulabhorn Hospital, Chulabhorn Royal Academy, Bangkok, Thailand.

Synovial hemangiomas are rare benign vascular anomalies enveloped by synovial lining, first documented by Bouchut in 1856 [1]. These neoplasms can arise within the intra-articular region often causing effusions and knee pain. Their cause remains unknown [2]. Prompt diagnosis and intervention are crucial to prevent chondral damage. Diagnosis, often delayed due to the lack of distinct clinical signs, relies on histopathological examination [3]. This report details a unique case featuring a painful infrapatellar mass confirmed as a synovial hemangioma. Notably, the absence of typical MRI findings emphasizes the significance of arthroscopic excision for diagnosis and symptom relief.

Case report: A 20-year-old female presented with persistent anterior left knee pain, exacerbated during activities involving stairs. Despite prior pain management and physical therapy, she had a painful lump beneath her patella that worsened over time. A previous arthrocentesis provided no relief. Physical examination revealed a palpable, immobile, 5 cm mass along the parapatellar tendon, limited knee flexion and extension, and normal ligament stability. MRI of left knee T1 FS with Gd showed a lobulated intra-articular mass in Hoffa's fat pad, resembling soft tissue chondroma (Fig. 1). Arthroscopic excision was performed, confirming histopathologic diagnosis as sections of synovium show numerous dilated blood vessels and venous proliferation (Fig. 2). Recovery was successful, with no residual tumor observed on follow-up MRI after one year.





Discussion: The case involves a unique presentation of synovial hemangioma, typically found in the suprapatellar pouch but within the infrapatellar region. The patient had a palpable mass, expediting diagnosis and improving clinical outcomes. Arthroscopic excision was chosen due to its minimally invasive nature and the well encapsulated mass's potential for complete removal.

Conclusion: Synovial hemangiomas are rare benign vascular anomalies that can occur in various anatomical structures enveloped by synovial lining, including intra-articular regions. Delayed diagnosis can lead to complications such as chondral impairment and secondary degeneration.

P1236
EFFICACY OF INTRA-ARTICULAR PLATELET-RICH PLASMA COMPARED WITH PLACEBO IN KNEE OSTEOARTHRITIS: A SYSTEMATIC REVIEW AND META-ANALYSIS

T. D. Thais[1], M. A. Maxime[1], S. B. Sabine[1], R. C. Roland[1]

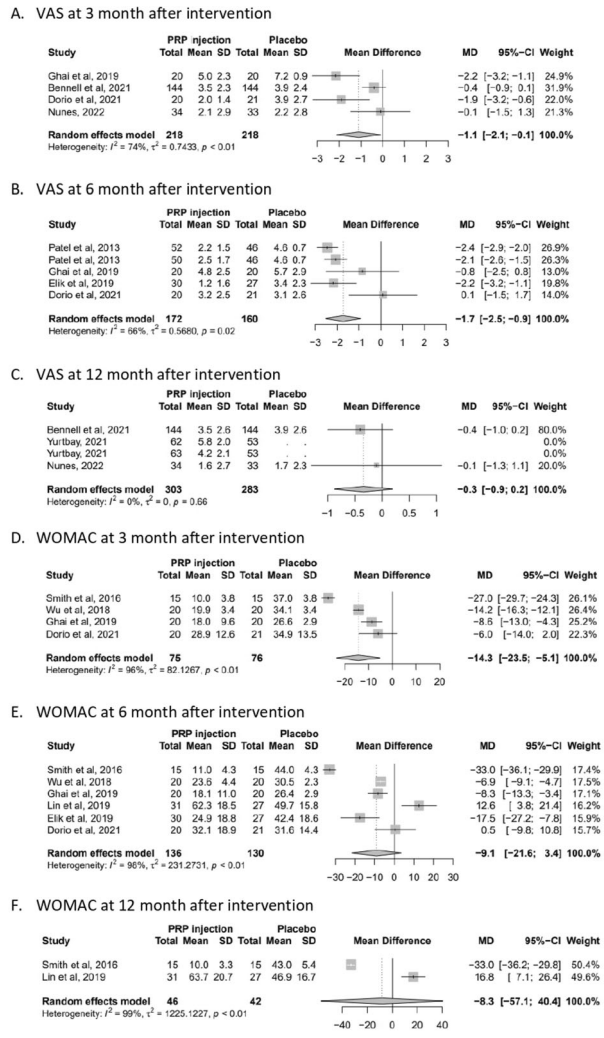
[1]Hospices Civils de Lyon, Lyon, France

Objective: Our primary aim was to evaluate the efficacy of intra articular platelet-rich plasma (PRP) injection on pain and function in knee osteoarthritis compared with intra-articular saline solution injection (placebo).

Methods: A search for randomized controlled studies (RCTs) performed on intra articular platelet-rich plasma injection compared with intra articular saline solution injection up to November 2022 (PROSPERO registration number: CRD42022311893) was undertaken in publication databases. Studies that reported pain and function evaluation with VAS or WOMAC, size sample, study date and location were included. A meta-analysis was conducted to identify the efficacy on pain and function of intra articular platelet-rich plasma injection.

Results: We identified 10 RCTs including 1006 patients (541 on PRP, 465 on placebo) in 7 countries, 68% were women. The mean age was 58.7 y. VAS analysis at 3 and 6 months after intervention was in favor of PRP use (respective MD -1.1 [-2.1; -0.1] and -1.7 [-2.5; -0.9]) with high heterogeneity, whereas no efficacy was shown at 12 months. WOMAC analysis at 3 months after intervention was in favor of PRP use (MD -14.3 [-23.5; -5.1]), but no efficacy was shown at 6 and 12 months.

Figure 1. VAS and WOMAC score at 3, 6 and 12 month after intervention



Conclusion: We have found a weak efficacy of PRP in knee osteoarthritis, up to 6 months after intervention, so the clinical relevance of PRP use is debatable. Further investigation should be

conducted to assess the efficacy of intra articular PRP depending on age, type and endotype of KOA.

P1237
COMPARISON OF TREATMENT OUTCOMES BETWEEN ATYPICAL FEMORAL FRACTURES WITH AND WITHOUT BONE-MODIFYING DRUGS FOR CANCER BONE METASTASIS: A RETROSPECTIVE STUDY

T. Fukui[1], K. Oe[1], Y. Kumabe[1], T. Niikura[2], R. Kuroda[1]

[1]Dept. of Orthopaedic Surgery, Kobe Univ. Graduate School of Medicine, [2]Dept. of Orthopaedic Surgery, Hyogo Prefectural Nishinomiya Hospital, Kobe, Japan

Objective: It has been suggested that the administration of bone resorption inhibitors for osteoporosis is associated with the occurrence of atypical femoral fractures (AFFs). On the other hand, higher doses of bone resorption inhibitors are usually administered to patients with cancer bone metastases (CBM) as bone-modifying drugs (BMDs) to treat bone-related events, and the relationship between BMD and AFF is attracting attention. The objective of this study was to compare the treatment courses between AFF patients with and without administration of BMD.
Methods: The subjects were AFF patients with BMD administration history, collected from past multicenter study (CBM-AFF group), and AFF patients without BMD administration who were treated at one university hospital (AFF group). The period from AFF surgery to radiographical bone union, the rate of prodromal symptoms, the rate of bilateral AFF cases, and the rate of cases in which bone resorption inhibitors were discontinued were compared between the two groups.
Results: The subjects were 30 limbs of 19 patients in the CBM-AFF group and 22 limbs of 21 patients in the AFF group, and no significant differences were observed in the gender ratio or age. In cases where osteosynthesis was performed for a complete fracture and bone union was confirmed, the average bone union time was 15.1 months (11 limbs) in the CBM-AFF group and 7.9 months (11 limbs) in the AFF group, which was significantly longer in the CBM-AFF group. While there was no significant difference in the rate of prodromal symptoms between the two groups, bilateral AFF cases were significantly more in the CBM-AFF group (13 out of 19 cases) than in the AFF group (1 out of 21 cases). The number of patients in whom bone resorption inhibitors were discontinued due to AFF was 15 in the AFF group and 0 in the CBM-AFF group.
Conclusion: Bone union could be delayed in AFF patients with BMD administration for CBM compared to those without it.

P1238
INSIGHTS INTO HIP HEALTH: PREVALENCE AND CO-EXISTENCE OF BONE, JOINT, AND MUSCLE DISORDERS—THE ROAD STUDY

T. Iidaka[1], G. Tanegashima[1], S. Muraki[2], H. Oka[3], K. Nakamura[4], T. Akune[5], S. Tanaka[6], N. Yoshimura[1]

[1]Dept. of Preventive Medicine for Locomotive Organ Disorders, 22nd Century Medical and Research Center, The Univ. of Tokyo, Tokyo, [2]Dept. of Preventive Medicine for Locomotive Organ Disorders, 22nd Century Medical & Research Center, Faculty of Medicine, Univ. of Tokyo, Tokyo, [3]Division of Musculoskeletal AI System Development, Faculty of Medicine, The Univ. of Tokyo, Tokyo, [4]Towa Hospital, Tokyo, [5]National Rehabilitation Center for Persons with Disabilities, Saitama, [6]Dept. of Orthopaedic Surgery, Faculty of Medicine, The Univ. of Tokyo, Tokyo, Japan

Objective: We investigated the prevalence and coexistence proportions of bone disease (osteoporosis, OP), joint disease (osteoarthritis, OA), and muscle weakness in the hip regions of Japanese men and women, based on data obtained from a large-scale nationwide cohort study entitled ROAD (Research on Osteoarthritis/Osteoporosis Against Disability).
Methods: We analyzed data from 1558 participants (505 men and 1053 women; mean age, 65.5 y) residing in mountainous and coastal communities, using information from the 3rd survey of the ROAD study. Radiographs were scored using the Kellgren/Lawrence (KL) grading system, and radiographic hip OA was defined as a KL score ≥ 2. OP at the femoral neck was defined based on WHO criteria. To calculate the cutoff values for quadriceps strength, we conducted ROC analysis with quadriceps strength as the independent variable and the presence or absence of sarcopenia as the dependent variable, stratified by sex.
Results: The prevalence of OP at the femoral neck was 4.1% and 16.0% in men and women, respectively. The prevalence of radiographic hip OA was 16.1% and 12.4% in men and women, respectively, and the prevalence of muscle weakness was 37.0% and 31.6% in men and women, respectively, in the 3rd survey. 62.1% of OP at the femoral neck and 56.3% of radiographic hip OA were accompanied by muscle weakness. The presence of muscle weakness was associated with OP at the femoral neck (odds ratio 2.14, 95%CI 1.47–3.12) and radiographic hip OA (odds ratio 1.74, 95%CI 1.22–2.47).
Conclusion: This population-based study provided epidemiological indices of OP at the femoral neck, radiographic hip OA, and muscle weakness in the hip joint. Muscle weakness was significantly associated with both OP at the femoral neck and radiographic hip OA.

P1239
PREOPERATIVE INCIDENCE AND RISK FACTORS OF DEEP VEIN THROMBOSIS IN JAPANESE PATIENTS UNDERGOING TOTAL HIP ARTHROPLASTY

T. Kaneko[1], K. Hayakawa[1], F. Tokimura[1], T. Miyazaki[1]

[1]Tokyo Metropolitan Institute for Geriatrics and Gerontology, Tokyo, Japan

Objective: Preoperative deep vein thrombosis (DVT) is a risk factor for postoperative venous thromboembolism (VTE), causing severe mortality. Early detection of preoperative DVT is essential to prevent postoperative VTE. However, little is known regarding preoperative DVT in patients undergoing major surgery. The present study aimed to determine the incidence and risk factors of preoperative DVT in patients admitted for total hip arthroplasty (THA).
Methods: From August 2017 to September 2022, 243 patients admitted for THA at Tokyo Metropolitan Geriatric Hospital were enrolled in this study. Patients medical records and preoperative laboratory data were retrospectively collected. According to the results of lower-limb ultrasonography, patients were divided into the non-DVT (n = 136) or the DVT group (n = 43). The incidence of DVT and independent risk factors for preoperative DVT were investigated using univariate and multivariate logistic regression analyses.
Results: The mean age was 74.0 ± 8.4 y. Preoperative DVT was diagnosed in 43 of the 243 (17.7%) patients. The risk of DVT was significantly high ($p < 0.05$) in patients with advanced age, increased D-dimer levels, and malnutrition status, as assessed by the Geriatric Nutritional Risk Index (GNRI). Multivariate analysis showed that advanced age, increased D-dimer level, and malnutrition status assessed by GNRI were independent risk factors for preoperative DVT.

Conclusion: A high incidence of preoperative DVT was observed in patients undergoing THA. Advanced age, increased D-dimer levels, and malnutrition assessed by the GNRI increased the risk of preoperative DVT. Screening high-risk subgroups for preoperative DVT is necessary to prevent postoperative VTE.

P1240
BONE STATE IN PATIENTS WITH ANKYLOSING SPONDYLITIS: ASSESSMENT OF POTENTIAL RISK FACTORS

T. Karasevska[1], O. Ivashkivskyi[2], I. Kutyrkina[3], H. Novytska[4], R. Potomka[4], M. Dzhus[1]

[1]Bogomolets National Medical Univ., [2]Communal Non-Commercial Institution "Oleksandrivska Clinical Hospital", [3]Medical center "Gerz", [4]Communal Non-Commercial Institution "Oleksandrivska Clinical Hospital", Kyiv, Ukraine

Objective: To determine the factors that may influence bone loss in Ukrainian patients with ankylosing spondylitis (AS).
Methods: This study included 69 patients with determined AS. We evaluated the influence of sex, age, level of vitamin D, BASFI, and BASDAI on BMD by DXA measurement.
Results: The study involved 16 female and 53 male patients. The average age of the patients was 42,9 ± 13,2 y; the average disease duration was 13,4 ± 9,8 y. Our study recognized osteoporosis in the lumbar spine in 30,4% and the femoral neck in 11,6%. There were no sex differences: in lumbar spine BMD (0,956 ± 0,24 vs. 0,971 ± 0,19 g/cm^2) or femoral neck BMD (0,796 ± 0,14 vs. 0,789 ± 0,12 g/cm^2) males vs. females respectively. The patients with a disease duration less than 10 years (6,7 ± 1,54) compared with the patients with a disease duration > 10 y (21,7 ± 11,2) had lower BASFI (23,9 ± 8,6 vs. 60,8 ± 26,9; t = -2,61; p = 0,02). However, there were no differences between groups in lumbar spine BMD (0,986 ± 0 vs. 1,104 ± 0,28 g/cm^2) or femoral neck BMD (0,858 ± 0,16 vs. 0,786 ± 0,11 g/cm^2). BASFI positively correlated with the age (rS = 0,88; p < 0,05) but was not statistically significant with the lumbar spine BMD or femoral neck BMD and vitamin D level. Otherwise, BASDAI negatively correlated with the lumbar spine BMD (rS = -0,77, p < 0,05) but was not significant with age, femoral neck BMD or vitamin D level.
Conclusion: Osteoporosis is common in patients with AS. The highest prevalence was on the lumbar spine compared with the femoral neck. The lumbar spine BMD negatively correlated with BASDAI but was insignificant in disease duration, BASFI, or vitamin D level in. Further research is needed to identify patients with AS at risk for the development of osteoporosis and its complications.

P1241
IS IT NECESSARY TO REPEAT BMD FOR PATIENTS RECEIVING DENOSUMAB? BASELINE RESULTS FROM A QUALITY IMPROVEMENT INITIATIVE

T. Khan[1], M. Alagha[2], C. Hoy[3], R. Clara[4], J. Thain[5], K. Clemens[1]

[1]Division of Endocrinology and Metabolism, Dept. of Medicine, Western Univ., [2]Dept. of Medicine, Western Univ., [3]Division of Endocrinology and Metabolism, Dept. of Medicine, Western Univ., [4]Quality Measurement and Clinical Decision Support, St. Joseph's Healthcare, [5]Division of Geriatrics, Dept. of Medicine, Western Univ., London, ON, Canada

Objective: The utility of repeating BMD in patients taking anti-osteoporosis therapy has been questioned, as a vanishingly small number of patients taking or denosumab demonstrate convincing evidence of bone loss. In this quality improvement project, we are aiming to reduce the proportion of patients who receive BMD testing to every 2 y or less, while receiving chronic denosumab therapy. At baseline, we assessed the proportion of patients who had convincing evidence of bone loss defined as loss of BMD at the same site on repeat measurements, or loss of BMD at multiple sites on one measurement, and those who required a change in therapy.
Methods: We assessed postmenopausal women who were adherent with denosumab and had at least two repeat BMD measurements following a baseline study.
Results: 54 consecutive patients with a mean age of 70.1 ± 8.3 y met inclusion criteria. They had received denosumab for a mean of 6.1 ± 2.7 y. Baseline BMD T-scores were -2.4 ± 1.2 at the lumbar spine (LS) and -2.3 ± 0.6 at the femoral neck (FN). The average interval between baseline and first followup BMD, and between the first and second followup BMD was 19.2 ± 8.5 months and 21.4 ± 12.5 months, respectively. Only 2 of 54 patients (3.7%) experienced significant loss of LS BMD, which stabilized for one, and improved for the other patient on repeat measure. Two of 54 patients experienced a decrease in FN BMD from baseline to the first repeat BMD (3.7%), which stabilized for both patients on repeat measurements. No patient experienced consistent loss of BMD at both sites between the baseline and final measurements. A patient who lost BMD also fractured and was switched to romosozumab from denosumab. Antiresorptive therapy was not changed in anyone else.
Conclusion: Our initiative suggests that among postmenopausal women treated with denosumab at the Osteoporosis and Bone Disease Program in London, Ontario, there was no convincing loss of BMD for > 97% of patients over time, and only one patient required a change in therapy (mostly due to a fracture while on treatment). We will investigate the utility and safety of reducing BMD testing in patients taking denosumab at our centre.

P1242
RELATIVE GROWTH RATES FOR HEIGHT AMONG CHILDREN AND ADOLESCENTS LIVING WITH HIV ON ANTIRETROVIRAL THERAPY IN ZIMBABWE AND ZAMBIA

T. M. Madanhire[1], A. M. Macdougall[2], L. K. Kasonka[3], H. M. Mabuda[3], M. C. Chisenga[3], T. B. Bandason[1], N. D. Dzavakwa[1], S. V. Simms[1], K. W. Ward[4], R. A. F. Ferrand[1], N. M. Mohammed[2], C. L. G. Gregson[5]

[1]The Health Research Unit, Harare, Zimbabwe, [2]London School of Hygiene and Tropical Medicine, London, UK, [3]Univ. Teaching Hospital, Lusaka, Zambia, [4]Univ. of Southampton, Southampton, UK, [5]Univ. of Bristol, Bristol, UK

Objective: Children with HIV (CWH) are now surviving to adulthood though they still exhibit impaired growth characterised by stunting and wasting. We aimed to identify the height growth patterns among CWH and determine age at peak-height-velocity (aPHV).
Methods: In this secondary analysis data were collected prospectively in the VITALITY randomised controlled trial conducted in Zimbabwe and Zambia (PACTR20200989766029). The trial recruited 842 CWH (11–19 y) established on ART for ≥ 6 months to determine whether vitamin-D_3/calcium supplementation improves bone health with follow-up to 96 weeks. Anthropometry was measured at 12-week intervals; weight- and height-for-age were calculated using UK-reference values, with z-score ≤ -2 classifying those underweight and stunted. Analysis of height trajectories was performed using the SuperImposition by translation and rotation (SITAR) adjusting for size, pubertal-timing and growth-rate.
Results: We recruited 448(53.2%) females and 394(46.8%) males; baseline median(IQR) age was 15.5 (IQR:13.2–17.9) y. CWH were

taking ART for median(IQR) 9.8(6.3–12.3) y of their lives and 81.9% (n = 688) were on an ART regimen containing tenofovir disoproxil fumarate. At baseline, 29.9% (n = 252) and 30% (n = 253) were stunted and wasted; mean(SD) height-for-age z-score was -1.68 (1.05) and -1.21 (1.05) for males and females respectively. Over 96 weeks (n = 786), median (IQR) height gains were 6.9 (1.7–10.6) cm and 2.1 (0.6–6.1) cm whilst aPHV was 15.0 y (PHV:8.2 cm/y) and 13.2 y (5.6 cm/y) for males and females respectively. Size was more strongly correlated with tempo in males than females (0.4 vs. 0.2), whilst size was more negatively correlated with velocity in females than males (-0.5 vs. -0.02).

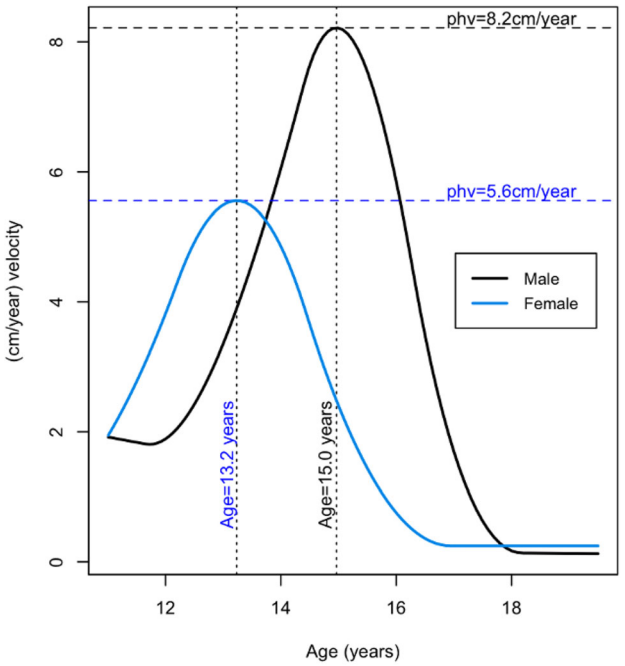


Figure 1. SITAR adjusted height velocity curves by sex

Conclusion: There is a high prevalence of stunting among CWH in Zimbabwe. Both males and females showed delayed PHV compared to UK estimates (females:11.7, males:13.6 y) with later puberty predicting greater overall height. However, slower growth rates predicted greater overall height attainment particularly in females. Findings raises concerns for persistent height deficits in adulthood known to impact human capital.

P1243
RELATIVE ASSOCIATIONS BETWEEN VITAMIN D METABOLITES AND BONE TURNOVER AMONG AFRICAN ADOLESCENTS WITH PERINATALLY ACQUIRED HIV

T. M. Madanhire[1], K. W. Ward[2], A. M. Macdougall[3], N. M. Mohammed[3], L. K. Kasonka[4], H. M. Mabuda[4], M. C. Chisenga[4], J. Tang[5], W. D. F. Fraser[5], T. B. Bandason[1], N. D. Dzavakwa[1], S. V. Simms[1], R. A. F. Ferrand[1], C. L. G. Gregson[6]

[1]The Health Research Unit, Harare, Zimbabwe, [2]Univ. of Southampton, Southampton, UK, [3]London School of Hygiene and Tropical Medicine, London, UK, [4]Univ. Teaching Hospital, Lusaka, Zambia, [5]Univ. of East Anglia, Norwich, UK, [6]Univ. of Bristol, Bristol, UK

Objective: Vitamin D metabolism can be dysregulated in people living with HIV. We aimed to determine the potential mechanism by which vitamin D metabolism regulates bone turnover in adolescents with perinatally acquired HIV in southern Africa.

Methods: A cross sectional study enrolled adolescents (11–19 y) with HIV taking antiretroviral therapy (ART) for ≥ 6 months. Sociodemographic, clinical and dietary data were recorded. Vitamin D_3 metabolites [25(OH)D, $1,25(OH)_2D$, $24,25(OH)_2D$], intact PTH and bone turnover markers (BTMs) [CTX and P1NP] were measured after fasting. Liquid chromatography tandem mass spectrometry measured vitamin D_3 metabolites, whilst intact PTH and BTMs were analysed by electrochemiluminescence immunoassay. Stratified by 25(OH)D [< 75 vs. ≥ 75 nmol/L], we assessed direct, indirect, and total effects between observed standardized vitamin D_3 metabolites, intact PTH and BTMs using structural equations modelling (SEM) adjusted for age, sex and country.

Results: The SEM showed PTH was positively associated [β = 0.21, 95%CI 0.10, 0.32] with $1,25(OH)_2D$ when 25(OH)D < 75 nmol/L with evidence of an interaction [β = -0.11, 95%CI: -0.20, -0.02] between PTH and 25(OH)D on $1,25(OH)_2D$. A positive relationship between 25(OH)D and $24,25(OH)_2D$ was seen irrespective of 25(OH)D level. $24,25(OH)_2D$ was inversely related to BTMs, particularly in those with 25(OH)D < 75 nmol/L; CTX: [β = -0.15, 95%CI: -0.24, -0.06] and P1NP: [β = -0.14, 95%CI: -0.22, -0.06]. A further interaction was identified between dietary calcium and 25(OH)D on PTH [-0.15 SD [95%CI: -0.22, -0.07].

Characteristic	Description	Result
N	842	
Sex	Female	53.2%
Age, y	Median (IQR)	15.5 (13.2-17.9)
Duration on ART, y	Median (IQR)	9.8 (6.3-12.3)
HIV viral load	>60 copies/ml	19.6%
25(OH)D, nmol/L	Mean (SD)	66.1 (16.5)
$1,25(OH)_2D$, pmol/L	Mean (SD)	210.6 (70.4)
$24,25(OH)_2D$, nmol/L	Mean (SD)	4.1 (1.6)
Intact PTH, pmol/L	Median (IQR)	4.3 (3.3-5.6)
CTX, µg/L	Median (IQR)	1.5 (0.9-2.1)
P1NP, µg/L	Median (IQR)	467.5 (210.3-850.6)

Conclusion: Associations between 25(OH)D, PTH, $1,25(OH)_2D$ and BTMs in adolescents living with HIV appear dependent on 25(OH)D concentrations and calcium intake. A novel pathway between 25(OH)D, $24,25(OH)_2D$ and BTMs was seen. Findings enhance understanding of vitamin D metabolism in people living with HIV.

P1244
ASSOCIATION BETWEEN 25-HYDROXYVITAMIN D AND PTH IN CHILDREN AND ADOLESCENTS LIVING WITH HIV IN ZAMBIA AND ZIMBABWE: A CROSS-SECTIONAL STUDY

T. M. Madanhire[1], K. W. Ward[2], A. M. Macdougall[3], N. M. Mohammed[3], L. K. Kasonka[4], H. M. Mabuda[4], M. C. Chisenga[4], J. Tang[5], W. D. F. Fraser[5], T. B. Bandason[1], N. D. Dzavakwa[1], S. V. Simms[1], R. A. F. Ferrand[1], C. L. G. Gregson[6]

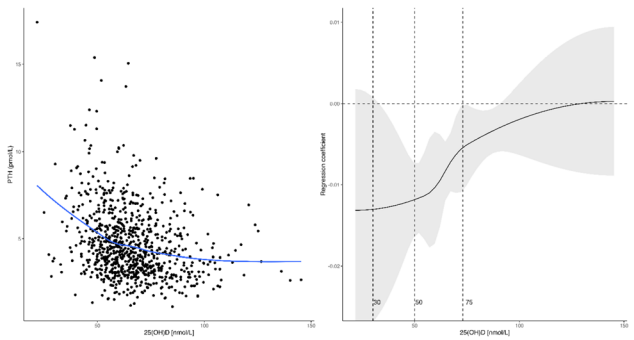
[1]The Health Research Unit, Harare, Zimbabwe, [2]Univ. of Southampton, Southampton, UK, [3]London School of Hygiene and Tropical Medicine, London, UK, [4]Univ. Teaching Hospital, Lusaka, Zambia, [5]Univ. of East Anglia, Norwich, UK, [6]Univ. of Bristol, Bristol, UK

Objective: Low vitamin D is commonly reported in the context of HIV infection, but no study has examined what constitutes 'adequate' vitamin D in those living with HIV. This study aimed to determine the association between total 25(OH)D and PTH in an adolescent population living with HIV in Zambia and Zimbabwe.

Methods: A cross-sectional study recruited adolescents (11–19 y) perinatally infected with HIV and established on antiretroviral

therapy (ART) for at least 6 months. Sociodemographic and clinical characteristics were recorded and anthropometry measured. Weight- and height-for-age were calculated using UK-reference values, with z-score $\leq$ -2 classifying those underweight and stunted. Fasted blood samples were used to measure vitamin D metabolites, intact PTH and bone turnover markers. Liquid chromatography tandem mass spectrometry methods were used for 25(OH)D and 1,25$(OH)_2$D whilst PTH was analysed by electrochemiluminescence immunoassay. The association between total 25(OH)D and PTH was determined by natural cubic spline regression modelling.

Results: The study enrolled 842 participants (female: 53.2%) with median age 15.5 (IQR 13.2–17.9) y. The median duration of ART was 9.8 [IQR 6.3–12.3] y, despite which 19.6% had an unsuppressed HIV viral load (> 60 copies/ml). Most (n = 688; 81.7%) were taking tenofovir disoproxil fumarate (TDF), 6.4% were taking efavirenz. Stunting and underweight were observed in 29.9% and 30.0% respectively. The mean (SD) concentrations of total 25(OH)D and 1,25$(OH)_2$D levels were 66.1(16.5) nmol/L and 210.6(70.4) pmol/L respectively, and median PTH level was 4.3 (IQR 3.3–5.5) pmol/L. There was an inverse nonlinear relationship between total 25(OH)D and PTH which generated an inflection point at 74.6 nmol/L (95%CI 74.5–75.2). Results were consistent by TDF and viral suppression.



Conclusion: The study identified an inverse relationship between 25(OH)D and PTH concentrations with a much weakened association when 25(OH)D exceeded 75 nmol/L. In the context of a population with very low dietary calcium intake, transitioning through puberty, and seasonal variation in 25(OH)D status, the impact of this observation on bone and other outcomes needs to be determined.

P1245
OSTEOCHONDRAL AUTOLOGOUS TRANSPLANTATION VERSUS ARTHROSCOPIC DEBRIDEMENT WITH DRILLING IN THE TREATMENT OF TALAR OSTEOCHONDRAL LESIONS AND DEFECTS

O. A. Burianov[1], A. P. Liabakh[2], T. M. Omelchenko[1], E. A. Levitskiy[1], O. A. Turchin[2], L. V. Khimion[3]

[1]Bogomolets National Medical Univ., Traumatology and Orthopaedic Dept., [2]State Institution "Institute of Traumatology and Orthopaedics of National Academy of Medical Sciences of Ukraine", Foot Pathology Dept., [3]Shupyk National Healthcare Univ. of Ukraine, Internal Diseases, Family Medicine, Hematology and Transfusiology Dept., Kyiv, Ukraine

Objective: To conduct a comparative analysis of the results of arthroscopic debridement with drilling (ADD) vs. osteochondral autologous transplantation (OAT) in the treatment of talar osteochondral lesions and defects (OHLD) based on the assessment of the function of the ankle joint, the level of pain and changes in the range of movements (ROM) in the affected joint.

Methods: The study included 40 patients with OHLD, with an average area of 3.14 cm^2 and a depth of 1.15 cm, located in the posterior and middle medial part of the talus block. In the group#1 performed ADD. In group#2—OAT. The results were evaluated before surgery, at 12 and 24 months. The level of pain to VAS, the function to AOFAS, the ROM in the joint were studied.

Results: After treatment, there was a significant reduction in pain with the best result in group#2 ($p < 0.05$). AOFAS showed that after 12 and 24 months the functional state of the joint in group#2 was better than in group#1 ($p < 0.01$). After 12 months, ROM increased significantly in both groups. After 24 months, there was no increase in ROM in group#1, and in group#2 the increase ROM was statistically significant ($p < 0.01$), which confirmed the higher prospects and stability of the result when performing OAT (Table 1).

Table 1. Comparison of the results of arthroscopic debridement with drilling (Group#1) vs. osteochondral autologous transplantation (Group#2)

Index (M±σ)	Before surgery		12 months after surgery		24 months after surgery	
	Group#1	Group#2	Group#1	Group#2	Group#1	Group#2
Pain (VAS, cm)	5,7±0,3	5,7±0,8	1,1±0,1	1,1±0,2	0,9±0,1	0,5±0,2
	p>0.1		p>0.1		p<0.05	
Function (AOFAS, points)	57,8±1,4	59,4±1,2	86,7±1,7	91,2±1,8	90,3±1,2	94,9±1,1
	p>0.1		p<0.01		p<0.01	
Foot extension, degrees	13,9±1,3	14,0±0,9	18,1±0,7	17,9±0,6	18,0±0,4	19,5±0,5
	p>0.1		p>0.1		p<0.01	
	Group#1		Group#2		before surgery/12	
Acceleration gain, degrees	4,2±0,6		3,9±0,4		months after surgery	
	p>0.1					
	Group#1		Group#2		12 months/24 months after surgery	
	0,1±0,04		1,6±0,1			
	p<0.01					
Foot flexion, degrees	23,0±1,1	22,9±1,2	27,8±0,9	27,6±1,0	28,0±0,8	30,7±0,9
	p>0.1		p<0.05		p<0.01	
Acceleration gain, degrees	Group 1		Group 2		before surgery/12 months after surgery	
	5,2±0,7		4,4±0,5			
	p>0.1					
	Group 1		Group 2		12 months/24 months after surgery	
	0,2±0,05		3,1±0,09			
	p<0.001					

Conclusion: OAT is better than ADD for talar OHLD, provides maximum recovery of the joint surface, significantly reduces pain and improves ankle function.

P1246
MORNING STIFFNESS AND DISEASE ACTIVITY LEVEL IN PATIENTS WITH RHEUMATOID ARTHRITIS UNDERGOING BIOLOGICAL THERAPY

J. Obradovic-Gajic[1], J. Zvekic-Svorcan[2], K. Boskovic[2], T. Nikolic[1], T. Jankovic[2], N. Igic[3]

[1]Special Hospital for Rheumatic Diseases, [2]Univ. of Novi Sad, Faculty of Medicine Novi Sad. Special Hospital for Rheumatic Diseases, [3]Univ. of Novi Sad, Faculty of Medicine Novi Sad, Novi Sad, Serbia

Objective: To examine the association between morning stiffness (MS) and the degree of disease activity in patients diagnosed with rheumatoid arthritis (RA) receiving biological therapy.

Methods: This prospective cross-sectional study involved 56 RA patients of both sexes treated with disease-modifying antirheumatic drugs (bMARDS) at the Special Hospital for Rheumatic Diseases, Novi Sad, Serbia. The study was approved by the institutional Ethics Committee (14/32–6/1–22) and all subjects signed informed consent form. The association between MS and composite indexes—Disease Activity Score 28 (DAS28), Simplified Disease Activity Index (SDAI), and Clinical Disease Activity Index (CDAI)—were analyzed using the SPSS version 24.

Results: The average age of the patients. 73.2% of whom were women, was 55.8 y. No MS was experienced by 28.6% of the sample, while 66.1% and 5.4% felt it for up to 2 h and for more than 2 h after waking up, respectively. The average DAS28 score was 2.92 and was statistically significantly related to the MS duration ($p < 0.001$). About half (52.2%) of all patients in remission based on this scale did not report MS, while the majority with low (78.6%) and moderate (83.3%) disease activity experienced MS for up to 2 h upon waking. The average CDAI score was 11.79 and was statistically significantly related to MS ($p < 0.01$). Most patients with low (57.1%), moderate (89.5%) and high (66.7%) disease activity according to this scale experienced MS for up to 2 h upon waking. The average SDAI score ($M = 12.14$) was also in a statistically significant relationship with MS ($p < 0.01$). MS up to 2 h was reported by the majority of patients with low (60.7%), moderate (81.8%) and high (66.7%) disease activity based on this scale. None of the subjects in remission suffered from morning stiffness.
Conclusion: RA patients receiving biological therapy, who are in remission or have low disease activity, experience no or mild morning stiffness.

P1247
BODY MASS INDEX AS A PREDICTOR OF PHYSICAL ACTIVITY AVOIDANCE

J. Zvekic-Svorcan[1], J. Krasic[2], A. Cvetinovic[2], A. Mikic[3], T. Nikolic[4], T. Jankovic[1], K. Boskovic[1]

[1]Univ. of Novi Sad, Faculty of Medicine Novi Sad, Special Hospital for Rheumatic Diseases, Novi Sad, [2]Univ. of Novi Sad, Faculty of Medicine Novi Sad, Novi Sad, [3]Univ. of Belgrade, Faculty of Philosophy, College of Social Work, Belgrade, [4]Special Hospital for Rheumatic Diseases, Novi Sad, Serbia

Objective: To investigate the role of BMI in the physical activity involvement.
Methods: The sample for this prospective cross-sectional study comprised 103 adult outpatients (aged 18 − 65 y) of both sexes treated at the Special Hospital for Rheumatic Diseases Novi Sad, Serbia. Upon the approval of the Institutional Review Board (14/01–9/1–23), the participants gave their informed consent in writing and were subjected to the weight, height, and waist circumference measurements, allowing their BMI (kg/m^2) to be calculated. All participants also completed The Functional Assessment of Chronic Illness Therapy—Fatigue Scale (FACIT-F) as well as the International Physical Activity Questionnaire (IPAQ). Categorical data were reported as frequencies and percentages, and numerical data were presented as arithmetic means and standard deviations, along with their full range of values. The predictive capacity of BMI was assessed via univariate logistic regression and univariate linear regression analyses, whereby $p \leq 0.05$ was considered statistically significant. All analyses were performed in SPSS ver. 24.
Results: Majority of the participants were women (84.5%), and the average age and BMI was 54.18 y and 28.16 kg/m^2, respectively, with the waist circumference in the 58.0 − 122.0 cm range. According to the BMI, 33.0% of the sample was of normal weight, 32.0% was overweight, 21.4% was obese, and 13.6% was morbidly obese. Based on their IPAQ scores, the physical activity of 68.0% of the respondents was low, while being moderate and high in 28.2% and 3.9% of the cases, respectively. The average self-reported fatigue level of 14.43 suggests that most of the participants do not have fatigue issues, which are unrelated to the BMI ($\beta = 0.153$, $p = 0.122$; CI 95%: [-0.066, 0.555]). On the other hand, those with higher BMI are statistically significantly less likely to partake in physical activities (OR = 0.926, $p = 0.032$, CI 95%: [0.862, 0.993]).
Conclusion: While BMI is unrelated to self-perceived fatigue, it is a significant predictor of physical activity avoidance.

P1248
INFLUENCE OF COMORBIDITIES ON FATIGUE AND PHYSICAL ACTIVITY AVOIDANCE

J. Krasic[1], A. Cvetinovic[1], J. Zvekic-Svorcan[2], T. Nikolov[3], D. Mikic[4], K. Boskovic[2]

[1]Univ. of Novi Sad, Faculty of Medicine Novi Sad, Novi Sad, [2]Univ. of Novi Sad, Faculty of Medicine Novi Sad. Special Hospital for Rheumatic Diseases, Novi Sad, [3]Special Hospital for Rheumatic Diseases, Novi Sad, [4]Univ. of Defence, Medical Faculty of the Military Medical Academy, Military Medical Academy, Pathology and Forensic Medicine Institute, Belgrade, Serbia

Objective: To investigate the impact of comorbidities on fatigue and physical activity avoidance.
Methods: This prospective cross-sectional study, which was approved by the Institutional Review Board (14/01–4/1–23) of the Special Hospital for Rheumatic Diseases in Novi Sad, Serbia, involved 103 outpatients of both sexes aged 18–65 y treated at this clinic. After signing the informed consent form, the participants completed the International Physical Activity Questionnaire (IPAQ) and The Functional Assessment of Chronic Illness Therapy—Fatigue Scale (FACIT-F), along with a questionnaire designed for this study to obtain information on their sex, age, menopause onset, and presence of comorbidities. The gathered data was analyzed using the SPSS ver. 24, whereby frequencies and percentages were used for categorical variables, while arithmetic means and standard deviations with ranges were reported for numerical variables. In addition, univariate logistic regression and univariate linear regression were performed to determine if presence of comorbidities is a statistically significant predictor of fatigue and sedentary lifestyle.
Results: The average age of the sample was 54.18 y. Among the 103 participants, 87 (84.5%) were women, with an average age at the menopause onset of 48.02. While comorbidities were reported by 66.0% of the respondents, at 43.7%, hypertension was the most prevalent. Although the average self- reported fatigue level of 14.43/52 was low, 70 (68.0%) of the sample reported low physical activity levels, while 29 (28.2%) were moderately and 4 (3.9%) were highly physically active. Further analyses indicated that presence of comorbidities was not a statistically significant predictor of physical activity avoidance (OR = 0.559, $p = 0.168$, CI 95%: [0.244, 1.278]) or fatigue ($\beta = 0.157$, $p = 0.114$; CI 95%: [- 0.752, 6.922]).
Conclusion: Presence of comorbidities does not influence the self-perceived fatigue and propensity for physical activity avoidance.

P1249
FATIGUE AS A PREDICTOR OF PHYSICAL ACTIVITY LEVEL

A. Cvetinovic[1], J. Krasic[1], J. Zvekic- Svorcan[2], T. Nikolov[3], A. Mikic[4], K. Boskovic[2]

[1]Univ. of Novi Sad, Faculty of Medicine Novi Sad, Novi Sad, [2]Univ. of Novi Sad, Faculty of Medicine Novi Sad. Special Hospital for Rheumatic Diseases, Novi Sad, [3]Special Hospital for Rheumatic Diseases, Novi Sad, [4]Univ. of Belgrade, Faculty of Philosophy, College of Social Work, Belgrade, Serbia

Objective: To investigate the impact of fatigue on the propensity toward physical activity avoidance.
Methods: This prospective cross-sectional study involving 103 male and female outpatients aged 18–65 y was conducted at the Special

Hospital for Rheumatic Diseases in Novi Sad, Serbia. Prior to commencing the investigations, approval was obtained from the Institutional Review Board (14/01–6/1–23) and all participants signed the informed consent form. Participants' age, sex, physical activity frequency, impact of physical activity participation on mood, typical bedtime, and average daily nap duration was gathered via a questionnaire designed specifically for this purpose. All respondents also completed the International Physical Activity Questionnaire (IPAQ) as well as The Functional Assessment of Chronic Illness Therapy—Fatigue Scale (FACIT-F). The obtained data was analyzed using the SPSS ver. 24, whereby categorical variables were reported as frequencies and percentages, while arithmetic means and standard deviations with ranges were used for numerical variables. Univariate logistic regression was performed to establish whether fatigue is a statically significant predictor of physical activity involvement at the $p \leq 0.05$ level of significance.

Results: At 84.5%, most of the analyzed sample (average age 54.18 y) were women, with 42.3% of the participants indicating that they partake in some form of physical activity 1–3 times per week. In only 3.9% of the cases, the self-reported physical activity level was high, and 91.3% individuals indicated that engagement in physical activity affected their mood. The most common bedtime was 22:00 ($\pm$ 4 h), with an average 60-min nap taken during the day. Although the average fatigue level (14.43 ± 9.36 based on a $0 - 52$ scale) was low, fatigue emerged as a statistically significant predictor of physical activity avoidance in this cohort (OR = 0.954, p = 0.036, CI 95%: $0.912 - 0.997$).

Conclusion: Fatigue level is negatively correlated with the likelihood of physical activity participation.

P1250
ENHANCING FRAGILITY FRACTURE TRACKING: ALGORITHMIC INTEGRATION OF REGISTER AND RADIOLOGICAL VISITS DATA

T. Nissinen[1], R. Sund[2], S. Suoranta[3], H. Kröger[3], S. Väänänen[1]

[1]Kuopio Univ. Hospital, Univ. of Eastern Finland, [2]Univ. of Eastern Finland, [3]Kuopio Univ. Hospital, Kuopio, Finland.

Objective: To evaluate how comprehensively fragility fractures can be tracked from the national medical registers, and to propose algorithmic methods for complementing the register data using time stamps of radiography visits recorded in the radiological image archive.

Methods: For the Kuopio Osteoporosis Risk Factor and Prevention Study (OSTPRE) cohort of 14,220 postmenopausal women, we analysed the data from the Care Register for Health Care, Register for Primary Health Care Visits, self-reports, radiological image archive, and patient records to identify the distal forearm and proximal humerus fractures that occurred between 2011–2021. Using this gold standard of fracture information, we validated the coverage of the registers and image archive and created algorithms to automatically identify fracture events from the registers and/or metadata of radiography visits.

Results: We show that distal forearm fractures and proximal humerus fractures cannot be comprehensively identified based on national registers only. To remedy this, we developed a straightforward algorithmic approach for improving the identification of these fracture types. In distal forearm fractures, our proposed method of combining register and image archive data lifted the coverage from 81 to 94% and reduced false discoveries from 6 to 2%. In proximal humerus fractures, the coverage remained at 73%, but the false discovery rate was reduced from 8 to 4%.

Conclusion: The proposed method offers a more reliable way of gathering fracture information from large retrospective datasets without manual review. Comprehensive fracture identification is essential in many research settings, such as incidence statistics, prevention studies, and the development of new risk assessment models.

P1251
PROSPECTS OF USING AUTOLOGOUS AND ALLOGENEIC BONE MARROW-DERIVED MESENCHYMAL STEM CELLS IN THE TREATMENT OF KNEE OSTEOARTHROSIS

M. Bazarov[1], T. Omelchenko[1], Y. Sobolevsky[1]

[1]Dept. of Traumatology and Orthopedics of the Bogomolets National Medical Univ., Kyiv, Ukraine

Objective: Through a systematic literature review, to explore the safety and effectiveness of treating osteoarthrosis (OA) using autologous and allogeneic mesenchymal stem cells derived from bone marrow (BM-MSC).

Methods: The search for original clinical studies on the use of autologous and allogeneic MSCs published in the last 10 y in English was conducted in the PubMed and Google Scholar databases using the key words (mesenchymal stem cells) (osteoarthrosis or osteoarthritis) (clinical studies) (cartilage regeneration). PRISMA guidelines were followed during the selection of articles.

Results: Based on the selection criteria, 14 clinical trials were identified, covering 429 patients with knee OA, mean age 55.6 y. They divided into 226 patients (153 women, 73 men) who received intra-articular injections of autologous BM-MSCs (from 2×10^6 to 1×10^8) and 203 patients (116 women, 87 men) who received intra-articular injections of allogeneic BM-MSCs (from 25×10^6 to 3×10^7). Patients were observed from 6 months to 2 y and were evaluated clinically, with MRI examination and WOMAC, VAS, Lequesne, KSS indicators. In addition, an analysis of the safety of MSC was carried out. Studies show that intra-articular injection of autologous and allogeneic MSCs leads to clinical and radiological improvements in patients with OA, such as reduced pain, improved joint mobility and regeneration of damaged tissues. High doses of MSCs show a more significant therapeutic effect, but can lead to adverse reactions in patients. The most common side effects usually included knee discomfort and swelling.

Conclusion: The use of autologous and allogeneic MSCs derived from bone marrow has proven to be an effective method for treating OA, capable of regenerating cartilage tissue and alleviating symptoms. Autologous and allogeneic MSCs showed a dose-dependent effect, so further studies are needed to establish optimal doses and safety. Based on these results, it can be concluded that the use of autogenous and allogeneic mesenchymal stem cells is a promising treatment method for OA, which may improve the quality of life of patients.

P1252
PLANT EXTRACTS HAVE INHIBITORY EFFECT ON RANKL EXPRESSION

T. P. Sataieva[1], V. Y. Malygina[1]

[1] V.I. Vernadsky Crimea Federal Univ., Simferopol, Russia

Objective: Medicinal plant extracts can be successfully taken as part of dietary supplements for preventing the risk of bone tissue destruction over time. Biologically active substances of medicinal herbs can affect the processes of bone formation by stimulating osteoblasts or inhibiting the activity of osteoclasts, which is important for the prevention of osteoporosis in women in the climatic period. The aim was to find most promising anti-resorptive herbal extracts.

Methods: The bioassay involved testing plant samples for the ability to inhibit RANKL expression under inflammatory conditions. These studies were performed on MG-63 human osteoblast-like osteosarcoma cells (ATCC, Manassas, VA) cultured in media free of phenol red, a dye with known estrogenic effects. The cells were incubated with plant extracts for 12 h. To induce RANKL expression, human recombinant IL-1β (10 ng/ml) was added to the cell culture. After completion of the incubation period, RANKL mRNA levels were analyzed by quantitative real-time PCR using DLUX primers for human RANKL and Superscript III Platinum reagents from Invitrogen (Carlsbad, CA). The expression level of RANKL was normalized to the expression level of the constitutive GAPDH gene. Values above 10% indicated a significant inhibition of RANKL synthesis. The study was carried out with the financial support of the RSF grant No. 23–15-20,015.
Results: The main factors regulating osteoclastogenesis are inflammatory cytokines and RANKL factor. Increased RANKL expression levels in the postmenopausal period leads to an increase in the number of mature osteoclasts. Increased expression of RANKL leads to the development of degenerative diseases of the musculoskeletal system, including rheumatoid arthritis and osteomyelitis. In contrast, substances that reduce RANKL activity increase bone density, volume, and strength. According to the obtained results the extracts from Gingko biloba – 31%, Rehmannia spp. – 74%, Siberian ginseng – 50% and Sophora japonica – 42% had the greatest activity against RANKL expression. Samples of extracts from pomegranate – 14%, green tea leaves – 19%, grape seeds and a Chinese angelica – 11% and 16%—had a moderate inhibitory effect on RANKL.
Conclusion: Anti-resorptive plant extracts may have an effect on the maintenance of bone mass by preventing excessive calcium loss from the bones. The most effective were pomegranate extract and grape seed extract. According to our observations, their use is accompanied by a decrease in the level of RANKL expression, which, in turn, can lead to inhibition of osteoclast activity and bone tissue destruction, therefore they can be used by peri- and postmenopausal women to maintain bone health.

P1253
FREQUENCY OF VITAMIN D INTAKE IN PATIENTS WITH INCOMPLETE SYSTEMIC LUPUS ERYTHEMATOSUS

T. Panafidina[1], T. Popkova[1], Y. Gorbunova[1], A. Lila[1]

[1] V.A.Nasonova Research Institute of Rheumatology, Moscow, Russia

Objective: Often, patients present with clinical symptoms and immunologic abnormalities suggestive of systemic lupus erythematosus (SLE), while not meeting classification criteria yet. This is referred to as incomplete SLE (iSLE). Currently, there are no recommendations for monitoring and therapy of patients with iSLE. The aim of the study was to determine the frequency of vitamin D intake in patients with iSLE in clinical practice.
Methods: iSLE(n = 60) was defined by rheumatologists as clinical diagnosis, not fulfilling ACR or SLICC criteria and had no classification or specific symptoms of other rheumatic diseases. The majority of the iSLE patients were female (97%), aged 38[26–47] y. The median age of iSLE diagnosis was 33[25–42] y, disease duration was 12[2–39] months, 20% of pts had a disease duration of $\geq$ 5 y. The following criteria were evaluated: menopausal status, BMI value and SLE-related factors (age at onset, disease duration, cumulative organ involvement, cumulative serology and ongoing therapy, SLE Disease Activity Index (SLEDAI-2 K) and the Systemic Lupus International Collaborating Clinics damage index (SDI), treatment). Universally, DXA is the mainstay for the diagnosis and monitoring of bone status.
Results: At the onset of iSLE diagnosis, the most patients had clinical and immunological signs–77%, clinical only-15%, immunological only-8%pts. The clinical manifestations were as follows: fever–30%, acute cutaneous lupus–21%, subacute–7%, discoid-2%, panniculitis-3%, non-scarring alopecia–10%, Raynaud phenomenon-5%, oral ulcers–9%, joint involvement–55%, serositis–8%, nephritis–10%, psychosis–5%, migraine–17%, leukopenia–21%, thrombocytopenia–14%, autoimmune hemolysis– 7%. Autoantibody profiles revealed the presence of ANA in 82% cases, anti-dsDNA—in 45%, anti-Sm—none, antiphospholipid antibodies(aPL)–in 36% of patients. Eighteen patients (31%) exhibited low complement. The median disease activity was low—SLEDAI-2 K 2[1–5] score and SDI – 0[0–0] score. Fractures of various localizations were detected in 13% of iSLE patients, osteoporosis (OP) was diagnosed in 5/60 (8%) of patients, menopause—in 23% of patients. Among 5 patients with OP + iSLE, none were taking bisphosphonates, fractures were reported in 1/5 (20%) and menopause in 2/5 (40%). All patients diagnosed with iSLE were given general recommendations by the rheumatologist—smoking cessation, no taking medications that provoke SLE (estrogens and so on), sun protection, regular exercise, balance diet, vitamin D intake. But only 27% of patients with iSLE took the recommended vitamin D regularly.
Conclusion: The potential immunomodulatory role of vitamin D in reducing the risk of progression of iSLE to SLE is attractive and has been discussed by many researchers, but at present no convincing evidence has been obtained. Nevertheless, in real clinical practice, we recommend that all patients with iSLE, including asymptomatic patients (i.e., with immunological disorders only—the "preclinical" variant of iSLE), should take vitamin D on a regular basis.

P1254
LONG-TERM RESULTS OF METAL-ON-METAL TOTAL HIP ARTHROPLASTY

T. Sasaki[1]

[1]Tokyo Metropolitan Ohkubo Hospital, Tokyo, Japan

Objective: Numbers of papers have been published concerning adverse reactions to metal debris (ARMD) following metal-on-metal (MOM) total hip arthroplasty (THA). Some patients who experience ARMD require revision surgery. The aim of this study is to evaluate the long-term results of MOM THA retrospectively.
Methods: We reviewed all patients who underwent THA from January 2007 to December 2015. MOM were used in 37 out of 274 cases (13.5%). PINNACLE cup system were used in 14 cases, and M2a-Taper system were used in 23 cases. The original diseases are 28 osteoarthritis, 5 osteonecrosis, 3 rheumatoid arthritis and 1 rapidly destructive hip coxarthropathy. We investigated the revision rate of each system and cup positions (anteversion and inclination) were assessed. We used CAT scan or MRI to assess aseptic loosening, metal hypersensitivity reactions, and pseudotumor formation.
Results: Six women with osteoarthritis experienced significant localized soft tissue reactions, and revisions were done. The average duration to revision was 41 months (range, 28–63). Of these the revision rate of PINNACLE cup system was 28.6% and of M2a-Taper cup system was 8.7%. There was no significant between these rate ($p = 0.17$ Fisher's exact test). Four patients had no signs nor symptoms, 1 patient complained of anterior thigh dullness and 1 patient had dislocation. The average cup anteversion was 15.7° and the average inclination was 49.2°.
Conclusion: MOM THA had higher incidence of revision due to localized soft tissue reactions. Since this reaction progress asymptomatically, all cases of MOM THA should be assessed periodically using CAT scan or MRI.

P1255
LEVEL OF 25(OH) VITAMIN D IN BLOOD SERUM IN PATIENTS WITH MILD DEGREE HYPERPARATHYROIDSIS

Y. POPENKO[1], T. Shaldybin[2], N. Shadchneva[1], A. Zakharova[1], E. Kuliyeva[1], V. Kaliberdenko[1], K. Kaladze[1]

[1] V.I. Vernadsky Crimean Federal Univ., [2]Medaira Clinic, Simferopol, Russia

Objective: In clinical practice, it is difficult to make a diagnosis in patients with of primary hyperparathyroidism (PHPT) mild degree, a normocalcemic variant of HPT in the absence of visualization of the parathyroid adenoma, and secondary hyperparathyroidism as a result of vitamin D deficiency.
Methods: A retrospective analysis of 215 electronic outpatient records of patients examined to exclude PHPT was carried out. Among those who applied, 97% were women. The patients were divided into 3 groups: the first group – 25 people with a PTH level (Me) of 160.08 pg/ml at age (Iu) 62 y; the second – 55 people with a PTH level of 99 pg/ml at the age of 62 y; the third (control) group consisted of 50 people with a normal PTH level of 52.8 pg/ml at the age of 51 years. In all patients, the blood levels of 25 (OH) D (Architect test system), PTH, total calcium, phosphorus, and alkaline phosphatase were examined. BMI, concomitant diseases (including urolithiasis, peptic ulcer), and incidence of fractures were assessed; Densitometry with assessment of BMD and ultrasound of the parathyroid glands were performed. Individuals with serum calcium levels above 2.9 mmol/l, GFR < 60 ml/min/1.73m^2, and a history of pathological fractures were excluded from these groups.
Results: The contents of 25(OH)D in the first and second groups with different degrees of increase in PTH in the blood did not differ (22.3 ± 5.57 and 21.6 ± 6.57 ng/ml. $p > 0.05$), but in in groups with hyperparathyroidism, the level of 25(OH)D was significantly lower than in the group with normal PTH levels (26.1 ± 7.17 ng/ml ($p < 0.00$). A weak negative correlation was revealed between the content of 25(OH) D and PTH in the blood of all subjects (-0.192 $p < 0.05$). The level of total calcium in the first GPT group was significantly higher (Me) 2.66 mmol/l. In the second group calcium content 2.39 mmol/l did not differ from the control group. In all groups, the level of 25(OH)D negatively correlated with BMI (-0.163, $p < 0.05$) and age (- 0.208, $p < 0.05$) A positive correlation between PTH and age was revealed (0.263, $p < 0.01$).No significant differences with other laboratory parameters were found in our study.
Conclusion: The level of 25 (OH) D in the blood serum was significantly lower in patients with hyperparathyroidism, but no significant difference was found between the first and second groups, which determines the need for functional tests for the differential diagnosis of HPT.

P1256
ASSESSMENT OF BONE METABOLISM IN SUCCESSFUL PANCREAS-KIDNEY TRANSPLANTATIION RECIPIENTS

T. Takayanagi[1], Y. Asada[1], Y. Yoshino[1], H. Sumioki[1], Y. Nakajima-Hasegawa[1], S. Kanie[1], I. Hiratsuka[1], M. Shibata[1], Y. Seino[1], A. Suzuki[1]

[1]Dept. of Endocrinology, Diabetes and Metabolism, Fujita Health Univ., Toyoake, Japan

Objective: Recent advances in immunosuppressive therapy for pancreas-kidney transplantation (SPK) potentiates longer survival of its recipient, and the assessment of long-term effect on bone metabolism is also needed.
Methods: T1DM patients (n = 34, M/F = 11/23, age 46.7 ± 8.7 years old) who underwent pancreas transplantation (PTx) including 28 SPK recipients. All patients were received prednisolone (4.9 ± 0.5 mg/d) throughout the observation period. Lumbar spine (LS) and femoral neck (FN) BMD was examined at baseline, 1 and 2 y after PTx as well as bone turnover markers. Total FN 2D-DXA images were analyzed using 3D-SHAPER^{TM} Software. There were 15 patients with anti-osteoporotic treatment; 9 with denosumab (Dmab group) and 7 with active vitamin D alone (Vit D group), whereas 18 patients were observed without treatment (Control group).
Results: All patients had become insulin-free and free from hemodialysis. At the baseline, the average LS and FN BMD T-scores were -1.35 ± 0.97 and -2.04 ± 0.76, respectively, and 12 patients were categorized as osteoporosis. After 2 y, the percent change from baseline in LS BMD was -3.1%($p < 0.05$) in control group, + 0.6% in Dmab group, and + 0.5% in Vit D group. TBS was not significantly changed in all groups. FN areal BMD (aBMD), trabecular volumetric BMD (vBMD), cortical surface BMD (sBMD), cortical thickness (Cth) decreased in control group, while Dmab and Vit D groups did not change either aBMD, vBMD, sBMD or Cth. There was a significant decrease in serum BAP and TRACP-5b in the Dmab group at 1 year after PTx and serum BAP decreased in Vit D group. The change of areal or volumetric BMD did not correlate with changes of BAP, TRACP-5b, osteocalcin or iPTH.
Conclusion: Bone structure would deteriorate after PTx without treatment and it is unlikely that the change of bone turnover markers have sufficient predictive value for bone loss.

P1257
EFFECTIVENESS OF TREATMENT OF FACET JOINT SYNDROME WITH THE USE OF ELECTRICAL STIMULATION

O. Tarasenko[1], T. Tarasenko[1], D. Rekalov[2]

[1]Kherson State Univ., Dnipro, [2]Zaporizhzhia State Medical and Pharmaceutical Univ., Zaporizhzhia, Ukraine

Objective: To determine the effectiveness of treatment of facet joint syndrome in the lumbar spine with the use of electrical stimulation.
Methods: A study was conducted of patients in whom clinical manifestations of facet joint syndrome in the lumbar spine were confirmed using radiological examination methods (CT, MRI). The level of pain syndrome was assessed on the VAS scale before the start of treatment, one day after treatment, one week and 1 month after the end of treatment. Along with traditional treatment (NSAIDs, muscle relaxants, etc.), applied electrical stimulation to the area of the affected facets in pulse mode, 5–10 min per session every day for a week on the Miosti 1000 device.
Results: The study included 68 patients (32 women and 36 men). The average age was 49.32 ± 0.70 y. 69.11% of patients were overweight. The patients were divided into 2 groups of 34 people. Patients in both groups were prescribed drug therapy with NSAIDs and muscle relaxants. Patients of the first group additionally underwent electrical stimulation of the area of the affected facet joints in a pulsed mode for 5–10 min per session every day for a week using the Miosti 1000 device. Before the procedure, the average pain level according to VAS in patients of the 1st group was 85 ± 2.3 mm, 2nd group—85 ± 4.3 mm. 1 day after the end of treatment, the level of pain in patients of the 1st group was 43 ± 4.4 mm, and in the 2nd group—52 ± 2.5 mm. 7 days after the end of treatment, the pain level was 38 ± 2.9 mm in group 1 and 50 ± 3.2 mm in group 2 of patients. 1 month after the end of treatment and manipulation, the pain level was 39 ± 2.5 mm in group 1 and 49 ± 2.7 mm in group 2.
Conclusion: The facet joint electrical stimulation is effective method in the complex treatment of the lumbar spine pain syndromes.

P1258
THE RESULTS OF ASIA–PACIFIC CONSENSUS MEETING ON LONG-TERM AND SEQUENTIAL THERAPY FOR OSTEOPOROSIS

T. W. Tai[1], C. H. Chen[2], J. S. Hwang[3], C. H. Wu[4]

[1]National Cheng Kung Univ. Hospital, National Cheng Kung Univ., Tainan, [2]Dept. of Orthopedics, Kaohsiung Medical Univ. Hospital, Kaohsiung Medical Univ., Kaohsiung, [3]Division of Endocrinology and Metabolism, Dept. of Internal Medicine, Chang Gung Memorial Hospital, Chang Gung Univ., Linkou, [4]Dept. of Family Medicine, College of Medicine, National Cheng Kung Univ., Tainan, Taiwan

Recognizing the significance of long-term and sequential therapy, the Taiwanese Osteoporosis Association (TOA) organized the "Asia–Pacific Consensus Meeting on Long-term and Sequential Therapy for Osteoporosis" in Taiwan on October 12 and 13, 2023. Endorsed by the Asian Federation of Osteoporosis Societies (AFOS). The experts attending the meeting presented the Asia–Pacific consensus on long-term and sequential therapy for osteoporosis, offering evidence-based recommendations for effective chronic condition management. Emphasizing optimal fracture prevention through an individualized approach, a panel of experts synthesized current literature and clinical expertise to develop 12 consensus statements. Key recommendations advocate for anabolic agents as the first-line treatment for those at very high fracture risk, transitioning to antiresorptive agents post-anabolic therapy. Anabolic therapy remains an option for individuals with new fractures or persistent high risk despite antiresorptive treatment.

The consensus addresses long-term anti-osteoporosis medication goals, recommends first-line treatments for those at very high fracture risk, and outlines the strategic integration of anabolic and antiresorptive agents in sequential therapy approaches. To manage medication-related complications, alternatives are proposed rather than discontinuation. In cases of inadequate response, switching to more potent medications is advised.

The consensus also underscores shared decision-making and the integration of country-specific case management systems, like fracture liaison services. Tailored to the Asia–Pacific region, this guide is a valuable resource for healthcare professionals, contributing to the ongoing evolution of osteoporosis management.

P1259
A SYSTEMATIC REVIEW OF CLINICAL GUIDELINES FOR OSTEOPOROSIS MANAGEMENT IN CHINA

T. Wei[1], L. Xu[2], S. Xiong[2], X. Zhang[3], M. Tian[3], M. Yang[4], Y. Wang[5], M. Chen[6], G. S. Kolt[1], L. Si[1]

[1]School of Health Sciences, Western Sydney Univ., Sydney, Australia, [2]The George Institute for Global Health, Faculty of Medicine and Health, Univ. of New South Wales, Sydney, Australia, [3]School of Public Health, Harbin Medical Univ., Harbin, China, [4]Dept. of Orthopaedics and Traumatology, Beijing Jishuitan Hospital, Beijing, China, [5]Dept. of General Medicine, The Second Affiliated Hospital of Harbin Medical Univ., Harbin, China, [6]Nanjing Medical Univ., Nanjing, China

Objective: To systematically review Chinese guidelines for osteoporosis management with other international guidelines, evaluating the similarities, differences, and conflicts in screening, diagnosis, and management.

Methods: A systematic search of Medline, Embase, Cochrane Library, and Web of Science was conducted for English-language papers. As well, a search of Chinese databases including the China National Knowledge Infrastructure and Wanfang, and the official websites of Chinese academic societies was conducted. The search included documents published up to August 2023. Screening of articles and data extraction were conducted by two independent reviewers. The methodological quality of guidelines was appraised with the Appraisal of Guidelines for Research & Evaluation II (AGREE II). The reporting of the systematic review followed PRISMA.

Results: After screening the 5212 records initially identified, 24 guidelines from 19 clinical societies were deemed eligible for data extraction (3 of which were updated versions of previous guidelines). The included guidelines commonly agreed on the definition and risk factors of osteoporosis, diagnostic criteria, and prevention strategies. There was a lack of consensus, however, on assessing osteoporosis-related fracture risks. Medications such as bisphosphonates were commonly recommended as treatment option in 23 (96%) guidelines. Denosumab, approved for use in China in 2019, was recommended as the first line treatment in 6 out of 9 guidelines that were published after 2019. There were 15 (63%) guidelines that highlighted the importance of traditional Chinese medicine in managing osteoporosis. Compared with clinical guidelines from the National Osteoporosis Guideline Group in the UK, there was a lack of specification in the level of evidence and recommendation in 63% of Chinese guidelines. When evaluating the guidelines using AGREE II, we found that 16 Chinese guidelines (67%) lacked the description of methodologies used in developing these guidelines.

Conclusion: The lack of consensus in guidelines poses a challenge for clinicians in managing osteoporosis in China. A widely accepted guideline that is developed based on the best evidence is needed in the Chinese context.

P1260
CYSTICERCOSIS OF THE BRAIN: CLINICAL CASE

A. Filipovich[1], T. Zagorskaya[2]

[1]National Science and Practice Centre of Medical Assessment and Rehabilitation, Yukhnovka, [2]Minsk Regional Children's Clinical Hospital, Minsk, Belarus

A 6-year-old child came to the polyclinic of the Minsk Regional Children's Clinical Hospital with reduced vision in the right eye, converging squint. A decrease in vision was noticed within 0.5 y. Neurological status: active, answers questions correctly. From the side of the cranial nerves—convergent squint of the right eye, amblyopia on the right, dyslalia. Tendon-peristal reflexes D = S. Babinsky's symptom from 2 sides. In the Romberg position, he is stable, he performs the finger-nose test clearly. The gait is steady. There are no changes in the general analysis of blood and urine, and in the biochemical analysis of blood. Examined by an ophthalmologist: the right eye is pale pink, the boundaries are clear, the vessels are not changed, the left eye is without pathology. Diagnosis: atrophy of the optic nerve of the right eye, strabismus converging with the paretic component (OD), vis OD – light perception, OS—1.0. X-ray computed tomography of the brain: In both hemispheres of the brain, many calcifications are determined up to 0.5 cm in diameter. There is an asymmetric (D > S) expansion of the ventricular system (lateral ventricles), with a change in the configuration of the anterior horn of the right lateral ventricle (to spherical), 1.8 × 1.9 cm in transverse dimension. The transparent septum is displaced to the left by 0.5 cm. The rest of the ventricular system is moderately dilated. **Conclusion:** computed tomographic signs of cerebral cysticercosis in the calcification stage. Internal hydrocephalus. Severe deformation of the right lateral ventricle, probably due to the presence of a cysticercus bladder. Ultrasound examination of the abdominal organs—no pathology. In the study of feces – eggs of worms were not found. Was examined by a neurosurgeon. Diagnosis: Consequence of the transferred

neuroinfection. According to CT data of the brain, there is an isolated expansion of the body of the right lateral ventricle without impairment of CSF circulation. Does not need neurosurgical treatment. Examination of an infectious disease specialist—antiparasitic therapy is recommended, albendazone for 10–14 d—15 mg/kg/d in two doses. An ELISA test for antibodies to taenia solium was recommended — the antibodies were determined. Results and its discussion. More often, clinically, cysticercosis of the brain is manifested by a convulsive syndrome. Convulsions can be generalized (with loss of consciousness) and partial (twitching of the limbs without loss of consciousness). Convulsions are often persistent, difficult to stop, pharmacoresistant. Patients are forced to take anticonvulsants for a long time in mono or combination therapy: carbamazepine, depakin, lamictal, topamax. Depending on the leading cerebral disorders, there are 5 main syndromes of this disease: hypertensive, occlusive, epileptic (convulsive), meningoencephalitic and psychopathological. Depending on the localization of the parasite, cysticercosis is distinguished supratentorial (cortex and meninges of the brain, intraventricular and mixed form), subtentorial (IV ventricle, cisterns of the posterior cranial fossa and mixed form) and generalized, a special variant is distinguished—racematous or branched (usually localized in the soft cerebral membranes of the base of the brain and can go to the spinal cord).

Conclusion: Children with a sharp decrease in vision should be examined by a neurologist to exclude brain pathology.

P1261
RARE LYSOSOMAL DISEASES IN NEUROLOGICAL PRACTICE

A. Filipovich[1], T. Zagorskaya[2]

[1]National Science and Practice Centre of Medical Assessment and Rehabilitation, Yukhnovka, [2]Minsk Regional Children's Clinical Hospital, Minsk, Belarus

In the neurological department of the Minsk Regional Children's Clinical Hospital, we recently observed 2 cases of lysosomal diseases—glycolipidosis with a predominant lesion of the nervous system: GM2 gangliosis—Tay-Sachs disease, and cerebrosidosis—Krabbe's disease. At the heart of Tay-Sachs disease is a genetically determined disorder of the metabolism of gangliosides, accompanied by their increase in the gray matter of the brain, liver, spleen. The type of inheritance is autosomal recessive, the deficiency of the enzyme hexosaminidase A is determined. The frequency of infantile gangliosidosis is 1: 250,000. Vision decreases and is rapidly lost, a special feature is the "cherry spot", which is translucent vessels at the site of destruction of several layers of the retina.

Here is a brief description of the case. Girl KD, 1 year 5 months, complaints of developmental delay—does not hold her head, does not turn over, does not sit, does not walk, does not talk. From 1 year 4 months, seizures appeared in the form of short-term tremors of the limbs. Twice, up to 1 year 5 months, she was treated in the neurological department due to delayed psychomotor development, was examined by geneticists in order to clarify the diagnosis. Objectively the head is macrocephalic in shape, does not hold the head, the large fontanelle is closed, does not turn over, does not sit, does not walk. Exotropia. Muscle tone is sharply reduced in the limbs, there is no support. Tendon-periosteal reflexes are reduced. R-CT of the brain: The cortex and white matter of the brain are well developed. No foci of pathological density were found in the brain matter. The ventricular system is moderately dilated. The lateral ventricles are symmetrical. The subarachnoid space of the cerebral hemispheres and cerebellum is uniformly expanded to 7 mm. **Conclusion:** CT—signs of mixed hydrocephalus. O. ophthalmologist: does not fix the toy, the direct reaction of the pupils is sluggish. The fundus of the eye: the optic nerve disks are pale, the contour is clear, the vessels are 1: 2 (3), the course is normal. In the macular zone, there is a bright red rounded dystrophic focus, rounded with a whitish corolla. Visible periphery without pathology. Diagnosis: Tay-Sachs disease. Partial atrophy of the optic nerves in both eyes. Results of genetic testing: 1. At the Institute of Genetics and Cytology of the National Academy of Sciences of Belarus (laboratory of nonchromosomal pathology), mitochondrial DNA was analyzed for the presence of T8993 G mutations (maternal inherited Lee syndrome) and A3343 G (MELAS syndrome), as well as for the presence of large deletions of MT DNA. PCR analysis of DNA samples isolated from leukocytes was carried out. According to the results of DNA analysis, these violations of the mitochondrial genome were not revealed. 2. Activity of lysosomal enzymes in leukocytes: decreased activity of β-hexosaminidase A: 10.7; 7.2 mmol/g/mg of protein (norm 180–470). Diagnosis: GM2—gangliosidosis. Tay-Sachs disease. The risk of having a child with such diseases in the family is 25%—high. Material from a sick girl and her parents was sent for DNA research to the Medical Genetic Research Center of the Russian Academy of Medical Sciences, Moscow—a partial analysis of the HEXA gene (Tay-Sachs disease, H1H 272800). Treatment is symptomatic, specific enzyme replacement therapy has not been developed. The girl received anticonvulsants: depakin, carbamazepine, topamax, as well as diacarb, asparkam, emoxipin.

Five years ago, another girl with a diagnosis of globoid cell leukodystrophy—Krabbe's disease underwent inpatient treatment twice in the neurological department of the ultrasound department of the Moscow Regional Children's Clinical Hospital. The child was admitted at the age of 3 months with complaints of delayed psychomotor development, constant unmotivated cry, malnutrition, then myoclonic convulsions appeared. The objective status was spastic tetraparesis, increased tendon-periosteal reflexes, pseudobulbar disorders, muscle hypertension, which was later replaced by hypotension. The disease progressed, due to a violation of swallowing, the child suffered aspiration pneumonia. According to a decrease in the activity of the enzyme galactosylceramide-β-galactosidase in the medical genetic center of Minsk, the diagnosis was made—Krabbe's disease. At the age of 1, the girl died. The type of inheritance of Krabbe's disease is autosomal recessive.

To date, there are enzyme replacement drugs for the treatment of a number of extremely rare diseases: mucopolysaccharidosis—types 1,2,6, Gaucher disease, Fabry disease, Pompe syndrome, but in case of brain damage, there is no enzyme therapy, since the drugs do not penetrate the blood–brain barrier. Intensive clinical research is underway around the world to develop effective enzyme replacement therapy.

P1262
BABY-SHAKEN SYNDROME

T. Zagorskaya[1], A. Filipovich[2]

[1]Minsk Regional Children's Clinical Hospital, Minsk, [2]National Science and Practice Centre of Medical Assessment and Rehabilitation, Yukhnovka, Belarus

Shaking baby syndrome – injuries caused to the baby as a result of strong shaking. In total, there are about 27 cases of Baby-Shaken syndrome per 100,000 infants worldwide. Most often, the culprits of shaking are fathers and stepfathers (68–83%), followed by nannies (8–17%) and mothers (9–13%). A constantly crying child can infuriate even a well-balanced adult. A few sudden movements are enough for a child to get a serious injury. The head of a child under the age of one year is too large for a weak neck, it swings intensely and abruptly. Blood vessels can be damaged, leading to hemorrhages, due to the immaturity of the brain, the processes of nerve cells, which

in children are not protected by the membrane, break off when shaken. In case of rough shaking of the baby, it is possible to separate the spinal cord from the brain at the level of the brainstem. The visual apparatus in infants is often affected, which is associated with the movement of the layers of the retina of the eye relative to each other. The classic triad of shaken baby syndrome is intracranial hemorrhage (predominantly subdural hematomas), cerebral edema, retinal hemorrhage. In 25% of cases, the shaking syndrome ends in the death of the infant from damage to vital brain centers, severe spinal injuries in the cervical spine. Complications of shaking syndrome include cortical blindness, hydrocephalus, convulsive seizures, cerebral palsy, delayed psychospeech and motor development, learning disabilities, and mental retardation. In the mildest cases, symptoms of severe brain dysfunction remain. In the clinic, we observed a case of Baby-Shaken syndrome in a 4-month-old child. The child was born from a second pregnancy due to grade 1 gestational anemia, colpitis, chronic nicotine intoxication, second vaginal birth at 37 weeks with a weight of 3.100 g. The child's father is 53 years old, the mother is 29 years old, the mother suffers from epilepsy. From the age of 2 months, the baby began to hold his head.

At the age of 4 months, the child was admitted to inpatient treatment with complaints from the parents of a short-term loss of consciousness against the background of crying, similar to a respiratory affective attack. During the examination of the child, no data on cranial nerve damage were revealed, tendon-periosteal reflexes were not altered, a large fontanelle 1.5 × 1.5 cm, not strained. He holds his head while lying on his stomach well. Support on the forefoot. No changes in blood tests were detected. The child underwent an ultrasound of the brain—an echo picture of a subdural ganglion cyst on the right, an X-ray of the skull in 2 projections—no violation of the integrity of the bones of the cranial vault was revealed. The child underwent an MRI of the brain, revealed subacute chronic subdural liquor-hemorrhagic clusters over both hemispheres of the brain and cerebellum in varying degrees of resolution, the largest in the frontal region—12 mm thick, in the posterior cranial fossa 2–3 mm thick with a shift of the median structures to the right at the level of the ventricles by 1.5–2 mm without compression of the brain. Mild expansion of the subarachnoid convexital and cisternal spaces of the brain. The ventricles of the brain are not dilated or deformed, the anterior horns of the lateral ventricles are at the level of the foramen of Monroe 6 and 4 mm, the width of the third ventricle is 5 mm, the width of the fourth ventricle is 12 mm. There is no occlusion of the cerebrospinal fluid pathways. He was examined by a neurosurgeon and diagnosed: Bilateral subdural cerebrorogemorrhagic clusters (Baby-Shaken syndrome). Given the absence of focal symptoms and signs of intracranial hypertension, surgical treatment is not currently required. Conservative treatment with glycine and magnetab was carried out. Examined by a VisOD|OS-object vision, the optic nerve discs on the fundus of the eye are normal, no pathology was detected at the time of examination. The child's parents are registered as socially dangerous, for more frequent visits by the district pediatrician and visiting nurses. The inadmissibility of rough shaking and other options for careless treatment of children, the involvement of relatives in caring for the baby, and the help of psychologists are explained.

P1263
TAY-SACHS DISEASE: CLINICAL OBSERVATION

T. Zagorskaya[1], A. Filipovich[2]

[1]Minsk Regional Children's Clinical Hospital, Minsk, [2]National Science and Practice Centre of Medical Assessment and Rehabilitation, Yukhnovka, Belarus

Tay-Sachs disease is based on a genetically determined disorder of ganglioside metabolism, accompanied by their increase in the gray matter of the brain, liver, and spleen.

Girl K.D., 1 year 5 months, complaints of developmental delay – does not hold her head, does not roll over, does not sit, does not walk, does not talk. From 1 year and 4 months, attacks appeared in the form of short-term trembling of the limbs. Twice up to 1 year and 5 months, she was treated in the neurology department due to delayed psychomotor development, examined by geneticists in order to clarify the diagnosis. Objectively: the head is macrocephalic, does not hold the head, the large fontanelle is closed, does not turn over, does not sit, does not walk. Divergent strabismus. Muscle tone is sharply reduced in the extremities, there is no support. Tendon-periosteal reflexes are reduced. **Conclusion:** CT scan – signs of mixed hydrocephalus. O. ophthalmologist. Diagnosis: Tay-Sachs disease. Partial atrophy of the optic nerves in both eyes.

Genetic test results: 1. At the Institute of Genetics and Cytology of the National Academy of Sciences of Belarus (Laboratory of Non-Chromosomal Pathology), mitochondrial DNA was analyzed for the presence of mutations T8993 G (maternal inherited Leigh syndrome) and A3343 G (MELAS syndrome), as well as for the presence of large MT DNA deletions. PCR analysis of DNA samples isolated from leukocytes was performed. According to the results of DNA analysis, these mitochondrial genome disorders were not revealed. 2. Activity of lysosomal enzymes in leukocytes: decreased activity of β-hexosaminidase A: 10.7; 7.2 mmol/g Diagnosis: GM2 – gangliosidosis. Tay-Sachs disease. The risk of having a child with such diseases in a family of 25% is high. The material of the sick girl and her parents was sent for DNA testing to the Research Center for Medical Genetics of the Russian Academy of Medical Sciences in Moscow—a partial analysis of the gene HEHA (Tay-Sachs disease, H1H 272800). Treatment is symptomatic, specific enzyme replacement therapy has not been developed. The girl received anticonvulsants: depakine, carbamazepine, topamax, as well as diacarb, asparkam, emoxypine.

P1264
STROKE IN CHILDREN: CLINICAL CASE

A. Filipovich[1], T. Zagorskaya[2]

[1]National Science and Practice Centre of Medical Assessment and Rehabilitation, Yukhnovka, [2]Minsk Regional Children's Clinical Hospital, Minsk, Belarus

Stroke occurs not only in adults, but also in children, the frequency of its development in children ranges from 0.2 to 79 cases per 100,000 children, depending on the territory and time of registration, and ranges from 55–70% of the total number of all types of strokes. There is no gender difference, however, many experts note that boys are slightly more likely to suffer among children under 3 years old, and girls are more likely to suffer among schoolchildren and adolescents.

The main causes of stroke in children are heart diseases-congenital heart defects, diseases of the blood system and coagulopathy, cerebrovascular malformations, Moya-Moya disease, vasulitis, hereditary and acquired vasculopathy, homocysteinuria, compression of the vertebral artery, autoimmune diseases. In 1998, focal cerebral arteriopathy was first described, which is currently one of the most common causes of stroke in children. Focal transient cerebral arteriopathy is an acquired arteriopathy (due to acute intestinal infection, streptococcal infection), damage to the junction area of the distal portion of the internal carotid artery, as well as the proximal sections of the middle and anterior cerebral arteries, associated with stroke in the basal nuclei of the brain. One of the main causes of stroke in children is head trauma. 9–23% of cases of stroke in children are cryptogenic. Even a slight fall from the sofa to the carpet provoked the development of a stroke in a child.

A 1-year-old girl was treated at the Minsk Regional Children's Clinical Hospital with a diagnosis of strokein the basin of the left middle cerebral artery (basal nuclei), probably due to a minor head injury, with pronounced right-sided hemiparesis, lower prosoparesis, acute period. Concomitant diseases: mild anemia of mixed genesis. Acute respiratory infection, rhinopharyngitis. A minor abnormality of the heart development: a functioning oval window, an additional chord of the left ventricle, circulatory insufficiency of the 0 degree. Upon admission to the intensive care unit, the child's condition is serious. There was weakness in the right limbs, the right arm was falling, and there was almost no support on the right leg. MRI of the brain was performed on the girl: In the basal nuclei of the left hemisphere (shell, posterior femur of the inner capsule, partially the head and body of the caudate nucleus), a site of cytotoxic edema without blood metabolites measuring 20 × 18x23mm is determined. Incomplete myelination in the subcortical and periventricular white matter of the cerebral hemispheres. The ventricles and subarachnoid spaces are not expanded or deformed. The anterior horns of the lateral ventricles at the level of the Monroe orifice are 5 mm; the width of the third ventricle is 3 mm; the width of the fourth ventricle is 12 mm. The median structures are shifted to the right by 3 mm. There is no occlusion of the cerebrospinal fluid pathways. Structures of the facial skull: swelling of the mucous membranes of the cells of the latticed bone and maxillary sinuses on both sides, enlarged pharyngeal tonsils. Structures of the base of the skull: the pituitary gland is located intracellularly, measuring 7 × 3x9mm, the pedicle is not displaced, the posterior lobe is differentiated, the structure is homogeneous. Structures of the posterior cranial fossa: pneumatization of the pyramids (middle ear) and mastoid processes on both sides is reduced, due to a slight swelling of the mucous membranes. Magnetic resonance angiography (TOF): without signs of thrombosis of the arterial main vessels of the base of the brain and their visualized branches. The posterior trifurcation of the left internal carotid artery, deviation of the basilar artery and V4 segments of both vertebral arteries is determined; the formation of a transverse sinus on the left from the upper sagittal and rectus sinus, and a transverse sinus on the left from the upper sagittal sinus.

Conclusion: Acute ischemia in the basal nuclei of the left hemisphere of the brain without signs of thrombosis of the arterial main vessels of the base of the brain. Swelling of the mucous membranes of the paranasal sinuses. The child underwent coagulogram, blood and urine tests, biochemical blood analysis, blood tests for autoimmune diseases, congenital thrombophilic mutations, and the content of homocysteine in the blood was determined. Markers of autoimmune diseases: ANA—otp., a/b2-glycoprotein Ig M—otp, a/cardiolipin Ig M—otp, a/cardiolipin Ig G—otp. Congenital thrombophilic mutations, FV Leiden—otp, FII G 20210A—otp. The child was examined by a hematologist: no hematological cause of ischemic heart attack was revealed in the volume of studies performed. An ultrasound examination of the heart was performed: a functioning oval window with a left–right shunt. The dimensions of the chambers and walls of the heart are normal. The valvular apparatus of the heart without structural changes. Regurgitation of the 0–1 degree on the tricuspid valve, pulmonary artery valve. Movable Chiari network of the right atrium cavity. False chord in the cavity of the left ventricle. There is no free fluid in the pericardial cavity. The contractile function of the myocardium of the left ventricle is satisfactory. Ultrasound examination of the vessels of the lower extremities—veins of both lower extremities of normal anatomy, passable, diameters within the age norm, no intraluminal neoplasms were detected, compression by the sensor is complete, blood flow rates are within the normal range. The child was consulted by a cardiosurgeon of the State Institution "RNPC of Pediatric Surgery": The closure of the existing functioning window can be shown if its connection with the development of a stroke is established. This is possible only in the presence of a right-left shunt at the level of an open oval window (paradoxical embolism), as well as an embolism substrate (in adult patients, these are blood clots in the varicose veins of the lower extremities).Given the lack of indications for surgical closure of a functioning oval window, the latter is currently not indicated. The girl received nootropic, vascular drugs, antioxidants in the treatment: ceralin, emoxypine, cytoflavin, vinpocetine, as well as for 1 month -a direct-acting anticoagulant—fragmin under the control of anti-Xa, which was canceled due to the exclusion of hereditary thrombophilia. Due to anemia, she received an iron-containing drug-ferrum FT, as well as folic acid. Physical therapy and massage were started early. As a result of the treatment, after 1 month, the strength in the right limbs was almost completely restored, the girl began to take toys with her hands, turn on the light, and after 3 weeks she began to walk independently. After 1.5 months, she underwent a second course of rehabilitation on the basis of the neurological department: medication with neuroprotectors, acupuncture, electrical stimulation, paraffin, ozokerite applications on the right extremities, physical therapy, massage. As a result, right-sided hemiparesis and lower prosoparesis regressed. The girl is on the dispensary register with a neurologist at her place of residence, if necessary, a hematologist's consultation is indicated, and MRI of the brain is monitored.

P1265
REHABILITATION OF CHILDREN WITH CEREBRAL PALSY AND CONVULSIVE SYNDROME AT THE MINSK REGIONAL CHILDREN'S CLINICAL HOSPITAL

T. Zagorskaya[1], A. Filipovich[2]

[1]Minsk Regional Children's Clinical Hospital, Minsk, [2]National Science and Practice Centre of Medical Assessment and Rehabilitation, Yukhnovka, Belarus

Children with cerebral palsy (ICP) undergo courses of rehabilitation: medication and physiotherapy, massage repeatedly, sometimes up to 10 courses on the basis of the neurology departments of the Minsk Regional Children's Clinical Hospital (MRCH). Comprehensive rehabilitation is aimed at restoring motor functions, normalizing muscle tone, normalizing or developing weakened or absent innate motor reflexes (stepping, protective, head-to-body, head-to-head reflex, support reflex), teaching the skills of sitting, standing, walking, manipulative activity, and speech functions. In the presence of convulsive syndrome, the selection of anticonvulsants is carried out: carbamazepine, depakine, convulsofin, lamictal, topamax, clonazepam in mono- or in case of ineffectiveness in duotherapy. The presence of convulsive seizures in a patient with cerebral palsy is a contraindication to physiotherapeutic treatment (FTL), therapeutic exercise (exercise therapy), massage, drug treatment has a number of limitations—a number of nootropic drugs that can provoke convulsive seizures are contraindicated: nootropics (aninalone, cerebrolysin, encephalobol, piracetam), anticholinesterase drugs: proserin,

neuromidine. Of the nootropic and vascular drugs, pantogam, gliatilin, cortexin, actovegin, emoxipine, mexibel, glycine, B vitamins (neurobex, magne-B6), vitamin E, muscle relaxants (midocalm) are used. In the absence of convulsive syndrome in children with cerebral palsy for 3 months, the patient begins to undergo FTL, exercise therapy, massage, acupuncture against the background of taking anticonvulsants. Anticonvulsants are taken for a long time – 2–3 y after the last attack. Massage is of particular importance for the treatment of cerebral palsy, the work with each muscle group should be approached selectively, taking into account its tone, the presence of contractures in the joints. Physiotherapeutic treatment includes electrotherapy: electrical stimulation of the back muscles, foot extensors, thigh muscles, buttocks; Phototherapy: UV, laser therapy, polarized light therapy, ultrasound therapy and drug phonophoresis: euphylline-dibazole biphoresis on the limbs and segments of the spinal cord, heat therapy (paraffin-ozokerite applications), hydrotherapy: hydromassage, whirlpool baths, reflexology.

As of January 1, 2012, there are 857 children with cerebral palsy in the Minsk region. In 2011, 226 patients with cerebral palsy (29.65% of morbidity) were treated at the Neurology Department. 47 case histories of children with cerebral palsy who underwent treatment in 2011 were analyzed. Convulsive seizures were observed in 18 patients (38%) In 3 patients (6%) children with cerebral palsy, convulsive seizures in the stage of drug remission (that is, they regularly take anticonvulsants), sulorogenic seizures were noted during the rehabilitation treatment, as a result of which rehabilitation by physiotherapeutic methods, massage was stopped, only permissible drug treatment was preserved.

P1266
IMPACTS OF ADHERENCE OF DENOSUMAB ON KIDNEY FUNCTION AND ALL-CAUSE MORTALITY IN TYPE 2 DIABETIC PATIENTS

T.-C. Lee[1], C.-H. Chen[2], P.-S. Ho[3]

[1]Dept. of Orthopaedics, Kaohsiung Medical Univ. Hospital, Kaohsiung Medical Univ., [2]Dept. of Orthopaedics, Kaohsiung Municipal Ta-Tung Hospital, Kaohsiung Medical Univ., [3]Dept. of Oral Hygiene, Kaohsiung Medical Univ., Kaohsiung, Taiwan

Objective: Patients with type 2 diabetes mellitus (T2DM) have many comorbidities, including osteoporosis. Hyperglycemia may directly suppress osteoblast-mediated bone formation which then increases susceptibility to fracture. Although previous studies revealed that denosumab seemed safe for osteoporotic patients with T2DM, the treatment adherence, renal function change, and mortality rate after treatment remain unclear.
Methods: A retrospective cohort study was conducted using an electronic health record database. New denosumab users between 2010–2017 were identified. After excluding type 1 DM, other prevalent osteoporotic drugs users, subjects with malignancy diagnosis, and died within 2 y after the index date, 536 subjects were analyzed according to their 2-y drug adherence. The one-year average estimated glomerular filtration rate (eGFR) was calculated. We defined high adherence (HA) users as receiving three or four doses and low adherence (LA) users as receiving one or two doses. All-cause mortality was analyzed by Kaplan–Meier curve and Cox regression model to compare denosumab users with HA and LA groups.
Results: We enrolled 536 subjects in the overall cohort (286 in HA group; 250 in LA group). Decline of eGFR was observed in both cohort subjects after denosumab initiation. There is no renal function difference between these two groups. The all-cause mortality rate of the HA groups is significantly lower than the LA groups, with an adjusted hazard ratio of 0.52 (CI = 0.29–0.92).
Conclusion: New denosumab users with T2DM showed decline of renal function status after treatment regardless of medication adherence. HA users may have a significantly reduced all-cause mortality risk in comparison of LA users without significant renal function decline.

P1267
EFFECT OF AEROBIC EXERCISE ON KINESIOPHOBIA AND FATIGUE IN RHEUMATOID ARTHRITIS PATIENTS

N. V. Aleksandrova[1], V. A. Aleksandrov[2], I. Y. Alekhina[3], A. V. Aleksandrov[4], M. V. Nikitin[5]

[1]Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky, Volgograd, [2]Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky, Volgograd State Medical Univ., the Dept. of Hospital Therapy, Volgograd, [3]Stavropol State Medical Univ., the Dept. of Hospital Therapy, Stavropol, [4]Volgograd State Medical Univ., the Dept. of Hospital Therapy, the Dept. of Laboratory Diagnostic, Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky, Volgograd, [5]"Sanatorium-resort complex "Vulan"—Branch Federal state budget institution "National Medical Research Center for Rehabilitation and balneology" of the Ministry of health of the Russian Federation, Gelendjik, Russia

Objective: To evaluate the effect of aerobic exercise (dosed walking) on the level of kinesiophobia and changes in chronic fatigue indices in patients with rheumatoid arthritis (RA).
Methods: 52 outpatients with RA (mean disease activity according to DAS28-ESR was 2.9 [2.1;3.2] points) were included in the study. All RA patients used dosed walking for 4 weeks (daily, duration 30–60 min, taking into account the tolerance of physical activity according to the 6MWD-test) and underwent a twofold questionnaire (before and after the rehabilitation cycle). The VAS screening scale and the BRAF-NRS V2 questionnaire were used to assess fatigue, The Tampa Scale for Kinesiophobia (TSK) was used to assess the level of kinesiophobia, and the 50-m walk test was used to assess the patients' functional status in dynamics.
Results: At the initial examination, the average level of kinesiophobia according to TSK was 72.7 [31;84] points, the average level of fatigue according to VAS was 44.8 [26;57] points. According to the results of questionnaire processing, RA patients were divided by the level of physical activity (by the average number of steps walked per day) into two groups: group I (sedentary lifestyle) included patients with $<$ 5500 steps/d, group II (mobile lifestyle) included patients with $\geq$ 6000 steps/d. There were no intergroup differences in DAS28-ESR activity, VAS pain, 50-m walk test ($p > 0.05$). The presence of kinesiophobia of varying severity (TKS scores from 18–68) was found in 69.2% of RA patients. There were significantly more patients with kinesiophobia in group I compared to group II ($p = 0.007$). In patients with sedentary lifestyle (group I), no significant changes in VAS and BRAF-NRS fatigue scores were registered ($p > 0.05$), but there was a decrease in total TKS scores ($p = 0.036$), mainly due to the psychological component of kinesiophobia. There was a decrease in BRAF-NRS scores on all fatigue scales: NRS severity ($p < 0.001$), NRS-effort ($p = 0.009$) and NRS-overcoming ($p = 0.011$) in the group of RA patients with a mobile lifestyle (group II). There was a decrease in walking time in the 50-m test ($p = 0.027$) and a decrease in the psychological and physical components of TKS ($p < 0.001$).
Conclusion: Aerobic exercises have a positive effect on the functional state of patients with RA, contribute to the reduction of fatigue and kinesiophobia. The use of the TKS technique in RA patients may be required to clarify the prognosis and to draw up an individual rehabilitation plan.

P1268
EFFECTIVENESS OF USING A FUNCTIONAL UNLOADING (VALGUS-VARUS) ORTHOSIS IN OSTEOARTHRITIS AND VARUS DEFORMITY OF THE KNEE JOINT

V. A. Nesterenko[1], M. M. Makarov[1], B. E. Bialik[1], M. S. Makarov[1], K. A. Karateev[1], B. V. Bialik[1], A. S. Arkhipov[1], K. A. Khramov[1], N. E. Naryshkin[1], R. A. Roskidailo[1], M. S. Maglevannyi[1], D. A. Dubinin[1], A. Kargalcev[1], E. Filatova[1]

[1] V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia

Objective: Orthosis is one of the widely used methods of conservative treatment of osteoarthritis (OA) of the knee joint (KJ). However, there is relatively little data in the literature on the use of functional, unloading (varus-valgus) orthoses. We aimed to evaluate the effectiveness and safety of the use of a functional, unloading (varus-valgus) orthosis in patients with OA 3st and varus deformity of the knee joint.
Methods: The analysis of the results of using a functional, unloading (varus-valgus) orthosis in 10 patients with OA 3st and varus deformity of the KJ, confirmed by X-ray examination. (30.0% of men and 70.0% of women, average age 64.5 ± 8.9 y, BMI 30 ± 3.4). The inclusion criteria were: osteoarthritis of the knee joint of stage II, III according to Kellgren-Lawrence, established according to clinical and X-ray examination, age from 45 to 85 years, VAS pain ≥ 40 mm. All patients were recommended to use a functional, unloading (varus-valgus) orthosis for 3 months. The orthosis was adjusted four times every 5–7 d during the first month. The result was evaluated according to the data of an outpatient examination and a telephone survey after 1 and 3 months.
Results: Throughout the follow-up period, all patients noted a significant decrease in pain intensity, but the dynamics of functional indicators was minimal. VAS initial value is 49.0 ± 11.3, in the first hour of use 22.0 ± 13.9, after 1 month. 14.0 ± 11.7, after 3 months. 13.0 ± 10.5. KOOS initially, after 1 and 3 months 43 ± 10,3, 58,7 ± 10,6, 60,0 ± 10,6. Against the background of using a functional, unloading (varus-valgus) orthosis of adverse reactions was not noted.
Conclusion: The functional, unloading (varus-valgus) orthosis significantly reduces the intensity of pain starting from the first hour of its use and maintains positive dynamics throughout the wearing of the orthosis.

P1269
EVALUATION OF EFFECTIVENESS OF PERIARTICULAR ADMINISTRATION OF LOW MOLECULAR WEIGHT HYALURONIC ACID PREPARATIONS IN RHEUMATIC DISEASES OF VARIOUS LOCALIZATION

V. A. Nesterenko[1], K. A. Karateev[1], M. M. Makarov[1], B. E. Bialik[1], M. S. Makarov[1], B. V. Bialik[1], Z. V. Zelenov[1], A. S. Arkhipov[1], K. A. Khramov[1], N. E. Naryshkin[1], R. A. Roskidailo[1], M. S. Maglevanniy[1], K. A. Kargaltsev[1], D. A. Dubinin[1], S. V. Stadnik[1]

[1] V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia

Objective: Rheumatic pathology of the periarticular soft tissues (RPPT), which includes tendinitis, enteritis, bursitis, tendovaginitis, fasciitis, is a common cause of acute and chronic musculoskeletal pain. Treatment of RPPT is based on the combined use of painkillers, physiotherapy and rehabilitation, as well as local injection therapy (LIT), including the administration of hyaluronic acid (HA). However, there is relatively little data on evaluating the effectiveness of the use of LIT with HA in these pathologies. We aimed to evaluate the efficacy and safety of LIT HA 500–730 kDa in patients with various RPPT.
Methods: The study group consisted of 30 patients with RPPT of various localization (subacromial impingement syndrome (SIS), lateral/medial epicondylitis, plantar fasciitis), 10 people with each pathology. (60.0% of women and 40.0% of men, age 56.1 ± 14.9 y), who underwent LIT with the use of low-molecular-weight HA in the parathyroid region with RPPT of various localization. All patients received 3 injections of low molecular weight HA at an interval of 7 ± 2 d. The inclusion criteria were: Age ≥ 18 y, diagnosed according to clinical and instrumental parameters (ultrasound, MRI) RPPT: SIS, lateral/medial epicondylitis, plantar fasciitis, moderate or severe pain (≥ 40 mm on a visually analog pain scale, VAS 0–100) for more than 3 months, insufficient effect from previous LIT with the use of glucocorticoids, the need for regular administration of nonsteroidal anti-inflammatory drugs. The result of treatment VAS evaluated after 1 and 3 months. according to a telephone survey.
Results: Against the background of therapy, the dynamics of pain and function were distributed as follows: at SIS VAS initial one, after 1 and 3 months was 57,5 ± 15,8, 37,5 ± 13,8, 33,7 ± 14,0, ASES is initial, after 1 and 3 months was 54,2 ± 13,7, 64,5 ± 10,3, 65,5 ± 9,8. With lateral epicondylitis, VAS the initial one, after 1 and 3 months was 54,0 ± 13,4, 35,0 ± 9,7, 34,0 ± 11,0, the Mayo Elbow Score questionnaire is initial, after 1 and 3 months it was compiled 72,0 ± 11,5, 79,2 ± 9,0, 82,7 ± 7,7. In plantar fasciitis VAS, after 1 and 3 months, was 60.0 ± 16,5, 36,6 ± 19,3, 34,4 ± 15,8. Foot Function Index is initial, after 1 and 3 months, was 47,2% ± 22,8, 39,6% ± 29,7, 39,0% ± 29,9. During the study, no one had any adverse reactions with LIT.
Conclusion: Low molecular weight LIT HA are an effective and safe method of treating RPPT of various localization.

P1270
WHAT IS THE ROLE OF INTRA-ARTICULAR INJECTIONS IN RHEUMATIC DISEASES?

V. A. Nesterenko[1], K. A. Karateev[1], M. M. Makarov[1], M. M. Makarov[1], B. E. Bialik[1], B. V. Bialik[1], F. E. Filatova[1], R. A. Roskidailo[1], K. A. Khramov[1], N. E. Naryshkin[1], M. S. Maglevannyi[1], D. A. Dubinin[1]

[1] V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia

Objective: One of the widely used methods of treatment of rheumatic diseases (RD) is intra-articular injections of glucocorticoids (IAI GC). However, there are still many questions about their effectiveness and duration of action. We aimed to evaluate the effectiveness and safety of IAI GC at RD.
Methods: The results of treatment of 290 patients with osteoarthritis (OA) and rheumatoid arthritis (RA) were analyzed (31.0% of men and 69.0% of women, average age 55.6 ± 12.6 y). All received IAI GC in the knee joint according to strict indications determined by the attending physician. The control group consisted of 112 patients with OA (28.6% of men and 71.4% of women, aged 59.3 ± 14.6 y). These patients received a course of IAI hyaluronic acid (HA). The result was evaluated according to a telephone survey after 2 weeks, 1 and 3 months.
Results: After the course of the IAI GC in 2 weeks, 1 month and 3 months. Patients showed a decrease in pain (numerical rating scale (NRS 0–10), Me [25%; 75%]) from 6.0 [4.0; 8.0] to 1,0 [0; 2,0], 2,0 [1,0; 4,0] and 2.5 [1.0; 4.0], respectively ($p < 0.001$). After 3 months, 63.8% of patients with no/mild pain (< 4 NRS), 30.3% with complete/almost complete absence of pain (≤ 1 NRS). The effect of IAI GC was higher in RA than in OA—pain after 3 months -4.0 [-2.0; -6.0] and -2.0 [-1.0; -5.0], p = 0.003. The effectiveness of IAI GC and

HA in OA did not differ: pain after 3 months was -2.0 [-1.0; -5.0] and -3.0 [-1.0; -5.0] p = 0.869. Against the background of treatment, no adverse reactions were noted.

Conclusion: IAI GC are an effective and safe method of temporary treatment of patients with the presence of RA.

P1271
WHICH AGE IS BETTER SUITED TO THERAPY FOR SUBACROMIAL IMPINGEMENT SYNDROME?

V. A. Nesterenko[1], K. A. Karateev[1], M. M. Makarov[1], B. E. Bialik[1], M. S. Makarov[1], R. A. Roskidailo[1], F. E. Filatova[1], S. V. Stadnik[1], K. A. Khramov[1], N. E. Naryshkin[1]

[1] V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia

Objective: Periarticular administration of platelet-rich plasma (PRP) and hyaluronic acid (HA) preparations is widely used for chronic pain in the shoulder joint. However, the effectiveness of these drugs in patients of different ages has not been sufficiently studied. We aimed to compare the effectiveness of PRP and HA in patients with chronic shoulder pain associated with subacromial impingement syndrome, depending on age and individual characteristics.

Methods: 100 patients, 54% men and 46% women, aged 51.5 ± 15.1, with shoulder pain (≥ 3 months) caused by subacromial impingement syndrome were examined and treated. Patients < 45 years old accounted for 34%, ≥ 45 years old – 66%. After the examination, the patients were randomly divided into 2 groups. Group 1 received 3 consecutive subacromial injections of PRP with an interval of 7 days, group 2 received 2 consecutive subacromial injections of HA with a similar interval. The dynamics of pain was assessed using a 100 mm visual analog scale (VAS), functional disorders according to ASES (American Shoulder and Elbow Surgeons Assessment) and CSS (Constant Shoulder Score), a decrease in the need to use NSAIDs 6 months after the course of treatment.

Results: The dynamics of pain and functional disorders in the treatment of PRP and HA did not differ. Pain decreased from 56.0 ± 14.6 to 31.8 ± 26.3 and from 57.6 ± 17.8 to 30.2 ± 26.3 (p = 0.768), ASES increased from 54.8 ± 13.8 to 74.6 ± 22.4 and 54.7 ± 15.1 to 77.3 ± 22.5 (p = 0.552), CSS from 59.2 ± 14.4 to 66.9 ± 17.4 and 47.8 ± 16.9 to 65.6 ± 19.3 (p = 0.245). In the treatment of PRP and HA, the dynamics of pain and functional parameters were significantly better in patients < 45 years old than in patients ≥ 45 years old. The pain level according to VAS after 6 months was 22.4 ± 26.3 and 35.5 ± 26.2 (p = 0.022), ASES 83.3 ± 20.9 and 72.1 ± 22.6 (p = 0.017), CSS 76.2 ± 16.1 and 63.2 ± 18.2 (p = 0.001). There was no need to take NSAIDs in 82.4% and 65.2% of patients (p = 0.103). No serious adverse reactions were noted. It was noted that the following factors had no effect on treatment: gender, BMI, baseline pain level, and the number of affected tendons.

Conclusion: The effectiveness of PRP and HA in chronic shoulder pain associated with subacromial impingement syndrome does not differ. The clinical response to both drugs was higher in people under 45 years of age.

P1272
EVALUATION OF EFFECTIVENESS OF HIGH MOLECULAR WEIGHT HYALURONIC ACID IN POST-TRAUMATIC OSTEOARTHRITIS OF THE KNEE JOINT

V. A. Nesterenko[1], B. E. Bialik[1], M. M. Makarov[1], K. A. Karateev[1], B. V. Bialik[1], S. V. Stadnik[1], M. S. Makarov[1]

[1] V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia

Objective: Osteoarthritis (OA) is a serious social and economic burden for the world's population. The prevalence of OA in the world is constantly growing, which is associated with an increase in the number of obese people, joint injuries, and increased life expectancy. One of the means of helping patients with stage 3 knee joint OA is intra-articular injections of high-molecular hyaluronic acid. However, there is little data in the literature on the effectiveness of such drugs, depending on the frequency of administration. We aimed to evaluate the effectiveness of a single or double administration of a high molecular weight hyaluronic acid preparation with chondroitin sulfate in post-traumatic osteoarthritis of the knee joint.

Methods: The study involved 61 patients with post-traumatic osteoarthritis of the knee joint stage 3. All patients underwent intra-articular administration of high molecular weight hyaluronic acid with chondroitin sulfate, 36 patients received a single injection and 25 received a twofold injection with an interval of 7 d. To evaluate the results, the intensity of pain was determined using a visual analog scale and the total score on a numerical rating scale before the start of treatment, 1, 3, 6 and 12 months after a course of intraarticular injections of hyaluronic acid by telephone interview.

Results: In the whole group, pain during movement initially, after 2 weeks, 1, 3, 6, 12 months was 6,7 ± 3,1, 4,0 ± 3,2, 4,3 ± 3,1, 4,6 ± 2,8, 4,5 ± 2,5, 5,3 ± 1,4 see VAS. The pain at rest was 2,7 ± 3,1, 1,5 ± 2,6, 1,8 ± 2,6, 2,1 ± 2,6, 2,2 ± 1,8, 2,6 ± 1,3 see VAS. The function indicators were initially, after 2 weeks, 1, 3, 6, 12 months 4,9 ± 3,6, 3,5 ± 2,9, 4,2 ± 2,9, 4,0 ± 3,2, 3,5 ± 2,7, 4,3 ± 1,9 according to the numerical rating scale (NRS). In the first group, there are similar indicators: pain when moving 6,7 ± 3,1, 4,0 ± 3,2, 4,3 ± 3,1, 4,6 ± 2,8, 4,5 ± 2,5, 5,3 ± 1,4 See VAS alone 2,7 ± 3,1, 1,5 ± 2,6, 1,8 ± 2,6, 2,1 ± 2,6, 2,2 ± 1,8, 2,6 ± 1,3 See VAS, function 4,9 ± 3,6, 3,5 ± 2,9, 4,0 ± 2,9, 4,0 ± 3,2, 3,5 ± 2,7, 4,3 ± 1,9 according to the NRS. In the second group, pain during movement initially, after 2 weeks, 1, 3, 6, 12 months 5,6 ± 2,1, 3,3 ± 1,7, 3,6 ± 1,8, 3,4 ± 1,6, 3,7 ± 2,4,3,0 ± 1,2 See VAS, pain at rest 2,6 ± 2,4, 1,9 ± 1,7, 1,8 ± 1,6, 1,8 ± 1,7, 1,5 ± 2,2, 0,6 ± 1,0 See VAS, function 4,0 ± 3,1, 3,3 ± 2,6, 3,6 ± 2,7, 3,4 ± 2,6, 3,3 ± 3,1, 2,6 ± 1,7 according to the NRS.

Conclusion: The use of HA with chondroitin sulfate is an effective and safe means of therapy for posttraumatic OA knee joint. A two-time administration of HA with chondroitin sulfate at an interval of 7 days has a higher effectiveness in reducing pain and increasing function.

P1273
STATE OF BONE METABOLISM IN PATIENTS WITH CHRONIC PERIODONTITIS, DEPENDING ON THE FORM AND SEVERITY OF BRONCHIAL ASTHMA

O. Y. Poleshchuk[1], O. P. Galkina[1], V. B. Kaliberdenko[1], K. N. Kaladze[1], J. A. Dovbnya[1], E. R. Kuliyeva[1], K. K. Kaladze[1]

[1] V.I. Vernadsky Crimean Federal Univ., Simferopol, Russia

Objective: All systemic diseases and their basic therapy, by changing the reactivity of the body, contribute to the occurrence and progression of periodontal tissue pathology. Inhaled glucocorticosteroids (GC), which are used in the treatment of bronchial asthma (BA), can cause systemic side effects like of bone metabolism. One of these effects of hormone therapy is a disorder of mineral metabolism. The consequence of long–term therapy is GC-induced osteoporosis. The objective method of bone tissue (BT) research is an ultrasonic densitometry. The indicators determined by this method give an idea of

both the BT state of the supporting skeleton and the maxillofacial region.

Methods: The study included 43 adolescents (14–16 years old) with a diagnosis of generalized periodontitis of mild severity, chronic course, suffering from BA. The treatment of generalized periodontitis (GP) was according to the protocol. The study was carried out by ultrasound osteodensitometry on the "Achilles + " with the determination of the density index (IP,%) of BT, wide-field attenuation of ultrasound (dB/MHz), of ultrasound propagation speed (UPS, m/s). The control group (CG) consisted of 20 somatically healthy adolescents of comparable age.

Results: The analysis of ultrasound parameters in adolescents with GP and persistent form of BA revealed a significant decrease in the values of density index (DI) BT 64.31 ± 1.41% ($p < 0.001$) and 98.05 ± 1.35 dB/Mhz ($p < 0.05$), UPS 1537.46 ± 2.29 m/s ($p < 0.05$). With mild BA degree indicators were unreliably lower than in CG—78.34 = 1.14%, 99.77 = 1.69 dB/MHz, 1543.29 = 2.61 m/s. In CG—87.26 ± 1.23%, 103.21 ± 2.71 dB/MHz, 1567.14 ± 2.49 m/s.

Conclusion: The phenomena of osteopenia are more pronounced in patients with moderate severity of asthma. Thus, therapeutic and preventive measures should be approached in a differentiated manner.

P1274
CORRECTION OF STRUCTURAL AND FUNCTIONAL PROPERTIES OF BONE TISSUE IN ADOLESCENTS WITH CHRONIC PERIODONTITIS ON THE BACKGROUND OF BRONCHIAL ASTHMA

O. Y. Poleshchuk[1], O. P. Galkina[1], V. B. Kaliberdenko[1], K. N. Kaladze[1], J. A. Dovbnya[1], E. R. Kuliyeva[1], K. K. Kaladze[1]

[1] V.I. Vernadsky Crimean Federal Univ., Simferopol, Russia

Objective: The problem of osteopenic syndrome in children has long been of interest to scientists. The risk group for osteoporosis includes patients suffering from bronchial asthma (BA). Hypoxia, chronic inflammatory process, respiratory acidosis and long-term used of glucocorticosteroids adversely affect the condition of the child's bone tissue (BT). These changes are reflected in the maxillofacial region, including in the alveolar processes of the jaws. Normalization of the bone metabolism processes in children with BA is the prevention of the progression of generalized periodontitis.

Methods: The study included 38 adolescents (14–16 years old) with a diagnosis of generalized periodontitis of mild severity, chronic course, suffering from BA. The patients were divided into 2 groups. The first group (G-1) consisted of 20 people, the second group (G-2) – 18 people. Patients in G-1 and G-2 received standard therapy (hypoallergenic balanced nutrition, active climatotherapy, hydrotherapy and balneotherapy, heliotherapy, physical therapy, massage, mud applications provided for by BA protocols). In G-2, in order to correct osteopenic syndrome, patients received the drug Calcemin (Sagmel, Inc. USA) 250 mg 1 tablet 2 times a day for 21 d. The control group (CG) consisted of 20 practically healthy peers.

Results: According to ultrasound osteodensitometry, before the therapy, 32 (82.1%) patients had a decrease in the density index (DI) BT from -1 to -2.5 SD, which indicated manifestations of osteopenia, and in 2 (5.2%) patients it was < -2.5 SD, which corresponded to osteoporosis. In G-1, after the end of therapy, the DI BT indicator did not significantly change. It was noted before treatment at the level of 80.03 ± 1.27%, after treatment – 81.0 ± 1.72% (p0.05). In G-2, a significant increase in the DI of BT was recorded from 82.32 ± 1.64% to 85.96 ± 1.23% (p0.05).

Conclusion: The presence of adolescents with BA suffering from generalized periodontitis in conditions of therapy contributes to the positive dynamics of changes in bone metabolism. The inclusion of the drug "Calcemin" in the therapeutic and prophylactic scheme of generalized periodontitis against the background of BA leads to an improvement in the ultrasound characteristics of BT.

P1275
CHANGES IN MINERAL BONE DENSITY IN PATIENTS WITH PRIMARY COXARTHROSIS AND OBESITY

N. O. Miagkaia[1], J. S. Saenko[1], N. V. Saenko[1], V. B. Kaliberdenko[1]

[1] V.I. Vernadsky Crimean Federal Univ., Simferopol, Russia

Objective: In most developed countries, obesity is becoming an "epidemic," which is a decisive factor in the development of osteoarthritis. As a result of excessive body weight, there is a change in the level of mineral bone density. However, existing data on the relationship between BMI and densitometric indicators of mineral bone density in patients with osteoarthritis of large joints are contradictory.

Methods: Analysis of mineral bone density and calculation of BMI was performed in 248 patients with varying degrees of primary coxarthrosis, aged 45 to 87 years, mean age—62.6 ± 8.2. Patients underwent BMI calculation using the standard formula and DXA of the lumbar spine and proximal femur with assessment by T-score. Based on the BMI values, patients were divided into 3 groups: normal weight (18.5–24.9), overweight (25–29.9), and obesity (30–50.7).

Results: The frequency of decreased mineral bone density was 84.6%—210 people (osteoporosis 44.2%—93 individuals, osteopenia 55.8%—117 individuals). There were no significant rank differences in mineral bone density and BMI in all three groups ($p = 0.36$). Evaluation of mineral bone density values in the lumbar spine showed no significant differences between all three groups ($p = 0.42$). No significant differences in mineral bone density values of the proximal femur were found depending on BMI ($p = 0.96$).

Conclusion: The obtained data indicate the absence of a direct correlation between mineral bone density and BMI in patients with primary coxarthrosis.

P1276
RISK FACTORS FOR DEVELOPMENT OF OSTEOPOROSIS IN PATIENTS WITH TYPE 2 DIABETES MELLITUS

Y. O. Popenko[1], T. V. Shaldybin[2], V. B. Kaliberdenko[1], E. R. Kulieva[1], L. O. Ametova[1]

[1] V.I. Vernadsky Crimean Federal Univ., [2]Medaira Clinic, Simferopol, Russia

Objective: It is known that diabetes mellitus is one of the risk factors for the development of osteoporosis. However, in patients with type 2 diabetes mellitus (T2DM), BMD and FRAX® scores often do not fall outside the normal range. Therefore, it is important to determine additional factors that determine the risk of developing osteoporosis in this category of patients.

Methods: According to retrospective analysis of 152 medical records of patients with T2DM aged from 40–70 y. Also BMI, concomitant diseases, as cases of fractures were assessed, and densitometry was performed to assess BMD. In all patients, the blood level of 25(OH)D was examined (Architect test system), the HbA1c level was determined by ion exchange chromatography. Statistical analysis was carried out using the Statistica 10.0 software package.

Results: The study found that 13 (8.5%) patients with T2DM had a normal BMI, and 139 (91.5%) had overweight or obesity. The duration of the disease ranged from 1.5–25 y ((Me) 10 [8; 21]). HbA1c level—(Me) 8.8 [8;12.4]%, when analyzing the level of 25(OH)D in the blood serum, it was found that 30 (20%) patients had

a normal level of the indicator, but in 122 (80%) patients with T2DM, this indicator corresponded to insufficiency or deficiency. From the anamnesis it is known that 15 patients (10%) had fractures in adulthood. Low BMD was diagnosed in 42 (30%) women with T2DM.
Conclusion: The patients with T2DM in most cases have vitamin D deficiency and normal BMD, according to densitometry. In patients with type 2 diabetes, factors such as age and a decrease in BMI increase the risk of developing fractures and developing osteoporosis.

P1277
CORAL-DERIVED CALCIUM SUPPLEMENT IN COMBINATION WITH IBANDRONATE IMPROVES BONE MINERAL DENSITY OF THE DISTAL RADIUS

V. Babalyan[1], N. Hutchings[2], M. Qefoyan[1], S. Baghdasaryan[1], S. Kara-Poghosyan[1], J. P. Bilezikian[3]

[1]Osteoporosis Center of Armenia, Yerevan, Armenia, [2]Univ. of California, Los Angeles, Los Angeles, USA, [3]Columbia Univ., New York, USA

Objective: Osteoporosis and fragility fractures are major causes of morbidity and mortality in older individuals, but can be prevented if diagnosed and treated appropriately, including supplementation with calcium and vitamin D to maintain appropriate calcium intake and reduce bone resorption. Coral-derived calcium complex is a novel formulation of calcium supplement whose effect on skeletal health has not been rigorously studied.
Methods: We conducted a 3-arm randomized clinical trial of the effect on BMD in untreated osteoporotic women as follows: A) supplementation with coral-derived calcium + vitamin D complex 900 mg + 1200 IU daily with ibandronate 150 mg monthly; o B) ibandronate 150 mg monthly and vitamin D 1200 IU daily; C) coral calcium + vitamin D complex 900 mg + 1200 IU daily alone. We tracked changes in BMD of the lumbar spine, femoral neck, and distal $^1/_3$ radius over one year. Participants were instructed to abstain from calcium- or vitamin D-containing supplements and from other medications designed to treat osteoporosis not provided by the study.
Results: We recruited 60 women with osteoporosis as determined by T-score < -2.5. There were no significant differences in baseline BMD for the three skeletal sites among the three groups. Study agents were well-tolerated; only 3 individuals withdrew. Group A demonstrated a statistically significant improvement in distal radius BMD from baseline. Mean lumbar spine and femoral neck BMD improved but not significantly so.. Group B demonstrated a statistically significant improvement in lumbar spine BMD from baseline. Trends for improvement in distal radius and femoral neck did not achieving significance. Group C did not experience statistically significant improvement in any of the three skeletal sites..
Conclusion: Coral-derived calcium is well-tolerated and with ibandronate improves BMD of the distal radius. The known efficacy of ibandronate in improving BMD of the lumbar spine was again demonstrated in this study.
Disclosures:
This study was funded in part by an unrestricted grant from Coral Calcium LLC, manufacturer of the coral-derived calcium supplement under investigation. Ibandronate was provided as an in-kind contribution from Innovapharm LLC.

P1278
INFLUENCE OF OBESITY ON LIPOPOLYSACHARIDE-BINDING PROTEIN INDICATORS IN WOMEN WITH POSTMENOPAUSAL OSTEOPOROSIS

V. Beloglazov[1], Y. Usachenko[1], V. Kaliberdenko[1], E. Kulieva[1]

[1] V.I. Vernadsky Crimean Federal Univ., Simferopol, Russia

Objective: Over the past decades, obesity and osteoporosis have become major global health problems as their prevalence increases. Low-grade systemic inflammation likely has negative effects on bone tissue, and increased adipogenesis in the bone marrow may lead to decreased bone mass in obese individuals. Postmenopausal osteoporosis is a common metabolic bone disease, and imbalance of the gut microbiota plays an important role in the development of this disease. Lipopolysaccharide (LPS), a component of gram-negative bacteria found in the intestines, can be released into the circulation and stimulate the immune system, increasing bone resorption. Excessive bone resorption plays a central role in the development of inflammatory diseases of the skeletal system, including osteoporosis. Thus, identifying agents that can effectively inhibit excess osteoclast formation and function is critical for the prevention and treatment of inflammatory bone loss. However, the effect of LPS on metabolic bone diseases is unknown.
Methods: 96 female patients diagnosed with postmenopausal osteoporosis were examined. All patients were divided into two clinical groups: group 1 – 42 women with postmenopausal osteoporosis and grade 1–2 obesity, average age 57.2 ± 1.8 y; Group 2 – 54 women with postmenopausal osteoporosis and normal BMI (without obesity), average age 55.7 ± 2.4 y. The comparison group consisted of 39 women comparable in age and gender, average age 56.4 ± 1.4 y. The level of lipopolysaccharide binding protein (LPB) in blood serum was determined by a quantitative highly sensitive enzyme immunoassay using the Hbt Human LPB ELISA kit, the results were expressed in μg/ml. Statistical processing of the results was carried out using statistical programs Microsoft Excel, Statistica 13.0 (StatSoft Inc.)
Results: In the first group of women with postmenopausal osteoporosis and obesity, the level of LPB in the blood serum was statistically significantly higher ($p < 0.001$), compared to the second group of women with normal BMI and the control group.
Conclusion: A relationship was found between postmenopausal osteoporosis, systemic inflammation and lipopolysaccharide binding protein (LPB) levels in patients with a combination of postmenopausal osteoporosis and obesity.

P1279
CLINICAL CASE: RESULTS OF ARTHROSCOPIC MOSAIC CHONDROPLASTY WITH SIMULTANEOUS CLOSE WEDGE MEDIAL HIGH TIBIAL OSTEOTOMY IN THE TREATMENT OF LATERAL POSTTRAUMATIC OSTEOARTHRITIS OF THE KNEE

V. Bialik[1], M. Makarov[1], S. Arkhipov[1], E. Bialik[1], A. Karateev[1], A. Gorelova[1], S. Maglevany[1], E. Naryshkin[1], A. Khramov[1], V. Nesterenko[1], A. Chernikova[1]

[1] V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia

Arthroscopic mosaic chondroplasty (AMC) and closing wedge medial high tibial osteotomy (CWM HTO) are joint-saving surgeries that are most often used alone to treat osteoarthritis (OA) of the knee. We present a clinical case of simultaneous performance of these two operations in a professional athlete.
Case report: Patient Zh, 25 years old, with pain in the left knee joint that arose after falling on his leg while jogging in 2019. A lateral meniscus tear was diagnosed and arthroscopic partial resection was performed, which did not lead to improvement. He continued to be treated with non-steroidal anti-inflammatory drugs, glucosamine sulfate (GS), and intra-articular injections (IAI) of hyaluronic acid preparations. In 2022, due to persistent pain (70 mm on the visual analogue scale (VAS)) and a decrease in sports activity, he turned to

us for advice. Clinically, the patient had valgus deformity of the knee, increasing in the standing position, pain in the lateral part of the knee, and slight lateral instability. According to X-ray data, signs of stage 2 knee OA with predominant damage to the lateral compartment and valgus deformity of the knee joint of 14 degrees were identified. MRI diagnosed a chondral defect of the lateral femoral condyle measuring 1.5 × 2 cm. Taking into account the simultaneous presence of a chondral defect according to MRI data and valgus deformity of the knee, we decided on a one-stage restoration of the cartilage of the lateral femoral condyle through AMC and correction of the mechanical axis of the lower limb (reducing the load on the lateral part of the knee) using a rare operation – CWM HTO. Osteochondral columns for AMC were taken from non-weight-bearing sections in the arch of the femur with their subsequent transplantation into the defect area. A CWM HTO was performed using a standard mini-approach, a bone wedge was removed from the medial part of the proximal epiphysis of the tibia, after which the proximal and distal fragments of the tibia were closed and the achieved correction was secured with an original fixator. Rehabilitation after surgery included wearing an orthosis and unloading the leg by walking with additional support on a crutch for 8 weeks, taking a course of glucosamine sulfate and IAI of platelet-rich plasma during the transition to walking with full support on the operated leg. The patient returned to sports 6 months after surgery. At the follow-up examination 1 year after the operation, the patient was not bothered by pain (VAS 0 mm), the function of the knee was completely restored, the patient actively participates in competitions.

Conclusion: The combination of joint-saving surgery and conservative treatment of OA allowed a young patient with OA to get rid of pain, restore the function of the knee and return to sports.

P1280
MULTIFOCAL AVASCULAR OSTEONECROSIS AFTER COVID-19: A CLINICAL CASE: 2 YEARS FOLLOW-UP

V. Bialik[1], A. Karateev[1], E. Bialik[1], M. Makarov[1], S. Makarov[1], V. Nesterenko[1], A. Chernikova[1], A. Gorelova[1]

[1] V. A. Nasonova Research Institute of Rheumatology, Moscow, Russia

SAR-CoV-2 (COVID-19) infection can cause endothelial dysfunction, vasculitis, and thromboembolic complications. One of the manifestations of vascular pathology in this disease is avascular osteonecrosis (AON) of bones.

Case report: A 30-year-old patient, who didn't suffer from musculoskeletal diseases and didn't have thrombosis, suffered moderate COVID-19 in February 2021, which required hospitalization. Therapy was carried out with antibiotics, glucocorticoids (up to 30 mg/d for 3 weeks), antiviral drugs, anticoagulants. She was discharged from the hospital after cessation of fever, saturation normalization, and a negative SAR-CoV-2 (PCR) test. The patient noted the appearance of pain in both hip, left ankle and right shoulder joints by mid-December 2021. On examination: pain and limitation of movement in both hip joints, the severity of pain according to the visual analog scale (VAS, 100 mm)—75 mm on the left, 60 mm on the right, pain in the left ankle joint (VAS 50 mm), on the right shoulder (VAS 40 mm). On MRI of December 2021: osteonecrosis femoral head (ONFH), osteonecrosis humeral head (ONHH) and talar osteonecrosis (TON) stage 2 by Ficat-Arlet. The patient received therapy with alendronic acid (70 mg/week), calcium 1000 mg/day, alfacalcidol and dipyridamole (75 mg/d for 3 months), unloading both legs by walking with additional support on crutches, 9 sessions nuclear magnetic resonance therapy and taking NSAIDs as needed from December 2021 to September 2022. During examination, the patient was diagnosed with homozygous methylenetetrafolatereductase (MTFFR) gene (thrombophilia), and therefore lifelong therapy with rivaroxaban at a dose of 10 mg/d was prescribed. An MRI scan from September 2022 revealed progression of ONFH from stage 2 to stage 4 in both hips, stage 3 ONHH, stage 2 TON, osteonecrosis condyles of the humerus 2 stage, extensive bone marrow infarcts of the femur and tibia, ending in the subchondral region, were also identified. In the period from October 2022 to October 2023, due to the progression of osteonecrosis to terminal stages, the patient underwent total hip arthroplasty of both hip joints and anatomical arthroplasty of left shoulder joint with a good functional result to date. The patient continues to experience pain in the right shoulder joint, ankle and left knee joint. The patient is currently awaiting replacement of the right shoulder joint. The dynamic monitoring of the patient continues.

Conclusion: This case demonstrates the aggressive and rapid development and progression of AON after COVID-19 against the background of an existing thrombophilic predisposition and the need for endoprosthetics of at least 4 joints in a young patient.

P1281
INFLUENCE OF TARTRAZINE ON HISTOLOGICAL STRUCTURE OF THE MANDIBULAR CONDYLAR CARTILAGE

V. Bibik[1], V. Luzin[1], N. Mosyagina[1], O. Churilin[1], E. Krivosheev[1]

[1]FSBEI HI, St. Luka LSMU of MOH of Russia, Lugansk, Russia

Objective: To test influence of tartrazine after 60-d application on histological structure of the mandibular condylar cartilage (MCC) and administration of mexidol.

Methods: The study involved 105 male rats with body weight of 200–210 g. The first group comprised the intact animals (C-group), the second group comprised the animals that received *per os* tartrazine in dosage of 1500 mg/kg of body weight for 60 d (T-group), and the third group received intraperitoneal mexidol together with tartrazine in dosage of 50 mg/kg (TM-group). Upon expiration of observation terms, HE stained frontal sections of mandibular condyles were put to morphometry.

Results: In animals of the T-group in readaptation period from 3rd to the 45th day, total width of the MCC was less than the values of the C-group by 9.11%, 8.86%, 7.37%, 5.79%, and 3.75%; width of the proliferation zone decreased by 10.82%, 10.41%, 7.67%, 4.80%, and 4.04% and width of the zone of subchondral osteogenesis – by 11.26%, 11.05%, 10.42% 8.42%, and 5.78% and osteoblasts number in zone of subchondral osteogenesis decreased by 10.46%, 10.47%, 9.01%, 7.17%, and 4.96%. In animals of the TM-group from 3rd to 45th day of readaptation, the total width of the MCC exceeded the values of the T-group by 3.00%, 3.15%, 2.54%, and 2.67%, width of the proliferation zone on the 3rd day – by 3.92%, width of the subchondral osteogenesis zone from 15–45 d – by 4.35%, 4.43%, and 4.35% and osteoblasts number in it – by the 3rd day of readaptation increased by 5.95%.

Conclusion: Intragastric administration of tartrazine in dosage of 1500 mg/kg/d for 60 d was accompanied by inhibition of the morpho-functional activity of the MCC, which is maximally expressed on day 3 after tartrazine discontinue and then gradually recovers. Administration of mexidol in dosage of 50 mg/kg of body weight had a positive effect on the recovery of MCC compared with T-group.

P1282
LIFETIME RISK OF FRACTURE AMONG POSTMENOPAUSAL WOMEN WITH OSTEOPOROSIS AND AT HIGH RISK OF FRACTURE

V. C. Brunetti[1], H.-C. Chien[2], M. Mcdermott[2], T.-C. Lin[2], M. Kim[2]

[1]Amgen Ltd., London, UK, [2]Amgen Inc., Thousand Oaks, USA

Objectives Data from countries in the European Union (EU) show that the lifetime risk of fracture ranges between 43–78% [1, 2], but recent data from the USA (US) is lacking. The aim of this study was to assess the cumulative lifetime risk of fractures among postmenopausal women with osteoporosis aged ≥ 50 y of age in the US.
Methods: We followed a retrospective cohort of high-risk postmenopausal women with osteoporosis, aged ≥ 50 y using Optum Clinformatics® Data Mart, covering individuals who were privately insured or possessed employer-sponsored Medicare Advantage plans, from Jan 1, 2021 (index date) until the earliest of: 1) osteoporotic fracture, 2) death, 3) disenrollment, or 4) end of the study period (Dec 31, 2021) to assess the 1-y incidence of osteoporotic fractures after index date. High risk of fracture was defined as a history of fracture at any time prior to index date or by the presence of ≥ 2 risk factors among the following: a) age ≥ 65 y, b) history of smoking or alcohol use, d) type 2 diabetes mellitus, e) oral steroid use, f) rheumatoid arthritis, and g) immobilization. The following osteoporotic fractures were included: hip/femur, pelvis, lower leg and ankle, forearm, upper arm, and vertebral fractures, identified using ICD-10 and procedure codes. We used the current probability method [3], which uses the incidence of fractures by age strata, population estimates for each age and all-cause mortality incidence to estimate the lifetime risk of fracture [4].
Results: A total of 1,275,854 women were included in the study, with a mean (SD) age of 75.6 (8.9) y. The 1-y incidence of fractures increased by age, from 0.9% in women aged 50–54 to 9.7% in women aged ≥ 90 y. The lifetime risk of fracture among women with osteoporosis aged ≥ 50 and at high risk of fracture was 79.2%. This risk was 76.3% for women aged ≥ 55 years and 72.1% for women aged ≥ 60 y.
Conclusion: Among over one million, high-risk postmenopausal women with osteoporosis, more than 2 out of 3 will experience a fracture at least once in their remaining lifetime. This data highlights the importance of appropriate screening, diagnosis, and management of osteoporosis in this high-risk patient population.

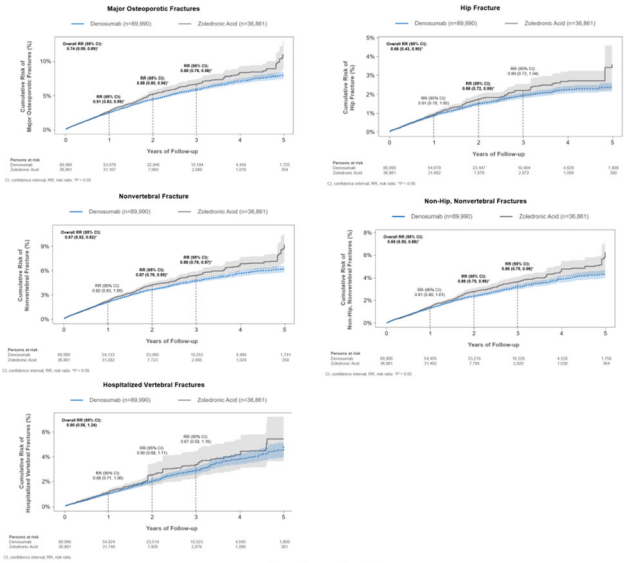
P1283
COMPARATIVE EFFECTIVENESS OF DENOSUMAB VERSUS ZOLEDRONIC ACID AMONG POSTMENOPAUSAL WOMEN WITH OSTEOPOROSIS IN THE U.S. MEDICARE PROGRAM

J. R. Curtis[1], T. Arora[2], Y. Liu[1], T.-C. Lin[3], L. Spangler[3], V. C. Brunetti[4], R. K. Stad[3], M. Mcdermott[3], B. D. Bradbury[3], M. Kim[3]

[1]Univ. of Alabama at Birmingham, Birmingham, USA, [2]Foundation for Advancing Science, Technology, Education and Research, Birmingham, USA, [3]Amgen Inc., Thousand Oaks, USA, [4]Amgen Ltd., London, UK

Objective: Although clinical trials have shown that denosumab (Dmab) significantly increases BMD at key skeletal sites more than zoledronic acid (ZA), evidence from randomized trials evaluating fracture outcomes is lacking. This retrospective cohort study evaluated the comparative effectiveness of Dmab vs. ZA in reducing fracture risk among women with postmenopausal osteoporosis (PMO) in the U.S.
Methods: Female Medicare fee-for-service beneficiaries ≥ 66 y of age who newly initiated Dmab (n = 89,990) or ZA (n = 36,861) between Jan 1, 2012 to Dec 31, 2018 with no prior history of osteoporosis treatment were followed from treatment initiation (index date) until the first instance of a given fracture outcome, treatment discontinuation (defined as the end of exposure according to usual dosing intervals + 60-d gap) or switch, Medicare disenrollment, death, end of available data (Dec 31, 2019), or 5 y post-index date. A doubly robust inverse-probability of treatment (weights estimated from multivariate logistic regression models) and censoring (weights estimated from multivariate Cox Proportional Hazards regression models) weighted function was used to estimate the relative risk (RR) associated with the use of Dmab compared with ZA for major osteoporotic (MOP; nonvertebral and hospitalized vertebral), hip, nonvertebral (NV; includes hip, humerus, pelvis, radius/ulna, other femur), non-hip, nonvertebral (NHNV), and hospitalized vertebral (HV) fractures for the overall study period and by year of follow-up.
Results: Over a maximum of 5 y of follow-up, Dmab reduced the risk of MOP by 26% (RR = 0.74; 95%CI: 0.59–0.89), hip by 34% (0.66; 0.43–0.90), NV by 33% (0.67; 0.52–0.82), and NHNV by 31% (0.69; 0.50–0.88), and HV fractures by 10% (0.90; 0.56–1.24) compared with ZA (Figure). Over time, Dmab reduced the risk of MOP fractures by 9% (0.91; 0.83–0.99) at year 1, 12% (0.88; 0.80–0.96) at year 2, and 12% (0.88; 0.78–0.98) at year 3. An increase in the magnitude of fracture risk reduction with increasing duration of exposure was also observed for other NV outcomes.



Conclusion: In a cohort of over 125,000 treatment-naive women with PMO, we observed robust, clinically meaningful reductions in the risk of MOP, hip, NV, and NHNV fractures for patients on Dmab compared to ZA, with greater reductions in fracture risk with longer duration of exposure.

P1284
STRESS FRACTURE OF BASE OF FIFTH METATARSAL BONE IN A PATIENT WITH OSTEOPOROSIS AND ESSENTIAL THROMBOCYTHEMIA (ET)

V. Dimitrioski[1], D. Jovanovska—Jordanovski[1], S. Lazarevska[2], D. Grujoska -Veta[3], M. Jakimova[4]

Macedonia, Skopje, North Macedonia

Dimitrioski V.[1], Jovanovska—Jordanovski D.[1], Grujoska -Veta D. [2], Lazarevska S. [3], Jakimova M.[4]

[1] PHI Health Center Skopje, Polyclinic Jane Sandanski, R. N. Macedonia, [2] PHI U. Clinic of Orthopaedic Diseases -Skopje, R. N. Macedonia, [3] Center for Physical and Kinesitherapy- Laser Med, Skopje N. Macedonia, [4] Private Orthopaedic Practice Orto Plus Ped, Skopje N. Macedonia.

Stress fractures arise as a result of microscopic injuries sustained when bone is subjected to repeated submaximal stresses. Our patient has comorbidities that further the causality into an insufficiency reaction stress fracture, where bone formation is impaired, in our case because of osteoporosis. This is a case of a female patient with a history of osteoporosis, essential thrombocythemia (ET) and a late discovery fracture of base of the fifth metatarsal bone.

Case report: 73 years female, 153.0 cm height, weight 55 kg, menopause at 48 y, history of pain in the lateral side of her right midfoot for a period of 6 months. VAS score 7 at first consult, 7 d later pain decreased with oral analgesics. The patient is treated for ET with HYDREA for several years. This patient was treated with a bisphosphonate for several years and after a drug pause she was restarted on bisphosphonate monthly. She also had a L1 vertebral fracture diagnosed and treated 12 months ago. After a physical examination, labs, X-ray, DXA scan, and a CT scan of the right foot were done. Radiography showed a fracture of the zone 1/zone 2 base of fifth metatarsal bone in sanationem. CT scan of foot confirmed an old fracture with bone callus forming. DXA scan: T-score L spine -3.4; T-score l hip -2.4. Labs: ionized Ca 1.31/ total body Ca 2.44/ vit. D 32.47.

Conclusion: A diagnosis of stress fractures must be taken in consideration when they occur in the older population despite treatment for osteoporosis.

P1285
OSTEOPOROSIS AND OSTEOPENIA IN ANKYLOSING SPONDYLITIS: A STUDY IN QSUT, ALBANIA

E. Guci[1], V. Duraj[1], L. Djepaxhia[1], A. Gremi[1], E. Arizi[1], L. Prifti[1], G. Leka[1], L. Gjoni[1]

[1]Qendra Spitalore Universitare Nene Tereza, Tirana, Albania

Objective: Ankylosing spondylitis is an inflammatory condition affecting the spine, which may lead to complications such as osteoporosis and osteopenia. The aim of this study is to evaluate the risk of osteoporosis and osteopenia in patients with ankylosing spondylitis.

Methods: We evaluated 102 patients suffering from ankylosing spondylitis in our hospital consulting center. We performed a complete history and physical review of past medical records and radiographs, complete blood count, c-reactive protein, erythrocyte sedimentation rate, HLA-B27, chemistry profile, TSH, urinalysis, 25-OH vitamin D. Our main focus was evaluating the risk of osteoporosis or osteopenia in ankylosing spondylitis patients using the DXA. We recorded comorbidities for each patient such as diabetes, COPD, cardiac insufficiency, neurological disorders.

Results: There were 28 females aged 26–65 y (27.4%) and 74 males aged 18–74 y (72.6%) included in our study. It has been seen that among the female patients 2 showed a T-score $>$ -1, 16 showed a T-score of -1 to -2.5 suggesting osteopenia and 10 showed a T-score $<$ -2.5 suggesting osteoporosis. Among the male patients 54 showed a T-score $<$ -2.5, 15 showed a T- score -1 to -2.5 and 5 showed a T-score $>$ -1.

Conclusion: Patients diagnosed with ankylosing spondylitis have a huge risk of developing osteoporosis or osteopenia. It also shows that osteoporosis is more common among male patients. The standard for diagnosis of osteoporosis in ankylosing spondylitis is a DXA of the spine and hip. It is important to evaluate the results of the DXA to establish an adequate therapy which should include preventive measures, in addition to bisphosphonates and when possible, TNFα inhibitors.

P1286
VALIDATION OF THE NOTTINGHAM HIP FRACTURE SCORE (NHFS) AMONG ITALIAN ORTHOGERIATRIC PATIENTS: RESULTS FROM A MULTICENTRIC STUDY

V. Gemo[1], F. Perini[1], C. Properzi[1], M. Baroni[1], M. Ferracci[1], C. Ruggiero[1], V. Bini[2], P. Montanari[3]

[1]Geriatric Unit and Orthogeriatric Service Univ. of Perugia, Perugia, [2]Statistics Section Univ. of Perugia, Perugia, [3]Geriatric and Orthogeriatric Unit Dept. of Neuromotor and Rehabilitation of Reggio Emilia, Reggio Emilia, Italy

Objective: Hip fracture is associated to high short and long-term mortality and disability with high human and social cost. The patient's characteristics in the preoperative phase and factors related to surgical treatment have an impact on functional recovery and survival. Several tools have been developed to assess the mortality risk associated with surgery. Of these, NHFS appears to be one of the most reliable. The aim of our study is to validate the reliability of NHFS in a cohort of Italian patients with femoral fractures and identify variables potentially capable of updating the prediction model in our population.

Methods: A multicenter prospective study was conducted on orthogeriatric patients admitted for hip fracture from the Hospital of Perugia and Reggio Emilia. All patients undergoing surgical treatment, also those with periprosthetic and pathologic fractures, were included without age limit. Personal and clinical information was collected through computerized medical records. 30-d survival status was identified through regional mortality registries. Bivariate and multivariate logistic regression was performed to assess 30-d risk of death according to hip surgery and other clinical, functional, and biochemical variables. The predictive accuracy of NHFS and other logistic regression models was quantified as area (AUC) under ROC curves.

Results: Data collected from 1189 patients, mostly women, with NHFS variably represented from 0 to 9 were examined. The tool was validated and recalibrated for the study population with an AUC of 0.662, similar to that estimated by ASA. Logistic regression also provided a significant association with the risk of death at 30 d after surgery for functional variables (ADL, IADL, and METs) that were analyzed in different models, whereas albumin, vitamin D, and polypharmacy were not significant.

Conclusion: NHFS appears a fairly reliable tool for estimating 30-day mortality from surgery in Italian orthogeriatric patients, however it seems that this estimate can be improved by considering other variables, in particular METs. The most effective way to

combine NHFS and METs into a score with better predictive power may be a future challenge.

P1287
LOWER LIMB STRENGTH ASSOCIATION WITH INCREASED RISK OF FRAILTY AND FALLS IN OLDER ADULTS

J. Kilaitė[1], V. Ginevičienė[2], A. Mastavičiūtė[2], R. Dadelienė[2], I. E. Jamontaitė[2], V. Alekna[2], E. Pranckevičienė[2], I. I. Ahmetov[2]

[1]Clinic of Internal Diseases and Family Medicine, Institute of Clinical Medicine, Faculty of Medicine, Vilnius Univ., [2]Faculty of Medicine, Vilnius Univ., Vilnius, Lithuania

Objective: To compare lower limb strength in older people who had frailty and had fallen and without these conditions.
Methods: The study included 55 community dwelling older adults (mean age 77.98 ± 7.62 y). An inclusion criterion to this cross-sectional study were: age 65 or more years, unrestricted mobility, MMSE ≥ 21. Lower limb strength was evaluated by 5-time chair stand test. If participants took 15 or more seconds to perform the test they were classified as having lower limb weakness. Frailty status was defined using Fried's criteria: weakness, low walking speed, low physical activity, weight loss, exhaustion. Participants were classified as robust, prefrail and frail if they scored 0, 1–2, 3 points, respectively. History of falls was assessed by asking whether the subject had experienced falls in the past 12 months. Correlation between lower limb strength between people with and without frailty and falls was assessed by Kruskal–Wallis test. Multinomial logistic regression was used to assess the odds of having frailty and falls if lower limb strength decreases.
Results: Out of all participants 12 (21.42%) were men and 43 (78.58%) were women. Out of all participants 22 (39.3%) were classified as having lower limb weakness, of which 2 (9.09%) were men and 20 (90.91%) were women. According to frailty status 13 (23.2%) participants were evaluated as being robust, 25 (44.6%) having pre-frailty and 17 (30.4%) were frail. Falls were reported in 34 (62.5%) participants. Frailty and falls were found in 16 (28.6%) participants: 5 (31.25%) men and 11 (68.75%) women. Kruskal–Wallis test showed that there was a statistically significant difference in lower limb strength between the older people with and without frailty and falls ($\chi^2 = 10.72$, p = 0.013). Logistic regression revealed that even in adjusted analysis decreasing lower limb strength was associated with increased risk of having frailty and falls (OR: 1.27 (1.03–1.58)). No such association were found when comparing lower limb strength in only frailty or falls groups.
Conclusion: Reduced lower limb strength was associated with frailty and increased risk of falling.

P1288
OSTEOPOROSIS RISK ASSESSMENT USING IOF AND FRAX QUESTIONNAIRES AND OTHER FACTORS

A. Zayaeva[1], I. Yatskov[1], A. Klimchuk[1], V. Beloglazov[1], V. Kaliberdenko[1], N. Shadchneva[1], D. Shaduro[1], E. Kulieva[1], S. Kulanthaivel[2]

[1] V.I. Vernadsky Crimean Federal Univ., Simferopol, Russia, [2]Naarayani Multispeciality Hospital, Erode, India

Objective: Currently more than 50% of patients with osteoporosis in Russia do not receive adequate examination and treatment, which is due insufficient equipment of medical institutions, the lack of education of the population, an incorrect approach to therapy and perception of the picture of the disease and its consequences. In this regard, we have engaged in the study of additional factors reflecting the degree of risk of osteoporosis.
Methods: The collection of statistical data was carried out in the process of interviewing patients of the "Clinical Hospital named after N.A. Semashko". During the survey, 100 patients (63 ± 25 y) were asked to answer questions from the International Osteoporosis Foundation (IOF) and Fracture risk assessment tool (FRAX) questionnaires, as well as additional questions about their feeding preferences and drug treatment, which may affect the level of calcium in the body.
Results: All respondents were at risk by at least 1 criterion. 49 people answered positively about previous fracture anamnesis, which acts as a fact of accomplished pathological fractures. 25 respondents took glucocorticoids for more than 3 months, and 11 people suffered from rheumatoid arthritis. 23 women have a history of early menopause, with one in five women reporting menstrual cycle interruptions of more than 12 months and removal of appendages during their lifetime. Every fourth patient abuses coffee, and every third—food salt. In addition, it turned out that every second patient suffered from hypertension, which, according to recent studies, is also a risk factor for osteoporosis. 14 patients regularly received monotherapy with loop diuretics, which, according to the latest data, affects the level of calciuria.
Conclusion: The IOF questionnaire considers more patient history data in comparison with the FRAX questionnaire, however, the FRAX questionnaire also takes into account the level of bone condition—mineral density, which undoubtedly speaks, on the one hand, about the high accuracy of the data, and on the other, about the high cost of the study. It may be advisable to identify a large risk group using an IOF survey, and then offer an IPC study and, consequently, a FRAX questionnaire.

P1289
QUESTIONNAIRE FOR THE STUDY OF CALCIURIA FACTORS IN THE PREVENTION OF OSTEOPOROSIS

A. Zayaeva[1], I. Yatskov[1], A. Klimchuk[1], V. Beloglazov[1], V. Kaliberdenko[1], N. Shadchneva[1], D. Shaduro[1], E. Dolya[1], E. Kulieva[1], S. Kulanthaivel[2]

[1] V.I. Vernadsky Crimean Federal Univ., Simferopol, Russia, [2]Naarayani Multispeciality Hospital, Erode, India

Objective: There is a huge number of risk factors of osteoporosis development, among which there are modifiable: taking glucocorticoids or low weight and unmodified factors: gender, chronic diseases, age over 60 y. Modifiable factors require immediate correction and play a primary role in the system of both primary and secondary prevention of osteoporosis. It has been noted that calcium intake and physical activity at a young age can be important factors determining peak bone mass. However, this is not enough in modern therapy, for effective prevention and treatment, it is also necessary to reduce the excretion of calcium from the body, most of which is excreted in the urine.
Methods: The questionnaire form was created, in which the received data were entered in the form of a survey. This form was tested on 100 patients of various medical profiles who were being treated in "Clinical Hospital named after N.A. Semashko".
Results: Among the nutritional factors, coffee, caffeinated beverages and edible salt have a direct effect on calciuria. In addition, a regular high protein load and the consumption of foods containing protein of animal origin influence the increased level of calcium in the urine. Loop diuretics and aminoglycosides are distinguished among medications. At the same time, the use of loop diuretics together with

thiazide reduces calciuria. Of the additional anamnestic factors, the presence of arterial hypertension in the anamnesis and special working conditions (chemical production) are noted, which also affects the level of calcium excretion.

Conclusion: The developed questionnaire was successfully applied, as a result of which patients of an increased risk group for the development of osteoporosis were successfully identified. Out of 100 people, 37 were at risk due to increased salt intake, 29-abused coffee. A 14 patients who is regularly received monotherapy with loop diuretics, 6 people were treated with antibiotics from the aminoglycoside group. In total, an increased risk, namely more than one risk factor, of an increase in calciuria was observed in 79 subjects, which indicates the need to revise the recommendations for the prevention of osteoporosis and lifestyle modification.

P1290
CHRONIC INFLAMMATION AS A RISK FACTOR FOR OSTEOPOROSIS IN PATIENTS WITH CHRONIC KIDNEY DISEASE UNDERGOING HEMODIALYSIS

A. Klimchuk[1], A. Zayaeva[1], I. Yatskov[1], V. Kaliberdenko[1], A. Petrov[1], E. Kulieva[1], S. Kulanthaivel[2]

[1] V.I. Vernadsky Crimean Federal Univ., Simferopol, Russia, [2]Naarayani Multispeciality Hospital, Erode, India.

Objective: Hemodialysis (HD) is the most common method of renal replacement therapy used in chronic kidney disease (CKD), and allows increasing the life expectancy of patients by 9–10 years. Anemia is one of the serious complications of end-stage CKD, which worsens the quality of life and survival of patients with HD and requires timely effective treatment.

Methods: The study included 14 patients with CKD undergoing hemodialysis at the "Clinical Hospital named after N.A. Semashko", complicated by anemia. The average age of patients was 47.41 ± 9.16 years old. The average duration of stay on hemodialysis was 67.1 ± 19.2 months. All patients received erythropoietin preparations at a dose of 6000 IU/week and iron preparations at a dose of 100 mg/week. The patients were divided into two groups. Group 1 included 7 people with a higher level of systemic inflammation in terms of C-reactive protein (CRP), group 2 – with less pronounced systemic inflammation. In all patients, the level of CRP and hemoglobin (Hb) was studied in 2 stages: before and 3 months after the start of the anemia treatment. The control group consisted of 14 relatively healthy people, comparable in gender and age, with normal CRP values (1.3 mg/l) and normal hemoglobin (Hb) levels.

Results: In group 1, the average value of CRP was 59.5 mg/l, in group 2—7.4 mg/l. In group 1, the Hb level before initiation of therapy was 78.4 g/l, and 3 months after the start of treatment increased by only 8.1% and amounted to 84.4 g/l ($p < 0.001$). The Hb level in group 2 before the start of treatment was 91.8 g/l, and after 3 months of therapy increased by 18.5% and amounted to 112.7 g/l ($p < 0.001$). The general correlation analysis revealed the presence of a negative linear relationship between the indicators of CRP and Hb ($r = -0.482$), at the significance level of $p = 0.027$.

Conclusion: The results of the study indicate a significant role of chronic systemic inflammation in the severity of anemia and the effectiveness of its therapy in patients with CKD on HD. It was found that in patients with lower CRP indices, the effectiveness of anemia treatment with iron and erythropoietin preparations is higher than among patients with its higher values ($p < 0.001$), which indicates the need to search for the causes and methods of correction of systemic chronic inflammation in patients with CKD on HD.

P1291
SECONDARY HYPERPARATHYROIDISM AND C-REACTIVE PROTEIN LEVELS AS RISK FACTORS FOR OSTEOPOROSIS IN PATIENTS WITH CHRONIC KIDNEY DISEASE UNDERGOING HEMODIALYSIS

A. Klimchuk[1], A. Zayaeva[1], I. Yatskov[1], V. Kaliberdenko[1], A. Petrov[1], E. Kulieva[1], S. Kulanthaivel[2]

[1] V.I. Vernadsky Crimean Federal Univ., Simferopol, Russia, [2]Naarayani Multispeciality Hospital, Erode, India

Objective: In the last decade, there has been an increase in patients with chronic kidney disease (CKD) undergoing renal replacement therapy (RRT). The main method of RRT is currently hemodialysis (HD). Extracorporeal methods of blood purification increase the life expectancy of patients with end-stage CKD, but the quality of life of these patients remains reduced. One of the reasons for this is a violation of phosphorus-calcium metabolism and the frequent development of secondary hyperparathyroidism (HPT). Currently, it is known that PTH is a universal uremic toxin, which leads to many complications.

Methods: The study included 10 patients with stage 5 CKD who have been on HD at the "N.A. Semashko Republican Clinical Hospital". The average age of patients was 45.62 ± 4.15 years old, the average duration of stay on hemodialysis was 54.1 ± 16.4 months. PTH and CRP levels were studied in all patients. The control group consisted of 10 relatively healthy people with normal values of CRP and PTH.

Results: The studied patients were divided into two groups according to the level of PTH. Group 1 included 5 patients with normal PTH levels (33.77 ± 8.35). Group 2 included 5 patients with elevated PTH (535.6 ± 289). When studying CRP, it was noted that in all patients participating in the study, this indicator exceeds the norm. Among group 1 patients, CRP was 8075 ± 1082, which is 4.8 times higher than normal ($p < 0.001$). In patients of group 2, CRP corresponded to 66.88 ± 11.29, which is 38 times higher than the indicators of healthy donors ($p < 0.001$). It was noted that in patients of group 2, the level of CRP was significantly higher ($p = 0.014$) than the level of this indicator in patients of group 1 and was positively correlated with the level of PTH ($r = 0.995$), at the significance level $p = 0.005$). There was no correlation between CRP and PTH in group 1 patients.

Conclusion: In patients with stage 5 CKD on HD with the development of GPT, an increase in PTH levels may contribute to the development of systemic inflammation common in this category of patients.

P1292
TUMOR NECROSIS FACTOR A RECEPTORS: A THERAPEUTIC TARGET IN THE TREATMENT OF AUTOIMMUNE DISEASES

A. Zayaeva[1], I. Yatskov[1], V. Kaliberdenko[1], E. Dolya[1], G. Koshukova[1], A. Klimchuk[1], V. Beloglazov[1], S. Kulanthaivel[2], E. Kulieva[1]

[1] V.I. Vernadsky Crimean Federal Univ., Simferopol, Russia, [2]Naarayani Multispeciality Hospital, Erode, India

Objective: Autoimmune rheumatic diseases are a group of diseases characterized by a self-sustaining, autoreactive adaptive immune response resulting in immune-mediated damage to target organs. It has been established that TNFα plays an important role in the development of inflammation as a pathological component of autoimmune diseases. Understanding of the mechanism of TNFα signaling has been expanded and applied to the treatment of autoimmune diseases, leading to the development of effective therapeutic agents, including TNFα inhibitors.

Methods: Using the NCBI PubMed search engine, 19 articles were selected that evaluated the efficacy, safety, and immunogenicity of TNFα receptor inhibitors.
Results: One of the new therapeutic approaches in the treatment of autoimmune diseases is the selective inactivation of TNFα receptors. Drugs whose mechanism is to block TNFα receptors are undergoing clinical trials. Atrosab, atrosimab, TNF-1 receptor silencer (TROS), R1antTNF, XPro1595 selectively block the TNFα type 1 receptor. In clinical studies, administration of atrosab to CIA rhesus monkeys resulted in a decrease in serum acute phase C-reactive protein (CRP) and IL-6 levels, prevented weight loss, delayed the onset of arthritis symptoms, and improved the clinical assessment of arthritis. A selective nanobody-based inhibitor of TNFR1 TROS reduced the secretion of IL-6, IL-8, and TNF in ex vivo cultured inflammatory colon biopsies from patients with active Crohn's disease. Due to the fact that activation of the type 2 receptor to TNFα leads to a cascade of anti-inflammatory reactions, it is advisable to use agonist drugs. One such drug is EHD2-sc-mTNFR2. In studies conducted in mice treated with a TNFR2 agonist, arthritis improved only after more than a 10-d follow-up period.
Conclusion: To date, a sufficient number of biosimilars of reference TNFα inhibitors have been created. New drugs, such as TNF receptor inhibitors, could be a breakthrough in the treatment of autoimmune diseases. Therefore, it can be assumed that much more attention will be paid to the understanding of TNFα signaling in the near future in order to develop effective tools for the treatment of other autoimmune diseases, as well as a wide range of diseases associated with TNF.

P1293
INPATIENT FALL RISK ASSESSMENT AND AVAILABLE INTERVENTIONS TO REDUCE IT

A. Zayaeva[1], N. Shadchneva[1], I. Yatskov[1], V. Kaliberdenko[1], E. Dolya[1], G. Koshukova[1], A. Klimchuk[1], E. Kulieva[1], S. Kulanthaivel[2]

[1] V.I. Vernadsky Crimean Federal Univ., Simferopol, Russia, [2]Naarayani Multispeciality Hospital, Erode, India

Objective: Patient falls in healthcare organizations have become a particularly pressing problem for healthcare systems worldwide. In addition to causing serious damage to their health, the resulting injuries lead to an increase in the duration and cost of treatment. The most significant components of a program aimed at improving patient safety in a hospital are: initial assessment of the risk of falls with the identification of individual risk factors, identification of risk zones, education of patients and their family members on fall prevention, training of medical staff, registration and analysis of all cases of falls.
Methods: 76 patients of therapeutic, pulmonologic, and neurologic departments aged 75–95 y (mean age 78.2 ± 3.3 y). All patients were risk assessed using the Morse Fall Scale, baseline and instrumental activity indices, nutritional risk, and tests to detect cognitive decline were calculated.
Results: Senile asthenia of varying severity was detected in 35% of patients, preasthenia in 29%, and 41% of patients were found to be in satisfactory condition. According to the Morse scale, all patients with asthenia and preasthenia had a risk of falls of 55 points or higher. Hearing and vision disorders were found in 90% of the patients studied, gait disturbance in 68%, balance disturbance, dizziness, and frequent urination in 48%. 30% of patients received drug therapy that aggravated the risk of falls (diuretics, tranquilizers, sedatives, sleeping pills, analgesics).
Conclusion: Morse Fall Scale assessment of the risk of falls in elderly patients is a simple and informative tool for predicting the risk of falls in hospital and a starting point for planning measures to reduce this risk. We consider it necessary to focus the attention of medical staff on the principles of safe behavior and to strengthen the control by the doctor and hospital administration on compliance with preventive measures.

P1294
A CLINICAL CASE OF MANIFESTATION OF COXARTHROSIS IN A PATIENT AFTER A NEW CORONAVIRUS INFECTION

A. Zayaeva[1], N. Shadchneva[1], I. Yatskov[1], V. Kaliberdenko[1], E. Dolya[1], G. Koshukova[1], A. Klimchuk[1], E. Kulieva[1], S. Kulanthaivel[2]

[1] V.I. Vernadsky Crimean Federal Univ., Simferopol, Russia, [2]Naarayani Multispeciality Hospital, Erode, India

Objective: The 2019 coronavirus disease (COVID-19) pandemic continues to impact the global community, and as understanding of its pathophysiology increases, so does interest in the various effects of the SARS-CoV-2 coronavirus that causes it. Studies in patients who have survived COVID-19 have shown significant adverse musculoskeletal effects. The negative effects of SARS-CoV-2 are due to direct (develops after contact of the virus with cells that have receptors) and indirect effects (systemic inflammation) on humans.
Methods: We analyzed anamnestic, clinical, laboratory and instrumental data of a clinical case of coxarthrosis development after COVID-19 infection in a 40-year-old man. Information from the medical history was provided by the Crimean Republic "Sudak Hospital".
Results: A 40-year-old man consulted a rheumatologist with complaints of severe pain in the joints of the hands and elbow joints of the hands of both hands, which restrained movements and impaired the quality of life. The pain lasted for about three months; the patient attributed it to a change in his diet. Five months before the above-mentioned complaints, the patient had COVID-19, in a mild form without complications. He consulted a rheumatologist and was diagnosed with reactive arthritis and then osteoarthritis of the sacroiliac joints. At the time of examination in neutrophils—82%, in biochemical analysis – elevated total cholesterol (7.94 mmol/L), elevated CRP (5.97 mg/L). Antibodies to cyclic citrulline-containing peptide (-), rheumatoid factor (-), prostate specific antigen (-). Neutralizing IgG antibodies to COVID-19 S-protein were 257 BAU/ml. The patient was referred to a pulmonologist for consultation. On referral to pulmonologist, Long-COVID-19 was diagnosed based on laboratory findings and CT scan of the lungs. X-ray showed deforming coxarthrosis. MRI – MR signs of osteoarthritis of the sacroiliac joints.
Conclusion: The current study showed that COVID-19 can possibly fulfill a destructive role in chronic diseases, particularly in coxarthrosis, and negatively affect the course of the disease. Under these circumstances, the recording and surveillance of people with new coronavirus infection and the implementation of qualified treatment and prophylaxis are of great practical importance.

P1295
OSTEOPOROSIS IN THE PRACTICE OF A DENTIST

G. Koshukova[1], A. Zayaeva[1], V. Beloglazov[1], I. Yatskov[1], V. Kaliberdenko[1], E. Dolya[1], E. Kulieva[1], S. Kulanthaivel[2]

[1] V.I. Vernadsky Crimean Federal Univ., Simferopol, Russia, [2]Naarayani Multispeciality Hospital, Erode, India

Objective: The most common manifestations of osteoporosis (OP) are vertebral compression fractures, fractures of the distal forearm, proximal femur, and proximal humerus. Today, OP is considered in the focus of interest of primary care physicians, where the main flow of potential patients is concentrated. In addition to changes in bone

microarchitectonics, bone deformation and pathologic fractures may occur. The symptomatology is very similar to periodontal disease, which may be present in parallel, but without adequate treatment, the result will be doubtful. It is therefore important to be examined by a dentist who will prescribe the appropriate examination, consultations with allied specialists.

Methods: Current information from the literature on the need to treat osteoporosis in the practice of the dentist was analyzed.

Results: There are no characteristic symptoms, including early symptoms. The following signs may be suspected: increased sensitivity of tooth enamel, severe exposure of tooth roots resulting in large gingival pockets, increased tooth mobility, pronounced loosening, excessive plaque formation. The most common causes of localized OP are diseases accompanied by local inflammation of the jaw OP are diseases accompanied by local inflammation of the jaw: osteomyelitis, periodontitis, periodontal disease, tumors – cysts or granulomas. The assessment of the degree of OP and jaw atrophy is very is very important from a prognostic point of view when planning prosthetics. Taking into account all concomitant conditions will make it possible to perform the most effective prosthetics, taking into account the preoperative indications for dental implantation. In people who wear dentures, the destructive processes in the oral cavity will occur faster because these structures are fixed directly on the bare tooth. It is important to be examined by specialists and to start treatment and further prevention of osteoporosis.

Conclusion: OP should be considered as a multidisciplinary problem that requires close attention from physicians of all specialties in order to carry out early prevention, diagnosis, timely treatment and prevention of complications.

P1296
APPLICATION OF BETAMETHASONE BY ELECTROFORESIS TO AVOID OSTEOPOROSIS DEVELOPMENT

G. Koshukova[1], A. Zayaeva[1], V. Beloglazov[1], I. Yatskov[1], V. Kaliberdenko[1], E. Kulieva[1], S. Kulanthaivel[2], E. Dolya[1]

[1] V.I. Vernadsky Crimean Federal Univ., Simferopol, Russia, [2]Naarayani Multispeciality Hospital, Erode, India

Objective: The problem of treatment of patients with rheumatoid arthritis (RA) remains relevant to date due to the progressive nature of the disease and high level of disability. There is still a need to search for additional methods of RA therapy that can enhance the anti-inflammatory effect of the current therapy without causing adverse events, including osteoporosis and contributing to the prolongation of remission of the disease.

Methods: We examined and treated 10 patients with a verified diagnosis of RA 1–2° of activity, receiving the same baseline therapy. Betamethasone electrophoresis was applied as an additional therapeutic factor using a local technique. The control group consisted of RA patients, comparable in sex, age, and RA activity, who were not treated with physical factors.

Results: Inclusion of betamethasone electrophoresis in the treatment complex resulted in statistically significant reduction of arthralgic syndrome and disease activity, confirmed by a decrease in pain intensity by DAS28 index. In the dynamics there was a decrease in acute-phase indices—ESR and CRP. Availability of prolonged betamethasone fraction and creation of local subcutaneous "depot" of the drug allowed to apply betamethasone electrophoresis according to the shortened scheme with preservation of the aftereffect. The analysis of adverse events indicated high efficiency and relative safety of the proposed method of treatment.

Conclusion: Physical therapy performed against the background of baseline therapy can reduce the severity of the inflammatory process and shorten the time of RA treatment. The use of betamethasone electrophoresis can be recommended as one of the components of complex treatment of RA at different stages of therapy and can be considered as a substitute for intra-articular injections of glucocorticoids as an available non-invasive method of treatment. In addition, this way of using betamethasone allows you to reduce the risk of unwanted side effects, including osteoporosis.

P1297
ASSESSMENT OF RISK OF OSTEOPOROSIS DEVELOPMENT IN FEMALE ADOLESCENTS WITH DYSMENORRHEA

S. Kulanthaivel[1], E. Kulieva[2], V. Kaliberdenko[2]

[1]Naarayani Multispeciality Hospital, Erode, India, [2] V.I. Vernadsky Crimean Federal Univ., Simferopol, Russia

Objective: Currently, one of the most significant problems of girls in adolescence is menstrual irregularities, which can cause secondary osteoporosis in adolescence. This has a huge human and socio-economic impact. The purpose of the study is to determine various aspects of the development of secondary osteoporosis in girls during adolescence.

Methods: We examined 173 girls aged 13–17 y who were under our supervision in a pediatric clinic. The girls were divided into four groups depending on menstrual irregularities. Depending on their age, the patients were divided into subgroups: girls 13–14 years old – group A, girls 15–17 years old—group B. The patients were divided into four groups depending on the condition. In the 1st group there were girls with delayed puberty [n = 33 + 27], in the 2nd group—girls with primary oligomenorrhea [n = 16 + 46], in the 3rd group—patients with polymenorrhea [n = 18 + 13], in 4th group (control) there were healthy girls [n = 10 + 10].

Results: According to correlation analysis, the influence of steroid hormone levels on bone tissue content has a cumulative effect in girls.

Conclusion: For adolescents with oligomenorrhea, polymenorrhea and secondary amenorrhea, disturbances in the correlations of gonadotropic hormones are observed. The relationships between calcium, phosphorus and magnesium are disturbed, which may indicate a violation of mineralization processes. According to the correlation analysis, direct average correlations between the concentration of steroid hormones and the structural and functional properties of bone tissue were identified in girls with adolescent pathology. The decrease in the concentration of progesterone in the blood of adolescent girls with menstrual cycle pathologies that occurs in connection with dysmenorrhea leads to a significant increase in the risk of developing osteoporosis and progression of scoliosis.

P1298
INDEX OF BONE STRENGTH IN ADOLESCENTS WITH GENERALIZED PERIODONTITIS, SUFFERING FROM IDIOPATHIC SCOLIOSIS, DEPENDING ON THE DEGREE OF SPINAL DEFORMITY

O. Galkina[1], V. Kaliberdenko[1], E. Kulieva[1], K. Khallaev[2]

[1] V.I. Vernadsky Crimean Federal Univ., Simferopol, Russia, [2]Dental clinic Dentamed Plyus, Tashkent, Uzbekistan

Objective: The prevalence of musculoskeletal pathology and the high incidence of periodontal pathology in children and adolescents is an important health problem. According to the data, there is a connection between the mechanism of structural and functional disorders of the body and periodontal diseases, which not fully studied yet.

Methods: The study included 108 adolescents aged 15.87 ± 0.09 y with generalized periodontitis (GP) suffering from idiopathic scoliosis (IS). The patients were divided into 3 groups according to the degree of curvature of the spine in accordance with the classification of V.D. Chaklin (1965). Group IS- I – curvature of the spine in the supine position does not disappear, C-shaped, the angle of curvature is up to 10°. Group IS-II – curvature of the spine is C-shaped or S-shaped, the angle of curvature is 11–30°. Group IS-III – S-shaped curvature of the spine, deformation of the ribs with the formation of a hump. The angle of curvature of the spine axis is 31–60°. The index of strength CT (STF,%) also was determined.
Results: The value of the CT strength index decreased with an increase in the degree of curvature of the spine ($p < 0.001$). The STF in the observation groups was as follows. In IS-I – 71.22 ± 8.58%; in IS-II – 62.08 ± 5.87%; in IS-III – 58.71 ± 3.34%. The sigma deviation in the IS-I group was -1.49, which corresponded to osteopenia. In the IS-II group, the deviation was noted at the level of -2.41, which also corresponded to osteopenia, but approached the border of the indicator of osteoporosis. In the IS-III group, the deviation was -2.74, which considered as osteoporosis. There were no differences in indicators depending on gender (p 0.05).
Conclusion: Adolescents with GP and IS in anamnesis have a decrease in the index of strength CT. The decrease in STF in adolescents with GP suffering from IS more pronounced in people with grade II and III scoliosis than in people with grade I scoliosis. These CT disorders can be considered as a systemic disorder of osteogenesis processes.

P1299
TREATMENT OF GENERALIZED PERIODONTITIS BY USING BIORESONANCE STIMULATION IN ADOLESCENTS WITH SCOLIOSIS

O. Galkina[1], V. Kaliberdenko[1], O. Poleshchuk[1], Z. Dovbnya[1], K. Kaladze[1], E. Kulieva[1], K. Khallaev[2]

[1] V.I. Vernadsky Crimean Federal Univ., Simferopol, Russia, [2]Dental clinic Dentamed Plyus, Tashkent, Uzbekistan

Objective: The diseases of the musculoskeletal system in some cases are associated with changes in the maxillofacial region. This is due to the unity of mechanisms in the chain of pathology development both in the supporting skeleton and in the bones of the facial skeleton.
Methods: 65 people aged 15–17 y with generalized periodontitis (GP) suffering from scoliosis were examined. The patients were divided into 2 groups – the main group (MG-35 people) and the comparison group (CG-30 people), which are comparable in terms of spinal curvature and gender. The periodontal status was determined in the groups using the oral hygiene index, the degree of gingival inflammation (PMA, Parma), the gingival bleeding index, the Russel periodontal index, CPI, and X-ray examination of the jaws (at the stage of GP diagnosis). The bone strength index (CT; STF,%) was studied using an Achilles + ultrasound densitometer (Lunar-General Electric Medical Systems, USA) before and after GP treatment (3 weeks after the start of treatment).
Results: After the end of GP treatment, there were no significant differences in the change in the values of periodontal indices in the observation groups. Analyzing the dynamics of STF,%, we found that in MG and in CG, the indicators were significantly higher ($p < 0.001$), compared with the values before treatment (in CG – 69.43 ± 7.22% and 71.91 ± 8.17%, respectively; in MG – 70.68 ± 10.11% and 81.71 ± 9.54%, respectively). It is noteworthy that the change in IP K in the exhaust gas was more dynamic ($p < 0.01$), in comparison with HS.
Conclusion: The positive dynamics of SF indicators in the study is regarded as a prognostically favorable sign of improvement in the CT condition of both the alveolar process (dental disease) and the spine (background pathology).

P1300
THE COURSE AND OUTCOMES OF ASEPTIC NECROSIS, DEPENDING ON THE THERAPY

G. Koshukova[1], A. Zayaeva[1], V. Kaliberdenko[1], E. Kulieva[1], S. Kulanthaivel[2]

[1] V.I. Vernadsky Crimean Federal Univ., Simferopol, Russia, [2]Naarayani Multispeciality Hospital, Erode, India

Objective: In recent years, there has been an increase in the number of patients with aseptic necrosis (AN) of various joints, which is associated with both a new coronavirus infection and uncontrolled use of glucocorticoids, which is diagnosed at stage II-III, which, when prescribed untimely and insufficient therapy, often requires joint replacement.
Methods: The analysis of clinical cases of the patients with persistent arthralgic syndrome who contacted to rheumatologist of the consultative polyclinic of «Republican Clinical Hospital named after N. A. Semashko".
Results: In the study of 17 patients (12 men and 5 women) aged from 34–67 y (average age 37.2 ± 9.3 y) who had no pathology of the musculoskeletal system with the appearance of persistent arthralgic syndrome after SARS COV-2 infection. According to the MRI results among the patients AN of large joints was founded– 11.8% of shoulder joints, 29.4% of knee joints and 58.8% of hip joints. The X–ray stage II was diagnosed in 6 patients, stage III in 10 patients, and stage IV in 1 patient. All patients received medications that divided into 3 groups: 1st (n = 5)—a combination of NSAIDs + calcium and vitamin D3; 2nd (n = 6) – a combination of NSAIDs + calcium and vitamin D3 + chondroitin/ glucosamine; 3rd (n = 6)—a combination of NSAIDs + calcium and vitamin D3 + bisphosphonates + chondroitin/ glucosamine + dipyridamole, pentoxifylline. The best results were observed in patients of group 3 who showed a decrease in pain syndrome and the absence of an increase in the area of necrosis.
Conclusion: When prescribing complex therapy at the early stages, including calcium, vitamin D3 with osteotropic minerals, bisphosphonates, slow-acting symptom-modifying drugs and drugs that improve the rheological properties of blood, the most favorable outcomes were noted with minimizing the need for surgical treatment. The duration of therapy should not be limited to a period of 3–4 weeks. It is advisable to conduct an MRI examination of the joints in patients in the absence of the effect of NSAID use to diagnose AN at earlier stages and prescribe complex therapy that has shown the best results.

P1301
FREQUENCY OF BONE FRACTURES IN PATIENTS WITH RHEUMATOID ARTHRITIS

A. Useinova[1], V. Kaliberdenko[1], S. Mar'yanenko[1], E. Kulieva[1], S. Khamidova[2]

[1] V.I. Vernadsky Crimean Federal Univ., Simferopol, Russia, [2]Tashkent State Pedagogic Univ. named after Nizami, Tashkent, Uzbekistan

Objective: Rheumatoid arthritis (RA) is a chronic autoimmune disease characterized by systemic damage to internal organs with the development of erosive arthritis and manifested by a decrease in physical activity, which leads to local and generalized loss of bone tissue with a violation of its microarchitectonics and manifested by frequent fractures.

Methods: The study included 474 RA patients diagnosed between the ages of 25–78, including 217 patients with the onset of the disease aged 25–44 y and 66 patients with the onset of the disease aged $\geq$ 60 y. The patients were divided into 2 groups depending on the age at the time of the onset of the disease, the first group (group I) consisted of patients who became ill at a young age, the second group (group II) included patients with the onset of the disease in old age. The distribution of patients into groups corresponded to the age classification of the WHO. The average age at the onset of the disease in group I was 35.0 years, in group II – 66.2 y. The average age at the time of examination in group I was 50.4 years, in group II – 71.2 y; the duration of RA was 14.4 y and 4.6 y, respectively.
Results: 40 (18%) patients in group I had a history of low-traumatic fractures, and 17 (26%) patients in group II. Among patients with fractures, 23 (57.5%) people received GC therapy for more than 3 months in group 1, and 6 (35%) people in group II. In group I, 16 (40%) and in group II, 3 (18%) people had two or more fractures in the anamnesis.
Conclusion: The fracture rate in the study groups was comparable ($p > 0.05$), despite the difference in age at the time of examination ($p < 0.05$). The frequency of repeated fractures was higher in patients who became ill at a young age, as a result of the long RA and taking GC.

P1302
CHANGES OF REGIONAL HEMODYNAMICS DURING COMPLEX TREATMENT OF PATIENTS WITH MANDIBULAR BODY FRACTURES

K. Kaladze[1], O. Poleshchuk[1], V. Kaliberdenko[1], O. Galkina[1], E. Kulieva[1]

[1] V.I. Vernadsky Crimean Federal Univ., Simferopol, Russia

Objective: It is well known that in the acute period of a traumatic illness, critical disturbances occur in the interdependent activities of the main regulatory systems—hemodynamics, endocrine, and immune. The purpose of this work was to study the recovery period in patients with fractures of the lower jaw under the influence of bioresonance therapy and the drug osteogenon on the process of fracture consolidation and the state of regional hemodynamics.
Methods: All patients first underwent splinting of bone fragments with a splint-brace with hooking loops according to Tigerstedt. The teeth were placed in the bite and fixed with a rubber rod. Bioresonance therapy was carried out according to the method we developed, the course of treatment was 10 procedures. Osteogenon (ossein-hydroxyapatite complex), used mainly for the prevention and treatment of systemic osteoporosis. The course of treatment with the drug is 2 tablets 2 times a day for 14 d. In group III, treatment was carried out according to the generally accepted method. The effectiveness of treatment was assessed by clinical and morphological data and the results of a functional research method (rheography) after immobilization and 2 weeks after the start of treatment. Rheograms were assessed according to 11 main parameters taking into account arterial and venous circulation.
Results: Almost all patients had displacement of bone fragments of the lower jaw. Impaired regional circulation was noted for all main indicators in 89% of patients. There was a decrease in the rheographic index and relative volumetric pulse, an increase in the relative β index, and a decrease in the catacrotic angle, which indicated a violation of both arterial and venous blood flow. After immobilization of the fragments, the bite was clinically restored, and radiographically, the displacement of the fragments was completely eliminated in 68% of cases. There was also a slight decrease in regional blood circulation after the application of splints, which, in our opinion, is associated with the reposition of fragments, since in this case additional damage to soft tissues, vessels, and nerves occurs. Regional blood circulation according to rheography during this period was more intense in patients of group II than in patients of group I and differed significantly from the norm in patients of group III.
Conclusion: Complex treatment of mandibular fractures with the inclusion of bioresonance therapy and osteogenon promotes earlier healing of mandibular fragments, restoration of working capacity and functional indicators.

P1303
INFLUENCE ON LOCAL IMMUNITY OF THE DRUG IMUDON IN COMPLEX TREATMENT OF PATIENTS WITH MANDIBULAR BODY FRACTURES

K. N. Kaladze[1], O. Poleshchuk[1], V. Kaliberdenko[1], O. Galkina[1], E. Kulieva[1], K. K. Kaladze[1]

[1] V.I. Vernadsky Crimean Federal Univ., Simferopol, Russia

Objective: In the acute period of a traumatic illness, critical disturbances occur in the interdependent activities of the main regulatory systems—hemodynamics, endocrine, and immune. Other indicators of the state of the internal environment of the body are also disrupted, which is manifested by a complex set of disorders and adaptive reactions aimed at preserving the vital functions of the body, as well as restoring impaired functions and structures. The purpose of the study. Considering the presence of these disorders, a local immunostimulant was introduced into the complex of treatment measures—the intraoral drug imudon, which stimulates the local immunity of the oral cavity, namely.
Results: The results of clinical and immunological examination of patients indicate a certain relationship between the severity of inflammatory phenomena and the state of the immune system and the influence of these processes on the consolidation of the mandibular fracture. Under the influence of imudon, in patients with mandibular fracture treatment, there was a significant ($p < 0.001$) decrease in lysozyme (by 6.52%) and SIgA (by 9.5%) in the oral fluid. The indicated indicators of local immunity of group I also decreased significantly ($p1 < 0.001$) in comparison with the control group. Less pronounced changes in local immunity after completion of the course of treatment were observed in patients who were treated using traditional methods. The data obtained indicate the pronounced immunomodulatory properties of the drug imudon, which rationally affects the immune status of the oral cavity.
Conclusion: It should be noted that the treatment method we have developed has a stimulating effect on the production of regulatory peptides, increases the body's adaptive abilities and, ultimately, makes it possible to increase the effectiveness of rehabilitation of patients with a mandibular fracture at the stages of inpatient and outpatient treatment.

P1304
RATE OF OSTEODESTRUCTIVE EVENTS IN PATIENTS WITH MULTIPLE MYELOMA THAT USE THE ANALOGUES OF THALIDOMIDE

L. Ametova[1], E. Kulieva[1], V. Kaliberdenko[1], A. Useinova[1]

[1] V.I. Vernadsky Crimean Federal Univ., Simferopol, Russia

Objective: The complications of multiple myeloma caused by osteodestructive processes are one of the most important problems that have a significant impact on the course of the disease, prognosis, and quality of life of patients.
Methods: The study included 19 patients with multiple myeloma (MM) who were on treatment in the Department of Hematology and

Chemotherapy of "Crimean Oncological Dispensary named after N. V. Efetov" in the period from 2019–2022, and received an analogue of thalidomide – lenalidomide.
Results: Osteodestructive processes were identified in 14 (82%) cases. The most frequent localization was observed in the cervical (C4), thoracic (Th10-12) and lumbar (L1-L5) segments of the spine, as well as the humerus and femur, and were represented by fractures. The formation of osteolytic foci in the bones of the pelvis, skull, sternum and visible parts of the ribs with the participation of a soft tissue component also was noted. In the comparison group (patients with MM who are not receiving therapy; n = 54), osteodestructive phenomena also occurred, but the frequency of their occurrence was slightly lower -38 cases—71%. The differences were statistically significant ($p < 0.05$).
Conclusion: An analysis of the frequency of osteodestructive phenomena against the background of the use of a thalidomide analogue, lenalidomide, showed a correlation between the occurrence of the syndrome under study and the use of the drug. At the same time, among patients who did not receive any of the possible drug therapies for multiple myeloma, osteodestructive syndrome was observed 11% less frequently, which indicates a link between bone damage and the use of lenalidomide. The study of the mechanism of occurrence of osteodestructive processes that occur and intensify against the background of taking thalidomide derivatives to assess the benefit-risk ratio, as well as other parameters, for example, the dose-dependent nature of the occurrence of these phenomena, requires further study.

P1305
SKELETAL DYSPLASIA AND GENETIC PREDICTORS

E. Kuliyeva[1], V. Kaliberdenko[1]

[1] V.I. Vernadsky Crimean Federal Univ., Simferopol, Russia

Objective: The number of patients with the signs of connective tissue dysplasia (CTD) has been a significant increase at the last time. The development of CTD is associated with both gene mutations and the influence of adverse environmental factors.
Methods: The analysis of research and scientific literary materials of foreign authors working on the study of skeletal dysplasia and genetic predictors that cause the disease.
Results: CTD deserves special attention in patients with frequent structural and functional disorders of musculoskeletal system (MSS), since a characteristic manifestation of this condition is sensitivity to physical exertion and a tendency to frequent injuries. In this regard, it seems relevant to analyze the presence of morphological signs of CTD in patients in order to determine the directions of prevention and correction of structural and functional disorders of CTD. Thus, according to research, frequent structural and functional disorders of the MSS after physical exertion usually occur in people of asthenic physique. According to the study, the patients with connective tissue dysplasia have limbs in the form of "spider fingers" or arachnodactyly, which is much more common in patients with structural and functional disorders of MMS. In addition, in the group of people with frequent structural and functional disorders of the MSS, kyphotic curvature of the spine with asymmetry of the shoulders, pelvic bones, chest deformities, and flat feet in combination with hallux valgus installation of the feet significantly prevailed.
Conclusion: In all patients with frequent structural and functional disorders of the MSS, there is a syndrome of CTD. In turn, early detection of morphological signs can contribute to the timely appointment of preventive measures in terms of physical activity and appropriate rehabilitation therapy to prevent the progression of the underlying disease.

P1306
EFFECTIVENESS OF EARLY SURGICAL CARE FOR CHILDREN WITH COMPLICATED SPINAL INJURY

A. Useinova[1], V. Kaliberdenko[1], E. Kuliyeva[1], L. Ametova[1]

[1] V.I. Vernadsky Crimean Federal Univ., Simferopol, Russia

Objective: This study is performed for evaluation the effectiveness of surgical treatment of patients with complicated spinal injury at the Department of Traumatology and Orthopedics of the Republican Children's Clinical Hospital.
Methods: From January to June 2022, 7 patients with complicated spinal injury were treated: 4 girls and 3 boys. The average age of patients is 14.7 y. Causes of injury: fall from height (4 cases), road accident (2 cases), sports injury (1 case). All patients suffered injuries to the lumbar spine (LI-LII vertebrae). 2 patients showed neurological deficits in the form of pelvic and motor disorders, the rest had transient movement disorders. Multidisciplinary teams of doctors have been formed for treatment. Patients underwent transpedicular fixation of the spine with laminectomy LI and partially LII. The sizes of screws and beams were selected individually depending on the MSCT data. The number of installed screws per operation varied from 4–8 pieces. Treatment in the intensive care unit lasted 1 d, and in the trauma department on average 26 d.
Results: All 100% of patients achieved stabilization of the damaged spinal motion segment. In 85.7% of patients, the neurological deficit completely regressed; 1 child retained moderate paraparesis of the lower extremities; positive dynamics were observed with the help of crutches. Verticalization occurred on average 3 d after surgery; there were no complications. All patients were transferred to the medical rehabilitation department.
Conclusion: In patients with spinal trauma and neurological disorders, it is recommended to undergo surgery within the first 24 h to prevent complications. This makes it possible to eliminate spinal instability and neurological disorders, reduce the time of treatment and rehabilitation, and return the patient to normal life. To do this, it is important to have a sufficient amount of medical supplies and equipment to provide emergency care around the clock.

P1307
PREVALENCE LEVEL AND COVERAGE OF PATHOGENETIC THERAPY FOR OSTEOPOROSIS AMONG PATIENTS OVER 50 YEARS OLD

A. Useinova[1], V. Kaliberdenko[1], L. Ametova[1], E. Kuliyeva[1]

[1] V.I. Vernadsky Crimean Federal Univ., Simferopol, Russia

Objective: This study is an estimation of the prevalence of osteoporosis (OP) and low-traumatic fractures, as well as to assess the absolute risk of fractures among patients over 50 y of age undergoing medical rehabilitation treatment.
Methods: The study involved patients over 50 y of age undergoing rehabilitation in a hospital; information on age, diseases and previous fractures was collected, and the risk of fractures was calculated using the FRAX model and statistical analysis of the data was carried out using the Microsoft Statistica program.
Results: Questionnaires of 600 patients with an average age of 64.25 ± 10.17 y and a BMI of 29.05 ± 10.8 kg/m^2 were studied, of which 91% of women were postmenopausal. 35.1% of those surveyed had a disability, and the majority underwent rehabilitation due to problems with the musculoskeletal system. A study of the rehabilitation routing scale showed that 85.2% of patients had severe disabilities. More than a third of patients surveyed were at high risk of fractures, especially among women. Less than 18.16% of them underwent bone densitometry of important parts of the skeleton.

30.1% were hospitalized for osteoporotic fractures or osteoporosis. More than a third of the patients surveyed had a high risk of fractures, especially among women, and many did not undergo osteodensitometry at all. 30.1% were hospitalized due to osteoporotic fractures or osteoporosis. A number of patients (5%) mistakenly considered chondroprotectors, painkillers and biologically active food supplements as drugs for the treatment of AP. At the time of the survey, 74 people (12.3% of all subjects) continued any therapy with OP.
Conclusion: The study showed a high prevalence of osteoporosis and the risk of low-energy fractures among patients over 50 years of age undergoing treatment in the medical rehabilitation department, and only 58.5% of them received appropriate pathogenetic therapy.

P1308
OSTEOPOROSIS PREVALENCE, RISK FACTORS, AND THEIR IMPACT ON HEALTH SELF-ASSESSMENT AMONG RURAL URAL WOMEN

V. Kondakova[1], A. Zacroeva[2]

[1]Nevyanskaya CRH, Nevyansk, [2]Ural State Medical Univ., Ekaterinburg, Russia

Objective: Investigate the prevalence of osteoporosis, its primary risk factors, and their correlation with self-rated health and future health prospects in a comprehensive rural sample of women over 50 in the Urals.
Methods: From 2021 to 2022, women over 50 in the rural area of Kalinovo, Sverdlovsk region, were subjected to clinical screening, including FRAX testing and risk assessment for major chronic non-communicable diseases. Parameters like waist circumference, glycemia, plasma cholesterol levels, physical activity, and quality of life (including health self-assessment on a 1–5 scale) were evaluated.
Results: Prior to densitometry, 66.9% were found without osteoporosis risk, and 4.5% were clinically diagnosed based on multiple low-energy fractures and FRAX risk. Post-densitometry, the prevalence of osteoporosis was reassessed. The prevalence of key osteoporosis and chronic disease risk factors was similar to national averages. Notable findings included a high incidence of low body weight and obesity.
Discussion: The data suggests a possibly lower diagnosed osteoporosis rate among rural residents compared to urban populations. However, real prevalence might be higher if densitometry was accessible to all women at risk according to clinical assessments.
Conclusion: Osteoporosis prevalence in rural areas might be lower than in urban populations, but high risk factor frequency, limited access to densitometry, and high mortality from hip fractures potentially underrepresent the burden of osteoporosis in rural communities.

P1309
SIGNIFICANCE OF THE JOINT APPARATUS FOR STABILIZATION OF ACROMIOCLAVICULAR JOINT

O. Byrianov[1], V. Kvasha[1], D. Chekushyn[1], Y. Sobolevskiy[1]

[1]Bogomolets National Univ., Kyiv, Ukraine

Objective: To define the significance of the ligaments in stabilization of the acromioclavicular joints by the digital mathematical imitation.
Methods: The software KOMPAS-3D has been used to reproduce the imitation model, in order to obtain the clavicle and scapula models, most approximated to the real, considering the anatomical peculiarities. The numeric model simulation of the scapula-clavicle deformations by numerous combinations of injured ligaments was held with numeric package Ansys Workbench, using the module static structural. In this simulation, the clavicle and scapula were represented as the rigid bodies – absolutely hard bodies with endless rigidity.
Results: The "clavicule-scapula" system rigidity, depending on the affected structures of:
a) the acromial-clavicular joint ligaments are unaffected, healthy condition is rigidity 19.5 N/mm.
b) injury of lig. Conoideum—15.1 N/mm.
c) injury of lig. Trapezoideum – 16 N/mm.
d) injury of lig. Acromioclaviculare superior – 13 N/mm.
e) injury of lig. Acromioclaviculare inferior—14.8 N/mm.
f) injury of lig. Acromioclaviculare superior plus inferior—8.5 N/mm.
g) injury of lig. Conoideum plus lig. Trapezoideum—11.6 N/mm.
Conclusion:
1. Loss of the rigidity in the system "clavicle-scapula" is more significant under the injuries of the lig. acromio-clavicular superior and inferior (8.5 N/mm) than under the injuries of the lig. conoideum and lig. trapezoideum (11.6 N/mm).
2. A widespread term "lig. Coracoclaviculare" presents significant difficulties, as it completely drops function of the lig. trapezoideum and lig. conoideum, thus, providing incorrect background for the operative interventions, aimed at restoring this region of the stabilizing acromial-clavicular joint complex.

P1310
POLYPLANAR LATERAL FIXATION OF SUPRACONDYLAR HUMERUS FRACTURES IN CHILDREN AND ADOLESCENTS

O. Burianov[1], V. Kvasha[1], V. Naumenko[1], D. Kovalchuk[1], O. Pylypchuk[1]

[1]Bogomolets National Univ., Kyiv, Ukraine

Objective: To provide a comparative analysis of treatment outcomes in children and adolescents with supracondylar humeral fractures treated with cross- and multiplane lateral fixation.
Methods: The outcomes of 183 patients with supracondylar humerus fractures from 2019–2022 were reviewed in this retrospective analysis. Patients were aged 7.38 ± 0.34 y. Clinical and instrumental examinations were performed when first diagnosed, treated and after fracture consolidation. The type of fracture was determined using the AO Pediatric Comprehensive Classification of Long-Bone Fractures (PCCF). Treatment outcome was assessed using the Mayo Clinic Elbow Performance Score (MEPS). The study included two groups: control (102 patients with crossed fixation) and main (73 patients with polyplane fixation). The comparative statistical analysis of the two groups, based on sex, age and type of bead, shows their reliability ($p > 0.005$). A polyplane navigator was used to ensure fragment fixation in the main group.
Results: The study found that the functional results of the treatment were unsatisfactory. In the control group, the unsatisfactory results were 6.1% for closed reduction with percutaneous fixation and external immobilization, and 8.8% for open reduction with pinning and external immobilization. In the main group, the unsatisfactory results were 5.1% for closed reduction with percutaneous fixation and external immobilization, and 6.8% for open reduction with pinning and external immobilization. Furthermore, the control group experienced iatrogenic ulnar nerve damage in 2.7% of cases, whereas this complication was absent in the main group of patients.
Conclusion: Polyplanar lateral fixation is a reliable method for fragment stabilization of supracondylar humeral fractures in children and adolescents. This method allows early post-trauma rehabilitation and improves functional outcomes. The possibility of iatrogenic ulnar nerve damage is also completely eliminated.

P1311
SECONDARY OSTEOPOROSIS IN PATIENT WITH NONSPECIFIC ULCERATIVE COLITIS: CASE REPORT

V. Labashova[1], Y. Dydyshka[1], V. Vadzjanova[1]

[1]Belarusian State Medical Univ., Minsk, Belarus

An important part of diagnostic and treatment of osteoporosis is the exclusion of secondary forms resulting from various pathological conditions and diseases. The success is largely determined by the awareness of doctors of various specialties and the possibility of long-term monitoring of the patient.

Case report: 59 years old female admitted for endocrine assessment due to revealed hypercalcemia. She suffered from lumbar bone pain, but did not pay much attention on it. She had no pathological fracture. Her height decreased by 2 cm for the last 10 y. Menopause lasted for 4 y. Initial chemistries showed serum calcium 2.9 mmol/l (2.2–2.55), phosphate 1.03 mmol/l, alkaline phosphatase 89 U/l, creatinine 68 umol/l. The rest of her laboratory results were unremarkable. During the examination ultrasound showed pathological zone near the right lobe of thyroid gland 9 × 5*7 mm (parathyroid gland?) Later laboratory investigations confirmed raised serum calcium 2.82 mmol/L, increased PTH 24.82 pmol/l (1.45–10.41) and deficiency 25-hydroxyvitamin D—21 nmol/l. DXA showed L1-4 T-score = -2,6 SD, total hip T-score = -1.7SD. The thorough examination of medical history revealed nonspecific ulcerative colitis that patient defined as a remission for at least 7 y. She was initiated vitamin D replacements. Hyperparathyroidism was determined as a secondary, osteoporosis was categorized M81.8—other osteoporosis without current pathological fracture. Follow up BMD 12 months lumbar spine BMD increased by 6.1% and total hip BMD increased by 5.2%. Serum calcium was 2.62 mmol/L, PTH 14.3 pmol/l (1.45–10.41) and 25-hydroxyvitamin D—43 nmol/l.

Conclusion: This case report aims to detect the importance of the exclusion a secondary reasons of osteoporosis.

P1312
OUR EXPERIENCE WITH DENOSUMAB AS A THERAPEUTIC TARGET IN PATIENTS WITH BREAST CARCINOMA

V. P. Popova[1], M. P. Geneva- Popova[2], S. P. Popova-Belova[2], M. D. Doykov[3], S. V. Valkanov[3], I. P. Popov[4]

[1]Dept. of Rheumatology, Medical Faculty, Medical Univ. of Plovdiv, [2]Dept. of Rheumatology, Medical Faculty, Medical Univ. of Plovdiv, [3]Dept. of Urology and General Medicine, Medical Faculty, Medical Univ. of Plovdiv, [4]Medical Faculty, Medical Univ. of Plovdiv, Plovdiv, Bulgaria

Objective: RANK blockade may play a central pathogenetic role in the tumorigenesis of breast carcinoma and some other tumors, as well as in their metastasis. Inhibition of the RANK/RANKL/OPG axis is key to the treatment of patients with metastatic tumors.

Methods: Breast cancer patients (N-78)—in II A and B and IIIA st TNM, according to the 8th revision of the American Joint Committee on Cancer (AJCC), divided into 2 main groups with (N-40) and without (N-38) osteoporosis. Inclusion criteria: Patients operated for breast carcinoma and on adjuvant treatment with aromatase inhibitors with high baseline levels of CA 15–3 and CEA-2 times above their upper reference value. Patients with osteoporosis are treated with a standard dose every 6 months with Denosumab, and the other group is a control group—with monitoring of tumor markers. Periodicity of the evaluation of the results is for 36 months. Screening of tumor markers is done at 0–6-12–24 and 36 months, DXA at 24 and 36 months. PET/ CT scan—baseline, at 12, 24 and 36 months.

Results: A significant decrease in the levels of tumor markers in the group treated with denosumab—in 65% of the patients treated with denosumab—they normalized as early as the 12th month, in 15% lower their levels by 50% of baseline levels, becoming permanent until the end of the observed period. Improved BMD ($P < 0.0001$) in the denosumab treatment group after 24 m (+ 8.5%) and 36 months (+ 10.6%), missing PET/CT scan data for local and/or distant metastasis.

Conclusion: Denosumab plays an important pathogenetic role in the treatment of patients with carcinomas and, in addition to improving BMD, it also affects markers related to metastasis and tumor progression, as well as having a good prognostic safety profile, even at doses lower than those used in metastatic tumors. Limitations—a small group of patients.

P1313
EXAMINATION OF THE LEVEL OF VIT D IN PATIENTS WITH OSTEOARTHRITIS OF THE KNEE JOINT

V. P. Popova[1], M. P. Geneva- Popova[2], S. P. Popova-Belova[2], M. D. Doykov[3], S. V. Valkanov[3], I. P. Popov[4]

[1]Dept. of Rheumatology, Medical Faculty, Medical Univ. of Plovdiv, [2]Dept. of Rheumatology, Medical Faculty, Medical Univ. of Plovdiv, [3]Dept. of Urology and General Medicine, Medical Faculty, Medical Univ. of Plovdiv, [4]Medical Faculty, Medical Univ. of Plovdiv, Plovdiv, Bulgaria

Objective: Osteoarthritis of the knee joints is a socially significant disease with a high rate of disability, leading indirectly to high mortality. Etiopathogenesis still has its ambiguities, but the role of calcitriol in this process is undisputed. The presence of vit D receptors (VDR) in striated muscle and chondrocytes, with relevance to their functionality and joint damage in osteoarthritis.

Methods: Retrospective study of 250 patients with OA of knee joints in Ro stage 2 (N- 76), Ro stage 3 (N- 124) and Ro stage 4 (N—50) according to Kellgren-Lawrence, with a study of serum levels of vit D once a year for 2 y, Po staging at 2 y. All patients received replacement therapy with calciumtriol 5000 IU daily.

Results: Vitamin D deficiency was found at the baseline in all three groups—in the patients as in the patients with 2 Rö stage in 54 (71%) with an average baseline level—23.4 ng/ml, in the group in 3 Ro stage in 87 (70%) 21.5 ng/ml, and in the group in 4 Ro stage in 46 patients (92%) the average value of calciferol was 24 ng/ml. The examination of the serum level in the 1st and 2nd years show persistence of vit. D deficit in all three groups, as follows: in the group with 2 Rö stage at 36% (N 27) in the 1st year and at 26% (N20) in the second year, In 3 Rö st. after 1 year at 39% (N 48) and 31% (N 38) in the 2nd year have a persistent vitamin D deficiency. In addition, in the absence of dynamics in the other factors related to OA, there is a worsening of its severity—a transition of 17% (N13) of the patients from the 2nd to the 3rd Ro stage. And in 26% (N20) there is a transition from 2 in 4 Rö st., also 33% (N41) pass from 3 to 4 Rö st.

Conclusion: Vitamin D has multiple pleiotropic effects Persistent vitamin D deficiency could be associated with deterioration of joint function and of local status with a transition to a higher Rho stage. Larger studies and timely replacement treatment are needed.

P1314
FIRST FRACTURE LIAISON SERVICE IN CROATIA: LEARNING THROUGH EXPERIENCE

A. Zrilic Vrkljan[1], M. Hrabar[1], J. Andric[1], S. Marusic[1], V. Pandzic Jaksic[1]

[1]Dept. of Endocrinology, Diabetes, Metabolic Diseases and Pharmacology, Dubrava Univ. Hospital, Zagreb, Croatia

Objective: The everyday practice of not receiving timely osteoporosis treatment after fragility fracture has been a long-standing unresolved issue in Croatia. In Dubrava University Hospital we finally implemented a Fracture Liaison Service (FLS) led by the Department of Endocrinology and including fragility fracture patients admitted to the Department of Traumatology and Orthopedics. After a period of adaptation, we achieved stable FLS screening and treatment initiation, so we aimed to analyze the results.
Methods: During 12 months between November 2022 and 2023, we screened 340 patients. After clinical and laboratory investigations we excluded 32 patients because of contraindications for osteoporosis treatment, 21 patients that died, and 10 that could not be contacted. From the remaining total of 277 patients that were followed through FLS 67 (24.2%) patients received in-hospital osteoporosis therapy or treatment recommendations and 210 were released with vitamin D supplementation and scheduled for endocrinologist visits the day when the first surgical control was planned. We collected demographic and clinical data and compared two groups: 139 (50.2%) patients who returned for consultation and received treatment and 71 (25.6%) patients who skipped recommendations and did not receive osteoporosis therapy.
Results: Patients who did not return for osteoporosis treatment after hospitalization were more often femoral fracture patients ($p = 0.02$), but they did not differ in age, gender, and presence of comorbidities like diabetes or malignant diseases. They also were less likely to take vitamin D supplementation before fracture ($p < 0.01$), their 25OH-vitamin D was lower ($p = 0.017$) and they had more secondary hyperparathyroidism ($p = 0.02$) but did not differ in other causes of secondary osteoporosis. Further analysis showed that although not showing up for endocrinologist consultation, 51 out of those 71 patients did return for surgical follow-up.
Conclusion: While huge improvements in comparison to previous practice without FLS are evident, we need to find effective modalities to initiate osteoporosis treatment in patients with the worst mobility. However, the fact that they mostly reached hospital for surgical follow-up suggests that a large improvement should be undertaken in patient education and general awareness about secondary fracture prevention. The initiation of osteoporosis treatment is only the beginning and long-term patient adherence with FLS supervision should be the goal.

P1315
SERUM 25-HYDROXYVITAMIN D LEVELS AND PSYCHOLOGICAL DISTRESS SYMPTOMS IN PATIENTS WITH TYPE 2 DIABETES MELLITUS

V. Pankiv[1]

[1]Ukrainian Scientific and Practical Center of Endocrine Surgery, Transplantation of Endocrine Organs and Tissues of the Ministry of Health of Ukraine, Kyiv, Ukraine

Objective: Type 2 diabetes mellitus pandemic has given rise to stress worldwide, especially in vulnerable people like those suffering from mental illness. This study aims to investigate the psychological distress perceived by a cohort of patients with major depressive disorder (MDD), and to analyze serum 25-hydroxyvitamin D [25(OH)D] levels as a potential predictor of distress severity.
Methods: 97 remitted MDD patients with type 2 diabetes were enrolled. An online dedicated survey was administered to evaluate diabetes related distress by using Psychological Distress Scale. Patients' medical records were reviewed to collect sociodemographic and clinical data, including serum 25(OH)D levels. A multivariate general linear model was adopted to test the effect of factors of interest on psychological distress.
Results: In our sample ($n = 97$), 28 subjects (28.9%) reported no likelihood of psychological distress, whereas 34 (35.1%) and 35 (36.0%) displayed mild and moderate-to-severe likelihood of psychological distress, respectively. Low serum 25(OH)D levels ($p = 0.05$) and MDD diagnosis ($p = 0.01$) specifically predicted the severity of psychological distress. Living alone, a longer duration of illness, and smoking habits were more frequently detected in subjects with diabetes related distress.
Conclusion: Low serum 25(OH)D levels and MDD diagnosis predicted an increased vulnerability to the stressful impact of the type 2 diabetes. Our results suggest that vitamin D may represent a biological factor mediating the psychological response to stress in individuals with affective disorders and provide further insight into tailoring intervention strategies.

P1316
ANALYSIS OF CAUSES AND RESULTS OF TREATMENT OF COMPLICATIONS AFTER HIP ARTHROPLASTY

V. Pidgaietskyi[1], T. Nizalov[1], M. Pidgaietskyi[1]

[1]SI "Institute of traumatology and orthopedics, AMS of Ukraine", Kyiv, Ukraine

Objective: To study the causes and results of treatment of complications of hip replacement.
Methods: The basis of the work was the analysis of the results of treatment of 364 patients with complications after hip replacement in 369 cases from 2005–2018. The structure of complications was as follows: aseptic loosening—158 cases (42.9%), dislocations of the prosthetic head—41 cases (11.1%), paraarticular heterotopic ossification—30 (8.0%), periprosthetic fractures of the femur—25 (6.8%), pain in the prosthetic joint (not associated with loosening)—35 (9.5%) and infectious complications in 80 cases (21.7%). The work used clinical, radiological, microbiological and statistical research methods.
Results: As a result of statistical analysis, a reliable χ^2 correlation was established between the loosening of the components and: the age of the patients; pathology of the hip joint; outdated prosthesis design; cystic reconstruction of the acetabulum and osteoporosis of the femur. Reliable causes of dislocations of the endoprosthetic head were established: overweight patients, incorrect position of components, small diameter heads using. The causes of paraarticular heterotopic ossification were significant osteophytes of the acetabulum before surgery and significant trauma of the operation. A reliable cause of periprosthetic fractures is osteoporosis of the femur. The cause of the pain syndrome not associated with the instability of the components was the pathology of the spine in the form of degenerative-dystrophic changes in the anterior column of the lumbar spine. The causes of a para-prosthetic infection were: chronic infectious diseases of the internal organs, instability of the components, more than 2 surgical operations carried out on this joint. Regarding the results of treatment of complications, it was found that in patients with instability of the components, the results of the reduction replacement of the latter were the best with minor defects of the acetabulum and femur (type I-II according to Paprosky). The effectiveness of surgical treatment of dislocations is significantly higher compared to their closed

elimination ($\chi^2 = 15$, $p < 0.01$). An effective method of treating heterotopic ossification is their prompt removal. The only effective treatment for periprosthetic fractures in all 100% of cases was an open reduction and osteosynthesis. In the treatment of paraprosthetic infections, sanitizing interventions without removing the components of the endoprosthesis are effective only up to 3 weeks. And in cases when the rehabilitation was inconclusive, effective in a reliable number of cases was two-stage revision prosthetics ($t = 11.2$, $p = 0.0028$), namely 24 cases, which amounted to 92.3%. In the case of vertebrogenic pain syndrome, the best results treatment was found in patients with lesions of the posterior column of the lumbar spine.
Conclusion: It was established that three groups of causes played a role in the development of complications of hip arthroplasty: the causes associated with the patient (overweight, hard physical labor, osteoporosis, cystic reshaping, the presence of inflammatory processes and associated pathologies); causes associated with the surgeon (planning errors and violation of the implantation technique) reasons associated with the design of the prosthesis (outdated prosthesis models and the effect on the body of the wear products of the friction pair). The development of various complications of hip replacement requires surgical revision procedures. It was established that the earlier revision of the hip joint was performed, the better its result.

P1317
CLUSTERS OF MULTIMORBIDITY AND THEIR LINK WITH REHABILITATION PROGRAMS OUTCOMES FOR KNEE OSTEOARTHRITIS

V. SĂLARU[1], L. Mazur-Nicorici[1], M. Cebanu[1], M. Garabajiu[1], N. Loghin-Oprea[1], V. Sadovici-Bobeică[1], S. Vetrila[1], M. Mazur[1], T. Rotaru[1], A. Vizdoaga[1]

[1]Nicolae Testemitanu State Univ. of Medicine and Pharmacy of the Republic of Moldova, Chisinau, Moldova

Objective: Multimorbidity is the co-existence of two or more chronic conditions in an individual, and is a common problem for patients in rehabilitation programs. Comorbidities are highly associated with knee osteoarthritis (OA), however different patterns of associated diseases could influence differently the outcomes of the physical rehabilitation program. We aimed to determine the impact of different multimorbidity clusters on the rehabilitation program outcomes in patients with knee osteoarthritis.
Methods: A prospective control case study was conducted in the University Rehabilitation Centre. The 138 consecutive OA patients underwent clinical examination, pain level according to the VAS scale, and Knee Injury and Osteoarthritis Outcome Score (KOOS) with 5 domains (Pain, Symptoms, ADL, Sport, QoL) for joint function assessment. Patients were classified into 3 clusters according to the profile of associated diseases: cluster 1- cardiovascular (hypertension, heart failure, atrial fibrillation, vascular or ischemic heart diseases), cluster 2-metabolic (diabetes mellites, obesity, fatty liver) patients, and cluster 3- mixt (cardiometabolic). The assessment was performed before (T0) and 10 d after following a standard rehabilitation program (T1).
Results: The cluster no. 1 (cardiovascular) contained 44 patients (32 females), mean age of 60,70 ± 1,2 y, in cluster no. 2 were 24 patients (14 females), with a mean age (M ± m) 64,38 ± 3,2 y, and cluster no. 3—70 patients (63 females), mean age 64,04 ± 0,9 y. The data from the pain and joint functionality assessment are presented in Table 1. At the initial assessment, the highest level of pain and lower joint function were in cluster 2 with similar data for cluster 3 ($p > 0,05$). After the 10 d of the standard rehabilitation program, significant improvements in joint function and pain control were identified in all 3 groups ($p < 0,01$). However, better results were in the cardiovascular cluster. The patients from the metabolic and mixt groups presented similar results, except for the KOOS symptoms in which the patient with metabolic multimorbidity had less control of OA symptoms.

Table 1. Functionality and pain level in 3 clusters of multimorbidity

Parameters	VAS	KOOS Pain	KOOS Symptoms	KOOS ADL	KOOS Sport	KOOS QoL
T0						
Metabolic	65,8±3,2	45,7±4,3	44,1±3,6	38,3±3,0	11,6±4,6	26,8±4,4
Met. vs. Cardio.	p<0,01	p<0,01	p<0,001	p<0,01	p<0,01	p<0,01
Cardiovascular	52,2±2,8	61,8±3,1	71,3±2,9	53,5±3,4	28,3±4,5	44,0±3,5
Cardio. vs. Mixt	p<0,001	p<0,01	p<0,001	p<0,001	p<0,001	p<0,001
Mixt (Cardiometabolic)	65,8±1,7	50,1±1,6	55,0±1,8	40,5±1,7	8,0±1,0	23,6±2,2
Met. vs. Mixt	p>0,05	p>0,05	p<0,01	p>0,05	p>0,05	p>0,05
T1 (after 10 d of a standard rehabilitation program)						
Metabolic	38,1±2,7	57,7±3,4	55,2±3,2	49,1±2,7	24,9±4,9	41,1±4,3
Met. vs. Cardio.	p<0,05	p<0,01	p<0,001	p<0,001	p>0,05	p<0,05
Cardiovascular	30,0±2,3	70,4±2,7	79,4±2,4	63,4±3,1	37,8±4,3	53,0±3,1
Cardio. vs. Mixt	p>0,05	p<0,001	p<0,001	p<0,001	p<0,001	p<0,001
Mixt (Cardiometabolic)	35,3±1,7	59,3±1,6	64,4±1,8	50,2±1,7	18,3±1,2	35,3±2,2
Met. vs. Mixt	p>0,05	p>0,05	p<0,05	p>0,05	p>0,05	p>0,05

Conclusion: Multimorbidity clusters were differentially associated with functional capacity and pain level in patients with osteoarthritis. Thus, the association of metabolic comorbidities appears to be related to worsening joint function and poor outcomes after the rehabilitation program.

P1318
CORRELATION OF VITAMIN D VALUES WITH BMI AND CRP LEVELS IN PATIENTS WITH EARLY SYMPTOMS OF INFLAMMATORY ARTHRITIS

A. Zoto[1], V. Salko[1]

[1]UHC"Mother Theresa", Tirana, Albania

Objective: Inflammatory arthritis affects people of every age, gender and ethnic background. Genetics, age and lifestyle can all play a part in increasing one's risk of developing inflammatory arthritis. Vitamin D is believed to have an immunomodulatory and anti-inflammatory action, and its deficiency has been linked with several autoimmune disorders, including rheumatoid arthritis (RA). We studied the correlation of vitamin D values with BMI and CRP levels in patients suspected or recently diagnosed with rheumatoid arthritis (RA) according to 2010 EULAR/ACR criteria, which haven't started specific therapy yet.
Methods: 65 patients suspected or diagnosed with RA are included in this study. No DMARDs have been started at the moment of evaluation. Beside other required examinations are included: vitamin D level, CRP and BMI calculation.
Results: Patients mean age (± SD), 47,3 yo (± 10.3). 25 patients included in the study have BMI < 25 kg/m^2,in this group mean value of vitamin D in the moment presented at doctor office is 35 ng/mL (sufficient range 30–60 ng/mL)and the mean value of CRP in this group resulted 1.1 ng/L (normal value CRP < 1 ng/L). The rest of 40 other patients resulted with BMI > 25 kg/m^2,in this group mean value of vitamin D in the moment presented at doctor office is 28 ng/mL and the mean value of CRP in this group resulted 1.8 ng/L.
Conclusion: An inverse correlation of BMI and Vitamin D levels was confirmed. Also a higher level of CRP was observed in patients with lower vitamin D level.

P1319
OSTEOPOROSIS IN PATIENTS WITH METABOLIC SYNDROME

A. Zoto[1], V. Salko[1], T. Backa[1]

[1]Rheumatology Service, Univ. Hospital Center "Mother Theresa", Tirana, Albania

Objective: Incidence of osteoporosis in patients with metabolic syndrome.
Methods: All patients included in the study were diagnosed with metabolic syndrome. The average duration of the disease is 5 y. 110 patients were included from which 60 females and 50 males. Post menopausal women were excluded from the study. The average age was 48 years old. Biochemical parameters, vitamin D level, calcium level were requested in every patient and also DXA at the femoral neck and lumbar spine were measured, including also BMI. Cut off of DXA to define osteoporosis is T-score $\leq$ -2,5.
Results: Out of 110 (100%) patients, 76 (69%) resulted with osteoporosis. In 60 (100%) female patients, 53 (88%) had osteoporosis. Out of 50 (100%) male patients, only 23 (46%) of them were diagnosed with osteoporosis. In the total of 76 (100%) patients with osteoporosis, 48 (63%) of them had osteoporosis only in the coxofemoral joints, 9 patients (12%) exclusively in the lumbar part and 19 patients (25%) in both coxofemoral and lumbar regions.
Conclusion: Metabolic syndrome is associated with a high incidence of osteoporosis in both female and male patients. The coxofemoral joints are the region most affected by osteoporosis. Patients with metabolic syndrome should be examined periodically for early diagnosis of osteoporosis and follow up should be mandatory in patients with established diagnosis of osteoporosis.

P1320
TOWARDS BEST PRACTICE WHEN DISCONTINUING DENOSUMAB: AN AUDIT OF THE BELFAST EXPERIENCE

V. Stokes[1], A. Baird[2], J. Cheng[3], C. Donaghy[4], G. Heyburn[2], J. Lindsay[5], B. Roberts[1], P. Hamilton[1]

[1]Dept. of Clinical Biochemistry, Royal Victoria Hospital, Belfast Health and Social Care Trust, [2]Dept. of Trauma and Orthopaedics, Musgrave Park Hospital, Belfast Health and Social Care Trust, [3]Dept. of Care of the Elderly, Musgrave Park Hospital, Belfast Health and Social Care Trust, [4]Dept. of Rheumatology, Musgrave Park Hospital, Belfast Health and Social Care Trust, [5]Dept. of Endocrinology, Royal Victoria Hospital, Belfast Health and Social Care Trust, Belfast, UK

Objective: Denosumab is commonly used in the treatment of osteoporosis, but stopping it has been associated with a rapid fall in bone density and an increase in fracture risk; best practice around the discontinuation of denosumab remains uncertain. We sought to audit local osteoporosis prescribing practice following denosumab discontinuation and assess subsequent fracture risk.
Methods: Electronic healthcare records were analysed for 37 patients in whom denosumab therapy was discontinued. The duration of treatment, subsequent drug prescriptions and incidence and nature of fractures post-discontinuation was noted.
Results: Denosumab had been used for between 3–10 y. After discontinuation, treatment options included oral bisphosphonate treatment for 6, 12, 18 or 24 months, or 1, 2 or 3 annual doses of intravenous zoledronic acid. Full data, including bone densitometry data from around 2 y post-discontinuation, was available for 19 patients. 32% of these patients had an incident fracture after stopping denosumab; 21% of these fractures were vertebral. 41% of patients had bone turnover markers checked to assist with therapeutic decision-making. In the 6 patients who received zoledronic acid, only half maintained the gain in BMD obtained with denosumab, and a third sustained a fracture.
Conclusion: Stopping denosumab is difficult as this practice is often associated with a decline in BMD and subsequent risk of fracture. Subsequent treatment with a bisphosphonate is often initiated in an attempt to attenuate this risk, but the data presented here suggest that this practice is not particularly effective. Better evidence-based strategies for stopping denosumab are urgently required.

P1321
ASSESSMENT OF MOTOR ACTIVITY OF PATIENTS UNDERGOING MEDICAL REHABILITATION

V. Vasileva[1], L. Marchenkova[1], A. Fesyun[1]

[1]Federal State Budgetary Institution "National Medical Research Center of Rehabilitation and Balneology" of the Ministry of Health of the Russian Federation, Moscow, Russia

Objective: To study the nature and degree of disorders of muscle strength, motor and coordination functions in patients undergoing medical rehabilitation and sanatorium treatment.
Methods: Single cross-sectional study included 160 patients aged 40–65 y with normal and overweight. The complex of the study included: functional tests and assess muscle strength and balance.
Results: In patients with obesity, compared with persons with normal body weight of the same age, significantly ($p < 0.05$) lower indicators of muscle strength of the right and left arms, strength of the abdominal and back muscles, lower endurance of the abdominal muscles and back muscles and longer time to complete the "get up and walk" test. Also, in obesity, it turned out to be significantly less time to maintain balance in the "stand on one leg" tests on the right and left legs with open eyes. A statistically significant direct relationship was found between the level of back muscle strength ($\gamma = -0.82$, $p = 0.0038$) and body weight. A significant relationship was also found between the level of endurance of the back muscles to physical activity and BMI, $\gamma = -0.79$, $p = 0.01$. At the same time, there was no relationship between age and the level of endurance of the back muscles to physical activity ($\gamma = 0.107$, $p = 0.36$).
Conclusion: In patients with obesity at the age of 40–65 y, compared with persons with normal body weight of the same age and gender, there is a statistically significant decrease in the muscle strength of the arms, abdomen and back, a longer time to complete the "get up" test and walk", as well as deterioration in the function of static balance according to the results of the "stand on one leg" test.

P1322
EFFECTIVENESS OF COMPLEX MEDICAL REHABILITATION OF PATIENTS WITH POSTTHROMBOPHLEBITIC SYNDROME AND OBESITY

V. Vasileva[1], T. Konchugova[1], T. Apkhanova[1], O. Yurova[1], A. Fesyun[1]

[1]Federal State Budgetary Institution "National Medical Research Center of Rehabilitation and Balneology" of the Ministry of Health of the Russian Federation, Moscow, Russia,

Objective: Comparative study of the influence of complex methods of medical rehabilitation, including various methods of laser blood irradiation (supravascular and intravenous), pulse magnetotherapy and dry carbon baths, on the dynamics of indicators of composite body composition according to bioimpedance measurements in patients with post-thrombophlebitic syndrome (PTPS) of the lower extremities and obesity.

Methods: A randomized prospective study was conducted on the basis of the Department of Medical Rehabilitation of Patients with Somatic Diseases of National Medical Research Center of Rehabilitation and Balneology of the Ministry of Health of Russia. The study included 40 patients with PTS of the lower extremities and accompanying obesity, the average age of which was 58.3 [51.5; 68.0] y), randomized to two groups. The patients of the 1st group received Intravenous laser blood irradiation (ILIB) (Lazmik, Russia), impulse magnetotherapy and dry carbon baths, as well as therapeutic gymnastics in the hall. The patients of the 2nd group received a complex that included supravascular laser irradiation of blood («Azor-2 K», Russia), pulse magnetic therapy, and dry carbon baths, as well as therapeutic gymnastics in the gym. Anthropometric measurements (body mass, malleolar volume) were used for the evaluation of antiedema and lipolytic effects after a comprehensive course of medical rehabilitation, as well as bioimpedance measurement of body composition ("MEDASS", Russia).
Results: In patients with PTS of the lower extremities and obesity, after carrying out a course of medical rehabilitation using preformed physical factors, including various methods of laser irradiation of the blood (supravascular and intravenous), a significant decrease in body weight indicators was observed ($p < 0.001$), a decrease in BMI ($p < 0.001$), total and extracellular fluid ($p < 0.001$) without significant differences between groups. A significant decrease in the index of fat mass (kg) ($p = 0.007$) was found in patients of the main group.
Conclusion: The method of bioimpedance measurement, used for the evaluation of the composite composition of the body, showed high sensitivity and allowed to establish the greater effectiveness of the developed complex, which includes ILIB with a wavelength of low-intensity laser radiation (NILI) of 635 nm in reducing fat mass.

P1323
ASSESSMENT OF QUALITY OF LIFE AND ANTHROPOMETRIC INDICATORS IN PATIENTS WITH METABOLIC SYNDROME UNDER THE INFLUENCE OF A NON-DRUG COMPLEX

V. Vasileva[1], A. Fesyun[1], T. Konchugova[1], T. Apkhanova[1], O. Yurova[1], D. Kulchitskaya[1]

[1]Federal State Budgetary Institution "National Medical Research Center of Rehabilitation and Balneology" of the Ministry of Health of the Russian Federation, Moscow, Russia, Moscow, Russia

Objective: Research of the effectiveness of a non-drug treatment method, including physiotherapeutic factors of general and local influence during physical activity and exercise therapy methods (balance therapy, hydrokinesitherapy, group physical therapy exercises in the gym, cycling training using a bicycle ergometer) compared with the use of physical therapy alone in patients with metabolic syndrome (MeS).
Methods: A randomized prospective study was conducted at the Department of Medical Rehabilitation of Adults for Patients with Somatic Diseases in the Federal State Budgetary Institution "National Medical Research Center" No. 2 of the Ministry of Health of Russia. The study included 40 patients with MeS, whose average age was 52.42 [48.0; 57.0] y, randomized into two groups. Patients of the 1st group received a complex non-drug method, including pneumocompression, electronic lymphatic drainage, transcranial magnetic stimulation and physical therapy methods, using balance therapy, hydrokinesitherapy, group therapeutic exercises in the hall and cycling training using a bicycle ergometer. Patients of group 2 received only a complex including the above methods of physical therapy. A course of non-drug treatment for patients in both groups was carried out against the background of a low-calorie diet.
Results: Patients of the main group after a course of non-drug treatment showed a significant decrease in body weight in kg ($p < 0.001$), a decrease in BMI in kg/m^2 ($p < 0.001$), and an improvement in overall mental wellbeing (GWB) ($p < 0.001$) and general physical wellbeing (GPW) ($p < 0.01$). Also, after the course of treatment, patients in group 1 (main) showed a significant decrease in waist circumference and hip circumference in cm ($p < 0.05$), compared with group 2, according to the Mann–Whitney test. The study obtained reliable data on the deterioration of OPB in the comparison group.
Conclusion: The use of a complex non-drug treatment method using electronic lymphatic drainage, pneumocompression, transcranial magnetic stimulation along with the use of exercise therapy methods led to an improvement in overall quality of life due to improvements in GPW and GWB on the corresponding scales.

P1324
COMPREHENSIVE ANALYSIS OF OMEPRAZOLE'S PROLONGED IMPACT ON BONE HEALTH AND FRACTURE RISK IN PATIENTS RECEIVING CALCIUM, VITAMIN D, AND ANTIRESORPTIVE THERAPIES

V. Vyskocil[1], R. Stepanova[2], M. Simeckova[3]

[1]Charles Univ. Hospital Osteocentre Dept. of Medicine II, Pilsen, [2]Anova CRO Praha, Praha, [3]ANOVO, Praha, Czech Republic

Objective: The investigation involved a cohort of 399 patients subjected to omeprazole treatment for a duration exceeding 2 y, with the objective of assessing its potential adverse impact on BMD in individuals concurrently administered with calcium, vitamin D, and antiresorptive drugs. A control group, comprising 340 patients, was meticulously selected to mirror the demographics of the study group. The principal endpoints encompassed alterations in BMD at the spine and hip, the incidence and specific localization of fractures, including the hip, spine, upper limbs, lower limbs excluding the hip, and other anatomical regions.
Methods: An analysis was conducted to scrutinize the influence of both the dosage and duration of omeprazole treatment, as well as BMD, on changes in the spine and hip (referred to as the active group). Additionally, the impact of vitamin D levels was investigated, with thresholds set at 50 nmol/L and 75 nmol/L. A substantial majority of treated patients exhibited a BMI exceeding 25 (81.1%), and in turn, exceeding 30 (44.5%). Notably, 81.7% of patients registered vitamin D values surpassing 50 nmol/L. The mean age of the cohort was 72.5 ($\pm$ 4.32) y. The prevalent dosage of omeprazole was 40 mg in 44.1% of cases and 20 mg in 40.6% of cases. The mean treatment duration was 6.4 ($\pm$ 3.23) y. Statistical testing involved the utilization of the t-test for independent groups, linear models, and Poisson regression.
Results: No statistically significant distinctions were discerned in BMD at the spine and left hip between the groups. The influence of omeprazole dosage and treatment duration, as scrutinized by a linear model, failed to attain statistical significance for both variables. Similarly, the effect of BMI on BMD percentage change in the spine or hip did not achieve statistical significance, irrespective of the BMI threshold set at 25 kg/m^2 or 30 kg/m^2. Vitamin D treatment exhibited no statistically significant impact on BMD changes in the hip or spine within both subgroups, considering thresholds of 50 nmol/L and 75 nmol/L. Furthermore, neither the dosage nor the duration of omeprazole treatment manifested an effect on the incidence of fractures. No statistically significant association was observed between the dose and duration of omeprazole treatment and the occurrence of fractures at the specified anatomical locations.

Conclusion: The purported impact of omeprazole dosage or treatment duration on BMD or fracture occurrence did not attain significance, when accounting for vitamin D levels and BMI. Additional scrutiny involving an expanded sample size and the incorporation of updated clinical data is imperative for a comprehensive understanding of the observed phenomena.

P1325
COMPARATIVE ANALYSIS OF BONE CEMENT IMPLANTATION SYNDROME IN CEMENTED BIPOLAR HEMIARTHROPLASTY: INFLUENCE ON PATIENTS WITH AND WITHOUT PREEXISTING HEART CONDITIONS

V. Yuenyongviwat[1], J. Janejaturanon[1], K. Iamthanaporn[1]

[1]Dept. of Orthopedics, Faculty of Medicine, Prince of Songkla Univ., Hatyai, Thailand

Objective: As the incidence of hip fractures rises among the elderly, hip replacement with a cemented femoral stem becomes a viable treatment option. However, concerns about potential complications, particularly Bone Cement Implantation Syndrome (BCIS), especially in patients with medical conditions, have prompted orthopedic surgeons to explore alternative approaches. This retrospective study compared BCIS incidence in patients with and without preexisting heart disease undergoing cemented bipolar hemiarthroplasty.
Methods: Retrospective data from 311 patients undergoing cemented bipolar hemiarthroplasty were analyzed, involving 188 individuals without preexisting heart disease and 123 with heart disease. Anesthetic records were reviewed to assess parameters related to BCIS. The severity of BCIS was systematically graded, emphasizing key metrics like hypotension, arterial desaturation, or loss of consciousness.
Results: No perioperative deaths occurred. BCIS grade 1 manifested in 13 cases (4.18% of the total patients), with no instances of grade 2 or 3. Notably, grade 1 BCIS was observed in only 2 cases with preexisting heart disease (1.63%). In the control group without preexisting heart disease, 11 cases demonstrated grade 1 BCIS (5.85%).
Conclusion: The incidence of BCIS in cemented bipolar hemiarthroplasty was minimal, with predominantly low severity. Importantly, preexisting heart disease did not demonstrate a significant increase in the risk of BCIS. This affirms the safety of cemented bipolar hemiarthroplasty for elderly patients.

P1326
FINITE ELEMENT MODEL OF SCREWS FOR CEMENT AUGMENTATION IN TOTAL KNEE ARTHROPLASTY WITH TIBIAL UNCONTAINED BONE DEFECT

V. Yuenyongviwat[1], A. Kwanyuang[2]

[1]Dept. of Orthopedics, Faculty of Medicine, Prince of Songkla Univ., [2]Institute of Biomedical Engineering, Faculty of Medicine, Prince of Songkla Univ., Songkhla Hatyai, Thailand

Objective: Addressing challenges in the management of medial uncontained tibial defects is crucial for the success of total knee arthroplasty (TKA), as these issues impact prosthesis stability and implant survival. While the utilization of screws and bone cement is a preferred approach, the literature lacks consensus on optimal screw insertion techniques. This study aims to fill this gap by investigating the biomechanical implications of different screw and cement placement strategies.
Methods: A finite element analysis was conducted using a knee prosthesis model featuring a defined uncontained tibial defect. Various parameters were systematically adjusted, including the number of screws (1, 2, 3 screws), screw lengths (10, 18, 30, 40 mm), lateral-medial screw positions (2, 4, 6 mm laterally), and abduction rotation angles (0, 5, 10, 15°). These adjustments were made to assess their individual and combined effects on the vertical displacement and abduction angles of the tibial tray.
Results: The inclusion of three-screw reinforcement significantly decreased vertical displacement, with the single screw in the middle position demonstrating superior performance in preventing abduction angle deformation compared to scenarios involving two screws at anterior and posterior positions without a middle screw. Longer screws and smaller abduction angles contributed to reduced movement of the tibial component. Additionally, lateral adjustment of the screw position led to increased vertical displacement values, reaching approximately 1.5% when shifted 6 mm laterally.
Conclusion: The finite element analysis suggests that, for addressing medial uncontained tibial defects, three-screw reinforcement is advantageous for larger defects. Longer screws and a smaller abduction angle are considered favorable. Furthermore, the study emphasizes the superiority of medial screw placement over lateral placement. It is crucial to highlight that further clinical validation is necessary to confirm the biomechanical implications observed in this study.

P1327
PREVALENCE AND ASSOCIATED RISK FACTORS OF OSTEOPOROSIS IN NURSING HOME RESIDENT: A CROSS-SECTIONAL STUDY

W. C. Lin[1], C.-T. Li[2], C.-C. Li[2], C.-H. Wu[3], T.-W. Tai[4]

[1]Dept. of orthopedics, Show Chwan Memorial Hospital, Changhua, [2]Institute of Gerontology, Collage of medicine, National Cheng Kung Univ., Tainan, [3]Institute of Gerontology, College of medicine, National Cheng Kung Univ., Tainan, [4]Dept. of orthopedics, National Cheng Kung Univ. Hospital, National Cheng Kung Univ., Tainan, Taiwan

Objective: To investigate the prevalence of undiagnosed osteoporosis in a nursing home, surpassing initial expectations.
Methods: A comprehensive assessment of osteoporosis prevalence utilized DXA, FRAX calculations, a structured questionnaire, and blood screening correlation, incorporating data from 57 residents at a nursing home. Additionally, osteoporosis severity in nursing home residents, matched for sex, age, and fracture history, was compared via DXA with 114 patients from a medical center.
Results: The study revealed an osteoporosis prevalence of 86.5%, with rates of 90.3% in women and 81.0% in men. Identified risk factors included female gender and low vitamin D levels. Fracture history, and TL-spine X-ray lateral view showed the potential as a preliminary screening tool for osteoporosis in nursing home settings.
Conclusion: Nursing home residents represent a unique population with a notably high osteoporosis prevalence, even when compared with counterparts in medical centers employing similar fracture characteristics. The findings serve as a valuable reference for evaluating and diagnosing osteoporosis among nursing home residents, offering a foundation for future research endeavors in this domain.

P1328
CHINESE MEDICINE ENHANCES BONE MARROW DENSITY IN OSTEOPOROSIS PATIENTS: A 12-YEAR REAL-WORLD SINGLE-CENTER STUDY IN TAIWAN

W. L. Chen[1], Y. L. Deng[1], C. Y. Hsu[1]

[1]Taichung Veterans General Hospital, Taichung, Taiwan

Objective: Osteoporosis constitutes a significant health concern, impacting human well-being. In Taiwan, many patients turn to traditional Chinese medicine (TCM) as an alternative medical treatment. However, there is currently limited data on the effectiveness of TCM in osteoporosis. This study aims to investigate the impact of TCM on bone marrow density (BMD).
Methods: Based on research utilizing the Taiwan Health Insurance Database previously, this study identified five commonly used TCM for osteoporosis patients. These include three single-herb medicines: Eucommia ulmoides, Dipsaci Radix, and Drynariae Rhizoma, as well as two formulas: Bawei Dihuang Pills and Guilu Erxian Guo. The cumulative dose criteria were set at 12 g or more for single-herb medicines and 80 g or more for formulas. A retrospective data analysis was conducted using the osteoporosis database from Taichung Veterans General Hospital, Taiwan. Patients concurrently using anti-osteoporosis medication were grouped and subjected to analysis.
Results: This study enrolled a total of 162 patients with BMD data both pre and post-taking TCM recorded between 2010–2022. The results indicated significant differences in BMD_FEMUR_LT(0.78 vs. 0.81, $P < 0.001$) and BMD_FEMUR_RT (0.78 vs. 0.79, $P = 0.001$) before and after TCM usage. However, no significant difference was observed in BMD_FEMUR among those who used TCM in conjunction with anti-osteoporosis medication. Possible explanation include that individuals combining Chinese and western medicine had lower BMD pre-treatment (0.67), indicating a more severe condition, thereby resulting in less pronounced improvements post-treatment. Additionally, significant differences were observed in TSCORE_FEMUR_LT(-1.68 vs. -1.18, $P < 0.001$), TSCORE_FEMUR_RT(-1.71 vs. -1.31, $P < 0.001$), and TSCORE_SPINE (-0.97 vs. -0.5, $P < 0.001$)after TCM usage. Combining TCM with anti-osteoporosis medication also demonstrated a significant difference in TSCORE_FEMUR_RT(-2.49 vs. -2.24, $P < 0.001$).
Conclusion: TCM can serve as a viable option among selective medications for osteoporosis patients. However, to better ascertain its effectiveness and safety, it is imperative to conduct more extensive large-scale research in the future.

P1329
PSORALEN MEDIATES WNT/BMP SIGNALING PATHWAY TO REGULATE BMSCS OSTEOGENIC DIFFERENTIATION

W. Li[1], F. Chen[2], M. Chen[3], Y. Zhong[1], F. Yang[1]

[1]Shaanxi Univ. of Chinese Medicine, Xianyang, China, [2]Baoji Hospital of Traditional Chinese Medicine, Baoji, China, [3]Hancheng Hospital of Traditional Chinese Medicine, Weinan, China

2 Affiliated Hospital of Shaanxi University of Chinese Medicine, Xi'an 712,083, China.

3 Baoji Hospital of Traditional Chinese Medicine, Baoji 721,001, China.

4 Hancheng Hospital of Traditional Chinese Medicine, Weinan 715,499, China.

Objective: To explore the mechanism of psoralen mediated Wnt/β-catenin and bone morphogenetic protein (BMP) signaling pathway to induce osteogenesis of BMSC.
Methods: Bone marrow mesenchymal stem cells (BMSCs) were treated with psoralen to detect its osteogenic differentiation. In addition, lentivirus and siRNA were used to construct cell models of β-catenin or BMP2 overexpression and knockdown, separately. They may help to clarify the role of β-catenin and BMP2 crosstalk in osteogenic differentiation of BMSCs. What's more, C57BL/6 mice were selected to be treated psoralen with psoralen to further verify the osteogenic effect.
Results: Various in vitro studies on BMSCs showed that psoralen could promote the osteogenic differentiation of BMSCs. Overexpression of β-catenin could promote the expression of BMP2 in BMSCs, and psoralen can enhance the effect of bone differentiation. Knockdown β-catenin decreased the expression of BMP2 and inhibited psoralen in promoting bone differentiation. In addition, it was found that the effect of psoralen on β-catenin level did not change significantly after overexpression or knockdown of BMP2, but the effect of psoralen on promoting bone differentiation was inhibited by knockdown of BMP2. In mice, psoralen intervention regulated the crosstalk of Wnt/β-catenin and BMP signaling pathway to reached to promote osteogenic differentiation of bone tissue.
Conclusion: Psoralen can activate β-catenin signaling pathway and upregulate the expression of BMP signaling pathway to increase the cross talk between β-catenin and BMP, to eventually reach to promote osteogenic differentiation of BMSCs.

1 Shaanxi University of Chinese Medicine, Xi'an 712,046, China.

2 Affiliated Hospital of Shaanxi University of Chinese Medicine, Xi'an 712,083, China.

3 Baoji Hospital of Traditional Chinese Medicine, Baoji 721,001, China.

Objective: Sarcopenia (SP) and osteoporosis (OP) are two common chronic musculoskeletal diseases in the elderly population. With the aging of the global population, the prevalence of OP and SP increases year by year, which seriously increases the risk of falls, fractures and hospitalization of the elderly. The diseases seriously damage the quality of life and health of the elderly, and create a heavy burden for our medical system and society. Therefore, in 2009, Binkley et al. developed the concept of Osteo-sarcopenia (OS) based on the same pathophysiological basis for SP and OP and the same adverse effects on physical health in older adults. However, there is still no authoritative organization or guide to put forward unified OS diagnostic criteria. Most of them are based on the diagnostic criteria of SP and OP, and the diagnostic criteria of both SP and OP are taken as the

judgment criteria of OS. The study of the relationship between muscle and bone and the intervention and treatment of muscle loss and bone mass loss can more effectively reduce the disability rate and fatality rate of this disease and improve the quality of life of the elderly.

Methods: OS subjects were initially screened according to the SARC-CalF questionnaires and International Osteoporosis Foundation (IOF) one-minute osteoporosis risk test, and were selected according to the inclusion and exclusion criteria of OS. Muscle strength was measured using a grip strength meter, and physical function was measured by 5-time chair stand test, 6-min walk test, stair-climb power test, timed-up-and go test and the Short Physical Performance Battery (SPPB). Pain using visual analogue scale (VAS) score and Assessment of health related quality of life in osteoporosis (ECOS-16) were used to evaluate the function of patients with osteoporosis. DXA was used to detect appendicular skeletal muscle mass (ASM) and BMD of the lumbar spine (1–4) and hip to explore musculoskeletal correlations and possible patterns of interaction in OS.

Results: OS subjects were significantly lower than normal subjects in muscle strength,

5-time chair stand test, 6-min walk test, stair-climb power test, timed-up-and go test, SPPB and other physical function indicators. DXA results showed that the ASM and the BMD of the lumbar spine (1–4) and hip in OS subjects was significantly lower than the normal. The reduction of muscle mass and bone mass in lumbar and hip joints was synergistic to some extent.

Conclusion: DXA can noninvasively evaluate musculoskeletal structures and their dynamic changes in OS population at the microscopic level. Therefore, DXA can be used for noninvasive early examination of the aged, which may clarify the muscle and bone loss of them to facilitate early intervention and reduce the risk of osteoporosis fracture.

P1331
TRENDS OF VERTEBRAL HEIGHT LOSS IN NORMAL OLDER POPULATION

C.-H. Chan[1], Y.-C. Lu[2], H.-Y. Wu[3], W. P. Chan[4]

[1]Dept. of Geography, National Taiwan Normal Univ., Taipei, [2]National Center for Geriatrics and Welfare Research, National Health Research Institutes, Yunlin, [3]Dept. of Radiology, Wan Fang Hospital, Taipei Medical Univ., Taipei, [4]Dept. of Radiology, Wan Fang Hospital, Taipei Medical Univ., Dept. of Radiology, School of Medicine, College of Medicine, Taipei Medical Univ., Taipei, Taiwan

Objective: To use an automatic vertebral compression fracture (VCF) detection method to investigate the percentage of vertebral height loss of normal aging population and to determine the differences in sex, age, and vertebrate level. Specific objectives included (1) the occurrence of the most severe VCFs in each sex, vertebral level and age group; (2) the distribution of the percentage of vertebral height loss by vertebral level, age, sex; and (3) the range of percentage of vertebral height loss by normal aging population.

Methods: All non-contrast MDCT images of 856 participants (300 women) with an average age of 59.6 y (aged 50–95) were collected between 4 January 2021 and 31 March 2022. The MDCT images were reconstructed into 2.5 mm thick slices for automatic VCF analysis by SmartBone software. The subjects were divided into seven age groups, each of 5 y. We assessed differences in VCF between seven groups and two sexes using ANOVA and independent T tests. The normal range of the percentage of vertebral height loss with a combination of all vertebral levels during normal aging using the normal distribution estimation method (95%CI) and the interquartile range method (1.5 interquartile range).

Results: The results showed that the most severe VCF usually occurred at T7, T11, and T12 in men. However, women generally had the most severe VCF from T5 to T8 between the ages of 50–60, and in the latter, the most severe VCF concentrated in T8. In addition, the increasing trends in vertebral height loss percentages by vertebral level and age group in men and women, and the progress in vertebral height loss in women, was similar to those in men. The percentage of vertebral height loss in the normal range of all age groups of both sexes exceeded 25%, where men and women losing 33% of vertebral height between 70–80 y of age.

Table 1. The vertebral height loss percentage of normal aging population

Sex	Age	Mean†	SD	Mean±2SD	Median	Q1	Q3	Range‡
Men	50-60	17.562	5.210	7.143-27.981	16.913	14.525	19.707	6.751 - 27.480
	60-70	18.470	6.077	6.315-30.625	17.616	15.013	20.612	6.615 - 29.010
	70-80	21.726	10.050	1.625-41.827	19.411	16.310	23.982	4.802 - 35.491
	80-100	23.224	9.301	4.622-41.827	20.782	18.161	25.134	7.701 - 35.594
Women	50-60	16.520	4.341	7.839-25.202	16.283	13.776	19.138	5.734 - 27.180
	60-70	18.271	4.800	8.671-27.871	17.747	15.221	20.653	7.073 - 28.801
	70-80	20.039	7.756	4.528-35.550	18.614	15.665	22.232	5.815 - 32.083
	80-100	21.260	7.547	6.167-36.353	20.518	17.079	23.344	7.681 - 32.742

† Different superscripts in the same column indicate significant difference (P value <0.05).
‡ The range was determined by two-step: first, we calculated Q1 – 1.5×interquartile range and Q3 + 1.5×interquartile range as lower and upper bounds, respectively, where interquartile range was obtained from the differences between Q1 and Q3. Second, we calibrated the lower and upper bounds with the minimum and maximum values within the lower and upper bounds, respectively.

Conclusion: For the first time, our results show trends in reduction in vertebral height during normal aging in older Asians, thereby providing a reference database for clinical practice in the diagnosis and treatment of osteoporotic compression fractures.

P1332
ASSOCIATION OF OSTEOPOROSIS AND EFFECTIVENESS OF ANTI-OSTEOPOROSIS TREATMENT WITH HEARING IMPAIRMENT: A NATIONWIDE, MATCHED CASE–CONTROL STUDY

S.-H. Hung[1], J. C. Hsu[2], C. F. Huang[3], W. P. Chan[4]

[1]Dept. of Otolaryngology, School of Medicine, College of Medicine, Taipei Medical Univ., Dept. of Otolaryngology, Wan Fang Hospital, Taipei Medical Univ., Taiwan, [2]Health Data Analytics and Statistics Center, Office of Data Science, Taipei Medical Univ., International PhD Program in Biotech and Healthcare Management, College of Management, Taipei Medical Univ., Taipei, [3]Faculty of Medicine, School of Medicine, National Yang Ming Chiao Tung Univ., Division of Family Medicine, En Chu Kong Hospital, Taiwan, New Taipei City, [4]Dept. of Radiology, School of Medicine, College of Medicine, Taipei Medical Univ., Dept. of Radiology, Wan Fang Hospital, Taipei Medical Univ., Taiwan, Taipei, Taiwan

Objective: To (1) assess the risk of hearing loss associated with osteoporosis or fragility fractures, and (2) investigate the prevention of hearing loss by anti-osteoporosis treatment.

Methods: This is a retrospective cohort study. Between 2011–2017, participants over age 50 y were extracted from the Taiwan National Health Insurance Research Database (NHIRD). The experimental group 1 consists of patients with osteoporosis or fragility fractures who have not received any medical treatment. The experimental group 2 includes patients with osteoporosis or fragility fractures who

have been treated with long-term anti-osteoporosis medications (group 2a, zoledronic acid or group 2b, denosumab). Participants who had hearing loss before entry date, received anti-osteoporosis treatment before, cancer history, death within one year of the entry date, incomplete information were excluded. Group 3 is a control population with participants without osteoporosis or fragility fracture or anti-osteoporosis treatment. In this study, prevalence rates were calculated on the basis of age, sex and CCI score to conduct matching in order to obtain control groups for both research objectives. The study used hearing loss as a major outcome and multiple comorbidities as adjustment factors. Survival curves and log-ranking tests were used, and Cox proportional risk regressions were used to compare risk differences between the experimental groups and the control group. In addition, this study conducted subgroup analysis based on patient sex, age and various comorbidities.

Results: After matching by age, sex, and CCI scores, there were 25,642 participants in group 1, 25,642 in group 2a, 25,642 in group 2b, and 550,124 participants in group 3 (control). The risk of hearing loss is significantly higher in patients with osteoporosis or fractures than in non-osteoporosis patients (adjusted HR 1.36; 95% CI, 1.33–1.38). In patients with osteoporosis or fractures, users of zoledronic acid injection (adjusted HR 0.87; 95%CI 0.81–0.93) and denosumab (adjusted HR 0.91; 95%CI 0.85–0.97) indicated a significantly lower risk of hearing loss than patients without an anti-osteoporosis treatment.

Conclusion: This study used nationwide database to confirm that osteoporosis or fragility fractures are associated with increased risk of hearing loss. In addition, the results show that patients taking anti-osteoporosis medication can reduce the risk of hearing loss.

P1333
DEEP LEARNING-ASSISTED QUANTITATIVE MEASUREMENT OF THORACOLUMBAR FRACTURE FEATURES ON LATERAL RADIOGRAPHS ACROSS DIVERSE CLINICAL EXPERTISE

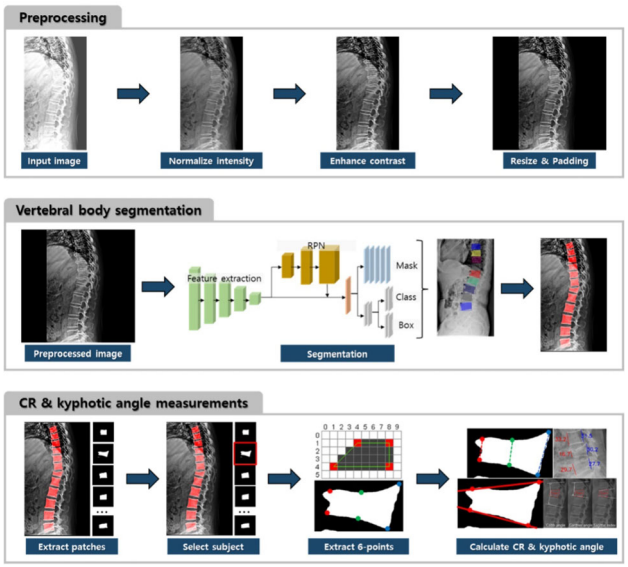
W. T. Yuh[1], K. D. An[1]

[1]Hallym Univ. College of Medicine/Neurosurgery, Dongtan Sacred Hospital, Hwaseong-Si, South Korea

Objective: To develop and validate a deep learning (DL) algorithm for the quantitative measurement of thoracolumbar (TL) fracture features, and to evaluate its efficacy across varying levels of clinical expertise.

Methods: Utilizing the Mask Region-Based Convolutional Neural Networks (Mask R-CNN) model, a DL algorithm was developed to quantify TL fracture features—compression rate (CR), Cobb angle (CA), Gardner angle (GA), and sagittal index (SI)—from lumbar spine lateral radiographs. A dataset of 1000 non-fractured and 318 fractured images was used for training, employing a 6-point labeling method. Validation involved 213 internal and 200 external fractured images. The measurements by an experienced radiologist were considered ground truth (GT) and assessed using the intraclass correlation coefficient. Additionally, we evaluated the agreement between the measurements of the GT and those of four readers, both with and without the assistance of the DL algorithm. The expertise of the four readers varied, including radiology and neurosurgery trainees, as well as an attending spine surgeon.

Results: The DL algorithm demonstrated good to excellent agreement with GT for CR, CA, GA, and SI in both internal (0.860, 0.944, 0.932, and 0.779, respectively) and external validations (0.836, 0.940, 0.916, and 0.815, respectively). DL-assisted measurement significantly improved most measurement values, particularly for trainees.



Conclusion: This study validated the DL algorithm as an accurate and effective tool for quantifying TL fracture features using radiographs. Implementing DL-assisted measurement is expected to expedite the diagnostic process and enhance the reliability of diagnoses, especially for trainees.

P1334
ASSESSMENT OF PATIENTS' BELIEFS REGARDING OSTEOARTHRITIS TREATMENT

A. Fazaa[1], W. Tekaya[1], S. Miladi[1], H. Boussaa[1], Y. Makhlouf[1], K. Ben Abdelghani[1], A. Laatar[1]

[1]Rheumatology Dept. of Mongi Slim Hospital, Tunis, Tunisia

Objective: To assess patients' beliefs regarding osteoarthritis (OA) medications and to investigate the factors influencing these beliefs.

Methods: We conducted a cross-sectional study including patients with OA (ACR criteria). Socio-demographic and disease-related data were collected. Beliefs about OA medications were evaluated using the Beliefs about Medicines Questionnaire-Specific (BMQ-S), presented in the form of two scores ranging from 5–25 and expressed as a necessity-concerns differential (NCD) ranging from -20 to + 20. Factors associated with BMQ-S variance were investigated. The significant level was $p < 0.05$.

Results: We included 36 patients, 7 men and 29 female, with a mean age of 62 y [32–82]. Among them, 30.6% were illiterate and 55.6% were homemakers. Comorbidities were present in 58.3% of cases. The majority of patients (72.2%) exhibited OA manifestations in more than one anatomical site, with knee OA (77.8%) being the most prevalent. The mean disease duration was 7.7 years [1–20]. Average visual analog scale (VAS) score was 47.2 mm [10–70]. During the latest consultation, 97.2% of patients received at least two types of treatments: first-tier analgesics (100%), topicals (83.3%), NSAIDs (69.4%), disease modifying osteoarthritis drugs (22,2%), second-tier analgesics (8.3%) and corticosteroid infiltrations (22.2%). Concerning beliefs, 69.4% of patients scored above 15 on the BMQ-S necessity subscale, with a mean score of 16.7 [10–22]. For BMQ-S concerns, the average score was 15.6 [9–23]. Side effects (69.4%) and dependence on treatment (50%) were the main concerns. The mean NCD was 1.1 [-11–10]. There was a significant negative association between educational level and BMQ-S necessity ($p = 0.02$). No statistically significant associations were observed between BMQ-S

necessity and VAS, comorbidity, disease duration, number of degenerative joint sites and number of prescribed medications. Similarly, no significant associations were found between NCD and the number of prescribed treatments, educational level and gender.

Conclusion: Our findings reveal a nuanced perspective among OA patients, characterized by a predominant conviction in the necessity of medications for health maintenance, juxtaposed with concerns about potential risks, particularly regarding side effects and treatment dependence. Understanding these nuanced insights is essential for tailoring patient-centered care in the effective management of OA.

P1335
EFZIMFOTASE ALFA IMPROVES SKELETAL MUSCLE SPARE RESPIRATORY CAPACITY IN A MOUSE MODEL OF HYPOPHOSPHATASIA

D. Devore[1], J. Ruanova[1], D. Dunn[1], W. Voegtli[1], M. Tarnopolsky[2], A. Petryk[1]

[1]Alexion, AstraZeneca Rare Disease, Boston, USA, [2]McMaster Institute for Research on Aging, Hamilton, ON, Canada

Objective: Hypophosphatasia (HPP) is a rare inborn error of metabolism caused by deficient alkaline phosphatase (ALP) enzyme activity and characterized by musculoskeletal manifestations, including muscle weakness. The mechanism underlying muscle weakness is poorly understood. We hypothesized that mitochondrial dysfunction contributes to muscle weakness independent of impaired bone mineralization in HPP and that the investigational ALP enzyme replacement therapy (ERT) efzimfotase alfa improves mitochondrial bioenergetics in a mouse model of HPP.

Methods: Skeletal muscle fiber bundles were isolated from age- and sex-matched wildtype and Akp2GW$^{-/-}$ mice (a model of HPP) treated with 2 mg/kg efzimfotase alfa or vehicle (phosphate buffer saline) subcutaneously every other day from postnatal day 3 to end of study (days 19–31). Oxygen consumption rate was analyzed in isolated muscle fiber bundles via Seahorse mitochondrial stress test and used to determine spare respiratory capacity (SRC). Bone mineralization was evaluated by x-ray in hind paw, femur, and tibia.

Results: SRC was reduced by 70% in vehicle-treated Akp2GW$^{-/-}$ mice compared with wildtype mice independent of bone mineralization. Efzimfotase alfa treatment significantly improved SRC in muscle fiber bundles of Akp2GW$^{-/-}$ mice to 107% of that of wildtype mice, a 257% increase relative to SRC in vehicle-treated Akp2GW$^{-/-}$ mice ($P = 0.0008$). The SRC improvement was similar in mice with and without radiographic evidence of impaired bone mineralization.

Conclusion: Efzimfotase alfa improved skeletal muscle SRC independent of bone mineralization in a mouse model of HPP. These data suggest potential benefits of treating muscle weakness in patients with HPP and warrant investigation of mechanisms of SRC impairment and benefits of ERT in HPP.

Disclosures:

DD, JR, DD, WV, and AP are employees of and may own stock/options in Alexion, AstraZeneca Rare Disease. MT is the President and CEO of Exerkine Corporation; the company has no patents or products in the HPP area.

P1336
IDENTIFICATION OF HUB GENES AND KEY PATHWAYS IN SARCOPENIA THROUGH BIOINFORMATICS ANALYSIS

W. W. Gui[1], C. P. Zhou[1], X. H. Lin[1]

[1]Dept. of Endocrinology and Metabolism, Sir Run Run Shaw Hospital, College of Medicine, Zhejiang Univ., Hangzhou, China

Objective: To identify hub genes and key pathways in sarcopenia through bioinformatics analysis of gene expression microarray data, which may explore new therapeutic targets for the treatment of sarcopenia.

Methods: Gene expression microarray data (GSE8479) related to sarcopenia were downloaded from the Gene Expression Omnibus (GEO) database. Differentially expressed analysis and weighted gene co-expression network analysis (WGCNA) were used to explore sarcopenia-related modules and hub genes. GO and KEGG pathway enrichment analysis were performed to explore the potential role of hub genes. Then the STRING online tool was utilized to create a protein–protein interaction (PPI) network, and the maximum clique centrality (MCC) method was employed to assess the hub genes within the interaction network. Additionally, a clinical prediction model was constructed. Finally, gene expression validation was performed using a sarcopenia mouse model.

Results: A total of 218 differentially expressed genes were identified, with 139 genes upregulated and 79 genes downregulated in sarcopenia. WGCNA analysis revealed that the blue module was most correlated with sarcopenia phenotype. GO enrichment analysis indicated that these intersection genes were mainly involved in biological processes such as "cellular respiration," "energy metabolism," and "enzyme activity." Additionally, KEGG enrichment analysis revealed their close association with signaling pathways related to "fatty acid metabolism" and "ATP metabolism." PKM, LDHA, TPI1, CYCS, and CDKN1A were identified to be hub genes in the network using PPI network and MCC analysis. After that, clinical models were constructed and was verified effective using ROC curves. A sarcopenia mouse model was successfully established, and qRT-PCR confirmed the increased expression of CDKN1A and decreased expression of TPI1 in the mouse model of sarcopenia.

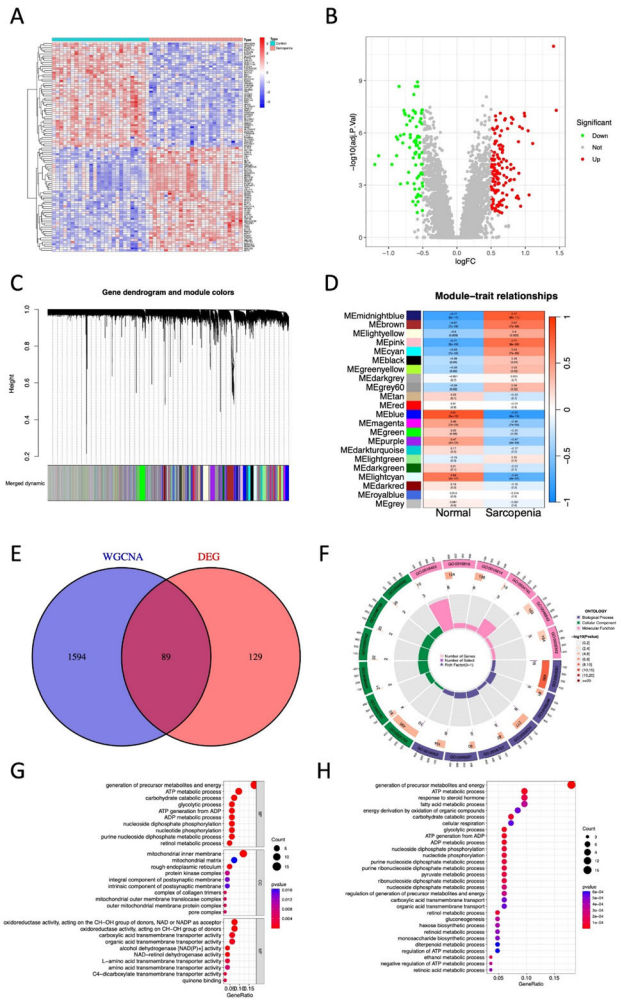

Figure 1. Genes differentially expressed between the sarcopenia and normal groups. (A) Heat map for differential expression analysis of GSE8479. (B) Volcanic map for differential expression analysis of GSE8479. Green represents downregulated genes, red represents upregulated genes, and black represents undifferentiated genes. (C) Dendrogram of all genes in the GSE8479 dataset was clustered on the basis of a topological overlap matrix (1-TOM). Each branch in the clustering represents a gene, while co-expression modules were constructed in different colors. (D) Module-trait heatmap of the correlation between the clustering gene module and sarcopenia in the GSE8479. (E) Venn diagram displayed 89 overlapping potential hub genes. (F) Circlize plot representing the GO analysis of differentially expressed genes. (G) GO enrichment analysis of hub genes. (H) KEGG pathway analysis of hub genes.

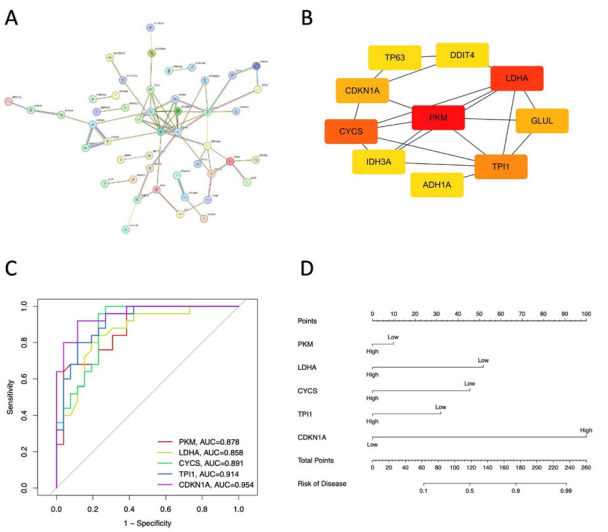

Figure 2. The construction of PPI network and clinical prediction model. (A) PPI network of hub genes. (B) The hub genes of the interaction network were obtained by MCC. (C) Nomogram model of hub genes. (D) ROC curves to assess the diagnostic efficacy of nomogram model and each hub gene.

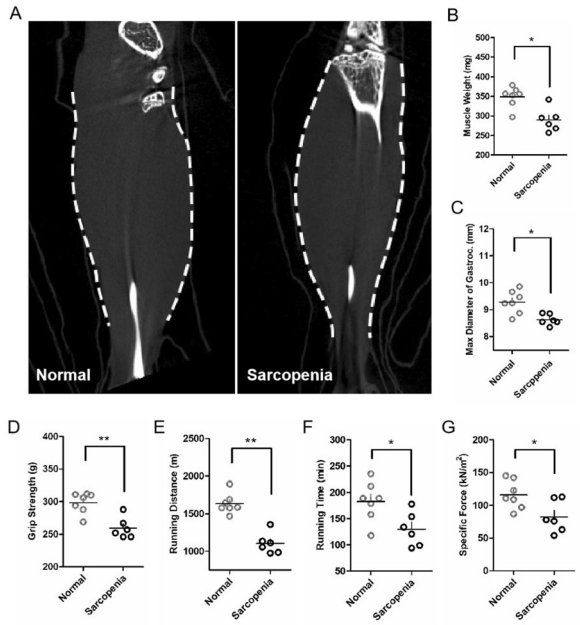

Figure 3. Phenotype identification of sarcopenia in aging mice. (A) μCT scanning of maximum diameter in the gastrocnemius muscle in aging mice and control young mice. (B) Average muscle weight between normal and sarcopenia mice. (C) Statistical analysis of diameter in the gastrocnemius muscle between normal and sarcopenia mice. (D) Statistical analysis of grip strength in sarcopenia mice compared to controls. (E) Treadmill test measuring average running distance in sarcopenia mice compared to controls. (F) Treadmill test measuring average running time in sarcopenia mice compared to controls. (G) Statistical analysis of gastrocnemius muscle contraction force in sarcopenia mice compared to controls using EMG.

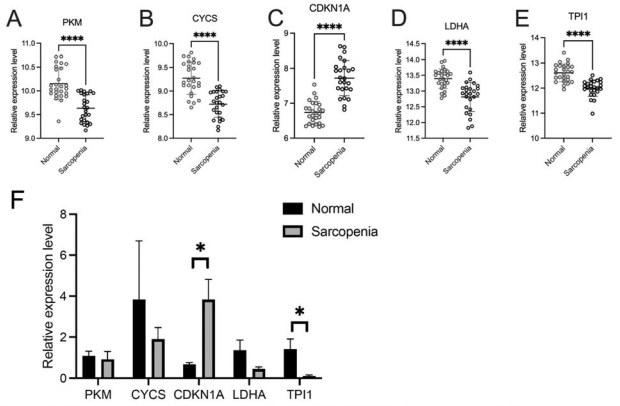

Figure 4. The expression of hub genes in GSE8479 and sarcopenia mouse model.

Conclusion: Through bioinformatics analysis of the GSE8479 dataset, it was revealed that the hub genes between sarcopenia and normal controls were mainly enriched in mitochondrial functional signaling pathways such as energy metabolism. A clinical prediction model was constructed using network hub genes, which may provide new therapeutic targets for sarcopenia.

P1337
ELEVATING OSTEOPOROSIS EDUCATION THROUGH MICROFILM-ENHANCED CASE-BASED LEARNING

W. Wei-Hsun[1]

[1]Changhua Christian Children's Hospital, Orthopaedic Dept., Changhua, Taiwan

Osteoporosis education plays a critical role in equipping healthcare professionals with the knowledge and skills necessary for effective patient care and management. Traditional didactic methods have limitations in engaging learners and preparing them for the intricacies of clinical practice. This abstract explores the transformative potential of microfilm technology in enhancing case-based learning within the context of osteoporosis education.

Microfilms offer an innovative approach to learning, blending visual storytelling with real-world scenarios to create an immersive and interactive educational experience. Through this technology, learners can engage with authentic patient cases, simulating clinical encounters that challenge their diagnostic and treatment decision-making abilities. The abstract examines the principles and methodologies for integrating microfilms into osteoporosis education and emphasizes the benefits that stem from this approach.

The use of microfilms in osteoporosis education not only deepens learners' understanding of the condition but also cultivates critical thinking and problem-solving skills essential in clinical practice. Moreover, it encourages active participation and collaborative learning, fostering a sense of teamwork and shared responsibility among healthcare professionals.

However, successful implementation of microfilms in osteoporosis education also raises questions and potential challenges, including the need for accessible technology, copyright considerations, and the development of engaging microfilm content. This abstract critically evaluates these aspects, shedding light on the strategies that can mitigate these challenges.

In conclusion, the incorporation of microfilms in osteoporosis education is a promising and dynamic approach that holds the potential to revolutionize the way healthcare professionals are trained in this field. By bridging the gap between theoretical knowledge and practical application, microfilm-enhanced case-based learning emerges as a powerful tool for fostering competency and excellence in osteoporosis management, ultimately leading to improved patient outcomes and quality of care.

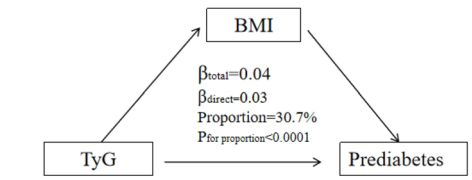
P1338
TRIGLYCERIDE-GLUCOSE INDEX, BODY MASS INDEX AND PREDIABETES: A SECOND ANALYSIS OF A POPULATION-BASED STUDY

W. Zhangxin[1]

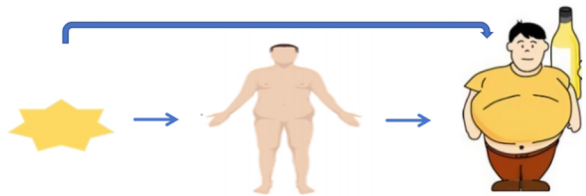
[1]Zhuzhou Hospital of Xiangya School of Medicine, Hunan, China

Objective: The triglyceride-glucose (TyG) index is a predictor of diabetes; however, Evidence and to what extent the TyG index is associated with prediabetes (Pre-DM) through BMI is unclear. Therefore, this study aimed to explore the complex association of the TyG index and BMI with Pre-DM using a cohort design.

Methods: This study was a cross-sectional study that enrolled 100,069 Chinese adults in a Chinese hospital from January 2010 to December 2014. Logistic regression model, generalized additive model (GAM), smooth curve fitting and a series of sensitivity analyses was used to evaluate the association between TyG index and Pre-DM. In order to determine whether BMI mediated the association between TyG index and Pre-DM, a mediation analysis was performed.



Mediation effect of BMI between TyG index and prediabetes



Results: During a maximum follow-up of 6.0 y, The prevalence of Pre-DM was 12.3%. After adjusting covariates, the results showed that TyG index was positively associated with Pre-DM ((OR = 2.1, 95%CI 2.0–2.1). In addition, the TyG index level has a non-linear relationship with the incidence of Pre-DM. And the sensitive analysis demonstrated the robustness of the results. Subgroup analysis showed a stronger association between TyG index and Pre-DM in females and the population with age $\leq$ 60 y, BMI $\leq$ 24 kg/m^2. Both the TyG index and BMI level were significantly associated with Pre-DM, BMI significantly mediated 30.7% of the associations between the TyG index and Pre-DM.

Conclusion: This study demonstrates a positive and non-linear relationship between TyG index and Pre-DM in Chinese people. The combination of a higher TyG index and higher BMI was associated with the highest risk of prediabetes. BMI could mediate the association between the TyG index and Pre-DM.

P1339
ENHANCING OSTEOPOROSIS CARE IN RURAL SETTINGS: A COMPREHENSIVE INTERVENTION APPROACH AND ITS IMPACT ON TREATMENT RATES

W.-J. Lai[1], S.-H. Fu[2], C.-Y. Wang[3]

[1]School of Medicine, China Medical Univ., Taichung, Taiwan, [2]Dept. of Orthopedics, National Taiwan Univ. Hospital Yun-Lin Branch, Douliu, Taiwan, [3]National Center for Geriatrics and Welfare Research, National Health Research Institutes, Douliu, Taiwan

Objective: To evaluate the impact of a comprehensive intervention on enhancing both the hospital arrival and treatment rate of anti-osteoporosis medication (AOM) within a rural community.
Methods: In this randomized controlled trial, 567 patients were allocated to three groups: Comprehensive Care (CC), Osteoporosis Care Only (OC), and Delayed Care (DC). The CC and OC groups received five interventions, encompassing professional and specialist support, increasing disease awareness, transportation assistance, peer support, and case management; the DC group received only the first two interventions.
Results: In the CC group, 73.3% (85 individuals) of the 116 participants recommended for hospital treatment successfully arrived, with 58.6% (68 individuals) receiving AOM. Conversely, in the DC group, only 4.1% (6 individuals) out of 146 recommended for hospitalization reached the hospital and received AOM after screening. Significantly divergent proportions were observed between the CC and DC groups concerning hospital arrival ($P < 0.001$) and AOM receipt ($P < 0.01$). Similar significant outcomes were noted in the OC group in comparison with DC group. In the OC group, 81% (124 individuals) of the 153 recommended for hospitalization arrived after intervention, and 69.3% (106 individuals) received AOM. The results were also significant when compared to the DC group ($P < 0.001$, $P < 0.001$, respectively).
Conclusion: The findings underscore the imperative for a comprehensive intervention to enhance osteoporosis treatment rates in rural regions. The notable increase in hospital arrival and treatment rates observed in both the CC and OC groups contrast with those in the DC group. These results emphasize the significance of incorporating healthcare professionals and specialists, increasing disease awareness, and offering supportive measures to facilitate rural patients in accessing healthcare services.

SUBSEQUENT FRACTURES IN POSTMENOPAUSAL WOMEN WITH FRAGILITY FRACTURES: INCIDENCE AND PATIENT CHARACTERISTICS FROM SIX EUROPEAN COUNTRIES

X. Chen[1], T. Rathod-Mistry[1], G. Fabiano[1], A. Moayyeri[2], J. Warden[2], C. Reyes[3], J. Brash[4], K. Verhamme[5], M. Mosseveld[5], S. Seager[4], R. Pinedo-Villanueva[1], E. H. Tan[1]

[1]Nuffield Dept. of Orthopaedics, Rheumatology and Musculoskeletal Sciences, Univ. of Oxford, Oxford, UK, [2]UCB Pharma, Slough, UK, [3]Fundació Institut Universitari per a la recerca a l'Atenció Primària de Salut Jordi Gol i Gurina, Barcelona, Spain, [4]IQVIA, London, UK, [5]Erasmus Univ. Medical Center, Rotterdam, Netherlands

Objective: To report the 2-y incidence of subsequent fracture in, and patient characteristics of, postmenopausal women with fragility fractures, using real-world data from six European countries.
Methods: A retrospective observational network cohort study was conducted using primary care databases from the UK (UK; CPRD), Germany (IQVIA DA), the Netherlands (IPCI), France (LPD), Italy (LPD) and Spain (SIDIAP). Databases were mapped to the OMOP Common Data Model. Women aged ≥ 50 y with an index fracture between April 2010 to April 2018 and ≥ 730 d observation period prior to the index fracture were eligible; women with a fracture < 730 d before index fracture were excluded. Incidence rate (IR) of subsequent fracture in the two years after index and cumulative incidence at the same and different fracture sites were estimated, accounting for death as competing risk. Patient characteristics were also recorded.
Results: Data were collected from 349,434 patients in total. IR varied between the six countries (IR per 1000 person-years [95%CI]; UK: 114.0 [111.7, 116.3], Spain: 142.0 [140.6, 143.4], the Netherlands: 164.2 [159.1, 169.5], Germany: 193.1 [190.9, 195.3], France: 202.2 [196.1, 208.5], Italy: 320.8 [314.6, 327.1]). Subsequent fractures most commonly occurred at the site of the index fracture. A higher proportion of patients with subsequent fracture than without had cardiovascular disease (CVD), rheumatoid arthritis, and use of medications including osteoporosis drugs, a trend generally seen across all countries excluding Spain (Table). In patients with a subsequent fracture, the proportion receiving osteoporosis medication at the index fracture date varied across countries (UK: 2.5%, the Netherlands: 2.9%, Spain: 5.8%, Germany: 13.2%, Italy: 13.7%, France: 15.9%).

Table. Patient characteristics of women aged ≥50 years with an index fracture with or without subsequent fracture in six European primary care databases

Patient characteristics for those with subsequent fractures are with reference to their first fracture date. Percentages of the mutually exclusive age groups may not add to 100% due to rounding. CPRD: Clinical Practice Research Datalink; DA: Disease-Analyser; IPCI: Integrated Primary Care Information; LPD: Longitudinal Patient Database; SIDIAP: Information System for Research in Primary Care.

Conclusion: There was considerable variation in IR of subsequent fracture between six large European countries, with IR being highest in Italy and lowest in the UK. Patients with subsequent fractures had higher rates of comorbidities and comedications. Identifying characteristics of these patients may prevent subsequent fracture and reduce the associated healthcare burden.

MUSCLE-SPECIFIC IGF2 KNOCKOUT INDUCE SARCOPENIA AND MUSCLE FUNCTIONAL DECLINE IN MICE

X. H. Lin[1], C. P. Zhou[1], G. L. Wang[2], W. W. Gui.[1]

[1]Dept. of Endocrinology and Metabolism, Sir Run Run Shaw Hospital, College of Medicine, Zhejiang Univ., [2]Dept. of

Orthopedics, Sir Run Run Shaw Hospital, College of Medicine, Zhejiang Univ., Hangzhou, China.

Objective: IGF2 is closely associated with the occurrence and development of primary and secondary muscle atrophy. This study investigates the role of IGF2 deficiency in inducing muscle atrophy using muscle-specific *Igf2* knockout mice, aiming to provide theoretical basis and new concepts for growth hormone supplementation therapy in muscle atrophy.

Methods: The expression profile of *Igf2* was analyzed using the Tabula Muris single-cell database. Muscle-specific *Igf2* knockout mouse models were constructed using the *Cre/LoxP* system and muscle-specific *Mck-cre* transgenic mice. Genotype identification and phenotype characterization were performed. The size and mass of the gastrocnemius muscle were observed through external morphology, dissection weighing, and HE staining. μCT scanning was conducted to assess muscle size, mass density, and maximum diameter. Electromyography (EMG) was used to measure gastrocnemius muscle contraction force, while the Md3000 animal grip strength meter was employed to evaluate grip strength. Treadmill tests were conducted to assess running endurance distance and time in both groups of mice. Finally, muscle tissue samples were subjected to transcriptome sequencing to observe the effects of *Igf2* deletion on downstream target genes, functional enrichment, and signaling pathways.

Results: The Tabula Muris single-cell database showed high expression of *Igf2* in limb muscle. We successfully constructed and identified muscle-specific *Igf2* knockout mice ($Mck^{+}Igf2^{fl/fl}$). μCT scanning and HE staining of the gastrocnemius muscle revealed a decrease in size, weight, density, maximum diameter, and average diameter in the knockout group compared to the control littermates. Electromyography measurements showed reduced gastrocnemius muscle contraction force in the $Mck^{+}Igf2^{fl/fl}$ group compared to the control group. Grip strength measurements using the Md3000 animal grip strength meter indicated weakened grip strength in the $Mck^{+}Igf2^{fl/fl}$ group. Treadmill tests demonstrated decreased running endurance distance and time in the $Mck^{+}Igf2^{fl/fl}$ mice. The results of transcriptome sequencing GO enrichment analysis showed that the functional differences in the two groups of mice were mainly enriched in muscle system process, RNA polymerase II transcription regulation, and the PI3K signaling pathway.

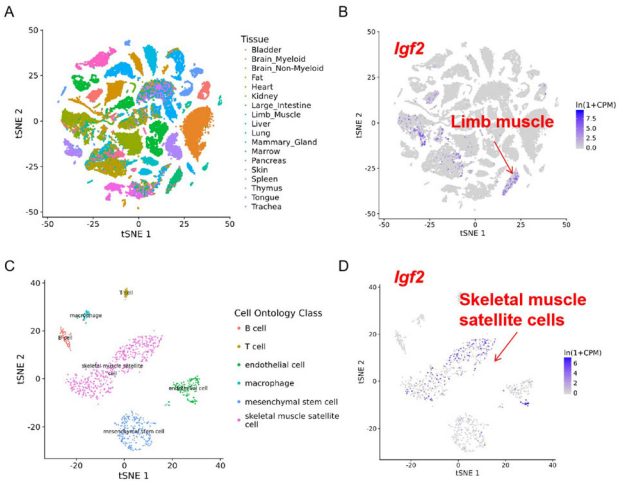

Figure 1. The results of Tabula Muris single-cell sequencing showed abundant expression of *Igf2* in skeletal muscle tissue. A. The tSNE visualization analysis of the first-level clustering of 20 organ single-cell transcriptome sequencing results from the Tabula Muris database. B. Distribution of *Igf2* in 20 organs. C. The tSNE visualization analysis of the second-level clustering of limb-muscle tissue samples. D. Enriched distribution of *Igf2* in the satellite cells of skeletal muscle subgroups.

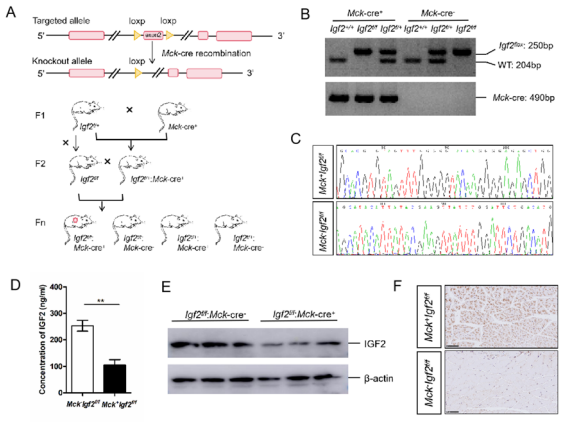

Figure 2. Mouse muscle-specific *Igf2* knockout strategy and identification. A. Schematic diagram of the construction of muscle-specific *Igf2* knockout mouse model ($Mck^{+}Igf2^{fl/fl}$). B. DNA genotype identification results of $Mck^{+}Igf2^{fl/fl}$ mice. C. DNA genotype identification gel electrophoresis sequencing results of $Mck^{+}Igf2^{fl/fl}$ mice. D. Determination of IGF2 concentration in skeletal muscle tissue of $Mck^{+}Igf2^{fl/fl}$ mice. E. Western blot analysis of IGF2 protein content in skeletal muscle tissue of $Mck^{+}Igf2^{fl/fl}$ mice. F. Immunofluorescence detection of IGF2 content in skeletal muscle of $Mck^{+}Igf2^{fl/fl}$ mice.

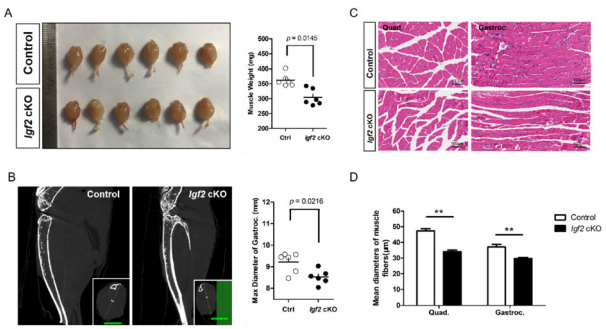

Figure 3. Phenotype identification of muscle atrophy in muscle-specific *Igf2* knockout mice. A. Overall appearance of gastrocnemius muscle in $Mck^{+}Igf2^{fl/fl}$ mice compared to control littermates. B. μCT scanning and statistical analysis of maximum diameter in the gastrocnemius muscle. C. Representative results of HE staining of gastrocnemius muscle and quadriceps muscle sections in $Mck^{+}Igf2^{fl/fl}$ mice and control mice. D. Statistical analysis of average diameter in the gastrocnemius muscle and quadriceps muscle of $Mck^{+}Igf2^{fl/fl}$ mice and control mice.

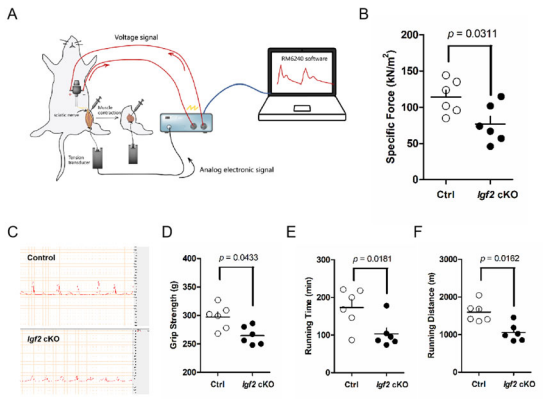

Figure 4. Functional identification of muscle in muscle-specific *Igf2* knockout mice. A. Schematic diagram of electromyography (EMG) measurement of gastrocnemius muscle contraction force. B. Statistical analysis of gastrocnemius muscle contraction force in $Mck^{+}Igf2^{fl/fl}$ mice compared to control littermates using EMG. C. Grip strength measurement using the Md3000 animal grip strength meter in both groups of mice. D. Statistical analysis of grip strength in $Mck^{+}Igf2^{fl/fl}$ mice compared to control littermates. E. Treadmill test measuring average running time in $Mck^{+}Igf2^{fl/fl}$ mice compared to control littermates. F. Treadmill test measuring average running distance in $Mck^{+}Igf2^{fl/fl}$ mice compared to control littermates.

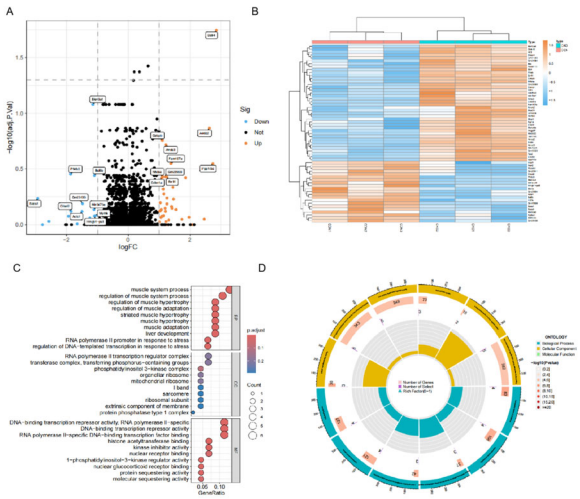

Figure 5. Transcriptome sequencing of skeletal muscle samples from muscle-specific *Igf2* knockout mice and control mice. A. Volcano plot showing the differentially expressed genes between the two groups of mice in the transcriptome sequencing. B. Heatmap displaying the top 50 differentially expressed genes identified in the transcriptome sequencing. C. Bubble plot illustrating the Gene Ontology (GO) functional enrichment analysis of differentially expressed genes. D. Circlize plot representing the GO analysis of differentially expressed genes.

Conclusion:*Igf2* is highly expressed in skeletal muscle tissue. Muscle-specific *Igf2* knockout mice exhibited reduced muscle size, weight, and density, weakened grip strength, decreased gastrocnemius muscle contraction force, and reduced running endurance distance and time. These findings suggest that IGF2 regulates muscle system processes through RNA polymerase II transcription and provide evidence that IGF2 supplementation may be a potential effective strategy for treating muscle atrophy.

P1342
RELATIONSHIP BETWEEN THE PRESENCE OF OSTEOPOROTIC FRACTURES AND SERUM ADIPONECTIN CONCENTRATION IN PATIENTS WITH RHEUMATOID ARTHRITIS

Y. Akhverdyan[1], B. Zavodovsky[1], E. Papichev[1], Y. Polyakova[1], L. Seewordova[1]

[1]Federal State Budgetary Institution «Research Institute of Clinical and Experimental Rheumatology named after A. B. Zborovsky», Volgograd, Russia

Objective: To study the possibility of predicting bone fractures in patients with rheumatoid arthritis (RA) and osteoporosis (OP) by determining the concentration of adiponectin (Ad) in the blood serum of patients.

Methods: We observed 109 patients diagnosed with RA, whose average age was 54.6 y [21.3–74.2], of which 93 (85.37%) were women and 16 (14.7%) men. According to the degree of RA activity, patients were distributed as follows: with activity 0 (DAS28 < 2.6)—19 people (17.43%), with low activity degree I (2.6 < DAS28 < 3.2)—26 people (23.85%), with an average degree of activity II (DAS28 ≥ 3.2—5.1)—57 people (52.29%), with a high degree of activity III (DAS28 > 5.1) there were 7 patients (6.42%). BMD assessment was performed using DXA.

Results: Depending on the presence of a diagnosis of OP, a group of patients with RA with AP (63 people) and a group of patients with RA without OP (46 patients) were identified. Patients were also divided into a group with a history of osteoporotic fractures (34 patients) and without fractures (75 patients). In patients with RA suffering from OP, the blood pressure level was significantly higher than in patients without OP (62.136 ± 24.541 and 35.672 ± 21.803 μg/ml, F = 12.46824, p = 0.00045). When comparing the Ad level of patients in the group with osteoporotic fractures (57.239 ± 31.932 μg/ml) with the group of patients without fractures (39.968 ± 23.279 μg/ml), a tendency towards an increase in Ad in patients with fractures was found, but it was not significant (p = 0. 0534). It was found that an increase in Ad concentration was associated with a decrease in CRP concentration (r =—0.2933, p = 0.0055) and an increase in ACCP (r = 0.3232, p = 0.0021).

Conclusion: In RA complicated by OP, an increase in the concentration of Ad is observed in the blood serum of patients. In the presence of pathological bone fractures in patients with RA, there is a tendency to increase blood serum blood pressure levels. There is a weak negative relationship between the concentration of Ad and CRP, and a weak positive relationship between Ad and ACCP.

P1343
MOBILITY OUTCOMES AFTER HOME- BASED AND INPATIENT REHABILITATION FOR LOWER LIMB FRACTURES IN A GERIATRIC POPULATION

Y. C. Ngui[1], G. M. Rajakaruna[1], C. Wickramasinghe[1], N. Andraweera[1]

[1]Dept. of Rehabilitation, Division of Aged Care, Rehabilitation, and Palliative Care, Modbury Hospital, Northern Adelaide Local Health Network, South Australia, Adelaide, Australia

Objective: Lower limb fractures remain a major public health concern in the geriatric population. We compared mobility outcomes after in-patient and home-based rehabilitation for lower limb fractures among geriatric patients.

Methods: Data from 81 patients admitted to Modbury Hospital home based rehabilitation services in South Australia were assessed. Falls risk scores and mini nutritional assessment scores were assessed on admission. Functional Independence Measure (FIM), de Morton Mobility Index (DEMMI) and Timed Up and Go (TUG) tests were performed on all patients at the time of admission and at discharge. Change in FIM, DEMMI and TUG scores between admission and discharge were calculated. The t-test was used to compare the mean differences between patients who had home based rehabilitation (n = 43) and those who had both inpatient and home-based rehabilitation (n = 43). Results were reported as mean ± SD (standard deviation). P value ≤ 0.05 was considered statistically significant.
Results: Of the 81 patients, 48 (59.2%) had fracture neck of femur. There were no significant differences between patients who underwent home based rehabilitation and those who underwent both inpatient and home-based rehabilitation in terms of age (80.3 ± 7.9 vs. 79.4 ± 8.7, p = 0.6), falls risk (3.3 ± 0.3 vs. 3.2 ± 0.4, p = 0.9) or mini nutritional assessment score (10.1 ± 0.7 vs. 10.1 ± 0.4, p = 0.9). There was no significant difference between patients who had home based rehabilitation compared to those who had both inpatient and home-based rehabilitation in change in FIM (6.8 ± 1.3 vs. 4.7 ± 2.3, p = 0.4), DEMMI (10.8 ± 2.2 vs. 9.8 ± 1.6, p = 0.7) or TUG scores (9.0 ± 4.3 vs. 7.5 ± 2.4, p = 0.7).
Conclusion: Older adults with lower limb fractures who received rehabilitation in the home had similar mobility outcome gains as those who received additional inpatient rehabilitation. Home-based rehabilitation alone may represent an effective alternative for treating older patients with lower limb fractures. Larger studies are required to validate these findings.

P1344
FALL RISK, FEAR OF FALLING AND FALL EFFICACY AFTER FRAGILITY HIP FRACTURE: WHAT SHOULD OCCUPATIONAL THERAPISTS PAY ATTENTION?

Y. Chan[1], C. Y. Chu[1], Y. K. Tan[1], S. T. Yip[1], N. F. Lui[1], K. L. Tiu[2], K. B. Lee[2], K. K. Li[2]

[1]Occupational Therapy Dept., Queen Elizabeth Hospital, [2]Dept. of Orthopedics & Traumatology, Queen Elizabeth Hospital, Hong Kong, Hong Kong SAR China

Objective: Fragility hip fracture (FHF), one of the common severe injuries of elderly after fall incident, is expected to increase under global ageing. Fear of falling (FoF) and actual falls are both strong predictors to FHF. Addressing fall risk and fall efficacy could be the strategies for secondary fall prevention through this lens. This study evaluates fall risk and fall efficacy among elderly with FoF following hip fracture.
Methods: Hip fracture patients, who aged 65 or above, attended Fragility Fracture Clinic between January 2018 to November 2023 were included in this retrospective study. The result of self-reported FoF was self-reported, by results all subjects were categorized into: Group A (with FoF) and Group B (without FoF). Fall risk and self-efficacy in daily activities for both two groups were measured by Fall Risk Assessment Test (FRAT) and Fall Efficacy Scale (FES), higher score means higher risk and better confidence respectively.
Results: 761 patients were included with mean age 82.4. Majority of patients (63.4%) had FoF. Total scores were categorized into three risk extents in FRAT: Low, Medium and High. 68.2% patients were classified in Low, 17.5% in Medium and 14.3% in High Risk. There was statistically significant difference in FRAT total score between two groups, which Group A had higher total score than B. Risk factors in FRAT: recent fall ($p < 0.01$), medication (p = 0.034) and psychological(p = 0.02), showed statistically significant differences between two groups, Group A scored higher than B. Patients with FoF might have higher fall tendency. Among the patients, 173 patients (76% with FoF; 23.8% without FoF) were assessed by FES. Mean FES score in Group A was 54.4 while Group B was 78.9. In Group A, 55.2% patients were classified as High Risk in FRAT with mean FES score 54.7. Group A might tend to have lower self confidence in fall prevention with higher actual fall risk than Group B. 12.7% patients reported no FoF with higher self-efficacy (FES mean score 77.7) was classified into High Risk, which indicated that they might not have clear perception towards their functional capacity.
Conclusion: Patients with FoF tended to have higher fall risk and lower self-efficacy. A proportion of elderly might have poor judgment in preventing falls. Education on self-management and fall prevention to elderly is paramount but challenging. Occupational therapists could address elderly's awareness to reduce fall incident.

P1345
DARIER ROUSSY DISEASE ASSOCIATED WITH OSTEOARTICULAR SARCOÏDOSIS: A CASE REPORT

S. Derbal[1], S. Agoubi[1], D. Chebbi[1], O. Hentati[1], F. Ben Dahmen[1], M. Abdallah[1], Y. Cherif[1]

[1]Univ. Tunis El Manar, Dept. of Internal Medicine, Regional Hospital of Ben Arous, Ben Arous, Tunisia

Sarcoidosis is a systemic granulomatous disease that usually affect the lungs and lymph nodes. Osteoarticular involvement which remains rare.
Case report: A 57-year-old patient with a medical history of mellitus diabetes consulted for painless swelling of the left stylus-radial joint and the first left phalanx since 6 months. The physical examination showed subcutaneous painless and mobile nodules on the posterior surface of the left forearm, consistent with the nodules of Darier Roussy. The joint, pleuropulmonary and ophthalmological examination was normal. The x-ray of the hand shows micro geodes and the joint ultrasound reveals bilateral synovitis without bone erosion. Chest CT scan reveals peri-lymphatic pulmonary micronodules with bilateral mediastinal and hilar adenomegaly and left axillary adenomegaly. The blood count, serum calcium, CRP and the rest of the assessment were normal except hypercalciuria at 8.12 mmol/24 h. Spirometry is normal and bronchoalveolar lavage showed lymphocytic fluid. The dosage of the converting enzyme was at 77 U/l. Pathological examination of the synovial biopsy of the left wrist revealed epithelioid and gigantocellular granulomas without caseous necrosis. The intradermal reaction to tuberculin was anergic with a negative search for BK in the sputum. The diagnosis of synovial and mediastino-pulmonary sarcoidosis with Darier Roussy disease is then made. The patient was treated with Plaquenil with disappearance of the subcutaneous nodules.
Conclusion: This case is interesting due to the presence of two rare manifestations of sarcoidosis: Darier Roussy nodules and asymmetrical synovial lesions. Pathological examination remains essential to make the diagnosis.

P1346
OSTEO-ARTICULAR TUBERCULOSIS IN ANTISYNTHETASE SYNDROME

S. Derbal[1], D. Chebbi[1], O. Hentati[1], Y. Cherif[1], F. Ben Dahmen[1], M. Abdallah[1]

[1]Univ. Tunis El Manar, Dept. of Internal Medicine, Regional Hospital of Ben Arous, Ben Arous, Tunisia

Rituximab (RTX) had already been effective in inflammatory myopathies with no response to conventional treatments, but it also induces depletion of B lymphocyte cells. This increases the risk of infection.
Case report: It's a 32-year-old patient with antisynthetase syndrome with muscular, pulmonary and false-route involvement and anti-JO1 antibodies. The patient was put on high-dose corticosteroids, immunoglobulin and an immunosuppressant. The patient's muscle damage remained resistant, and she was put on RTX after a pre-therapeutic workup including a negative interferon-y release test. The patient continued to have osteoarticular flare of the wrist and tenosynovitis of the hand, followed by arthritis of the ankles. Joint involvement was migratory and resistant to corticosteroids. She also described fluctuating fever. She was admitted with a right shoulder joint tumefaction. She had a biological inflammatory syndrome. The shoulder's MRI showed a fistulous subcutaneous collection in the subacromial bursa. Joint puncture revealed a purulent fluid with positive tuberculosis PCR. The patient underwent surgical treatment in association with anti-tuberculosis therapy. Anatomo-pathological study confirmed the presence of a gigantic cell granuloma with caseous necrosis.
Conclusion: Tuberculosis of the osteoarticular system is rare, and tendon involvement is exceptional. The contribution of the interferon-y release test is not always sensitive in this location.

P1347
CRYPTOCOCCUS INFECTION AND SARCOÏDOSIS: A CASE REPORT

S. Derbal[1], D. Chebbi[1], O. Hentati[1], Y. Cherif[1], F. Ben Dahmen[1], M. Abdallah[1]

[1]Univ. Tunis El Manar, Dept. of Internal Medicine, Regional Hospital of Ben Arous, Ben Arous, Tunisia

Cryptococcosis is a fungal infection caused by Cryptococcus neoformans or Cryptococcus gattii, involving patients with immunocompromising factors, such as human immunodeficiency virus, malignancies, transplantation and use of immunosuppressing drugs. Osteoarticuar involvement is uncommon but more frequent with sarcoïdosis. Patients with sarcoidosis are vulnerable to cryptococcosis even if they weren't on immunosuppressing treatment.
Case report: A 43-year-old woman how was flowed since 4 y for systemic sarcoïdosis with heart, pulmonary, lymph nodes and hematological involvement. She was on corticosteroid and methotrexate. The immunosuppressing drug was prescribed for a progressive and symptomatic interstitial lung disease. Eighteen months later, she had several cutaneous abscesses of the left lower limb. The histopathology exam and the fungal culture confirms a Cryptococcus Neoformans infections. She had topic treatment without clinical improvement. She was admitted for fever and painful subcutaneous lumber swelling. The tomography and the MRI confirm subcutaneous and paravertebral abscess without other organ involvement. She underwent urgent chirurgical treatment. The laboratory test fungal culture confirms Cryptococcus Neoformans paravertebral infections. Corticosteroid and methotrexate had been discounted. Che received anti-fungal systemic treatment with good outcome.
Conclusion: The association between sarcoidosis and Cryptocosis infections has been already descripted. This association may be due to the low CD4 T-cell count associated with sarcoidosis.

P1348
SECONDARY PSEUDOMYOPATHY DURING TERTIARY HYPERPARATHYROÏDISM

S. Derbal[1], S. Agoubi[1], D. Chebbi[1], O. Hentati[1], F. Ben Dahmen[1], M. Abdallah[1], Y. Cherif.[1]

[1]Univ. Tunis El Manar, Dept. of Internal Medicine, Regional Hospital of Ben Arous, Ben Arous, Tunisia

Acquired myopathy is an inflammatory clinico-pathological entity which can result of endocrine disorders. Thyroid, parathyroid, and even adrenal dysfunction can cause muscle damage through alteration of muscle cell metabolism.
Case report: A 49-year-old patient with medical history of arterial hypertension, chronic renal failure at the hemodialysis stage, complained of myalgia of both hips with progressive impotence, bilateral knee arthralgias and dysphagia to solids for 3 months. The examination found diffuse spontaneous and provoked myalgia with a bilateral and symmetrical proximal muscle deficit with positive comb and stool signs. The rest of the examination was unremarkable. Biological tests showed normocytic anemia, hypercalcemia at 3.65 mmol/l. All the rest of tests, particularly CPK and LDH and protein electrophoresis, were normal. MRI of the pelvis confirmed the presence of myopathy localized in the right adductor muscles in association with left trochanteric bursitis. Antinuclear antibodies were positive at 1/80 with a homogeneous appearance. The myositis kit, anti-ENA antibodies, anti-native DNA, rheumatoid factor and anti-CCP are all negative. The TSH and FT4 dosage was normal but a PTH was elevated at 2265 pg/ml. The diagnosis of endocrine secondary pseudomyopathy due to tertiary hyperparathyroidism was made. A subtotal parathyroidectomy was planned.
Conclusion: This case highlights secondary endocrine pseudomyopathy. Careful examination could guide the diagnosis which would be easy if the muscular manifestations occur, but much more delicate if they initiate the disease.

P1349
DYSTROPHIC KYPHOSCOLIOSIS IN NEUROFIBROMATOSIS TYPE I: A NEW CASE

M. Timoumi[1], S. Derbal[1], D. Chebbi[1], O. Hentati[1], F. Ben Dahmen[1], M. Abdallah[1], Y. Cherif[1]

[1]Univ. Tunis El Manar, Dept. of Internal Medicine, Regional Hospital of Ben Arous, Ben Arous, Tunisia

Neurofibromas are benign neural tumors deriving from the peripheral nerve sheath which are classified into three types of neurofibromatosis: neurofibromatosis 1 (NF1) previously known as von Recklinghausen disease, neurofibromatosis 2 (NF2) and schwannomatosis. NF1 is usually diagnosed in childhood, while NF2 and schwannomatosis are usually diagnosed in early adulthood. We will present the case of a 57 years old woman with NF1 with extensive dystrophic kyphoscoliosis.
Case report: The patient with a history of asthma for 20 y, cerebral ischemic stroke, mellitus diabetes, poorly balanced arterial hypertension, was admitted to the department of Internal Medicine for vitamin B12 deficiency which was discovered in the presence of macrocytosis without anaemia, associated with tingling paresthesia in

the 2 lower limbs. The anti-parietal cell and intrinsic factor antibodies were positive but there was no evidence of bulbar atrophy on gastric endoscopy. The disease started in childhood at the age of 4 y with the appearance of multiple pigmentary macules, gonadotropic and corticotropic insufficiency and delayed stature-weight, extensive kyphoscoliosis with advanced right convexity and vertebral rotary subluxation, dehiscence of the left occipital bone with ectasia and protrusion of the sigmoid sinus. However, the neurological examination did not reveal seizures, or signs of spinal cord compression or other neurological abnormalities. The patient suffered also from osteoporosis and hypovitaminosis D. All investigations of arterial hypertension especially of pheochromocytoma were negative. Cardiac and arterial ultrasound showed pulmonary arterial hypertension at 42mmhg with partially thrombosis of the right internal carotid artery aneurysm. Furthermore, the search of associated neoplasia was negative. Because of the extensive skeletal abnormalities, she did not underwent surgical procedure.

Conclusion: NF1 is considered as a multisystem disorder requiring management by multiple disciplines since it has dermatological, cardiovascular, endocrine, gastrointestinal, and orthopedicosteo-articular features. Skeletal abnormalities may be disabling. Therefore, medical interventions may improve the quality of life of patients.

P1350
LATE ONSET PAGET DISEASE OF PELVIC BONE IN ELDERLY: A CASE REPORT

S. Derbal[1], M. Timoumi[1], D. Chebbi[1], O. Hentati[1], F. Ben Dahmen[1], M. Abdallah[1], Y. Cherif[1]

[1]Univ. Tunis El Manar, Dept. of Internal Medicine, Regional Hospital of Ben Arous, Ben Arous, Tunisia

Paget disease of bone is usually diagnosed by accidental finding of osteolytic lesion. Nevertheless, it is crucial to differentiate the disease from metabolic and metastatic bone disorders in elderly patients.

Case report: An 88-year-old woman with a personal history of arterial hypertension, mellitus diabetes and osteoporosis was admitted to the department of internal medicine for sicca syndrome. The physical examination revealed arthralgias and bilateral pelvic pain. No other physical abnormalities were noticed. The blood chemistry results showed only mild elevation of alkaline phosphatase. The pelvic plain film showed asymmetric cortical thickening, sclerosis with coarsened trabeculae, in the pelvic bone. Thes lesions prevailed in the left site. Considering the image results clinical symptoms, the patient was diagnosed of asymptomatic Paget's disease without extended bone involvement. There was no evidence for bone metastasis. The patient was followed in the outpatient department with no fracture or other deformity.

Conclusion: Paget's disease and metastatic bone disorders shared similar clinical and laboratory features in elderly. The doctor might ensure accurate diagnosis of Paget's disease to prevent further extensive bone lesions and their poor outcomes.

P1351
SARCOIDOSIS AND CALCIUM HOMEOSTASIS DISTURBANCES: A RETROSPECTIVE STUDY

S. Derbal[1], D. Chebbi[1], Y. Cherif[1], O. Hentati[1], F. Ben Dahmen[1], M. Abdallah[1]

[1]Univ. Tunis El Manar, Dept. of Internal Medicine, Regional Hospital of Ben Arous, Ben Arous, Tunisia

Objective: Sarcoidosis is a systemic granulomatous disease. Hypercalcemia remains rare during sarcoidosis, in 10% of patients approximately. It is often not threatening. And transient. Hypercalciuria is much more common. It may affect 40–65% of patients. Increase production of 1,25-dihydroxyvitamin D3 is the main cause of calcium homeostasis disorders in sarcoidosis.

Methods: It's a retrospective single-center study. We included all patients followed for systemic sarcoidosis from January 2016 to December 2023. Epidemiological, clinical, biological, pathological, imaging and evolving data were reviewed from the patient files.

Results: We included 85 patients followed for sarcoidosis. Disorders of calcium metabolism were documented in 17.64% of patients. They were 13 women and two men. The mean age was 52.8 y. Mediastinal or pulmonary involvement was diagnosed in 13 patients. Five patients had elevated angiotensin-converting enzyme levels. All patients had systemic sarcoidosis. Hypercalcemia, documented in 4.7% of patients, ranged from 2.65–3.3 mmol/l. Hypercalcemia was rarely threatening with improvement after hydration. Hypercalciuria was documented in 12.9% of cases. There were no statistically significant differences in clinical or laboratory characteristics between the two groups of patients with or without abnormal calcemia or calciuria. Five patients required systemic corticosteroids for other organ involvement.

Conclusion: Hypercalcemia and hypercalciuria are not as common as described in the literature concerning calcium metabolism in sarcoidosis. Vitamin D deficiency, which is common in our population, may be a likely explanation. A multicenter study is needed to reassure these data.

P1352
OSTEOARTICULAR INVOLVEMENT IN PATIENTS WITH SARCOIDOSIS: A RETROSPECTIVE STUDY

S. Derbal[1], S. Agoubi[1], D. Chebbi[1], O. Hentati[1], F. Ben Dahmen[1], M. Abdallah[1], Y. Cherif.[1]

[1]Univ. Tunis El Manar, Dept. of Internal Medicine, Regional Hospital of Ben Arous, Ben Arous, Tunisia

Objective: Sarcoidosis is a systemic granulomatous disease. Osteoarticular involvement is frequent in sarcoidosis. It occurs in more than 50% of cases. However, bone damage or involvement is very rare and occurs in only 3–13% of people.

Methods: It's a retrospective single-center study. We included all patients followed for sarcoidosis from January 2016 to December 2023. Epidemiological, clinical, biological, pathological, imaging and evolving data were reviewed from the patient files. We included patients with osteoarticular involvement to analyse the clinical and radiological pattern.

Results: Data of 85 patients followed for sarcoidosis were analysed. We included 30 patients (35,3%) with osteoarticular involvement. They were 29 women and one man. The average age was 53.3 y. Osteoarticular involvement revealed the disease in 33.3% of cases. Arthritis or joint pain were polyarticular in all cases. Three patients had bone sarcoidosis with granuloma in bone biopsy in the cases. In one case, it revealed the disease. All patients had systemic sarcoidosis with mediastino-pulmonary involvement in 96.6%. Other organ involvement and symptoms were sicca syndrome, neurological, ocular, hepatosplenic and cardiac in 33.3%, 16.6%, 16.6%, 13.3% and 6.6% of cases respectively. Two patients had Lofgren syndrome. Two patients had hypercalcaemia and six patients had hypercalciuria. Angiotensin-converting enzyme levels were increased in 43.3% of cases. Nine patients (30%) had abnormal finding on joint imaging assessment. Corticosteroid therapy was prescribed in 56,6% of patients with a good outcomes.

Conclusion: Joint pain or arthritis are oligoarticular or polyarticular. Isolated diagnosis is not evident for bone sarcoidosis, so imaging and biopsies are useful. Osteoarticular involvement is probably

underdiagnosed since it is often asymptomatic. Assessing asymptomatic lesions with imaging investigation must be more frequent.

P1353
EFFECTS OF TOTAL KNEE AND HIP ARTHROPLASTY ON SLEEP QUALITY

Y. El Mabrouk[1], L. Rouached[2], S. Zanned[2], A. Ben Ammou[1], A. Ben Abid[1], M. Bellil[1], S. Bouden[2], A. Ben Tekaya[2], I. Mahmoud[2], R. Tekaya[2], O. Saidane[2], M. Kooli[1], M. Ben Salah[1], L. Abdelmoula[2]

[1]Charles Nicolle Hospital, Orthopedic Surgery Dept., [2]Charles Nicolle Hospital, Rheumatology Dept., Tunis, Tunisia

Objective: Symptomatic osteoarthritis is a prevalent indication for total knee and hip arthroplasty (TKA and THA). Pain associated with osteoarthritis often leads to sleep disturbances in affected individuals. This study aims to evaluate the impact of TKA and THA on the sleep quality of patients with osteoarthritis.
Methods: Conducted as a cross-sectional study from July 2022 to July 2023, this research included patients undergoing primary or secondary TKA or THA. Data collected encompassed sociodemographic information, comorbidities, prosthesis indications, and postoperative therapeutic interventions (analgesia, rehabilitation, psychotherapy). Pain intensity was assessed using the visual analog scale (VAS) ranging from 0–100. Sleep quality was measured through the Pittsburgh Sleep Quality Index (PSQI), evaluating seven domains: subjective sleep quality, sleep latency, sleep duration, habitual sleep efficiency, sleep disturbances, use of sleeping medication, and daytime dysfunction over the last month. Each domain scored from 0 (no difficulty) to 3 (severe difficulty), with an overall score ranging from 0 (good) to 21 points (poor sleeper). Catastrophism was assessed using the Pain Catastrophizing Scale (PCS), with a PCS > 30 indicating a high level of catastrophism.
Results: The study comprised 87 patients with a mean age of 54.24 ± 15.7 and a sex ratio (M/F) of 1.02. THA and TKA were performed in 55% and 45% of cases, respectively. Comorbidities included fibromyalgia (16%), depressive syndrome (11%), and anxiety disorder (2%). Prosthetic surgery addressed primary osteoarthritis in 55% and secondary osteoarthritis in 42%, with various etiologies. PSQI mean score was 7.7 ± 6.7 [0–21], with 40%, 30%, and 24% having PSQI scores ≤ 5, $5 <$ PSQI score ≤ 11, and PSQI score > 11, respectively. PCS mean was 17.25 ± 8.9 [2–40], with 12% having a PCS > 30. Perioperative psychological support was reported by 26% of patients. PSQI score correlated significantly with fibromyalgia ($p = 0.000$), pain VAS ($p = 0.000$), rheumatic disease ($p = 0.000$), knee osteoarthritis severity ($p = 0.011$), and PCS ($p = 0.000$). THA patients had higher PSQI scores (> 11) compared to TKA (35 vs. 10%, $P = 0.000$).
Conclusion: TKA and THA represent effective interventions for addressing pain and functional loss in symptomatic osteoarthritis. These procedures contribute to long-term improvements in sleep quality for individuals with symptomatic osteoarthritis.

P1354
ASSESSMENT OF PATIENT-REPORTED PAIN, FUNCTION AND QUALITY OF LIFE OUTCOME FOLLOWING TOTAL HIP AND TOTAL KNEE ARTHROPLASTIES

L. Rouached[1], Y. El Mabrouk[2], S. Zanned[1], A. Ben Ammou[2], A. Ben Abid[2], M. Bellil[2], S. Bouden[1], A. Ben Tekaya[1], I. Mahmoud[1], R. Tekaya[1], O. Saidane[1], M. Kooli[2], M. Ben Salah[2], L. Abdelmoula[1]

[1]Charles Nicolle Hospital, Rheumatology Dept., [2]Charles Nicolle Hospital, Orthopedic Surgery Dept., Tunis, Tunisia

Objective: Total hip and total knee arthroplasties (THA, TKA) are widely acknowledged as reliable surgical procedures for restoring patient functionality. However, there is limited data characterizing the recovery process using validated knee and hip-related questionnaires. We aimed to evaluate patient-reported Pain, Function, and Quality of Life outcome after THA and TKA for osteoarthritis, utilizing the Knee Injury and Osteoarthritis Outcome Score (KOOS) and Hip Disability and Osteoarthritis Outcome Score (HOOS).
Methods: A cross-sectional study was conducted from July 2022 to July 2023, involving patients undergoing THA or TKA for primary or secondary osteoarthritis in the department of rheumatology and orthopedic surgery. Sociodemographic data, comorbidities, prosthesis indications and postoperative therapeutic modalities (analgesia, rehabilitation, psychotherapy) were collected. Pain intensity was assessed using the visual analog scale (VAS) ranging from 0–100. The functional impact of knee and hip osteoarthritis was evaluated using the KOOS-Physical Function Shortform (KOOS-PS) and HOOS-Physical Function Shortform (HOOS-PS), respectively. It contains 12 questions, with each question scored from zero (no knee or hip problems) to four (extreme knee or hip problems) points. The summary knee or hip impact score is calculated as an average of the Pain, Function, and Quality of Life scale scores. Overall, scores range from 0 to 100, where, in contrast to the individual questions, 0 is the worst possible and 100 is the best possible score.
Results: 87 patients participated, with a mean age of 54.24 ± 15.7 and a sex-ratio of 1.02. 55% received a total hip prosthesis, and 45% received a total knee prosthesis. Comorbidities included fibromyalgia (16%), depressive syndrome (11%), and anxiety disorder (2%). Primary osteoarthritis accounted for 55% of cases, while secondary osteoarthritis constituted 42%, with various etiologies: 14% for aseptic osteonecrosis, 4% for sequelae of septic arthritis and in one case for articular chondrocalcinosis. Mean KOOS and HOOS scores were 54.8 ± 22.5 and 56.1 ± 21.2, respectively, with over 50% of patients scoring above 50. Psychological support was reported by 26% of patients and significantly associated to HOOS ($p = 0.000$), but not to KOOS ($p = 0.3$), and those undergoing physical therapy (68%) demonstrated higher scores ($p = 0.000$). Low KOOS scores were significantly associated with fibromyalgia, pain VAS, rheumatic disease, knee osteoarthritis severity, and BMI (all $p < 0.005$). Low HOOS scores were associated with fibromyalgia, pain VAS, and the presence of rheumatic disease (all $p < 0.01$), but not with hip osteoarthritis severity or BMI.
Conclusion: Primary TKA may lead to improved patient-reported outcomes, particularly in those undergoing physical therapy. Comprehensive care is essential to enhance the quality of life for these patients.

P1355
UNITING THE DICHOTOMY BETWEEN PRIMARY AND SECONDARY PREVENTION OF OSTEOPOROSIS: A COMMUNITY- BASED INTERVENTION

Y. El Miedany[1], A. Gadallah[2], M. Sarhan[3], M. Elgaafary[2], A. Ahmed[3]

[1]Canterbury Christ Church Univ., Canterbury, UK, [2]Ain Shams Univ., Cairo, Egypt, [3]Egyptian Food Bank, Cairo, Egypt

Objective: Osteoporotic fractures, are associated with consequent negative impacts on health, quality of life, functional ability as well as independence. The overarching goal of treating osteoporotic patients is to reduce the incidence of fractures, yet interventions that support early detection of osteoporosis and prevention of osteoporotic fractures are underutilized. Recently, a groundbreaking collaboration between the WHO with ESCEO and the IOF for the prioritization of osteoporosis and fragility fracture prevention within global healthcare policy. In concordance with this new approach, this project has been

launched to lay the groundwork for a national approach for prevention of osteoporosis and fragility fractures in Egypt. Aims: 1. to set up a national program implementing "Targeting to Treat" approach to identify and treat subjects at high or very high risk of fragility fracture in care homes in Egypt. 2. To assess the applicability of using a comprehensive questionnaire for assessing the risk of fractures in older adults in the community. 3. To evaluate the evidence on interventions for preventing fracture in older adults.

Methods: This is a national quality improvement program adopting a Plan, Do, Study, Act (PDSA) cycle methodology. The project is a joint activity provided by the Egyptian Food bank and the Egyptian Academy of Bone and Muscle Health in collaboration with the ministry of Social Solidarity. All older adults living in care homes in Egypt, aged 50-years and above have been invited to join this project of primary prevention of osteoporosis. A list of eligible patients was generated through the national record. Every participant has been invited to complete a questionnaire to assess for Fracture risk, Falls risk, Sarcopenia Risk, functional disability, as well as comorbidities and current medications intake. US scan of the heals will be carried out for every enrolled person. Patients at high/very high fracture risk will be subjected to DXA scan. Rehabilitation program will be provided by local physio teams under supervision of the Rehab physicians to reduce sarcopenia and fall risk. Patient education and counselling program will be provided by the treating doctors. This work describes the protocol of the activity which has been set up in Cairo and Giza as an initial phase. Blood tests for Vitamin D serum levels and bone profile will be assessed for all subjects enrolled in this work. Supplement therapy will be provided for those participants wherever required.

Results: Reviewing the self-completed questionnaire will facilitate the recognition of subjects at high / very high fracture risk, high falls risk as well as sarcopenia risk. The patients will be stratified according to the underlying pathology and risk factors. Rehab program will be set up to tackle these risk factors. The Egyptian food bank will provide food and vitamin D supplement to the elder in need, identified based on their lab tests. Osteoporosis therapy will be offered according to national guidelines to the patients according to their fracture risk. Regular monitoring of the patients will be carried out to check for the progress of the falls and sarcopenia status as well as adherence to therapy.

Conclusion: This community intervention program of screening for osteoporosis, falls and sarcopenia along with continued medical care and patient education is expected to result in a significant improvement in the musculoskeletal healthcare in the care homes that we hope to expand to cover all the care homes at the national level. Providing comprehensive pharmacological as well as non-pharmacological management is expected to reduce the risk of developing fragility fractures.

P1356
BRIDGING THE BINARIES: CLOSING THE GAP BETWEEN PRIMARY AND SECONDARY PREVENTION OF OSTEOPOROSIS AND FRAGILITY FRACTURE

Y. El Miedany[1], A. Baraka[2], M. Elgaafary[3], W. Elwakil[2]

[1]Canterbury Christ Church Univ., Canterbury, UK, [2]Alexandria Univ. faculty of Medicine, Alexandria, Egypt, [3]Ain Shams Univ., Cairo, Egypt

Objective: Osteoporotic fractures, are associated with consequent negative impacts on health, quality of life, functional ability as well as independence. The overarching goal of treating osteoporotic patients is to reduce the incidence of fractures, yet interventions that support early detection of osteoporosis and prevention of osteoporotic fractures are underutilized. Recently, the WHO, IOF and ESCEO announced a collaborative 5-y collaborative agreement to set up strategic roadmap of osteoporosis and fracture prevention within global healthcare agendas. In concordance with this new deal, this project has been set up to lay the groundwork for the prioritization of osteoporosis and fragility fracture prevention in Egypt. We aimed to implement a national community-based program implementing Targeting to Treat approach to identify and treat subjects at high or very high risk of fragility fracture in the Egyptian community and to assess the satisfaction of internal (physicians) and external customers (clients/participants) about the program. 2. assess the doctors' knowledge, attitude, training and experience of the medical students and training doctors involved in the project. 3. Assess the impact of the service on the patient's bone and muscle health.

Methods: This is a national community program carried out using one of the quality improvement tool that is PDC/SA cycle: Plan, Do, Check/Study, Act (PDCSA) cycle methodology. The project is a joint activity provided by Alexandria University and the Egyptian Academy of Bone and Muscle health. Training program will be offered to 5th year medical students and junior physicians house officers on bone and muscle health. A baseline questionnaire will be used to assess the medical students and trainees' perception and performance regarding osteoporosis and risk of fracture. All adults, 50-years old and above, living in the community in Alexandria, will be invited to join this project of primary prevention of osteoporosis. After taking the patient's consent, every participant will be invited to complete a questionnaire to assess the risks for fracture, falls, sarcopenia, as well as functional disability, comorbidities and current medications intake. US scan of the heels will be carried out for every person. Patients at high/very high fracture risk will have a DXA scan. Rehabilitation program will be provided by local physio teams under supervision of the rehab physicians. Patient education and counselling program will be provided by the treating doctors to overcome risk of fall and sarcopenia. This work describes the protocol of the activity which has been set up in the governorate of Alexandria as initial phase.

Results: Reviewing the self-completed questionnaire will facilitate the recognition of subjects at high / very high fracture risk, high falls risk as well as sarcopenia risk. The patients will be stratified according to their underlying pathology and risk factors. Rehab program will be set up to address the common risk factors. Osteoporosis therapy will be offered according to national guidelines to the patients according to their fracture risk. Regular monitoring of the patients will be carried out to check for the incidence of the falls and sarcopenia status as well as adherence to therapy. The doctors' perception and performance will be assessed by asking the contributing doctors to complete a second copy of the questionnaire and an observation checklist.

Conclusion: The program of screening for osteoporosis, falls and sarcopenia along with continued medical care and patient education is expected to result in a significant improvement in the musculoskeletal healthcare in the community in northern Egypt that will be a drive to be expanded a national level. There will be also paralleled by a positive impact on the training doctors knowledge and experience that is expected to reflect positively on the older adult musculoskeletal care.

P1357
ALL ONE MUSCULOSKELETAL HEALTH: A NATIONAL CAMPAIGN FOR EARLY OSTEOPOROSIS DIAGNOSIS AND PREVENTION OF FRAGILITY FRACTURES—A PROJECT BY THE EGYPTIAN ACADEMY OF BONE HEALTH

Y. El Miedany[1], M. Elgaafary[2], N. Gadallah[2], S. Mahran[3], W. Hassan[4], M. Abu Zaid[5], W. Elwakil[6]

[1]Canterbury Christ Church Univ., Canterbury, UK, [2]Ain Shams Univ., Cairo, Egypt, [3]Assiut Univ., Assiut, Egypt, [4]Benha Univ., Benha, Egypt, [5]Tanta Univ., Tanta, Egypt, [6]Alexandria Univ. Faculty of Medicine, Alexandria, Egypt

Objective: Osteoporosis and its associated fragility fractures are a top priority, and efforts are focussing on early detection and smarter solutions to prevent its linked fractures. All One Musculoskeletal Health is a collaborative, multisectoral, and transdisciplinary approach which can be implemented at the local, regional, national, and global levels, with the goal of achieving optimal health outcomes recognizing the interconnection between different medical specialties dealing with bone and muscle health. This project launched by the Egyptian Academy of Bone Health has evolved beyond the traditional approaches and offers comprehensive whole health strategy. It will take forward and develop a new suite of services designed to strengthen bone and muscle health, transform physical health, build financial wellness, and help people, stakeholders, as well as professional organizations unleash their full potential. Aims: 1. to set up a national program implementing "All One Musculoskeletal Health" approach to identify and treat subjects at high or very high risk of fragility fracture in Egypt. 2. To evaluate the evidence on interventions for preventing fragility fracture in older adults targeting the reduction of osteoporotic fractures by 25% in 2026.

Methods: A 5-step framework that provides structure for using a One Musculoskeletal Health approach in stratifying and recognizing the patients at risk of developing osteoporosis or at high risk of sustaining a fracture. These include: step 1-Engagement: which include identifying and engaging relevant specialties with relevance to bone and muscle health and potential stakeholders. Step 2 – Assessment: Conduct gap analysis, map infrastructure, understand limitations and disparities in resources within the relevant specialties. In addition, economic assessment is carried out. Step 3-Planning: Develop plans and protocols for prioritizing bone and muscle health that include and leverage all relevant One Health segments. Step 4-Implementation: Implementing the programs that facilitate identifying patients at high risk of osteoporosis, fractures, falls as well as sarcopenia. Step 5-monitoring and evaluation of outcomes: Identify outcomes, provide management, assess improvement upon weaknesses of One musculoskeletal Health systems and/or programs.

Results: One Musculoskeletal Health program is expected to be an effective approach to build multidisciplinary sustainable coordination and collaboration across all the medical and surgical specialties dealing with bone and muscle health. Statistical analysis is expected to change the map of bone health management at the national level. Initiating such coordination through a disease-specific program (osteoporosis) that adopts a One Health approach to initially focus on a key priority parameter is expected to be more tractable in the short term. Individual patient's risks are identified based on baseline questionnaire. Clinical assessment, investigations, and management plan are set tailored to the individual patient's risk(s). Osteoporosis therapy is provided according to national protocols. Reassessment and evaluation of outcomes are carried out on regular basis, subject the patient's condition. National data register will be set.

Conclusion: The All One Musculoskeletal Health is expected to provide whole national bone and muscle health support, improve access to care, and solutions for what matters most right now. All One musculoskeletal Health is transforming the older adults experience by combining all the benefits of digital and traditional management approach to bring fast, effective, high-quality care for all. This expansion into whole health solutions also includes a renewed vision for the future with a drive towards positive change powered by people who care. By promoting the involvement of different medical and surgical specialties, the All One musculoskeletal Health approach can achieve the best health outcomes for people at risk of osteoporosis or sustaining a fragility fracture.

P1358
A PILOT STUDY OF THE IMPACT OF FRACTURE SITES ON QUALITY OF LIFE AMONG ELDERLY

Y. Z. Lin[1], K. L. Wu[2], C. H. Wu[3], Y. F. Chang[3], J. C. Hsu[4]

[1]National Cheng Kung Univ. School of Pharmacy, Tainan, [2]Dept. of Family Medicine, Tainan Municipal Hospital (Managed by Show Chwan Medical Care Corporation), Tainan, [3]Dept. of Family Medicine, National Cheng Kung Univ. Hospital, College of Medicine, National Cheng Kung Univ., Tainan, [4]Taipei Medical Univ. International Ph.D. Program in Biotech and Healthcare Management, Taipei, Taiwan.

Objective: Due to the elderly population growing, the prevalence of osteoporosis and fractures in Taiwan increased rapidly. The aim of the study is to analyze the impact between fracture site and quality of life for osteoporosis and fracture prevention.

Methods: We enrolled the subjects who was $\geq$ 65 years old and diagnosed with osteoporosis in out-patient setting of Family Medicine Department at National Cheng Kung University Hospital from Feb 2020 to Aug 2020. Each participant filled out a structured questionnaire with the help of administrative staff well-trained in conducting face-to-face interviews. After excluding missing BMD and fractures data, a total of 83 subjects were enrolled to our final analysis. We use EuroQol 5-dimentional questionnaire (EQ-5D) and visual analogue scale (VAS) to assess quality of life, and calculated EQ-5D index by time trade-off. The impact of fracture and quality of life was analyzed. Moreover, the impact between different fracture site and EQ-5D index was also assessed.

Results: A total of 83 subjects, the average age was 73.5 $\pm$ 6.2 years old, and female was 94.0%. Among these subjects, 33 had no fracture history, 41 had spine fracture, 6 had hip fracture, and 6 had other site fracture. The average EQ-5D index without/with fracture history was 0.72 $\pm$ 0.18 and 0.55 $\pm$ 0.27 respectively ($p = 0.001$). The average VAS without/with fracture history was 71.70 $\pm$ 10.87 and 64.00 $\pm$ 14.11 respectively ($p = 0.01$). Besides, the average EQ-5D index in hip and spine fracture was 0.37 $\pm$ 0.21 and 0.55 $\pm$ 0.28 respectively. We also found that 81.8% of subjects without fracture was freely movable. However, 0% and 44.7% of subjects with hip and spine fracture was freely movable, in spite of fractures had happened over 5 years.

Conclusion: In elderly, compared with the subjects without fracture, subjects who had fracture history had lower quality of life, in spite of fractures had happened over 5 years. Furthermore, hip fracture had lowest quality of life, especially in mobility and daily activity.

P1359
N-TERMINAL PRO-BRAIN NATRIURETIC PEPTIDE LEVELS IN PATIENTS WITH RHEUMATOID ARTHRITIS WITH THE INEFFECTIVENESS OF BASIC ANTI-INFLAMMATORY THERAPY

Y. Gorbunova[1], I. Kirillova[1], T. Popkova[1], E. Nasonov[1]

[1]VA Nasonova Research Institute of Rheumatology, Moscow, Russia

Objective: N-terminal pro-brain natriuretic peptide (NT-proBNP)—an amino acid peptide that is located in the myocardium and is released into the blood in response to an increase in volume and pressure in the left or right ventricles. Its high prognostic significance was noted in the development of cardiovascular diseases (CVD) in rheumatoid arthritis (RA) and in the general population. According to the literature, the level of NT-proBNP is closely related to the level of proinflammatory cytokines (TNFα, IL-6), which play an important role in the pathogenesis of RA. We aimed to clarify the value of NT-proBNP in RA patients with the ineffectiveness of basic anti-inflammatory therapy, to compare the level of NT-proBNP with traditional risk factors (TFR) CVD and markers of inflammation.
Methods: The study included 43 patients with RA (34 women/9 men) with the ineffectiveness of basic anti-inflammatory drugs; median (Me) age was 53 [38; 63] y (49% of patients older than 55 years); disease duration—60 [36; 180] months; with high disease activity—DAS28—5,9 [5,2; 6,4] points. The majority of patients were seropositive for IgM rheumatoid factor (81.4%) and for antibodies to cyclic citrullated peptide (74.4%). At the time of inclusion in the study, 44% of patients received methotrexate (MTX) (median dose—15 (15;20) mg/week.), 35%—leflunomide, 9.3%—sulfasalazine, 7%—hydroxychloroquine, 67.4%—glucocorticoids (median dose—5 (4;8) mg/d.), 74%—nonsteroidal anti-inflammatory drugs, 12%—statins. In 19% of patients, the inefficiency of 3 or more of basic anti-inflammatory drugs was noted. In RA patients, a high incidence of TRF was found: arterial hypertension—in 12%, dyslipidemia—40%, smoking—10%, overweight—42%, burdened heredity for CVD—37%, hypodynamia—77% of patients. The control group consisted of 27 healthy donors, comparable to patients by age and gender. The concentration of NT-proBNP was determined in blood serum by electrochemiluminescence (Roche Diagnostics, Switzerland), values less than 125 pg/ml were taken as normal values. All patients completed the HAQ (Health Assessment Questionnaire) before being included in the study.
Results: Patients with RA had higher levels of NT-proBNP (114.8 [45.1; 277.5] pg/ml) compared to the healthy control group (52 [40.5; 69.1] pg/ml, $p < 0.05$). In 19 (44%) patients with RA, the level of NT-proBNP exceeded the norm ($\geq$ 125 pg/ml), and in the control group remained within the normal range. Patients with RA, depending on the level of NT-proBNP, were divided into two groups: group 1 (n = 19) with the level of NT-proBNP $>$ 125 pg/ml; group 2 (n = 24)—with the value of this indicator $\leq$ 125 pg/ml. Group 1 patients were older (62 [49; 69] vs. 43 [37; 55]) and had a higher HAQ value (1.75 [1.38; 1,9] vs. (1,37 [1; 1,6]) than group 2 patients. In the whole group (n = 43), the level of NT-proBNP positively correlated with age (r = 0.55; p = 0.0002), BMI (r = 0.38; p = 0.2), HAQ level (r = 0.41; p = 0.008). In group 1, there was a direct correlation between the concentration of NT-proBNP with the activity of RA (DAS28) (r = 0.48; p = 0.02) and age (r = 0.46; p = 0.03), the reverse was observed with the level of total cholesterol (r = -0.44; p = 0.03).
Conclusion: The level of NT-proBNP in the serum of RA patients with the ineffectiveness of basic anti-inflammatory therapy is higher than in the control group. Elevated levels of NT-proBNP were associated with age, RA activity, an increase in BMI, and an indicator of HAQ health assessment.

P1360
ASSESSMENT OF PAIN AND HEALTH STATUS OF A PATIENT WITH EARLY RHEUMATOID ARTHRITIS, DEPENDING ON BODY MASS INDEX

Y. Gorbunova[1], L. Kondratyeva[1], T. Popkova[1], E. Nasonov[1]

[1]VA Nasonova Research Institute of Rheumatology, Moscow, Russia

Objective: Adipose tissue produces a large number of different proinflammatory cytokines (IL-1, IL-6, TNFα, leptin) involved in the pathogenesis of RA. Obesity in rheumatoid arthritis (RA) is associated with high activity of the disease, with rare achievement of remission, decreased effectiveness of therapy, as well as worse patient ratings of pain severity and overall health status on a visual analog scale (VAS). We aimed to clarify the effect of BMI on the patient's pain and health indicators according to VAS in patients with early RA.
Methods: The study included 74 patients (54 women/20 men) with early RA (ACR/EULAR criteria, 2010), 56 [46,0; 61,0] y, without experience of taking glucocorticoids and disease-modifying antirheumatic drugs. The median duration of the disease was 7.0 [4.0; 8.0] months, seropositivity according to IgM RF and ADC, with high RA activity (DAS28 5.6 [5.0; 6.3]; SDAI 35.4 [27.0; 45.8], CDAI 31.0 [26.0; 44.0]). Leptin levels were measured using ELISA enzyme immunoassay (DBS – Diagnostics Biochem Canada Inc.). Leptin levels were considered elevated at values $\geq$ 11.1 ng/ml for women, $\geq$ 5.6 ng/ml for men. Overweight status/Obesity was determined according to the criteria of the WHO in patients with a BMI $\geq$ 25 kg/m^2. The assessment of pain and health status by the patient (doctor) was carried out using a visual analog scale (VAS), with a gradation from 0–100 mm.
Results: Overweight/obesity was found in 39 (52.7%) patients with early RA, 33 (44.6%) of 47 patients had high levels of leptin. Patients with early RA, depending on the level of BMI $\geq$ 25 kg/m^2, were divided into 2 groups: I (n = 39)—overweight/obese RA patients (BMI $\geq$ 25 kg/m^2); II (n = 35) – normal BMI ($<$ 25 kg/m^2). When comparing the groups, they significantly differed in age: 56 vs. 47 years; pain level: 61 vs. 50 mm; level VAS according to the patient: 60 vs. 50 mm; level VAS according to the doctor: 56 vs. 46 mm; blood pressure indicators: SBP (127 vs. 117 mmHg) and DBP (81 vs. 73 mmHg). ($p < 0.05$ in all cases). The pain index correlated with the level of ESR (r = 0.41, p = 0.008), CRP (r = 0.46, p = 0.003); BMI with the level of TG (r = 0.33, p = 0.04) and leptin (r = 0.37, p = 0.02) in the overweight/obese group. There is a direct correlation between BMI with glucose level (r = 0.37, p = 0.02), CRP level with the number of swollen joints (r = 0.38, p = 0.02) and morning stiffness (r = 0.56, p = 0.009) in the normal weight group.
Conclusion: Patients with early RA and overweight/obese had higher pain levels and health status according to a visually analog scale, compared with patients with a normal BMI.

P1361
COMPARISON OF THREE-DIMENSIONAL PROXIMAL FEMUR BONE STRUCTURE ACCORDING TO BONE EROSION IN POSTMENOPAUSAL FEMALE RHEUMATOID ARTHRITIS PATIENTS

Y. J. Choi[1], J. W. Kim[2], J. Y. Jung[2], C. H. Suh[2], Y. S. Chung[1], H. A. Kim[2]

[1]Dept. of Endocrinology and Metabolism, Ajou Univ. School of Medicine, [2]Dept. of Rheumatology, Ajou Univ. School of Medicine, Suwon, South Korea

Objective: Rheumatoid arthritis (RA) is commonly acknowledged as one of the important causes of secondary osteoporosis. It is also

widely recognized that patients with RA who have bone erosion likely have more severe disease activity. A novel software allows the 3-dimensional (3D) analysis of both trabecular and cortical compartments separately using DXA scans. Thus, this new tool is expected to contribute to better analysis of secondary osteoporosis, particularly in RA with bone erosion, where the involvement of cortical bone would be predominant. This retrospective study aims to compare the 3D bone structure according to bone erosion in postmenopausal female RA patients.
Methods: This study had a cross-sectional design. 171 postmenopausal women with RA aged 50 years or older were included in this study. Demographic and disease-specific parameters were documented, including anti-rheumatic treatment, bone erosion status, and previous fractures. The 3D bone structure analyses were conducted on the DXA hip scans using a 3D reconstruction tool.
Results: The study involved 94 patients in the erosion (-) group and 77 in the erosion (+) group. No significant differences in age, BMI, or comorbidities were observed, including osteoporosis and osteoporosis medication history. Disease duration, cumulative glucocorticoid doses, and disease activity parameters were significantly higher in the erosion (+) group. In the evaluation of 3D bone structure (cortical (CvBMD) and trabecular (TvBMD) volumetric BMD (mg/cm^3), the integral (IvBMD) of both compartments), the only significant differences observed between the two groups were in the 3D bone structures associated with the femur neck. After adjustment for other confounding factors, such as disease duration and cumulative steroid doses, only CvBMD exhibited a significant inverse relationship with disease activity score 28 (DAS28) (ß = -24.693, p = 0.023).
Conclusion: Using this novel 3D analysis tool, we found that the femur neck region might be predominantly impacted in RA patients with bone erosion. Additionally, it was feasible to verify using the tool that the disease's activity primarily affects the cortical bone in individuals with RA.

P1362
USE OF DUAL-ENERGY COMPUTED TOMOGRAPHY IN PATIENTS WITH UNDIFFERENTIATED ARTHRITIS: DATA FROM A PILOT RESEARCH

Y. Kuzmina[1], E. Panina[1], O. Zhelyabina[1], M. Eliseev[1], M. Chikina[1]

[1] V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia

Objective: To analyze the experience of practical use of dual-energy computed tomography (DECT) in patients with arthritis of the joints of the lower limb.
Methods: The study included 13 patients (10 men and 3 women) who applied to the V.A. Nasonova Research Institute of Rheumatology with acute arthritis of the joints of the lower limb. The average age of the patients was 50 y. Patients underwent standard examination methods to verify the diagnosis of gout (puncture of the affected joint, ultrasound, radiography, determination of serum uric acid (sUA) level), and the level of C-reactive protein (CRP) was additionally assessed. According to the examination results, not a single patient met the 2015 ACR-EULAR Gout Classification Criteria. To verify the diagnosis, all patients underwent DECT of the joints of the lower limb. The study was performed on a Siemens SOMATOM Definition Flash computed tomograph with subsequent evaluation of the resulting images in the Syngo DE Gout application.
Results: In none of the patients did puncture of the affected joint confirm the presence of monosodium urate crystals in the synovial fluid. A sUA level of more than 360 μmol/l was detected in 9 (69.2%) patients from the group, the CRP level exceeded the norm (> 5 mg/l) in 5 (38.5%) patients. According to radiography of the joints of the lower limb, only 3 (23.1%) showed typical changes characteristic of gout. Ultrasound gave a positive result in 5 (38.5%) patients, but raised doubts, while in 7 patients (53.8%) DECT was decisive for the diagnosis of gout.
Conclusion: DECT is a promising method, along with ultrasound, for the diagnosis of gout in patients with undifferentiated arthritis and suspected microcrystalline disease.

P1363
USE OF DUAL-ENERGY COMPUTED TOMOGRAPHY IN PATIENTS WITH ATYPICAL LOCALIZATION OF GOUT: DESCRIPTION OF A CASE SERIES

Y. Kuzmina[1], M. Eliseev[1], O. Zhelyabina[1], E. Panina[1], M. Chikina[1]

[1] V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia

Objective: To analyze the practicality of using dual-energy computed tomography (DECT) in patients with gout and lesions of the axial skeleton.
Methods: Included 7 patients (4 men and 3 women) with a previously established diagnosis of gout based on the 2015 ACR-EULAR Gout Classification Criteria, aged 37–80 y, with pain and limited function in the spine (4 patients) and in the projection of large joints (hip (2 patients) and shoulder joints (1 patient)). 2 patients had a combination of gout and ankylosing spondylitis. In all patients, serum uric acid (sUA) level was assessed at the time of presentation and consistent MRI and DECT of the affected joints and spine were performed. The study was performed on a Siemens SOMATOM Definition Flash computed tomograph with subsequent evaluation of the resulting images in the Syngo DE Gout application.
Results: In 6 patients (85.7%) the sUA level exceeded the upper limit of normal (> 360 μmol/l). According to the results of MRI, none of the patients showed signs of deposition of monosodium urate (MSU) crystals in the examined area. In 6 patients (85.7%), DECT confirmed lesion to the axial skeleton as part of gout. In 1 patient (14.3%), DECT revealed a combination of gout and calcium pyrophosphate crystal deposition disease in the shoulder joint.
Conclusion: The use of DECT is practical and expedient for assessing the presence of MSU crystals in the axial joints and spine in patients with atypical gout.

P1364
COMPARISON OF BONE MINERAL DENSITY BETWEEN VETERANS AND NON-VETERANS AND ITS IMPACT ON FRACTURE RISK ASSESSMENT

Y. L. Teng[1], S. Y. Lin[1], T. Y. Chen[2], H. T. Lee[3], Y. M. Chen[4]

[1]Osteoporosis Prevention Center, Taichung Veterans General Hospital, [2]Neurosurgery, Taichung Veterans General Hospital, [3]Lee General Hospital, [4]Division of Allergy, Immunology and Rheumatology, Taichung Veterans General Hospital, Taichung, Taiwan.

Objective: Veterans are a special group of people with special characteristics. With the aging of this population, the issue of osteoporotic fractures has become more and more important. This study aims to compare the BMD and fracture rates between male veteran patients and non-veteran patients.
Methods: A retrospective analysis was conducted from January 2010 to December 2022, involving 1427 veterans who underwent DXA for the first time at Taichung Veterans General Hospital. Veteran patients were matched by age and gender with non-veteran patients in a 1:1 ratio. Conditional logistic regression was used to analyze factors

related to fractures and to explore differences in BMD, bone quality, and fracture sites among first-time fracture cases.
Results: There was no significant difference in the average age between veterans and non-veterans (76.58 ± 10.92 vs. 76.58 ± 10.92; $p = 1.000$). Conditional logistic regression revealed that, despite better L spine BMD in veterans (HR: 0.39; $p < 0.001$), it was associated with a higher fracture rate (HR: 1.200; $p = 0.005$). Further analysis within the fracture group showed that veterans had higher BMD and T-scores than non-veterans ($p < 0.001$), more fractures occurred in the Radius ($p = 0.036$), and Osteoarthritis was more prevalent in the chronic disease aspect ($p < 0.001$).
Conclusion: Despite better BMD in veterans, a higher fracture incidence was noted. We speculated that more prevalent osteoarthritis in veterans may lead to the formation of bone spurs, potentially misinterpreted as actual bone tissue in DXA scan. It is recommended that future radiological assessments of BMD take this condition into consideration to enhance the accuracy of results. This study provides crucial clinical insights for developing more effective guidelines for BMD assessment.

P1365
HOW TO MONITOR AND DISCRIMINATE CAUSES OF LOWER LIMB SWELLING DURING HOME-BASED REHABILITATION AFTER TOTAL KNEE ARTHROPLASTY? A DELPHI STUDY

Y. Lin[1], R. Hong[1], L. Hui-Wu[1]

[1]Shanghai Ninth People's Hospital, Affiliated to Shanghai Jiaotong Univ. of Medicine, Shanghai, China

Objective: Swelling in the lower limbs after total knee arthroplasty (TKA) hinders surgical outcomes. Prolonged duration of swelling requires monitoring and remote management during home-based rehabilitation. Various causes of swelling exist, but there is a lack of indicators to monitor and discriminate different causes of lower limb swelling, making it difficult to implement targeted interventions. This study aims to clarify the indicators to monitor and discriminate the causes of lower limb swelling during home-based rehabilitation after TKA by literature research and consulting experts from various disciplines.
Methods: The Delphi method was used. Based on literature research and analysis, a preliminary draft of indicators was developed. Fifteen experts from different disciplines were invited to evaluate the validity of the indicators and provide modification suggestions. Through two rounds of consultations, consensus was reached among the experts.
Results: After two rounds of Delphi consultations, consensus was reached. Agreement scores ranged from 4.40–5.00, with low variability (standard deviation 0.00–0.91) and high consistency (coefficient of variation 0.00–0.20). $P < 0.05$ in the Kendall's W with an agreement rate of 80.00–100%. In the final set of indicators, there were five primary indicators (representing four swelling causes and a general category), along with 23 secondary indicators and 40 tertiary indicators (further subdivisions of the secondary indicators).
Conclusion: This study has preliminarily established indicators for at-home differentiation of swelling post-TKA caused by four distinct reasons. Further research is needed to validate the value of these indicators in distinguishing the causes of swelling. In the future, the development of remote monitoring systems or devices to collect data on these indicators could enable personalized interventions tailored to specific swelling causes for patients.

P1366
RELATIONSHIP BETWEEN COMMUNITY-DWELLING ELDERLY INDIVIDUALS WITH PRE-FRAILTY AND APPETITE

Y. M. Yoshiki[1], M. I. Masakazu[1], W. I. Wataru[1], S. T. Shotaro[1], R. I. Risa[1], K. N. Kazuma[1], H. K. Hayato[1], M. N. Misa[1], F. T. Fumie[1], T. M. Tatsunori[1], T. K. Takanari[1]

[1]Osaka Kawasaki Rehabilitation Graduate School, Kaizuka, Japan

Objective: To investigate the relationship between community-dwelling elderly individuals with pre-frailty and appetite. Previous studies have shown an association between malnutrition and appetite, and nutritional intervention and exercise therapy are recommended to prevent pre-frailty; however, loss of appetite before nutritional intervention may not lead to improvement.
Methods: This cross-sectional study included 204 elderly individuals (151 females and 53 males age 74.1 ± 6.6 years old) aged ≥ 65 y, who underwent health check-ups in Kaizuka, Osaka between August and September 2023. The measurement items included are frailty and pre-frailty, appetite, eating habits, depressive tendency, cognitive function, attention function, and body composition. Statistical analysis robust and pre-frailty are grouped based on Fried et al.'s definition, and associations with assessment items were analyzed by univariate analysis. Binomial logistic regression analysis was performed to examine the independent associated factors, with items that showed significant differences, sex and age, and presence of pre-frailty as independent, control, and dependent variables, respectively. The significance level was set at 5%.
Results: Robust and pre-frailty was present in n = 99 (48.5%) and n = 105 (51.5%), respectively. Pre-frailty inpatients showed lower appetite, depressive tendency, and attention function, of which appetite (odds ratio [OR], 95%CI = 3.5 [1.5–8.2]) and depressive tendency (OR 95%CI = 5.8 [2.0–215.2]) are independently associated with pre-frailty.
Conclusion: We found independent associations between pre-frailty and appetite and depressive tendency of community-dwelling elderly individuals. Therefore, it was speculated that the presence of pre-frailty may be influenced by psycho-psychological decline and the resulting loss of appetite.

P1367
LOW DAILY PHYSICAL ACTIVITY IS AN IMPORTANT FACTOR FOR EARLY LOSS OF CORTICAL BONE MINERAL DENSITY

Y. Polyakova[1], E. Papichev[1], L. Seewordova[1], Y. Akhverdyan[1], B. Zavodovsky[1]

[1]Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky, Volgograd, Russia

Objective: When examining patients without significant therapeutic pathology, women under 60 years of age began to be increasingly identified with a predominant decrease in BMD in the proximal femur. Significant risk factors for decreased BMD in these patients include low physical activity and high social employment. We aimed to assess the incidence of decreased BMD of the proximal femur in women under 60 y of age in the absence of endocrine and rheumatic pathology.
Methods: A retrospective analysis of outpatient records of patients who were examined at the Center for Osteoporosis of the Federal

State Budgetary Institution «Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky», Volgograd, was carried out. Risk factors were re-analyzed in 30 patients under 60 years of age with a predominance of decreased BMD of the proximal femur over BMD of the lumbar vertebrae. BMD was determined by DXA using a Lunar DPX (GE) apparatus. BMD status was assessed using T and Z-score criteria in g/cm^2.

Results: Of the 30 women under 60 y of age with a predominant decrease in BMD in the proximal femur over the lumbar vertebrae, 29 use a personal car as a means of transportation in everyday life, 14 live in high-rise buildings and constantly use the elevator. Moreover, in all cases there is a more significant decrease in indicators for T(Z)Total. The incidence of decreased BMD in the lumbar spine was 67%, in the femoral neck 93.3%, and in the proximal femur 100%. In a statistical analysis of the average T-criterion values, the highest value was found in the lumbar vertebral bodies TL1-L4 = -1.22 $\pm$ 0.52, TNeck = -1.57 $\pm$ 0.44, the lowest in the proximal femur—TTotal =—1.74 $\pm$ 0.43 standard deviations, respectively.

Conclusion: Significant limitation of physical activity on the lower extremities, due to constant movement by car, regular use of the elevator, in the absence of additional physical activity, can be considered as a separate risk factor for a decrease in BMD of the proximal femur. Probably, the obtained results can be considered as a significant risk factor for the development of osteoporosis and hip fracture at a younger age.

P1368
BOLSTERING CARDIOPULMONARY, BALANCE AND ACTIVITIES OF DAILY LIVING FUNCTION USING DEEP-LEARNING PLATFORM FOR CEREBRAL PALSY

Y. S. An[1], C. H. Park[1], S. H. Min[1]

[1]Funrehab, Daejeon, South Korea

Adolescents with hemiplegic cerebral palsy undergo conventional physical therapy (CPT) to improve static and dynamic balance, activities of daily living (ADL) and cardiopulmonary function. However, during the COVID-19 pandemic, the primary problems associated with direct, labor-intensive hands-on therapy worsened. To overcome this problem, we developed an innovative deep learning-based rehabilitation application (DRA) to provide a motivational and chaffed platform for such individuals. We compared the effects of DRA and CPT on 6-min walking test (6 MWT), Borg rating of perceived exertion scale (RPE), Berg balance scale (BBS), functional ambulation category (FAC), and modified Barthel index (MBI) in adolescents with hemiplegic cerebral palsy. A convenience sample of 30 adolescents with hemiplegic cerebral palsy was randomized into either the DRA or CPT group. DRA and CPT were administered to the participants, with each session lasting 30 min and apportioned thrice a week for a total of four weeks. ANOVA was performed and the level of significance was set at $P < 0.05$. The analysis indicated that DRA showed therapeutic effects on 6 MWT, BBS, and MBI compared to CPT. Our results provide evidence that DRA can improve cardiopulmonary function, balance, and ADL more effectively than CPT in adolescents with hemiplegic cerebral palsy.

P1369
BOLSTERING PAIN, DISABILITY AND RESPIRATORY FUNCTION IN MUSCULOSKELTAL PAIN USING INTERACTION DEEP-LEARING MANAGEMENT PLATFROM

Y. S. An[1], S. H. Min[1], C. H. Park[1]

[1]Funrehab, Daejeon, South Korea

Low back pain impairment has a wide-ranging impact on both biological and psychosocial aspects. This study aimed to compare the effects of artificial intelligence–based self-back management with digital application physical therapy (APT) and conventional physical therapy (CPT) on back pain intensity, respiratory function, limited functional disability, and quality of life in 100 patients with low back pain. A convenience sample of 100 participants (mean age 35.5 $\pm$ 8.8 y; 20 females) was recruited and underwent either APT or CPT for 30 min sessions, three times a week over a 4-week period. The outcome measures included the (1) Oswestry disability index (ODI), (2) Quebec back pain disability scale (QUE), (3) Roland–Morris disability questionnaire (RMDQ), (4) numeric pain rating scale (NPRS), (5) short form-12 (SF-12), and (6) maximum inspiratory (MIP) and expiratory (MEP) pressures. Statistical analyses included ANOVA to determine intervention-related changes in these outcome variables. ANOVA revealed a positive effect on clinical outcome measures after 8 weeks of both APT and CPT. In conclusion, APT was a successful intervention for clinical outcome measures (ODI, RMDQ, and NPRS), maximum respiratory pressure (MIP and MEP), and quality of life (SF-12). Most importantly, APT demonstrated more positive effects on COVID-19 transmission risk, cost-effectiveness, accessibility, and real-time feedback than CPT. This study compared the effects of APT and CPT in patients with LBP. We demonstrated that APT was as effective as CPT in improving structure/functional impairment, activity limitation, and participation restriction domains.

P1370
HOME-BASED EXERCISE REDUCES FALLS IN COGNITIVELY FRAIL OLDER ADULTS WHO HAVE PREVIOUSLY FALLEN

R. S. Falck[1], C. L. Hsu[2], J. C. Davis[3], Y. S. Seo[1], J. Rice[1], E. Dao[1], L. Dian[4], K. Madden[4], D. A. Skelton[5], N. Parmar[4], W. L. Cook[4], K. M. Khan[6], T. Liu-Ambrose[1]

[1]Dept. of Physical Therapy, Faculty of Medicine, Univ. of British Columbia, Vancouver, Canada, [2]Dept. of Rehabilitation Sciences, Hong Kong Polytechnic Univ., Kowloon, Hong Kong SAR China, [3]Faculty of Management, Univ. of British Columbia-Okanagan Campus, Kelowna, Canada, [4]Dept. of Medicine, Division of Geriatric Medicine, Faculty of Medicine, Univ. of British Columbia, Vancouver, Canada, [5]Dept. of Physiotherapy and Paramedicine, Glasgow Caledonian Univ., Glasgow, UK, [6]Dept. of Family Practice, Faculty of Medicine, Univ. of British Columbia, Vancouver, Canada

Objective: Fragility hip fractures are one of the most serious consequences of falls amongst older adults with osteoporosis. Cognitive frailty, characterized by concurrent physical frailty and mild cognitive impairment, increases fall risk. Exercise is an evidence-based strategy to prevent falls. We examined the effects of home-based exercise on

subsequent falls amongst community-dwelling cognitively frail older adults who have previously fallen.
Methods: A sub-group analysis of a 12-month, single-blind, randomized controlled trial amongst 344 adults $\geq$ 70 y who had fallen in the past 12 months. Participants were randomized to either 12 months of home-based exercise (EX; n = 172) or usual care (CON; n = 172). In this sub analysis, we included 192 cognitively frail participants (EX = 93; CON = 99) with Short Physical Performance Battery (SPPB) scores $\leq$ 9/12 and Montreal Cognitive Assessment (MoCA) scores $<$ 26/30. Our primary outcome was falls rate based on self-reported falls over 12 months. Secondary outcomes were core components of cognitive frailty (i.e., SPPB and MoCA). We also explored whether adherence moderated the effect of EX on outcomes.
Results: At 12 months, falls rates were 35% lower in EX vs. CON (IRR = 0.65; p = 0.042). The mean monthly adherence was 45.5%. SPPB performance significantly improved amongst EX participants who completed $\geq$ 45.5% of EX sessions vs. those with completed $<$ 45.5% of sessions (estimated mean difference: 0.94; p = 0.022).
Conclusion: Exercise is a promising strategy for reducing subsequent falls in people with cognitive frailty. Greater exercise adherence improved physical function in this population.

P1371
EFFECT OF A HOME-BASED EXERCISE ON FALLS RISK IN COGNITIVELY IMPAIRED OLDER ADULTS POST HIP FRACTURE: A RANDOMIZED CONTROLLED TRIAL

Y. S. Seo[1], L. Dian[2], J. C. Davis[3], D. Tai[1], D. A. Jehu[4], P. Guy[5], D. M. Roffey[5], L. Lai[2], T. Liu-Ambrose[1]

[1]Dept. of Physical Therapy, Faculty of Medicine, Univ. of British Columbia, Vancouver, Canada, [2]Dept. of Medicine, Division of Geriatric Medicine, Faculty of Medicine, Univ. of British Columbia, Vancouver, Canada, [3]Faculty of Management, Univ. of British Columbia-Okanagan Campus, Kelowna, Canada, [4]Dept. of Community & Behavioural Health Sciences, Augusta Univ., Augusta, USA, [5]Dept. of Orthopaedics, Faculty of Medicine, Univ. of British Columbia, Vancouver, Canada

Objective: 95% of hip fractures (HF), one of the most serious consequences of osteoporosis, are caused by falls in older adults. HF intervention studies have largely excluded those with cognitive impairment. We examined the effect of a home-based program of progressive strength and balance training exercises in reducing falls risk amongst older adults with mild cognitive impairment (MCI) who sustained a fall-induced HF.
Methods: We conducted a 6-month single-blinded randomized controlled trial amongst 60 adults aged $\geq$ 65 years with MCI (i.e. Montreal Cognitive Assessment scores $<$ 26/30) who sustained a HF due to a non-syncopal fall in the past 12 months and were discharged home. Participants were randomized to: 1) a home-based exercise program delivered by a physical therapist in addition to standard of care provided by a geriatrician (EX; n = 30); or 2) standard of care alone (CON; n = 30). The primary outcome was falls risk as measured by the Physiological Profile Assessment (PPA). The PPA computes a standardized fall risk score (z-score) based on performance of 5 physiological domains (i.e. vision, proprioception, strength, reaction time and balance). We conducted an interim analysis of efficacy using analysis of covariance, adjusting for baseline PPA and relevant covariates.
Results: The mean age of the 60 participants was 79.5 y and 72% were females. 12/60 participants are currently in the trial and the last assessment will be in March 2024. Attrition to date is 21% (EX = 4; CON = 9). For the 34 participants (EX = 19; CON = 15) who completed the trial, falls risk was reduced in EX vs. CON at 6 months (p = 0.026; estimated mean difference: 0.74; 95%CI: 0.09–1.39).
Conclusion: Home-based progressive strength and balance training exercises show promise in reducing falls risk after a fall-induced HF amongst older adults with MCI.
Acknowledgements: TLA is a Tier 1 Canada Research Chair (CRC). JCD is a Tier 2 CRC. Funding was provided by Amgen to TLA.

P1372
SARCOPENIA RISK FACTOR FOR FALLS AND FRACTURES

Y. Safonova[1]

[1]North-Western State Medical Univ. named after I.I. Mechnikov, St. Petersburg, Russia

Objective: Association of falls and fractures with sarcopenia in older people.
Methods: The study involved 230 patients aged 65 years and older (mean age 74.0 $\pm$ 6.5 y) living in the community dwelling. The diagnosis of sarcopenia was consistent with the recommendations of the EWGSOP (2018).
Results: Sarcopenia was found in 28.7% of the elderly, severe sarcopenia in 21.3%. In sarcopenic patients, the frequency of falls over 12 months was higher than in non-sarcopenic patients (90.9 vs. 26.8%, $p < 0.001$). The risk of falls in sarcopenic patients was 2.07 (95%CI 1.86–2.30, $p < 0.001$) times, and in those with severe sarcopenia it was 3.02 (95%CI 1.79–5.11, $p < 0.001$) times is higher compared to non-sarcopenic patients. The incidence of fractures in sarcopenic patients was higher than in non-sarcopenic patients (37.7 vs. 26.7%, $p < 0.01$). In people with sarcopenia, the risk of fracture was 1.52 (95%CI 1.01–2.28; p = 0.049) times, and hip fracture was 2.28 (95%CI 1.28–4.05; p = 0.003) times higher than in non-sarcopenic patients.
Conclusion: The incidence of falls and fractures is higher in sarcopenic patients than in non-sarcopenic patients.

P1373
LINKS TO USEFUL RESOURCES INCREASE EFFECTIVENESS OF THERAPY FOR DISEASES OF THE MUSCULOSKELETAL SYSTEM

Y. U. Polyakova[1], L. Seewordova[1], Y. Akhverdyan[1], E. Papichev[1], B. Zavodovsky[1]

[1]Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky, Volgograd, Russia

Objective: Treatment of musculoskeletal disorders cannot be considered separately from lifestyle modification. To correct physical activity and normalize nutrition, additional consultations with specialists are required. Distributing information leaflets or links to Internet resources can be considered as assistance in solving the task. Aim: increase the effectiveness of non-drug therapy (NT) by introducing online resources during the appointment.
Methods: Monitoring of effective access to information resources was carried out under various modes of presenting information during reception. Group 1 (100 initial patients) was given a leaflet with examples of exercises and a leaflet with dietary recommendations at the appointment. The 2nd group (100 patients) was told about the benefits of exercise and proper nutrition, with an emphasis on the fact

that the references were in the doctor's report. The 3rd group (100 patients) received a link on the doctor's computer at the appointment and was told about the benefits of physical therapy and proper nutrition. The 4th group (100 patients) were shown 2–4 exercises at the appointment, involving the patient in their implementation, and were given a leaflet or a link to a video and recommendations on proper nutrition.

Results: At the follow-up appointment, it was revealed that, regardless of the information provided, almost 80% of patients with gout complied with dietary recommendations to one degree or another, at least in the first month of observation. The calculation of calcium intake in 9% was carried out by patients who were given a leaflet, in 23% of cases—by patients who were given a link to the IOF Calcium Calculator and in 78% of cases, if the doctor visited the site during the appointment and showed how the intake calculation was carried out calcium. Completion of the exercises was 82% if the exercises were performed together with the doctor during the appointment, 57% when opening a link to a site with a video (лечебная гимнастика—РАОП; здоровьесуставов.рф/video) and 17% when handing out leaflets with exercises.

Conclusion: Implementation of NT recommendations is highly dependent on the presentation of information. The best result is achieved when the patient is involved in the implementation of recommendations directly at the doctor's appointment.

P1374
EFFICIENT REVERSAL OF DISEASE PHENOTYPES OF GMPPB-DYSTROGLYCANOPATHY WITH THE ACTIVATION OF WNT SIGNALING PATHWAY AND AAV GENE THERAPY

Z. W. Fu[1], Y. W. Wang[2]

[1]Fudan Univ., Shanghai, China

It has been found lately that diverse forms of congenital muscular dystrophy are congenital disorders of glycosylation, composing a clinically heterogeneous group of disorders collectively referred to as dystroglycanopathy (DGP). Recently, clinical cases have been reported in patients with muscular dystrophy with mutations in guanosine diphosphate mannose (GDP—mannose) pyrophosphorylase B (GMPPB), most of which are of compound mutations. However, it is not clear if and how GMPPB mutations or variations in GDP-mannose levels directly contribute to muscular dystrophy, nor did the molecular mechanisms affecting disease progression being identified. To establish the role of GMPPB in muscular dystrophy, we constructed GMPPB mutant mouse lines and found that two of these alterations are lethal in the homozygous forms. Besides, a heterozygous GMPPB mouse line exhibited reduced muscle strength, decreased locomotor ability, elevated creatine kinase levels and increased number of central nuclei. We further show that the ability of muscle regeneration in these mice is decreased post muscle injury. Reduced myotube diameter and fusion index are evident in GMPPB mutant myoblasts and muscle stem cells isolated from heterozygous mice upon induction of muscle differentiation. To identify the pathways mediating impaired muscle development in GMPPB-deficient contexts, we conducted genomic studies and found that Wnt/β-catenin pathway undergoes significant alterations. Ectopic activation of Wnt signaling alleviates the block of muscle differentiation in GMPPB-deficient cells. Additionally, the muscle regeneration post muscle injury is restored in vivo by pharmacological activation of Wnt signaling, as well as by AAV gene replacement therapy. Overall, these findings provide direct evidence supporting that GMPPB loss-of-function leads to onset of dystroglycanopathy diseases, and further extend understanding of the role of GMPPB in the disease progression. Gene therapy and Wnt pathway activating agents are potential effective intervention routes for these pathological conditions and further preclinical DGP studies are warranted.

P1375
METHOD FOR ASSESSING THE PROBABILITY OF DEVELOPING PSORIATIC ARTHRITIS IN PATIENTS WITH PSORIASIS

Y. Y. Liashko[1]

[1]Institute of Advanced Training and Retraining of Healthcare Personnel of Belarusian State Medical Univ., Minsk, Belarus

Objective: To assess the probability of developing PsA in patients with psoriasis based on inflammatory changes in synovial-entheseal structures.

Methods: The study included 139 subjects aged 18–55 y, divided into three groups: patients diagnosed with PsA—52; patients with skin psoriasis and without signs of PsA according to PEST criteria—56 and control healthy group—30. In patients of groups I and II, the following signs were assessed: Nail Psoriasis Severity Index (NAPSI), body surface area (BSA), Psoriasis Area Severity Index (PASI). Activity indices were calculated to evaluate disease activity in group: DAS28, ASDAS, BASDAI, functional activity indices: BASFI. All patients underwent ultrasound examination of 14 entheses: 7 on each side. The following were assessed: disruption of the fibrillar pattern, presence of enthesophyte and erosion of the attachment site, PD activity during enthesis at the insertion site and 2 mm from it, tendon thickness in a longitudinal section at a distance of 5 mm from the insertion site, presence/absence of bursitis in 4 periarticular bursae at both sides.

Results: To predict the probability of developing PsA, the tendon index TI was developed as the ratio of the difference between the arithmetic mean of the thickness of 12 tendons and the arithmetic mean of the thickness of the control tendon to the arithmetic mean of the thickness of the control tendon. The TI threshold value, above which thickening may be a sign of PsA, was determined by ROC analysis. AUC was 0.916, sensitivity 81.6%, specificity 76.9%. Multiple logistic regression analysis was performed to identify the relationship between the probability of patients developing PsA and the characteristics measured in them. Significant signs are: TI, bursitis, BSA, PASI. AUC was 0.876, sensitivity 80.77%, specificity 85.71%, threshold criterion 0.604.

Conclusion: The developed model for assessing the probability of developing PsA in patients with psoriasis includes the developed TI as one of the prognostic signs. The model makes it possible to predict whether the examined patient belongs to either the group of patients with the subclinical phase of PsA, or to the group with isolated skin manifestations.

P1376
HEMATOPOIETIC AUTOPHAGY DEFECT CONTRIBUTES TO BONE LOSS

Y. Y. Yuan[1], Y. J. X. Xu[2], J. H. L. Lin[1]

[1]Arthritis Clinical and Research Center, Peking Univ. People's Hospital, Beijing, [2]Dept. of Orthopaedics, the Second Affiliated Hospital of Soochow Univ., Suzhou, China

Objective: Hematopoietic disorders are known to increase the risk of complications such as osteoporosis. However, a direct link between hematopoietic cellular disorders and osteoporosis has been elusive. Here, we demonstrate that the deterioration of hematopoietic autophagy is coupled with osteoporosis in humans and animal models.

Methods: (1) In clinical research, physical examination results of 4979 healthy individuals were analyzed for blood count and BMD. Femur or tibia-derived bone marrow were obtained from young normal BMD patient (BMD > -1.0, age < 40 y) and aged osteoporosis patients(BMD < -2.5, age > 60 y). Bone marrow monocytes were stained by CD34 and CD45 antibody. LC3 expression of bone marrow hematopoietic cells were measured by ImageStream. (2) In animal research, bone marrow was collected from ovariectomized mice and control mice. The proportion and cell apoptosis of hematopoietic stem and progenitor cells were measured by flow cytometry. P62 and LC3 expression of hematopoietic stem and progenitor cells were detected by western blotting. Hematopoietic stem and progenitor cells autophagy function was observed by image flow cytometry double staining. (3) Then we performed mice deleted Atg7 gene, using an Vav-Cre transgene, which targets cells at bone marrow hematopoietic cells ($Atg7^{f/f}$;Vav-Cre); the control group was $Atg7^{f/f}$ genomic DNA from skin samples of harvested mice were used to genotype animals by PCR. Bone marrow hematopoiesis cells LC3-I and LC3-II protein expression were measured to confirm autophagy disordered. Mice were euthanized at 8 weeks. Calcein of 30 mg/kg was injected 7 days and 2 d before harvested. Tibiae and femora were collected. μCT was performed for BMD, cortical thickness and trabecular bone quantification. Bone trabecular was observed by electron microscopic images. Harvested bone tissues were sectioned for hematoxylin and eosin (H&E), tartrate-resistant acid phosphatase (TRAP), Collagen1, and osteocalcin staining. Osteoblasts and osteoclasts were quantified for histomorphometry. Phalloidin staining of action was performed on tibia for immunofluorescence. Femora were tested in 3-point bending for bone biomechanical properties. Skeleton samples were stained by Alcian blue solution and Alizarin red S solution. Bone tissue was observed by scanning electron microscope. (4) $Atg7^{f/f}$;Vav-iCre bone tissue was collected for TMT labeled proteome analysis. Western blot was used to verified the proteome results. (5) $Atg7^{f/f}$;Vav-iCre tibia CD31hiEMCNhi vessel was observed by immunofluorescence. mRNA of vessels metabolism was measured.

Results: (1) Red blood cell count was reduced in both male and female osteoporotic patients. Human hematopoietic stem progenitor cells (CD34 + CD45 +) LC3 protein was inhibited in aged people, which related to decreased autophagy. (2) The proportion of hematopoietic stem and progenitor cells was increased in ovariectomized mice. However, the apoptosis of hematopoietic stem and progenitor cells was also increased. Bone marrow hematopoietic stem cells displayed a reduced basal autophagy activity in ovariectomized mice. Hematopoietic stem cells frequency in hematopoietic stem and progenitor cells was also reduced in ovariectomized mice. (3) Deletion of Atg7 in hematopoietic system caused low bone mass. $Atg7^{f/f}$;Vav-iCre mice BMD was lower. μCT analysis revealed that trabecular number, bone volume/tissue volume, cortical thickness were decreased. Quantification of tetracycline labeling showed reduced mineralized surface in $Atg7^{f/f}$;Vav-iCre mice, which resulted in a low bone formation rate. The H&E staining showed $Atg7^{f/f}$;Vav-iCre mice trabecular degeneration and more fat tissue. The TRAP staining showed there was more abundance and activity of osteoclasts in $Atg7^{f/f}$;Vav-iCre mice. Scanning electron microscope depicted trabecular microstructure destruction. There is no size difference in skeleton staining. The absence of Atg7 in hematopoietic resulted in weak bone biomechanical strength properties. (4) Integrative proteomics functional enrichment of differentially quantified proteins showed $Atg7^{f/f}$;Vav-Cre mice bone tissue immune response upregulated while skeletal system morphogenesis and development downregulated. STAT1, STAT3 and p38 in Th17 cell differentiation were up regulated. Collagen1 in ECM-Receptor interaction was downregulated. immunohistochemical of bone tissue verified collagen1 protein expression decreased. (5) Bone CD31hiEMCNhi vessel was inhibited in $Atg7^{-/-}$ mice. RT-PCR showed Vegfa was downregulated in $Atg7^{-/-}$ mice.

Conclusion: Hematopoietic autophagy defect causes disruption of CD31hiEMCNhi vessel via inhibition of Vegfa, resulting in bone loss. We therefore propose that hematopoietic autophagy is required for the integrity of H vessels that bridge blood and bone cells and that its deterioration leads to osteoporosis.

P1377
COMPARISON BETWEEN AUTOLOGOUS BONE AND BONE MORPHOGENETIC PROTEIN 2 IN BONE REGENERATION USING NEW MASQUELET TECHNIQUE RABBIT MODEL

Y. Yamamoto[1], T. Fukui[1], K. Oe[1], Y. Kumabe[1], K. Sawauchi[1], R. Yoshikawa[1], K. Takase[1], R. Nishida[1], H. Kondo[1], T. Niikura[2], R. Kuroda[1]

[1]Kobe Univ. Graduate School of Medicine/Dept. of Orthopaedic Surgery/Kobe Univ. Hospital/Japan, Kobe, [2]Hyogo Prefectural Nishinomiya Hospital/Dept. of Orthopaedic Surgery/Japan, Nishinomiya, Japan

Objective: The Masquelet technique is a relatively new treatment for critical-sized bone defects. Although good results have been reported, pain and bleeding associated with autologous bone grafting are negative aspects to the patients. Recently, using bone morphogenetic protein 2 (BMP-2) as a noninvasive bone regeneration therapy has attracted attention, but its difference with autologous bone grafting is unknown. In this study, we created a new Masquelet model of rabbit femoral bone defects and compared the bone regenerative effects between autologous bone and β-tricalcium phosphate (β-TCP) granules containing BMP-2.

Methods: 24-week-old New Zealand white rabbits were used. In the first operation, a 20-mm defect was created in the femur, internally fixed with a locking plate and screws, and filled with bone cement. In the second operation, the bone cement was removed after 4 weeks and formation of an induced membrane around the defect was confirmed. The autologous bone graft group (n = 12) and BMP-2 group (n = 5) were filled with the bilateral iliac bones and β-TCP containing BMP-2, respectively. At 12 weeks after the second operation, bone union and regeneration were evaluated by radiologically (modified Lane–Sandhu radiographic scoring system), histologically, and biomechanically by three-point bending tests and compared.

Results: Radiological assessment using X-rays showed that both groups achieved bone union; therefore, a new Masquelet technique model of rabbit femoral defects could be created successfully. Additionally, the BMP-2 group had better bone union, although there was no significant difference between the two groups. Histological evaluation showed good bone regeneration in both groups. Biomechanical evaluation showed no significant differences in ultimate stress, extrinsic stiffness, and failure energy, but they tended to be higher in the autologous bone graft group.

Conclusion: A new Masquelet technique model of rabbit femoral bone defects was created successfully. Although the BMP-2 group tended to be mechanically weaker than the autologous bone graft group, the results suggest that bone regeneration treatment is equiv-

alent to autologous bone graft and may eliminate the need for an autograft.

P1378
STUDY ON THE MECHANISM OF INHIBITING TITANIUM PARTICLE-INDUCED OSTEOLYSIS BY ARC THROUGH INFLAMMATORY FACTORS AND GUT MICROBIOTA

L. Tang[1], Y. Zhang[1], Y. Zhou[1], Q. Dong[2], P. Sun[1]

[1]The First Affiliated Hospital of Guangdong Pharmaceutical Univ., Guangzhou, [2]Yunfu Hospital of Traditional Chinese Medicine, Yunfu, China

Objective: To investigate the mechanism of Arctiin (ARC) inhibiting titanium particle-induced osteolysis around the skull in mice based on the changes of inflammatory factors and gut microbiota.
Methods: Twenty 7-week-old, female C57BL/6 J mice were randomly divided into four groups (5 mice for each group): blank group (SHAM), model group (Vehicle), ARC low-dose group (L-ARC) and ARC high-dose group (H-ARC). L-ARC and H-ARC groups were intraperitoneally injected with ARC 5 mg/kg/d and 10 mg/kg/d respectively on the basis of Vehicle, and SHAM and Vehicle groups were intraperitoneally injected with the same dose of normal saline. After treatment for 2 weeks, the following parameters of skulls: BMD, BV/TV, Tb.N, BS/BV, Tb.Sp and Tb.Th were detected by μCT. The levels of TRACP5b, CTX, OCN, IL-6, TNF-α and IL-10 in serum samples were detected by ELISA. 16S rRNA sequencing was used to analyze the structure and abundance of gut microbiota.
Results: BMD, BV/TV, Tb.N, BS/BV, Tb.Th, OCN and IL-10 were significantly decreased in Vehicle group compared with SHAM group ($P < 0.01$, $P < 0.05$); Tb.Sp, TRACP5b, CTX, IL-6 and TNFα were significantly increased ($P < 0.05$, $P < 0.01$). Compared with Vehicle group, BMD, BV/TV, Tb.N, BS/BV, Tb.Th and OCN in L-ARC group had an increasing trend ($P > 0.05$), Tb.Sp, TRACP5b and CTX had a decreasing trend ($P > 0.05$), TNFα and IL-6 were significantly decreased ($P < 0.05$), and IL-10 was significantly increased ($P < 0.05$). Compared with Vehicle group, the levels of BMD, BV/TV, Tb.N and IL-10 in H-ARC group were significantly increased ($P < 0.05$, $P < 0.01$), the levels of TRACP5b, CTX, IL-6 and TNFα were significantly decreased ($P < 0.05$, $P < 0.01$), while the levels of BS/BV, Tb.Th and OCN had an increasing trend ($P > 0.05$), Tb.Sp had a decreasing trend ($P > 0.05$). At the phylum level, compared with SHAM group, F/B ratio had an increasing trend in Vehicle group ($P > 0.05$); However, compared with Vehicle group, the F/B ratio of L-ARC and H-ARC groups were significantly decreased ($P < 0.01$). At the genus level, compared with SHAM group, the abundance of Ileibacterium in Vehicle group had an increasing trend ($P > 0.05$), the abundance of Prevotellaceae_UCG-001 and Rikenellaceae_RC9_gut_group in Vehicle group had a decreasing trend ($P > 0.05$). While compared with Vehicle group, the abundance of Ileibacterium in L-ARC and H-ARC groups were significantly decreased ($P < 0.05$); the abundance of Prevotellaceae_UCG-001 and Rikenellaceae_RC9_gut_group in L-ARC and H-ARC were significantly increased ($P < 0.05$).
Conclusion: ARC can inhibit titanium particle-induced osteolysis in mice by suppressing inflammation and modulating the structure of gut microbiota in a dose-dependent manner.

ABLATION OF VITAMIN D RECEPTOR INDUCED FIBROSIS OF SKELETAL MUSCLE IN AT2R(-/-) MICE

Y.-D. Wei[1], Y.-X. Guo[1], S.-H. Xia[1], Z.-H. Jia[2], Y. Zhang[1]

[1]Spine Disease Research Institute, Longhua Hospital, Shanghai Univ. of Traditional Chinese Medicine, Shanghai, [2]National Key Laboratory for Innovation and Transformation of Luobing Theory, Shijiazhuang, China

Objective: To investigate the potential regulatory role of angiotensin type 2 receptor (AT2R) and vitamin D receptor (VDR) on fibrosis of skeletal muscle in mice.
Methods: Grip strength tests were performed on 16-week-old wild-type (WT) and AT2R(-/-) mice, and on 12-week-old AT2R(-/-) mice and AT2R(-/-)/VDR(-/-) (DKO) mice. The wet weight ratio and the molecular expressions of fibrotic and profibrotic factors were measured in mice hindlimb muscles.
Results: 1. As compared to WT mice, there was no significant difference in the wet weight ratio of the hindlimb skeletal muscles of AT2R(-/-) mice, while, the mRNA expression of fibronectin (FN), CTGF, VEGF ($P < 0.05$) and myostatin (MSTN) displayed the decreasing trend. The protein expression of TGFβ and Col-IV was significantly downregulated ($P < 0.05$) associated with a marked reduce in content of MSTN ($P < 0.05$) in skeletal muscle of AT2R(-/-) mice. 2. In a comparison with AT2R(-/-) mice, the DKO mice showed the significant upregulation ($P < 0.05$) in protein expression of the fibrotic indicators like Col-IV, TGF-ß and VEGF, along with a profound elevation in protein expression of renin ($P < 0.05$). The immunofluorescence detection indicated that the relative fluorescence intensity and the fluorescence area of FN were both enhanced in the gastrocnemius muscle of DKO mice ($P < 0.05$).
Conclusion: The knockout of AT2R gene might alleviate the degree of muscle fibrosis in mice. Importantly, VDR ablation exacerbated skeletal muscle fibrosis of AT2R knockout mice, which was, at least partially, attributed to the over-activity of renin-angiotensin system that could lead to tissue fibrosis.

ELDECALCITOL PROTECTS MUSCLE TISSUE OF MICE FROM FIBROSIS ASSOCIATED WITH SENESCENCE

Y.-X. Guo[1], X.-M. Li[2], Z.-Y. Zhang[3], Z.-H. Jia[4], Y. Zhang[1]

[1]Spine Disease Research Institute, Longhua Hospital, Shanghai Univ. of Traditional Chinese Medicine, Shanghai, [2]Dept. of Orthopaedics, Cangzhou Hospital of Integrated TCM-WM, Cangzhou, [3]Dept. of Endocrine, Cangzhou Hospital of Integrated TCM-WM, Cangzhou, [4]National Key Laboratory for Innovation and Transformation of Luobing Theory, Shijiazhuang, China

Objective: Our early studies explored the key roles of vitamin D receptor (VDR) in protecting tissue fibrosis using VDR(-/-) mice and VDR agonists. Recently we published a paper demonstrating that vitamin D/VDR signaling ameliorated skeletal muscle atrophy by suppressing renin-angiotensin system (RAS). The present study aimed to investigate the preservation of VDR agonist eldecalcitol against muscle fibrosis associated with aging and the underlying mechanism.
Methods: The male C57BL/6 mice were divided into 3 groups ($n = 10$ in each group): mice in normal control treated daily with vehicle, mice in aging model group treated daily with D-gal (300 mg/kg, i.p., one classical inducer for aging) for 8 weeks, thereafter mice

in model group and in treatment group were treated with D-gal or combined with intraperitoneal injection (3 times per week) of eldecalcitol (0.05 μg/kg) for subsequent 8 weeks. The frozen slides of gastrocnemius were stained with H&E and sirius. The activity of senescence-associated-β-galactosidase (SA-β-Gal) was measured by staining kit. Immunoblotting was used to detect expressions of fibrotic factors and those involved in angiotensin II (Ang II, active peptide within RAS)/TGFß/ß-catenin pathway.

Results: Eldecalcitol (ELD) enhanced muscle index of tibialis anterior and gastrocnemius, grip strength and weight-loaded swimming time of mice with D-gal-induced senescence. ELISA detections showed the reduction and elevation of myostatin and irisin, respectively, in serum of ELD-treated mice in a comparison with those in model group. Histological staining demonstrated the repression of ELD on the decrease in area of myofibers and the accumulation in extracellular matrix as well as that ELD profoundly reduced the SA-β-Gal-positive area among muscle fibers. Molecular measurements demonstrated that ELD inhibited the upregulation in protein expression of fibrotic factors including type I and type III collagens, fibronectin, and profibrotic signaling factors including renin, Ang II, TGFß, ß-catenin, and tissue inhibitors of metalloproteinase (TIMP)-1 and 2 in muscle of D-gal-evoked aging mice.

Conclusion: VDR agonist eldecalcitol displayed beneficial effects on skeletal muscle function and strength in mice associated with D-gal-induced senescence by alleviating muscular dystrophy and fibrosis via suppressing Ang II/ TGFß/ß-catenin pathway.

Acknowledgments: This study was supported in part by National Key R&D Program from Ministry of Science and Technology of China (2023YFC3504305), National Natural Science Foundation of China (82,074,468), and Chugai Pharma China Co., Ltd.

TARGETING THE RANK/RANKL/OPG BONE PATHWAY AS TREATMENT STRATEGY FOR CONGENITAL MUSCULAR DYSTROPHY TYPE 1A

Z. Bouredji[1], A. Argaw[1], J. Frenette[1]

[1]Centre Hospitalier Universitaire de Québec, Centre de Recherche du Centre Hospitalier de l'Université Laval (CRCHUQ-CHUL), Axe Neurosciences, Université Laval., Quebec City, QC, Canada

Objective: Congenital muscular dystrophy type 1A (CMD1A) is a lethal genetic neuromuscular disease caused by mutations in the LAMA2 gene that encodes the laminin α2 subunit, a structural protein ensuring muscle integrity during contractions. A large proportion of the children affected by CMD1A does not reach adolescence. Dystrophic muscles undergo cycles of degeneration and regeneration combined with chronic inflammation and an irreversible fibrosis. Several studies have shown that bone and muscle loss occur simultaneously in several neuromuscular diseases. Our team hypothesized that the RANK/RANKL/OPG system, the main regulator of bone remodeling, plays a key role in bone-muscle crosstalk. The interaction between RANK and its ligand RANKL is responsible for bone resorption, while osteoprotegerin (OPG) acts as a soluble RANKL receptor inhibits bone breakdown. We previously showed that a 10-d treatment with full-length OPG fused to a Fc fragment (FL-OPG- Fc) restored muscle function in mdx mice, and one-month treatment with anti-RANKL increased dystrophic bone and muscle functions. Our recent work also showed that RANKL neutralization modulated NF-κB activation and prevented dystrophic hearts from hypertrophy. The present study investigated whether FL-OPG-Fc or anti-RANKL protect skeletal muscle and bone in CMD1A.

Methods: We tested the effects of these treatments in male dy^{2J}/dy^{2J} mice (CMD1A mouse model), a more severe and genetically different dystrophic mice model. Four weeks old dy^{2J}/dy^{2J} mice received either FL-OPG-Fc [1 mg/kg/d] for 10 days or an anti-RANKL [4 mg/kg/3d] for 28 d. The contractile properties of slow and fast twitch skeletal muscles and the mechanical bone properties of tibiae were assessed ex vivo.

Results: Our results show that acute treatment with FL-OPG-Fc significantly improves the absolute and specific strength of dystrophic skeletal muscles. Although to a lesser extent, anti-RANKL treatment also improves dystrophic skeletal muscle force. Noteworthy, dy^{2J}/dy^{2J} mice display bone weakness and prolonged treatment with anti-RANKL improves bone stiffness and ultimate load. FL-OPG-Fc seems to be more efficient than the anti-RANKL in protecting skeletal muscles, suggesting that FL-OPG-Fc may also act independently of RANKL inhibition.

Conclusion: Our results open potentially new clinical applications for the protection of skeletal muscles and bones in CMD1A.

P1382
CORRELATION BETWEEN BMD AND SHORT STATURE IN THALASSEMIA MAJOR PATIENTS

Z. Hamidi[1], M. R. Mohajeri-Tehrani[1], B. Larijani[1]

[1]Endocrinology and Metabolism Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran Univ. of Medical Sciences, Tehran, Iran

Objective: Thalassemias are the most prevalent monogenic diseases in the world. Beta thalassemia major type features serious anemia that requires continuous lifesaving blood transfusions. It is endemic in Iran. Short stature is a common problem in these patients. There are different factors that cause shortening of spine. Pathological macro and micro-fractures due to low BMD that is also a common complication in thalassemia, are named as risk factor. We tested this relationship in Iranian thalassemia major children. For better understanding of association of BMD and short stature in our pediatric patients, we also assessed the correlation of shortness with BMAD (bone mineral apparent density), an adjusted form of BMD in children.

Methods: The participants in this study were 110 β-thalassemia major girls and boys aged 3–18 y. They were referred to BMD department of Endocrinology and Metabolism Research Institute of Tehran University of Medical Sciences. A medical history obtained about any drug or disease that affects BMD. No one was a current or chronic user of systemic steroids. Thalassemics with major risk factor for osteoporosis omitted from this study. BMD of femoral neck and spine L2-L4, measured by one DXA machine (Hologic Discovery) and by one operator. Estimated volumetric BMAD was calculated for the lumbar spine (LSBMAD) and femoral neck (FNBMAD). Continuous variables were summarized as means, standard deviations (SDs), and ranges. Categorical variables were summarized as simple percentages. The independent-samples t-test procedure was used for comparison of means of the two groups.

Results: Mean age of patients was 9.6 ± 4.3 y/o. Mean height was 130 ± 21. From 110 participants, 37 were females. Short stature prevalence found 13%. Mean of femoral BMD and BMAD, spinal BMD and BMAD was 0.579 ± 0.134 g/cm^2, 0.162 ± 0.096 g/cm^3, 0.563 ± 0.118 g/cm^2 and 0.107 ± 0.015 g/cm^3, respectively. BMD and BMAD of spinal and femoral regions were not significantly different in short stature in comparison to height patients.

Conclusion: BMD in absolute form and in adjusted form (BMAD), showed no significant correlation with short stature in thalassemia major children. We can conclude that low BMD has no association with short stature in these patients.

P1383
RELATIONSHIP BETWEEN VITAMIN D RECEPTOR GENE POLYMORPHISM (TAQI) AND VITD-TOTAL LEVEL IN POSTMENOPAUSAL WOMEN OF EASTERN SLOVAKIA

M. Mydlárová Blaščáková[1], Z. Lörinczová[2], S. Žiláková[1], K. Kubalová[1], G. Sabolová[1], L. Mikulová[3], S. Dubecká[4]

[1]Dept. of Biology, Faculty of Humanities and Natural Sciences, Univ. of Prešov, Prešov, [2]Osteocentre, AGEL Hospital Košice-Šaca, Košice-Šaca, [3]Dept. of Technical Disciplines in Health Care, Faculty of Health Care, Univ. of Prešov, Prešov, [4] V. Internal Clinic, Faculty of Medicine of the Univ. of Comenius and Univ. Hospital Bratislava-Ružinov, Bratislava, Slovakia

Objective: Osteoporosis is a polygenic and multifactorial disease characterized by an increased risk of fractures, reduced BMD. Genetic and environmental factors play a key role in the etiology of osteoporosis. The vitamin D receptor gene (VDR) is an important candidate gene for the modification of BMD levels and the development of osteoporosis. Several polymorphic variants (ApaI, BsmI, FokI, TaqI, Cdx2) have been identified in the VDR gene, which may lead to changes in the protein sequence or affect the degree of gene expression, thus contributing to the development of osteoporosis. In our study we focused on the molecular- genetic analysis of polymorphic variant of the TaqI VDR gene and its association with the vitamin D-total level in postmenopausal women from eastern Slovakia.
Methods: The study population consisted of 299 postmenopausal women who were divided into three groups based on densitometric examination and medical screening: control group (CG = 68), osteopenia (OPE = 130), osteoporosis (OPO = 101). A peripheral blood sample was used for molecular genetic analysis, which was collected in S-Monovette tubes (K_3EDTA). DNA isolation was carried out according to a standard protocol using the commercial NucleoSpin Blood kit (Macherey–Nagel, Germany). Genotyping of the TaqI (rs731236) polymorphism of the VDR gene was performed by real-time PCR, using the TaqMan probe and the StepOne Real-Time PCR system (Applied Biosystems, USA). Biochemical analysis of VITD-total was performed in blood serum using Cobas e411 analyzer (Roche, Japan).
Results: Using chi-square test, we did not detect statistically significant difference in the representation of TaqI VDR gene polymorphism genotypes between the monitored groups of women with osteoporosis ($\chi^2 = 2.485$, $p = 0.647$). When comparing the values multiple times, through the analysis of variance, we found a statistically significant difference in the biochemical parameter VITD-total between all monitored groups of women in the genotypes: AA ($p < 0.05$), AG ($p < 0.01$) and GG ($p < 0.05$).
Conclusion: Women diagnosed with osteoporosis with at least one minor G allele had the lowest VITD-total values. This study expand knowledge about the genetic variability of the TaqI VDR gene polymorphism in the female population of eastern.

P1384
ENHANCING QUALITY OF CARE FOR PATIENTS WITH HIP FRACTURES AND PREVENTION OF INPATIENT FALLS WITHIN THE UK USING DATA DRIVEN FEEDBACK FROM NATIONAL AUDITS: RESULTS OF A VIRTUAL QUALITY IMPROVEMENT COLLABORATIVE

Z. Mohsin[1], L. Thomas[2], C. Cormack[2], R. Dickinson[2], J. Evans[2], S. Nisar[2], F. Roberts[2], S. Doyle[2], L. Quinney[2], A. Smith[2], K. Whitehead[2], J. Whitney[2], A. Johansen[2], J. Dean[2], B. Wiles[2], S. Nedungayil[2], M. K. Javaid[1]

[1]Univ. of Oxford, [2]Royal College of Physicians, London, UK

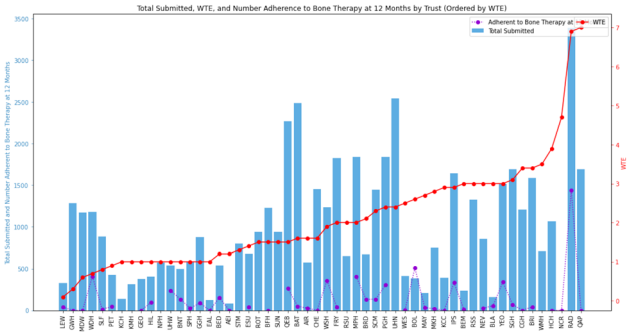
Objective: The UK healthcare system faces the significant burden of managing approximately 75,000 hip fractures and 250,000 inpatient falls annually. Quality Improvement (QI) initiatives offer a means to enhance care delivery. This study reports on a pilot virtual collaborative by the Falls and Fragility Fracture Audit Programme (FFFAP) aimed at refining inpatient fall prevention and hip fracture management.
Methods: Utilising the Institute for Healthcare Improvement (IHI) model, a virtual training collaborative was deployed over 11 months for 9 healthcare professional teams. The program's impact was measured via pre- and post-intervention questionnaires, analysed against Moore's outcomes.
Results: The intervention led to all teams exhibiting actionable learning and attaining level 5 in Moore's outcome framework, heightened motivation, improved team dynamics, and better interteam collaboration. Notably, 6 teams completed a QI project, with two achieving substantial improvements. Importantly, all initiatives prioritised patient engagement and a patient-centric design. However, none of the sites achieved their stated aims.
Conclusion: The collaborative training notably advanced the expertise and teamwork of healthcare professionals. However, further work is required to study the causes of lack of translation of quality improvement measures into improvement in patient outcomes.

P1385
DO FRACTURE LIAISON SERVICE (FLS) STAFFING LEVELS PREDICT FLS SERVICE PERFORMANCE?

Z. Mohsin[1], R. Shrestha[1], B. Wiles[2], C. Cockill[3], R. Pinedo-Villanueva[1], A. Johansen[2], M. Sanchez[1], M. K. Javaid[1]

[1]Univ. of Oxford, London, [2]Royal College of Physicians, London, [3]Yeovil District Hospital, Yeovil, UK.

Objective: While FLSs are widely recommended to deliver secondary fracture prevention, staffing levels vary considerably between services. This is important because staffing is a major cost for an FLS. We examined the relationships between whole time equivalent (WTE) staffing levels and clinical outcomes.
Methods: We used data from the UK FLS Database (FLS-DB) 2021 Organisational Data and FLS-DB 2021 Clinical Data and combined WTE of nurse and administrator time for each FLS. WTE were compared to number of patient records submitted and adherence to bone therapy at 12 months.
Results: There was a positive correlation between increased WTE and total cases submitted ($r = 0.43$, $p = 0.004$) as well as 12-month patient adherence to bone protective treatment at 12 months ($r = 0.46$, $p = 0.002$) (Figure). However, removing an influential outlier from the data (by Robust Anomaly Detection) led to both correlations becoming not significant (total cases submitted, $r = 0.26$, $p = 0.1$, and adherence to bone protective treatment at 12 months, $r = 0.13$, $p = 0.4$).



Conclusion: While staff levels in FLSs are a key driver of FLS costs, they do not directly correlate with several key clinical outcomes. This finding suggests that factors beyond staffing levels predict FLS performance. Future research is needed to explore the relationship between FLS staffing and performance.

P1386
REPRESENTATION AND IMPACT OF NEWS MEDIA MESSAGES ABOUT OSTEOPOROSIS AND ITS TREATMENT: A MULTI-METHOD STUDY WITH RECOMMENDATIONS FOR IMPROVEMENT

R. Jones[1], C. Jinks[1], S. Holohan[2], Z. Paskins[1]

[1]Keele Univ., School of Medicine, [2]Keele Univ., School of Social, Political and Global Studies, Newcastle, UK

Objective: To explore (i) representations of osteoporosis and its treatment in news media (ii) investigate the impact of media representations on people's perceptions of the condition, and (iii) to develop recommendations for how to best communicate about osteoporosis and its treatment in future.
Methods: (i) A news media study (n = 218) used framing analysis to explore representations of osteoporosis and its treatment. (ii) Focus groups (n = 4) examined impact of media messages on perceptions of the condition, and its treatment, among people at risk of, with, or treating osteoporosis. Findings were synthesized to inform draft recommendations and finalised in stakeholder discussion.
Results: Study (i) found osteoporosis was framed as either a biomedical condition, lifestyle issue, or through human-interest stories. Study (ii) identified news stories elicited uncertainty, perpetuated stigma and stereotypes, and had little impact on participants. 33 recommendations spanned 4 areas: (1) identity of osteoporosis, (2) positive living and fracture prevention, (3) making information clear and accessible and (4) signposting. Recommendations highlighted the importance of:

- clearly defining osteoporosis, its cause, who is affected, how it is managed and its consequences (1).
- avoiding sensationalised messages which place blame on those affected and reducing stigma through promotion of positive portrayals of people living with osteoporosis (2).
- avoiding technical language and ensuring inclusivity by bringing in authentic voices of those with lived experience (3).
- directing audiences to relevant information and support (4).

Conclusion: This is the first study to generate evidence-based recommendations outlining how to best communicate osteoporosis and its treatment in the media. The recommendations have relevance for any audience intending to communicate about osteoporosis.
Acknowledgments: This work is funded by a Versus Arthritis PhD Scholarship. ZP is funded by the National Institute for Health Research (NIHR) (Clinician Scientist Award (CS-2018–18-ST2-010)/NIHR Academy). CJ is part funded by the NIHR Applied Research Collaboration (ARC) West Midlands.
Disclosures:
ZP has received consultancy and grant funding from UCB Pharma.

P1387
CURRENT OSTEOPOROSIS CARE IN UK PRIMARY CARE SETTINGS: A NATIONAL ESURVEY

A. Hawarden[1], N. Cox[1], L. Bullock[1], J. Protheroe[1], C. Jinks[1], Z. Paskins[1]

[1]Primary Care Centre Versus Arthritis, School of Medicine, Keele Univ., Newcastle-under-Lyme, UK

Objective: To identify current practice and perceptions of osteoporosis care in UK primary care settings.
Methods: Primary care staff were invited, via social media and research/professional networks, to participate in a national eSurvey. Participants were asked about professional role, experience of, confidence in, and challenges of delivering osteoporosis care.
Results: Data were collected August-November 2023. 341 participants completed or partially completed the eSurvey, consisting of 309 healthcare professionals (HCPs) and 32 non-HCPs (e.g., managers). Most respondents were GPs (207, 61%). 96% (325/338) of respondents agreed that osteoporosis is an important condition. However, only 20% (60/302) of HCPs reported osteoporosis care to be high priority. The majority of HCPs, were worried about the long-term side effects of osteoporosis medicines (67%, 204/306), and were not confident making recommendations about treatment breaks (64%, 193/301) or interpreting the numeric results of DXA scans (52%, 157/301). Osteoporosis care was reported to be predominantly delivered by GPs, Pharmacists and Nurse Practitioners. 247 (80%) HCPs were prescribers, most commonly using NICE guidance (160, 65%) to guide treatment decisions. 97 (39%) do not routinely provide, or direct to, patient information and 116 (47%) do not routinely arrange a medication review after prescribing osteoporosis medicines. When arranged, medication reviews are commonly generic annual reviews (75%, 97/130) and not osteoporosis specific. 176 HCPs reported conducting medication reviews and commonly asked about side effects (94%), adherence (94%) and drug administration (74%). Few enquired about back pain (44%) or height loss (29%). 19% (55/289) of HCPs reported low knowledge of osteoporosis. Improved postgraduate education, increased consultation time, and tools for risk/benefit communication were the highest rated options to help improve osteoporosis care.
Conclusion: To our knowledge, this is the first national survey of osteoporosis care in UK primary care settings. A qualitative study will further explore eSurvey results, with the long-term aim to develop resources to support evidence-based osteoporosis care.

HEMATOLOGICAL COMPLICATIONS OF BIOTHERAPIES IN RHEUMATIC DISEASES

Z. S. Zanned[1], B. S. Bouden[1], R. L. Rouached[1], B. A. Ben Tekaya[1], M. I. Mahmoud[1], T. R. Tekaya[1], S. O. Saidane[1], A. L. Abdelmoula[1]

[1]Rheumatology Dept.—Charles Nicolle Hospital Tunis, Tunis, Tunisia

Objective: Biotherapies have revolutionized the management of several chronic inflammatory rheumatic diseases. Although their efficacy is proven, some adverse effects have been reported, such as hematological complications. We aimed to study the frequency of hematological adverse effects in patients treated with biotherapies.
Methods: A single-center retrospective study was conducted. Patients diagnosed with rheumatoid arthritis (RA) or spondyloarthritis (SpA) between 1992–2016 and treated with biotherapies were included. Clinical and treatment-related data, including hematological adverse events, were studied.

Results: 82 patients were included. 29 men and 54 women. The mean age was 49,3 y (22–75 y). 48 were diagnosed with RA and 35 with SpA (14 ankylosing spondylitis, 11 inflammatory bowel disease-associated SpA and 10 psoriatic arthritis). 29 patients were treated with infliximab (35%), 20 with etanercept (25%), 11 with adalimumab (13%), 20 with rituximab (25%) and 2 with tocilizumab (2%). Eight cases of hematological complications were reported (10%): 2 cases of thrombocytopenia and 6 cases of leukopenia (3 cases neutropenia and 3 cases lymphopenia). Five of these were treated with infliximab, 1 with adalimumab and 1 with rituximab. The average time onset was 8 months (1–24). In 1 case, discontinuation of infliximab and switch to etanercept was accompanied by normalization of the cell blood count. In the other cases, treatment was continued with regular monitoring.
Conclusion: Blood count disorder is not an uncommon phenomenon under biological treatment, reported in 10% of this series. It is mostly observed in patients receiving infliximab.

P1389
ARE VIRAL INFECTIONS FREQUENT IN PATIENTS TREATED WITH BIOTHERAPIES?

B. S. Bouden[1], Z. S. Zanned[1], R. L. Rouached[1], B. A. Ben Tekaya[1], M. I. Mahmoud[1], T. R. Tekaya[1], S. O. Saidane[1], A. L. Abdelmoula[1]

[1]Rheumatology Dept.—Charles Nicolle Hospital Tunis, Tunis, Tunisia

Objective: Biotherapies are widely used to treat chronic inflammatory rheumatic diseases such as rheumatoid arthritis (RA) and spondyloarthritis (SpA). Among the side effects, several studies have reported an increased risk of opportunistic infections such as tuberculosis, parasitic and viral infections. We aimed to study the frequency of viral infections in patients treated with biotherapies.
Methods: A single-center retrospective study was conducted. Patients diagnosed with RA or SpA between 1992–2023 and treated with biotherapies were included. Clinical and treatment-related data, including viral complications, were studied.
Results: 84 patients were included. 29 men and 55 women. The average age was 59 y (22–75 y). 50 were diagnosed with RA. 34 SpA (13 ankylosing spondylitis, 11 inflammatory bowel disease-associated spa and 10 psoriatic arthritis). 29 patients were treated with infliximab, 20 with etanercept, 11 with adalimumab, 21 with rituximab and 3 with tocilizumab. Seven episodes of viral infections were reported (8%): two cases of herpes zoster, two cases of herpes simplex infection and three cases of reactivated hepatitis B. Six patients were on TNFα inhibitors: 4 infliximab and 2 etanercept. one patient was on rituximab. These infections were diagnosed after an average of 36 months from the start of treatment with biotherapies (6–60 months). The two cases of herpes zoster were cured after discontinuation of etanercept and initiation of acyclovir. The herpes simplex infection was managed with acyclovir, and infliximab treatment has been resumed 2 weeks after. The 3 cases of hepatitis B were controlled by antiviral treatment.
Conclusion: Biological therapies, especially TNFα inhibitors, may lead to an increased risk of viral infections. These infections were reported in 8% of our patients.

P1390
QUALITY OF LIFE AND ANXIETY-DEPRESSIVE DISORDERS IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS

Z. S. Zanned[1], B. S. Bouden[1], R. L. Rouached[1], B. A. Ben Tekaya[1], M. I. Mahmoud[1], T. R. Tekaya[1], S. O. Saidane[1], A. L. Abdelmoula[1]

[1]Rheumatology Dept.—Charles Nicolle Hospital Tunis, Tunis, Tunisia

Objective: Axial spondyloarthritis (AxSpA) is a chronic inflammatory rheumatic disease that affects young adults and can cause significant pain and functional disability. It may be accompanied by fatigue, anxiety and even depression which can have a negative impact on quality of life (QoL). The aim of the study was to assess the level of QoL and the association of anxiety, depression and clinical factors with the quality of life of patients with AxSpA.
Methods: We conducted a cross-sectional study, including patients diagnosed with AxSpA according to ASAS 2009 criteria, followed at a Tunisian Rheumatology Department. For each patient, sociodemographic, disease, and treatment data were assessed. Each patient completed the Hospital Anxiety and Depression Scale (HAD) questionnaire to screen for anxiety and depression, and the ASQol: Ankylosing Spondylitis Quality of Life questionnaire to assess quality of life (QoL) (score ranging from 0 (good QoL) to 18 (poor QoL)).
Results: Our study included 105 patients with AxSpA, 67.6% of whom were men, with a mean age of 41.9 ± 13.76 y and a mean disease duration of 11.81 y [1–50]. Mean BASDAI was 4.46 ± 2.5 and mean BASFI was 4.87 ± 2.18. Mean CRP was 24.12 ± 10.2 mg/l. 62.3% of patients had coxitis, 9.1% of whom had undergone total hip replacement. Regarding the treatment, 10.47% were on biotherapy. Depression was noted in 49.5% of patients, with a mean HADS depression of 10.41 ± 3.6. Anxiety was noted in 64.7% of patients, with a mean HADS anxiety of 9.82 ± 4.3. For the quality-of-life score, the mean ASQoL was 8.27 ± 4.71. A high ASQoL, indicating impaired quality of life, was significantly associated with an early age of onset ($p = 0.04$) and high CRP levels ($p = 0.01$). A significant relationship was also found between HAD and hip involvement ($p = 0.001$) and HAD correlated positively with BASDAI ($p = 0.002$).
Conclusion: These findings should encourage practitioners to screen AxSpA patients for anxiety and depressive disorders. Controlling factors associated to these indices, including inflammation, high disease activity and the presence of hip involvement is crucial to promote QoL.

P1391
TUBERCULIN SKIN TEST AND INTERFERON-GAMMA TESTS IN SCREENING OF LATENT TUBERCULOSIS BEFORE BIOLOGICAL TREATMENT

B. S. Bouden[1], Z. S. Zanned[1], R. L. Rouached[1], B. A. Ben Tekaya[1], M. I. Mahmoud[1], T. R. Tekaya[1], S. O. Saidane[1], A. L. Abdelmoula[1]

[1]Rheumatology Dept.—Charles Nicolle Hospital Tunis, Tunis, Tunisia

Objective: Among the infectious complications of biotherapies, tuberculosis reactivation is a not an uncommon complication. Therefore, it is essential to screen for latent tuberculosis (LTBI) prior to starting biologic therapy. Two types of screening tests for LTBI are currently available: the tuberculin skin test (TST) and the interferon-gamma release assay (IGRA). We aimed to compare the results of these two methods in the detection of latent tuberculosis.
Methods: Patients with rheumatoid arthritis (RA) or spondyloarthritis (SpA) at a rheumatology department, and eligible for biotherapy were included between 2020–2023. All these patients had an IGRA test and a TST.
Results: 130 patients including 43 men and 87 women were included. The mean age was 48 y (25–79). 99 had RA and 31 had SpA. All patients had their BCG vaccination correctly, and 12 of them had previously contracted active tuberculosis. Sputum BK tests were positive in 9 (6.9%) patients. A thoracic CT scan was requested for 48

patients and showed: signs of tuberculosis in 21 (16.15%), interstitial involvement in 11 (8.4%) patients and pulmonary fibrosis in 9 (6.9%) patients. The TST was positive in 34 patients (26.15%) and negative in 96 (73.8%). The IGRA test was positive in 25 patients (19.2%) and negative in 105 patients (80,7%). In 14 cases (10.7%), the IGRA test was negative and the TST positive, while in 5 cases (3.8%), it was the opposite. In all other cases, the findings of the 2 tests were matching. By applying the kappa test, we observe a moderate strength of agreement between these two methods (k = 0.575).

Conclusion: The risk of reactivation of latent tuberculosis increases with biotherapy, hence the importance of a good screening tool during the pre-treatment assessment and chemoprophylaxis, especially in an endemic country like ours.

P1392
WORK INSTABILITY AND ITS ASSOCIATED FACTORS AMONG PATIENTS WITH SPONDYLOARTHRITIS

Z. S. Zanned[1], R. L. Rouached[1], B. S. Bouden[1], B. A. Ben Tekaya[1], M. I. Mahmoud[1], T. R. Tekaya[1], S. O. Saidane[1], A. L. Abdelmoula[1]

[1]Rheumatology Dept.—Charles Nicolle Hospital Tunis, Tunis, Tunisia

Objective: Patients with spondyloarthritis often encounter challenges in maintaining employment due to the disease's impact on their work ability. This study aimed to assess the relationship between disease activity, function, and the work instability. Then, to identify factors associated with moderate to high levels of work instability.

Methods: A cross-sectional observational study was conducted. Demographic data (age, gender, educational level) and disease-related parameters (disease activity using BASDAI and ASDAS-CRP, CRP, VAS, functional ability with BASFI, extra articular manifestation) were collected Depression and anxiety were assessed using the Hospital Anxiety and Depression Scale (HAD). We also assessed whether the patient assisted regularly to their checkups in the last year. Job characteristics and workplace adaptations were recorded. Work instability was evaluated using AS-WIS, with results categorized as low (less than 10), medium (10–17), and high (above 17). Statistical analysis was performed using SPSS26 with the Mann–Whitney U test, χ^2 test, and Spearman's correlation.

Results: The study included 41 patients (M/F sex ratio was 2.72) with a mean age of 39.34 ± 12.58. Extra articular manifestations were present in 12 patients, including uveitis (16.7%), restrictive lung disease (25%), inflammatory bowel disease (33.3%), and psoriasis (25%). Disease parameters revealed a mean BASDAI of 3.08 ± 1.6, ASDAS-CRP 2.53 ± 1.13, and BASFI 4.18 [0.5–8.5]. Patients were under NSDAIDs in 24,1%, csDMARDS in 22,3%, and bDMARDs in 22%. Eleven patients (26,8%) had regular physical reeducation. Educational levels varied, with 31.8% having elementary education, 44% high school, and 24.4% university. The mean depression score was 5,74 ± 1,9 and the mean anxiety score was 4,54 ± 1,6. The mean AS-WIS score was 11,17 [2–18], Work instability was present in 58.8% of patients. Work instability was significantly associated with extra articular manifestations ($p = 0.004$) and lower educational levels ($p = 0.013$). Regular check-ups and physical reeducation were associated with work stability ($p = 0.04$ and $p = 0.01$, respectively). Significant correlations were observed between AS-WIS and disease parameters (BASDAI $R = 0.58; p < 0.001$, ASDAS-CRP $R = 0.46; p = 0{,}015$, BASFI $R = 0.66; p < 0.001$ and VAS $R = 0.70$, $p < 0.01$). Finally, AS-WIS correlated with HAD with its two components A and D ($R = 0.52$; $p = 0.001$ and $R = 0.63; p < 0.001$ respectively).

Conclusion: Work instability in patients with spondyloarthritis is closely linked to disease activity, functional ability, and indicators of psychiatric comorbidity. Regular monitoring and physical reeducation appear to be associated with improved work stability.

P1393
LOSS OF BODY WEIGHT IS DOSE-DEPENDENTLY ASSOCIATED WITH REDUCTIONS IN SYMPTOMS OF HIP OSTEOARTHRITIS

Z. Salis[1], R. Gallagher[2], L. Lawler[2], A. Sainsbury[3]

[1]Univ. of Geneva, Geneva, Switzerland, [2]Prima Health Solutions, Sydney, Australia, [3]Univ. of Western Australia, Perth, Australia

Objective: The burden of hip osteoarthritis (OA) on individuals and countries is substantial, significantly impacting daily activities and quality of life and incurring considerable economic costs. With no cure currently available for hip OA, effective management strategies, particularly weight loss, are crucial. Although weight loss is a recommended strategy for managing hip OA, the evidence is primarily from knee OA studies and is therefore not directly applicable to hip OA. This study aims to fill this gap by examining the impact of weight loss on HOA symptoms.

Methods: 1408 individuals diagnosed with hip OA were enrolled in an 18-week weight-loss program. All participants had clinically confirmed symptomatic hip osteoarthritis and a BMI of 25 kg/m^2 or higher. The weight-loss program was a remotely delivered intervention spanning 18 weeks, incorporated a low energy diet (phased use of meal replacements and portion-controlled light meals) and a lifestyle modification program plus a self-directed in-home Strength, Mobility and Pain Management program. The program aimed to achieve a 7–10% reduction in body weight over its 18-week period, emphasizing the transformation of the dietary habits of participants. At baseline and at the end of the 18-week period, body weight and all five subscales of the Hip disability and Osteoarthritis Outcome Score (HOOS) (pain, other symptoms, function in daily living, sports and recreation, and quality-of-life) were measured, with scores ranging from 0 (worst symptoms) to 100 (no symptoms). Linear regression, controlling for sex and baseline values of age, BMI, and HOOS, was used to evaluate the relationship between categories of weight loss ($\leq 2.5\%$, > 2.5–5.0%, > 5.0–7.5%, > 7.5–10%, and $> 10\%$ of baseline weight), and changes in all five subscales of the HOOS.

Results: Participants had a mean ± standard deviation (SD) age of 65.14 ± 9.42 y; 70% were female; the mean ± SD BMI was 34.12 ± 5.19 kg/m^2; and 78% had a BMI classified as obese (i.e., ≥ 30 kg/m^2). A statistically significant dose–response relationship was observed between weight loss categories and all five subscales of the HOOS, such that greater weight loss was associated with greater scores (i.e., fewer symptoms) (Table 1). The greatest improvement was in the quality-of-life subscale (mean ± SD point: 14.42 ± 18.62, 31.14% from the baseline) in the $> 10\%$ weight loss category (Table 1).

Table 1. Relationship between the different weight loss categories (according to percentage body weight loss) and HOOS subscales. Values are the mean±SD unless indicated otherwise. A positive difference for the Hip Disability and Osteoarthritis Outcome Score (HOOS) subscales indicates an improvement. MCII: Minimal clinically important improvement;

Conclusion: Our findings suggest that weight loss could reduce the symptoms of hip OA, supporting the potential of weight loss as an effective treatment strategy for hip OA.

P1394
BISPHOSPHONATES SHOW NO ASSOCIATION WITH PREVENTING, SLOWING, OR DELAYING RADIOGRAPHIC CHANGES AND PAIN IN HIP OSTEOARTHRITIS: A FOUR-YEAR STUDY IN FEMALE ADULTS USING DATA FROM THE OSTEOARTHRITIS INITIATIVE STUDY

Z. Salis[1]

[1]Univ. of Geneva, Geneva, Switzerland

Objective: To investigate the potential impact of bisphosphonates on radiographic changes and pain in individuals with no or early stages of hip osteoarthritis (OA).

Methods: This study examined data from the Osteoarthritis Initiative (OAI), which included 4,088 hips from 2,057 participants, predominantly with no or early stages of radiographic hip OA at baseline. Bisphosphonate users were identified as those who reported usage at least three times, including at baseline and during the subsequent 1-y, 2-y, 3-y, and 4-y follow-up visits. Non-users were participants who did not use bisphosphonates in the 5 y preceding the baseline and at subsequent follow-up visits. Generalized estimating equations were performed to assess the association between bisphosphonate use and outcomes relating to radiographic changes and pain in hip OA over a 4-y follow-up.

Results: The analysis revealed no statistically significant difference between bisphosphonate users and non-users concerning radiographic changes and pain in hip OA over 4 ys. Specifically, the odds ratios for the incidence and progression of radiographic hip OA were 0.58 (95%CI: 0.27 to 1.22) and 0.80 (95%CI: 0.49 to 1.32), respectively (Table 1). Furthermore, the odds ratios for the development and resolution of frequent hip pain were 1.04 (95%CI: 0.76 to 1.42) and 0.99 (95%CI: 0.72 to 1.36), respectively (Table 2).

Table 1. Association of bisphosphonate use and incidence and progression of radiographic hip OA, and worsening individual radiographic features of the hip OA, during 4-y follow-up in radiographic hip OA cohort, as shown in univariate and multivariable analyses.

* Defined as bisphosphonate use at least three examinations, including baseline and follow-up visits (1-year, 2-year, 3-year, and 4-year). ^Non-users were identified as those who did not use bisphosphonates in the preceding 5 years and at any of the examined time points. Multivariable analysis was adjusted for the baseline values of age, BMI, and analgesic use. CI: Confidence Interval; OA: Osteoarthritis.

Conclusion: The findings from this longitudinal study do not suggest an association between bisphosphonate use and the prevention, slowing, or delay of development and progression of radiographic changes or pain in hip OA among individuals with no or early stages of hip OA over a 4-y follow-up.

ELDECALCITOL INHIBITS BONE TURNOVER AND INCREASES BONE MASS VIA ACTING ON BMSCS

A. Xiong[1], Y. Gu[1], H. Li[1], M. Lin[1], R. Zhang[2], D. Bikle[3], Z. Xie[1]

[1]National Clinical Research Center for Metabolic Diseases, Hunan Provincial Key Laboratory of Metabolic Bone Diseases, and Dept. of Metabolism and Endocrinology, The Second Xiangya Hospital of Central South Univ., Changsha, China, [2]Dept. of Medical Laboratory, Hunan Normal Univ. School of Medicine, Changsha, China, [3]Veterans Affairs Medical Center, Univ. of California San Francisco, San Francisco, USA

Objective: Eldecalcitol (ELD) is an active vitamin D analogue that has been shown to inhibit bone turnover and increase bone mass, but the underlying mechanism is unclear. Bone marrow mesenchymal stem cells (BMSCs) are the progenitor cells of osteoblasts, and we hypothesized that ELD increases bone mass by acting on BMSCs. To test the hypothesis, we investigated the effect of ELD on bone mass and osteogenic differentiation of BMSCs in the vitamin D receptor (VDR) conditional knockout mice (VDR-cKO).

Methods: VDR-cKO mice were generated by breeding floxed-VDR mice and PRX1-Cre mice. Floxed-VDR mice were used as a control. Both control and VDR-cKO mice were treated with ELD at a dose of 50 ng/kg or vehicle for 4 weeks. μCT was performed to examine the bone mass and bone microstructure morphometrics of femur. Calcein double-labeling, ALP, and TRAP staining were used to examine the

bone mineral apposition rate (MAR), the number of osteoblasts, and osteoclasts, respectively. Primary BMSCs were isolated from 8-week-old wildtype mice and cultured in osteogenic medium. Cells were treated with ELD at concentrations of 10^{-10}, 10^{-9}, or 10^{-8} M for 7 d. The expression of RANK in BMSCs was reduced by siRNA and cells were then treated with 10^{-9} M ELD for 72 h. The mRNA and protein expression levels of RANK, RANKL and osteogenic differentiation markers including ALP and RUNX2 were examined by quantitative PCR.

Results: μCT showed that control mice treated with ELD showed increases in bone mass, bone volume percentage, and bone trabecular number as well as decreases in bone trabecular separation compared to those treated with the vehicle. Calcein double-labeling, ALP, and TRAP staining showed that control mice treated with ELD showed decreases in MAR, number of positive osteoblasts and osteoclasts compared to those treated with the vehicle. However, the effects of ELD were blocked by conditional knockout of VDR in BMSCs in mice. Treatment of BMSCs with ELD inhibited expressions of differentiation markers including ALP, RUNX2 and RANKL, and promoted RANK expression in BMSCs in a dose-dependent manner. However, the inhibitory effect of ELD on the expression of ALP, RUNX2, and RANKL was blocked by downregulation of RANK in BMSCs.

Conclusion: ELD inhibits bone turnover and increases bone mass via acting on the VDR of BMSCs. ELD inhibits osteogenic differentiation and RANKL expression via promoting the expression of RANK in BMSCs.

SY1
EARLY DETECTION OF OSTEOARTHRITIS: A SPECIFIC QUESTIONNAIRE FOR CLINICAL ASSESSMENT OF KNEE OA

A. Migliore[1]

[1]Head of Rheumatology Unit at San Pietro Fatebenefratelli Hospital, Rom, Italy

Latest global estimates suggest 595 million people were living with OA in 2020. The knee joint was the most affected site reported.

Despite the vast overall burden of disease an official definition of early stage of osteoarthritis (EOA) and its classification criteria are still lacking. Their validation would facilitate an early diagnosis to identify symptomatic knee OA and maximize the opportunity for treatment in the initial phase.

A novel tool to assess knee EOA has been created by a technical experts panel from the International Symposium Intra Articular Treatment (ISIAT) and is presented here by its primary author. The questionnaire is designed for diagnostic and follow-up assessment and considers two domains (Clinical Features and Patients Reported Outcome) for a total of 11 questions. The questions mainly explore the field of early symptoms and patients reported outcomes. This tool will provide guidance on treatment decisions (if pharmacological or non-pharmacological intervention is required) and will be used to monitor symptom progression and disease evolution.

SY2
EXPLORING SYSADOAS IN THE MANAGEMENT OF OSTEOARTHRITIS

N. Fuggle[1]

[1]Associate Professor of Rheumatology, MRC Lifecourse Epidemiology Centre, University of Southampton, Southampton, United Kingdom

The early stages of osteoarthritis provide a potential window of opportunity to change the disease trajectory and improve quality of life. For this reason, early diagnosis allows timely disease management and burden reduction. By using a multimodal approach including a range of non-pharmacological and pharmacological interventions throughout the course of the disease, there is a greater opportunity for effective symptomatic treatment and a possible opportunity to slow disease progression. Dr. Fuggle's presentation will focus on the role of symptomatic slow-acting drug for osteoarthritis (SYSADOAs) in the early stages of this important condition with particular focus on prescription grade glucosamine sulphate. Attention will be paid to the key efficacy and safety data for this medicine which forms an important part of the ESCEO guidelines for the management of osteoarthritis.

SY3
BALANCE BETWEEN EFFECTIVENESS AND SAFETY WHEN CHOOSING NSAIDS FOR OSTEOARTHRITIS TREATMENT

E. Choy[1,2]

[1]Head of Rheumatology and Translational Research Division of Infection and Immunity, Cardiff University School of Medecine, Cardiff, United Kingdom, [2]Director of the Cardiff Regional Experimental Arthritis Treatment and Evaluation (CREATE) Centre, Cardiff University School of Medicine, Cardiff, United Kingdom

Non-steroidal anti-inflammatory drugs (NSAIDs) are broadly recommended by treatment guidelines as a pharmacological option for the symptomatic relief of osteoarthritis. Medicines in the drug class are crudely divided into two groups; COX-2 selective agents and non selective medicines that inhibit both the COX-2 and COX-1 isoforms. COX-2 selective agents have been associated with a reduced propensity for gastrointestinal harms when compared to non-selective agents, and recent data has added to what is known around their cardiovascular and renal harms. Professor Choy's presentation will focus on an update on the management of osteoarthritis with consideration of key efficacy and safety data for the COX-2 selective NSAID-celecoxib.

SY4
FLSS NEED TO CHANGE: WHY, WHAT AND HOW

UCB[1]

[1]UCB, Brussels, Belgium

Professor Kassim Javaid.
University of Oxford, Oxford, UK
Join esteemed expert Professor Kassim Javaid as he shares his clinical experience with establishing an efficient fracture liaison service (FLS) in post-fracture care, and the essential role it plays in the identification of osteoporosis patients at very high fracture risk (VHFR).

Drawing on his expertise, Professor Javaid will share his thoughts on **why** the traditional FLS system needs updating to meet the current challenges in fragility fracture care and describe **what** common barriers are impeding FLS optimisation. The session will focus on **how** to make practical and sustainable improvements, including how to take advantage of digital solutions, to achieve FLS goals and more comprehensive identification processes for VHFR patients.

This session will give delegates the tools to review and advance new and existing FLS plans to improve clinical outcomes for their patients at the highest risk of fracture. The interactive format encourages the audience to provide their comments, thoughts and questions throughout.

SY5
CLOSING THE TREATMENT GAP WITH ROMOSOZUMAB▼ FIRST: EVIDENCE FROM THE REAL WORLD

UCB[1]

[1]UCB, Brussels, Belgium

With almost three-quarters of patients at high risk of fracture going untreated, the need to close the treatment gap in osteoporosis has never been more pressing.[1] Join us for this enriching and thought-provoking session to explore strategies that you can implement in your own clinical practice to streamline identification of patients at the highest risk of fracture and ensure eligible patients receive romosozumab first in sequential treatment.*.[2]

Our international panel of experts in bone health, Chair Professor Richard Keen (Royal National Orthopaedic Hospital, UK), Professor Bente Langdahl (Aarhus University Hospital, Denmark), Professor Serge Ferrari (Geneva University Hospitals, Switzerland), and Professor Carmelinda Ruggiero (University of Perugia, Italy), will bring their invaluable insights and extensive real-world clinical experiences of adopting a 'romosozumab-first' approach to proactively close the treatment gap in osteoporosis, which delegates can draw from to guide future clinical decision-making.

Be an active participant and help shape the discussion at this interactive session at WCO-IOF-ESCEO 2024!

*Within the licensed population.

In the EU, romosozumab is indicated in treatment of severe osteoporosis in postmenopausal women at high risk of fracture.[2]

This promotional symposium is only open to healthcare professionals who are registered for WCO-IOF-ESCEO 2024.

This promotional symposium is sponsored and organised by UCB Biopharma SRL and is co-supported by Amgen. UCB/Amgen medicines will be discussed at this meeting. UCB is a sponsor of WCO-IOF-ESCEO 2024.

Romosozumab prescribing information is available at booths 13 and 14. Licenses may vary by country. Please always refer to the Prescribing Information (PI) in your country before prescribing any drug.

▼This medicinal product is subject to additional monitoring. This will allow quick identification of new safety information. Healthcare professionals are asked to report any suspected adverse reactions. Adverse events should be reported. Reporting forms and information can be found from your local regulatory authority. Adverse events should also be reported to UCB.

SY6
EVOLVING PERSPECTIVES IN ADULT PATIENTS WITH PAEDIATRIC-ONSET HYPOPHOSPHATASIA: FROM DIAGNOSIS TO EFFECTIVE MANAGEMENT

M. L. Brandi[1], L. Seefried[2], A. Khan[3]

[1]University of Florence, Florence, Italy, [2]Julius Maximilian University of Würzburg, Würzburg, Germany, [3]McMaster University, Ontario, Canada

This symposium will be presented by a panel of expert clinical researchers emphasizing the importance of recognizing hypophosphatasia (HPP) in adults (and not solely in children) and the evolving landscape of diagnosis and treatment of adults with paediatric-onset HPP.

Overcoming the Diagnostic Challenge in HPP

Maria Luisa Brandi (University of Florence, Florence, Italy)

With a goal to improve healthcare professionals' diagnosis of HPP and drawing on the latest research and support tools, Prof. Brandi will discuss when to suspect HPP, the challenges of diagnosing HPP, which tests to prioritize, the importance of early detection, and the profound impact on patient outcomes.

Integrative Strategies in HPP Management

Lothar Seefried (Julius Maximilian University of Würzburg, Würzburg, Germany)

Dr. Seefried will focus on comprehensive management strategies and approaches for treating adult patients with paediatric-onset HPP. He will review functional assessment and other tools used for monitoring treatment efficacy in clinical practice. In this context, he will also elaborate on bone health in HPP and how this is different from common osteoporosis.

Bringing Adult Patients With Paediatric-onset HPP into the Spotlight: Case Studies

Aliya Khan (McMaster University, Ontario, Canada)

Prof. Khan will present 2-3 cases that exemplify the diagnostic journey and subsequent management of adult patients. Focusing on the impact of muscle weakness and pain, she will highlight the benefits of early treatment intervention based on data from recent studies and discuss lessons learned for future practice.

The symposium will conclude with all speakers advocating for a multidisciplinary approach involving endocrinologists, rheumatologists, and geneticists to diagnose and monitor HPP. Attendees will have the opportunity to ask questions, engage in discussion, and gain a deeper understanding of the complex nature of HPP diagnosis and management.

M/INT/Med HPP/0002 | February 2024This satellite symposium is fully funded and organised by Alexion, AstraZeneca Rare Disease and is intended for Healthcare Professionals only. Alexion medicines in the context of HPP management will be discussed at this meeting. Some content may be deemed promotional in your territory.

SY7
UPDATE ON PHARMACEUTICAL-GRADE CHONDROITIN SULFATE – FROM ESCEO ALGORITHM TO CLINICAL DATA

J.-Y. Reginster[1,2]

[1]King Saud University (KSU), College of Science, Riyadh, Saudi Arabia, [2]World Health Organisation Collaborating Center for Epidemiology of Musculoskeletal Health and Aging, Liège, Belgium

The ESCEO algorithm for the management of knee osteoarthritis recommends pharmaceutical-grade Chondroitin Sulfate (CS) as one of the first-line background treatments for patients with mild to moderate osteoarthritis. ESCEO strongly discourages the use of other preparations of CS, including Food Supplements. CS has been widely investigated for its capacity to reduce pain and function disability in patients with knee OA. It has also been shown to reduce the progression of the disease, i.e. joint space narrowing. In a double-blind, placebo-controlled, three-arm study, CS (800 mg/day) reduces pain and improves Lequesne index to the same extend as Celecoxib, a reference NSAIDs currently licenced and marketed for the treatment of knee OA. Both formulations provide higher benefit compared to placebo. In long-term studies, comparing CS (800 mg/day) to placebo, CS fully prevented the loss in joint space observed in the placebo group, both when looking at the minimal joint space or at the average joint space. Furthermore, CS is the only medication currently

recommended for the symptomatic management of hand OA. Safety of CS was evidenced from systematic literature reviews and subsequent meta-analyses, showing no increase in adverse events, at any body system. Subsequent analyses of large real-life database suggest that CS might be effective in reducing the risk of cardiovascular or cerebrovascular disorders in patients currently exposed to the medication at a minimal dose of 800 mg/day and for a minimal duration of 90 days. This outstanding combination of high symptomatic and structural efficacy compared to a convincing safety profile justifies the choice by ESCEO of CS (800 mg/day and 1200 mg/day) as an appropriate first-line background treatment for the management of knee OA.

SY8
ENHANCING JOINT CARE: INTEGRATING ULTRASOUND GUIDANCE AND ADVANCED HYALURONIC ACID FORMULATIONS IN INTRA-ARTICULAR INJECTIONS

E. Lanza[1]

[1]Research Fellow - Diagnostic and Interventional Radiology Humanitas University - Pieve Emanuele IRCCS Humanitas Research Hospital - Rozzano, Milano, Italy

The use of ultrasound in guiding intra-articular injections is a significant advance in musculoskeletal interventions, specifically in the administration of hyaluronic acid (HA) for joint viscosupplementation. This technique enables clinicians to accurately target the intra-articular space, enhancing the efficacy and safety of the procedure, and is rooted in precision medicine.

Recent developments in HA formulations (e.g. NAHYCO® technology) have focused on prolonging the viscoelastic properties of synovial fluid, with the aim of reducing the frequency of injections required for sustained therapeutic effect. This evolution in treatment products is pivotal in patient-centric care, minimizing discomfort and potential complications associated with frequent intra-articular access.

The combined use of advanced imaging techniques and novel HA products represents a paradigm shift in joint treatment. Ultrasound guidance affords real-time visualization, ensuring precise HA delivery and optimal distribution within the joint. This approach is applicable to a wide spectrum of joints, making it a versatile tool in the management of various joint pathologies. There is ample literature evidence suggesting that the use of ultrasound guidance during injection into any joint, including the knee, enhances accuracy and should be deemed a mandatory part of providing optimal medical care.

A critical aspect of this lecture is to present evidence from recent reviews comparing viscosupplementation under imaging guidance versus landmark-based techniques. These studies underscore the superiority of ultrasound-guided injections in terms of accuracy, patient outcomes, and overall effectiveness of the HA therapy.

In summary, the integration of ultrasound guidance with advanced HA formulations in intra-articular injections provides a more precise and tailored approach to joint care. This presentation offers a comprehensive overview, emphasizing the importance of image-guided precision and innovative therapeutics in modern joint treatment.
