Motivations

Anticoherent states are maximally entangled symmetric multiqubit states, optimal for rotation and magnetic field sensing[1]. Despite growing interest[2], a general experimental protocol for their generation has remained elusive, until now.
Anticoherent states

An anticoherent state to order t is an isotropic state for which the moments of $\mathbf{J} \cdot \mathbf{n}$ up to order t are independent of the direction $\mathbf{n}$, i.e.

$$\mathrm{Tr}[\rho(\mathbf{J} \cdot \mathbf{n})^k] \neq f(\mathbf{n}) \quad \text{for } k = 1, 2, \ldots, t$$

We can quantify the degree of anticoherence of any state $|\psi\rangle$ through the measure of anticoherence[3]

$$\mathcal{A}_t^{\mathrm{Bures}} = 1 - \sqrt{\frac{\sqrt{t+1} - \sum_{i=1}^{t+1}\sqrt{\lambda_i}}{\sqrt{t+1}-1}}$$

5-anticoherent state

where the λ_i are the Schmidt coefficients of $|\psi\rangle$. This measure can serve as a figure of merit for numerical optimisation.

Any symmetric multiqubit state can be expanded in the tensor multipolar basis

$$\rho = \sum_{L=0}^{N} \sum_{M=-L}^{L} \rho_{LM} T_{LM}.$$

In this manner, a state is anticoherent of order t iff

$$\rho_{LM} = 0 \text{ for } L = 1, 2, \ldots, t \text{ and } M = -L, \ldots, L$$

Hence, in order to generate anticoherent states, the goal is to completely depopulate the lower state multipoles ρ_{LM}.

Pulse-based protocol

Our protocol consists of a sequence of n_C cycles in which we apply first a rotation followed by a squeezing[4]

$$\Pi_y(\theta) = e^{-iJ_y\theta} \qquad \Pi_{z2}(\eta) = e^{-iJ_z^2\eta}$$

such that the final state is

$$|\psi_{n_C}\rangle = \left(\prod_{i=1}^{n_C} \Pi_{z2}(\eta_i)\Pi_y(\theta_i) \right) |\psi_0\rangle$$

where $\theta_1 = 0$ and the initial state is $|\psi_0\rangle = e^{-iJ_x\pi/2}|0\rangle^{\otimes N}$ where $|0\rangle$ is the qubit ground state.

Initial state multipoles $N = 4$

Pulses dynamics
↔ : Rotation   ↕ : Squeezing

From a physical point of view, our protocol exploits the fact that the rotations (resp. squeezings) only couple multipoles with the same L (resp. M). Moreover, during a squeezing along z, the transitions for $M = 0$ are forbidden.

For different number of qubits N and anticoherence order t, we use the Nelder-Mead algorithm to find the $2n_C$ parameters θ_i and η_i that maximises $\mathcal{A}_t^{\mathrm{Bures}}$.
Numerical results

For all $N \leq 48$, the optimised parameters are able to generate the highest order anticoherent state allowed.

State multipoles evolution for $N = 6$ and $t = 3$
Achieved anticoherence for a fixed number of cycles n_C

For each anticoherence order ($t = 2, 3$ and 4), there is a threshold number of cycles above which the state is perfectly anticoherent (up to numerical errors).

For $N = 48$, we obtain a 9-anticoherent state, the maximal order for this N, verifying $\mathcal{A}_9^{\mathrm{Bures}} > 0.99$ with $n_C = 14$.

High-dimensional systems

We observe that, for even N, in order to generate an anticoherent state of order 2, we can take $\eta_1 = \frac{\pi}{2}$, $\theta_2 = -\frac{\pi}{2N}$ and $\theta_3 = \frac{\pi}{2}$ and only optimise over η_2 and η_3.
It allows us to obtain the scaling laws $\eta_2 = \frac{3}{4\sqrt{N}}$ and $\eta_3 = \frac{5}{2N}$ that we can exploit to generate anticoherent states with $N = 10000$ verifying $1 - \mathcal{A}_2^{\mathrm{Bures}} < 10^{-3}$.

Perspectives

- Test the protocol in experiments with spin or Bose-Einstein condensate systems.
- Use anticoherent states for improved gyroscopy or magnetometry applications in the lab.
