In the oncology indication group, 57,8% of the MRONJ cases were due to the use of zoledronate, while in the anti-osteoporotic indication group only 8,3% of the MRONJ. In patients treated for osteoporosis, zoledronic acid showed a significant negative standardized residual (−3.1), indicating a lower than expected frequency of MRONJ. In oncological indications, zoledronic acid exhibited a significant positive standardized residual (+3.5), reflecting a higher than expected frequency ($p=0.01$).
In the anti-osteoporotic indication group the 57,8% of the patients with MRONJ were on oral BF therapy and 28,57% with denosumab.
CONCLUSIONS
The drug most associated with the development of MRONJ in our sample of patients was zoledronic acid, being the development of this entity much more frequent when it is administered as an oncological treatment. Therefore, it could be hypothesised that the risk of MRONJ does not depend so much on the drug as on the indication and administration schedule, but more studies are needed to clarify the association.

ARTHROSCOPIC SYNOVECTOMY IN DIFFUSE-TYPE TENOSYNOVIAL GIANT CELL TUMOR OF THE KNEE USING MODIFIED POSTERIOR PORTALS

E. Naryshkin[1], M. Makarov[1], A. Khramov[1], V. Nesterenko[2], E. Bialik[1], V. Bialik[1], S. Maglevaniy[1], A. Dubinin[1], T. C. Phan[1], A. Roskidajlo[1]

[1]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia; [2]V.A. Nasonova Research Institute of Rheumatology, Москва, Russia, Moscow, Russia

Introduction: Diffuse-type tenosynovial giant cell tumor (DT-TGCT) of the knee is a locally aggressive disease associated with pain, functional limitation, and a high risk of recurrence. Complete synovectomy is technically demanding, especially in the posterior compartments and in cases with extra-articular extension.
The aim of this study was to evaluate mid-term clinical outcomes, recurrence rate, and complications of arthroscopic synovectomy for diffuse-type TGCT of the knee using a system of modified posterior arthroscopic portals as part of a combined treatment strategy.
Methods: Twenty-seven patients with histologically confirmed DT-TGCT of the knee underwent arthroscopic synovectomy. A systematic arthroscopic technique was applied, including resection of pathological synovium from anterior and posterior compartments. Modified posterior portals were used: upper and lower posterolateral portals, upper and lower posteromedial portals, and an additional portal in the projection of a popliteal cyst when present. Pain was assessed using the Visual Analog Scale (VAS). All patients were referred for adjuvant radiotherapy. The follow-up period ranged from 1 to 4 years. Recurrence, complications, and revision surgeries were analyzed.
Results: Mean VAS pain score decreased from 7.0 preoperatively to 2.2

postoperatively. Local recurrence occurred in two patients (7.4%) and required revision surgery; both revisions were successfully performed arthroscopically. In both cases, recurrence was associated with insufficient preoperative assessment, resulting in residual tumor nodules within a popliteal cyst in one patient and beneath the lateral meniscus in the other. One patient developed a postoperative popliteal artery aneurysm requiring surgical treatment in a vascular surgery department. Conclusion: Arthroscopic synovectomy using modified posterior portals combined with adjuvant radiotherapy provides significant pain relief and satisfactory mid-term outcomes in patients with diffuse-type TGCT of the knee. Careful preoperative planning and thorough assessment of posterior and extra-articular tumor involvement are essential to minimize recurrence and vascular complications.

A NOVEL COMBINED DOUBLE-BUNDLE ACL RECONSTRUCTION USING A MODIFIED QUADRICEPS TENDON GRAFT

E. Naryshkin[1], M. Makarov[1], S. Maglevaniy[1], A. Rozov[1], A. Kargaltsev[1], T. C. Phan[1], V. Nesterenko[2], E. Bialik[1]

[1]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia; [2]V.A. Nasonova Research Institute of Rheumatology, Москва, Russia, Moscow, Russia

Introduction: Despite numerous techniques for anterior cruciate ligament (ACL) reconstruction, achieving optimal rotational stability while preserving synergistic structures remains challenging. Double-bundle reconstruction improves knee kinematics, while combined ACL and anterolateral procedures enhance rotational control. However, most techniques rely on hamstring grafts, potentially compromising important dynamic stabilizers of the knee.

The aim of this study was to describe a novel combined ACL reconstruction technique that integrates a double-bundle concept, a modified quadriceps tendon graft, and an anterolateral stabilization component while preserving hamstring integrity.

Methods: The technique is based on harvesting a quadriceps tendon graft with a bone block and an extended superficial tendon flap using a minimally invasive approach. The graft is prepared to form two functional bundles suitable for double-bundle reconstruction. A single tibial tunnel is created, and the bone block is fixed with an interference screw. On the femoral side, two independent tunnels are drilled for the anteromedial and posterolateral bundles. The anteromedial bundle is fixed using a cortical suspension device, while the posterolateral bundle is passed transosseously and fixed with an interference screw. The free graft end is then routed along the lateral aspect of the knee toward Gerdy's tubercle and fixed to the tibia, providing additional anterolateral stabilization.

Results: This technique allows preservation of all hamstring tendons, maintaining the integrity of ACL synergists. The combined approach provides enhanced anterior and rotational knee stability while minimizing donor-site morbidity.

Conclusion: The proposed method is reproducible and anatomically, combining several established surgical principles into a single comprehensive reconstruction strategy. Further clinical studies are required to evaluate long-term outcomes and biomechanical advantages

P537

COMPLICATIONS AND STABILITY AFTER BONY INCREASED OFFSET REVERSE SHOULDER ARTHROPLASTY: RHEUMATOID ARTHRITIS VERSUS OSTEOARTHRITIS

A. Bimbaeva[1], E. Naryshkin[1], M. Makarov[1], E. Bialik[1], V. Nesterenko[2], A. Rozov[1], A. Roskidajlo[1], S. Maglevaniy[1]

[1]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia; [2]V.A. Nasonova Research Institute of Rheumatology, Москва, Russia, Moscow, Russia

Background. Reverse shoulder arthroplasty with bony increased offset (BIO-RSA) is widely used to improve shoulder stability and range of motion. However, the influence of underlying joint pathology on postoperative complications and implant stability remains unclear, particularly in patients with inflammatory diseases and compromised bone quality.

Purpose. To compare complication rates and postoperative stability after BIO-RSA in patients with rheumatoid arthritis (RA) and osteoarthritis (OA).

Methods. A retrospective cohort study included 50 patients who underwent BIO-RSA. Thirty-two patients were diagnosed with rheumatoid arthritis, and eighteen patients had primary osteoarthritis. Osteoporosis was present in all patients. In both groups, BIO-RSA with glenoid bone grafting was performed according to standard technique. All patients received preoperative subacromial glucocorticosteroid injections. Postoperative assessment focused on complications, including dislocation and periprosthetic humeral fractures, as well as radiographic evaluation of graft integration.

Results. Bone graft integration was achieved in all patients, regardless of diagnosis. Postoperative dislocation occurred more frequently in the osteoarthritis group (three cases) compared to the rheumatoid arthritis group (one case). Periprosthetic humeral fractures were observed in two patients in each group. No cases of graft resorption or loosening were identified during follow-up. Despite the presence of systemic inflammatory disease and osteoporosis, patients with rheumatoid arthritis did not demonstrate a higher risk of instability.

Conclusion. BIO-RSA provides reliable stability and acceptable complication rates in both rheumatoid arthritis and osteoarthritis. Rheumatoid arthritis was not associated with an increased risk of postoperative instability compared to osteoarthritis. These findings suggest that underlying inflammatory pathology alone should not be considered a negative prognostic factor for BIO-RSA outcomes.

P538

OPERATIVE TREATMENT OF HAND AND WRIST OSTEOARTHRITIS: A SYSTEMATISED REVIEW

E. Ntouvali[1]

[1]Diagnostic and Therapeutic Center of Athens "Hygeia" S.A., Athens, Greece, Athens, Greece

OBJECTIVES: This study aimed to the collection and critical appraisal of representative data on the surgical management of hand and wrist osteoarthritis (OA) to accentuate the paucity of evidence supporting the underlying decision-making process.**MATERIAL AND METHODS:**A meticulous literature survey from inception to 26/01/2026 was conducted in PubMed,Cochrane Library,PubMed Central (PMC),UpToDate and Google Scholar using the search terms:"hand";"1st CMC";"finger joint";and "wrist",each coupled with:"osteoarthritis";"operative treatment";and "surgical management".Screening of Titles and Abstracts,subsequent screening of entire Articles, and duplicate removal were performed by the Author.All accessible full-text articles in English,German and French regarding the operative treatment of hand and wrist OA were included.**RESULTS:**Depending on disease stage;physician training,professional experience and preferences;individual-patient requirements and expectations;and healthcare-system limitations,hand and wrist OA can be surgically managed by means of arthroscopic debridement;reconstruction,interposition,haematoma and distraction,or excision arthroplasty;partial or complete arthrodesis;and finger and wrist denervation.Arthroscopic debridement is presumably reserved for mildly to moderately symptomatic patients,whereas arthroplasty,arthrodesis,and denervation are generally employed in more advanced cases of hand and wrist OA;however,in practice this rule is not always adhered to.Moreover,the aforesaid procedures are often used in combination.In addition,patient satisfaction from the operative treatment of hand and wrist OA is influenced by many factors besides the outcome of the surgery per se.Lastly,disease- and/or procedure-specific patient reported outcome measures (PROMs) for the postoperative evaluation of such patients are currently lacking.**CONCLUSIONS:**Arthroscopic debridement;arthroplasty;arthrodesis;denervation of the finger and wrist joints;and combinations thereof are reportedly used in the surgical management of hand and wrist OA.High-quality clinical trials and appropriate PROMs are required to establish evidence-based guidelines for a standardised application of the aforementioned methods by the treating physicians.

P539

OBESITY PARADOX REVISITED: THE ROLE OF MUSCLE IN THE LINK BETWEEN BODY COMPOSITION AND DEPRESSION IN AGING

E. Pınar[1], S. Özkök[1], E. Aşcı Civelek[1], ?. Can Ceylan[1], Z. Fetullahoğlu[1], T. Erdoğan[1], M. A. Karan[1], G. Bahat[1], ?. Z. Şahin Tırnova[1]

[1]Istanbul University, Istanbul Medical Faculty, Department of Internal Medicine, Division of Geriatrics, Istanbul, Türkiye

Introduction:
Depression is a common geriatric syndrome associated with negative outcomes such as lower quality of life and cognitive decline. Current evidence suggests associations between depression and both sarcopenia and obesity, yet the body composition phenotype most strongly linked to depression remains unclear. This study aimed to examine the relationship between different body composition phenotypes and depression in older adults.

Methodology:
This cross-sectional study included outpatients aged ≥60 years who underwent comprehensive geriatric assessment between 2012–2024 at a university hospital. Depression was defined as a score ≥14 on the Yesavage Geriatric Depression Scale. Handgrip strength was measured using a hydraulic dynamometer. Body composition was evaluated via bioelectrical impedance analysis. Sarcopenia was defined according to EWGSOP2 criteria (low muscle strength and mass), and obesity as increased fat percentage. Sarcopenic obesity was defined per ESPEN/EASO consensus as low strength + low muscle mass + high fat percentage. Cut-offs were adjusted for sex and population(1,2). Participants were categorized into four phenotypes: non-sarcopenia non-obesity (reference), sarcopenia-only, sarcopenic obesity, and obesity-only. Univariable and multivariable analyses were used to assess associations with depression.

Results:
A total of 590 patients(median age 74, 68.6% female) were included. Depressive mood was present in 201 (34.1%) of them. Among them, phenotype distribution was: reference 50.5%, sarcopenia-only 16.0%, sarcopenic obesity 14.0%, and obesity-only 19.5% (p = 0.007). The significant difference arose from obesity-only group, where depression was less common. After adjusting for confounders, obesity-only (non-sarcopenic) group had significantly lower odds of depression (OR = 0.483, 95% CI: 0.299–0.780, p = 0.003)(Table 1).

Table-1: Results of multivariable regression analysis: Association of body composition phenotypes with depressive mood.

	Depressive mood present OR (%95 CI)	*p* value
Body phenotypes		
Non-sarcopenic non-obese	Reference	
Sarcopenia-only	0.757 (0.414-1.384)	0.757
Sarcopenic obesity	0.700 (0.372-1.319)	0.270
Obesity-only	0.483 (0.299-0.780)	0.003

Note: Model was adjusted for *age, sex, education level, cognitive impairment, frailty, history of falls,* and *polypharmacy.*

Discussion:
Our study expands the scope of the obesity paradox in older adults, suggesting that this entity may only be valid in the presence of adequate muscle reserves. Large-scale longitudinal studies are needed to confirm these findings.

P540

CUMULATIVE RISK OF MALNUTRITION, FRAILTY AND PROBABLE SARCOPENIA AS AN INDEPENDENT PREDICTOR OF FALLS IN OLDER ADULTS

E. Pınar[1], E. Aşcı Civelek[1], ?. Can Ceylan[1], Z. Şahin Tırnova[1], Z. Fetullahoğlu[1], T. Erdoğan[1], S. Özkök[1], M. A. Karan[1], G. Bahat[1]

[1]Istanbul University, Istanbul Medical Faculty, Department of Internal Medicine, Division of Geriatrics, Istanbul, Türkiye

Background: Malnutrition, frailty, and probable sarcopenia are closely interrelated and individually associated with falls, however, they are generally assessed as separate entities in routine geriatric practice. The extent to which their coexistence confers an incremental risk beyond single-condition assessment remains unclear. Evaluating their cumulative burden may therefore provide clinically relevant information for fall risk stratification, particularly in outpatient settings where early identification of high-risk individuals is crucial.

Methods:

Patients who admitted to a geriatric outpatient clinic of a university hospital, aged 65 years and older, were recruited to this cross-sectional study. They were evaluated for the presence of geriatric syndromes such as malnutrition, frailty, sarcopenia, cognitive impairment (MMSE < 24), depression (GDS-full form ≥ 11), polypharmacy (≥5 medications), urinary incontinence, visual problems. Malnutrition risk was assessed using the Mini Nutritional Assessment–Short Form (MNA-SF ≤ 11), frailty using the FRAIL Scale (≥3), and probable sarcopenia according to EWGSOP2 criteria (low muscle strength). Population and sex-specific thresholds were used for sarcopenia (F<20, M<35). A cumulative score (range 0–3) was constructed by assigning one point for each condition. Additionally 0, 1 points were defined as low risk and 2, 3 points were defined as high risk. The primary outcome was self-reported fall within the past year. Logistic regression models were adjusted for age, sex, and body mass index (BMI), and subsequently for all other geriatric syndromes.

Results:

This study included 1,219 adults aged ≥65 years (mean age 75.5 ± 6.8 years; 68.3% female). Fall incidence was found as 40.3%. Frailty, malnutrition, probable sarcopenia were found to be in 19.8%, 26.9% and 42.2% of the study population, respectively. Despite conceptual overlap, no significant multicollinearity was established between the three conditions. Presence of each of frailty, sarcopenia and malnutrition increased the risk of falls with OR 1.785 (95% CI, 1.33-2.395; p=<0.001), OR 1.503 (95% CI, 1.16-1.948; p=0.002), OR 1.943 (95% CL, 1.484-2.545; p=<0.001), respectively (adjusted for age, sex and BMI). High cumulative risk (2–3 points) was independently associated with a significantly increased risk of falling (OR 1.61, 95% CI 1.00–2.57; p=0.049) after adjustment for cognitive impairment, depressive symptoms, polypharmacy, urinary incontinence, visual problems, age, sex, and BMI. A dose–response pattern persisted: compared with 0 point, the odds of falling increased stepwise (1 point: OR 1.35; 2 points: OR 1.71; 3 points: OR 2.47), although full adjustment attenuated statistical significance.

Conclusions:

The cumulative burden of malnutrition, frailty, and probable sarcopenia is an independent predictor of falls. Simple integrated geriatric assessment may enhance fall and fracture risk identification in routine outpatient care.

P541

MUCOPOLYSACCHARIDOSIS AS A RISK FACTOR FOR OSTEOPOROSIS

E. Rapushi[1], A. Zoto[1], V. Salko[1], I. Hoxha[1], F. Zenelaj[1], E. Zicishti[1], A. Babameto[1]

[1]UHC Mother Theresa, Department of Internal Medicine, Tirana, Albania

Object: To evaluate Mucopolysaccharidosis as a risk factor for osteoporosis.

Mucopolysaccharidosis (MPS) are a group of metabolic disorders caused by the lack or dysfunction of lysosomal enzymes, necessary to break down molecules called glycosaminoglycans (GAGs). These long chains of sugar carbohydrates are found inside cells that help form bones, cartilage, tendons, cornea, skin and connective tissue. The incidence of the disease is very rare.

Material and methods: In total, 23 individuals diagnosed with MPS were included in the study, a retrospective study. All individuals diagnosed through clinical examination, urinalysis (mucopolysaccharides excreted in urine), enzyme levels and genetic analysis. Based on clinical, laboratory and genetic examinations in the study group, the results were: MPS I (Hurler syndrome) 2 patients, MPS III (Sanphilippo syndrome) 2 patients, MPS IV (Morquio syndrome) 10 patients, MPS VI (Maroteaux-Lamu syndrome) 6 patients, MPS VII (Sly syndrome) 2 patients, MPS IX (Natowicz syndrome) 1 patient. All patients had their bone density (DXA) assessed using the T-score value in the lumbar and coxofemoral regions.

Results: The mean age of the study group was 18±5.4 years. The highest incidence of MPS was in groups IV and VI. DXA in the lumbar spine T-score was -2.3±1.9 and T-score in coxofemoral region was 2.5±1.6. From the DXA data, bone density resulted low in both regions, but the lowest density is in the coxofemoral region. DXA in the group with the highest incidence (IV, VI) resulted in a lumbar T-score of -2.5±1.2 and in the coxofemoral region, with a T-score of -2.8±0.9.

Conclusion: From the study data, it has resulted that the density is low in all patients with MPS. This shows that MPS as a metabolic disorder is a risk factor for low bone density. Despite the small number of patients studied, due to the low incidence of this disorder, it is noticed that bone density is lower in patients in groups IV and VI, who also present more advanced skeletal dysplasias.

P542

DEFINING REMISSION IN CHRONIC INFLAMMATORY RHEUMATISM: INSIGHTS FROM PATIENTS

S. Rahmouni[1], E. Razgallah[2], W. Letifi[1], K. Zouaoui[1], S. Rekik[1], H. Sehli[1], S. Boussaid[1]

[1]Rabta Hospital, Tunis, Tunisia; [2]rabta hospital, Tunis, Tunisia

Introduction:

Differences between patient and physician perspectives on the definition of disease remission have been documented in chronic inflammatory rheumatism (CIR) (1). Such discrepancies may contribute to patient dissatisfaction and adversely affect treatment outcomes.

The objective of our survey was to explore patient perceptions of the comprehensive factors that determine remission of their disease.

Methods:
A crosssectional study was conducted among patients diagnosed with chronic inflammatory rheumatism (CIR), specifically rheumatoid arthritis (RA) or spondyloarthritis (SpA). A fivequestion questionnaire encompassing clinical, biological, and radiological determinants of remission was designed and administered to participants by telephone.
Results:
Our study included 56 patients with a mean age of 50.8 ± 13.5 years. The maletofemale ratio was 0.65. Sixtyeight percent of patients had rheumatoid arthritis (RA) and 35.7% had spondyloarthritis (SpA). The mean disease duration was 10.5 ± 7.4 years. Treatments at the time of the survey were: methotrexate monotherapy in 23.6%, methotrexate combined with a biologic in 27.3%, while 27.3% of patients were on biologic monotherapy.
In response to the questionnaire, only 32.1% of patients indicated awareness of the method their physician uses to evaluate disease activity, while 25.9% reported that their physician had previously explained this assessment approach. Most patients defined remission based on the following criteria: absence of pain or physical symptoms (84%), ability to resume all daily physical activities (93%), regained autonomy and absence of limitations (94.7%), normalization of biological and radiographic tests (69.6%), and reduction or discontinuation of current medication (64%).
Comparison of responses between the RA and SpA patient groups revealed a statistically significant difference in defining remission as the normalization of biological and radiographic tests (p=0.014). In contrast, no significant differences were noted for the remaining criteria: absence of pain or physical symptoms (p=0.105), ability to resume all daily physical activities (p=0.598), regained autonomy and absence of limitations (p=0.263), and reduction or discontinuation of medication (p=0.250).
Conclusion:
Remission was predominantly defined by patients based on the absence of pain, restoration of autonomy, and resumption of daily activities. In contrast, biological and radiological criteria were regarded as secondary in their perception. These findings underscore the need to incorporate patient perspectives to enable more patientcentered and satisfactory management.

CLINICAL PROFILES OF GERIATRICONSET SPONDYLOARTHRITIS

K. Zouaoui[1], E. Razgallah[1], S. Rahmouni[1], S. Rekik[1], S. Boussaid[1], H. Sehli[1]

[1]Rabta Hospital, Tunis, Tunisia

Introduction:
Spondyloarthritis (SpA) predominantly affects younger individuals. However, cases in the geriatric population are increasingly reported, likely due to increased life expectancy. Lateonset SpA may present differently than early-onset forms. The objective of our study was to investigate the characteristics of this disease.
Methods:
A retrospective descriptive study spanning four years (20212024) was carried out, enrolling cases of geriatriconset spondyloarthritis (SpA) diagnosed at a Tunisian rheumatology unit. Patient sociodemographic, clinical, biological, and radiological data were systematically collected.
Results:
We recruited 22 patients with a mean age of 64.8 ± 9.2 years. The maletofemale ratio was 1.44. Sixtytwo percent of patients were illiterate, and 12.5% had attained secondarylevel education. Fortythree percent lived in rural areas. More than half (54.5%) had axial SpA, while 45.5% had both axial and peripheral involvement. Among the latter, 20% presented with axial onset, 40% with peripheral onset, and 40% with combined axial and peripheral onset at presentation. The mean age at diagnosis was 62 ± 10 years, with a diagnostic delay of 1.7 ± 2.8 years. Only one patient had associated inflammatory bowel disease, and one had cutaneous psoriasis. Uveitis was observed in two patients. Comorbidities including diabetes, hypertension, dyslipidemia, and osteoporosis were present in 18.2%, 31.8%, 22.7%, and 28.6% of cases, respectively. Only 4.5% reported a family history of SpA, and similarly 4.5% had a family history of psoriasis. Fortyone percent were smokers. Impaired general health was noted in 39% of patients. On clinical examination, sacroiliac pain was present in 68% of patients, while cervical and lumbar stiffness were reported in 71.4% and 86.4%, respectively. The mean BASDAI (Bath Ankylosing Spondylitis Disease Activity Index) score was 4.44 ± 2.12. Four patients (19%) had unilateral hip involvement on radiography, and one patient had bilateral hip involvement. The mean Creactive protein (CRP) level was 47.3 ± 46 mg/L. Regarding diseasemodifying treatment, 77.3% used nonsteroidal antiinflammatory drugs, 27% required a first biologic therapy, and 13.6% a second biologic therapy.
Conclusion:
The diagnosis of lateonset spondyloarthritis (SpA) can be difficult given the common occurrence of systemic features. Ensuring a correct diagnosis enables optimal patient care and therapeutic intervention.

P544
IMAGING-BASED EARLY DETECTION OF INFLAMMATORY BONE AND ENTHESEAL CHANGES IN PSORIATIC ARTHRITIS: IMPLICATIONS FOR OSTEOPOROSIS RISK

E. Russu[1], L. Gonta[2], L. Chislari[3], L. Dutca[3], L. Groppa[3]

[1]"Nicolae Testemitanu" State Medical and Pharmaceutical University; "Timofei Mosneaga" Republican Clinical Hospital, Chisinau, Moldova; [2]Republican Diagnostic Centre, Chisinau, Moldova; [3]"Nicolae Testemitanu" State and Pharmaceutical University, Chisinau, Moldova

Objectives:

To evaluate the diagnostic performance of musculoskeletal ultrasound (US) and magnetic resonance imaging (MRI) in detecting subclinical synovio-entheseal and inflammatory bone changes in patients with psoriasis and early psoriatic arthritis (PsA), and to explore their implications for early bone loss and secondary osteoporosis risk.
Material and Methods:

This prospective observational study included 214 patients with early PsA (≤24 months) and 136 psoriasis patients without arthritis (total n=350). The PsA group comprised 63.6% males, mean age 36.2±8.9 years, and the psoriasis-only group 60.3% males, mean age 35.1±9.4 years (p=0.42). All participants underwent standardized musculoskeletal US (gray-scale

and power Doppler) and MRI of peripheral and sacroiliac joints (STIR, T1-weighted), focusing on entheseal and bone marrow involvement. Imaging was compared with clinical assessment. Psoriasis-only patients were followed for 24 months. Statistical analyses included diagnostic accuracy measures, correlation analysis, multivariate logistic regression and ROC curves.

Results:

Imaging detected subclinical synovial, entheseal and inflammatory bone changes in 52.8% of psoriasis patients without clinical arthritis, compared with 18.6% identified by clinical examination alone (p<0.001). US showed high diagnostic accuracy for peripheral enthesitis (sensitivity 88.4%, specificity 82.1%), while MRI demonstrated superior detection of early axial and bone involvement, identifying active sacroiliitis and bone marrow edema in 31.7% of patients with normal radiographs. Power Doppler-positive enthesitis independently predicted progression to PsA (OR 4.62, 95% CI 2.01-10.63, p<0.001). MASEI correlated with clinical enthesitis scores (r=0.61, p<0.001), disease activity (DAPSA: r=0.58, p<0.001) and bone marrow edema. Combined US+MRI assessment showed excellent diagnostic performance (AUC 0.91, 95% CI 0.86-0.95).

Conclusions:

Advanced imaging reveals clinically occult inflammatory and bone-related changes in over half of psoriatic patients at risk for PsA. US reliably detects peripheral enthesitis, while MRI is crucial for identifying early axial disease and inflammatory bone involvement undetectable by conventional radiography. These findings support a link between inflammation-driven bone remodeling and increased risk of secondary osteoporosis and highlight the value of integrating US and MRI into early PsA diagnostic pathways.

P545

SEROLOGICAL AND GENETIC BIOMARKERS IN EARLY PSORIATIC ARTHRITIS: IMPLICATIONS FOR INFLAMMATORY BONE LOSS AND OSTEOPOROSIS RISK

E. Russu[1], L. Gonta[2], L. Chislari[3], E. Deseatnicova[3], L. Dutca[3], O. Chetrus[3], L. Groppa[3]

[1]"Nicolae Testemitanu" State Medical and Pharmaceutical University; "Timofei Mosneaga" Republican Clinical Hospital, Chisinau, Moldova; [2]Republican Diagnostic Centre, Chisinau, Moldova; [3]"Nicolae Testemitanu" State and Pharmaceutical University, Chisinau, Moldova

Objectives:

To evaluate the diagnostic and prognostic value of serological inflammatory markers and HLA class I genetic variants in early psoriatic arthritis (PsA), with particular emphasis on their associations with inflammatory bone involvement, early structural progression and potential risk of secondary osteoporosis.

Material and Methods:

A prospective observational study included 214 patients with early PsA (disease duration ≤24 months). The cohort comprised 136 males (63.6%) and 78 females (36.4%), with a mean age of 36.2±8.9 years. All patients underwent baseline assessment of serological inflammatory markers, including C-reactive protein (CRP), erythrocyte sedimentation rate (ESR) and serum calprotectin. Genetic profiling focused on HLA class I (HLA-B locus). Clinical phenotype and disease activity were evaluated using DAPSA, ASDAS-CRP, and validated enthesitis scores. Early structural damage and bone-related progression were assessed by conventional radiography at baseline and after 12 months. Statistical analysis included correlation analysis, multivariate logistic regression and receiver operating characteristic (ROC) curve analysis to evaluate diagnostic and prognostic performance of biomarkers.

Results:

HLA-B27 was present in 11.2% of patients and was independently associated with axial involvement (OR 3.74, 95% CI 1.62-8.64, p=0.002) and a higher enthesitis burden (MASES 8.3±2.1 vs 6.4±1.9, p<0.001), suggesting increased inflammatory stress at the bone-enthesis interface. In contrast, non-B27 HLA-B alleles (B*08, B*38, B*39) were significantly associated with peripheral and digital phenotypes, including dactylitis (OR 2.89, 95% CI 1.41-5.92, p=0.004).

Elevated CRP (>5 mg/L) was observed in 61.5% of patients and correlated with higher disease activity (DAPSA: r=0.62, p<0.001); however, 38.5% of patients with clinically active disease had normal CRP values. ESR demonstrated weaker correlations with activity (r=0.34, p=0.018).

Serum calprotectin was elevated in 68.4% of patients, particularly in polyarticular PsA, and showed strong correlations with swollen joint count (r=0.69, p<0.001), DAPSA (r=0.71, p<0.001) and radiographic progression at 12 months (β=0.48, p=0.003). Calprotectin demonstrated superior predictive accuracy for active disease and early structural progression (AUC 0.88, 95% CI 0.83-0.93) compared with CRP (AUC 0.74) and ESR (AUC 0.66).

Conclusions:

In early PsA, genetic background and inflammatory biomarkers are closely linked to disease phenotype, structural progression and inflammatory bone involvement. HLA-B27 is associated with axial disease and severe enthesitis, while non-B27 alleles favor peripheral phenotypes. Among serological markers, calprotectin outperforms conventional acute-phase reactants in reflecting disease activity and predicting early structural damage, supporting its role as a biomarker of inflammation-driven bone remodeling. These findings highlight the relevance of serological and genetic profiling for early identification of PsA patients at increased risk of secondary osteoporosis and skeletal fragility.

P546

EARLY CLINICAL MANIFESTATIONS AND COMPOSITE SCORES IN PSORIATIC ARTHRITIS: CLINICAL–IMAGING CORRELATES OF INFLAMMATORY BONE INVOLVEMENT AND OSTEOPOROSIS RISK

E. Russu[1], L. Gonta[2], O. Chetrus[3], L. Chislari[3], E. Deseatnicova[3], L. Dutca[3], L. Groppa[3]

[1]"Nicolae Testemitanu" State Medical and Pharmaceutical University; "Timofei Mosneaga" Republican Clinical Hospital, Chisinau, Moldova; [2]Republican Diagnostic Centre, Chisinau, Moldova; [3]"Nicolae Testemitanu" State and Pharmaceutical University, Chisinau, Moldova

Objectives:

To analyze the relationships between early clinical manifestations of psoriatic arthritis (PsA) and validated composite disease activity scores, with particular focus on entheseal and axial involvement as markers of inflammation-driven bone remodeling and potential risk of secondary osteoporosis.

Material and Methods:
This prospective observational study included 214 patients with early PsA (disease duration ≤24 months) and a control group of 126 patients with rheumatoid arthritis (RA). The PsA cohort comprised 136 males (63.6%) and 78 females (36.4%), with a mean age of 36.2±8.9 years, while the RA group included 79 females (62.7%) and 47 males (37.3%), mean age 38.1±9.6 years (p=0.18).
Key clinical manifestations assessed in PsA included dactylitis, enthesitis and inflammatory back pain. Disease activity was quantified using validated composite indices for peripheral and axial inflammation (DAPSA, ASDAS-CRP), clinical enthesitis scores (MASES, LEI) and ultrasound-based entheseal assessment (MASEI), reflecting inflammation at the bone–enthesis interface. Statistical analyses included group comparisons, correlation analysis, multivariate regression models and receiver operating characteristic (ROC) curve analysis.
Results:
Dactylitis was identified in 35.2% of early PsA patients and in 0% of RA controls (p<0.001), yielding a specificity of 100% and a positive likelihood ratio >10 for early PsA diagnosis. Clinical enthesitis was present in 92.6% of PsA patients compared with 18.4% of RA controls (OR 8.71, p<0.001), indicating a marked predominance of bone-enthesis involvement in PsA. Mean MASES scores were significantly higher in PsA (7.2±2.4) than in RA (0.9±0.6, p<0.001), while ultrasound-derived MASEI values demonstrated substantial separation between groups (51.3±5.1 vs 17.6±4.8, p<0.001). Peripheral and axial inflammatory activity showed strong interdependence, with robust correlations between DAPSA and ASDAS-CRP (r=0.74, p<0.001), suggesting parallel activation of inflammatory pathways affecting both joints and bone-related structures.
MASEI correlated significantly with MASES (r=0.61, p<0.001), DAPSA (r=0.58, p<0.001) and ASDAS-CRP (r=0.55, p<0.001), supporting the concept that entheseal inflammation reflects a systemic process influencing bone remodeling. Multivariate regression identified dactylitis (β=0.41, p<0.001) and MASEI ≥18 (β=0.46, p<0.001) as independent predictors of high disease activity. ROC analysis confirmed excellent discriminative performance for combined clinical–ultrasound criteria (AUC 0.92, 95% CI 0.88–0.96).
Conclusions:
Early PsA is characterized by a distinctive pattern of dactylitis and widespread entheseal involvement that closely correlates with composite measures of peripheral and axial disease activity. Given the central role of the enthesis-bone interface in PsA, these clinical-imaging correlations likely reflect inflammation-driven bone remodeling, potentially contributing to secondary osteoporosis. Integrating targeted clinical features with quantitative ultrasound-based entheseal assessment may improve early diagnosis of PsA while simultaneously identifying patients at increased risk of skeletal fragility.

P547
SARCOPENIA, SARCOPENIC OBESITY AND OSTEOPOROSIS IN PSORIATIC AND RHEUMATOID ARTHRITIS: BEYOND BODY MASS INDEX

M. Grosu[1], L. Groppa[1], E. Deseatnicova[1], E. Russu[1]

[1]State University of Medicine and Pharmacy Nicolae Testemitanu, Chișinău, Moldova

Objectives:
To assess the prevalence and clinical impact of sarcopenia and sarcopenic obesity on bone mineral density (BMD), disease activity and fracture risk in patients with psoriatic arthritis (PsA) and rheumatoid arthritis (RA).
Material and Methods:
A cross-sectional study included 86 patients with inflammatory arthritis, divided into PsA (n=44) and RA (n=42). The cohort comprised 57 women (66.3%) and 29 men (33.7%), with a mean age of 54.1±9.7 years and mean disease duration of 9.2±4.8 years.
Body composition was assessed using DXA, including appendicular lean mass index (ALMI) and fat mass index. Sarcopenia was defined according to EWGSOP2 criteria, while sarcopenic obesity was defined as low muscle mass combined with excess fat mass. BMD was measured at the lumbar spine and femoral neck. Disease activity was assessed using DAPSA (PsA) and DAS28-CRP (RA). Multivariate regression, mediation analysis and ROC curve analysis were applied.
Results:
Sarcopenia was identified in 24.4% of patients, while sarcopenic obesity was present in 19.8%, with higher prevalence in RA than PsA (26.2% vs 13.6%, p=0.04). Patients with sarcopenic obesity exhibited significantly lower femoral neck BMD compared with non-sarcopenic obese patients (-2.01±0.38 vs −1.28±0.31 T-score, p<0.001).
Appendicular lean mass correlated positively with lumbar spine BMD (r=0.52, p<0.001), whereas fat mass showed no protective effect after adjustment for inflammation. High disease activity was independently associated with reduced muscle mass (β=-0.41, p=0.002).
Multivariate models demonstrated that sarcopenic obesity was a stronger predictor of osteoporosis than BMI alone (OR 3.76, 95% CI 1.61-8.77, p=0.002). Mediation analysis revealed that muscle mass mediated 38% of the effect of inflammation on bone loss. ROC analysis showed superior predictive accuracy of combined ALMI and disease activity for osteoporosis (AUC 0.87, 95% CI 0.79-0.94) compared with BMI-based models (AUC 0.69).
Conclusions:
In psoriatic and rheumatoid arthritis, sarcopenia and sarcopenic obesity are prevalent and strongly associated with reduced bone mineral density, independent of body mass index. Loss of muscle mass represents a key mediator linking inflammation to osteoporosis. These findings emphasize the need to move beyond BMI and incorporate body composition assessment into routine evaluation of skeletal risk in inflammatory arthritis, supporting integrated strategies targeting inflammation, muscle preservation and bone health.

P548
ANTI-TNF–ASSOCIATED SEVERE HEART FAILURE IN ANKYLOSING SPONDYLITIS SUCCESSFULLY MANAGED BY SWITCHING TO SECUKINUMAB: A CASE REPORT

E. S. Kang[1], J. H. Jung[1]

[1]Department of Rheumatology, Korea University Ansan Hospital, Ansan, Republic of Korea, Ansan, South Korea

Background
Tumor necrosis factor inhibitors (TNFi) are widely used in ankylosing spondylitis (AS); however, concerns remain regarding their potential association with new-onset or worsening heart failure. Evidence guiding optimal biologic switching strategies in this context is limited.
Case Presentation
A 48-year-old man was diagnosed with ankylosing spondylitis in December 2023 and was initiated on adalimumab therapy in May 2024. In October 2024, he presented with acute dyspnea and generalized edema

and was hospitalized. Evaluation revealed newly diagnosed severe heart failure with reduced ejection fraction (EF 22%) and concomitant acute kidney injury. There was no prior history of cardiac disease.

Adalimumab was discontinued due to concern for TNFi-associated cardiomyopathy, and the patient was treated with guideline-directed medical therapy for heart failure. Cardiac function gradually improved, with follow-up echocardiography in March 2025 demonstrating recovery of left ventricular systolic function (EF 53%). Given the need for continued control of inflammatory spinal disease, secukinumab was initiated as an alternative biologic agent. Following the switch, the patient remained clinically stable without recurrence of heart failure symptoms, and ankylosing spondylitis disease activity was well controlled.

Discussion

TNF inhibitors have been implicated in the development or exacerbation of heart failure, particularly in patients with reduced ejection fraction. This case highlights the importance of recognizing potential cardiac adverse events associated with TNFi therapy and supports the role of IL-17 inhibition as a safer alternative in patients with AS and heart failure. Careful cardiovascular monitoring and interdisciplinary management are essential in such cases.

Conclusion

This case underscores the potential risk of severe heart failure associated with adalimumab in ankylosing spondylitis and suggests that switching to secukinumab may be an effective and safer therapeutic strategy, with potential reversibility of TNFi-associated cardiomyopathy.

Figure 1. Anteroposterior pelvic radiograph demonstrating bilateral sacroiliitis, consistent with ankylosing spondylitis.

POLYMYOSITIS PRESENTING AS ILIOPSOAS MUSCLE INFLAMMATION MIMICKING RHABDOMYOLYSIS AND INFECTION: A CASE REPORT

E. S. Kang[1], J. H. Jung[1]

[1]Department of Rheumatology, Korea University Ansan Hospital, Ansan, Republic of Korea, Ansan, South Korea

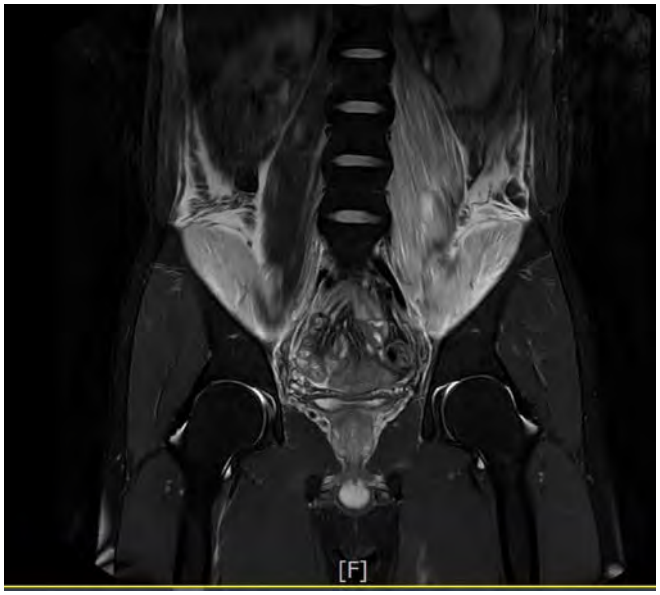
Background

Inflammatory myopathies may present with atypical manifestations, occasionally mimicking infectious or metabolic muscle disorders. Imaging plays a crucial role in early diagnosis, particularly when conventional diagnostic tests are inconclusive.

Case Presentation

A 24-year-old man presented to the emergency department with acute abdominal pain and fever on April 18 and was admitted to the infectious disease service with suspicion of iliopsoas muscle rhabdomyolysis. Initial evaluation focused on infectious and metabolic causes.

Pelvic magnetic resonance imaging performed on April 29 revealed diffuse swelling and enhancement of the bilateral iliopsoas muscles, along with multiple patchy, cotton ball–like enhancing lesions in the bilateral gluteus, adductor, and paraspinal muscles. Diffuse peritoneal and retroperitoneal infiltration with fascial thickening was also observed. These findings raised suspicion for inflammatory myopathy, including polymyositis or dermatomyositis. No significant joint lesions were identified.



An iliopsoas muscle biopsy was performed on May 3, and the patient was subsequently transferred to the rheumatology service for further evaluation and management. Electromyography performed on May 4 showed no definitive evidence of myopathy. However, based on characteristic MRI findings, clinical features, and exclusion of infection, polymyositis was diagnosed.

Treatment was initiated with oral glucocorticoids at a dose of 0.5 mg/kg/day, followed by gradual tapering. Methotrexate was introduced as a steroid-sparing agent. The patient showed marked clinical improvement, and disease activity has remained well controlled on methotrexate monotherapy.

Conclusion

This case illustrates that polymyositis can present with acute systemic symptoms and imaging findings suggestive of rhabdomyolysis or infection. MRI can provide critical diagnostic clues even when electromyography is negative, enabling timely initiation of immunosuppressive therapy and favorable outcomes.

Figure 1. Coronal pelvic MRI demonstrating diffuse high signal intensity and swelling of the bilateral iliopsoas muscles with involvement of adjacent pelvic musculature, consistent with inflammatory myopathy.

P550

JUSTIFICATION OF THE EFFECTIVENESS OF SODIUM SELENITE FOR CORRECTING CHANGES IN THE MORPHOMETRIC PARAMETERS OF BONE REGENERATE CAUSED BY PROLONGED ADMINISTRATION OF TARTRAZINE

E. S. Novik[1], V. N. Morozov[1]

[1]Belgorod National Research University, Belgorod, Russia

Introduction: Tartrazine is a synthetic dye that is widely used in the food and pharmaceutical industries. It is known that tartrazine can cause DNA damage, induce the development of oxidative stress in cells, and lead to their apoptosis, but the issue of pharmacological correction of this effect remains poorly studied.

The aim of the study is to justify the effectiveness of sodium selenite as a corrector of adverse changes in the histological structure bone regenerate caused by prolonged administration of tartrazine.

Methods: In group I, white sexually mature male rats received a physiological solution intragastrically for 60 days, and on the 61st day, a fracture of the tibia was modeled by creating a through defect in the proximal metaphysis. In group II, under similar conditions, a tartrazine solution was administered at a dose of 750 mg/kg body weight, and in group III, sodium selenite was additionally administered intramuscularly at a dose of 40 mcg/kg body weight. Measurements of the morphometric parameters of the bone regenerate forming in the tibia were conducted on days 3, 10, 15, 24, and 45 after the operation using the computer program NDP.view2. Statistical processing of the data from the control and experimental groups was carried out in the «JASP» program.

Results: In animals of group II, a decrease in the area of woven bone and lamellar bone was observed by 36.69% and 53.72% on day 10, by 28.79% and 24.56% on day 15, by 24.13% and 22.00% on day 24 ($p<0.05$ in call cases), and by 9.92% ($p>0.05$) and 13.95% ($p<0.05$) on day 45. In group III, the corrective effect of sodium selenite was recorded on day 24: an increase in the area of woven bone and lamellar bone of the bone regenerate by 23.34% and 19.07% ($p<0.05$).

Conclusion: The introduction of sodium selenite at a dose of 40 mcg/kg against the background of 60 days of exposure to tartrazine at a dose of 750 mg/kg reduces the severity of changes in the morphometric parameters of bone regenerate the areas of woven and lamellar bones on the 24th day of the experiment.

P551

DIFFERENTIAL EFFECTS OF OSTEOPOROSIS THERAPIES ON TRABECULAR BONE SCORE: A SYSTEMATIC REVIEW AND META-ANALYSIS

E. Shevroja[1], D. Vieira[1], E. Gonzalez Rodriguez[1], O. Lamy[1], K. Hind[2], D. Hans[1]

[1]Lausanne University Hospital, Lausanne, Switzerland; [2]Faculty of Health and Medicine, Lancaster University, Lancaster, United Kingdom

Background: Bone mineral density (BMD) measured by DXA is widely used for fracture risk assessment and for monitoring response to osteoporosis therapy. BMD is also an accepted imaging endpoint in osteoporosis clinical trials, supported by recent regulatory decisions recognising DXA-derived BMD as a valid surrogate for fracture outcomes. Trabecular bone score (TBS), derived from the same DXA image, independently predicts fracture and provides complementary information on bone microarchitecture. As imaging-based endpoints continue to play a central role in the evaluation of osteoporosis therapies, a clearer understanding of how different pharmacological treatments influence TBS is increasingly important. In this context, TBS may offer additional insight into treatment effects on bone quality beyond changes in BMD alone

Methods: A systematic review and meta-analysis were conducted according to a protocol registered in PROSPERO. PubMed, Embase, Web of Science, CENTRAL, publisher platforms, and clinical trial registries were searched. Eligible studies included men or women aged ≥40 years with TBS assessed by DXA, evaluating pharmacological osteoporosis therapies compared with no treatment or an active comparator. The primary outcome was mean percentage change in TBS from baseline. Study selection, data extraction, and risk-of-bias assessment were performed independently by two reviewers. Randomised and non-randomised studies were analysed separately using random-effects inverse-variance models. Heterogeneity was assessed using the I^2 statistic.

Results: Sixty studies published up to October 2025 were included (17 RCTs, 43 non-randomised). In placebo-controlled trials, bisphosphonates were associated with small, non-significant changes in TBS at 12m (mean difference [MD]0.52%, 95% CI −0.58 to 1.63; I^2=0%), with similar findings at 24m. Denosumab significantly increased TBS at 12 months (MD 1.41%, 95% CI 0.29 to 2.54; I^2=0%) and up to 10y. Anabolic therapies showed larger effects: teriparatide significantly increased TBS at 24m (MD 2.53%, 95% CI 1.74 to 3.32; I^2=0%), while romosozumab produced a marked increase at 12m (MD 4.16%, 95% CI 3.68 to 4.64; I^2=60.5%). Romosozumab also resulted in greater TBS gains than alendronate and denosumab at 12m.

Conclusions: Anti-osteoporotic therapies demonstrate distinct, treatment-specific patterns of change in TBS. Antiresorptive agents primarily stabilise trabecular microarchitecture, whereas anabolic

therapies induce earlier and more pronounced improvements. These findings reflect the molecule mechanisms of action and support the use of TBS as a complementary DXA-derived imaging outcome alongside BMD to characterise treatment response and inform treatment selection and sequencing in osteoporosis management.

P552

COMPARATIVE EFFECTIVENESS OF HIGH-MOLECULAR-WEIGHT HYALURONIC ACID VERSUS LOW-MOLECULAR-WEIGHT HYALURONIC ACID COMBINED WITH AMINO ACID–PEPTIDE SUPPLEMENTATION IN KNEE OSTEOARTHRITIS

E. Sonbahar Bolat[1]

[1]Department of Physical Medicine and Rehabilitation, Baltalimanı Bone Diseases Education and Research Hospital, Istanbul, Türkiye, İSTANBUL, Türkiye

Objective(s)
Previous studies comparing hyaluronic acid preparations with different molecular weights have shown inconsistent effects on pain and function in knee osteoarthritis. Recently, combination approaches using low-molecular-weight hyaluronic acid with amino acid–peptide supplementation have been introduced; however, direct comparative evidence with conventional high-molecular-weight hyaluronic acid remains limited. This study aimed to retrospectively compare these two approaches on pain and functional outcomes in knee osteoarthritis.

Materials and Methods
This retrospective comparative study included 50 patients with symptomatic knee osteoarthritis treated with a **single-dose intra-articular injection** of either high-molecular-weight hyaluronic acid (Group 1, n=25) or low-molecular-weight hyaluronic acid combined with amino acid–peptide supplementation (Group 2, n=25). Pain was assessed using the Visual Analog Scale (VAS), and functional outcomes were evaluated with the Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC). Assessments were performed at baseline and at 1-month follow-up. Between-group differences in the magnitude of change were analyzed.

Results
Both groups demonstrated significant improvements in WOMAC stiffness, function, and total scores after treatment (all $p<0.05$). A significant reduction in VAS pain was observed in Group 2 ($p=0.005$), while the reduction in Group 1 was not statistically significant ($p=0.083$). Group 1 showed significantly greater improvements than Group 2 in WOMAC pain ($p=0.035$), stiffness ($p=0.006$), function ($p=0.007$), and total scores ($p=0.008$). No significant between-group difference was found for VAS change ($p=0.186$).

Conclusion(s)
Both treatments were effective in improving symptoms and function in knee osteoarthritis. While VAS pain reduction was more pronounced in the combination group, high-molecular-weight hyaluronic acid provided greater overall improvement in WOMAC outcomes. Given the limited number of direct comparative studies, these findings suggest that different viscosupplementation strategies may result in distinct short-term clinical responses.

P553

EFFECT OF A NEW DIETARY SUPPLEMENT (AVOCADO/SOYBEAN UNSAPONIFIABLES 1:2, ROSEHIP EXTRACT, RESVERATROL, ZINC CITRATE) ON CLINICAL MANIFESTATIONS OF KNEE OSTEOARTHRITIS

A. Lila[1], E. Taskina[1], E. Vukailovich[1], N. Kashevarova[1], E. Strebkova[1], N. Savushkina[1], E. Sharapova[1], T. Korotkova[1], A. Khalmetova[1], L. Alekseeva[1]

[1]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia

OBJECTIVE: To evaluate the effect of a new dietary supplement containing avocado and soybean unsaponifiables (300 mg), rosehip fruit extract (300 mg), resveratrol (70 mg), and zinc citrate (12 mg) on clinical manifestations of knee osteoarthritis (OA).

MATERIALS AND METHODS: This 3-month prospective study included 50 women aged 40–75 years (mean age 58.3±10.1 years) with knee osteoarthritis (ACR criteria), Kellgren–Lawrence grade II–III, and walking pain ≥40 mm on the visual analogue scale (VAS). Median disease duration was 5 [3; 8] years. All patients provided written informed consent.

Patients received the dietary supplement (two capsules once daily). Nonsteroidal anti-inflammatory drugs (NSAIDs) were allowed on demand. Three study visits were scheduled. Treatment efficacy was assessed by changes in walking pain VAS, WOMAC, KOOS, EQ-5D, patient global assessment of health (VAS), physician- and patient-rated treatment efficacy, and NSAID use.

RESULTS: After 1 month of therapy, significant improvement was observed in all assessed parameters ($p<0.05$), except for WOMAC stiffness (Table 1). By month 3, WOMAC stiffness also significantly decreased, while improvement of other outcomes was maintained.

At visit 3, a good treatment response (≥50% pain reduction) was achieved in 60% of patients, and walking pain ≤40 mm VAS was observed in 88%. NSAID dose reduction or discontinuation occurred in 40% of patients at visit 2 and in 48% at visit 3.

Table 1. Dynamics of clinical parameters during therapy, Me [25th; 75th percentiles]

Parameters	V1	V2	V3	p
Pain, VAS (mm)	51 [48; 56]	43 [30; 51]	24 [12; 33]	**<0,001*** **<0,001****

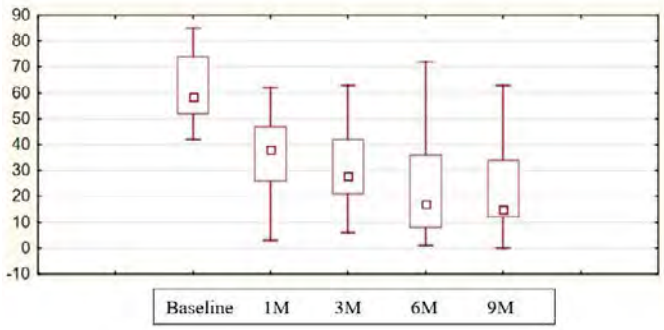
* Differences between V2 and V1

** Differences between V3 and V1

CONCLUSIONS: The results of this study demonstrate a rapid and clinically meaningful effect of the new dietary supplement in patients with knee osteoarthritis.



P554

EFFICACY OF A COMBINATION OF GLUCOSAMINE AND CHONDROITIN SULFATE SUPPLEMENTED WITH UNDENATURED TYPE II COLLAGEN, B VITAMINS, GINGER EXTRACT, AND ASCORBIC ACID IN PATIENTS WITH KNEE OSTEOARTHRITIS

A. Lila[1], E. Strebkova[1], E. Taskina[1], N. Kashevarova[1], N. Savushkina[1], E. Sharapova[1], T. Korotkova[1], A. Khalmetova[1], D. Kudinsky[1], L. Alekseeva[1]

[1]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia

Objective. To evaluate the efficacy of a dietary supplement containing glucosamine (1500 mg), chondroitin sulfate (1000 mg), undenatured type II collagen (UC-II, 40 mg), a B-vitamin complex, vitamin C (100 mg), and ginger root extract (300 mg) in patients with knee osteoarthritis (OA).
Material and Methods. This prospective randomized study included 40 women aged 40–75 years with confirmed knee OA (ACR criteria), Kellgren–Lawrence grade I–III, and walking pain ≥40 mm on the visual analogue scale (VAS). Median age was 61.5 [57.5;69] years. All participants received oral dietary supplement therapy with the above combination for 6 months, followed by a 3-month observation period to assess the aftereffect. Total study duration was 9 months.
Results. The dietary supplement demonstrated a significant clinical effect during treatment and follow-up. After 1 month, walking pain VAS decreased significantly ($p<0.01$; Fig. 1) and remained reduced throughout therapy and 3 months after discontinuation. Pain <40 mm VAS was achieved in 52.5% of patients at 1 month, 67.5% at 3 months, and 80% at 6 months; during follow-up, 75% of patients-maintained pain <40 mm. Significant improvement was observed in all WOMAC domains ($p<0.01$ vs baseline): pain decreased from 221 [150;303] mm to 149 [114;199], 104 [57;172], 74.5 [40;152], and 66.5 [39;106] mm at 1, 3, 6, and 9 months, respectively; stiffness from 93.5 [58;128] to 68 [35;90], 42.5 [18;79], 32 [14;74], and 24.5 [15;51] mm; physical function from 904 [563;1075.5] to 658 [399;755], 432 [271;674], 288.5 [181;585], and 252 [148;440] mm. All patients demonstrated significant improvement in KOOS and patient global assessment of health VAS throughout treatment and follow-up ($p<0.01$).
Conclusion. The dietary supplement provided a sustained analgesic effect and significantly improved stiffness, physical function, and quality of life in patients with knee OA over the long term.
Figure 1. Dynamics of knee pain intensity (VAS) during treatment with the dietary supplement containing UC-II, glucosamine, chondroitin sulfate, B vitamins, vitamin C, and ginger root extract

P555

COMPARATIVE CHARACTERISTICS OF PATIENTS WITH DIFFERENT OSTEOARTHRITIS PHENOTYPES: INTEGRATION OF CLINICAL AND LABORATORY PARAMETERS

A. Lila[1], E. Strebkova[1], E. Taskina[1], N. Kashevarova[1], N. Savushkina[1], A. Khalmetova[1], A. Petrachkova[1], E. Samarkina[1], D. Kudinsky[1], L. Alekseeva[1]

[1]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia

Objective. To compare clinical and laboratory characteristics in patients with osteoporotic (OP-OA) and metabolic (Met-OA) phenotypes of knee osteoarthritis (OA).

Material and Methods. This prospective study included 122 patients with knee OA (ACR criteria), Kellgren–Lawrence grade II–III. 46 patients had the OP-OA phenotype (osteoporosis and/or osteopenia based on axial skeleton densitometry) and 76 had the Met-OA phenotype. Clinical and laboratory assessments were performed in all patients.

Results. Compared with OP-OA, patients with Met-OA were older, had longer disease duration, higher body mass index, and worse clinical outcomes, including knee pain (VAS), WOMAC (total score and subscales), KOOS, and patient global assessment of health (Table 1). Met-OA was associated with higher levels of systemic inflammation and cartilage degradation markers: CRP (1.9 [1.0; 3.5] vs 1.2 [0.7; 1.8]

mg/L; p=0.009) and COMP (23.4 [15.3; 32.7] vs 15.0 [10.5; 25.1] pg/mL; p=0.004). MMP-9 levels tended to be higher in Met-OA (3.9 [1.6; 6.8] vs 1.8 [0.8; 4.0] ng/mL; p=0.077). Positive correlations were observed between Met-OA and CRP (r=0.33; p<0.01), COMP (r=0.37; p<0.01), and MMP-9 (r=0.25; p=0.02).

Table 1. Comparative clinical characteristics of patients with different knee OA phenotypes

Parameters	OP-OA	Met-OA	p
Age, years, M±SD	55.4 ± 10.2	59.9 ± 8.6	**p=0.02**
OA duration, years, Me [25th-75th percentiles]	3 [1;10]	9 [3;15]	**p<0.01**
BMI, kg/m², M±SD	26.7 ± 5.1	34.2 ± 6.1	**p<0.01**
Pain (VAS), mm, Me [25th-75th percentiles]	40 [10;50]	53 [43;70]	**p<0.01**
WOMAC pain, мм, Me [25th-75th percentiles]	128.5 [40;160]	195 [130;270]	**p<0.01**
WOMAC stiffness, mm, Me [25th-75th percentiles]	50 [20;70]	80 [50;116]	**p<0.01**
WOMAC physical function, mm, Me [25th-75th percentiles]	342.5 [110;695]	696 [470;924]	**p<0.01**
WOMAC total, mm, Me [25th-75th percentiles]	507.5 [210;870]	1030 [680;1280]	**p<0.01**
KOOS, %, Me [25th-75th percentiles]	57 [48; 85]	47 [35;60]	**p<0.01**
Global assessment of health (VAS), mm, Me [25th-75th percentiles]	30 [15;50]	50 [40;60]	**p<0.01**

Conclusion. Met-OA is associated with more severe clinical manifestations and increased systemic inflammation and cartilage degradation compared with OP-OA. Integration of clinical and immunological markers may improve OA phenotyping and support personalized treatment strategies.

P556

ASSOCIATION BETWEEN VITAMIN D3 AND COMORBID CONDITIONS IN PATIENTS WITH KNEE OSTEOARTHRITIS

N. Kashevarova[1], E. Taskina[1], E. Strebkova[1], E. Sharapova[1], N. Savushkina[1], S. Glukhova[1], E. Samarkina[1], L. Alekseeva[1], A. Lila[1]

[1]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia

PURPOSE: To evaluate the association between vitamin D3 status and comorbid conditions in patients with knee osteoarthritis (OA).

METHODS: The study included 171 women with knee OA (Kellgren–Lawrence grade I–III) who provided informed consent. Mean age was 53.5±9.9 years, body mass index (BMI) 29.8±6.4 kg/m², and disease duration 3 [1;7] years. Data on anthropometry, medical history, clinical examination, and comorbidities were collected.

The prevalence of comorbidities was: ischemic heart disease (IHD) 8.2%, metabolic syndrome 29.2%, arterial hypertension (AH) 36.2%, diabetes mellitus 8.7%, cardiac arrhythmias 14.0%, previous myocardial infarction 0.6%, hypertriglyceridemia (HTG) 34.5%, liver steatosis 10.5%, and hyperuricemia 21.6%.

RESULTS: Normal vitamin D levels (≥30 ng/mL) were found in 62 patients (36.3%, Group 1), insufficiency (20–30 ng/mL) in 66 (38.6%, Group 2), and deficiency (<20 ng/mL) in 43 (25.1%, Group 3). Groups were comparable in age (52 [43;62] vs 54 [46;62] vs 54 [45;61] years) and disease duration (2 [1;5] vs 3 [2;8] vs 4 [2;6] years; p>0.05).

Patients with vitamin D insufficiency or deficiency had significantly higher body weight (69.0 [60.0;82.0] vs 82.0 [68.0;96.0] vs 81.0 [72.0;91.5] kg), BMI (24.6 [22.5;28.1] vs 30.4 [26.2;35.7] vs 31.0 [27.6;31.0] kg/m²), and waist circumference (82.0 [72.0;93.0] vs 91.0 [82.0;100.0] vs 90.0 [85.0;106.0] cm; p<0.05).

Higher frequencies of IHD (3.85% vs 9.43% vs 21.8%), HTG (8.0% vs 22.0% vs 12.5%), and AH (31.4% vs 60.4% vs 53.7%) were also observed in groups with reduced vitamin D levels (p<0.05). Spearman correlation analysis confirmed associations between vitamin D insufficiency/deficiency and body weight, BMI, waist circumference, IHD, HTG, and AH (Table 1).

Table 1. Correlation coefficients between vitamin D insufficiency/deficiency and osteoarthritis-related factors.

Parameter	r	p
Body weight	-0.29	0.03
Body mass index	-0.35	0.002
Waist circumference	-0.27	0.001
Ischemic heart disease	-0.26	0.001
Hypertriglyceridemia	-0.28	0.008
Arterial hypertension	-0.24	0.01

CONCLUSIONS: Vitamin D deficiency and insufficiency in patients with knee OA may be associated with increased cardiovascular risk, supporting hypovitaminosis D as a potentially modifiable risk factor for cardiovascular comorbidity.

P557

PERSPECTIVES OF MULTIMODAL THERAPY FOR OSTEOARTHRITIS IN PATIENTS WITH MODERATE AND/OR SEVERE KNEE PAIN: FOCUS ON THE COMBINATION OF DMOADS AND VISCOSUPPLEMENTATION

E. Strebkova[1], E. Taskina[1], A. Lila[1], N. Kashevarova[1], N. Savushkina[1], E. Sharapova[1], A. Khalmetova[1], T. Korotkova[1], A. Demina[1], E. Zonova[2], A. Klimenko[3], L. Alekseeva[1]

[1]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia; [2]Novosibirsk State Medical University, Novosibirsk, Russia; [3]Pirogov Russian National Research Medical University, Moscow, Russia

Objective. To assess the efficacy of multimodal therapy combining disease-modifying osteoarthritis drugs (DMOADs: chondroitin sulfate (CS) and glucosamine (G)) with intra-articular injection of a synthetic

viscoprosthesis (IA-SV) versus monotherapy in knee osteoarthritis (OA).

Material and Methods. This randomized comparative study included 63 patients aged 40–75 years with knee OA, Kellgren–Lawrence grade II–III, and pain >40 mm (VAS). Mean age was 65.1±8.1 years. Patients were assigned to three groups: Group 1 (n=22) received DMOADs (CS 800 mg/day and G 1000 mg/day for 6 months) combined with a single IA-SV; Group 2 (n=20) - single IA-SV; Group 3 (n=21) - DMOADs monotherapy for 6 months. Total follow-up duration was 9 months.

Results. All groups demonstrated significant reductions in knee pain VAS and improvements in all WOMAC subscales. After 1-month, significant pain reduction (p<0.05) was observed in Groups 1 and 2 (Table 1). In Group 1, patient global assessment of health improved after 1 month (50 [40;55] vs 60 [50;65] mm; p=0.008), whereas in Groups 2 (53 [50;65] vs 75 [55;80] mm; p=0.013) and 3 (50 [49;55] vs 68.5 [60;75] mm; p=0.013) significant improvement was observed only after 3 months. In the multimodal therapy group, CRP levels decreased after 3 months and remained reduced (1.3 [0.6;3.1] vs 1.2 [0.6;2.2] mg/L; p=0.02); in the other groups, significant changes were observed only at the end of follow-up. All treatments were well tolerated.

Table 1. The dynamics of knee pain (VAS)

Parameter	M	Group 1	Group 2	Group 3	p*	p^1	p^2	p^3
Pain VAS, mm, Me [25th-75th percentiles]	Baseline 1 6 9	58.5[53; 62] 36 [24;47] 23.5 [11;39] 25 [13;39]	55 [52;65] 27.5 [19;38] 17.5[8;22] 11 [5;30]	52 [48;60] 44 [37;48] 21 [15;35] 15 [8;25]	0.32 0.06 0.61 0.49	**0.003** **0.016** **0.003**	**<0.001** **<0.001** **<0.001**	**0.096** **<0.005** **<0.001**

M, month; p, between-group comparison (Kruskal–Wallis test; p<0.05 significant); p1, within-group change vs baseline (V1) in Group 1; p2, within-group change vs baseline (V1) in Group 2; p3, within-group change vs baseline (V1) in Group 3 (p<0.05 significant).*

Conclusion. Multimodal therapy demonstrated significant efficacy and safety in knee OA. Combination of viscosupplementation with DMOADs was associated with rapid analgesic effect, improved quality of life, and reduction in CRP levels.

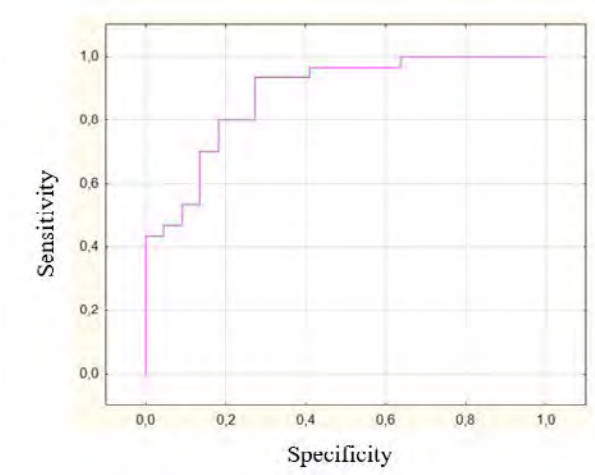
P558

FREE LEPTIN INDEX AND HYPERLEPTINEMIA AS POTENTIAL MARKERS OF METABOLIC OSTEOARTHRITIS

A. Lila[1], E. Strebkova[1], E. Taskina[1], N. Kashevarova[1], N. Savushkina[1], A. Khalmetova[1], A. Petrachkova[1], E. Samarkina[1], A. Avdeeva[1], L. Alekseeva[1]

[1]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia

Objective. Obesity is an important factor in the development and progression of osteoarthritis (OA). To compare adipose tissue–related metabolic markers in patients with different OA phenotypes.



Material and Methods. This single-center cross-sectional study included 122 patients with knee OA (ACR criteria), Kellgren–Lawrence grade II–III, who provided informed consent. According to phenotype, 76 patients (62.3%) had metabolic OA (Met-OA) and 46 (37.7%) had osteoporotic OA (OP-OA; osteoporosis and/or osteopenia based on axial skeleton densitometry). Blood immunological assessment included adipokines (leptin, resistin, visfatin) and soluble leptin receptors (sOB-R).

Results. Compared with OP-OA, Met-OA patients were older (59.9±8.6 vs 55.4±10.2 years; p=0.02), had longer disease duration (9.0 [3.0;15.0] vs 3.0 [1.0;10.0] years; p=0.002), higher body mass index (34.2±6.1 vs 26.7±5.1 kg/m²; p<0.0001), and greater knee pain by VAS (53.0 [43.0;70.0] vs 40.0 [10.0;50.0] mm; p=0.001). Hyperleptinemia (leptin ≥11.1 ng/mL in women and ≥5.6 ng/mL in men) was detected in 76.08% of OP-OA and 97.37% of Met-OA patients. Met-OA was associated with higher leptin levels, higher free leptin index (leptin/sOB-R ×100), and lower sOB-R levels compared with OP-OA (p<0.05; Table 1). No between-group differences were found for visfatin or resistin (p>0.05). Regression analysis confirmed associations between Met-OA and hyperleptinemia (β=0.32; p<0.0001), leptin levels (β=0.44; p<0.0001), and inverse association with sOB-R (β=−0.28; p=0.017). The strongest association was observed for the free leptin index (β=0.55; p<0.0001), which was also supported by ROC analysis (AUC=0.88).

Table 1. Comparative analysis of adipose tissue–related markers in patients with different OA phenotypes

Parameters	OP-OA	Met-OA	p
Leptin, ng/ml, Me [25th-75th percentiles]	19.21 [11.9;32.9]	43.8 [25.5;71.4]	**<0.0001**
sOB-R, ng/ml, [25th-75th percentiles]	16.33 [13.4;18.7]	13.3 [12.08;15.13]	**0.009**
Free leptin index	131.2 [66.5;259.2]	414.5 [223.8;692.6]	**<0.0001**
Visfatin, ng/ml, Me [25th-75th percentiles]	30.2 [24.4;45.8]	33.1 [26.8;43.8]	0.68
Resistin, ng/ml, [25th-75th percentiles]	7.1 [6;10.2]	8 [7;10.2]	0.51

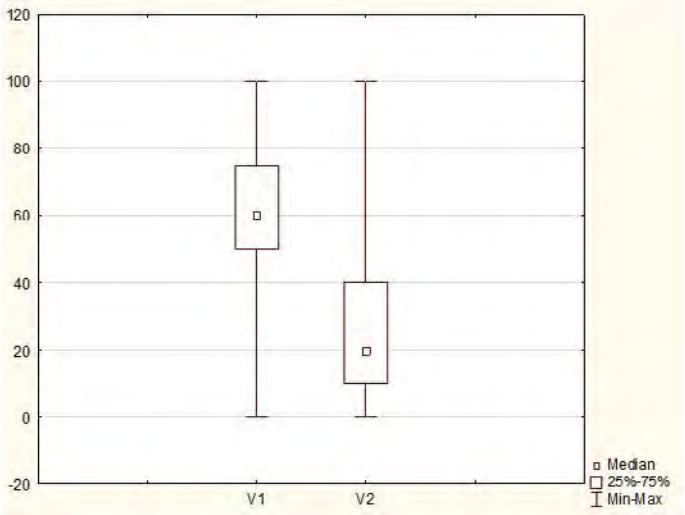
Figure 1. ROC curve for prediction of Met-OA based on a high free leptin index (AUC=0.88)

Conclusion. Hyperleptinemia and the free leptin index may be considered potential biomarkers of the metabolic phenotype of knee OA.

P559

EFFICACY OF BIOACTIVE CONCENTRATE OF SMALL MARINE FISH IN ELDERLY PATIENTS WITH NONSPECIFIC LOW BACK PAIN

E. Taskina[1], A. Lila[1], E. Strebkova[1], N. Kashevarova[1], N. Savushkina[1], A. Khalmetova[1], A. Petrachkova[1], L. Alekseeva[1]



[1]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia

Objective. To evaluate the efficacy of SYSADOA (bioactive concentrate of small marine fish (BCSMF) containing chondroitin sulfate, amino acids, peptides, sodium, potassium, calcium, magnesium, iron, copper and zinc ions) therapy in elderly patients (over 60 years old) with nonspecific low back pain (LBP) in a multicenter observational study.

Materials and methods. The study included 5 135 patients with nonspecific LBP. The average age was 68.3±6.3 y.o, the body mass index was 28.7±4.7 kg/m2. The duration of the study is from 20 to 31 days, the number of visits is 2: visit 1 (V1)– the beginning of therapy, visit 2 (V2) – within 10 days after the completion of the 1st course of treatment. BCSMF was prescribed 1 ml intramuscular daily No. 20 or 2 ml intramuscular every other day No. 10.

Results. During the course of treatment, there was a significant pain on VAS decreased from 60 [50; 75] to 20 [10; 40] mm; p<0.0001 (Fig. 1); an improvement in the quality of life according to EQ-5D from 0.52 [-0.02; 0.59] to 0.76 [0.69; 1] points (p<0.0001) and an increase in patient global assessment of health VAS from 50 [30; 60] to 70 [60; 90] mm (p<0.0001). Accordingly, the median reduction in pain (according to VAS) was 57.1 [37.5; 75] %, and the median improvement in patient global assessment of health VAS - 50 [14.3; 100] %. A good response to therapy (pain reduction by ≥50%) was detected in 65.1% of cases; a decrease in pain on VAS to <40 mm was detected in 83.2%. The marked improvement observed in most patients led to a decrease in the need for NSAIDs: 75.1% of patients received them at the beginning of therapy, and 68.9% at the end of treatment (OR=1.36; 95% CI 1.24–1.49; p<0.0001). Attention was drawn to the high adherence to treatment (96.6±11.6%), which was >80% in 93.7% of cases.

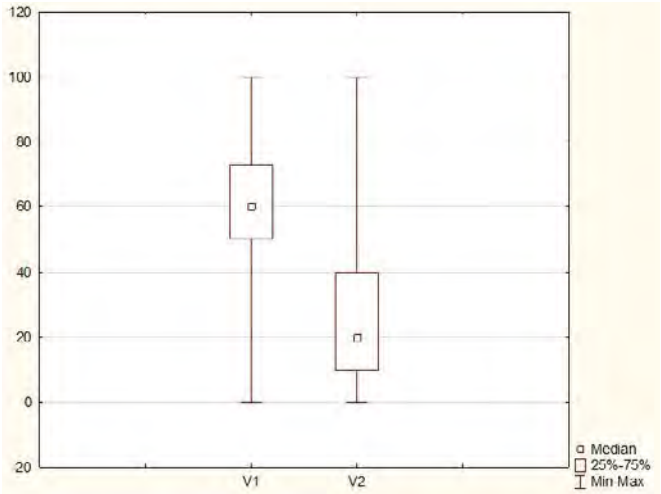
Fig. 1. Dynamics of pain on VAS in non-specific LBP during therapy

Conclusion. The confirmed symptomatic effect of BCSMF justifies the rationality of its use in geriatric practice in nonspecific LBP

P560

EFFICACY OF BIOACTIVE CONCENTRATE OF SMALL MARINE FISH IN ELDERLY PATIENTS WITH HIP OSTEOARTHRITIS

E. Taskina[1], E. Strebkova[1], N. Kashevarova[1], N. Savushkina[1], A. Khalmetova[1], A. Petrachkova[1], L. Alekseeva[1], A. Lila[1]



[1]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia

Objective. To evaluate the efficacy of SYSADOA (bioactive concentrate of small marine fish (BCSMF) containing chondroitin sulfate, amino acids, peptides, sodium, potassium, calcium, magnesium, iron, copper and zinc ions) therapy in elderly patients with hip osteoarthritis (OA) in a multicenter observational study.

Materials and methods. The study included 4 377 patients with hip OA (ACR criteria). The average age was 68.6 ± 6.4 y.o, the body mass index was 28.9 ± 4.9 kg/m2, the median duration of hip OA was 84 (48-120) months. The duration of the study is from 20 to 31 days, the number of visits is 2: visit 1 (V1) – the beginning of therapy, visit 2 (V2) – within 10 days after the completion of the 1st course of treatment. BCSMF was prescribed 1 ml intramuscular daily No. 20 or 2 ml intramuscular every other day No. 10.

Results. During the course of treatment, there was a significant pain on VAS decreased from 60 (50-73) to 20 (10-40) mm, p<0.001 (Fig.1); improved quality of life according to EQ-5D from 0.52 (-0.02-0.62) to 0.76 (0.62-1) points (p<0.05) and an increase in patient global assessment of health VAS from 50 (30-62) to 80 (60-90) mm (p<0.0001). Accordingly, the median reduction in pain (according to VAS) was 50 (33.3-75) % and the median improvement in patient global assessment of health VAS – 40 (14.3 – 100)%. More than half of the patients (60.8%) demonstrated a good response to therapy (reduction of pain during movement ≥50% compared to baseline). In 66.1% of patients, the intensity of hip pain decreased <40 mm by VAS.

Fig. 1. Dynamics of hip pain (according to VAS) during drug treatment

Conclusion. The results of an observational study confirm the symptomatic effect of BCSMF and the expediency of its use in patients over 60 years of age with hip OA.

P561

METABOLIC CHANGES IN ENERGY METABOLISM AND INFLAMMATION IN THE PERIPHERAL BLOOD MONONUCLEAR CELLS CULTURED WITH CAPSAICIN FROM PATIENTS WITH END-STAGE OSTEOARTHRITIS

E. Tchetina[1], M. Cherkasova[1]

[1]Nasonova Research Institute of Rheumatology, Moscow, Russia

Objectives: To examine metabolic changes in the expression of genes associated with energy metabolism in the **peripheral blood mononuclear cells** (PBMCs) obtained from patients with end-stage osteoarthritis (OA) prior to arthroplasty and cultured with capsaicin.
Methods: Twenty six patients with end-stage OA (median age 60 years) were examined. PBMCs were isolated prior to arthroplasty using Ficoll density gradient and cultured with 0.1 μM **capsaicin** during 24h. Cell viability was monitored with 0.2% Trypan blue staining. Total RNA isolated from these cells was used for gene expression studies performed with quantitative real-time RT-PCR.
Results:Capsaicin was capable of modifying gene expression in cultured PBMCs from the examined patients with OA compared with untreated cells. Expression of the Krebs cycle component succinate dehydrogenase, and electron transport chain element, uncoupling protein 1 was significantly upregulated in concert with ATP-synthase gene. Simultaneous upregulation of the autophagy-related ULK1 was observed along with downregulation of the inflammation-related tumour necrosis factor α and IL-1β genes expression compared with untreated counterparts.
Conclusion: The upregulation of genes associated with energy metabolism accompanied by downregulation of inflammation-related TNFα and IL-1β in PBMCs obtained from patients with end-stage osteoarthritis prior to arthroplasty, indicates the involvement of whole cell metabolism in the manifestations of OA disease.

P562

CAPSAICIN EFFECTS ON THE EXPRESSION OF TYPE II COLLAGEN AND GENES ASSOCIATED WITH ENERGY METABOLISM AND INFLAMMATION IN THE ARTICULAR CARTILAGE EXPLANTS FROM PATIENTS WITH END-STAGE OSTEOARTHRITIS

E. Tchetina[1], M. Cherkasova[1]

[1]Nasonova Research Institute of Rheumatology, Moscow, Russia

Objectives: To examine metabolic changes in the expression of genes associated with energy metabolism in the articular cartilage explants obtained from patients with end-stage osteoarthritis (OA) prior to arthroplasty and cultured with capsaicin.
Methods: Seventeen patients with end-stage OA (median age 62 years) were examined. Full-depth explants of human OA knee articular cartilage from arthroplasty were cultured with 0.1 μM capsaicin during 24h. Total RNA isolated from these cells was used for gene expression studies performed with quantitative real-time RT-PCR.
Results: Capsaicin was capable of modifying gene expression in cultured articular cartilage explants from the examined patients with OA compared with untreated counterparts. Gene expression of glycolysis –related pyruvate kinase, the Krebs cycle component succinate dehydrogenase, and electron transport chain element, uncoupling protein 1 was significantly upregulated compared with untreated controls. Simultaneous upregulation of the autophagy-related ULK1 was observed along with downregulation of the inflammation-related tumour necrosis factor α gene expression. Type II collagen gene expression was also upregulated. No significant changes in the expression IL-1β gene were noted in cartilage explants from the examined patients with OA cultured with capsaicin compared with untreated counterparts.
Conclusion: The upregulation of genes associated with energy metabolism and type II collagen accompanied by downregulation of inflammation-related TNFα in articular cartilage explants obtained from patients with end-stage osteoarthritis from arthroplasty in the presence of capsaicin, indicates the involvement of whole cell metabolism in the manifestations of OA disease.

P563

DISTURBANCES IN CENTRAL SENSITIZATION ARE ASSOCIATED WITH PAIN AND ALTERATIONS IN GENE EXPRESSION IN THE PERIPHERAL BLOOD OF PATIENTS WITH RHEUMATOID ARTHRITIS

E. Tchetina[1], A. Potapova[1], A. Karateev[1], A. Lila[1]

[1]Nasonova Research Institute of Rheumatology, Moscow, Russia

Objective: To determine the effect of CS severity score on the expression of genes associated with inflammation, tissue destruction, and central metabolic processes in the peripheral mononuclear blood cells (PBMCs).
Methods: The blood of 59 patients with RA (11 men and 48 women, average age 52.0 years, ranged from 19 to 75 years) was examined. Clinical status was assessed using the DAS28 index, serum levels of CRP, ASPA, and RF. To assess the CS score, the severity of pain,

anxiety, depression, fatigue and signs of fibromyalgia, the CSI, VAS, BPI, Pain DETECT, HADS, FSS, FIRST, FACIT-F questionnaires were used, respectively. Protein expressions in PBMCs were quantified by ELISA. Gene expression was determined using reverse transcriptase and quantitative real-time RT-PCR (qRT-PCR) for expression of genes related to carbohydrate and fatty acid metabolism.

Results: All examined patients with RA had high disease activity. Patients were divided into 4 subgroups according to the severity of CS. Significantly higher expression of genes associated with the functioning of the pentose phosphate pathway, antioxidant protection, electron transport chain, fatty acid metabolism, and tissue destruction was found with increasing severity of RA compared to the healthy subjects. In contrast, the expression of the proinflammatory cytokine (IL-1β) did not differ from the control while the expression of the TNFα gene increased only in patients with severe and extreme CS scores compared to control individuals.

Conclusions: Disturbances caused by CS lead to a significantly higher severity of RA in patients, despite active antirheumatic therapy. The severity of the disease at the cellular level may be explained by dysregulated expression of genes associated with central metabolic processes, despite low levels of proinflammatory cytokine gene expression.

P564

CALCANEAL ULTRASOUND PARAMETERS IN ADULT MALES: NORMATIVE DATA IN A TURKISH POPULATION SAMPLE

A. Yaliman[1], M. G. Gunver[2], E. Topsakal[1], D. Sindel[1], A. Oral[1]

[1]Department of Physical Medicine and Rehabilitation, Istanbul Faculty of Medicine, Istanbul University, Istanbul, Türkiye; [2]Department of Biostatistics, Istanbul Faculty of Medicine, Istanbul University, Istanbul, Türkiye

Objective: Quantitative ultrasound (QUS) of the calcaneus is a practical, radiation-free method for evaluating bone quality and fracture risk. Although QUS is increasingly used in clinical and epidemiological settings, age- and population-specific normative data for adult men remain limited. This study aimed to establish age-stratified normative reference values for calcaneal QUS parameters in healthy Turkish men.

Methods: This cross-sectional study included 909 healthy men aged 17–93 years. Broadband ultrasound attenuation (BUA) and speed of sound (SOS) were measured at the left calcaneus using the Sahara® Clinical Bone Sonometer. Quantitative Ultrasound Index (QUI) and estimated bone mineral density (eBMD) were calculated using manufacturer-provided formulas. Participants were stratified into six age groups by decades. Normative means and lower and upper reference limits were determined using the Golden Ratio in Statistics (GRiS) method to account for skewed distributions.

Results: Age-related variations were observed across all QUS parameters. BUA, QUI, and eBMD reached their highest normative mean values in the 30–39 age group (77.85 dB/MHz, 95.76, and 0.529 g/cm², respectively), while SOS peaked earlier, in the 17–29 age group (1551.78 m/s), and remained relatively stable thereafter. Following peak values, all parameters demonstrated a gradual age-related decline, which was more pronounced for BUA, QUI, and eBMD than for SOS. The lowest mean values were generally observed in the older age groups, particularly among men aged ≥70 years. No statistically significant differences were detected between consecutive age groups, indicating a progressive rather than abrupt deterioration in bone-related ultrasound parameters. Normative reference ranges showed considerable width across all ages, highlighting substantial inter-individual variability.

Conclusion: This study provides the first comprehensive, age-specific normative calcaneal QUS reference data for adult Turkish men. The findings demonstrate a gradual decline in bone ultrasound parameters after early adulthood and support the use of age-adjusted QUS reference values in clinical screening and epidemiological studies of male bone health.

P565

ISOLATED MUSCULOCUTANEOUS NERVE NEUROPATHY FOLLOWING CARDIAC SURGERY ANESTHESIA: A CASE REPORT

M. C. K. Calkin Korkmaz[1], M. K. A. Karacaatli Erdogan[1], Z. Yasar Aydin[1], S. H. Haliloglu[1], E. U. Ulger[1]

[1]Kartal Dr. Lütfi Kırdar City Hospital, Istanbul, Türkiye

Introduction

Isolated musculocutaneous nerve neuropathy is a rare condition and an uncommon postoperative complication. The musculocutaneous nerve arises from the lateral cord of the brachial plexus and innervates the biceps brachii and brachialis muscles, playing a major role in elbow flexion. Injury to this nerve typically causes weakness of elbow flexion, biceps muscle atrophy, decreased biceps reflex, and sensory disturbance over the anterolateral forearm.

Reported etiologies include trauma, strenuous exercise, improper positioning, shoulder surgery, and nerve compression at the level of the coracobrachialis muscle. Postoperative isolated musculocutaneous nerve injury related to anesthesia is extremely rare. We present a case of isolated musculocutaneous neuropathy following cardiac surgery anesthesia.

Case Report

A 22-year-old woman presented to the Physical Medicine and Rehabilitation clinic four weeks after elective cardiac valve surgery because of weakness in right elbow flexion. She had no history of trauma, neuromuscular disease, or upper extremity surgery.

On examination, muscle strength of the right biceps brachii was 3/5 and forearm supination was 4/5. Visible atrophy of the right biceps muscle was present. The right biceps deep tendon reflex was decreased. Sensory examination revealed paresthesia over the anterolateral aspect of the right forearm, and Tinel's sign was positive at the mid-upper arm. Cervical radiculopathy tests were negative.

Electromyography performed in the fourth postoperative week demonstrated severe partial axonal injury of the right musculocutaneous nerve. Conservative treatment including vitamin B12, alpha-lipoic acid, neuromuscular electrical stimulation, and strengthening exercises was initiated. At the three-month follow-up, muscle strength had fully recovered.

Discussion

Isolated musculocutaneous nerve neuropathy is rare and may be overlooked in postoperative patients. Possible mechanisms include prolonged compression, traction, or improper arm positioning during anesthesia. The absence of neuropathic pain and the presence of isolated motor weakness are consistent with previous reports.

Electromyography is essential for diagnosis, and most cases show excellent recovery with conservative treatment. Awareness of this rare complication is important for early diagnosis and prevention of long-term functional impairment.

P567

THE MEAN VALUES OF TRAIL IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS AND HEALTHY CONTROLS

E. V. Papichev[1], L. E. Sivordova[1], Y. R. Akhverdyan[1], Y. V. Polyakova[1], B. V. Zavodovsky[1]

[1]Research institute of clinical and experimental rheumatology n.a. A.B. Zborovsky, Volgograd, Russia

Background. Overproduction of type I interferons (IFNs) is observed in patients with systemic lupus erythematosus (SLE). These cytokines activate various immune cells and contribute to disease progression. However, type I IFNs also play a crucial role in the immune response to viral infections by inducing the production of diverse proteins. One such protein is TNF-related apoptosis-inducing ligand (TRAIL), a member of the TNF superfamily that induces apoptosis via death receptors. Given its association with IFNs and immune cell activation, it is of interest to study serum TRAIL levels in patients with SLE compared with healthy controls.
Aim. To compare mean serum TRAIL levels in patients with SLE and healthy controls.
Materials and methods. Serum levels of TRAIL were measured in 29 patients with SLE (28 women and 1 man) and 9 conditionally healthy individuals (5 women and 4 men) using a commercial test system (Cloud-Clone Inc., Cat. No. SEA139Hu). All patients with SLE fulfilled the 2019 EULAR/ACR classification criteria and were ANA-positive. The median disease duration was 6.0 [2.5–12.0] years. Statistical analysis was performed using «*Statistica 10.0*» software. Results were considered statistically significant at $p < 0.05$.
Results. Patients with SLE and healthy controls were comparable in age (43.1 ± 12.9 years vs 23 [23.0–62.0] years; U = 124.0, $p = 0.726$), weight (70.0 [60.0–81.0] kg vs 80.2 ± 13.3 kg; U = 88.5, $p = 0.125$), and BMI (25.7 [23.3–30.1] kg/m² vs 27.1 ± 3.1 kg/m²; U = 114.5, $p = 0.505$). Median serum TRAIL levels did not differ significantly between patients with SLE and healthy controls (8.65 [8.17–9.63] pg/mL vs 8.30 [8.04–8.77] pg/mL; U = 96.5, $p = 0.205$). Additionally, no significant differences were observed in TRAIL levels among patients with low, moderate, high, or very high disease activity according to the SELENA-SLEDAI score.
Conclusions. Serum TRAIL levels were comparable between patients with SLE and healthy controls. No significant association was found between SLE disease activity measured by SELENA-SLEDAI and serum TRAIL levels.

P568

TRAIL IN PATIENTS WITH RHEUMATOID ARTHRITIS AND ANKYLOSING SPONDYLITIS

E. V. Papichev[1], B. V. Zavodovsky[1], Y. V. Polyakova[1], L. E. Sivordova[1], Y. R. Akhverdyan[1]

[1]Research institute of clinical and experimental rheumatology n.a. A.B. Zborovsky, Volgograd, Russia

Objective. TNF-related apoptosis-inducing ligand (TRAIL) is an interferon-γ–induced protein, a death-receptor ligand capable of activating the extrinsic apoptotic pathway. Synovial cells from patients with rheumatoid arthritis (RA) express a functional TRAIL death receptor 5 and undergo TRAIL-mediated apoptosis. However, information on the role of TRAIL in the diagnosis of ankylosing spondylitis (AS) – another rheumatic disease with relatively high population prevalence – is limited. Therefore, it is of interest to compare serum TRAIL levels in patients with RA, AS, and healthy controls.
Aim. To compare mean serum TRAIL levels in patients with RA and AS with those in healthy controls.
Materials and methods. Serum TRAIL levels were measured in 18 patients with RA (15 women and 3 men), 16 patients with AS (5 women and 11 men), and 9 conditionally healthy individuals (5 women and 4 men) using a commercial test system (Cloud-Clone Inc., Cat. No. SEA139Hu). All patients with RA fulfilled the 2010 ACR/EULAR classification criteria, and patients with AS fulfilled the ASAS classification criteria. The median disease duration was 5.0 [2.8–14.0] years for RA and 13.5 [9.0–29.0] years for AS. Statistical analysis was performed using «*Statistica 10.0*» software. Results were considered statistically significant at $p < 0.05$.
Results. Patients with AS were younger than those with RA (46.8 ± 10.9 years vs 55.7 ± 12.1 years; $t = 2.25$, $p = 0.032$). However, serum TRAIL levels did not correlate with age in patients with RA ($\rho = 0.003$; $p = 0.990$) or AS ($\rho = -0.09$; $p = 0.735$). Median TRAIL levels were comparable between women and men in both the RA group (12.9 ± 7.63 pg/mL vs 14.7 [10.6–30.1] pg/mL; U = 15.5, $p = 0.441$) and the AS group (8.29 [8.04–8.53] pg/mL vs 8.53 [8.04–8.77] pg/mL; U = 20.5, $p = 0.461$). Serum TRAIL levels were significantly higher in patients with RA (13.8 ± 8.06 [9.82–17.8] pg/mL) than in patients with AS (8.41 [8.04–8.65] pg/mL; Z = 3.55, $p = 0.0004$) and healthy controls (8.30 [8.04–8.77] pg/mL; Z = 2.73, $p = 0.006$).
Conclusions. Serum TRAIL levels were not associated with age or sex in patients with RA or AS. Patients with RA had significantly higher serum TRAIL levels than patients with AS and healthy controls.

P569

TRANSITION BETWEEN 2019 AND 2025 SARCOPENIA DEFINITIONS BY THE ASIAN WORKING GROUP FOR SARCOPENIA IN COMMUNITY-DWELLING OLDER ADULTS

N. Adulkasem[1], E. Vanitcharoenkul[1], A. Unnanuntana[1], P. Chotiyarnwong[1]

[1]Department of Orthopedic Surgery, Faculty of Medicine SIriraj Hospital, Mahidol University, Bangkok, Thailand, Bangkok, Thailand

Objective

The Asian Working Group for Sarcopenia (AWGS) has revised its diagnostic criteria over time, most recently in 2025. The impact of these updates on sarcopenia classification in real-world Asian populations has not been fully established. This study compared the characteristics and diagnostic transitions of community-dwelling older adults between the 2019 and 2025 definitions.

Material and Methods

We conducted a secondary analysis of a nationwide epidemiological study of community-dwelling Thai adults aged ≥60 years (n = 2,456). Muscle mass was measured using bioelectrical impedance analysis, handgrip strength with a digital dynamometer and physical performance using gait speed, five-times sit-to-stand and timed up-and-go tests. Sarcopenia was classified according to AWGS 2019 and 2025 definitions. Diagnostic transitions between the 2019 and 2025 criteria were visualized using a Sankey diagram. Characteristics and functional measures were then compared between concordant and reclassified groups.

Results

Sarcopenia prevalence increased following the AWGS definition update (18.1% in 2019 vs 28.3% in 2025). The AWGS 2025 definition identified more individuals with higher BMI and those aged <65 years, while functional profiles remained comparable to those identified by earlier definitions. For possible sarcopenia, prevalence decreased substantially under AWGS 2025 compared with AWGS 2019 (51.2% vs 93.7%). However, a greater proportion of individuals classified as possible sarcopenia under AWGS 2025 were subsequently confirmed as true sarcopenia (55.4% vs 19.3%). Diagnostic transition analysis showed that 14.9% of participants were newly classified as sarcopenic under AWGS 2025. Characteristics and functional deficits of the reclassified sarcopenia group were similar to the concordant sarcopenia group. Participants reclassified to non-sarcopenia showed no clear distinction from either concordant group.

Conclusions

The AWGS 2025 criteria capture a broader population with sarcopenia, including younger and higher-BMI individuals, while maintaining diagnostic consistency with earlier definitions. The updated approach improves practical applicability and enhances identification of individuals with meaningful sarcopenic characteristics. Further longitudinal studies are needed to refine age-specific cut-offs and clarify the clinical significance of borderline group.

P570

CHEMERIN AND RESISTIN RATIOS IN SERUM AND SYNOVIAL FLUID OF OSTEOARTHRITIS PATIENTS: A POSSIBILITY OF INTERRELATED INFLAMMATORY AND METABOLIC PATHWAYS

E. Vasileva[1], R. Karalilova[2], T. Stankova[3], R. Staynova[4], A. Boyanova[5], A. Lilova[6]

[1]Deaprtment of Propedeutics of Internal Diseases, Faculty of Medicine, Medical University Plovdiv, Plovdiv , Bulgaria; [2]Department of Propedeutics of Internal Diseases, Faculty of Medicine, Medical University Plovdiv, Plovdiv , Bulgaria; [3]Department of Medical Biochemistry, Faculty of Pharmacy, Medical University Plovdiv, Plovdiv , Bulgaria; [4]Department of Organisation and Ecoomics of Pharmacy, Faculty of Pharmacy, Medical University Plovdiv, Plovdiv, Bulgaria; [5]Department of Organisation and Economics of Pharmacy, Faculty of Pharmacy, Medical University Plovdiv, Plovdiv, Bulgaria; [6]Association "Women without Osteoporosis", Plovdiv , Bulgaria

Objective: To evaluate chemerin and resistin ratios in serum and synovial fluid of patients with osteoarthritis and to investigate their associations with inflammatory markers and ultrasonographic disease severity.

Material and Methods: This pilot study was conducted at the Clinic of Rheumatology, "Kaspela" University Hospital, Plovdiv, between January 2020 and January 2023. A total of 28 patients with knee osteoarthritis (KOA) were included (7 males, 21 females; mean age 66 ± 8.7 years). Inclusion criteria were knee joint pain accompanied by at least three of the following: age ≥40 years, morning stiffness ≤30 minutes, knee joint edema, and absence of palpable warmth in the affected joint. Serum samples were obtained from all patients, while synovial fluid was collected from 16 patients after ultrasonographic confirmation of joint effusion. Concentrations of chemerin, resistin, interleukin-6 (IL-6), and tumor necrosis factor-α (TNF-α) in serum and synovial fluid were measured using enzyme-linked immunosorbent assay (ELISA). Erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), and serum uric acid (UA) were also assessed. All participants underwent ultrasonographic evaluation of the knee joint, with disease activity scored according to Outcome Measures in Rheumatology (OMERACT) definitions. Written informed consent was obtained from all participants in accordance with the Declaration of Helsinki.

Results: The serum chemerin-to-resistin ratio was 28.2 ± 15.3 (median 25.8), while the synovial fluid chemerin-to-resistin ratio was higher at 44.8 ± 32.0 (median 39.3, IQR 27.7–61.8). The serum-to-synovial fluid chemerin ratio was 6.3 ± 3.1 (median 6.1, IQR 4.7–7.9), and the serum-to-synovial fluid resistin ratio was 8.3 ± 6.1 (median 8.0, IQR 5.0–11.5). Correlation analyses demonstrated a significant positive association between the serum chemerin/resistin ratio and ESR (rs = 0.522, p = 0.004) as well as UA (rs = 0.501, p = 0.007). The synovial fluid chemerin/resistin ratio was negatively correlated with CRP (rs = −0.695, p = 0.003). Additionally, the serum-to-synovial fluid chemerin ratio correlated positively with CRP (rs = 0.534, p = 0.033). No other statistically significant associations were observed.

Conclusion: The observed relationships between chemerin/resistin ratios and inflammatory biomarkers support a potential role for interconnected inflammatory–metabolic pathways in knee osteoarthritis. Further longitudinal studies with larger patient cohorts are required to clarify these complex interactions.

P571

EVALUATION OF BONE TURNOVER MARKERS (CTX, PINP, AND OSTEOCALCIN) IN OSTEOPOROTIC WOMEN TREATED WITH DENOSUMAB: A RETROSPECTIVE ANALYSIS

E. Xherahu[1], T. Cico[2], A. Zoto[2], V. Salko[3]

[1]Department of Intern Medicine, Memorial Regional Hospital, Fier, Albania; [2]Department of Intern Medicine, Division of Rheumatology, Mother Teresa University Hospital Center, Tirana, Albania; [3]Speciality Health Center, Kamez, Tirana, Albania

Objective: To evaluate changes in biochemical bone turnover markers (BTMs), specifically C-terminal telopeptide (CTX), procollagen type 1 N-terminal propeptide (PINP), and osteocalcin in female patients with osteoporosis undergoing denosumab therapy, while providing demographic and therapeutic clinical data.
Methods: This retrospective study included 50 female patients (mean age 69.1 ± 8.5 years) diagnosed with osteoporosis and treated with denosumab (60 mg subcutaneous injection every 6 months), accompanied according to the protocol with daily supplementation of Calcium (1000 mg) and Vitamin D3 (min. 800 IU).The mean treatment duration was 25 ± 8 months. Serum levels of CTX, PINP, and osteocalcin were collected from medical records at baseline and during follow-up. Relative percentage changes from baseline were analyzed.
Results: Denosumab treatment was associated with a rapid and profound suppression of bone resorption, evidenced by a mean reduction in CTX of 73% ($p < 0.001$). Bone formation markers PINP and osteocalcin showed a more gradual decline, with mean reductions of 40% and 34%, respectively ($p < 0.01$). These biochemical changes remained stable throughout the follow-up period in the majority of the cohort.
Conclusion: In this retrospective analysis, denosumab demonstrated a potent inhibition of bone resorption followed by a secondary reduction in bone formation, reflected by characteristic shifts in CTX, PINP, and osteocalcin. Monitoring these markers serves as a valuable clinical tool for assessing treatment efficacy and guiding the management of denosumab therapy.

P572

REMISSION AND LOW DISEASE ACTIVITY WITH RAPID DOSE ESCALATION OF METHOTREXATE IN RHEUMATOID ARTHRITIS: PHYSICIAN AND PATIENT ASSESSMENT

E. Y. Polishchuk[1], V. N. Amirjanova[1], E. L. Nasonov[1]

[1]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia

Objective: To determine the frequency of remission and low disease activity (LDA) achieved with rapid dose escalation of subcutaneous methotrexate (sc MTX) in patients with rheumatoid arthritis (RA), as assessed by both physician and patient.
Methods: The study included 107 RA patients over 18 years old with high disease activity (DAS-28 ≥5.1), who had failed prior oral MTX therapy for at least 6 months or who had not received MTX. MTX therapy was started at a dose of 15 mg/week. During the first month of therapy, the dose of sc MTX was rapidly escalated from 2.5 mg/week once a week to 22.5 mg/week and then, if the response was inadequate, the dose of sc MTX could be increased to 25 mg/week. Disease activity was assessed at 4, 12, and 24 weeks by the physician using the DAS28-CRP (Disease Activity Score 28 C-reactive protein) and by the patient using the RAPID-3 (Routine Assessment of Patient Index Data 3).
Results: Following rapid sc MTX dose escalation, a reduction in disease activity was observed as early as the first month: DAS28 decreased from 5.8±0.75 to 4.96±0.83 (p=0.001), and the patient-assessed RAPID-3 index decreased from 16.2±4.6 to 12.3±4.2 (p=0.01). By weeks 12 and 24, DAS28 activity decreased to 4.00±1.0 and 2.93±1.05, respectively; RAPID-3 scores decreased to 7.32±4.52 and 5.56±4.66, respectively. According to DAS28, LDA was achieved in 1.1% of patients at 4 weeks, 5.6% at 12 weeks, and 27.8% at 24 weeks. DAS28 remission was observed in 12.2% of patients at 12 weeks and 36.7% at 24 weeks. According to RAPID-3, LDA at 4, 12, and 24 weeks was noted in 2.8%, 23.8%, and 22.9% of patients, respectively, while remission was observed in 1.9%, 6.7%, and 35.2% of patients, respectively.
Conclusion: In patients with high RA activity, the therapeutic strategy of initiating treatment with subcutaneous MTX at 15 mg/week and rapidly escalating the dose by 2.5 mg weekly up to 22.5–25 mg/week enables the achievement of treatment targets (remission and LDA according to DAS28) in 17.8% of patients by month 3 and in 64.5% by month 6. Patient assessment (RAPID-3) at month 3 was higher, amounting to 30.5%, while at month 6 it was similar, amounting to 58.1%.

P573

TOLERABILITY OF RAPID DOSE ESCALATION OF METHOTREXATE IN RHEUMATOID ARTHRITIS PATIENTS IN REAL-WORLD CLINICAL PRACTICE

E. Y. Polishchuk[1], V. N. Amirjanova[1], E. L. Nasonov[1]

[1]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia

Objective: To analyse the tolerability of rapid dose escalation subcutaneous methotrexate (sc MTX) in patients with rheumatoid arthritis (RA) with high disease activity in real-world clinical practice.
Methods: The study included 107 RA patients over 18 years old with high disease activity (DAS-28 ≥5.1), who had failed prior oral MTX therapy for at least 6 months or who had not received MTX. MTX therapy was started at a dose of 15 mg/week. During the first month of therapy, the dose of sc MTX was rapidly escalated from 2.5 mg/week once a week to 22.5 mg/week and then, if the response was inadequate, the dose of sc MTX could be increased to 25 mg/week. Tolerability was assessed at each visit (weeks 4, 8, 12, 18, and 24). In cases of poor drug tolerability or the occurrence of adverse events (AEs), the medication was either discontinued or its dose was reduced.
Results: Prior to the initiation of sc MTX, 43.5% of patients were receiving oral MTX at doses ranging from 10 to 20 mg/week (13% - 10 mg/week, 25% - 15 mg/week, 2.2% - 17.5 mg/week, 3.3% - 20 mg/week). Systemic glucocorticoids (GCs) were used by 26.1% of patients at doses not exceeding 10 mg/day (1.1% - 2.5 mg/day; 16.3% - 5.0 mg/day; 1.1% - 7.5 mg/day; 7.6% - 10.0 mg/day); 7.6% of patients required intra-articular GC injections. Patients receiving and not receiving GCs had a similar number of AEs (p>0.05); however, the number of infections was significantly higher in patients on GC therapy (9.5% vs. 0.0%, respectively, p=0.009). With rapid dose escalation sc MTX up to 22.5 mg/week by week 4, nausea appeared in 27.2% of patients and persisted until week 24 of therapy but did not necessitate discontinuation. Vomiting and diarrhea occurred in

2 patients; these symptoms resolved spontaneously by the end of the study. Dyspepsia persisted in 7.6% of patients. 2 patients experienced respiratory tract infections. Anemia and thrombocytopenia were noted in 3 patients at weeks 4 and 12, which resolved spontaneously by week 18. One patient developed a skin rash at week 12. No patient exhibited elevated transaminase levels. There were no serious AEs requiring discontinuation of sc MTX, allowing 92.2% of patients to continue treatment at a dose of 22.5 mg/week by week 24. After 4 weeks, the sc MTX dose was increased to 25 mg/week in 28.3% of patients who did not achieve a 50% improvement according to ACR criteria, provided the drug was well-tolerated. The dose was reduced to 20 mg/week in 6.5% of patients due to gastrointestinal AEs.
Conclusion: The safety profile with rapid dose escalation of sc MTX was acceptable. Early initiation of sc MTX in patients with high disease activity can be considered as the basis for an effective treatment strategy for RA.

P574

THE QUALITY OF LIFE IN PATIENTS WITH RHEUMATOID ARTHRITIS DURING RAPID ESCALATION OF SUBCUTANEOUS METHOTREXATE DOSE

E. Y. Polishchuk[1], V. N. Amirjanova[1], E. L. Nasonov[1]

[1]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia

Objective: To assess the quality of life (QoL) in patients with rheumatoid arthritis (RA) during rapid escalation of the subcutaneous methotrexate (sc MTX) dose in real-world clinical practice.
Methods: The study included 107 RA patients over 18 years of age with high disease activity (DAS-28 ≥5.1), who had failed prior oral MTX therapy for at least 6 months or were MTX-naïve. MTX therapy was initiated at a dose of 15 mg/week. During the first month, the sc MTX dose was rapidly escalated weekly by 2.5 mg/week up to 22.5 mg/week and, in case of an inadequate response, could be further increased to 25 mg/week. QoL was assessed using the EQ-5D (European Quality of Life Questionnaire 5 Dimensions) questionnaire. Anxiety and depression levels were evaluated using the HADS (Hospital Anxiety and Depression Scale), and pain and fatigue levels were measured on a visual analog scale (VAS) from 0 to 100 mm. Assessments were performed at 4, 12, and 24 weeks of the study.
Results: At baseline, patients had low QoL (mean EQ-5D index 0.34±0.29), pronounced joint pain (65.5±13.0 mm on VAS), and fatigue (56.1±20.6 mm on VAS). The mean HADS anxiety score was 7.5±3.1, and the depression score was 7.8±3.8. Following rapid dose escalation of sc MTX, the EQ-5D QoL index improved rapidly to 0.54±0.20 at 4 weeks, 0.64±0.17 at 12 weeks, and 0.78±0.23 at 24 weeks ($p < 0.001$), driven by reduced difficulties in walking and self-care, improvements in usual daily activities, decreased pain, and reduced anxiety and depression symptoms. QoL levels close to average values (EQ-5D index ≥0.52) were recorded in 88.8%, 94.4%, 95.3%, and 97.2% of patients at 4, 12, and 24 weeks, respectively. Population-level QoL (EQ-5D =1.0) was achieved by 45% of patients by week 24. Pain levels decreased to 46.8±15.3 mm within the first month and continued to decline to 35.2±12.4 mm at 12 weeks and 20.5±9.7 mm at 24 weeks. Positive dynamics in fatigue were also noted: 40.2±16.8 mm at 4 weeks, 28.9±12.2 mm at 12 weeks, and 18.1±7.1 mm at 24 weeks. Anxiety levels decreased to 5.1±2.3 at 4 weeks, 3.5±1.5 at 12 weeks, and 2.4±1.1 at 24 weeks. Depression scores also showed a steady decline to 5.8±3.2, 4.1±2.8, and 2.5±1.3 points on the HADS scale, respectively.
Conclusion: Following rapid escalation of the sc MTX dose, patients' QoL according to the EQ-5D index improved rapidly from very low (mean 0.34) to satisfactory (0.78, population norm =1.0). This improvement was due to reduced difficulties in walking and self-care, enhanced performance of usual daily activities, and decreased pain, fatigue, anxiety, and depression symptoms.

P575

COMPARISON OF FOOT ALIGNMENT AFTER TOTAL ANKLE ARTHROPLASTY AND ANKLE ARTHRODESIS : INTERMEDIATE-TERM OUTCOMES

E. Yeo[1], J. Park[1]

[1]Veterans Health Service Medical Center, Seoul, South Korea

Background: After ankle arthrodesis(AA), it is increased range of motion in adjacent joints. In this study we sought to comparison of foot alignment after total ankle arthroplasty(TAA) and ankle arthdrodesis(AA).
Methods: The study included 74 patients of TAA(30 patients) and AA(44 patients) performed between June 2010 and March 2016. We assessed clinical outcomes with the American Orthopaedic Foot and Ankle Society(AOFAS)hindfoot score and visual analog scale(VAS), and foot alignment with tibial anterior surface angle(TAS), talar tilt angle(TT), hindfoot alignment angle(HAA), calcaneal pitch angle(CPA), meary;s angle(MA) at preoperative and last follow up.
Results: Both TAA and AA groups, clinical outcomes significantly improved. In the TAA, TT and HAA significantly declined(p=0.00, p=0.00 respectively) ,but TAS and CPA, MA did not differ significantly(p=0,072, p=0.42, p=0.45 respectively). In the AA, TT and HAA, MA significantly declined (p=0.00, p=0.00,p=0.00 respectively), but TAS and CPA did not differ significantly(p=0,36, p=0.76 respectively). In comparison of TAA and AA, TT, HAA, MA was statistically significant (p=0.00, p= 0.008, p=0.00 respectively)
Conclusions: Both TAA and AA groups were improved pain scores and functional outcomes. We were able to detect statistically significant differences in TT and HAA, MA in comparison of TAA and AA. MA showed significant changes only in the AA. We suspect that changes of MA are responsible for the higher rates of talonavicular arthritis.

P576

ASSOCIATION BETWEEN CUSHING'S SYNDROME AND HYPEROSTOSIS FRONTALIS INTERNA WITH INCREASED CRANIAL BONE THICKNESS

E. Yivli[1], O. Topaloğlu[1], T. Bayraktaroğlu[1]

[1]Zonguldak Bülent Ecevit University, Zonguldak, Türkiye

Objective(s):
To investigate the prevalence of hyperostosis frontalis interna (HFI) and its association with cranial bone thickness in patients with endogenous Cushing syndrome.

Material and Methods:
This retrospective cross-sectional study included adult patients with endogenous Cushing syndrome followed at a tertiary endocrinology

center between January 2010 and December 2025 who had available cranial magnetic resonance imaging. Patients were classified according to the presence of HFI on cranial MRI. Frontal, parietal, and occipital bone thicknesses were measured on T1-weighted axial images. Clinical characteristics and biochemical parameters were compared between HFI-positive and HFI-negative groups.

Results:
Among 26 patients with Cushing syndrome, HFI was identified in 9 patients, corresponding to a prevalence of 34.6%. No significant differences were observed between HFI-positive and HFI-negative groups regarding age, disease duration, cortisol, insulin-like growth factor-1, prolactin, fasting plasma glucose, or HbA1c levels. Frontal bone thickness was significantly greater in HFI-positive patients ($p < 0.001$). Parietal and occipital bone thicknesses were also significantly increased in the HFI-positive group ($p = 0.002$ and $p = 0.013$, respectively). Sex distribution, presence of diabetes or hypothyroidism, Cushing etiology, and menopause or Cushing-related hypogonadism did not differ between groups.

Conclusion(s):
Despite the well-known catabolic effects of chronic hypercortisolism on bone, this study demonstrates that HFI is highly prevalent in patients with Cushing syndrome and is accompanied by increased cranial bone thickness. The overlap between the endocrine and metabolic disturbances associated with Cushing syndrome including hypogonadism, androgen suppression, relative estrogenic activity, central obesity, and hyperleptinemia and the hormonal and vascular mechanisms implicated in the pathogenesis of hyperostosis frontalis interna suggests that Cushing syndrome may constitute a distinct biological risk milieu favoring selective cranial bone remodeling. These findings indicate that bone involvement in Cushing syndrome is not limited to systemic osteoporosis but may also include regional osteogenic responses in cranial bones.

P577

LIVING LABS AS INNOVATIVE PLATFORMS FOR FUNCTIONAL ASSESSMENT AND FALL PREVENTION IN OSTEOPOROSIS AND SARCOPENIA CARE

E. Zigoura[1], W. Morganti[1], E. Seminerio[1], M. Vigo[1], G. Bodo[2], A. Piccardo[2], M. Laffranchi[2]

[1]E.O. Galliera Hospital, Genoa, Italy; [2]Italian Institute of Technology, Genoa, Italy

Background
Living Labs, integrating digital technologies into real-world clinical environments, offer a novel opportunity for ecological, continuous, and objective functional assessment embedded in routine care. Traditional fall risk assessment relies largely on episodic clinical evaluations, which may fail to capture real-life functional performance and early functional decline.
Objective
To evaluate, within the framework of the RAISE project (Robotics and AI for Socio-Economic Empowerment), the role of an intra-hospital Living Lab equipped with non-invasive sensor technologies as a functional laboratory for fall risk assessment and prevention in geriatric patients with osteoporosis and sarcopenia.
Materials and Methods
An integrated non-invasive sensor network was implemented within a hospital-based Living Lab, including sensing textiles embedded in beds and chairs, a sensorised floor, and AI-enabled cameras.
Participants aged ≥65 years referred to the outpatient clinic of our department underwent a multidimensional functional assessment, including sarcopenia screening (SARC-F, bioimpedance analysis, handgrip strength).
Functional parameters such as gait speed, sit-to-stand transitions, spatial trajectories, and sedentary behaviour were continuously collected and compared with standard clinician-based evaluations.
Results
The Living Lab system proved to be reliable, secure, and well accepted by users. Preliminary data showed a high concordance (>80%) between technology-based functional measures and clinician-based assessments. Mobility-related parameters, particularly walking speed and time spent in sedentary positions, emerged as the most discriminative features in identifying subjects at higher functional vulnerability, consistent with known predictors of falls and fractures.
Conclusion
By enabling ecological, continuous, and objective functional evaluation, living labs offer a promising tool to enhance personalised interventions, support real-world evidence generation, and ultimately reduce fall-related fractures in routine care settings.

P578

SARCOPENIA IN TRANSFUSION-DEPENDENT THALASSEMIA: EVIDENCE OF ACCELERATED MUSCULOSKELETAL AGING

E. Zigoura[1], W. Morganti[1], E. Seminerio[1], M. Vigo[1], A. R. Floris[1], E. Balocco[1]

[1]E.O. Galliera Hospital, Genoa, Italy

Objective
Sarcopenia is a complex deterioration of muscle mass and function, typically associated with aging. However, its prevalence in younger populations, particularly those with chronic diseases, remains poorly documented. The effect of iron overload on osteoporosis is well-documented, and ferroptosis can impact muscle deleteriously. Thus, individuals with Transfusion-Dependent Thalassemia (TDT) may be at increased risk.
The aim is to assess the prevalence of sarcopenia in TDT patients referring to the Galliera Hospital in Genoa (Italy).
Material and Methods
This retrospective observational study included patients with major/intermediate β-thalassemia. Demographic data and nutritional status (Mini-Nutritional Assessment, MNA) were collected. Participants underwent DEXA to measure femoral neck and lumbar spine (L1–L4) bone mineral density (BMD), and muscle mass with the Relative Skeletal Muscle Index (RSMI). Muscle strength was assessed with Hand Grip (HG). Dynapenia was defined as HG <16 kg in females and <27 kg in males; sarcopenia as RSMI <5.5 kg/m² in females and <7 kg/m² in males. Osteoporosis was classified by a BMD T-score <−2.5.
Results
The sample included 87 participants (mean age 46.5±12.72; 35.6% males). While age did not differ between genders, significant differences were found in HG (F:13.2±2.85 Vs. M:21.9±8.7; p<.001), RSMI (F:5.77±0.95 Vs. M:6.89±0.99; p<.001), and MNA scores (F:25.1±2.9 Vs. M:26.6±2.7; p=0.028). Dynapenia was found in 65/87 patients (74.7%), and sarcopenia in 30/87 (34.5%). Osteoporosis was identified in 49/87

patients (56.3%) based on either femoral neck or lumbar spine BMD. Eighteen patients (20.7%) had both sarcopenia and osteoporosis.

Conclusions

These findings indicate that patients with thalassemia represent a population at increased risk for early-onset muscle and bone impairment. The presence of sarcopenia and osteoporosis at substantially younger ages than expected in the general population suggests an accelerated aging process in individuals with TDT.

P579

PREGNANCY- AND LACTATION-ASSOCIATED OSTEOPOROSIS WITH VERTEBRAL HEIGHT LOSS/FRAGILITY FRACTURES TREATED WITH TERIPARATIDE: TWO CASES

E. Çetin Duru[1], G. Yaşa Öztürk[1], F. B. Koçyiğit[1]

[1]Adana City Training and Research Hospital, University of Health Sciences, ADANA , Türkiye

Background: Pregnancy- and lactation-associated osteoporosis (PLO) is an uncommon cause of severe skeletal fragility in otherwise healthy young women, typically presenting in late pregnancy or early postpartum with disabling back pain and, frequently, multiple vertebral fragility fractures. Although physiological bone loss during lactation is usually transient and reversible, a small subset of women develop clinically significant osteoporosis and fractures, most often involving the thoracolumbar spine. Proposed susceptibility factors include low pre-pregnancy bone mass, low body mass index, family history of osteoporosis, and other unrecognized contributors. Given the rarity of PLO and the limited evidence base, diagnosis relies on careful exclusion of secondary causes and confirmation with imaging and DXA. Therapeutic strategies are individualized, and anabolic therapy has been increasingly reported in severe vertebral fracture presentations.

Objective: To describe the clinical presentation, imaging findings, and bone mineral density profile of two postpartum women with PLO-related vertebral fractures treated with teriparatide.

Materials and Methods: Two postpartum women who presented to the Physical Medicine and Rehabilitation outpatient clinic with acute back pain and were diagnosed with PLO were evaluated. Demographic and clinical characteristics, neurological examination findings, and laboratory tests assessing calcium–phosphate metabolism and potential secondary causes of osteoporosis were reviewed. Spine MRI was assessed to document vertebral levels with height loss and associated imaging features, and DXA was used to measure bone mineral density at the lumbar spine (L1–L4) and left hip (femoral neck and total hip). Both patients received individualized treatment plans including initiation of teriparatide and supplementation with calcium and vitamin D. A thoracolumbosacral orthosis with steel stays was recommended for stabilization, and medical therapy for pain palliation was prescribed. Follow-up was recorded; repeat DXA at 6 months was available for Case 1, while Case 2 remained under ongoing treatment.

Case 1: A 28-year-old primiparous woman (height 165 cm, weight 50 kg; BMI 18.4 kg/m²) presented 3 months postpartum after 12 weeks of lactation with acute thoracolumbar pain and reported height loss. There was no neurological deficit. MRI of the thoracic spine demonstrated acute compression fractures at T10–T11 with mild central height loss and associated bone marrow edema. Lumbar MRI revealed mild height loss at the inferior endplate of L2 and the superior endplates of L4 and L5. She had low BMI and a maternal history of osteoporosis; there was no smoking, alcohol use, secondary medication exposure, or known endocrine disease. Laboratory evaluation showed 25(OH)D 40.2 ng/mL, calcium 9.8 mg/dL, phosphate 3.1 mg/dL, PTH 44 pg/mL, ALP 112 U/L, creatinine 0.6 mg/dL, ESR 2 mm/h, and CRP 1.5 mg/L. Baseline DXA demonstrated severe lumbar osteoporosis (L1–L4 T/Z −4.0/−4.2) with less severe hip involvement (femoral neck T/Z −2.2/−2.2; total hip T/Z −1.9/−2.0). After 6 months of teriparatide, lumbar spine T/Z improved to −3.0/−3.0; femoral neck remained stable (T/Z −2.2/−2.0), and total hip was similar (T/Z −2.0/−1.9).

Case 2:

A 29-year-old primiparous woman (height 152 cm, weight 53 kg; BMI 22.9 kg/m²) developed back pain one month postpartum and breastfed for 6 months. No neurological deficit was present. MRI reported mild concave vertebral height loss at T12, L4, and L5. She had no family history of osteoporosis and no smoking, alcohol use, secondary medication exposure, or known endocrine disease. Laboratory tests were not suggestive of secondary osteoporosis or systemic inflammation (ESR 5 mm/h, CRP 1.7 mg/L, calcium 9.7 mg/dL, phosphate 4.01 mg/dL, 25[OH]D 49.2 ng/mL, PTH 40 pg/mL, ALP 108 U/L, TSH 3.5 mIU/L, Hb 12.2 g/dL, WBC 5.58×10⁹/L). Baseline DXA demonstrated severe lumbar osteoporosis (L1–L4 T/Z −4.1/−3.8) and osteopenic hip measurements (femoral neck T/Z −2.4/−2.1; total hip T/Z −1.9/−1.6). Teriparatide with calcium and vitamin D supplementation was initiated, and follow-up is ongoing.

Table 1. Clinical characteristics and DXA findings

Variable	Case 1	Case 2
Age (years)	28	29
Height / weight	165 cm / 50 kg	152 cm / 53 kg
BMI (kg/m²)	18.4	22.9
Parity	G1P1	G1P1
Postpartum timing at presentation	3 months	1 month
Lactation duration	12 weeks	6 months
Neurological deficit	No	No
Main MRI levels with height loss	T10–T11 (acute, edema); L2, L4–L5	T12, L4–L5
DXA baseline L1–L4 (T / Z)	−4.0 / −4.2	−4.1 / −3.8
DXA baseline femoral neck (T / Z)	−2.2 / −2.2	−2.4 / −2.1
DXA baseline total hip (T / Z)	−1.9 / −2.0	−1.9 / −1.6
DXA at 6 months (T / Z)	L1–L4: −3.0 / −3.0; neck: −2.2 / −2.0; total: −2.0 / −1.9	Ongoing

Discussion

Both patients presented in the early postpartum period with significant back pain and radiological vertebral height loss, accompanied by markedly reduced lumbar spine BMD (baseline L1–L4 T-scores around −4), while hip involvement was comparatively less severe. This pattern aligns with published cohorts in which PLO most commonly affects the trabecular-rich spine and manifests with thoracolumbar vertebral fractures and height loss. In Case 1, low BMI and a maternal history of osteoporosis may have represented predisposing factors, whereas Case 2 illustrates that severe lumbar osteoporosis can occur even without

an obvious risk profile, consistent with reports that many women have no clear secondary cause at presentation. A structured evaluation to exclude secondary osteoporosis is essential and was supported by largely unremarkable calcium–phosphate and endocrine markers in both cases. Management in PLO is not standardized; however, conservative measures (pain control, bracing, and calcium/vitamin D supplementation) are widely used, and recent systematic evidence suggests that active pharmacologic intervention may be considered in severe cases. Notably, Case 1 demonstrated a substantial lumbar spine improvement after 6 months of teriparatide (T/Z from −4.0/−4.2 to −3.0/−3.0), consistent with published case-based evidence and pooled analyses indicating meaningful spine BMD gains with anabolic therapy.

Conclusion: Pregnancy- and lactation-associated osteoporosis should be considered in the differential diagnosis of severe postpartum back pain, particularly when accompanied by height loss or imaging abnormalities. Early recognition with MRI and DXA, exclusion of secondary osteoporosis, and timely supportive management are critical. In severe presentations, anabolic therapy such as teriparatide may be a reasonable option; in our series, lumbar spine BMD improved after 6 months in one patient, while treatment and follow-up remain ongoing in the second case.

Disclosures: The authors declare no conflicts of interest.

EARLY DETECTION OF SKELETAL FRAGILITY IN BREAST CANCER PATIENTS WITH RADIOFREQUENCY ECHOGRAPHIC MULTI SPECTROMETRY (REMS)

F. A. Lombardi[1], F. R. Contaldo[2], F. Conversano[1], G. Del Vecchio[2], R. Forcignanò[3], R. Franchini[1], M. Muratore[4], G. Peluso[5], P. Pisani[1], S. Casciaro[1]

FRC, FC, GDV, RF, RF, MM, GP and PP equal contributors in alphabetic order.

Objective(s): Patients with cancer are particularly prone to skeletal deterioration and fragility fractures as a result of the disease itself and/or its treatment. Alterations in sex hormone levels, including testosterone and oestradiol which are key regulators of bone metabolism, play a central role in hormone-dependent cancers, such as breast cancer, contributing to bone loss and structural deterioration. This condition may be further exacerbated by aromatase inhibitors, including letrozole, which are generally associated to a significant decrease in bone mineral density (BMD).

Therefore, the present study aimed to evaluate the impact of letrozole therapy on fracture risk in breast cancer patients using Radiofrequency Echographic Multi-Spectrometry (REMS) technology.

Materials and Methods: Caucasian women with a diagnosis of breast cancer underwent REMS scans of lumbar spine (L1-L4). The technology integrates quantitative indicators of bone mass, namely BMD, T-score and Z-score, with a quantitative parameter of bone quality expressed by the Fragility Score (FS), to automatically classify patients into one of the seven risk classes (R1–R7), along with a corresponding probability to experience a short-term (within 5 years) major osteoporotic fracture.

Results: A total of 42 women were enrolled and included in the study with the following anthropometric characteristics: mean age = 63.78 ± 7.79 years and mean BMI = 27.94 ± 4.18 kg/m². The densitometric examinations showed reduced bone density (mean T-score -1.9 ± 0.8) and microarchitecture deterioration (mean FS = 55.34 ± 3.03). The fracture risk analysis classified patients in high-risk classes. Notably, 40% of patients treated with letrozole were classified in the highest risk classes (R5-R7).

Conclusion(s): Overall, the findings of this study highlight the significant skeletal fragility experienced by women affected by breast cancer. REMS has been shown to be a reliable, non-invasive technique for the early detection of fracture risk, providing a valuable alternative to conventional assessment methods. Therefore, REMS could be an important tool in managing osteoporosis in oncology patients, helping to reduce skeletal complications and preserve quality of life.

INTEGRATED REMS AND MICRORNA-BASED EVALUATION OF MUSCULOSKELETAL IMPAIRMENT IN TYPE 2 DIABETES MELLITUS (T2DM)

F. A. Lombardi[1], C. Stomaci[2], P. Pisani[1], A. C. Ştețco[2], A. Barca[3], F. Conversano[1], E. Casciaro[1], F. R. Contaldo[2], R. Franchini[1], L. Antelmi[4], T. Verri[2], S. Casciaro[1]

[1]Institute of Clinical Physiology, National Research Council, Lecce, Italy; [2]Department of Biological and Environmental Sciences and Technologies, University of Salento, Lecce, Italy; [3]Department of Experimental Medicine, University of Salento, Lecce, Italy; [4]Department of Research and Development, Echolight S.p.a., Lecce, Italy

Objective(s): Type 2 diabetes mellitus (T2DM) is frequently associated with an increased risk of fragility fractures despite patients showing normal bone mineral density (BMD), a condition known as "diabetic bone paradox". This phenomenon is driven by bone alterations related to chronic hyperglycaemia, advanced glycation end products (AGEs) and impaired collagen-cross linking and it is often accompanied by muscle conditions such as sarcopenia. The aim of this study was to explore the relationship between T2DM and locomotory system using Radiofrequency Echographic Multi Spectrometry (REMS) technology integrated to an *in silico* analysis of circulating microRNAs (miRNAs).

Materials and Methods: Individuals with (patient group) or without (healthy control group) T2DM condition were enrolled. Bone health status was evaluated by REMS-derived T-score and Fragility Score (FS) at both lumbar spine and femoral neck, whereas muscle health status was evaluated by REMS muscle quality index (MQI) at forearm and thigh. In parallel, an *in silico* analysis was performed using the HMDD v4.0, InteractiVenn, miRDB, WebGestalt and STRING databases to identify common miRNAs between T2DM, sarcopenia and osteoporosis, along with their target genes and hub proteins.

Results: The study included 48 subjects (24 per group), aged 60–80 years and with a BMI of 21–33 kg/m². MQI values were significantly higher in T2DM patients than in the control group at both thigh (84.13 ± 12.27 *vs*. 67.35 ± 17.60; $p < 0.0001$) and forearm (59.84 ± 9.71 *vs*. 36.22 ± 3.57; $p < 0.0001$). Bone assessment showed REMS-derived T-scores = −1.6 ± 0.64 and −1.6 ± 0.58, with reduced FS values (54.2 ± 14 and 49.3 ± 12) at lumbar spine and femoral neck, indicating increased skeletal fragility. Bioinformatic analysis identified 6 common miRNAs associated to T2DM, sarcopenia, and osteoporosis, targeting genes mainly involved in collagen organisation, bone remodelling, and muscle metabolism.

Conclusion(s): Patients with T2DM show concomitant impairment of bone quality and muscle status that cannot be fully captured by BMD alone. Integrating REMS-derived musculoskeletal assessment with miRNA bioinformatic analysis is a promising, non-invasive strategy for early detection of T2DM-related musculoskeletal deterioration and improved fracture risk stratification.

P582

REMS-BASED EVALUATION OF FRACTURE RISK IN KIDNEY TRANSPLANT RECIPIENTS

A. Mordocco[1], F. R. Contaldo[2], G. Del Vecchio[2], G. Peluso[3], F. A. Lombardi[4], C. Stomaci[2]

[1]"Santa Barbara" Hospital, Rogliano, Cosenza, Italy; [2]Department of Biological and Environmental Sciences and Technologies, University of Salento, Lecce, Italy; [3]Department of Innovative Enginnering, University of Salento, Lecce, Italy; [4]Institute of Clinical Physiology, National Research Council, Lecce, Italy

FRC, GDV, GP, FAL and CS equal contributors in alphabetic order

Objective(s): Kidney transplantation is an invasive procedure often associated with long-term musculoskeletal complications, including reduced bone mineral density (BMD) and altered trabecular microarchitecture, resulting in an increased fracture risk. Immunosuppressive therapy and disruption of the parathyroid hormone–vitamin D–FGF23 axis further contribute to bone damage. This study aimed to evaluate short-term fracture risk in kidney transplant recipients using Radiofrequency Echographic Multi Spectrometry (REMS).

Materials and Methods: Inclusion criteria were as follows: men and women who had previously undergone a kidney transplant. All participants underwent REMS evaluation of the lumbar spine (L1–L4). This ultrasound-based technique analyses native radiofrequency signals by comparing them with a reference database, allowing the assessment of bone quantity (BMD, T-score, Z-score) and bone quality through the Fragility Score (FS), an index that indicating microarchitectural deterioration and skeletal fragility. By integrating REMS T-score and REMS FS, patients were automatically classified into one of the seven risk classes (R1–R7) along with a probability to experience a short-term(within 5 years) major osteoporotic fracture.

Results: At the end of the enrolment, *n* = 50 individuals were included in the analysis (mean age = 55–85 years and mean BMI = 18–26 kg/m²). The analysis of the short-term fracture risk revealed that all the participants were categorised into high-risk classes, and predominantly within R5 and R6. The corresponding estimated five-year probability of major osteoporotic fractures was found to range from 3.5% to 6% in R5, increasing to 6% - 10% in R6.

Conclusion(s): These findings demonstrate that kidney transplant recipients are at substantial risk of fragility fractures, emphasising the importance of regular bone health monitoring. REMS is a valuable non-invasive approach for evaluating bone density and microarchitecture. These findings support the implementation of early, individualised preventive strategies to reduce fracture occurrence and improve long-term patient management.

BONE PROFILE IN PATIENTS AFTER LIVER TRANSPLANTATION: A CROSS-SECTIONAL ANALYSIS

F. Alam[1], O. Alsaed[1], I. Abdulmomen[1], N. Abdulla[1], A. Lutf[1], S. Al Emadi[1]

[1]Hamad General Hospital, Doha, Qatar

Background:
Osteoporosis is a well-recognized complication in patients following liver transplantation (LT). Data on bone health in post-LT populations from the Middle East remain limited.

Objectives:
To determine the prevalence of osteoporosis and fragility fractures and to assess bone mineral density (BMD) and trabecular bone score (TBS) in patients after liver transplantation.

Methods:
This cross-sectional study included 80 post-liver transplant patients. Demographic data, etiology of liver disease, comorbidities, and fracture history were collected. Bone mineral density (BMD) was assessed using dual-energy X-ray absorptiometry (DXA), and trabecular bone score (TBS) was evaluated where available. Osteoporosis and osteopenia were defined according to World Health Organization criteria.

Results:
The mean age was 57.3 ± 13.5 years, with 58.8% males. Qatari nationals comprised 38.8% of the cohort. The most common cause of chronic liver disease leading to LT was hepatitis C virus infection (43.8%), followed by cryptogenic cirrhosis (12.5%), alcohol-related liver disease (11.3%), non-alcoholic steatohepatitis (10%), hepatitis B virus infection (8.8%) and autoimmune hepatitis (8.8%).
DXA data were available for 74 patients. Osteoporosis was present in 37.8%, osteopenia in 36.5%, and normal BMD in 25.7%. TBS assessment (n = 32) showed degraded or partially degraded bone microarchitecture in 37.6%, while 62.5% had normal TBS.
Fragility fractures were documented in 13.8% of patients, with vertebral fractures being the most frequent (45.5%), followed by proximal humerus (45.5%), distal radius (27.3%), distal fibula (9.1%). Multiple fractures were observed in 3.8% of patients. Osteoporosis and osteopenia was observed in 63.6% and 27.3% of patients with fragility fracture. Common comorbidities included diabetes mellitus (61.3%), chronic kidney disease (33.8%).

Conclusion:
Bone disease is highly prevalent among post-liver transplant patients, with a substantial burden of osteoporosis, impaired bone microarchitecture, and fragility fractures. These findings highlight the importance of routine bone health assessment and early intervention strategies in the post-transplant population to reduce fracture risk and improve long-term outcomes.

P584

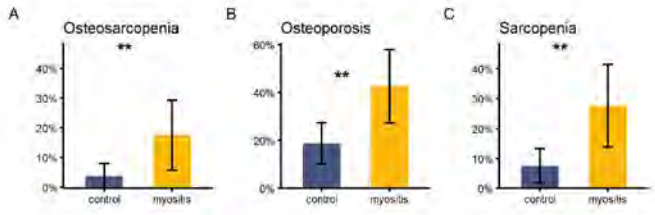
OSTEOSARCOPENIA AND MUSCULOSKELETAL PHENOTYPES IN DIFFERENT IDIOPATHIC INFLAMMATORY MYOPATHIES: A CROSS-SECTIONAL DXA STUDY

F. Aldegheri[1], A. Fassio[1], R. Bixio[1], M. Appoloni[1], G. Adami[1], D. Gatti[1], M. Rossini[1], O. Viapiana[1], G. Orsolini[1]

[1]Rheumatology Unit, Department of Medicine, University of Verona, Verona, Italy

Objectives

To assess osteosarcopenia prevalence in IIM and characterize dual-energy X-ray absorptiometry (DXA)-derived musculoskeletal phenotypes.



Material and Methods

Patients fulfilling the 2017 EULAR/ACR criteria for IIM were compared with age- and sex-matched controls (1:2). DXA assessed body composition and bone mineral density. Sarcopenia and osteoporosis were defined by EWGSOP2 and WHO criteria, and osteosarcopenia as their coexistence. Lower limb lean mass percentage was calculated as a ratio of lower limb lean to total lower limb mass. Univariable logistic regression analyses were used to screen predictors of osteosarcopenia, followed by multivariable models adjusted for age and sex.

Results

Forty patients with IIM (median age 61 years, 75% female) and 80 matched controls were included. Osteosarcopenia was more prevalent in IIM than in controls (17.5% vs 3.7%, p=0.026). Osteoporosis (42.5% vs 18.8%, p=0.011) and sarcopenia (27.5% vs 7.5%, p=0.007) were also more frequent in the IIM group (**figure 1**).

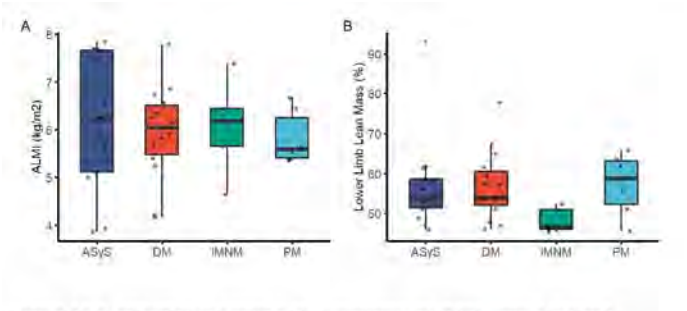


Figure 1. Prevalence of osteosarcopenia (A), osteoporosis (B), and sarcopenia (C) in myositis and controls (%, 95% CI).

Legend: control and myositis groups are shown in blue and yellow bars, respectively. Error bars represent 95% confidence intervals. Asterisk (*) indicates a statistically significant difference between groups (p < 0.05).

Appendicular Lean Mass Index (ALMI) did not differ across subtypes, while immune-mediated necrotizing myopathy showed a numerically lower lower limb lean mass percentage (p = 0.057, **figure 2**).

Figure 2. Prevalence of osteosarcopenia (A), osteoporosis (B), and sarcopenia (C) in myositis and controls (%, 95% CI).

Legend: ASyS, antisynthetase syndrome; DM, dermatomyositis; IMNM, immune-mediated necrotizing myopathy; PM, polymyositis. ALMI was calculated as appendicular lean mass divided by height squared. Lower limb lean mass is expressed as percentage of total lean mass.

In univariable analyses, BMI was associated with osteosarcopenia and remained the only independent predictor in multivariable models (OR 0.50 per kg/m², 95% CI 0.29–0.87). No association was observed for disease duration or cumulative glucocorticoid exposure.

Conclusions

Osteosarcopenia is a frequent condition in IIM, substantially more prevalent than in healthy controls and not explained by disease duration or cumulative glucocorticoid exposure, suggesting a disease-related musculoskeletal phenotype. DXA-derived phenotypes highlight heterogeneity in muscle distribution across IIM subtypes and may support a phenotype-based approach to clinical assessment.

P585

REAL-WORLD REBOUND PATTERN OF SERUM COLLAGEN TYPE I C-TELOPEPTIDE AFTER DENOSUMAB DISCONTINUATION AND ZOLEDRONATE RESCUE IN POSTMENOPAUSAL OSTEOPOROSIS AND CANCER TREATMENT-INDUCED BONE LOSS

F. Aldegheri[1], A. Fassio[1], M. Appoloni[1], R. Denise[1], F. Ruzzon[1], D. Bertelle[1], G. Adami[1], D. Gatti[1], M. Rossini[1], O. Viapiana[1]

[1]Rheumatology Unit, Department of Medicine, University of Verona, Verona, Italy

Background. Denosumab (Dmab) discontinuation induces rebound bone resorption, only partially prevented by zoledronate (ZOL). However, both the continuous temporal pattern of rebound under real-world conditions and the biological determinants of rebound magnitude remain insufficiently characterized.

Methods. We retrospectively studied 65 women discontinuing Dmab who received a single 5-mg ZOL infusion 6 months later (30 postmenopausal osteoporosis (PMO), 35 cancer treatment–induced bone loss (CTIBL). Serial serum CTX measurements (190 observations) from −30 to +360 days relative to ZOL were analyzed using linear mixed-effects models with patient-level random intercepts and natural cubic splines for time, adjusted for age and Dmab duration. Rebound magnitude was defined as the absolute increase in CTX from on-Dmab levels. Linear regression models evaluated the independent associations of prior BMD gain, duration of Dmab exposure, and depth of CTX suppression during Dmab (CTX drop from pre-Dmab to nadir) with rebound magnitude.

Results. CTX exhibited a reproducible non-linear trajectory, with a rapid

rise and peak at 6–9 months after ZOL followed by partial decline by 12 months; spline models substantially outperformed linear specifications (ΔAIC >20). Rebound trajectories were similar between PMO and CTIBL (time×group p>0.3). Rebound magnitude was not associated with BMD gain at any skeletal site (all p>0.12), whereas greater CTX suppression during Dmab and longer Dmab exposure independently predicted higher rebound levels (CTX drop p=0.022). Only one vertebral fracture occurred during follow-up.

Figure 1. s-CTX-I trajectories following Dmab discontinuation and zoledronate infusion: overall cohort (panel A), PMO and CTIBL subgroups (panel B). No significant between group were observed

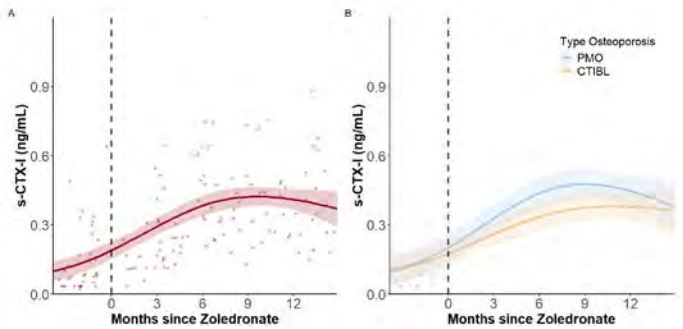

Table 1. Baseline characteristic of the included subjects. Data are expressed as mean (SD).

	All (n= 66)	PMO (n= 30)	CTIBL (n= 36)	p-value
Age (years)	69.09 (9.92)	72.17 (7.56)	66.53 (10.98)	0.0167
BMI (kg/m²)	24.16 (3.56)	24.08 (3.65)	24.22 (3.54)	0.8748
Menopause age (years)	47.56 (5.86)	47.37 (6.94)	47.72 (4.89)	0.8142
eGFR (mL/min)	70.99 (17.44)	67.45 (12.95)	73.93 (20.15)	0.1197
Dmab duration (years)	5.00 (2.35)	6.57 (2.27)	3.69 (1.47)	< 0.001
s-CTX-I under Dmab (ng/mL)	0.12 (0.12)	0.11 (0.13)	0.12 (0.12)	0.7342
T score LS	-1.61 (1.04)	-1.81 (1.07)	-1.41 (1.07)	0.0816
T score FN	-1.60 (0.82)	-1.86 (0.69)	-1.54 (0.89)	0.1010
T score TH	-1.04 (0.88)	-1.23 (0.85)	-0.89 (0.89)	0.1138
BMD LS (g/cm²)	0.84 (0.12)	0.82 (0.12)	0.85 (0.12)	0.1092
BMD FN (g/cm²)	0.65 (0.09)	0.63 (0.08)	0.67 (0.10)	0.1144
BMD TH (g/cm²)	0.85 (0.10)	0.83 (0.10)	0.87 (0.10)	0.0835
% BMD gain during Dmab – LS	17.3 (14.5)	22.5 (15.0)	12.8 (11.7)	0.0097
% BMD gain during Dmab – FN	6.1 (11.2)	9.87 (12.4)	2.87 (8.95)	0.0151
% BMD gain during Dmab – TH	2.7 (8.9)	3.81 (10.0)	1.71 (7.44)	0.3099

Legend: PMO = Postmenopausal Osteoporosis, CTIBL = Cancer Treatment Induced Bone Loss, BMI = Bone Mass Index, eGFR = estimated Glomerular Filtration Rate, Dmab = Denosumab, s-CTX-I = serum C-terminal telopeptide of type I collagen, LS = Lumbar Spine, TH = Total Hip, FN = Femoral Neck

Conclusions. This real-world study provides a dual contribution: it defines the non-linear temporal signature of post-Dmab rebound despite ZOL rescue and demonstrates that rebound magnitude is driven by the depth of prior turnover suppression rather than densitometric response. These findings support turnover-guided, biologically informed strategies for post-Dmab management.

P586

DEVELOPMENT AND EXPERT VALIDATION OF AN INTERNATIONAL POSTMENOPAUSAL OSTEOPOROSIS RISK ASSESSMENT AND LIFESTYLE (IPORL) QUESTIONNAIRE

F. Alradini[1], A. Alblooshi[2]

[1]Department of Family and Community Medicine, College of Medicine, Princess Nourah bint Abdulrahman University, Riyadh, Saudi Arabia; [2]Department of Medical Education, College of medicine and health Sciences, United Arab Emirates (UAE) University, Al Ain, Abu Dhabi, United Arab Emirates

Background: Osteoporosis affects over 200 million women globally, contributing to significant morbidity and socioeconomic burden. Despite the availability of standardized tools such as FRAX and OKAT, few instruments comprehensively assess both biomedical and lifestyle risk factors while remaining adaptable for Postmenopausal women internationally.

Objective: To develop and establish the content validity of an internationally adaptable osteoporosis risk and lifestyle questionnaire for postmenopausal women.

Methods: A 60-item questionnaire was constructed from four validated frameworks: The Menopause Rating Scale (MRS), The Osteoporosis Knowledge Assessment Tool (OKAT), WHO FRAX clinical risk factors, and WHO STEPwise (STEPS) approach. Sociodemographic data were incorporated as the first section of the instrument. Twenty-two multidisciplinary experts in endocrinology, gynecology, family medicine, orthopedics, and public health independently rated each item for relevance, clarity, and necessity on a 4-point scale. The Item-level Content Validity Index (I-CVI) for relevance and modified kappa (k*) were calculated as well as comment burden for each item. Qualitative feedback underwent further content analysis. Decisions to retain, revise, or remove items were based on integrated quantitative and qualitative analysis of experts' recommendations.

Results: Quantitative analysis showed relevance I-CVI values ranging from 0.68–1.00 (S-CVI = 0.92); k* values 0.67–1.00, indicating good to excellent agreement. Comment burdens per item were predominantly low, with 36 items (60%) receiving 0–2 comments, 17 items (28%) receiving 3–5 comments, and only 7 items (12%) receiving six or more comments. Therefore, 32 items retained, 27 revised, and 1 removed. Following further qualitative analysis of the experts' comments, 26 were retained, 32 revised, and 2 removed (household income and menstrual irregularity). Overall, 98% of expert-endorsed items were retained or refined, yielding a 58-item final version.

Conclusion: The International Postmenopausal Osteoporosis Risk assessment and Lifestyle Questionnaire (IPORL-Q) comprising 58 items across five sections 1) Sociodemographic, 2) The Menopause Rating Scale (MRS), 3) Osteoporosis Knowledge Assessment Tool (OKAT), 4) WHO FRAX clinical risk factors, and 5) The WHO STEPwise (STEPS) approach. The IPORL-Q demonstrates excellent content validity, linguistic clarity, and adaptability for global use. It provides a robust foundation for psychometric validation and cross-cultural research in postmenopausal osteoporosis assessment and prevention.

PERSISTENTLY LOW SERUM ALKALINE PHOSPHATASE IN ADULTS: PREVALENCE AND CLINICAL CHARACTERISTICS AT A TERTIARY CARE HOSPITAL

F. Alshahrani[1], S. Alsuliman[2], R. Alkalefah[2], S. Almutairi[2], Y. Aleidi[3], M. Almohaya[4]

[1]King Abdulaziz Medical City, Ministry of National Guard Health Affairs., Riyad, Saudi Arabia; [2]King Saud bin Abdulaziz University for Health Sciences, college of medicine, Riyad, Saudi Arabia; [3]King Saud bin Abdulaziz University for Health Sciences, college of medicine., Riyad, Saudi Arabia; [4]King Fahad Medical City, Riyad, Saudi Arabia

Background: Alkaline phosphatase (ALP) is an essential enzyme in skeletal and mineral metabolism. While elevated ALP levels are routinely investigated, persistently low ALP values are often overlooked, despite their potential link to hypophosphatasia (HPP). This study aimed to assess the prevalence and clinical characteristics of adults with persistently low ALP.

Methods: We conducted a retrospective review of adult patients with serum ALP testing at King Abdulaziz Medical City, Riyadh, from January 2017 to December 2024. Among 243,362 adult patients with 928,403 ALP measurements, individuals with +≥2 low ALP results (<40 IU/L) were identified and secondary causes of low ALP were excluded. Clinical, biochemical, imaging, and family data were analyzed.

Results: 7,307 patients (3.0%) had at least one ALP measurement <40 IU/L. Of these, 179 had ≥2 low ALP results. After excluding 154 patients with secondary causes or incomplete data, 25 patients (0.07%) were identified as having persistently low ALP. The mean age was 52.2 years (range: 18–92), with a female predominance (68%). The mean nadir ALP was 30.2 IU/L, and the mean ALP across all measurements was 34.9 IU/L. Musculoskeletal pain (92%) and fatigue (79%) were the most frequent symptoms, followed by dental abnormalities (50%)., anxiety (33%), and depression (29%). Nearly half of the cohort (46%) reported fractures, predominantly vertebral, hip, and metatarsal. DXA scans (n =10) showed osteopenia or osteoporosis in half of the patients. Subgroup analysis demonstrated significant negative correlations between ALP levels and musculoskeletal symptoms (p = 0.021). Familial clustering was observed in 25% of index patients. Notably, persistently low ALP values were consistently under-recognized in clinical documentation.

Conclusion: Persistently low ALP is uncommon but clinically significant. Most affected patients exhibited symptoms overlapping with HPP, and familial clustering suggests a genetic predisposition. Recognition of this biochemical marker is essential to prevent misdiagnosis and avoid inappropriate therapies such as bisphosphonates. Systematic screening and incorporation of genetic testing and family evaluation may improve early identification of HPP and refine diagnostic algorithms.

Keywords: Alkaline phosphatase, Hypophosphatasia, Rare bone disease, Musculoskeletal pain, Biochemical marker

SUSTAINED INCREASES IN LUMBAR SPINE AND HIP BMD AFTER 10 YEARS OF DENOSUMAB THERAPY

F. Brennan[1], D. Fitzpatrick[1], N. Maher[1], G. Steen[1], D. Mathews[1], R. Lannon[1], C. O'Carroll[1], K. Mccarroll[1], A. Masood[1]

[1]Bone Health Unit, Mercer's Institute for Successful Ageing, St James's Hospital, Dublin, Ireland

Introduction: Denosumab treatment over 10 years results in sustained increases in BMD at the lumbar spine and hip and lower fracture rates. In the FREEDOM trial, this BMD rise was greatest in the earlier years of therapy with the rate of increase declining over time. However, data on efficacy and safety is lacking beyond 10 years. We present the case of female who demonstrated large and continued rises in BMD beyond 10 years of treatment

Case: An 80-year-old woman was referred to our Bone Health Clinic in 2012 for advice regarding osteoporosis diagnosed one year earlier after routine DXA revealed a lumbar spine T-score of -4.2 (0.585 g/cm²) and total hip T-score of -4.0 (0.503 g/cm²). Her GP commenced alendronate 70 mg once weekly. She had no prior fragility fractures and aside from menopause, the only osteoporosis risk factor was previous smoking. Based on her preference, we switched her treatment to denosumab and she was discharged back to her GP.

She continued denosumab over the next decade but in her 10th year of treatment she fell and sustained a left hip fracture. Repeat DXA revealed a T-score of -2.7 (0.754 g/cm²) in lumbar spine and -3.0 (0.572 g/cm²) in total hip and with a suppressed C-telopeptide cross-link type 1 collagen (CTX) of 0.078 ng/ml. Our orthogeriatric service advised her to continue denosumab for another 3 years. Follow up DXA three years later revealed a significant improvement in BMD at lumbar spine and total hip with respective T-scores of -2.1 (0.814 g/cm²) and -2.7 (0.610 g/cm²) representing a BMD increase of 8.0% and 6.6%. Denosumab was continued with a plan for review in two years and advice given that therapy may need to be lifelong.

Discussion: This case illustrates that continued denosumab therapy beyond 10 years can be associated with further clinically significant increases in BMD at both the lumbar spine (8.0%) and total hip (6.6%) over a subsequent 3 years. Most guidelines do not address longer-term use (>10 years) though the Endocrine Society advises it in patients at high risk of fracture. Further increases in BMD may allow some patients to achieve a desirable treatment target though studies on safety and efficacy are needed.

P589

RECURRENT ANTERIOR UVEITIS SECONDARY TO DENOSUMAB

F. Brennan[1], A. Carroll[1], D. Fitzpatrick[1], J. O'Toole[2], M. Kavanagh[1], N. Maher[1], G. Steen[1], N. Fallon[1], R. Lannon[1], K. Mccarroll[1]

[1]Bone Health Unit, Mercer's Institute for Successful Ageing, St James's Hospital, Dublin, Ireland; [2]Mercer's Institute for Successful Ageing, St James's Hospital, Dublin, Ireland

Presentation: Bisphosphonates including zoledronic acid have been associated with the development of uveitis. However, to our knowledge acute uveitis has never been described in association with denosumab therapy. We report on a female who was diagnosed with acute uveitis within hours of receiving her denosumab injection on two separate occasions.

Case report:
A woman in her 50s attending our bone health clinic in 2012 was started on denosumab for the treatment of osteoporosis. Medical history included COPD, hypertension and hereditary optic atrophy. After 5 hours of receiving her second injection of denosumab she developed bilateral painful red eyes. Slit lamp examination demonstrated conjunctival injection and inflammatory cells in the anterior chamber and there was normal intraocular pressure. Fundoscopy revealed no acute changes, and no macular oedema. She was diagnosed with acute uveitis and was treated with steroid antibiotic eye drops for 4 weeks with symptoms and signs fully resolving. Six months later, within 3 hours of her third denosumab injection she developed a painful red eye. Urgent ophthalmology assessment again confirmed a diagnosis of anterior uveitis with symptoms rapidly resolving with steroid drops. Her denosumab was stopped and investigation for idiopathic causes of uveitis including syphilis, sarcoidosis and TB were negative. HLA-B27 was positive, though there were no clinical manifestations of autoimmune disease at any point. Furthermore, on follow up over 13 years there has been no recurrence of uveitis.

Discussion/Conclusion:
To our knowledge, this is the first described case of an association of denosumab therapy with uveitis and meets the Naranjo criteria for probable causation. The occurrence of uveitis within hours of denosumab administration on two occasions combined with the long term absence of recurrence on stopping suggests it may be a precipitating factor. Drug associated anterior uveitis in predisposed patients with HLA B27 positivity is reported as have drug reactions in association with HLA-B27 and other HLA genotypes. This suggests that denosumab may have been a precipitant of uveitis in our patient who had an underlying predisposition due to HLA-B27 positivity.

P590

LARGE INCREASE IN HIP AND SPINE BMD AFTER COMBINATION THERAPY WITH DENOSUMAB AND TERIPARATIDE: REAL WORLD EXPERIENCE

F. Brennan[1], A. Carroll[1], D. Fitzpatrick[1], M. Memon[1], G. Steen[1], N. Fallon[1], C. O'Carroll[1], D. Mathews[1], R. Lannon[1], K. Mccarroll[1]

[1]Bone Health Unit, Mercer's Institute for Successful Ageing, St James's Hospital, Dublin, Ireland

Introduction: Combination therapy with denosumab and teriparatide results in greater gains in bone mineral density (BMD) than either therapy alone. This has been demonstrated in the DATA study and some clinical case series. We report on changes in BMD and bone turnover markers (BTMs) resulting from combination therapy with teriparatide and denosumab in a specialist bone health clinic.
Materials and Methods: We retrospectively identified patients at our osteoporosis clinic who had completed two years of combined teriparatide and denosumab therapy (started concurrently). All patients had densitometric (DXA) measured areal BMD at the hip and lumbar spine within the 12 months before starting and after 24 months of combined therapy. We examined for changes in BTM and BMD due to treatment.
Results: 13 patients were identified and the mean age was 79 years (range 68-89). Mean T score at the lumbar spine was -3.8 and at total hip -2.8. The mean change in BMD at the lumbar spine (excluding 3 patients where it could not be assessed) was 0.103g/cm 2 ($p<0.0001$) representing an 18.0% increase. Of eleven patients where changes in hip BMD were assessed (excluding one interval hip replacement and another hip fracture 5 months after starting treatment), the mean increase was 0.051g/cm 2 ($p=0.002$) representing a 9.3% improvement. After 6 months of treatment there was a decline in mean C-terminal telopeptide (CTx) from 0.247ng/ml at baseline to 0.169 ($P=0.367$) and an increase in Procollagen type 1 N-terminal propeptide (P1NP) from 44.7ng/mL to 54.5 ($P=0.274$), though these differences were not statistically significant.
Conclusion: Combination therapy with teriparatide and denosumab resulted in significant gains in BMD at the spine (18.0%) and hip (9.3%). The lack of significance in bone turnover markers is likely due to the small sample size. While only a small patient sample, this compares more favourably than teriparatide monotherapy in trials. A limitation is that some patients had a DXA up to 12 months prior to starting the combination which may account for a small component of the BMD rise. Results confirm the real-world effectiveness therapy in clinical practice.

P591

ROBOTIC TRANSTHORACIC EXCISION OF MEDIASTINAL PARATHYROID ADENOMA

M. O'Connor[1], A. Compton[2], F. Brennan[2], N. Fallon[2], G. Steen[2], N. Maher[2], C. O'Carroll[2], D. Matthews[2], C. Timon[3], G. Fitzmaurice[4], D. Fitzpatrick[2], R. Lannon[2], K. Mccarroll[2]

[1]Mercer's Institute for Successful Ageing, St James's Hospital, Dublin, Ireland; [2]Bone Health Unit, Mercer's Institute for Successful Ageing, St James's Hospital, Dublin, Ireland; [3]Department of ENT Surgery, St James's Hospital, Dublin, Ireland; [4]Department of Cardiothoracic Surgery, St James's Hospital, Dublin, Ireland

Introduction: Primary hyperparathyroidism results from a parathyroid adenoma in 80% of cases. However, 10-20% of patients have an ectopic gland which can be more difficult to locate on imaging and to remove surgically. We present the case of female with a mediastinal parathyroid adenoma which was surgically resected under robotic assisted thoracoscopy.

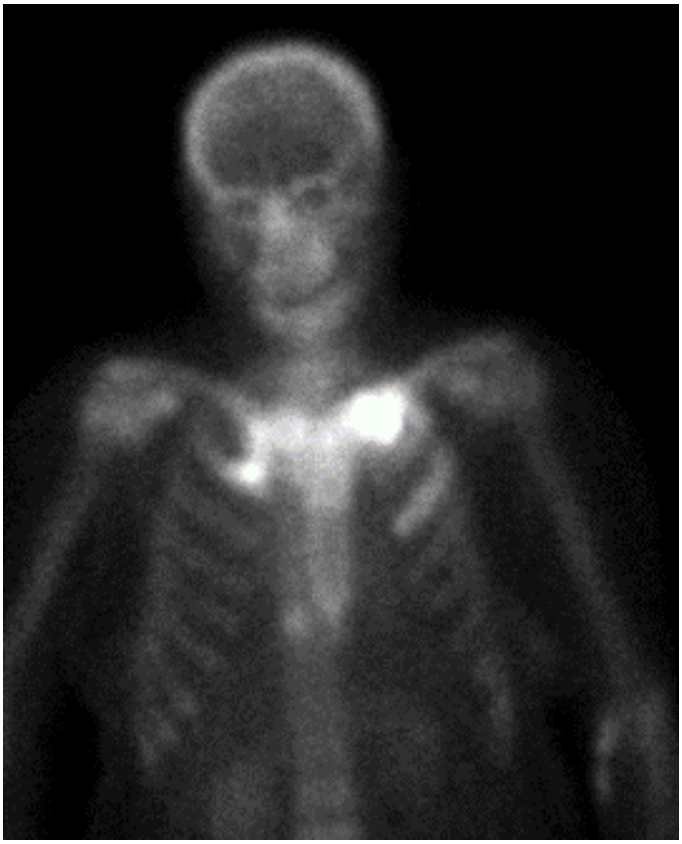
Case Report: A 46-year-old female was referred to our Bone Health Clinic with a diagnosis of osteoporosis on a background of early menopause. Screening blood tests revealed a mild hypercalcaemia (serum calcium 2.51mmol/L) and elevated parathyroid hormone (PTH) of 115.4 pg/mL consistent with primary hyperparathyroidism. A sestamibi scan identified a focus of intense uptake in the superior mediastinum consistent with a retrosternal parathyroid adenoma. Ultrasound also demonstrated a hypoechoic nodule in the left lobe of thyroid suggesting an additional left superior parathyroid adenoma. MRI imaging of neck and thorax revealed only an enhancing 4 mm parathyroid adenoma in the superior mediastinum. Minimally invasive explorative surgery was initially done via a transcervical approach and the left superior parathyroid gland was removed. However, her serum PTH and calcium remained elevated and she was referred to the cardiothoracic surgeons. To re-examine the location of mediastinal adenoma, a multiphase CT and sestamibi scan was done, which identified a sub centimetre nodule anterior to the descending aorta. Under robotic assisted thoracoscopy, no parathyroid adenoma was visualised but a 6mm nodule of mediastinal thymus tissue was removed which corresponded to the location on imaging. This was confirmed histologically as parathyroid tissue within fatty thymus. Her calcium and PTH normalised postoperatively to a respective 2.19 nmol/l and 40 pg/ml and have remained normal.

Discussion: Mediastinal parathyroid adenomas may be difficult to localise intraoperatively highlighting the value of prior imaging with MRI or multiphase CT. When surgical resection is not possible via the transcervical approach, robotic assisted thoracoscopy can be used to remove adenomas, avoiding the morbidity associated with sternotomy or thoracotomy.

P592

SAPHO SYNDROME TREATED WITH ZOLEDRONIC ACID AND ANTI-TNFA (INFLIXIMAB) THERAPY: A CASE REPORT

F. Brennan[1], J. O'Toole[2], A. Compton[1], A. Masood[1], N. Maher[1], G. Steen[1], N. Fallon[1], C. O'Carroll[1], B. Wynne[3], F. O'Shea[4], D. Fitzpatrick[1], R. Lannon[1], K. Mccarroll[1]



[1]Bone Health Unit, Mercer's Institute for Successful Ageing, St James's Hospital, Dublin, Ireland; [2]Mercer's Institute for Successful Ageing, St James's Hospital, Dublin, Ireland; [3]Department of Dermatology, St James's Hospital, Dublin, Ireland; [4]Department of Rheumatology, St James's Hospital, Dublin, Ireland

Introduction: SAPHO syndrome (Synovitis, Acne, Pustulosis, Hyperostosis, Osteitis) describes a spectrum of rare inflammatory osteoarticular and dermatological diseases. Case reports and observational data suggest that anti-TNFα and bisphosphonate treatment improves disease activity and symptoms. We present the case, clinical course and treatment of a female diagnosed with SAPHO syndrome and osteoporosis.

Case: A 55-year-old female presented with a 2-year history of sternal and shoulder pain to her GP. X-ray showed sternoclavicular hyperostosis with subsequent CT demonstrating diffuse sclerotic and lytic changes in the sternum, clavicles and ribs. A routine screening DXA also demonstrated osteoporosis (lowest T score -2.5 lumbar spine) and she was referred to our bone health clinic. Serum alkaline phosphatase (ALP) was mildy elevated at 127 IU/L as was serum Procollagen type 1 N-terminal propeptide (PINP) at 80.1ng/m. Due to potential GI intolerance of oral bisphosphonates, treatment with zoledronic acid was planned and she was further investigated with an isotope bone scan. This showed a classic "bulls head appearance' due to avid uptake in sternum, medial clavicles and first ribs (see below). Serum electrophoresis, viral and connective tissue disease screen were all unremarkable. Several months later she developed a pustular skin rash and diffuse polyarthralgia associated with raised inflammatory markers and normal rheumatoid factor, anti CCP and HLAB27. After review by rheumatology, and dermatology SAPHO syndrome was considered the likely diagnosis and she was started on infliximab with a view to longer term adalimumab. After reassessment by our bone health service, she promptly received zoledronic acid (5mg). Six months later, her bone formation marker (PINP) decreased to 38.6 pg/ml and ALP to 95 IU/L . By 18 months, she had near complete resolution of her clinical symptoms.

Discussion: This case demonstrates the challenges in diagnosing SAPHO syndrome given its rarity. Currently, there are no randomised trials as regards treatment though improvement in disease activity and symptoms is described with infliximab as we found in our patient. Bisphosphonates including zoledronic acid have also been associated with improvement in pain, bone marrow odoema and osteoarticular function. The decline in PINP supports the recent suggestion that bisphosphonates may be a necessary 'bone remodelling therapy' in this syndrome.

The image (below) of the classic "bull's head" pattern seen on isotope bone imaging in SAPHO syndrome.

PUSH TOOL: MAINTAINING FUNCTIONAL CAPACITY AND WELL-BEING IN NURSING HOME RESIDENTS

F. Buckinx[1], H. Benabdallah[2], A.-G. Brassard[3], M.-O. Dugas[4], M.-J. Kergoat[5], E. Duchesne[3], M. Aubertin-Leheudre[5]

[1]Research Unit in public health, epidemiology and health economics, University of Liège, Liège, Belgium; [2]Faculté de Médecine, département de médecine, Université de Montréal, Montréal, Canada; [3]Faculté de Médecine, département de réadaptation, Université Laval, Laval, Canada; [4]Groupe de recherche interdisciplinaire sur les maladies neuromusculaires (GRIMN), CIUSSS-SLSJ, Saguenay, Saguenay, Canada; [5]Centre de Recherche de l'Institut universitaire de gériatrie de Montréal, Montréal, Canada

Background: Physical activity benefits frail older adults in nursing homes, yet numerous barriers hinder the safe and effective prescription of exercise. To address these challenges, the PUSH tool (Promoting aUtonomy through exerciSe in nursing Home) was developed, facilitating the prescription of tailored, autonomous exercise programs. This pilot interventional study evaluated the impact of the PUSH tool over six months on functional capacities, well-being, and usability in nursing home residents.

Methods: The study was conducted in two nursing homes in the province of Québec, Canada (Saguenay and Montréal). Residents were assigned to a control group receiving usual care (n=12) or an intervention group receiving usual care plus PUSH (≥2 sessions/week, n=15). The PUSH tool uses a decision tree based on validated physical tests to assess muscle strength, balance, and endurance in ambulatory and wheelchair-bound residents, and provides individualized strength, balance, and walking or wheelchair-propulsion exercises. Assessments were conducted at baseline and after six months, including lower-limb strength (30-second sit-to-stand [30s-STS]), functional performance (Short Physical Performance Battery [SPPB] and handgrip strength [HS]), mobility (Timed Up and Go [TUG], 5-times sit-to-stand [5×STS], and gait speed), balance (Berg Balance Scale [BBS]), perceived health, well-being, and usability (System Usability Scale [SUS]) of the PUSH tool.

Results: The 30s-STS, gait speed, and SPPB scores were maintained in the PUSH group at six months, whereas the control group showed a significant deterioration ($p<0.05$); between-group differences were not statistically significant, except for the 30s-STS and SPPB scores. Both groups declined in TUG and 5×STS, but deterioration was 2–3 times greater in the control group. Participants in the intervention group reported improvements in perceived health and overall well-being. The SUS score of the PUSH tool was rated 74% by residents and 88% by healthcare professionals.

Conclusion: The PUSH tool is feasible, easy to use, and well accepted by both staff and residents. While physical performance decline was largely mitigated rather than reversed, the program improved residents' perceived health and well-being, supporting its potential to promote autonomy in long-term care settings.

P594

FALLS AMONG COMMUNITY-DWELLING OLDER ADULTS: PREVALENCE, CIRCUMSTANCES, RISK PROFILES, AND IMPLICATIONS FOR PREVENTION

F. Buckinx[1], A. Bolduc[2], L. Boucher[2], B. Fillion[3], M.-C. Babin[4], M. Cimon[5], J. Morissette[5], A. Maheu[6], J. Filiatrault[2], M. Aubertin-Leheudre[7]

[1]Department of Public health, Epidemiology and Health Economics, University of Liège, Liège, Belgium; [2]Centre de recherche de l'Institut universitaire de gériatrie de Montréal (IUGM), Centre intégré universitaire de santé et de services sociaux (CIUSSS) du Centre-Sud-de-l'Île-de-Montréal, Montréal, Canada; [3]Direction régionale de santé publique de Montréal, CIUSSS du Centre-Sud-de-l'Île-de-Montréal, Montréal, Canada; [4]Direction régionale de santé publique, Centre intégré de santé et de services sociaux (CISSS) de Lanaudière, Joliette, Lanaudière, Canada; [5]Direction régionale de santé publique, CISSS de Laval, Laval, Canada; [6]GMF-U Bordeaux-Cartierville, CIUSSS du Nord-de-l'Île-de-Montréal, Montréal, Canada; [7]Centre de Recherche de l'Institut universitaire de gériatrie de Montréal, Montréal, Canada

Objective: Falls are a major public health concern among older adults worldwide, leading to injuries, hospitalizations, and mortality. Falls arise from complex interactions between individual (age-related changes, comorbidities), behavioral (previous falls, sedentary lifestyle), environmental (home hazards, uneven surfaces), and socio-economic (social isolation, limited access to care) factors. Despite over two decades of fall prevention initiatives in Quebec, adverse outcomes persist. This narrative review summarizes the latest evidence on the prevalence, circumstances, outcomes, and risk profiles of falls among community-dwelling adults aged ≥50 years with the aim of informing

targeted prevention strategies.
Methods: Scientific databases (Medline, Embase, CINAHL, Web of Science) and grey literature were searched. Studies describing fall prevalence, circumstances, outcomes and risk factors were included; those focusing on institutionalized populations were excluded. Data extraction focused on demographics, health status, fall circumstances, injuries, recurrence, and post-fall care.
Results: 48 documents were retained. Fall prevalence ranged from 23–75% over 12 months, increasing with age and among women, and varying by functional status. Falls occurred indoors (42–53%) and outdoors (47–58%), mainly during walking, stair use, or daily activities. Peaks occurred during winter and daytime. Injuries affected 8–66% of falls and included contusions, fractures, and sprains. Post-fall care included medical consultations (45–73%), emergency visits (20–37%), and hospitalization (21–42%). Faller profiles varied: active, healthy older adults mostly fell outdoors with minor injuries, while frail or dependent adults fell indoors during low-intensity activities with higher injury rates. Environmental hazards, social cohesion, and neighbourhood design influence risk, and predictive tools such as the Canadian 1stFall algorithm help identify high-risk individuals.
Conclusion: Falls among community-dwelling older adults are common and multifactorial. Effective fall prevention requires tailored, multicomponent strategies addressing physical, behavioral, social, and environmental factors, involving both older adults and their caregivers.

P595

EFFECTS OF PREHABILITATION PROGRAMMES ON POSTOPERATIVE OUTCOMES IN OLDER ADULTS UNDERGOING MAJOR ABDOMINAL, CARDIAC OR VASCULAR SURGERY: A SYSTEMATIC REVIEW

F. Buckinx[1], A.-F. Rousseau[2], E. Louis[3], A. De Roover[4], O. Detry[4], R. Durieux[5], S. Gillain[6], A. Kaba[7], J.-F. Kaux[8], V. Tchana-Sato[5], O. Bruyère[1]

[1]Research Unit in public health, epidemiology and health economics, University of Liège, Liège, Belgium; [2]Intensive Care Department, University Hospital of Liege, Liège, Belgium; [3]Hepato-Gastroenterology and Digestive Oncology Department, University Hospital of Liege, Liège, Belgium; [4]Department of Abdominal Surgery and Transplantation, University Hospital of Liege, Liège, Belgium; [5]Division of Cardiovascular and Thoracic Surgery, University Hospital of Liege, Liège, Belgium; [6]Geriatric Department, University Hospital of Liege, Liège, Belgium; [7]Department of Anaesthesiology, Service of Abdominal Surgery, University Hospital of Liege, Liège, Belgium; [8]Department of Physical Medicine, Rehabilitation and Sports Traumatology, SportS2, FIFA Medical Centre of Excellence, FIMS Collaborative Centre of Sports Medicine, University Hospital of Liege, Liège, Belgium

Objective: Older adults undergoing major abdominal, cardiac, or vascular surgery are highly vulnerable to postoperative complications, prolonged hospitalisation, functional decline, and mortality. Sarcopenia and frailty reduce physiological reserve, underscoring the potential role of prehabilitation in improving resilience to surgical stress and postoperative outcomes. The objective of this systematic review was to evaluate the effects of exercise-based prehabilitation, alone or combined with nutritional, psychological, or educational components, on postoperative outcomes, including complications, length of stay, readmissions, mortality, quality of life, and economic indicators, as well as on body composition, functional reserve, and biological markers, in adults aged ≥65 years undergoing major abdominal, cardiac, or vascular surgery.
Material and Methods: Medline, Scopus and EMBASE were searched for Randomised Controlled trials assessing prehabilitation programmes in older adults undergoing major abdominal, cardiac or vascular surgery. Data on study characteristics, interventions, outcomes, and methodological quality were extracted and synthesized narratively.
Results: Nine studies (n = 36–182; mean/median age 68–82) were included. Interventions lasted 2–6 weeks and involved exercise alone or multimodal programmes, delivered in-person, remotely, or via hybrid approaches. Vascular surgery studies showed modest reductions in complications and hospital stay, whereas abdominal surgery studies generally reported no significant improvements, except for isolated reductions in severe complications or gains in functional reserve. No studies involving cardiac surgery were identified.
Conclusion: Prehabilitation in older adults remains understudied, especially in frail patients, the oldest old, and cardiac surgery. Robust trials are needed to assess individualized, multimodal, sarcopenia-targeted interventions and to integrate biological markers to clarify underlying mechanisms.

P596

EFFECT OF A MULTIMODAL PREHABILITATION PROGRAM ON MUSCLE STRENGTH, RECOVERY, AND BIOLOGICAL RESPONSES IN OLDER ADULTS UNDERGOING MAJOR SURGERY: A RANDOMIZED CONTROLLED TRIAL PROTOCOL

F. Buckinx[1], A.-F. Rousseau[2], E. Louis[3], E. Cavalier[4], A. De Roover[5], O. Detry[5], R. Durieux[6], S. Gillain[7], A. Kaba[8], J.-F. Kaux[9], V. Tchana-Sato[6], O. Bruyère[1]

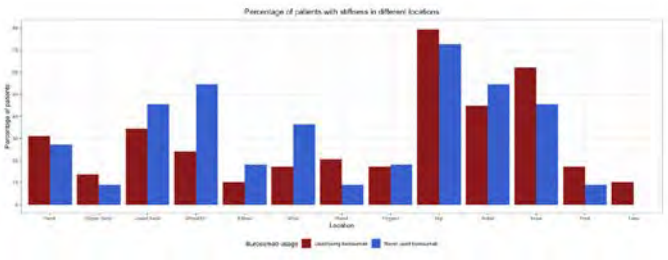
[1]Research Unit in public health, epidemiology and health economics, University of Liège, Liège, Belgium; [2]Intensive Care Department, University Hospital of Liege, Liège, Belgium; [3]Hepato-Gastroenterology and Digestive Oncology Department, University Hospital of Liege, Liège, Belgium; [4]Department of Clinical Chemistry, University Hospital of Liege, Liège, Belgium; [5]Department of Abdominal Surgery and Transplantation, University Hospital of Liege, Liège, Belgium; [6]Division of Cardiovascular and Thoracic Surgery, University Hospital of Liege, Liège, Belgium; [7]Geriatric Department, University Hospital of Liege, Liège, Belgium; [8]Department of Anaesthesiology, Service of Abdominal Surgery, University Hospital of Liege, Liège, Belgium; [9]Department of Physical Medicine, Rehabilitation and Sports Traumatology, SportS2, FIFA Medical Centre of Excellence, FIMS Collaborative Centre of Sports Medicine, University Hospital of Liege, Liège, Belgium

Objective: Older adults undergoing major surgery are at high risk of postoperative complications and incomplete recovery, largely driven by sarcopenia and impaired muscle strength. While multimodal prehabilitation improves outcomes in younger populations, evidence in

older adults remains limited, and the biological mechanisms underlying interindividual response to prehabilitation remain poorly understood. This randomised controlled trial (RCT) aims to evaluate the effect of a 4-week multimodal prehabilitation program on muscle strength and postoperative recovery in older adults, and to explore genomic, proteomic, and lipidomic profiles associated with response to prehabilitation.

Methods: This RCT will include 178 adults aged ≥65 years scheduled for major abdominal, cardiac, or thoracic surgery. Participants will be randomized (1:1), stratified by ASA score and type of surgery, to either a multimodal prehabilitation program or usual care. The intervention combines online adapted resistance exercise, tailored nutritional counselling, and integrated physical and nutritional health literacy support delivered over four weeks preoperatively. The primary outcome is lower-limb muscle strength (30-second chair-stand test). Secondary outcomes include functional capacity (SPPB, TUG), muscle power (5-times sit-to-stand test), postoperative complications (Clavien–Dindo), length of stay, readmissions, quality of life (SF-12, EQ-5D), recovery (QoR-15), health literacy, and cost–benefit outcomes. Assessments will be conducted at baseline, post-intervention, and three months post-surgery. Baseline blood samples will be collected to perform genomic (MTHFR, ACTN3, NRF2 variants, and polygenic risk score for muscle strength), proteomic (Olink®), and lipidomic (targeted and untargeted LC–MS/MS) analyses. These biological markers will be integrated as covariates to identify profiles associated with response or non-response to prehabilitation.

Conclusion: This study will generate high-quality evidence on the clinical effectiveness and cost-benefit of multimodal prehabilitation in older surgical patients, while providing novel insights into biological determinants of prehabilitation response. These findings may support the development of personalised perioperative care strategies in ageing surgical populations.



P597

PATTERNS OF SELF-REPORTED STIFFNESS PATTERNS IN ADULTS WITH X- LINKED HYPOPHOSPHATAEMIA (XLH): HIGH PREVALENCE OF UPPER LIMB INVOLVEMENT

F. Clemeno[1], O. Gardiner[2], P. Copley[2], N. Duff[2], E. Snell[2], N. Gray[1], A. Turner[1], R. Pinedo-Villanueva[1], M. K. Javaid[1]

[1]NDORMS, University of Oxford, Oxford, United Kingdom; [2]XLH-UK, Kington, United Kingdom

Objective:
Adults reported that stiffness is often not included in clinicians' assessment of XLH. Clinical trials have demonstrated that burosumab significantly reduces stiffness in adults with XLH. Our objective was to further characterise stiffness in adults living with XLH.
Methods
Adults participating in the Rare and UnDiagnosed studY (RUDY) with a self-reported diagnosis of XLH were included if they completed the painDETECT, an assessment of stiffness that included a body map, and a current medication form. Hierarchical clustering was used to identify clusters of joint stiffness locations that were reported as stiff or painful. The number of clusters selected was based on the Silhouette score, the Gap statistic, and a visual inspection of the dendrogram.
Results
33 adults with XLH had complete stiffness data. The proportion of adults reporting stiffness is shown in Figure 1 and shows a higher prevalence of stiffness in the shoulders (55%), wrist (35%) and ankles (55%) in adults not on burosumab. Of the patients with reported stiffness, 100% of non-burosumab users reported severe and extreme stiffness compared with approximately 38.5% of burosumab users (p<0.01). Stiffness of ≥2 hours was also more common in non-burosumab users overall. Four distinct stiffness clusters were identified with a low Silhouette score of 0.21, and a specific cluster for spine and shoulder stiffness.
Conclusion.
Stiffness was commonly reported in the upper limbs and ankles as well as the back, hips and knees and was commonly severe/ extreme in non-burosumab users in 4 clusters. These findings suggest the aetiology of stiffness could differ between joints and may respond differentially to therapies.
FIGURE 1: Percentage of adults with XLH with stiffness in different joints by burosumab use.

ASSESSMENT OF EFFECTIVENESS IN MEDICATION COMBINED WITH EXCERCISE AIMED AT PREVENTION OF BOTH OSTEOPOROSIS AND FRAILTY IN ELDERLY PATIENTS AFFECTED BY BREAST CANCER

F. D'Amico[1], R. D'Amico[2]

[1]Department of Biomedical Sciences School of Medicine University of Messina, Messina, Italy; [2]Medical Rehabilitation Unit IRCCS Oasi Maria SS Troina Enna, Troina, Italy

Objective: prevention of Osteoporosis is a major objective in the management of patients treated for breast cancer with aromatase inhibitors. Denosumab proved effective in prevention of fractures in subjects whose breast cancer was treated with aromatase inhibitors. We evaluated the effectiveness of combined medical treament with a self sufficient occupational therapy project to be carried out at home.
Methods: 18 elderly patients affected by breast cancer were followed for 12 months. A post surgery preventative treatment with aromatase inhibitors combined with Denosumab was prescribed in order to prevent fractures. From T0 to T24 the design of the study included: 1) blood tests; 2) spine and femur bone density scan DEXA; 3) lumbar dorsal spine morphometry; 4)short physical performance battery (SPPB). SPPB evaluates physical performance whose level scores between 0 and 12. In 10 patients (Group A) we evaluated the effectiveness of Denosumab treament on osteoporosis prevention, while in group B 8 patients were treated with a combination of Denosumab and occupational therapy for effectiveness. Subjects were instructed on how to perform specific excercises at home.
Results: Group A patients (mean age 73 ± 4 years) had an average SPPB

score 7 (p 0.05) at T0. Group B patients (mean age 72±3 years) had an average SPPB score 7 (p 0.05). At T 24 group A patients average SPPB score was 9 (p 0.05) showing an improvement in gait rate. At T24 group B patients had a an average SPPB score 10 (p 0.05) showing improvement in balance & gait rates.

Conclusion: This study proved the effectiveness of combined treatment with Denosumab and occupational therapy in elderly patiens affected by breast cancer in post surgery treatment with aromatase inhibitors. The focus was on keep in check severity markers, preventing fracture risk and improving physical performance.

P599

DOES TIMING MATTER? REAL-WORLD COST-EFFECTIVENESS OF EARLY ULTRASOUND-GUIDED CORTICOSTEROID INJECTION IN SHOULDER PAIN

F. E. Fontg Manzano[1], F. Orient Lopez[1], D. Sanchez Corretger[1], B. Zeballos Buscaglia[1], C. Agudo Fernandez[1]

[1]Hospital Universitari Sagrat Cor Quironsalud, Barcelona, Spain

Objective(s)

To compare the clinical effectiveness and cost-effectiveness of physiotherapy with or without ultrasound-guided corticosteroid injection in patients with shoulder pain, and to explore the potential economic impact of an early injection strategy.

Material and Methods

A retrospective real-world observational study was conducted in a rehabilitation service. A total of 162 patients with shoulder pain were included: 126 received physiotherapy alone and 36 received physiotherapy combined with ultrasound-guided corticosteroid injection. Pain intensity was assessed using the visual analogue scale (VAS) and upper limb function using the disability of the arm, shoulder and hand (DASH) questionnaire. Healthcare costs, sick leave and total costs were recorded. Clinical response was defined as an improvement of at least 2 points in VAS and 10 points in DASH. Cost-effectiveness was evaluated using the incremental cost-effectiveness ratio (ICER), expressed as euros per DASH point gained. An exploratory post hoc simulated scenario assuming early injection at treatment onset was performed to estimate its potential economic impact.

Results

Both treatment strategies resulted in significant improvements in pain and function. No statistically significant differences were observed between groups in final VAS or DASH scores. The combined treatment group showed higher healthcare costs, mainly related to the cost of injection and a higher number of physiotherapy sessions. Total costs, including sick leave, showed high variability and did not differ significantly between groups. In the simulated early injection scenario, mean healthcare and total costs were reduced while maintaining similar functional improvement, resulting in a negative ICER and suggesting a potentially dominant strategy.

Conclusion(s)

In real-world practice, adding ultrasound-guided corticosteroid injection to physiotherapy does not improve final clinical outcomes and increases healthcare costs. However, an early injection strategy may reduce costs without compromising effectiveness, indicating that treatment timing could be a relevant factor in optimizing the management of shoulder pain. Prospective studies are needed to confirm these findings.

P601

ASSOCIATION BETWEEN PHQ-9 SCORE AND DXA-MEASURED BONE MINERAL DENSITY IN POSTMENOPAUSAL WOMEN IN NORTH MACEDONIA

A. Vasilevska[1], F. Gucev[1], M. Bojadjioska[1], E. Sekuloska[1], M. Nikolovska-Kotevska[1], L. Damjanovska-Krstic[1], A. Karadzova-Stojanoska[1], S. Pavlova[1], S. Vidinikj[1], D. Spasovski[1], B. Osmani[1], S. Petrova[1], L. Xhemaili-Jakupi[1], B. Hamiti[1], R. Vejseli[1], S. Gjorgjevska[1], B. Kalchovska[2], J. Dimovski[3]

[1]PHI University Clinic for Rheumatology, Skopje, North Macedonia; [2]PHI University Clinic for Physical Medicine and Rehabilitation, Skopje, North Macedonia; [3]Medical Faculty, University "Sts.Cyril and Methodius", Skopje, North Macedonia

Objective

Osteoporosis is the most common metabolic bone disease and its association with depression has been described in recent investigations. This study provides the first population-based data exploring the relationship between depressive symptoms and bone mineral density in postmenopausal women in North Macedonia, a region currently absent from international osteoporosis–mental health literature. This study aimed to evaluate the association between depressive symptom severity and bone mineral density in postmenopausal women without malignancy.

Material and Methods

This is a cross-sectional study of 100 patients referred for Dual-Energy X-ray Absorptiometry. Depressive symptoms were assessed using Patient Health Questionnaire-9 (PHQ-9). Bone mineral density was measured at the lumbar spine (L1-L4), femoral neck, and total hip, and expressed as T-scores. All patients were postmenopausal women, with no malignancies.

Result

Patients were divided into groups of normal bone density (n=13), osteopenia (n=57) and osteoporosis (n=30). Significant correlations were seen only in participants with osteopenia, where PHQ-9 scores correlated with Neck mean (r=0.029, p=0.027) and Total mean (r=0.35, p=.008). No significant associations were found in the other two groups. These findings suggest a worse mental effect on patients with lower bone density on their hips, as against lumbar spine.

Conclusion

Depressive symptoms were associated with lower bone mineral density only among patients with osteopenia, which was not seen in the group with osteoporosis. It is worth noting that the group of participants was small, making statistical significance more difficult. We are planning to expand this research in the future. Depression may play a role in early bone loss but does not appear to influence bone density once osteoporosis is established. Mental health takes a great toll on individuals which in turn impedes work, addressing it early on is extremely important.

P602

DEPRESSIVE SYMPTOMS AND OSTEOPENIA: IS MENTAL HEALTH ALREADY RELEVANT BEFORE OSTEOPOROSIS DEVELOPS?

R. Vejseli[1], F. Gucev[1], M. Bojadjioska[1], E. Sekuloska[1], M. Nikolovska-Kotevska[1], L. Damjanovska-Krstic[1], A. Karadzova-Stojanoska[1], S. Pavlova[1], S. Vidinikj[1], D. Spasovski[1], B. Osmani[1], S. Petrova[1], L. Xhemaili-Jakupi[1], A. Vasilevska[1], B. Hamiti[1], S. Enimiteva-Veleva[2], B. Kalchovska[3]

[1]PHI University Clinic for Rheumatology, Skopje, North Macedonia; [2]PHI General Hospital Strumica, Strumica, North Macedonia; [3]PHI University Clinic for Physical Medicine and Rehabilitation, Skopje, North Macedonia

OBJECTIVE

Osteoporosis and depression are chronic diseases that affect large populations with notable impact on morbidity, mortality and quality of life. The potential association between osteoporosis and depression has been noted in recent studies. Our goal is to examine the relationship between depressive symptoms and bone mineral density (BMD) across individuals with normal bone density, osteopenia and osteoporosis.

MATERIAL AND METHODS

A cross-sectional analysis was conducted in 100 post-menopausal female patients. Bone mineral density was carried out with Dual-Energy X-ray Absorptiometry, while depressive symptoms were scored based on Patient Health Questionnaire-9 (PHQ-9). Correlations between PHQ-9 scores and BMD T-scores at lumbar spine (L1-L4), femoral neck, and total hip were calculated. All patients were postmenopausal women with no malignancies or hip replacement surgeries.

RESULTS

PHQ-9 scores showed a weak but significant correlation with total hip T-scores (r=0.226, p=0.024), while associations with lumbar spine and femoral neck T-scores were not significant. Depressive symptoms were significantly associated with lower bone mineral density only in patients with osteopenia (Neck mean: r=0.29, p=0.027, Total Mean: r=0.35, p=0.008). No significant correlations were found in individuals with normal bone density or osteoporosis.

CONCLUSIONS

Depressive symptoms are linked to reduced bone mineral density in individuals. These findings suggest that mental health may be relevant early in the trajectory of bone loss, highlighting potential value of identifying and addressing depressive symptoms before osteoporosis develops.

P603

EVIDENCE-BASED STRATEGIES FOR IMPROVING BONE HEALTH IN OLDER ADULTS THROUGH ORTHOGERIATRIC CARE AND RISK COMMUNICATION

F. Kamberi[1], V. Pulomemoj[2], T. Kokuri[3]

[1]University of Vlore "Ismail Qemali", Scientific Research Centre for Public Health, Faculty of Health, Vlora, Albania; [2]Department of Biomedicine and Prevention, University of Rome Tor Vergata, Rome, Italy; [3]Charité Universitätsmedizin Berlin, Berlin, Germany

Objective: The objective of this study was to assess risk perception, chronic pain patterns, and bone health–related behaviors among elderly patients with chronic conditions in primary health care settings, and to identify key barriers and facilitators for orthogeriatric success. Particular emphasis was placed on the role of risk communication and a patient–family–healthcare practitioner–centered approach in optimizing osteoporosis prevention, fracture reduction, and engagement with health services.

Materials and Methods: This research integrates findings from several cross-sectional and observational studies conducted in Albania between 2017 and 2024, including primary health care centers and a regional hospital. Data were collected from healthcare professionals and elderly patients with chronic conditions (mean age ≥65 years) using structured questionnaires, focus group discussions, and retrospective clinical record reviews. Variables included socio-demographic characteristics, professional backgrounds of healthcare staff, and types of chronic non-oncological pain, osteoporosis risk factors, fracture patterns, patient education strategies, and perceptions of risk communication during health emergencies. Screening tools, such as the IOF One-Minute Osteoporosis Risk Test, were applied in community settings. Statistical analyses were performed using SPSS, with significance set at $p < 0.05$.

Results: Healthcare providers were predominantly female (86.7%), with a mean age of approximately 30 years, and over half (57.5%) had ≤5 years of professional experience. Most were based in urban centers (85%). Chronic non-oncological pain was highly prevalent, with chronic back pain (70.8%) and joint pain (61.7%) being the most frequently reported conditions.

Among elderly patients, frequent falls (22%), low-impact fractures (15%), thyroid disorders (50%), diabetes (40%), low body mass index, smoking, and family history were common osteoporosis-related risk factors. Fractures were more frequent in men, particularly hip fractures in those aged ≥60 years, and were predominantly caused by falls and visual impairment.

Patient education relied mainly on individual counseling (68.3%) and family involvement (50.8%), while formal educational seminars were limited (9.2%). Identified barriers included low trust in health authorities, fragmented risk communication, insufficient clinical documentation, and limited access to specialized resources (51.7%). Facilitators included physiotherapy involvement (48.3%) and cost-effective community screening tools.

Conclusions: Optimizing bone health behaviors in older adults requires strengthened risk communication, interdisciplinary orthogeriatric collaboration, and active engagement of patients and families. Addressing communication gaps, improving professional training, enhancing documentation quality, and expanding access to preventive screening and rehabilitation services are essential to reducing fractures and improving outcomes in aging populations.

P604

MULTIMORBIDITY AND PROGRESSION OF RADIOGRAPHIC KNEE OSTEOARTHRITIS: DOES SEX MATTER?

F. Kirkham-Wilson[1], L. Westbury[1], G. Bevilacqua[1], F. Laskou[1], N. Fuggle[1], E. Dennison[1]

[1]MRC Lifecourse Epidemiology Centre, Southampton, United Kingdom

Objective
To examine morbidity burden in relation to progression of knee osteoarthritis (OA) and whether this association differs by sex using longitudinal data from the Hertfordshire Cohort Study.
Material and Methods
Participants (192 men and 183 women) were community-dwelling UK residents born, and continuing to live, in Hertfordshire. At baseline (1998–2004) and follow-up (2011), health questionnaires were completed, and knee radiographs were taken and graded using the Kellgren and Lawrence (K&L) system. Medical history, including medication use, was recorded at baseline and follow-up; number of body systems medicated was derived and used as a marker of morbidity level. Longitudinal change in K&L score was assessed at four sites (the tibiofemoral and patellofemoral compartments of each knee) and categorised as 0, 1 or 2/3. The site showing the greatest deterioration for each individual was used in the analysis.
Results
Mean (SD) age at baseline was 64.8 (2.7) years; mean (SD) BMI was 26.7 (4.1). Baseline radiographic knee OA (K&L ≥ 2 at the worst site) was present in 36% of men and 34% of women. No radiographic progression was observed in 34% of men and 19% of women during follow-up, while 23% of men and 31% of women progressed by at least two grades. The median number of systems medicated at baseline was one in both sexes, and two at follow-up, with all derivations exclusive of musculoskeletal and joint disease medications. Among women, number of systems medicated was associated with OA progression after adjustment for age and follow-up time (odds ratio [95% CI] for being in a higher progression category: 1.36 [1.05, 1.74] per additional system medicated), but no association was found in men 1.13 [0.84, 1.52]). This association in women remained similar after additionally adjusting for BMI (1.33 [1.03, 1.72]).
Conclusion
Radiographic knee OA progression was common in both sexes, with higher rates among women who had greater comorbidity. Further research into this apparent sex difference is warranted, as it may provide insights into the pathogenesis of OA.

P605

REPRODUCTIVE FACTORS AND OSTEOARTHRITIS: CAN OBSERVATION INFORM INTERVENTION IN FUTURE WORK?

F. Kirkham-Wilson[1], L. Westbury[1], F. Laskou[1], G. Bevilacqua[1], E. Dennison[1]

[1]MRC Lifecourse Epidemiology Centre, Southampton, United Kingdom

Objective
To determine if there are associations between reproductive factors and the development or worsening of osteoarthritis (OA) in women using data from the longitudinal Hertfordshire Cohort Study (HCS).
Methods and Materials
Data were analysed from 196 female participants in HCS with median age at baseline (1998–2004) of 65.8 years, and median age at follow-up (2011) of 75.6 years. The following potential exposures were ascertained at baseline: intermenstrual period from menarche to menopause (years), number of pregnancies, and use of oral contraceptives (OCP) and hormone replacement therapy (HRT). The following outcomes were considered: presence of clinical OA at the knee, hip, or hand at follow-up; radiographic OA at the knee or hip at follow-up; and worsening of knee Kellgren and Lawrence (K&L) grade over follow-up (yes/no). Associations were examined using logistic regression. Initial models were adjusted for age; mutually-adjusted models included all exposures along with age and BMI.
Results
Ever use of HRT was associated with reduced odds of radiographic knee/hip OA at follow-up after age adjustment (odds ratio (95% CI): 0.46 (0.24, 0.89), p=0.020) and in the mutually-adjusted model (0.43 (0.19, 0.96), p=0.040). Ever use of OCP was linked to lower odds of worsening knee K&L grade over follow-up after age adjustment (0.42 (0.20, 0.91), p=0.027) and in the mutually adjusted model (0.26 (0.10, 0.68), p=0.006). No other associations were statistically significant (p>0.05).
Conclusion
HRT and OCP use were associated with reduced risk of radiographic knee/hip OA and OA progression respectively, suggesting that these factors may impact development of OA. These results point to a possible effect of exogenous sex hormones in the pathogenesis of OA; further work is now indicated.

P606

RISK FACTORS FOR RECURRENT FALLS IN MIDLIFE: FINDINGS FROM THE HEALTH AND EMPLOYMENT AFTER FIFTY (HEAF) STUDY

F. Laskou[1], S. D'Angelo[1], L. D. Westbury[1], K. Walker-Bone[1], E. M. Dennison[1]

[1]MRC Lifecourse Epidemiology center Southampton, Southampton, United Kingdom

Objectives
Recurrent falls are associated with significant morbidity. Although most research focuses on older adults, falls have also been reported under the age of 65. This study aimed to quantify the prevalence of falls and recurrent falls among late middle-aged community-dwelling adults, and to identify the sociodemographic, lifestyle, and health-related factors

associated with recurrent falls.

Material and Methods

The Health and Employment After Fifty (HEAF) study is a longitudinal cohort of men and women recruited when aged 50-64 years from across England. At baseline and each of 5 follow-ups, participants reported falls in the preceding year. Participants were categorised as *recurrent fallers* if they experienced more than one fall on at least two occasions, non-fallers if they never reported a fall, or intermediate fallers if they reported at least a fall but not recurrent. Multinomial logistic regression was used to examine associations between fall category and potential risk factors, with estimates presented as relative risk ratios (RRR) with 95%CI.

Results

Of the 8,134 participants recruited, 7,051 were included in the analysis. The prevalence of any falls ranged from 14-18% at each follow-up. 437 (6%) participants were classified as recurrent fallers, 2,738 (39%) as intermediate and 3,876 (55%) as non-fallers. Independent predictors of being a recurrent faller (vs non-faller) included: being a woman, not-married, unemployed or retired, and having a mortgage (vs owning one's home outright). Several health-related factors were also significant ($p<0.05$), such as being obese, fair/poor self-rated health, depression, poor sleep, slow walking speed, and memory problems. Effect sizes ranged between 1.3 (1.0-1.7) (obesity) and 4.7 (3.3-6.8) (slow walking speed). Most of these factors were also significant for the intermediate fallers category, although associations were generally weaker. The final model correctly classified 60% of participants into their fall category.

Conclusions

Recurrent falls in mid-life were relatively common in this cohort of unselected community- dwelling UK adults. Several demographic and health-related factors were identified as predictors of recurrent falls, suggesting potential targets for early identification and risk mitigation in this age group.

P607

SOCIODEMOGRAPHIC DETERMINANTS OF TREATMENT ADHERENCE FOLLOWING HIP FRACTURE: DATA FROM A PORTUGUESE FLS

F. Magalhães[1], R. Soares[1], D. Augusto[1], F. Cunha-Santos[1], C. Vaz[1], N. Madeira[1], J. Fonseca Ferreira[1]

[1]Rheumatology Department, Local Health Unit of Guarda, Guarda, Portugal, Guarda, Portugal

Objective: To evaluate the association between medication adherence, objectively assessed through the Portuguese Medical Electronic Prescription platform (PEM) and sociodemographic variables, and therefore to identify patient profiles at increased risk of suboptimal treatment adherence.

Material and Methods: A prospective cohort was established within an FLS, consecutively enrolling patients with hip fractures between October 2019 and December 2025. Medication adherence was assessed using records from the PEM platform and categorized as complete, partial, or none. Sociodemographic variables included age (<75 vs ≥75 years), sex, marital status (partnered vs non-partnered), place of residence (community-dwelling vs institutionalised), and economic insufficiency. Associations between adherence and sociodemographic variables were analysed using chi-square tests, with statistical significance defined as $p < 0.05$.

Results A total of 168 patients were included, with medication dispensing data available for 151 patients (89.9%). The cohort was predominantly female (76.2%) and representative of an older hip fracture population (mean age 77.2 ± 8.6 years). Among patients with available data, 71.3% were partnered, 35.1% had economic insufficiency, and most lived independently in the community (82.7%). Complete medication dispensing was observed in 76.2% of patients, while 11.3% demonstrated partial dispensing and 12.6% did not dispense any prescribed medication, resulting in an overall non-adherence rate of 24.0%. Medication adherence did not differ significantly according to sex (76.4% in women vs 73.9% in men, $p = 0.827$), marital status (76.4% in partnered vs 74.4% in non-partnered patients, $p=0.796$), place of residence (77.0% in community-dwelling vs 63.6% in institutionalized, $p=0.518$), or economic insufficiency (72.4% vs 78.3%, $p = 0.611$). Patients aged ≥75 years demonstrated lower adherence compared with younger patients (71.1% vs 84.9%), although statistical significance ($p = 0.059$) was not reached.

Conclusion: Despite structured follow-up within an FLS, nearly one quarter of hip fracture patients did not fully adhere to prescribed osteoporosis treatment. While most sociodemographic factors were not significantly associated with adherence, increasing age and economic vulnerability showed clinically relevant trends towards lower medication uptake. Objective monitoring through electronic prescription platforms may facilitate early identification of patients at risk of non-adherence and support targeted strategies to optimise secondary fracture prevention.

P608

DENSE BONES, FRAGILE OUTCOMES: THE PARADOX OF OBESITY IN HIP FRACTURE

F. Magalhães[1], R. Soares[1], D. Augusto[1], F. Cunha-Santos[1], C. Vaz[1], N. Madeira[1], J. Fonseca Ferreira[1]

[1]Rheumatology Department, Local Health Unit of Guarda, Guarda, Portugal, Guarda, Portugal

Objective: To evaluate the association between body mass index (BMI) and bone mineral density (BMD) assessed by dual-energy X-ray absorptiometry (DXA) in patients with hip fracture followed in a Fracture Liaison Service (FLS).

Materials and Methods: A prospective observational cohort was established within an FLS, consecutively enrolling patients with hip fracture between October 2019 and December 2025. Analyses were restricted to patients with available femoral neck T-score and BMI data. BMI was analysed as a continuous variable and categorised as underweight (<18.5 kg/m²), normal weight (18.5-24.9 kg/m²), overweight (25.0-29.9 kg/m²), obesity class I (30.0-34.9 kg/m²) and obesity class II (≥35.0 kg/m²). BMD and T-scores were obtained at the femoral neck, total hip and lumbar spine. Serum calcium, phosphate, 25-hydroxyvitamin D and parathyroid hormone (PTH) were recorded. Group comparisons were performed using one-way ANOVA, and multivariable linear regression was used to assess independent associations with femoral neck T-score. Statistical significance was defined as $p < 0.05$.

Results: Among 168 patients included in the FLS cohort, 101 patients with available DXA and BMI data were analysed. The mean age was 76.3 ± 9.0 years, and the population was predominantly female (82.2%). Within the analysed cohort, 6.9% of patients were underweight, 48.5% had normal weight, 32.7% were overweight, and 11.9% were obese (class I and II combined). Mean T-scores differed significantly across BMI categories at all skeletal sites, showing a progressive increase from underweight to obese individuals. At the lumbar spine (L1-L4), mean T-scores increased from -3.47 (underweight) to -2.13 (normal weight), -1.39 (overweight), and -0.44 (obese), with a similar pattern observed at the total hip (-3.52, -2.40, -1.51, and -1.18, respectively; all $p < 0.001$). BMI

explained approximately 19%, 25% and 28% of the variability in lumbar spine, femoral neck and total hip T-scores, respectively. In multivariable linear regression analysis, BMI remained independently associated with femoral neck T-score ($\beta = 0.45$, $p < 0.001$) after adjustment for age, vitamin D, PTH and serum calcium. Increasing age and higher PTH levels were independently associated with lower femoral neck T-scores. No significant differences in serum calcium, vitamin D or PTH levels were observed across BMI categories.

Conclusion: In patients with hip fracture followed in an FLS, increasing BMI was associated with a marked and progressive increase in BMD across clinically relevant skeletal sites. However, this apparent densitometric advantage did not translate into fracture protection, supporting a dissociation between bone density and fracture risk in obese patients. These findings suggest that reliance on DXA-derived BMD alone may underestimate fracture risk in this population.

P609

REDUCING THE BURDEN OF BONE HEALTH MONITORING IN WOMEN WITH BREAST CANCER; A PILOT STUDY OF ACCEPTABILITY

F. Manning[1,2], M. G. Wallis[2], B. Lopez[3], D. Joyce[3], N. Healy[2]

[1]University of Exeter, Exeter, United Kingdom; [2]Cambridge University Hospitals Foundation Trust, Cambridge, United Kingdom; [3]IBEX Innovations Limited, Sedgefield, United Kingdom

Objective(s)

A pilot study of a new intervention, IBEX BH, which measures bone density from wrist X-rays undertaken on mammography equipment was undertaken. The study investigated experience and acceptability of the intervention with female patients.

Material and Methods

Women with breast cancer awaiting DXA were recruited to undertake an additional wrist X-ray as part of their mammography follow-up. They were surveyed on their experience and invited to attend a follow-up focus group.

Thematic qualitative analysis was undertaken using the theoretical framework of acceptability (TFA) as a guide.

Results

Surveys were received from all 15 women who completed the pilot, and 5 participated in the follow up focus group.

Codes related to all 7 themes of the TFA. Highlights include 'Affective Attitude'- participants were generally positive about the intervention feeling 'none' (n=13) or 'positive' (n=2) impact of the additional scan on their mammography appointment, with one FG participant stating '*if it's that quick, it's amazing*'. One of the main positives seen was the potential to reduce hospital visits, travel and burden (perceived effort).

'*The main issue for me was just the travel time to and from the hospital and trying to find parking.*'

Whilst the intervention was received well, 'Intervention Coherence' was mixed, with some not understanding the link between their breast cancer treatment and bone health indicating a wider issue. Participants also provided feedback that could improve experience of the intervention e.g. having the opportunity to cover up after the breast scan for the wrist X-ray.

Conclusion(s)

The high acceptability of the intervention and indications for improvement support the justification for a larger clinical study to further develop clinical validity of the IBEX BH mammography method, and the suitability of the adapted clinical pathway.

This intervention provides an exciting opportunity to improve the care of women with breast cancer and reduce burden on the patient and healthcare service.

P610

DEVELOPMENT AND VALIDATION OF A DXA-BASED RADIOMICS MODEL FOR FRAGILITY FRACTURE RISK PREDICTION IN OBESE ELDERLY INDIVIDUALS

F. N. Chuan[1], Y. Y. Gao[2]

[1]Department of Endocrinology, Chongqing University Fuling Hospital, Chongqing, China, Chongqing, China; [2]Department of Nephrology, Chongqing University Fuling Hospital, Chongqing, China, Chongqing, China

Objective: To develop and validate a radiomics model based on dual-energy X-ray absorptiometry (DXA) lumbar spine and hip images for predicting fragility fractures in obese elderly individuals.

Methods: In this cross-sectional study, 506 patients aged ≥ 60 years admitted between July 2024 and March 2025 were enrolled and categorized by prior fragility fracture history. Participants were randomly assigned to a training set (n=353) and validation set (n=153). Regions of interest on DXA images (lumbar spine, femoral neck, total hip) were delineated in 3D Slicer, and radiomics features were extracted. Features with high reproducibility underwent least absolute shrinkage and selection operator (LASSO) reduction, and a logistic regression model was built. Predictive performance was assessed using receiver operating characteristic (ROC) curves, calibration, and decision curve analysis, compared with bone mineral density (BMD).

Results: Of the included participants, 101 (19.96%) had a prior fragility fracture. A total of 2,553 radiomics features were extracted, of which 1,853 demonstrated high intra- and inter-observer reproducibility. After LASSO feature reduction, 14 features were retained to construct the radiomics model. In the training and validation sets, the model achieved AUCs of 0.776 and 0.787, respectively, both significantly higher than those of conventional BMD. The radiomics model also demonstrated superior calibration and clinical utility compared to BMD.

Conclusions: This DXA-based radiomics model provides a non-invasive, low-cost, and effective tool for stratifying fragility fracture risk in obese elderly individuals, with better performance than conventional BMD.

P611

VERTEBROPLASTY IN FRAGILITY VERTEBRAL FRACTURES: WHEN NORMAL BONE MINERAL DENSITY IS A WARNING SIGN. A CASE OF IGG-KAPPA MULTIPLE MYELOMA.

F. Rivas Santirso[1], P. Rivas Calvo[2]

[1]Rheumatology and Rehabilitation Clinic RC, Segovia, Spain, Segovia, Spain; [2]Rheumatology and Rehabilitation Clinic RC, Segovia, Spain & Universidad San Pablo CEU, Madrid, Spain, Segovia & Madrid, Spain

Objective(s)

Vertebroplasty is widely used for pain control in osteoporotic vertebral fractures. However, secondary causes of bone fragility such as multiple myeloma may mimic primary osteoporosis and lead to therapeutic failure and diagnostic delay.

Material and Methods

We report the clinical, radiological, densitometric and laboratory findings of a 73-year-old male with progressive dorsolumbar pain and multiple atraumatic vertebral fractures treated with vertebroplasty.

Results

Vertebroplasty was performed at D8 and D11 in 2023 and at L2 in 2025. Despite these procedures and stepwise analgesic treatment, severe refractory pain persisted with marked functional impairment. Dual-energy X-ray absorptiometry showed normal bone mineral density at the lumbar spine, hip and forearm, discordant with the number and severity of fractures. Imaging revealed multiple vertebral compression fractures, new acute/subacute fractures at D12 and L3, and signs of previous cementoplasty. Laboratory tests showed an erythrocyte sedimentation rate of 89 mm/h with normal C-reactive protein, normal calcium-phosphate metabolism and bone turnover markers, and an IgG-kappa monoclonal spike, leading to the diagnosis of multiple myeloma.

Conclusion(s)

The coexistence of multiple vertebral fractures with normal bone mineral density should raise suspicion of secondary bone fragility. Vertebroplasty without a comprehensive etiological work-up may result in poor clinical response and delayed diagnosis. Multiple myeloma should be systematically ruled out in patients with refractory pain and recurrent vertebral fractures despite normal densitometry.

Figure 1. Spine MRI. (A) Compression fracture at D8 and cemented fracture at D11 (22-11-2023). (B) Acute/subacute fractures at D12 and L3 with sequelae of previous fractures at D8, D11 and L2 (08-08-2025).

P612

PAGET'S DISEASE OF BONE IN CLINICAL PRACTICE: CHARACTERIZATION OF A POLYOSTOTIC CASE SERIES AND CLINICAL IMPLICATIONS

F. Rivas Santirso[1], P. Rivas Calvo[2]

[1]Rheumatology and Rehabilitation Clinic RC, Segovia, Spain, Segovia, Spain; [2]Rheumatology and Rehabilitation Clinic RC, Segovia, Spain & Universidad San Pablo CEU, Madrid, Spain, Segovia & Madrid, Spain

Objective(s)
To analyze the clinical, biochemical and radiological characteristics, skeletal involvement patterns and treatment of a series of patients with Paget's disease of bone (PDB), highlighting clinically relevant findings in real-world practice.

Material and Methods
A descriptive study including seven patients diagnosed with PDB was conducted. Demographic data, personal and family history, clinical presentation, extent and localization of skeletal involvement, biochemical parameters, imaging findings, disease phase, complications and treatment were collected. Diagnosis was confirmed by bone scintigraphy, and disease activity was assessed using serum alkaline phosphatase (ALP) levels.

Results
The mean age at diagnosis was 62 years; four patients were female and three were male. No family history of PDB was identified. Associated comorbidities included rheumatoid arthritis, erosive osteoarthritis, chondrocalcinosis and post-polio syndrome. All patients presented with polyostotic involvement. The pelvis and femur were the most frequently affected sites, while lumbar spine involvement was observed in two cases. Mechanical hip pain was the most common presenting symptom, and one patient presented with knee monoarthritis. Serum ALP levels were elevated in all patients, and hypercalcemia was detected in three cases. Five patients were in the active phase of disease at diagnosis. During follow-up, two patients developed long bone fractures involving the humerus and femur. All patients were treated with bisphosphonates: oral risedronate (n=4) or intravenous zoledronic acid (n=3).

Conclusion(s)
This series shows that Paget's disease of bone may predominantly present as a polyostotic condition with preferential involvement of the pelvis and long bones, which is associated with a relevant risk of fractures. Persistent elevation of serum ALP proved to be a reliable marker of disease activity. The coexistence of Paget's disease with inflammatory and erosive joint disorders observed in our series supports current concepts of PDB as a disorder with osteoimmunological involvement, and warrants further investigation into shared pathogenic mechanisms.

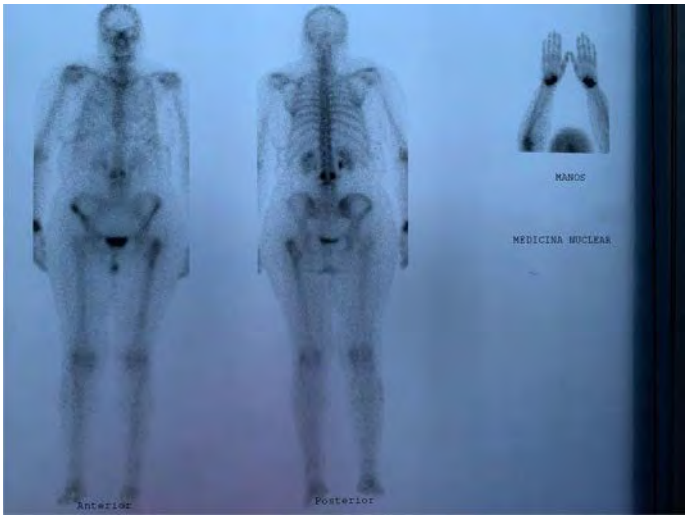

Figure 1. Bone scintigraphy with 99mTc in a 61-year-old woman with rheumatoid arthritis and polyostotic Paget's disease of bone. The metabolic phase shows pathological tracer hyperfixation at L3–L4, right iliac spine, right sacroiliac joint and the proximal third of the left femur, as well as increased uptake in both shoulders and knees, with significant pathological deposits in the wrists.

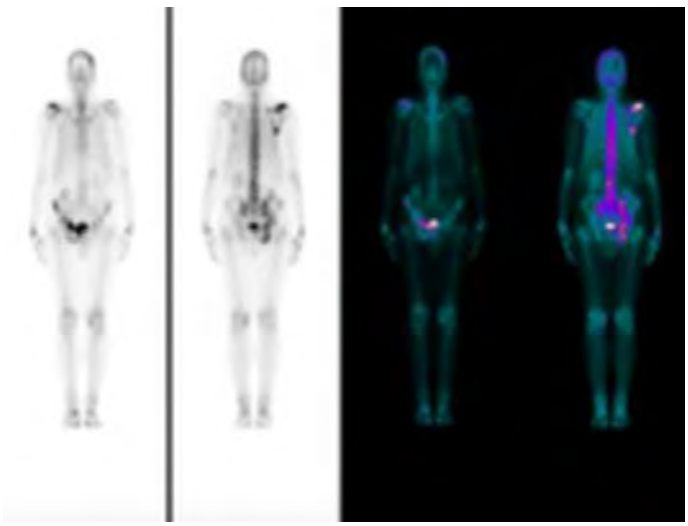

Figure 2. Bone scintigraphy with 99mTc-HDP in a 63-year-old man with erosive osteoarthritis and polyostotic Paget's disease of bone, demonstrating increased tracer uptake in the metacarpophalangeal joint of the first digit, bilateral interphalangeal and carpal joints, as well as in the left parietal bone, right scapula, L3 vertebra and right hemipelvis.

Figure 3. Plain radiograph of the knee in a 75-year-old man who presented with knee monoarthritis. The image shows bone changes consistent with Paget's disease affecting the femur and tibia, together with radiographic evidence of chondrocalcinosis.

Figure 4. Three-dimensional computed tomography (CT) reconstruction of the pelvis in a 63-year-old woman. The image shows altered bone density involving the iliac bone, ischium and pubis, with irregularity of the pubic symphysis. Compensatory pelvic tilt secondary to limb length discrepancy due to neurological deficit of the left lower limb is observed. The patient has a history of post-polio syndrome, with bone and muscle atrophy of the left lower limb and hypoplasia of the left femur. A large uterine fibroid is also identified.

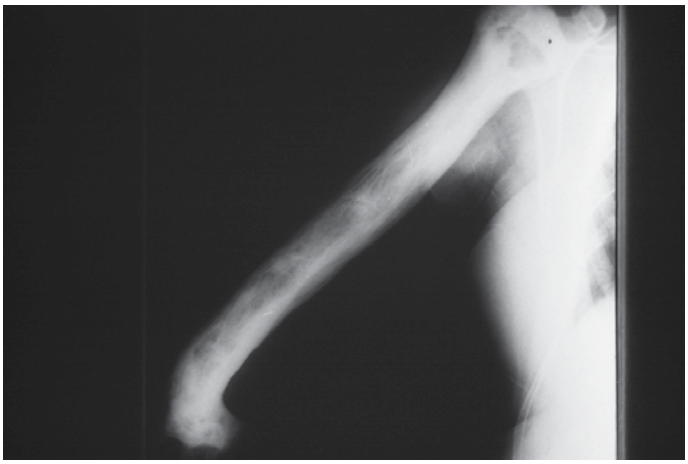

Figure 5. Plain radiograph of the right humerus in a 67-year-old woman with polyostotic Paget's disease of bone, demonstrating a pathological diaphyseal fracture through abnormal bone characterized by diffuse cortical thickening, osseous expansion, coarse trabecular pattern and patchy heterogeneous sclerosis, radiographic features typical of Paget's disease.

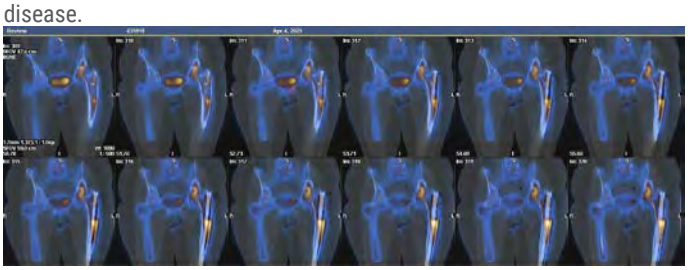

Figure 6. 99mTc-HDP SPECT-CT study in a 77-year-old woman with polyostotic Paget's disease of bone and a pathological femoral diaphyseal fracture treated with osteosynthesis. Markedly increased osteogenic activity is observed in the left iliac wing and along the diaphysis of the left femur, involving the outer cortex and bone marrow, findings consistent with active Paget's disease.

P613

REDEFINING ELIGIBILITY FOR OSTEOANABOLIC TREATMENT: IDENTIFYING VERY HIGH FRACTURE RISK GROUPS AMONGST OLDER SWEDISH WOMEN

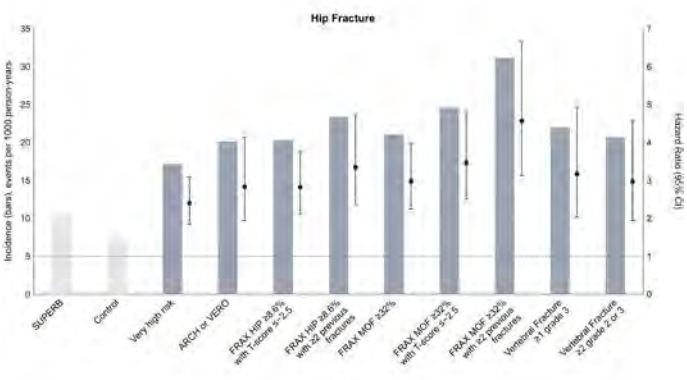
F. Winge Hyde[1], M. Zoulakis[1], R. Jaiswal[1], K. Axelsson[1], H. Litsne[1], M. Lorentzon[2]

[1]University of Gothenburg, Mölndal, Sweden; [2]University of Gothenburg and Sahlgrenska University Hospital, Mölndal, Sweden

Aims

This study aimed to identify specific subgroups of older women whose fracture incidence equals or exceeds that of populations currently eligible for osteoanabolic therapy under Swedish guidelines (modelled on the ARCH and VERO trials), thereby informing proposals to broaden treatment eligibility.

Material and Methods



We analyzed data from the SUPERB cohort, a population-based study comprising 3,028 women aged 75–80 years living in Gothenburg, Sweden. Participants were stratified into risk categories based on the inclusion criteria of the ARCH and VERO trials, alongside groups defined by vertebral fracture status and other very high fracture risk (VHFR) categories defined by FRAX® probabilities (Major Osteoporotic Fracture [MOF] ≥32% or Hip Fracture ≥8.6%) and specific clinical determinants, including low bone mineral density (BMD). Incidence rates for hip and any clinical fracture were calculated over a mean follow-up of approximately 7 years. Cox proportional hazards regression was used to estimate hazard ratios (HR) and 95% confidence intervals (CI) comparing VHFR groups with the non-VHFR group.

Results

The analysis demonstrated that several groups identified via FRAX-based VHFR thresholds, with or without the addition of other clinical risk factors such as osteoporosis prevalence (T-score ≤−2.5) or multiple prior fractures, exhibited fracture incidence rates and HRs comparable to, and in certain instances exceeding, those observed in the 'ARCH or VERO' characteristics reference group. In total, 1,028 (34%) women belonged to any VHFR group (Figure). Notably, a solitary prevalent grade 3 vertebral fracture was associated with hip fracture incidence of 22.0 per 1,000 person-years and any clinical fracture incidence of 135.3 per 1,000 person-years, exceeding rates observed in the composite trial-eligible population. Furthermore, participants classified as VHFR by FRAX (MOF ≥32%) with multiple prior fractures exhibited the highest hip fracture incidence (31.2 per 1,000 person-years).

Conclusion

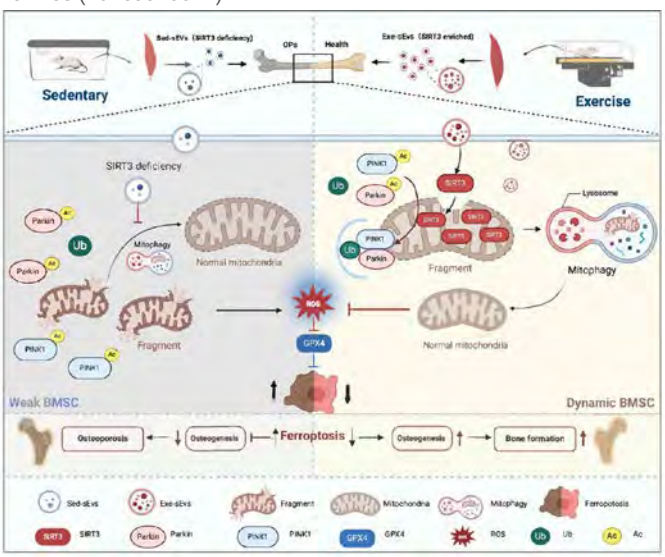
Over a third of the older women in the SUPERB cohort had VHFR. Current reimbursement criteria for osteoanabolic therapy appear unduly restrictive, excluding a substantial cohort of women whose risk of fragility fracture is equivalent to that of patients included in the ARCH-Vero trials.

P614

ENDURANCE EXERCISE INDUCED SKELETAL MUSCLE-DERIVED SIRT3-ENRICHED SMALL EXTRACELLULAR VESICLES ALLEVIATE OSTEOPOROSIS BY SUPPRESSING FERROPTOSIS

F. Xu[1], M.-H. Zheng[2], L.-Q. Yuan[1]

[1]National Clinical Research Center for Endocrine and Metabolic Diseases, Hunan Provincial Key Laboratory of Metabolic Bone Diseases, The Second Xiangya Hospital of Central South University,, Changsha, China; [2]National Clinical Research Center for Endocrine and Metabolic Diseases, Hunan Provincial Key Laboratory of Metabolic Bone Diseases, The Second Xiangya Hospital of Central South University, Changsha, China



Objectives: Endurance exercise (Exe) demonstrates reliable beneficial effects in maintaining bone health and alleviating osteoporosis progression. However, the precise mechanisms underlying Exe-mediated muscle-bone crosstalk remain to be fully elucidated. Here, we identified that Exe-enhanced secretion of skeletal muscle-derived small extracellular vesicles (Mus-sEVs) as a critical inter-tissue communication modality.

Material and Methods: Eight-week male mice in the Exe group were forced to run and then Mus-sEVs were isolated and injected to ovariectomy (OVX)-induced and age-related mouse. μCT, immunohistochemical analysis, and Immunofluorescence were used to measure bone biomarkers. The AAV9 containing EGFP reporter, a muscle-specific promoter MHCK7, and a specific shSIRT3 fragment (AAV9-shSIRT3) were constructed to knockdown the expression of SIRT3 in muscle. BMSC-specific aptamers connected SIRT3-sEVs were used to deliver SIRT3 efficiently into the bone.

Results: Exe-induced Mus-sEVs (Exe-sEVs) ameliorated bone loss in both OVX-induced and age-related mouse models by enhancing the osteogenic differentiation of bone marrow mesenchymal stem cells (BMSCs). Mechanistically, proteomic profiling demonstrated predominant enrichment of Exe-sEV cargo in ferroptosis-related pathway, while pharmacological activation of ferroptosis conversely abolished their bone-protective effects in OVX-induced murine models. Subsequent investigations elucidated that SIRT3 accumulation in Exe-sEVs suppressed ferroptosis, thereby facilitating BMSCs osteogenesis and counteracting OVX-induced osteoporosis. Furthermore, targeted delivery of SIRT3-overexpressing sEVs to bone tissue via a BMSC-specific aptamer significantly alleviated bone loss in OVX mice.

Conclusion: Our study delineates endurance exercise-mediated muscle-bone crosstalk and establishes Exe-induced muscle-derived sEVs as a promising therapeutic alternative for osteoporosis prevention.

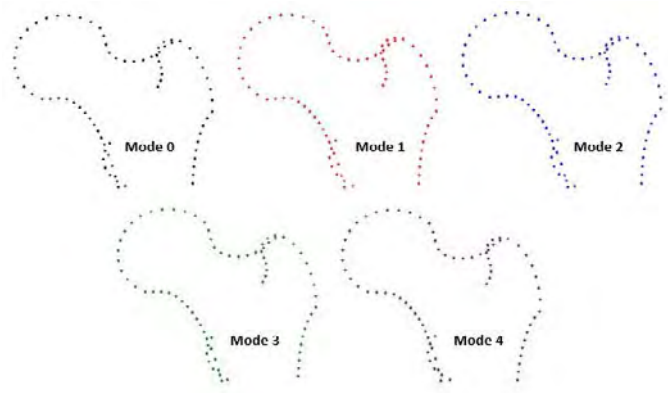
STATISTICAL SHAPE MODELING OF THE PROXIMAL FEMUR IN MEXICAN WOMEN AND ITS ASSOCIATION WITH REGIONAL BONE MINERAL DENSITY

G. A. Cruz-Priego[1], F. Medina-Rodríguez[2], R. Torres-González[3], P. Clark[1]

[1]Faculty of Medicine of National Autonomous University of Mexico, Mexico City, Mexico; [2]Unidad Médica de Alta Especialidad (UMAE). "Dr. Victorio de la Fuente Narváez", Instituto Mexicano del Seguro Social (IMSS), Mexico City, Mexico; [3]Dirección de Educación e Investigación en Salud de la UMAE de Traumatología, Ortopedia y Rehabilitación "Dr. Victorio de la Fuente Narváez", IMSS. Mexico city, Mexico., Mexico City, Mexico

Objective(s): To characterize proximal femur morphology in Mexican women using statistical shape modeling (SSM) and examine its relationship with site-specific bone mineral density (BMD), focusing on structural configurations potentially linked to fracture vulnerability.

Material and Methods: A cross-sectional analysis of 284 DXA hip scans was performed using BoneFinder software to generate statistical shape models. Active Shape Models identified modes of morphological variation after automated placement of 65 landmarks. Shape modes were summarized using BoneFinder (1), and regional BMD (neck, upper/lower neck, Ward's triangle, trochanter, diaphysis, total hip) was extracted from DXA reports. Descriptive statistics and 95% CIs were calculated by shape mode. No multivariable models were used given the exploratory design.



Results: Seventeen morphotypes were identified. The first five modes captured 80% of morphological variability (Figure 1). Three dominant configurations emerged: (1) long, narrow necks with valgus alignment (Mode 2); (2) short, wide necks (Mode 3); and (3) intermediate shapes (Mode 0). Mode 2 showed the lowest BMD across fracture-prone regions—superior neck (0.735 g/cm²) and Ward's triangle (0.721 g/cm²)—while Mode 0 exhibited the highest regional BMD. Morphologies with long, slender necks, flattened heads, and valgus angles corresponded to biomechanical disadvantage consistent with patterns reported internationally.

Conclusion(s): This is the first study to apply SSM to characterize proximal femur morphology in Latin American women. Distinct morphotypes—particularly those with long, narrow, valgus-oriented necks—were associated with low regional BMD, suggesting increased structural vulnerability. Integrating morphometric and densitometric information may enhance fracture-risk assessment and support development of population-specific prediction models.

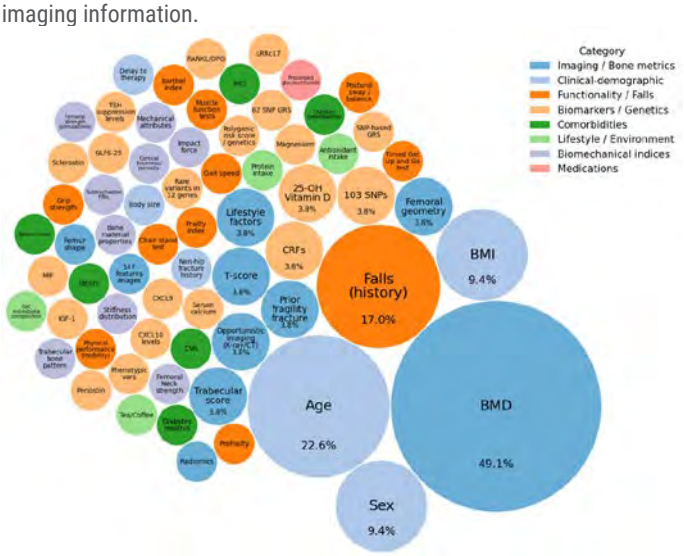
EMERGING APPROACHES FOR FRACTURE RISK PREDICTION: A SCOPING REVIEW OF MULTIDOMAIN MODELS AND NOVEL TOOLS

G. A. Cruz-Priego[1], P. Clark[1], R. A. Gomez-Diaz[2], B. Araiza-Nava[1]

[1]Faculty of Medicine of National Autonomous University of Mexico, Mexico City, Mexico; [2]Unidad de Investigación Médica en Epidemiología Clínica, Hospital de Especialidades, Centro Médico Nacional Siglo XXI, Instituto Mexicano del Seguro Social, Mexico City, Mexico

Objective(s): To map and characterize tools, algorithms, and models proposed to predict fragility fracture risk in adults without external validation, identifying predictor domains, methodological trends, and gaps in real-world applicability.

Material and Methods: A scoping review was conducted following Arksey



& O'Malley and PRISMA-ScR guidance. Searches in MEDLINE, Cochrane Library and Healthevidence (updated June 2025) identified studies proposing prediction tools or assessing novel predictors of incident osteoporotic fractures. Two reviewers performed independent screening and data extraction. Predictors were grouped into clinical, functional, imaging-based, biomechanical, biochemical, and genomic domains.

Results: Fifty-three studies (2016–2024) were included. Traditional regression-based models (e.g., POL-RISK, HKOS, CFracture, FREM) relied mainly on age, sex, prior fracture, BMI, comorbidities, falls, and medication exposures. Emerging approaches expanded into functional measures (grip strength, gait speed, timed up-and-go, postural sway), advanced imaging (finite-element DXA/CT, radiomics, deep learning from radiographs), biochemical markers (e.g., CXCL9, sclerostin, periostin), and polygenic scores. Machine-learning tools often improved discrimination, particularly for short-term risk prediction, but external validation was rare. Predictors clustered into eight domains, as illustrated in **Figure 1**, showing the increasing multidimensionality of fracture-risk modeling.

Conclusion: Fracture-risk prediction is rapidly evolving beyond BMD and FRAX toward multidomain models integrating functional performance, imaging-derived biomechanics, AI-based features, and molecular signals. However, the absence of robust external validation, calibration reporting, and real-world feasibility limits clinical translation. Future development should prioritize multicohort validation, integration across predictor domains, transparency for AI-based tools, and applicability in diverse global populations.

Figure 1. Distribution of variables included in unvalidated fracture risk prediction models according to predictor domain.

Bubble sizes represent the relative frequency of each predictor among the 53 studies included in this scoping review. Predictors are grouped into eight domains: larger bubbles indicate variables most frequently incorporated in fracture prediction models, whereas smaller bubbles correspond to exploratory or emerging predictors (e.g., gut microbiota composition, splenectomy, or ulcers). The figure illustrates the progressive expansion of fracture risk modeling beyond bone density toward multidomain approaches that integrate functional, biological, and imaging information.

INFRASTRUCTURE AND PSYCHOLOGICAL FACTORS AS FRACTURE RISK IN INSTITUTIONALIZED ELDERLY: A PROSPECTIVE OBSERVATIONAL STUDY

G. C. M. Miguel[1,2], C. N. Nakamura[1], E. C. Cassalho[1], M. C. Cavalcante[1], V. M. Melatti[1], N. N. Nonose[2], A. N. Ninomiya[2]

[1]Universidade São Francisco, Bragança Paulsita, Brazil; [2]Hospital Universitário São Francisco na Providência de Deus, Bragança Paulista, Brazil

Objective(s)

To investigate relationships between environmental infrastructure, psychological factors, and fracture risk in institutionalized elderly residents, and to identify modifiable risk factors for comprehensive fall prevention interventions.

Material and Methods

A 12-week prospective observational qualitative study was conducted in a public nursing home with weekly assessments. Sixteen elderly residents (mean age 78 years) were recruited through purposive sampling. Data collection included: structured interviews (covering sociodemographic characteristics, fall history, physical activity patterns, assistive device use), environmental observations using a standardized facility assessment checklist, and institutional medical records analysis. Psychological assessment included validated instruments for fear of falling and perceived loneliness. Thematic analysis identified patterns linking environmental and psychological factors to fall/fracture risk. Data saturation was confirmed after 14 interviews.

Results

Physical activity participation was high (81% regular practitioners), correlating with reduced falls. However, 25% reported prior fracture-related hospitalizations. Adapted infrastructure (non-slip flooring, grab bars) significantly reduced fall incidents in compliant users. Environmental hazards identified included suboptimal handrail utilization and water infiltration during precipitation. Psychological barriers were significant: fear of falling (68%) and social isolation (56%) independently predicted reduced mobility, paradoxically increasing fall risk through deconditioning. Low assistive device adoption reflected psychological reluctance rather than availability. Calcium supplementation and glucocorticoid monitoring demonstrated clinical importance in fracture prevention.

Conclusion(s)

Environmental infrastructure alone is insufficient for fall prevention; concurrent psychological support addressing fear and isolation is essential. A comprehensive approach integrating architectural modifications, mental health interventions, and medication optimization represents the most effective fall/fracture prevention strategy. Findings support development of integrated institutional protocols addressing physical-psychological-pharmacological domains.

IMPORTANCE OF PHYSICAL ACTIVITY IN FALL PREVENTION IN ELDERLY: A SYSTEMATIC LITERATURE REVIEW

G. C. M. Miguel[1,2], N. S. Santos[2], V. M. Moraes[2], W. O. Oliveira[2], N. N. Nonose[1], A. N. Ninomiya[1]

[1]Hospital Universitário São Francisco na Providência de Deus, Bragança Paulista, Brazil; [2]Universidade São Francisco, Bragança Paulsita, Brazil

Objective(s)

To identify populations susceptible to osteoporosis, elucidate pathophysiological mechanisms, and evaluate the role of physical activity in fall prevention and bone health among elderly.

Material and Methods

A systematic literature review was conducted using PubMed, SciELO, and Google Scholar databases. Studies published between 2001 and 2024 were included, focusing on elderly with osteoporosis, physical activity interventions, and fall prevention outcomes. Selection criteria prioritized clinical trials, experimental studies, and systematic reviews. Analysis focused on musculoskeletal physiology, bone remodeling, and exercise mechanisms in aging populations.

Results

Aging impairs physiological adaptation to physical stress, promoting osteoporosis and sarcopenia. Osteoporosis reduces bone mass, increasing fracture risk particularly in postmenopausal women and low-weight individuals. Sarcopenia, characterized by progressive loss of muscle mass and strength, increases fall risk. After age 30, muscle fiber quantity and functionality decline significantly, contributing to frailty. Combined with sedentary lifestyle, polypharmacy, and chronic diseases, sarcopenia and osteoporosis affect 30% of elderly over 65 years and 50% of those over 80 years. Falls have both physical and psychological impacts, including fear, insecurity, and social isolation. Regular physical activity, including resistance and balance exercises, reduces osteoporosis and sarcopenia effects, promoting functional independence. Evidence demonstrates that muscle strengthening programs and postural balance training are effective fall prevention strategies.

Conclusion(s)

Regular physical activity, encompassing resistance training and balance exercises, is essential for fall prevention and improved quality of life in elderly. These interventions reduce osteoporosis and sarcopenia effects while promoting functional independence. Additionally, a safe adapted environment is fundamental to minimize fall risk. Physical activity combined with environmental modifications represents an effective strategy for maintaining health and quality of life in aging populations. Multifactorial approaches integrating exercise, environmental safety, and medical monitoring are recommended for comprehensive fall prevention.

CLINICAL PROFILE AND FRACTURE RISK FACTORS IN COMMUNITY-DWELLING ELDERLY: A PRIMARY CARE STUDY

G. C. M. Miguel[1,2], G. O. Oliveira[2], M. A. Alves[2], G. S. Silva[2], A. N. Ninomiya[1], N. N. Nonose[1]

[1]Hospital Universitário São Francisco na Providência de Deus, Bragança Paulista, Brazil; [2]Universidade São Francisco, Bragança Paulsita, Brazil

Objective(s)

To assess clinical profile and fracture risk factors in elderly patients registered in primary health centers (UBSs), evaluating comorbidities, assistive device use, home environmental hazards, and bone health screening gaps.

Material and Methods

Cross-sectional observational study conducted in 14 elderly residents (mean age 76 years) registered in community-based primary health centers (UBSs) between September-December 2024. Data collection included home visits with standardized questionnaires addressing: clinical conditions, medication use, fall history, mobility device utilization, and domiciliary environment assessment. Fracture risk was evaluated using FRAX Brazil tool. Ethical approval and informed consent (TCLE) were obtained for all participants.

Results

Home environmental hazards were prevalent: loose rugs (61.5%), stairs without handrails (62.9%), irregular flooring (62.5%). Safety adaptations were limited: bathroom grab bars (38.5%), slip-resistant flooring (23.1%), but adequate night lighting present (69.2%). Mobility device use (canes/walkers) was reported by 57.1% of participants, while 50% of residences had access difficulties. Regarding bone health status: 50% demonstrated intermediate fracture risk, 2 participants with elevated risk (14.3%), but zero participants had undergone bone density testing. Home-based fall risk factors (inadequate lighting, poor stair condition, absence of assistive devices) were identified as modifiable intervention targets.

Conclusion(s)

Despite presence of selective safety elements, substantial fracture

risk factors persist in domiciliary environments of community-dwelling elderly. Critical gap exists in preventive bone health screening (zero densitometry testing). Combined environmental adaptation, clinical evaluation, and safety education are essential for fracture prevention and healthy aging. Findings underscore necessity for integrated public health policies addressing environmental modification, bone health assessment, and fall prevention in primary care settings.

MEDICAL STUDENT COMPETENCY DEVELOPMENT THROUGH FALL PREVENTION EXTENSION PROJECT IN ELDERLY: OUTCOMES ON PRACTICAL AND THEORETICAL SKILLS

G. C. M. Miguel[1,2], C. N. Nakamura[2], D. S. Santos[2], M. B. Bezerra[2], Y. S. Servette[2], N. N. Nonose[1], A. N. Ninomiya[1]

[1]Hospital Universitário São Francisco na Providência de Deus, Bragança Paulista, Brazil; [2]Universidade São Francisco, Bragança Paulsita, Brazil

Objective(s):
To evaluate impact of a fall prevention extension project on medical student competency development in geriatric care, environmental safety assessment, and evidence-based fracture prevention strategies.

Material and Methods:
Pre-post intervention study of 31 medical students (14 female, 17 male; various academic years) participating in fall prevention extension project approved by Ethics Committee (CAAE 83246224.8.0000.5514). Data collection via validated questionnaires administered via Google Forms before and after project participation, assessing knowledge gains, clinical skills, and confidence in geriatric patient management.

Results:
Post-intervention: 87.1% students reported increased capacity for elderly patient care; 96.8% demonstrated competency in environmental safety assessment. All participants (100%) rated project activities as effective for academic development, highlighting exposure to underrepresented patient demographics, enhanced understanding of elderly vulnerability, and ability to identify fall-fracture risk factors. Students developed practical skills in FRAX application, environmental hazard identification, and preventive counseling strategies.

Conclusion(s):
Extension projects integrating theory with clinical practice effectively enhance medical student competency in geriatric medicine and fracture prevention. Direct elderly patient engagement develops holistic understanding of aging-related vulnerabilities and enables evidence-based preventive intervention skills. Such initiatives strengthen medical training while simultaneously benefiting community through applied knowledge and improved elderly care practices.

CLINICAL PROFILE AND FRAGILITY FRACTURES IN OUTPATIENTS: AN ORTHOPEDIC DEPARTMENT ANALYSIS

G. C. M. Miguel[1,2], M. B. Bezerra[2], R. D. Duarte[2], G. B. Boutros[2], G. A. Attie[2], J. I. Izzo[2], N. N. Nonose[1], A. N. Ninomiya[1]

[1]Hospital Universitário São Francisco na Providência de Deus, Bragança Paulista, Brazil; [2]Universidade São Francisco, Bragança Paulsita, Brazil

Objective(s): To characterize demographic, clinical, and environmental risk factors associated with fragility fractures in a population attending an orthopedic clinic.

Material and Methods: This cross-sectional study evaluated 33 orthopedic outpatients (age 12–93 years) approved by Ethics Committee (CAAE 83246224.8.0000.5514). Data collection included demographics, fracture history, anthropometric measures, comorbidities, and home safety assessment via structured Google Forms questionnaires.

Results: Among participants, 57.6% had sustained fractures (87.9% female; predominantly age 66–75 years). Bone density evaluation confirmed secondary osteoporosis in 63.6%. Mobility difficulties requiring assistive devices were reported by 78.8%. Environmental risks (loose rugs, slippery floors) were present in 24.2% of homes. Fear of falls impacted quality of life despite relatively safe residences. Only 48.5% engaged in regular social activities.

Conclusion(s): Advanced age, female sex, and mobility limitations are primary fracture risk factors in this population. Multifactorial interventions addressing environmental safety, mobility promotion, psychological support regarding fall anxiety, and bone health optimization are essential to reduce fragility fracture incidence and enhance healthy aging.

OSTEOSARCOPENIA IN AGING: NONPHARMACOLOGICAL INTERVENTIONS THROUGH RESISTANCE TRAINING AND TARGETED NUTRITIONAL SUPPLEMENTATION

G. C. M. Miguel[1,2], T. Junior[3]

[1]Hospital Universitário São Francisco na Providência de Deus, Bragança Paulista, Brazil; [2]Universidade São Francisco, Bragança Paulsita, Brazil; [3]Universidade Federal do Paraná, Curitiba, Brazil

Objective(s): To synthesize evidence regarding osteosarcopenia syndrome combining osteoporosis and sarcopenia, and evaluate efficacy of resistance training and nutritional supplementation as nonpharmacological management strategies.

Material and Methods: Systematic literature review of PubMed database (2014–2024) using terms: "osteoporosis," "sarcopenia," "osteosarcopenia," "supplementation," "exercise training." Inclusion criteria: clinical trials, systematic reviews, meta-analyses evaluating resistance/weight-bearing exercise and nutritional interventions in elderly populations. DEXA, muscle mass assessment, and functional capacity measures were primary outcome variables.

Results: High-intensity resistance and weight-bearing exercise programs (2–3 sessions/week) demonstrated significant improvements in bone density and muscle strength in elderly. Resistance training reduced fracture-fall risk while increasing functional capacity. Nutritional interventions—calcium, vitamin D, vitamin K, magnesium from food sources preferred over isolated supplements—combined with adequate protein intake (including whey protein) and essential amino acids (creatine, branched-chain amino acids) enhanced muscle mass and strength gains. Multimodal interventions combining exercise plus nutrition showed superior outcomes versus monotherapy.

Conclusion(s): Osteosarcopenia represents prevalent, debilitating condition in aging populations amenable to evidence-based nonpharmacological management. Combining regular resistance training with optimized nutrition targeting bone and muscle health reduces falls, fractures, and functional decline, improving quality of life and independence in elderly. Lifestyle modifications constitute foundational strategy for prevention and disease mitigation.

COMORBIDITY OF OSTEOPOROSIS AND DEPRESSION IN INSTITUTIONALIZED ELDERLY: THERAPEUTIC ROLE OF STRUCTURED ACTIVITIES

G. C. M. Miguel[1,2], G. S. Souza[2], I. A. Alvarenga[2], Y. H. Haddad[2], N. N. Nonose[1], A. N. Ninomiya[1]

[1]Hospital Universitário São Francisco na Providência de Deus, Bragança Paulista, Brazil; [2]Universidade São Francisco, Bragança Paulsita, Brazil

Objective(s):
To examine the bidirectional relationship between osteoporosis and depression in institutionalized elderly and evaluate physical activities as therapeutic intervention for both conditions.
Material and Methods:
Systematic literature review conducted via PubMed using descriptors: "osteoporosis," "depression," "comorbidity," "elderly," "risk factors." Analysis focused on articles published within past 10 years examining pathophysiological mechanisms linking both conditions and therapeutic interventions in institutional settings.
Results:
Strong evidence supports significant association between osteoporosis and depression. Shared mechanisms include hormonal alterations (elevated cortisol, reduced estrogen/testosterone), systemic inflammation, and side effects of selective serotonin reuptake inhibitors (SSRIs) on bone metabolism. Physical activity emerged as key protective factor, improving bone density, mood, self-esteem, and social integration. Regular exercise programs combining resistance training and weight-bearing activities demonstrated efficacy in reducing depression symptoms while enhancing bone health outcomes.
Conclusion(s):
Depression and osteoporosis represent interconnected conditions in elderly populations that mutually exacerbate outcomes. Implementing structured physical activity programs (exercise, dance, painting, recreational activities) in long-term care facilities demonstrates potential to prevent and manage both conditions simultaneously, improving residents' quality of life and functional independence.

FRACTURE RISK ASSESSMENT IN INSTITUTIONALIZED ELDERLY USING FRAX: AN OBSERVATIONAL STUDY IN A PUBLIC NURSING HOME

G. C. M. Miguel[1,2], N. Z. Zordan[2], M. A. Antonialli[2], J. F. Ferreira[2], C. N. Nakamura[2], N. N. Nonose[1], A. N. Ninomiya[1]

[1]Hospital Universitário São Francisco na Providência de Deus, Bragança Paulista, Brazil; [2]Universidade São Francisco, Bragança Paulsita, Brazil

Objective(s):
To evaluate 10-year fracture risk using the FRAX tool in institutionalized elderly residents and identify clinical factors associated with increased fracture vulnerability.
Material and Methods:
Observational, analytical field study in 16 residents (age 61–89 years) of a public long-term care facility. FRAX data collected for 10-year fracture risk prediction. Inclusion criteria: cognitive capacity and communicative ability. Exclusion: non-institutionalized elderly, age <40 or >90 years, incomplete medical records. Ethics approval: CAAE 83246224.8.0000.5514. Descriptive statistics calculated; variables correlated.
Results:
Mean age 74.68±7.2 years; female predominance (68.75%). Residents >80 years demonstrated higher fracture probability, particularly those with age >80 years, previous fractures, corticosteroid use, and positive family history. Limited osteoporosis knowledge: 43.75% unaware of condition. Majority (56.3%) classified as intermediate fracture risk. Risk stratification using FRAX effectively identified vulnerable individuals independent of bone mineral density availability.
Conclusion(s):
FRAX represents accessible, practical tool for fracture risk stratification in institutionalized elderly. Implementation of FRAX assessment combined with complementary bone density evaluation facilitates early therapeutic intervention, preventing fragility fractures, reducing morbidity, and decreasing healthcare costs in this vulnerable population.

ENVIRONMENTAL AND BEHAVIORAL RISK FACTORS FOR FRACTURES IN DEMENTIA: A HOME SAFETY EVALUATION STUDY

G. C. M. Miguel[1,2], A. M. Moreira[2], I. S. Silveira[2], V. C. Chain[2], N. N. Nonose[1], A. N. Ninomiya[1]

[1]Hospital Universitário São Francisco na Providência de Deus, Bragança Paulista, Brazil; [2]Universidade São Francisco, Bragança Paulsita, Brazil

Objective(s):
To identify environmental and behavioral factors associated with falls and fractures in community-dwelling elderly with dementia and develop targeted prevention strategies.
Material and Methods:
This observational study conducted home safety evaluations in Bragança Paulista municipality (n=16 elderly with dementia). Assessments evaluated demographic data, anthropometric measures, fracture history (post-age 60), presence of osteoporosis, tobacco/alcohol use, sedentarism, and home hazards (loose rugs, bathroom supports, handrails on stairs, floor regularity/adherence, carpet presence, light switch location). Ethics Committee approval (CAAE 83246224.8.0000.5514).

Results:
Female predominance among fall victims (62.5%). Majority of falls occurred during daytime; primary location was home. Significant risk factors included low body weight (BMI <18.5), active smoking status, and osteoporosis diagnosis. These conditions increased probability of major fractures and hip fractures. Dementia significantly increased fall-fracture risk independent of age, sex, marital status, health conditions, alcohol use, and medication consumption.
Conclusion(s):
Dementia substantially elevates fall-fracture risk in elderly, even when controlling for traditional variables. Multifactorial interventions addressing both home modification and cognitive-behavioral support are essential for preventing fractures in this vulnerable population.

FRACTURE RISK ASSESSMENT TOOL (FRAX) IN ORTHOPEDIC PRACTICE: STRATIFICATION OF FRAGILITY FRACTURE RISK IN ELDERLY PATIENTS

G. C. M. Miguel[1,2], A. S. Simões[2], M. B. Brasilio[2], M. B. Bezerra[2], N. J. Júnior[2], N. N. Nonose[1], A. N. Ninomiya[1]

[1]Hospital Universitário São Francisco na Providência de Deus, Bragança Paulista, Brazil; [2]Universidade São Francisco, Bragança Paulsita, Brazil

Objective(s):
To apply the Fracture Risk Assessment Tool (FRAX) for evaluating 10-year fracture risk in elderly orthopedic clinic patients and stratify fracture risk profiles.
Material and Methods:
Observational study of 33 orthopedic clinic patients (age 40–93 years; 88% female; 82% elderly). FRAX data were collected via structured online questionnaires (CAAE 83246224.8.0000.5514). Clinical variables extracted included age, gender, body mass index, fragility fracture history, parental hip fracture history, corticosteroid use, rheumatoid arthritis status, and alcohol consumption. Bone mineral density (femoral neck) was available in 15 patients (DEXA).
Results:
FRAX stratification revealed: very high major fracture risk (39.4%, n=13), high risk (15.2%, n=5), intermediate risk (15.2%, n=5), and low risk (21.2%, n=7). Mean major fracture probability was 10% over 10 years; hip fracture probability approximately 6%. Among 15 patients with femoral neck BMD: eight classified as very high hip fracture risk, two high, five low.
Conclusion(s):
FRAX effectively identifies high-risk elderly patients requiring therapeutic intervention. This accessible tool enables fracture risk stratification regardless of BMD availability, facilitating early preventive management and reducing fragility fracture burden and associated healthcare costs.

LOWER EXTREMITY FRACTURES IN PATIENTS WITH SPINAL CORD INJURY SEQUELAE: COMPARATIVE ANALYSIS OF CONSERVATIVE AND SURGICAL MANAGEMENT

G. C. M. Miguel[1,2], A. T. Tescarolli[1], N. N. Nonose[1], R. B. Buainain[1], A. N. Ninomiya[1]

[1]Hospital Universitário São Francisco na Providência de Deus, Bragança Paulista, Brazil; [2]Universidade São Francisco, Bragança Paulsita, Brazil

Objective(s)
To report three cases of spinal cord injury (SCI) patients who sustained lower extremity fractures (4 total fractures), and to compare clinical outcomes, morbidity, and mortality between conservative and surgical management approaches.
Material and Methods
Retrospective case series review of three patients with spinal cord injury who sustained lower extremity fractures, with analysis of post-operative results and complications. Comparison included conservative treatment (immobilization) versus surgical management (intramedullary nailing, Girdlestone procedure, external fixation). Literature review was performed for comparative and supplementary data. Institutional Ethics Committee approval was obtained (CEP # 3.543.715, Universidade São Francisco).
Results
Case 1: Paraplegic male (L2 level, 10-year post-injury) presenting with two tibial fractures secondary to wheelchair fall. Right tibial fracture treated with intramedullary nailing; left tibial fracture managed conservatively with immobilization. Both fractures achieved consolidation. Case 2: Tetraplegic male (C4/C5 level, 28-year post-injury) presenting with subtrochanteric fracture treated surgically with Girdlestone procedure. Fracture healed without complications. Case 3: Paraplegic male (T10/T11 level, 5-year post-injury) presenting with proximal tibial fracture treated with Ilizarov external fixation. Fracture achieved complete consolidation. All three patients demonstrated low-energy trauma mechanisms. None had prior osteoporosis screening or prevention strategies. Surgical fixation (particularly internal fixation) demonstrated superior rehabilitation outcomes, shorter hospitalization, and improved patient mobilization compared to conservative management, despite equivalent union rates.
Conclusion(s)
Spinal cord injury patients demonstrate significantly elevated risk for lower extremity fractures, particularly in paraplegic individuals. While no difference in mortality and morbidity was observed between conservative and surgical approaches, surgical fixation (especially internal fixation)

provided superior functional outcomes during rehabilitation, including reduced immobilization periods, shorter hospital stay, and improved mobilization. Early osteoporosis detection and prevention represents critical opportunity for reducing fragility fracture risk in SCI population. Further prospective studies are warranted to optimize fracture management protocols in this vulnerable population.

SERUM LEVELS OF 25-VITAMIN D AND CALCIUM IN PATIENTS WITH DISTAL RADIUS FRACTURES: AN EMERGENCY DEPARTMENT STUDY

G. C. M. Miguel[1,2], V. W. Wagatsuma[1], R. B. Buainain[1], N. N. Nonose[1], A. N. Ninomiya[1]

[1]Hospital Universitário São Francisco na Providência de Deus, Bragança Paulista, Brazil; [2]Universidade São Francisco, Bragança Paulsita, Brazil

Objective(s)

To evaluate serum levels of 25-vitamin D and calcium in patients with distal radius fractures presenting to the emergency department of a university hospital.

Material and Methods

This was a prospective, descriptive, quantitative observational study conducted over three months (April-June 2018) at the Emergency Department of Hospital Universitário São Francisco (HUSF), Bragança Paulista, SP, Brazil. Patients with distal radius fractures admitted to emergency services were enrolled. Data collected included: age, sex, profession, weight, height (BMI calculation), physical activity level, comorbidities, fracture type and classification, trauma mechanism, dominant versus non-dominant hand involvement, and reduction outcomes. Single blood sample was obtained by nursing staff at presentation for serum calcium and 25-vitamin D measurement. Ethics Committee approval was obtained (CEP # 2.602.136, April 16, 2018, Hospital Universitário São Francisco).

Results

Ten patients met inclusion criteria (mean age 61.8 years; 80% female, 20% male). Fractures included 6 comminuted and 4 simple types. All fractures resulted from low-energy trauma (falls from standing height). Serum calcium levels ranged from 8.1-9.8 mg/dL: 7 patients normocalcemic, 3 hypocalcemic. Serum vitamin D levels ranged from 16.6-38.1 ng/mL, with mean below normal range: 5 patients insufficient (21-29 ng/mL), 3 deficient (<20 ng/mL), 2 normal (≥30 ng/mL). Comorbidities included hypertension (60% of sample), smoking (10%), and diabetes (10%). BMI >25 in 60% of patients. Successful reduction achieved in 100% of cases. Analysis demonstrates reduced serum vitamin D levels are common in distal radius fracture patients presenting to emergency care, particularly in elderly population with low-energy trauma mechanisms.

Conclusion(s)

Reduced serum vitamin D levels appear associated with increased frequency of distal radius fractures in the emergency department population. The majority of patients presented with insufficient or deficient vitamin D status. These findings suggest vitamin D assessment at acute fracture presentation may identify at-risk populations for prevention interventions. Vitamin D deficiency may contribute to poor

bone quality and increased fracture susceptibility. Further prospective studies with larger samples, extended follow-up, multicenter design, and assessment of potential confounding variables are needed to confirm the association between vitamin D status and distal radius fracture risk in acute care settings. Screening for and correction of vitamin D deficiency may represent an important prevention strategy for reducing fracture recurrence.

Acknowledgments

This study was approved by the Research Ethics Committee of Hospital Universitário São Francisco (CEP # 2.602.136, approved April 16, 2018). We acknowledge the support of nursing and orthopedic staff at Hospital Universitário São Francisco.

THE IMPACT OF DELAYED DRUG THERAPY ON OSTEOGENESIS IMPERFECTA DUE TO PUBLIC HEALTH SYSTEM

G. C. M. Miguel[1,2], R. B. Buainain[1], N. N. Nonose[1], A. N. Ninomiya[1], W. C. M. Miguel[2]

[1]Hospital Universitário São Francisco na Providência de Deus, Bragança Paulista, Brazil; [2]Universidade São Francisco, Bragança Paulsita, Brazil

INTRODUCTION: Osteogenesis imperfect (OI) is a genetic disorder with heterogeneous manifestations, characterized mainly by fragility in the bones due to defects in the structure or quantity of type 1 collagen (1). The main clinical manifestations of this disorder are: skeletal deformities, blueish scleras, imperfect dentinogenesis and deafness. The diagnosis can be done *in utero* by the ultrasounds. After birth, the diagnosis becomes prominently clinical, with supplementary lab work and imaging scans (2). Treatment should be precocious and multidisciplinary, using drug therapy with Pamidronate Disodium in patients under 18 years old, with the intention of diminishing the risk of fractures (3).

DESCRIPTION OF CASE

M.V.S.C., 1 year and 3 months old, female, born at 40 weeks of gestation, no family history of OI. The hypothesis of OI came up with the 30 week ultrasound, that showed long bones dysplasia (femur=4,45cm consistent with a 24 week fetus; ulna=4,47cm consistent with a 28 week fetus), and the suspicion of a fracture in the right femur. At birth, radiological exams highlighted bone thinning, including in the skull (Picture 03), as well as a fracture in the right femur. The case was forwarded to a reference service where the patient was diagnosed with OI Type III in the Sillence Classification.

Due to the lack of availability of the medication through the public health system, the start of treatment with Pamidronate Disodium was delayed. In the mean time the patient had various fractures throughout her first year of life.

At 1 year of age, the patient received her first dose of Pamidronate Disodium, wich is an inhibitor of bone reabsorption mediated by osteoclasts (1st day: 0,25mg/kg, 2nd and 3rd days: 0,5mg/kg). And also takes Cholecalciferol, 4 drops/day, and calcium carbonate, 500mg/day. In addition to the drug treatment, the patient also is also being monitored by a multidisciplinary team.

After beginning medication, the patient hasn't had any more fractures until now, which supports the importance of the drug therapy at the prognosis.

CONCLUSION

This report is a classic example of how drug therapy benefits the prognosis, with the caveat of an early intervention being needed. However, the late start to the therapy due to the lack of availability of the medication through the public health system at first, leads to the worsening of the clinical presentation during the waiting time for the medication, resulting in various fractures during this period.

REMS-BASED EVALUATION OF SKELETAL FRAGILITY IN PATIENTS WITH TYPE 2 DIABETES MELLITUS (T2DM)

M. La Spada[1], G. Del Vecchio[2], J. Bagli[3], G. Sorce[3], G. Pirrello[3]

[1]Head of the Reference Centre, Internal Medicine, Regional Reference Center for the Prevention, Diagnosis and Treatment of Osteoporosis, PTA Albanese, ASP Palermo, Palermo, Italy; [2]Department of Biological and Environmental Sciences and Technologies, University of Salento, Lecce, Italy; [3]Internal Medicine, Regional Reference Center for the Prevention, Diagnosis and Treatment of Osteoporosis, PTA Albanese, ASP Palermo, Palermo, Italy

Objective(s): Type 2 diabetes mellitus (T2DM) has emerged as a relevant risk factor for skeletal fragility despite exhibiting normal or even increased bone mineral density (BMD) when assessed by standard densitometric technologies such as dual-energy X-ray absorptiometry (DXA). This phenomenon is known as the "diabetic bone paradox," suggests an impairment of bone quality. In this context, this study aimed to evaluate BMD in patients with T2DM using Radiofrequency Echographic Multi Spectrometry (REMS) in comparison with DXA. In addition, bone quality was explored through the REMS Fragility Score (FS).

Materials and Methods: Inclusion criteria were: Caucasian individuals, both genders, with a diagnosis of T2DM that underwent both DXA and REMS scans at the same axial reference sites (lumbar spine and femur). Bone quantity was assessed by DXA- and REMS-BMD, whereas bone quality was evaluated using REMS-FS, a non-dimensional parameter ranging from 0 to 100, where higher values indicate a higher compromised microarchitectural framework. Comparisons between DXA- and REMS-BMD were analysed using paired *t*-test.

Results: A total of n = 99 patients (mean age = 73.1 ± 7.9 years) were included in the analysis. REMS-BMD values were significantly lower than DXA-BMD at the total hip (0.776 ± 0.116 *vs*. 0.834 ± 0.146 g/cm²) and femoral neck (0.630 ± 0.110 *vs*. 0.717 ± 0.133 g/cm²; $p < 0.0001$ for both). The mean REMS-FS was 45.4 ± 9.4, indicating compromised bone microarchitecture. Similar findings were observed at the lumbar spine.

Conclusion(s): This study demonstrated significant differences between REMS and DXA in the assessment of BMD in patients with T2DM, with REMS-BMD showing lower values, and thus revealing a higher prevalence of osteopenic/osteoporotic condition, as expected. Furthermore, the inclusion of bone quality analysis through REMS-FS enables the evaluation of skeletal microarchitectural and fragility, providing additional insights into the effects of T2DM on bone health. Overall, these findings support the potential role of REMS as a valuable tool to improve osteoporosis diagnosis and fracture risk assessment in patients with T2DM.

PREVIOUS FRACTURES AS A DETERMINANT OF FRAGILITY RISK IN SYSTEMIC SCLEROSIS

G. Del Vecchio[1], F. Conversano[2], M. La Spada[3], F. A. Lombardi[2], G. Peluso[4], P. Pisani[2], A. Semeraro[5], S. Casciaro[2]

[1]Department of Biological and Environmental Sciences and Technologies, University of Salento, Lecce, Italy; [2]Institute of Clinical Physiology, National Research Council, Lecce, Italy; [3]Head of the Reference Centre, Internal Medicine, Regional Reference Center for the Prevention, Diagnosis and Treatment of Osteoporosis, PTA Albanese, ASP Palermo, Palermo, Italy; [4]Department of Innovative Enginnering, University of Salento, Lecce, Italy; [5]U.O.S. Reumatologia "P.O. Valle D'Itria", Martina Franca, ASL – Taranto., Martina Franca, Italy

FC, MLS, FAL, GP, PP and AS equal contributors in alphabetic order

Objective(s): Patients affected by systemic sclerosis, a rare connective tissue disease characterized by progressive fibrosis of the skin and other internal organs, are at increased risk of osteoporosis due to chronic inflammation, reduced mobility and glucocorticoid therapy. In addition, comorbidities, including rheumatoid arthritis, thyroid disorders, hypercholesterolemia and previous fragility fractures, may further exacerbated the risk. This study aimed to assess skeletal fragility in patients with systemic sclerosis using Radiofrequency Ecographic Multi Spectrometry (REMS) technology, with a focus on the impact of previous fractures.

Materials and Methods: REMS femoral scans were performed on Caucasian men and women diagnosed with systemic sclerosis. REMS provides information on both bone quantity (BMD, T-score and Z-score) and bone quality (through the Fragility Score, FS). By combining T-score and FS, REMS also classify patients into 7 risk classes (named from R1–R7), each with a progressive probability to develop a short-term (within five-years) hip fracture.

Results: The study included 85 patients (mean age 65.13 ± 11.57 years; mean BMI 25.89 ± 3.75 kg/m²). REMS assessment revealed an average T-score of −2.2 ± 0.8 and an average FS of 66.43 ± 20.45, thus indicating a deterioration of both bone quantity and quality parameters. The fracture risk stratification showed that the 81% of the patients was classified in the high-risk categories (R5–R7). Specifically, individuals with a history of previous fractures were more frequently represented in the high-risk classes: the 30.8% of these patients, for example, was classified in R7.

Conclusion(s): Patients with systemic sclerosis exhibit a markedly elevated susceptibility to fragility with more than 80% classified in the high-risk classes. Moreover, a history of previous fractures was found to further exacerbate the risk, suggesting an additive effect of multiple predisposing factors. These findings highlight the importance of early bone assessment in this high-risk population. In this context, REMS technology emerges as a valuable, non-invasive tool for identifying individuals at increased fracture risk and supporting targeted prevention strategies.

MUSCULOSKELETAL ASSESSMENT BY RADIOFREQUENCY ECHOGRAPHIC MULTI SPECTROMETRY (REMS) IN WOMEN WITH OVARIAN CANCER

V. A. Capozzi[1], M. Capurso[1], A. De Finis[1], G. Del Vecchio[2], D. Sabia[1], R. Berretta[1]

[1]Unit of Gynecology and Obstetrics, University Hospital of Parma, Parma, Italy; [2]Department of Biological and Environmental Sciences and Technologies, University of Salento, Lecce, Italy

Objective(s): Cancer and related treatments are commonly associated with functional impairment and reduced physical activity, which together represent major determinants of health-related quality of life. These alterations often lead to progressive musculoskeletal deterioration, increasing the risk of frailty, falls, and fractures, particularly in oncological populations. This study aimed to evaluate the musculoskeletal system in women with ovarian cancer by using the Radiofrequency Echographic Multi Spectrometry (REMS) technology.

Materials and Methods: Inclusion criteria encompassed Caucasian women with a diagnosis of ovarian cancer who underwent REMS-based assessment of bone and muscle status at femur and thigh, respectively. REMS is a non-invasive and ultrasound-based technology that enables an integrated evaluation of the musculoskeletal system. Bone health is assessed by both bone quantity (BMD, T-score and Z-score) and bone quality (Fragility Score, FS) parameters. FS is a dimensionless and BMD-independent score ranging from 0 to 100, with higher values indicating greater compromised microarchitectural structure and increased skeletal fragility. Likewise, muscle health status is evaluated by a quantitative parameter strictly related to qualitative (muscle quality index, MQI) features.

Results: A total of n = 20 women were included in the analysis (mean age = 59.7 ± 12.5 years). Ovarian cancer patients showed a lower mean total femoral BMD compared with controls (0.770 ± 0.150 *vs*. 0.790 ± 0.120; p = 0.447). Bone quality analysis revealed higher FS values in comparison to controls (40.03 ± 7.46 *vs*. 34.79 ± 18.11; p = 0.46). Likewise, muscle assessment impaired thigh muscle quality (MQI = 62.57 ± 10.7).

Conclusion(s): These findings highlight the impairment of the musculoskeletal system in ovarian cancer women. Early and targeting intervention may be crucial to prevent progression towards osteoporotic and/or sarcopenic conditions, which can significantly impair mobility and quality of life and increase the rate of disability, fractures, hospitalization and mortality. In this context, REMS technology may represent a valuable tool for the integrated assessment of the musculoskeletal fragility, with potential implications for clinical practice and preventive strategies.

P633

SUSTAINED EFFECTIVENESS OF CR500 TOPICAL HYDROGEL IN MILD TO MODERATE KNEE OSTEOARTHRITIS: EVIDENCE FROM A RETROSPECTIVE FOLLOW-UP STUDY

G. Doro[1], P. Petrillo[1], L. Forte[2], F. Zerbinati[1]

[1]Orthopedics and Traumatology Department, Humanitas Mater Domini, Varese, Italy; [2]Contrad Swiss SA, Lugano, Switzerland

Introduction
Hyaluronic acid is widely used for symptomatic osteoarthritis, and its benefit typically lasts six months, requiring repeated treatments. Well tolerated and non-invasive alternatives capable of symptom control and delaying further medical interventions for osteoarthritis remain a clinical need.

Objectives
To assess the long-term clinical effectiveness and satisfaction in patients treated with CR500 hydrogel for mild to moderate knee osteoarthritis.

Material and Methods
A retrospective follow-up study was conducted in 35 out of 38 patients enrolled in the CR500 trial (NCT05661162). Participants were contacted at least 24 months after the last study visit. The primary endpoint was the change in Lequesne Knee Index (LKI) between the last study visit (V4) and the follow-up visit (V5). Secondary endpoints included recurrence of pain for the same condition, need and timing of additional therapies and long-term patient satisfaction with CR500. Paired non-parametric analyses and descriptive statistics were performed.

Results
29 out of 35 eligible patients were successfully contacted and included in the follow-up analysis. In the overall population, mean LKI decreased from 5.88 ± 2.1 at V4 to 4.98 ± 3.1 at V5, corresponding to a 15.3% improvement, showing a trend toward statistical significance (p=0.084). Excluding patients who underwent knee replacement (n=27), LKI improvement became significant, reaching 23.6% (p=0.009). Excluding patients who underwent or were scheduled for knee replacement (n=22), the LKI improvement increased to 30.9% and remained statistically significant (p=0.0019).
Although most patients reported recurrence of knee pain at the follow up visit, 55.6% described lower pain intensity compared to baseline, while 6.9% reported no recurrence. The mean interval between CR500 treatment and the first subsequent therapy for symptom recurrence was 9.6 ± 10.6 months.
Long-term satisfaction was high, with 82.8% of patients willing to repeat CR500 treatment and no negative responses reported.

Conclusions
These follow-up data suggest sustained algofunctional benefit, delayed need for additional interventions, exceeding the average effect reported for viscosupplementation cycles, and high patient satisfaction beyond 24 months, supporting the role of CR500 therapy as a non-invasive option for mild to moderate knee osteoarthritis, with a clinically meaningful duration of effect of at least nine months.

POST-COVID-19–ASSOCIATED UNILATERAL LOWER LIMB LYMPHEDEMA: A CASE REPORT

M. C. K. Calkin Korkmaz[1], S. H. Haliloglu[1], M. K. A. Karacaatli Erdogan[1], Z. Yasar Aydin[1], G. G. Gunes[1]

[1]Kartal Dr. Lütfi Kırdar City Hospital, Istanbul, Türkiye

Introduction
Lymphedema is a chronic disorder caused by impaired lymphatic drainage, resulting in progressive tissue swelling, fibrosis, and functional limitation. Secondary lymphedema is most commonly associated with malignancy, oncologic surgery, radiotherapy, infection, trauma, or venous pathology. Coronavirus disease 2019 (COVID-19) is characterized by systemic inflammation, endothelial dysfunction, and microvascular injury. While vascular and thrombotic complications of COVID-19 have been extensively reported, potential involvement of the lymphatic system remains poorly understood. Recently, isolated case reports have suggested that COVID-19 infection or vaccination may trigger lymphatic dysfunction, leading to secondary lymphedema. These observations raise awareness of COVID-19 as a possible novel risk factor for lymphatic failure.

Case Report
A 75-year-old woman presented with progressive swelling of the left lower extremity that had developed approximately one month prior to admission. Her medical history was unremarkable for malignancy, previous surgery, radiotherapy, trauma, or known venous disease. She had been hospitalized two months earlier for COVID-19 infection due to respiratory symptoms and received inpatient treatment without requiring intensive care unit admission or mechanical ventilation. One month after discharge, she noticed gradual, painless swelling of her left leg. She denied erythema, fever, skin lesions, or symptoms suggestive of cardiac, renal, or hepatic disease.
Physical examination revealed non-erythematous swelling extending from the ankle to the thigh, consistent with early-stage lymphedema. There were no signs of infection or skin breakdown. Duplex Doppler ultrasonography demonstrated normal venous flow, with no evidence of deep vein thrombosis or venous insufficiency. Cross-sectional imaging excluded pelvic or abdominal masses and malignancy, and laboratory findings were unremarkable. After exclusion of alternative etiologies, a diagnosis of secondary unilateral lower limb lymphedema associated with prior COVID-19 infection was established. Conservative management, including compression therapy, skin care, and therapeutic exercises, resulted in partial improvement during follow-up.

Discussion
This case illustrates the development of unilateral lower limb lymphedema following COVID-19 infection in an elderly patient without classical risk factors for secondary lymphedema. COVID-19–related endothelial dysfunction, inflammatory cytokine release, and microvascular injury may also affect lymphatic vessels due to shared structural and functional characteristics with the vascular endothelium. Proposed mechanisms include inflammatory obstruction of lymphatic channels, lymphatic endothelial damage, and reduced lymphatic contractility. Advanced age, reduced lymphatic reserve, hospitalization, and decreased mobility during acute illness may further predispose patients to post-COVID lymphatic dysfunction. Although rare, similar cases reported in the literature support a possible association. Recognition of post-COVID lymphedema is essential for early diagnosis and prevention of long-term morbidity.

P636

A YOUNG MALE OSTEOPOROSIS PATIENT PRESENTING WITH BILATERAL ASEPTIC NECROSIS OF THE FEMORAL HEAD

S. H. Haliloglu[1], M. K. Çalkın Korkmaz[1], G. I. Ince[1]

[1]Health Sciences University Kartal Dr. Lutfi Kırdar City Hospital, Physical Medicine and Rehabilitation, Istanbul, Türkiye

INTRODUCTION

Osteoporosis is frequently associated with postmenopausal women and advanced age, leading to delays in diagnosis and treatment in young men. The SFR-GRIO (French Society of Rheumatology- Group for Research and Information on Osteoporosis) approach recommends treatment for men with a T-score <−1 in men with severe osteoporotic fractures, <−2 in those with any fracture, and all men with a T-score <−3. Bisphosphonates are among the basic treatment options in male osteoporosis.

CASE REPORT

A 26-year-old male patient was consulted due to suspected sacroiliitis and fasciculations in the left leg. The patient had been receiving hyperbaric oxygen therapy for 9 days with a diagnosis of early-stage femoral head avascular necrosis (AVN) and had bilateral hip-groin pain for 3 months. The pain was mechanical in nature and persisted at night (VAS: right 4, left 10). Physical examination revealed limited movement of the left hip due to pain; FABERE and FADIR tests showed bilateral pain. Laboratory investigations revealed no pathology except for a slight elevation of CRP. A plain pelvic X-ray was normal. Magnetic resonance imaging showed subchondral bone marrow edema in the left femoral head consistent with Stage 1 AVN. Bone scintigraphy showed minimally increased activity in the left femoral head. Rheumatological disease was ruled out. BMD measurements showed T and Z scores between -2.6 and -3.2 in the lumbar spine and femur, leading to a diagnosis of osteoporosis. The patient received zoledronic acid infusion. Endocrinological evaluation revealed low total testosterone and high prolactin and cortisol levels; further investigation into secondary causes of osteoporosis was planned.

DISCUSSION

This case is noteworthy because it is a young male osteoporosis patient presenting with AVN clinical presentation, exhibiting inflammatory and mechanical hip pain without significant systemic findings. Although osteoporosis is not frequently associated with pain, it should definitely be considered in the differential diagnosis even in young male patients when appropriate clinical clues are present.

P637

MICRORNAS AS INTEGRATORS OF BONE REMODELING AND SYSTEMIC METABOLISM IN OSTEOPOROSIS

G. Iacobescu[1], B. Serban[2], M. I. G. Popa[2], C. Cirstoiu[2]

[1]University Emergency Hospital Bucharest, Department of Orthopedics and Traumatology, "Carol Davila" Univesity of Medicine and Pharmacy, Bucharest, Romania; [2]University Emergency Hospital Bucharest, Department of Orthopedics and Traumatology, "Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania

Objectives

The objective of this study is to provide a critical analysis of the most recent scientific evidence identifying microRNAs which are involved in the interaction between osteoblasts and osteoclasts, as well as in regulating body metabolism in osteoporosis. These results will identify how a decreased level of bone strength may be influenced by disturbances in metabolic processes in addition to disturbances in the inflammatory process and hormonal levels.

Materials and Methods

Using a structured literature review of studies indexed in PubMed from 2020 to 2026, we identified both experimental and translational studies using a systematic search strategy related to the role of miR-21, miR-29, miR-133a and miR-214 in controlling bone remodeling, the intercellular communication between different cell types involved in bone remodeling and metabolic signaling pathways. The research studies were chosen based upon the ability of each study to provide a mechanistic explanation of how the microRNAs studied interact with other cells within the bone environment including an evaluation of the use of extracellular vesicles for delivering miR-21, miR-29, miR-133a and miR-214 to osteoblasts.

Results

Research conducted during the past five years provides strong evidence demonstrating that the four microRNAs described above play important roles in regulating the three components of bone remodeling i.e., osteoblast differentiation, osteoclast activity and osteocyte signaling. miR-214 was demonstrated to be one of the most significant osteoclast derived extracellular vesicle cargoes that inhibit osteoblast differentiation thereby negatively coupling osteoblasts and osteoclasts. In contrast, miR-21 and miR-29 exhibit context dependent regulation of bone formation and resorption and their effect on bone turnover varies depending on whether there are inflammatory or metabolic conditions present. miR-133a is consistently associated with low BMD and therefore may represent a potential circulating biomarker for assessing risk of developing osteoporosis.

Conclusion

Collectively, the findings of this study suggest that the four microRNAs discussed above serve as central regulators of both bone remodeling and systemic metabolism in osteoporosis. Understanding the context dependent and pleiotropic action of these microRNAs is necessary to develop biomarkers for detecting individuals at increased risk for developing osteoporosis and to design microRNA-targeting therapeutic approaches that can selectively target specific tissues involved in bone remodeling.

P638

SEASONAL VARIATION IN RECRUITMENT IN LONG-TERM CARE RESEARCH: INSIGHTS FROM THE PREVENT TRIAL

G. Ioannidis[1], S. Feldman[2], P. Katz[3], A. P. Costa[1], C. Kennedy[1], J. D. Adachi[1], L. Giangregorio[4], H. Boyd[5], G. Heckman[6], P. Hewston[1], J. Hirdes[7], J. Holroyd-Leduc[8], M. Howard[5], J. Ho[9], S. Jaglal[10], S. Kaasalainen[11], L. Kristof[5], A. Lau[1], J. Lee[1], C. Mcarthur[12], S. Marr[1], D. O'Donnell[13], I. B. Rodrigues[14], K. Shankardass[15], H. Siu[5], S. Straus[16], S. Thrall[1], J.-E. Tarride[17], L. Thabane[17], S. Hafid[17], J. Tung[9], W. Lok Ok Choo[1], L. M. Hillier[1], L. L. Kane[1], A. M. Azizudin[1], T. Dias Desinghe[18], A. Papaioannou[1]

Objective(s) In Canada, despite challenges, long term care (LTC) research is critical to improving practice and addressing outcomes such as falls and fractures. The objective of this analysis was to examine seasonal variation in recruitment in LTC research using preliminary data from the PREVENT trial.

Material and Methods LTC homes across Ontario, Canada were invited to participate in the PREVENT trial between 2024–2025. Recruitment engagement was defined as any response (yes/no) by the home (≥50 beds) to the invitation to participate in the trial. Response rates were summarized descriptively overall and by season (winter (Jan-Mar), spring (Apr-Jun), summer (Jul-Sep), and fall (Oct-Dec)), and examined by home size (50–99 beds, ≥100 beds), profit status (for-profit, not-for-profit), and rurality (census metropolitan area (CMA), census agglomeration (CA), rural).

Results Between 2024 and 2025, 576 homes were contacted and 348 (60%) LTC homes responded to the PREVENT trial invitation, including 104 (30%) small (50-99) and 238 (70%) large homes (≥100 beds), 189 (55%) for-profit and 157 (45%) not-for-profit homes and 224 (65%) CMA, 53 (15%) CA and 69 (20%) rural homes. Recruitment varied by season, with the highest engagement in spring (51%), followed by summer (25%), winter (20%), and fall (3%). Engagement was highest in spring across all categories, including home size (small (51%), large (53%)), profit status (for-profit (58%), not-for-profit (44%)), and rurality (CMA (51%), CA (62%), and rural (45%)). The lowest engagement rates were observed in the fall (small (3%), large (2%), for-profit (3%), not-for-profit (4%), CMA (3%), CA (2%), and rural (4%)).

Conclusion(s) Recruitment to LTC research in PREVENT, showed clear seasonal variation, with higher engagement in spring across home size, profit status, and rurality. This variation likely reflects fluctuations in organizational capacity, staff availability, and planning cycles. Higher spring engagement aligns with new fiscal year planning, government regulations and fewer competing demands. Lower fall and winter engagement may coincide with accreditation, infectious outbreaks and vaccine campaigns. Strategically aligning recruitment with seasonal variation can improve efficiency by concentrating resources during high-yield periods and reducing operational barriers to LTC research participation.

P639

THE SILENT EPIDEMIC: IDENTIFYING AND MANAGING UNDIAGNOSED OSTEOPOROSIS IN SPINE FRACTURE PATIENTS

G. Kakadiya[1]

[1]Ashirwad Spine Hospital, Surat, India

Background: Osteoporosis is a major public health concern, yet it remains profoundly underdiagnosed, particularly in patients who have already experienced a fragility fracture. Vertebral compression fractures (VCFs) are frequently the first clinical manifestation but often go unrecognized or untreated, contributing to a high risk of subsequent, debilitating fractures. This care gap highlights the failure of secondary fracture prevention efforts.

Objective: This study aimed to determine the prevalence of previously undiagnosed osteoporosis in patients presenting with acute vertebral fractures and to evaluate the feasibility and effectiveness of implementing a standardized, inpatient-initiated fracture risk assessment and management protocol in this high-risk population.

Methods: A prospective study was conducted on 150 patients (mean age 72, 78% female) admitted with a new symptomatic VCF. All patients underwent bone mineral density (BMD) measurement via dual-energy X-ray absorptiometry (DEXA) and a comprehensive medical history review to ascertain prior diagnosis and treatment status. Patients diagnosed with osteoporosis (T-score ≤ -2.5) or osteopenia were initiated on a guideline-based treatment plan before discharge.

Results: Of the 150 patients, 105 (70.0%) were diagnosed with osteoporosis, and 30 (20.0%) with osteopenia, totaling 90% who required pharmacological intervention. Crucially, 95% of these patients had no prior formal diagnosis or anti-osteoporotic treatment initiated by their primary care provider. The implementation of the systematic management protocol resulted in a 98% rate of appropriate treatment initiation and patient education at discharge.

Conclusion: Undiagnosed osteoporosis is rampant among patients with vertebral fractures, confirming the "silent epidemic" status. Systematic screening using DEXA and immediate initiation of secondary fracture prevention protocols are critical interventions required within the acute care setting to address this significant public health failure and reduce the burden of recurrent fragility fractures.

P640

RISK ASSESSMENT FOR SECONDARY FRACTURES FOLLOWING INITIAL VERTEBRAL COMPRESSION: A PREDICTIVE MODELS

G. Kakadiya[1]

[1]Ashirwad Spine Hospital, Surat, India

Objective: Secondary vertebral compression fractures (sVCFs) represent a common and debilitating complication following an initial VCF, leading to increased morbidity, mortality, and healthcare costs. This study aimed to develop and validate robust predictive models capable of accurately assessing an individual patient's risk of developing sVCFs.
Methods: A retrospective cohort of 850 patients with a history of initial VCF was analyzed. Data encompassing demographic, clinical (e.g., age, sex, BMI), pharmacologic (e.g., anti-osteoporosis treatment history), and radiographic parameters (e.g., T-score, initial fracture severity via Genant classification, sagittal balance metrics such as Sagittal Vertical Axis (SVA)) were collected. We employed several machine learning methodologies, including Logistic Regression, Random Forests, and Gradient Boosting Machines (GBM), to identify the optimal model for predicting sVCF incidence within a 2-year follow-up period.
Results: The Gradient Boosting Machine (GBM) model exhibited the superior predictive performance, achieving an Area Under the Curve (AUC) of 0.88 (95% CI: 0.85–0.91) on the validation set. Feature importance analysis revealed that low Bone Mineral Density (T-score), advanced age, and pre-existing sagittal malalignment (increased SVA) were the most significant predictors of secondary fracture risk. The model stratified patients into three distinct risk groups (low, moderate, high), with the high-risk group demonstrating a 5.4-fold increased hazard ratio compared to the low-risk group.
Conclusion: Predictive models, particularly the GBM approach, offer a powerful and non-invasive tool for personalized risk stratification of sVCFs. Implementing this model in clinical practice can facilitate the early identification of high-risk patients who would benefit most from aggressive prophylactic measures, such as immediate anti-osteoporosis therapy, targeted exercise, or tailored bracing, thereby potentially improving outcomes and reducing the burden of recurrent fractures.

P641

HIGH-RESOLUTION PERIPHERAL QUANTITATIVE CT (HR-PQCT) ANALYSIS OF TRABECULAR BONE MICROARCHITECTURE IN THE LUMBAR SPINE

G. Kakadiya[1]

[1]Ashirwad Spine Hospital, Surat, India

Introduction: High-resolution peripheral quantitative computed tomography (HR-pQCT) provides exquisite detail of bone microarchitecture *in vivo*, but its application has been historically limited to peripheral appendicular sites. The lumbar spine (LS) is a critical site for osteoporotic fracture, and standard dual-energy X-ray absorptiometry (DXA) often fails to capture crucial microarchitectural deterioration. This study aimed to investigate the feasibility of adapting and utilizing HR-pQCT technology to non-invasively analyze the trabecular microarchitecture of the L3 vertebral body and to characterize its relationship with clinical bone mineral density (BMD) measures.
Methods: A custom, high-resolution scanning protocol was developed using a standard HR-pQCT system to acquire axial images of the L3 vertebral body in a cohort of 50 older adults (25 male, 25 female, mean age 72 ± 8 years). Images were processed using dedicated registration and segmentation algorithms to isolate the central trabecular compartment, free from cortical shell artifacts. Key microarchitectural parameters were calculated, including trabecular bone number (Tb.N), trabecular thickness (Tb.Th), trabecular separation (Tb.Sp), bone volume fraction (BV/TV), and volumetric BMD (vBMD). These parameters were correlated with standard LS DXA T-scores and fracture history.
Results: The HR-pQCT protocol successfully generated high-quality, three-dimensional images of the L3 trabecular architecture, demonstrating clear differences between subjects with and without a history of fragility fracture. LS vBMD derived from HR-pQCT showed a strong correlation with DXA T-scores ($r=0.78, p<0.001$). Crucially, microarchitectural parameters—particularly reduced Tb.N and increased Structure Model Index (SMI), indicating a shift towards rod-like structures—provided discriminatory power independent of DXA T-score (Odds Ratio for fracture per standard deviation reduction in Tb.N: 2.5, 95% CI: 1.3–4.9, $p=0.005$).
Conclusion: The non-invasive HR-pQCT technique is feasible for detailed *in vivo* assessment of trabecular microarchitecture within the lumbar spine. This innovative application offers a potent research tool for characterizing age-related and disease-related structural decline at a critical fracture site, potentially enabling superior fracture risk stratification beyond current clinical standards.

P642

METFORMIN AS PART OF THE PROTOCOL IN THE TREATMENT OF KNEE OSTEOARTHRITIS?

G. Kavaja[1], B. Kavaja[2], S. Tonuzi[1]

[1]Durres Regional Hospital, Durres, Albania; [2]Faculty of Medicine, Tirane, Albania

Background. Osteoarthritis and type 2 diabetes mellitus often occur together as a consequence of risk factors such as age and obesity. High blood sugar levels enable the production of elements that damage cartilage and bone, while diabetes-related inflammation and impaired metabolism damage joint health, worsening the clinical course of OA and the pain of patients.
Objective. This study aims to evaluate the effects of metformin on knee pain in patients diagnosed with OA and DM.
Methods. The study included patients presenting to the rheumatology clinic with the main complaint of knee pain. Patients were divided into 2 groups. The first group included 50 patients (mean age 58.6) diagnosed with knee osteoarthritis according to EULAR criteria (presence of pain, morning stiffness, limitation of range of motion in one or 2 joints, narrowing of the joint space on radiographs). The second group included 48 patients (mean age 60.2) diagnosed with knee osteoarthritis and type 2 diabetes mellitus treated with metformin 500 mg twice a day. Exclusion criteria were the presence of other diseases such as diabetes mellitus treated with insulin, cardiovascular diseases and other inflammatory rheumatic diseases. Patients in both groups were evaluated at the beginning of the study, after 3 months and at the end of 6 months through clinical assessment (WOMAC, VAS scale) and laboratory examinations (ERS, CRP, fasting and 2-hour postprandial glucose levels). Both groups, which had similar characteristics regarding age, gender, BMI and severity of osteoarthritis, were treated for osteoarthritis according to established protocols.

Results. In the group of patients with osteoarthritis and diabetes mellitus, a greater reduction in pain, morning stiffness and improvement in functional activity (according to WOMAC and VAS scale) was evidenced compared to the group of patients with osteoarthritis alone in both control phases ($p < 0.05$). The values of acute phase tests of inflammation were lower in the group treated with metformin, measured after 3 months and 6 months compared to the beginning of the study ($p < 0.005$).
Conclusion. These results show that the presence of metformin use during osteoarthritis disease has influenced the alleviation of symptoms and clinical signs as well as inflammation indicators. Further studies are needed to determine a more important role for the use of metformin in the treatment of osteoarthritis even in patients without diabetes mellitus.
Keywords. Osteoarthritis, diabetes mellitus, VAS scale

P643

MCCUNE–ALBRIGHT SYNDROME IN CLINICAL PRACTICE: THREE-CASE SERIES FROM ARGENTINA.

G. Kluwak[1], M. Giannattasio[2], C. Ramacciotti[3], M. C. Pereyra[4], F. Berti[4], O. D. Messina[5]

[1]Unidad de Salud Osea Grupo Oroño, Rosario, Argentina; [2]Hospital Néstor Kirchner El cruce, F. Varela, Argentina; [3]Hospital Privado Universitario de Córdoba, Córdoba, Argentina; [4]Clínica Universitaria Reina Fabiola, Córdoba, Argentina; [5]Fundación de Investigaciones Reumatológicas y Osteológicas, Buenos Aires, Argentina

Introduction: McCune–Albright syndrome (MAS) is a rare sporadic disorder characterized by fibrous dysplasia, café-au-lait skin pigmentation, and endocrine hyperfunction. Skeletal involvement may progress leading to deformities, fractures, chronic pain, and significant morbidity in adulthood.
Herein, we report three adult cases from Argentina illustrating the clinical heterogeneity and longterm burden of MAS.

Objective: report clinical cases highlighting skeletal involvement and disease-related complications.
Case 1. A 44-year-old woman with MAS, diagnosed in the presence of café-au-lait skin pigmentation, fibrous dysplasia, and a history of precocious puberty and hyperthyroidism. She showed radiological progression of fibrous dysplasia. At evaluation, she presented inflammatory polyarthritis and was diagnosed with seropositive rheumatoid arthritis. Imaging revealed extensive craniofacial fibrous dysplasia with middle and inner ear involvement. Laboratory evaluation showed increased FGF23 levels. Treatment with intravenous zoledronic acid was initiated.

Case 2. A 21-year-old woman with polyostotic MAS, diagnosed in early childhood due to peripheral precocious puberty treated with GnRH analogs. She sustained rib fractures requiring surgical resection and prosthetic reconstruction, with histological confirmation of fibrous dysplasia. Imaging showed extensive skeletal involvement, including ribs, spine, pelvis, and hips, with an expansive lytic iliac lesion and soft tissue extension. She is currently managed with intravenous pamidronate, and analgesics for chronic pain, under multidisciplinary follow-up with significant impact on quality of life.

Case 3. A 40-year-old woman with long-standing polyostotic MAS, diagnosed after precocious puberty and confirmed by bone biopsy in adolescence. She presents extensive skeletal involvement, chronic disabling bone pain without history of fractures. Imaging revealed marked craniofacial involvement and widespread uptake on bone scintigraphy. She has associated endocrinopathies, including hypothyroidism. Despite prolonged intermittent oral bisphosphonate therapy, pain and biochemical activity persist, with limited access to advanced antiresorptive treatments, resulting in significant impairment of quality of life.

Conclusion: These three cases illustrate the marked clinical heterogeneity of McCune–Albright syndrome in adults, with variable skeletal burden, endocrine involvement, and impact on quality of life. A multidisciplinary approach and individualized long-term follow-up are essential to optimize outcomes in this rare disorder.

P644

HODGKIN LYMPHOMA WITH INITIAL BONE INVOLVEMENT: ANALYSIS OF A CLINICAL CASE

M. Giannattasio[1], P. Bizarri[1], M. Girardi[2], M. D. Posadas[3], R. Patiño[4], M. Fabra[5], G. Kluwak[6]

[1]Hospital Nestor Kirchner, El cruce. Fcio Varela, Fcio Varela , Argentina; [2]Hospital Nestor Kirchen, EL cruce. Fcio Varela, Fcio Varela , Argentina; [3]Hospital Nestor Kirchner, EL cruce. Fcio Varela, Fcio Varela , Argentina; [4]Hospital Luisa C. de Gandulfo, Lomas de Zamora , Argentina; [5]Hospital Luisa C de Gandulfo, Lomas de Zamora , Argentina; [6]Grupo Oroño, Rosario , Argentina

Bone lymphomas are rare (3–8% of primary bone cancers), with B-cell lymphoma being the most common. Hodgkin lymphoma (HL) accounts for only 3%. A distinction must be made between primary bone lymphoma, where bone is the only affected site, and initial bone involvement by HL, where simultaneous lymphadenopathy is frequent. This entity typically presents between the second and fifth decades of life and shows a marked male predominance (4:1). Pain is often the sole symptom and is frequently misinterpreted as other conditions such as osteomyelitis or arthritis. The most commonly affected sites are the pelvis, spine, and proximal femur. Radiologically lesions may appear lytic, sclerotic, or mixed lesions. Combined chemotherapy and radiotherapy have demonstrated high response rates, with 10-year survival ranging from 60% to 84%.
Objective:
To analyze a case of Hodgkin lymphoma with bone involvement, highlighting the clinical features and diagnostic approach to facilitate early identification of this entity arising from an uncommon location. To analyze a case of Hodgkin lymphoma with bone involvement, highlighting its clinical presentation and diagnostic approach in order to facilitate early recognition of this rare manifestation.
Clinical Case:
A 22-year-old female patient presented in 2025 with progressive, incapacitating pain in the left hip. It was initially interpreted as osteoarthritis, and she received nonsteroidal anti-inflammatory drugs without improvement. Four months later, she developed fever. A CT scan of the chest, abdomen, and pelvis revealed multiple mediastinal and pulmonary lymphadenopathies, as well as lytic lesions in the left iliac crest. Subsequent PET/CT and biopsy of a mediastinal mass confirmed the diagnosis of classic Hodgkin lymphoma (CD30+/CD15+). She completed chemotherapy and is currently under interdisciplinary follow-up by hematology-oncology, traumatology, and endocrinology. The

mediastinal disease is in remission, with residual bone lesion sequelae. Bone biopsy results are pending. She received two doses of zoledronic acid due to low bone mass and severe pain in the affected region.
Conclusion:
This case highlights the need to approach patients with bone pain unresponsive to analgesics from a broader perspective, incorporating more specific complementary diagnostic methods to identify less frequent but more severe conditions.

P645

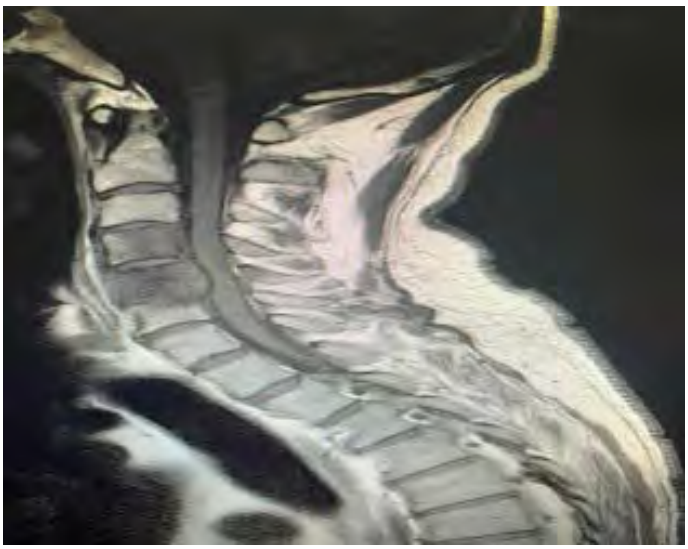
ANALYSIS OF ADVERSE EFFECTS OF ZOLEDRONIC ACID IN THE TREATMENT OF OSTEOPOROSIS

A. Zayaeva[1], G. Koshukova[1], Y. Shulezhko[1]

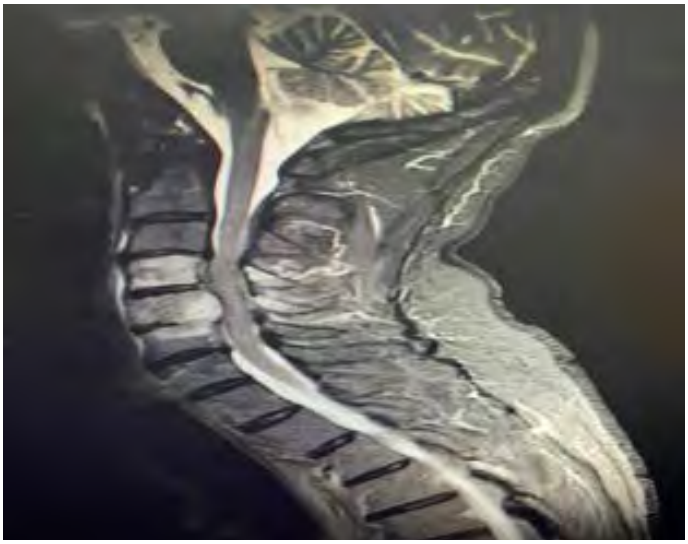
[1]V.I. Vernadsky Crimean Federal University, Simferopol, Russia

Introduction. Zoledronic acid (ZA) belongs to the latest, third-generation bisphosphonates (BPs), which have a selective effect on bone tissue. Along with therapeutic effects, ZA can cause some adverse effects (AEs). The main side effects (SE) of ZA are temporary, minor in severity.
Objective. To analyze the occurrence of AEs associated with the use of ZA in patients undergoing treatment for osteoporosis (OP).
Materials and methods. 32 patients (29 women and 3 men), mean age 54.23±7.12 years, with a diagnosis of Osteoporosis. The occurrence of AEs during the IV infusion of ZA 5 mg in 12 months with a therapy duration of 1 to 3 years was evaluated. The AEs were divided into acute phase reactions (APRs) – occurring directly during the period of the drug administration and postinfusion reactions (PIR): early (up to 14 days after the infusion) and late (after 14 days). The follow-up period was 12 months (n=32), 24 months (n=21), and 36 months (n=15).
Results. In general, patients showed good tolerance to IV infusion of ZA - 31.3% of patients did not note any AEs. APRs were recorded in 4 patients (12.5%) in the form of arterial hypertension (n=2), headache (n=1) and hyperthermia (n=1). All AEs were regarded as moderate intensity, not requiring infusion interruption. Most of the AEs occurred in the early post-infusion period – 62.5% (n=20). Among the early APRs, hyperthermia (56.3%) prevailed, with a duration of 1 to 8 days. Arthralgia (53.1%), myalgia (46.9%), and influenza-like syndrome (34.3%) were also observed with high frequency. Less common (1-10%) symptoms included palpitations, dizziness, hypotension, transient facial flushing, hyperhidrosis, and nausea. Among the late-onset APRs, muscle cramps (31.3%), asthenia (25.0%), and jaw osteonecrosis (9.4%) were prevalent, with 2 out of 3 patients with jaw osteonecrosis having a malignant neoplasm.
Conclusions: The side effects were mild and short-lived, and similar to other side effects. Early adverse events, such as hyperthermia, arthralgia/myalgia, and flu-like symptoms, were observed with the highest frequency,and they were effectively managed with the use of NSAIDs.

P646



CERVICAL PAIN REVEALING LUNG CANCER: A CASE REPORT



H. Ben Ayed[1], G. Majouli[1], L. Ben Ammar[1], I. Fenniche[1], R. Dhahri[1], I. Gharsallah[1], S. Ouali Besseghaier[2], M. Aloui[2]

[1]Rheumatology department, Principal Military Hospital of Tunis, Tunis, Tunisia; [2]Radiology department, Principal Military Hospital of Tunis, Tunis, Tunisia

Introduction
Cervical pain is a common complaint and is most often benign. However, persistent cervicalgia associated with general condition deterioration or neurological signs should raise suspicion of an underlying malignant disease. We report a case of cervical pain revealing metastatic lung cancer, highlighting the importance of early recognition of red flags.

Case Presentation
A 58-year-old man with a past medical history of resolved hepatitis B and treated pulmonary tuberculosis, presented with chronic cervical pain evolving over five months. He did not report morning stiffness nor nocturnal awakenings. However, he complained of an unintentional weight loss of 10 kg over one year.
Physical examination revealed painful and restricted cervical spine mobility, associated with pyramidal signs, including brisk deep tendon reflexes in all four limbs and bilateral motor weakness of the gluteus maximus muscles. Laboratory investigations were strictly normal.
Computed tomography (CT) of the cervical spine demonstrated multiple lytic lesions involving C4 to C6 with epidural extension. Spinal magnetic resonance imaging confirmed a multifocal infiltrative lesion responsible for cervical spinal cord compression, maximal at the level of C5. (Figures 1 and 2)

Figures 1 and 2: Infiltrative lesion of the C4–C6 vertebral bodies, hypointense on T1

(Figure 1) and intermediate signal on T2 (figure 2).
Thoraco-abdomino-pelvic computed tomography revealed a left apical lung mass associated with bilateral pulmonary nodules.
A CT-guided percutaneous lung biopsy confirmed a moderately differentiated pulmonary adenocarcinoma. The patient was transferred to the neurosurgery department for cervical spine stabilization and subsequently referred to oncology for further management.

Discussion
Spinal involvement is a frequent manifestation of metastatic lung cancer and may be the first clinical presentation. Cervical localization, although less common than thoracic or lumbar involvement, is particularly severe because of the high risk of spinal cord compression and neurological complications.
This case illustrates that normal laboratory findings do not exclude a neoplastic cause in the presence of persistent pain and neurological signs. Imaging is therefore decisive.

Conclusion
Inflammatory cervical pain may reveal metastatic lung cancer. Early identification of warning signs is essential to improve neurological and functional outcomes.

P647
CALCIFIC LIGAMENTITIS OF THE LATERAL COLLATERAL LIGAMENT: A RARE CAUSE OF ACUTE KNEE PAIN

H. Ben Ayed[1], G. Majouli[1], L. Ben Ammar[1], I. Fenniche[1], R. Dhahri[1], I. Gharsallah[1], S. Ouali Besseghaier[2], M. Aloui[2]

[1]Rheumatology department, Principal Military Hospital of Tunis, Tunis, Tunisia; [2]Radiology department, Principal Military Hospital of Tunis, Tunis, Tunisia

Introduction

Calcification of the ligaments and tendons is a heterogeneous disease characterized by the storage of calcium hydroxyapatite crystals in various shapes and sizes on or between the collagen fibrils. It's a well-known pathology involving the shoulder joint. However, there are few reports on the lateral collateral ligament (LCL) calcification.

Case Presentation

We present a case of a 60-year-old woman with insulin-dependent diabetes, with no prior history of knee pain, who presented with an acute left knee pain associated with complete functional impairment. Pain intensity was rated at 9/10 on the visual analogue scale. There was no history of trauma, fever, or general condition deterioration. Osteoarticular examination was unremarkable except for the left knee, which was swollen, with a positive patellar tap and reduced range of motion due to pain. The diagnosis of septic arthritis was suspected. Laboratory investigations revealed leukocytosis of 11,000/mm³, associated with an elevated C-reactive protein level of 20 mg/L. Arthrocentesis of the left knee revealed inflammatory synovial fluid containing 3500 white blood cells/mm³, predominantly neutrophils. Standard radiography of the left knee revealed a well-defined calcific deposit in the soft tissue adjacent to the lateral femoral condyle (Figure 1)

Figure 1: Anteroposterior radiograph of the knee joint shows a well-defined
calcific deposit in the soft tissue adjacent to the lateral femoral condyle

A primary bone tumor, benign or malignant, was suspected, and septic arthritis was ruled out after negative synovial fluid cultures.
After 48 hours, the patient experienced spontaneous resolution of pain with normalization of CRP levels.
A repeat radiograph showed a marked reduction in the size of the calcified lesion. Hydroxyapatite crystal arthropathy was suspected and subsequently confirmed by knee computed tomography, which showed a thickened, irregular, and partially calcified lateral collateral ligament at its femoral condylar insertion, with a calcific deposits within the synovial recess associated with reactive synovitis.

Discussion
Calcific ligamentitis of the LCL is an extremely rare cause of lateral knee Pain (1). Only 16 cases were reported in the literature (1,2)

Conclusion
Calcification of the LCL should be considered in case of acute knee pain, particularly in elderly and diabetic patients. Recognition of this entity allows avoidance of inappropriate treatment and unnecessary invasive investigations.

EFFECT OF SMOKING ON DISEASE ACTIVITY IN ANKYLOSING SPONDYLITIS: A RETROSPECTIVE STUDY

H. Ben Ayed[1], G. Majouli[1], I. Fenniche[1], M. Dahmen[2], K. Hached[2], L. Ben Ammar[1], A. Dghaies[1], R. Dhahri[1], I. Gharsallah[1], I. Mejri[3], Z. Moetamri[3]

[1]Rheumatology department, Principal Military Hospital of Tunis, Tunis, Tunisia; [2]Faculty of Medecine of Tunis, Tunis, Tunisia; [3]Pneumology department , Prinicipal military hospital of Tunis, Tunis, Tunisia

Introduction

Ankylosing spondylitis (AS) is a chronic inflammatory rheumatic disease primarily affecting the axial skeleton. Its clinical course may be influenced by environmental factors, among which smoking has been identified as a potential aggravating factor. However, the precise impact of smoking status and cumulative tobacco exposure on AS disease activity remains controversial.

Objective

To evaluate the effect of smoking on the clinical and biological activity of ankylosing spondylitis.

Methods

A retrospective descriptive study was conducted over a 12-month period (January–December 2024) in the Rheumatology Department of the Principal Military Instruction Hospital of Tunis. Patients fulfilling the ASAS 2009 classification criteria for ankylosing spondylitis were included.

Clinical and paraclinical data were collected from patients' medical records. Participants were divided into two groups according to smoking status:

Group 1 (G1): non-smokers or former smokers who had quit smoking for more than 12 months

Group 2 (G2): current smokers or recent quitters (≤ 12 months)

Disease activity was assessed using validated indices, including the Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) and the Ankylosing Spondylitis Disease Activity Score with C-reactive protein (ASDAS-CRP). Patient-reported outcomes and inflammatory biomarkers were also analyzed.

Results

The study population was predominantly male (86%, n = 44), with a mean age of 42 ± 11 years and a mean disease duration of 10 ± 8 years. Group 1 included 32 patients, while Group 2 included 23 patients. Among smokers, the mean cumulative tobacco exposure was 19.2 ± 11.5 pack-years (PY).

Smoking patients exhibited significantly higher disease activity compared to non-smokers. ASDAS-CRP was significantly higher in smokers than in non-smokers (2.74 ± 1.1 vs. 2.04 ± 0.72; p = 0.03). BASDAI was also higher in smokers (3.21 ± 1.78 vs. 2.34 ± 1.22), showing a trend toward statistical significance (p = 0.051).

Significant positive correlations were observed between smoking status and ASDAS-CRP (r = 0.270; p = 0.048), as well as between smoking status and patient global assessment (r = 0.281; p = 0.045), reflecting a greater perceived disease burden among smokers. In contrast, cumulative tobacco exposure expressed in pack-years was not significantly associated with any disease activity parameter. No significant association was found between smoking status and inflammatory biomarkers.

Conclusion

Smoking is associated with increased disease activity in ankylosing spondylitis. The absence of a relationship with cumulative tobacco exposure suggests that the detrimental effect is primarily related to current smoking status. These findings support the role of smoking as a modifiable risk factor and emphasize the importance of smoking cessation as an integral component of the comprehensive management of patients with ankylosing spondylitis.

P649

THERAPEUTIC MAINTENANCE OF METHOTREXATE IN RHEUMATOID ARTHRITIS

H. Ben Ayed[1], G. Majouli[1], I. Fenniche[1], L. Ben Ammar[1], R. Dhahri[1], I. Gharsallah[1], S. Ouali Besseghaier[2], M. Aloui[2]

[1]Rheumatology department, Principal Military Hospital of Tunis, Tunis, Tunisia; [2]Radiology department, Principal Military Hospital of Tunis, Tunis, Tunisia

Introduction: Methotrexate (MTX) remains the cornerstone of conventional disease-modifying therapy in rheumatoid arthritis (RA). Evaluating its long-term therapeutic maintenance provides key insights into both its effectiveness and tolerability in real life clinical practice.

Objective: To assess the maintenance rate of MTX in patients with RA and to identify clinical and immunological factors associated with treatment discontinuation.

Methods: We conducted a retrospective study including patients meeting the 2010
ACR/EULAR classification criteria for RA. Demographic, clinical, immunological, and therapeutic data were extracted from medical records. Statistical analyses were performed using SPSS version 25, with a significance threshold set at $p < 0.05$.

Results: Seventy patients (55 women and 15 men) with a mean age of 55.2 ± 13 years and a mean disease duration of 8.66 ± 5.5 years, were included . Immunological assessment showed positivity for rheumatoid factor (RF) in 68.2%, anti-cyclic citrullinated peptide antibodies (ACPA) in 87%, and antinuclear antibodies (ANA) in 32% of patients. The mean baseline disease activity assessed by the DAS28-ESR was 3.5 ± 1.45. MTX was prescribed to 64 patients (91.4%). Mean treatment duration was 52.1 ± 50.9 months, with extremes of 1 month and 240 months. MTX retention rates were 77.1% at 1 year, 68.6% at 2 years, and 37.1% at 5 years.

The main reasons for MTX discontinuation were secondary inefficacy (n = 14), primary inefficacy (n = 2), desire for pregnancy (n = 3), gastrointestinal intolerance (n= 1), hematotoxicity (n = 2), and development of rheumatoid nodules (n = 2).

Statistical analysis revealed a significant negative correlation between MTX treatment duration and ANA positivity (r = -0.248, p = 0.015), as well as with the duration of symptoms before MTX initiation (r = -0.48, p = 0.01).

Conclusion:
This study confirms the central role of MTX in RA, with satisfactory short- and medium-term retention rates that decline markedly by 5 years. ANA positivity and longer symptom duration before treatment initiation appear to predict shorter MTX maintenance. These findings highlight the importance of early MTX initiation and suggest that ANA status may influence therapeutic response, warranting tailored monitoring.

P650

EFFECT OF SMOKING ON RESPIRATORY FUNCTION IN PATIENTS WITH ANKYLOSING SPONDYLITIS: A RETROSPECTIVE STUDY

H. Ben Ayed[1], G. Majouli[1], I. Fenniche[1], M. Dahmen[2], K. Hached[2], L. Ben Ammar[1], R. Dhahri[1], I. Gharsallah[1], A. Dghaies[1], I. Mejri[3], Z. Moetamri[3]

[1]Rheumatology department, Principal Military Hospital of Tunis, Tunis, Tunisia; [2]Faculty of Medecine of Tunis, Tunis, Tunisia; [3]Pneumology department , Prinicipal military hospital of Tunis, Tunis, Tunisia

Introduction Ankylosing spondylitis (AS) is a chronic inflammatory rheumatic disease primarily affecting the axial skeleton. It may lead to respiratory impairment due to thoracic ankylosis and, occasionally, parenchymal or pleural involvement. Smoking, a well-known risk factor for pulmonary disease and systemic inflammation, may exacerbate these respiratory complications.

Objective To assess the effect of active smoking and cumulative tobacco exposure on respiratory parameters in patients with ankylosing spondylitis.

Methods A retrospective descriptive study was conducted including patients with AS fulfilling the ASAS 2009 classification criteria. All patients underwent a comprehensive respiratory evaluation, including clinical assessment, chest radiography, spirometry with measurement of forced vital capacity (FVC) in upright and supine positions, and thoracic ultrasonography assessing diaphragmatic excursion, thickness, and the presence of B-lines.
Patients were divided into two groups: non-smokers or former smokers abstinent for more than 12 months, and active smokers or recent quitters (≤ 12 months). Cumulative tobacco exposure was quantified in pack-years (PY).

Results Fifty-five patients were included, predominantly male (86%), with a mean age of 42 ± 11 years. Active smokers (n = 32) had a mean cumulative tobacco exposure of 19.2 ± 11.5 PY.
FVC in both upright and supine positions was significantly lower in smokers (p = 0.022 and p = 0.013, respectively), with a significant negative correlation between smoking status and supine FVC (r = −0.297; p = 0.034). No significant differences were observed in forced expiratory volume (FEV_1), FEV_1/FVC ratio (Tiffeneau index), or the prevalence of restrictive ventilatory defects between groups.
Ultrasonographic assessment revealed reduced inspiratory thickness of the right hemidiaphragm in smokers compared to non-smokers (3.07 ± 0.64 mm vs. 3.38 ± 0.40 mm; p = 0.04). In contrast, diaphragmatic excursion, thickening fraction, and the presence of B-lines did not differ significantly. Clinical respiratory symptoms, auscultatory findings, and radiographic abnormalities were comparable between groups.
Multivariate analysis showed that reduced FVC was independently associated with higher BMI, increased BASMI score, and absence of biologic therapy, whereas smoking status was not an independent predictor.

Conclusion In patients with ankylosing spondylitis, smoking is associated with reduced forced vital capacity and decreased diaphragmatic thickness. However, these effects appear to be indirect, likely mediated by thoracic ankylosis and suboptimal inflammatory control. These findings highlight the importance of smoking cessation in conjunction with optimal rheumatologic management to preserve respiratory function in this population.

IMPACT OF METABOLIC SYNDROME ON CLINICAL AND THERAPEUTIC FEATURES OF KNEE OSTEOARTHRITIS

G. Matoussi[1], H. Bettaieb[1], M. Boudokhane[1], S. Jouini[1], M. H. Douggui[1], S. Belakhel[1], C. Besrour[2], W. Helali[1], R. Bourguiba[1]

[1]FSI hospital la Marsa, Tunisia, Tunisia; [2]FSI hospital la Mrsa, Tunisia, Tunisia

Background: Knee osteoarthritis (KOA) is a leading cause of pain and disability. Beyond mechanical factors, metabolic syndrome (MetS) is increasingly recognized as a contributor through metabolic and inflammatory pathways. Data from North African populations remain limited.
Objective: To compare clinical features and therapeutic management of KOA in patients with and without MetS.
Methods: This cross-sectional study included 100 patients with KOA followed in our rheumatology department. Patients were classified as MetS+ or MetS− according to IDF 2009 criteria. Demographic, clinical, and therapeutic data were collected. Pain was assessed using the visual analog scale (VAS). Statistical comparisons were performed with significance set at $p < 0.05$.
Results: Among 100 patients (79 women, 21 men; mean age 62.9 ± 9.8 years), disease duration averaged 4 years. Fifty-two percent had MetS. MetS+ patients had older age at disease onset (59.6 ± 9.9 vs. 55.1 ± 8.3 years; p = 0.017). They more frequently reported joint instability, with higher rates of knee crepitus (69.2% vs. 43.7%; p = 0.009), joint locking (48.1% vs. 8.3%; p < 0.001), and giving way (67.3% vs. 43.8%; p = 0.026). VAS scores were significantly higher in MetS+ (65 ± 12.9 vs. 45.8 ± 11.8; p < 0.001). Patellar grind test was more often positive (98.1% vs. 81.3%; p = 0.006), as was tibiofemoral joint line tenderness (25.0% vs. 4.2%; p = 0.004). No significant differences were found regarding disease duration, gait disturbance, use of analgesics, NSAIDs, symptomatic slow-acting drugs, knee brace, or rehabilitation.
Conclusion: MetS was associated with a more painful and symptomatic phenotype of KOA, supporting the concept of a metabolic form of the disease. Systematic screening and integrated management of MetS may be essential in these patients.

INFLUENCE OF DEMOGRAPHIC CHARACTERISTICS ON THE PRESENCE OF METABOLIC SYNDROME IN PATIENTS WITH KNEE OSTEOARTHRITIS

G. Matoussi[1], H. Bettaieb[1], M. Boudokhane[1], S. Jouini[1], S. Belakhel[1], C. Besrour[2], M. H. Douggui[1], W. Helali[1], R. Bourguiba[1]

[1]FSI hospital la Marsa, Tunisia, Tunisia; [2]FSI hospital la Mrsa, Tunisia, Tunisia

Introduction Metabolic syndrome (MS)—defined by abdominal obesity, hypertension, dyslipidemia, and insulin resistance—is increasingly recognized as a contributor to chronic diseases, including osteoarthritis [1]. Sociodemographic characteristics may influence its prevalence, but few studies have examined their role in knee osteoarthritis (KOS).

Objective To evaluate the impact of sociodemographic characteristics on the presence of MS in patients with KOS.

Methods This cross-sectional study was conducted at the Rheumatology outpatient clinic of our hospital over six months (April–October 2025). Patients were classified according to the presence or absence of MS using International Diabetes Federation (IDF 2009) criteria. Variables included age, sex, occupation, physical activity, smoking, education, residential environment, and clinical parameters. Comparisons between MS+ and MS− groups were performed with significance set at $p < 0.05$.

Results One hundred patients (79 women, 21 men) were included, mean age 62.9 ± 9.8 years, mean disease duration 4 years. Fifty-two percent had MS. Patients with MS were significantly older than those without (64.9 ± 9.7 vs 60.7 ± 9.7 years; $p = 0.026$). The age of symptom onset was also higher in the MS+ group (59.6 ± 9.9 vs 55.1 ± 8.3 years; $p = 0.017$). Occupational distribution differed ($p = 0.006$): in MS+, 71.2% were housewives, 21.2% retirees, and 7.7% employed, compared to 33.3% employed, 52.1% housewives, and 14.6% retirees in MS−. No significant differences were observed for sex ($p = 0.97$), physical activity ($p = 0.48$), smoking status ($p = 0.431$), educational level ($p = 0.97$), or residential environment ($p = 0.71$).

Conclusion In patients with KOS, advanced age, later age of symptom onset, and certain occupations—particularly being a housewife—are associated with MS. These findings highlight the importance of considering sociodemographic and clinical factors when assessing metabolic risk, to improve prevention and management strategies.

ASSOCIATION BETWEEN PRE-FRACTURE CARE ADHERENCE AND POST-FRACTURE OUTCOMES: A RETROSPECTIVE ITALIAN COHORT STUDY

I. C. Antonazzo[1], C. Fornari[1], D. Rozza[1], P. Ferrara[1], A. Zucchi[2], S. Tillati[2], R. Ciampichini[2], L. G. Mantovani[1], M. L. Brandi[3], G. Mazzaglia[1]

[1]Center for Public Health Research, University of Milan–Bicocca, Monza, Italy, Monza, Italy; [2]Epidemiology Unit, Bergamo Health Protection Agency, Bergamo, Italy, Bergamo, Italy; [3]Italian Fragility Fracture Observatory (OFF Italia), Italy, Italy, Italy

Objectives Osteoporotic fractures represent a major contributor to global morbidity, disability, and excess mortality. While international societies recommend broad approach to improve patient management, existing evidence focuses predominantly on pharmacological interventions rather than the overall pre-fracture care pathway. Therefore, this study investigated the association between pre-fracture patient management and the subsequent risk of re-fracture and mortality in fractured individuals.

Material and Methods We first conducted a review of national and international osteoporosis guidelines published since 2015 to identify best-practice indicators. Subsequently, we performed a retrospective cohort study using healthcare administrative databases from the Local Health Protection Agency of Bergamo, Italy. We included individuals aged 65 years or older with a diagnosis of osteoporotic hip/femur fracture between January 1, 2012, and December 31, 2023 (Index Date, ID). Patients with less than 5 years of data availability were excluded. Adherence to identified indicators in the year preceding the ID was categorized as low (0–1 indicators), medium (2–3), or high (4+). We assessed the likelihood of initiating anti-fracture therapy post-ID using logistic regression. The association between indicators' adherence and both mortality (Cox regression) and re-fracture risk (Fine-Gray model) after adjusting for confounding via inverse probability of treatment weighting was investigated.

Results Seven indicators were identified: pharmacologic treatment, vitamin D/calcium optimization, laboratory assessment of bone dysfunction, testing for secondary osteoporosis causes, bone mineral density evaluation, specialist consultation, and physical therapy. The study included 8,741 subjects: 5,441 low, 2,776 medium, and 524 high adherent. Most individuals demonstrated low adherence to these indicators in the year preceding the index date. High pre-fracture indicators' adherence significantly increased the likelihood of post-fracture therapy uptake, ranging from an OR of 1.27 (95% CI 1.04–1.54) for those with 1 indicator to 8.61 (5.09–14.55) for those with 5+ indicators. Furthermore, high indicators' adherence was associated with reduced mortality risk in patients aged 85+ years (HR: 0.80; 0.73-0.86), and a significantly lower risk of re-fracture in the overall population (HR: 0.74; 95% CI 0.64–0.86).

Conclusions This study highlights that early engagement of patients at risk of fracture significantly improves management trajectories even after a fracture event. Public health interventions aiming to increase awareness among patients and clinicians are warranted to optimize patient management and reduce the overall burden of osteoporosis.

P654

SACRAL CHORDOMA DEMYSTIFIED: FROM NOTOCHORDAL ORIGINS TO MULTIMODAL MANAGEMENT

G. Muscatella[1], M. Montatore[1], F. Masino[1], R. Gifuni[2], A. Sciacqua[2], M. Balbino[2], G. Guglielmi[2]

[1]Department of Clinical and Experimental Medicine, Foggia University School of Medicine, Viale L. Pinto 1, Foggia, Italy; [2]Department of Clinical and Experimental Medicine, Foggia University School of Medicine, Viale L. Pinto 1,, Foggia, Italy

Objective:
To provide radiologists and clinicians with a concise, educational overview of sacral chordomas, emphasizing their pathophysiology, imaging hallmarks, surgical challenges, and current limitations of adjuvant therapy. The aim is to enhance recognition, guide multidisciplinary management, and highlight areas for future research.

Methods:
Sacral chordomas are rare malignant tumors originating from notochordal remnants. Despite low-grade histology, they are locally aggressive, growing adjacent to critical structures such as the rectum, bladder, and sacral nerve roots. **CT and MRI** are essential: CT evaluates bony destruction and central calcifications, while MRI delineates soft tissue extension, neural involvement, and helps in preoperative planning. Histopathology confirms diagnosis via physaliferous cells. Literature and institutional experience were integrated to provide a comprehensive educational perspective.

Results:
CT commonly demonstrates lobulated, destructive masses with intralesional calcifications. MRI clearly defines soft tissue and neural involvement, crucial for surgical strategy. **Wide en bloc resection** is the standard approach, yet achieving clear margins is often challenging. Radiotherapy can reduce recurrence risk but is not curative. Imaging remains pivotal for diagnosis, operative planning, and follow-up, allowing early detection of recurrence and aiding long-term surveillance. Figures illustrate typical imaging features (Fig 1).

Conclusion:
Sacral chordomas are a diagnostic and therapeutic challenge due to their invasive behavior and anatomical constraints. Radiologists play a central role in early identification, characterization, and guidance of multidisciplinary care. Awareness of imaging hallmarks, combined with precise radiologic evaluation, supports optimized surgical planning and follow-up. Continued research into targeted molecular therapies is urgently needed to improve long-term outcomes.

Limitations:
Findings are based on literature and institutional experience; patient-specific variability may limit generalizability.

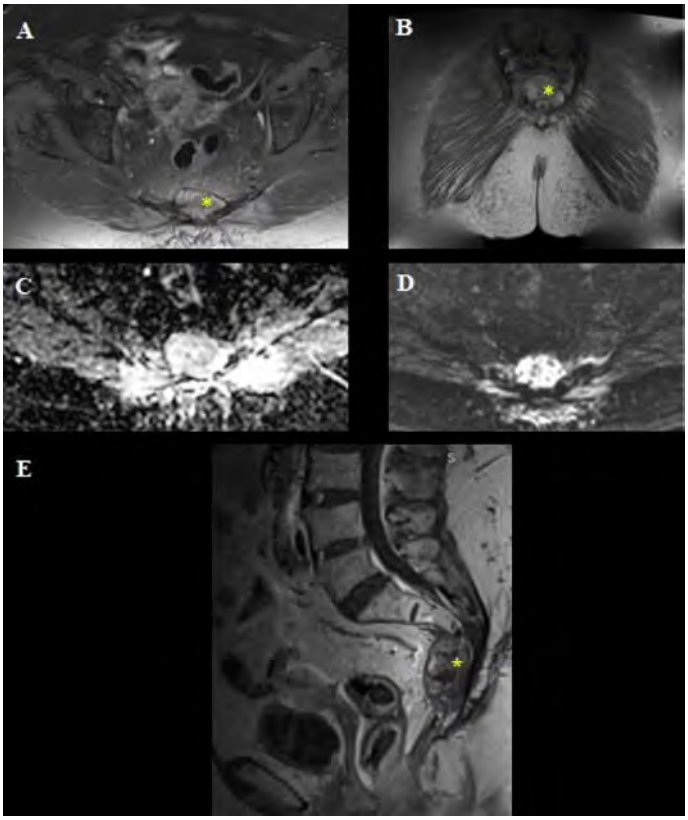

Fig 1:*MRI images of a sacral cordoma: A) Axial image in proton density (PD) sequence showing the chordoma (indicated with a yellow asterisk), which appears well-circumscribed with irregular margins, typical of chordomas, reflecting their heterogeneous composition, including mucinous, cartilaginous, and necrotic elements. B) Coronal image in PD, showing the same lesion with variable signal intensity due to its mixed tissue composition. C) Diffusion-weighted imaging (DWI) at b=50 s/mm², demonstrating no signal restriction, suggesting low cellularity, which is characteristic of chordomas. The use of b=50 is appropriate for low-cellularity tumors, where diffusion is less restricted. D) Apparent Diffusion Coefficient (ADC) map, confirming the lack of signal restriction and supporting the low cellularity of the chordoma, with higher ADC values due to reduced cellularity. E) Sagittal image in T1-weighted sequence, where the lesion appears heterogeneously iso- to hypointense compared to surrounding muscle, with a less dense central region, consistent with the typical appearance of chordomas due to their mucinous and cartilaginous components.*

P655

LIPOMA ARBORESCENS OF THE SHOULDER: A RARE CASE ASSOCIATED WITH ROTATOR CUFF TEAR

G. O. Ergin Ergani[1]

[1]Department of Physical Medicine and Rehabilitation, Etlik City Hospital, Ankara, Türkiye

Introduction: Lipoma arborescens is a rare, benign synovial disorder characterized by villous lipomatous proliferation of the synovial membrane. It most commonly affects the knee joint, while shoulder involvement is uncommon and has been reported as isolated case reports. This report presents a rare case of shoulder lipoma arborescens associated with rotator cuff tear, shoulder pain and subacromial impingement symptoms.

Clinical case: A 62-year-old male patient presented with left shoulder pain for over one year with progressive worsening in recent months. He denied any history of trauma. Physical examination revealed full shoulder range of motion with pain during abduction and internal rotation. Neer, Hawkins and Jobe tests were positive. Drop arm test was negative. Magnetic resonance imaging (MRI) revealed full-thickness tear of the supraspinatus tendon, subacromial-subdeltoid bursal effusion and a lobulated, villous proliferative mass within the subdeltoid bursa showing hyperintense signal on T1-weighted images with signal suppression on fat-saturated sequences (Figure). The lesion was diagnosed as lipoma arborescens based on MRI findings. Surgical intervention was recommended; however the patient declined surgery. Conservative treatment including physical therapy and non-steroidal anti-inflammatory drugs resulted in symptomatic and functional improvement.

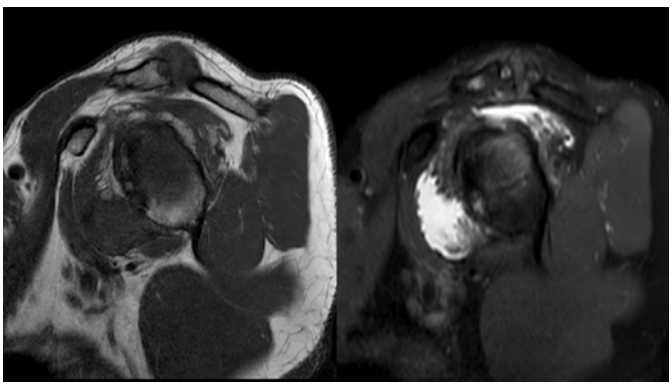

Figure: T1-weighted and fat-suppressed T2-weighted shoulder MRI images show villous fatty synovial proliferation consistent with lipoma arborescens.

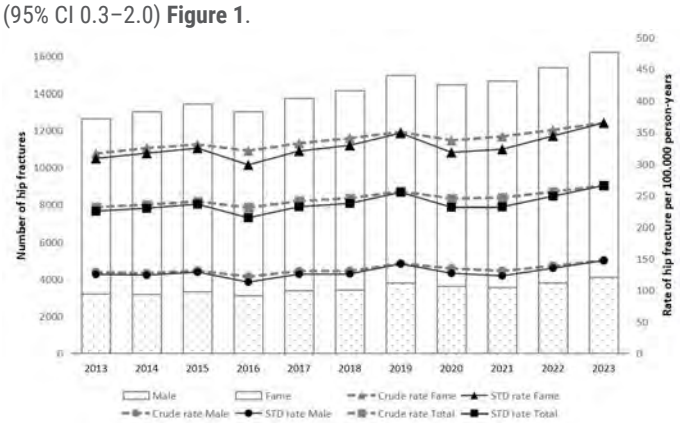
Discussion: The etiology of lipoma arborescens remains unclear and has been associated with mechanical irritation, degenerative and inflammatory joint diseases. It typically presents as monoarticular involvement of the knee; however, rare cases affecting the shoulder, elbow and wrist have been reported. Early recognition is important, as prolonged synovial proliferation may contribute to persistent inflammation. MRI is the key modality for diagnosis with distinctive features.

Conclusion: This case contributes to the limited literature on shoulder involvement and emphasizes the need for awareness in musculoskeletal practice.

P656

NATIONAL TRENDS IN THE INCIDENCE OF HIP FRACTURES IN PORTUGAL, 2013-2023



G. P. Pimentel[1], P. L. Lourenço[2], A. M. Marques[3], J. Pereira da Silva[1]

[1]Department of Rheumatology, Coimbra Local Health Unit, Coimbra, Portugal; [2]Department of Orthopaedics, Coimbra Local Health Unit, Coimbra, Portugal; [3]UICISA:E – Health Sciences Research Unit: Nursing, Nursing School of the University of Coimbra, Coimbra, Portugal

Objective(s):
To describe temporal trends in the incidence and hospital burden of proximal femoral fractures (PFF) in Portugal between 2013 and 2023 and to compare incidence patterns in 2019-2023 versus 2006-2010[1].

Materials and methods: We conducted a nationwide retrospective cross-sectional study including all adults aged 40 years or older admitted with PFF to public hospitals in mainland Portugal (2013-2023). Episodes were identified in the National Hospital Discharge Register using ICD-9-CM code 820 (until 2016) and ICD-10-CM code S720 (from 2017 onwards). Demographic data, length of stay, surgery within 48 hours, and in-hospital mortality were extracted. Crude and age-standardized incidence rates per 100.000 inhabitants were calculated using population estimates and the age structure of 2023 as a reference. Time trends were analyzed using generalized linear models (Poisson/negative binomial), and the results were compared with published data for 2006-2010.

Results: Between 2013 and 2023, 159.725 admissions for PFF were recorded. In mainland Portugal, annual cases increased from 12.663 in 2013 to 16.200 in 2023 (+27.9%), corresponding to an average of 322 additional fractures per year. Over the same period, the total resident population in mainland Portugal increased by 2.1% (9.937.008 *vs* 10.142.079), whereas the population aged ≥40 years increased by 11.4% (approximately 5.5 to 6.1 million). The average age at admission for PFF was 81.6 years (women 82.7; men 78.4). Among surgically treated patients, 44% underwent surgery within 48 hours The average length of stay was 15.2 days and in-hospital mortality was 5.6%, being higher in men than in women (9.3% vs. 4.4%; p<0.001). In the population aged ≥40 years, the crude incidence increased from 231 to 266 per 100.000 inhabitants, while the age-standardized incidence increased from 225 to 266 per 100.000 inhabitants, with an average annual increase of 1.2% (95% CI 0.3–2.0) **Figure 1**.

Compared with 2006–2010, admissions in 2019–2023 increased by 46.4%, driven mainly by men aged 55–69 and women aged 50–69, while incidence stabilized or decreased slightly in older age groups. **Figure 2**.

Conclusion: From 2006 to 2023, hip fracture admissions increased in Portugal, alongside a rise in age-standardized incidence that cannot be explained by population ageing alone. This increase is concentrated among younger men, whereas incidence has stabilized or decreased in older age groups, supporting targeted prevention strategies and wider implementation of Fracture Liaison Services.

P657

NURSES' PERCEIVED COMPETENCIES AND ORGANISATIONAL BARRIERS IN FRACTURE LIAISON SERVICES IN PORTUGAL: A CROSS-SECTIONAL SURVEY

G. P. Pimentel[1], A. M. Marques[2]

[1]Department of Rheumatology of the Local Health Unit of Coimbra/School of Nursing of the University of Coimbra, Coimbra, Portugal; [2]UICISA: E - Health Sciences Research Unit: Nursing of the School of Nursing of the University of Coimbra, Coimbra, Portugal

Objective: To characterise Portuguese nurses' perceived clinical competencies for secondary prevention of fragility fractures and to identify key organisational barriers reported by nurses working in Fracture Liaison Services (FLS).

Methods: A cross-sectional, anonymous online survey was conducted among Portuguese nurses involved in secondary prevention care for patients with fragility fractures in acute hospital settings. Participants included nurses from 11 of the 16 nationally registered FLS, as well as nurses providing equivalent care in hospitals without an established FLS. The questionnaire was informed by the Global Fragility Fracture Network (FFN) Secondary Fragility Fracture Prevention Competency Framework and included: sociodemographic and professional characteristics; FLS status (existing/implementation stage); perceived clinical competencies across six domains (15 items; Likert scale 1–5); and organisational barriers and service conditions for FLS delivery. Descriptive statistics were used to summarise responses. Internal consistency of the competency scale was assessed using Cronbach's alpha. Differences in perceived competency by FLS status (with vs without FLS) were explored using Mann–Whitney U tests.

Results: A total of 46 nurses participated (80.4% female). Most held a nursing degree (69.6%) or a master's degree in nursing (30.4%). Participants were geographically diverse. The perceived competency scale demonstrated good internal consistency (Cronbach's alpha = 0.83). Overall perceived competency was moderate-to-high (mean 3.55/5), with the lowest scores observed in the Monitoring domain (mean 2.99/5). Nurses working in settings with an FLS reported higher overall competency scores than those without an FLS (3.78 *vs* 3.43; p = 0.032), particularly in Patient & Public Support (4.00 *vs* 3.33; p = 0.005) and Osteoporosis & Bone Health Management (4.20 *vs* 3.54; p = 0.001). **Table 1**

Competency domain (FFN framework)	Mean ± SD
Competency 1 – Patient & Public Support	3.55 ± 0.74
Explaining fragility fractures and osteoporosis	3.76 ± 0.85
Knowledge of support resources and referral pathways	3.26 ± 0.98
Developing or improving educational materials	3.20 ± 1.17
Competency 2 – Identification & Fracture Risk Assessment	3.27 ± 0.80
Using fracture risk assessment tools	2.70 ± 1.26
Interpreting DXA and other diagnostic tests	**2.17 ± 0.95**
Discussing fracture risk factors with patients	3.91 ± 0.81
Competency 3 – Osteoporosis & Bone Health Management	3.75 ± 0.63
Advising on bone-healthy lifestyle changes	3.98 ± 0.77
Knowledge of pharmacological osteoporosis treatments	3.48 ± 0.94
Identifying and addressing barriers to treatment adherence	3.67 ± 0.82
Competency 4 – Falls Prevention	3.78 ± 0.65
Performing basic falls risk assessment	**4.30 ± 0.63**
Knowledge of falls prevention services and programmes	3.20 ± 0.96
Competency 5 – Monitoring	**2.99 ± 1.01**
Monitoring treatment adherence	2.87 ± 1.33
Assessing side effects and adjusting care plans	2.52 ± 1.01
Competency 6 Service Development, Improvement & Leadership	**3.93 ± 0.53**
Basic knowledge of quality improvement	3.33 ± 0.90
Contributing to clinical pathways and peer education	**4.37 ± 0.68**
Overall competency score	**3.55 ± 0.50**

Organisational barriers were rated high overall (mean 3.90/5), with the strongest barriers being lack of dedicated time for FLS activities (mean 4.30/5), lack of specific training (mean 4.06/5) and limited management support (mean 4.03/5). Perceived adequacy of FLS resources/conditions was also high (mean 3.92/5), particularly physical space (mean 4.18±0.68), while staffing, protected time, information systems and leadership support clustered around 3.88–3.91. **Table 2**

Domain	Mean ± SD
B1 – Overall organisational barriers score	**3.90 ± 0.52**
Insufficient human resources	3.55 ± 1.12
Lack of dedicated time for FLS activities	**4.30 ± 0.64**
Lack of specific training	4.06 ± 0.83
Poor coordination between services	3.85 ± 0.80
Lack of management support	4.03 ± 0.85
Inadequate information systems	3.88 ± 0.82
Low patient adherence	3.61 ± 0.79
B2 – Overall adequacy of FLS resources/conditions	**3.92 ± 0.47**
Resources to perform expected activities	3.76 ± 0.71
Sufficient human resources	3.91 ± 0.81
Sufficient time allocated for FLS activities	3.91 ± 0.88
Adequate physical space	4.18 ± 0.68
Information systems that facilitate case identification and follow-up	3.88 ± 0.86
Support from leadership/management	3.88 ± 0.70

Conclusion: Portuguese nurses reported moderate-to-high perceived competencies, higher in established FLS settings; however, monitoring gaps and organisational constraints (limited time, training and management support) may hinder optimal delivery, highlighting the need for structured education and protected resources.

CANNABINOIDS AND OSTEOBLASTOGENESIS: NATURAL MOLECULES INVOLVED IN PROMOTING OSTEOBLASTOGENESIS

G. Palmini[1], I. Falsetti[2], S. Donati[2], F. Marini[1], R. Zonefrati[1], L. Margheriti[3], A. Moro[3], F. Ranaldi[2], T. Iantomasi[2], M. L. Brandi[1]

[1]Fondazione Italiana Ricerca sulle Malattie dell'Osso (F.I.R.M.O) Onlus, Florence, Italy; [2]Department of Experimental and Clinical Biomedical Sciences, University of Florence, Florence, Italy; [3]Stabilimento Chimico Farmaceutico Militare (SCFM)_Agenzia Industrie Difesa (AID), Florence, Italy

Objectives: In recent years, several studies have demonstrated the direct involvement of the endocannabinoid system (SE) in the modulation of various physiological processes, including bone remodeling, with particular attention to the mineralization process. Therefore, the aim of the study presented here was to evaluate the effects of anandamide (AEA), the main endogenous cannabinoid, and cannabidiol (CBD) and cannabigerol (CBG), two of the main phytocannabinoids present in Cannabis sativa, on the osteogenic differentiation process in primary human pre-osteoblast lines.
Materials and methods: The study used a cell pool with three adipose-derived mesenchymal stem cell lines (PA) as a bioassay to examine the role of SE in pre-osteoblast differentiation and maturation. After confirming mesenchymal stemness markers via confocal laser microscopy and assessing the cell pool's differentiation potential, the gene expression levels of SE components (e.g., *CBR1*, *CBR2*, *DAGLa*, *FAAH*, *TRPV1*, *GPR55*) were evaluated. The effects of AEA, CBD, and CBG at various concentrations (1 nM to 10 µM) on osteogenic differentiation were then investigated through enzymatic activity of alkaline phosphatase (ALP), hydroxyapatite (HA) deposit analysis, and marker gene expression (i.e. *ALPL*, *OPG*, *OCN*, *RUNX2* and *COL1A1*).
Results: The data obtained confirmed the presence of SE in the prepared bioassay, and the analyses evaluating the effects of AEA, CBD, and CBG at different concentrations over time showed that both CBD and CBG promote osteogenic differentiation, increasing ALP activity and the amount of HA produced under treatment, as observed for AEA. Similarly, data on the gene expression of markers of pre-osteoblast maturation into mature osteoblasts showed an extremely positive effect of treatment with CBD and CBG.
Conclusions: The results show endogenous cannabinoids positively affect mineralization, along with two key phytocannabinoids from Cannabis sativa. These findings encourage further research into other phytocannabinoids and therapeutic Cannabis preparations by Stabilimento Chimico Farmaceutico Militare for bone mineralization. Future results could lead to new Cannabis sativa treatments for bone diseases involving loss and mineralization issues.

PRELIMINARY MIRNA CODES IN SMALL CELL OSTEOSARCOMA TO IDENTIFY NEW BIOMARKERS FOR A NEW AND SPECIFIC DIAGNOSTIC AND THERAPEUTIC METHODOLOGY

G. Palmini[1], S. Donati[2], I. Falsetti[2], F. Marini[1], R. Zonefrati[1], A. Franchi[3], C. Mazzanti[4], F. Lessi[4], L. Margheriti[5], A. Moro[5], F. Ranaldi[2], T. Iantomasi[2], M. L. Brandi[1]

[1]Fondazione Italiana Ricerca sulle Malattie dell'Osso (F.I.R.M.O) Onlus, Florence, Italy; [2]Department of Experimental and Clinical Biomedical Sciences, University of Florence, Florence, Italy; [3]3Department of Translational Research and of New Technologies in Medicine and Surgery, university of Pisa, Pisa, Italy; [4]Fondazione Pisana per la Scienza (FPS), Pisa, Italy; [5]Stabilimento Chimico Farmaceutico Militare (SCFM)_Agenzia Industrie Difesa (AID), Florence, Italy

Objectives: Human Small Cell Osteosarcoma (SCO) is a rare, aggressive form of Osteosarcoma (OS), with small, spindle-shaped cells producing an altered bone matrix called "osteoid". Despite aggressive treatments, SCO has a poor prognosis. The discovery of microRNAs (miRNAs) opened a new research field to study cellular processes, especially in cancer. Recent studies show their role in tumorigenesis through oncogene and tumor-suppressor pathways. This study presents preliminary results on "miRNA codes" that may characterize SCO cancer stem cells (CSCs), aiming to identify new molecular targets for more effective therapies against SCO CSCs.
Materials and methods: The human SCO sample was collected after informed consent was obtained, approved by the local Ethical Committee. First, the primary cancer cell line SCO was established. The CSC subpopulation was then isolated. Several cellular assays and stainings, as well as molecular analyses, were performed to demonstrate the CSC phenotype. In addition, we evaluated the expression of a group of miRNAs in SCO-CSCs (i.e., miR-1, miR-9, miR-18a, miR-200, miR-141, miR-199, miR-25, miR-423, miR-25, miR-744, miR-500, miR-654, miR-221, miR-296, miR-184, miR-365, Let-7e, Let-7f, and miR-320d). We also evaluated the expression of a group of miRNAs in exosomes released by SCO-CSCs (i.e., miR-1125-5p, miR-2861, miR-299-5p, miR-106b-5p, miR-195-5p, miR-320d, miR374a, miR-4295, miR-375-5p, miR-138-5p, and miR-506-5p).
Results: The miRNA expression analyses revealed that miR-744, miR-654, miR-221, miR-296, miR-184, miR-365, Let-7f, Let-7g, Let-7c, Let-7e, and miR-320d are all upregulated in SCO-CSCs compared with the SCO primary cell line. At the same time, the analysis of exosomal miRNA revealed that miR-1125-5p, miR-2861, miR-299-5p, miR-106b-5p, miR-195-5p, miR-320d, miR-4295, miR-375-5p, miR-138-5p, and miR-506-5p are all highly expressed in exosomes released by SCO-CSCs.
Conclusions: These findings identify, for the first time, a miRNA signature of the cancer stem cell subpopulation in this highly aggressive OS form. The initial analysis of exosomal miRNAs from these cells suggests which miRNAs may influence SCO progression, relapse, and metastasis. These results pave the way for the discovery of new biomarkers for rapid diagnosis and the development of more effective precision therapies.

MEDICAL AND BIOLOGICAL ASPECTS OF CORRECTION OF THE CONSEQUENCES OF SCOLIOTIC DEFORMITY IN STUDENTS

E. E. Ibragimova [1], G. V. Reshetnik [2], D. E. Emirova[1]

[1]Crimean Engineering and Pedagogical University named after Fevzi Yakubov,Simferopol, Russia, [2] V. I. Vernadsky Crimean Federal University, Simferopol,Russia

Introduction: The increase in diseases of the organs of support and movement is facilitated by an increase in genetic developmental abnormalities, as well as factors related to urbanization, physical inactivity and environmental disturbances. A steady increase in the prevalence of musculoskeletal disorders among students is associated with prolonged static stress that is typical for the educational process. Disorders of musculoskeletal system (MSS) in girls can have long-term consequences that negatively affect reproductive health. Therefore, it is necessary to monitor the condition of the spine and timely corrective intervention (kinesitherapy) to minimize destructive changes in the biomechanics of the MSS.

Methods: The assessment and detection of spinal column deformity in students was carried out by physical methods.

Results: Disorder of the spring function of the spine provokes early fatigue, decreased cognitive performance and headaches. The progression of spinal deformity entails visceral migration. To stabilize the static component, it is necessary to strengthen the muscular corset. Patients with MSS disorders have a decreased spinal mobility in all planes due to hypofunction of the back and abdominal muscles. Scoliosis reduces respiratory reserves, deformity of vertebrae and intervertebral discs is accompanied by compromise of the ligamentous-muscular system and is an etiological factor for abdominal organ dysfunction.

Conclusion: Correction of idiopathic scoliosis in students assigned to special medical groups requires using of scientifically based and individualized approaches within the framework of recreational physical education. The main directions should be aimed at eliminating muscle imbalance, improving postural control and preventing further progression of deformity. It is important to perform exercises with a metered asymmetric load, including specific strengthening of weakened muscles (concave side of the arch) and stretching excessively tense ones (convex side) based on the principles of a neutral pelvic position.

P661

OSTEOSARCOPENIA AND RISK OF ALL-CAUSE MORTALITY FOR COMMUNITY-DWELLING OLDER ADULTS: THE BUSHEHR ELDERLY HEALTH (BEH) PROGRAM

G. Shafiee[1], N. Fahimfar[2], M. Sanjari[3], K. Khalagi[2], I. Nabipour[4], R. Heshmat[1]

[1]Chronic Diseases Research Center, Endocrinology and Metabolism Population Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran, Tehran, Iran; [2]Osteoporosis Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran., Tehran, Iran; [3]Osteoporosis Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran, Tehran, Iran; [4]The Persian Gulf Tropical Medicine Research Center, Bushehr University of Medical Sciences, Bushehr, Iran, Bushehr, Iran

Background Osteosarcopenia is an increasingly recognized geriatric syndrome with a considerable prevalence which increases morbidity and mortality. This study assessed osteosarcopenia as risk factors for all-cause mortality during 7-year follow-up.

Methods: The Bushehr Elderly Health (BEH) Program is a prospective population-based cohort study, which aims to investigate the incidence of non-communicable diseases and their risk factors among people over 60 years old in Bushehr, Iran. Osteopenia/ osteoporosis was defined as a T-score ≤ -1.0 standard deviation below the mean values of a young healthy adult. We defined sarcopenia as reduced skeletal muscle mass index plus low muscle strength and/or low physical performance. Osteosarcopenia was considered as the presence of both osteopenia/osteoporosis and sarcopenia. Participants were categorized in three groups: reference group with no sarcopenia and no osteopenia, sarcopenia or osteopenia group and osteosarcopenia (sarcopenia + osteopenia) group. Hazards ratios (HR) for mortality were calculated with Cox proportional hazards models.

Results Among 2426 participants, 532 (22.2%) had osteosarcopenia. Over a median follow-up of 7.4 years, 558 (23%) died. Individuals with osteosarcopenia had a significantly higher mortality rate of 52.8 per 100 person-years (95% CI: 45.7-61.0) compared to those without osteosarcopenia, who had a mortality rate of 17.8 per 100 person-years (95% CI: 12.8-24.7). The risk of all- cause mortality among older adults based on osteosarcopenia status, with hazard ratios (HRs) presented across three models. In Model 1 (crude), older adults with osteopenia/ sarcopenia had a significantly increased mortality risk (HR: 1.63, 95% CI: 1.15–2.30), while those with osteosarcopenia exhibited the highest risk (HR: 3.07, 95% CI: 2.15–4.39). After adjusting for age and sex in Model 2, the mortality risk remained elevated in osteopenia/sarcopenia and also osteosarcopenia groups. In Model 3, adjusted for age, sex, body mass index, physical activity, current smoking, protein intake and high fat mass; the highest mortality risk remained in individuals with osteosarcopenia (HR: 1.94, 95% CI: 1.29–2.93), followed by those with osteopenia/sarcopenia group (HR: 1.74, 95% CI: 1.20–2.53).

Conclusion While sarcopenia or osteopenia increase mortality risk, their combination as osteosarcopenia, is a significant predictor of all-cause mortality among older adults. Therefore, it is important to diagnose and treatment of osteosarcopenia to reduce mortality rate among community-dwelling older adults.

P662

IMPACT OF ROMOSOZUMAB ON QUALITY OF LIFE IN WOMEN WITH OSTEOPOROSIS: A PROSPECTIVE PILOT STUDY

G. Voltan[1], C. Mogno[1], G. Contini[1], M. Ferrarese[1], V. Camozzi[1]

[1]University Hospital of Padua, Padova, Italy

Background: Romosozumab is a monoclonal anti-sclerostin antibody with a dual anabolic and antiresorptive mechanism of action and currently represents the most effective therapy in terms of bone mineral density (BMD) increase and fracture risk reduction in patients with osteoporosis. While its skeletal efficacy is well established, data on its impact on patient-reported outcomes, particularly quality of life (QoL), are currently lacking. The aim of this study was to evaluate the effect of Romosozumab on QoL in women treated for osteoporosis.

Methods: This was a prospective, single-center study including 59 postmenopausal women with osteoporosis treated with Romosozumab according to national reimbursement criteria. Quality of life was assessed using the validated ECOS-16 questionnaire at baseline, 6 months and 12 months. Biochemical parameters were collected at baseline, 6 and 12 months, while BMD at the lumbar spine and femoral sites was evaluated by DXA at baseline and after 12 months of treatment.

Results: At the time of analysis, 14 patients had completed the full 12-month course of romosozumab. After 12 months of therapy, a significant increase in BMD was observed at both the lumbar spine (0.744 vs 0.619 g/cm², p=0.029) and the femoral site (0.623 vs 0.585 g/cm², p=0.001). Quality of life significantly improved as early as 6 months of treatment, with a reduction in ECOS-16 score (50.0 vs 54.33, p=0.013), which was maintained at 12 months (47.17 vs 54.33, p=0.041). Notably, the percentage increase in BMD was inversely correlated with ECOS-16 score at 12 months (Spearman's rho = −0.709, p=0.022), indicating that greater skeletal gains were associated with better patient-reported quality of life.

Conclusions: Romosozumab confirms its efficacy as a highly effective treatment for osteoporosis and is associated with a clinically meaningful improvement in quality of life. Given that lower ECOS-16 scores reflect better QoL, the observed inverse correlation between BMD gain and QoL score suggests that skeletal improvement translates into tangible clinical benefits for patients. This pilot study provides the first prospective evidence that romosozumab therapy positively impacts quality of life in addition to its well-established effects on bone mass, supporting the inclusion of patient-reported outcomes in future osteoporosis trials.

P663

MANAGEMENT PATTERNS, QUALITY OF CARE AND ECONOMIC BURDEN OF HIP FRAGILITY FRACTURES IN A TERTIARY TRAUMA CENTRE: A PHARMACIST-LED PRE-FLS ANALYSIS

H. A. Benabdoun[1,2], A. Y. Arab[2], B. A. Basri[2], M. A. Megraoui[2], R. C. Rabehi[2], S. N. Sharif[2]

[1]Hôpital du Sacré-Coeur de Montréal, Montreal, Canada;
[2]Université de Montréal, Montreal, Canada

Objective(s) To describe the demographic, clinical, pharmacological, and economic profile of patients admitted for hip fragility fractures at a tertiary trauma centre (Montreal, Canada) prior to the implementation of a Fracture Liaison Service (FLS).

Material and Methods This retrospective study included patients ≥50 years admitted for hip fragility fractures (April 2019-March 2023). A pharmacist reviewed medical records to assess outcomes including fracture history, osteoporosis (OP) therapy at admission and discharge, discharge destination, and acute hospitalization costs. Reasons for non-management at discharge were assessed based on documented clinical justifications.

Results A total of 272 patients were included (mean age: 80 years). A prior fragility fracture was documented in 23% of patients. At admission, 22% were receiving OP therapy (77% bisphosphonates). At discharge, 34% had an OP prescription. Across the total cohort, new treatments were initiated in 14.6% of patients (mainly bisphosphonates and denosumab). While 66% of patients were discharged without therapy, 83% of them (54.8% of the total cohort) lacked documented clinical justification. The primary identified barriers to management reflected professional, patient-related, and systemic factors. Importantly, 14% of untreated patients (9% of the total cohort) had a prior fragility fracture history. Overall, 70.1% of patients experienced suboptimal management. Mean acute hospitalization costs averaged $21,079 CAD per patient. Furthermore, 48% of patients were discharged to rehabilitation centres and 8% to long-term care facilities.

Conclusion(s) This pharmacist-led assessment reveals critical care gaps in the care continuum, with 70% of patients receiving suboptimal management without justification. These findings, and the underlying professional and systemic barriers, concur with existing literature on post-fracture management deficiencies. The high hospitalization costs and frequent discharge to rehabilitation facilities highlight a significant economic burden. Integrating a pharmacist within an FLS framework is essential to assess systematically treatment eligibility and address these barriers, offering a high-value opportunity to reduce avoidable expenditures and improve secondary prevention.

P664

THE RELATIONSHIP BETWEEN SARCOPENIC OBESITY AND FALLS IN OLDER ADULTS: A CROSS-SECTIONAL STUDY

H. Arıcı[1], T. Erdoğan[1], S. Özkök[1], D. Seyithanoğlu[1], Z. Tırnova[1], S. Güven[1], D. Çetin[1], G. Bahat[1], M. A. Karan[1]

[1]Istanbul University, Istanbul Faculty of Medicine, Department of Internal Medicine, Division of Geriatric Medicine, Istanbul, Türkiye

Objective: Falls represent a leading cause of morbidity and disability in the geriatric population. While sarcopenia is a well-established risk factor for falls due to loss of muscle mass and function, the impact of sarcopenic obesity remains controversial. This study aimed to evaluate the relationship between different body composition phenotypes (sarcopenia, obesity, and sarcopenic obesity) and the risk of falls in community-dwelling older adults.

Methods: Comprehensive geriatric assessment was performed for all participants. Sarcopenia and sarcopenic obesity are defined based on population-based validated SMMI and Handgrip results. The history of falls in the last 12 months was recorded. Participants were divided into four phenotypes (non-sarcopenic-non-obese, obese only, sarcopenic only, and sarcopenic-obese). Univariate logistic regression analyses were conducted to identify potential risk factors associated with falls.

Results: This cross-sectional study included 1625 community-dwelling older adults (mean age 75.9±6.5 years) and population was predominantly female (67.3%). A total of 630 (38.8%) participants reported at least one fall in the previous year. Univariate analysis revealed that age (OR: 1.02, p=0.004), female gender (OR: 1.62, p<0.001), low physical activity (OR: 4.67, p=0.004), frailty (OR: 2.20, p<0.001), and fear of falling (OR: 2.42, p<0.001) were significant predictors of falls. Regarding body composition phenotypes, patients with "Sarcopenia Only" had a significantly increased risk of falls (OR: 1.67, 95% CI: 1.17–2.39, p=0.005). However, "Sarcopenic Obesity" was not significantly associated with fall risk (OR: 1.35, 95% CI: 0.98–1.85, p=0.066). Obesity alone also didn't have a significant association (OR: 089, CI: 0.79-1.15, p=0.408)

Conclusion: In our study, while sarcopenia was identified as a strong and independent risk factor for falls, sarcopenic obesity was not. The absence of this strong association in the presence of obesity suggests that increased body mass may play a neutralizing or modifying role against sarcopenia-related instability. Considering these findings, when planning weight loss strategies for sarcopenic obese older adults, priority must be given to preserving muscle mass to avoid disrupting this existing protective balance

Table.2 Univariate Logistic Regression Analysis of Risk Factors for Falls

Variables	Missing n (%)	OR	95% CI	p-value

IMPACT OF VITAMIN D STATUS ON FRAILTY AND FALL RISK IN INTERNAL MEDICINE PATIENTS: A REAL-WORLD CROSS-SECTIONAL ANALYSIS

H. B. Koç[1]

[1]Alanya Alaaddin Keykubat University, Faculty of Medicine, Department of Internal Medicine, Antalya, Türkiye

Background:
Frailty and falls are major contributors to morbidity in older adults and internal medicine patients. Vitamin D deficiency is highly prevalent and may accelerate musculoskeletal decline by impairing muscle strength, balance, and bone metabolism. Real-world data evaluating this association in routine internal medicine practice are limited.
Objectives:
To assess the relationship between serum vitamin D levels, frailty severity, and fall risk in adult internal medicine patients, and to identify clinical predictors of high-risk frailty profiles.
Methods:
We performed a cross-sectional analysis of adult patients admitted to an internal medicine department over six months. Demographic characteristics, comorbidities, medication use, and laboratory parameters were recorded. Frailty was assessed using the Clinical Frailty Scale (CFS), and fall risk using the Morse Fall Scale (MFS). Serum 25(OH)D levels were categorized as sufficient (>30 ng/mL), insufficient (20–30 ng/mL), or deficient (<20 ng/mL). Multivariable regression was performed to explore independent associations.
Results:
Among evaluated patients, vitamin D deficiency was highly prevalent. Lower 25(OH)D levels were significantly associated with higher CFS

scores, increased fall risk, reduced functional status, and greater multimorbidity burden. Patients with deficiency demonstrated a disproportionate frequency of previous falls and markedly impaired mobility. Vitamin D status remained an independent predictor of frailty after adjusting for age, sex, anemia, renal function, and polypharmacy.
Conclusions:
Vitamin D deficiency is strongly linked to frailty severity and elevated fall risk in real-world internal medicine patients. Early identification and corrective supplementation may offer a simple, cost-effective intervention to reduce adverse outcomes. Routine vitamin D screening should be considered in risk-stratification strategies in internal medicine practice.

P666
CORRELATION OF DREISER FUNCTIONAL SCORE WITH RADIOGRAPHIC AND ULTRASOUND HAND ABNORMALITIES IN DIGITAL OSTEOARTHRITIS

H. Boussaa[1], N. Zaghdoudi[1], Y. Makhlouf[1], S. Miladi[1], A. Fazaa[1], K. Ben Abdelghani[1], A. Laatar[1]

[1]Department of Rheumatology, Mongi Slim University Hospital, Tunis, Tunisia

Background: Digital osteoarthritis (OA) is a prevalent condition that often leads to significant functional impairment. Clinical evaluation alone may underestimate structural changes in hand joints. Conventional radiography is widely used to detect osteophytes, joint space narrowing, and subchondral sclerosis, while ultrasound can provide additional detail on synovitis, small osteophytes, and enthesitis.
This study aimed to investigate the correlation between the Dreiser functional score and structural abnormalities detected by both radiography and ultrasound in patients with digital OA.
Methods: We conducted a cross-sectional study including patients fulfilling the 2023 classification criteria for hand OA. Functional impairment was assessed using the Dreiser score. All patients underwent standard radiography and ultrasound examination of both hands. Radiographs were evaluated for osteophytes, joint space narrowing, subchondral sclerosis, and cysts. Ultrasound was used to detect osteophytes, erosions, synovitis, and distal enthesitis of the extensor digitorum tendon. The dorsal aspect of metacarpal-phalangeal, proximal inter-phalangeal and distal inter-phalangeal joints were systematically assessed. The relationship between Dreiser scores and ultrasound findings was analyzed using Spearman correlation coefficients, with $p<0.05$ considered statistically significant.
Results: We evaluated 600 joints in 20 patients (mean age 65±9 years; 90% female). The mean disease duration was 3 years [2-4.75]. Dreiser scores ranged from 2 to 17 (median 8.5).
Radiographic analysis showed that all patients presented with at least one joint space narrowing, with a mean number of 5.1±3.6 [1–13]. Osteophytes were observed in 75% of patients, with a mean number of 3.2±2.9 [0–9]. Subchondral sclerosis and cysts were found in 8 patients (40%), with a mean number of 1.4±2.5 [0–8] and 1±2.3 [0-10], respectively. Ultrasound detected osteophytes in 16% of joints, synovitis in 2%, erosions in 1%, and enthesitis in 34%.
A moderate positive correlation was observed between the Dreiser functional score and the total number of ultrasound-detected osteophytes ($r = 0.661$, $p = 0.05$) and synovitis ($r = 0.588$, $p = 0.047$), whereas erosions and enthesitis showed weaker associations. No significant correlations were found between the Dreiser functional score and radiographic abnormalities.
Conclusion: The Dreiser functional score correlates with structural changes detected by ultrasound in patients with digital OA, particularly osteophytes and synovitis. Ultrasound may complement functional assessment, providing a more comprehensive evaluation of hand involvement. Integrating imaging into routine assessment could improve monitoring and individualized management of digital OA.

P667
HAND ULTRASOUND ASSESSMENT OF TENDON INVOLVEMENT IN PSORIATIC ARTHRITIS VERSUS DIGITAL OSTEOARTHRITIS

H. Boussaa[1], N. Zaghdoudi[1], Y. Makhlouf[1], S. Miladi[1], A. Fazaa[1], K. Ben Abdelghani[1], A. Laatar[1]

[1]Department of Rheumatology, Mongi Slim University Hospital, Tunis, Tunisia

Background: Tendon involvement is a hallmark of psoriatic arthritis (PsA), while its presence in digital osteoarthritis (OA) is less well characterized. Ultrasound (US) allows sensitive detection of tendinopathy, tenosynovitis, and enthesopathy, providing insights into structural differences between inflammatory and degenerative hand disorders.
This study aimed to compare the prevalence and patterns of tendon abnormalities on US in patients with PsA versus digital OA.
Methods: We conducted a cross-sectional study including patients with peripheral PsA and digital OA fulfilling CASPAR and 2023 EULAR classification criteria, respectively. Each patient underwent a clinical examination followed by a standardized US assessment. The wrists, metacarpophalangeal (MCP), proximal (PIP) and distal interphalangeal (DIP) joints were systematically examined in gray scale (GS) and power Doppler (PD). The following elementary lesions were assessed: tenosynovitis of extensor digitorum and flexor tendons, extensor peritendon inflammation, and distal extensor tendon enthesitis. A binary scoring system was applied (0 = absent, 1 = present) for all evaluated lesions. Statistical analyses compared lesion prevalence between groups, using chi-square and Fisher's exact tests as appropriate, with $p<0.05$ considered significant.
Results: A total of 1200 joints in 20 patients with PsA (mean age 55 ± 12 years; 65% female) and 20 patients with digital OA (mean age 65 ± 9 years; 90% female) were assessed. Tenosynovitis of flexor tendons was significantly more frequent in PsA in GS (30% vs 5%, $p=0.003$) and PD (15% vs 0%, $p=0.025$). No significant differences were noted between the two groups for the extensor carpi ulnaris and the extensor digitorum tendons. GS extensor peritendon inflammation at MCP joints was exclusively observed in PsA patients (13% vs 0%, $p<0.001$). Distal enthesitis of extensor tendon was more frequent in PsA patients (39% vs 34%), but the difference was not statistically significant ($p=0.35$). Regarding elementary lesions of enthesitis, erosions were significantly more frequent in PsA patients (9% vs 1%, $p<0.001$). No significant differences were noted for calcifications, enthesophytes, and thickness and/or hypoechogenicity of the tendon insertion.
Conclusion: US reveals distinct tendon involvement patterns in PsA versus digital OA. Flexor tenosynovitis and extensor peritendon inflammation predominate in PsA. Ultrasound can therefore aid in differentiating inflammatory versus degenerative hand disease and guide personalized management.

P668

ASSESSMENT OF CARDIOVASCULAR RISK IN PATIENTS WITH HAND OSTEOARTHRITIS

H. Boussaa[1], N. Zaghdoudi[1], Y. Makhlouf[1], S. Miladi[1], A. Fazaa[1], K. Ben Abdelghani[1], A. Laatar[1]

[1]Department of Rheumatology, Mongi Slim University Hospital, Tunis, Tunisia

Background

Hand osteoarthritis (OA) is the second most common form of the disease, affecting approximately 10% of the population. Hand OA patients appear to have a pro-atherogenic profile. Nevertheless, its possible link with cardiovascular risk has been little investigated.

The aim of this study was to assess the cardiovascular risk using European Society of Cardiology (ESC) risk scores in patients with hand OA.

Methods

Patients fulfilling the 2023 EULAR classification criteria for hand OA were included. Demographic characteristics, body mass index (BMI), cardiovascular risk factors (CVRFs), and clinical and functional data of hand OA were recorded. Cardiovascular risk was assessed using ESC-recommended SCORE2-based tools (SCORE2, SCORE2-Diabetes, or SCORE2-OP), according to age and diabetes status, and classified into low–moderate, high, and very high-risk categories based on estimated 10-year cardiovascular risk. Associations between SCORE2 and clinical variables were explored using Spearman's correlation. A p value inferior to 0.05 was considered statistically significant.

Results

Twenty patients were included (18 women, 2 men), with a mean age of 65±9 years [46–87]. The mean disease duration was 3 years [2-4.75]. The mean VAS pain was 40±16 mm [0-70]. The mean Dreiser functional index was 8.5 ±5.25 [2-17]. The median number of tender joints was 1 (IQR 25-75%; 0-3.75). Bouchard's and Heberden's nodes were observed in 65% and 90% of patients, respectively. Radiographic analysis showed that all patients had at least one joint space narrowing, with a mean number of 5.15 ± 3.66 [1–13]. Osteophytes were observed in 15 of 20 patients (75%), with a mean number of 3.2 ± 2.91 [0–9]. Subchondral bone sclerosis was identified in 8 patients (40%), with a mean number of 1.45 ± 2.52 [0–8]. Subchondral cysts were detected in 8 patients (40%).

Seventy-five percent of participants were aged 60 years and above. Mean BMI was 28 ± 5 kg/m2 [22–44], with 50% overweight, 30% obese, and 20% normal weight. Seven patients had hypertension (35%), six had diabetes (30%), four had dyslipidemia (20%), and three were smokers (15%). Four patients (20%) presented a combination of hypertension, diabetes, and dyslipidemia. Sixteen patients had 0–1 CVRF, while four had ≥2 CVRFs. Seven patients had a complete lipid profile allowing cardiovascular risk estimation. All evaluable patients were classified as having very high cardiovascular risk, with estimated 10-year risk ranging from 12% to 32% (mean SCORE2: 19.85 ± 7.15).

A strong positive correlation was observed between age and SCORE2 ($r = 0.875$, $p = 0.014$). No significant correlations were found between SCORE2 and disease duration ($r = -0.08$, $p = 0.865$), pain VAS ($r = -0.03$, $p = 0.935$), number of affected joints ($r = 0.187$, $p = 0.688$), Dreiser functional index ($r = 0.180$, $p = 0.699$), joint space narrowing ($r = 0.234$, $p = 0.613$), osteophytes ($r = 0.357$, $p = 0.432$), subchondral sclerosis ($r = 0.474$, $p = 0.282$), or subchondral cysts ($r = 0.128$, $p = 0.784$).

Conclusion

Hand OA may represent an underrecognized marker of heightened cardiovascular risk. The consistent identification of very high cardiovascular risk in all evaluable patients underscores the need for systematic cardiovascular risk assessment and early preventive interventions in this population. Large-scale case–control studies are needed to further clarify and confirm the association between hand OA and cardiovascular risk.

P669

MINIMUM FIVE-YEAR RESULTS OF ARTHROSCOPIC MANAGEMENT WITH LABRAL PRESERVATION IN BORDERLINE HIP DYSPLASIA

H. Cho[1], W. C. Chung[2]

[1]Department of Orthopedic Surgery, Gwangju Veterans Hospital, Gwangju, South Korea; [2]Department of Orthopaedic Surgery, St. Carollo Hospital, Suncheon, South Korea

Purpose: This study examined the patient-reported outcome scores at mid-term follow-up after arthroscopic labral preservation in patients with borderline hip dysplasia.

Materials and Methods: Data were collected retrospectively from patients who underwent arthroscopic labral preservation. Among the 61 patients classified with hip dysplasia, patients with arthritis beyond Tönnis grade II were excluded, Patients with subchondral bony exposure were excluded even if they had arthritis of Tönnis grade I. Forty-two patients with borderline hip dysplasia were enrolled among patients whose lateral center edge angle (LCEA) was between 18° and 25°. The PRO scores including the modified Harris hip score (mHHS), hip outcome score activities of daily living (HOS-ADL), hip outcome score sport-specific subscale (HOS-SSS) and visual analog scale (VAS), were collected and compared preoperatively, and then at one year and a minimum of five years after surgery.

Results: The mean preoperative LCEA and Tönnis angle were 20.9° (range, 18° to 25°) and 6.3° (range, 0° to 18°), respectively. The mean follow-up was 64.8 (range, 60 to 84) months. The mean mHHS increased from 73.5 before surgery to 86.2 in the fifth year after surgery ($p<0.01$), the mean HOS-ADL from 70.5% before surgery to 84.9% in the fifth year after surgery ($p<0.01$), and the mean HOS-SSS from 51.4 before surgery to 69.4 in the fifth year after surgery ($p<0.01$). The mean VAS score improved from 6.3 before surgery to 1.5 in the fifth year after surgery ($p<0.01$).

Conclusion: Arthroscopic labral preservation performed in appropriately selected patients with borderline dysplasia showed good results at mid-term follow-up. In borderline hip dysplasia without the progress of osteoarthritis and subchondral bone exposure, arthroscopic labral preservation may be considered a good and less invasive option.

Key words: hip, labrum, acetabular dysplasia, arthroscopy

PATIENT-REPORTED OUTCOME MEASURES OF STAGED DIRECT ANTERIOR APPROACH AND DIRECT LATERAL APPROACH FOR TOTAL HIP ARTHROPLASTY PERFORMED ON THE SAME PATIENT

H. Cho[1], W. C. Chung[2]

[1]Department of Orthopedic Surgery, Gwangju Veterans Hospital, Gwangju, South Korea; [2]Department of Orthopaedic Surgery, St. Carollo Hospital, Suncheon, South Korea

Purpose: Total hip arthroplasty (THA) is performed using various approaches, including posterior, lateral, and direct anterior approaches.

The most beneficial method is controversial. Each approach has its advantages and disadvantages. This study compared patient satisfaction after bilateral THA using the direct anterior and lateral approaches on the same patient, considering the advantages and disadvantages of each approach.

Materials and Methods: This study examined 30 patients who underwent bilateral THA: two with femoral neck fractures, 18 with osteonecrosis of the femoral head, six with borderline dysplasia-induced hip osteoarthritis, and four with degenerative hip osteoarthritis.

Without distinguishing between the left and right sides, THA was performed randomly using the direct anterior approach on one side and the lateral approach on the other. The results of THA were compared using different approaches on the same patient, and patient satisfaction was evaluated.

Results: Surgery using the direct anterior approach for THA showed favorable results in terms of the initial postoperative pain compared to surgery using the lateral approach. On the other hand, there was no significant difference observed after one month post-surgery. Among the participants, three preferred the direct anterior approach; four preferred the lateral approach, and 23 reported no preference.

Conclusion: In THA, the direct anterior approach may offer advantages in terms of initial postoperative pain and rehabilitation compared to the lateral approach. Nevertheless, the pain and joint function one month after surgery were similar between the two approaches.

Therefore, the choice of approach should be determined by the surgeon's preference or experience, as both methods appear rational.

Key words: total hip arthroplasty, direct anterior approach, lateral approach

P671

HEAD INJURY AND THE RISK OF HIP FRACTURE IN OLDER ADULTS AGED 65–84 YEARS

R. Aga[1,2,3], K. Holvik[2], A. J. Søgaard[2], H. E. Meyer[2,3]

[1]Oslo University Hospital, Department of Orthopaedic Emergency, Oslo, Norway; [2]Norwegian Institute of Public Health, Oslo, Norway; [3]University of Oslo, Oslo, Norway

Objectives: Head injury is common in older adults, but its association with hip fracture is understudied. We therefore examined the association between head injury and subsequent hip fracture in the general elderly population.

Material and Methods: We linked registry data for all residents of Oslo aged 65–84 years in 2012 (n = 60,357) and followed them for the first hip fracture through 2022 using the Norwegian Patient Registry. To reduce the influence of competing mortality, followup was censored at age 85. We defined head injuries as accidental falls accompanied by ICD-10 codes S01–S09. The large majority were treated at the emergency outpatient clinic of Oslo University Hospital. We estimated age-adjusted hazard ratios (HR) with 95% confidence intervals (CI) for hip fracture in Cox proportional hazards regression in men and women separately, using the first incident fall as a time-varying exposure. In a supplementary analysis, we split follow-up time after the injury into less than one year and one year or more.

Results: During follow-up, a first fall injury was recorded in 21.3% of men (n = 5,762) and 28.0% of women (n = 9,352); among these, 1,781 men and 1,818 women sustained a head injury in the fall. There were 1,194 incident hip fractures in men and 2,192 in women. Fallers with a head injury had an increased risk of hip fracture: HR 2.28 (95% CI 1.82–2.85) in men and 1.59 (95% CI 1.30–1.95) in women compared to non-fallers. The risk was greatest during the first year after the head injury (HR=3.78 in men and HR=2.33 in women) but remained significantly elevated thereafter.

Conclusion: Head injury is common among older adults and is associated with a markedly increased risk of hip fracture, especially during the first year after the injury. This information may be useful when considering follow-up and preventive measures for older adults after a fall with head injury.

P672

THE ROLE OF THE CYP1A1 GENE IN LONG-TERM GLUCOCORTICOID-RELATED ADVERSE EFFECTS

H. Florez[1], E. Gonzalez[2], K. Cajiao[1], J. L. Carrasco[3], J. Hernández-Rodríguez[4], S. Prieto-González[4], M. C. Cid[4], A. Monegal[1], N. Guañabens[1], P. Peris[1]

[1]Metabolic Bone Diseases Unit. Department of Rheumatology. Hospital Clinic, University of Barcelona., Barcelona, Spain; [2]Department of Immunology. Hospital Clinic, University of Barcelona., Barcelona, Spain; [3]Biostatistics, Department of Basic Clinical Practice, University of Barcelona, Barcelona, Spain., Barcelona, Spain; [4]Vasculitis Research Unit, Department of Autoimmune Diseases, Hospital Clínic, University of Barcelona, Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Barcelona, Spain, Barcelona, Spain

Long-term glucocorticoid (GC) use can produce adverse effects (AE) including obesity, diabetes, osteoporosis and fractures. The variability in AE severity suggests a genetic influence. *CYP1A1*, a cytochrome P450 family enzyme involved in GC metabolism may play a role.

Objective

This study aimed to genotype *CYP1A1* variants in patients on chronic GC treatment and analyze their relationship with long-term AE.

Material and Methods

Seventy patients (56±16.6 years; 71.4% female; 47.1% postmenopausal) receiving chronic GC treatment (≥5 mg/day/>3 months) were included. Clinical data were collected at baseline and at 5 years of follow-up, including OP risk factors, previous and incidental fractures, GC-dose and duration, disease activity, anthropometric data, bone metabolism parameters, bone mineral density (BMD) and trabecular bone score (TBS) (by DXA), and vertebral fractures (X-ray). *CYP1A1* gene sequencing was performed by NGS using Amplicon Deep Sequencing on an Ion Torrent platform as described in Mensa-Vilaró et al.[1]

Results

Four *CYP1A1* polymorphisms were identified: rs41279188, rs1048943, rs1799814 and rs4646422. Nine patients had rs1048943, nine rs1799814, one rs4646422 and one rs12086634 polymorphisms, respectively. Patients with rs1799814 polymorphism (13%) had higher BMI (29.3 *vs.* 25.5; p=0.019) and greater BMI change over 5 years (ΔBMI: 1.7 *vs.* -0.32;p=0.03; adjusted for cumulative GC dose). Additionally, they presented lower bone turnover markers (NTx: 21 vs. 40 nMol/mMol, p=0.003, CTx: 0.16 vs. 0.29 ng/mL, p=0.068, OC: 16.6 vs. 19.3 ng/mL, p=0.059). No associations were found between *CYP1A1* polymorphisms and the presence of osteoporosis and/or fractures, BMD or TBS values.

Conclusion

The *CYP1A1* rs1799814 polymorphism is associated with more severe GC-related AE, suggesting reduced GC metabolism.

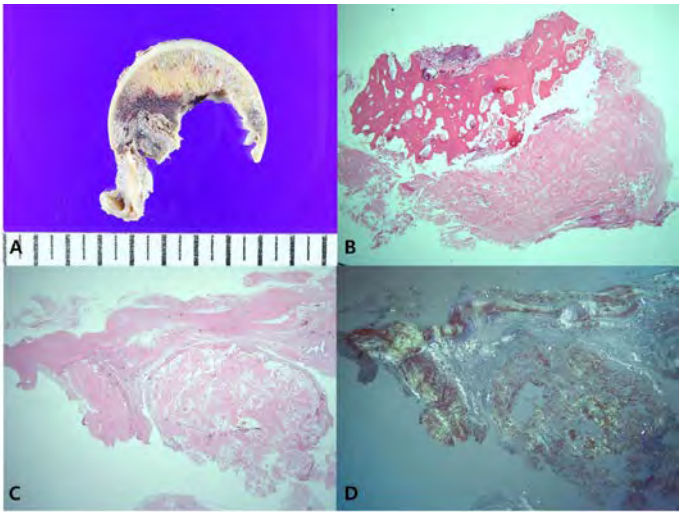
BILATERAL AMYLOID ARTHROPATHY OF THE HIP JOINT PRESENTED WITH PATHOLOGIC FRACTURE IN A HEMODIALYSIS PATIENT -A CASE REPORT-



H. G. Ryu[1]

[1]Seoul medical center, Seoul, South Korea

CASE REPORT: Pathological fractures occur when bones are weakened by disease, and hip fractures in particular are of great significance because they impact morbidity, survival, and quality of life. This case involves a patient undergoing long-term dialysis who developed amyloidosis in both hip joints, leading to a pathological fracture of the right femoral neck and an impending fracture of the left femoral neck. Bilateral total hip arthroplasty was performed with a favorable short-term prognosis. A 48-year-old male patient, previously ambulatory without assistance, presented to the hospital with pain in the right hip joint, despite having no history of trauma. Imaging revealed a subcapital fracture of the right femoral neck, accompanied by extensive osteolysis and bone erosion involving both femoral necks. Hip MRI demonstrated heterogeneous deposits with low signal intensity on T1-weighted images and high signal intensity on T2-weighted images, characteristic of amyloid deposition in both hip joints, leading to pathological fracture of the right femoral neck. Severe bone erosion in the left femoral neck suggested an impending fracture, leading to the decision to perform bilateral total hip arthroplasty. No evidence of amyloid accumulation was found in other organs, and no systemic diseases such as multiple myeloma were detected. This case reports a localized form of amyloidosis related to long-term hemodialysis in both hip joints, a condition not previously reported in Korea. At the one-year follow-up, the patient demonstrated no surgical complications, including aseptic loosening, dislocation, infection, periprosthetic fracture, or implant failure. He was able to walk independently without a limp.

Key words: amyloidosis, pathologic fracture, total hip arthroplasty

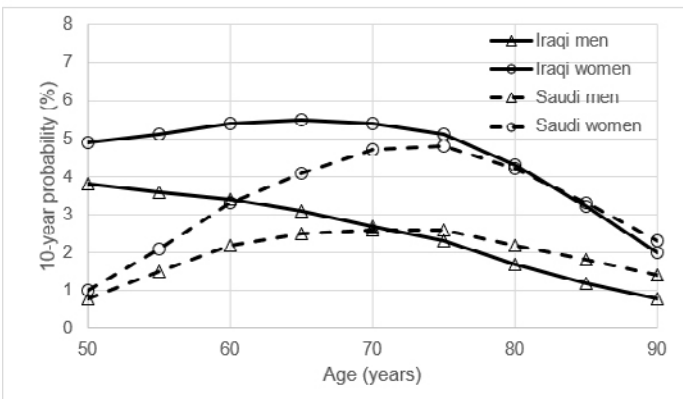
Introduction The aim of this study was to describe the epidemiology of femoral fractures in the Republic of Iraq, and to develop a corresponding country-specific FRAX® tool for the prediction of fracture.



Methods Femoral fracture data were retrieved from the Iraqi government's Ministry of Health and the Kurdistan region's Ministry of Health for the years 2022-2023 in the Republic of Iraq. The age- and sex-specific incidence of hip fracture in Iraqi residents and national mortality rates were used to create a FRAX® model. Fracture probabilities were compared with those from neighbouring countries' existing FRAX models. In order to compare Iraqi hip fracture probabilities with those in other regions of the world, the remaining lifetime probability of hip fracture from the age of 50 years was calculated for men and women.

Results Fracture rates were low but comparable to neighbouring countries and, for hip fracture, closest to estimates from Saudi Arabia at older ages. Ten-year fracture probabilities, of a major osteoporotic fracture or hip fracture were slightly lower in Iraq than in neighbouring countries (Saudi Arabia shown in Figure). For hip fracture at younger ages, the difference was more pronounced. Lifetime probabilities for hip fracture at the age of 50 years Iraq were approximately 1 in 18 for women and 1 in 24 for men.

Conclusion This new FRAX model will enhance accuracy of determining fracture probability among the Iraqi population and help guide decisions about treatment

Figure. 10-year probability of hip fracture (upper panel) and major osteoporotic fracture (lower panel) in women with no risk factors by age from Iraq and Saudi Arabia. Body mass index set to 25kg/m^2.

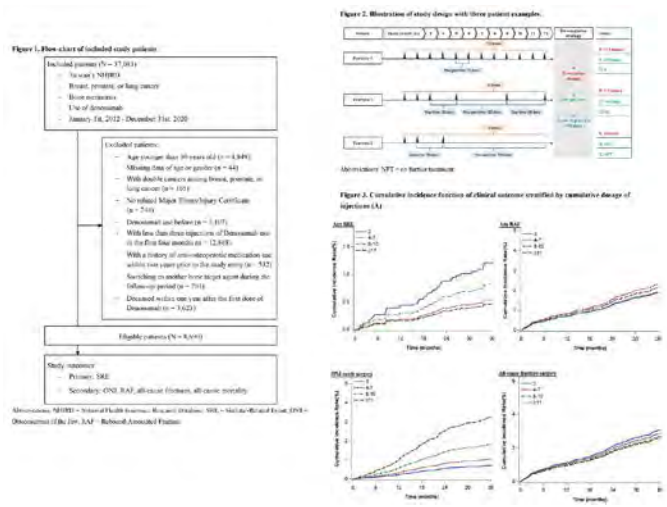
Objectives The construct for FRAX model outputs depends on country specific fracture incidence and mortality. The current FRAX model for Czechia is based on hip fracture data from 2008-2009. New data are available for years 2011-2022. The aim of the present study was to examine the impact of these more recent data on the FRAX probability outputs for Czechia.

Material and Methods Hip fracture incidence for Czechia from 2011-2022 were investigated and years chosen, with concurrent Czechia mortality data from the UN, to build a new FRAX model for Czechia. The new FRAX model for Czechia was compared to the old model derived using hip fracture and mortality data from 2008-2009. For both the old and new models, a ratio from Malmö was used to calculate the incidence of clinical spine, forearm, humerus fractures. The 10-year probability of major osteoporotic fracture (MOF) was used when comparing old and new FRAX model.

Results Given that hip fracture incidence declined significantly by 0.7% per year in men between 2011 and 2022 and by 1.8% per year in women, it was determined that the most recent years should be used as the reference period for the FRAX model. However, as the COVID-19 pandemic affected both fracture incidence and mortality during 2020–2022, data from 2017–2019 were chosen instead. The new 10-year probability of major osteoporotic fracture was lower than the old model, except for the age 90 years. For younger women the difference between the old and new FRAX model was minor up to the age of 65 years (Figure). From the age of 70 years the difference between the old and new model was greater, with the new model having lower probabilities. The largest difference between old and new model was seen for age 80 where the difference was 5% points (19% vs 14%).

Conclusion Use of the more recent hip fracture incidence data impacts on the outputs from FRAX, leading to lower probabilities than the old model. These findings support the need for an updated FRAX model for calculating fracture probabilities in Czechia.

Figure The 10 year probability of a major osteoporotic fracture (%) for a woman with BMI 25 kg/m^2 where the BMD was not known.



P677

DENOSUMAB DE-ESCALATION STRATEGIES AND CLINICAL OUTCOMES IN PATIENTS WITH BONE METASTASES: A NATIONWIDE COHORT STUDY

H. K. Yen[1], C. C. Hung[2], J. Y. Hsu[3], S. H. Fu[2], C. Y. Wang[4], W. H. Lin[1]

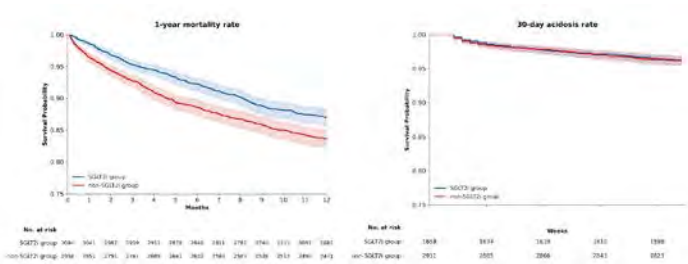
[1]Department of Orthopaedic Surgery, National Taiwan University Hospital, Taipei, Taiwan; [2]Department of Orthopedics, National Taiwan University Hospital Yun-Lin Branch, Douliu, Taiwan; [3]Department of Orthopedic Surgery, National Taiwan University Hospital, Taipei, Taiwan, Taipei, Taiwan; [4]National Center for Geriatrics and Welfare Research, National Health Research Institutes, Huwei, Taiwan

OBJECTIVE(S): Long-term denosumab therapy requires balancing skeletal protection against cumulative toxicities, such as osteonecrosis of the jaw (ONJ), and the potential risk of rebound fractures upon discontinuation. This study evaluated the real-world impact of different de-escalation strategies on the risks of skeletal-related events (SREs), ONJ, and rebound-associated fractures (RAFs) in patients with bone metastases.

MATERIAL AND METHODS: This nationwide, retrospective cohort

study utilized data from Taiwan's National Health Insurance Research Database. We identified 8,690 patients with breast, prostate, or lung cancer and confirmed skeletal metastases who initiated denosumab therapy between 2012 and 2020. Patients were categorized based on treatment patterns within the first year using three strategies: cumulative dosage (3, 4-7, 8-10, or≥11 injections), maximum injection interval (≤60, 61-90, >90 days, or no further treatment), and frequency of gaps >60 days. The primary outcome was any SRE requiring surgery, and secondary outcomes included surgically treated ONJ and RAFs.

RESULTS: Compared with patients receiving ≥11 doses, those receiving only 3 doses had a significantly increased risk of SREs (adjusted hazard ratio [aHR], 3.20; p = 0.03), but a markedly lower risk of ONJ (aHR, 0.21; p < 0.001). Intervals of 61–90 days did not significantly elevate SRE risk compared to intervals ≤60 days. However, it is crucial to note that extending the maximum injection interval beyond 90 days was associated with a significantly higher SRE risk (aHR, 2.50; p = 0.003). Across all strategies, de-escalation approaches consistently reduced the risk of ONJ but were not associated with an increased risk of surgically treated RAFs.



CONCLUSION(S): Extending the denosumab dosing interval up to 90 days appears to be a safe strategy that maintains protection against SREs while reducing the risk of ONJ. However, extending intervals beyond 90 days or administering very low cumulative dosages is associated with a loss of skeletal protection. While the risk of severe rebound fractures appears low, these findings support the feasibility of modest de-escalation in clinical practice, pending confirmation by randomized controlled trials.

P678

PRIORITIZING EARLY SURGICAL INTERVENTION FOR HIP FRACTURE IN SGLT2 INHIBITOR USERS: A REAL-WORLD STUDY ON SURVIVAL AND METABOLIC SAFETY

H. K. Yen[1], S. H. Fu[2], C. Y. Wang[3]

[1]Department of Orthopaedic Surgery, National Taiwan University Hospital, Taipei, Taiwan; [2]Department of Orthopedics, National Taiwan University Hospital Yun-Lin Branch, Douliu, Taiwan; [3]National Center for Geriatrics and Welfare Research, National Health Research Institutes, Huwei, Taiwan

Background: Current guidelines recommending a 3- to 4-day preoperative washout for sodium-glucose cotransporter 2 inhibitors (SGLT2i) to prevent diabetic ketoacidosis (DKA) conflict with the urgent need for hip fracture surgery (including fixation and arthroplasty). This study evaluated whether the survival benefits of early surgical intervention (SI; ≤2 days) outweigh the risks of insufficient medication washout.

Methods: We utilized a global real-world database (TriNetX) to conduct a retrospective cohort study of patients with type 2 diabetes who sustained hip fractures. Two propensity score-matched analyses were performed (1) SGLT2i users versus non-users, both receiving early surgery; and (2) SGLT2i users stratified by surgical timing into early (≤2 days) versus delayed (>2 days) cohorts. The primary endpoint was 1-year all-cause mortality. Secondary endpoints included 30-day DKA and complications.

Results: SGLT2i use was associated with higher 1-year and 30-day survival compared with non-use (hazard ratio [HR], 0.74; 95% confidence interval [CI], 0.64-0.86), without increasing the 30-day risk of DKA. Among SGLT2i users, early SI was associated with significantly better 1-year survival compared with delayed surgery (HR, 0.69; 95% CI, 0.53 to 0.88). The 30-day risks of DKA (1.4% vs. 1.2%) and all-cause mortality did not differ significantly between the early and delayed groups.

Conclusions: Early SI for hip fractures in SGLT2i users confers a significant survival benefit without a measurable increase in metabolic complications. Strict adherence to prolonged washout protocols may be counterproductive; multidisciplinary management facilitating early surgery should be prioritized over medication discontinuation.

P679

EVALUATION OF FRAX FOR PREDICTING OSTEOPOROTIC FRACTURES IN PATIENTS WITH CANCER

H. Koyanagi[1], K. Saito[2], S. Tsujino[2], T. Gokita[2]

[1]Department of Rehabilitation Medicine, Saitama Cancer Center, Saitama, Japan; [2]Department of Orthopaedic Surgery, Saitama Cancer Center, Saitama, Japan

Background

Patients with cancer are at increased risk of osteoporosis and osteoporotic fractures due to the effects of chemotherapy, radiotherapy, hormonal therapy, and steroid treatment. In the general population, the Fracture Risk Assessment Tool (FRAX) is widely used to estimate fracture risk; however, its usefulness in patients with cancer has not been sufficiently validated.

Objective

To evaluate whether the FRAX score is useful for predicting osteoporotic fractures in patients with cancer and to examine its limitations.

Methods

This retrospective cohort study included 215 patients with cancer who received osteoporosis treatment at our outpatient clinic between January 2022 and December 2024. Patients with multiple myeloma, bone metastases, pathological fractures, age ≤40 years, or a follow-up period of less than 6 months were excluded. The primary outcome was the occurrence of major osteoporotic fractures (vertebral, hip, humeral, or forearm fractures) during the follow-up period. FRAX scores were compared between patients with and without fractures. The predictive ability of FRAX was evaluated using receiver operating characteristic (ROC) curve analysis.

Results

There was no significant difference in FRAX scores between the fracture and non-fracture groups. ROC analysis demonstrated a low predictive performance of FRAX for osteoporotic fractures, with an area under the curve (AUC) of 0.52. Kaplan–Meier analysis also showed that FRAX was not a significant risk factor for fracture occurrence.

Discussion

The present study suggests that FRAX may have limited ability to predict osteoporotic fractures in patients with cancer. Possible reasons include: (1) FRAX is designed to estimate 10-year fracture risk, whereas the observation period in this study was relatively short; (2) early initiation

of osteoporosis treatment in patients at high fracture risk may have introduced confounding effects due to treatment intervention; and (3) cancer-specific risk factors, such as cancer type, treatment modality, and cancer-related alterations in bone metabolism, are not sufficiently reflected in FRAX. Although FRAX cannot be considered ineffective in patients with cancer, its application should be interpreted with caution.

Conclusion

The usefulness of FRAX for predicting osteoporotic fractures in patients with cancer appears to be limited. Comprehensive fracture risk assessment that incorporates cancer-specific risk factors, rather than reliance on FRAX alone, is required in this population.

P680

ROMOSOZUMAB FOLLOWING DENOSUMAB: A CASE OF NEW VERTEBRAL FRACTURE DESPITE BMD IMPROVEMENT

H. Lassoued[1], O. Lamy[2], C. Leyvraz[3], E. Gonzalez-Rodriguez[1]

[1]rheumatology department , bone disease center, Lausanne, Switzerland; [2]Internal medecine department, Bone disease center, Lausanne, Switzerland; [3]Faculty of biology and medecine, Unil, Lausanne, Switzerland

Background

The effectiveness of Romosozumab in postmenopausal women previously treated with antiresorptive agents remains controversial. Evidence suggests that its efficacy may be diminished when used as second-line therapy following prior antiresorptive treatment. We report a case of vertebral fracture progression in a patient initiated on Romosozumab after prolonged denosumab therapy.

Case Summary

A 68-year-old woman with a known diagnosis of osteoporosis since 2016 was treated with denosumab for six years. The last injection was administered in March 2023, followed by the initiation of oral alendronate in September 2023. In January 2024, she presented with acute lower back pain. A CT scan revealed recent vertebral compression fractures at D11 and D12, along with older fractures at D3, D6, and D9. Given the occurrence of multiple fractures, monthly treatment with Romosozumab, 210 mg was initiated in March 2024. In January 2025, during the 10th dose of Romosozumab , the patient reported a recurrence and worsening of lumbar pain. A repeat CT scan revealed new vertebral fractures at D8 and D10. Laboratory investigations showed normal calcium and phosphate levels, a supratherapeutic vitamin D level at 120 nmol/l, and preserved renal function. The C-terminal telopeptide (CTX) level was at 300 ng/l (N< 643). Secondary causes of osteoporosis were rule out: thyroid function was normal, there was no evidence of monoclonal gammopathy, tryptase level was within normal range, and celiac disease serology was negative. Bone densitometry after 12 months of romosozumab treatment revealed a 30% improvement in spinal bone mineral density (BMD), with stable BMD at the hip.

Conclusion

Despite a significant increase in spinal BMD, romosozumab was insufficient to prevent further vertebral fractures in this patient. This case highlights the potential limitations of romosozumab when used after denosumab, possibly due to the rebound effect associated with denosumab discontinuation. It underscores the importance of careful planning in sequential osteoporosis therapy, particularly after long-term use of potent antiresorptive.

P681

HYPEROSTOSIS FRONTALIS INTERNA MIMICKING RECURRENT CRANIAL TUMOR: A DIAGNOSTIC CHALLENGE

H. Lassoued[1], O. Lamy[2], E. Gonzalez-Rodriguez[1]

[1]rheumatology department , bone disease center, Lausanne, Switzerland; [2]Internal medecine department, Bone disease center, Lausanne, Switzerland

Background:

Hyperostosis Frontalis Interna (HFI) is a benign, usually asymptomatic condition characterized by irregular thickening of the inner table of the frontal bone. It is most commonly identified incidentally on skull radiographs or CT/MRI scans, particularly in postmenopausal women. Diagnosis can be challenging due to overlapping radiological features with metabolic, neoplastic, and sclerosing bone disorders.

Case Presentation:

We report the case of a 56-year-old woman with a history of surgical excision of an intraosseous and intracranial meningioma in 2019, initially revealed by frontal swelling. Postoperative complications included compressive pneumocephalus and hematoma requiring re-intervention, followed by a favorable outcome with transient speech disturbances.

She presented with a firm frontal swelling contralateral to the initial surgical site, without increased cranial circumference or neurological symptoms. The patient reported no bone pain, headaches, or hearing impairment. Laboratory investigations showed normal phosphocalcium balance, normal parathyroid hormone and thyroid-stimulating hormone levels, and supratherapeutic vitamin D levels. Bone mineral density was normal.

Imaging revealed diffuse thickening of the cranial bones. A recurrent intraosseous meningioma was considered unlikely due to the diffuse rather than focal involvement. Paget's disease was excluded based on the absence of bone pain, deformity, increased cranial circumference, and normal alkaline phosphatase levels. Metabolic disorders such as hyperparathyroidism, hypoparathyroidism, and acromegaly were ruled out by clinical and laboratory findings. Hemoglobinopathies, myeloproliferative disorders, mastocytosis, autosomal dominant osteopetrosis, and Van Buchem disease were also excluded based on normal blood counts, tryptase levels, bone densitometry, and scintigraphic findings.

Hyperostosis Frontalis Interna was ultimately retained as the most consistent diagnosis.

Conclusion:

This case highlights the diagnostic challenge posed by Hyperostosis Frontalis Interna in patients with a history of cranial tumors. In the absence of clinical, metabolic, or radiological features supporting alternative etiologies, HFI should be considered to avoid unnecessary investigations and interventions.

P682

CORYLIFOL A SUPPRESSES OSTEOCLASTOGENESIS AND ALLEVIATES OVARIECTOMY-INDUCED BONE LOSS VIA ATTENUATING ROS PRODUCTION AND IMPAIRING MITOCHONDRIAL FUNCTION

H. Li[1], W. Deng[2], Y. Li[1], J. Xu[3], S. Zhang[1]

[1]Guangzhou university of chinese medicine, Guangzhou, China; [2]Guangzhou university of chinese medicin, Guangzhou, China; [3]ShenZhen Institute of Advanced Technology, Chinese Academy of Sciences,, Shenzhen, China

Osteoporosis is a systemic disease characterized by an imbalance in bone homeostasis, where osteoblasts fail to fully compensate for the bone resorption induced by osteoclasts. Corylifol A, a flavonoid extracted from Fructus psoraleae, has been identified as a potential treatment for this condition. Predictions from network pharmacology and molecular docking studies suggest that Corylifol A exhibits strong binding affinity with NFATc1, Nrf2, PI3K, and AKT1. Empirical evidence from in vivo experiments indicates that Corylifol A significantly mitigates systemic bone loss induced by ovariectomy by suppressing both the generation and activation of osteoclasts. In vitro studies further showed that Corylifol A inhibited the activation of PI3K-AKT and MAPK pathways and calcium channels induced by RANKL in a time gradient manner, and specifically inhibited the phosphorylation of PI3K, AKT, GSK3 β, ERK, CaMKII, CaMKIV, and Calmodulin. It also diminishes ROS production through Nrf2 activation, leading to a decrease in the expression of key regulators such as NFATcl, C-Fos, Acp5, Mmp9, and CTSK that are involved in osteoclastogenesis. Notably, our RNA-seq analysis suggests that Corylifol A primarily impacts mitochondrial energy metabolism by suppressing oxidative phosphorylation. Collectively, these findings demonstrate that Corylifol A is a novel inhibitor of osteoclastogenesis, offering potential therapeutic applications for diseases associated with excessive bone resorption.

P683

ISOIMPERATORIN ATTENUATES BONE LOSS BY INHIBITING THE BINDING OF RANKL TO RANK

H. Li[1], W. Deng[2], Y. Li[1], S. Zhang[1], J. Xu[3]

[1]Guangzhou university of chinese medicine, Guangzhou, China; [2]Guangzhou university of chinese medicin, Guangzhou, China; [3]ShenZhen Institute of Advanced Technology, Chinese Academy of Sciences,, Shenzhen, China

Osteoporosis, an immune disease characterized by bone mass loss and microstructure destruction, is often seen in postmenopausal women. Isoimperatorin (ISO), a bioactive, natural furanocoumarin isolated from many traditional Chinese herbal medicines, has therapeutic effects against various diseases; however, its effect on bone homeostasis remains unclear. In this study, we investigated the effect of ISO on the differentiation and activation of osteoclast and its molecular mechanism in vitro, and evaluated the effect of ISO on bone metabolism by ovariectomized (OVX) rat model. In *vitro* experiments showed that ISO affected RANKL-induced MAPK, NFAT, NFATc1 trafficking and expression, osteoclast F-actin banding, osteoclast-characteristic gene expression, ROS inhibitory activity, and calcium oscillations, NF-κB signaling pathway. *In vivo* experiments showed that oral administration of ISO effectively reduced bone loss caused by ovariectomy and retained bone mass. Collectively, ISO inhibits RANK/RANKL binding, thereby reducing the activity of NFATc1, calcium, and ROS and inhibiting osteoclast generation. In addition, ISO protects bone mass by slowing osteoclast production and downregulating NFATc1 gene and protein expression in the bone tissue microenvironment and inhibits OVX-induced bone loss *in vivo*.

P684

EPIMEDIN B ATTENUATES OVARIECTOMY-INDUCED BONE LOSS BY SUPPRESSING OSTEOCLASTOGENESIS THROUGH DECREASING ROS PRODUCTION AND TARGETING ESR1

H. Li[1], Y. Lai[2], Y. Li[1], T. Zhou[2], J. Yang[2], H. Chen[3], P. Gu[4], X. Deng[4]

[1]Guangzhou university of chinese medicine, Guangzhou, China; [2]Liwan District TCM Orthopedics Hospital of Guangzhou (Xiguan TCM Orthopedics Hospital), Spinal Orthopedics,, Guangzhou, China; [3]Guangzhou Zengcheng District Hospital of Traditional Chinese Medicine,, Guangzhou, China; [4]Nanchang Hongdu Hospital of Traditional Chinese Medicine, Nanchang, China

Excessive activation of osteoclasts plays a pivotal role in the pathophysiology of osteoporosis, which is predominantly characterized by bone resorption. However, therapeutic strategies targeting osteoclasts remain limited. In this study, we investigated the inhibitory effects of Epimedin B (EB) on osteoclastogenesis and its potential anti-osteoporotic properties. An ex vivo osteoclast differentiation model was established using BMMs. Osteoclastogenesis was assessed via TRAP staining and F-actin ring formation. Hydroxyapatite bone plates were employed to evaluate the impact of EB on bone resorption function. Network pharmacology predictions combined with transcriptomic analysis were employed to untangle the signaling pathways and targets regulated by EB. Cellular thermal shift assays were performed to validate EB-interacting proteins. The expression levels of osteoclast-specific and ROS-related proteins/genes, as well as phosphorylation changes in signaling pathways, were quantified by Western blot and RT-PCR. Protein expression and mitochondrial ROS levels were detected by fluorescence staining, while intracellular ROS generation was measured via flow cytometry. An ovariectomized (OVX) mouse model of osteoporosis was established to evaluate the bone-protective effects and in vivo mechanisms of EB. The results demonstrated that EB significantly suppressed RANKL-induced osteoclast differentiation, particularly during the early phase and cytoskeletal organization stage, while also inhibiting bone resorption activity in mature osteoclasts. Mechanistic studies revealed that EB directly binds to ESR1 and protects it from degradation. Furthermore, EB was found to downregulate the expression of osteoclast-specific genes/ proteins and inhibit the phosphorylation of MAPK and PI3K-AKT pathways. Furthermore, EB activated the AMPK pathway, subsequently initiating the Nrf2-mediated antioxidant system, leading to reduced ROS levels. Notably, EB markedly rescued ovariectomy-induced bone loss, with efficacy comparable to estrogen therapy, an effect associated with suppressed osteoclast activity and AMPK pathway activation. These findings provide, for the first time, novel theoretical evidence and a potential therapeutic strategy for EB in the

prevention and treatment of osteoporosis.

P685

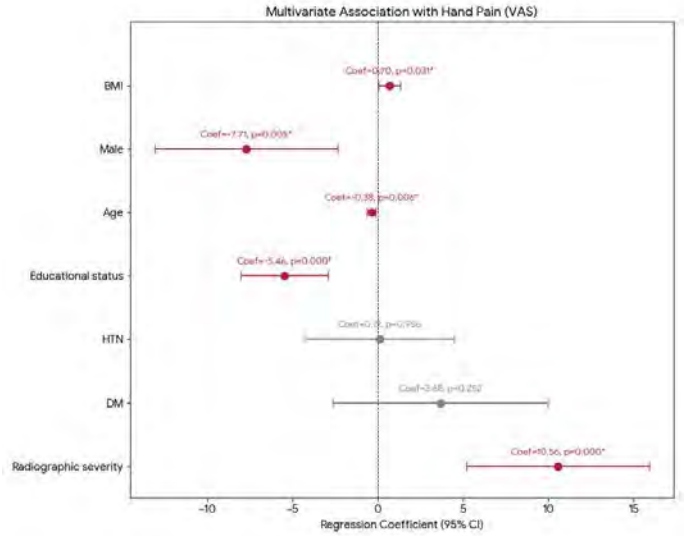
ASSOCIATION BETWEEN METABOLIC MARKERS AND SYMPTOM SEVERITY IN PATIENTS WITH HAND OSTEOARTHRITIS: A REAL-WORLD DATA ANALYSIS

H. N. Lee[1], S.-I. Lee[2], Y.-H. Cheon[2], H. J. Lim[2], K. S. Park[3], H.-O. Kim[1]

[1]Rheumatology/Internal medicine/Changwon gyeongsang national university hospital, Changwon, South Korea; [2]Rheumatology/Internal medicine/Gyeongsang national university hospital, Jinju, South Korea; [3]Preventive Medicine/Institute of Health Sciences/Gyeongsang national university hospital, Jinju, South Korea

Background:
Osteoarthritis (OA) is increasingly recognized as a metabolic disorder, often termed Metabolic OA.While the association between metabolic factors and OA is well-established in weight-bearing joints like the knee, research specifically targeting hand OA—a non-weight-bearing joint—remains limited. This study aimed to validate the hypothesis that hand OA represents a metabolic phenotype by analyzing the impact of obesity on symptom severity using real-world data from a hospital-based clinical cohort.

Methods:
We analyzed cross-sectional data from a hospital-based cohort of patients with hand OA (N=655). Body Mass Index (BMI) was analyzed as the primary indicator of metabolic status. The clinical outcomes were hand pain intensity and functional disability (AUSCAN score). Multivariate linear regression analyses were performed to determine independent associations, adjusting for potential confounders including age, sex, socioeconomic status, lifestyle factors, comorbidities, and radiographic OA severity.



Results:
In the multivariate model, BMI was identified as an independent risk factor for aggravated hand pain (estimate:0.695, 95% CI: 0.063–1.328, P=0.031), confirming that higher systemic adiposity contributes to worse pain outcomes even in non-weight-bearing joints. While BMI was not significantly associated with functional disability (AUSCAN score, P=0.715) (Table 1), Diabetes Mellitus emerged as a significant predictor for worse function (P=0.025) (Figure 1).

Conclusion:
Using clinical cohort data, this study provides empirical evidence supporting the Metabolic OA phenotype in the hand, demonstrating that systemic metabolic burden independently exacerbates pain severity. These findings suggest that the mechanism of pain in hand OA involves systemic inflammation driven by adiposity rather than mechanical loading alone. Consequently, weight management and metabolic control should be emphasized as integral components of therapeutic strategies for patients with hand OA.

Table 1. Multivariate Linear Regression Analysis of BMI on Hand Pain and Function (Adjusted for Sex, Age, Education, Smoking, Alcohol, Hypertension, Diabetes, and OA Severity)

Predictor (BMI)	3.676 (-0.63 – 8.98)	0.025	1.63 (-1.01 – 4.28)	0.252
OA Severity	10.888 (2.55 – 19.23)	<0.001	4.08 (-1.31 – 10.36)	0.13
Education	-2.468 (-5.05 – 0.11)	<0.001	-4.4 (-7.52 – -1.28)	0.001
Age (years)	-0.376 (-0.444 – -0.307)	0.000	-0.116 (-0.168 – -0.063)	0.515
Sex (M/F)	-1.701 (-5.63 – 2.23)	0.002	-1.76 (-6.31 – 2.79)	0.001
BMI (kg/m²)	0.695 (0.063 – 1.328)	0.031	0.143 (-0.824 – 0.824)	0.712

EFFICACY OF TNF INHIBITORS IN COXITIS ASSOCIATED WITH SPONDYLOARTHRITIS

H. Saghi[1], H. Hachfi[1], D. Khalifa[1], F. Fhima[1], N. El Amri[1], R. Fakhfakh[1], K. Baccouche[1], E. Bouajina[1]

[1]Farhat Hached Hospital Rheumatology Department, Sousse, Tunisia

Objective : Coxitis has always been considered a marker of severity in chronic inflammatory rheumatic diseases. It compromises functional prognosis and represents a turning point in the course of the disease. The aim of this study was to evaluate the effectiveness of anti–TNF-alpha therapy in the treatment of coxitis in patients with spondyloarthritis (SpA).

Material and Methods: This was a retrospective study including 25 patients followed for SpA according to the ASAS 2009 criteria, complicated by coxitis. All patients were treated with anti–TNF-alpha agents after failure of first-line therapy with nonsteroidal anti-inflammatory drugs (NSAIDs).

Results: The study included 5 women and 20 men with a mean age of 31.9 years. Patients were diagnosed with radiographic spondyloarthritis in 72% of cases, psoriatic arthritis in 20%, and inflammatory bowel disease–associated SpA in 8%. All patients presented with coxitis, which was bilateral in 80% of cases. Etanercept was the most commonly used anti–TNF-alpha agent (9 cases, 36%), followed by infliximab (7 cases, 28%), certolizumab (5 cases, 20%), and adalimumab (4 cases, 16%). Evaluation performed at a mean of 12 months after initiation of anti–

TNF-alpha therapy showed a reduction in BASDAI of at least 42.8%, with improvement in hip mobility in 15 cases (60%), and a decrease in the Lequesne functional index to less than 11 points in 5 patients (20%). Follow-up pelvic radiographs showed stabilization of lesions in the majority of cases (21 patients, 84%), without the need for surgical intervention.

Conclusion: Coxitis is a marker of disease severity and a major source of functional disability in SpA. Its assessment should be systematic from the time of diagnosis. Our study suggests that biological therapy with anti–TNF-alpha agents may allow stabilization of lesions and prevent progression of coxitis.

P688
EFFICACY AND SAFETY OF RITUXIMAB IN RHEUMATOLOGY

H. Saghi[1], H. Hachfi[1], F. Fhima[1], R. Fakhfakh[1], N. El Amri[1], D. Khalifa[1], K. Baccouche[1], E. Bouajina[1]

[1]Farhat Hached Hospital Rheumatology Department, Sousse, Tunisia

Objectiv : Biologic therapies play an increasingly important role in the management of autoimmune diseases, and rituximab is no exception. Rituximab is a chimeric anti-CD20 monoclonal antibody. In rheumatology, it is approved for the treatment of rheumatoid arthritis (RA) and is also used in several other autoimmune diseases. The aim of this study was to evaluate the indications, efficacy, and safety of rituximab in patients followed in a rheumatology setting.

Material and Methods: This was a retrospective study including 40 patients followed in the Rheumatology Department who received rituximab between 1999 and 2025. Each treatment course consisted of two intravenous infusions of 1 g administered 15 days apart.

Results: The study population included 35 women and 5 men, with a mean age of 50.37 years (range 23–73). Rituximab was prescribed for RA in 26 cases (65%). The main indications in RA were interstitial lung disease in 10 cases (38.5%), failure of methotrexate combined with sulfasalazine in 9 cases (34.6%), failure of anti-TNF therapy in 6 cases (23.1%), and contraindication to anti-TNF agents in 1 case (3.8%). Rituximab was also used in overlap syndromes in 6 patients (15%), predominantly RA–systemic lupus erythematosus overlap in 3 cases. In these patients, treatment was initiated after failure of methotrexate in 2 cases and failure of both anti-TNF and anti–IL-6 therapy in 1 case. Rituximab was prescribed in systemic sclerosis in 3 cases (7.5%) due to persistent active disease despite corticosteroids, colchicine, and nifedipine; in systemic lupus erythematosus in 3 cases (7.5%) following failure of corticosteroids combined with hydroxychloroquine in 2 cases and hydroxychloroquine plus an immunosuppressive agent in 1 case; in polymyositis in 1 case (2.5%) after failure of corticosteroids and azathioprine; and in Still's disease in 1 case (2.5%) due to persistent disease activity despite corticosteroids and methotrexate. Twenty-six patients (65%) received one treatment course, 8 patients (20%) received two courses, 4 patients (10%) received three courses, and 2 patients (5%) received seven courses. The mean interval between courses was one year. Clinical outcome under rituximab was favorable in 77.5% of cases (31 patients), with a mean follow-up of 6 months. Rituximab was well tolerated overall. Mild immediate infusion-related allergic reactions were observed in 4 cases and were rapidly controlled. One case of recurrent infectious pneumonia was reported.

Conclusion: In our series, rituximab demonstrated significant therapeutic efficacy, particularly in rheumatoid arthritis. Its safety profile was satisfactory, with a low incidence of adverse events. These findings support the use of rituximab as an effective therapeutic option, especially in severe disease refractory to conventional treatments and anti–TNF-alpha agents.

P689
KNOWLEDGE AND MANAGEMENT OF GOUT IN GENERAL PRACTICE

H. Saghi[1], R. Grassa[2], N. Ben Chekaya[1], S. Zrour[2], I. Bejia[2]

[1]Fattouma Bourguiba University Hospital Rheumatology Department, Monatir, Tunisia; [2]Fattouma Bourguiba University Hospital Rheumatology Department, Monastir, Tunisia

Objective :
Gout, the leading chronic metabolic arthropathy, results from the deposition of monosodium urate crystals. Management by general practitioners is common, highlighting the importance of this study in Tunisia. The aim of this study was to assess the diagnostic and therapeutic management of gout by primary care physicians in Tunisia.
Material and Methods :
This was a cross-sectional study of primary care physicians, using an online questionnaire to assess the diagnostic and therapeutic management of gout
Results :
Forty doctors completed the questionnaire; the average age was 28.6 years, with a standard deviation of 3.6. Eleven doctors (27.5%) indicated that they had received training in rheumatology. Fifty-two point five percent of general practitioners estimated the frequency of consultations for gout attacks to be between 1 and 10 per year.
The main diagnostic criteria were hyperuricemia (82.5%) and the presence of arthritis (77.5%). After a first gout attack, 37 doctors (92.5%) recommended a systematic biological work-up. Regarding the type of tests, 35 doctors (89.7%) recommended a uric acid blood test, followed by creatinine (61.5%), an inflammatory panel (51.3%), and a lipid panel (28.2%).
For crisis management, 80% prescribed monotherapy, primarily colchicine (90%) and NSAIDs (22.5%). No doctor reported prescribing oral corticosteroids. In the event of colchicine side effects, 42.5% suggested allopurinol as a replacement, 37.5% discontinued colchicine, 22.5% recommended an analgesic, and 17.5% suggested reducing the dose. In the case of severe attacks or ineffective treatment, 50% of doctors referred gout patients to rheumatologists.
Fifty-five percent of general practitioners considered hypouricemic treatment after several gout attacks, 50% after a first gout attack, 47.5% in the presence of nephropathy or renal colic, 45% in the presence of tophus, 30% in the presence of asymptomatic chronic hyperuricemia, and 30% in the presence of radiological signs.
In terms of therapeutic objectives, 17% of practitioners aimed to lower uricemia to below 50 mg/L, 37.5% to below 60 mg/L, and 20% to below 70 mg/L. The maximum dose of allopurinol not to be exceeded was 600 mg, as noted by 52.5% of practitioners; 300 mg, 900 mg, and 1200 mg were indicated by 32.5%, 12.5%, and 2.5%, respectively.
Regarding patient education, the majority of doctors advised proper monitoring of treatment for comorbidities (82.5%) and restriction of red meat and blue fish (77.5%).
Conclusion :

This study highlights the gout management practices of general practitioners in Tunisia, revealing gaps in the management of acute attacks and the prescription of treatments. It suggests the need for continued medical education for general practitioners.

P690

DIAGNOSTIC YIELD OF CT-GUIDED DISCO-VERTEBRAL BIOPSY IN INFECTIOUS SPONDYLODISCITIS

H. Saghi[1], D. Khalifa[1], R. Fakhfakh[1], N. El Amri[1], H. Hachfi[1], K. Baccouche[1], E. Bouajina[1]

[1]Farhat Hached Hospital Rheumatology Department, Sousse, Tunisia

Objective: Infectious spondylodiscitis is a severe and potentially life-threatening condition that may compromise both vital and functional prognosis. Diagnosis is primarily based on imaging, particularly spinal magnetic resonance imaging (MRI), which allows early suspicion of the disease. However, identification of the causative pathogen remains a major challenge for optimizing antimicrobial therapy. In this context, computed tomography (CT)-guided disco-vertebral biopsy (DVB) represents a key diagnostic tool.

The aim of this study was to assess the diagnostic value of CT-guided disco-vertebral biopsy in establishing the etiological diagnosis of infectious spondylodiscitis.

Patients and Methods This retrospective study included patients diagnosed with infectious spondylodiscitis between 1998 and 2025. All patients had a clinical and radiological suspicion of infectious spondylodiscitis. Most of them underwent CT-guided disco-vertebral biopsy. Demographic characteristics and clinical data were analyzed. Comparisons were performed between patients with positive microbiological and/or histological findings and those with negative results.

Results The study population consisted of 54 men and 47 women, with a male-to-female ratio of 1.15. The mean age was 58.41 years (range: 15–95). The median duration of symptoms was 60 days (range: 10–365). Back pain was present in all cases, while fever was observed in 44.8%. The mean erythrocyte sedimentation rate (ESR) was 79.01 mm/h (range: 1–185). Lumbar spine involvement was the most frequent (62.2%). Associated epiduritis was observed in 60.4% of cases. CT-guided disco-vertebral biopsy was performed in 46.9% of patients and yielded a diagnostic rate of 17.6% (8/46). Pathogen identification was achieved in 61.1% of pyogenic spondylodiscitis cases, 33.3% of tuberculous cases, and 5.5% of brucellar cases. Histopathological examination proved to be the most sensitive diagnostic modality. In our series, the only factor significantly associated with successful microbial isolation was the presence of positive blood cultures (p = 0.02). No statistically significant association was found with symptom duration (p = 0.7), fever (p = 0.3), associated epiduritis (p = 0.2), spondylodiscitis localization (p = 0.5), ESR (p = 0.7), or C-reactive protein levels (p = 0.08).

Conclusion CT-guided disco-vertebral biopsy demonstrated a modest diagnostic yield (17.6%), with better pathogen identification in pyogenic spondylodiscitis. Histopathological examination remains the most sensitive diagnostic tool. In our cohort, only positive blood cultures were significantly associated with microbial isolation, while no other clinical, biological, or radiological factors showed a significant correlation.

P691

EPIDURAL INVOLVEMENT IN INFECTIOUS SPONDYLODISCITIS: FREQUENCY AND ASSOCIATED FACTORS

H. Saghi[1], D. Khalifa[1], R. Fakhfakh[1], N. El Amri[1], H. Hachfi[1], K. Baccouche[1], E. Bouajina[1]

[1]Farhat Hached Hospital Rheumatology Department, Sousse, Tunisia

Objective: Infectious spondylodiscitis is a severe condition frequently complicated by epidural involvement. Epidural extension represents a feared complication, associated with significant morbidity and mortality. Early diagnosis and prompt initiation of appropriate treatment are crucial to improve both functional and vital outcomes. The aim of this study was to assess the incidence of epidural involvement in infectious spondylodiscitis, describe its clinical characteristics, and identify factors associated with its occurrence.

Material and Methods: This retrospective study included patients with infectious spondylodiscitis confirmed by imaging over a 27-year period. Clinical, biological, and radiological data were analyzed to determine the prevalence of epidural involvement, its characteristics, and factors associated with its development.

Results The study population consisted of 54 men and 47 women, with a male-to-female ratio of 1.15. The mean age was 58.41 years (range: 15–95). The median duration of symptoms was 60 days (range: 10–365). Back pain was present in all patients, while fever was observed in 44.8%. Neurological deficits were reported in 25 patients (26.6%).

The mean erythrocyte sedimentation rate (ESR) was 79.01 mm/h (range: 1–185). Lumbar spine involvement was the most common localization (62.2%). Associated epidural involvement was identified in 60.4% of cases. Among these patients, 22 cases (37.9%) were related to tuberculosis, 17 cases (29.3%) to pyogenic organisms, and 12 cases (20.7%) to brucellosis, while no pathogen was identified in 12.1% of cases.

No statistically significant association was found between epidural involvement and the isolated pathogen (p = 0.08) or the localization of infectious spondylodiscitis (p = 0.7). Among the factors analyzed, no significant association was observed between epidural involvement and diabetes mellitus (n = 12; p = 0.4), chronic kidney disease (n = 3; p = 0.4), history of malignancy (n = 1; p = 0.3), long-term corticosteroid therapy (n = 1; p = 0.1), degenerative spine disease (n = 11; p = 0.2), prior infection (n = 10; p = 0.3), previous spinal surgery (n = 3; p = 0.2), or prior epidural injection (n = 1; p = 0.1).

Conclusion Epidural involvement is a frequent complication of infectious spondylodiscitis, occurring in more than half of the cases in our series. However, no specific clinical, biological, or radiological factors were significantly associated with its occurrence.

P692

ASSOCIATION BETWEEN MMP-3 LEVELS AND STRUCTURAL DAMAGE IN SPONDYLOARTHRITIS

K. Zouaoui[1], N. Mejri[1], S. Rahmouni[1], A. Krir[2], W. Tekaya[1], E. Rabhi[1], S. Rekik[1], S. Boussaid[1], H. Sahli[1]

[1]Rheumatology Department, LA RABTA Hospital, Tunis, Tunisia; [2]Biochemistry Department, Pasteur Institute, Tunis, Tunisia

Objective :
The objective of this study was to evaluate the association between MMP-3 levels and structural damage in patients with spondyloarthritis, and to assess the potential role of MMP-3 as a biomarker of structural involvement.
Methods :
A 6-month cross-sectional study was conducted including patients who met 2009 ASAS Criteria of spondyloarthritis. Clinical, paraclinical and therapeutic data were collected. Structural damage was quantified using the Modified Stoke Ankylosing Spondylitis Spinal Score (mSASSS). MMP3 levels were measured in all patients using an ELISA technique.
Results:
The study involved 73 patients with SpA with a sex ratio (M/F) of 2.04. The mean age of patients was 41,6 ± 12,3 [18–75] years and the mean disease duration was about 12,6 ± 8,4 [0 – 36] years. In this work, 97.3% of patients presented with axial SpA and 86.3% had radiographic axial SpA. Furthermore, 57.5% of patients had peripheral involvement, including 39.7% with joint involvement and 28.8% with enthesitis. The median C-reactive Protein (CRP) level was 5 mg/L IQR [25;75] [2; 10.3]. The mean ASDAS-CRP was 2.34 ± 1.19. The median mSASSS score was 4 IQR [25;75] [1.25; 7]. Forty-four patients were treated with anti-TNF alpha. The mean MMP-3 levels were 25.15 ng/mL ± 12.27 [4,4-61,2]. Correlation analysis between serum MMP-3 levels and the mSASSS radiographic score revealed no statistically significant association (p=0.460).
Conclusion:
In our study, no significant association was found between structural damage and MMP-3 levels in patients with SpA. Further longitudinal studies are needed to better characterize this link.

P693

A STUDY OF SPONDYLOARTHRITIS PROFILES IN THE ELDERLY

K. Zouaoui[1], E. Razgallah[1], S. Rahmouni[1], S. Rekik[1], S. Boussaid[1], H. Sahli[1]

[1]Rheumatology Department, LA RABTA Hospital, Tunis, Tunisia

Objective:
The objective of this study was to examine the characteristics of this condition.
Methods:
We conducted a retrospective descriptive study collecting cases of spondyloarthritis in elderly patients diagnosed in a Tunisian rheumatology department. Sociodemographic, clinical, biological, and radiological data were collected.
Results:
We enrolled 22 patients with a mean age of 64.8 ± 9.2 years. The sex ratio (M/F) was 1.44. Sixty-two percent of the patients were illiterate, and 12.5% had attained a secondary education level. Forty-three percent of the patients lived in rural areas. More than half of the patients (54.5%) had axial spondyloarthritis, while 45.5% had both axial and peripheral spondyloarthritis. Among the latter, 20% had axial onset, 40% peripheral onset, and 40% both axial and peripheral onset. The mean age at diagnosis was 62 ± 10 years, with a diagnostic delay of 1.7 ± 2.8 years. One patient had associated inflammatory bowel disease, and one patient had cutaneous psoriasis. Uveitis was observed in two patients. Comorbidities including diabetes mellitus, arterial hypertension, dyslipidemia, and osteoporosis were present in 18.2%, 31.8%, 22.7%, and 28.6% of cases, respectively. Only 4.5% of patients had a family history of spondyloarthritis, and similarly, 4.5% had a family history of psoriasis. Forty-one percent of patients were smokers. General health deterioration was noted in 39% of patients. Regarding clinical examination findings, sacroiliac joint pain was present in 68% of patients, while cervical and lumbar stiffness were reported in 71.4% and 86.4% of patients, respectively. The mean Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) score was 4.44 ± 2.12. Four patients (19%) had unilateral coxitis on X-ray, and one patient had bilateral coxitis. The mean C-reactive protein (CRP) level was 47.3 ± 46 mg/L. With respect to disease-modifying treatment, 77.3% of patients were treated with nonsteroidal anti-inflammatory drugs, 27% required initiation of a first biologic therapy, and 13.6% required a second biologic therapy.
Conclusion:
The diagnosis of late-onset spondyloarthritis can be challenging due to the high frequency of systemic manifestations. Establishing an accurate diagnosis allows for optimal patient management.

P694

SERUM 25(OH)D LEVELS AFTER THE COVID-19 ERA: A LARGE COHORT ANALYSIS

D. Gogas Yavuz[1], H. Salva Coban[1], S. Girgin[2], E. Kalintas Zihni[3], P. Ay[2], G. Haklar[3]

[1]Marmara University School of Medicine, Department of Endocrinology and Metabolism, Istanbul, Türkiye; [2]Marmara University School of Medicine, Department of Public Health Division, Istanbul, Türkiye; [3]Marmara University School of Medicine, Department of Biochemistry, Istanbul, Türkiye

Background/Aim: Vitamin D deficiency affects approximately 60% of the Turkish population, largely due to limited access to vitamin D–fortified foods and inadequate supplementation practices. Following the COVID-19 pandemic, an increase in vitamin D use and prescribing has been observed in clinical practice. This study aimed to evaluate serum 25-hydroxyvitamin D (25(OH)D) concentrations in hospitalized adults during the post-COVID era and to assess whether increased supplementation translated into improved population-level vitamin D status.
Methods: Serum 25(OH)D measurements from adult inpatients admitted to a tertiary-care university hospital between January 2022 and December 2024 were retrospectively analyzed. Patient age at sampling, sex, serum 25(OH)D, parathyroid hormone (PTH), and calcium levels were extracted from hospital records; individuals aged <18 years were excluded. Serum 25(OH)D was measured using a chemiluminescence immunoassay (CLIA). Vitamin D deficiency was defined as 25(OH)D <20 ng/mL and severe deficiency as <10 ng/mL.
Results: A total of **124,067** measurements were included. The median 25(OH)D level was **17.4ng/mL** (25th–75th percentile:**10.2–24.3**) in the overall cohort. Median 25(OH)D levels were **16.9ng/mL(10.4–25.6)**

in females and **18.0ng/mL(12.7–24.5)** in males, with a statistically significant difference (**p<0.001**). Serum 25(OH)D levels increased with advancing age, and differences across age groups were significant (**p<0.001**). (Table-1) Seasonal variation was consistent across 2022–2024, with higher levels in summer and lower levels in winter (**p<0.001**). (Figure-1) Vitamin D deficiency was present in **59.3%** (n=73,551), and severe deficiency (<10 ng/mL), a threshold associated with increased osteomalacia risk, occurred in **20.1%** (n=24,962). Vitamin D toxicity was rare, detected in **15 individuals** (<0.001%). Compared with our 2016 cohort (deficiency **57.8%**, severe deficiency **25%**), overall deficiency remained similar (59.3%), while severe deficiency declined (20.1%) in the post-COVID era.

Conclusion: Despite an apparent rise in vitamin D supplementation following the COVID-19 pandemic, the overall prevalence of vitamin D deficiency in hospitalized adults remained persistently high and comparable to pre-pandemic data. Although severe deficiency decreased, the ongoing burden of deficiency suggests that individual supplementation alone is insufficient at the population level. Strengthened public health strategies, including targeted screening of high-risk groups and expanded vitamin D food fortification policies may be required to achieve meaningful improvements in vitamin D status in Türkiye.

Variable	Category	Median (25th–75th percentile)	p-value
Sex	Female	16.90 (10.40–25.60)	<0.001
	Male	18.00 (12.70–24.50)	
Age Group (years)	18–29	14.40 (9.65–20.80)	<0.001
	30–39	15.60 (10.30–22.57)	
	40–49	16.90 (10.99–24.38)	
	50–59	18.51 (12.00–26.50)	
	60–69	20.10 (12.80–28.30)	
	70–79	20.76 (12.66–29.90)	
	≥80	19.80 (11.10–30.30)

IDENTIFICATION OF A 25(OH)D THRESHOLD FOR PARATHYROID HORMONE ELEVATION IN VITAMIN D DEFICIENCY

D. Gogas Yavuz[1], H. Salva Coban[1], S. Girgin[2], E. Kalintas Zihni[3], P. Ay[2], G. Haklar[3]

[1]Marmara University School of Medicine, Department of Endocrinology and Metabolism, Istanbul, Türkiye; [2]Marmara University School of Medicine, Department of Public Health Division, Istanbul, Türkiye; [3]Marmara University School of Medicine, Department of Biochemistry, Istanbul, Türkiye

Aim: Vitamin D (25(OH)D) deficiency is a common cause of secondary hyperparathyroidism and may adversely affect bone health. Although 25(OH)D levels <20 ng/mL are frequently associated with elevated parathyroid hormone (PTH), the magnitude of PTH response varies substantially between individuals. We aimed to characterize the relationship between 25(OH)D and PTH and to identify a potential threshold for PTH elevation in a large Turkish population.

Method: A total of 20,245 individuals who presented to Marmara University were included in the study. All patients had serum 25(OH) D levels ≤30 ng/mL and an estimated glomerular filtration rate (eGFR) ≥90 mL/min/1.73 m². All patients were older than 18 years of age. Elevated parathyroid hormone levels were defined as concentrations exceeding the upper limit of the laboratory reference range (60 pg/mL). Demographic variables (age and sex) and biochemical measurements including serum calcium, phosphorus, and 25(OH)D levels were obtained from the hospital electronic medical records.

Results: 20,245 patients included in the study, 16,538 (81.7%) had parathyroid hormone levels <60 pg/mL, while 3,707 (18.3%) had levels ≥60 pg/mL. The median 25(OH)D level was 16.73 (3.04-30.00) ng/mL in patients with PTH <60 pg/mL and 12.60 (3.01–30.00) ng/mL in those with PTH ≥60 pg/mL (p<0.001). (Table-1)

A modest inverse correlation was observed between 25(OH)D and PTH levels (r = −0.20). Piecewise linear regression identified a breakpoint at approximately **11.4 ng/mL** of 25(OH)D, beyond which the slope of the relationship between vitamin D and PTH changed. (Figure-1) Below this threshold, decreasing 25(OH)D levels were associated with a steeper rise in PTH (slope ≈ −2.26), whereas above the breakpoint PTH values showed a much flatter pattern with respect to 25(OH)D (slope ≈−0.30).

Conclusion: These findings indicate that PTH elevation becomes more pronounced when 25(OH)D concentrations fall below approximately 11.4 ng/mL in this CKD-free population. Previous studies have reported PTH plateaus or inflection points between 10–30 ng/mL. Additional studies incorporating skeletal endpoints and longitudinal clinical outcomes are warranted to determine the clinical relevance of this biochemical threshold.

Parathyroid Hormone Levels	<60 pg/mL	≥60 pg/mL	p-value
25-OH Vitamin D ng/mL (n=20,250)) Median (Min–Max)	16.73 (3.04-30.00)	12.60 (3.01–30.00)	<0.001
Age (n=20,250) Median(Min-Max)	50 (18-98)	54 (18-98)	<0.001
Calcium mg/dl (n=20,250) Median(Min-Max)	9.6 (5-10.6)	9.5 (6.5-10.6)	<0.001
Phosphorus mg/dl (n=18,842) Median(Min-Max)	3.5 (0.6-8.7)	3.4 (1.1-6.4)	<0.001

OSTEOPOROSIS IN NURSING HOME RESIDENTS: PREVALENCE, RISK FACTORS, AND EFFECTIVENESS OF SCREENING STRATEGIES COMPARED TO COMMUNITY-DWELLING ELDERLY

H. Y. Cheng[1], W. C. Lin[1], C. T. Li[2], Y. F. Chang[3], C. S. Chang[3], C. H. Wu[3], T. W. Tai[1]

[1]Department of Orthopedics, National Cheng Kung University Hospital, College of Medicine, National Cheng Kung University, Tainan, Taiwan; [2]Institute of Gerontology, College of Medicine, National Cheng Kung University, Tainan, Taiwan; [3]Department of Family Medicine, National Cheng Kung University Hospital, Tainan, Taiwan

Objectives: This study investigated the prevalence and severity of osteoporosis in nursing home residents compared to community-dwelling elderly, evaluated multiple screening strategies, and identified risk factors to improve diagnostic approaches in this high-risk population.
Methods: This cross-sectional study examined 148 nursing home residents from Guo-Xin Nursing Home and compared findings with 148 age- and sex-matched controls from the community. Data collection included demographic variables, medical history, fracture history, biochemical markers (vitamin D, PTH, albumin), sarcopenia measurements, osteoporosis screening tools (OSTAi/MOSTAi), and dual-energy X-ray absorptiometry (DXA). Multiple diagnostic strategies were compared for effectiveness.
Results: Osteoporosis prevalence reached 72.3% by DEXA among nursing home residents versus 50% in controls (p<0.001), with significantly higher rates in women (86.8%) than men (49.1%). Nursing home residents demonstrated significantly lower bone mineral density at all sites compared to matched controls (femoral neck: 0.552 vs 0.664, p<0.001). Combined screening using fracture history, plain radiography, OSTAi/MOSTAi, and DXA identified 89.2% of cases. Female gender, lower body weight, reduced mobility, and lower grip strength emerged as significant risk factors. OSTAi/MOSTAi showed moderate screening utility.
Conclusions: Nursing home residents exhibit exceptionally high osteoporosis prevalence and severity compared to community-dwelling elderly. Multi-modal screening approaches provide optimal screening power. These findings support the need for proactive and systematic osteoporosis screening in nursing home residents to facilitate timely diagnosis and management.

P697

ASSOCIATION BETWEEN DIETARY PROTEIN INTAKE AND FRAILTY IN IRANIAN OLDER ADULTS: A CROSS-SECTIONAL ANALYSIS FROM THE BIRJAND LONGITUDINAL AGING STUDY

H.-S. Ejtahed[1], A. Ramezani[1], M. Khorashadizadeh[2], H. Fakhrzadeh[1], F. Sharifi[1]

[1]Tehran University of Medical Sciences, Tehran, Iran; [2]Birjand University of Medical Sciences, Birjand, Iran

Objective: Frailty is a geriatric syndrome associated with adverse health outcomes, and nutrition has been identified as a modifiable risk factor. However, evidence remains inconsistent regarding the impact of proteins with various sources on frailty. We aim to examine the association between animal- and plant-based protein intake and frailty, with the goal of informing future nutritional recommendations for the elderly.
Materials and Methods: This cross-sectional study utilized data from 1,265 community-dwelling adults aged ≥60 years enrolled in the second phase of the Birjand Longitudinal Aging Study (BLAS). Frailty status was assessed using a 50-item Frailty Index and categorized as robust, prefrail, and frail. Dietary protein intake was estimated via a validated food frequency questionnaire. The main sources of animal proteins include chicken, eggs, fish, and red meat, while the sources of plant proteins include soybeans, legumes, and nuts. Associations were examined using regression models, adjusted for demographic, clinical, nutritional, lifestyle, and biochemical factors.
Results: A total of 1,265 older adults (mean age = 72.5 ± 6.7 years; 51.2% female) were included, comprising 47.0% robust, 47.5% pre-frail, and 5.5% frail participants. Frailty was associated with older age, female sex, obesity, lower education, physical inactivity, diabetes, and lower hemoglobin levels (all p < 0.001). Mean total protein intake decreased progressively from robust (65.6 ± 34.6 g/day) to frail (48.8 ± 26.9 g/day; p < 0.001). In multinomial regression, animal protein intake was associated with frailty. This association lost significance after adjusting for covariates. Vegetable protein intake showed no significant relationship with either pre-frailty or frailty in any model. However, in the energy decomposition model, higher protein energy percentage showed an inverse association with frailty (RRR = 0.600; 95% CI: 0.364–0.989; p = 0.045), suggesting protective effects of protein density.
Conclusions: Higher total protein intake was associated with reduced odds of frailty in older Iranian adults, independent of protein source. These findings highlight the importance of achieving adequate daily protein intake as a primary nutritional strategy for frailty prevention. Longitudinal and interventional studies are warranted to establish causality.

P698

INVESTIGATING THE ASSOCIATION BETWEEN GUT MICROBIOTA AND SARCOPENIA IN OLDER ADULTS

H.-S. Ejtahed[1], F. Ramezani Kashal[2], F. Sharifi[3], S. Najafi[2], F. Ettehad[1], M. Moodi[4], E. Shafaei[4], M. Khorashadizadeh[4], R. Heshmat[2], G. Shafiee[2]

[1]Obesity and Eating Habits Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran; [2]Chronic Diseases Research Center, Endocrinology and Metabolism Population Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran; [3]Elderly Health Research Center, Endocrinology and Metabolism Population Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran; [4]Birjand University of Medical Sciences, Birjand, Iran

Objective: Investigating the gut microbiota has become a promising avenue for understanding the gut-muscle axis and its role in age-related conditions like sarcopenia. Although numerous studies reported altered gut microbial communities in individuals with sarcopenia—pointing to

gut dysbiosis as a potential driver of chronic inflammation and muscle deterioration—findings vary across geographical and ethnic backgrounds. This study examines the association between gut microbiota and sarcopenia in a sample of older adults from Iran.

Materials and Methods: Fecal samples were obtained from 293 participants (aged 60 years and above) enrolled in the Birjand Longitudinal Aging Study. The gut microbiota was analyzed using quantitative PCR with genus-specific primers targeting 12 bacterial genera. Sarcopenia was diagnosed based on anthropometric measures, body composition (assessed by bioelectric impedance analysis), handgrip strength, and gait speed. Participants were classified into sarcopenic and non-sarcopenic groups according to the European Working Group on Sarcopenia in Older People (EWGSOP). Associations between bacterial abundance and sarcopenia—as well as its individual components—were evaluated.

Results: Of the 293 elderly subjects, 112 (38.2%) were identified with sarcopenia. Higher levels of Akkermansia were significantly associated with increased likelihood of sarcopenia. Furthermore, Akkermansia abundance negatively correlated with handgrip strength, skeletal muscle index (SMI), and gait speed ($p < 0.05$). Each unit increase in Akkermansia was linked to a 9% rise in the odds of low SMI and an 8% increase in the odds of slow gait speed. Both Akkermansia and Lactobacillus were associated with elevated odds of sarcopenia (7% and 8%, respectively). In contrast, Roseburia exhibited a protective effect, with each unit increase reducing the odds of sarcopenia by 11.5%. Roseburia was also positively correlated with gait speed ($p < 0.05$).

Conclusions: This research highlights significant relationships between specific gut bacteria and sarcopenia. While Akkermansia and Lactobacillus were associated with higher sarcopenia risk, higher levels of Roseburia appeared beneficial. These results support the potential of targeting gut microbiota as an innovative strategy for preventing and managing sarcopenia.

P699

THREE-YEAR REAL-WORLD EFFECTS OF DENOSUMAB ON BONE MINERAL DENSITY ACCORDING TO PRIOR OSTEOPOROSIS TREATMENT IN KOREAN POSTMENOPAUSAL WOMEN

H. Kim[1,2], H.-Y. Kim[3], J.-Y. Han[2]

[1]Department of Obstetrics and Gynecology, Seoul National University College of Medicine, Seoul, South Korea; [2]Department of Obstetrics and Gynecology, Seoul National University Hospital, Seoul, South Korea; [3]Department of Obstetrics and Gynecology, Chungnam National University Hospital, Daejeon, South Korea

Objective: This study aimed to evaluate the 3-year effectiveness of denosumab stratified by previous osteoporosis treatment status in routine clinical practice in Korea.

Materials and Methods: We retrospectively reviewed the medical records of postmenopausal women with osteoporosis who received denosumab at a tertiary medical center between 2017 and 2023. Participants were categorized into three groups based on treatment prior to denosumab initiation: treatment-naïve, prior bisphosphonate users, and prior selective estrogen receptor modulator (SERM) users. Longitudinal changes in BMD at the lumbar spine, femoral neck, and total femur were analyzed over a 3-year period using linear mixed-effects models adjusted for age and body mass index at index bone densitometry.

Results: Among 365 postmenopausal women, 250 (68.5%) were treatment-naïve, 81 (22.2%) had previously received bisphosphonates, and 34 (9.3%) had been treated with SERMs. At the lumbar spine, BMD increased over 3 years in all treatment groups, from 0.819 g/cm² at baseline to 0.950 g/cm² in treatment-naïve patients, 0.911 g/cm² in prior bisphosphonate users, and 0.912 g/cm² in prior SERM users. Differences in lumbar spine BMD by prior treatment status were significant at year 1 ($P = 0.001$) and year 2 ($P = 0.01$), but not at year 3 ($P = 0.09$). At the femoral neck, BMD remained relatively stable in treatment-naïve patients (0.690 to 0.703 g/cm² at year 3), whereas a decline was observed at year 3 among prior bisphosphonate and SERM users (to 0.675 and 0.674 g/cm², respectively); however, no significant differences between treatment groups were detected at any time point. At the total femur, BMD increased from 0.709–0.710 g/cm² at baseline to 0.730–0.769 g/cm² at year 3, with significant differences by prior treatment status observed at year 1 ($P = 0.0003$), but not at later time points.

Conclusions: In this real-world cohort of Korean postmenopausal women with osteoporosis, denosumab was associated with sustained increases in BMD at the lumbar spine and total femur over 3 years across different prior treatment groups.

Acknowledgments: This work was supported by the New Faculty Startup Fund from Seoul National University. The funding source had no role in the study design, data collection, analysis, interpretation, manuscript writing, or the decision to submit the paper for publication.

FEATURES OF MUSCULOSKELETAL MASS AND METABOLIC RISKS IN PATIENTS WITH OSTEOARTHRITIS OF LARGE JOINTS: DATA FROM DENSITOMETRIC AND BIOIMPEDANCE ASSESSMENT OF BODY COMPOSITION

I. Bashkova[1], A. Timofeeva[2], I. Kiseleva[2], E. Andronnikov[2]

[1]Chuvash State University named after I.N. Ulyanov; Federal Center for Traumatology, Orthopedics and Arthroplasty (Cheboksary), Cheboksary, Russia, Cheboksary, Russia; [2]Federal Center for Traumatology, Orthopedics and Arthroplasty (Cheboksary), Cheboksary, Russia, Cheboksary, Russia

The aim of the study was to analyze the assessment of body composition in patients with osteoarthritis (OA) of large joints of the lower extremities in need of arthroplasty using bioimpedance analysis (BIA) and dual–energy X-ray absorptiometry (DXA).

Materials and methods. The study included 39 patients divided into 2 groups, comparable in age and gender composition. The main group included 21 patients with knee joint OA of the III radiological stage, the control group included 18 patients with traumatic knee injury with minimal clinical manifestations. Body composition was assessed using bioimpedance analysis (ABC-01 "MEDASS") and DXA (GE Lunar Prodigy Advance) using the "Whole Body" software.

Results. When comparing the results of BIA in patients of the main group, significantly higher% of fat mass (52.6 [50.1; 54.7]% vs. 43.5 [39.5; 50.9]%, $p<0.001$), extracellular fluid content (17.8 [17.0; 19.4] kg vs. 14.9 [13.5; 17.2] kg, $p=0.020$), the mineral part of bone tissue (2.76

[2.70; 3.03] kg versus 2.29 [2.07; 2.66] kg, p=0.009), but lower values of specific basal metabolism (735.6 [695.9; 761.5] kcal/sq.m/day. against 778.2 [761.2; 808.1] kcal/sq.m.m/day, p=0.020). In patients with OA of large joints, the proportion of musculoskeletal tissue was significantly lower (42.2 [37.1; 44.0]% versus 43.9 [43.3; 45.9]%, p=0.033), there was a tendency to decrease the proportion of active cell mass (p=0.071) and phase angle (p=0.060).

Densitometric assessment of body composition revealed a statistically significant increase in the body fat index in patients of the main group (20.8 [17.7; 25.2] kg/sq.m versus 12.5 [9.6; 20.2] kg/sq.m, p=0.002), % of body fat (54.3 [52.2; 57.6]% versus 45.4 [39.2; 53.3]%, p<0.001), the ratio of body fat to limb fat (0.59 [0.53; 0.63] vs. 0.51 [0.45; 0.58], p=0.028), lean mass index (19.78 [17.55; 22.57] vs. 17.66 [14.58; 19.82], p=0.035). At the same time, the ratio of lean mass to fat mass turned out to be statistically significantly better in patients without OA (1.30 [0.97; 1.59] versus 0.90 [0.83; 1.0], p<0.001). Indexed appendicular skeletal muscle mass (AMSM) was significantly higher in patients of the main group (13.9 [11.4; 15.2] kg/sq.m versus 12.0 [9.9; 12.9] kg/sq.m, p=0.014), however, the ratio of AMSM to BMI in this group of patients was significantly lower (0.72 [0.67; 0.93] versus 1.03 [0.83; 1.10], p=0.003). There was a tendency to increase BMD in the spine (p=0.159) and decrease in the pelvic bones (p=0.517) in patients of the main group.

Conclusion. In patients with knee OA undergoing arthroplasty, the phenotype of sarcopenic obesity was revealed, characterized by abdominal fat distribution (p<0.001) and a decrease in the proportion of musculoskeletal tissue (p=0.033) with an increased absolute mass of the mineral part of the bone (p=0.009). The low ratio of muscle mass to BMI (p=0.003) and the abdominal type of fat distribution define this category of patients as a metabolic risk group requiring a comprehensive assessment of body composition (including DXA and BIA) when planning orthopedic treatment.

P701

CLINICAL AND ANAMNESTIC PREDICTORS OF OSTEOPOROSIS IN YOUNG WOMEN: IMPORTANCE FOR EARLY DIAGNOSIS AND PREVENTION OF FRACTURES

I. Bashkova[1], I. Kiseleva[2]

[1]Chuvash State University named after I.N. Ulyanov; Federal Center for Traumatology, Orthopedics and Arthroplasty (Cheboksary), Cheboksary, Russia, Cheboksary, Russia;
[2]Federal Center for Traumatology, Orthopedics and Arthroplasty (Cheboksary), Cheboksary, Russia, Cheboksary, Russia

The aim of the study was to retrospectively study the risk factors for osteoporosis (OP) and osteoporotic fractures in women of reproductive age.

Materials and methods. The study included 70 women of reproductive age with preserved menstrual function who applied to the OP Prevention Center during the calendar year. Risk factors for OP and osteoporotic fractures were assessed, concomitant diseases were analyzed, pharmacological history was clarified, and serum levels of total calcium, phosphorus, alkaline phosphatase, creatinine, and total 25-hydroxyvitamin D (25(OH)D) were determined. Dual-energy X-ray absorptiometry (DXA) of the central skeletal regions (Lunar Prodigy Advance) was performed in 60 patients.

Results. The median age of the patients was 41 [35; 45] years (hereinafter referred to as Me [Q1; Q3]). The median body mass index (BMI) was 21.7 [19.8; 23.1] kg/m^2, 25.7% of women had a BMI of less than 20 kg/m^2, and 14.3% of women had grade 1-2 obesity. According to the results of the DXA, the median Z-criterion in the lumbar spine (LS) was -1.0 [-1.9; -0.3] SD, in the proximal thigh (PT) -1.0 [-2.0; -0.6] SD. In 21.7% of cases, a decrease in bone mineral density (BMD) was found below the age-related population norm (Z-criterion below -2.0 SD). 17 women (24.3%) had a history of having suffered a low-energy fracture, while 4 patients had a history of 2 pathological fractures. In the structure of low–energy fractures: fractures of the femoral neck in 8 people (2 of them on both sides), compression fractures of the vertebral bodies in 5 people, distal third of the forearm bones in 3 people, neck of the humerus in 2 people. Every 3rd patient with a pathological fracture had a BMI of less than 20 kg/m^2. 7 patients with a history of DXA fractures showed a decrease in BMD below the age norm, while only 2 suffered from rheumatic disease, for which they took glucocorticoids (GC). The other 15 patients did not receive GC. In patients with pathological fractures, compared with women without a history of fractures, BMD per LS (0.752 [0.712; 0.883] g/cm^2 vs. 0.840 [0.731; 0.943] g/cm^2, p=0.29) and PT (0.926 [0.883; 1.170] g/cm^2 vs. 1,072 [0.927; 1.180] g/cm^2, p=0.041) was lower. The BMI in women with pathological fractures was slightly lower than in women without a history of fractures (20.6 [18.8; 22.5] kg/m^2 versus 21.8 [20.1; 25.2] kg/m^2, p=0.066).

The indicators characterizing the activity of mineral metabolism: the content of total calcium, inorganic phosphorus, and alkaline phosphatase in the blood were within the values of the reference intervals. The median serum level is 25(OH)D was 20.4 [15.2; 33.8] ng/ml. Vitamin D deficiency was found in 19.3% of women, vitamin D deficiency in 45.6%. When analyzing concomitant diseases that can lead to the development of secondary OP, it turned out that 21 patients (30%) had immuno–inflammatory rheumatic disease (rheumatoid arthritis in 15 people, systemic lupus erythematosus in 3 people, ankylosing spondylitis in 2 people, nonspecific aortoarteritis in 1 person). Other patients also had a history of chronic obstructive pulmonary disease (3 people), oncohematological diseases (3 people), epilepsy (1 person), primary biliary cirrhosis of the liver (1 person), diffuse toxic goiter (1 person), Vogt-Koyanagi-Harada syndrome (1 person). 17 women (24.3%) took systemic GC. Smoking was detected in only 2 cases. There were no other bad habits.

Correlation analysis revealed positive correlations between BMI and BMD in LS (r=+0.39, p=0.019), and BMD in PT (r=+0.30, p=0.039). There were no statistically significant correlations between serum vitamin D levels and BMD, BMI.

Conclusion. The study revealed a high prevalence of OP risk factors in women of reproductive age. Every 4th patient had a history of a low-energy fracture, and every 5th had a reduced BMD. The key associated factors were low body mass index (BMI < 20 kg/m^2) and vitamin D deficiency (found in 45.6% of women). Concomitant rheumatic diseases and GC intake also played a significant role. The results obtained emphasize the need for targeted screening for OP, vitamin D level control, and body weight correction in young women at risk for the prevention of pathological fractures.

P702

EXPERIMENTAL STUDY OF THE EFFECT OF TIBIAL BONE DEFECT ON ORGANOMETRIC PARAMETERS OF THE IMMUNE SYSTEM UNDER THE INFLUENCE OF SODIUM BENZOATE

I. Belik[1], N. Mosyagina[1], N. Gal'Cenko[2], D. Vailenko[1]

[1]FSBEI HI ST. LUKA LSMU of MOH of Russia; Human anatomy

department, Lugansk, Russia; [2]Lugansk city polyclinic № 11, LPR, Lugansk, Russia

Objective of the study was to examine the effect of tibial bone defect on organometric parameters of the immune system under the influence of sodium benzoate. In the modern world, scientific and technological progress and accelerated rhythm of life contribute to the growth of traumatism, including severe fractures, which are often accompanied by complications and decreased immunity. This requires studying the role of the immune system in the process of bone repair. Also relevant is the problem of environmental safety of food products that affect human health and are actively researched by scientists.
Material and methods. The study was conducted on 60 male white rats weighing 200-210 g, divided into control and study groups. The rats of the study group received 1 ml of sodium benzoate (500 mg/kg) through a probe for 60 days. Then a defect of 2.2 mm in diameter was applied under anesthesia. The animals were removed from the experiment on days 3, 10, 15, 24, and 45. All procedures were in accordance with the European Convention for the Protection of Vertebrate Animals.
Results. Against the background of 60-day administration of sodium benzoate (500 mg/kg) in rats with tibial bone defects, a decrease in the weight of thymus and spleen on the 3rd, 10th, 15th and 24th days compared to the control group was observed. On the 45th day the differences remain statistically significant. Linear indices of thymus and spleen (length, width, thickness) were also reduced on the 3rd day, further the values leveled off.
Conclusion. Application of metadiaphyseal defect in tibiae and sodium benzoate increased the duration of decrease in mass, length, width and thickness of spleen and thymus.

P703

CLINICAL CHARACTERISTICS, TREATMENT AND FOLLOW-UP OF PATIENTS WITH OSTEOGENESIS IMPERFECTA IN A TERTIARY HOSPITAL

I. Calvo Zorrilla[1], I. Urionaguena Onaindia[1], N. Vegas Revenga[1], O. Ibarguengoitia Barrena[1], N. Plaza Aulestia[1], L. B. Ibarrola Paino[1], D. Montero Seisdedos[1], X. Cenicacelaya Olabarrieta[1], J. F. García Llorente[1]

[1]Galdakao-Usansolo University Hospital, Rheumatology, Galdakao, Spain

Objective:

To describe the clinical, densitometric (DXA) and therapeutic characteristics of patients with osteogenesis imperfecta (OI) followed at a tertiary care hospital.
Material and Methods:

A retrospective, observational and descriptive study was performed using electronic medical records of patients diagnosed with OI. Demographic variables, fracture history, DXA assessments performed and results obtained, prescribed treatments, and clinical follow-up were analyzed.
Results:

Twenty-one patients were included, with a mean age of 38.8±21.3 years; 52% were women. Genetic testing was performed in eight patients, all diagnosed with type I OI.

A history of fractures was present in 86% of patients, with a median of three fractures per patient. The most frequent fracture sites were the femur (n=11), wrist (n=5) and vertebrae (n=3), predominantly during childhood.
DXA was performed in 13 patients at the lumbar spine and in 4 at the hip (Table 1).
Bisphosphonates were the most frequently used treatments (n=9). Three patients received osteoanabolic therapy (two with teriparatide and one with romosozumab). Twelve patients had no history of antiresorptive or osteoanabolic treatment. Calcium and vitamin D supplementation were prescribed in seven and thirteen patients, respectively.
Sixty-two percent were followed in specialised clinics.
Conclusions:

This series shows a high fracture burden in patients with OI, together with limited use of DXA, suboptimal calcium and vitamin D supplementation, and low exposure to bone-targeted therapies.
These findings highlight the importance of specialized follow-up and optimization of diagnostic and therapeutic strategies, particularly in patients with OI who present risk factors for osteoporosis and low bone mineral density values on DXA.

Table 1. Bone densitometry results

Lumbar spine	
Patients with DXA, n (%)	**13** (61.19%)
T/Z-score, mean ± SD	−2.03 ± 1.76
T/Z-score, median and IQR	−2.0 [−3.2 a −0.8]
Minimum T/Z-score	-5.2
Maximum T/Z-score	+1.2
Patients with osteopenia (T/Z −1,0 to −2.5), n (%)	9 (69%)
Patients with osteoporosis (T/Z ≤ −2.5), n (%)	5 (38.5%)

Fémur total	
Patients with DXA, n (%)	**4** (19.0%)
T/Z-score, mean ± SD	−2.02 ± 1.15
T/Z-score, median and IQR	−2.05 [−3.4 a −0.5]
Minimum T/Z-score	−3.4
Maximum T/Z-score	−0.5
Patients with osteopenia (T/Z −1,0 to −2.5), n (%)	3 (75%)
Patients with osteoporosis (T/Z ≤ −2.5), n (%)	2 (50%)

SEQUENTIAL TREATMENT AFTER ROMOSOZUMAB AND ANTIFRACTURE EFFECT IN REAL-WORLD CLINICAL PRACTICE

I. Calvo Zorrilla[1], I. Urionaguena Onaindia[1], N. Vegas Revenga[1], O. Ibarguengoitia Barrena[1], N. Plaza Aulestia[1], D. Montero Seisdedos[1], L. B. Ibarrola Paino[1], X. Cenicacelaya Olabarrieta[1], J. F. García Llorente[1]

[1]Galdakao-Usansolo University Hospital, Rheumatology, Galdakao, Spain

Objective:
To analyse post-romosozumab (ROMO) sequential therapy, antifracture effectiveness and changes in bone mineral density (BMD) in real-world clinical practice.
Material and Methods:
A retrospective, observational and descriptive study was conducted

including patients who completed 12 months of ROMO treatment between November 2022 and December 2025 in a tertiary care hospital. Demographic characteristics were collected, as well as the occurrence of fragility fractures (FF) during treatment and follow-up, and previous anti-osteoporotic therapies and subsequent sequential treatment. In patients with bone densitometry (DEXA) performed before and after treatment, changes in BMD were analysed.

Results:

Thirty-two female patients were included, with a mean age of 71.0 ± 7.2 years and a high fracture burden (median of 2 FF per patient, IQR 1). Vertebral fractures were the most frequent, occurring in 31 patients (96.8%), often followed by wrist (21.8%), hip (12.5%), and humeral fractures (3.1%).

Prior to ROMO, most patients had received bisphosphonates (75%), while five patients (15.6%) were treatment-naïve. Vitamin D and calcium supplementation were prescribed to 87.5% and 65.6% of patients, respectively.

During ROMO treatment, one fracture (3.1%) occurred at the tibia and was therefore not considered osteoporotic. No new FF were observed during the subsequent follow-up (mean duration 9.7 ± 9.2 months).

After ROMO, denosumab was the most frequent sequential therapy (n=25), followed by bisphosphonates (n=7), mainly administered intravenously.

In the 20 patients with paired DXA measurements, BMD increased at all sites, predominantly at the lumbar spine (mean increase, 0.071 g/cm²), versus the femoral site (0.042 g/cm²) Table 1.

Conclusions:

In this real-world cohort of patients at very high fracture risk, ROMO followed by appropriate sequential therapy was associated with a very low incidence of FF and significant improvements in BMD.

These findings reinforce the importance of structured sequential treatment strategies after anabolic therapy and support the need for ongoing clinical follow-up to better characterise long-term antifracture outcomes after ROMO.

Table 1. Bone densitometry before and after romosozumab (n = 20)

Densitometric variable	Pre-ROMO (mean ± SD)	Post-ROMO (mean ± SD)	Mean change
Lumbar spine T-score	−3.39 ± 1.22	−2.87 ± 0.80	+0.52
Lumbar spine BMD (g/cm²)	0.764 ± 0.112	0.835 ± 0.097	+0.071
Total femur T-score	−2.54 ± 0.70	−2.34 ± 0.76	+0.20
Total femur BMD (g/cm²)	0.693 ± 0.084	0.735 ± 0.097	+0.042

ROMO: romosozumab; SD: standard deviation; BMD: bone mineral density

P705

DETERMINING INVOLUNTARY MOTOR RESPONSES AND VOLUNTARY MOTOR FUNCTIONS IN PATIENTS WITH POST-STROKE ATAXIA IN MEDICAL REHABILITATION PRACTICE

A. Filipovich[1], I. Chapko[1]

[1]Republican Scientific and Practical Center for Medical Expertise and Rehabilitation, Yukhnovka, Belarus

The relevance of developing a method for determining involuntary motor responses and voluntary motor functions in patients with cerebrovascular accidents (CVA) stems from the need to improve the principles of assessing self-care and independent mobility in the context of planning and analyzing the effectiveness of rehabilitation care.

In the last decade, this has been driven by aspects of the practical implementation of the provisions of the International Classification of Functioning, Disabilities, and Health (ICF) in the medical rehabilitation (MR) (habilitation) of individuals with disabilities.

A clinical and functional assessment of the health status of 72 patients with ataxia caused by circulatory disorders in the vertebrobasilar system (VBS) was conducted: 58 (80.6%) men and 14 (19.4%) women.

By disease duration, the examined individuals were distributed as follows: up to one year – 10 people. (13.9%); 1 to 3 years old – 27 patients (37.5%); 3 to 10 years old – 23 patients (31.9%); over 10 years old – 12 patients (16.7%). Statodynamic disturbances in patients with CVA in the VBB manifested themselves as ataxia of varying severity (72 patients; 100.0%): mild ataxia in 34 patients (47.2%), moderate ataxia in 29 patients (40.3%), and severe ataxia in 9 patients (12.5%). Determination of involuntary motor response and voluntary motor functions (using the ICF) included assessment by categories: b755 (involuntary motor response functions), b760 (control of voluntary motor functions).

An assessment of involuntary motor response function (b755) was performed to determine the integrity of involuntary contractions of large and large muscles or the entire body, induced by body position, balance, and threatening stimuli.

The examination was conducted to check the function of postural reactions, alignment, equilibrium reactions, adaptive reactions, postural maintenance, and defensive reactions. A specialist performed a series of tests: Romberg, Stuart-Holmes, Babinski (to identify asynergy), and Orzechowski; stabilometry data were analyzed.

An assessment of voluntary motor control (b760) was performed to determine functions associated with the control and coordination of voluntary movements. The examination was conducted to check the coordination, smoothness, clarity, and coordination of movements and included tests for dynamic ataxia: finger-nose, heel-knee, and index ataxia; dysmetria and hypermetria; adiadochokinesis; and the Schilder test.

A rehabilitation assessment was conducted on 29 patients with moderate ataxia. Patients were characterized by unsteadiness in the simple Romberg test with stability and instability in the sensitized Romberg test. Stabilometry parameters: balance function quality 40-65%;

statokinesiogram area 350-1000 mm2, for the Romberg test with open eyes – 250-1000 mm2; There were moderate impairments in coordination tests: the degree of deviation in coordination tests (finger-nose, finger-fingers, index) was 5-7 cm. The patient changed body posture using additional muscle effort from the lower extremities and trunk, with additional support from the arms, at a slow pace and hesitantly. The ability to maintain stability when bending was moderately limited.

Maintaining body position while standing was difficult for most patients and required additional support. Maintaining an elevated upper body position while sitting was accomplished using trunk muscles and partial support from the arms. Prolonged maintenance of a standing posture during everyday activities was accomplished with the help of a cane.

The problems and limitations in controlling involuntary motor reactions and voluntary motor functions identified in the patients were used to formulate a rehabilitation diagnosis and to set MR tasks for specialists in the multidisciplinary rehabilitation team.

P706

NON-INVASIVE PREVENTION OF FRAGILITY FRACTURES: THE ROLE OF REMS IN THE SVOLTA PROJECT

I. Covelli[1], C. Greggi[2], G. Mezzaglia[3,4], B. Moretti[1], L. Murena[5], A. Notarnicola[1], S. M. Pecce[2], E. Piccirilli[2], C. Ratti[5], G. Solarino[1], U. Tarantino[2], M. L. Brandi[4]

[1]University Orthopaedic Clinic, Azienda Consorziale Policlinico di Bari, Bari, Italy; [2]Policlinico Tor Vergata, Roma, Italy; [3]Department of Medicine and Surgery, University of Milano–Bicocca, Milano, Italy; [4]Italian Fragility Fracture Observatory (OFF Italia), Firenze, Italy; [5]Orthopaedic and Traumatology Clinic, Azienda Sanitaria Universitaria Giuliano Isontina (ASUGI), Trieste, Italy

Objective(s): Osteoporotic fractures significantly impair quality of life and increase the risk of subsequent fractures. Continuous monitoring of patients with prior fragility fractures is essential for secondary prevention and fracture risk stratification. This study proposes an integrated follow-up model based on Radiofrequency Echographic Multi-Spectrometry (REMS) to assess fracture risk, monitor bone quality and prevent re-fractures in frail patients.
Materials and Methods: Clinical data were collected from a multicentre study involving Policlinico University Hospital in Bari, Tor Vergata University Hospital in Rome and Giuliano Isontina University Hospital in Trieste. Caucasian patients of both genders, aged between 50 and 75, with a history of primary fragility fractures, were enrolled in the study. All patients underwent a REMS scan of the spine, and the scan parameters (T-score, fragility score and fracture risk classification) were recorded to enable targeted monitoring.
The following work is part of the SVOLTA Project (Sviluppo di un Servizio per la preVenzione e riduziOne delLe fratTure da frAgilità) carried out with the technical and financial support of the Ministry of Health - CCM.
Results: A total of 38 patients (35 women and 3 men) were included. Wrist fractures were the most prevalent (45%), followed by vertebral (21%) and humeral fractures (13%). The analysed patient group showed reduced bone density values (mean T-score = -1.9 ± 0.9) and poor bone microarchitecture quality (mean fragility score = 38.18 ± 8.03). In particular, the 82% was classified into medium-high risk classes (R4-R7), each associated to a probability of imminent (within 5 years) risk of major fragility fractures. Each of them has been assigned to a specific therapy and monitoring programme on the base of their identified risk class, thus improving patient assignment and personalised management
Conclusion(s): In conclusion, the presented model suggests that using REMS technology to follow up with patients who have previously experienced fragility fractures would improve secondary prevention, optimise continuity of care, reduce fragility fractures and lower costs for the National Health Service.

P707

EVALUATION PAIN INTENSITY IN LUMBOSACRAL RADICULOPATHY BY INFRARED THERMOGRAPHY

I. Dimitrijevic[1], M. Kocic[2], M. Lazovic[3], D. Mancic[4], R. Filipov[1]

[1]Institute for Treatment and Rehabilitation "Niska Banja", Nis, Serbia; [2]Clinic for Physical Medicine and Rehabilitation, Clinical Center Nis, Nis, Serbia; [3]State University of Novi Pazar, Novi Pazar, Serbia; [4]Dept. of Electronics, Faculty of Electronic Engineering, University of Niš, Nis, Serbia

Objective: Lumbosacral radiculopathy is a pathological process characterized by spinal nerve root dysfunction that leads to abnormal changes in skin temperature of the affected lower extremity. The aim of this study is to examine the correlation between the values of the regional hyporthermia of the affected lower extremity and the intensity of pain in the patients with unilateral lumbosacral radiculopathy.
Material and Methods: The prospective randomized study included 75 outpatients with unilateral lumbosacral radiculopathy that were diagnosed by clinical and electromioneurographic examinations. The intensity of pain at rest as well as pain intensity during active movement of the lumbar spine was measured by visual analogue scale (VAS). Infrared thermovision camera (Varioscan high resolution 3021) recorded the symmetrical regions of interest in lower extremities (ROIs). Quantitative analysis of the obtained thermograms was calculated the values of the regional hyporthermia of the affected extremity (ΔT) as the temperature difference in mean value temperature ROI of unaffected and affected lower extremity. The correlation of the values of the regional hyporthermia with the intensity of pain was then determined.
Results: Significant and strong correlation was found between values of regional hyporthermia and pain intensity at rest (r=0,887; p<0.001), as well as pain intensity during active movement of the lumbar spine (r=0.890; p<0.001).
Conclusion: In patients with unilateral lumbosacral radiculopathy, the values of regional hyporthermia of the affected lower extremity are correlated with pain intensity.

P708

COMPARATIVE EFFECTIVENESS OF OSTEOPOROSIS TREATMENTS IN TYPE 2 DIABETES MELLITUS: POOR GLYCEMIC CONTROL ATTENUATES TREATMENT-RELATED BMD GAINS IN REAL-WORLD PRACTICE

I. Erturk[1], A. Sarısaltık[2], D. Yavuz[3]

[1]Marmara University School of Medicine Department of Internal Medicine, Istanbul, Türkiye; [2]Marmara University School of Medicine Department of Public Health, Istanbul , Türkiye; [3]Marmara University School of Medicine Department of Internal Medicine Section of Endocrinology and Metabolism, Istanbul, Türkiye

Objective: Type 2 Diabetes Mellitus (T2DM) is associated with an increased fracture risk independent of bone mineral density (BMD), and it is thought that its adverse effects on bone quality and microarchitecture

may influence the response to osteoporosis treatment. The aim of this study was to evaluate the effectiveness of anti-osteoporotic treatments on BMD in patients with T2DM and to compare treatment responses with non-diabetic patients and according to glycemic control levels.
Materials and Methods: In this single-center retrospective study, 420 patients with T2DM (68.4 ± 10.1 years; F/M: 376/44) and 438 non-diabetic patients (69.6 ± 9.2 years; F/M: 396/42) who were followed for osteoporosis were included. First- and second-year outcomes were analyzed for alendronate (A), zoledronic acid (ZA), and denosumab (Dmb), while first-year outcomes were analyzed for teriparatide (T) and romosozumab (Rb). Lumbar spine (L1–L4) and femoral neck BMD measured by dual-energy X-ray absorptiometry (DXA), as well as bone turnover markers, were evaluated. Patients with T2DM were further stratified into subgroups according to baseline HbA1c levels. Mann–Whitney U, Kruskal–Wallis, and Wilcoxon signed-rank tests were used for statistical analyses, and $p < 0.05$ was considered statistically significant.
Results: At the end of the first year, significant increases in L1–L4 and femoral neck BMD were observed under A, ZA, Dmb, and T treatments in both diabetic and non-diabetic groups compared with baseline. No significant difference was found between T2DM and non-diabetic groups in terms of treatment-related BMD percentage changes. In the T2DM group, increases in femoral neck BMD and T-scores were significantly lower in patients with HbA1c >8% compared with those with better glycemic control ($p = 0.033$ and $p = 0.007$, respectively). Among treatment-naive patients, vertebral BMD increase with ZA therapy was significantly higher than in those previously treated for osteoporosis ($p < 0.001$).
Conclusion: In this study, the presence of T2DM itself was not associated with a reduced response to osteoporosis treatment. However, poor glycemic control in patients with T2DM may negatively affect treatment response at the cortical bone level. These findings highlight the importance of considering glycemic control status, in addition to the presence of diabetes, when planning anti-osteoporotic treatment in patients with T2DM.

P709

RESPONSE TO OSTEOPOROSIS TREATMENT IN PATIENTS WITH CHRONIC KIDNEY DISEASE: A REAL-WORLD STUDY

I. Erturk[1], A. Sarısaltık[2], D. Yavuz[3]

[1]Marmara University School of Medicine Department of Internal Medicine, Istanbul, Türkiye; [2]Marmara University School of Medicine Department of Public Health, Istanbul , Türkiye; [3]Marmara University School of Medicine Department of Internal Medicine Section of Endocrinology and Metabolism, Istanbul, Türkiye

Objective : Chronic kidney disease (CKD) is associated with disturbances in bone metabolism and increased fracture risk, while evidence regarding the efficacy of osteoporosis treatments in this population is limited. This study aimed to evaluate the effects of alendronate, zoledronic acid, denosumab, and teriparatide on bone mineral density (BMD) in patients with and without CKD.
Materials and Methods: This retrospective study included 454 osteoporotic patients followed for at least one year. Of these, 170 had CKD (mean age 72.2 ± 11.1 years; female/male: 135/35) and 284 had normal renal function (mean age 71.0 ± 8.9 years; female/male: 258/26). CKD stages were classified according to estimated glomerular filtration rate as stage 1 (n=12), stage 2 (n=44), stage 3a (n=63), stage 3b (n=41), stage 4 (n=4), and stage 5 (n=8). In the CKD group, 44 patients received alendronate, 36 zoledronic acid, 82 denosumab, and 8 teriparatide; in the non-CKD group, 60 received alendronate, 64 zoledronic acid, 144 denosumab, and 24 teriparatide. Due to the limited number of patients with CKD stages 4–5, analyses by CKD stage were restricted to stages 1–3b; however, comparisons between treatment modalities were performed in the overall CKD cohort. Lumbar spine (L1–L4) and femoral neck BMD values at baseline and after one year were obtained from medical records. Appropriate parametric or non-parametric tests were used, and $p < 0.05$ was considered statistically significant.
Results: Baseline lumbar spine BMD was higher in the CKD group compared with controls (0.911 ± 0.143 vs. 0.857 ± 0.140; $p<0.001$), whereas baseline femoral neck BMD was lower in patients with CKD (0.726 ± 0.112 vs. 0.749 ± 0.119; $p=0.01$). After one year of treatment, changes in BMD at both the lumbar spine and femoral neck were similar between CKD and non-CKD groups. Treatment response did not differ significantly across CKD stages (1–3b). Among patients with CKD, no significant differences in BMD gains were observed between alendronate, zoledronic acid, denosumab, and teriparatide.
Conclusion : In this real-world cohort, patients with CKD showed comparable BMD responses to osteoporosis treatment as those with normal renal function. Treatment efficacy was not influenced by CKD stage, and commonly used anti-osteoporotic agents demonstrated similar effectiveness in the CKD population. These findings support the use of standard osteoporosis therapies in appropriately selected patients with CKD, although prospective studies with fracture outcomes are warranted.

P710

CALCIFEDIOL INFLUENCES THE PROLIFERATION AND MYOGENIC DIFFERENTIATION OF HUMAN SKELETAL MUSCLE SATELLITE CELLS: AN IN VITRO STUDY

I. Falsetti[1], G. Palmini[2], S. Donati[1], R. Zonefrati[2], T. Iantomasi[1], M. L. Brandi[2]

[1]Department of Experimental and Clinical Biomedical Sciences, University of Florence, Florence, Italy; [2]Fondazione Italiana Ricerca sulle Malattie dell'Osso (F.I.R.M.O Onlus), Florence, Italy

Introduction: Calcifediol is the primary circulating precursor to the biologically active form of Vitamin D (VitD). VitD has emerged as an important regulator of skeletal muscle physiology. However, the direct effects of calcifediol on human satellite cells (SCs) remain poorly characterized. The aim of this study was to investigate the effects of calcifediol on the proliferation and myogenic differentiation of human SCs.
Materials and methods: SCs were isolated from skeletal muscle biopsies obtained from three healthy adult volunteers after signing an informed consent form approved by the Local Ethics Committee. Primary SC lines were established and characterized through cellular and molecular biology analyses. Cells were treated with three concentrations of calcifediol (10^{-5}-10^{-7} M). Cell viability after 48 hours was evaluated using an MTS assay and acridine orange staining. Cell proliferation was analyzed after 3, 6, and 9 days of treatment. Myogenic differentiation was evaluated by quantifying myogenic marker expression using TaqMan technology. In addition, the effects of calcifediol on the expression of cell cycle–related genes (*PLK1* and *CCND1*) and on apoptosis were investigated.
Results: Three primary SC lines were established from muscle biopsies

and displayed a confirmed stem cell phenotype. Treatment with calcifediol did not significantly affect SCs' viability at any concentration tested. In contrast, calcifediol significantly reduced SCs proliferation compared with untreated controls. This antiproliferative effect was accompanied by a marked increase in the expression of *Myogenic Regulatory Factors*, *Desmin*, *Myosin Heavy Chain* (indicating enhanced myogenic differentiation), and the *VDR* during myogenic differentiation. To explore the molecular mechanisms underlying these effects, cell cycle regulation and apoptosis were assessed. Calcifediol treatment resulted in a significant downregulation of *PLK1* and *CCND1* expression, while no changes in apoptosis were observed.
Conclusions: These findings suggest that calcifediol directly influences human skeletal muscle cells. The reduction in SCs proliferation appears to be mediated by cell cycle regulation rather than apoptosis. These results support a role for calcifediol in skeletal muscle biology and provide a foundation for future studies aimed at elucidating the cellular and molecular mechanisms through which VitD metabolites regulate muscle regeneration.
Acknowledgments: Supported by Bruno Farmaceutici.

EFFECT OF FIBROBLAST GROWTH FACTOR 23 ON THE PROLIFERATION AND MYOGENIC DIFFERENTIATION OF SATELLITE CELLS ISOLATED FROM HUMAN SKELETAL MUSCLE BIOPSIES

I. Falsetti[1], G. Palmini[2], S. Donati[1], R. Zonefrati[2], T. Iantomasi[1], M. L. Brandi[2]

[1]Department of Experimental and Clinical Biomedical Sciences, University of Florence, Florence, Italy; [2]Fondazione Italiana Ricerca sulle Malattie dell'Osso (F.I.R.M.O Onlus), Florence, Italy

Introduction: X-linked hypophosphataemia (XLH) is a rare inherited musculoskeletal disorder caused by inactivating mutations in the *PHEX* gene. These mutations lead to elevated circulating levels of Fibroblast Growth Factor 23 (FGF23), resulting in chronic hypophosphataemia and hypophosphataemic rickets, of which XLH represents the most common genetic form. In addition to its well-established effects on bone metabolism, XLH is frequently associated with muscle weakness and reduced physical performance. However, the direct effects of FGF23 on skeletal muscle cells remain poorly understood. The aim of this study was to evaluate the impact of different concentrations of FGF23 on proliferation and myogenic differentiation in an *in vitro* model of human skeletal muscle satellite cells (SCs).
Materials and methods: SCs were isolated from skeletal muscle biopsies obtained from three healthy adult volunteers. Primary SC lines were established and characterized for stem cell identity using molecular and cellular biology analysis. Cells were treated with FGF23 at three different concentrations (1, 10, and 100 ng/mL). Cell proliferation was evaluated by bromodeoxyuridine incorporation, and myogenic differentiation was assessed by TaqMan analysis of myogenic marker expression. The expression of *FGF23 receptors* and the co-receptor *α-KLOTHO* was investigated under the same experimental conditions.
Results: All primary SC lines displayed a confirmed stem cell phenotype. Treatment with FGF23 for 48 hours did not induce significant changes in SC proliferation compared with untreated controls, suggesting that FGF23 does not affect cell proliferation under these experimental conditions. In contrast, FGF23 treatment resulted in a significant reduction in the expression of *Myogenic Regulatory Factors*, *Desmin*, *Irisin*, *Myostatin*, and *Myosin Heavy Chain* at 24 and 48 hours. Notably, a concomitant downregulation of *FGF23 receptor* expression and *α-KLOTHO* was also observed compared with untreated SCs.
Conclusions: This study provides the first evidence that FGF23 negatively modulates myogenic differentiation in human skeletal muscle SCs without affecting their proliferative capacity. These findings suggest a direct role for FGF23 in impairing muscle differentiation and may help explain the muscle dysfunction commonly observed in patients with XLH.

EXPERIENCE OF A MULTIDISCIPLINARY CLINIC WITH ULTRASOUND SUPPORT IN HAND AND ELBOW MUSCULOSKELETAL PATHOLOGY

I. Figueroa[1], B. Rodríguez –Fuensalida[1], J. Rivadeneira[1], L. Sabaté[1], S. Farietta[1], J. Moranta[1]

[1]Hospital Clínic de Barcelona, Barcelona, Spain

Background
Musculoskeletal disorders of the hand and elbow represent a frequent reason for referral to Rheumatology, Orthopaedic Surgery and Rehabilitation, with often overlapping etiologies that complicate diagnosis and lead to multiple consultations, complementary tests, and treatments.
Objective: To evaluate the usefulness of a multidisciplinary clinic with ultrasound support aimed at optimizing diagnostic and therapeutic efficiency.
Materials and Methods
A prospective study was conducted including all patients referred to the multidisciplinary unit between April 2024 and November 2025. Ultrasound assessment was performed, and clinical data were collected, including age, sex, referring service, previous diagnosis, ultrasound findings, secondary diagnostic or therapeutic changes, follow-up by specialty and therapeutic decision.
Results
Seventy-eight patients were evaluated, of whom 62.82% were women. The mean age was 53.75 ± 14.22 years. The main reasons for consultation were: symptoms or clinical manifestations (pain/paresthesia/swelling/functional limitation) in 24 patients (30.76%); completion of diagnostic evaluation of previously diagnosed conditions (degenerative arthropathies, De Quervain tenosynovitis, post-traumatic lesions) in 28 patients (35.89%); neuropathies in 11 patients (13.92%); tendon injuries in 9 patients (11.39%) and miscellaneous conditions in 6 patients (7.79%). The specialty with the highest number of referrals was Orthopaedic Surgery, with 31 patients.
A diagnostic change was generated in 69.23% of patients after the multidisciplinary consultation. Eight patients were diagnosed with inflammatory arthropathy, including 2 with psoriatic arthritis, 3 with rheumatoid arthritis, 3 with calcium pyrophosphate deposition disease and 5 with other rheumatologic conditions.
Among the evaluated patients, 9 underwent surgical intervention, 11 received ultrasound-guided injections, 15 received rehabilitative treatment and additional diagnostic studies for rheumatologic pathology were requested in 15 patients.
Conclusion
The multidisciplinary hand and elbow clinic represents a highly efficient care model, particularly when supported by musculoskeletal ultrasound. It enhances diagnostic accuracy, optimizes clinical decision-making from

the perspective of each specialty and improves patient management by reducing reconsultations, duplication of diagnostic tests and unnecessary procedures. Future studies should assess its pharmaco-economic impact and its effect on reducing waiting times.

P713

REPEATED ROMOSOZUMAB TREATMENT IN SEVERE OSTEOPOROSIS: A 10-YEAR CASE HISTORY WITH MULTIPLE FRACTURES AND COMPLEX THERAPY SEQUENCING

I. Frieling[1]

[1]Osteoporosezentrum Hamburg Neuer Wall, Hamburg, Germany

Objective(s):
Romosozumab is approved as an osteoanabolic therapy for high-risk patients with severe osteoporosis, but data on repeated cycles are limited. We report a patient with multiple vertebral fractures and a complex disease course who received two cycles of romosozumab.

Material and Methods:
A woman, born 1953, first presented in 2014 after spontanous L3 and L4 fractures occured. Before her first visit she received denosumab from 2011–2013, which was stopped without follow-up therapy. She had severe osteoporosis (lumbar spine T-score -3.8). Laboratory evaluation showed the typical constellation of primary hyperparathyroidism with elevated PTH, hypercalcemia and hypophosphatemia. After resection of parathyroid adenoma she received Zoledronate from 2014–2018, stabilizing bone density and preventing new fractures. After therapy pause in 2018, bone density decreased by 2020.

Results:
In 2020, the first 12-month romosozumab cycle was given, followed by alendronate. Lumbar spine T-score improved from -3.3 to -2.6, hip values remained stable, and bone microarchitecture improved. No fractures occurred. After two years of alendronate, bone density stabilized, but in 2024, a slight decrease was seen (lumbar spine T-score -2.6 to -2.7; left hip -2.2 to -2.5; right hip -2.4 to -2.8). Due to persistent osteoporosis and prior fractures, a second romosozumab cycle was started. 2 months after beginning a metatarsal stress fracture occurred, but the patient remained otherwise stable. Bone density improved again (lumbar spine T-score -2.7 to -2.0). Laboratory parameters remained normal.

Conclusion(s):
This case shows that repeated romosozumab cycles can be effective and safe in severe osteoporosis with multiple prior therapies. The patient benefited from both cycles with increased bone density. Without the consistent repeated administration of romosozumab, further, possibly more serious fractures would likely have occurred, given the continuing high-risk situation. Sequential therapy planning is essential, especially after denosumab discontinuation due to rebound risk. Further data on repeated romosozumab use are needed.

P714

REAL-WORLD USE, EFFECTIVENESS AND SAFETY OF OSTEOANABOLIC THERAPIES IN A TERTIARY HOSPITAL: EXPERIENCE WITH ROMOSOZUMAB AND ABALOPARATIDE

I. J. Lorente Betanzos[1], R. Gonzalez Mazario[1], I. Balaguer Trull[1], P. Martinez Calabuig[1], M. Sanmartin Martinez[1], B. Gomez Correas[1], J. Fragio Gil[1], I. Martinez Cordellat[1], J. J. Lerma Garrido[1], A. Rueda Cid[1], C. Campos Fernandez[1], L. Salvador Maicas[1]

[1]Hospital General Universitario de Valencia, Valencia, Spain

Objective(s)
To describe clinical characteristics, densitometric outcomes, safety and treatment persistence in postmenopausal women treated with romosozumab or abaloparatide in real-world clinical practice.

Material and methods
Retrospective observational study in a tertiary hospital. Postmenopausal women with severe osteoporosis and very high fracture risk who initiated romosozumab or abaloparatide between May 2023 and December 2025 were included. Demographic data, prior osteoporosis treatments, densitometric changes assessed by standard dual-energy X-ray absorptiometry (DXA), fractures, major adverse cardiovascular events and reasons for treatment discontinuation were collected.

Results
Ninety-five patients were included (100% women): 62 received romosozumab and 33 abaloparatide. Mean age was 65 +/- 8.0 years in the romosozumab group and 69 +/- 9.6 years in the abaloparatide group; hypertension was more frequent in the abaloparatide group.
In the romosozumab group, 41/62 patients (66.1%) had available pre- and post-treatment DXA after 12 months. Mean change in T-score was +0.96 +/- 0.69 at the lumbar spine and +0.29 +/- 0.48 at the femoral neck, corresponding to mean bone mineral density increases of +0.17 ± 0,18 g/cm2 and +0.05 ± 0,08 g/cm2, respectively. Lumbar spine T-score improvement of at least 0.5 was achieved in 80.5% and of at least 1.0 in 39.0%. No fractures occurred during treatment; one traumatic fracture was recorded after treatment completion. No major cardiovascular events were observed. Treatment discontinuation occurred in 3.3%.
In the abaloparatide group, 3/33 patients (9.1%) completed the planned 18-month treatment. Post-treatment DXA was available in one patient only, precluding aggregated densitometric analysis. Treatment discontinuation occurred in 26.9%, mainly due to neurovegetative or cardioperceptive adverse effects. No major cardiovascular events were recorded.

Conclusion(s)
In real-world clinical practice, romosozumab and abaloparatide were prescribed to patients with different clinical profiles. Romosozumab was associated with clinically relevant densitometric improvements and high treatment persistence, whereas tolerability was the main limiting factor for abaloparatide.

P715

CASE REPORT WITH OSTEOPOROSIS IN A 35-YEAR-OLD FEMALE PATIENT WITH ARTIFICIALLY INDUCED MENOPAUSE

I. Jovanović Vasović[1], J. Vasović[2]

[1]Institute For Treatment and Rehabilitation "Niška Banja" Niš Serbia, Niška Banja, Serbia; [2]Institute for Health Protection of Railway Workers of Serbia, Niš, Niš, Serbia

Introduction:
Osteoporosis is a chronic metabolic bone disease characterized by reduced bone mineral density and impaired bone microarchitecture, leading to an increased risk of fractures. Although it is most commonly associated with the postmenopausal period, osteoporosis can also develop in younger women, particularly in cases of premature or surgically induced menopause. The abrupt loss of estrogen plays a key role in accelerated bone loss, which may result in the early onset of severe clinical manifestations of the disease.

Case Presentation:
We present a 35-year-old female patient who developed advanced osteoporosis following surgically induced menopause after bilateral oophorectomy. The patient presented with progressive thoracolumbar back pain, fatigue, and a subjective reduction in body height. Her medical history revealed no previous osteoporotic fractures and no positive family history of osteoporosis.
Dual-energy X-ray absorptiometry (DXA) revealed markedly reduced bone mineral density values at the lumbar spine and hip, with T-score values consistent with severe osteoporosis. Radiological examination of the spine confirmed the presence of vertebral compression fractures. Laboratory evaluation, including parameters of calcium metabolism, vitamin D levels, parathyroid hormone, and thyroid function tests, excluded secondary causes of osteoporosis.

Therapeutic Approach:
Following the diagnosis, intensive treatment was initiated, including the use of antiresorptive and/or osteoanabolic agents, along with mandatory supplementation with calcium and vitamin D. Non-pharmacological measures were also recommended, including tailored physical activity, modification of risk factors, and education on fall prevention. The option of hormone replacement therapy was considered in accordance with current clinical guidelines and the patient's individual risk profile.

Discussion:
This case highlights the severity and rapid progression of osteoporosis in patients with surgically induced menopause at a young age. Estrogen deficiency leads to an imbalance between bone resorption and formation, resulting in accelerated bone loss and an increased risk of fractures. Early identification of at-risk patients and a multidisciplinary therapeutic approach are essential to prevent serious complications.

Conclusion:
Surgically induced menopause at a young age represents a significant risk factor for the development of advanced osteoporosis. This case underscores the importance of timely screening, continuous monitoring, and individualized treatment strategies to reduce fracture risk and preserve quality of life.

P716

INFLUENCE OF MUSCLE STRENGTH AND BALANCE ON FUNCTIONAL PERFORMANCE IN POSTMENOPAUSAL OSTEOPOROSIS WOMEN

I. M. Borda[1], R. Ungur[1]

[1]University of Medicine and Pharmacy Iuliu Hatieganu, Rehabilitation Department, Rehabilitation Hospital, Cluj-Napoca, Romania

Objective: The purpose of this study was to evaluate muscle strength and balance in postmenopausal osteoporosis women and to correlate them with the functional performance.
Methods: 53 postmenopausal women (58.2 ± 5.9 years) diagnosed with osteoporosis were included in this cross-sectional study. The weight, height, age at menopause were registered in all patients. Osteoporosis was established by bone mineral density measurement, performed at the lumbar spine (L2-L4) and at the femoral neck and total hip, by the dual-energy X-ray absorbtiometry method. Knee extensor strength was assessed by the isokinetic method at the angular velocity of 120°/s, using a Gymnex Iso 2 Dynamometer. Balance was evaluated by Berg Balance Scale (BBS). Timed up-and-go (TUG) test, chair rising test (CRT) and 6-minute walk (6MW) test were used to assess functional performance. The analyses of the relationship between muscle strength, balance and functional performance parameters was based on Pearson's correlation coefficients, with significance set at $p<0.05$.
Results: Knee extensor strength positively correlated with CRT ($r=0.392$, $p<0.05$) and 6MW test ($r=0.466$, $p<0.05$), and negatively with TUG score ($r=-0.389$, $p<0.05$). Balance (BBS) also positively correlated with CRT ($r=0.287$, $p<0.05$) and 6MW test ($r=0.325$, $p<0.05$), and negatively with TUG score ($r=-0.273$, $p<0.05$). BBS score positively correlated with knee extensor strength ($r=0.517$, $p<0.05$).
Conclusions: Muscle strength and balance significantly correlated with the functional performance in postmenopausal osteoporosis women. These results suggest the importance of physical exercise in these patients, in which the rehabilitation programs should emphasize balance training and muscle strengthening, in order to improve functionality.

P717

ARE THERE DIFFERENCES IN BONE MINERAL DENSITY BETWEEN THE USE OF UPADACITINIB AND ADALIMUMAB?

I. Ovcina[1], S. Popovic Pejicic[2], J. Mrdja[1], S. Saric[1], D. Popovic[1], J. Zec[3], L. Bozic Majstorovic[1]

[1]University Clinical Centre of the Republic of Srpska, Banjaluka, Bosnia & Herzegovina; [2]Faculty of Medicine, University of Banjaluka, Banjaluka, Bosnia & Herzegovina; [3]Institute of Physical Medicine, Rehabilitation and Orthopedic Surgery "Dr. Miroslav Zotovic", Banjaluka, Bosnia & Herzegovina

Introduction: The aim was to demonstrate differences in bone mineral density (BMD) between patients treated with adalimumab (ADA) and upadacitinib (UPA).
Materials and Methods: A total of 28 patients with rheumatoid arthritis were included, with 14 treated with ADA and 14 with UPA. Demographic

and osteodensitometric data were collected. Parameters were compared between the two groups.
Results: The mean age in the UPA group was 59.57±10.02 years, while in the ADA group it was 59.71±7.92 years. In the UPA group, 10 patients (71.4%) were female, compared to 9 patients (64.3%) in the ADA group. The mean BMD at L1–L4 was 1.034 vs. 0.947 g/cm^2, with mean T-scores of −1.25 vs. −2.09, respectively. The mean BMD at the left hip was 1.016 vs. 0.971 g/cm^2, with T-scores of −1.29 vs. −1.96. The mean BMD at the right hip was 1.016 vs. 0.959, with T-scores of −1.286 vs. −2.07 g/cm^2. Comparison between groups revealed statistically significant differences in all parameters ($p<0.05$), except for BMD of the left hip.
Conclusion: Age and sex distribution were similar between the two groups. However, patients treated with UPA had higher BMD values and more favorable T-scores at the lumbar spine and hips compared to those treated with ADA. Statistically significant differences were confirmed in all parameters except for BMD of the left hip, where the difference was not significant. These findings suggest a potentially more favorable effect of UPA on bone mass preservation.

P718

VITAMIN D LEVELS AND HIP FRACTURE SEVERITY AMONG ELDERLY DIABETIC PATIENTS WITH HIP FRACTURES WITH AND WITHOUT ADEQUATE GLYCAEMIC CONTROL

I. Papaioannou[1], G. Pantazidou[2], I. Lianou[1], T. Repantis[1], Z. Kokkalis[3], N. Georgopoulos[4], E. Jelastopulu[5], A. Baikousis[1]

[1]Orthopedic Department, General Hospital of Patras, Greece, Patras, Greece; [2]University of Patras, Public Health Postgraduate Program, Greece, Patras, Greece; [3]Orthopaedic Surgery, Medical School, University of Patras, Greece, Patras, Greece; [4]Endocrinology, University Hospital of Patras, Greece, Patras, Greece; [5]Department of Public Health, University of Patras, Greece, Patras, Greece

Objectives: The purpose of this study is to identify differences in vitamin D (VD) levels and hip fracture severity among elderly diabetic patients with hip fractures, comparing those with and without adequate glycemic control.
Material and Methods: We retrospectively studied 65 elderly patients (>65 years old) with osteoporotic hip fractures and either impaired glycaemic control or known type 2 diabetes mellitus, treated between January 2021 and January 2022. Serum 25-hydroxy vitamin D (25OH Vit D) was measured using an automated enzymatic immunoassay. Hip fractures were classified as extracapsular (intertrochanteric) or intracapsular (subcapital). Severe subcapital fractures were defined as grades 3 or 4 according to the Garden classification, while severe intertrochanteric fractures were defined as grades A2.2, A2.3, and all A3 fractures according to the AO/OTA classification.
Results: Among the participants in our study, 45 (69.2%) had inadequately controlled HbA1c levels, with values over 6.5%, and 20 (30.8%) had adequately controlled levels, with values at or below 6.4%. Patients with poorly controlled T2DM had higher VD levels of 10.09 ± 4.93 ng/mL, higher PTH levels of 58.9 ± 49.99 ng/mL, and more unstable hip fractures (77.7%). In comparison, diabetic patients with adequate glycemic control had lower VD levels of 9.82 ± 5.57 ng/mL, lower PTH levels of 50.73 ± 34.01 ng/mL, and 70% had unstable hip fractures. No statistically significant differences were observed in fracture severity, VD, and PTH between the two groups, as indicated by p-values of 0.502, 0.844, and 0.507, respectively.
Conclusions: There is consensus that VD deficiency is closely related to T2DM, and based on our study, the differences in VD levels among diabetic patients, whether well controlled or not, are minimal. Hypovitaminosis D was severe regardless of glycemic control status. More notable differences were observed in PTH levels and hip fracture severity. Poor glycemic control was associated with more severe hip fractures and higher PTH levels. However, PTH levels in diabetic groups (with or without adequate control) were significantly lower compared to their non-diabetic counterparts (as shown in our completed study). Clinicians should be aware of the paradox identified in our study: low VD levels are not associated with elevated PTH in diabetic patients, and relatively elevated PTH may indicate poorly controlled type 2 diabetes mellitus (T2DM). Finally, a severe comminuted hip fracture in an elderly diabetic patient should prompt suspicion of poor glycemic control.

P719

PARAMETERS AFFECTING VITAMIN D LEVELS AND HIP FRACTURE SEVERITY AMONG ELDERLY DIABETIC PATIENTS WITH HIP FRACTURES

I. Papaioannou[1], G. Pantazidou[2], I. Lianou[1], T. Repantis[1], Z. Kokkalis[3], N. Georgopoulos[4], E. Jelastopulu[5], A. Baikousis[1]

[1]Orthopedic Department, General Hospital of Patras, Greece, Patras, Greece; [2]University of Patras, Public Health Postgraduate Program, Greece, Patras, Greece; [3]Orthopaedic Surgery, Medical School, University of Patras, Greece, Patras, Greece; [4]Endocrinology, University Hospital of Patras, Greece, Patras, Greece; [5]Department of Public Health, University of Patras, Greece, Patras, Greece

Objectives: The purpose of this study is to identify parameters that affect vitamin D (VD) levels and hip fracture severity among elderly diabetic patients with hip fractures.
Material and Methods: We retrospectively studied 65 elderly patients (>65 years old) with osteoporotic hip fractures and impaired glycemic control or previously diagnosed type 2 diabetes mellitus, who were treated between January 2021 and January 2022. The 25-hydroxy vitamin D (25OH Vit D) level was measured using an automated enzymatic immunoassay. Hip fractures were classified as extracapsular (intertrochanteric) or intracapsular (subcapital). Severe subcapital fractures were defined as grades 3 or 4 according to the Garden classification, while severe intertrochanteric fractures were defined as grades A2.2, A2.3, and all A3 fractures according to the AO/OTA classification. The duration of diabetes mellitus, type of antidiabetic pharmaceutical therapy, and number of antidiabetic agents were examined as possible parameters affecting VD levels and hip fracture severity.
Results: Among the participants in our study, 60% (39 patients) were treated with antidiabetic pills, 6.2% (four patients) with insulin alone, 16.9% (11 patients) with a combination of pills and insulin, and 16.9% (11 patients) were newly diagnosed, with treatment determined by endocrinologists. Forty percent (26 patients) of diabetic patients were treated with only one antidiabetic agent, 43.1% (28 patients) with more than one pharmaceutical agent, and 16.9% (11 patients) were newly diagnosed. Most diabetic patients had T2DM for more than five years (63.07%, 41 patients), while 20% (13 patients) had T2DM for less than five years. According to the statistical analysis, VD levels and hip fracture severity were not significantly different. However, lower VD levels were

observed in newly diagnosed patients (VD 8.05 ± 4.33) and those receiving insulin monotherapy (VD 7.6 ± 2.6). These subgroups may have the poorest glycemic regulation. Diabetic patients with T2DM duration of less than five years experienced more severe hip fracture patterns (84.6% unstable fractures). Finally, patients who received oral antidiabetic drugs combined with insulin (90.9% unstable fractures) also had more comminuted fractures. It is important to note that these findings had no statistical significance.
Conclusions: There is consensus that VD deficiency is closely related to T2 diabetes mellitus, particularly in elderly patients with poorly controlled diabetes. Lower vitamin D levels are often associated with more severe fractures. However, the literature on this topic is limited, and further research is required. To date, no study has linked the prevalence of hip fracture severity to glycemic control in elderly diabetic patients, although diabetics have an increased incidence of hip fractures and higher mortality. Clinicians should note that the lowest VD levels were observed in newly diagnosed patients with T2 diabetes mellitus and those receiving insulin monotherapy; these subgroups may also have the poorest glycemic regulation. Hip fracture severity was more prevalent in patients with T2DM duration of less than five years (including newly diagnosed patients) and in those who received oral antidiabetic drugs in combined with insulin.

P720

BIOCHEMICAL PROFILES AND SURGICAL FINDINGS OF PATIENTS WITH ASYMPTOMATIC AND SYMPTOMATIC PRIMARY HYPERPARATHYROIDISM AT RIGA EAST UNIVERSITY HOSPITAL: A THREE-YEAR ANALYSIS (PART III)

E. Priede[1], D. Sturite[2], I. Rasa[3]

[1]Rīga Stradiņš University, Riga, Latvia; [2]Rīga Stradiņš University, Latvian Osteoporosis and Bone Metabolic Diseases Association, Riga, Latvia; [3]Rīga Stradiņš University, Riga East University Hospital, Latvian Osteoporosis and Bone Metabolic Diseases Association, Riga, Latvia

Objectives. With the increasing prevalence of routine biochemical screening, asymptomatic primary hyperparathyroidism (APHPT) has become more common. However, the factors contributing to this asymptomatic presentation are still not well understood, and many patients qualify for surgical intervention. This study aims to compare the clinical, biochemical, and surgical pathology characteristics of patients with APHPT to those who are symptomatic.
Materials and methods. This retrospective study involved 177 adult patients diagnosed with primary hyperparathyroidism between January 2021 and January 2024. Patients were categorised as either asymptomatic or symptomatic based on their clinical presentation. Clinical characteristics, biochemical parameters, and histopathological data were extracted from medical records and analysed for differences between the two groups.
Results. Among the 177 patients studied, 85 (48.0%) were APHPT. Within this group, 48 patients (56.5%) met at least one surgical criterion, with elevated calcium levels being the most common criterion. Asymptomatic patients tended to be younger, whereas symptomatic patients exhibited higher median concentrations of intact parathyroid hormone (iPTH) (>212 pg/mL;p=0.004) and lower glomerular filtration rates (GFR) (p=0.047). No significant differences were found in serum calcium or vitamin D concentrations between the groups. Factors associated with the asymptomatic group included being under 65 years of age (OR=0.52, CI 0.28–0.94;p=0.030) and having lower iPTH levels (<212 pg/mL; OR=0.54, CI 0.29-0.99;p=0.046). Conversely, a reduced GFR (<60 ml/min) was associated with an increased likelihood of symptomatic disease (OR=2.70, CI 1.00-7.29;p=0.043). Postoperative histopathological data were available for 113 patients, with 45 being asymptomatic and 68 symptomatic. The predominant finding in both groups was a single adenoma, identified in 106 patients (94.0%). In contrast, double adenomas (n=2;1.7%) and parathyroid hyperplasia (n=3;2.6%) were observed exclusively among symptomatic patients. Parathyroid carcinoma was identified in one patient from each group.
Conclusions. Over fifty per cent of asymptomatic patients met the criteria for surgical intervention. The biochemical disease burden and surgical pathology were similar across both groups, suggesting that the presence of symptoms does not necessarily correspond with the severity of the disease. This underscores the importance of timely evaluation and management for APHPT.

P721

ENVIRONMENTAL IMPACT OF A FRACTURE LIAISON SERVICE: A CARBON FOOTPRINT ANALYSIS

A. Singh[1], A. Williams[1], R. Kaur[1], S. Shah[1], R. Singh[2], I. Singh[3]

[1]Bone Health/FLS team, Aneurin Bevan University Health Board, Wales, Ystrad Mynach, United Kingdom; [2]Economy/Finance Student, St Johns College, Cardiff, Cardiff, United Kingdom; [3]Consultant Geriatrician, Aneurin Bevan University Health Board and National Clinical Lead, Bone Health, Wales, Ystrad Mynach, United Kingdom

Objectives: Fracture Liaison Service (FLS) exemplifies a proactive, integrated approach to fracture prevention and management, enhancing patient outcomes while ensuring quality, sustainability, and efficiency in healthcare. The objective of this study was to quantify the environmental impact of FLS consultations by converting patient travel distance into carbon footprint.
Materials and Methods: We conducted a retrospective review of all patients assessed by the Aneurin Bevan FLS (AB-FLS) over a three-year period (2022–2024). Data collected included patient demographics and travel distance from place of residence to the Bone Health Unit. Patients admitted with fragility fractures were excluded. For outpatients managed through the AB-FLS model, travel distance using Google Maps was calculated for the first consultation only. Carbon footprint was estimated by applying an emission factor of 0.4 kg CO per mile, based on a typical petrol passenger vehicle.
Results: Over three years, 6,477 patients with fragility fractures were assessed (mean age 78±10 years, range 50–105); 77.2% were female (n=4,999). Of these, 53.3% (n=3,451) were managed as outpatients. 755 patients excluded for missing data. Consequently, travel analysis was based on 2,696 patients attending a first consultation, with an expected total of 87,176 miles.
Miles avoided included telephone assessments for oral bone therapy (n=863; 27,104 miles), virtual management via general practitioners (n=39; 1,818 miles), discharge after initial assessment with GP follow-up (n=448; 14,016 miles), and patients declining further treatment (n=398; 13,108 miles). Total miles avoided for the first consultation were 56,046. Miles used for in-person parenteral treatments were 13,616 for denosumab (n=398), 4,068 for zoledronic acid (n=412), and 1,720 for

anabolic therapy (n=68). An additional 11,726 miles were incurred by 334 patients attending in-person bone health clinics. Total miles used for consultations and parenteral treatments were 31,130.
Overall, net miles avoided were 24,916 over three years, corresponding to 9,966 kg of CO emissions avoided, demonstrating a net carbon-negative impact of the service
Conclusion: Over the past three years, the AB-FLS has consistently identified increasing numbers of patients while maintaining a net carbon-negative impact. By reducing unnecessary patient travel through telephone-based assessments, the service lowers the environmental burden associated with traditional hospital visits.

P722

CLINICAL OUTCOMES OF A FRACTURE LIAISON SERVICES: A COMPARISON OF PATIENTS AGED <80 AND ≥80 YEARS

I. Singh[1], R. Kaur[2], A. Singh[2], A. Williams[2], V. Pulakattu Kuzhiyil[2], S. Shah[2], A. Vinod[2], C. Edwards[3]

[1]Consultant Geriatrician, Aneurin Bevan University Health Board and National Clinical Lead, Bone Health, Wales, Ystrad Mynach, United Kingdom; [2]Bone Health/FLS team, Aneurin Bevan University Health Board, Wales, Ystrad Mynach, United Kingdom; [3]Consultant Clinical Scientist, Aneurin Bevan University Health Board, Wales, Newport, United Kingdom

Objectives: Fracture Liaison Services (FLS) aim to prevent secondary fractures by ensuring quality care for patients over 50. This study assesses clinical outcomes in an existing FLS for patients above and below 80 years and evaluates re-fracture and mortality outcomes.
Methods and materials: We retrospectively reviewed 5320 patients seen by Aneurin Bevan FLS (AB-FLS) from January 2022 to June 2024 using national FLS Database (FLS-DB) data. Patients were categorized as: below 80 and above 80 years. Data on previous fractures, re-fractures were collected. Patients were followed until December 31, 2025, for re-fractures and mortality.
Results: The cohort's mean age was 78.4 years (range 50–105) with a marked female predominance (77.9%, p<0.0001). Nearly half of patients had a prior fracture history (49.1%, n=2,608), with a mean interval of 6 years (range 0–36). Most patients lived in the community (94.4%), while 5.6% resided in care homes.
The AB-FLS reviewed 2,797 patients aged 50–80 years (52.6%) and 2,523 patients aged over 80 years (47.4%). Female representation was significantly higher in the under-80 group (52.5%, n=2,177/4,145) and lower in those aged over 80 (47.5%, n=1,968/4,145; p<0.001). Osteoporosis treatment was initiated in 65.5% of patients (n=3,485/5,320).
Over a four-year follow-up period, 82.4% of patients (n=4,386/5,320) experienced no re-fractures. Overall, 17.6% (n=931/5,320) sustained a re-fracture, with a mean time to event of 301 days (range 2–1,088 days). Re-fracture rates were significantly higher in patients aged over 80 years compared with those under 80 (9.5%, n=498 vs 8.1%, n=433, p=0.01), and occurred earlier (mean 278 vs 328 days).
At 12 months, 11.1% of patients (n=593/5,320) had re-fractured, with higher rates in the over-80 group (6.2%, n=330; mean 137 days) compared with the under-80 group (4.9%, n=263; mean 152 days; p=0.004).
One-year mortality was significantly higher in patients aged over 80 years (11.9%, n=633) compared with those under 80 (4.5%, n=239; p<0.0001). By four years, 23.7% of the cohort had died (n=1,259), with mortality remaining significantly higher in the over-80 group (17.1%, n=909) than in the under-80 group (n=350; p<0.0001).
Conclusion: The AB-FLS has demonstrated equitable care over the consecutive 2.5 years; however, further assessment over a longer timeframe is needed for confirmation. Given the significantly higher risk of re-fracture and mortality in older patients, secondary fracture services should be tailored to better address the needs of this population, ensuring true equity in healthcare delivery.

P723

PRUDENT USE OF ANABOLIC TREATMENT FOR VERY-HIGH RISK FRAGILITY FRACTURE PATIENTS: SINGLE-CENTRE REAL-WORLD DATA.

R. Kaur[1], A. Williams[1], A. Singh[1], C. Edwards[2], G. Rose[1], I. Singh[3]

[1]Bone Health/FLS team, Aneurin Bevan University Health Board, Wales, Ystrad Mynach, United Kingdom; [2]Consultant Clinical Scientist, Aneurin Bevan University Health Board, Wales, Newport, United Kingdom; [3]Consultant Geriatrician, Aneurin Bevan University Health Board and National Clinical Lead, Bone Health, Wales, Ystrad Mynach, United Kingdom

Objective**:** The objective of this study was to quantify imminent fracture risk before and after commencing anabolic agents.
Materials and Methods: We conducted a retrospective review of all patients who were commenced anabolic therapy between 2023 and 2025. The study was done at a single centre, the Aneurin Bevan Fracture Liaison Service (AB-FLS). Data collected included patient demographics, fracture type, bone mineral density (T-scores), biochemical markers (serum calcium, alkaline phosphatase (ALP), and 25-hydroxyvitamin D), and average duration of anabolic therapy received. Re-fracture events following the index fracture were recorded both before and after commencement of anabolic therapy.
Results: 168 patients received anabolic drugs (Abaloparatide=56; Romosozumab=60; Teriparatide=52), average age was 70±6.9 years. Nine patients received Abaloparatide for primary fracture prevention.
The average t-scores for spine and femur were -3.1 (-0.1 to −5.5) and -2.7 (-0.3 to −4.6) respectively. Mean Calcium=2.4 (1.31–2.67); ALP=94.2 (44–318); eGFR=70.6 (25–90); PTH=5.7 (1.8–13.1); and Vitamin D was 90.6 (15–281).
The average duration since treatment initiation was 97 days (10-249) for Abaloparatide, 383 days (49-802) for Romosozumab, and 141 days (7-271) for Teriparatide.
No imminent fractures occurred in patients receiving Abaloparatide either before or after treatment initiation. Prior to anabolic therapy, seven imminent fractures occurred in the Romosozumab group, with a mean time of 141 days before treatment initiation (07 to 277 days), and three imminent fractures occurred in the Teriparatide group, with a mean of 117 days before treatment initiation (55 to 231 days).
Following initiation of anabolic therapy, one imminent fracture occurred in the Romosozumab group at 160 days, and two occurred in the Teriparatide group at a mean of 130 days (70–189 days).
Conclusion: In this single-centre cohort of very high–risk patients, 5.9% sustained an imminent fracture while awaiting initiation of anabolic therapy, occurring at a mean of 129 days, and a further 1.8% experienced re-fracture after treatment commencement, at a mean of 145 days. These findings support prudent and timely identification of very high-risk patients and minimising delays in initiating anabolic therapy through targeted quality improvement initiatives.

P724

THE BURDEN OF RARE GENE VARIANTS ASSOCIATED WITH LOW BONE MASS AND DYSLIPIDEMIA IN THE DEVELOPMENT OF COMBINED PATHOLOGY OF THE BONE AND CARDIOVASCULAR SYSTEMS IN WOMEN

I. Skripnikova[1], M. Myagkova[1], M. Kolchina[1], O. Kosmatova[1], V. Vygodin[1], A. Meshkov[1]

[1]Federal State Institution «National Medical Research Center for Therapy and Preventive Medicine» of the Ministry of Healthcare of the Russian Federation, Moscow, Russia

Objective: To estimate the relationship of rare gene variants associated with low bone mineral density (BMD) and dyslipidemia with a combination of osteopenic syndrome (OPS) and subclinical atherosclerosis (AS) in women.

Methods: Targeted sequencing of whole blood samples from 308 peri- and postmenopausal women aged 45-82 years was performed. Rare gene variants associated with monogenic diseases with low BMD (*BMP1, COL1A1, COL1A2, ALPL, ENPP1, SLC34A1, LRP5, WNT1, FBN1, TGFBR2, LMNA, NOTCH2, PLS3*) and with monogenic dyslipidemia and AS (*LDLR, APOE*), were selected, which are combined and summarized according to the principle of entry into the gene's networks (integral genetic factors: E-ECM, E-MIN, E-WNT, E-TGFB, E-OTHER, E-ALL, E-ATHER). Carotid ultrasound, multispiral computed tomography, and dual-energy X-ray absorptiometry were performed.

Results: In the group of women with a combination of signs of subclinical AS and OPS (presence of at least one atherosclerotic plaques and/or Agatston calcium index ≥1 unit and low BMD) variants of the *SLC34A1* gene (0% vs 7.2%, p=0.008) and variants from three groups of genes E-ALL (9.7% vs 24.8%, p=0.047), E-MIN (0% vs 9.2%, p=0.003), E-TGFB (0% vs 4.6%, p=0.033) were significantly more frequent compared to the group without this combination of signs. In the single-factor analysis, E-ALL increased the chance of detecting a combined pathology by 3.2 times (95%CI, 1.04-9.07). The risk ratio for *SLC34A1* was 1.2 (95%CI, 1.12-1.28), for E-MIN – 1.2 (95%CI, 1.12-1.29), for E-TGFB – 1.2 (95%CI, 1.12-1.27). In the multivariate regression analysis (adjusted for age ≥55 years, body mass index <20 kg/m^2, intima-media complex thickness ≥0.9 mm, total cholesterol ≥5.0 mmol/l, bone resorption marker CTx >1,008 ng/ml, SCORE ≥1%, FRAX ≥7% for the main fractures and FRAX ≥0.3% for hip fracture), the independent role of none of the studied genetic integral factors in the development of combined pathology has not been confirmed.

Conclusion: A clear trend towards an increased frequency of integral genetic factors, representing the sum of rare gene variants associated with monogenic diseases with low BMD, was observed in patients with a combination of AS and OPS, but did not reach statistical significance, likely due to insufficient sample size or the predominance of clinical risk factors.

P725

JUVENILE IDIOPATHIC ARTHRITIS AND ORAL HEALTH: AN UNDERESTIMATED LINK ?

L. Kharrat[1], I. Slimene[1], F. Majdoub[1], I. Cherif[1], D. Kaffel[1], H. Ferjani[1], K. Maatallah[1], D. Ben Nessib[1], W. Hamdi[1]

[1]Rheumatology, Mohamed Kassab Institute, Manouba, Tunisia, Tunis , Tunisia

Objective:
to evaluate the prevalence of poor oral health in patients with JIA and its associated factors
Methods:
We conducted a cross-sectional study involving patients diagnosed with JIA according to the 2001 criteria of the International League of Associations for Rheumatology (ILAR). For each patient, demographic and disease-related data were collected, including age, sex, disease duration, erythrocyte sedimentation rate (ESR), C-reactive protein (CRP) levels, and disease activity measured using the JADAS10-ESR score. Poor oral health was defined by a history of dental caries or the presence of dental plaques on examination.
Results:
Thirty-two patients were included in the study (15 boys and 17 girls), with a mean age of 12.7 ± 4.9 years. The mean disease duration was 4.3 ± 4.3 years. JIA most represented subtypes were as follows: Enthesitis-related arthritis (ERA): 31.3% (n = 10), Polyarticular JIA: 25% (n = 8), Systemic JIA and Oligoarticular JIA in 15% of cases each (n = 5). The mean ESR and CRP levels were 29.1±27.9 mm/h and 23.6±28.6 mg/L, respectively. The mean JADAS10-ESR score was 12.6 ± 6.7.
A history of dental caries was reported in 46.9% of patients (n = 15). On examination, 11 patients had dental plaque.
Patients with poor oral health had higher ESR and JADAS10-ESR scores (VS : 36.6±33.7 vs 19.8±11.9mm ; p=0.06 ;CRP : 29.5±33.8 vs 15.6±18.4mg/L ; p=0.2 ; JADAS-10 VS : 13.9±7 vs 10.8±6.3 ; p=0.27).
However, poor oral health was significantly associated with higher parental visual analog scale (VAS) for pain (6.54 ±1.36 vs 4.62 ± 1.99, p = 0.04).
No statistically significant associations were found between poor oral health and sex, age at disease onset, disease duration, JIA subtype, or CRP levels.
Conclusion:
In our cohort of children with JIA, we found that dental caries are common , affecting half of the patients in this cohort. This result is consistent with findings in the literature [1]. Although disease activity was found to be higher in patients with poor oral health, this was not statistically significant in our study. Grevich et al. have shown that gingival inflammation may occur independently of oral hygiene, suggesting a possible link between gingivitis and JIA [2]

HYPERTROPHIC OSTEOARTHROPATHY REVEALING AN UNDERLYING MEDIASTINAL TUMOR: A CASE REPORT

L. Kharrat[1], I. Slimene[1], F. Majdoub[1], I. Cherif[1], D. Kaffel[1], H. Ferjani[1], K. Maatallah[1], D. Ben Nessib[1], W. Hamdi[1]

[1]Rheumatology, Mohamed Kassab Institute, Manouba, Tunisia, Tunis , Tunisia

Hypertrophic osteoarthropathy (HOA) is an entity characterized by periostitis of long bones and digital clubbing. HOA can be primary, or secondary, associated mainly with lung disease(1).

A 49-year-old-woman with a history of hypothyroidism (post total-thyroidectomy for goiter) presented with inflammatory arthralgia in the four limbs alongside non-dermatomal cervical radiculopathy, all evolving for three months prior to consultation. On examination, a hypertrophic and swelling aspect of limbs, with digital clubbing were found. She had no synovitis of small joints and no palpable lymph nodes. The rest of the examination was unremarkable.

Blood analysis found a high protein-C-reactive level of 187 (reference range (RR)<5mg/L), anemia with hemoglobin level of 8g/dL (RR :12g/dL), hypoalbuminemia of 19 (RR :40g/L), elevated liver enzymes levels: alanine-aminotransferase of 55 (RR <35UI/L), alkaline phosphatase of 395 (RR <104UI/L), gamma-glutamyl transferase of 138 (RR <40UI/L). kidney function, corrected calcium levels and white blood count were normal.

Cervical X-ray showed signs of degenerative cervical disease. Chest X-ray showed superior and anterior mediastinal enlargement. Hands and feet x-rays showed signs of periostitis with hair-on-end aspect(fig1,2).

Body scan showed three cervical masses and an irregular, heterogeneous retrosternal mediastinal mass in contact with the aorta and carotid artery, measuring 47×57×92mm suggestive of a germ cell tumor(fig3) and two hepatic nodules. The periosteal reaction was found in the sternum, clavicles and scapulae.

HOA secondary to a mediastinal tumor was suspected. A biopsy of the cervical masses came back inconclusive.

The patient was treated with Non-Steroidal Anti-Inflammatory Drugs (NSAID) and a dose of zoledronic acid (4mg) with no clinical improvement of the arthralgia nor of the swelling.

A CT-guided biopsy of the mediastinal mass was planned but the patient developed respiratory deterioration with acute multiorgan failure and died before further diagnostic procedures could be performed.

Conclusion :

HOA can have a rheumatological presentation with arthralgia or arthritis of the extremities and digital clubbing. HOA can be paraneoplastic and should be considered even in young patients, as it may be the revelation of a life-threatening underlying malignancy. Treatment consists mainly in that of the underlying condition. Symptomatic management includes NSAIDs, low steroid doses and bisphosphonate (2,3).

DECREASED BONE MINERAL DENSITY IN YOUNG MALE PATIENTS WITH SPONDYLOARTHRITIS: FOCUS ON THE ASSOCIATED FACTORS

I. Slimene[1], F. Majdoub[1], L. Kharrat[1], D. Ben Nessib[1], I. Cherif[1], D. Kaffel[1], W. Hamdi[1]

[1]Rheumatology, Mohamed Kassab Institute, Manouba, Tunisia, Tunis , Tunisia

Objective
To evaluate bone mineral density (BMD) in young men patients with spondyloarthritis (SpA) and
identify the factors associated with its decrease.
Methods
A monocentric retrospective study was conducted, including male patients under 50 years of age
With SpA. Collected data: SpA phenotypes, ongoing treatments (non-steroidal anti-inflammatory drugs (NSAIDs) and/or biologics), erythrocyte sedimentation rate (ESR), C-reactive protein (CRP) levels, and disease activity scores: Ankylosing Spondylitis Disease Activity Score-ESR/CRP (ASDAS-ESR, ASDAS-CRP) and Bath Ankylosing Spondylitis Disease Activity Index (BASDAI).BMD was measured using dual-energy X-ray absorptiometry (DXA) at the anteroposterior lumbar spine (LS) and femoral necks (FN). Bone mass (BM) was expressed in g/cm², and Z-scores were expressed as standard deviations (SD). Decreased BMD was defined as a Z-score below -2 SD. A history of low-energy fractures was noted.
Results:
We included 30 male patients younger than 50 years with a mean age of 39.2 ± 8.7 years. SpA was axial and radiographic in 29 patients, and peripheral in 25 patients (articular and entheseal involvement were found in 23 and 8 patients, respectively). NSAIDs were used by 28 patients, and 11 patients were on biologics. The mean CRP level was 18.8 ± 16.6 mg/L, and the mean ESR was 30.6 ± 28.34 mm/h.
The mean ASDAS-CRP, ASDAS-ESR, and BASDAI scores were 3.3 ± 0.8, 2.8 ± 1.0, and 4.1 ± 2.1, respectively.
Eleven patients had a decreased BMD and none of them had a personal history of low-energy fractures. The mean LS Z-score and BM were -1.1 ± 1.3 SD ([-3.4,1.8]) and 1.0 ± 0.2 g/cm² ([0.5,1.4]), respectively. The mean FN Z-score and BM were -0.8 ± 1.0 SD ([-2.5,0.6]) and 0.9 ± 0.2 g/cm²([0.6,1.2]), respectively.
No association was observed between peripheral SpA and decreased Z-scores at the FN (-1±1 vs -0.2±0.5ds, p=0.1), nor with BM in the LS or FN (1.0 ± 0.2 g/cm² vs 1.1 ± 0.3 g/cm², p = 0.60, and 0.9 ±0.2 g/cm² vs 1.0 ± 0.1 g/cm², p = 0.22), respectively.
Decreased BMD was not associated with high ESR nor ASDAS-ESR levels (40.2 ± 32.1 mm/h vs. 25.6 ± 25.6 mm/h, p = 0.65 and 2.9 ± 1 vs. 2.7 ± 1, p = 0.73, respectively).
Patients on biologics had lower Z-score in both LS and FN, with no statistically significant association (-1.5±1.1SD vs -0.8±1.3SD, p=0.43 and -1.1±1SD vs -0.6±0.9SD, p=0.93).
Conclusion:
A decrease in BMD was frequent in young male patients with SpA, particularly in those with a peripheral phenotype. No associations were found between BMD decrease and disease activity score. Other factors associated with this decrease in BMD should be investigated in young men with
SpA.

P728

IS THERE A CAUSE-AND-EFFECT CORRELATION BETWEEN FAT MASS AND BONE MINERAL DENSITY AMONG YOUNG MEN WITH SPONDYLOARTHRITIS?

F. Majdoub[1], I. Slimene[1], L. Kharrat[1], D. Ben Nessib[1], I. Cherif[1], D. Kaffel[1], W. Hamdi[1]

[1]Rheumatology, Mohamed Kassab Institute, Manouba, Tunisia, Tunis , Tunisia

Objective : To assess the impact of fat mass distribution on bone mineral density (BMD) among young male patients with spondyloarthritis (SpA).

Methods: A retrospective study was conducted including male patients younger than 50 years diagnosed with SpA. Anthropometric data included weight, size and body mass index (BMI). Lean Mass (LM), Fat Mass (FM) and its gynoid and android distribution were assessed using dual-energy X-ray absorptiometry (DXA). BMD was measured at the anteroposterior lumbar spine (LS) and femoral necks (FN). Bone mass (BM) and Z-Scores were expressed in g/cm² and standard deviations (SD) respectively. Decreased BMD was defined as a Z-score below -2 SD.

Results: Thirty male patients younger than 50 years were included. The mean age was 39.2 ± 8.7 years. SpA was axial and radiographic in 29 patients and peripheral in 25 patients. The mean body weight and BMI were 70.3 ± 18.5 kg and 23.8 ± 6.11 kg/m², respectively. The mean FM and LM were 24.4±11.2% and 75.6±11.2%, respectively. The means for android and gynoid fat mass were: 38.9±9.9% and 33.8±8.1%, respectively.

Eleven patients had decreased BMD: the mean LS Z-score and BM were -1.1 ± 1.3 SD ([-3.4,1.8]) and 1.0 ± 0.2 g/cm² ([0.5,1.4]), respectively. The mean FN Z-score and BM were -0.8 ± 1.0 SD ([-2.5,0.6]) and 0.9 ± 0.2 g/cm² ([0.6,1.2]), respectively.

Decreased BMD was observed among a decreased weight (68±19.3kg vs 71.6±18.5kg, p=0.52), BMI (23.2±6.9kg/m2 vs 24.2±5.8kg/m2, p=0.61) and the decrease in FM (23.9±12.4% vs 24.7±11%, p=0.43). FM was not significantly correlated to BM in LS and FN (ρ=0.15, p=0.47 and ρ=0.51, p=0.017; respectively). Gynoid fat mass was not significantly correlated to BM in FN (ρ=0.29, p=0.31).

Conclusion: The WHO Adult BMI Classifications categorizes our population as having average normal weight [1]. A decreased in FM was found among one-third of young male patients with SpA and BMD. FM percentage and its distribution were not correlated with BMD. Larger-scale studies in this population, investigating whether adiposity has a protective effect, remain to be conducted.

DOES BODY COMPOSITION HAVE AN IMPACT ON DISEASE ACTIVITY IN YOUNG MALE PATIENTS WITH SPONDYLOARTHRITIS?

I. Slimene[1], F. Majdoub[1], L. Kharrat[1], D. Ben Nessib[1], I. Cherif[1], D. Kaffel[1], W. Hamdi[1]

[1]Rheumatology, Mohamed Kassab Institute, Manouba, Tunisia, Tunis , Tunisia

Objective :
To assess the impact of body composition in fat mass and lean mass on disease activity in young male patients with spondyloarthritis (SpA).

Methods
A monocentric retrospective study was conducted, including male patients under the age of 50 years old diagnosed with SpA. Collected data: SpA phenotypes, ongoing treatments (non- steroidal anti-inflammatory drugs (NSAIDs) and/or biologics), erythrocyte sedimentation rate (ESR), C-reactive protein (CRP) levels, and disease activity scores: Ankylosing Spondylitis Disease Activity Score-ESR/CRP (ASDAS-ESR, ASDAS-CRP) and Bath Ankylosing Spondylitis Disease Activity Index(BASDAI). Anthropometric data included weight, size, and body mass index (BMI). Lean Mass (LM) and Fat Mass (FM), as well as their gynoid and android distribution were assessed using dual-energy X-ray absorptiometry (DXA).

Results:
Thirty male patients under the age of 50 were included in the study. The mean age was 39.2 ± 8.7 years. SpA was axial and radiographic in 29 patients. SpA was peripheral in 25 patients. The mean weight and BMI were 70.3 ± 18.5 kg and 23.8 ± 6.1 kg/m², respectively.
The mean FM and LM percentages were 24.4 ± 11.2% and 75.6 ± 11.2%, respectively. The mean percentages for android and gynoid FM were: 38.9 ± 9.9% and 33.8 ± 8.1%, respectively. Twenty-eight patients were treated with NSAIDs, and 11 patients with biologic therapy. The mean CRP and ESR levels were 18.8 ± 16.6 mg/L and 30.6 ± 28.34 mm/h, respectively. The mean ASDAS-CRP, ASDAS-ESR and BASDAI scores were 3.3 ± 0.8, 2.8 ± 1.0, and 4.1 ± 2.1, respectively.
FM was correlated to ESR levels and activity scores: ASDAS-CRP, ASDAS-ESR and BASDAI (ρ=-0.38, p=0.08; ρ=-0.54, p=0.01; ρ=-0.54, p=0.04; and ρ=-0.62, p=0.005).
LM was positively correlated with activity scores: ASDAS-CRP, ASDAS-ESR and BASDAI (ρ = 0.54, p =0.01; ρ = 0.54, p = 0.04; and ρ = 0.62, p = 0.005, respectively). LM was not correlated to ESR levels(ρ=0.38, p=0.08).
A statistically significant association was found between hip involvement and decreased FM (22 ±11.6% vs. 32.7 ± 3.6%, (p = 0.004)). No associations were found between hip involvement and gynoid FM nor android FM (32.9±9.3% vs 36.2±3.06%, (p=0.14); 36.9±10.4% vs 43.3±8.2, (p=0.72)respectively).
Peripheral SpA phenotype was associated to increased LM (77.3 ± 11.6% vs. 67.8 ± 3.9%, p = 0.01).

Conclusion
In young male patients with SpA, LM was associated with disease activity scores [1] and peripheral phenotype. Decreased FM was associated with Hip involvement. While another study [1] showed that the axial phenotype of SpA was associated with higher LM, ours did not find a similar result. Further multicentric researches are needed to evaluate these associations and their potential impact on therapeutic approaches.

CAN HIP INVOLVEMENT AND SPINE SYNDESMOPHYTES AFFECT BONE MINERAL DENSITY IN SPONDYLOARTHRITIS?

F. Majdoub[1], I. Slimene[1], L. Kharrat[1], D. Ben Nessib[1], I. Cherif[1], D. Kaffel[1], W. Hamdi[1]

[1]Rheumatology, Mohamed Kassab Institute, Manouba, Tunisia, Tunis , Tunisia

Objective
To evaluate the impact of hip involvement and spinal syndesmophytes associated with spondyloarthritis (SpA) on bone mineral density (BMD).

Methods
A monocentric retrospective study was conducted including male patients younger than 50 years old, who met the diagnostic criteria for SpA. The collected data included SpA phenotype, presence of hip involvement (coxitis) or spinal syndesmophytes. Bone mineral density (BMD) was measured using dual-energy X-ray absorptiometry (DXA) at the anteroposterior lumbar spine (LS) and femoral necks (FN). Bone mass (BM) was expressed in g/cm² and Z-scores expressed as standard deviations (SD). Decreased BMD was defined as a Z-score below -2 SD.

Results:
We included 30 patients. The mean age was 39.2 ± 8.7 years. SpA was radiographic in 29 patients. Peripheral articular involvement was observed in 23 patients, and enthesitic involvement in 8patients. Hip involvement (coxitis) was noted in 23 patients, and syndesmophytes were identified in 16 patients.
Eleven patients had a decreased BMD (Z-score < -2 SD). The mean LS Z-score and BM were -1.1 ± 1.3SD (range -3.4 to 1.8) and 1.0 ± 0.2 g/cm² (range 0.5-1.4), respectively. The mean FN Z-score and BM were -0.8 ± 1.0 SD (range -2.5 to 0.6) and 0.9 ± 0.2 g/cm² (range 0.6-1.2), respectively. None of the patients had a personal history of low-energy fractures.

Analytical findings:
No significant association was found between hip involvement and decreased BMD in either LS or FN(1.0±0.2 g/cm³ vs 1.0±0.3 g/cm³, p=0.34; and 0.9±0.2 g/cm³ vs 1.0±0.1 g/cm³, p=0.22), nor with Z-scores in either LS or FN (-1.1±1.2 SD vs -1.0±1.5 SD, p=0.78; and -1.0±1.0 SD vs -0.3±0.5 SD, p=0.07).
Similarly, no significant association was found between syndesmophytes and BM in LS and FN (1.1 ±0.2 g/cm² vs. 1 ± 0.2 g/cm², p = 0.5; and 0.9 ± 0.1 g/cm² vs. 0.9 ± 0.2 g/cm², p = 0.37), nor with Z-scores in LS and FN (-0.6 ± 1.3 SD vs. -1.3 ± 0.9 SD, p = 0.23; and -0.7 ± 0.8 SD vs. -0.9 ± 1.1 SD, p =0.19).

Conclusion:
Decreased BMD was observed in one third of young male patients with SpA. No associations were found between structural changes and bone

mineral density. Despite the structural changes observed, a larger-scale study among young men would be necessary to better assess the factors associated with decreased bone mineral density.

P731

FEAR OF FALLING AMONG OLDER WOMEN LIVING IN THE COMMUNITY

I. Tamulaityte-Morozoviene[1], R. Stukas[1], V. Alekna[2], M. Tamulaitiene[2], J. Dadoniene[1]

[1]Faculty of Medicine of Vilnius University, Vilnius, Lithuania; [2]National Osteoporosis Center, Vilnius, Lithuania

Objective
This study aimed to evaluate fear of falling, as psychological consequence, among elderly women living in the community.
Material and Methods
Women aged ≥60 years attending the National Osteoporosis Center for diagnostic or treatment purposes were included in the study. Data were collected via structured telephone interviews assessing falls and related outcomes over the preceding 12 months. Demographic and fall data were obtained using a study-specific questionnaire, while fear of falling was evaluated using the Falls Efficacy Scale International (FES-I).
Results
The study included 940 community-dwelling older women (mean age 73.7±5.9 years). Falls were reported by 361 participants (37.1%), with approximately one-third experiencing two or more falls within one year. Most fallers reported injuries, including bone fractures in 23.3% of investigated individuals. Fear of falling was reported by 75.4% of fallen women, the score of FES-I was 20.43±6.43. Women with fall related fracture more often reported fear of falling (OR = 4.94, p <0.0001). Fear of falling was reported by all women with hip or vertebral fractures and by 90.2% of women with wrist fracture. The moderate correlations between the number of falls and fear of falling (r=0.376; p<0,001) and between the number of falls and risk of falling (r=-0.357; p<0,001) were found.
Conclusions
Fear of falling was reported by approximately one-third of respondents who were included in the study. Three-quarters of those who have experienced falls reported fear of falling and nearly half of fallen individuals reported limitations in their daily activities.

ANALYTICAL PERFORMANCE EVALUATION OF THE NEW DOUBLE-ANTIBODY SANDWICH MINDRAY TOTAL VITAMIN D ASSAY AND COMPARISON VERSUS LIQUID CHROMATOGRAPHY TANDEM MASS SPECTROMETRY AND COMMERCIAL IMMUOASSAYS

I. Trifonidi[1], P. Lukas[2], E. Chronopoulos[3], E. Cavalier[2], K. Makris[4]

[1]Clinical biochemistry Department, KAT General Hospital, Laboratory of Research of Musculoskeletal System "Th. Garofalidis", KAT General Hospital, Medical School, University of Athens, Athens, Greece; [2]Department of Clinical Chemistry, University of Liege, CHU de Liege, Liege, Belgium; [3]Laboratory of Research of Musculoskeletal System "Th. Garofalidis", KAT General Hospital, Medical School, University of Athens, Athens, Greece; [4]Clinical biochemistry Department, KAT General Hospital, Laboratory of Research of Musculoskeletal System "Th. Garofalidis", KAT General Hospital, Medical School, University of Athens, Athens, Greece

Objectives: Vitamin D plays an important role in maintaining calcium and phosphorus homeostasis. Vitamin D deficiency may lead to skeletal problems such as rickets, osteomalacia, progressive bone loss and osteoporosis. As it has recently been implicated also in several non-skeletal diseases, requests for its measurement have increased exponentially. Assessment of vitamin D status by measurement of 25-hydroxyvitamin-D in most clinical laboratories is performed by immunoassays.
In this study we provide analytical evaluation of the new non-competitive chemiluminescent immunoassay from Mindray (Mindray total-Vitamin D-II). Its clinical performance was compared with two commercial competitive and one non-competitive chemiluminescent immunoassays against a Vitamin D standardization Program Traceable liquid chromatography-tandem mass spectrometry (LC-MSMS) using clinical samples from Greek volunteer donors.
Materials and Methods: Mindray Vitamin D-II stability of calibration, precision, linearity, recovery limits of blank, detection and quantification were assessed by standard protocols. For the method comparison 163 (serum and K_3-EDTA plasma) samples were obtained from healthy Greek donors. Correlation between methods was evaluated using Passing-Bablok and Bland-Altman analysis. Concordance correlation coefficient was calculated in order to evaluate the agreement between methods.
Results: Calibration proved to be stable for at least 30 days, precision measured with kit controls as well as with in-lab prepared serum pools was excellent showing CV's at all levels <4.00%. The assay is linear at least up to 83 ng/mL. The limit of quantification was found to be 2.49 ng/mL and mean recovery was found to be 105.07% (95%CI 102.74-177.40) Comparisons between serum and K_3EDTA plasma exhibited excellent correlation K_3EDTA=0.983XSerum+0.248 proving that both media can be used interchangeably with this assay. Comparison with the LC-MSMS showed excellent linear correlation (Mindray=0.982XLC-MSMS-2.303) and there was only a small negative bias (-2.3 ng/mL) that could be corrected with calibration as no proportional bias was detected in our comparisons (slope includes 1).
Conclusions: The Mindray total-vitamin D-II assay demonstrated very good analytical performance correlated well with LC-MSMS and compared well with other immunoassays supporting its use in routine clinical practice

CLINICAL AND LABORATORY CHARACTERISTICS OF GOUT PHENOTYPES: ASSOCIATION OF INTESTINAL PERMEABILITY MARKERS WITH TOPHUS FORM OF THE DISEASE

I. Yatskov[1], V. Beloglazov[1], K. Bubley[1], A. Gorlov[1], A. Labozinskaya[1]

[1]V.I. Vernadsky Crimean Federal University, Simferopol, Russia

Objective: To evaluate the features of the identified clinical and pathogenetic clusters in patients with gout and to determine the frequency of the tophus form in the phenotype with impaired intestinal barrier function.
Materials and methods: Based on cluster analysis, patients were divided into groups depending on the level of inflammatory and metabolic markers. The frequency of tophus occurrence in the selected clusters is analyzed.
Results: Three different phenotypes were identified during theanalysis. Cluster 1 ("Phenotype with a permeable intestine", n=18) attracts special attention. Patients in this group are characterized by the highest levels of markers of impaired barrier function: the level of lipopolysaccharide-binding protein (LBP) was 26.1 [22.6; 30.7] ng/ml, zonulin — 74.7 [58.9; 120.1] ng/ml. High BMI (31.38 [30.64; 35.06] kg/m^2) and elevated transforming growth factor levels (6.32 [3.33; 30.5] ng/ml) were also noted. When analyzing the severity of the course, it was found that the frequency of tophus gout in cluster 1 is 44.4% (8 out of 18 patients). This indicates a significant contribution of endotoxinemia to the chronization of the process and the formation of tofuses. For comparison, Cluster 2 ("Metabolic") was also characterized by a high BMI (39.79 kg/m^2) and markers of vascular dysfunction (nitric oxide synthase 3: 6.6 ng/ml) and the highest bactericidal permeability-increasing protein level of 298 pg/ml [249; 367.2], but the presence of the tophus form of gout in this cluster did not detected. Cluster 3 ("Hyporesponders") demonstrated minimal metabolic dysfunction and presumably the lowest intestinal permeability (LBP 11.65 ng/ml) and the lowest BMI, while 14 out of 36 patients had tophus gout, which corresponds to 28% within this cluster.
Conclusion: The "permeable intestine" phenotype is associated not only with high levels of LBP and zonulin, but also with a high incidence of tophus gout (44.4%). This allows us to consider intestinal permeability correction as a potential target for the prevention of severe forms of gout.

THE LANDSCAPE OF RENAL OSTEODYSTROPHY IN EUROPE: A FIRST REPORT FROM THE EUROD BONE BIOPSY DATABASE

I. Ystrøm[1], S. Salam[2], G. Spasovski[3], A. Ferreira[4], A. C. Ferreira[4], S. Keronen[5], H. Kröger[6], P. Evenepoel[7], H. S. Jørgensen[1]

[1]Department of Clinical Medicine, Aarhus University, Aarhus, Denmark; [2]Division of Clinical Medicine, University of Sheffield, Sheffield, United Kingdom; [3]Methodius, Skopje, North Macedonia; [4]Nova Medical School, Lisbon, Portugal; [5]Department of Nephrology, Helsinki University Hospital, Helsinki, Finland; [6]Kuopio Musculoskeletal Research Unit, University of Eastern Finland, Kuopio, Finland; [7]Department of Medicine, Division of Nephrology, UZ Leuven, Leuven, Belgium

Objective: Renal osteodystrophy (ROD) is a major complication of chronic kidney disease (CKD), yet its epidemiology is poorly defined due to the declining use of bone biopsy both in clinical practice and research. Earlier studies indicated a shift from high to low turnover bone disease in CKD[1], but the current spectrum of ROD is uncertain. This study reports from a multicenter bone biopsy database to address this knowledge gap.
Methods: Bone biopsies from 5 countries, collected between 1998 and 2025 were included. Biopsies were from patients across the spectrum of kidney dysfunction, including pre-dialysis, on dialysis, and after kidney transplantation. All centers reported the TMV classification for bone turnover (low, normal, high), mineralisation (normal, abnormal), and volume (low, normal, high). In addition, re-classification to common diagnostic definitions were performed using previously published cut-offs[2].
Results: A total of 851 bone biopsies were available. Of these, 155 were excluded (duplicates, incomplete registrations, or performed on clinical indication). The remaining 696 research-indication biopsies were stratified on CKD grade: Predialysis (CKDG4-5; n=135), on dialysis (CKDG5D, n=335), and post-transplant (TX, n=225). Median age at time of biopsy was 57 years, 32% were female, and 19% had diabetes mellitus. Antiosteoporosis medication was rarely used (CKDG4; 0%, CKDG5D: 2%, TX: 6%). TMV-classification showed high variation depending on cutoffs applied (**Fig** 1). By the original report, normal bone turnover was the most common presentation for all patients. For tetracycline-labeled biopsies (N=341) additional diagnostic definitions were applied. By the Malluche definition[1], the majority of patients in CKDG4-5 and CKDG5D had high bone turnover. This was also the case with the Recker definition[3,4], which labeled all patients as either high or normal bone turnover. Bone mineralization defects were reported for a notable proportion of patients in CKDG4-5, as well as TX
Conclusion: The presentation of ROD was mainly normal to high bone turnover in bone biopsies performed in research context over the past two decades in Europe. Contrary to previous reports, low bone turnover was not dominant. Classification was highly variable depending on diagnostic cutoffs applied, and further efforts should be directed at harmonizing diagnostic criteria. The presence of abnormal bone mineralisation in a sizeable number of patients deserves further attention.

THE IMPACT OF OSTEOPOROSIS AND COMORBIDITIES ON DISEASE SEVERITY AND FUNCTIONAL IMPAIRMENT IN PATIENTS WITH OSTEOARTHRITIS

J. A. Aleksic[1], G. F. Gojkovic[1], Z. S. J. Zvekic Svorcan[2], N. Nikcevic Krivokapic[3]

[1]Railway Healthcare Institute, Belgrade, Serbia; [2]University of Novi Sad, Medical Faculty od Novi Sad, Special Hospital for Rheumatic Diseases, Novi Sad , Serbia; [3]Special Hospital for Cerebrovascular Diseases, Belgrade, Serbia

OBJECTIVES: Osteoarthritis (OA) is a chronic degenerative joint disease affecting cartilage, subchondral bone, and synovium. Osteoporosis (OP) frequently coexists with OA, and both conditions share common risk factors such as aging, obesity, and systemic inflammation. Their coexistence may adversely influence disease severity, functional capacity, and clinical outcomes, emphasizing the need for an integrated approach to musculoskeletal health.
AIM: To assess the prevalence of osteoporosis in patients with primary osteoarthritis and to evaluate the impact of osteoporosis and associated comorbidities on disease severity and functional impairment.
MATERIAL AND METHODS: This cross-sectional study included 135 patients of both sexes diagnosed with primary OA according to ACR criteria. Clinical evaluation was performed in all patients. Radiographic severity of OA was assessed using the Kellgren–Lawrence (KL) grading system. Bone mineral density (BMD) was measured by dual-energy X-ray absorptiometry (DXA) at central skeletal sites (lumbar spine and hip). Disease severity and functional status were evaluated using the WOMAC index. Comorbidities, including osteoporosis, were identified based on medical history, laboratory data, and imaging findings. Statistical analyses were conducted to assess associations between OA severity, BMD, and comorbid conditions.
RESULTS: The mean age of patients was 64.3 ± 7.8 years, with a predominance of women (77%). Osteoporosis was diagnosed in 39% of patients, particularly among postmenopausal women and individuals older than 65 years. The most prevalent comorbidities were hypertension (59%), obesity (47%), hyperlipoproteinemia (34%), and type 2 diabetes mellitus (29%). Patients with concomitant OA and OP had significantly higher WOMAC scores for pain ($p = 0.01$) and physical function impairment ($p < 0.01$). Advanced KL grades (III–IV) were associated with reduced BMD at the femoral neck ($p = 0.001$) and lumbar spine ($p = 0.003$). Obesity and metabolic syndrome were associated with greater disease severity and functional decline.
CONCLUSION: Osteoarthritis and osteoporosis frequently coexist and are associated with increased disease burden and functional impairment. Early identification of osteoporosis and comorbidities in patients with OA, along with integrated management strategies targeting both joint and bone health, may improve clinical outcomes and reduce disability.

P738

BONE STRUCTURE BEYOND MINERAL DENSITY: INTEGRATION OF QUANTITATIVE ULTRASOUND WITH DUAL-ENERGY X-RAY ABSORPTIOMETRY IN A LARGE CLINICAL COHORT

D. Carbajal[1], I. Cruz[1], R. Zavaleta[1], J. A. Tamayo[1]

[1]Salud a lo Largo de la Vida, Ciudad de México, Mexico

Objectives

To evaluate the complementary contribution of quantitative ultrasound to the assessment of bone quality beyond bone mineral density measured by dual-energy x-ray absorptiometry in routine clinical practice.

Material and method

A descriptive observational study was conducted in 12,000 patients routinely evaluated in an outpatient setting for comprehensive bone health assessment. The cohort was predominantly female, aged 30 to 80 years, mainly over 60 years of age, and included patients with metabolic and systemic conditions such as diabetes mellitus, thyroid disorders, obesity, arterial hypertension, and renal transplantation. Bone mineral density was assessed by dual-energy x-ray absorptiometry at the lumbar spine, proximal femur, and forearm. Bone quality was additionally evaluated using quantitative ultrasound through speed of sound measurements performed at the forearm and tibia of the non-dominant limb. In a subgroup of patients, serial assessments were performed to evaluate longitudinal changes in densitometric and acoustic parameters.

Results

Quantitative ultrasound provided information not captured by bone mineral density alone. Speed of sound values reflected variations in bone elastic properties and structural integrity, even among patients with similar bone mineral density. These findings are consistent with previous evidence showing that quantitative ultrasound can assess aspects of bone quality partially independent of bone mineral density and discriminate fracture risk (1–3). In patients with metabolic disorders, particularly diabetes mellitus, discrepancies were observed between densitometric and acoustic measurements, consistent with reports describing preserved or increased bone mineral density associated with impaired bone mechanical properties and increased skeletal fragility (4). During follow-up, changes in acoustic parameters were detected that were not consistently paralleled by changes in bone mineral density.

Conclusion

• Bone strength is determined by the interaction between mineral content and organic matrix properties. While dual-energy x-ray absorptiometry quantifies bone mineral density at central and peripheral sites, quantitative ultrasound provides complementary information on bone elastic and microstructural characteristics. The integration of both techniques allows a more comprehensive assessment of bone quality and its evolution in heterogeneous clinical populations, with potential implications for skeletal fragility risk stratification.

TRANSLATING MOLECULAR INSIGHTS INTO CLINICAL PROGRESS: RJX-01 FOR MUSCLE RECOVERY AND OSTEOSARCOPENIA THERAPY

A. Ugarte[1], S. Verheijden[1], L. Meuleners[1], E. Mercken[1], A. Beliën[1], J. Aerssens[1]

[1]Rejuvenate Biomed, Diepenbeek, Belgium

Objective

A phase 1b trial using an immobilization (casted leg) model showed that 6-week treatment with RJx-01 improved muscle strength and fatigue resistance. The molecular mechanisms behind RJx-01's effects remained largely unexplored and warrant further study. A phase 2 trial evaluating RJx-01 in hospitalization-associated sarcopenia among COPD patients is currently ongoing. Moving forward, we propose a second phase 2 trial targeting osteosarcopenia.

Material and Methods

In a phase 1 sub-study (placebo versus RJx-01-treated healthy males), transcriptomic profiling (RNA-seq) was performed on muscle biopsies from the immobilized leg at baseline, after 2 weeks immobilization, and after 4 weeks recovery.

Results

Transcriptomic analysis revealed significant changes post-immobilization in both groups: reduced expression of genes linked to mitochondrial energy metabolism and increased expression of genes related to inflammation, immune activation, and collagen fibrosis. After 4 weeks recovery, gene set enrichment analysis showed normalization of these disrupted pathways in the RJx-01 group but not in the placebo group. Complementary hematoxylin & eosin staining confirmed sustained inflammation in placebo subjects during recovery, which was reversed in RJx-01-treated subjects.

Osteosarcopenia is characterized by dynamic crosstalk between bone and muscle, mediated by a range of bioactive factors including myokines, osteokines, and adipokines. Recent studies indicate osteosarcopenia increases risk of disability, frailty, falls, fractures, hospitalization, and mortality compared to either condition alone (osteoporosis, sarcopenia). While pharmacological treatments exist for bone loss, there is an unmet need for sarcopenia therapies. Based on our phase 1 findings, we propose a placebo-controlled phase 2 study to evaluate whether a 6-months RJx-01 treatment can preserve muscle strength and function in postmenopausal osteosarcopenia patients. We hypothesize that RJx-01, combined with standard bone-loss therapy, may improve functional outcomes.

Conclusion

RJx-01 enhances muscle strength and recovery, supported by molecular and histological evidence. The proposed phase 2 trial will determine if RJx-01 can address the unmet need for sarcopenia treatment in osteosarcopenia patients, aiming to improve clinical outcomes and reduce disability.

Disclosures: All co-authors were employed or funded by Rejuvenate Biomed nv.

P740

THE BONE–MUSCLE–FUNCTION UNIT AND FUNCTIONAL IMPAIRMENT ACROSS AGE GROUPS IN INDIVIDUALS WITH AND WITHOUT KNEE OSTEOARTHRITIS

J. B. Aily[1], J. G. Maciel[2], S. M. Mattiello[1]

[1]Federal University of São Carlos, São Carlos, Brazil; [2]University of São Paulo, Ribeirão Preto, Brazil

Objective(s)

To investigate the contribution of bone mineral density within the functional bone–muscle unit, and its associations with body composition, muscle strength, and physical function across age groups in individuals with knee osteoarthritis (OA).

Material and Methods

This cross-sectional study included 80 community-dwelling participants stratified by OA status and age (40–50 and 70–80 years; n = 20 per group): participants with and without knee OA. Areal bone mineral density at the femoral neck (BMD_FN) and appendicular lean mass (ALM) were assessed using dual-energy X-ray absorptiometry (DXA). Isometric knee extensor peak torque was measured using a Biodex dynamometer and normalized to ALM to define muscle quality. Pain and physical function were assessed using the WOMAC questionnaire and performance-based functional tests. Two-way ANOVA examined the effects of OA status and age group on bone mineral density, body composition, muscle strength, muscle quality, and functional outcomes. Multivariable linear regression models were applied to identify determinants of functional impairment, adjusting for age, body mass index, ALM, BMD_FN, and OA status, to explore the independent contribution of bone mineral density within the bone-muscle-function continuum.

Results

Femoral neck bone mineral density was preserved across OA status and age groups (all $p > 0.05$). Appendicular lean mass was significantly lower in older participants compared with younger participants, irrespective of OA status ($p = 0.016$). Knee extensor peak torque and muscle quality were significantly reduced in individuals with knee OA and in older adults (all $p \leq 0.023$). Functional impairment, assessed by WOMAC scores and performance-based tests, was markedly greater in individuals with knee OA compared with those without OA ($p < 0.001$). In adjusted regression models, knee OA status emerged as the strongest determinant of functional impairment ($\beta = 24.85$; 95% CI: 20.16–29.53; $p < 0.001$), whereas femoral neck bone mineral density and appendicular lean mass were not independently associated with physical function.

Conclusion(s)

Knee OA is associated with pronounced impairments in muscle strength, muscle quality, and physical function, despite preserved femoral neck bone mineral density. Although bone mineral density was not independently associated with functional outcomes, its preservation in the presence of marked muscle and functional deficits highlights the limitations of bone density alone as a marker of musculoskeletal health. These findings reinforce the importance of integrated assessment of the bone–muscle–function unit to characterize musculoskeletal aging and functional decline in knee OA.

Disclosures

The authors declare no conflicts of interest.

P741

AGE-RELATED ALTERATIONS IN MUSCLE ARCHITECTURE AND MUSCLE QUALITY WITHIN THE FUNCTIONAL MUSCLE–BONE UNIT PRECEDE FUNCTIONAL IMPAIRMENT IN KNEE OSTEOARTHRITIS

J. B. Aily[1], J. G. Maciel[2], S. M. Mattiello[1]

[1]Federal University of São Carlos, São Carlos, Brazil; [2]University of São Paulo, Ribeirão Preto, Brazil

Objective(s)
To investigate whether age-related alterations in quadriceps muscle architecture and muscle quality, as components of the functional muscle–bone unit, are associated with physical function across age groups in individuals with knee osteoarthritis (OA).

Material and Methods
This cross-sectional study included 80 community-dwelling participants stratified by OA status and age (40–50 and 70–80 years; n = 20 per group). Vastus lateralis muscle architecture, including muscle thickness (MT), pennation angle (PA), and fascicle length (FL) was assessed using two-dimensional B-mode ultrasonography. Isometric knee extensor peak torque was measured using a Biodex dynamometer. Body composition and appendicular lean mass (ALM) were assessed by dual-energy X-ray absorptiometry (DXA), and muscle quality was defined as knee extensor peak torque normalized to ALM. Pain and self-reported physical function were assessed using the WOMAC questionnaire, and functional performance was evaluated using the 30-second sit-to-stand test. Two-way ANOVA examined the effects of OA status and age group on muscle architecture, muscle quality, and functional outcomes. Multivariable linear regression models identified determinants of functional impairment, adjusting for age, sex, body mass index, ALM, and OA status.

Results
Participants with knee OA demonstrated reduced quadriceps MT, FL, PA, and muscle quality compared with age-matched individuals without knee OA (all $p \leq 0.001$). Significant main effects of OA status and age group were observed for muscle architecture parameters and muscle quality, with no interaction effects. Functional impairment, assessed by WOMAC scores and the sit-to-stand test, was significantly greater in individuals with knee OA than in those without OA ($p < 0.001$). In adjusted models, knee OA status was the strongest determinant of functional impairment ($\beta = 23.13$; 95% CI: 17.84–28.43; $p < 0.001$), while alterations in muscle architecture and muscle quality characterized musculoskeletal deficits across OA and age groups, suggesting compromised mechanical loading within the muscle-bone unit.

Conclusion(s)
Knee OA is associated with pronounced impairments in quadriceps muscle architecture and muscle quality, particularly in older adults. Notably, alterations in muscle architecture and muscle quality seem to occur before marked functional impairment, highlighting early deficits within the functional muscle–bone unit. Targeting muscle architecture and muscle quality may represent relevant strategies to support muscle–bone interactions, mechanical loading, and musculoskeletal health across aging in individuals with knee OA.

PHYSICAL ACTIVITY TRAJECTORIES OVER 8 MONTHS IN KNEE OSTEOARTHRITIS: THE ROLE OF BASELINE ACTIVITY LEVEL AND ADIPOSITY

J. B. Aily[1], N. A. Casonato[1], F. E. Sette[1], D. K. White[2], S. M. Mattiello[1]

[1]Federal University of São Carlos, São Carlos, Brazil; [2]University of Delaware, Newark, United States

Objective(s)
To investigate whether baseline adiposity and physical activity predict 8-month changes in objectively measured physical activity in individuals with knee osteoarthritis (OA).

Material and Methods
Participants with knee OA were assessed at baseline and after 8 months in a longitudinal observational study. Physical activity was objectively measured using wearable monitors and expressed as average daily step count. Adiposity was assessed at baseline using fat mass index (FMI), derived from body composition measurements. Eight-month change in physical activity was calculated as follow-up (8 months) minus baseline step counts. Associations between baseline FMI, baseline physical activity, and changes in steps/day were examined using multivariable linear regression models. Models were adjusted for baseline step count to account for initial activity levels and regression to the mean, as well as for age and sex. Unstandardized regression coefficients and 95% confidence intervals were reported, and model fit was assessed using the coefficient of determination (R^2).

Results
A total of 68 participants were included in the analysis. Baseline physical activity and FMI varied across individuals. In adjusted regression models, baseline physical activity was a significant predictor of 8-month change in daily step count ($\beta = -0.45$, $p < 0.001$), indicating that individuals with higher activity levels at baseline experienced smaller increases or greater reductions in steps over time. Baseline FMI was not associated with changes in physical activity ($\beta = 58.1$, $p = 0.46$). Age and sex were not significantly associated with changes in physical activity. The final model explained approximately 31% of the variance in 8-month change in steps/day.

Conclusion(s)
In individuals with knee OA, baseline physical activity, but not adiposity, predicts short-term changes in objectively measured physical activity. These findings indicate that lower initial activity levels may be associated with less favorable activity trajectories, irrespective of adiposity status. From a clinical and behavioral perspective, interventions designed to increase physical activity in individuals with knee OA may be most effective when prioritizing patients with lower baseline activity levels, irrespective of adiposity status.

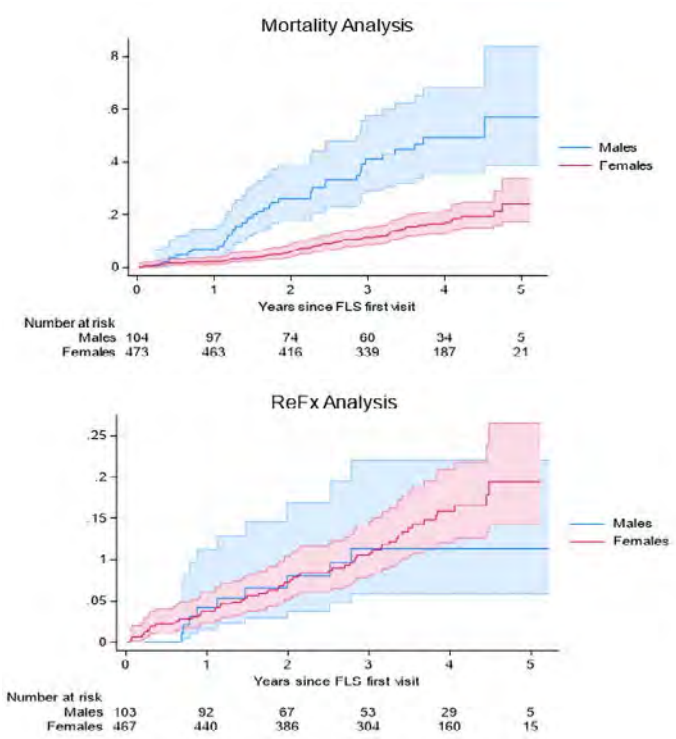
REFRACTURE RISK AND LONG-TERM MORTALITY IN FRAGILITY FRACTURE PATIENTS: A 5-YEAR LONGITUDINAL ANALYSIS

J. Bocio-Nuñez[1], D. Garcia-Romero[1], M. Giner[2], B. Hernandez-Cruz[1], M. A. Vazquez-Gamez[2], F. J. Olmo-Montes[1], J. Barrera-Barrera[1], E. Luna-Rodriguez[1], M. L. Serrano Guijo[1], M. A. Colmenero[1], M. A. Rico-Corral[1], M. Carmona-Garrido[1], J. J. Perez-Venegas[1], M. J. Montoya-Garcia[2]

[1]University Hospital Virgen Macarena, Seville, Spain; [2]University of Seville, Medical Faculty, Seville, Spain



Introduction and Objectives: The high burden of fragility fractures (FF) necessitate robust secondary prevention. This study investigated subsequent fracture (Re-Fx) incidence and five-year mortality in patients aged ≥50 post-initial FF, identifying clinical determinants influencing these outcomes.

Materials and Methods: A prospective cohort study included 577 patients (recruited 2018–2021; mean follow-up 3.2 years) managed within a Fracture Liaison Service (FLS). The study was approved by the Regional Human Research Ethics Committee. Analysis involved univariate and multivariate regression models to identify independent predictors of Re-Fx and mortality.

Results: The cohort was 82% female (mean age 74). Index fractures were primarily hip (41.6%) and vertebral (29.1%). Notably, 67.8% lacked a prior osteoporosis diagnosis. Significant baseline vulnerabilities were identified: 12% moderate-to-severe dependency, 54% limited physical activity, 50% moderate-to-high fall risk, and 50% high FRAX risk. Comorbidities (32%), fall-risk-increasing drugs (36%), and medications associated with bone loss (25%) were prevalent. Only 36% had received prior anti-osteoporotic treatment.

During follow-up, 70 Re-Fx (12.1%) and 110 deaths (18.5%) were recorded. Mortality was significantly higher in men (37.5%) than women (14.5%), a disparity increasing over time (Figure 1). Multivariate analysis showed that optimal nutritional status and potent antiresorptives (zoledronic acid, denosumab) or anabolic agents—compared to oral bisphosphonates—were independent protective factors against Re-Fx (Figure 2). Regarding mortality, female sex and favorable nutritional status were associated with higher survival, while advanced age was the primary risk factor.

Conclusion: FLS patients represent a high-risk geriatric population with imminent threats of Re-Fx and mortality. While refracture rates align with international cohorts, the stark sex-based mortality disparity is a critical finding. Results underscore the need for personalized, sex-specific interventions and prioritizing potent pharmacological therapies and nutritional support in secondary prevention.

P744

IMPROVING UPTAKE OF ANABOLICS IN OLDER HIP FRACTURE PATIENTS

J. Chillala[1], A. Hayes[1]

[1]Trafford Hospital, Manchester Foundation Trust, Manchester, United Kingdom

Objective

Anabolics such as romosusomab have been shown to be a far more effective treatment than bisphosphonates for osteoporosis, with evidence in older patients[1] as well as young, yet uptake remains poor. Patients are often not considered for treatment due to frailty and physical ability to self inject medication and yet this is the group with highest risk of falls and further fractures. Our study looked at whether we should be involving families/carers at an early stage, patients at present can't be considered for treatment unless prepared to self inject.

Methods

We collected data from patients on Elm Unit, a 30 bedded purpose built post hip fracture assessment and rehabilitation unit in Trafford Hospital. These patients have already had a hip fracture and therefore very high risk of imminent future fracture.

We looked at patients who would have been excluded from anabolic treatment consideration due to frailty/physical ability to self administer or because patient had fear of needles.

Our method involved approaching families at the bedside and contacting by phone , with patients' permission to see if they would be willing to administer monthly romosusomab injections at home .

We also looked at number of patients who were happy to self inject

Results

10 patient families/carers were happy to administer romosusomab to the patient at home if this was the best medication. This was a significantly higher number than expected. These patients would typically have been

given zolendronic acid on the ward.
9 patients were happy to self administer romosusomab.

Conclusion

The study showed that more families/carers were willing to give injections for their relatives than we expected. Clinicians need to ensure discussions occur with families/carers before excluding patients from possible anabolic treatments due to frailty/ physical ability

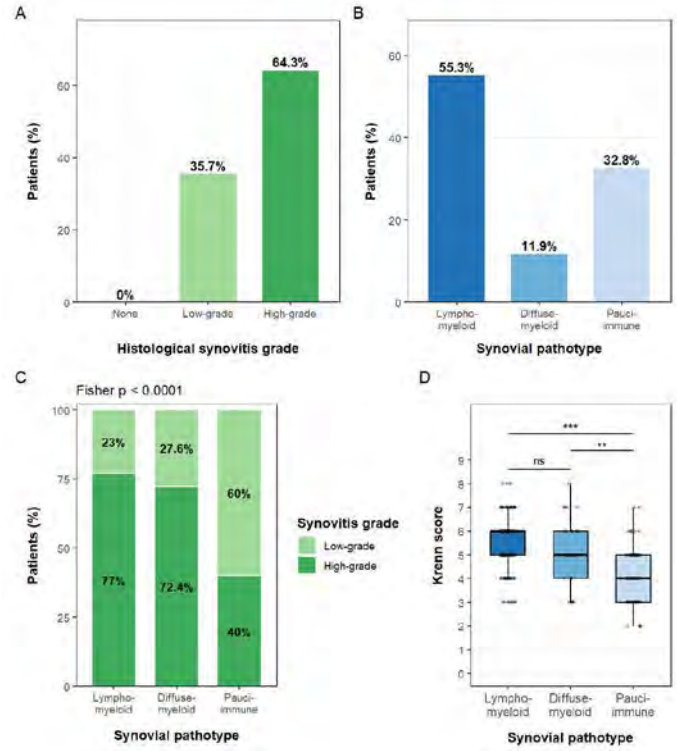
REVISITING OSTEOARTHRITIS AS AN INFLAMMATORY DISEASE: CHARACTERIZATION OF SYNOVITIS GRADING AND SYNOVIAL PATHOTYPES IN SURGICAL SPECIMENS

B. Bianchi[1], R. Righi[2], M. Gambarotti[2], D. Giuggioli[1], R. Caporali[3], F. Ursini[4], J. Ciaffi[4]

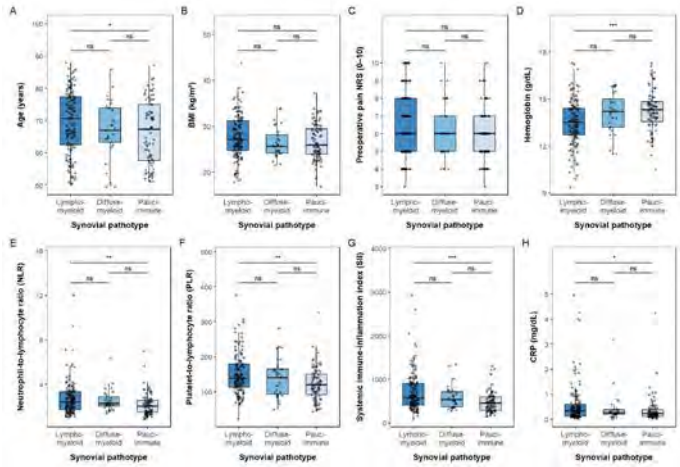
[1]University of Modena, Modena, Italy; [2]IRCCS Rizzoli Orthopedic Institute, Bologna, Italy; [3]University of Milan; ASST Gaetano Pini, Milan, Italy; [4]University of Bologna; IRCCS Rizzoli Orthopedic Institute, Bologna, Italy

Objective



To quantify synovitis severity and define synovial inflammatory pathotypes in advanced osteoarthritis (OA) surgical specimens, and to examine their associations with clinical, laboratory, and radiographic features.

Methods



Synovial tissue samples were obtained intraoperatively from adult patients undergoing primary orthopedic surgery for OA at multiple joint sites (predominantly hip and knee). Synovitis was graded on H&E using the Krenn score and classified as none (0-1), low-grade (2–4) or high-grade (≥5). Immunohistochemistry for CD3, CD20, CD68, and CD138 was semi-quantitatively scored to assign synovial pathotypes (lympho-myeloid, diffuse-myeloid, pauci-immune). Continuous variables were compared using Kruskal–Wallis tests with Dunn post-hoc tests, and categorical variables using Fisher's exact test.

Results

A total of 244 synovial specimens were analyzed. The overall median Krenn score was 5 (IQR 4–6), with 64.3% classified as high-grade synovitis and 35.7% as low-grade (Figure 1A). The lympho-myeloid pathotype was most prevalent (55.3%), followed by pauci-immune (32.8%) and diffuse-myeloid (11.9%) (Figure 1B). Although all pathotypes included both low- and high-grade synovitis, the proportion of high-grade synovitis differed substantially (77.0% lympho-myeloid, 72.4% diffuse-myeloid, 40.0% pauci-immune; Figure 1C). Total Krenn scores showed a clear gradient across pathotypes: median 4 (IQR 3–5) in pauci-immune, 5 (IQR 4–6) in diffuse-myeloid, and 6 (IQR 5–6) in lympho-myeloid tissues (Kruskal–Wallis p<0.001), with higher scores in lympho-myeloid and diffuse-myeloid versus pauci-immune (p<0.001 and p=0.001, respectively) (Figure 1D).

Across clinical/laboratory parameters (Figure 2A–H), age varied modestly (p=0.038), BMI did not differ significantly (p=0.120), and preoperative pain was similar across pathotypes (p=0.059). Hemoglobin differed (p<0.001), with lower values in lympho-myeloid versus pauci-immune synovium (p<0.001). Systemic inflammatory indices displayed a consistent gradient: NLR (p=0.0026), PLR (p=0.0033), SII (p<0.001), and CRP (p=0.033) were higher in lympho-myeloid than pauci-immune tissues, with no significant differences between lympho-myeloid and diffuse-myeloid groups.

Conclusions

Advanced OA surgical synovium shows high inflammatory burden and reproducible immune pathotypes, with a marked histological and systemic inflammatory gradient from pauci-immune to lympho-/diffuse-myeloid profiles.

P747

RISK OF FRAGILITY FRACTURE IN PPI USERS: WHAT DOES THE EVIDENCE TELL US?

J. De Carvalho Magalhães[1], L. Azevedo[2], O. G. Hierro[3], A. Sousa Miranda[3], J. Frazão[4], C. Vaz[5]

[1]ULS Barcelos-Esposende; USF BarcelSaúde; Faculdade de Medicina da Universidade do Porto, Barcelos, Portugal; [2]ULS Barcelos-Esposende; USF St. António, Barcelos, Portugal; [3]ULS Barcelos-Esposende; USF Esposende Norte, Barcelos, Portugal; [4]ULS S. João; Departamento de Nefrologia; Faculdade de Medicina da Universidade do Porto; RISE, Porto, Portugal; [5]ULS S. João; Departamento de Reumatologia; Faculdade de Medicina da Universidade do Porto; RISE, Porto, Portugal

Objective
The objective was to evaluate the association between use of proton pump inhibitors (PPIs) and fragility fractures risk.
Material and Methods
A systematic search for studies published from 2010 onwards was conducted in the PubMed, Scopus, Cochrane, and Web of Science databases, using terms related to osteoporosis, fragility fracture, and PPIs. Observational studies (cohorts and case-control studies) and meta-analyses were included. Unpublished/unavailable studies, cross-sectional studies, case reports/case series, basic research, and commentaries/editorials were excluded. The methodological quality was assessed using CASP checklists. Evidence was synthesized narratively, including meta-analyses heterogeneity (I2). The level of evidence and the strength of the recommendation were classified using the SORT scale.
Results
1,385 studies were identified of which 27 were included (11 cohorts, 7 case-control studies, 9 meta-analyses), evaluating more than 15,052,802 participants. Meta-analyses consistently indicated a significant increased risk of fragility fractures (RR 1.16–1.58), with higher risk for vertebral fractures (RR 1.50-1.58) compared to hip fractures (RR 1.20-1.30) and with variable heterogeneity (I2 2.38–89.7%). Case-control studies generally indicated a modest association (OR 1.09–1.44), and cohort studies indicate a modest but significant risk (HR 1.25–1.53).
Conclusions
Evidence suggests a modest yet robust association between PPI use and increased risk of fractures, particularly vertebral and hip fractures. However, the high heterogeneity and observational nature of the studies prevents a conclusion of causality. Based on Level 2 evidence, allowing for a moderate strength of recommendation (Grade B-SORT), caution is essential in the prescription of long-term PPI therapy, and periodic re-evaluation is advised, especially in patients with risk factors for fragility fractures.

P749

PHARMACOTHERAPY CHANGE PATTERNS AFTER FRAGILITY FRACTURE IN PATIENTS RECEIVING BONE-ACTIVE MEDICATION: A FRACTURE LIAISON SERVICE QUALITY IMPROVEMENT COHORT STUDY

H. Ansari[1], A. Yang[1], R. Sujic[1], E. Bogoch[1,2], V. Elliot-Gibson[1], R. Jain[3], J. Weldon[3], D. Linton[1], J. E. M. Sale[1,2]

[1]Unity Health Toronto, Toronto, Canada; [2]University of Toronto, Toronto, Canada; [3]Osteoporosis Canada, Toronto, Canada

Objective: We examined pharmacotherapy change patterns in fragility fracture patients who fractured while taking bone active medication, and were screened by Ontario's Fracture Screening and Prevention Program (FSPP). A secondary objective was to identify baseline characteristics associated with receiving a pharmacotherapy change recommendation.
Material and Methods: The cohort included fragility fracture patients (50+ years), who fractured while taking bone active medication, were screened by the FSPP during 2017-2024, and subsequently evaluated by bone health specialists. Descriptive statistics were used to summarize baseline factors and pharmacotherapy patterns. Factors associated with receiving a recommendation to change medication were investigated using multivariable regression.
Results: Of 828 patients meeting eligibility criteria, 60.4% (n=500) were advised to change medication, 33.9% (n=281) to remain on the same medication, and 2.7% (n=22) to discontinue the medication. Data were unavailable for 3.0% (n=25). Of those advised to change medication, 83.6% (n=418) were changed to denosumab, 5.2% (n=26) to teriparatide, and 2.4% (n=12) to risedronate. Older age was associated with a higher likelihood of receiving a recommendation to change medication [1.84 (95% CI: 1.15-2.95)], while being on denosumab was associated with a lower likelihood [0.07 (95% CI: 0.05-0.11)].
Conclusions: Findings suggest that a fracture on treatment prompted re-evaluation and treatment escalation in many cases, while younger age and prior denosumab use were associated with lower likelihood of switching, likely reflecting a multitude of clinical considerations and jurisdiction-specific reimbursement constraints. This study provides real-world insights on pharmacotherapy change patterns in a high-risk, understudied patient cohort from a jurisdiction-wide Fracture Liaison Service, addressing a group with therapeutic uncertainty.

"DON'T TELL ME I'M GOING TO FEEL JOY": THE EMOTIONAL BURDEN OF INFORMAL CAREGIVERS OF PATIENTS WITH A FRAGILITY FRACTURE DISCHARGED FROM A REHABILITATION HOSPITAL

K. Hodwitz[1], M. El-Hussein[2], J. Cameron[3], L. M. Meadows[4], J. Watt[1], M. Ashe[5], J. Phan[1], F. Aghajafari[4], L. Funnell[6], J. E. M. Sale[1,3]

[1]Unity Health Toronto, Toronto, Canada; [2]Mount Royal University, Calgary, Canada; [3]University of Toronto, Toronto, Canada; [4]University of Calgary, Calgary, Canada; [5]University of British Columbia, Vancouver, Canada; [6]Patient Partner, Surrey, Canada

Objective: Few studies have examined the emotional experience of caregiving for individuals with a fragility fracture or the contextual factors that may influence this experience. Our objective was to explore the experience of caring for someone after a fragility fracture to understand the nuances of the emotional experience and identify ways to better support informal caregivers.

Material and Methods: Using a phenomenological approach, we recruited primary caregivers of fragility fracture patients who were discharged from a rehabilitation hospital in an urban setting in Canada. We conducted individual interviews with caregivers and analyzed the data according to Giorgi's procedures to describe the structure of caregivers' emotional experience.

Results: We interviewed 32 caregivers (19 female, 13 male) ranging in age from 37-95 years old. Most participants were caring for a parent (59%) or spouse (22%). "Don't tell me I'm going to feel joy" encapsulated the experience that caregiving was complex, comprised of tensions internally and with care recipients, and exacerbated by various pressures to adopt the caregiver role. As a result, caregivers often felt reluctant to voice displeasure or ask for help, exacerbating their burden and making them feel they must suffer in silence.

Conclusions: Our study demonstrates the multifaceted nature of caregivers' emotional burden and highlights the pressures caregivers of fragility fracture patients feel to take on caregiving roles without complaint or assistance. Our findings highlight the need to acknowledge the emotional complexity of caregiving, empower caregivers to ask for help, and develop meaningful supports and policies to alleviate caregiver burden.

THE EXPERIENCE OF PATIENTS SCREENED THROUGH AN ONTARIO FRACTURE LIAISON SERVICE DURING COVID

J. E. M. Sale[1,2], L. Frankel[1], V. Elliot-Gibson[1], E. Bogoch[1,2], L. M. Meadows[3], L. Funnell[4], A. Yang[1], R. Jain[5], J. Weldon[5], D. Theriault[5]

[1]Unity Health Toronto, Toronto, Canada; [2]University of Toronto, Toronto, Canada; [3]University of Calgary, Calgary, Canada; [4]Patient Partner, Surrey, Canada; [5]Osteoporosis Canada, Toronto, Canada

Objective: We examined the health care experiences of patients screened through an Ontario Fracture Liaison Service during COVID.

Materials and methods: A phenomenological study was conducted. Eligible patients were English-speaking males and females, ≥50 years old, with a fragility fracture who presented as outpatients at one of six Fracture Screening and Prevention Program (FSPP) sites across Ontario during COVID (2020-2022). Patients were interviewed (60-90 minutes) by telephone. Analysis was guided by Giorgi's procedures.

Results: We interviewed 21 patients (12 females, 9 males) aged 63-85 years old. This sample size met sample size requirements for phenomenological studies*. Based on our analysis, we developed two themes: 1) Patients expressed minimal concern about COVID while attending fracture clinic appointments, or during hospital admission. They attributed this to extensive COVID protocols, such as masking and social distancing, which made them feel safe. Some participants reported that the health care providers with whom they interacted appeared anxious, which was perceived to affect the quality of care they received; 2) Patients perceived that services in the hospital and fracture clinic were well organised and efficient during COVID, noting short wait times, clear communication and ease of booking appointments. However, many participants suggested that their experience outside the FSPP setting was not as satisfactory. Participants described challenges in receiving timely follow-up care, arranging physiotherapy and contacting their family doctor.

Conclusions: Fracture patients reported satisfaction with the care they received in the hospital and FSPP setting during COVID. In contrast, access to health care outside the FSPP setting was challenging, highlighting gaps in continuity of care during this period.

INCREASED RISK OF ATRIAL FIBRILLATION IN YOUNG ADULTS WITH GOUT: A NATIONWIDE COHORT STUDY

E. S. Kang[1], J. H. Jung[1]

[1]Department of Rheumatology, Korea University Ansan Hospital, Ansan, Republic of Korea, Ansan, South Korea

Objective: To investigate the association between gout and incident AF in a large nationwide cohort of Korean adults aged 20–39 years.
Methods: This retrospective cohort study analyzed 6,506,721 individuals from the Korean National Health Insurance Service (NHIS) database. Gout and AF were identified using ICD-10 codes M10 and I48, respectively. Cox proportional hazards regression models were used to estimate hazard ratios (HRs) and 95% confidence intervals (CIs) for incident AF after adjusting for demographic, lifestyle, and clinical factors.
Results: During a median follow-up of 11.49 years, gout was associated with a significantly increased risk of AF (fully adjusted HR, 1.44; 95% CI, 1.31–1.58). The cumulative incidence of AF was significantly higher in the gout group (log-rank P < .001). Subgroup analyses demonstrated stronger associations among non-obese individuals and those with chronic kidney disease (CKD).
Conclusions: Gout was associated with an increased risk of atrial fibrillation among young adults. These findings suggest that gout may serve as a clinically relevant risk marker for AF, underscoring the need for proactive cardiovascular risk assessment in this population.

P753

THE CORRELATION BETWEEN CHANGES IN RADIOLOGICAL CERVICAL PARAMETERS AND FACIAL ASYMMETRY

J. Hankollari[1], N. Leka[2]

[1]Albanian University, Tirana, Tirane, Albania; [2]University of Medicine, Tirana, Tirana, Albania

Objectives: In my daily practice as a rheumatologist, one of the most frequent complaints I deal with is related to the cervical spine. When posture changes of the cervical spine occur, it is often obvious that facial asymmetry exists. The aim of this study is to identify changes in the cervical spine that correlate with facial (a)symmetry. Identifying a potential correlation would be of great clinical significance, as doctors who treat cervical spine pathologies would be more cautious about problems related to facial asymmetry.
Material and Methods: 32 patients aged 18-64 years were included in this prospective study who had complaints about their cervical spine. Cervical radiographs were used to assess parameters such as C2–C7 Lordosis (CL), T1 Slope (T1S), Thoracic Inlet Angle (TIA), Neck Tilt (NT), C2–C7 Sagittal Vertical Axis (C2–C7 SVA), cervical and cranial tilting for each patient. The assessment of facial asymmetry was done through inspection and P-A cephalometric.
Results: Changes in cervical radiographic parameters occurred in 53.13 % of patients. The parameters that were most altered were: C2–C7 Lordosis (CL), T1 Slope (T1S), C2–C7 Sagittal Vertical Axis (C2–C7 SVA), cervical and cranial tilting. Facial asymmetry was found in 64.71% of patients who experienced changes in these parameters, whereas only 20% of cases without cervical radiological parameters had facial asymmetry.
Conclusions: Facial asymmetry is more prevalent in patients with changes in cervical radiological parameters than in those without cervical radiological parameters changes.

P754

JUVENILE PAGET DISEASE WITH NOVEL COMPOUND HETEROZYGOUS SEQUENCE VARIANTS IN THE TNFRSF11B GENE: CASE REPORT FROM THE CZECH REPUBLIC AND OVERVIEW

J. Horáčková[1], R. Taslerová[2], M. Bayer[3], L. Pavlíková[1], V. Palička[4]

[1]Department of Clinical Biochemistry and Diagnostics and Osteocenter, University Hospital Hradec Kralove and Faculty of Medicine in Hradec Kralove, Charles University, Hradec Králové, Czechia; [2]Department of Pathology, University Hospital Brno, Brno, Czechia; [3]Pediatric Osteology, Department of Children and Adolescents, Third Faculty of Medicine, Charles University and Faculty Hospital Kralovske Vinohrady, Prague, Czechia; [4]Department of Clinical Biochemistry and Diagnostics and Osteocenter, University Hospital Hradec Kralove and Faculty of Medicine in Hradec Kralove, Charles University, Czech Republic, Hradec Králové, Czechia

Objectives:
Juvenile Paget disease (JPD) is an extremely rare autosomal recessive skeletal disorder characterized by markedly increased bone turnover, resulting in skeletal deformities, increased fracture susceptibility, and various extraskeletal manifestations. The disease is caused by pathogenic variants in the **TNFRSF11B** gene encoding osteoprotegerin, a key regulator of osteoclast-mediated bone resorption. While most reported JPD cases have been found to carry homozygous *TNFRSF11B* variants, compound heterozygous variants are rare.

Methods and Results:
We report the first diagnosed case of juvenile Paget disease in the Czech Republic, presenting with a mild disease phenotype. The first fractures occurred at the age of three years. Additional clinical manifestations included characteristic skeletal deformities, macrocephaly, arched chest, valgus deformity of the lower extremities, lateral femoral bowing, and anterior bowing of the tibiae. Extraskeletal findings comprised mild mixed hearing impairment, angioid streaks of the choroidea, and transient immunodeficiency.
Molecular genetic analysis using Sanger sequencing was performed in the patient and both clinically unaffected parents. This revealed a unique compound heterozygous genotype in **TNFRSF11B**, consisting of a paternally inherited splice-site variant **c.30+5G>A, p.(?)** and a maternally inherited missense variant **c.329G>T, p.(Gly110Val)**, neither of which has been previously reported in association with JPD. We describe the diagnostic work-up, therapeutic management, and long-term follow-up of the patient.

Conclusion:
The identification of these novel *TNFRSF11B* variants extend knowledge of JPD. Early diagnosis and timely initiation of antiresorptive therapy effectively reduce fracture incidence, limit progression of skeletal

deformities, and significantly improve quality of life. This case of osteoprotegerin deficiency further contributes to the understanding of its role not only in skeletal homeostasis but also in extraskeletal systems.

DECREASED BONE MINERAL DENSITY IS ASOCCIATED WITH SUBCLINICAL ATHEROSCLEROSIS IN ASYMPTOMATIC NONDIABETIC POSTMENOPAUSAL WOMEN

J. I. Ismaili[1], V. Muharremi Berisha[2], A. Poniku[3], R. Tafarshiku[4], G. Bajraktari[3], M. Y. Henein[5], A. Batalli[3]

[1]Clinic of Rheumatology University Clinical Centre of Kosova, Prishtina, Albania; [2]Clinic of Endocrinology University Clinical Centre of Kosova, Prishtina, Albania; [3]Clinic of Cardiology University Clinical Centre of Kosova, Prishtina, Albania; [4]Clinic of Endocrinology University Clinical Centre of Kosova, Prishtina, Albania; [5]University of Umea, Umea, Sweden

Background/Objectives: Estrogen deficiency is strongly related to osteoporosis, but its role in the development of atherosclerotic cardiovascular disease (CVD), particularly in postmenopausal women, is unclear. The aim of this study was to assess the relationship between osteopenia and subclinical atherosclerosis in asymptomatic non-diabetic postmenopausal women.

Methods: This prospective study included 117 consecutive postmenopausal women (mean age 59 ± 7 years) referred from the outpatient Rheumatology Clinic of the University Clinical Centre of Kosovo, recruited between September 2021 and December 2022. Clinical, biochemical, bone mineral density (BMD), carotid ultrasound and coronary CT angiography data were analyzed. Subclinical atherosclerosis was diagnosed as the presence of carotid plaques and/or increased intima-media thickness (CIMT) > 1.0 mm.

Results: Of the 117 studied women, 83 (71%) had osteopenia or osteoporosis (T-score < −1 SD), who had higher prevalence of carotid artery plaques (27.7 vs. 8.8%, p = 0.019), compared to those with normal BMD. They were, also, older (p < 0.001), had a longer duration of menopause (p = 0.004) and higher CAC scores (p < 0.019), compared to those without plaques. In multivariate analysis [odds ratio 95% confidence interval], age [1.244 (1.052–1.470), p = 0.001], osteoporosis [0.197 (0.048–0.806), p = 0.024] and CAC score > 10 HU [0.174 (0.058–0.806), p = 0.006] were independently associated with the presence of carotid plaques. **Conclusions:** Reduced BMD is highly prevalent in asymptomatic non-diabetic postmenopausal women and is associated with a high prevalence of subclinical carotid atherosclerosis. Age, osteoporosis and CAC score > 10 HU were independently associated with atherosclerotic carotid plaque formation. These findings highlight the potential pathophysiological link between osteoporosis and subclinical atherosclerosis.

A 10-YEAR LABORATORY DATA ANALYSIS OF TRENDS IN SERUM VITAMIN D CONCENTRATIONS AND DISTRIBUTION IN LATVIA (2015-2025)

J. Iljina[1], E. Priede[1], A. Krisane[2], I. Rasa[3]

[1]Rīga Stradiņš University, Riga, Latvia; [2]E.Gulbis Laboratory Ltd., Riga, Latvia; [3]Rīga Stradiņš University, Riga East University Hospital, Latvian Osteoporosis and Bone Metabolic Diseases Association, RIGA, Latvia

Objectives. This study aimed to compare serum 25-hydroxyvitamin D (25(OH)D) concentrations and vitamin D status distribution between 2015 and 2025; additionally, it sought to evaluate whether the population's vitamin D concentrations have improved over the ten years marked by increased awareness and recommendations for supplementation in Latvia.

Materials and Methods. A retrospective analysis was performed using routine serum 25-hydroxyvitamin D test results from adults aged ≥18 years in 2015 and 2025. Vitamin D concentrations were compared between years, seasons, and across age and sex using appropriate parametric and non-parametric statistical tests.

Results. A total of 348536 serum 25(OH)D analyses were included, with the number of tests increasing from 67088 in 2015 to 281448 in 2025. Mean vitamin D concentrations were significantly higher in 2025 compared with 2015 (36.31±0.03 vs 27.06±0.04 ng/mL, p<0.001). Females had higher mean vitamin D levels than males (35.13±0.03 vs 33.14±0.05 ng/mL, p<0.001). Vitamin D levels increased progressively with age, from 30.63 ng/mL in individuals <30 years to 38.08 ng/mL in those aged ≥70 years (all pairwise p<0.001). Seasonal variation was observed in both years, with lower median vitamin D levels in winter than in summer in 2015 (25.48 vs 27.07 ng/mL, p<0.001) and 2025 (30.10 vs 37.50 ng/mL, p<0.001). Winter vitamin D levels were significantly higher in 2025 compared with 2015 (p<0.001). The distribution of vitamin D status changed substantially over time, with deficiency decreasing from 23.9% in 2015 to 11.2% in 2025, insufficiency from 36.5% to 23.4%, and optimal vitamin D levels increasing from 4.5% to 13.0% (χ^2=20,713.09, p<0.001).

Conclusions. Over the past decade, vitamin D concentrations in the population have increased, with a higher proportion of individuals now achieving sufficient and optimal status. This trend may reflect improved awareness of the importance and pleiotropic effects of vitamin D and supports continued efforts to strengthen public health strategies.

CELL CYCLE-MEDIATED BIDIRECTIONAL REGULATION OF OSTEOBLAST-OSTEOCLAST BALANCE BY BIOMODIFIED MAGNESIUM PHOSPHATE CEMENT FOR OSTEOPOROTIC BONE REGENERATION

J. Jiang[1,2], W. Wang[2], Z. Zhao[3]

[1]Medical School of Southeast University, Nanjing, China; [2]Department of Spine Center, Zhongda Hospital affiliated to Southeast University, Nanjing, China; [3]School of Materials Science and Engineering, Southeast University, Nanjing, China

Objective: We developed a multifunctional modified magnesium phosphate cement incorporating ferulic acid-loaded nanoparticles to regulate osteoblast-osteoclast balance via AKT1/p21/CDK2 pathway for osteoporotic bone regeneration.
Methods: HMSNs were synthesized and modified with ferulic acid, polydopamine coating, and tannic acid to develop a multifunctional magnesium phosphate cement. The material was characterized for physicochemical properties and drug release behavior. In vitro studies evaluated cell viability, osteogenic differentiation, and osteoclast inhibition, focusing on the AKT1/p21/CDK2 pathway regulation. The therapeutic efficacy was assessed in an ovariectomy-induced osteoporotic rat model with femoral defects using micro-CT and histological analysis.
Results: The modified cement exhibited superior properties with 96.5% injectability, enhanced compressive strength (70.6±5.9 MPa), controlled degradation (5.19% at 28 days), and NIR-responsive drug release (96.37% over 7 days), while maintaining excellent biocompatibility (>95% cell viability). Network pharmacology and molecular docking confirmed ferulic acid's regulation of AKT1/p21/CDK2 pathway. The material significantly promoted G1/S phase transition, enhanced osteogenic differentiation (2.8-fold ALP activity, 3.2-fold mineralization), and improved bone microenvironment through regulating inflammatory and angiogenic factors (all $p<0.01$). In vivo studies demonstrated that the experimental group achieved 2.85-fold higher bone volume/total volume ratio (BV/TV) compared to the control group. Histological analysis confirmed significant enhancement in osteoporotic bone defect repair.
Conclusion: This responsive cement system shows promising potential for osteoporotic bone regeneration through cell cycle-mediated regulation, offering new strategies for bone tissue engineering applications.

P758

THE TRAJECTORY OF HEALTH DECLINE FOLLOWING SPINAL COMPRESSION FRACTURE IN GERIATRIC PATIENTS: A REVIEW ARTICLE

J. Josh[1], J. Jeremy[1], J. Jose[1]

[1]hadassah ein kerem, Jerusalem, Israel

Objectives:
This paper aims to overview the clinical implication and overall health consequences of spinal compression fractures in the geriatric population
Material and Methods:
This paper reflects a comprehensive review of publications from PubMed, orthopedic associations, online publications and relevant medical literature, focusing on the incidence, clinical presentation, and long-term complications of the "vertebral fracture cascade."
Results:
Spinal compression fractures are highly prevalent among elderly patients, often secondary to osteoporosis. In this vulnerable population, a single fracture can trigger a cascade of secondary complications across multiple organ systems, leading to progressive health decline. Acute back pain commonly results in reduced mobility and increased risk of subsequent falls. These events heighten the likelihood of pulmonary, pressure ulcers and urinary tract infections, which in turn may contribute to cardiovascular complications and elevated mortality risk. Preexisting comorbidities further exacerbate this downward trajectory. Long-term adverse health outcomes frequently include chronic pain, spinal deformity, diminished range of motion, and functional disability ultimately impairing quality of life and fostering dependency.
Conclusion:
Spinal compression fractures in geriatric patients often initiate a self-perpetuating cycle of declining health, driven by immobility, recurrent falls, and systemic complications. Effective management should emphasize prevention of primary fractures, early detection, and a multidisciplinary approach that integrates both the musculoskeletal and geriatric care. Early recognition and interruption of this "cascade to dependency" is crucial to improving functional outcomes and overall quality of life in this population.

P759

AWAKE PERCUTANEOUS FIXATION FOR UNSTABLE FRACTURES OF THE SPINE IN HIGH-RISK PATIENTS

J. Josh[1], J. Jose[1], R. Harem[1], G. Barkay[1]

[1]hadassah ein kerem, Jerusalem, Israel

Objectives:
The incidence of unstable fractures in elderly or medically compromised patients is on the rise. This cohort population presenting for surgery poses a significant challenge for surgeons. The risks associated with general anesthesia and surgery may outweigh the potential benefits. For patients classified as ASA 3-4, the risk is even greater due to the higher likelihood of intraoperative complications. An alternative to general anesthesia is undergoing surgery awake under mild sedation. In this study we aimed to assess the perioperative outcomes of patients with osteoporosis undergoing an awake spinal percutaneous fixation with mild sedation and local anesthesia.
Methods:
This study included a prospective observational analysis evaluating patients with ASA 3-4 with osteoporosis who presented with unstable spinal fractures at a level one trauma center. These patients underwent awake spinal percutaneous fixation with mild sedation and local anesthesia. Data on demographics, radiology, and outcomes were collected.
Results:
A total of 64 patients underwent surgery between 2019 and 2023. The average follow-up duration was 12 months (range: 8-24 months), with 33 females and 31 males. The average age was 77.7 years, and all patients had an ASA score of 3-4. The injury types included 29 extension fractures, 254 unstable burst fractures, 7 Chance fractures, and 2 teardrop fractures. All patients received unilateral fixation, with one patient undergoing bilateral fixation. Cement augmentation was performed in 50

patients. There were no neurological complications, and only one case of infection was reported, occurring 4 months post-surgery. All patients were discharged ambulatory.
At the 2-week follow-up, the average VAS score decreased from a preoperative score of 9 (range: 8-10) to 2 (range: 0-4) (P<0.01). Postoperative X-rays taken at 6 and 12 weeks confirmed fracture healing. At the final follow-up, four cases of hardware loosening were identified, however those cases remained asymptomatic and did not require revision surgery.
Conclusions:
Our findings suggest that awake fixation is a safe and feasible alternative to undergoing the procedure under general anesthesia for extreme cases. This approach, however necessities a dedicated multidisciplinary team, including an anesthesiologist and a radiologist, to ensure the procedure is performed safely and efficiently.

P760

THE CONTRIBUTION OF FIBROMYALGIA TO NEUROPATHIC PAIN AND CENTRAL SENSITIZATION IN DIABETES

M. Boudokhane[1], J. Jouini[1], H. Bettaeib[1], G. Mattoussi[1], S. Bellakhal[1], W. Helali[1], C. Besrour[1], R. Bourguiba[1]

[1]Internal Medicine of the Internal Security Forces Hospital in La Marsa, Tunis, Tunis, Tunisia

Introduction :
While chronic pain in diabetes is commonly ascribed to peripheral neuropathy, diffuse and treatment-resistant pain patterns suggest an underlying central pain component, including central sensitization and fibromyalgia.
Objective :
To assess the contribution of central sensitization and fibromyalgia to the expression of chronic pain in diabetic patients presenting with neuropathic pain.
Methods :
This observational study included 100 diabetic patients with chronic pain, followed at the Department of Internal Medicine of the Internal Security Forces Hospital in La Marsa, Tunis, between February and June 2025. Neuropathic pain was assessed using the DN4 questionnaire, central sensitization was evaluated with the Central Sensitization Inventory (CSI), and fibromyalgia was diagnosed according to the 2016 American College of Rheumatology (ACR) criteria. Pain intensity, functional impact, and therapeutic response were subsequently analyzed.
Results :
One hundred diabetic patients (mean age 58 ± 10 years; 54% male; mean duration of diabetes 12 ± 6 years) with chronic pain lasting more than six months were included. Painful diabetic neuropathy was identified in 78% of patients (DN4 ≥ 4). Elevated central sensitization scores (CSI ≥ 40) were observed in 46% of patients, and 32 patients (32%) fulfilled the 2016 ACR criteria for fibromyalgia. Patients with associated fibromyalgia reported significantly higher pain intensity (mean VAS 7.6 ± 1.2 vs. 5.4 ± 1.5; p < 0.001), comparable DN4 scores to those without fibromyalgia (5.8 ± 1.3 vs. 5.6 ± 1.4; p = 0.48), but a markedly greater functional impact (mean FIQ 62 ± 14 vs. 34 ± 16; p < 0.001). Pain severity was not correlated with peripheral neuropathy parameters (p = 0.62), but showed a significant correlation with central sensitization scores (r = 0.61; p < 0.001). Patients presenting both painful diabetic neuropathy and fibromyalgia exhibited a poorer response to conventional neuropathic pain treatments, with only 28% reporting clinically meaningful improvement, compared with 57% of patients without fibromyalgia (p = 0.01). These findings suggest that pain in patients with diabetes is not solely driven by peripheral mechanisms, but frequently involves central sensitization, with a clinical phenotype closely resembling fibromyalgia.
This interaction between neuropathy and central sensitization may account for a subset of so-called "refractory" pain syndromes and underscores the need for a multidimensional approach to pain assessment and management.
Conclusion :
Central sensitization and fibromyalgia are highly prevalent among diabetic patients with chronic pain and substantially shape clinical manifestations and treatment outcomes. Identifying these conditions remains a major challenge for rheumatologists but is essential for achieving diagnostic precision, therapeutic optimization, and improved pain management in this population.

P761

GOUT IN PATIENTS WITH TYPE 2 DIABETES: A MORE SEVERE AND UNDERTREATED DISEASE? A REAL-WORLD STUDY

M. Boudokhane[1], J. Jouini[1], G. Mattoussi[1], H. Bettaeib[1], S. Bellakhal[1], W. Helali[1], C. Besrour[1], R. Bourguiba[1]

[1]Internal Medicine of the Internal Security Forces Hospital in La Marsa, Tunis, Tunis, Tunisia

Introduction :
Gout frequently coexists with type 2 diabetes mellitus (T2DM) and adds to the morbidity of a population already burdened by cardiometabolic comorbidities. However, data characterizing the severity of gout and its management among patients with T2DM in routine clinical practice remain limited.
Objectives :
To assess the clinical severity of gout and the quality of its management in patients with T2DM.
Methods :
We conducted a retrospective observational study including 100 patients with T2DM and a confirmed diagnosis of gout, followed in an Internal Medicine Department. Data regarding gout characteristics, comorbidities, and treatments were collected. Gout severity was assessed by annual flare frequency, polyarticular involvement, presence of tophi, and gout-related hospitalizations. Quality of management was evaluated based on the use of urate-lowering therapy (ULT), achievement of target serum uric acid (SUA) levels (<360 µmol/L), and colchicine use.
Results :
The study included 100 patients (mean age 58 ± 10 years; 54% male; mean duration of diabetes 12 ± 6 years). Cardiometabolic comorbidities were frequent: hypertension (78%), obesity (52%), dyslipidemia (61%), and chronic kidney disease stage ≥3 (46%). Gout had a high clinical burden: mean annual flares 2.0 ± 1.1, 44% experiencing ≥2 flares/year, polyarticular involvement in 41%, and tophi in 28%. Gout-related hospitalizations occurred in 22%.
Management was suboptimal: only 66% received ULT, with a mean allopurinol dose of 190 ± 60 mg/day and only 18% titrated to >300 mg/day. Target SUA (<360 µmol/L) was achieved in 39% of patients. Recurrent colchicine use was reported in 58%, and 12% required repeated NSAID courses. Patients with chronic kidney disease were less likely to receive ULT and less likely to achieve target uric acid, highlighting treatment gaps in high-risk subgroups.
Conclusion :

In this real-world cohort, gout in patients with T2DM was associated with substantial clinical severity and suboptimal management. These findings emphasize the need for improved recognition and optimized treatment strategies for gout in this high-risk population.

P762

IMPACT OF SGLT2 INHIBITORS ON GOUT OUTCOMES IN PATIENTS WITH TYPE 2 DIABETES: A REAL-WORLD STUDY

M. Boudokhane[1], J. Jouini[1], H. Bettaeib[1], G. Mattoussi[1], S. Bellakhal[1], W. Helali[1], C. Besrour[1], R. Bourguiba[1]

[1]Internal Medicine of the Internal Security Forces Hospital in La Marsa, Tunis, Tunis, Tunisia

Objective:
To investigate the association between SGLT2 inhibitor use and gout burden in patients with T2DM.
Methods :
We conducted a retrospective, single-center observational study including 100 patients with type 2 diabetes mellitus (T2DM) and a confirmed diagnosis of gout, followed in the Internal Medicine Department of the Hospital of the Internal Security Forces in La Marsa. Patients were categorized according to exposure to sodium–glucose cotransporter 2 inhibitors for at least six months (SGLT2i+ vs SGLT2i−). The primary outcome was the annual rate of gout flares. Secondary outcomes included changes in serum uric acid (SUA) levels, attainment of target uricemia (<360 µmol/L), use of urate-lowering therapy (ULT), colchicine use, and gout-related hospitalizations.
Results :
Among the 100 patients, 48% were treated with SGLT2 inhibitors. Baseline characteristics were comparable between groups, including age, sex, diabetes duration, and baseline SUA levels. During follow-up, patients in the SGLT2i+ group experienced a significantly lower mean annual number of gout flares compared with the SGLT2i− group (1.2 ± 0.8 vs 2.1 ± 1.1 flares/year, p=0.002). A significant reduction in mean SUA levels was observed in the SGLT2i+ group (−78 ± 34 µmol/L, p<0.001), whereas no significant change was noted in patients not receiving SGLT2 inhibitors. Achievement of target uricemia occurred more frequently in the SGLT2i+ group (62% vs 38%, p=0.01). The proportion of patients requiring colchicine for acute flares was significantly lower among SGLT2i-treated patients (35% vs 57%, p=0.03). Rates of gout-related hospitalization were reduced in the SGLT2i+ group, although this difference did not reach statistical significance. No increase in adverse events was observed. The association between SGLT2i use and reduced flare frequency persisted independently of concomitant ULT.
Conclusion :
In this real-world cohort of patients with T2DM, SGLT2 inhibitor therapy was associated with a significant reduction in gout flares and improved serum uric acid control. These findings suggest that SGLT2 inhibitors may provide clinically meaningful benefits beyond glycemic control and represent a promising adjunctive strategy in the management of gout among diabetic patients.

P763

APPENDICULAR SKELETAL MUSCLE MASS INDEX AND FALL RISK AMONG OLDER PATIENTS IN REHABILITATION UNIT

M. Karlonaite[1], U. Kanapickaite[1], D. Meckauskiene[1], J. Kilaite[1], A. Apsega[1]

[1]Vilnius University, Vilnius, Lithuania

Objective
Our purpose was to evaluate the relationship between appendicular skeletal muscle mass index (ASMI) and fall risk in older adults.
Material and Methods
A cross-sectional study enrolled 60 years and older individuals during inpatient rehabilitation after hip or knee arthroplasty, pelvic or femoral fractures and other chronic conditions e.g. lumbar stenosis. Body composition was assessed using bioelectrical impedance analyser Accuniq BC300. ASMI was calculated as the sum of lean muscle mass of the upper and lower limbs divided by height squared (kg/m^2). Fall risk was assessed by: Tinetti Performance Oriented Mobility Assessment (POMA), Timed-Up-and-Go test (TUG). High fall risk was defined as a POMA score <19 points and TUG time ≥ 20 seconds. Data was analysed using SPSS ver.27.0: Spearman's correlation, Mann-Whitney U test were performed.
Results
The study Participants' (38 (86.4% women), 6 (13.6% men)) mean age was 73.4 ± 9.1 years. POMA showed high fall risk in 16.1% of patients, TUG test in 33.3% of patients. The mean of ASMI was 7.726 ±1.366 kg/m^2, ranging from 5.57 to 11.46 kg/m^2. ASMI score showed a weak correlation with TUG time (r = -0.457, p=0.005). There was no significant correlation between ASMI and POMA scores. ASMI was significantly lower in the TUG high fall risk group (median = 6.91 kg/m^2, IQR 6.68-7.30) than in the group without high fall risk (median = 7.76 kg/m^2, IQR 7.35-9.21) (p=0.026). There was no significant difference in ASMI between the POMA groups.
Conclusions
Results of this study indicate a relationship between ASMI and fall risk in older adults. Patients with high fall risk assessed by the TUG test have lower ASMI than those without high fall risk.

P764

NUTRITIONAL STATUS AND FALL RISK AMONG OLDER ADULTS DURING INPATIENT REHABILITATION

U. Kanapickaite[1], M. Karlonaite[1], D. Meckauskiene[1], J. Kilaite[1], A. Apsega[1]

[1]Vilnius University, Vilnius, Lithuania

Objective
The purpose of the study was to evaluate the relationship between nutritional status and fall risk in older patients undergoing rehabilitation.
Material and Methods
A cross - sectional study included 60 years and older adults undergoing inpatient rehabilitation after pelvic or femoral fractures, hip or knee replacement or chronic diseases such as spinal stenosis. Patients with a Mini-Mental State Examination score of 18 or higher were included in the study. Nutritional Status was assessed by full form of Mini Nutritional

Assessment (MNA) and Nutritional Risk Screening 2002 (NRS). Based on NRS scores, patients with a score of 3 and more are suggested to be at risk of malnutrition. Based on full MNA, nutritional status was evaluated according to the following scores: malnourished (<17), at risk of malnutrition (17-23.5) and well- nourished (24-26). Fall risk was evaluated by the Timed Up and Go test (TUG) and Tinetti Balance Assessment Test (TT). High risk of falls was defined as TUG score ≥ 15 seconds and TT as < 19 points. Pearson 's correlation, Mann Whitney U tests were performed using SPSS ver.27.0.
Results
We enrolled 38 participants (86.4% women), whose mean age was 73.4±9.1 years. Based on MNA, 6 (13.6%) patients were malnourished, 24 (54.5%) were at risk of malnutrition, 14 (31.8%) were well-nourished. According to NRS, 40.4% were at risk of malnutrition. Based on the TUG and TT, a high risk of falls was identified in 61.1% and 16.1%, respectively. A moderate correlation between TUG and NRS (r = 0.573; p < 0.001) and negative weak correlation between TUG and MNA score (r = - 0.450; p = 0.004) was determined. There was no significant correlation between TT and MNA scores. A negative weak correlation was found between TT and NRS (r = - 0.463; p = 0.009). Patients with high fall risk according to TUG test had higher NRS scores – 2.5 (IQR 2.0-3.25) compared to those without fall risk – 1.5 (IQR 1.0- 2.0) (p = 0.013). According to TT, patients with high fall risk had higher NRS – 2.5 (IQR 1.0 - 4.0) compared with those without fall risk - 2.0 (IQR 1.25 - 3.0) (p = 0.029). There was no significant difference in MNA scores between groups with high fall risk and without high fall risk.
Conclusions
Findings of our study suggest that nutritional status in older patients undergoing rehabilitation is associated with a risk of falls. Patients with higher risk of fall had higher NRS score than those without high fall risk according to TUG and TT.

P765
NUTRITIONAL STATUS AND INCIDENCE OF SARCOPENIA IN OLDER ADULTS WITH CHRONIC HEART FAILURE

J. Kilaitė[1], V. Ginevičienė[2], E. Pranckevičienė[2], A. Urnikytė[2], R. Dadelienė[3], A. Mastavičiūtė[1], I. E. Jamontaitė[3], I. I. Ahmetov[2], V. Alekna[1]

[1]Vilnius University, Faculty of Medicine, Institute of Clinical Medicine, Clinic of Internal Diseases and Family Medicine, Vilnius, Lithuania; [2]Vilnius University, Faculty of Medicine, Translational Health Research Institute, Vilnius, Lithuania; [3]Vilnius University, Faculty of Medicine, Department of Rehabilitation, Physical and Sports Medicine, Vilnius, Lithuania

Objective: The aim of this study was to investigate the nutritional status and influencing factors of sarcopenia in older adults with chronic heart failure (CHF).

Materials and methods: An inclusion criteria to this cross-sectional study were: age 65 or more years, diagnosis of CHF, unrestricted mobility, MMSE ≥ 21. Nutritional status was assessed by Mini Nutritional Assessment (MNA). Based on MNA score participants were classified as having normal nutrition, being at risk of malnutrition, or being malnourished. Sarcopenia was defined according to European Working Group on Sarcopenia in Older People criteria made in 2018. Body composition was measured by dual-energy x-ray absorptiometry (iDXA, GE Lunar, USA), muscle strength was evaluated measuring handgrip strength (JAMAR, Patterson Medical, UK), and physical performance was evaluated by the gait speed test. Chi-squared test was used to assess differences between sarcopenia and nutritional status groups. Multivariate logistic regression analysis was used to assess the odds of having sarcopenia if MNA score decreases.

Results: The study included 117 community dwelling older adults with heart failure: 21 (17.9%) men and 96 (82.1%) women. Mean age was 83.32±7.11 years, ranging from 65 years to 97 years. Out of all participants 61 (52.1%) were classified as having sarcopenia, of which 15 (24.6%) were men and 46 (75.4%) were women. According to MNA score 44 (37.6%) participants were in normal nutritional status, 58 (49.6%) were risk of malnutrition and 15 (12.8%) were malnurished. There was a statistically significant difference between nutritional status groups and sarcopenia category: participants without sarcopenia were in normal nutrition group while participants with sarcopenia were malnourished or at risk of malnutrition ($\chi 2$ = 15.95, p < 0.0001). Multivariate logistic regression analysis revealed that higher BMI and MNA were protective factors for sarcopenia (OR: 0.7, 95%CI (0.57;0.85), OR: 0.76, 95%CI (0.62;0.93)), respectively. Higher fat mass was associated with the risk of sarcopenia (OR: 1.1 (1.02;1.18)) in older adults with CHF, after adjusting for confounding factors.

Conclusion: Results of our study shows that in older adults with CHF and sarcopenia malnutrition is more prevalent than in participants without sarcopenia. In addition higher BMI and MNA reduced the risk of sarcopenia.
This project has received funding from the Research Council of Lithuania (LMTLT), agreement No S-MIP-22-36.

BIOMARKER EVIDENCE OF ACCELERATED BIOLOGICAL AGING IN HIP FRACTURE PATIENTS WITH OSTEOPOROSIS/OSTEOPENIA/ PATHOLOGIC PFRACTURE

J. Klein-Seetharaman[1], J. Hart[1], K. Doshi[2]

[1]Arizona State University, Phoenix, United States; [2]Mayo Clinic Scottsdale, Scottsdale, United States

Objective: To study if hip fracture patients exhibit biomarker profiles consistent with accelerated biological aging independent of chronological age.
METHODS: This cross-sectional study analyzed Mayo Clinic platform data from 2000 to 2024, comparing biomarker profiles between hip fracture patients with osteoporosis/osteopenia/pathologic fracture (Cohort A) and general population controls (Cohort B). Both cohorts were restricted to ages 60-80 years to minimize age confounding, with mean age difference of <1 year. We examined 10 pre-specified aging biomarkers and conducted comprehensive screening of 10,921 laboratory tests. Effect sizes were calculated using Cohen's D.
RESULTS: Among 10 pre-specified biomarkers, minimal differences were observed for albumin (D=-0.26) and P1NP (D=-0.09). However, comprehensive screening identified strong evidence for accelerated aging across multiple physiological systems. Large effects (|D|≥0.8) were observed for proinsulin elevation (D=+1.15, indicating metabolic dysfunction), hematocrit reduction (D=-0.95, anemia/frailty), and

potassium elevation (D=+0.77, kidney dysfunction). Medium effects (|D|=0.5-0.8) included IGF-1 decline (D=-0.58, growth hormone axis decline) and HDL cholesterol elevation (D=+0.71, likely treatment effect). Small-to-medium effects included interleukin-18 elevation (D=+0.45, chronic inflammation). Paradoxically, some markers showed favorable changes likely reflecting medical treatment, such as eGFR (D=+0.47), vitamin D (D=+0.24), and calcium D=+0.24).
CONCLUSIONS: Individuals with osteoporosis, osteopenia, and hip fracture demonstrate biomarker patterns suggestive of accelerated biological aging across metabolic, hematologic, renal, endocrine, and inflammatory systems, independent of chronological age. The large effect size for proinsulin suggests severe metabolic dysfunction, while reduced hematocrit indicates diminished hematologic reserves characteristic of frailty. Although treatment effects complicate interpretation, they do not fully explain the multi-system aging pattern. These findings support the hypothesis that hip fractures are associated with advanced biological aging and suggest potential targets for comprehensive geriatric interventions beyond traditional bone-directed therapies. Longitudinal studies are needed to establish temporal relationships and causality.

P767

VERTEBRAL FRACTURES BY VFA/DXA: THE FACTS AND THE DEFINITIONS

J. L. A. Morales Torres[1], J. Romero Ibarra[2], J. Morales Vargas[1], H. Avila Armengol[3]

[1]Morales Vargas Centro de Investigacion, Leon, Mexico; [2]Hospital Aranda de la Parra, Leon, Mexico; [3]Reumatologia, Universidad de Guadalajara, Guadalajara, Mexico

A vertebral fracture (VF) usually means osteoporosis (OP). Defined as ≥20% loss of vertebral height, it was found in 65.8% of patients (aged ≥ 65 years) in a densitometry unit[1], utilizing Vertebral Fracture Assessment by DXA (VFA/DXA). We analyze some implications of these findings
Objective:
To specify the characteristics of VF according to a pragmatic approach for their definition in the clinic.
Methods:
This retrospective study includes patients referred for densitometry on a iDXA GE-Lunar device, who had a VFA/DXA, by proposed criteria[2]. We define VF as a loss of vertebral body height of ≥20% in one or more vertebral areas[3], analyzing concordance of 2 observers identifying the number of vertebrae affected; percentage of VF grade 1 to 3; percentage of multiple (3 or more) VF and association with BMD value and OP. We report with simple descriptive statistics and a concordance analysis between observers.
Results:
We included 1226 patients (91.9% women, mean age of 74 ± 8.5 years); 807 (65.8%) had at least one VF. Most fractures (61.8%) were grade 1, but 56% of patients had 3 or more VF. More affected levels were from T6 to T9 and T11-T12. OP was significantly more common in the spine (79.1%) and femur (83.3%) in those with VF ($p<0.05$). Interobserver agreement was moderate when using the kappa coefficient ($\kappa = 0.60$), but increased to good when applying Gwet's AC1 (AC1 = 0.69; 95% CI 0.55–0.83), suggesting an effect of prevalence on kappa value.
Discussion: Is the 20% limit adequate to define the presence of a fracture? Different screening methods result in differences in the prevalence of VF. Overdiagnosis may occur, but the main problem is lack of identification. The definition used here for VFA/DXA is easy to apply and may result in increased case detection. Patients with grade 1 VF or even borderline have a higher risk of fractures, but those with multiple VF or even a single definable VF require treatment, keeping close surveillance on those with borderline changes.
Conclusions:

This definition reveals a high frequency of VF by VFA/DXA, highlighting the prevalence of multiple VF. All of them should be treated properly

ASSOCIATION BETWEEN 25-HYDROXYVITAMIN D (25OHD) LEVEL, BODY MASS INDEX (BMI), AND SEASON IN ADULT WOMEN

J. L. Mansur[1], M. J. Castro[2]

[1]Center of Endocrinology and Osteoporosis La Plata, Argentina, La Plata, Argentina; [2]) Universidad de Buenos Aires. Facultad de Farmacia y Bioquímica. Departamento de Fisicomatemática, Buenos Aires, Argentina

Objective

To evaluate the association between BMI and 25OHD level in a population of adult women who did not receive Vit D supplementation, considering the influence of season, and to describe the distribution of vitamin D levels according to BMI.

Materials and methods

Observational study in 750 adult women from La Plata, Argentina, who were not receiving vitamin D supplementation. BMI, 25OHD level, and season were recorded.

Continuous variables were described using descriptive statistics, and associations were assessed using Spearman's rank correlation coefficient. Group comparisons were performed using parametric or non-parametric tests as appropriate. A p-value < 0.05 was considered statistically significant.

Results:

BMI x: 26.5 ± 5.9 kg/m², with a median of 25.2 kg/m²; 18.9% of the women were overweight and 3.5% met the criteria for obesity.

25OHD level showed an asymmetric distribution, with mean of 22.0 ± 8.3 ng/mL and a median of 21.5 ng/mL (IQR 15.9–27.1); 85.7% of the sample had levels below 30 ng/mL, while 14.0% had levels ≥30 ng/mL, including 3.3% with levels ≥40 ng/mL.

Association between BMI and 25OHD level: a statistically significant negative correlation was found, with lower vitamin D levels observed as BMI increased ($\rho = -0.20$; $p < 0.0001$).

25OHD levels varied significantly according to season (KW, H = 78.25; $p < 0.0001$). Median levels were highest during the summer (25.95 ng/mL) and lowest in winter (18.60 ng/mL), with intermediate values in autumn (23.45 ng/mL) and spring (21.10 ng/mL). Post-hoc analysis showed

significant differences between seasons.

25OHD levels according to BMI (Table).

25OHD	Obese women	No obese women
<20 ng/mL	55,2 %	36,5 %
20-30 ng/mL	38,8 %	46,4 %
30-40 ng/mL	4,2 %	13,1 %
>40 ng/mL	1,8 %	3,9 %

Conclusion

In adult women, insufficient vitamin D levels were frequently observed. While a small proportion reached concentrations ≥30 ng/mL without supplementation, level ≥40 ng/mL, which would be necessary for non-skeletal functions (such as the prevention of autoimmune diseases, etc), were exceptional. 25OHD levels were inversely associated with body mass index and showed marked seasonal variation, with deficient values being more frequent in obese women.

P769

OPTIMIZING GUIDELINE-BASED SCREENING FOR ADULTS IN SOUTHWESTERN ONTARIO WITH MULTIPLE ENDOCRINE NEOPLASIA TYPE 1 (MEN1) SYNDROME: A QUALITY IMPROVEMENT (QI) INITIATIVE

J. Lesarge[1], S. van Uum[1], T. Khan[1]

[1]The University of Western Ontario, Department of Endocrinology and Metabolism, St. Joseph's Health Care London, London, Canada

Objective: Through a QI framework, we aim to improve adherence to guideline-based screening in adults with MEN-1 in Southwestern Ontario by at least 20% by 2030.
Material and Methods: We conducted a retrospective 5-year chart review of all adults with MEN1 followed by Southwestern Ontario's Tertiary Care Centre (n=26) to assess baseline adherence to the 2025 MEN1 guidelines, defined as the proportion of completed investigations relative to those due. To improve adherence, we sent patient-specific recommendations to their endocrinologist, disseminated and presented on the 2025 MEN1 guidelines within the division, and placed a guideline summary printout in clinical areas.
Results: Baseline screening adherence varied. For parathyroid hyperplasia, serum calcium was assessed at diagnosis in 57% and annually in 78%. For dp-NETs, serum fasting gastrin was assessed at diagnosis in 62% and annually in 38%; pancreatic imaging was assessed at diagnosis in 69% and follow up imaging in 100%. For sellar masses, prolactin and IGF-1 were assessed at diagnosis in 71% and 59% and annually in 67% and 31%, respectively; sellar imaging was assessed at diagnosis in 47% and follow up imaging in 85%. Screening adherence for thymic, bronchopulmonary, adrenal, and breast tumours had similar variable adherence. Patients had a mean of 9.7 clinical visits over the last 5-years.
Conclusion**:** Despite frequent follow up, adherence to MEN1 guideline-recommended screening is variable. Our targeted QI interventions may improve guideline-concordance and patient outcomes. If successful, these insights and strategies could be considered at other centres. Future work will evaluate intervention impact and refine strategies within the QI framework.

THORACIC SPONDYLODISCITIS PRESENTING WITH BACK PAIN: A CASE REPORT

J. López Díez[1], C. Celada Roldán[2], J. A. López Díez[1], M. A. Cerezuela Abarca[2], C. Luna Rodríguez[1]

[1]Cartagena Este Health Care Center, Cartagena, Spain; [2]San Antón Health Care Center, Cartagena, Spain

Objectives: Spondylodiscitis is an infection of the body and vertebral disc whose early detection and treatment can prevent future relevant pathologies, such as compressive myelopathy. It is important to perform a detailed physical examination and complementary tests that avoid a late diagnosis that increases the comorbidity of the condition. We present a case of 66-year-old male who presented with back pain and diagnosed to have spondylodiscitis.
Material and Methods: A 66-year-old male with no medical comorbidities, with 4 months history of upper back pain and intermittent fever of up to 39oC coinciding with the same. Associated morning stiffness was present. He has received analgesic treatment without improvement. Dorso-lumbar X-ray: vertebral degenerative changes. Laboratory analysis revealed high acute inflammatory parameters and nuclear magnetic resonance of thoracic spine revealed signs of osteomyelitis in the disc-vertebral body complex D8-D9 with a large anterior paravertebral and epidural abscess causing severe dorsal stenosis with spinal cord compression and signs of compressive myelopathy. Blood cultures: Staphylococcus aureus positive.
Results: Based on collected results, we have concluded that diagnosis was infectious spondylodiscitis with left paravertebral abscess and antibiotic therapy was performed. The patient is currently without back pain or fever.
Conclusions: Early diagnosis of bacterial spondylodiscitis remains a challenge due to the nonspecific signs and symptoms reported by the patient and the wide variability of laboratory results and imaging. The basis for early diagnosis remains the clinical suspicion at the time of initial treatment.

DIAGNOSTIC CHALLENGES IN A RARE SYSTEMIC INFLAMMATORY SYNDROME IN THE ELDERLY

J. López Díez[1], C. Celada Roldán[2], J. A. López Díez[1], M. A. Cerezuela Abarca[2], C. Luna Rodríguez[1], P. Saura Pérez[1], F. Rider Garrido[2], M. C. Alcaraz Salvago[1], J. L. García Gil[1]

[1]Cartagena Este Health Care Center, Cartagena, Spain; [2]San Antón Health Care Center, Cartagena, Spain

Objectives: Adult Onset Still's disease (AOSD) is an inflammatory disorder characterized by quotidian (daily) fevers, arthritis, and an evanescent rash. It is a rare inflammatory disorder of unknown etiology. Due to lack of definitive diagnostic test, the diagnosis of AOSD can only be made after exclusion of other causes. We present a case of adult

onset Still's disease.
Matherial and methods: An 84-year-old woman with two weeks histoy of fever, polyarthritis with edema in both hands, sore throat and erythematous macular rash on the arms, neckline and back that did not improve despite conservative treatment. Exploration and complementary tests: good general condition with good vital signs. Highlight the lung auscultation crackles in the right base, with rest unremarkable exploration. Hemogram with predominantly polymorphonuclear leukocytosis, elevated acute phase reactants, ferritin, and transaminases. Referred for hospital admission. Negative blood cultures, urine antigen detections, and autoimmunity. Chest, hands, wrists, lumbar spine, pelvis, and sacroiliac X- rays with marked signs of generalized degenerative osteoarthritis without lytic or blastic lesions. Chest CT showing bilateral pleural effusion and minimal pericardial effusion.
Results: When infectious and tumor processes were ruled out, treatment with high-dose steroids was started, associating weekly methotrexate. Clinical judgment: adult Onset Still's disease. She is doing well and is completely symptom free.
Conclusions: Adult Still's disease is a systemic inflammatory pathology with a prevalence of 1/100,000 people, whose diagnosis and etiology remain unclear, and may be related to viral infections, a certain seasonality in the symptoms, as well as activity factors and prognosis, the concentration of interleukin 1 and the increase in serum ferritin. Since the delay in its diagnosis leads to a worsening in the prognosis of patients (40% will have a chronic course), it is essential a high clinical suspicion based on the Yamaguchi criteria (fever with evening peaks, rash, inflammatory arthralgia, intense sore throat, and leukocytosis with a predominance of polymorphonuclear cells and hyperferritinemia) for optimal and early treatment.

CALCIUM KNOWLEDGE AND DAILY CALCIUM INTAKE AMONG MEN AGED 18 YEARS AND OLDER IN THE WESTERN REGION OF MONGOLIA

J. M. Jaalkhorol[1], A. S. H. Avirmed[2], N. E. Narangerel[2], B. A. Banzragch[2]

[1]Department of Health Research, School of Graduate School, Mongolian National University of Medical Sciences , Department of Anthropology, Ludwik Hirszfeld Institute of Immunology and Experimental Therapy, Polish Academy of Sciences, Wroclaw, Poland, Ulaanbaatar, Mongolia; [2]Department of Health Research, School of Graduate School, Mongolian National University of Medical Sciences, Ulaanbaatar, Mongolia

Objective: Calcium is essential for bone structure, muscle contraction, nerve transmission, and blood clotting, and inadequate intake increases the risk of osteoporosis. International studies have mostly focused on adolescent and menopausal women, so there is a need for a broader study regardless of age or gender.To determine the knowledge and daily intake of calcium among men over 18 years of age in Uvs aimag, a western aimag, and to assess the influencing factors.
Methods: A cross-sectional study was conducted involving 109 men aged 18 to 75 who received care at the general hospital of Uvs province in the Western region. Daily calcium intake was assessed using the International Osteoporosis Foundation (IOF) questionnaire for calcium intake evaluation. The study results were analyzed using SPSS version 26 software.
Results: The average age of the participants was 44.39 ± 2.47 years. Among the male participants, 62.4% had a low level of knowledge about calcium, 13.8% had a moderate level, and 23.8% had a high level. Additionally, 45.9% of participants had very low daily calcium intake (<500 mg), 41.3% had insufficient intake (500–1000 mg), and 12.8% had adequate intake (1000 mg). The level of calcium knowledge among participants showed a statistically significant association with vitamin D intake and education level ($p = 0.001$). However, no statistically significant differences were observed between calcium knowledge and participants' age, BMI, smoking status, or alcohol consumption. Participants' education level was significantly associated with average daily calcium intake ($p = 0.001$). Furthermore, calcium knowledge was positively correlated with daily calcium intake ($r = 0.827$, $p < 0.003$).
Conclusion: The average daily calcium intake among adult men in the Western provinces was 603 mg, which is insufficient. Since lower levels of knowledge were associated with reduced calcium intake, it is necessary to enhance education and awareness efforts.

P773
RISK FALL ASSESSMENT AMONG RESIDENTS OF ULAANBAATAR CITY

J. M. Jaalkhorol[1], D. A. Dashtseren[2], T. S. G. Tsetseg[3], N. E. Narangerel[4], M. M. Myagmar[5]

[1]Department of Health Research, School of Graduate School, Mongolian National University of Medical Sciences , Department of Anthropology, Ludwik Hirszfeld Institute of Immunology and Experimental Therapy, Polish Academy of Sciences, Wroclaw, Poland, Ulaanbaatar, Mongolia; [2]Department of Preventive Medicine, School of Public Health, Mongolian National University of Medical Sciences, Ulaanbaatar, Mongolia; [3]Mongolian Naran Society for Osteoarthritis and Musculoskeletal Health, Ulaanbaatar, Mongolia; [4]Department of Health Research, School of Graduate School, Mongolian National University of Medical Sciences, Ulaanbaatar, Mongolia; [5]Digital Center of Diagnostic Radiology, Ulaanbaatar, Mongolia

Objective: As of 2024, a total of 47 individuals aged 45 to 85 have died as a result of falls in Mongolia. Therefore, it is imperative to evaluate the risk of falls among the population, identify contributing risk factors, and implement effective prevention strategies to reduce accidents and related injuries nationwide. To assess the risk of falls among individuals aged 45 and over receiving care at referral hospitals in Ulaanbaatar city.
Methods: A cross-sectional study was conducted involving 408 participants aged 45 and above receiving care at referral hospitals in Ulaanbaatar city to assess the risk of falls using the International Fall Risk Assessment Tool (FRAT) questionnaire. The study results were analyzed using SPSS version 26 software.
Results: The average age of the participants was 59.2 ± 6.54 years, with 40% male and 60% female. Among the participants, 45.3% (n=185) were classified as having a low risk of falling, 33.6% (n=137) had a moderate risk, and 21.1% (n=86) had a high risk. Logistic regression analysis was conducted to identify risk factors influencing falls. The results showed the following significant factors: Whether the shoe sole slips: OR = 0.226, 95% CI (confidence interval) 0.119–0.428, p <0.001. Whether sudden, unsafe movements occur when changing position: OR = 0.262,

95% CI 0.143–0.48, p <0.001. Use of additional assistive devices while walking: OR = 0.209, 95% CI 0.11–0.397, p <0.001. Presence of anxiety or unstable emotional state: OR = 0.276, 95% CI 0.148–0.514, p< 0.001. Tendency to be disobedient or resistant to others' instructions: OR = 0.33, 95% CI 0.183–0.596, p <0.001. Difficulty recognizing the surrounding environment: OR = 0.354, 95% CI 0.187–0.671, p <0.001. History of previous falls: OR = 4.737, 95% CI 2.151–10.429, p<0.001 these factors were found to significantly affect the assessment of fall risk.

Conclusion: Fifty-five percent of the participants were at moderate to high risk of falls, and those with a history of previous falls had a 4.7 times higher risk. Therefore, it is necessary to develop a comprehensive fall risk assessment method tailored to the general population.

X-LINKED HYPOPHOSPHATEMIA IN ADULTS: PHENOTYPE, GENOTYPE, AND THERAPEUTIC MANAGEMENT (CASE SERIES)

J. Manzaneque Sánchez[1], P. León Rubio[1], L. Álvarez Ortiz[1], R. Gil Vélez[1], I. V. Cabello Chaves[2], A. Tristancho Pérez[3]

[1]Department of Rheumatology, Virgen del Rocío University Hospital, Seville, Spain; [2]Department of Nephrology, Virgen del Rocío University Hospital, Seville, Spain; [3]Clinical Pharmacology Department, Virgen del Rocío University Hospital, Seville, Spain

Introduction: X-linked hypophosphatemia (XLH) is an inherited FGF23-mediated phosphate-wasting disorder leading to chronic hypophosphatemia and osteomalacia. Adult XLH is frequently underrecognized and may range from mild symptoms to disabling pain and pseudofractures.

Methods: Descriptive case series of six adults with XLH followed in a joint Rheumatology–Nephrology clinic. We systematically collected phenotype and orthopedic history, fasting serum phosphate and related biochemistry, bone scintigraphy, DXA (Dual-energy X-ray absorptiometry), PHEX genotype, and treatments. Clinical and biochemical response after therapy was assessed in routine care.

Results: Six adults (5 women), age range 26–64 years; short stature was common and 4/6 had childhood skeletal deformities with prior corrective surgery and/or multiple orthopedic procedures. DXA was available in most patients (5/6), with generally normal/high lumbar spine values and femoral neck osteopenia in some. Three patients were managed with conventional therapy (oral phosphate plus active vitamin D) and had no active scintigraphic lesions (one old femoral fracture). Three patients received burosumab; bone scintigraphy showed active skeletal lesions in two (2/3) and no active fractures in one (1/3). One patient had stage 1 chronic kidney disease.

Conclusions: Adult XLH shows marked phenotypic heterogeneity. In this real-world multidisciplinary cohort, half of patients received burosumab, often in the context of active skeletal lesions and/or limitations of conventional therapy. Structured adult follow-up integrating phenotype, imaging and genotype may support timely treatment selection and reduce fracture-related morbidity.

Tables and figures

Table 1. Adult XLH cases (n=6): phenotype, PHEX genotype, treatment and key investigations.

SEX-SPECIFIC BONE ADAPTATION AFTER 4 MONTHS OF MILITARY BASIC TRAINING: DIVERGENT DXA AND PQCT FINDINGS IN SPANISH ARMY TRAINEES

J. Moran[1], J. M. Lavado-García[1], J. D. Pedrera-Zamorano[1], R. Roncero-Martín[1], M. L. Canal-Macias[1], C. J. Bote-Mohedano[2], R. Rey-Sanchez[1], O. Leal-Hernández[1], L. M. Puerto-Parejo[1], F. Lopez-Espuela[1], J. Fabregat-Fernández[1]

[1]Grupo de Investigación en Enfermedades Metabólicas Óseas, Departamento de Enfermería, Universidad de Extremadura, CACERES, Spain; [2]Centro de Formación de Tropa 1. Caceres. Ejercito de tierra., CÁCERES, Spain

Objective

To quantify 4-month changes in total-body bone outcomes assessed by DXA and pQCT during military basic training, and to explore sex-specific determinants of response.

Material and Methods

Prospective analysis of Spanish Army trainees assessed at baseline and after 4 months. Primary outcomes were DXA total-body areal BMD (g/cm²) and pQCT total volumetric density (mg/cm³). Analyses were stratified by sex. Paired changes (Δ) were evaluated after testing Δ normality with Shapiro–Wilk: paired t-test with Cohen's dz if normal, otherwise Wilcoxon with effect size r. Sensitivity analyses excluded extreme Δ outliers (±3×IQR). Associations were examined using sex-specific OLS models with HC3 robust errors (dependent: ΔDXA or ΔpQCT; predictors: baseline bone value, age, Δ lean mass [or Δ weight/BMI if needed], baseline 25(OH)D, Δ25(OH)D, vitamin D/calcium supplementation).

Results

Men (N=104): DXA BMD increased from median 1.197 [IQR 1.153–1.278] to 1.235 [1.179–1.299]. In sensitivity analysis (paired n=90), mean

ΔDXA was +0.025±0.035 g/cm² (p<0.001, dz=0.717). pQCT total density showed no meaningful change (sensitivity paired n=86: Δ −0.19±11.06 mg/cm³, non-significant).

Women (N=26): DXA BMD increased (mean 1.136→1.155 g/cm²; p=0.004; dz=0.62). In contrast, pQCT total density decreased (Wilcoxon p=0.0048; sensitivity paired n=23: mean Δ −8.6±14.9 mg/cm³; p=0.005; r=−0.53).

Across both sexes, 25(OH)D rose by ~9–10 units on average, but robust models did not identify consistent predictors of ΔDXA or ΔpQCT (all p>0.28 in men for ΔDXA; none significant in women; weak, non-significant negative trends for Δ25(OH)D with ΔpQCT). Supplementation was rare (vitamin D 3%; calcium 0%).
Conclusion

After 4 months of military basic training, total-body DXA BMD increased significantly in both sexes (small-to-moderate in men; moderate in women). However, pQCT total density remained stable in men and decreased in women, suggesting sex-specific adaptation and/or methodological differences between areal and volumetric metrics that may mask compartmental remodeling. Future studies should include paired trabecular/cortical pQCT measures and larger female samples.

P777

COMPARTMENT-SPECIFIC BONE ADAPTATION DURING 4-MONTH BASIC MILITARY TRAINING: SEX-SPECIFIC PQCT CHANGES, DXA–PQCT DISCORDANCE AND THE ROLE OF 25OHD

J. Moran[1], J. D. Pedrera-Zamorano[1], J. M. Lavado-García[1], C. J. Bote-Mohedano[2], R. Roncero-Martín[1], F. Lopez-Espuela[1], R. Rey-Sanchez[1], M. L. Canal-Macias[1], L. M. Puerto-Parejo[1], O. Leal-Hernández[1], J. Fabregat-Fernández[1]

[1]Grupo de Investigación en Enfermedades Metabólicas Óseas, Departamento de Enfermería, Universidad de Extremadura, CACERES, Spain; [2]Centro de Formación de Tropa 1. Caceres. Ejercito de tierra., CÁCERES, Spain

Objective
To assess sex-specific, compartmental bone adaptation to 4-month basic military training and whether 25-hydroxyvitamin D (25OHD), supplementation and lean mass gain predict peripheral quantitative computed tomography (pQCT) changes and discordance with dual-energy X-ray absorptiometry (DXA).
Material and Methods
Baseline and 4-month measures were analysed separately in men and women. Primary outcomes were Δ pQCT trabecular and cortical+subcortical volumetric density. Predictors were age, baseline bone value, baseline 25OHD, Δ25OHD, vitamin D/calcium supplementation (yes/no) and Δ lean mass. Δ was second minus baseline. Models used OLS with HC3 robust errors; sensitivity excluded extreme Δ outliers (±3×IQR). Within-individual trabecular–cortical contrasts used Wilcoxon when non-normal.
Results
Men (N=104; pQCT Δ n=90): Δtrabecular and Δcortical did not differ (Wilcoxon p=0.80). DXA–pQCT total discordance was 40/87 (46%), with no association with baseline 25OHD (p=0.56) or Δ25OHD (p=0.21); Δ lean mass showed a trend to lower discordance in logistic models (p=0.055). Compartment models (n=88) showed no significant 25OHD effects; the inverse association of Δ25OHD with Δcortical was not significant (p=0.22).

Women (N=26; pQCT Δ n=24): trabecular–cortical change differed (Wilcoxon p=0.031), reflecting cortical decline with trabecular stability. Discordance was 16/24 (67%) and was not associated with baseline 25OHD (p=0.98) or Δ25OHD (p=0.46). In compartment models (n=24), no predictor (including baseline 25OHD or Δ lean mass) significantly explained Δtrabecular or Δcortical.
Conclusion(s) Bone adaptation to training was compartmental and sex-specific: women showed cortical loss with trabecular–cortical decoupling, whereas men showed modest, homogeneous changes. DXA–pQCT discordance was frequent and not explained by 25OHD. Δ lean mass may relate to lower discordance in men, warranting confirmation.

P778

BASELINE BONE HEALTH AND MODIFIABLE RISK FACTORS IN SPANISH ARMY RECRUITS PRIOR TO BASIC TRAINING: SEX-SPECIFIC ASSOCIATIONS OF VITAMIN D AND BODY COMPOSITION WITH DXA AND PQCT PARAMETERS

J. Moran[1], J. M. Lavado-García[1], J. D. Pedrera-Zamorano[1], C. J. Bote-Mohedano[2], F. Lopez-Espuela[1], R. Roncero-Martín[1], R. Rey-Sanchez[1], M. L. Canal-Macias[1], L. M. Puerto-Parejo[1], J. Fabregat-Fernández[1], O. Leal-Hernández[1]

[1]Grupo de Investigación en Enfermedades Metabólicas Óseas, Departamento de Enfermería, Universidad de Extremadura, CACERES, Spain; [2]Centro de Formación de Tropa 1. Caceres. Ejercito de tierra., CÁCERES, Spain

Objective
To describe baseline bone health in Spanish Army recruits before basic training and assess modifiable factors (25-hydroxyvitamin D [25OHD], supplementation, body composition) associated with a low bone profile by DXA and pQCT.
Material and Methods
Cross-sectional baseline-only analysis; sexes analysed separately. Primary outcomes: DXA total areal BMD (g/cm²) and pQCT total volumetric density (mg/cm³). Predictors: 25OHD (ng/mL; <20 deficient, 20–29 insufficient, ≥30 sufficient), vitamin D/calcium supplementation (yes/no), DXA lean mass (kg), BMI (kg/m²), age (years). Low bone profile = lowest within-sex quartile (Q1). OLS with HC3 robust errors; logistic models compared Q1 vs non-Q1 with reduced predictors.
Results
Men: N=104 (25OHD n=102; DXA n=102; pQCT n=92). Vitamin D: deficient 2.9%, insufficient 56.9%, sufficient 40.2%. Low DXA-Q1: 26/102; low pQCT-Q1: 23/92. OLS showed no associations for 25OHD, lean mass, BMI or age with DXA or pQCT total (all p≥0.20). For low DXA-Q1, lean mass showed a protective trend (per +5 kg, OR 0.62; 95% CI 0.37–1.04; p=0.069); 25OHD was not associated (OR 1.00; p=0.99). No predictors were significant for low pQCT-Q1 (all p≥0.29). Women: N=26 (pQCT n=25). Vitamin D: deficient 11.5%, insufficient 57.7%, sufficient 30.8%. Low DXA-Q1: 8/26; low pQCT-Q1: 7/25. Lean mass was positively associated with DXA (p=0.020) and pQCT total (p=0.028); 25OHD showed a trend for pQCT (p=0.086). Logistic models were unstable; low pQCT-Q1 predictors were non-significant (p≥0.11).

Conclusion
Vitamin D insufficiency was frequent (~58% in both sexes). Baseline bone parameters were more strongly linked to lean mass in women, while in men associations with 25OHD or body composition were not robust. Findings support sex-specific prevention emphasizing lean-mass accrual in women and vitamin D screening prior to training.

P779

MUSCLE–BONE COUPLING DURING 4-MONTH BASIC TRAINING: DOES LEAN-MASS GAIN TRANSLATE INTO BONE GAIN? SEX-SPECIFIC SLOPES USING DXA AND PQCT

J. Moran[1], J. M. Lavado-García[1], J. D. Pedrera-Zamorano[1], C. J. Bote-Mohedano[2], R. Roncero-Martín[1], R. Rey-Sanchez[1], M. L. Canal-Macias[1], F. Lopez-Espuela[1], L. M. Puerto-Parejo[1], J. Fabregat-Fernández[1], O. Leal-Hernández[1]

[1]Grupo de Investigación en Enfermedades Metabólicas Óseas, Departamento de Enfermería, Universidad de Extremadura, CACERES, Spain; [2]Centro de Formación de Tropa 1. Caceres. Ejercito de tierra., CÁCERES, Spain

Objective
To test whether 4-month lean mass gain (Δ lean mass) during basic military training translates into bone gain (primary: Δ pQCT total volumetric density; secondary: Δ DXA total BMD), and to estimate sex-specific slopes and the prevalence of muscle–bone decoupling.

Material and Methods
Military recruits were assessed at baseline and after approximately 4 months of basic training; men and women were analysed separately. Muscle: DXA total lean mass (kg). Bone: pQCT total density (mg/cm³; primary) and DXA total BMD (g/cm²; secondary). Per sex, ordinary least squares models with HC3 robust errors were fitted: Δbone ~ Δlean mass + baseline bone value + age + baseline lean mass + ΔBMI. Decoupling (pQCT) was defined a priori as within-sex Q3 of Δlean mass combined with Q1 of ΔpQCT total; a residual-based variant was also used (Δlean mass ≥Q3 and model residual ≤Q1).

Results
Men: pQCT model n=90; DXA model n=88. For pQCT, the slope was β=−2.17 mg/cm³ per kg (p=0.21); sensitivity β=−0.80 (p=0.30). For DXA BMD, β=−0.0016 g/cm² per kg (p=0.51); sensitivity β=+0.0038 (p=0.132). Decoupling prevalence was 4.4% (Q3−Q1) and 3.3% (residual-based).

Women: pQCT model n=24; DXA model n=25. For pQCT, β=−0.49 mg/cm³ per kg (p=0.71); sensitivity β=+0.60 (p=0.33). For DXA BMD, β=+0.00070 g/cm² per kg (p=0.93), with no relevant sensitivity changes. Decoupling prevalence was 8.3% by both definitions. Between-sex differences in decoupling were not significant (Fisher p≈0.60; residual-based p≈0.28).

Conclusion(s)
During basic military training, lean-mass gain over 4 months was not associated with consistent whole-bone gains on pQCT or DXA in either sex. Decoupling was uncommon (about 3–8%) and did not differ by sex, suggesting limited short-term translation of lean-mass gain into measurable global bone accrual in this military setting.

P780

BODY COMPOSITION REDISTRIBUTION DURING 4-MONTH BASIC MILITARY TRAINING AND BONE HEALTH: SEX-SPECIFIC ASSOCIATIONS OF REGIONAL LEAN MASS AND ANDROID–GYNOID FAT PATTERNS WITH DXA/PQCT OUTCOMES

J. Moran[1], J. M. Lavado-García[1], J. D. Pedrera-Zamorano[1], C. J. Bote-Mohedano[2], R. Roncero-Martín[1], R. Rey-Sanchez[1], M. L. Canal-Macias[1], L. M. Puerto-Parejo[1], F. Lopez-Espuela[1], O. Leal-Hernández[1], J. Fabregat-Fernández[1]

[1]Grupo de Investigación en Enfermedades Metabólicas Óseas, Departamento de Enfermería, Universidad de Extremadura, CACERES, Spain; [2]Centro de Formación de Tropa 1. Caceres. Ejercito de tierra., CÁCERES, Spain

Objective
To test whether regional body composition changes, rather than BMI, predict bone adaptation during basic military training, using change in total dual-energy X-ray absorptiometry (DXA) bone mineral density (BMD) as primary outcome and change in peripheral quantitative computed tomography (pQCT) total volumetric density as complementary.

Material and Methods
Participants underwent baseline and 4-month follow-up DXA/pQCT; men and women were analysed separately. Exposures were follow-up minus baseline (Δ): lower-limb lean mass (sum of both legs, DXA), android–gynoid fat ratio (A/G; android/gynoid fat mass), waist circumference and BMI. Outcomes were ΔDXA total BMD (g/cm²) and ΔpQCT total density (mg/cm³). Associations between Δoutcomes and Δexposures were tested with Spearman correlations. For ΔDXA, multivariable ordinary least squares with HC3 robust errors compared: Model A (age, baseline DXA, ΔBMI) and Model B (age, baseline DXA, Δlower-limb lean, ΔA/G, plus ΔBMI). A quadrant phenotype (median split of Δlower-limb lean up/down × ΔA/G down/up) compared ΔpQCT across quadrants (Welch t).
Results

ΔDXA: In both sexes, ΔBMI, Δwaist and ΔA/G showed small, non-significant associations; Δlower-limb lean did not independently predict ΔDXA. Model B modestly increased explained variance in women (R^2 0.25 vs 0.12), but regional predictors remained non-significant. In men, baseline DXA showed a strong negative coefficient consistent with mathematical coupling of baseline and change.

ΔpQCT: Women (n=24) showed a moderate negative association between ΔA/G and ΔpQCT (ρ=−0.52, p=0.009; sensitivity ρ=−0.46, p=0.029), indicating that greater reductions in relative central fat were associated with better pQCT adaptation. Δlower-limb lean was also negatively associated (ρ=−0.48, p=0.016; sensitivity p=0.050). Men (n=87) showed weak positive trends for Δlower-limb lean (ρ=+0.20, p=0.070) and ΔA/G (ρ=+0.17, p=0.11; sensitivity p=0.057). Quadrant analyses were non-significant in both sexes.
Conclusion(s)

During basic training, where the body changes appears more informative than how much it changes (BMI). In women, reductions in central fat pattern (A/G decrease) were associated with better volumetric bone adaptation (pQCT), whereas ΔBMI was uninformative. In men, regional

signals were weaker and did not reach significance. These data support sex-specific, regional targets over BMI alone.

P781

ULTRASOUNDGUIDED RADIOFREQUENCY ABLATION OF GENICULAR NERVES FOR CHRONIC KNEE PAIN: A FIVEYEAR SINGLECENTER RETROSPECTIVE STUDY

J. Nurkovic[1], A. Habibovic[2], A. Nicevic[2], S. Habibovic[3], S. Nicevic[2]

[1]Center for Regeneration and Rehabilitation, Novi Pazar, Serbia; [2]General Hospital, Novi Pazar, Serbia; [3]Public Health Institute, Novi Pazar, Serbia

Background and aims

Radiofrequency (RF) ablation of the genicular nerves has emerged as a promising interventional modality for the management of chronic osteoarthritic knee pain and persistent postsurgical pain (PPSP). This technique is particularly relevant in patients who demonstrate inadequate response to conventional pharmacological and nonpharmacological therapies.

Methods

A retrospective, singlecenter cohort study was undertaken at the Center for Regeneration and Rehabilitation, Novi Pazar, Serbia, spanning the period from October 2020 to November 2025. The study population comprised patients who received ultrasoundguided conventional radiofrequency (RF) ablation of the genicular nerves for chronic knee pain. In addition to evaluation of the entire cohort, subgroup analyses were conducted based on pain etiology, specifically persistent postsurgical pain (PPSP) and degenerative knee pain. Primary outcome measures included the global perceived effect (GPE), Numeric Rating Scale (NRS) for pain intensity, opioid consumption, and treatment safety. These parameters were assessed at six weeks, six months, twelve months, and crosssectionally at variable time points. Treatment success was defined as a GPE score of ≥ 50%.

Results

Of the 148 patients screened, 125 met the inclusion criteria and were enrolled in the study, comprising 33 cases of persistent postsurgical pain (PPSP) and 92 cases of degenerative knee pain. Treatment success was achieved in 104 of 125 interventions (83.2%) at six weeks, with comparable outcomes across both subgroups. Followup evaluations demonstrated that pain reduction was sustained in 92% of patients at six months and in 71% at twelve months, with the mean duration of therapeutic effect following RF treatment calculated at 9.1 months. Safety assessments performed at six weeks and at the subsequent evaluation point confirmed a favorable safety profile of the intervention.

Conclusion

Conventional radiofrequency (RF) ablation of the genicular nerves demonstrated encouraging outcomes in the study cohort, achieving a success rate exceeding 83.2% among patients refractory to standard medical management. The intervention was welltolerated, with a mean duration of therapeutic effect of 9.1 months.

P782

CRITERIA FOR EVALUATING PAIN IN PATIENTS WITH PELVIC DISORDERS IN POST -TRAUMATIC AND DEGENERATIVE STENOSIS OF THE SPINAL CANAL

I. Chapko[1], J. Ovsyanik[1], A. Filipovich[1]

[1]Republican Scientific and Practical Center for Medical Expertise and Rehabilitation, Yukhnovka, Belarus

The criteria for evaluating the pain syndrome (BS) in patients with dysfunctions of the pelvic organs (NFTO) with stenosis of the vertebral canal (SEC), as a result of an injury or degenerative-dystrophic process of the thoracic and (or) lumbar spine, recommended for use in the medical and social examination) Rehabilitation (MR). A clinical and functional assessment of the condition of 65 NFTO patients under SEC: 40 (61.5%, CI: 49.1-72.4) men and 25 (38.5%, CI: 27.6-50.6) women. The age distribution of patients according to it seemed that most examined men were represented in groups: 41-50 years-19 people. (47.5%, DI: 33.0-62.5) and up to 40 years-13 people. (32.5%, DI: 20.1-48.0). Most of the examined women (48.0%) were in the age range of 41-50 years (12 people, DI: 30.0-66.5). According to the duration of the disease, patients were distributed as follows: up to one year - 26 people. (40.0%; DI: 29.0-52,1); From 1 year to 3 years-22 people. (33.8%, CI: 23.5-46.0); From 3 to 10 years-17 people. (26.2%, DI: 17.0-38.0). According to the etiological factor, the distribution of patients in the studied group was as follows: NFTO at the SEC at the level of the chest and (or) lumbar spine - 34 people. (52.3%, DI: 40.4-64.0), PSMT of the thoracic and (or) lumbar spine-15 people. (23.1%, DI: 14.5-34.7), a combination of PSMT and post-traumatic SPK-16 people. (24.6%, DI: 15.8-36.3).

Disorders of the statodynamic function in patients due to the reza (central spastic, sluggish peripheral, combined) varying severity were detected in 63 cases (96.9%, DI: 89.5-99.2). Along with impaired distinguishing functions (100% of cases) and statodynamic function, mental disorders (22 people, 33.9%, CI: 23.5-46.0), and blood circulation functions were often observed. (47.7%, CI: 36.0-59.6). BS of varying degrees of severity was detected in 63.0%, other types of disorders, partially exacerbating the severity of life restrictions: violations of surface, as well as deep sensitivity, neurotrophic disorders - in 69.9%. When analyzing the functional status, the degree of severity of the NFTO, changes in the state of health at all stages of the MR and ITU in patients with PSMT and SPK, scales and questionnaires were used.

EFFECTS OF ACUTE AND CHRONIC STRESSORS ON SPONTANEOUSLY HYPERTENSIVE RATS: BONE MORPHOFUNCTIONAL ANALYSIS BY IMMUNOHISTOCHEMISTRY, MMP-2 AND MMP-9 ZYMOGRAPHY, AND MICRO-COMPUTED TOMOGRAPHY

J. P. Mardegan Issa[1], M. P. Paulini[1], D. L. Pitol[1], G. C. Do Nascimento[1], D. V. Buchaim[2], R. L. Buchaim[3]

[1]University of Sao Paulo/ Department of Basic and Oral Biology, School of Dentistry of Ribeirão Preto, Ribeirão Preto, Brazil; [2]Medical and Pharmacy School, University Center of Adamantina, Adamantina, Brazil; [3]University of Sao Paulo, Department of Biological Sciences, Bauru School of Dentistry (FOB/USP), Bauru, Brazil

Background: Hypertension and psychological stress are prevalent conditions that may adversely affect bone health, yet their combined impact on bone remodeling remains underexplored. Objective: This study aimed to investigate the effects of acute and chronic stress on bone structure and remodeling in normotensive and spontaneously hypertensive rats. Methods: Forty male rats (20 normotensive Hannover and 20 spontaneously hypertensive) were randomly assigned to control, acute stress, or chronic variable stress groups. Acute stress consisted of a single 2-hour restraint session, while chronic variable stress involved five different stressors over 10 days. Bone remodeling was assessed using micro-computed tomography (micro-CT) for structural analysis, immunohistochemistry for VEGF, bone sialoprotein (BSP), osteocalcin (OCN), and TRAP, as well as enzymatic activity analysis (MMP-2 and MMP-9). Results: Micro-CT analysis revealed no significant changes in trabecular bone volume or cortical thickness during the study period. However, stress exposure reduced osteoblast activity (OCN, BSP), increased matrix remodeling enzymes (MMP-2, MMP-9), and promoted angiogenic signaling (VEGF). Notably, TRAP-positive osteoclasts were observed exclusively in stress- exposed animals, indicating elevated bone resorption. Conclusions: Stress induces early cellular and enzymatic changes in bone remodeling that precede detectable structural modifications by micro-CT, potentially compromising bone quality in hypertensive subjects. These findings highlight the importance of addressing psychological stress in populations at risk for bone fragility.

Keywords: Hypertension; Psychological Stress; Bone Remodeling; Osteoblast; Osteoclast; VEGF; Bone Sialoprotein; Osteocalcin; Matrix Metalloproteinases; Trabecular Bone; Corticosterone; Animal Model.

BIOMATERIALS FUNCTIONALIZED WITH GENISTEIN ENHANCE BONE REPAIR IN OVARIECTOMIZED RATS

J. P. Mardegan Issa[1], N. Dantas Duarte[2], M. Paulini[1], P. Noronha Lisboa-Filho3[3], R. Okamoto[4]

[1]University of Sao Paulo/ Department of Basic and Oral Biology, School of Dentistry of Ribeirão Preto, Ribeirão Preto, Brazil; [2]Department of Diagnosis and Surgery, Araçatuba School of Dentistry (FOA-UNESP), São Paulo State University, Araçatuba 16015-050, Brazil, Araçatuba, Brazil; [3]Department of Physics, Bauru School of Sciences, São Paulo State University (FC-UNESP), Bauru 17033-360, São Paulo, Brazil, Bauru, Brazil; [4]Department of Basic Sciences, Araçatuba School of Dentistry (FOA-UNESP), São Paulo State University, Araçatuba 16015-050, Brazil, Araçatuba, Brazil

Introduction:Estrogen deficiency is the primary cause of osteoporosis, compromising bone quality and potentially impairing peri-implant repair. Functionalizing biomaterials to enhance their osteoconductive properties can improve their regenerative potential. Genistein, a soy isoflavone phytoestrogen, interacts with estrogen receptors in osteoblasts, promoting their proliferation and differentiation through classical genomic pathways while also inhibiting osteoclast activity and modulating oxidative stress. This study aimed to investigate the effects of genistein incorporated into two different biomaterials, bioactive glass and deproteinized bovine bone, via sonochemistry, on peri-implant bone repair in ovariectomized rats.Method:Forty animals were randomly assigned to four groups (n=10): BG – bioactive glass; BG+GEN –bioactive glass with genistein; BO – deproteinized bovine bone; and BO+GEN – deproteinized bovine bone with genistein. After 30 days of ovariectomy, bilateral peri-implant defects were created in the tibial metaphysis, filled with the designated biomaterial, followed by titanium implant placement. Calcein and alizarin were administered on postoperative days 14 and 24, respectively. Animals were euthanized at 28 days. RT-PCR of RANKL, OPG, and IBSP was analyzed, while micro-CT was performed to quantify bone volume fraction (BV/TV) and trabecular separation (Tb. Sp). Additionally, confocal microscopy was used to measure the mineral apposition rate (MAR).Results:Higher expression levels of RANKL, OPG, and IBSP were detected in the BG+GEN and BO+GEN groups (two-way ANOVA, $p<0.05$). A significant interaction between biomaterial type and genistein was observed for RANKL and OPG, whereas IBSP showed independent effects of both variables. Micro-CT showed significantly increased BV/TV and decreased Tb.Sp in groups treated with genistein-functionalized biomaterials compared to controls (two-way ANOVA, $p<0.05$). No differences were observed among groups regarding MAR (two-way ANOVA, $p>0.05$).Conclusion:These findings suggest that local delivery of genistein incorporated into biomaterials enhances peri-implant bone repair in estrogen-deficient conditions.FAPESP 22/07158-8 and 24/05906-2

JOINT POSITION SENSE IN ACTIVE OLDER WOMEN WITH AND WITHOUT OSTEOARTHRITIS: A PILOT STUDY

J. Pazini[1], K. Borges dos Santos[1]

[1]Federal University of Technology - Parana, Curitiba, Brazil

ABSTRACT

Introduction: Population aging poses multiple challenges to health, such as the decline in proprioception - that is, the perception of the body in space - which plays a fundamental role in movement accuracy and fall prevention. Older adults with osteoarthritis may present even greater impairments in proprioception due to degenerative changes in articular cartilage and chronic inflammation, factors that can affect the integrity and sensitivity of articular, muscular, and tendinous mechanoreceptors, resulting in deficits in sensory feedback and neuromuscular control.

Objective: To compare performance on joint position sense tests between active older women with and without osteoarthritis.

Method: Eighteen older women who practiced aquatic activities - nine healthy (66 ± 6 years) and nine with osteoarthritis (67 ± 5 years) - were assessed using joint position sense tests of the hip and ankle with a goniometer (repositioning to a target of 30% of the maximum range of motion for each joint). Group comparisons were performed using Student's t test, with a significance level set at $p < 0.05$.

Results: The mean percentage errors in detecting the reference angle for the hip and ankle were 2.39 (± 1.72) and 5.72 (± 5.21) for healthy older women, and 3.08 (± 2.73) and 5.36 (± 4.39) for older women with osteoarthritis, respectively. No significant differences were found between groups ($p = 0.53$ and $p = 0.87$).

Conclusion: The fact that all participants maintained an active lifestyle may explain the similarity in results between older women with and without osteoarthritis. Although this research constitutes a pilot study at this initial stage, it reinforces the importance of aquatic exercise as a strategy to prevent degeneration of the proprioceptive system.

P786

MACROPHAGE INFLAMMATORY PROTEIN-3 (MIP-3A) IN AUTOIMMUNE DISEASES

J. Polyakova[1], L. Sivordova[1], E. Papichev[1], Y. Akhverdyan[1], B. Zavodovsky[1]

[1]Zborovsky Research Institute of Clinical and Experimental Rheumatology, Volgograd , Russia

The primary mechanism controlling leukocyte migration in health and disease is mediated by the chemokine superfamily. One chemokine implicated in the pathogenesis of autoimmune diseases is macrophage inflammatory protein-3 (MIP-3α).

In the respiratory tract, MIP-3α is known to function as an antimicrobial peptide, targeting both gram-positive and gram-negative bacteria. In autoimmune diseases, it acts as a chemokine, attracting immature dendritic cells, B-, and T-lymphocytes to the site of injury.

In diabetic nephropathy, high glucose levels in proximal tubular cells trigger MIP-3α synthesis, which may be associated with the development of chronic low-intensity inflammation in the kidneys.

However, increased MIP-3α levels are not observed during low-intensity inflammation in osteoarthritis and atherosclerosis.

We compared MIP-3α levels in healthy individuals, those with seropositive diseases: RA and SLE, and those with seronegative ankylosing spondylitis. Patients with RA, SLE, and AS were comparable in age: 55.7±12.1 (49.7-61.7), 43.1±12.9 (38.2-48.0), and 46.8±10.9 (41.0-52.6) years, respectively. Women predominated in the RA and SLE group, while patients with AS were predominantly male. All patients had a normal BMI, which was slightly higher in the spondyloarthritis group (26.5 [23.4-33.1]; 25.7 [23.3-30.1]; 27.3±4.49 (24.9-29.7), respectively). We found that the MIP-3α level was 319.7±98.3 (244.1-395.2) in healthy individuals, in patients with RA -649.4 [373.6-2350], Z=2.29; p=0.0221; in patients with SLE -363.8 [321.2-404.2], Z=-1.05; p=0.295 and in patients with AS, respectively - 296.6 [258.9-345.7.4], Z=-0.74; p=0.462. From the presented data it is evident that the highest MIP-3α level, significantly different from the comparison group (healthy individuals), was detected in patients with RA; the minimum - in patients with AS, without a significant difference from the group of healthy individuals and SLE patients. As can be seen from the obtained results, a significant difference in MIP-3α levels compared to the comparison group was found only in patients with RA. In patients with SLE, which shares an autoimmune B-cell phenotype with RA, MIP-3α values were significantly lower and comparable to those in the healthy control group, while in patients with AS, they were even slightly lower than those in the healthy control group.

We continue to study the relationship between chemokine levels, particularly MIP-3α, in the most common autoimmune diseases depending on activity, comorbidity, stage, and duration.

P787

CHANGES IN BONE MINERAL DENSITY, PAIN AND MOBILITY DURING SPECIFIC PHARMACOLOGICAL OSTEOPOROSIS THERAPY

A. Sallakhi[1], J. R. Andresen[2], G. Schröder[3], H.-C. Schober[4]

[1]Division of Endocrinology, Rheumatology and Acute Geriatrics, Clinic Ottakring, Vienna, Austria., Vienna, Austria; [2]Division of Orthopaedics, Department of Orthopaedics and Trauma Surgery, Medical University of Vienna, Vienna, Austria; [3]Clinic for Orthopaedics and Trauma Surgery, Sana Hospital Bad Doberan, Academic Teaching Hospital of the University of Rostock, Hohenfelde, Germany; [4]Practice for Orthopedics and Osteology, OrthoCoast, Wolgast, Germany

Objectives

Back pain and limited pain-free mobility are common in osteoporosis; pain-related inactivity causes muscle loss, reduced standing/walking capacity, and higher fall risk. We assessed bone status, pain-free standing/walking time, and back pain intensity during specific pharmacological osteoporosis therapy (SPOT).

Methods

In this prospective real-life analysis, 178 patients with a confirmed osteoporosis

(T-score ≤ -2,5 SD) were observed over a median period of 4 years. All participants received a guideline-based SPOT and were divided into two therapy groups: antiresorptive therapy (bisphosphonates & denosumab) and osteoanabolic therapy (teriparatide). Both therapy groups included mono- and sequential therapies. Pain-free standing time (PST) / walking time (PWT) in minutes (min), as well as back pain intensity (BP) using a numerical rating scale (NRS), were measured at the start (T0) and the end (T1) of the observation period. In addition,

T-score values were determined by DXA bone density measurement (Lunar Prodigy). Statistical analysis was performed using linear mixed models with random intercept, estimated via the Restricted Maximum Likelihood (REML) method, and tested by the Likelihood Ratio Test (LRT) for significant interactions. Effect sizes were calculated according to Cohen's d. The significance level was set at $p < 0,05$.

Results

In the total cohort, a significant increase in PST and PWT, as well as a significant reduction in BP intensity, were observed. Mean PST increased by approximately 31 min ($p < 0,038$, $d \approx 0,45$), and the mean PWT increased by approximately 37,5 min ($p < 0,031$, $d \approx 0,42$). Mean BP intensity on the NRS decreased by approximately 1,5 points ($p = 0,001$, $d \approx 0.6$). Mean T-score improved by 0,45 SD ($p < 0,001$; $d \approx 0,72$). There was no significant difference between the antiresorptive and osteoanabolic therapy groups regarding the temporal course.

Conclusion

SPOT significantly improved bone density, pain, and mobility. Longer pain-free standing/walking indicates restored load tolerance; lower pain likely supports activity and may counter secondary sarcopenic deconditioning. SPOT benefits bone metabolism and function; structured strength and coordination training should complement therapy.

P788

HOUNSFIELD UNITS IN LUMBAR SPINE AND PROXIMAL FEMUR AS PREDICTORS OF OSTEOPOROSIS AND SACRAL INSUFFICIENCY FRACTURES IN ELDERLY PATIENTS: A RETROSPECTIVE COHORT STUDY

J. R. Andresen[1], G. Schröder[2], H. C. Schober[3], T. Haider[4], R. Andresen[5]

[1]Division of Orthopaedics, Department of Orthopaedics and Trauma Surgery, Medical University of Vienna, Vienna, Austria; [2]Clinic for Orthopaedics and Trauma Surgery, Sana Hospital Bad Doberan, Academic Teaching Hospital of the University of Rostock, Hohenfelde, Germany; [3]Practice for Orthopedics and Osteology, OrthoCoast, Wolgast, Germany; [4]Division of Trauma Surgery, Department of Orthopaedics and Trauma Surgery, Medical University of Vienna, Vienna, Austria; [5]Institute for Diagnostic and Interventional Radiology / Neuroradiology, Westkuestenklinikum Heide, Academic Teaching Hospital of the Universities of Kiel, Luebeck und Hamburg, Heide, Germany

Objectives

Sacral insufficiency fractures (SIF) typically affect older, osteoporotic patients and are often underdiagnosed due to non-specific lower back or pelvic pain. This study aimed to compare trabecular bone density in Hounsfield Units (HU) at the lumbar spine and proximal femur between patients with and without SIF, and to assess the diagnostic performance of HU values for predicting osteoporosis and fractures.

Methods

In this retrospective study, 253 patients with clinical suspicion of SIF were analyzed over 3 years. Group 1 (n=98) had confirmed SIF (FFP-classified); Group 2 (n=155) had no SIF or spine/hip fractures. HU values were measured in CT scans using ellipsoidal ROIs (L1–L3) and irregular ROIs in the proximal femur. Additional imaging (MRI, X-ray) was used to detect vertebral and hip fractures. 25-OH-vitamin D levels and pain intensity (VAS) were recorded. Statistical analyses included t-tests, Mann-Whitney U, Hedges' g, and ROC curves.

Results

SIF patients were significantly older than controls (78.95 vs. 70.62 years, $p < 0.001$). HU values were markedly lower in the SIF group: lumbar spine 44.8 vs. 105.7 HU ($p < 0.001$; $g = 2.48$), femur 47.0 vs. 148.0 HU ($p < 0.001$; $g = 2.28$). Patients with hip fractures had even lower femoral HU values (14.2 vs. 70.6; $p < 1e-12$). FFP type II accounted for 61.3% of SIF; unstable types (IIIc, IVb/c) for 38.7%. Among SIF patients, 232 silent vertebral and 30 prior hip fractures were detected. Immobilizing pain increased with fracture instability (VAS 7 vs. 9; $p < 0.05$). ROC analysis showed strong predictive performance for osteoporosis (AUC LWS-HU = 0.92, femur-HU = 0.98) and for SIF (AUC LWS-HU = 0.98, femur-HU = 0.97). Vitamin D deficiency (< 20 ng/ml) was found in 92.9% of all patients; mean levels were 3.72 ng/ml (SIF) vs. 8.24 ng/ml (controls; $p < 0.05$). HU thresholds for osteoporosis were ~96–98 HU.

Conclusion

HU values from routine CT scans allow reliable osteoporosis diagnosis and fracture risk estimation. SIFs indicate advanced osteoporosis, often accompanied by silent vertebral fractures. Severe vitamin D deficiency is a common and relevant risk factor. Severe immobilizing pain is found with increasingly unstable SIF.

P789

ATYPICAL FORM OF STIFF PERSON SYNDROME

J. R. Jebri[1], B. L. Ben Ammar[2], B. H. Ben Ayed[1], F. I. Fenniche[1], D. R. Dhaheri[1], G. I. Gharsallah[1]

[1]military hospital of Tunisia, Tunis, Tunisia; [2]miliyary hospital of Tunisia, Tunis, Tunisia

Background:

Stiff person syndrome (SPS) is a rare neurological disorder of autoimmune origin, characterized by progressive muscle stiffness, painful spasms, and increased sensitivity to external stimuli. It typically affects middle-aged women. We report a series of four cases of SPS occurring in young men hospitalized in a rheumatology department during the year 2025, highlighting an atypical demographic and clinical presentation.

Case reports

Case 1: The first case involved a 25-year-old man who presented with diffuse mechanical spinal pain evolving over five years, associated with a sensation of persistent muscle tightness. Physical examination revealed paravertebral muscle contracture predominantly on the right side, without spinal deformity, axial stiffness, or sacroiliac tenderness. Radiographic assessment and thoraco-abdomino-pelvic computed tomography were unremarkable, notably showing no evidence of sacroiliitis. Electromyography (EMG) demonstrated continuous motor unit activity at rest in the paravertebral muscles, suggestive of SPS.

Case 2: The second case concerned a 21-year-old man who consulted for mechanical low back pain of three months' duration. Physical examination showed paravertebral muscle contracture associated with lumbar stiffness. Radiographs and magnetic resonance imaging (MRI) of the lumbar spine and sacroiliac joints were normal. EMG revealed continuous muscle activity at rest, consistent with SPS. Anti–glutamic acid decarboxylase (anti-GAD) antibodies were negative. A paraneoplastic origin was ruled out by a normal thoraco-abdomino-pelvic CT scan. The clinical course was marked by worsening low back pain and the subsequent development of painful lower limb muscle spasms.

Case 3: The third case involved a 41-year-old man presenting with painful

contractures of the cervical and lumbar paravertebral muscles as well as the abdominal wall, associated with lower limb spasms. Physical examination confirmed diffuse muscle contracture. Brain and spinal MRI showed no abnormalities. Anti-GAD antibodies were positive, and EMG confirmed the diagnosis by demonstrating spontaneous continuous activity in both agonist and antagonist muscles, predominantly affecting the paravertebral muscles. A paraneoplastic etiology was excluded.

Case 4: The fourth case was a 42-year-old man with a history of coronary artery disease treated with coronary stenting, who presented with chronic mechanical neck pain and bilateral lower limb muscle spasms. Examination revealed contracture of the cervical paravertebral and trapezius muscles. Spinal and pelvic MRI were normal, while EMG demonstrated continuous paravertebral muscle activity at rest.

Conclusion

SPS is a rare disorder resulting from impaired gamma-aminobutyric acid–mediated inhibitory neurotransmission. While it most commonly affects women around the age of 45, our series illustrates an atypical presentation in young male patients. Two patients showed favorable clinical improvement with benzodiazepines, whereas two required escalation to rituximab therapy.

P790

OSSIFYING MYOSITIS: THREE CASE REPORTS WITH DIFFERENT LOCALIZATIONS

J. R. Jebri[1], B. S. Ben Jemaa[1], G. Z. Gassara[1], F. A. Fekih[1], F. H. Fourati[1]

[1]Hedi Chaker hospital, Sfax, Tunisia

Background:
Ossifying myositis (OM) is a rare benign condition characterized by heterotopic ossification within skeletal muscles, accounting for approximately 0.7% of soft tissue pseudotumors. It typically affects young individuals, most often following trauma, although non-traumatic forms have also been described. The pelvic and scapular girdle muscles are most commonly involved. Early diagnosis remains challenging due to nonspecific clinical and radiological features.

Objectives:
To report three cases of ossifying myositis with different anatomical localizations and to highlight diagnostic and therapeutic aspects.

Results:
Case 1 involved a 34-year-old woman with no history of trauma who presented with progressive inflammatory pain and swelling of the right elbow for one month. Physical examination showed a painful swollen elbow with limited range of motion and no systemic signs. Laboratory tests, including muscle enzymes and inflammatory markers, were normal. Initial radiographs revealed only soft tissue swelling. Magnetic resonance imaging demonstrated an infiltrative mass within the brachial muscle with heterogeneous enhancement, raising suspicion of a tumoral process. Surgical biopsy confirmed the diagnosis of ossifying myositis. Conservative treatment with nonsteroidal anti-inflammatory drugs (NSAIDs) and joint rest was initiated. A follow-up computed tomography scan later demonstrated characteristic lamellar ossification. The outcome was favorable with pain resolution and improved mobility after NSAIDs and physiotherapy.

Case 2 concerned a 29-year-old woman presenting with acute right shoulder pain and functional impairment without preceding trauma. Examination revealed a painful, inflamed shoulder with complete functional limitation. Laboratory investigations were normal. Standard radiographs were unremarkable, whereas computed tomography showed multiple calcifications involving the deltoid, supraspinatus, and infraspinatus muscles. Bone scintigraphy confirmed the diagnosis, revealing hyperfixation without bone involvement. Treatment with NSAIDs and physiotherapy led to clinical improvement. Long-term follow-up scintigraphy showed marked regression of hyperfixation areas.

Case 3 involved an 18-year-old woman presenting with jaw pain and progressive limitation of mouth opening. Imaging revealed ossifying myositis of the left masseter and pterygoid muscles. Clinical examination showed severe trismus and submandibular masses. Laboratory tests were normal. Bone scintigraphy confirmed the diagnosis. Initial NSAID therapy was insufficient, and bisphosphonates were added, resulting in favorable clinical evolution.

Conclusion:

Circumscribed ossifying myositis is a rare benign condition affecting young patients and may mimic malignant soft tissue tumors in its early stages. Awareness of its clinical and radiological evolution, along with appropriate imaging follow-up, can prevent unnecessary invasive procedures. Prognosis is generally favorable with conservative symptomatic treatment, and surgery should be reserved for complicated cases.

P791

CLINICAL AND RADIOLOGICAL FEATURES OF RENAL OSTEODYSTROPHY: EXPERIENCE FROM A RHEUMATOLOGY DEPARTMENT

J. R. Jebri[1], G. Z. Gassara[1], B. S. Ben Jemaa[1], F. A. Fekih[1], F. H. Fourati[1]

[1]Hedi Chaker hospital, Sfax, Tunisia

Background:
Renal osteodystrophy (ROD) encompasses various bone abnormalities associated with chronic kidney disease (CKD), including secondary hyperparathyroidism, osteomalacia, and adynamic bone disease, accounting for its clinical and radiological heterogeneity.

Objectives:
To describe the clinical and radiological features of ROD in patients managed in a rheumatology department.

Methods:
A descriptive retrospective study was conducted including patients diagnosed with ROD between 2010 and 2023. Diagnosis was based on clinical, biological, and radiological findings.

Results:
Eleven patients were included (mean age: 52.2±20 years; male/female ratio: 1.75). Most patients (72.7%, n=8) had longstanding CKD (mean duration 13.8±8 years), while three were diagnosed incidentally, including cases related to chronic NSAID use with hypertension. CKD etiologies included diabetic nephropathy (n=5), segmental and focal hyalinosis (n=2), and oxalosis (n=1). All patients were at end-stage renal disease requiring hemodialysis; kidney biopsy was performed in three cases. The mean interval between nephropathy diagnosis and osteoarticular manifestations was 9.9±7 years.

Osteoarticular symptoms included back pain (54.5%), large joint polyarthralgia (45.5%), myalgia (18.2%), diffuse bone pain (18.2%), and buttock pain (9%). Lumbar stiffness was universal, and hip stiffness was present in 63.6%. Functional impairment affecting gait due to gluteal and quadriceps weakness occurred in 18.2%. Laboratory findings showed anemia (81.8%), hypocalcemia (36.7%), hyperphosphatemia

(18.2%), elevated alkaline phosphatase (100%), elevated PTH (72.7%), extremely low 25-OH vitamin D (<8 ng/ml in all patients), and hypogammaglobulinemia (18.2%).
Radiological abnormalities were polymorphic: diffuse demineralization (18.2%), osteocondensation (54.1%), mixed lesions (36.7%), "heart-shaped" pelvis (18.2%), vertebral fractures (18.2%), femoral neck fractures/fissures (27.3%), salt-and-pepper skull (45.5%), subperiosteal resorption (45.5%), pseudo-widened sacroiliac joints (45.5%), pubic symphysis widening (27.3%), ligament calcifications (50%), and coxopathy (54.5%). Brown tumors were observed in two patients, and parathyroid nodules were detected in five (45.5%). Surgical intervention was indicated in three patients, but two could not undergo anesthesia. All patients received analgesics and vitamin D supplementation.
Conclusion:
ROD exhibits marked clinical and radiological heterogeneity, with secondary hyperparathyroidism being the most frequent form. Awareness of its diverse presentations facilitates timely diagnosis and management.

P792
ARTICULAR MANIFESTATIONS IN BEHÇET'S DISEASE: ANALYSIS OF 148 CASES

J. R. Jebri[1], S. M. Somai[1], A. I. Arbaoui[1], D. F. Daoud[1], B. B. Ben Dhaou[1], B. F. Boussema[1]

[1]Habib Thameur Hospital, Tunis, Tunisia

Background:
Behçet's disease is a systemic vasculitis affecting arteries and veins of various calibers. It is associated with mucocutaneous signs and multi-system involvement. Articular manifestations can be an initial or revealing feature of the disease.
Objectives:
To describe the clinical characteristics and patterns of joint involvement in patients with Behçet's disease.
Methods:
This retrospective descriptive study included 148 patients hospitalized for Behçet's disease in the Internal Medicine Department of Habib Thameur Hospital, Tunis, over a period of six years (2015–2020). Data on demographic, clinical, and laboratory features were collected and analyzed.
Results:
Joint involvement was observed in 30% of patients (n=45), with a mean age of 34.2 years (range 14–54) and a male-to-female ratio of 2.75. Articular symptoms were the initial manifestation in 12 patients and revealed the disease in 23.6% of cases. During disease evolution, joint manifestations occurred in 10 patients (6.7%) after a mean delay of 69.5 months from diagnosis. Inflammatory polyarthralgia was the most frequent presentation (93.3%, n=42), while non-destructive arthritis was present in 57.7% (n=26). Joint involvement was monoarticular in 33.3% of cases, oligoarticular in 22.2%, and polyarticular in four patients. The large joints of the lower limbs (knees and ankles) were predominantly affected (86.6%), whereas small joints were less frequently involved. Additional findings included inflammatory low back pain (n=10), popliteal cysts (n=3), and inflammatory sacroiliitis (n=1). All patients with joint involvement also had mucocutaneous lesions; ophthalmological involvement occurred in 33.3% (n=15), vascular involvement in 26.6% (n=12), and neurological involvement in 24.4% (n=11). HLA-B51 was present in 20% (n=9), and 20 patients showed biological inflammatory syndrome. All patients received NSAIDs in combination with colchicine and corticosteroids. Evolution was favorable in most cases; relapse occurred in 11.1% (n=5), and one patient experienced disabling recurrent monoarthritis of the knee.
Conclusion:
Joint involvement is a common systemic manifestation of Behçet's disease and may be the presenting feature. Monoarticular involvement of large lower limb joints is the most typical pattern. Overall prognosis is favorable with symptomatic treatment, although recurrent or disabling arthritis can occur in rare cases.

P793
CLINICAL AND BIOLOGICAL FEATURES OF RHUPUS: ANALYSIS OF 12 CASES

J. R. Jebri[1], G. Z. Gassara[1], F. A. Fekih[1], B. S. Ben Jemaa[1], F. H. Fourati[1]

[1]Hedi Chaker hospital, Sfax, Tunisia

Introduction: Rhupus is an overlap syndrome combining systemic lupus erythematosus (SLE) and rheumatoid arthritis (RA). It is a rare condition, poorly described in the literature due to its low global prevalence (0.09%). This rarity underscores the importance of characterizing its clinical, biological, and therapeutic features.
Patients and Methods: We conducted a retrospective descriptive study, including 12 patients who fulfilled both the ACR criteria for SLE and RA over a 13-year period (2010–2023). The aim was to describe the epidemiological, clinical, and therapeutic aspects of rhupus.
Results: The mean age of our patients was 48 years (range 20–70), and all were female. Two patients had a history of miscarriage. In most cases (58.3%, n=7), RA was diagnosed prior to SLE. Articular involvement was universal: 83.3% (n=10) presented with bilateral, symmetric polyarthritis; one patient had oligoarticular involvement, and another experienced polyarthralgia without arthritis. Cutaneous manifestations occurred in 58.3% of patients (n=7), including photosensitivity in all cases and malar rash in 41.6% (n=5). Systemic symptoms, such as fever and general malaise, were noted in one-third of cases. Three patients had associated sicca syndrome.
Hematological abnormalities were common: lymphopenia in 75%, anemia in 66.6%, and leukopenia in five patients. Inflammatory markers (ESR and CRP) were elevated in 83.3% of cases. Immunologically, ANA titers were strongly positive (1:1280) in four patients, moderate (1:640) in half, and low (1:160) in 25%. Anti-dsDNA antibodies were positive in 50% of patients, and anti-Sm antibodies in 25%. Rheumatoid factor and anti-CCP antibodies were detected in seven and five patients, respectively; only one patient had positive anticardiolipin antibodies. All patients had erosive joint disease, with subclinical synovitis detected by ultrasound in two cases.
Therapeutically, half of the patients required high-dose corticosteroids for serositis (n=3) or hematological flare (n=3), while the others received low-dose corticosteroids (10–15 mg/day). RA-targeted disease-modifying therapy was administered in 11 patients, most commonly as combination therapy (methotrexate–hydroxychloroquine), with monotherapy in four cases. One patient did not receive RA-specific therapy due to inactive disease. Disease course was favorable in most cases; three patients experienced recurrent serositis flares, and two developed corticosteroid-induced osteoporosis.
Conclusion: Rhupus is a rare condition dominated by articular involvement. Hematological flares and serositis are not uncommon and may require high-dose corticosteroids. RA-targeted disease-modifying therapy should be prescribed routinely, but treatment regimens must be

individualized.

P794

CLINICAL AND BIOLOGICAL FEATURES OF INFECTIOUS SPONDYLODISCITIS IN ELDERLY PATIENTS

J. R. Jebri[1], B. L. Ben Ammar[2], B. H. Ben Ayed[1], F. I. Fenniche[1], D. R. Dhaheri[1], G. I. Gharsallah[1]

[1]military hospital of Tunisia, Tunis, Tunisia; [2]miliyary hospital of Tunisia, Tunis, Tunisia

Introduction: Infectious spondylodiscitis (IS) is a severe infection involving the intervertebral disc and adjacent vertebral bodies. Age is a significant determinant of prognosis in this condition.
Objective: To analyze the clinical, biological, and therapeutic characteristics of IS in elderly patients.
Methods: We conducted a retrospective study in a rheumatology department from 2009 to 2022, including 72 patients diagnosed with IS. Patients were divided into two age groups: <65 years (younger adults) and ≥65 years (elderly). Clinical, laboratory, and treatment data were compared between the groups.
Results: Elderly patients accounted for 30.5% of cases (n = 22). Immunosuppressive risk factors, including diabetes (40%) and prior neoplasms (15%), were more prevalent among the elderly, though without statistical significance. Inflammatory back pain was the primary symptom in both groups. Fever was more common in elderly patients, whereas general malaise was more frequent among younger adults. Neurological signs and cauda equina syndrome were more frequently observed in the elderly, without statistical significance. Radiographs revealed vertebral fractures and disc space narrowing predominantly in elderly patients, while erosions and geodes were more common in younger adults. MRI identified epiduritis and paravertebral abscesses mainly in the elderly. Cervical involvement was more frequent in older patients, whereas thoracic, multifocal, and tuberculous forms were more prevalent in younger adults. All patients received antibiotic therapy. Favorable outcomes were achieved in 81.3% of younger adults, whereas elderly patients experienced higher rates of neurological complications and mortality (15%, p = 0.01).
Conclusion: IS in elderly patients is associated with a poorer prognosis compared to younger adults, with increased neurological complications and mortality. This adverse outcome is likely related to comorbidities and age-related immunosuppression, highlighting the need for early diagnosis and tailored management in this vulnerable population.

P795

PREVALENCE AND ASSOCIATED FACTORS OF TUBERCULOSIS IN PATIENTS WITH RHEUMATOID ARTHRITIS

J. R. Jebri[1], B. L. Ben Ammar[2], B. H. Ben Ayed[1], F. I. Fenniche[1], D. R. Dhaheri[1], G. I. Gharsallah[1]

[1]military hospital of Tunisia, Tunis, Tunisia; [2]miliyary hospital of Tunisia, Tunis, Tunisia

Introduction:
Tuberculosis (TB) is an infectious disease that predominantly affects immunocompromised individuals. Chronic inflammatory rheumatic diseases constitute a favorable background for the development of tuberculosis. Rheumatoid arthritis (RA), through its underlying pathophysiological mechanisms, increases the risk of both active and latent tuberculosis. This risk is further exacerbated by the use of corticosteroid therapy and biological agents.
Objectives:
The aim of this study was to evaluate the prevalence of tuberculosis among patients with rheumatoid arthritis and to identify the factors associated with the occurrence of tuberculosis infection.
Materials and Methods:
This was a retrospective descriptive study conducted over a 15-year period, including all patients diagnosed with rheumatoid arthritis who were hospitalized in a rheumatology department. Clinical, biological, and therapeutic data were collected, as well as potential risk factors associated with tuberculosis infection.
Results:
A total of 128 patients with rheumatoid arthritis were included. The mean age was 53.03 ± 12.8 years, with a marked female predominance (female-to-male ratio of 3). Comorbidities were present in 49 patients, including diabetes mellitus in 18%, hypertension in 14.9%, and dyslipidemia in 19% of cases. Two patients had a history of treated pulmonary tuberculosis. Rheumatoid arthritis was seropositive in 78.9% of patients and erosive in 70.3%, with a mean disease duration of 8.88 ± 7.5 years. Extra-articular manifestations were observed in 71 patients, with pulmonary involvement in 21.1% of cases. Nearly half of the patients had active disease (49.7%) associated with a biological inflammatory syndrome (49.4%). Corticosteroid therapy was prescribed in 112 patients, and 33.6% received biological therapy. Methotrexate was the most frequently prescribed conventional synthetic DMARD (91.4%), followed by sulfasalazine (15.6%) and leflunomide (10.9%).
The prevalence of tuberculosis, including latent and active forms, was 5.4% (n = 7). Tuberculin skin testing was positive in 3.1% of patients, while interferon-gamma release assay (QuantiFERON®) was positive in five cases. The mean delay between RA diagnosis and tuberculosis onset was 88.8 months. All patients who developed tuberculosis had received long-term corticosteroid therapy, with a mean daily dose of 10 mg for at least three years. All were treated with conventional synthetic DMARDs, and six patients were receiving anti-TNF therapy.
Conclusion:
In our cohort, the prevalence of tuberculosis was relatively low. Corticosteroid therapy and immunosuppressive treatments, particularly anti-TNF agents, were identified as major predisposing factors for tuberculosis infection in patients with rheumatoid arthritis

P798

THE ROLE OF BONE MINERAL DENSITY ADDED TO FRACTURE RISK ASSESSMENT TOOL (FRAX) IN THERAPEUTIC DECISION MAKING FOR OSTEOPOROSIS IN A MALAYSIAN POPULATION

J. Ratnasingam[1], D. Nga[2], J. K. Khoo[1], M. Niyaz[3], L. Lai Fun[4], S. Velaiutham[5], S. C. Thambiah[6], S. H. Foo[7], T. Ong[8], S. P. Chan[9], S. S. Yeap[4], F. L. Hew[4]

[1]Endocrine Unit, Department of Medicine, Faculty of Medicine, Universiti Malaya, Kuala Lumpur, Malaysia; [2]Jeffrey Cheah School of Medicine and Health Sciences, Monash University Malaysia, Malaysia, Selangor, Malaysia; [3]Dharumavantha Hospital, Maldives, Maldives, Maldives; [4]Puchong Specialist Clinic, Selangor, Malaysia; [5]Endocrine Unit, Hospital Pulau Pinang, Georgetown, Malaysia; [6]Universiti Putra Malaysia, Seri Kembagan, Malaysia; [7]Endocrine Unit, Department of Medicine, Hospital Selayang, Kuala Lumpur, Malaysia; [8]Geriatric Unit, Department of Medicine, Faculty of Medicine, Universiti Malaya, Kuala Lumpur, Malaysia; [9]Subang Jaya Medical Centre, Selangor, Malaysia

Objective: Fracture Risk Assessment tool(FRAX) is widely used to asses fracture risk and the interventional thresholds(IT) are used to identify patients for treatment. Adding femoral neck bone mineral density(BMD) to the FRAX tool is not mandatory. In this study we aimed to examine the role of BMD added to FRAX in therapeutic decision making for osteoporosis in a Malaysian population.

Materials and Methods : FRAX risk factors and femoral neck BMD data were collected from five different centres across different regions in Malaysia. Participants consisted of post-menopausal women and men between ages 40-90 years who underwent routine BMD scans. 10-year probability of major osteoporotic fracture(MOF) and hip fracture(HF) were calculated using the FRAX tool with (FRAX+BMD) and without BMD (FRAX-BMD). Correlation between both 10-year probability of MOF and HF using the FRAX tool +/- BMD values were analysed. Concordance and discordance percentages for changes in therapeutic decision making using FRAX+BMD and FRAX-BMD against the conventional IT were analysed.

Results: A total of 1914 participants were analysed (mean age: 65.3 ± 9.9 years, 86.1% post-menopausal women). FRAX scores increased with age for both groups. There was a strong overall correlation between FRAX + BMD and FRAX–BMD for MOF ($r = 0.81$, $p < 0.001$) and HF ($r = 0.66$, $p < 0.002$). When comparing FRAX+BMD and FRAX-BMD using the conventional IT, the concordance rates for therapeutic decision making were 89.5% for MOF and 79.0% for HF. On the other hand, the discordance rates were 10.5% for MOF (5.5% for upward reclassification and 5.0% for downward reclassification) and 21.0% for HF (11.2% for upward reclassification and 9.8% for downward reclassification). Concordance rates declined with increasing age groups: 40-59 years (99.3%); 60-69 years (92.5%); 70-79 years (81.2%); 80-90 years (67.1%) for MOF.

Conclusion : Our study showed that FRAX-BMD had good correlation with FRAX+BMD in a Malaysian population and is an acceptable alternative for making treatment decisions in situations where BMD services are not readily available. FRAX-BMD provided an age dependant treatment decision option with higher scores in the older age group compared to FRAX+BMD.

LARGE LANGUAGE MODELS. (LLMS) IN OSTEOPOROSIS: APPLICATIONS IN PATIENT EDUCATION AND CLINICAL DECISION SUPPORT: A SCOPING REVIEW

J. Rosen[1], P. Kartik[2], M. O'Riordan[3], N. Fuggle[4]

[1]University of Warwick, Coventry, United Kingdom; [2]Kettering General Hospital, Kettering , United Kingdom; [3]University of Southampton, Southampton, United Kingdom; [4]MRC Lifecourse Epidemiology Center, University of Southampton, Southampton, United Kingdom

Objectives:
Characterise the current use of LLMs in osteoporosis care, with specific attention to applications in patient education and clinical decision support, and to identify reported benefits, limitations, and future implementation considerations.
Materials and Methods:
A scoping review was conducted in accordance with JBI and PRISMA-ScR guidelines. Systematic searches of MEDLINE, Scopus, PubMed, and Web of Science were performed for English-language studies published between 2020 and 2025. Eligible studies described the use of LLMs in osteoporosis for either patient-facing or clinician-facing applications. Data were extracted and thematically analysed.
Results:
Ten studies met inclusion criteria. Patient-directed tools demonstrated high response accuracy and accessibility, though concerns regarding information completeness and variable readability were noted. Clinical decision support applications addressed triage, fracture risk assessment, and treatment recommendation, with several achieving high concordance with clinical guidelines.
Conclusion:
LLMs demonstrate emerging promise in supporting osteoporosis care. Further development requires prospective validation, integration with clinical workflows, and alignment with regulatory and ethical standards to ensure safe and effective use.

BONE TURNOVER MARKERS AND FRAX IN DIABETIC OSTEOPOROSIS PATIENTS

J. S. Hwang[1]

[1]Division of Endocrinology and Metabolism, Department of Internal Medicine, Chang Gung Memorial Hospital, Chang Gung University, Taipei, Taiwan

Introduction: Diabetes mellitus is associated with an increased risk of fractures, which is not explained by bone mineral density. Furthermore, in the Fracture Risk Assessment Tool (FRAX) model, common risk factors and BMD were underestimated the fracture risk in type 2 diabetes patients, thus adjustment methods to improve FRAX estimation of fracture risk in T2DM have been proposed, including reducing T-score by 0.5 standard deviations, increasing age input by 10 years, and selecting rheumatoid arthritis as a proxy for T2DM. Although, glycemic control

condition, the duration of disease, hypoglycemia, risk of falling, and adverse effects of medication, which could lead to higher fractures in diabetic patients, and many studies have investigated biochemical bone turnover rate in diabetes patients, no definite inferences can be made, but bone turnover markers have useful in fracture risk assessment and monitoring treatment efficacy in postmenopausal osteoporosis. The aim of this study is to evaluate the bone turnover and fracture risk in postmenopausal osteoporosis women with diabetes.

Methods: This cross-sectional study investigated patients who were postmenopausal osteoporosis women with diabetes at endocrine clinic. In this study, country-specific fracture risk for 10-year probability of a hip or major osteoporotic fracture, were calculated by the WHO Collaborating Center, using the FRAX algorithm. The FRAX algorithm includes femoral neck BMD, age, sex, body mass index, previous history of fracture, parental history of hip fracture, current smoking, recent use of corticosteroids, presence of rheumatoid arthritis, and at least 3 alcoholic beverages per day, we selected rheumatoid arthritis as a proxy for T2DM to adjust FRAX estimation of fracture risk in diabetes patient. A single, fasting blood sample to assess bone markers, and other biochemical tests were performed in the study visit. Patients were measure the bone specific alkaline phosphatase (BSALP) for formation markers, and beta-crosslaps (b-CTx) for resorbtion markers were analyzed the bone turnover rate.

Results: In this cross-sectional study, we investigated 80 Taiwanese postmenopausal women, with 42 subjects diabetes and 38 non-diabetes at osteoporosis clinic, aged between 50 and 78 years, had high risk for fractures by adjusted FRAX®, defined as 10-year major osteoporotic fracture probability (≥ 20%) or hip fracture probability (≥ 3%), and found both bone formation and resorption markers were elevated.

Conclusions: Our findings suggest that in diabetes osteoporosis women have high risk for fractures by diabetes adjusted FRAX®, with 10-year major osteoporotic fracture probability or hip fracture probability and high bone markers, but no significant difference bone markers in diabetes and non-diabetes osteoporosis women.

P801

ARIAT (RECOMMENDATION ON PHARMACOLOGICAL THERAPY IN OSTEOARTHRITIS OF THE KNEE AND HIP (ARGENTINIAN RECOMMENDATIONS OF INTRAARTICULAR THERAPIES)

J. Scali[1], O. Messina[2], O. Rillo[3], G. Casado[4], G. Nasswetter[1], M. Riopedre[1], D. Sevilla[5], N. Racca[1], V. Castro[1], R. Boyd[1], F. Spikermann[1], R. Berruzzo[1], J. Ju[1]

[1]ARIAT ARGENVISCO, Buenos Aires, Argentina; [2]IRO MEDICAL CENTRE, CIUDAD AUTÓNOMA DE BS. AS., Argentina; [3]Hospital Pirovano, Buenos Aires, Argentina; [4]Hospital Militar Central, Buenos Aires , Argentina; [5]Hospital Durand, Buenos Aires, Argentina

Osteoarthritis (OA) is the most prevalent rheumatic disease with around 600 million individuals suffering ir worldwide .There are evident differences regarding pharmacological therapies , especially with the role assigned to SySADOA and viscosupplementation . The aim of this group was to make a Consensus on pharmacological treatment of the knee and hip OA among argentine experts in this field . Seven of them were rheumatologists , three orthopaedics , two physicians specialized in sport medicine . Publications for the last 12 years were reviewed and those that met the required levels of evidence were selected . Virtual meetings and three in person meetings were held for the entire panel of experts . Grade scale were used to determine agreement of the statements presented to the panel .Twenty seven statements about Knee and Hip OA treatmet were included .Agreement were reached in 19 out of the 27 statements related to the use of analgesics , NSAIDs , duloxetin , IA , PRP and IA glucocorticoids and time to surgery and viscosupplementation . There was disagreement related to the use of viscosupplementation in Stage 4 of the Kellgren - Lawrence (KL) radiological classification. There was no definitions about the use of strong hypnoanalgesics , COXibs , muscle relaxants and the use of cannabinoids .

The ARIAT group recommends prescribing SySADOA and viscosupplementation in grades I , II and III of the Kellgren - Lawrence OA radiological state . Body weight reduction was strongly recommended in both knee and hip OA . Phisical therapies and active excercises are recommended in both knee and hip OA . In Grade IV OA surgery should not be delayed .

P802

LONG-TERM TRENDS AND SEASONAL VARIABILITY OF SERUM 25-HYDROXYVITAMIN D IN ENDOCRINE OUTPATIENTS (2018–2024)

J. Smaha[1], M. Kužma[1], P. Jackuliak[1], J. Payer[1]

[1]5th Department of Internal Medicine, Comenius University and University Hospital, Bratislava, Bratislava , Slovakia

Objective

To assess long-term trends, seasonal variability and prevalence categories of serum 25-hydroxyvitamin D (25(OH)D) concentrations in endocrine outpatients.

Material and Methods

We retrospectively analysed all serum 25(OH)D measurements performed in an endocrine outpatient clinic between January 2018 and December 2024. Vitamin D deficiency was defined as <20 ng/mL, insufficiency as 20–30 ng/mL and optimal concentration as ≥30 ng/mL. Seasonal differences were assessed by month and season using non-parametric tests, and long-term trends were analysed by linear regression.

Results

A total of 615 patients (74.5% women) with 1,357 serum 25(OH)D measurements were included. Mean 25(OH)D concentration was 26.1 ± 10.2 ng/mL and was higher in women than in men ($p<0.001$). Overall, 28.4% of measurements were in the deficient range, 38.7% insufficient and 32.9% optimal. Deficiency prevalence peaked in 2020 (38.8%) and declined to 21.4% in 2024, while the proportion of optimal concentrations increased over time. Mean 25(OH)D rose from 25.2 ± 8.5 ng/mL in 2018 to 28.2 ± 10.4 ng/mL in 2024, showing a significant upward trend ($\beta=+0.50$ ng/mL/year, $p<0.001$). Marked seasonality was observed ($p<0.001$), with lowest concentrations in winter (23.8 ± 10.7 ng/mL) and highest in autumn (27.9 ± 9.8 ng/mL). Monthly values were significantly higher from June to September compared with December to March ($p<0.001$).

Conclusion

Vitamin D deficiency remains frequent among endocrine outpatients, despite a gradual improvement over time. Persistent and pronounced seasonal variability supports season-aware interpretation and management of 25(OH)D in routine endocrine practice.

P803

GUT MICROBIOTA AND BONE MASS AFTER OVARIECTOMY IN WOMEN: A PROSPECTIVE STUDY

J. Stepan[1], M. Kverka[2], Z. Jackova[2], S. Coufal[2], M. Kostovcik[2], H. Hruskova[3]

[1]Department of Rheumatology, First Faculty of Medicine, Charles University in Prague, Prague, Czechia; [2]Institute of Microbiology, Czech Academy of Sciences, Prague, Czechia; [3]3Department of Obstetrics and Gynecology, First Faculty of Medicine, Charles University in Prague, Prague, Czechia

Objective: Prospective studies in experimental ovariectomy models [1] and in postmenopausal women [2] support an association between estrogens, gut microbiota, and bone health. This study [3] aimed to determine whether, in women experiencing acute estrogen deficiency after ovariectomy, the primary driver of decreased bone mineral density (BMD) is an immune response in the bone marrow or whether this immune response is triggered by changes in the gut microbiota.

Material and Methods: We enrolled 31 women of childbearing potential who underwent bilateral ovariectomy and did not receive hormone therapy. Stool and blood samples were collected every 6 months for 18 months following surgery. In addition, samples were collected from 13 women who began receiving estradiol (1 mg per day) 6 months after ovariectomy. Fecal bacterial composition was assessed by sequencing the 16S rRNA gene using Illumina MiSeq. Blood concentrations of estradiol, FSH, bone metabolism biomarkers, and markers of low-grade inflammation were measured. Bone mineral density (BMD) was evaluated at the lumbar spine, proximal femur, and femoral neck using GE Lunar bone densitometry.

Results. At 6 months post-ovariectomy, significant changes were observed in hormone levels, BMD, and bone metabolism; however, there were no significant alterations in gut microbiota α- or β-diversity. A decline in bacterial diversity became evident only at 18 months following surgery. Changes in gut microbiota diversity in untreated women became apparent later and were associated with persistently increased bone resorption and continued BMD decline. Estrogen treatment effectively prevented bone loss, and corrected intestinal dysbiosis. Notably, changes in bacterial α-diversity and taxonomy, including an increase in Lactococcus lactis, were observed after 12 months of estradiol therapy. Body mass index (BMI) was the most significantly associated with microbiota variance. Microbiota was not a suitable predictive factor for the state of bone metabolism. Sources of variability in microbiota composition are more related to interindividual differences than hormonal status.

Conclusion: Estrogens have the potential to prevent the alteration of the gut microbial composition.

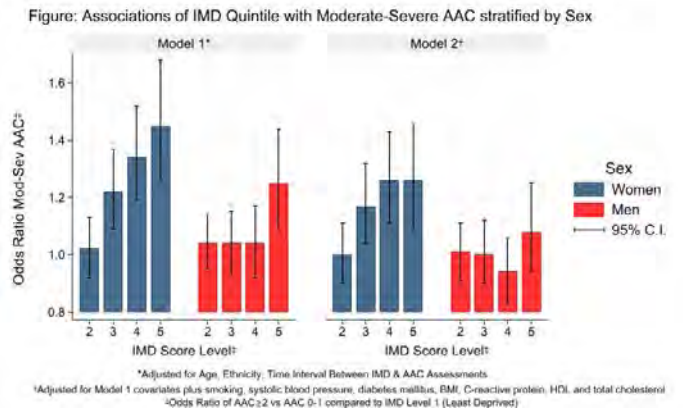
NEIGHBORHOOD SOCIOECONOMIC DEPRIVATION IS MORE STRONGLY ASSOCIATED WITH MACHINE-LEARNING ASSESSED ABDOMINAL AORTIC CALCIFICATION FROM BONE DENSITY VERTEBRAL FRACTURE ASSESSMENT (VFA) IMAGES IN WOMEN THAN IN MEN

J. T. Schousboe[1], J. Webster[2], J. R. Lewis[3], A. Gebre[3], A. Saleem[4], S. Z. Gilani[4], C. Smith[3], W. D. Leslie[5], N. Harvey[6], M. Sim[3]

[1]HealthPartners Institute, Research & Evaluation Division, Bloomington, United States; [2]Oxford University, Applied Health Research Unit, Nuffield Department of Population Health, Oxford, United Kingdom; [3]Edith Cowan University, Nutrition & Health Innovation Research Institute, Perth, Australia; [4]Edith Cowan University, Center for Artificial Intelligence & Machine Learning, Perth, Australia; [5]University of Manitoba, Departments of Medicine and Radiology, Winnipeg, Canada; [6]University of Southampton, MRC Lifecourse Epidemiology Centre, Southampton, United Kingdom



Objective: To examine the association of neighborhood deprivation with subclinical atherosclerosis, assessed as abdominal aortic calcification (AAC), stratified by sex.

Materials and Methods: Our study population was 38,907 (51.7% female, mean[SD] age 55.1 [7.6] years) residents of England enrolled in the UK Biobank study without cardiovascular disease diagnosis, who had bone density lateral spine VFA imaging a mean (SD) 9.5 (2.3) years between 2006-2010 (baseline visit). Neighborhood deprivation was assessed as Index of Multiple Deprivation (IMD) at baseline, along with other covariates. IMD score was categorized into five levels using national quintile cutpoints for England. A validated automated machine-learning algorithm was applied on VFA images to score and categorize ML-AAC24 as none-low (ML-AAC24 score <2) or moderate-severe (ML-AAC24 score ≥ 2). Logistic regression was used to estimate the association of IMD quintiles 2 through 5 vs quintile 1 (the least deprived) with moderate-severe ML-AAC. The base model was adjusted for age, ethnicity, sex, and years between baseline and VFA imaging dates. The full model additionally adjusted for systolic blood pressure, smoking status, diabetes mellitus, body mass index, C-reactive protein, HDL and total cholesterol levels. Analyses were done separately for men and women and associations of IMD with ML-AAC in women vs men compared with Stata *suest* command.

Results: Adjusted for base model covariates, increasing neighborhood deprivation was monotonically associated with higher odds of having moderate-severe ML-AAC in women (**Figure**). In contrast, only men residing in the most deprived neighborhoods had an increased odds of moderate-severe AAC, compared to the least deprived (difference women vs men p-value 0.006). After multivariable adjustment, the associations were attenuated, but were still significant for women (OR 1.26, 95% CI 1.09 to 1.46, for quintile 5 vs quintile 1), whereas no association of IMD with AAC was seen for men (OR 1.08, 95% CI 0.94 to 1.25, for quintile 5 vs quintile 1; difference women vs men p-value 0.005).

Conclusions: Residence in socioeconomically deprived neighborhoods is associated with increased ML-AAC in women more than in men. Further studies are needed to explain the greater impact of neighborhood

deprivation on women vs men.

P805

BEHAVIORS AND BARRIERS TO DISCUSSING ABDOMINAL AORTIC CALCIFICATION (AAC) IN PRIMARY CARE: A CLINICIAN SURVEY

J. T. Schousboe[1], J. M. Dinh[2], L. J. Zibley[2], M. S. Beran[3], A. D. Gillesby[3], K. Ehresman[3], C. Smith[4], J. R. Lewis[4], J. Y. Ziegenfuss[2], M. M. Jaka[2]

[1]HealthPartners Institute, Research & Evaluation Division, Bloomington, United States; [2]Center for Evaluation & Survey Research, HealthPartners Institute, Bloomington, United States; [3]Research & Evaluation Division, HealthPartners Institute, Bloomington, United States; [4]Edith Cowan University, Nutrition & Health Innovation Research Institute, Perth, Australia

Objective: Abdominal aortic calcification (AAC) is associated with incident cardiovascular disease (CVD) events and fractures (Fx) independent of other risk factors, can be detected on bone density lateral spine images intended for vertebral fracture assessment (VFA), and hence may add to both CVD and Fx risk assessments.

Materials and Methods: We conducted a survey of 216 primary care physicians who order bone density tests, constructed designed using the Capability, Opportunity, Motivation and Behaviors (COM-B) model which specifies target behaviors or practices and categorizes barriers to those practices. We queried them about their current practices if they receive a report of AAC being present on a bone density image, and what barriers they experience conveying the presence of AAC and its significance to their patients.

Results: 74 clinicians (55 physicians and 19 nurse practitioners or physician assistants) responded, a response rate of 34%. Among all respondents, 64 (86%) indicated that discussing AAC, if present, would be somewhat or very important to discuss with patients, and 34 (46%) somewhat or strongly agreed that they knew how to incorporate AAC results into cardiovascular disease risk assessment for their patients. Similarly, 35 (47%), 32 (43%), and 31 (42%) indicated they would always or often talk to patients about the association of AAC and higher risk of CVD, recommend lifestyle changes, and recommend medication changes to lower CVD risk. Few (5, <7%) would refer patients on to cardiology. The majority (61, 82%) identified time as a significant barrier to communicating AAC results to their patients. Forty six (62%) perceived that a patient information handout (**Figure**) used in clinical trials regarding AAC would be useful and potentially time-saving communicating with patients about their AAC.

Conclusion: Bone density test images can opportunistically identify individuals with moderate to severe AAC, who are high risk of CVD events and higher risk of Fx. However, for this to be done systematically in clinical practice, primary care physicians need more information about the prognostic significance of AAC and a streamlined time-efficient process to incorporate the presence of AAC into their current cardiovascular risk and fracture risk assessment practices.

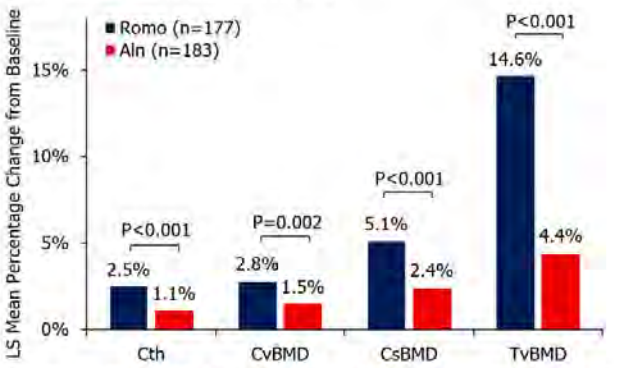
HIP BONE COMPARTMENT RESPONSES TO ROMOSOZUMAB VERSUS ALENDRONATE IN PATIENTS WITH DIABETES: A SUBGROUP ANALYSIS FROM THE ARCH TRIAL USING 3D-DXA MODELLING

S. Ferrari[1], N. Napoli[2], B. L. Langdahl[3,4], K. Luijtens[5], J. Timoshanko[6], L. Humbert[7], M. Bracco[7]

[1]University Hospital of Geneva, Division of Bone Diseases, Geneva, Switzerland; [2]University of Rome, Unit of Endocrinology and Diabetes Campus Bio-Medico, Rome, Italy; [3]Aarhus University, Department of Endocrinology, Aarhus, Denmark; [4]Aarhus University, Department of Clinical Medicine, Aarhus, Denmark; [5]UCB, Brussels, Belgium; [6]UCB, Slough, United Kingdom; [7]3D-SHAPER Medical, Barcelona, Spain

Objective(s): Type 2 diabetes mellitus (T2DM) is linked to increased fracture risk.[1] The paradox of preserved bone mineral density (BMD) and trabecular bone structure but impaired cortical bone parameters in T2DM underscores the importance of advanced imaging for fracture risk assessment. We sought to evaluate changes in hip bone parameters

with romosozumab (Romo) versus alendronate (Aln) in postmenopausal women with osteoporosis (OP) and T2DM.



Materials and Methods: In ARCH (NCT01631214)[2], postmenopausal women with OP were randomised to monthly subcutaneous Romo (210 mg) or weekly oral Aln (70 mg) for 12 months (blinded). We analysed a subset of 360 women (Romo: n=177; Aln: n=183) who had T2DM at baseline and total hip Dual-Energy X-ray Absorptiometry (DXA) scans available. Cortical thickness (Cth), cortical volumetric BMD (CvBMD), cortical surface BMD (CsBMD) and trabecular volumetric BMD (TvBMD) estimates were obtained with 3DShaper Research software (v2.14, 3D-Shaper Medical, Barcelona, Spain). Percentage changes from baseline to Month 12 between treatments were assessed using an ANCOVA model adjusted for baseline covariates.

Results: Baseline characteristics, including mean (standard deviation) age (Romo: 75.8 [7.2] vs Aln: 75.5 [6.9] years), prevalence of severe vertebral fracture (66% vs 62%, respectively) and total hip areal BMD (0.659 [0.087] vs 0.651 [0.085] g/cm^2, respectively) were comparable between groups and generally consistent with overall ARCH populations.[2] At Month 12, Romo resulted in greater increases in all hip compartment-specific parameters vs Aln (least squares mean difference in cortical parameters: 1.3–2.7%; TvBMD: 10.2%; **Figure**).

Conclusions: In postmenopausal women with OP and T2DM, Romo demonstrated greater hip structural and density improvements vs Aln. The magnitude and pattern of these responses in the T2DM subgroup were consistent with the overall ARCH population.[3] Thus, T2DM did not attenuate the clinical efficacy of Romo.

SERUM PER- AND POLYFLUOROALKYL SUBSTANCES (PFAS) AND BONE MINERAL DENSITY IN NORWEGIAN ADOLESCENTS: SEX-SPECIFIC ASSOCIATIONS AND MIXTURE EFFECTS

J. Wang[1], M. Averina[2], S. Huber[2], G. Grimnes[3], G. Fosse[2], ?. Bjørnerem[4], E. Evensen[5], R. Joakimsen[3], J. Johansson[6]

[1]UiT-The Arctic University of Norway, Tromsø, Norway; [2]Department of Laboratory Medicine, University Hospital of North Norway, Tromsø, Norway; [3]Tromsø Endocrine Research Group, Department of Clinical Medicine, UiT-The Arctic University of Norway, Tromsø, Norway; [4]Department of Obstetrics and Gynecology, University Hospital of North Norway, Tromsø, Norway; [5]Department of Health and Care Sciences, Faculty of Health Sciences, UiT-The Arctic University of Norway, Tromsø , Norway; [6]Department of Community Medicine, Faculty of Health Sciences, UiT-The Arctic University of Norway, Tromsø , Norway

Abstract

Background: Adolescence is the critical period for the development of peak bone mass (PBM). Per- and polyfluoroalkyl substances (PFAS) are widespread endocrine disruptors that may disturb skeletal development, but evidence in Nordic adolescents is limited.

Objectives: To evaluate sex-specific associations between serum PFAS and areal bone mineral density (aBMD) Z-scores among Norwegian adolescents.

Methods: This cross-sectional study utilised data from Fit Futures 1 (2010–2011), a cohort of adolescents in Northern Norway. Eighteen serum PFAS were quantified, and aBMD Z-scores (femoral neck, total hip, total body) were calculated using dual-energy X-ray absorptiometry. We used multivariable linear regression and mixture analyses (quantile g-computation and Bayesian kernel machine regression) to estimate sex-specific associations.

Results: Among 889 participants (421 girls and 468 boys; mean age 16.2 years), eight PFAS had detection rates >70%. The sum of linear and branched perfluorooctane sulfonic acid (ΣPFOS) had the highest median concentration (6.23 ng/ml). Perfluorononanoic acid (PFNA) (β = −0.16 per doubling, 95% CI: −0.26, −0.06) and perfluorodecanoic acid (PFDA) (β = −0.15 per doubling, 95% CI: −0.24, −0.06) showed consistent inverse association with total body aBMD. Mixture analyses suggested modest overall adverse mixture effects, with limited evidence of interaction between PFAS. Sex-specific patterns showed more pronounced inverse associations in boys.

Conclusions: Higher concentrations of several PFAS, most consistently PFNA and PFDA, were associated with lower aBMD Z-scores, with stronger inverse patterns in boys. These findings suggest possible sex-specific vulnerabilities in bone accrual, underscoring the need for longitudinal studies to clarify long-term skeletal impacts.

P808

ASSESSING THE STANDARD OF CARE FOR VERY HIGH FRACTURE RISK (VHFR) PATIENTS USING REAL-WORLD UK DATA

J. Warden[1], A. Moayyeri[1], J. Timoshanko[1]

[1]UCB, Slough, United Kingdom

Objective: Osteoporosis (OP) guideline updates and expert consensus reveal strong convergence around several clinical characteristics that consistently define those at very high fracture risk (VHFR). In this study, we examined these different VHFR definitions to compare fracture rates and current treatment patterns.

Material and Methods: We conducted a retrospective observational study using CPRD Aurum linked primary care data and secondary care data from Hospital Episode Statistics England. The study period covered Jan 2010 to Oct 2023; patients were eligible for inclusion if they met any criteria between Jan 2012 and Dec 2021. The cohort included women aged ≥50 years meeting at least one of ten VHFR definitions (Table 1), derived from literature review and National Osteoporosis (OP) Guideline Group guidance. Key outcomes included OP diagnosis, time to treatment initiation, therapy type, and subsequent fx incidence.

Results: VHFR cohort sizes (not mutually exclusive) ranged from 3,032 in the very low BMD T-score ≤3.5 to 222,821 in the major osteoporosis fx cohort (Table 1). OP diagnosis at baseline varied between 8.7-39.7%, increasing during follow-up to 17–91.1%. Except for high dose glucocorticoid cohort, over 20% of each cohort experienced a fx within two years of index, with higher rates among fx-based VHFR definitions (40% of multiple vertebral fracture cohort had a subsequent fracture within two years). Fracture based definition cohorts had the lowest treatment rates, with an average of 18.3% and 39.5% receiving therapy from baseline to follow-up. Median time to treatment was 2–5 months for anti-resorptives and 8–12 months for osteoanabolic. Treatment sequencing analysis showed oral bisphosphonates dominated first-line, with ~87% starting on alendronate.

Conclusion: Although patients with VHFR face a 20-40% two-yr fx risk, many remain undertreated. There is a continued reliance on alendronate, even though guidelines recommend starting with osteoanabolic therapy to rapidly reduce fx-risk. This highlights the importance of better identifying VHFR and prioritizing their clinical care.

Table 1: Study Cohort definitions for very high fracture risk (VHFR)

Fracture Based VHFR (Note was date that the patient fully met the criteria of the definition)	Cohort Size	2-year rate per 1,000PY	Mean Age	Osteoporosis Treatment at Follow Up %
Recent Major Osteoporosis Fracture:	122,582	311.26	78.91	42.1
Multiple Fractures:	204,962	399.42	74.35	36.0
Fall with Fracture History:	160,515	273.46	78.16	34.9
70+ with Fracture History:	170,869	275.93	82.13	38.3
Recent Typical Osteoporosis Fractures:	222,821	283.21	74.98	33.8
Multiple Vertebra Fractures:	14,105	410.14	78.01	32.6
Glucocorticoid based VHFR				
Continued Glucocorticoid use with Fracture History:	51,884	188.49	74.24	35.2
High dose Glucocorticoid:	42,921	84.58	71.6	45.3
Bone Mineral Density based VHFR				
WHO Severe Osteoporosis Low BMD ≤-2.5:	8,403	142.95	70.73	77.2
Very Low BMD ≤-3.5 hip or spine:	3,032	156.91	71.49	80.1

P809

INEQUALITIES IN THE USE OF TOTAL HIP REPLACEMENT TO TREAT HIP FRACTURE: A POPULATION-BASED STUDY

J. Webster[1], A. Johansen[2], X. Griffin[3], E. Morris[1], S. Shepperd[1], R. Goldacre[1]

[1]Applied Health Research Unit, Nuffield Department of Population Health, University of Oxford, Oxford, United Kingdom; [2]University Hospital of Wales and School of Medicine, Cardiff University, Cardiff, United Kingdom; [3]Bone and Joint Health, Queen Mary University London, London, United Kingdom

Objective

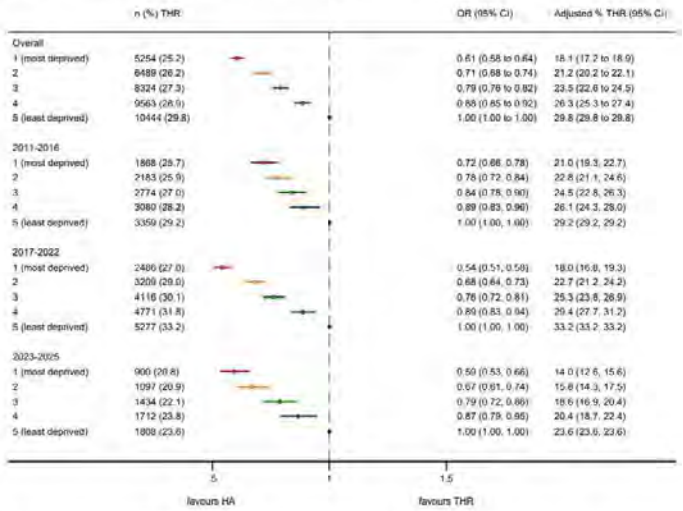
To investigate variation in total hip replacement (THR) use for treating displaced intracapsular hip fracture in relation to socio-economic deprivation and across the English National Health Service (NHS).

Methods

A population-based study was conducted using data from the National Hip Fracture Database (NHFD) (April 2011–June 2025). Adults aged ≥60 years with a displaced intracapsular hip fracture who fulfilled national guidelines to be offered a THR and were treated with THR or hemiarthroplasty (HA) were included. The primary outcome was THR surgery (versus HA). Variation in THR use was explored by quintiles of the Index of Multiple Deprivation (IMD) at admission using logistic regression. Interactions between IMD and study period (2011-2016, 2017-2022, and 2023-2025) were explored. THR use was compared across hospitals through period-specific logistic regression models. All models adjusted for patient-level demographic and clinical characteristics.

Results

From April 2011 to June 2025, 144,192 patients presented to an NHS hospital in England with a displaced intracapsular hip fracture, were eligible for THR, and were treated with THR or HA. THR rates were significantly lower with increasing deprivation (**Figure 1)**; the casemix-adjusted deprivation gap between the most and least deprived quintiles was wider in 2023-2025 (OR 0.59, 95% CI 0.53 to 0.66) than in 2011-2016 (0.72, 0.66 to 0.78) (LR test $\chi 2 = 36.5$, $p_{interaction} < 0.0001$). Large between-hospital differences in THR use were observed. From 2023 to 2025, across 134 hospitals, the THR rate ranged from 0.6% to 53.2%, or from 0.6% to 49.2% after casemix adjustment. There was slightly less variation in later years than earlier years [adjusted mean THR rate 22.1% (SD 9.2%) in 2023-2025; 30.0% (9.5%) in 2017-2022; and 27.4% (11.3%) in 2011-2016; Levene's test of variances p=0.03].



Conclusion

The use of THR to treat hip fracture among eligible patients is low, and varies widely by area-based deprivation and the treating hospital. These inequalities have remained wide over the past decade. Further research is needed to understand if differences in hospital resources, surgeon preferences, residual patient casemix, or other factors are driving these inequalities.

TARGET-GUIDED FACTOR VIII REPLACEMENT MODEL IN HEMOPHILIA A FRACTURE SURGERY: PERIOPERATIVE HEMOSTATIC OUTCOMES AND SAFETY

J. Wenchen[1]

[1]Department of Orthopedics, The First Affiliated Hospital of Xi'an Jiaotong University, Xi'an, China

Objective: To evaluate the effectiveness and safety of a target-guided replacement strategy for coagulation factor VIII (FVIII) combined with dynamic monitoring during fracture surgery in patients with hemophilia A, and to establish a standardized, reproducible perioperative management model.

Methods: A retrospective analysis was conducted in 10 male patients with hemophilia A who underwent fracture surgery at our hospital between January 2020 and June 2024 (age range, 18–49 years; mean, 32.8 years). Fracture sites included the femur (n=4), tibia/fibula (n=3), humerus (n=2), and radius/ulna (n=1), with 3 open fractures. FVIII replacement was guided by the hematology department and performed until coagulation indices reached target levels before surgery. The intraoperative FVIII activity target was 100–150%, and 80–120% during the first 72 hours postoperatively. FVIII activity and activated partial thromboplastin time (APTT) were measured preoperatively and at 24 and 72 hours postoperatively. Intraoperative blood loss, wound healing, complications, and radiographic bone union were recorded.

Results: All patients underwent surgery successfully after FVIII activity reached the target range. The mean intraoperative blood loss was 240 ± 65 mL, all within controllable limits. Postoperative FVIII levels remained within the desired range, and APTT normalized gradually. Nine cases achieved primary wound healing, and one case of mild oozing was controlled with short-term dosage adjustment. No rebleeding, deep infection, or inhibitor formation occurred. At the 6-month follow-up, radiographic bone union was confirmed in all patients without functional impairment.

Conclusion: Target-guided FVIII replacement combined with dynamic monitoring can maintain stable coagulation and significantly reduce perioperative bleeding risk in fracture surgery for hemophilia A. This strategy ensures surgical safety and bone healing, providing a quantifiable and reproducible model for perioperative management.

P811

ALKYL CHAIN–MODIFIED TERIPARATIDE WITH ALBUMIN BINDING FOR LONG-CIRCULATING AND RESPONSIVE NANOTHERAPY IN OSTEOPOROSIS

L. Shuai[1], C. Renwei[1], L. Yongcan[2], Y. Guocan[2], J. Xieyuan[1]

[1]Department of Orthopaedics and Traumatology, Beijing Jishuitan Hospital, Capital Medical University, Beijing, China., Beijing, China; [2]Key Laboratory of Bioorganic Phosphorus Chemistry & Chemical Biology, Department of Chemistry, Tsinghua University, Beijing 100084, P. R. China., Beijing, China

Teriparatide as a pivotal clinical drug for osteogenesis therapy is severely constrained by its short half-life, the propensity to induce osteoclastic activity at high concentration, and the requirement for frequent administration. Although responsive drug delivery systems have been explored to address these limitations, their effectiveness remains unsatisfactory because teriparatide is a high-molecular-weight, highly hydrophilic peptide, leading to low drug-loading efficiency and pronounced burst release. Herein, we design an alkyl chain-modified teriparatide molecule, in which the introduced alkyl moiety contains a cleavable disulfide bond and enables strong interactions with serum albumin in blood, thereby markedly prolonging the systemic half-life of teriparatide. Furthermore, the modified teriparatide can co-assemble with vitamin D and polyethylene glycol to form well-defined nanoparticles for osteoporosis therapy. The studies in vivo demonstrate that this nanosystem exhibits pronounced advantages in extending drug half-life, facilitating responsive release, and significantly enhancing bone mineral density, highlighting its great potential for effective osteoporosis treatment.

P812

TYPE 1 DIABETES AND BONE: ASSOCIATIONS WITH PERIPHERAL ARTERIAL CALCIFICATIONS USING HIGH-RESOLUTION PERIPHERAL QUANTITATIVE COMPUTED TOMOGRAPHY

J. Y. Wang[1,2], C. E. Nevarez[1], K. M. Okazaki[1,3], F. Johannesdottir[3,4], M. L. Bouxsein[3,4], E. W. Yu[1,3]

[1]Massachusetts General Hospital, Endocrine Unit, Boston, United States; [2]Centre Hospitalier Universitaire de Montréal, Montreal, Canada; [3]Harvard Medical School, Boston, United States; [4]Beth Israel Deaconess Medical Center, Center for Advanced Orthopedic Studies, Boston, United States

Objectives: The pathophysiology underlying increased bone fragility in type 1 diabetes [T1D] remains unclear. This study aimed to compare peripheral arterial calcifications [PAC], assessed by high-resolution peripheral quantitative computed tomography [HR-pQCT], between

individuals with T1D and non-diabetic controls. Secondary objectives in T1D were to evaluate associations between PAC severity and HR-pQCT bone indices, hip and spine BMD, bone turnover markers, and fracture history.

Materials and Methods: This cross-sectional study analyzed baseline data from the BEACON (T1D Bone HEAlth CONnection) cohort. HR-pQCT scans of the distal radius and tibia were assessed for PAC by two independent readers and scored using a standardized 12-point scale (maximum 6 points each for the radius and tibia). Scores were averaged across readers. Severe PAC was defined as a total score >5. Clinical data were obtained via questionnaires, chart review, physical examination, laboratory assessments, and dual-energy x-ray absorptiometry [DXA]. Descriptive statistics and univariate and multivariate regression analyses were performed. Data are presented as median (IQR).

Results: We included 96 participants with T1D (age 64 [59, 67] years; 51% male; HbA1c 7.0% [6.3–7.7]) and 55 controls (age 65 [61, 69] years; 52% male). Interrater agreement for PAC severity was excellent (Cohen's κ = 0.916). Participants with T1D had a higher prevalence of severe PAC (64% vs 10%), cardiovascular disease (22% vs 6%), and fragility fractures (26% vs 4%) than controls (all p<0.001). After adjustment for age, sex, and body mass index, severe PAC in T1D was associated with lower tibial cortical volumetric BMD (adjusted difference -4.7%, p = 0.011; Figure 1). No differences were observed in radius HR-pQCT parameters, hip or spine DXA-BMD, bone turnover markers, nor fracture history between severe and non-severe PAC groups.

Conclusions: PAC assessed by HR-pQCT was markedly higher in individuals with T1D compared with controls, despite relatively good glycemic control. In T1D, severe PAC was associated with reduced tibial cortical vBMD. Further studies are needed to elucidate the interplay between vascular calcification and bone health in diabetes.

HR-pQCT Parameter at the Tibia	Adjusted % Difference* Severe vs. Non-Severe PAC	p-value
Bone Density		
Total vBMD (mgHA/cm3)	0.23 [-7.02, 8.05]	0.951

BONE METABOLISM IN ADOLESCENTS UNDERGOING METABOLIC AND BARIATRIC SURGERY: TEEN-LABS COHORT 15-YEARS LATER

K. M. Okazaki[1], J. Y. Wang[1,2], M. Detella[3], M. A. Bredella[4], J. Ryder[3,5], T. Inge[3,5], M. Misra[6], E. W. Yu[1,7]

[1]Massachusetts General Hospital, Endocrine Unit, Boston, United States; [2]Centre Hospitalier Universitaire de Montréal, Montreal, Canada; [3]Lurie Children's Hospital, Department of Surgery, Chicago, United States; [4]NYU Langone Health, Department of Radiology, New York, United States; [5]Northwestern Feinberg School of Medicine, Chicago, United States; [6]University of Virginia, Pediatrics Department, Charlottesville, United States; [7]Harvard Medical School, Boston, United States

Objectives: Little is known about the long-term effects of metabolic and bariatric surgery [MBS] on bone health during adolescence, a critical bone acquisition period. We aimed to compare areal and volumetric bone mineral density [aBMD; vBMD] between young women with history of MBS during adolescence and matched controls. We further aimed to evaluate whether demographics, surgical factors, and bone turnover markers correlated with BMD in the MBS group.

Materials and Methods: We conducted a cross-sectional substudy of the Teen-LABS cohort, that followed adolescents and young adults before and after MBS for 15 years. Female participants who underwent Roux-en-Y gastric bypass [RYGB] or vertical sleeve gastrectomy [VSG] were included and matched to controls by sex, age (± 5 years), body mass index [BMI] (± 5 kg/m^2), race and ethnicity. Spine, total hip [TH] and femoral neck [FN] aBMD were evaluated using dual-energy X-ray absorptiometry, and vBMD using quantitative computed tomography. C-terminal telopeptide of type 1 collagen [CTX] and procollagen 1 N-terminal propeptide [P1NP] were measured. Partial Pearson's correlations were performed accounting for time since surgery and BMI.

Results: We included 20 women with history of MBS (14 RYGB and 6 VSG, mean time since surgery 13.4 ± 2.6 years, current weight loss 23.5 ± 22.0 kg) and 28 matched controls. The average age of the cohort was 30.0 ± 5.5 years, and mean BMI was 39.8 ± 10.3 kg/m^2. Compared to controls, the MBS group had 7.4% lower spine aBMD and 14.6% lower spine vBMD (p≤ 0.03, Figure 1), but there were no significant differences in hip BMD nor bone turnover markers. Within the MBS group, P1NP was correlated with TH, FN and spine aBMD (r = -0.57 to -0.64; all p ≤ 0.01), whereas CTX was correlated with TH aBMD, TH vBMD and FN vBMD (r = -0.50 to -0.62; p ≤ 0.03). Weight change 6 months after surgery, but not at later time points, was correlated with FN vBMD (r = 0.60, p = 0.01). Race, ethnicity and type of surgery were not associated with BMD.

Conclusions: Young adults with history of MBS during adolescence had lower BMD at the spine but not at the hip compared to matched controls. Bone turnover markers and initial 6-month post-surgical weight loss correlated with BMD. More studies are needed to evaluate mechanisms driving these long-term skeletal changes in adolescents undergoing MBS.

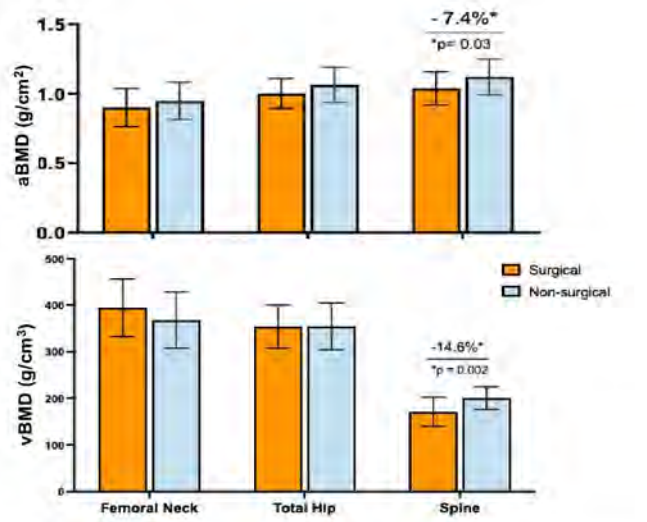

Figure 1. Comparison of Bone Density Between Metabolic and Bariatric Surgery Group and Matched Controls after ≥8 Years
Data are presented as mean ± standard deviation (SD).
Upper Panel: aBMD assessed by DXA is lower at the spine for surgical group.
Lower Panel: vBMD assessed by QCT is lower at the spine for surgical group.
Abbreviations: aBMD, areal bone mineral density; vBMD, volumetric bone mineral density; DXA, dual-energy x-ray absorptiometry; QCT, quantitative computed tomography

P814

COMPARISON OF EFFICACY AND SAFETY OF DENOSUMAB WITH ELDECALCITOL OR NATIVE VITAMIN D IN POSTMENOPAUSAL CHINESE WOMEN WITH OSTEOPOROSIS (ESCORT)

Y. Zeng[1], Q. Tang[1], J. Yang[1], Q. Li[1], L. Yang[1], B. Zhang[1], M. Che[1], Y. Peng[1]

[1]Department of Osteoporosis, Honghui Hospital, Xi'an Jiaotong University, Xi'an, China, Xi'an, China

Background: Denosumab is among the most widely used agents for osteoporosis management, and eldecalcitol (ELD) is also a common therapeutic option in this field. ELD effectively elevates bone mineral density (BMD) in osteoporotic patients, independent of baseline vitamin D status or calcium intake. However, the efficacy of denosumab combined with either ELD or native vitamin D in postmenopausal Chinese women with osteoporosis has not been established.
Methods: In this single-center, randomized, open-label, active-controlled clinical trial, postmenopausal women with osteoporosis (lumbar spine [LS], total hip [TH], or femoral neck [FN] BMD T-score ≤ −2.5, or low bone mass with fragility fracture history) were enrolled at Xi'an Honghui Hospital, China, and were randomly assigned (1:1) to receive ELD (0.75 μg orally daily) (ELD group) or denosumab (60mg subcutaneously every 6 months) plus either native vitamin D (800 IU orally daily) with calcium (600 mg orally daily) (Control group) for 12 months. The primary endpoint was the change from baseline in LS-BMD (L1–L4) at 12 months. Secondary endpoints included changes from baseline in FN- and TH-BMD, bone turnover markers, serum parathyroid hormone, quality of life, and the incidence of new fractures.
Results: Of 100 randomized patients, 45 patients in the ELD group and 46 in the control group were included in the efficacy analysis. At baseline, the absolute values of LS-BMD T-score were 0.68 ± 0.06 in the Eld group and 0.70 ± 0.05 in the control group, respectively. After 12 months of treatment, these values changed to 0.73 ± 0.07 (Eld group) and 0.74 ± 0.06 (Control group)the LS-BMD increased significantly in both groups (both $P < 0.05$), with a greater increase in the ELD group than in the control group (6.75% vs. 4.99%), yielding a statistically significant between-group least-squares mean difference of 1.75% ($P = 0.038$). Compared with the control group, β-CTX level was significantly higher in the ELD group at 3 months (0.05 vs. 0.03 ng/mL, $P = 0.002$), with the trend persisting through 6 and 12 months. Eight fractures were reported (one non-vertebral in the ELD group; one vertebral and six non-vertebral in the control group). No significant between-group differences were observed in FN- or TH-BMD, quality of life, or overall adverse event rates. Both regimens were generally well tolerated, without clinically meaningful calcium-related safety signals.
Conclusions: Combination therapy with denosumab and eldecalcitol improved LS-BMD more effectively than denosumab with native vitamin D and calcium.
Clinical trial registration number: NCT05884372
Keywords: Postmenopausal osteoporosis; Vitamin D; Bone mineral density; Bone turnover markers; Denosumab; Eldecalcitol

DIFFERENCES IN PATIENT ATTITUDES TOWARD THE USE OF ARTIFICIAL INTELLIGENCE IN HEALTHCARE IN RELATION TO DIGITAL BEHAVIORAL CHARACTERISTICS

J. Zvekic Svorcan[1], T. Bjeletic[1], T. Jankovic[1], A. Mikic[2], J. Aleksic[3], V. Tomicic[4], K. Boskovic[1]

[1]University of Novi Sad, Faculty of Medicine Novi Sad. Special Hospital for Rheumatic Diseases Novi Sad., Novi Sad, Serbia; [2]University of Belgrade, Faculty of Philosophy, Belgrade. Academy for Human Development, Belgrade., Belgrade, Serbia; [3]Railway Healthcare Institute., Belgrade, Serbia; [4]University of Novi Sad, Faculty of Medicine Novi Sad., Novi Sad, Serbia

Objective: To examine differences in patient attitudes with a range of claims about artificial intelligence (AI) and the health of digitally active patients in everyday life.
Material and Methods: The prospective cross-sectional study, approved by the Ethics Committee, included 101 patients of both sexes treated at the Special Hospital for Rheumatic Diseases in Novi Sad, Republic of Serbia, who signed an informed consent to participate in the research. Data was gathered via a questionnaire compiled by the examiner, exploring patients' attitudes toward AI and health, and was processed using SPSS v. 25.
Results: The sample (101 patients, 83.2% female, 16.8% male), reported on the social network use—YouTube (66.3%), Facebook (63.4%), Instagram (42.6%), TikTok (18.8%), LinkedIn (6.9%), X/Twitter (5.9%), Threads (2.0%), Snapchat (1%) - as well as messaging applications: Viber (94.1%), Messenger (59.4%), WhatsApp (46.5%), Telegram (11.9%), and Skype (1.0%). While only 13.9% of respondents use some kind of health monitoring application, 62.4% indicated they would be willing to use such an app, and 40.6% know someone who already does.
The number of messaging apps used by respondents was significantly related to the degree of agreement with statements about AI in healthcare (p=9.019). The lowest average score was recorded for respondents who do not use any applications (M=2.79, SD=0.54), while the highest was associated with the use of 3+ applications (M=3.42, SD=0.52).

Respondents who indicated willingness to use a health monitoring application showed a significantly higher (p=0.001) level of agreement with statements about the usefulness of AI in healthcare (M=3.40, SD = 0.49) compared to those who would not use such apps (M=2.90, SD=0.46).
Likewise, individuals who know someone using a health monitoring application indicated a statistically significantly (p=0.031) higher degree of agreement with statements about the usefulness of AI in healthcare (M=3.35, SD=0.53) compared to those who do not (M=3.12, SD=0.52).
Conclusion(s): Digital engagement and exposure to technological innovations (number of applications, willingness to use health applications, contact with technology users) is linked to a greater propensity to accept AI in healthcare.

P816

ASSOCIATION BETWEEN SOCIODEMOGRAPHIC CHARACTERISTICS AND PATIENT TRUST IN THE USE OF ARTIFICIAL INTELLIGENCE IN HEALTHCARE

T. Bjeletic[1], S. Delezan[1], T. Jankovic[1], K. Boskovic[1], T. Nikolov[2], T. Nikolic[2], J. Zvekic Svorcan[1]

[1]University of Novi Sad, Faculty of Medicine Novi Sad. Special Hospital for Rheumatic Diseases Novi Sad., Novi Sad, Serbia; [2]Special Hospital for Rheumatic Diseases Novi Sad., Novi Sad, Serbia

Objective: This study aimed to evaluate the association between patients' sociodemographic characteristics and their level of trust in the application of artificial intelligence (AI) in healthcare.
Material and Methods: A retrospective cross-sectional study included 297 patients from the Special Hospital for Rheumatic Diseases Novi Sad, Serbia. Data were obtained from a database containing sociodemographic variables, including age, sex, educational level, marital status, and place of residence. Attitudes toward AI were measured using a structured 24-item questionnaire with a five-point Likert scale, assessing trust in AI, perceived discomfort, and preference for human supervision. Associations between sociodemographic factors and attitudes toward AI were analyzed. Internal consistency of the domains was assessed using Cronbach's alpha coefficient. Statistical analyses were performed using Python, with significance set at $p < 0.05$.
Results: The mean age of participants was 53 years, with women representing 78% of the sample. Trust in AI varied by education and residence. Participants with less than eight years of education reported the highest trust (M = 3.19), followed by those with more than 12 years (M = 3.17), while those with 8–12 years showed the lowest trust (M = 3.02). Urban residents reported greater trust (M = 3.11) than suburban (M = 3.02) and rural residents (M = 3.05). Similar trends were observed for discomfort and preference for human oversight, with higher scores among those with lower education and non-urban residence. No consistent differences were observed by sex or marital status.
Conclusion: Sociodemographic factors, particularly education and place of residence, significantly influence patient trust, discomfort, and oversight preferences regarding AI in healthcare. These findings emphasize the need to consider educational and contextual differences when implementing AI-supported clinical tools to ensure equitable, transparent, and acceptable adoption.

P817

THE IMPACT OF AGE ON THE BARRIERS TO PHYSICAL ACTIVITY IN RHEUMATOLOGY PATIENTS

V. Tomicic[1], T. Bjeletic[2], T. Jankovic[2], K. Boskovic[2], J. Zvekic Svorcan[2]

[1]University of Novi Sad, Faculty of Medicine Novi Sad., Novi Sad, Serbia; [2]University of Novi Sad, Faculty of Medicine Novi Sad. Special Hospital for Rheumatic Diseases Novi Sad., Novi Sad, Serbia

Objective: Rheumatic diseases include a wide range of chronic ailments affecting the musculoskeletal system and often compromise functional ability and quality of life. Although physical activity plays an important role in the treatment and prevention of complications in rheumatological patients, engagement in regular exercise is often limited by various barriers. To examine the association between age and potential barriers to physical activity in rheumatological patients.
Material and Methods: Following the approval by the Ethics Committee, this retrospective-prospective study, involving 52 rheumatology patients aged 18–65 years, was conducted at the Special Hospital for Rheumatic Diseases in Novi Sad, Serbia. Data were collected using a sociodemographic questionnaire, the International Physical Activity Questionnaire (IPAQ) questionnaire, as well as additional questions inquiring into barriers to physical activity. Statistical processing was performed in SPSS v. 24.
Results: The sample comprised 84.6% women and 15.4% men. About half of the respondents did not participate in regular physical activity, while the other half engaged in exercise of varying intensity. Irrespective of age, lack of knowledge and the need for professional guidance during exercise was the most frequently reported barrier to physical activity (42.3%), followed by lack of time (28.8%) and financial limitations (19.2%), Pearson χ^2=1.878, df=4, p=0.758. Likelihood Ratio=2.546, p=0.636 confirms this conclusion, while Linear-by-Linear Association=1.748, p=0.186 indicates absence of a significant linear relationship between age and barrier. Thus, similar patterns in perceived physical activity barriers are exhibited by younger and older individuals. Moreover, Pearson's R= -0.185, p=0.189, and Spearman's correlation= -0.177, p=0.208 point toward a weak (statistically insignificant) negative association between age groups and barriers.
Conclusion(s): Age does not appear to influence the types of barriers to physical activity, as "I need someone to show me how" and "I haven't thought about it" are the most frequently cited reasons by all age groups, although high cost and skepticism about the effects of exercise are also mentioned by some respondents.

P818

PARENTAL SLEEP QUALITY DURING PEDIATRIC INPATIENT REHABILITATION: A PILOT STUDY

M. Stanic[1], R. Krasnik[1], J. Zvekic-Svorcan[2], A. Mikov[1], M. Kovacevic[3], D. Vuklis[3], D. Dedic Novakovic[4], J. Stupar[1], M. Kolundzic[5]

[1]University of Novi Sad, Faculty of Medicine Novi Sad. Institute of Child and Youth Health Care of Vojvodina, Novi Sad, Serbia; [2]University of Novi Sad, Faculty of Medicine Novi Sad. Special Hospital for Rheumatic Diseases, Novi Sad, Serbia; [3]University of Novi Sad, Faculty of Medicine Novi Sad, Novi Sad, Serbia; [4]University of Novi Sad, Faculty of Medicine Novi Sad. Oncology Institute of Vojvodina, Sremska Kamenica, Serbia; [5]Health Center Novi Sad, Novi Sad, Serbia

Objective: To assess sleep quality and daytime sleepiness in parents of children undergoing inpatient rehabilitation and to identify hospital-related factors associated with impaired sleep.
Material and Methods: This pilot cross-sectional study included 30 parents whose children were hospitalized for at least two days at the Clinic for Physical Medicine and Rehabilitation, Institute for Health Care of Children and Youth of Vojvodina, Novi Sad, Serbia. The study was approved by the Ethics Committee of the Institute (No. 1904/2025), and all participants provided informed consent. Sleep quality was assessed using the Pittsburgh Sleep Quality Index (PSQI), a validated questionnaire evaluating subjective sleep quality, latency, duration and disturbances, while daytime sleepiness was assessed using the Epworth Sleepiness Scale (ESS). A sociodemographic and hospitalization-related questionnaire focusing on environmental conditions during hospitalization was also administered. Non-parametric statistical methods were applied.
Results: The mean PSQI score was 5.57 ± 2.76, indicating borderline poor sleep quality, while the mean ESS score was 6.43 ± 4.01, corresponding to normal daytime sleepiness. A significant negative correlation was found between sleep duration and PSQI ($\rho = -0.684$; $p < 0.001$), while sleep latency showed a positive correlation with PSQI ($\rho = 0.469$; $p = 0.009$). Hallway lighting during nighttime was significantly associated with increased daytime sleepiness ($p = 0.049$). More than 40% of parents reported sleep difficulties during hospitalization. All parents shared a hospital room with their child, and 60% shared the same bed.
Conclusion: Parents of children undergoing inpatient rehabilitation frequently experience impaired sleep quality, influenced by environmental and hospitalization-related factors. Improving hospital sleep conditions for parents may enhance family well-being and support more effective participation in the rehabilitation process.

P819

URINARY TRYPTOPHAN–KYNURENINE METABOLITE PROFILES IN OLDER ADULTS WITH DYNAPENIA AND SARCOPENIA

J. Śliwowski[1], A. Wojszel[2], J. Rentflejsz[2], E. Gorodkiewicz[3], J. Godzień[4], M. Ciborowski[4], Z. B. Wojszel[5]

[1]Medical University of Bialystok, Department of Geriatrics, Interdisciplinary Students' Scientific Group, Białystok, Poland; [2]Medical University of Bialystok, Doctoral School, Białystok, Poland; [3]University of Bialystok, Faculty of Chemistry, Bioanalysis Laboratory, Białystok, Poland; [4]Medical University of Bialystok, Clinical Research Centre, Metabolomics and Proteomics Laboratory, Białystok, Poland; [5]Medical University of Bialystok, Department of Geriatrics, Białystok, Poland

Objectives: With advancing age, increased activity of the kynurenine pathway may contribute to the development of dynapenia and sarcopenia by enhancing oxidative stress and impairing mitochondrial function in skeletal muscle. Given the limited data in older populations, this study aimed to assess urinary concentrations of tryptophan (TRP) and its metabolites—kynurenine (KYN), 3-hydroxykynurenine (3-HK), and 3-hydroxyanthranilic acid (3-HAA)—in older adults with preserved muscle mass and strength (group A), isolated dynapenia (group B), and sarcopenia (group C).
Materials and Methods: Patients aged ≥60 years hospitalized in a geriatric ward were included. Dynapenia was defined as low handgrip strength (<16 kg in women and <27 kg in men). Sarcopenia was diagnosed based on the coexistence of dynapenia and low appendicular skeletal muscle mass (ASM; <20 kg in men and <15 kg in women), assessed by bioimpedance using the Sergi's equation. Serum TRP, KYN, and 3-HK were determined using RP-HPLC-UV, and 3-HAA using RP-HPLC. Statistical analyses included Spearman correlation, the Kruskal–Wallis test, and logistic regression.
Results: The study included 133 participants (mean age 79.0 ± 7.3 years; 72.9% women), with 61.9% classified in group A, 6.3% in group B, and 31.7% in group C. Median urinary concentrations of KYN and 3-HK increased progressively from group A to group C, although these differences did not reach statistical significance (KYN $p=0.08$; 3-HK $p=0.06$), while urinary TRP and 3-HAA showed similar non-significant patterns ($p>0.1$). Both ASM and ASM/height² were significantly and inversely associated with urinary 3-HK levels ($p=0.001$ and $p=0.02$, respectively). In logistic regression analysis, only older age was independently associated with a higher likelihood of sarcopenia (OR=1.14; 95% CI 1.07–1.22; $p<0.001$), regardless of urinary KYN and 3-HK concentrations or sex.
Conclusions: In older adults, urinary kynurenine pathway metabolites show trends toward higher levels with worsening muscle status and are associated with lower muscle mass indices, particularly 3-hydroxykynurenine. However, age remains the dominant determinant of sarcopenia in this population. These findings suggest that urinary kynurenine metabolites may reflect early metabolic alterations related to muscle decline, but their independent role as markers of sarcopenia requires further investigation.
Acknowledgments: The authors would like to thank dr. Łukasz Ołdak for conducting biochemical analyses.

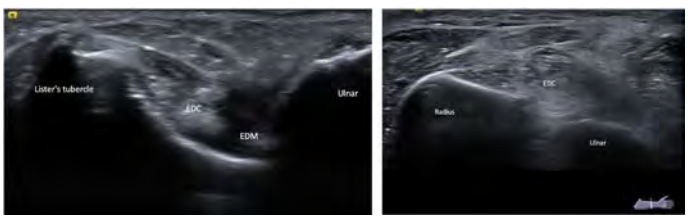
RADIAL NEUROPATHY-LIKE PRESENTATION OF DIGITAL EXTENSOR TENDON RUPTURE IN END-STAGE RENAL DISEASE: A CASE REPORT

J.-C. Lin[1]

[1]Department of Physical Medicine and Rehabilitation, College of Medicine, National Cheng Kung University, Tainan, Taiwan



OBJECTIVE(S) To describe a rare case of digital extensor tendon rupture mimicking radial neuropathy in a patient with end-stage renal disease (ESRD).

MATERIAL AND METHODS A 59-year-old man with ESRD on maintenance hemodialysis, and a history of thyroid papillary carcinoma and renal hyperparathyroidism treated surgically, presented with four months of sudden right wrist soreness and difficulty lifting objects. He denied trauma or repetitive wrist use. Examination showed inability to extend the ulnar four digits (Figure 1). Radial neuropathy was suspected, but nerve conduction studies and electromyography were normal. Ultrasound demonstrated complete rupture of the right extensor digitorum communis (EDC) and extensor digiti minimi (EDM) tendons at the carpal level with EDC muscle atrophy (Figure 2). The patient underwent operative repair, with intraoperative confirmation of complete rupture of the second to fifth extensor tendons at zone VI. Tendon transfer was performed.

Figure 1. Impaired extension of the ulnar four digits.

Figure 2. Ultrasound showing rupture of EDC and EDM tendons.

RESULTS Ultrasound identified tendon rupture despite normal electrophysiologic studies, enabling timely surgical management. Postoperative recovery was uneventful, and tendon rupture was confirmed as the cause of finger extension loss.

CONCLUSION(S) Spontaneous tendon rupture occurs in up to 15% of hemodialysis patients, usually involving large tendons such as the quadriceps, patellar, or Achilles tendons. This case demonstrates an uncommon rupture of the EDC and EDM tendons presenting with radial neuropathy-like weakness. Clinicians should consider digital extensor tendon rupture in dialysis patients with sudden finger extension deficits even without trauma. Ultrasound is essential for distinguishing tendon pathology from neuropathic mimics and guiding appropriate management.

DISCLOSURES None.

CURRENT VALUE OF ARTIFICIAL INTELLIGENCE IN PHYSICAL AND REHABILITATION MEDICINE: A SYSTEMATIZED NARRATIVE REVIEW

E. Denoz[1], N. Durieux[2], G. Briganti[3,4], A. Cioppa[5], J.-F. Kaux[6]

[1]Department of Physical and Rehabilitation Medicine, Faculty of Medicine, University of Liège, Liège, Belgium; [2]Department of Psychology, University of Liège, Liège, Belgium; [3]Department of Computational Medicine and Neuropsychiatry, Faculty of Medicine, University of Mons, Mons, Belgium; [4]Department of Clinical Sciences, University of Liège, Liège, Belgium; [5]Computer vision and data analysis, Montefiore Institute, Faculty of Applied Sciences, University of Liège, Liège, Belgium; [6]Department of Physical and Rehabilitation Medicine, Faculty of Medicine, University Hospital of Liège, Liège, Belgium

Background

Functional limitations and mobility impairments arising from a wide range of conditions represent a growing public health challenge and contribute to an increased demand for Physical and Rehabilitation Medicine (PRM). This demand aligns with the framework of the World Health Organization's 'Rehabilitation 2030' initiative, which emphasizes equitable access to rehabilitation as a core global health priority. Artificial intelligence (AI) could offer promising opportunities to support this objective. In this context, exploring how AI is currently implemented in PRM is essential to better understand its documented contributions to date and future potential.

Objectives

The main objectives of this systematized narrative review are to (1) synthetize current studies exploring how AI is used in PRM, and (2) assess its relevance by identifying existing knowledge gaps to inform future research directions and potential applications in the field.

Material and Methods

Medline (Ovid) and Embase (www.embase.com) were searched in order to find studies published from 2020, focused on AI and PRM. Published studies in French or in English were included.

Results

A total of 87 references were found, including 32 on Medline and 55 on Embase. After removing 19 duplicates, 68 references were screened based on title and abstract. Full-text assessment was performed for 53 articles, leading to the inclusion of 37 studies. Currently, only a few articles show that, although some AI tools are already used in limited contexts in PRM, their integration remains mainly exploratory and potential.

Conclusions

To date, most articles in which AI is discussed in PRM report potential leads, without practical use or reported prospective clinical validation. A hybrid approach, combining human judgment and empathy with AI's efficiency, could substantially contribute to improving standardization and clinical decision support in PRM settings as well as improving education and research in rehabilitation.

CORTICAL THICKNESS AND POROSITY OBTAINED USING BI-DIRECTIONNAL AXIAL TRANSMISSION DIFFERENTIATE BETWEEN INTRA- AND EXTRA-CAPSULAR HIP FRAGILITY FRACTURES

J.-G. Minonzio[1], C. Espinoza[1], V. Garcia[2], E. Madrid[3], J. L. Dinamarca-Montecinos[4]

[1]Universidad de Valparaiso/ Faculty of Engineering/ School of Informatics, Valparaiso, Chile; [2]Universidad de Valparaiso/ Geropolis, Valparaiso, Chile; [3]Universidad de Valparaiso/ Faculty of Medicine, Valparaiso, Chile; [4]Hospital Dr. Gustavo Fricke/ Adult Orthopedics and Traumatology Ward/Orthogeriatric Program, Viña del Mar, Chile

Intra- and extracapsular hip fragility fractures (ICF and ECF) are still mainly considered as one entity, despite evidences [1]. Their differentiation should improve their prevention and treatments. Quantitative Ultrasound (QUS) have demonstrated a clear potential for fragility fracture assessment [2]. Bi-Directionnal Axial Transmission (BDAT) allows to estimate cortical thickness (Ct.Th) and porosity (Ct.Po) at the forearm, showing discrimination perfomances similar to DXA [3].

In this study, 130 participants (100 women, 30 men) were included, 60 without history of fragility fracture (NF group), and 70 with recent hip fragility fracture from Hosp. Dr G. Fricke. Differences in age (74 ± 7 *vs* 80 ± 8 years, $p < 0.001$), weight (68 ± 13 *vs* 60 ± 13 kg, $p < 0.001$) and BMI (27 ± 4 *vs* 23 ± 4 kg.m^{-2}, $p < 0.001$) were observed. BDAT parameters were found significantly different for Ct.Th (2.9 ± 0.6 *vs* 2.6 ± 0.8 mm, $p = 0.02$), Ct.Po (10 ± 4 *vs* 13 ± 5%, $p = 0.001$) and the ratio Ct.Po/Ct.Th (3.6 ± 1.5 *vs* 5.2 ± 1.8, $p < 0.001$). The highest discrimination was obtained considering the area under the ROC curve (AUC) and the odds ratio (OR) for the ratio Ct.Po/Ct.Th, adjusted with age and BMI: AUC = 0.81 [0.73 - 0.86] and OR = 1.63 [1.01 - 2.63] ($p = 0.04$).

When comparing 31 ICF to NF, Ct.Po was found significantly different (12.4 ± 4.5 %, $p = 0.02$) while no significant difference were observed for Ct.Th. Differently, when comparing 39 ECF to NF, both parameters were found different: Ct.Th (2.5 ± 0.9 mm, $p = 0.004$) and Ct.Po (13.4 ± 5.1%, $p = 0.001$). Morever, the ICF group was found younger (78 ± 8 *vs* 82 ± 8, $p = 0.03$) in agreement with previous studies [1]. ICF and ECF were also differentiated by the ratio Ct.Po/ Ct.Th (4.6 ± 1.6 *vs* 5.6 ± 1.8, $p = 0.02$) with the age, BMI-adjusted discrimination equal to AUC = 0.73 [0.62 - 0.83] and OR = 1.92 [1.03 - 3.57] ($p = 0.04$).

This study confirms that BDAT is useful obtaining scientific data and performing hip fragility fracture risk assessment, in particular where DXA is not available. Moreover, cortical thickness and porosity, can be clinical interpreted in terms of bone quantity and quality, as shown here for ICF and ECF differentiation.

IMPROVED 10-YEAR FRACTURE RISK PREDICTION WITH THE "BONE STRAIN INDEX" BEYOND BONE MINERAL DENSITY AND FRAX® IN COMMUNITY-DWELLING OLDER WOMEN

J. M. K. De Filette[1], A. Bellanger[2], L. Rinaudo[3], F. M. Ulivieri[4], I. Calderone[3], S. Cuttone[3], D. Sanchez-Rodriguez[5], F. Baleanu[1], A.-S. Hambye[6], F. Benoit[5], M. Surquin[5], L. Iconaru[1], J.-J. Body[1], P. Bergmann[6]

[1]Endocrinology, CHU Brugmann, Brussels, Belgium; [2]Translational Research Unit, CHU Brugmann, Université Libre de Bruxelles, Brussels, Belgium; [3]Tecnologie Avanzate T.A. SRL, Turin, Italy; [4]Bone Metabolic Unit, Casa di Cura La Madonnina, Gruppo San Donato, Milan, Italy; [5]Geriatrics, CHU Brugmann, Université Libre de Bruxelles, Brussels, Belgium; [6]Nuclear Medicine, CHU Brugmann, Université Libre de Bruxelles, Brussels, Belgium

Objectives: The Bone Strain Index (BSI), derived from finite element analysis of DXA, quantifies mechanical strain within bone. Its predictive value for fragility fractures in older women remains to be established in large prospective studies.
Methods: This prospective cohort study assessed the association between BSI, incident and major osteoporotic fractures (MOF) in 3338 community-dwelling older women (age 64-77 years) during a 5-year and 10-year follow-up. BSI was calculated at the lumbar spine, total hip, and femoral neck using baseline DXA scans. Incident fragility and MOF were radiographically validated. Discriminative performance was assessed using ROC curves, optimal cut-offs (Youden index), and Cox proportional-hazards models adjusted for age, areal bone mineral density (aBMD), or FRAX® score.
Results: During the 10-year follow-up, 803 women (24.1%) sustained at least one fragility fracture, including 525 MOF. Higher BSI values were significantly associated with increased fracture risk at 5 and 10 years, independently of age, aBMD, or FRAX®. Total hip BSI showed the strongest performance among all sites (AUC 0.63 at 5 and 10 years), outperforming lumbar spine BSI (AUC 0.58). Each 1-SD increase in total hip BSI was associated with higher fracture risk (HR 1.42 [1.32–1.53] at 5 years; 1.41 [1.34–1.49] at 10 years), which remained significant after FRAX® adjustment (HR 1.24 [1.14–1.35]).
Conclusions: BSI independently predicted incident fragility fractures and MOF during a 5-year and 10-year follow-up in community-dwelling older women. Total hip BSI showed stronger predictive performance than lumbar spine BSI, and both provided discriminative value beyond aBMD and FRAX®.

P826

SYSTEMIC INFLAMMATION PREDICTS BONE FRAGILITY IN ADULT-ONSET STILL'S DISEASE: A CROSS-SECTIONAL ANALYSIS

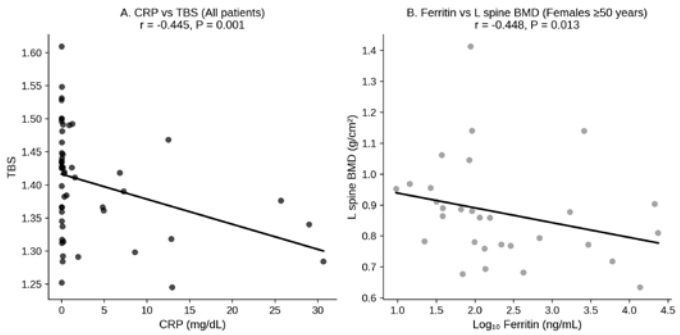
J.-W. Kim[1], J.-Y. Jung[2], H.-A. Kim[2], Y. J. Choi[3]

[1]Ajou university of school of medicine, Rheumatology, Suwon-si, Gyeonggi-do, South Korea; [2]Ajou university school of medicine, Rheumatology, Suwon-si, Gyeonggi-do, South Korea; [3]Ajou University School of Medicine, Endocrinology and Metabolism, Suwon-si, Gyeonggi-do, South Korea

Background: Adult-onset Still's disease (AOSD) is characterized by systemic inflammation with marked elevations in C-reactive protein (CRP) and ferritin. Although chronic inflammation is a well-known contributor to bone fragility, the impact of AOSD-specific inflammatory activity on bone density and microarchitecture remains unclear.

Methods: We retrospectively analyzed AOSD patients who met the Yamaguchi criteria and underwent dual-energy X-ray absorptiometry (DXA) between 2010 and 2023. Bone mineral density (BMD) at the lumbar spine, femoral neck, and total hip was measured, and trabecular bone score (TBS) was evaluated. Associations between inflammatory markers (CRP, ferritin) and bone parameters were analyzed using Spearman correlations and multivariable logistic regression.

Results: A total of 54 patients with AOSD were included, with a mean age of 58.2 ± 12.0 years and 81.5% being female. Mean BMD values were 0.950 ± 0.206 g/cm² (L spine), 0.769 ± 0.139 g/cm² (femoral neck), and 0.819 ± 0.147 g/cm² (total hip). Osteoporosis and osteopenia were identified in 40.7% and 38.9% of patients, respectively. Higher CRP levels correlated negatively with TBS (r = −0.445, P = 0.001). After adjustment for age, sex, and BMI, CRP remained an independent predictor of osteoporosis (OR 1.13, 95% CI 1.01–1.28, P = 0.037). In a subgroup analysis of patients aged ≥50 years, log-transformed ferritin showed a strong association with osteoporosis (OR 5.01, 95% CI 1.52–16.51, P = 0.008). Cumulative glucocorticoid exposure was not significantly related to any bone outcomes.



Conclusions: Our findings suggest that systemic inflammation—reflected by elevated CRP and ferritin—plays a central role in impaired bone health among patients with AOSD. Inflammation-related bone fragility appears to be an underrecognized complication, highlighting the need for routine bone health assessment in this population.

Table 1. Basline characteristics (n=54)

Variable	Value
Age, years	58.2 ± 12.0
Female, n (%)	44 (81.5)
BMI, kg/m²	22.9 ± 2.8
Disease duration, months	29.5 (4.5-83.5)
Laboratory findings at BMD	
CRP, mg/dL	0.14 (0.04-1.51)
Ferritin, ng/mL	129 (49-373)
Cumulative steroid, mg	5,062 (1,181-9,690)
Bone densitometry	

L spine BMD, g/cm²	0.950 ± 0.206
Femoral neck BMD, g/cm²	0.769 ± 0.139
Total hip BMD, g/cm²	0.819 ± 0.147
TBS	1.404 ± 0.081
Bone status, n (%)	
Osteoporosis	22 (40.7)
Osteopenia	21 (38.9)
Normal	11 (20.4)

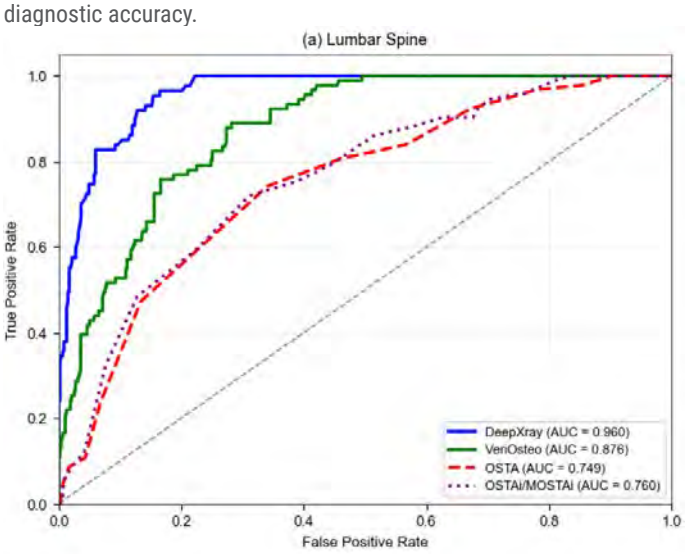
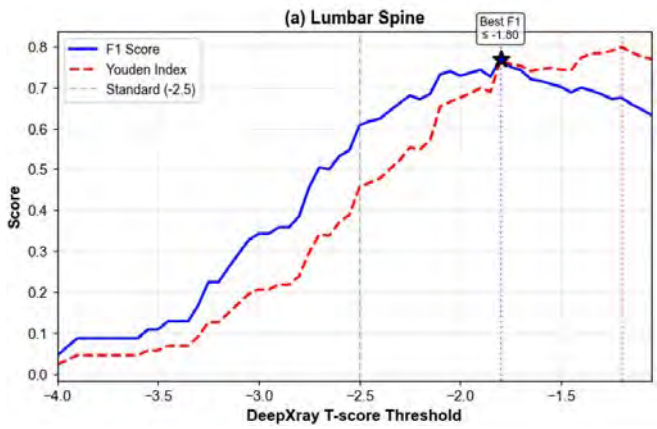
P827

AI-BASED BONE MINERAL DENSITY PREDICTION FROM PLAIN RADIOGRAPHS FOR OSTEOPOROSIS SCREENING: SINGLE-TOOL THRESHOLD OPTIMIZATION VERSUS MULTIMODAL STRATEGIES

J.-Y. Hsu[1], S.-H. Fu[2], C.-C. Hung[2], G. H. Chang[1], C.-Y. Wang[3]



[1]Program for Precision Health and Intelligent Medicine, Graduate School of Advanced Technology, National Taiwan University, Taipei City, Taiwan; [2]Department of Orthopedics, National Taiwan University Hospital Yun-Lin Branch, Douliu, Taiwan; [3]National Center for Geriatrics and Welfare Research, National Health Research Institutes, Huwei, Taiwan



Objective: To compare the diagnostic performance of AI-based bone mineral density (BMD) prediction tools using plain radiographs with traditional questionnaire-based screening methods for osteoporosis detection, and to evaluate whether threshold optimization of single AI tools could achieve superior performance compared to multimodal screening strategies or traditional questionnaire-based screening approaches.

Material and Methods: This cross-sectional study included 578 participants (73.2% women, mean age 62.2±10.9 years) who underwent both plain radiographs and dual-energy X-ray absorptiometry (DXA). Two AI tools predicted BMD: DeepXray analyzed lumbar spine and pelvic radiographs, while VeriOsteo analyzed the T12-L1 region from chest radiographs. AI predictions were calibrated using manufacturer-specific Hologic transformation formulas. Traditional tools included Osteoporosis Self-Assessment Tool for Asians (OSTA) and OSTAi/MOSTAi. Diagnostic performance was evaluated using receiver operating characteristic analysis, and threshold optimization was performed to maximize F1 scores.

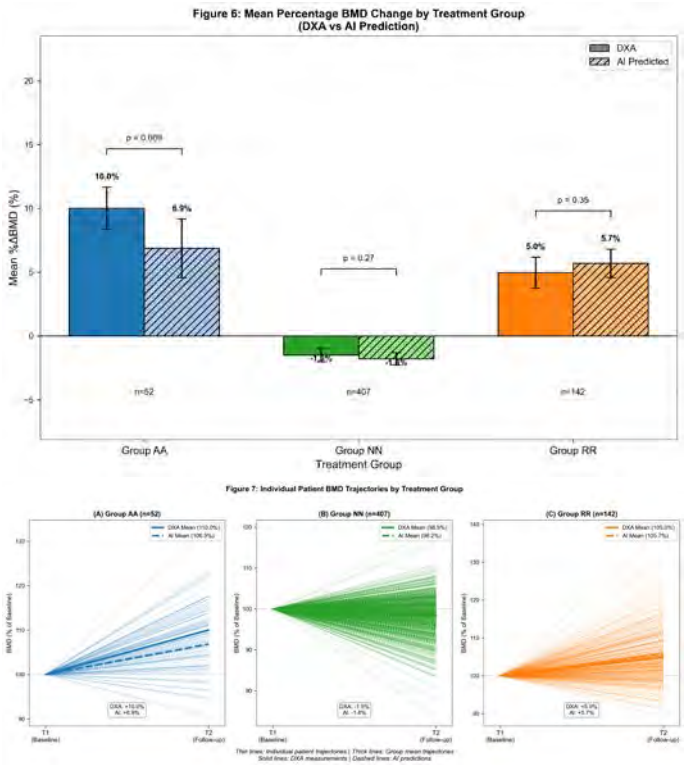
Results: Osteoporosis prevalence was 16.1% for lumbar spine and 30.1% for any skeletal site. For lumbar spine detection, DeepXray achieved the highest area under the curve (AUC=0.960, 95% CI: 0.923-0.997), outperforming VeriOsteo (0.876), OSTA (0.749), and OSTAi/MOSTAi (0.760). At standard thresholds, AI tools demonstrated high specificity (DeepXray: 98.9%) but lower sensitivity (47.1%), while traditional tools showed higher sensitivity (OSTA: 74.2%) but lower specificity (68.0%). Threshold optimization revealed that DeepXray alone with liberalized threshold (T-score ≤-1.80) achieved optimal performance (F1=0.772) with 83.9% sensitivity and 93.8% specificity, matching or exceeding constrained parallel combination strategies (F1=0.629).

Conclusion: Single AI tool (DeepXray) with optimized threshold outperforms multimodal combination strategies or traditional questionnaire-based screening approaches, representing a simplified yet highly effective approach for osteoporosis screening that eliminates the need for questionnaire-based assessments while achieving superior diagnostic accuracy.

P828

AI-BASED BMD PREDICTION ACROSS OSTEOPOROSIS TREATMENT STATES: IMPLICATIONS FOR MONITORING ANABOLIC AND ANTIRESORPTIVE THERAPY

J.-Y. Hsu[1], S.-H. Fu[2], Y.-C. Wang[3], C.-C. Hung[2], G. H. Chang[1], C.-Y. Wang[4]



[1]Program for Precision Health and Intelligent Medicine, Graduate School of Advanced Technology, National Taiwan University, Taipei City, Taiwan; [2]Department of Orthopedics, National Taiwan University Hospital Yun-Lin Branch, Douliu, Taiwan; [3]Department of Medical Imaging, National Taiwan University Hospital Yunlin Branch, Douliu, Taiwan; [4]National Center for Geriatrics and Welfare Research, National Health Research Institutes, Huwei, Taiwan

Objective(s) To evaluate the performance of an AI algorithm for predicting lumbar spine bone mineral density (BMD) from routine radiographs across different osteoporosis treatment states, including anabolic therapy, antiresorptive therapy, and no treatment.

Material and Methods This retrospective study included 601 patients with 1202 paired spine radiograph-DXA measurements from a tertiary medical centre in Taiwan. Patients were categorized into three groups: anabolic therapy (AA, n=52; teriparatide or romosozumab), antiresorptive therapy (RR, n=142; bisphosphonates or denosumab), and no treatment (NN, n=407). A commercially cleared AI algorithm was applied to predict lumbar spine BMD. Cross-sectional agreement was assessed using intraclass correlation coefficient (ICC). Longitudinal performance was evaluated using ICC for BMD change and paired comparisons of percent BMD change (%ΔBMD) between DXA and AI predictions.

Results Cross-sectional agreement was excellent across all groups: ICC 0.88-0.92 for AA, 0.92 for NN, and 0.86-0.87 for RR. Longitudinal agreement varied substantially: NN showed moderate agreement (ICC=0.50), AA fair agreement (ICC=0.33), and RR poor agreement (ICC=0.15). Critically, AI significantly underestimated BMD gains during anabolic therapy (DXA +10.0% vs AI +6.9%, p=0.009), while no significant differences were observed for NN (DXA -1.5% vs AI -1.8%, p=0.27) or RR (DXA +5.0% vs AI +5.7%, p=0.35). Three-class classification agreement (±5% threshold) was 67-68% for AA and NN but only 49% for RR.

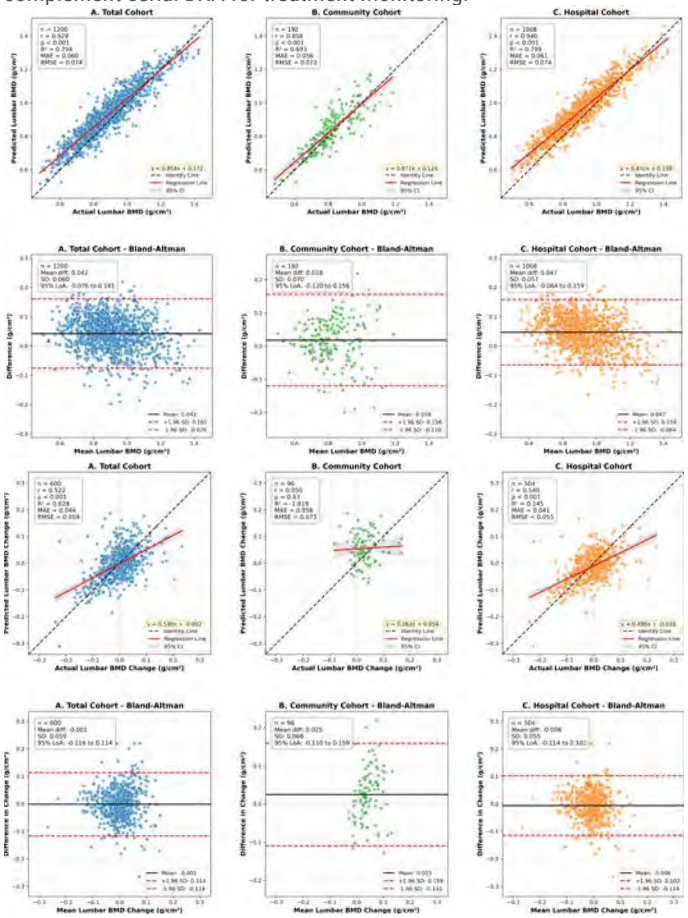
Conclusion(s) AI-based BMD prediction demonstrates consistent cross-sectional accuracy regardless of treatment status. However, longitudinal tracking capability varies by treatment type, with AI potentially underestimating rapid BMD gains during anabolic therapy. Clinicians should interpret AI-predicted BMD changes cautiously when monitoring treatment response, particularly for anabolic agents.

P829

AI-BASED LUMBAR SPINE BMD ESTIMATION FROM ROUTINE RADIOGRAPHS: CROSS-SECTIONAL ACCURACY AND LONGITUDINAL TRACKING IN A MULTICENTRE STUDY

J.-Y. Hsu[1], S.-H. Fu[2], C.-C. Hung[2], G. H. Chang[1], C.-Y. Wang[3]

[1]Program for Precision Health and Intelligent Medicine, Graduate School of Advanced Technology, National Taiwan University, Taipei City, Taiwan; [2]Department of Orthopedics, National Taiwan University Hospital Yun-Lin Branch, Douliu, Taiwan; [3]National Center for Geriatrics and Welfare Research, National Health Research Institutes, Huwei, Taiwan



Objective(s) To evaluate cross-sectional accuracy and longitudinal tracking capability of a commercially cleared AI algorithm for predicting lumbar spine bone mineral density (BMD) from routine radiographs in hospital and community settings.

Material and Methods This retrospective multicentre study included adults from a tertiary medical centre, affiliated regional hospital, and rural community centres in Taiwan (March 2014 to December 2024) with paired spine radiographs (kidney-ureter-bladder, thoracolumbar, or lumbosacral) and lumbar DXA within 6 months at baseline and follow-up. DeepXray Spina, a commercial AI software with FDA/TFDA clearance, was applied without modification. Cross-sectional agreement was assessed using Pearson correlation, intraclass correlation coefficient (ICC), and Bland-Altman analysis. Longitudinal performance was evaluated using ICC for BMD change and three-class classification (decrease, no change, increase) using a ±5% least significant change threshold.

Results Of 644 participants, 600 were included (mean age 59.4 years [SD 13.6]; 75.2% women; 504 hospital, 96 community). Median follow-

up was 897 days (IQR 713-1709). Cross-sectional agreement was excellent (r=0.93; ICC=0.90; RMSE=0.074 g/cm²) with minimal bias (mean difference 0.04 g/cm²). Longitudinal agreement for BMD change was moderate overall (ICC=0.52), with better performance in hospital (ICC=0.54) than community settings (ICC=0.04). Three-class classification achieved 61.5% overall agreement (κ=0.31), with sensitivity 56.5% for detecting significant decreases.

Conclusion(s) This AI algorithm demonstrates excellent cross-sectional accuracy supporting opportunistic osteoporosis screening from routine radiographs. Moderate longitudinal performance, constrained by DXA precision limits, indicates algorithm refinement is needed before AI can complement serial DXA for treatment monitoring.

P831

INVESTIGATION OF THE THERAPEUTIC OUTCOMES OF ZOLEDRONIC ACID INJECTION AFTER 3 DOSES IN OSTEOPROTIC PATIENTS WITH LOW TRAUMA FRACTURES AT A TERTIARY HOSPITAL, OMAN. A RETROSPECTIVE STUDY.

K. Al Balushi[1], H. Al Harthi[2], D. Lekshmi[3], S. Al.Qassabi[1]

[1]Khoula Hospital, Muscat, Oman; [2]Ministry of Health, Muscat, Oman; [3]Collegeof Pharmacy, NationalUniversity, Muscat, Oman

Objectives:
To assess the therapeutic outcomes of three annual doses of zoledronic acid (ZA) in osteoporotic patients with low-trauma fractures treated at tertiary hospital, Oman. Specifically, it evaluates changes in bone mineral density (BMD) following treatment and to assess response variation across different age groups.

Methodology:
This retrospective observational study was conducted at the orthopedic department using patient records from January 2011 to June 2025. Data was extracted from the electronic medical record system. Statistical analysis was performed using SPSS version 26.
The incidence of osteoporotic fractures was reported as percentages with 95% confidence interval (CI). Pre and post categorical comparisons were tested by McNemar tests. A p-value of <0.05 was considered statistically significant.

Results:
A total of 249 patients were included in this study. The mean ± SD age was 64.92±7.66 years. At baseline, the median BMD of the spine was 0.70 g/cm2, and the spine T score was -3.10. The median BMD for the hip was 0.69 g/cm2 (IQR: 0.62 to 0.79), and the hip T score was -2.0 (IQR: -2.60 to -1.20). Before treatment, 86 patients had an incidence of osteoporotic fractures, and after treatment, the incidence decreased to 36. The difference between pre and post treatment incidence was statistically significant (p<0.001). Regarding the BMD scores before and after treatment, BMD of spine increased from 0.70 to 0.75 g/cm2, which was statistically significant (p<0.001). Similarly, the BMD of spine T score increased from -3.10 to -2.67, p<0.001. Regarding hip score, BMD increased from 0.69 to 0.72 g/cm2, which was statistically significant (p=0.004). The BMD hip T score also increased from -2.0 to -1.90, p=0.007. Above 70 years of age group showed a statistically significant reduction from 47.6% to 23.8%, p=0.017. For hip BMD, a significant increase was observed only in the age group of 50 - 60 years where the median score significantly increased from 0.75 to 0.78 g/cm². The remaining age groups showed no significant difference in BMD change (p>0.05).

Conclusion:
Three doses of ZA were associated with a significant reduction in osteoporotic fracture incidence and improvements in BMD among patients. However, significant improvement in hip BMD was mainly seen in patients aged 50–60 years, suggesting age-related variation in treatment response.

P832

DEVELOPMENT OF PREDICTION MODEL FOR 1-YEAR MORTALITY AFTER HIP FRACTURE SURGERY

K. Alexiou[1], A. Koutalos[2], S. Varitimidis[2], T. Karachalios[2], K. Malizos[2]

[1]University of Thessaly, Department of Physiotherapy, Lamia, Greece; [2]University of Thessaly, Department of Orthopaedic Surgery and Musculoskeletal Trauma, Larissa, Greece

Purpose: Hip fractures are associated with increased morbidity and mortality. The identification of risk factors of mortality could improve patient care. The aim of the study was to identify risk factors of mortality twelve months after surgery for a hip fracture and construct a mortality index.
Methods: Prospectively collected data from 597 patients with hip

fractures that were treated in the tertiary hospital, and another 147 patients that were treated in a secondary hospital were available. The perioperative data were collected from medical charts and interviews. Functional Assessment Measure score, Short Form-12 and mortality were recorded at 12 months. Patients and surgery variables that were associated with increased mortality were used to develop a mortality index.

Results: Mortality for the whole cohort was 19.4% at one year. From the variables tested only age >80 years, ASA category, time to surgery (>48 h), CCI, sex, use of anti-coagulants, and BMI >25 were associated with increased mortality and used to construct the mortality index. The area under the curve for the prediction model was calculated at 0.814. Functional outcome at one year was similar to preoperative status, even though their level of physical function dropped after the hip surgery and slowly recovered.

Conclusion: The mortality prediction model that was developed in this study calculates the risk of death at one year for patients with hip fractures, it is simple, and could detect high risk patients that need special management.

Keywords: hip fractures; mortality; functional outcome; time to surgery

P833

BALANCING THE "DO NO HARM" PRINCIPLE IN GLUCOCORTICOID THERAPY: A CRITICAL ASSESSMENT OF GLUCOCORTICOID-INDUCED OSTEOPOROSIS

S. Delezan[1], L. Drazic[2], K. Boskovic[1], J. Zvekic - Svorcan[1], N. Nenadov Jovanovic[1]

[1]University of Novi Sad, Faculty of Medicine Novi Sad. Special Hospital for Rheumatic Diseases Novi Sad., Novi Sad, Serbia; [2]Special Hospital for Rheumatic Diseases Novi Sad., Novi Sad, Serbia

Objective: To present complications of long-term glucocorticoid (GC) therapy in a patient with rheumatoid arthritis (RA), with emphasis on secondary osteoporosis and fracture risk.

Materials and Methods: We report a 73-year-old woman with seropositive RA diagnosed in 2006. Comorbidities included asthma, hypertension, hypothyroidism, and ocular pathology. Menopause occurred at 48 years. Initial RA treatment consisted of methotrexate and hydroxychloroquine, with intermittent GC use, and vitamin D supplementation due to osteopenia on DXA. Tocilizumab induced remission for one year, after which methotrexate was continued. Disease progression was accompanied by systemic manifestations (anemia, pleuritis with empyema, scleritis, latent tuberculosis) and elevated inflammatory markers, requiring high-dose GC therapy and escalation to etanercept, with gradual GC tapering. In June 2025, after minor trauma, the patient developed left hip and groin pain with impaired weight-bearing. Clinical examination showed limited hip motion without synovitis. Pain VAS was 7/10. FRAX (Serbia) showed a 26% risk of major osteoporotic fracture and 17% risk of hip fracture; FRAX PLUS increased major fracture risk to 32%. Pelvic X-ray, laboratory tests and DXA were performed.

Results: Imaging revealed fractures of the left pubic bone rami with minimal displacement. Laboratory findings showed anemia, mildly elevated inflammatory markers, and increased bone resorption markers. DXA confirmed osteoporosis, with normal TBS. Anti-osteoporotic treatment with denosumab was continued alongside ongoing RA therapy and vitamin D supplementation.

Conclusion: Prolonged high-dose glucocorticoid therapy was the principal cause of secondary osteoporosis, leading to pathological fractures despite preventive measures, highlighting the need for early and aggressive bone protection in GC-treated RA patients.

P834

ASSOCIATION BETWEEN VERTEBRAL BODY HEIGHTS AND OSTEODENSITOMETRY FINDINGS

S. Delezan[1], J. Zvekic - Svorcan[1], T. Jankovic[1], N. Bastaja[1], T. Tasic[1], T. Bjeletic[1], K. Boskovic[1]

[1]University of Novi Sad, Faculty of Medicine Novi Sad. Special Hospital for Rheumatic Diseases Novi Sad., Novi Sad, Serbia

Objective: The aim of this study was to evaluate whether a direct association exists between DXA-derived parameters and a reduction in vertebral body height.

Materials and Methods: DXA measurements including lumbar spine T-score (L1–L4) and bone mineral density (BMD) were analyzed together with the trabecular bone score (TBS) L1–L4. Vertebral body heights were measured in millimeters at three points (anterior, middle, and posterior) from L1 to L5 on lateral lumbar spine radiographs. Vertebral deformities were classified according to the Genant classification. Data were obtained from the "Improvement of diagnostic, treatment and rehabilitation methods in special hospitals of the cross-border area" (RE-TREAD) project database (Project ID: HR-RS00005).

Results: A total of 27 patients were included. One male patient had no available DXA data, while in one female patient vertebral body heights from L3 to L5 could not be measured due to severe scoliosis. TBS could not be calculated in four patients (14.8%) because of high body mass index (BMI), and TBS values were unavailable in three patients (11.1%). The mean lumbar T-score was −0.29, the mean BMD was 1.146, and the mean TBS value was 1.345. For L1, the mean anterior, middle, and posterior heights were 32.4 mm, 24.9 mm, and 33.8 mm, respectively. According to the Genant classification, 18.5% of vertebrae were classified as grade 0, 51.9% as grade 1, 22.2% as grade 2, and 7.4% as grade 3. At L2, mean anterior, middle, and posterior heights were 34.0 mm, 26.9 mm, and 34.9 mm, with 40.8% classified as grade 0 and 59.2% as grades 1–2. For L3, mean heights were 35.3 mm (anterior), 28.2 mm (middle),

and 34.2 mm (posterior), with grade 1 deformities being most prevalent (53.8%). At L4, mean heights were 35.0 mm, 29.6 mm, and 32.6 mm, with 69.2% classified as grade 0. L5 showed the least deformity, with 96.2% classified as grade 0.

Conclusion: The mean TBS value indicates degraded trabecular microarchitecture, whereas the mean BMD value falls within the normal range. Vertebral deformities were most frequently observed at the L1 level, with Genant grade 1 being the most common. Given the increased mechanical load at transitional spinal segments, these findings are consistent with biomechanical expectations.

P835

CHANGES IN BONE AND MINERAL METABOLISM BEFORE AND AFTER KIDNEY TRANSPLANTATION: A SINGLE-CENTRE STUDY IN LATVIA

K. Bozunova[1], I. Skrastina[2], I. Rasa[3], I. Folkmane[4]

[1]Rīga Stradiņš University, Riga East University Hospital, Latvian Osteoporosis and Bone Metabolic Diseases Association, Riga, Latvia; [2]Rīga Stradiņš University, Riga, Latvia; [3]Rīga Stradiņš University, Riga East University Hospital, Latvian Osteoporosis and Bone Metabolic Diseases Association, Riga , Latvia; [4]Rīga Stradiņš University, Pauls Stradiņš Clinical University Hospital, RIGA, Latvia

Objectives: Kidney transplant recipients face increased risks of bone and mineral disorders due to CKD-MBD and immunosuppressive therapy effects. Highlighting these post-transplant metabolic changes aims to inform clinical management and improve patient outcomes.

Materials and Methods: This single-centre observational study included adult patients who underwent kidney transplantation between January 1, 2023 and December 31, 2024. Of 102 transplantations, 96 patients were included in the final analysis. Clinical characteristics, dialysis modality, comorbidities, glucocorticoid use, laboratory parameters, hyperparathyroidism status, parathyroidectomy, and fracture history were analysed before and after transplantation.

Results: The cohort included 96 patients (mean age 50.4±12.9 years; 54.2% male). Before transplantation, 94.8% of patients received dialysis. Arterial hypertension was present in 96.9%, and diabetes mellitus in 8.3%. Secondary or tertiary hyperparathyroidism was observed in 96.9% of patients, and 7.3% had undergone parathyroidectomy. After transplantation, renal function and mineral metabolism significantly improved: serum creatinine and phosphorus decreased, while calcium and vitamin D levels increased, accompanied by a marked reduction in iPTH levels. Persistent hyperparathyroidism was observed in 70.8% of patients, and 4.2% required post-transplant parathyroidectomy. Diabetes mellitus prevalence increased to 33.3%, and 87.5% of patients received long-term oral glucocorticoid therapy. Fractures were present in 13.6% pre-transplantation, while new fractures occurred in 8.4% post-transplantation, emphasising ongoing fracture risk.

Conclusions: Kidney transplantation significantly improved renal function and mineral metabolism; however, issues such as persistent hyperparathyroidism, high glucocorticoid exposure, metabolic comorbidities, and an ongoing risk of fractures emphasise the need for long-term monitoring of bone health in kidney transplant recipients.

P836

FUNCTIONAL BALANCE AND FEAR OF FALLING IN PATIENTS WITH KNEE OSTEOARTHRITIS: A PILOT STUDY

N. Bastaja[1], T. Tasić[1], S. Deležan[1], T. Bjeletić[1], B. Erdeljan[2], T. Janković[1], K. Bošković[1]

[1]University of Novi Sad, Medical Faculty of Novi Sad. Special Hospital for Rheumatic Diseases Novi Sad., Novi Sad, Serbia; [2]Special Hospital for Rheumatic Diseases Novi Sad, Novi Sad, Serbia

Background

Knee osteoarthritis is a degenerative joint disease with increasing prevalence and represents a common cause of pain and functional limitation in older adults. These impairments are often associated with balance deficits and an increased fear of falling, which may further compromise mobility and quality of life. Early identification of balance impairment and fear of falling is essential for optimal rehabilitation planning.

Objective

The aim of this study was to assess balance performance and fear of falling in patients with knee osteoarthritis using the Berg Balance Scale (BBS) and the Falls Efficacy Scale (FES).

Methods

This cross-sectional study included 38 patients diagnosed with knee osteoarthritis who were treated at the Special Hospital for Rheumatic Diseases in Novi Sad, Serbia. Functional balance was assessed using the Berg Balance Scale, while fear of falling was evaluated with the Falls Efficacy Scale. Based on the obtained scores, fall risk and the intensity of fear of falling were analyzed. Statistical analysis was performed using StatSoft Statistica software. The data were obtained from a registry established as part of the project 'Improvement of Diagnostic,Treatment, and Rehabilitation Methods in Special Hospitals of the Cross-Border Area', Identification Numer: HR-RS00005.

Results

The mean age of participants was 71 years, and the majority were women (74%). According to the Berg Balance Scale, 31 patients (81.5%) were classified as having a low risk of falling, 5 patients (13.2%) had a moderate risk, and 2 patients (5.3%) were at high risk of falling. Assessment with the Falls Efficacy Scale showed that 18 patients (47.4%) had low fear of falling, 15 patients (39.5%) had moderate fear, and 5 patients (13.1%) reported a high level of fear of falling. More than half of the participants (52.6%) demonstrated moderate to high fear of falling despite predominantly satisfactory balance performance.

Conclusion

Fear of falling is present in patients with knee osteoarthritis across different levels of objectively assessed balance, including those with low fall risk. The combined use of the Berg Balance Scale and the Falls Efficacy Scale allows a more comprehensive evaluation of functional stability and may contribute to improved planning of individualized rehabilitation interventions.

P837

ASSESSMENT OF DEPRESSIVE SYMPTOMS IN OLDER ADULTS WITH KNEE OSTEOARTHRITIS: A PILOT STUDY

T. Tasić[1], N. Bastaja[1], S. Deležan[1], T. Bjeletić[1], T. Janković[1], J. Zvekić Svorcan[1], K. Bošković[1]

[1]University of Novi Sad, Medical Faculty of Novi Sad. Special Hospital for Rheumatic Diseases Novi Sad., Novi Sad, Serbia

Objective: Patients with gonarthrosis are often limited by pain and function impairment, which significantly affects their daily lives and may lead to depressive symptoms. This study aimed to examine the relationship between depressive symptoms and knee osteoarthritis in adults aged ≥ 65 years.

Materials and Methods: A cross-sectional study was conducted in Special Hospital for Rheumatic Diseases Novi Sad, Republic of Serbia. The data were used from a registry created as part of the project: Improvement of diagnostic, treatment, and rehabilitation methods in special hospitals of the cross-border area, identification number: HR-RS00005. This research included 63 patients aged ≥ 65 years diagnosed with knee osteoarthritis according to clinical and radiographic criteria. Depressive symptoms were assessed using the Short Form of the Geriatric Depression Scale (GDS-SF), where scores from 0-5 indicated the absence of depressive symptoms, 6–9 indicated mild depressive symptoms, and 10–15 indicated moderate to severe depressive symptoms. Data on age, sex, body mass index, sociodemographic characteristics, and level of physical activity were also collected. Statistical analyses were performed using StatSoft Statistica software.
Results: The mean age of the participants was 72.03 years, with 79.36% being female, and 20.63% male. In the majority of patients (84.12%), no depressive symptoms were recorded, while 11.11% exhibited mild signs of depression and 4.76% showed more pronounced symptoms. According to gender, 82% of women showed no depressive symptoms, 12% exhibited mild symptoms, and 6% exhibited more severe symptoms, whereas 92.3% of male participants had no symptoms, and 7.69% had mild depressive symptoms. No significant differences were observed between groups in body mass index, sociodemographic characteristics, or level of physical activity ($p > 0.05$).

Conclusion: Early recognition of depressive symptoms in older adults with knee osteoarthritis may improve overall treatment effectiveness and patient well-being.

P838

SAFETY PROFILE OF ROMOSOZUMAB IN THE OLDEST-OLD (≥85 YEARS): A COMPARATIVE REAL-WORLD PHARMACOVIGILANCE ANALYSIS VS. OLDER ADULTS (65-84 YEARS)

K. Cingar Alpay[1], D. Ozata[1], T. Emiroglu Gedik[1], U. D. Erdincler[1]

[1]Istanbul University-Cerrahpasa, Cerrahpasa Medical School, Department of Internal Medicine, Division of Geriatrics, Istanbul, Türkiye, Istanbul, Türkiye

Objective: Romosozumab is a potent anabolic agent indicated for severe osteoporosis. However, pivotal clinical trials have often underrepresented the "oldest-old" population (≥85 years). Given the drug's boxed warning for cardiovascular risk, understanding its safety in this specific age demographic is critical. This study aimed to evaluate and compare the real-world safety profile of romosozumab in the oldest-old (≥85 years) versus younger geriatric patients (65-84 years) using the FDA Adverse Event Reporting System (FAERS).
Material and Methods: We queried FAERS for romosozumab-related adverse events (AEs) from approval to January 2026, stratifying cases into Older Adults (65-84 years) and Oldest-Old (≥85 years). Disproportionality analysis was performed using Reporting Odds Ratios (ROR) with 95% confidence intervals (CI). Group differences in AEs and fatal outcomes were assessed using Chi-square or Fisher's exact tests.
Results: A total of 4,371 geriatric cases were included in the analysis (n=3,555 aged 65-84; n=816 ≥85); both cohorts were predominantly female (>85%). AE profiles differed distinctively. The 65-84 group frequently reported administration site reactions (pain 5.3%, swelling 2.7%) and fatigue (2.8%). In contrast, the ≥85 group had a higher burden of severe systemic events. Falls were the most frequent AE in the oldest-old (n=124, 15.2%), a twofold increase vs. the younger cohort (ROR 2.06, 95% CI 1.65–2.59). Cardiac Failure was a significant signal in the oldest-old (6.5% vs. 1.9%; ROR 3.56, 95% CI 2.47–5.14). Fatal outcomes were significantly higher in the ≥85 group (15.9% vs 6.6%; ROR 2.68, 95% CI 2.13–3.37).
Conclusion: This analysis reveals age-related differences in romosozumab-associated AEs. While adults aged 65–84 years more frequently reported local administration site reactions, reports from patients aged ≥85 years had significantly higher reporting odds for falls, cardiac failure, and fatal outcomes. Falls were the most commonly reported adverse event in the oldest-old group; however, these observations cannot be interpreted as evidence of causality and may reflect underlying frailty and comorbidity burden in this population. Findings highlight the need for careful cardiovascular risk assessment when prescribing romosozumab to the oldest-old.

P839

MANIFESTATIONS, PROGRESSION, AND TREATMENT IMPACT OF ENZYME REPLACEMENT THERAPY IN ADULTS WITH HYPOPHOSPHATASIA (HPP): A 3-YEAR PROSPECTIVE STUDY

K. Dahir[1], S. Ing[2], D. Lenis[3], G. Lyons[4], E. Rush[5]

[1]Endocrinology and Diabetes, Vanderbilt University Medical Center, Nashville, United States; [2]Division of Endocrinology, Diabetes, and Metabolism, Wexner Medical Center, Ohio State University, Columbus, United States; [3]Health Economics and Outcomes Research, Alexion, AstraZeneca Rare Disease, Barcelona , Spain; [4]Health Economics and Outcomes Research, Alexion, AstraZeneca Rare Disease, Boston, United States; [5]Division of Clinical Genetics, Children's Mercy Kansas City, Kansas City, United States

Objectives To characterize the progression of HPP-related symptoms prior to treatment and assess the impact of enzyme replacement therapy (ERT) on pain and health-related quality of life.
Material and Methods We conducted a longitudinal survey of adults with HPP. Interviews were performed at baseline (prior to ERT initiation) and at 3, 6, 12, and 36 months. Patient-reported outcomes included RAPID3, PHQ-9, WPAI:SHP, PROMIS-29, TSQM and qualitative assessments of symptom chronicity and escalation. Inverse probability of response weighting (IPRW) was implemented to account for attrition bias in loss-to-follow-up. The IPRW modelled the probability of a patient being lost-to-follow-up at each time point *t* that the PROs were measured. Adjustment variables included age, sex, baseline RAPID3 score, and symptom evolution to compute IPRW weights for each participant at each time point to account for potential bias in loss-to-follow-up.
Results Seventy-two adults (mean age 46 years; 83% female) were analysed. The most frequently cited troublesome symptoms included fractures (36%), joint pain (28%), bone pain (21%), and dental issues (22%). Most participants (87%) reported at least one systemic symptom, notably pain (71%), fatigue or cognitive difficulties (50%), and neurological symptoms (e.g. neuropathy, headaches) (22%). Prior to treatment with ERT, nearly 90% reported that at least one of their 3 most troublesome symptoms worsened and 37% indicated that symptoms have increased in frequency or have become chronic over the past five years prior to treatment. At baseline, 65% had high disease activity per RAPID3, 29% had moderate activity, 4% had low activity, and 1% were in remission. At 12 months after ERT initiation, 23% had high disease activity, 37% had moderate activity, 16% had low disease activity, and 24% achieved remission. At 36 months, 14% had high disease activity, 46% had moderate activity, 5% had low activity, and 35% were in remission.
Conclusions Adults with HPP frequently experience chronic musculoskeletal pain, fractures, and systemic manifestations. Prior to treatment initiation, HPP is associated with symptom worsening. In this real-world cohort, ERT was associated with reduced disease activity and higher remission rates at 12 months, with remission proportions increasing at 36 months.

P840

POLYMORPHIC VARIANTS OF THE ADAMTS5 GENE AS MARKERS OF PHENOTYPIC TRAITS OF CONNECTIVE TISSUE DYSPLASIA

K. E. Akhiiarova[1], R. I. Khusainova[2], A. V. Tyurin[2]

[1]Bashkir State medical University, Department of Internal Diseases and Clinical Psychology, Ufa, Russia; [2]Bashkir State medical University,Department of Internal Diseases and Clinical Psychology, Ufa, Russia

Objective(s). Connective tissue dysplasia (CTD) is a hereditary, multifactorial condition characterized by systemic disturbances in the development, maturation, and metabolism of the extracellular matrix. CTD is a significant predictor for the early onset of osteoarthritis, osteoporosis, and other pathologies, necessitating timely diagnosis and preventive interventions.
This study aimed to investigate associations between three polymorphic variants of the *ADAMTS5* and CTD as a whole, as well as with specific CTD phenotypic traits.
Material and Methods. A cross-sectional study was conducted involving 181 subjects (35 males, 19.3%) with a mean age of 21.9±2.9 years. All participants underwent clinical examination to identify CTD signs using the modified Kadurina table (Tyurin AV). Subsequently, molecular genetic analysis was performed. Data were processed using Excel 2024 and GraphPad Prism 8.
Results. Clinical examination identified CTD signs in 130 subjects (71.8%). Comparative analysis of allele and genotype frequencies for *ADAMTS5* loci (rs226794, rs9978597, rs2830585) revealed significant associations. Allele A and genotype AA of rs226794 were associated with internal organ hernias (pFDR=0.015 and pFDR=0.007, respectively). Allele T and genotype TT of rs9978597 were associated with CTD (pFDR=0.003 and pFDR=0.004), skin hyperelasticity (pFDR=0.03 for both), and hypotension (pFDR=0.015 and pFDR=0.02).
Conclusion. The *ADAMTS5* polymorphic variant rs226794 is a risk marker for internal organ hernias, while rs9978597 is a risk marker for CTD, skin hyperelasticity, and hypotension.
Keywords: Connective tissue dysplasia, CTD, ADAMTS5, SNP

GLOBAL DETERMINANTS OF THE OSTEOPOROSIS TREATMENT GAP: A SYSTEMATIC REVIEW

K. Gril Rogina[1], L. Petravić[2], C. Oikonomidis[1]

[1]National Institute of Public Health, Maribor, Slovenia; [2]University Medical Center Maribor, Maribor, Slovenia

Objective: To systematically identify and categorise patient-, physician-, and healthcare system-related factors contributing to the global osteoporosis treatment gap.
Material and Methods: This systematic review was conducted in accordance with PRISMA guidelines. PubMed, Scopus, Web of Science, ScienceDirect, and Europe PMC were searched for original research studies examining osteoporosis treatment gaps in adult populations, including studies published up to 7th April 2025. Risk of bias was assessed using the Newcastle–Ottawa Scale and CASP checklists, as appropriate. Findings were synthesised narratively and categorised by

contributing factors.
Results: Forty-three original studies were included. Reported treatment gap estimates ranged from 38.8% to 94.6% across countries and healthcare settings. Lower treatment rates were associated with patient-related factors such as male sex, lower socioeconomic status, and specific comorbidities, as well as healthcare system-related factors including limited physician awareness, institutional barriers, and inadequate interprofessional communication. Higher treatment rates were associated with older age, family history of osteoporosis, prior diagnosis or bone mineral density testing, and effective care coordination through specialised programmes.
Conclusion: Substantial global gaps in osteoporosis treatment persist, particularly following fragility fractures. These gaps are driven by patient-, physician-, and system-level factors, with consistent disparities related to sex, ethnicity, comorbidities, and socioeconomic status. Addressing these gaps will require integrated care pathways, improved clinical education, and scalable models for coordinated post-fracture management.

REFINING OSTEOPOROSIS CLASSIFICATION USING BMD T-SCORE-ADJUSTED FOR TRABECULAR BONE SCORE (TBS): REAL-WORLD EVIDENCE IN WOMEN AGED ≥40 YEARS

K. Hind[1,2], A. Walstra[2], D. Krueger[3], N. Binkley[3], F. Thimary[4], A. Fahrleitner-Pammer[4], M. Küzma[5], J. Payer[5], K. Chun[6], A. Sherman[6], K. Jones[6], J. Bencardino[6], G. Guglielmi[7], M. Davies[2], M. De Gruttola[2], G. Gatineau[2,8], D. Hans[2,8]

[1]Faculty of Health and Medicine, Lancaster University, Lancaster, United Kingdom; [2]Medimaps Group, Geneva, Switzerland; [3]School of Medicine and Public Health, University of Wisconsin, Wisconsin, United States; [4]Department for Internal Medicine, Medical University Graz, Graz, Austria; [5]Comenius University Faculty of Medicine, University Hospital, Bratislava,, Slovakia; [6]Department of Radiology, Montefiore Medical Center, The University Hospital for Albert Einstein College of Medicine, New York, United States; [7]Department of Clinical and Experimental Medicine, Foggia University School of Medicine, Foggia, Italy; [8]Interdisciplinary Centre of Bone Diseases, Bone and Joint Department, Lausanne University Hospital (CHUV) & University of Lausanne, Lausanne, Switzerland

Objectives: Trabecular bone score (TBS), derived from DXA, is a validated surrogate of bone microarchitecture and is routinely integrated into clinical DXA workflows. Adjustment of BMD T-scores for TBS is an established function of TBS software in women, enabling incorporation of microarchitectural information into standard osteoporosis classification. In light of recent regulatory decisions recognising DXA-derived BMD as an accepted imaging endpoint in osteoporosis clinical trials, refinement of BMD-based classification using complementary measures such as TBS is of increasing relevance. This study quantified the impact of BMD T-score adjustment using TBS version 4 on osteoporosis classification in women aged ≥40 years in real-world clinical populations.
Methods: Reclassification analyses were performed in 14,640 women aged ≥40 years from international, multi-ethnicity real-world clinical cohorts in the USA and Europe. Osteoporosis categories (normal, osteopenia, osteoporosis) were defined using BMD T-scores alone and after adjustment for TBS (TBS Osteo Advanced, version 4). Analyses were conducted using site-specific BMD (total hip, femoral neck, lumbar spine) and the minimum BMD T-score. Diagnostic category shifts were assessed overall and by age group and summarised using the net reclassification index (NRI).
Results: Adjustment of BMD T-scores for TBS resulted in consistent upward reclassification of bone fragility across skeletal sites and age groups. Overall, 4,996 women (34%) were classified as osteoporotic using BMD alone, increasing to 6,494 women (44%) following TBS v4 adjustment (NRI +11%). Reclassification demonstrated a clear age gradient, with the largest effect in women aged 40–44 years (NRI +28%) and progressively smaller effects with advancing age; a modest net downward reclassification was observed only in women aged ≥85 years (NRI −2.0%). Upward reclassification was primarily driven by transitions from osteopenia to osteoporosis (1,696 women; 12%), while downward reclassification from osteoporosis to osteopenia was uncommon (209 women; 1%). By skeletal site, osteoporosis prevalence increased from 15% to 21% at the total hip, from 21% to 30% at the femoral neck, and from 22% to 34% at the lumbar spine.
Conclusions: BMD T-score adjustment using TBS v4 resulted in clinically meaningful reclassification of osteoporosis in women aged ≥40 years, predominantly from osteopenia to osteoporosis. Effects were consistent across skeletal sites and most pronounced at the lumbar spine, with the largest reclassification observed in women aged 40–44 years. These findings support the complementary use of TBS v4 with BMD to refine osteoporosis classification and may facilitate earlier identification of women at higher fracture risk.

P844

CLINICAL AND ECONOMIC IMPACT OF TRABECULAR BONE SCORE (TBS) IN OSTEOPOROSIS MANAGEMENT

F. Borgström[1], J. Kanis[2], K. Hind[3,4], Z. Németh[1], M. Davies[4], D. Hans[4,5]

[1]Quantify Research, Stockholm, Sweden; [2]Centre for Metabolic Bone Diseases, University of Sheffield, Sheffield, United Kingdom; [3]Faculty of Health and Medicine, Lancaster University, Lancaster, United Kingdom; [4]Medimaps Group, Geneva, Switzerland; [5]Interdisciplinary Centre of Bone Diseases, Bone and Joint Department, Lausanne University Hospital (CHUV) & University of Lausanne, Lausanne, Switzerland

Objective: Osteoporosis is associated with substantial clinical and economic burden due to fragility fractures leading to pain, disability, and increased mortality. Trabecular bone score (TBS) is a validated index of bone microarchitecture derived from DXA and used alongside bone mineral density (BMD), to improve the identification of individuals at increased fracture risk. TBS also enhances fracture risk prediction when incorporated into tools such as FRAX®. This study evaluated the cost-effectiveness of adding TBS to FRAX® with BMD in osteoporosis management within a Scandinavian healthcare setting.
Methods: A patient level state transition Markov cost-effectiveness model was developed. The model comprised 10 health states, including fracture-specific and post-fracture states and death. Individual patient characteristics were drawn from a population-based UK cohort (n = 50,366) constructed to reflect the age distribution and prevalence of FRAX® clinical risk factors in the general population. These characteristics

defined individual risk profiles, while fracture probabilities, costs, and health outcomes were parameterised to reflect the Swedish healthcare setting using the country-specific FRAX® algorithm. Fracture risk estimation incorporated both short-term imminent risk following sentinel fractures and long-term fracture probabilities derived from FRAX® with BMD alone or FRAX® adjusted for TBS. Cost-effectiveness outcomes were compared for FRAX® + TBS versus FRAX® alone.

Results: Incorporation of TBS into FRAX®-based risk assessment was cost-saving compared with FRAX® alone, resulting in lower healthcare costs and higher quality-adjusted life years (QALYs). In the target population defined as individuals within ±5% of the FRAX® 10-year major osteoporotic fracture intervention threshold, FRAX® + TBS was associated with an incremental cost reduction of 2,228 SEK and a gain of 0.006 QALYs per patient.

At the population level, this corresponds to 60 QALYs gained per 10,000 individuals and total cost savings of around €2.0 million, equivalent to approximately −€33,000 per QALY gained. These results were driven by improved risk reclassification at the intervention threshold, with a NRI of 11.8% and nearly one-third of individuals near the threshold reclassified from no treatment to treatment when TBS was incorporated. Cost-saving findings were robust across sensitivity analyses varying age, fracture history, T-score thresholds, eligibility criteria, and the unit cost of TBS, and remained cost-saving when applied to the full population cohort.

Conclusions: Incorporation of TBS into FRAX®-based fracture risk assessment can improve health outcomes while reducing healthcare costs compared with FRAX® using BMD alone. By improving risk classification at treatment thresholds, TBS enables more efficient allocation of osteoporosis therapy without increasing patient burden. These results support adoption of TBS-adjusted FRAX® as a standard component of osteoporosis risk assessment in clinical and policy decision-making.

P845

ASSOCIATIONS BETWEEN MODIFIABLE LIFESTYLE FACTORS AND INCIDENT FRACTURE OVER TEN YEARS OF FOLLOW-UP: DATA FROM THE GEELONG OSTEOPOROSIS STUDY

K. Anderson[1], D. Hakamuwa Lekamlage[1], L. Williams[1], K. Holloway-Kew[1], A. Suleiman[1], J. Pasco[1,2,3,4]

[1]Deakin University, IMPACT (Institute for Mental and PHysical Health and Clinical Translation), Geelong, Australia; [2]Barwon Health, Geelong, Australia; [3]Department of Medicine-Western Health, The University of Melbourne, St Albans, Australia; [4]Department of Epidemiology and Preventative Medicine, Monash University, Melbourne, Australia

Objective

Absolute fracture risk is used to determine intervention thresholds and guide treatment. However, many factors involved in its computation are not modifiable, precluding individuals from pro-active involvement in preventative health care. This study aimed to develop a best-fit model of modifiable factors that could be identified and acted upon by an individual.

Material and Methods

This study included 1126 women and 978 men from the Geelong Osteoporosis Study. Fragility fractures of all bones excluding skull and digits were identified by radiological review and participants followed up for 10 years unless censored by event (first fracture) or death. Missing predictor data were handled using multiple imputation by chained equations. Three variable-selection approaches were compared to identify the best-fitting Cox proportional hazards model: stepwise selection using the Akaike Information Criterion (AIC), regularized least absolute shrinkage and selection operator (LASSO) regression, and univariable screening. Candidate predictors included measured (body mass index, waist circumference, timed-up-and-go (TUG) test, gait speed, blood pressure, cholesterol, fasting blood glucose) and self-reported (medication use, mobility, self-rated health, current smoking, calcium deficiency, alcohol intake, falls, sun exposure, poor sleep, pain, anxiety, depression) variables. All analyses were conducted using R 4.4.1.

Results

The StepAIC-based model demonstrated slightly better performance (pooled C-index=0.731), with lower AIC and BIC values across all imputed datasets. The final model included age (HR:1.04, 95%CI 1.03-1.05), BMI (0.94, 0.90-0.98), male sex (0.49, 0.36-0.67), better self-rated health (0.73, 0.53-1.02), oral glucocorticoid use (2.10, 0.98-4.51), antifracture medication use (1.62, 0.99-2.66), summer sun exposure (1.28, 0.99-1.65), high density lipoprotein cholesterol (1.68, 1.16-2.46), waist circumference (1.02, 1.00-1.04), gait speed (1.45, 0.91-2.29) and TUG (1.03, 1.00-1.05).

Conclusion

These data suggest that individuals may be able to reduce their fracture risk, even if only marginally, through careful consideration of summer sun exposure, medication use, cholesterol, reducing waist circumference and improving mobility.

P846

EFFICACY OF THE VDMT TECHNIQUE IN NEUROMA PREVENTION AND IMPROVED PROSTHETIC MOBILITY AFTER MINE-EXPLOSION–RELATED AMPUTATIONS

O. Burianov[1], K. Honchar[1], O. Smyk[1], M. Pasenko[1], Y. Sobolevskiy[1]

[1]Bogomolets National Medical University, Kyiv, Ukraine

Background: Mine-explosion–related amputations remain a major medical and social problem, particularly in military and post-conflict populations. A frequent late complication is symptomatic neuroma formation causing residual limb pain (RLP) and phantom limb pain (PLP), which significantly impair prosthetic use and patient independence. Conventional nerve management, including distal nerve resection, often fails to prevent recurrence. The Vascularized Denervated Muscle Target (VDMT) technique has been proposed as a physiological method for peripheral nerve implantation to reduce neuroma formation.

Methods: A prospective randomized study (2022–2025) included 50 patients (mean age 34.7 ± 6.8 years) with transfemoral or transtibial amputations after mine-explosion injuries. All patients had chronic pain (VAS ≥ 6) and ultrasound-confirmed neuromas. Patients were randomized into a VDMT group (n = 25) or a control group treated with distal nerve resection (n = 25). Pain intensity (VAS) and prosthetic mobility using the Locomotor Capabilities Index (LCI-5) were assessed preoperatively and at 3, 6, and 12 months.

Intervention: In the VDMT group, severed nerves were implanted into a vascularized, denervated muscle segment. Controls underwent standard distal nerve resection. All patients received standardized rehabilitation and prosthetic fitting. Follow-up included ultrasound evaluation for neuroma recurrence and LCI-5 assessment.

Results: Baseline VAS scores were comparable (7.84 ± 0.98 vs. 7.76

± 1.12). At 12 months, pain was significantly lower in the VDMT group (2.36 ± 0.67 vs. 5.42 ± 1.01; p < 0.001); minimal pain (VAS ≤ 2) was observed in 80% versus 20% of controls. LCI-5 improved from 24.1 ± 3.9 to 47.6 ± 4.2 in the VDMT group and from 23.7 ± 4.1 to 33.8 ± 5.6 in controls (p < 0.01). Independent prosthetic ambulation was achieved in 84% versus 32%. Neuroma recurrence occurred in 4% of VDMT patients and 44% of controls.

Conclusion: VDMT provides superior pain control, prevents neuroma recurrence, and significantly improves prosthetic mobility compared with distal nerve resection in mine-explosion–related lower limb amputations.

Keywords: amputation, VDMT, neuroma prevention, prosthetic mobility, LCI-5, residual limb pain, phantom limb pain

TRENDS IN FRACTURE INCIDENCE AND FRACTURE PROGNOSTIC VALUE OF A BASELINE FEMORAL NECK (FN) BMD MEASUREMENT: THE ROTTERDAM STUDY (1989-2019)

K. Huininga[1], F. Koromani[1], K. Trajanoska[1], N. Harvey[2], J. A. Kanis[3], H. Johansson[3], E. V. McCloskey[3], M. C. Zillikens[1], E. F. van Velsen[1], F. Rivadeneira[1]

[1]Department of Internal Medicine, Erasmus University Medical Center, Rotterdam, Netherlands; [2]MRC Lifecourse Epidemiology Centre, University of Southampton, Southampton, United Kingdom; [3]Centre for Metabolic Bone Diseases, University of Sheffield, Sheffield, United Kingdom

Objectives

Evaluate long-term trends in fracture incidence during three decades of follow-up (FUP) in a population-based setting; describe skeletal location patterns; and evaluate the prognostic value of a baseline femoral neck (FN) BMD measurement.

Material and Methods

Participants aged >45 years from the Rotterdam Study (N=14,465) were included at baseline. Fractures between 1989-2019 were identified through hospital and general practitioner records comprising 220,000 person-years (mean FUP 14.3, SD 7.2 years). Incidence rates (IRs) per 1,000 person-years were estimated and compared across three decades (1989–2000, 2000–2010 and 2010–2019) using Poisson regression. Patterns of fracture co-occurrence across sites – humerus, spine, hip wrist– were evaluated. Hazards ratios (per unit decrease in FN T-score) were obtained from Cox models adjusted for age, sex, BMI and subcohort; and stratified by: less than 10; between 10 and 20; and above 20 years FUP time.

Results

Of 4,563 participants with fractures, 19.5% sustained (non-simultaneous) fractures at multiple sites (Figure). The most frequent fracture sites (IR per 1000 years) were spine (IR 5.58), hip (IR 4.35), and wrist (IR 3.88). As compared to 1989–2000, fractures incidence in 2010-2019 declined for hip (IRR 0.33, 95%CI 0.21–0.5) and wrist (IRR 0.25, 95%CI 0.16–0.37), but increased for spine (IRR 2.44, 95%CI 1.82-3.32). A baseline FN BMD T-score was associated with increased hip fracture risk within 10 (HR 1.43 95% CI 1.26-1.59); between 10 and 20 (HR 1.36 95% CI 1.32–1.45); and after 20 (HR 1.26 95% CI 1.18–1.35) years of FUP.

Conclusions

Fracture incidence patterns across three decades have seen a decline of 67 to 75% in hip and wrist, respectively; and ~2.4 fold rise in spine. A single FN BMD remained associated with hip fracture risk across all decades, supporting its long-term prognostic relevance despite attenuation over time.

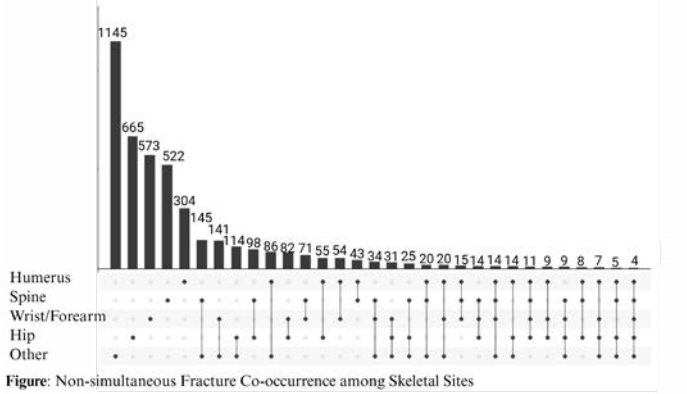

Figure: Non-simultaneous Fracture Co-occurrence among Skeletal Sites

P848

LONG-TERM EVALUATION OF HIP FRACTURE RISK USING FRAX - WITH AND WITHOUT BMD: THE ROTTERDAM STUDY (1989-2019)

K. Huininga[1], F. Koromani[1], K. Trajanoska[1], N. Harvey[2], J. A. Kanis[3], H. Johansson[3], M. C. Zillikens[1], E. F. van Velsen[1], F. Rivadeneira[1]

[1]Department of Internal Medicine, Erasmus University Medical Center, Rotterdam, Netherlands; [2]MRC Lifecourse Epidemiology Centre, University of Southampton, Southampton, United Kingdom; [3]Centre for Metabolic Bone Diseases, University of Sheffield, Sheffield, United Kingdom

Objectives

Evaluate FRAX-based predictive discrimination for hip fractures, with and without inclusion of femoral neck BMD; age-specific performance and risk reclassification relative to fracture probabilities intervention thresholds in a population-based setting.

Material and Methods

Rotterdam Study participants (N=14,465) aged >45 years were included at baseline. Fractures between 1989-2019 were identified through general practitioner and hospital records during a mean follow-up (FUP) of 14.3 years (SD 7.2). Ten-year hip probabilities were calculated using (Dutch) FRAX, *with* and *without BMD*. Predictive discrimination for hip fractures was assessed using AUCs, overall and stratified by age group, at both 10 and upto 30 years FUP. Reclassification between FRAX models was based on UK NOGG risk categories.

Results

Ten-year AUCs for hip fractures for FRAX -without BMD was 0.81 (95%CI 0.79-0.83) and *-with BMD* 0.80 (95%CI 0.77-0.82); and >10 years AUC for FRAX *-without BMD* was 0.75 (95%CI 0.73-0.77) and -with BMD 0.76 (95%CI 0.74-0.77). Overall agreement between FRAX models declined with age, with 93% in subjects <65, 89% in 65–74, 67.6% in 75–84, and 51.2% in ≥85 years old. Inclusion of BMD resulted in 2.3% downward and 4.6% upward reclassification in those <65, 5.8% downward and 5.0% upward reclassification in those aged 65–74, 29.4% downward and 3.0%

upward reclassification in those aged 75–84, and 47.2% downward and 1.6% upward reclassification in those aged ≥85 years old.

Conclusions

FRAX demonstrated good discrimination for hip fracture risk at 10 years. Modest attenuation was observed after longer follow-up. Inclusion of FN BMD had little impact on overall discrimination, but substantially influenced age-specific intervention thresholds, particularly in older age groups. Pronounced downward reclassification after BMD inclusion may reflect survival selection in older individuals with better bone health; where inclusion of measured BMD shifts risk estimates below intervention thresholds.

P849

THE SINTER STUDY: A RECALL-BY-GENOTYPE DESIGN WITH MULTIDIMENSIONAL MUSCULOSKELETAL PHENOTYPING ACROSS INTERNAL-MEDICINE OUTPATIENT CLINICS

F. Koromani*[1], K. Huininga*[1], S. Li[1], K. Trajanoska[1], K. Berk[1], M. Boon[1], L. Chaker[1], P. van Daele[1], J. Hofland[1], M. van Hoek[1], M. Hemmelder[1], J. Roeters van Lennep[1], M. Medici[1], J. Olieman[1], B. Ozcan[1], R. Peters[1], F. Mattace-Raso[1], E. Mulugeta[1], E. F. C. van Rossum[1], J. van Rooij[1], A. Uitterlinden[1], W. Visser[1], E. F. van Velsen[1], M. C. Zillikens[1], F. Rivadeneira[1]

[1]Department of Internal Medicine, Erasmus University Medical Center, Rotterdam, Netherlands

Objectives

We describe the design of the EraSmus medIcal CeNTer skEletal fRagility (SINTER) Study, an observational clinical study integrating polygenic risk stratification with advanced musculoskeletal imaging and functional phenotyping to improve characterisation of skeletal fragility in chronic conditions.

Methods and Materials

SINTER is conducted across nine internal medicine outpatient clinics in two stages. First, 5,650 patients undergo genotyping. Second, ~1,500 individuals from the extremes of the polygenic score for bone mineral density (PGSBMD), plus 400 patients with mastocytosis are recalled for musculoskeletal phenotyping. Imaging includes DXA, EOS Edge imaging for three-dimensional spinal alignment and global biomechanics, and peripheral quantitative computed tomography for volumetric density and microarchitectural assessment. Skeletal material and tissue-level properties are assessed using quantitative ultrasound and reference point indentation. Muscle function and physical performance are evaluated using mechanography and handgrip strength. Lifestyle data are extracted from questionnaires, alongside patient-reported outcomes and perceptions related to musculoskeletal health. To validate the RbG design, simulation analyses were performed in the population-based Rotterdam Study, comparing clinical and skeletal characteristics between individuals selected from low and high extremes of the PGSBMD distribution.

Results

Ethical approval has been obtained, and recruitment is ongoing. In the Rotterdam Study, selection based on PGSBMD extremes, results in the expected separation in femoral neck BMD and osteoporotic fracture prevalence, while clinical and lifestyle characteristics remain well balanced, supporting the randomisation properties of the RbG approach (Table).

Conclusions

SINTER establishes a clinically embedded research framework that integrates genetic information with advanced musculoskeletal imaging and functional assessment. Validation in an independent population-based cohort demonstrates that RbG stratification based on polygenic scores achieves randomisation-like balance of clinical characteristics while enriching for skeletal fragility phenotypes, supporting its use for mechanistic musculoskeletal research.

Table. Characteristics of the study population compared between low and high BMD wPGS.

	Low BMD wPGS n=666	High BMD wPGS n=666	P-value
wPGS BMD (SD)	4.67 (0.13)	5.72 (0.14)	<0.001

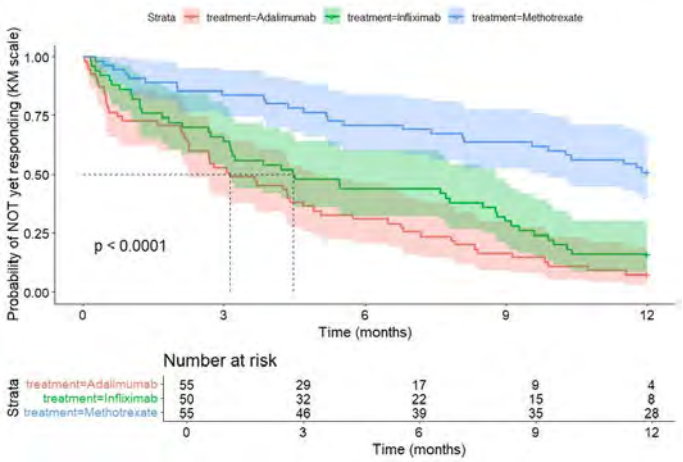
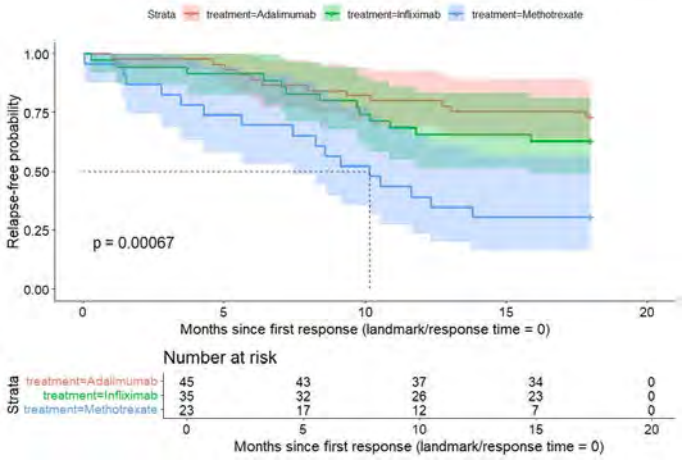
DYNAMICS OF TREATMENT RESPONSE, RETENTION, AND RELAPSE IN RHEUMATOID ARTHRITIS TREATED WITH BIOLOGIC DMARDS

M. S. Ravshanova[1], K. I. Ibragimov[1], S. K. Ziyadullayev[2]



[1]Samarkand State Medical University, Samarkand , Uzbekistan; [2]Kimyo International University in Tashkent, Samarkand, Uzbekistan

Objectives. I this study we aimed to compare time to initial clinical response, treatment retention, and relapse-free survival among patients with RA treated with adalimumab, infliximab, or methotrexate.



Results. Time to initial clinical response differed significantly between treatment groups (log-rank p<0.0001). At 3 months, response was achieved by 27/55 patients (49.1%) receiving adalimumab, 19/50 (38.0%) receiving infliximab, and 11/55 (20.0%) receiving methotrexate. At 6 months, cumulative response increased to 38/55 (69.1%), 27/50 (54.0%), and 19/55 (34.5%), respectively.

By 12 months, response was observed in 50/55 patients (90.9%) treated with adalimumab, 42/50 (84.0%) with infliximab, and 28/55 (50.9%) with methotrexate. Treatment retention over 24 months also differed significantly (log-rank p<0.0001). At 12 months, retention was maintained in 41/55 patients (74.5%) receiving adalimumab, 39/50 (78.0%) receiving infliximab, and 26/55 (47.3%) receiving methotrexate. At 24 months, retention declined to 33/55 (60.0%), 32/50 (64.0%), and 14/55 (25.5%), respectively.

Among patients who achieved an initial clinical response, relapse-free survival differed significantly between groups (log-rank p=0.00067). At 12 months after response, relapse-free survival was maintained in 28/35 responders (80.0%) treated with adalimumab, 17/25 (68.0%) treated with infliximab, and 9/20 (45.0%) treated with methotrexate.

At 18 months, relapse-free survival decreased to 26/35 (74.3%), 15/25 (60.0%), and 6/20 (30.0%), respectively.

Conclusions. Biologic DMARDS outperformed methotrexate across three complimentary time-to-event outcomes including response initiation, treatment retention, and duration of response. Adalimumab had the most advantageous overall profile by facilitating a more rapid clinical response, ensuring enhanced treatment persistence, and offering superior relapse-free survival.

P851

CONTINUATION RATE AND BONE MINERAL DENSITY RESPONSE TO ROMOSOZUMAB IN PATIENTS WITH RHEUMATOID ARTHRITIS: A REAL-WORLD STUDY

K. Kaoru[1], T. Tomonori[1], Y. Yoshiko[1]

[1]Kobayakawa Orthopedics and Rheumatology Clinic, Fukuroi, Japan

Objective:
Patients with rheumatoid arthritis (RA) are at increased risk of osteoporosis and fractures due to chronic inflammation and glucocorticoid exposure. Romosozumab has been shown to improve bone mineral density (BMD) and reduce fracture risk; however, real-world data in RA patients remain limited. This study compared 12-month continuation rates and BMD changes between RA and non-RA patients treated with romosozumab in routine clinical practice.

Material and Methods:
We retrospectively analyzed 331 patients who initiated romosozumab at a single outpatient clinic between January 2021 and January 2023. Patients were categorized into RA and non-RA groups. The primary outcome was 12-month treatment continuation rate. Secondary outcomes included percentage change in BMD at the lumbar spine (LS), total hip (TH), and femoral neck (FN) among patients completing 12 months. BMD was measured by dual-energy X-ray absorptiometry (DXA). Mann–Whitney U and Wilcoxon signed-rank tests were used, with significance set at p<0.05.

Results:
The RA group included 22 patients (mean age 75.4 years; 100% female; BMI 24.47 kg/m²; glucocorticoid use 27.3%). The non-RA group included 222 patients (mean age 77.1 years; 92.3% female; BMI 25.02 kg/m²; glucocorticoid use 1.4%). Baseline BMD (RA vs non-RA) was 0.735 vs 0.706 g/cm² at LS, 0.575 vs 0.611 at TH, and 0.569 vs 0.578 at FN. One-year BMD changes were 11.6% vs 14.2% (LS), 1.7% vs 3.8% (TH), and 1.9% vs 3.6% (FN), with no significant differences. The 12-month continuation rate was significantly higher in the RA group than in the non-RA group (84.6% vs 75.1%, p=0.00195). Both groups demonstrated significant BMD increases from baseline.

Conclusion:
Romosozumab demonstrated favorable adherence and clinically meaningful BMD gains in RA patients, comparable with non-RA patients. Higher continuation in the RA cohort may reflect structured follow-up and multidisciplinary care typical in RA management. Tailored adherence strategies within rheumatology practice may further optimize outcomes in high-risk patients.

P852

A RARE CASE OF MULTIPLE CRANIAL NERVE PALSIES IN A YOUNG MALE WITHOUT RADIOLOGICAL CORRELATE

K. Kour[1]

[1]AIIMS , VIJAYPUR ,JAMMU, JAMMU, India

Multiple cranial nerve palsies presenting simultaneously are rare and usually suggest serious central nervous system, infectious, or infiltrative pathology. Autoimmune etiologies are uncommon but increasingly recognized causes. We report a rare case of multiple cranial nerve palsies in a young male with no radiological correlate and an elevated rheumatoid factor, raising suspicion of autoimmune cranial neuropathy.
A 26-year-old male presented with acute onset bilateral lower motor neuron facial weakness, diplopia, dysphagia, dysphonia, and difficulty in chewing. Neurological examination revealed involvement of cranial nerves V, VI, VII, IX, and X, with preserved consciousness, normal limb power, intact reflexes, and absence of long-tract or cerebellar signs. Comprehensive laboratory evaluation showed mild neutrophilic leukocytosis with normal inflammatory markers. Cerebrospinal fluid analysis was unremarkable with normal biochemistry, minimal lymphocytic cells, and sterile cultures. Neuroimaging, including contrast-enhanced MRI of the brain and NCCT, revealed no structural lesions or meningeal enhancement. Serological testing demonstrated a significantly elevated rheumatoid factor without clinical evidence of articular involvement.
Differential diagnoses considered included infective cranial neuritis, post-infectious inflammatory neuropathy, Guillain–Barré syndrome variants, sarcoidosis, skull base pathology, and idiopathic cranial polyneuropathy. In the absence of supportive radiological or cerebrospinal fluid findings, an autoimmune cranial neuropathy possibly related to underlying rheumatoid arthritis was considered. The patient was managed conservatively with supportive care, eye protection, nutritional support, physiotherapy, and neurovitamin supplementation. Corticosteroids were deferred due to lack of definitive inflammatory evidence.
At two-week follow-up, partial improvement in facial movements and swallowing was observed, with stable residual bulbar symptoms.
This case highlights the diagnostic challenge posed by multiple cranial nerve palsies with normal imaging and emphasizes the importance of considering autoimmune mechanisms, including rheumatoid arthritis–associated neuropathy, even in the absence of classical systemic manifestations. A structured diagnostic approach and supportive management with close follow-up remain essential in such cases.

P853

DOES ROUTINE DOPPLER SONOGRAPHY IMPROVE THE DETECTION AND CLINICAL OUTCOME RELATED WITH DEEP VEIN THROMBOSIS AFTER TOTAL KNEE ARTHROPLASTY? : A REAL-WORLD COMPARISON OF TWO CLINICAL PATHWAYS?

K. Kwangkyoun[1], P. Parag[2]

[1]Konyang University Hospital/department of Orthopedic surgery, Daejeon, South Korea; [2]Malabar Medical College & Research Centre, Kozhikode, India

Background: Deep vein thrombosis (DVT) and pulmonary embolism (PE) are well known to be very serious complications that occur frequently after TKA. Furthermore, not only appropriate treatment, but also efforts to detect and prevent these complications can become legal issues in medical disputes. While routine Doppler screening can detect asymptomatic DVT, the benefit of these finding is uncertain. This study aimed to (1) compare the detection of DVT between routine Doppler sonography and symptom-guided imaging, (2) determine the association of symptoms with diagnostic yield, and (3) assess whether screening for PE is necessary in patients diagnosed with DVT or vice versa.
Patients and Methods: A retrospective cohort of 582 patients undergoing primary TKA (2017–2021) was analyzed. In clinical pathway 1 (CP1, n=282), routine bilateral Doppler sonography was performed on postoperative day 6. In clinical pathway 2 (CP2, n=300), Doppler sonography was only performed if symptoms or indicators were present, as indicated by our institution's modification of the Wells criteria. In both pathways, computed tomography (CT) pulmonary angiography was performed for all patients with confirmed DVT, and Doppler sonography was performed for all patients with confirmed PE. All patients received standardized thromboprophylaxis. All patients were evaluated for readmissions within 90 days.
Results: DVT was diagnosed in 6 patients (2.1%) in CP1 and 1 patient (0.3%) in CP2 (OR 6.5, 95% CI 0.78–54.3; P=0.061). Pulmonary embolism (PE) diagosed in 8 patients (2.8%) in CP1 and 4 patients (1.3%) in CP2 (OR 2.16, 95% CI 0.64–7.26; P=0.202). Clinical symptoms or signs significantly increased the diagnostic yield for PE (OR 15.1, 95% CI 3.93–57.7; P<0.001), but not for DVT (OR 1.93, 95% CI 0.22–16.9; P=0.451). In 7 patients diagnosed with DVT, three patients (two in CP1 and one in CP2) were subsequently found to have PE, despite the absence of PE-related symptoms or signs. Notably, none of the 12 patients diagnosed with PE had no concurrent DVT. No readmissions for thromboembolic events occurred within 90 days after discharge.
Conclusions: Routine Doppler sonography in asymptomatic patients is not improve the detection and clinical outcome related with DVT following TKA. Clinical symptoms or signs were more strongly associated with PE than with DVT. Doppler sonography is required to detect DVT in patients with confirmed PE, while routine CT pulmonary angiography in case of DVT is not recommended.

P854

BICARBONATE CONCENTRATION IS ASSOCIATED WITH LOWER BONE MINERAL DENSITY AT THE FEMORAL NECK AND MID-FOREARM IN WOMEN

K. L. Holloway-Kew[1], K. B. Anderson[1], M. A. Kotowicz[1], W.-H. Liao[2], M. Henneberg[3], J. A. Pasco[1]

[1]Deakin University, Geelong, Australia; [2]MacKay Memorial Hospital, Taipei, Taiwan; [3]Adelaide University, Adelaide, Australia

Objective(s)

Bone undergoes constant remodelling, influenced by many factors, including acid/base balance. This study examined associations between bicarbonate, a major contributor to acid-base balance, and bone mineral density (BMD).

Material and Methods

Participants (n=873, age 21-93yr) were women from the Geelong Osteoporosis Study. Bicarbonate concentrations were measured in fasting blood samples. BMD was measured at the femoral neck, lumbar spine, ultra-distal forearm and mid-forearm using a Lunar DPX-L densitometer.

Linear regression was used to examine cross-sectional associations between serum bicarbonate values and BMD, adjusting for anthropometric variables, lifestyle factors, medical conditions and medication use (menopausal hormone therapy, aspirin, nonsteroidal anti-inflammatory drugs, diuretics). Participants taking glucocorticoids or bisphosphonates were excluded. Analyses were stratified by the median age (52 years) due to a bicarbonate*age interaction term.

Results

For participants aged <52yr, higher bicarbonate was associated with lower BMD T scores at the femoral neck (adjusted coefficient; 95%CI: -0.188; -0.351, -0.024, p=0.024) and mid-forearm (-0.050; -0.089, -0.011, p=0.012).

Results were similar for participants aged ≥52yr, where the effect was more pronounced. Higher bicarbonate was associated with lower BMD T scores at the femoral neck (-0.964; -1.692, -0.235, p=0.010) and mid-forearm (-0.121; -0.173, -0.069, p<0.001).

No associations were found at other sites.

These novel results may be explained by differences in sample characteristics; women with higher bicarbonate (≥27mmol/L, n=311) were older, more likely to have a prior fracture, to be taking aspirin or diuretics, and had lower kidney function. Additionally, mean bicarbonate concentration was different between the two age groups (<52yr: 24.8±2.5 mmol/L vs ≥52yr: 26.1±2.8, p<0.001).

Conclusion(s)

In women, higher bicarbonate was associated with lower BMD at the femoral neck and mid-forearm, which contrasts with the few previous studies on this topic (1,2,3). This may be due to differences between groups or statistical methods.

P855

BICARBONATE CONCENTRATION IS ASSOCIATED WITH HIGHER VALUES FOR A MARKER OF BONE RESORPTION IN WOMEN

K. L. Holloway-Kew[1], K. B. Anderson[1], M. A. Kotowicz[1], W.-H. Liao[2], M. Henneberg[3], J. A. Pasco[1]

[1]Deakin University, Geelong, Australia; [2]MacKay Memorial Hospital, Taipei, Taiwan; [3]Adelaide University, Adelaide, Australia

Objective(s)

Bone remodelling can be disturbed by factors such as mechanical loading, hormones and acid-base balance. This study examined associations between bicarbonate, a contributor to acid-base balance, and markers of bone turnover.

Material and Methods

Participants (n=873, age 21-93yr) were women drawn from the Geelong Osteoporosis Study. Fasting blood samples were analysed for bicarbonate concentration, C-terminal telopeptide (CTx, bone resorption) and procollagen type I N-propeptide (P1NP, bone formation). CTx and P1NP values were non-parametric and transformed using natural logarithms prior to analyses.

Cross-sectional associations between serum bicarbonate concentration and CTx or P1NP were examined using linear regression, adjusting for lifestyle variables, medical conditions, anthropometric measurements and medication use (menopausal hormone therapy, aspirin, nonsteroidal anti-inflammatory drugs, diuretics). Participants taking glucocorticoids or bisphosphonates were excluded. The association between age and CTx/P1NP was non-linear, and thus a cubic age term was included in the models. Analyses were stratified by the median age (52yr) due to a bicarbonate*age interaction term.

Results

For women aged <52yr, in unadjusted analyses, increasing bicarbonate concentrations were associated with greater values for CTx (coefficient; 95%CI: 0.024; 0.007, 0.040, p=0.005), but not P1NP (0.014; -0.001, 0.028, p=0.065). Following adjustment, the association with CTx was sustained (0.026; 0.011, 0.040, p=0.001), and the result for P1NP remained non-significant (0.009, -0.005, 0.023, p=0.202).

Among women aged ≥52yr, results were similar, greater bicarbonate concentrations were associated with higher values for CTx (0.020; 0.006, 0.034, p=0.006), but not P1NP (0.011; -0.002, 0.024, p=0.109). After adjustment, the associations were explained for CTx (0.005; -0.009, 0.019, p=0.474) and P1NP remained non-significant (0.006; -0.007, 0.018, p=0.387).

Conclusion(s)

Among women aged <52yr, higher bicarbonate concentrations were associated with higher values for the bone resorption marker CTx. No associations were observed for the bone formation marker P1NP.

P856

ASSESSING FRACTURE RISK IN SARCOPENIC TYPE 2 DIABETES (T2DM) PATIENTS: A CROSS-SECTIONAL STUDY IN A TERTIARY CARE HOSPITAL

K. Laoticharoen[1], P. Phudphong[1], N. Adulkasem[2]

[1]Division of Endocrinology and Metabolism, Department of Medicine, Faculty of Medicine, Vajira Hospital, Navamindradhiraj University, Bangkok, Thailand; [2]Department of Orthopedics Surgery, Faculty of Medicine, Siriraj Hospital, Mahidol University, Bangkok, Thailand

Objectives

Sarcopenia, characterized by reduced skeletal muscle quantity and quality, is frequently observed in individuals with type 2 diabetes mellitus (T2DM). Both conditions are independently associated with an increased risk of fragility fractures. However, the relationship among T2DM, sarcopenia, and fragility fracture risk remains unclear. This study aimed to compare fracture risk between T2DM patients with and without sarcopenia and to examine factors associated with sarcopenia.

Material and Methods

We conducted a cross-sectional study involving 250 adults with T2DM. Sarcopenia was diagnosed according to the Asian Working Group for Sarcopenia (AWGS) 2025 criteria. Ten-year probabilities of major osteoporotic and hip fractures were estimated using the Thai FRAX® tool. Demographic data, anthropometric measurements, basal metabolic rate (BMR), diabetes-related variables, laboratory parameters, and medication use were collected. Univariable and multivariable logistic regression analyses were performed to determine factors independently associated with sarcopenia.

Results

Sarcopenia was identified in 48.4% of participants. FRAX®-estimated 10-year hip fracture probability was significantly higher among participants with sarcopenia (1.3% vs 1.0%, p=0.035), whereas no significant difference was observed for major osteoporotic fracture risk (4.7% vs 3.8%, p=0.066). Diabetes duration, glycemic control, and medication use were comparable between groups. Multivariable analysis identified low BMR (OR 6.30; 95% CI 3.21–12.34) and low calf circumference (OR 2.48; 95% CI 1.00–6.12) as independent factors associated with sarcopenia.

Conclusions

Among patients with T2DM, sarcopenia was associated with higher FRAX®-estimated hip fracture risk, whereas major osteoporotic fracture risk did not differ. These findings suggest that sarcopenia may represent an additional determinant of hip fracture risk in T2DM, underscoring the potential importance of optimizing muscle health alongside glycemic management. Patients with low BMR and small calf circumference may require closer evaluation for sarcopenia. Prospective studies are needed to further elucidate the relationship among T2DM, sarcopenia, and fragility fracture risk.

P857

MRI SEVERITY MATTERS : PREDICTING RETURN TO SPORT AFTER BONE STRESS INJURIES IN ELITE FEMALE GYMNASTS

K. Le[1], H. Dumoulin[1], S. Grange[1], P. Edouard[1]

[1]CHU Hôpital Nord, Saint Etienne, France

Objectives

Bone stress injuries (BSI) are frequent in elite female artistic gymnastics and represent a major cause of training interruption. Magnetic resonance imaging (MRI) is the reference modality for diagnosis and severity assessment, but its prognostic value for return to sport remains insufficiently documented in this population. Our study aims to assess the association between MRI severity and time to return to sport in elite female artistic gymnasts with BSI, and to explore the relationship between lesion location, MRI severity, and clinical recovery.

Methods

We conducted a retrospective monocentric study including elite female artistic gymnasts followed at a national training center between 2014–2020 and 2023–2025 with MRI-confirmed BSI. Time to return to unrestricted training was recorded. MRI severity was assessed using the Fredericson classification and analysed as an explanatory variable. MRI examinations were independently reviewed by two blinded readers. Lesion locations were categorized as high-risk or low-risk sites. Associations between MRI severity and return-to-sport delay were analysed using Spearman's correlation coefficient. Inter-reader agreement was evaluated as an exploratory secondary outcome.

Results

Sixteen gymnasts were included. Mean time to return to sport was 3.4 ± 3.1 months (range <1 to 12 months). MRI severity was significantly correlated with return-to-sport delay ($\rho = 0.66$, $p = 0.011$), with higher severity associated with longer recovery. High-risk lesion locations were more frequently associated with greater MRI severity and prolonged return-to-sport delay compared with low-risk sites, although this association did not reach statistical significance. Inter-reader agreement for MRI severity assessment was low overall and decreased for the most severe MRI patterns.

Conclusions

MRI severity of bone stress injuries is associated with time to return to sport in elite female artistic gymnasts, supporting its prognostic value beyond diagnosis. Lesion location may further influence injury severity and clinical recovery. Limited inter-reader agreement for severe patterns highlights the need for improved imaging standardization and suggests that complementary CT-like MRI sequences could enhance cortical lesion assessment and support return-to-sport decision-making.

P858

ELEVATED PRO-BNP AND LOW-GRADE INFLAMMATION ARE ASSOCIATED WITH LOW BMD IN SYSTEMIC SCLEROSIS, A CASE CONTROL STUDY

K. Lillpers[1], K. Andreasson[1], S. Najibi[1], A. Woolf[2], R. Hesselstrand[1], K. Akesson[2], M. Kapetanovic[1]

[1]Rheumatology, Clinical Sciences Lund, Lund University, Lund, Sweden; [2]Orthopedics, Dept Clinical Sciences, Lund University, Malmö, Sweden

Objectives: Bone mineral density (BMD) is compromised in patients with systemic sclerosis (SSc) compared to the background population[1]; less is known about contributing factors. This study evaluates established risk factors for low BMD in SSc patients compared to controls, in addition to SSc disease-related features and predictability for BMD.
Methods: The study includes 211 SSc patients, 182 women and 29 men (mean age 61 yrs, mean disease duration 9 yrs) regularly followed at the Rheumatology Department, Skåne University Hospital, Lund, Sweden and 505 age- and sex-matched controls. Data collection: BMD hip and spine (DXA), BMI, SSc-features, biomarkers and potential risk factors through an extensive questionnaire.
Multinomial logistic regression analysis was used to calculate odds ratio (OR) for low BMD; multiple linear regression for associations between T-score and SSc-related variables and lifestyle factors; and machine learning to fit a model to predict total hip T-score in SSc.
Results: NT-proBNP and markers of inflammation were independently associated with low BMD in SSc patients (p<0.001), as were diffuse cutaneous disease subtype, finger ulcers, vital lung capacity and anti-topoisomerase I antibodies (ATA). In addition, BMI, menopausal status, low physical activity and higher medication burden were associated with lower hip T-score. Predictive modelling identified BMI and NT-proBNP as the strongest determinants of hip T-score in SSc patients.
Conclusion: This large case–control study finds elevated NT-proBNP, indicators of low-grade inflammation and indicators of disease severity negatively associated with BMD. In addition, it confirms that several established risk factors associated with low BMD, including low BMI and being post-menopausal influence bone health in patients with SSc. This highlights the importance of BMD assessment to identify at-risk SSc patients beyond traditional risk stratification.

P859

FACTORS ASSOCIATED WITH PROLONGED HOSPITAL STAYS IN JUVENILE IDIOPATHIC ARTHRITIS

K. Lobna[1], O. Rania[1], M. Fatma[1], C. Ines[1], K. Dhia[1], F. Hanene[1], M. Kaouther[1], B. Dorra[1], H. Wafa[1]

[1]institut Mohamed Kassab d'orthopédie, Tunis, Tunisia

Background: Juvenile idiopathic arthritis (JIA) is a chronic pediatric rheumatic disease. Hospitalizations are a major component of care, yet factors contributing to prolonged hospital stays in JIA remain poorly understood.
Objective: To investigate factors associated with the length of hospital stay in JIA.
Material and Methods: We conducted a retrospective study including patients with JIA who met the 2010 International League of Associations for Rheumatology (ILAR) classification criteria. Collected data included demographic and clinical characteristics, inflammatory markers (ESR, CRP), and disease activity assessed using JADAS-10 (ESR and CRP) for all subtypes and JSpDA for ERA and psoriatic arthritis and the Juvenile Spondyloarthritis Disease Activity Index (JSpDA) for enthesitis-related arthritis (ERA) and psoriatic arthritis subtypes.
Results:
Ninety-one patients were included (46 boys, 45 girls). The mean age was 15.9 ± 6.0 years, with a mean age at disease onset of 9.4 ± 4.2 years and a mean disease duration of 6.4 ± 4.6 years. ERA was the most common JIA subtype (42.9%), followed by oligoarthritis (30.8%). Mean ESR and CRP were 27.1 mm/h and 16.5 mg/L, respectively. Mean JADAS10-ESR and JADAS10-CRP scores were 19.6 and 16.0. The mean hospital stay was 10.2 days.Length of hospital stay was associated with JIA subtype. The longest stays were observed in patients with systemic JIA (16.7 ± 12.4 days; **p = 0.03**).Prolonged hospital stay was associated with the presence of sacroiliac joint pain (14 ± 15 vs. 8 ± 9 days; **p = 0.05**), hip involvement (16 ± 15 vs. 8 ± 9 days; **p = 0.02**), and the use of DMARDs (csDMARDs: 14 ± 12 days, **p = 0.01**; bDMARDs: 15 ± 13 days, **p = 0.005**). Length of hospitalization was correlated with age (r = 0.2; **p = 0.013**), age at disease onset (r = 0.31; **p = 0.004**), and body mass index (r = 0.31; **p = 0.02**). It was also positively correlated with patient, parent, and physician global assessments (PGA) (**p = 0.008**, **0.006**, and **0.001**, respectively), CRP levels (r = 0.4; **p = 0.006**), ESR (r = 0.24; **p = 0.02**), number of painful joints (r = 0.23; **p = 0.03**), and disease activity indices JADAS-10-ESR (r = 0.31; **p = 0.013**) and JADAS-10-CRP (r = 0.4; **p < 0.001**).No significant associations were found between hospitalization duration and sex, disease onset pattern, enthesitis, uveitis, diagnostic delay, or JSpDA score.
Conclusion: Duration of hospitalization in JIA patients was associated with JIA subtype, obesity, coxitis, use of DMARDs, early disease onset, and elevated inflammatory markers and disease activity. Early and optimal management is necessary to reduce hospitalization duration in children with JIA.

P860

LOWER BONE REMODELLING AND EARLIER MORTALITY IN FEMALES: A HISTORICAL EXAMPLE

K. M. Cooke[1], C. Mcfadden[1], P. Mahoney[2], J. J. Miszkiewicz[1,3]

[1]School of Social Science, University of Queensland, Brisbane, Australia; [2]School of Natural Sciences, University of Kent, Canterbury, United Kingdom; [3]Vertebrate Evolution, Development & Ecology, Naturalis Biodiversity Center, Leiden, Netherlands

Objective
This study investigates variation in femur cortical bone remodeling among medieval females and males of low social status across age groups to assess how compounded biological and social stressors inform present-day disparities in bone health.
Material and Methods
Age was recorded from skeletal remains in 410 medieval individuals (n=207 females, n=203 males) exhumed from a low-status cemetery in Canterbury, UK. Histology sections prepared from the right midshaft femur were examined using static histomorphometry to estimate localised bone remodelling rates calculated from secondary osteon

densities. Based on absence of normal data distribution, age was correlated with bone remodelling rates using Spearman's Rho tests, while males and females were compared using a Mann-Whitney U test. Relative risk (RR) ratios, calculated by ages 25, 30, 40, and 50 years, were computed to evaluate whether females experienced an increased risk of premature death over males.
Results
In both males and females, bone remodeling rates were moderately positively correlated with age (p<0.0001, Rho males=0.25, females=0.28), but females had statistically significantly lower remodeling rates compared to males when adjusted for age and bone robusticity (p=0.0001). An inflated risk of premature death was found for females over males up until 50 years old, with females experiencing an almost four-fold increased risk of death by 25 years of age (RR=3.92, p<0.05).
Conclusions
Our finding suggests that skeletal maintenance was compromised in the females in this low-status medieval cohort, likely due to the cumulative effects of social and biological stressors. By demonstrating a link between lower bone remodeling and earlier female mortality in a socially disadvantaged medieval sample, we highlight the enduring relationship between inequality, skeletal health, and survival that continues to hold relevance for modern medical research[1,2].

RISK FACTORS AFFECTING EMERGENCY DEPARTMENT VISIT IN PATIENT WITH GOUT

K. M. Kyeong Min[1]

[1]Hallym University Dongtan Sacred Heart Hospital, Gyeonggi-do, South Korea

Background/Purpose: This study aimed to identify the risk factors that significantly influence Emergency Department(ED) visits in patients with gout.
Methods: In this nationwide population based retrospective cohort study using National Health Insurance Database, we evaluated patients who were newly diagnosed with gout and initiated urate lowering therapies during the period of January 2012 to December 2017. The primary outcome of interest was the occurrence of ED visits within one year from the index date. Logistic regression analysis was conducted to determine the factors associated the outcome.
Result: Our analysis included a toal of 901,211 eligible patients with gout, The average age of the patients was 53.4 years and 613,931(67.6%) were male. Over a one year period following the index date, 8,613 patients visited the ED with an incidence rate of 9.56(95% CI: 9.36-9.76) per 1000 person-years. Male gout patients had an ED visit rate of 1.03 per 1,000 person-years, whereas the rate for female gout patients was substantially higher at 7.88 per 1,000 person-years. Logistic regresssion analysis revealed that severeal factors were associated with ED visits. These factors included patients older age, female, residing in rural regions, those with the lowest income level, and those with higher CCI scores. Regarding gout medications, patients with a history of receiving colchicine demonstrated the highest odds ratio among gout medication(OR 2.55;95% CI:2.45-2.67).
Conclusion: This study showed the increase trends of incidence of gout and ED visits within one year after diagnosis. Female gout patients had a higher rate of ED visits than male gout patients during the same person-year period. The associated factors related to ED visits included patients older age, residing in rural regiosn, those with the lowerest income level, and those with higher CCI scores. Clinicians should consider these trends and make greater efforts to appropriately treat and educate patients with gout.

P862

THE NECESSITY OF FRACTURE PREVENTION IN PATIENTS WITH PROSTATE CARCINOMA

K. Marković[1]

[1]Institution, Niš, Serbia

Introduction:
Prostate cancer (PCa) is the fourth most frequently diagnosed malignancy in men and accounts for 26% of all newly diagnosed cancers in men.
Androgen deprivation therapy (ADT) improves PCa treatment outcome – but adversely affects CVD, worsens metabolic profile, insulin resistance, atherosclerosis and reduces bone density.
Aim:
Bone mineral density (BMD) monitoring for fracture prevention in prostate cancer patients undergoing ADT.
Materials and methods:
50 men underwent ADT for PCa, who were noted to have decreased bone density. These patients had no history of medical conditions leading to secondary osteoporosis. 12 of them had fractures - which is why they were referred for densitometry, the rest came on the advice of a specialist (16) and on their own initiative (22). The average age of the patients was 68.3 ± 6.6 years. Medicines included vitamin D and bisphosphonates (BP).
The evaluation method examined the rate of change in BMD before treatment of reduced BMD and one year (respectively two days) after the administration of therapy. As a control, a group of men without PCa (n = 50) was selected, which was matched by age and risk factors. Significant differences were observed only in serum 25(OH)D levels - the group without PCa had higher vitamin D values.
Results:
At the beginning, the control group had higher BMD values in the lumbar spine by 78%, in the femoral neck by 61% and in the hip as a whole by 71%. After two years, this group recorded a decrease in BMD that was not statistically significant. In the first group, 15 patients with osteoporosis were registered (BP was included), 19 patients had osteopenia (vitamin D was included), 16 patients had normal BMD.
BMD of the first group - with osteoporosis, increased by 7.1% at the lumbar spine (LS). An increase in BMD of 5.5 was recorded at the neck of the femur (FN), overall there was an increase in BMD of the femur by 6.6%.
The BMD of the first group - with osteopenia, decreased by 7.3% after one year from the introduction of the LS supplement. A decrease in BMD of 5.7% was recorded at FN, and overall there was a decrease in BMD of the femur by 3.9%.
The BMD of the first group that had a normal finding decreased by 3.6% at LS after two years. A decrease in BMD of 2.7% was recorded at VBK, and overall there was a decrease in BMD of the femur by 2.4%.
In all cases there was a statistically significant difference (p < 0.01). And in one year, 6 new fractures were registered in the first group, one in the

group with osteoporosis and 5 in the group with osteopenia.
Conclusion:
It was found that in patients with prostate cancer on ADT therapy, there is a significant decrease in BMD compared to a group of patients without PCa.

P863

DENOSUMAB PRODUCES GREATER EARLY SUPPRESSION OF BONE TURNOVER MARKERS THAN ZOLEDRONATE IN POSTMENOPAUSAL WOMEN WITH PRIMARY HYPERPARATHYROIDISM: A RANDOMIZED TRIAL

K. Mlekus Kozamernik[1], G. Vidmar[2], L. Lezaic[3], M. Hocevar[4], T. Kocjan[1]

[1]UMC Ljubljana, Dept of Endocrinology, Diabetes and Metabolic Diseases, Ljubljana, Slovenia; [2]Faculty of Medicine, University of Ljubljana, Ljubljana, Slovenia; [3]UMC Ljubljana, Dept of Nuclear Medicine, Ljubljana, Slovenia; [4]Institute of Oncology Ljubljana, Ljubljana, Slovenia

Objective: To compare the effects of denosumab and zoledronate on bone turnover markers (BTMs) and to identify clinical factors associated with treatment response in postmenopausal women with primary hyperparathyroidism (PHPT) and osteoporosis.
Methods: In this randomized, open-label pilot trial (ClinicalTrials.gov NCT04085419), 40 postmenopausal women with PHPT and osteoporosis were assigned to denosumab 60 mg subcutaneously every 6 months (DMAB) or zoledronate 5 mg intravenously once yearly (ZOL). Mean age was 73.0 ±7.8 years, time since menopause was 22.6 ±10.0 years, and BMI was 27.8 ±5.1 kg/m^2. Serum C-terminal telopeptide of type I collagen (CTX), procollagen type I N-terminal propeptide (P1NP), and bone-specific alkaline phosphatase (BAP) were measured at baseline and at 3, 6, 12, 18, and 24 months. Linear mixed models were used to evaluate associations of age, time since menopause, and BMI with changes in BTMs from baseline.
Results: At 3 months, CTX levels were lower with DMAB than with ZOL, with a greater percent reduction from baseline (99% vs. 83%; p=0.031). Between-group differences in CTX were no longer observed at later time points. P1NP levels were lower with DMAB at 3 months, and percent reductions from baseline were greater with DMAB than with ZOL across follow-up (e.g., 3 months: 82% vs. 71%; p=0.006). BAP levels were lower with DMAB at 24 months, with greater percent reductions at 3 and 12 months compared with ZOL. In mixed-effects models, older age was associated with greater suppression of CTX and P1NP, whereas longer time since menopause and higher BMI were associated with smaller decreases in these BTMs.
Conclusion: In postmenopausal women with PHPT and osteoporosis, DMAB produced greater early reductions in CTX and P1NP than ZOL. CTX between-group differences were not sustained. In contrast, BAP suppression with DMAB was evident at selected time points, with lower levels at 24 months and larger percent reductions at 3 and 12 months. Age, time since menopause, and BMI significantly modified treatment-related BTM responses.

P864

THE USE OF POLARIZED POLYCHROMATIC LIGHT IN THE TREATMENT OF ODONTOGENIC PERIOSTITIS

A. A. Gavrilenko[1], L. A. Filippova[1], K. N. Kaladze[1], O. Y. Poleshchuk[1], K. K. Kaladze[1]

[1]V.I. Vernadsky Crimean Federal University, Simferopol, Russia

The purpose of the work. To improve the treatment results of odontogenic periostitis by including polychromatic polarized light phototherapy sessions in the local therapy regimen.
Materials and methods. The study involved 40 patients with acute purulent odontogenic periostitis, divided into two equal groups – the main and the control. All patients underwent standard periosteotomy with preservation or removal of the causal tooth, as well as conventional general therapy. In the control group, the wound was treated daily with an aqueous antiseptic solution after surgery. UHF therapy was used as physiotherapy. In the main group, after opening the abscess, the wound was washed with a chlorhexidine solution, then a bandage with Sanguiritin was applied for 15 minutes, after which Emalan gel was applied. Additionally, patients in the main group underwent local irradiation with polychromatic polarized light using a Bioptron device. The effect was carried out externally, in the projection of the wound, at an angle of 90 ° to the skin from a distance of 3-5 cm. The duration of the procedure was 6 minutes, and the course included 8 daily sessions. Based on the results of observations, it was found that patients in the main group had more active wound repair processes, a faster decrease in general and local signs of inflammation, earlier cleansing of the wound from purulent-necrotic contents, shorter treatment time and a reduced risk of local infectious and inflammatory complications.
Conclusions. The use of polychromatic polarized light from the Bioptron device in the complex treatment of acute purulent odontogenic periostitis, due to its anti-inflammatory, decongestant, analgesic and regenerating effects, promotes faster relief of inflammation, activation of recovery processes and reduction of treatment time. This method can be recommended for use in surgical dentistry both for therapy and for the prevention of postoperative infectious and inflammatory complications.

P865

THE USE OF XENOGENIC OSTEOBIOL DERMA GRAFT FOR SOFT TISSUE AUGMENTATION IN CONDITIONS OF IMMEDIATE IMPLANTATION AFTER TOOTH EXTRACTION

L. A. Filippova[1], A. A. Gavrilenko[1], K. G. Bom[1], K. N. Kaladze[1], O. Y. Poleshchuk[1], K. K. Kaladze[1]

[1]V.I. Vernadsky Crimean Federal University, Simferopol, Russia

Derma xenogenic graft for soft tissue augmentation during the single-stage implantation procedure based on a comprehensive analysis of clinical, cytological and X-ray data.
Materials and methods. The study was conducted at the clinical base of the Ecodent dental clinic. The study included 10 patients (aged 30-50 years) both sexes with dental defects included, without a burdened somatic status. Immediate dental implantation was performed under local infiltration anesthesia Sol. Ultracaini 4% (1.7 ml). After detachment of the circular ligament, an atraumatic tooth extraction was performed

with maximum preservation of the bone structures of the alveoli and the root septum. The implants were installed in accordance with the standard protocol of simultaneous intervention. Bone defects between the wall of the well and the surface of the implant were filled with osteoplastic Gen-Os (Osteobiol) material. An Osteobiol Derma resorbable collagen membrane was placed on top of the augmentate and the installed implant, under the mucoposteal flap, followed by its adaptation and fixation with guide sutures.
Results. The study confirmed the high clinical efficacy of Osteobiol Derma. The postoperative period in all patients was physiological, with no signs of inflammation or rejection. Clinical and cytological monitoring data indicated a high intensity and harmonious course of reparative processes in the area of intervention. X-ray analysis (after 3 months) showed a significant reduction in the bone defect due to the formation of mature newly formed bone tissue. There was a controlled, gradual resorption of the membrane, which was accompanied by full-fledged bone regeneration according to the *restitutio ad integrum* type. These factors ensured stable protection and safety of the graft, creating optimal conditions for successful osseointegration of the installed implants.
Conclusions. The use of Osteobiol Derma collagen membrane as part of the immediate implantation protocol is an effective technique that provides stable protection of bone augmentate and acts as a guiding barrier for epithelial tissue that does not require removal. The key advantages determining clinical success and favorable aesthetic outcome are atraumatic use, high biocompatibility, controlled rate of resorption and the ability to vascularize. The set of listed characteristics allows us to recommend the widespread introduction of this technique into clinical practice as an effective means of preventing dental deformities and complications during single-stage implantation.

P866

TRAUMATIC SPINAL CORD DISEASE AND FEATURES OF MUSCLE TISSUE METABOLISM

N. N. Kaladze[1], K. N. Kaladze[1], O. Y. Poleshchuk[1], K. K. Kaladze[1]

[1]V.I. Vernadsky Crimean Federal University, Simferopol, Russia

The purpose of this study was to analyze the state of the muscular system in patients with TBSM depending on the location of spinal cord injury.
Materials and methods. 90 male patients with TBSM aged from 26 to 45 years were examined. The localization of the injury was distributed as follows: cervical spine – 18 people, thoracic spine – 22, lumbar spine – 50 people. In addition to standard clinical methods, to assess muscle tissue damage, the concentration of myoglobin in blood serum was determined by enzyme immunoassay (ELISA) using the solid-phase principle.
Results. Analysis of myoglobin levels in the main group of patients with TBSM revealed a statistically significant ($p<0.001$) increase in this indicator (38.60±2.10 micrograms/l) compared with the control group (26.80±1.04 micrograms/l). The data obtained indicate the inflammatory nature of the increase in myoglobin concentration, which indicates the development of not only dystrophic but also inflammatory processes in muscle tissue in patients with TBSM.
Conclusions. Thus, in patients with traumatic spinal cord disease, there is a violation of the trophic skeletal muscles, which is confirmed by an increased level of serum myoglobin. The severity of these disorders correlates with the level of spinal injury, and an increase in myoglobin is noted not only in severe, but also in relatively mild cases of the disease. This is due to concomitant systemic disorders such as persistent inflammatory activity and the development of endothelial dysfunction. Together, these factors worsen disorders of tissue nutrition and disrupt the physiological mechanism of muscle contraction at all its stages.

P867

FEATURES OF REGIONAL BLOOD FLOW IN PATIENTS WITH MANDIBULAR FRACTURES ON THE BACKGROUND OF PHYSIOPHARMACOTHERAPY

K. N. Kaladze[1], O. Y. Poleshchuk[1], K. K. Kaladze[1]

[1]V.I. Vernadsky Crimean Federal University, Simferopol, Russia

Circulatory disorders in the area of a mandibular fracture significantly affect bone tissue repair and the duration of the rehabilitation period (according to a number of authors).
The aim of the study was to evaluate the dynamics of recovery, as well as the effect of bioresonance therapy and its combination with Osteogenon on fracture consolidation and the state of local blood flow in the injured area.
Materials and methods. The study included 120 male patients aged 18-58 years with fractures of the mandible. The participants were randomized into three groups of 40 people each.
All patients underwent primary immobilization of fragments using a Tigerstedt splint with occlusion restoration. Group I: received a course of bioresonance therapy (BRS device). From day 2, the impact was carried out on the collar area, from day 5 - additionally on the fracture area. The parameters (power, time) gradually increased. The course consisted of 10 procedures. Group II: received combination therapy: bioresonance stimulation (according to the same scheme) and the drug Osteogenon. Group III (control): treatment according to the standard protocol (splinting, anti-inflammatory therapy, UHF). The effectiveness of the treatment was assessed on the basis of clinical and radiological data and rheography immediately after immobilization and after 2 weeks. The control indicators were obtained during the examination of 15 healthy individuals. The data was processed statistically.
Results. Upon admission, edema, hematomas, and dislocation of fragments were noted in patients of all groups. According to rheographic data, violations of regional hemodynamics were detected in 89% of patients (decreased rheographic index, angle of collapse, etc.), which indicated a deterioration in both arterial inflow and venous outflow. After splinting, the bite was restored, and the X-ray bias was eliminated in 68% of cases. However, at this stage, there was a slight deterioration in blood flow, probably due to additional tissue injury during reposition. Later, patients of groups I and II who received physiopharmacotherapy showed a faster disappearance of edema and hematomas compared with the control group. Clinical and radiological signs of consolidation, as well as recovery of working capacity, occurred earlier in the main groups. Rheographic examination after 2 weeks showed the most intensive restoration of regional blood circulation in patients of group II (combination therapy). The indicators of group I also exceeded the control ones, where hemodynamics remained significantly changed.
Conclusions. Comprehensive treatment of fractures of the mandible using bioresonance therapy and the drug Osteogenon helps to accelerate the consolidation of fragments, improve regional blood flow, reduce rehabilitation time and restore functional parameters.

P868

THE PROBLEM OF INCREASING THE EFFECTIVENESS OF THERAPY FOR TRAUMATIC OSTEOMYELITIS OF THE LOWER JAW

S. G. Bezrukov[1], G. G. Roganov[1], K. N. Kaladze[1], O. Y. Poleshchuk[1], K. K. Kaladze[1]

[1]V.I. Vernadsky Crimean Federal University, Simferopol, Russia

The aim of the study was to evaluate how the addition of Bestim to standard therapy affects the treatment outcomes of patients with traumatic osteomyelitis of the mandible.
Materials and methods: 58 patients with this diagnosis participated in the study. They were divided into two groups: the control group (27 people), which received only standard treatment, and the main group (29 people). Standard therapy for all included jaw immobilization (if necessary) and traditional postoperative drug support. The patients of the main group additionally received Bestim intramuscularly, once a day, with a course of 5 to 7 injections. Prior to the start of treatment, all patients had characteristic clinical and radiological signs of a purulent-destructive process in the lower jaw. The analysis of the immune status revealed significant violations: the level of IgA was reduced by 39%, and IgM – by 24,7%, indicating systemic immunodeficiency, moderate inflammation and metabolic hypoxia. The dynamics of the recovery of immunogram parameters served as an important criterion for evaluating the effectiveness of both the operation (sequestrectomy) and the correction of secondary immunodeficiency. In the main group, normalization of IgM and IgG levels was observed by the 10th day of treatment, and IgA by the 21st day. In the control group, the recovery of these indicators occurred much later.
Conclusion: The addition of the immunomodulatory and antioxidant drug Bestim to the complex therapy of traumatic osteomyelitis of the mandible significantly increases its effectiveness. This is confirmed by a faster normalization of immunological parameters (7-14 days earlier than in the control group), a decrease in the frequency of local complications by 28,4% and a decrease in the number of disease recurrences by 7,7%.

P869

ASSESSMENT OF CHANGES IN CLINICAL AND BIOCHEMICAL PARAMETERS OF ORAL FLUID IN CARIES

O. Y. Poleshchuk[1], K. N. Kaladze[1], K. K. Kaladze[1]

[1]V.I. Vernadsky Crimean Federal University, Simferopol, Russia

Objective: to determine the variability of oral fluid parameters depending on the time of year, to identify the most significant indicators for oral fluid with varying degrees of intensity of the carious process, as well as to establish a correlation between these indicators.
Materials and methods. The material for the study was the oral fluid of 50 patients aged 20-36 years, obtained by spitting into glass tubes in the morning from 8 to 9 o'clock 1-1.5 hours after brushing their teeth. There are 2 groups according to the value of the index of the intensity of dental damage by the carious process (KPU). Examination of the oral cavity and determination of biochemical parameters of oral fluid were performed twice: in spring and autumn. The first group (OH-I) consisted of patients with a compensated form of the carious process: 20 people in spring (CP=3.26+1.55) and 20 people in autumn (CP=2.68+1.67); the second group (OH-II) — with a decompensated form of the carious process: 10 people (KPU =11). The examination consisted of taking into account the medical history data, an objective examination of the oral cavity with the determination of hygiene indices.
Results. According to our data, the content of calcium in the oral fluid in the autumn period in OH-I is 3.4±0.009, OH-II is 1.5±0.012 mmol/l. Phosphorus OH-I 14.5±0.48, OH-II 3.1±0.03 mmol/l. The alkaline phosphatase indices of OH-I are 36.1±1.56 and OH-II are 107.3±1.18 E/L. In spring, the calcium indices are 1.63±0.078 and 1.36±0.03 mmol/l, respectively. Phosphorus is 6.7±0.23 and 2.79±0.16 mmol/l. Alkaline phosphatase 34.4±0.61 and 87.3±0.898 E/l. There is a tendency to an increase in the content of calcium and phosphorus in the oral fluid, and an increase in the activity of the alkaline phosphatase enzyme with an increase in the CP index. In addition, there was a parallel decrease in the content of calcium and phosphorus in autumn compared to their values in spring. However, in the second study group, these indicators are lower than in the first group, which may be due rather to the depletion of the body's reserve forces against the background of intense demineralization and an increase in the number of affected teeth, although a seasonal decrease in calcium and phosphorus levels is also observed.
Conclusion. Thus, the dependence of the biochemical composition of the oral fluid on the degree of intensity and prevalence of the carious process was revealed. Seasonal fluctuations in the content of calcium and phosphorus in the oral fluid were noted. A correlation has been established between the content of calcium, phosphorus and alkaline phosphatase in saliva.

P870

CORRECTION OF OSTEOPENIC SYNDROME IN CHILDREN WITH BRONCHIAL ASTHMA

O. Y. Poleshchuk[1], K. N. Kaladze[1], K. K. Kaladze[1]

[1]V.I. Vernadsky Crimean Federal University, Simferopol, Russia

The purpose of our study was to study the effect of sanatorium–type treatment (SCL) on the structural and functional properties of bone tissue (SPS CT) in children in remission of bronchial asthma.
Materials and methods. We observed 103 children (from 7 to 16 years old) with remission of bronchial asthma (BA) and manifestations of osteopenic syndrome, diagnosed by ultrasound osteodensitometry, which was performed using the "Ahilles+" device (USA). Among the examined OH children with osteopenic syndrome, intermittent asthma was detected in 14 (13.6%) patients, mild persistent in 40 (38.8%) and moderate persistent in 49 (47.6%) patients. The control group (KG) consisted of 30 healthy peers.
The results of the study. In children with asthma, manifestations of nonspecific connective tissue dysplasia syndrome were detected in 64 (62.1%) patients, disharmonious physical development – in 67 (65%). According to ultrasound osteodensitometry, all patients with asthma included in the study showed a decrease in CT values of less than -1 SD. In 90 of 103 (87.3%) patients with ASTHMA, its value ranged from -1 to -2.5 SD, which indicated manifestations of osteopenia, and in 6 (5.8%) patients it was below -2.5 SD, which corresponded to osteoporosis. All examined children with asthma were divided into groups. The first group, consisting of 41 people, received a standard complex of SCL. The second group, consisting of 62 children, simultaneously took the drug Osteobios (Italy). Under the influence of SCL, IP CT tended to decrease from 80.01±1.18% to 76.0±1.64%. The SRU indicator is significant (p <0.001) It also decreased from 1544.23±2.29 m/s to 1531.46±2.24 m/s. The magnitude of the SHOW did not significantly change during therapy. The highest values of ultrasound osteodensitometry were recorded in the 2nd

group of patients. The average value of the SRU increased (p <0.001) by 15 m/s (from 1543.21 ±2.27 to 1560.01±2.095 m/s) and almost reached the values of KG. The CP of CT increased (p <0.05) from 79.08±1.26% to 86.70±1.49%, which indicated an increase in CT strength, but remained lower than in healthy children. The SHOW value was 104.91±1.78 dB/MHz versus the initial value of 100.05±1.69 dB/MHz.
Conclusions. Thus, the entire complex of SCL had a positive effect on the dynamics of ultrasound densitometry CT. A significant improvement in SPS CT was noted in the group who received the antihomotoxic drug Osteobios against the background of SCL.

P871

DETECTION OF UNDIFFERENTIATED CONNECTIVE TISSUE DYSPLASIAS IN ADOLESCENTS WITH DENTOFACIAL ABNORMALITIES

O. Y. Poleshchuk[1], K. N. Kaladze[1], K. K. Kaladze[1]

[1]V.I. Vernadsky Crimean Federal University, Simferopol, Russia

The aim of our work was to assess the possibilities and the need for diagnosis of undifferentiated connective tissue dysplasias (NDST) by orthodontist doctors at the stage of treatment planning.
Materials and methods. A total of 54 adolescents (main group - PH) aged 12 to 15 years with various dentoalveolar anomalies (DFA) and deformities were followed up to study the prevalence of NDST in this cohort. For comparison, we estimated the prevalence of NDST signs among 50 adolescents in the control group (CG) who did not initially have information about the presence of HRA.
Results and their discussion. According to the results of our study, the prevalence of BAT according to the identified clinical signs in adolescents was 56.7%. In 30.7%, spinal deformities were detected, in 30.1% - asthenic type of constitution, in 15.1% - visual impairment in the form of astigmatism. In CG and OG patients, the CIC index was 8.4 and 9.1, respectively. The level of oral hygiene according to IG values in 44.6% of the examined patients was satisfactory, in 55.4% - unsatisfactory; CG parameters did not significantly differ from those of the patients (48.2% and 51.8%, respectively). The prevalence of inflammatory periodontal diseases by group was 35.1% and 29.9%, with bleeding and RMA indices of 1.7% and 14.8% (CG) and 1.6% and 15.4% (OH). Based on the results of the data obtained, out of 24 existing for the diagnosis of "large" and "small" signs of NDST, we identified the 10 most significant. According to the priority of the significance of the diagnostic coefficients of the discharge of "large" stigmas, we consider it sufficient at the primary reception to assess the type of adolescent constitution. Diagnostically reliable "small" stigmas of NDST can be directly types of dentoalveolar anomalies.
Conclusions. The results made it possible to determine that the prevalence of ZFA in combination with signs of BAT in the population of adolescents is 2.7 times higher than CG. The presence of ZFA itself may be one of the markers of NDST, especially in combination with the "large" and/or "small" dysplastic stigmas that we identified in 89.1% of OHT adolescents and in 40.5% of CG adolescents.

P872

SCIENTIFIC SUBSTANTIATION OF THE USE OF METERED-DOSE PHYSICAL ACTIVITY IN THE REHABILITATION OF CHILDREN WITH PRIMARY ARTERIAL HYPOTENSION

N. N. Kaladze[1], K. N. Kaladze[1], O. Y. Poleshchuk[1], K. K. Kaladze[1]

[1]V.I. Vernadsky Crimean Federal University, Simferopol, Russia

The purpose of the study. The aim was to analyze the specifics of physical development and metabolic disorders in children with PAH in order to develop a pathogenetically based methodology for the use of metered-dose physical activity. Scandinavian walking was considered as a therapeutic factor.
Materials and methods. In the period from June 2022 to March 2023, 67 children aged 7-12 years with a diagnosis of PAH who underwent a Nordic walking course were monitored. The program consisted of 10 daily workouts lasting 45-60 minutes each, the structure of which included a warm-up, the main part (training and practice), a game break and a hitch. Dynamic monitoring included daily monitoring of blood pressure (BP), heart rate (HR), and respiratory rate (HRR). Before and after the course, the body's functional reserves were assessed based on the results of the Barbell and Gencha tests, the 6-minute walking test (6-MST), as well as bioimpedance and bicycle ergometry data.
Results. The initial average blood pressure in the group was 79/42 mmHg. During the classes, 98% of patients showed positive dynamics: by the end of the 10-day course, the average blood pressure steadily increased to 92/60 mmHg. The achieved effect persisted for three days after the completion of the program. The results of functional tests (Barbell, Genchi, 6-MSHT) also demonstrated a statistically significant improvement, which indicates an increased adaptive capacity of the cardiovascular and respiratory systems to physical exertion.
Conclusion. A course of metered-dose training in the form of Nordic walking, consisting of 10 daily sessions, helps to normalize blood pressure levels in children with primary arterial hypotension to age-appropriate levels. In parallel, there is an increase in exercise tolerance and an improvement in the functional state of the cardiorespiratory system, which confirms the rehabilitation potential of this technique.

P873

ETHOLOGICAL AND IMMUNOLOGICAL CHARACTERISTICS OF CHILDREN WITH BRONCHIAL ASTHMA AT DIFFERENT STAGES OF THE DISEASE

N. N. Kaladze[1], K. N. Kaladze[1], O. Y. Poleshchuk[1], K. K. Kaladze[1]

[1]V.I. Vernadsky Crimean Federal University, Simferopol, Russia

The aim of the work was to study the specifics of behavioral patterns and their relationship with immune parameters in pediatric patients with asthma.
Materials and methods: The study included 137 children aged 7-16 with asthma: 103 patients in the acute phase and 34 in remission undergoing sanatorium rehabilitation. The control group consisted of 28 healthy peers. The following methods were used: computer spirography (FVC, PSV,

OFV1, MOS50, MOS75), ethological observation, immunophenotyping of lymphocytes (determination of the absolute and relative number of CD3+, CD4+, CD8+, CD16+, CD22+ cells, immunoregulation index — IRI) and statistical analysis with the calculation of correlations.
Results: Ethological features: the most active communication channels in all children were facial expressions, postures and gestures. However, in the AD group, there was a change in the balance between them characteristic of healthy children: exacerbation of the disease correlated with increased facial activity against a background of decreased gestures and vocalizations, the persistent course of AD, unlike intermittent, was characterized by the dominance of facial expressions with a decrease in the activity of the postural and manipulative channels. A typical behavioral profile was aggressive-warning behavior, which included elements of submission (submission), autoaggression, and somatogenic depression. Increased aggression and depression against the background of reduced acts of grooming (self-cleaning, preening) served as an ethological marker of the activity and severity of the pathological process. Significant correlations were found between behavior and the function of external respiration (FVD): vocal activity positively correlated with MOS50, and grooming with FVC, PSV and MOS75. Anxiety had an inverse relationship with VVC. There was a statistically significant decrease in the absolute values of CD3+, CD16+, CD4+, CD8+ lymphocytes in both phases of the disease. In the acute phase, IRI and the relative number of B-lymphocytes (CD22+) significantly decreased. In the remission phase, there was an increase in the relative values of CD4+, CD16+, CD22+, and the IRI exceeded the control values. The level of total IgE was significantly increased at all stages of the disease. Interrelation of ethological and immunological parameters: Active gestures, manipulation of objects, and vocalization were associated with better cellular immunity. High facial activity, on the contrary, reflected its insufficiency and a decrease in IRI. Correlations between signs of aggressive behavior and atopy may indicate a common genetic basis. Acts of grooming served as a marker of reducing the body's allergic mood. The parameters of cellular immunity (CD8+, CD4+, CD16+, CD22+) were closely related to the parameters of FVD (OFV1, MOS50, MOS75), and the nature of the relationship in children with asthma was similar to that in the control group.
Conclusion: Children with bronchial asthma have a significant strain on the immune system in conditions of chronic disease, which is clearly reflected in specific changes in non-verbal behavior. The revealed complex correlations, as well as the positive dynamics of a number of indicators during the period of sanatorium treatment, justify the expediency of actively including methods based on nonverbal interaction in rehabilitation programs for this category of patients.

P874

FEATURES OF FUSION OF THE FRACTURE OF THE LOWER JAW AGAINST THE BACKGROUND OF THE USE OF THE DRUG "OSTEOGENON"

K. N. Kaladze[1], O. Y. Poleshchuk[1], K. K. Kaladze[1]

[1]V.I. Vernadsky Crimean Federal University, Simferopol, Russia

The purpose of the study: to study the effect of the drug "Osteogenon" on bone mineralization in the regenerate zone in patients with fractured mandible.
Material and methods: The study involved 80 male patients aged 20 to 48 years with a unilateral fracture in the molars or angle of the mandible. The participants were divided into two groups. In the main (I) group, Osteogenon was included in the treatment regimen, while patients in the control (II) group received standard therapy. An Achilles ultrasound densitometer (Lunar) was used to assess the condition of bone tissue. Parameters such as the ultrasound propagation velocity (SRU), broadband ultrasound attenuation (WDE), and the density index (DDI), reflecting the structural and functional properties of bone, were analyzed.
Results: Initial densitometry in all patients showed a decrease in all the studied parameters: SRU to 1540 ±9.59 m/s, SHA to 107.3±3.2 dB/MHz, IP to 90.71±2.3%. These changes indicate the activation of bone remodeling processes with increased osteoblast activity and increased resorption. Repeated examination on day 21 revealed significant differences between the groups. In group I, who received Osteogenon, there was a significant increase in CP to normal values (from 1531±13.21 to 1568±4.25 m/s; $p<0.001$) and a significant increase in IP (from 89.55±3.2 to 96.3±2.0; $p<0.01$), while the SHAW index remained unchanged. In group II, the dynamics was less pronounced, and the IP value even decreased slightly (from 95.3±3.1 to 94.4±2.8), which is statistically unreliable.
Conclusion: In patients with a mandibular fracture, significant bone structure disorders are recorded before treatment, corresponding to the degenerative syndrome in 60.83% of patients. During therapy, there was a tendency towards normalization of densitometric parameters in both groups, which indicates the consolidation of the fracture. The most pronounced positive dynamics, especially in terms of the speed of ultrasound propagation and the density index, was recorded in the group receiving Osteogenon. This suggests that the inclusion of this drug in the complex treatment helps to accelerate the processes of mineralization and fracture fusion.

P875

SEASONAL FLUCTUATIONS IN VITAMIN D LEVELS IN CHILDREN WITH CHRONIC PYELONEPHRITIS

N. N. Kaladze[1], K. N. Kaladze[1], O. Y. Poleshchuk[1], K. K. Kaladze[1]

[1]V.I. Vernadsky Crimean Federal University, Simferopol, Russia

The purpose of this study is to study these seasonal changes in children diagnosed with chronic pyelonephritis (CP).
Methods: 120 children (10-15 years old) from Crimea with CP in remission participated in the study. The children were divided into 4 equal groups of 30 people according to the survey season (winter, spring, summer, autumn). All participants underwent a comprehensive examination, which included: assessment of bone density using ultrasound densitometry, blood and urine analysis for calcium, phosphorus and kidney function, determination of the concentration of key hormones (parathyroid hormone, calcitriol, calcitonin, growth hormone) and markers of bone formation and destruction.
Results. In children with CP, the incidence of decreased bone density was highest in spring (48% of cases, peak in March), which is 12% higher than in other seasons. The more severe form (osteoporosis) was more common in autumn and spring. Even in the absence of pronounced changes in bone density in children with CP, an imbalance in the hormonal regulation of bone metabolism was revealed, which can be considered an early (prelatent) stage of osteopenia. In particular, a reduced level of calcitriol** (the active form of vitamin D) in the blood was found. The level of calcitriol directly depended on body weight, the degree of physical development and the content of growth hormone in the child. The severity of the revealed hormonal disorders varied depending on the time of the year.
Conclusions. The data obtained indicate the need for targeted prevention

of vitamin D deficiency and related osteopenia in children with chronic pyelonephritis. Given the slow cycle of bone tissue renewal, the authors recommend an annual preventive intake of vitamin D preparations, starting in November, with mandatory follow-up medical monitoring. The optimal duration of such a course for this group of patients requires further study.

P876

CHARACTERISTICS OF THE STRUCTURAL AND FUNCTIONAL STATE OF BONE TISSUE IN PATIENTS WITH JURA, DEPENDING ON DISEASE DURATION

N. N. Kaladze[1], K. N. Kaladze[1], O. Y. Poleshchuk[1], K. K. Kaladze[1]

[1]V.I. Vernadsky Crimean Federal University, Simferopol, Russia

Objective: To study the structural and functional state of bone tissue (SPS CT) in children with JRA, depending on disease duration.
Materials and Methods: We examined 102 children aged 6 to 15 years with a reliable and definite diagnosis of JRA. Articular JRA was present in 80 (78.4%) children, and articular-visceral JRA was present in 22 (21.6%). The majority of children had a slowly progressive course (73 (71.5%)), while 22 (21.6%) had a rapidly progressive course and 7 (6.9%) had no noticeable progression. The examination was conducted according to the generally accepted rheumatology protocol.
Results. A CT scanning probe (SPS) study in patients with JRA revealed that the CT index decreased with increasing disease duration. For JRA lasting up to 1 year, the CT index was 62.9±1.9%, for patients from 1 to 3 years, it was 66.1±1.7%, and for patients with JRA lasting more than 3 years, it was 63.1±1.12%, which is significantly lower than the norm ($p<0.01$). A relationship was established between the duration of JRA and the severity of CT abnormalities. Total bone density insufficiency was detected in 3 patients (25%) with a disease duration of up to 1 year, 18 (69%) with a disease duration of 1 to 3 years, and 81 (94%) with a disease duration of more than 3 years (the percentage of patients is taken from the total number of children with JRA of the corresponding disease duration). The incidence of osteopenia and osteoporosis with a disease duration of up to 1 year was 21% and 4%, respectively; 59% and 10% with a disease duration of 1 to 3 years; and 84% and 40% with a disease duration of more than 3 years.
Conclusions. Children with JRA exhibit bone metabolism disorders, manifested by deterioration of bone strength characteristics and decreased osteodensitometry parameters. The severity of these disorders depended on the duration and type of the disease.

P877

OSTEOSARCOPENIA IS AN INDEPENDENT FACTOR RELATED TO FRAILTY IN OCTOGENARIANS

K. N. Yılmaz[1], S. Arı[1], M. K. Kılıç[1], A. Okyar Baş[1]

[1]Ankara Training and Research Hospital / Geriatric medicine, Ankara, Türkiye

Objectives: The aging process is characterized by a progressive decline in musculoskeletal health, frequently resulting in osteoporosis (OP) and sarcopenia. In this study, we aimed to investigate the relationship between these individual conditions and their coexistence as osteosarcopenia (OS) with frailty in a cohort of patients aged 80 years and older.
Methods: Following the screening of 223 patients, 120 patients met the inclusion criteria and proceeded to the final analysis. A comprehensive geriatric assessment (CGA) was performed on each participant. The Clinical Frailty Scale (CFS >4 = frail) was used for the assessment of frailty. Probable sarcopenia (PS) is defined as low handgrip strength. (<16 kg for female, < 27 kg for male). OP was defined by a T-score of -2.5 or lower; or the presence of documented fragility fractures. The patients with both OP and sarcopenia were accepted as OS.
Results: A total of 120 patients aged 80 years or older were included in the study. The median (IQR) age was 84.9 (81.9- 87.2) years and 60.0 % (n=72) were female. Patients were divided into two groups according to frailty status. In the frail group (n=77, 64.2 %), patients were older, more dependent in the ADLs, more likely to be female, and mostly had malnutrition risk, dementia, congestive heart failure, depression, and a history of fall in the previous year. The prevalences of OP, PS, and OS were 10.0 % (n=12), 35.0% (n=42), and 41.7 % (n=50), respectively. Patients living with frailty had a higher prevalence of PS and OS than the non-frail group.(Table 1)The logistic regression analyses, OS was related to a 4 times increased frailty risk, independent of age and sex (OR: 4.32, 95% CI: 1.21- 15.45, p= 0.024).(Table 2)
Conclusion: OS is an independent factor closely intertwined with frailty in patients aged 80 years and older. These findings suggest that identifying this coexistence of OP and sarcopenia is essential to better manage and prevent frailty in the oldest-old population.

RARE BONE DISEASES: DIAGNOSIS AND MANAGEMENT ABOUT 21 PATIENTS

K. Nassar[1], M. Errabti[2], M. Maghfour[2], S. Zaher[2], A. Ajerouassi[2], W. Rachidi[2], S. Janani[2]

[1]Rheumatology department, Ibn Rochd University Hospital, Hassan II University of Medicine and Pharmacy, CASABLANCA, Morocco; [2]Rheumatology department, Ibn Rochd University Hospital, Hassan II University of Medicine and Pharmacy, Casablanca, Morocco

Introduction: Rare bone diseases constitute a heterogeneous genetic or acquired origin group, characterized by bone fragility that leads to an increased risk of fractures and deformities. Although rare, they present a diagnostic and therapeutic challenge due to their clinical variability.
The objective of our study is to describe the clinical, biological, and radiological characteristics of a cohort of patients with various rare bone diseases, in order to optimize the diagnostic and therapeutic approach.
Materials and Methods: This is a descriptive retrospective study conducted in the rheumatology department of the University Hospital Center of Casablanca. The inclusion criteria were patients being monitored for rare and bone diseases treated at the specialized hospital unit.
Results: We collected data from 21 patients. Paget's disease and osteogenesis imperfecta were the most common conditions, with seven patients each. Fibrous dysplasia and melorheostosis were identified in two patients each. Meanwhile, Van Buchem's disease, pycnodysostosis, and cleidocranial dysplasia were reported in only one patient each. The average age at diagnosis varied depending on the pathology, ranging from 16 years for cleidocranial dysplasia to 60.5 years for Paget's disease. A female predominance was observed in Paget's disease (4F/3M), whereas a male predominance was noted in osteogenesis imperfecta (3F/4M). Melorheostosis exhibited a balanced distribution (1F/1M). Conversely, pycnodysostosis and Van Buchem's disease had a male distribution. However, cleidocranial dysplasia and fibrous dysplasia affected female cases. The consanguinity context was reported in osteogenesis imperfecta, pycnodysostosis, and cleidocranial dysplasia. Almost all patients (90.47%) experienced bone pain. Deformities predominated in Paget's disease, osteogenesis imperfecta, fibrous dysplasia, and melorheostosis, while craniofacial and dental dysmorphologies characterized Van Buchem's disease, pycnodysostosis, and cleidocranial dysplasia. Polyostotic forms were predominant in Paget's disease (n=6) and fibrous dysplasia (n=2). Multiple fractures were observed in all patients with osteogenesis imperfecta (n=7), fibrous dysplasia (n=2), and pycnodysostosis (n=1). However, no cases were reported for melorheostosis, Van Buchem's disease, or Paget's disease.
Radiographs revealed specific characteristics according to the pathology. Paget's disease presented mixed osteolytic and osteosclerotic lesions. Osteogenesis imperfecta showed a "sandwich" appearance, while fibrous dysplasia resulted in a "shepherd's crook" deformity with "ground-glass" areas. Melorheostosis was characterized by "candle flow"-like cortical hyperostosis and ectopic ossifications. Van Buchem's disease involved cortical thickening alongside maxillary bone condensation. Pycnodysostosis manifested as diffuse bone hyperdensity, clavicular and mandibular hypoplasia, and resorption of the phalangeal tufts. Lastly, cleidocranial dysplasia associated macrocephaly with suture closure defects, clavicular hypoplasia, distal phalangeal hypoplasia with lengthening of the second metacarpals, pelvic hypoplasia with bilateral coxa vara, and anterolisthesis of L5-S1 due to congenital isthmic lysis. Bone densitometry indicated osteoporosis in seven patients, primarily in osteogenesis imperfecta (n=6), and osteopenia in two patients (Paget's disease n=1, osteogenesis imperfecta n=1). An elevation of bone remodeling markers (CTX) was noted in three cases (Paget's disease n=2, fibrous dysplasia n=1) and of alkaline phosphatases in one case of osteogenesis imperfecta.
Therapeutic Approach: Bisphosphonates, particularly zoledronic acid, alendronic acid, and pamidronate, formed the cornerstone of treatment in Paget's disease, osteogenesis imperfecta, melorheostosis, and cleidocranial dysplasia. A short course of corticosteroids in combination with symptomatic treatment was used to relieve pain in Van Buchem's disease.
Discussion and Conclusion: Fragilizing osteopathies, although rare, are characterized by significant clinical heterogeneity, ranging from simple bone pain to severe deformities and pathological fractures. Their diagnosis relies on a rigorous correlation between clinical and paraclinic.

P879

THE EFFECT OF NIGHTTIME ORTHOSIS USES ON MORNING STIFFNESS AND GRIP STRENGTH IN PATIENTS WITH RISARTHROSIS

K. Nazarova[1], L. Marchenkova[1]

[1]Federal State Budgetary Institution "National Medical Research Center for Rehabilitation and Balneology" of the Ministry of Health of the Russian Federation, Moscow, Russia

Aim. To evaluate the relationship between the nighttime duration of wearing an orthosis for rest and the severity of morning stiffness and grip strength in patients with stage I-II rhizarthrosis.
Materials and methods. A prospective single-center study included 38 women with a confirmed diagnosis of rhizarthrosis. All patients wore a standard rigid orthosis for the thumb during night sleep. The participants were divided into three groups depending on the average duration of orthosis use at night: group 1 (n=13) - less than 4 hours, group 2 (n=12) - 4-6 hours, group 3 (n=13) - more than 6 hours. The main result was an assessment of the intensity of morning stiffness on a 10-point visual analog scale (VAS) after waking up. The secondary result was grip strength (in kg), measured using a dynamometer in the morning before removing the orthosis and after morning SARAH training. The assessments were carried out at the initial stage and after 4 weeks of using the orthosis.
Results. After 4 weeks, a significant negative correlation was found between the duration of wearing the orthosis and morning stiffness ($p= -0.72$, $p<0.01$). Group 3 (>6 hours) showed the most pronounced decrease in pain compared to VAS from 6 [5; 7] mm to 2 [1.4; 3] mm ($p<0.001$), ahead of groups 1 and 2 ($p<0.05$). The morning grip strength before removing the orthosis was significantly higher in group 3, 14.1 [11.3; 16.9] kg compared with group 1, 18.5 [15.3; 20.7] ($p<0.05$). After the exercises, grip strength was equal in all groups, but the dynamics of recovery was more pronounced in group 3.
Conclusions. Using an orthosis to rest at night for more than 6 hours leads to a statistically significant and clinically significant reduction in morning stiffness and an improvement in initial grip strength in patients with rhizarthrosis. To achieve optimal clinical effect, patients should be advised to wear the orthosis for at least 6 hours continuously during sleep. Further research is needed to establish the long-term effect of orthosis on disease progression.

P880

ANALYSIS OF DISEASE INCIDENCE, CLINICAL MANIFESTATIONS, AND ASSESSMENT OF TREATMENT EFFECTIVENESS IN PATIENTS WITH ANKYLOSING SPONDYLITIS IN KAZAKHSTAN

K. Nurgaliyev[1], B. Issayeva[1], S. Issayeva[1]

[1]Kazakh National Medical University named after S.D.Asfendiyarov, Almaty, Kazakhstan

Background/Purpose: To investigate the incidence rates and clinical manifestations of ankylosing spondylitis (AS), as well as to assess the effectiveness and safety of golimumab (GLM) in the treatment of patients in real-world clinical practice.

Methods: National epidemiological data from the Ministry of Health of the Republic of Kazakhstan covering the period 2014–2023 were analyzed, including official statistical yearbooks and the consolidated healthcare utilization reporting form (Form No. 12). Adult patients (≥18 years) with a confirmed diagnosis of ankylosing spondylitis (AS) according to the ASAS 2009 classification criteria who were receiving biologic therapy within the framework of the Guaranteed Volume of Free Medical Care were included in the analysis (Kazakhstan's state-funded healthcare program providing free access to essential medical services, including biologic therapies). Golimumab (GLM), a tumor necrosis factor-α (TNF-α) inhibitor, was prescribed following the decision of a multidisciplinary expert committee after comprehensive evaluation of patients' medical history, clinical manifestations, and laboratory and imaging findings. In the prospective cohort, 102 patients fulfilling the inclusion criteria and presenting with active disease were treated with GLM at a dose of 50 mg administered subcutaneously every 4 weeks for a period of 3 years. Treatment effectiveness was evaluated based on changes in disease activity assessed by the ASDAS, and the by BASDAI, and predefined clinical response criteria. Treatment safety, including combination therapy with conventional DMARDs, was assessed through systematic monitoring of adverse events (AEs).

Results: In 2014, the total number of patients with ankylosing spondylitis (AS) in Kazakhstan was 3,331, including 1,162 women. Over a 10-year period, the cumulative increase in AS prevalence across the country reached 64.7%. Male patients predominated (65.1%), consistent with established epidemiological patterns. In the study cohort, males accounted for 74.5% of patients, and individuals of Asian ethnicity comprised 66.7%. Disability related to AS was documented in 31.4% of patients, while 61.8% were employed or actively studying. Body mass index (BMI) was reduced in 5.9% of patients, normal in 50.0%, and increased in 44.1%. Smoking was reported by 55.9% of patients. The mean age at first visit was 39.3 ± 11.6 years (range 16–68 years). The median disease duration was 12 years [Q1; Q3: 7–19]. A proportion of patients had been followed by other specialists (neurologists, orthopedists), and the median diagnostic delay from symptom onset to AS diagnosis was 5 years [Q1; Q3: 2–9], ranging from 0 to 38 years. HLA-B27 positivity was detected in 79.4% of patients. High or very high disease activity was observed in 91.2%, and functional class II–IV was documented in 50.0%. Extra-axial clinical manifestations (peripheral arthritis, enthesitis, dactylitis) were present in 91.2% of patients, while extra-skeletal manifestations (uveitis, inflammatory bowel disease, psoriasis, nephropathy) were observed in 67.6%. Disease-related complications, including osteoporosis, vertebral compression fractures, and joint arthroplasty, were identified in 34.3% of patients. Comorbid conditions (arterial hypertension, diabetes mellitus, ischemic heart disease, gastropathy) were present in 59.8%. The median fecal calprotectin level was 39.1 μg/g [Q1; Q3: 23.6–73.4]. At baseline, 92.1% of patients were receiving NSAIDs, 73.5% conventional DMARDs (methotrexate, leflunomide, sulfasalazine), and 34.3% corticosteroids. Prior to registry inclusion, 24.5% of patients had been treated with biologic agents (adalimumab, infliximab, or golimumab), while 75.5% were biologic-naïve. The median baseline BASDAI score was 5.5 [Q1; Q3: 4.4–7.0], and the ASDAS-ESR was 3.2 [Q1; Q3: 2.8–3.5]. A significant reduction in disease activity was observed over the course of therapy ($p < 0.001$). During follow-up, 65.7% of patients achieved major clinical improvement (ASDAS decrease ≥2.0), and 25.5% achieved clinically important improvement (ASDAS decrease ≥1.1). Switching from golimumab to another biologic agent due to clinically insufficient response was required in 7.1% of patients. Golimumab was discontinued in two patients due to suspected pulmonary tuberculosis and in one patient due to suspected malignancy. An allergic reaction to golimumab was reported in one patient (0.9%).

Conclusion: Analysis of epidemiological indicators confirms that ankylosing spondylitis remains a significant healthcare burden in Kazakhstan, underscoring the need for increased clinical awareness, earlier diagnosis, and timely implementation of innovative therapeutic strategies.

P881

EFFECTIVENESS AND SAFETY OF UPADACITINIB IN PATIENTS WITH RHEUMATOID ARTHRITIS

R. O. Mnevets[1], I. Ostrovska[2], K. Ostrovskyy[3]

[1]Educational and Scientific Center "Institute of Biology and Medicine", Taras Shevchenko National University of Kyiv. State Institution "Ukrainian Center of Maternity and Childhood of the National Academy of Medical Sciences of Ukraine", Kyiv, Ukraine; [2]Dept. of Therapy, Shevchenkivskyi District Outpatient Dept. #2, Kyiv, Ukraine; [3]Pharmaceutical Product Development, Warsaw, Poland

Objectives: Upadacitinib (UPA) is a selective oral Janus kinase (JAK) inhibitor with a preferential inhibition of JAK1 over JAK2, JAK3, and TYK2.

Material and Methods: The study included 28 adult patients with active RA (DAS28-ESR >3.2) and an inadequate response (IR) to ≥1 conventional synthetic disease-modifying antirheumatic drug (csDMARD) (71% to methotrexate) and/or ≥1 biological or targeted synthetic DMARD (24% to TNF-α inhibitors). All patients received UPA at a dose of 15 mg once daily. Disease activity was assessed using composite indices (DAS28-ESR, SDAI, CDAI) at baseline and after 3, 6, and 12 months of therapy. Treatment response was evaluated according to EULAR criteria. All adverse events (AEs) were systematically recorded. Statistical analysis was performed using non-parametric tests (Wilcoxon signed-rank test for paired samples), with data presented as mean ± standard deviation or median.

Results: A statistically significant reduction in all disease activity indices was observed after 12 months of therapy ($p < 0.001$ for all comparisons to baseline). The median DAS28-ESR decreased from 5.1 to 2.2 [1.2; 3.3], SDAI from 27.5 to 7.6 [3.0; 10.9], and CDAI from 24.5 to 7.5 [3.0; 10.5]. According to the EULAR response criteria, clinical improvement was achieved in 86.7% of patients at 3 months, 76.9% at 6 months, 92.3% at 9 months, and 87.5% at 12 months (completer analysis). The proportion of patients achieving a good EULAR response increased from 53.3% (8 out of 15) at month 3 to 87.5% (7 out of 8) by month 12. The rate of low disease activity (CDAI ≤10) reached 75% (6 out of 8) among

completers at the 12-month visit. Adverse events were reported in 14% of patients (n=3). The most common AEs were mild upper respiratory tract infections. No serious adverse events, including major adverse cardiovascular events (MACE), venous thromboembolism (VTE), or deaths, were recorded during the observation period.

Conclusions: In this small real-world with active RA and prior inadequate response to therapy, upadacitinib at a dose of 15 mg once daily demonstrated significant and sustained clinical effectiveness, with a high rate of low disease activity achievement. The safety profile was favorable and consistent with data from pivotal clinical trials. The main limitations of this study are its small sample size, single-center design, and the absence of a control group. The obtained results support the effectiveness and acceptable tolerability of upadacitinib in routine clinical practice for managing complex RA cases.

P882

CLINICAL COURSE OF GOUT IN CANCER PATIENTS

R. O. Mnevets[1], K. Ostrovskyy[2], I. Ostrovska[3]

[1]Educational and Scientific Center "Institute of Biology and Medicine", Taras Shevchenko National University of Kyiv. State Institution "Ukrainian Center of Maternity and Childhood of the National Academy of Medical Sciences of Ukraine", Kyiv, Ukraine; [2]Pharmaceutical Product Development, Warsaw, Poland; [3]Dept. of Therapy, Shevchenkivskyi District Outpatient Dept. #2, Kyiv, Ukraine

Objective: The management of gout in oncology patients is clinically challenging. Hyperuricemia can be both a pre-existing condition and a consequence of cancer or its treatment. Chemotherapy, radiation, and major surgery can enhance catabolism and tumor cell lysis, leading to increased uric acid (UA) production. This elevates the risk of acute gout flares and urate nephropathy, particularly in the context of tumor lysis syndrome. This study aimed to retrospectively analyze the onset and course of gout in patients with concomitant malignancies to optimize hyperuricemia management strategies in this population.

Material and Methods: A retrospective analysis was performed using medical records of 47 patients (24 men, 23 women) diagnosed with both gout and cancer, treated at a multidisciplinary center between 2021 and 2025. Inclusion criteria: age >18, verified gout diagnosis (by ACR/EULAR 2015 criteria or presence of tophi), active malignancy. We assessed: chronological relationship between gout and cancer onset, serum UA dynamics during cancer treatment, frequency of acute arthritis, and efficacy/adjustments of urate-lowering therapy (ULT). Descriptive statistics were applied.

Results:

1. Demographics and Cancer Types. Mean age: men 66±12 yrs, women 64±14 yrs. Predominant cancers: prostate cancer (PCa) in men (n=16; 66.7%), breast cancer (BCa) in women (n=7; 33.3%).
2. Gout Onset vs. Cancer Diagnosis. Gout preceded cancer diagnosis in 57% of PCa patients. All bladder cancer patients (n=4) had pre-existing gout. In Hodgkin's lymphoma and renal cell carcinoma patients, acute gout debuted during chemotherapy.
3. Hyperuricemia and Gout Course During Treatment. In PCa patients with previously controlled gout, serum UA increased by 21-85% after cancer diagnosis/surgery, necessitating ULT intensification in 65.7% (switch from allopurinol to febuxostat). Acute flares within the first post-operative month occurred in 61.7% of surgically treated patients. Target UA (<360 µmol/L) was difficult to achieve in metastatic PCa. Conversely, two bladder cancer patients achieved sustained normouricemia and could discontinue allopurinol after radical cystectomy.
4. Impact of Different Cancer Therapies. Chemotherapy was associated with high UA levels (>650 µmol/L) and new-onset acute arthritis. Hormonal therapy (aromatase inhibitors, tamoxifen for BCa) did not significantly worsen gout control. Targeted therapy in one case was associated with normouricemia. Radiation therapy showed no significant impact on flare frequency.
5. Specifics in Female Patients. Patients with thyroid cancer (n=3) had a persistent gout course with frequent flares that continued post-operatively despite ULT.

Discussion: Our findings align with known pathophysiology of hyperuricemia in cancer. Increased catabolism post-surgery and the cytolytic effect of chemotherapy are potent triggers for acute gout, even with baseline ULT. The variable response (worsening in PCa vs. improvement in bladder cancer) requires further study but may be related to surgery extent, renal function, and metabolic effects of hormonal therapy. The neutral impact of some targeted and hormonal therapies on UA levels is a favorable finding for comorbidity management.

Conclusions: The development of cancer, especially metastatic disease, is associated with a more severe gout course, frequently requiring ULT intensification. Chemotherapy and major surgeries are high-risk periods for acute gout flares, mandating proactive UA monitoring and management. The effect of anticancer treatment on UA levels and gout activity is heterogeneous and depends on tumor type, treatment modality (cytoreductive vs. hormonal/targeted), and likely baseline renal function.

P883

SHOULDER PAIN AFTER ACUTE SPINAL CORD INJURY: SYSTEMATIC REVIEW – PRELIMINARY RESULTS

K. Pithon[1,2], A. Cliquet[1,3], L. Paul[4]

[1]State University of Campinas, Campinas, Brazil; [2]Southwest Bahia State University, Jequié, Brazil; [3]University of São Paulo, Campinas, Brazil; [4]Glasgow Caledonian University, Glasgow, United Kingdom

Objective: The aims of this study were (1) to review the literature on shoulder pain in individuals with acute SCI (2) to summarise prior research regarding shoulder pain during rehabilitation treatment.

Material and Methods: A systematic literature search was conducted in MEDLINE (Ovid), CINAHL (EBSCOhost), Cochrane Library, Pedro and EMBASE. The literature was searched from the earliest record until April 2025. Inclusion criteria: Adults with acute (<1 year) SCI; shoulder pain as outcome measure; full-text articles published in English. Excluded criteria: participants with other conditions or where the data from the SCI participants could be extracted. Studies was not excluded on the basis of quality or methodological rigour. Titles and abstracts were screened by two reviewers and then the full text of relevant articles were similarly screened using Covidence systematic review software. Data of included studies was extracted into an excel spreadsheet and the quality was assessed.

Results: 14 studies were included (totalling 2510 participants), one clinical trial, 4 observational study, 9 prospective or retrospective. Four studies came from the same research programme; two studies from one multicentral rehabilitation programme. Studies have shown that shoulder pain is a common condition in patients with spinal cord injury, even in the acute phase. Shoulder pain was more prevalent in those with tetraplegia. Rehabilitation programs in the acute phase can be effective

in the early identification and management of shoulder pain. However, due to its multifactorial causes, a consistent treatment protocol has not been observed. Studies have used various methods to assess pain, such as asking about the presence of pain; pain rating scales; or the use of validated questionnaires.
Conclusion: . Although there is consensus that shoulder pain is a common condition in patients with spinal cord injury and a rehabilitation programme is necessary, the evidence remain insufficient to consistently assess its cause, prevention, or treatment.

P884

ASSOCIATION OF MALNUTRITION SCORES WITH OSTEOSARCOPENIA IN MIDDLE-AGED AND OLDER ADULTS: A CROSS-SECTIONAL STUDY

K. Prokopidis[1], G. Duque[2]

[1]University of Glasgow, Institute of Cardiovascular and Medical Sciences, School of Cardiovascular and Metabolic Health, Glasgow, United Kingdom; [2]Bone, Muscle and Geroscience Group, Research Institute of the McGill University Health Centre, McGill University, Montreal, Canada

Objectives: The aim of this study was to explore the association of malnutrition indices, such as the geriatric nutritional risk index (GNRI) and the controlling nutritional status (CONUT) scores, with osteosarcopenia.
Methods: In this cross-sectional study, we used data from the National Health and Nutrition Examination Survey cycles 2011-2014. Participants were aged 50-85 years and osteosarcopenia was defined according to established criteria [(diagnosis of osteoporosis or osteopenia and low handgrip strength (HGS)]. Multivariable logistic regression models, adjusted for age, sex, race, education, body mass index, comorbidities, physical activity, and protein intake, were used to examine associations of GNRI (<98 vs. ≥98) and CONUT (≥2 vs. 0-1) with markers of osteosarcopenia. Linear regression was used to investigate the bidirectional association of osteosarcopenia markers with malnutrition, continuously.
Results: Among 2733 adults (58.3 ± 11.8 years; 1372 men/1361 women), a lower GNRI score was associated with higher odds (OR) of osteopenia and low HGS [3.98, 95% confidence interval (CI) 1.47 – 10.74, p = 0.01] and osteoporosis and low HGS (3.11, 95%CI 1.40 – 6.90, p < 0.01), a relationship driven by low HGS (3.06, 95%CI 1.38 – 6.78, p < 0.01). No associations were observed with higher CONUT (p>0.05). These were translated into linear associations of low HGS (b = 1.61, p = 0.02) and osteopenia and low HGS (b = 1.73, p = 0.02), but not osteoporosis and low HGS (b = 1.91, p = 0.05) with higher GNRI. Similar OR were observed in adults >65 years in relation to lower GNRI with low HGS (2.35, 95%CI 1.04 – 5.31, p = 0.04), osteopenia and low HGS (3.39, 95%CI 1.36 – 8.45, p = 0.01), osteoporosis and low HGS (2.72, 95%CI 1.00 – 7.40, p = 0.05).
Conclusions: Lower GNRI, but not higher CONUT score, is strongly associated with osteosarcopenia measures in middle-aged-to-older adults. These results may support nutritional interventions to mitigate musculoskeletal decline.

P885

IMPACT OF DIGITAL PATIENT-REPORTED OUTCOME MONITORING ON TREATMENT ADHERENCE AND DISEASE ACTIVITY CONTROL IN RHEUMATOID ARTHRITIS IN THE REPUBLIC OF TAJIKISTAN

K. R. Mahmudzoda[1], E. Y. Polishchuk[2], A. E. Karateev[2], A. M. Lila[3], V. N. Khlaboshchina[2]

[1]Avicenna Tajik State Medical University, Dushanbe, Tajikistan; [2]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia; [3]V.A. Nasonova Research Institute of Rheumatology; Russian Medical Academy of Continuous Professional Education of the Ministry of Healthcare of the Russian Federation, Moscow, Russia

Objective: To evaluate the impact of regular digital monitoring of patient-reported outcomes (PROs) on treatment adherence and disease activity control in patients with rheumatoid arthritis (RA), and to correlate patient engagement in digital monitoring with clinical treatment outcomes.
Methods: A prospective observational study included 500 RA patients under follow-up in rheumatology departments of the Republic of Tajikistan. The mean age was 52.6 ± 11.4 years; 78% were women, and the mean disease duration was 6.8 ± 4.9 years. A Telegram bot was used for remote monitoring, allowing patients to self-assess pain, fatigue, functional limitations, psycho-emotional state, and treatment satisfaction on a weekly basis. Treatment adherence was indirectly assessed based on the regularity of PRO submissions, self-reported compliance with medical prescriptions, and stability of parameters between visits. Disease activity was assessed during in-person visits at baseline and after 6 months of follow-up using the DAS28 index. Patients were stratified based on their level of engagement in digital monitoring (regular vs. irregular PRO submissions).
Results: Regular use of digital PRO monitoring was recorded in 72% of patients, including those residing in rural areas. By the second visit, patients with regular PRO submissions showed an average reduction in DAS28 score of −1.6 ± 0.8, while those with irregular monitoring showed a reduction of −1.1 ± 0.7. Remission or low disease activity according to DAS28 was achieved in 45% of highly engaged patients and 31% of those with low engagement. Patients actively using the Telegram bot demonstrated greater improvement in PROs, including pain and functional limitations, along with less variability in subjective symptoms between visits. In contrast, irregular PRO submission was associated with a higher likelihood of persistent moderate or high RA activity and unstable subjective symptom dynamics.
Conclusion: Regular digital monitoring of PRO is associated with higher treatment adherence and better control of RA activity. The use of digital PROs enhances patient engagement in the treatment process and improves clinical outcomes, supporting the feasibility of integrating digital monitoring tools into routine RA management practice.

P886

PATIENT-REPORTED OUTCOMES AS A MEDIATOR BETWEEN ANTIRHEUMATIC THERAPY AND CLINICAL OUTCOMES IN RHEUMATOID ARTHRITIS: DIGITAL MONITORING DATA FROM THE REPUBLIC OF TAJIKISTAN

K. R. Mahmudzoda[1], E. Y. Polishchuk[2], A. E. Karateev[2], A. M. Lila[3], V. N. Khlaboshchina[2]

[1]Avicenna Tajik State Medical University, Dushanbe, Tajikistan; [2]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia; [3]V.A. Nasonova Research Institute of Rheumatology; Russian Medical Academy of Continuous Professional Education of the Ministry of Healthcare of the Russian Federation, Moscow, Russia

Objective: To assess the role of patient-reported outcomes (PROs) as a mediator between administered antirheumatic therapy and changes in disease activity in patients with rheumatoid arthritis (RA).

Methods: A prospective observational study included 500 RA patients under follow-up in rheumatology departments of the Republic of Tajikistan. The mean age was 52.6 ± 11.4 years, 78% were women, and the mean disease duration was 6.8 ± 4.9 years. A Telegram bot was used for remote patient monitoring, enabling regular collection of PROs (pain, fatigue, functional limitations, psycho-emotional state, treatment satisfaction) between physician visits. RA activity was assessed during in-person visits at baseline and after 6 months of follow-up using the DAS28 and CDAI indices. A correlation analysis was performed to examine the relationship between changes in PROs and the dynamics of disease activity indices, and a mediation analysis was conducted to evaluate the influence of PROs on the efficacy of RA therapy.

Results: Higher baseline disease activity according to DAS28 was associated with worse PRO scores. Changes in PROs recorded via digital monitoring demonstrated a moderate correlation with the dynamics of DAS28 (r = 0.61) and CDAI (r = 0.57). In some patients, PRO improvement was recorded earlier than a clinically significant decrease in disease activity indices at the follow-up visit.

Mediation analysis revealed that PRO improvement accounted for a significant portion of the therapy's effect on reducing RA activity: up to 40% of the overall treatment effect on DAS28 dynamics was mediated through improvement in PROs. In patients with an insufficient response to therapy, unfavorable PRO dynamics persisted despite reductions in laboratory and clinical activity markers.

Conclusion: PROs play a significant mediating role between antirheumatic therapy and clinical outcomes in RA patients. Digital monitoring of PROs enables the detection of changes in patient status that are not fully captured by standard clinico-laboratory disease activity indices, thereby complementing traditional approaches to therapy efficacy assessment. Integrating PROs in a digital format into routine RA monitoring practice enhances the accuracy of treatment response evaluation and improves the patient-centered focus of clinical management.

P888

MEAN ARTERIAL PRESSURE IS A NOVEL VASCULAR MARKER OF OSTEOPENIA AND OSTEOPOROSIS IN PATIENTS WITH TYPE 2 DIABETES

K. S. Goh[1], S. Low[2]

[1]Changi General Hospital, Singapore, Singapore; [2]Khoo Teck Puat Hospital, Singapore, Singapore

Objectives

Mean arterial pressure (MAP) is a vascular marker which indicates the average pressure in arteries during a complete heartbeat cycle. It reflects overall cardiovascular health. Given the shared biological mechanisms underlying hypertension and osteoporosis such as diabetes, inflammation, oxidative stress and increased angiotensin, we investigated the relationship between MAP with osteopenia and osteoporosis.

Materials and Methods

This cross-sectional study was conducted on 95 patients with type 2 diabetes (T2D). MAP was calculated as systolic blood pressure [(SBP) + 2 x diastolic blood pressure (DBP)]/3. We used dual-energy x-ray absorptiometry (DEXA) to derive T-score. Osteopenia was defined as T-score between -1.0 and -2.5. Osteoporosis was defined as T-score < -2.5. Logistic and linear regressions were used to examine the relationship between MAP with binary outcome (osteopenia and osteoporosis) and continuous outcome (DEXA T-score) respectively, adjusting for demographics, clinical variables, medications and physical activity.

Results

The mean age was 59.6 (SD 11.9) years. The mean MAP was 97.0 (SD 10.2). The prevalence of osteopenia and osteoporosis was 54.7% (49.4% osteopenia, 10.5% osteoporosis). Compared to Tertile 1, Tertile 3 MAP was associated with higher odds of osteopenia and osteoporosis with OR 4.79 (95%CI 1.63,14.06; p=0.004) in crude analysis. In the fully adjusted analysis, the association persisted with OR 5.79 (95%CI 1.30, 25.80; p=0.021). On the contrary, SBP and DBP were not associated with osteopenia and osteoporosis. Tertile 3 MAP was also associated with lower DEXA T-score in crude (coefficient -0.84, 95%CI -1.48, -0.19; p=0.011) and fully adjusted (coefficient -0.99, 95%CI -1.74, -0.25; p=0.010) analyses.

Conclusions

There was a non-trivial prevalence of osteopenia in patients with T2D. Higher MAP was independently associated with osteopenia and osteoporosis. The findings suggest that the combined effect of SBP and DBP was more pronounced in osteopenia and osteoporosis than either component alone. Further studies are needed to elucidate the underlying pathophysiological mechanism.

QUANTITATIVE ASSESSMENT OF EFFUSION-SYNOVITIS IN KNEE OSTEOARTHRITIS AND COMPARISON WITH GOLD-STANDARD RADIOLOGICAL READINGS

K. Sheikhi Valashani[1,2], F. Eckstein[1,2] , T. Winkler[3,4], F. W. Roemer[5, 6], A. Guermazi[6, 7], W. Wirth[1,2]

[1.] Chondrometrics GmbH, Freilassing, BY, Germany, [2.] Center of Anatomy and Cell Biology & Ludwig Boltzmann Institute for Arthritis and Rehabilitation, Paracelsus Medizinische Privatuniversitat, Salzburg, Salzburg, Austria, [3.] Center for Musculoskeletal Surgery, Charite - Universitatsmedizin Berlin, Berlin, BE, Germany, [4.] Julius Wolff Institute, Charite - Universitatsmedizin Berlin, Berlin, BE, Germany, [5.] Radiology, Universitatsklinikum Erlangen, Erlangen, BY, Germany, [6.] Boston Imaging Core Lab LLC, Boston, MA, United States, [7.] VA Boston Healthcare System, West Roxbury, MA, United States

Objectives To quantify effusion-synovitis (ES) volume using MRI and fully automated AI-based technology, and to compare measurements between knees classified as having effusion vs. without effusion based on expert semi-quantitative (sq) MRI readings.

Methods In this preliminary analysis, ES was graded by expert MOAKS readings (grades 0–3) in 168 knees (66% female; age 63±9 y; BMI 31±5.0 kg/m²) from the OA Initiative. ES volume (mm³) was determined using an in-house convolutional neural network (CNN)-based segmentation algorithm applied to axial reformatted DESS MRI. The model was trained using 395 knees with semiautomated, quality-controlled segmentation (214 grade 0, 181 grades 1-3). Owing to limited numbers of higher grades in the test set, comparison was restricted to effusion presence (MOAKS grades 0 vs. 1–3). Group differences were assessed using independent-samples t-tests and effect sizes using Cohen's d with 95% confidence intervals.

Results Of the 168 knees in the test, 114 had effusion and 54 did not based on expert sq readings. ES volume tended to be greater in knees with effusion compared to those without, with an effect size (Cohen's d) of 0.30 (95% CI −0.02 to 0.63).

Conclusions These preliminary results suggest that differences in expert semi-quantitative ES MOAKS scores (presence and absence of ES) are reflected in quantitative ES volumes derived from fully automated segmentation. Visual inspection revealed instances of oversegmentation by the CNN algorithm, and measures will be implemented to further improve technical accuracy. Additional analyses using larger datasets will enable comparisons across individual MOAKS effusion grades and evaluation of automated ES measures against external benchmarks, such as osteoarthritis progression and Hoffa synovitis, to allow greater analytic granularity and assess their relative clinical performance (Eckstein et al., same conference).

P890

PRACTICE PATTERNS AND PERCEPTIONS IN AVASCULAR NECROSIS (AVN) MANAGEMENT: A NATIONWIDE SURVEY AMONG INDIAN ORTHOPAEDICIANS

S. Agarwala[1], M. Vijayvargia[1], P. Palkar[2], K. Shriram Dhanasekaran[2], S. Mehta[2]

[1]Department of Orthopedics & Traumatology, P.D. Hinduja Hospital & Med.Res.Centre, Mumbai, India; [2]Medical Affairs, Cipla, Mumbai, India

Background: Avascular Necrosis (AVN) is a progressive bone disorder often culminating in joint collapse and disability. Post-COVID-19, anecdotal reports suggested a surge in AVN cases, warranting systematic evaluation of perceptions and management strategies among Indian Orthopaedicians.

Objective: To assess current clinical perspectives on AVN etiology, post-pandemic trends, therapeutic and surgical preferences across disease stages.

Methods: A structured questionnaire comprising 18 items was disseminated to Orthopaedicians nationwide (N=625). Responses were analyzed descriptively to identify common trends in etiology, treatment awareness, and management patterns for early (Ficat 0–II) and advanced (Ficat III-IV) AVN.

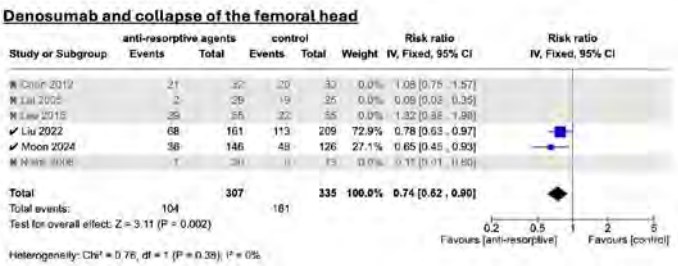
Results: Corticosteroid exposure was perceived as the leading cause of AVN (47.2%), followed by trauma (24.5%) and chronic alcoholism (11.8%). A majority (81.4%) reported that the post-COVID spike in AVN cases persists, attributing it primarily to corticosteroid use (61.4%). Bilateral hip involvement was most frequently encountered (54.9%). For early-stage AVN, 83.4% were aware of pharmacological management; bisphosphonates were considered the most effective drug class (56.5%). Clinical improvement was expected within 4–12 weeks (57.1%), with a typical treatment horizon of two years (51.2%) with bisphosphonates. Notably, 58.7% favored medical therapy over surgical decompression, and 59.0% perceived its success rate as superior to biological therapy in early stages. In advanced AVN, Ficat stage III, core decompression combined with stem-cell therapy was preferred (39.0%), followed by osteoblast implantation (20.2%), and for Ficat stage IV, total hip replacement (THR) (19.2%). Post-THR, sitting on the floor was the most restricted activity (33.3%). Implant longevity was estimated at 15–20 years by 56.6% of respondents. Adjunctive strategies when bisphosphonates were deemed marginal included physical therapy (62.4%), calcium/vitamin D supplementation (58.4%), and combination bisphosphonate regimens (57.4%). Gentle range-of-motion exercises (63.7%) and non-weight-bearing activities (59.7%) were widely recommended.

Conclusion: Corticosteroid use remains the predominant perceived driver of AVN, which has attributed to the post-COVID AVN surge. Awareness of medical management in early AVN, especially with bisphosphonate regimens, is strong among the doctors, who generally expect clinical benefit within 4–12 weeks and practice a management horizon of ~2 years. These findings underscore the need for evidence-based guidelines on steroid stewardship, pharmacologic optimization, and rehabilitation protocols.

P891

DENOSUMAB DEMONSTRATES EFFECTIVENESS IN PREVENTING FEMORAL HEAD COLLAPSE FOLLOWING NON-TRAUMATIC OSTEONECROSIS

K. Sukhonthamarn[1], N. Niyomrattanakit[1], W. Tangphromphan[1], W. Kosuwon[1]



[1]Khon Kaen University, Khon Kaen, Thailand

Introduction: The use of traditional anti-resorptive agents, such as bisphosphonates, to prevent femoral head collapse in atraumatic osteonecrosis of the femoral head (ONFH) has yielded inconclusive results. Denosumab, a potent RANKL inhibitor, has shown superior efficacy in increasing bone mineral density and reducing fracture risk. This systematic review and meta-analysis aimed to evaluate the efficacy of denosumab and other anti-resorptive agents in preventing femoral head collapse and improving functional outcomes.

Materials and Methods: A comprehensive search was performed across PubMed, CENTRAL, and Scopus for studies published through November 2025. Primary outcomes included the rate of femoral head collapse and conversion to total hip replacement (THR). Secondary outcomes included functional scores (Harris Hip Score [HHS] and WOMAC). Heterogeneity was assessed using I^2 and chi-square statistics; a random-effects model was applied if $I^2 > 50\%$

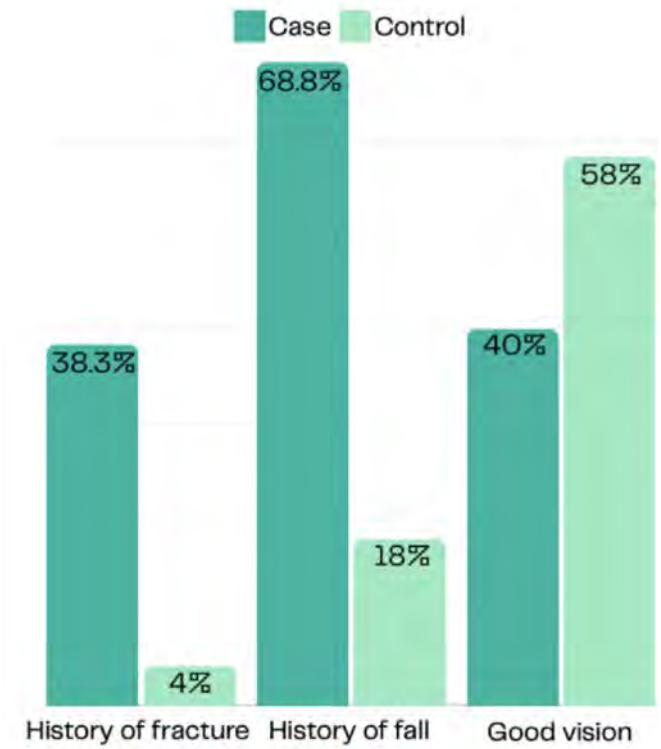
Results: Six studies (904 hips) were included for analysis from an initial 238 records. Interventions included alendronate (n=3), zoledronate (n=1), and denosumab (n=2). Initially, pooled results for all anti-resorptive agents showed no statistically significant difference in collapse prevention compared to controls. However, sensitivity analysis specifically for denosumab demonstrated a significant reduction in femoral head collapse (Risk Ratio [RR] = 0.74; 95% CI: 0.62–0.90; p=0.002; I^2=0%). No significant difference was observed in THR conversion rates across the anti-resorptive groups. While functional scores (HHS and WOMAC) favored anti-resorptive treatment, the results did not reach statistical significance.

Conclusion: This meta-analysis supports the efficacy of denosumab in reducing the incidence of femoral head collapse in patients with non-traumatic ONFH, whereas results for traditional bisphosphonates remain inconsistent. Further large-scale, randomized controlled trials are warranted to confirm the long-term clinical benefits of high-potency anti-resorptive agents in this population.

P892

FACTORS ASSOCIATED WITH FALL-INDUCED HIP FRACTURES IN ELDERLY PATIENTS

K. Sukhonthamarn[1], P. Pandaeng[1], A. Aussawapinyopak[1], C. Vichapatana[1], W. Kosuwon[1]



[1]Khon Kaen University, Khon Kaen, Thailand

Background and Objectives: Fall-induced hip fractures in the elderly significantly impair quality of life and are associated with high mortality rates. Identifying and managing modifiable risk factors are critical steps in fracture prevention. This study aims to evaluate the correlation between potential predictors of falls and the incidence of hip fractures among elderly patients at a university-based tertiary care center.

Methods: A case-control study was conducted involving 180 subjects, including elderly patients with fall-induced hip fractures and age-matched controls. Data were collected using standardized questionnaires. Statistical analysis was performed using Fisher's exact test and Chi-square tests to determine associations between clinical variables and fracture occurrence.

Results: The study achieved a response rate of 90.91% (180/198). Analysis revealed that an increased frequency of falls and hip fractures was most strongly associated with a **history of fracture within the past year** and a **history of falls within the past year**. Conversely, **preserved visual acuity** was identified as a significant protective factor against both falls and subsequent hip fractures. Other assessed risk factors did not demonstrate a statistically significant association with the outcomes in this cohort.

Conclusion: In the elderly population, a history of falls or fractures within the previous year serves as a primary predictor for hip fracture risk. Furthermore, good vision is a key protective factor. Targeted screening of fall history and regular visual assessments should be integrated into geriatric fall-prevention programs to reduce the incidence of hip fractures.

P893

DEEP LEARNING BASED OPPORTUNISTIC OSTEOPOROSIS SCREENING ON CHEST RADIOGRAPHS WITH UNCERTAINTY AND CALIBRATION

K. W. Kim[1], M. Kim[1], G. Lee[1], N. Kim[2]

[1]Promedius Inc., Seoul, South Korea; [2]University of Ulsan College of Medicine, Asan Medical Center, Seoul, South Korea

Objective: To evaluate the performance of AI-based opportunistic osteoporosis (OP) screening with predictive uncertainty and calibration in heterogeneous clinical environments.
Material and Methods: Two AI-based screening models were developed using chest radiographs (CXRs): a model distinguishing non-OP from OP (Model M1), and the other model classifying normal, osteopenia (OPe), and OP (Model M2). These models were trained on CXRs from a tertiary hospital (Hospital A; N, Ope %, OP %; 62,420, 34.82, 5.85, respectively). Internal (A; 15,357, 34.42, 6.21, respectively), and external 1 from a secondary hospital (Hospital B; 3,338, 34.90, 8.78, respectively) in South Korea, and external 2 validation from a global platform in America (Hospital Cs; 1,026, 53.31, 19.49, respectively) were performed. To enable fair comparison, performance was evaluated using the area under the receiver operating characteristic curves (AUCs) and the area under the precision-recall curves (AUPRCs) for screening OP. Uncertainty estimation was conducted using the Laplace approximation, and calibration was assessed using expected calibration error (ECE).
Results: Both models achieved identical AUCs of 0.96 and 0.92 in A and B, respectively. In Cs, M1 demonstrated a significantly higher AUC than M2 (0.84 vs. 0.81; DeLong $p = 0.01$). Despite comparable AUC performance, M2 consistently achieved higher AUPRC across all cohorts (0.73, 0.53, and 0.61) than M1 (0.70, 0.52, and 0.60). In addition, M2 exhibited higher uncertainty across internal, external, and global validations (48.83 ± 17.36%, 48.86 ± 18.05%, and 57.41 ± 22.03%) compared with M1 (40.77 ± 12.32%, 43.34 ± 20.57%, and 49.89 ± 22.77%), respectively (Wilcoxon $p < 0.01$). Despite this increased uncertainty, M2 demonstrated superior calibration with lower ECE values in Hospitals A and B (2.83% and 3.70%) than M1 (6.71% and 7.01%), respectively. However, under a strong domain shift in Cs, the ECE of M2's degraded substantially (23.40%), whereas M1 remained relatively stable (6.15%).
Conclusion: Both models demonstrated comparable performance across cohorts for opportunistic OP screening; however, M2 showed improved performance under class imbalance and more conservative behavior in ambiguous cases, as reflected by higher predictive uncertainty and better calibration.

P894

IMPACT OF PROJECTION VIEWS (PA VS. AP) ON AI-BASED OSTEOPOROSIS SCREENING USING CHEST RADIOGRAPHS

G. Lee[1], J. Park[1], K. W. Kim[1], Y.-C. Ha[2]

[1]Promedius Inc., Seoul, South Korea; [2]Department of Orthopaedic Surgery, Seoul Bumin Hospital, Seoul, South Korea

Objective: To evaluate the diagnostic performance of an AI-based osteoporosis screening model using chest radiographs (CXRs), with a specific focus on performance differences between posterior–anterior (PA) and anterior–posterior (AP) views in a real-world clinical setting.
Materials and Methods: This retrospective study included CXRs from 969 patients acquired at a specialized musculoskeletal hospital in Seoul between July 2021 and December 2024. The dataset comprised 555 PA images (osteoporosis prevalence 31.35%, female 68.83%, age 69.55 ± 10.04 years) and 414 AP images (prevalence 50.00%, female 71.01%, age 73.87 ± 12.17 years). All CXRs were paired with dual-energy X-ray absorptiometry (DXA) results obtained within a 3-month interval. An AI model originally trained using PA CXRs was evaluated without retraining. Diagnostic performance was assessed using AUROC, sensitivity, specificity, accuracy, and F1-score.
Results: The model demonstrated higher diagnostic performance on PA images than on AP images. For PA views, the AUROC was 0.8618, with a sensitivity of 91.95% and a specificity of 56.69%. For AP views, the AUROC was 0.7480, with a sensitivity of 56.04% and a specificity of 78.74%. Overall accuracy was comparable between PA and AP views (67.75% vs. 67.39%), and the F1-score showed only a modest difference (PA: 0.6413; AP: 0.6321).
Conclusion: An AI-based osteoporosis screening model trained on PA chest radiographs demonstrated robust performance in standard PA imaging and preserved clinically meaningful diagnostic capability when externally validated on AP views. These findings support the feasibility of opportunistic osteoporosis screening using CXRs in heterogeneous real-world settings. Incorporating AP-specific training or calibration strategies may further enhance performance and facilitate broader clinical deployment across diverse acquisition protocols.

EARLY-ONSET HYPOPARATHYROIDISM IN OSTEOPENIC RODENT MODELS ASSOCIATED WITH BILATERAL HYDRONEPHROSIS AND SPONTANEOUS HYPERTENSION

K. Wongdee[1], P. Suntornsaratoon[2], R. Aeimlapa[2], W. Tiyasatkulkovit[3], P. Adulyaritthikul[4], N. Panupinthu[2], N. Charoenphandhu[2]

[1]Faculty of Allied Health Sciences, Burapha University, Chonburi, Thailand; [2]Department of Physiology, Faculty of Science, Mahidol University, Bangkok, Thailand; [3]Department of Biology, Faculty of Science, Chulalongkorn University, Bangkok, Thailand; [4]Center of Calcium and Bone Research (COCAB), Faculty of Science, Mahidol University, Bangkok, Thailand

Enlargement of the pelvicalyceal structures, as observed in bilateral hydronephrosis, leads to damage to renal tubular cells, thereby impairing calcium and bone metabolism. In addition, chronically elevated blood pressure, as seen in essential hypertension, is associated with microvascular damage in various organs, including the renal parenchyma, and induces systemic inflammation, which in turn interferes with bone remodeling. Herein, we investigated dysregulation of calciotropic hormones in two inherited rodent models, namely ICR/Mlac-*hydro* mice (Hydro) and spontaneously hypertensive rats (SHR). The results showed that both young Hydro mice and SHR (age ≤3 months) exhibited reductions in femoral maximum load, yield load, and stiffness, as determined by a three-point bending test. Using synchrotron radiation Fourier-transform infrared (SR-FTIR) spectroscopy, osteopenia and impaired mechanical properties were found to be associated with alterations in the organic composition of bone tissue. Meanwhile, circulating levels of intact parathyroid hormone (iPTH) in young Hydro mice and SHR were markedly

lower than those in age-matched wild-type rodents, suggesting that early-onset hypoparathyroidism contributes to impaired bone metabolism. Further longitudinal studies revealed that reduced iPTH levels persisted into advanced ages. In conclusion, unlike many osteoporotic rodent models characterized by secondary hyperparathyroidism, Hydro mice and SHR exhibit early-onset hypoparathyroidism, which may explain how bilateral hydronephrosis and hypertension aggravate bone loss, leading to osteopenia and an increased risk of fracture. This project was approved by the Mahidol University Institutional Animal Care and Use Committee.

P896

THE CILIA-WNT AXIS AS A THERAPEUTIC TARGET FOR SOX9 MRNA-LNP IN OSTEOARTHRITIS

K. Yoonhee[1], H. Seungwoo[1,2]

[1]Kyungpook National University, Daegu, South Korea; [2]Kyungpook National University Hospital, Daegu, South Korea

Background: Osteoarthritis (OA) is the most prevalent joint disease, imposing a substantial burden on healthcare systems; however, no approved disease-modifying OA drugs (DMOADs) currently exist to halt structural progression. Current guidelines largely prioritize pain relief, and while numerous compounds have been tested, reproducible structure-modifying efficacy remains elusive. Consequently, therapeutic strategies are shifting toward enhancing endogenous cartilage regeneration. SRY-box transcription factor 9 (Sox9) is identified as the master regulator of chondrogenesis, essential for driving hyaline matrix synthesis (e.g., COL2A1, ACAN) and stabilizing the chondrocyte phenotype by restraining hypertrophic drift and counteracting RUNX2 signaling. Although viral vectors delivering Sox9 have demonstrated potential in cartilage repair, clinical translation is hindered by safety concerns and delivery challenges. Therefore, developing an effective non-viral delivery system, such as lipid nanoparticles (LNPs), to transiently but potently augment Sox9 signaling represents a promising approach to re-establish chondrocyte homeostasis.
Objective: This study aimed to investigate the therapeutic efficacy and underlying molecular mechanisms of intra-articular delivery of Sox9 mRNA encapsulated in lipid nanoparticles (LNPs) in a rat surgical OA model.
Methods: Sox9 mRNA was synthesized and encapsulated into LNPs using a microfluidic system. The physicochemical properties were characterized by dynamic light scattering, scanning electron microscopy, and FT-IR. In vitro validation was performed using IL-1β-stimulated chondrocytes. For in vivo evaluation, a rat anterior cruciate ligament transection with partial medial meniscectomy (ACLT+pMMx) model was established. Rats received intra-articular injections of Sox9 mRNA-LNPs, Lorecivivint (positive control), or PBS. Therapeutic outcomes were assessed via weight-bearing index, micro-CT, and histological scoring. Additionally, bulk RNA sequencing of articular cartilages was conducted to elucidate transcriptomic alterations and chondrocyte subpopulation shifts.
Results: Sox9 mRNA-LNPs exhibited stable physicochemical properties and robustly induced Sox9 protein expression in vitro. In vivo, intra-articular administration of Sox9 mRNA-LNPs significantly attenuated pain behavior and preserved articular cartilage structure compared to the PBS-treated group, demonstrating therapeutic efficacy comparable to that of Lorecivivint. Immunofluorescence confirmed enhanced Sox9 and suppressed MMP13 expression within the cartilage. Transcriptomic profiling revealed that Sox9 treatment enriched pathways associated with cilium movement and cytosolic calcium regulation, while concurrently suppressing pathological Wnt signaling. Furthermore, deconvolution analysis demonstrated that Sox9 therapy restored the cellular landscape by increasing the fractions of regulatory and proliferative chondrocytes while reducing the effector chondrocyte subpopulation compared to OA controls.
Conclusion: Intra-articular delivery of Sox9 mRNA-LNPs effectively retards OA progression and provides pain relief. Mechanistically, this therapeutic effect is mediated by enhancing cilium movement and suppressing pathological Wnt signaling, which in turn restores the anabolic balance and modulates chondrocyte subpopulations toward a regenerative phenotype.
Keywords: Osteoarthritis; Sox9; Lipid nanoparticles; mRNA therapy; Cilia; Wnt signaling

FAHR SYNDOM IN A PATIENT WITH 25(OH) VITAMIN D DEFICIENCY

K. Zakharova[1], M. Perepelova[1], L. Dzeranova[1], E. Pigarova[1]

[1]Endocrinology research centre, Moscow, Russia

Introduction. Fahr syndrome (FS) is a rare neurodegenerative disorder characterized by bilateral, symmetrical calcification of the basal ganglia, resulting in a wide range of progressive motor and cognitive impairments. FS is most often associated with dysregulation of phosphocalcic metabolism.
Results. A 54 year old female presented for evaluation of basal ganglia calcification. Specific to FS computed tomography (CT) changes visualized in 2018 due to migraine attack: headache attacks with no aura first started in her early 30's. Laboratory studies: total serum calcium 2.12 mmol/l (RR: 2.15-2.55), 25(OH)VitD 10 ng/ml (RR: 30.0-100.0) and PTH 90 pg/ml (RR: 15.0-65.0) – suggesting secondary hyperparathyroidism. After a 3-month treatment with loading dose of cholecalciferol, the level of 25(OH)VitD increased to 36 ng/ml with total calcium of 2.22 mmol/l and PTH 52 pg/ml. Bone densitometry was performed: BMD of the lumbar spine of -0.4, total hip -1.9, femoral neck -1.2 by a Z-score. In 2023 the episode of vision loss occurred. No evidence of post-ischemic changes were identified using MRI, the detected alterations in the subcorctical nuclei bilaterally and in both cerebellar hemispheres at the level of dentate nuclei most likely to be attributed to a neurodegenerative disease, such as Fahr syndrome. Due to a long period of cholecalciferol 20.000 IU treatment there was a high level of PTH again up until 93 pg/ml with hypocalcaemia (total calcium 2.08 mmol/l) and magnesium level of 0.82 mmol/l (RR: 0.70-1.05), 25(OH)VitD – 44.7 ng/ml. Ditamin D metabolite profile defined 25-OH-D2 deficiency (<0.5 ng/ml (20.0-60.0)) with normal levels of all of the other 25(OH)VitD forms. The patient received different doses of calcium citrate: from 260 to 760 mg per day. Despite that hypocalcaemia persisted (calcium corrected for albumin 2.06 mmol/l) with PTH level of 68 ng/ml. Either way, the bone density at the level of the spine improved by 2.0% (-0.2 by a Z-score).
Conclusion. FS is most commonly caused by hypoparathyroidism or pseudohypoparathyroidism, with an estimated prevalence of approximately 1:1,000,000. In our clinical case, FS developed in the setting of secondary hyperparathyroidism, a finding that warrants consideration in the differential diagnosis of neurodegenerative disorders.

P898

ATTITUDES TOWARD OPPORTUNISTIC AI SCREENING FOR OSTEOPOROSIS VIA CHEST RADIOGRAPHS: A QUALITATIVE STUDY

K. Zheng[1], J. Choi[2], J. Jung[2], S. L. Silverman[1,3]

[1]OMC Clinical Research Center, Beverly Hills, United States; [2]Promedius Inc., Seoul, South Korea; [3]Cedars-Sinai, Los Angeles, United States

OBJECTIVE(S): To explore patient acceptance, trust, and perceived value of AI-generated bone health reports derived from routine chest radiographs, comparing experiences between patients with and without prior DEXA scanning.

MATERIAL AND METHODS: Two 90-minute moderated focus groups were conducted at a specialized osteoporosis clinic (median participant age ~66). One group included patients who had previously undergone DEXA scans, and the other included patients without DEXA experience. All participants reviewed sample AI-generated Analysis Reports. Sessions were audio-recorded, transcribed, and analyzed using NVivo software with thematic coding, coding matrices, and word frequency queries.

RESULTS: Four core themes were consistent across both groups: (1) conditional trust in AI, which improved with physician involvement; (2) desire for greater clarity and context in AI-generated reports, particularly numeric values and comparisons; (3) limited willingness to pay unless tools were endorsed by physicians or covered by insurance; and (4) the importance of physician oversight to aid understanding and decision-making. Notably, participants without prior DEXA experience expressed stronger skepticism toward AI's commercial motives and raised ethical concerns regarding data use and corporate benefit.

CONCLUSION(S): While patients in both groups expressed openness to AI-based tools for bone health, they emphasized the need for clear communication, physician involvement, and transparency in purpose. Ethical concerns, especially from non-DEXA participants, highlight the need to frame AI tools as patient-centered and clinically integrated.

DISCLOSURES: Stuart Silverman, M.D. is a consultant to Promedius. This study was funded by Promedius Inc., which had no role in data analysis or interpretation.

P899

ADVANCED HAEMOPHILIC ARTHROPATHY: IMAGING SEVERITY AND THERAPEUTIC INTERVENTIONS IN A TERTIARY HOSPITAL

L. Mendez Diaz[1], R. J. Gil Velez[1], L. Alvarez Ortiz[1], J. Manzaneque Sanchez[1]

[1]Hospital Virgen del Rocio, Sevilla, Spain

Background: Patients with haemophilia A and B (HA/HB) frequently experience hemarthrosis, leading to progressive joint damage and haemophilic arthropathy. This condition evolves through different stages and may require specific interventions such as synoviorthesis or arthroplasty in advanced cases.
Objectives: To analyse imaging findings in patients with haemophilic arthropathy and to evaluate the association between haemophilia type and severity and the need for synoviorthesis or arthroplasty.
Methods: A retrospective descriptive study was conducted in patients with HA/HB and hemarthrosis between 2010 and 2024. Haemophilia severity was classified as moderate or severe based on clotting factor activity. Arthropathy was assessed using the Arnold and Hilgartner radiological scale (AHRS). Ultrasound (US), magnetic resonance imaging (MRI) and computed tomography (CT) were analysed for hemarthrosis, synovial hypertrophy and structural damage. Associations were evaluated using the chi-square test.
Results: 95 patients were included. The knee was the most frequently affected joint (51.6%), followed by the ankle (25.3%) and elbow (17.9%). AHRS assessment was available in 92 patients, with 50% presenting scores ≥3. MRI was the most commonly used imaging modality (65.3%), frequently showing advanced structural alterations. Synoviorthesis was performed in 22 patients (23.2%), predominantly in HA. A significant association was observed between severe HA and synoviorthesis requirement (p=0.044). Arthroplasty was performed in 13 patients (13.7%), mainly involving the knee, with no significant association with haemophilia type or severity.
Conclusion: Haemophilic arthropathy frequently affects the knee and often presents with advanced structural damage. Severe HA is associated with a higher need for synoviorthesis, likely due to increased hemarthrosis frequency. Early diagnosis and optimised management are essential to improve outcomes in these patients.

HAEMOPHILIC ARTHROPATHY AND JOINT BLEEDING: INFLUENCE OF DISEASE SEVERITY AND TREATMENT

L. Mendez Diaz[1], L. Alvarez Ortiz[1], J. Manzaneque Sanchez[1], R. J. Gil Velez[1], C. Aguilera Cros[1]

[1]Hospital Virgen del Rocio, Sevilla, Spain

Background: Haemophilia A and B (HA/HB) are X-linked recessive disorders associated with bleeding risk. Haemophilic arthropathy is a major cause of morbidity and reduced quality of life. Bleeding frequency and joint damage vary according to haemophilia type and severity, presence of inhibitor and therapeutic regimen (TR).

Objectives: To analyse baseline characteristics of patients with haemophilia and hemarthrosis (H), evaluate the association between haemophilia type, severity, Arnold and Hilgartner radiological scale (AHRS) and number of H, and assess the relationship between inhibitors, TR and number of H.

Methods: Retrospective descriptive study including patients with HA/HB and H under clotting factor treatment between 2010–2024. Severity was classified as moderate or severe according to clotting factor activity. TR was categorised as on-demand or prophylaxis. Inhibitor positivity was defined as >0.6 Bethesda units (BU) for factor VIII and ≥0.3 BU for factor IX. Total H included objectified and at-home episodes. Associations were analysed using Spearman correlation and Mann-Whitney U-test.

Results: A total of 95 patients were included. A statistically significant association was found between haemophilia type and number of total H ($p<0.001$), with fewer H in HA (median 4) than HB (median 20). Similar results were observed for objectified and at-home H. No association was found between HA severity and number of H. AHRS stage was positively correlated with total H ($p=0.002$; $r=0.315$) and at-home H ($p=0.007$; $r=0.281$). Inhibitors were present in 23.2% of patients, with no association with H. TR was on-demand in 49.5% and prophylaxis in 50.5%, with no association with H.

Conclusion: Patients with HB showed a higher number of H compared to HA, possibly influenced by outliers. Higher AHRS stages were associated with increased H, reflecting greater joint damage. No association was found between inhibitors or TR and H. Further studies are needed to identify predictors of hemarthrosis and improve patient outcomes.

PSORIATIC ARTHRITIS AND METABOLIC SYNDROME. MUSCULOSKELETAL AND METABOLIC MANIFESTATIONS

L. Athanassiou[1], I. Kostoglou-Athanassiou[2], N. Sarianidou[1], S. Mitsoulis[1], M. Tsipou[1], P. Athanassiou[1]

[1]Department of Rheumatology, St. Paul's Hospital, Thessaloniki, Greece; [2]Department of Endocrinology, Diabetes and Metabolism, Asclepeion Hospital, Voula, Athens, Greece

Psoriatic arthritis is an autoinflammatory disease with multiple musculoskeletal and skin manifestations. The disease is known to be accompanied by metabolic syndrome. The presence of the metabolic syndrome may aggravate the inflammatory nature of psoriatic arthritis as metabolic syndrome is known to be associated with an inflammatory phenotype. The aim was to describe the intimate relationship of psoriatic arthritis with metabolic manifestations taking the form of the metabolic syndrome.

Within a cohort of 30 patients, 17 male and 13 female, aged 25-56 years, the presence of musculoskeletal complications as well as metabolic manifestations was studied. In particular, the presence of arthritis and sarcopenia was noted. The presence of abdominal obesity was noted. The presence of diabetes mellitus type 2 was noted. The presence of arterial hypertension and hyperlipidemia was noted.

Within the cohort of 30 patients, 18 patients, 12 male and 6 female, aged 26-54 years were found to fulfill the criteria of metabolic syndrome, as they were found to have abdominal obesity, diabetes mellitus type 2, arterial hypertension and hyperlipidemia. The presence of metabolic syndrome was related with increased disease activity of psoriatic arthritis.

Psoriatic arthritis appears to be related with metabolic syndrome. Abdominal obesity, diabetes mellitus type 2, arterial hypertension and hyperlipidemia are observed in patients with psoriatic arthritis. The presence of metabolic syndrome is related with an inflammatory phenotype and appears to be related with increased disease activity in patients with psoriatic arthritis. The presence of metabolic syndrome in patients with psoriatic arthritis requires dose modification of the treatment applied for the management of psoriatic arthritis.

P902

PREGNANCY AND LACTATION ASSOCIATED VERTEBRAL FRACTURES. REPORT OF A CASE

L. Athanassiou[1], P. Athanassiou[1], N. Sarianidou[1], S. Mitsoulis[1], M. Tsipou[1], C. Melangeli-Domazinaki[2], X. Poimenidi[2], I. Kostoglou-Athanassiou[3]

[1]Department of Rheumatology, St. Paul's Hospital, Thessaloniki, Greece; [2]Second Department of Medicine, Asclepeion Hospital, Voula, Athens, Greece; [3]Department of Endocrinology, Diabetes and Metabolism, Asclepeion Hospital, Voula, Athens, Greece

The presence of pregnancy and lactation associated vertebral fractures is a very rare event which occurs port partum in female patients. The etiology and pathophysiology of the disorder remains unknown. Factors like calcium metabolism during pregnancy and lactation are considered in the pathophysiology of the disorder. According to other authors, the developCase reportment of pregnancy and lactation associated vertebral fractures may be the outcome of preexisting and developing osteopenia and osteoporosis which appear due to disordered calcium metabolism during pregnancy and lactation. The aim was to describe the case of a female patient who developed multiple vertebral fractures during lactation of her first healthy child.

A female primipara patient aged 38 years had a normal pregnancy and delivered normally a healthy male infant. During the lactation period of this infant the patient started having serious pain over the spine and started to develop difficulty in carrying her child. However, lactation continued normally. As the pain became unbearable CT scanning of the spine MRI of the spine were performed.

Evaluation of the spine with CT and MRI revealed the presence of nine compression vertebral fractures. Vitamin D levels were within the normal range. The administration of teriparatide was initiated. Over a period of 6 months the patient started to improve. Pain remitted and she was able to carry and care for the infant.

In conclusion, the case of a patient with multiple pregnancy and lactation associated vertebral compression fractures is described. This is an extremely rare case of pregnancy and lactation associated vertebral fractures. Although, case reports have appeared in the literature of pregnancy and lactation associated vertebral fractures, the pathophysiology of the condition has not yet been clarified. However, it appears that either with the administration of alphacalcidol or teriparatide the condition improves and the patient requires only careful follow-up.

P903

MULTIPLE SUCCESSIVE FRACTURES IN PATIENTS WITH PRIMARY HYPERPARATHYROIDISM AS A CAUSE OF MORBIDITY AND MORTALITY

L. Athanassiou[1], P. Athanassiou[1], N. Sarianidou[1], S. Mitsoulis[1], C. Melangeli-Domazinaki[2], X. Poimenidi[2], A. Fortis[2], I. Kostoglou-Athanassiou[3]

[1]Department of Rheumatology, St. Paul's Hospital, Thessaloniki, Greece; [2]Second Department of Medicine, Asclepeion Hospital, Voula, Athens, Greece; [3]Department of Endocrinology, Diabetes and Metabolism, Asclepeion Hospital, Voula, Athens, Greece

Primary hyperparathyroidism is a disease characterized by the presence of hypercalcemia, hypercalciuria and increased PTH levels. The disease may be due to one or multiple parathyroid adenomas or to parathyroid hyperplasia. The differential diagnosis remains difficult, even after the excision of one or more parathyroid adenomas. The disease is treated by surgery or conservatively. It causes osteoporosis which becomes evident by fractures.

The aim was to present a cohort of 3 patients with primary hyperparathyroidism who were treated by surgery, i.e. surgical excision of the adenoma or adenomas. Following surgical excision of the adenoma the patient remained biochemically cured for a period of 5 to 10 years. However, in all three of the patients hyperparathyroidism recurred with increased PTH and calcium levels.

In the course of follow-up all three patients developed multiple successive fractures which rendered the patients unable to walk and move without help. The successive fractures led to operative treatment of the fractures. However, patients were unable to move unassisted and despite medical treatment for osteoporosis their quality of life was dismally affected considerably.

In conclusion, primary hyperparathyroidism remains a disease which is

very difficult to treat adequately. In the long – term follow up it may cause successive fractures which render the patient unable to walk unassisted and greatly affect quality of life.

P904

MULTIPLE SCLEROSIS AND OSTEOPOROSIS

L. Athanassiou[1], P. Athanassiou[1], N. Sarianidou[1], S. Mitsoulis[1], C. Melangeli-Domazinaki[2], X. Poimenidi[2], A. Fortis[2], I. Kostoglou-Athanassiou[3]

[1]Department of Rheumatology, St. Paul's Hospital, Thessaloniki, Greece; [2]Second Department of Medicine, Asclepeion Hospital, Voula, Athens, Greece; [3]Department of Endocrinology, Diabetes and Metabolism, Asclepeion Hospital, Voula, Athens, Greece

Multiple sclerosis is an autoimmune demyelinating disease which may affect patient mobility. The disease is characterized by autoimmune etiology. The disease may lead to multiple falls as it affects patient balance and mobility. The aim was to present a cohort of 10 female patients aged 45-67 years, with multiple sclerosis who developed osteoporosis and fractures.

A group of 10 female patients, aged 45-67 years old, who presented with multiple sclerosis and osteoporosis or osteopenia is presented. In the course of the disease, patients were evaluated for the presence of osteoporosis. A subgroup of 6 patients underwent multiple falls which in 4 patients led to fractures.

DEXA scans were performed for the measurement of bone mineral density which revealed osteoporosis in 6 patients and osteopenia in 4 patients. A subgroup of 6 patients underwent multiple falls which in 4 patients led to fractures, hip fractures in 3 patients and vertebral fractures in 1 patient. Patients were administered vitamin D and calcium. In the patients with osteoporosis alphacalcidol 1 μg daily and effervescent alendronate 70 mg once weekly were administered. All patients underwent physical therapy evaluation to improve balance and mobility and prevent further falls.

In conclusion, a cohort of patients with multiple sclerosis is presented who developed osteoporosis. Multiple sclerosis is known to be associated with osteoporosis. The disease affects patient mobility and balance and may lead falls. All patients should be administered treatment for the prevention of osteoporosis and osteopenia as well as treatment for osteoporosis. Physical therapy evaluation and treatment for the prevention of falls should also prescribed. Osteoporosis in the context of multiple sclerosis is thought to be due to mobility limitations as well as to the immune modulating treatment for the autoimmune inflammatory process.

P905

EFFECT OF METFORMIN ON CLINICAL OUTCOMES IN OBESE PATIENTS WITH KNEE OSTEOARTHRITIS: A ONE-YEAR PROSPECTIVE CONTROLLED STUDY

L. Baghdasaryan[1], M. Ghasaboghlyan[2], V. Mukuchyan[3], S. Manukyan[4], V. Babalyan[5], A. Mardyan[3]

[1]Vardanants Innovative Center of Medicine, Department of Rheumatology, Yerevan, Armenia; [2]EcoSense Diagnostic Center, Department of Endocrinology, Yerevan, Armenia; [3]Nairi Medical Center, Department of Rheumatology, Yerevan, Armenia; [4]St. Grigor Illuminator Medical Center, Department of General Therapy, Yerevan, Armenia; [5]Osteoporosis Center, Yerevan, Armenia

Background: Knee osteoarthritis (KOA) is frequently associated with obesity and metabolic dysfunction. Metformin has demonstrated potential anti-inflammatory and weight-modulating effects, which may influence KOA symptoms. However, its clinical benefit in obese KOA patients remains understudied.

Objectives: The main goal of this study was to assess the impact of metformin on pain and functional outcomes in obese patients with radiographically confirmed knee osteoarthritis over a 12-month period, compared with a control group receiving chondroitin sulfate.

Methods: This prospective controlled study included 82 patients with KOA (Kellgren–Lawrence grade II–III), BMI > 35 kg/m², followed for 12 months. The metformin group (n=40) consisted of patients with newly diagnosed or newly treated type 2 diabetes who initiated metformin therapy at baseline according to standard metabolic syndrome and glucose management protocols. The control group (n=42) included non-diabetic KOA patients receiving chondroitin sulfate (placebo comparator). Both groups were comparable at baseline in terms of age, sex, OA severity, and baseline VAS/WOMAC scores. Assessments were performed every 3 months using the Visual Analog Scale (VAS) and Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC). BMI was monitored throughout follow-up.

Results: The metformin group demonstrated greater improvement in pain and functional outcomes compared with controls. Mean VAS decreased from approximately 7.5 to 5.5 in the metformin group versus 7.5 to 6.5 in the control group, while WOMAC scores improved from 78 to 57 versus 80 to 74, respectively ($p < 0.05$). Mean BMI decreased from 37 to 32 in the metformin group, whereas it remained stable or slightly increased in controls (36 to 37). The reduction in BMI in the metformin group likely reflects lifestyle modification accompanying diabetes management and may have partially mediated the observed symptomatic improvement.

Conclusion: Metformin use in obese patients with KOA was associated with clinically meaningful reductions in pain and functional impairment over 12 months compared with placebo. These findings suggest a potential therapeutic role of metformin in metabolically driven osteoarthritis phenotypes. The beneficial effect may be mediated both by metabolic improvement and weight reduction. Further randomized controlled trials are warranted to confirm these observations and clarify mechanistic pathways.

P906

UROGENITAL INFECTIONS IN ANKYLOSING SPONDYLITIS: INFLAMMATORY BONE LOSS AND IMPLICATIONS FOR SECONDARY OSTEOPOROSIS

L. Chislari[1], E. Russu[2], E. Deseatnicova[1], D. Sasu[1], L. Groppa[1]

[1]"Nicolae Testemitanu" State Medical and Pharmaceutical University, Chisinau, Moldova; [2]"Nicolae Testemitanu State Medical and Pharmaceutical University; "Timofei Mosneaga" Republican Clinical Hospital, Chisinau, Moldova

Objectives:
To evaluate the impact of chronic and recurrent urogenital infections on inflammatory activity, bone remodeling and risk of secondary osteoporosis in patients with ankylosing spondylitis (AS).
Material and Methods:
A prospective observational study included 162 patients with ankylosing spondylitis, diagnosed according to modified New York criteria. The cohort comprised 108 males (66.7%) and 54 females (33.3%), with a mean age of 38.4±9.2 years and mean disease duration of 7.6±4.1 years. A history of urogenital infection (bacterial urethritis, prostatitis, cervicitis or recurrent urinary tract infection) within the previous 5 years was documented in 68 patients (42.0%).
Clinical activity was assessed using ASDAS-CRP, BASDAI and inflammatory markers (CRP, ESR). Bone-related outcomes included inflammatory bone involvement on MRI and surrogate markers of bone loss (radiographic structural changes and fracture risk indicators). Statistical analyses comprised group comparisons, correlation analysis, multivariate logistic regression and ROC curve analysis.
Results:
Patients with a documented history of urogenital infection exhibited significantly higher disease activity compared with those without infection (ASDAS-CRP 3.2±0.6 vs 2.6±0.5, p<0.001). Elevated inflammatory markers were more frequent in the infection-associated group (CRP >10 mg/L in 61.8% vs 38.7%, p=0.004).
MRI evidence of active osteitis and bone marrow edema was observed more frequently in patients with prior urogenital infection (47.1% vs 26.5%, p=0.008), suggesting enhanced inflammation-driven bone remodeling. Multivariate analysis identified history of urogenital infection as an independent predictor of high disease activity (OR 3.21, 95% CI 1.64-6.29, p<0.001) and inflammatory bone involvement (OR 2.74, 95% CI 1.38–5.46, p=0.004).
Markers suggestive of increased skeletal fragility were more prevalent in the infection-associated group, including higher prevalence of vertebral structural damage and reduced bone integrity indicators. ROC analysis demonstrated good predictive performance of urogenital infection history for identifying patients with inflammatory bone involvement (AUC 0.79, 95% CI 0.71-0.86).
Conclusions:
Urogenital infections are frequently observed in patients with ankylosing spondylitis and are associated with higher inflammatory activity, increased bone marrow inflammation and features suggestive of accelerated bone loss. These findings support the concept that persistent mucosal immune activation triggered by urogenital pathogens may contribute to inflammation-driven bone remodeling and secondary osteoporosis in AS. Systematic assessment and timely management of urogenital infections may represent an important adjunctive strategy for reducing skeletal complications and improving long-term bone health in ankylosing spondylitis.

P907

GUT MICROBIOME DYSBIOSIS IN ANKYLOSING SPONDYLITIS: INFLAMMATORY BONE LOSS AND IMPLICATIONS FOR OSTEOPOROSIS

L. Chislari[1], E. Russu[2], E. Deseatnicova[1], D. Sasu[1], L. Groppa[1]

[1]"Nicolae Testemitanu" State Medical and Pharmaceutical University, Chisinau, Moldova; [2]"Nicolae Testemitanu State Medical and Pharmaceutical University; "Timofei Mosneaga" Republican Clinical Hospital, Chisinau, Moldova

Objectives:
To investigate the relationship between gut microbiome dysbiosis and inflammatory activity in ankylosing spondylitis (AS), with a focus on inflammation-driven bone remodeling and potential risk of secondary osteoporosis.
Material and Methods:
A prospective observational study included 75 patients with ankylosing spondylitis (42 males, 33 females; mean age 36.8±9.7 years; mean disease duration 8.2±3.6 years) and 25 age- and sex-matched healthy controls. AS was diagnosed according to modified New York criteria. None of the patients were receiving biologic therapy at inclusion, and antibiotics or probiotics were discontinued ≥3 months prior to sampling. Disease activity was assessed using ASDAS-CRP, BASDAI, and inflammatory markers (CRP, ESR). Fecal samples were collected and gut microbiota composition was analyzed using 16S rRNA gene sequencing (V3-V4 region). Alpha diversity indices, Firmicutes/Bacteroidetes (F/B) ratio, taxonomic abundance, multivariate analyses and receiver operating characteristic (ROC) curves were applied. Associations between microbial patterns, disease activity and bone-related inflammatory features were explored.
Results:
Patients with AS demonstrated a significant reduction in gut microbial diversity compared with controls (Shannon index, p=0.004), indicating intestinal dysbiosis. The Firmicutes/Bacteroidetes ratio was significantly lower in AS patients (mean 1.1 vs 1.9 in controls, p<0.01), reflecting depletion of beneficial Firmicutes and overrepresentation of Bacteroidetes.
Taxonomic analysis revealed increased abundance of Prevotella, Dialister and Collinsella, alongside significant reductions in Bacteroides and Lachnospira, key producers of short-chain fatty acids involved in bone-protective and anti-inflammatory pathways. Principal component analysis demonstrated clear separation between AS patients and controls, confirming a distinct microbial signature associated with disease.
Prevotella abundance showed a strong positive correlation with disease activity (ASDAS-CRP, r=0.56, p<0.001) and systemic inflammation, suggesting a role in sustaining inflammation-driven bone loss. ROC analysis demonstrated good discriminatory performance of Prevotella abundance for identifying AS patients (AUC 0.82). The dysbiotic profile observed is consistent with activation of the IL-23/IL-17 axis, known to promote osteitis, pathological bone remodeling and increased risk of osteoporosis in AS.
Conclusions:
Ankylosing spondylitis is associated with a distinct gut microbiome dysbiosis characterized by reduced microbial diversity, imbalance of Firmicutes/Bacteroidetes ratio and overrepresentation of pro-inflammatory taxa such as Prevotella. These alterations correlate with disease activity and may contribute to inflammation-driven bone

remodeling and secondary osteoporosis. Gut microbiome profiling may provide novel biomarkers for disease activity and skeletal risk assessment, supporting integrative strategies targeting both intestinal dysbiosis and bone health in ankylosing spondylitis.

P909

PREDICTION OF BONE REMODELING DISORDERS AND OSTEOPOROSIS DEVELOPMENT IN RHEUMATOID ARTHRITIS

L. E. Sivordova[1], Y. V. Polyakova[1], E. V. Papichev[1], Y. R. Akhverdyan[1], B. V. Zavodovsky[1]

[1]Research institute of clinical and experimental rheumatology n.a. A.B. Zborovsky, Volgograd, Russia

Objective: Imbalance of bone remodeling often leads to the development of osteoporosis (OP) [1, 2]. Search for markers for the early prediction of bone metabolism disorders in rheumatoid arthritis (RA) is a pressing scientific challenge.

Aim: To identify markers for the early prediction of osteoporosis (OP) development in patients with RA.

Materials and Methods: RA was diagnosed according to the 2010 ACR/EULAR criteria. The study included 88 women with RA, with an average age of 47.5±9.6 years and an average disease duration of 7.9±5.2 years. All subjects underwent LUNAR DPX-Pro osteodensitometry. The diagnostic value of the parameters was determined using ROC analysis.

Results: 25-OH vitamin D had high prognostic value in predicting the development of AP. The diagnostic decision point was a level of 58.741 ng/mL (sensitivity of the method 95.45%, specificity 37.88%). N-terminal propeptide of procollagen type 1 (P1NP) was also a valuable diagnostic marker for AP in RA. The diagnostic decision point was 50.225 ng/mL (sensitivity 71.21%, specificity 81.82%). C-telopeptide of type I collagen had sufficient predictive power for osteoporosis (sensitivity 36.36%, specificity 90.91%).

Conclusions: Thus, in RA, 25-OH vitamin D, C-telopeptide of type I collagen, and P1NP levels have high prognostic value and can be used for the early diagnosis of bone metabolism disorders and prediction of osteoporosis development.

A STUDY OF THE LEVELS OF THE CHEMOATTRACTANT PROTEIN MCP-1 IN PATIENTS WITH RHEUMATIC DISEASES AND HEALTHY INDIVIDUALS

L. E. Sivordova[1], Y. V. Polyakova[1], E. V. Papichev[1], Y. R. Akhverdyan[1], B. V. Zavodovsky[1]

[1]Research institute of clinical and experimental rheumatology n.a. A.B. Zborovsky, Volgograd, Russia

Objective: Monocyte chemoattractant protein-1 (MCP-1) is a key chemokine regulating the migration and infiltration of monocytes, macrophages, and other immune cells into sites of inflammation and tissue damage. It plays a critical role in chronic inflammation, cancer, and metabolic diseases, acting as a potent proinflammatory cytokine. Studying its role in the pathogenesis of rheumatic pathologies is of great scientific interest.
Aim: To determine MCP-1 levels in patients with rheumatic diseases and healthy individuals.
Materials and Methods: The study included 18 patients with rheumatoid arthritis, 29 patients with systemic lupus erythematosus (SLE), 16 patients with ankylosing spondylitis (AS), and 9 apparently healthy individuals without complaints of joint pain (control group). MCP-1 levels were determined by ELISA using commercial assays.
Results: In the control group of healthy individuals, the MCP-1 level was 300.0 [290.0-380.0] pg/ml. In RA, the average MCP-1 concentration was 361.0 [310.6-411.5] pg/ml. In SLE - 388.2 [310.6-450.3] pg/ml. In patients with AS - 438.7 [411.5-504.7] pg/ml. Based on the obtained data, the reliability of differences in the average MCP-1 level between conditionally healthy individuals and patients with rheumatic diseases was studied. The following data were obtained: the reliability of differences between the control group and the RA group was Z = 0.80; p = 0.425; with the SLE group Z = -1.36; p = 0.175; with the AS group - Z = 2.52; p = 0.0118.
Conclusions: Thus, there is evidence that MCP-1 is closely associated with chronic diseases such as obesity, diabetes, cardiovascular disease, and cancer. The role of this protein in rheumatic diseases remains understudied. Our study revealed a statistically significant difference between MCP-1 levels in healthy individuals and patients with ankylosing spondylitis (Z=2.52; p=0.0118). No significant differences were found between MCP-1 levels in patients with RA and SLE.

PATHWAYS OF "INTERNET+ NURSING" EMPOWERING COMMUNITY-HOME INTEGRATED MEDICAL AND ELDERLY CARE SERVICES UNDER THE MEDICAL CONSORTIUM MODEL: A MIXED-METHODS STUDY

L. Fan[1], Y. J. Qiu[1]

[1]Shapingba Hospital, Chongqing University, Chongqing, China

Objective: To explore the implementation pathways and effectiveness of "Internet+ Nursing" in enhancing community-home integrated medical and elderly care service capacity within the medical consortium framework in China.
Methods: A sequential explanatory mixed-methods design was employed from March 2022 to September 2024. In Phase I, a cross-sectional survey was conducted among 1,248 elderly residents and 386 nurses across 12 community health centers within three medical consortiums. The Nursing Service Capacity Scale and Elderly Care Needs Questionnaire were administered. In Phase II, semi-structured interviews with 32 stakeholders (administrators, nurses, patients, caregivers) explored facilitators and barriers. The Consolidated Framework for Implementation Research guided pathway development. A 6-month pilot intervention was subsequently implemented in six communities.
Results: The "Internet+ Nursing" pathway model comprising four dimensions—platform construction, resource integration, competency enhancement, and quality monitoring—was established. Post-intervention, nursing service accessibility increased by 42.6% (P<0.001), service response time decreased from 48.2±12.5 to 18.6±8.3 hours (P<0.001), and elderly satisfaction scores improved significantly (87.32±6.45 vs. 71.28±8.92, P<0.001). Healthcare resource utilization efficiency within the consortium increased by 35.8%. Qualitative findings revealed critical success factors including leadership support, digital literacy training, and seamless information sharing.
Conclusions: The "Internet+ Nursing" empowerment pathway effectively strengthens community-home integrated care capacity under the medical consortium model, offering a scalable framework for addressing aging population healthcare demands in developing countries.

P912

EXTENDED 18-MONTH LONGITUDINAL EVALUATION OF BODY COMPOSITION CHANGES UNDER GENDER-AFFIRMING HORMONE THERAPY IN A COLOMBIAN TRANSGENDER COHORT

L. Forero[1], A. S. Sierra[1], N. C. Camargo[1]

[1]FUNDACION UNIVERSITARIA CIENCIAS DE LA SALUD, BOGOTA, Colombia

Background: Gender-affirming hormone therapy (GAHT) produces gradual modifications in muscle and fat distribution. Evidence describing long-term body composition trends in Latin-American transgender populations remains scarce.

Objective: To assess 18-month longitudinal changes in body composition among transgender adults undergoing GAHT at the San José Hospital, Bogotá, Colombia.

Methods: A retrospective cohort including adults with confirmed gender dysphoria treated between 2019 and 2025 was analyzed. Body composition was measured by bioelectrical impedance (OMRON HBF-514C) at baseline, 3, 6, 12, and 18 months. Variables included BMI, total fat percentage, muscle mass, and visceral fat. Statistical comparisons used Wilcoxon and Friedman tests with p<0.05 considered significant.

Results: Fifty-nine patients (64% transgender men) were evaluated, with a median age of 23 years (IQR 21–29). After 18 months of GAHT, transgender men demonstrated a significant increase in muscle mass (p=0.007) and reduction in visceral fat (p=0.002), without relevant BMI variation. Transgender women showed modest increases in fat mass but stable BMI and muscle mass.

Conclusion: At 18 months of GAHT, transgender men maintained favorable body recomposition characterized by muscle gain and visceral fat reduction, while transgender women exhibited mild fat redistribution. These findings support the clinical use of bioelectrical impedance as a sensitive monitoring tool beyond BMI in transgender metabolic follow-up.

Keywords : Gender-affirming hormone therapy; body composition; bioelectrical impedance; transgender adults; visceral fat.

P913

HOW MUCH DO POSTMENOPAUSAL WOMEN KNOW ABOUT OSTEOPOROSIS? INSIGHTS FROM THE OKAT QUESTIONNAIRE

L. Gader[1], M. Ardhaoui[1], R. Sarraj[1], M. Brahem[1], O. Jomaa[1], S. Abdellatif[1], M. Younes[1]

[1]Taher Sfar University Hospital, Mahdia, Mahdia, Tunisia

Background:
Postmenopausal osteoporosis (PMO) is a major public health concern due to the high risk of fractures and their associated consequences. Despite the proven effectiveness of available treatments, therapeutic adherence remains frequently suboptimal. Patients' disease-related knowledge may influence adherence. However, this aspect remains insufficiently explored.

Objective:
To assess osteoporosis-related knowledge among women with PMO and to explore factors associated with knowledge levels.

Methods:
A cross-sectional study was conducted including women followed for PMO and treated with bisphosphonates. Osteoporosis-related knowledge was assessed using the Osteoporosis Knowledge Assessment Tool (OKAT), a validated 20-item questionnaire covering general knowledge, nutrition, physical activity, and treatments. Each correct answer scored one point, with a total score ranging from 0 to 20. Knowledge levels were classified as low (0–10), moderate (11–15), or high (16–20).

Results:
Fifty patients were included, with a mean age of 65.3 ± 9.7 years [48–76]. Mean age at menopause was 46.8 ± 4.3 years. Among participants, 53.3% were illiterate, 68.9% lived in urban areas, and 71.1% were homemakers.

The main comorbidities were arterial hypertension (28.9%), diabetes mellitus (29.5%), and dyslipidemia (28.9%).

The mean lumbar spine T-score was −3.5 ± 0.46, and the mean femoral T-score was −0.42 ± 1.87. A history of osteoporotic fractures was reported in 57.8% of patients, mainly involving the distal radius (34.6%), vertebrae (19.2%), and femoral neck (11.5%).

All patients were receiving oral bisphosphonates (alendronate in 34.1% and risedronate in 59.1%), with correct adherence to intake rules reported in 93.3% of cases.

The mean OKAT score was 11.4 ± 4.6 [2–18]. Knowledge level was low in 33.3% of patients, moderate in 53.3%, and high in 13.3%. Higher OKAT scores were significantly associated with younger age (< 60 years) ($p = 0.048$), rural residence ($p = 0.043$), and higher educational level ($p = 0.02$).

Conclusion:
Osteoporosis-related knowledge among women with postmenopausal osteoporosis remains limited to moderate despite established pharmacological treatment. Knowledge levels were associated with age, educational attainment, and place of residence, underscoring the importance of developing tailored patient education strategies.

P914

WHEN TREATMENT FAILS TO BE TAKEN: IMPACT OF THERAPEUTIC ADHERENCE ON QUALITY OF LIFE IN POSTMENOPAUSAL OSTEOPOROSIS

L. Gader[1], M. Ardhaoui[1], M. Brahem[1], O. Jomaa[1], R. Sarraj[1], S. Abdellatif[1], M. Younes[1]

[1]Taher Sfar University Hospital, Mahdia, Mahdia, Tunisia

Background:
Postmenopausal osteoporosis is a chronic disease associated with skeletal fragility and a significant alteration in patients' quality of life. Despite the availability of effective therapies, therapeutic adherence remains suboptimal in routine clinical practice, potentially reducing treatment benefits. The impact of poor adherence on quality of life in postmenopausal osteoporosis remains insufficiently explored. The objective of this study was to assess therapeutic adherence and analyze its impact on quality of life.

Patients and methods:
We conducted a cross-sectional study including patients followed for osteoporosis. Sociodemographic and clinical data were collected from medical records and patient interviews. Therapeutic adherence was assessed using the Medication Adherence Rating Scale (MARS-5), a 5-item questionnaire with scores ranging from 5 to 25, with higher scores indicating better adherence. Quality of life was assessed using the Evaluation of Osteoporosis Quality of Life Questionnaire (ECOS-16), which ranges from 16 to 80, with higher scores indicating greater impairment of quality of life.

Results:
Fifty female patients were included, with a mean age of 65.3 ± 9.7 years (range 53–76). More than half were illiterate (53.3%), 68.9% lived in urban areas, and 71.1% were housewives. The majority of patients had a middle socioeconomic level (46.7%), followed by a low level (33.3%). A history of osteoporotic fractures was present in 57.8% of patients.
The mean MARS-5 score was 20.3 ± 2.4, with high adherence (MARS-5 > 20) observed in 60% of patients. The mean ECOS-16 score was 52.1 ± 12.8 (range 23–71). Quality of life impairment was mainly driven by physical and emotional domains. The highest mean score was observed in physical function (18.4 ± 4.2), followed by emotional status (14.2 ± 3.8). Pain and mobility domain scores were 11.5 ± 3.1 and 8.0 ± 2.5, respectively. Items related to fear of falling and difficulty bending over showed the highest levels of impairment.
The mean MARS-5 score was significantly higher in patients with primary or secondary education compared with illiterate patients ($p = 0.004$), and in rural compared with urban patients ($p = 0.03$). Quality of life impairment was significantly associated with fracture history ($p < 0.01$), socioeconomic status ($p < 0.001$), educational level ($p = 0.021$), and living environment ($p = 0.037$). Better treatment adherence was associated with less impaired quality of life, with a significant negative correlation between MARS-5 and ECOS-16 scores ($p = 0.04$).

Conclusion:
Suboptimal therapeutic adherence in postmenopausal osteoporosis is associated with poorer quality of life, particularly affecting physical and emotional dimensions, highlighting adherence as a key target to improve quality of life.

P915

WHAT IS THE RELATIONSHIP BETWEEN STRUCTURAL PROGRESSION AND QUALITY OF LIFE IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS?

L. Gader[1], R. Sarraj[1], M. Brahem[1], M. Ardhaoui[1], O. Jomaa[1], S. Abdellatif[1], M. Younes[1], C. Zayani[1]

[1]Taher Sfar University Hospital, Mahdia, Mahdia, Tunisia

Background
Axial spondyloarthritis (axSpA) is a chronic inflammatory rheumatic disease that may lead to progressive structural damage, resulting in impaired spinal mobility and functional disability. The relationship between radiographic structural damage, functional impairment, and quality of life in axSpA remains incompletely understood. The aim of this study was to evaluate the impact of radiographic structural damage on functional disability and quality of life in patients with axSpA.
Patients and Methods
This was a cross-sectional study including patients fulfilling the ASAS 2010 classification criteria for axSpA. Structural damage was assessed using two radiographic scores: the modified Stoke Ankylosing Spondylitis Spine Score (mSASSS, 0–72) and the Bath Ankylosing Spondylitis Radiology Index (BASRI, 0–16). Functional disability was evaluated using the Bath Ankylosing Spondylitis Functional Index (BASFI) and the Health Assessment Questionnaire (HAQ). Quality of life was assessed using the Ankylosing Spondylitis Quality of Life questionnaire (ASQoL).
Results
A total of 51 patients were included, with a mean age of 43.9 ± 15.8 years (range 18–76), including 33 men (64.7%). The mean disease duration was 9.2 ± 8.8 years (range 1–36). The mean BASFI score was 4.0 ± 1.9 (range 0–8.5), with significant functional disability (BASFI > 4) observed in 27 patients (52.9%). The mean HAQ score was 0.83 ± 0.62 (range 0–2.7), indicating moderate to severe functional difficulty (HAQ > 1) in 18 patients (35.3%). The mean ASQoL score was 6.2 ± 4.3 (range 0–16).

The mean mSASSS was 19.3 ± 16.2 (range 0–66), and the mean BASRI total score was 5.5 ± 4.1 (range 0–16). Both structural scores were significantly correlated with functional disability, as shown by their association with BASFI (BASRI: p = 0.040; mSASSS: p < 0.001) and HAQ (BASRI: p = 0.011; mSASSS: p = 0.002). They were also significantly associated with impaired quality of life assessed by ASQoL (BASRI: p = 0.011; mSASSS: p < 0.01).

Conclusion

Radiographic structural damage in axial spondyloarthritis is significantly associated with functional disability and impaired quality of life.

P917

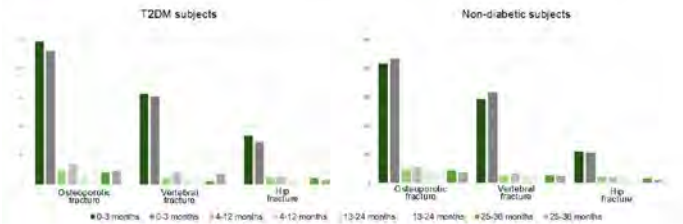
THE EFFECT OF POOR ADHERENCE IN THE EFFECTIVENESS OF OSTEOPOROSIS TREATMENT IN PATIENTS WITH TYPE 2 DIABETES MELLITUS: A POPULATION-BASED COHORT STUDY

L. Gomez Rodriguez[1], C. Carbonell-Abella[1], P. Satorra Herbera[2], C. Reyes[3], M. A. Pou Gimenez[1], C. Diaz Torné[4], C. Tebé-Cordomí[2], D. Martinez-Laguna[1]

[1]Primary Care. Institut Català de la Salut. GREMPAL Research Group, Jordi Gol Institute for Primary Care Research (IDIAP), Autonomous University of Barcelona, Barcelona, Spain; [2]Biostatistics Support and Research Unit, Germans Trias i Pujol Research Institute and Hospital (IGTP), Barcelona, Spain; [3]Sardenya Primary Health Care Center, EAP Sardenya- Research Institute Sant Pau (EAP Sardenya-IR Sant Pau), Barcelona, Spain, Barcelona, Spain; [4]Rheumatology Department, Hospital de Sant Pau, Barcelona, Spain

Introduction: Adherence to osteoporosis medications (OM), as with other chronic diseases, is low. Previous studies have observed that poor adherence is associated with a higher risk of osteoporotic fracture (OF). However, there is limited evidence on whether this also applies to patients with type 2 diabetes mellitus (T2DM).

Aim: To analyze the effectiveness of OM in real-life conditions in patients with T2DM compared to non-diabetics, based on adherence to OM.



Methods: A population-based cohort study was conducted in primary care. All subjects who started an OM between 2012 and 2016 were selected from the SIDIAP database, which contains pseudo-anonymized clinical information from over 5.5 million patients in Catalonia. Exclusion criteria included prior OM use in the previous 12 months, history of neoplasia, Paget's disease, or HIV infection. Up to three non-diabetic subjects were matched to each T2DM subject by propensity score. Adherence was estimated using the medication possession ratio (MPR), with poor adherence defined as MPR <0.8. Effectiveness was analyzed by calculating incidence rates of hip fracture, vertebral fracture and OF in the periods 0–3 months, 4–12 months, 13–24 months, and 25–36 months.

Results: Of the 42,946 patients who started an OM, 5,828 were T2DM patients and 37,118 were non-diabetics. Of these, 34,545 (80.4%) received oral bisphosphonate (BF), 4,215 (9.8%) denosumab, 2,769 (6.5%) SERM, and 1,417 (3.3%) teriparatide. Poor adherence to BF was observed in 52.6% of T2DM patients versus 49.8% of non-diabetics; with denosumab, 9.8% vs. 9.3%; with SERM, 34.1% vs. 43.3%; and with teriparatide, 33.6% vs. 38.4%.

Incidence of fractures after matching, in all analyzed periods, in T2DM and non-diabetic subjects, according to treatment adherence, is presented in Figure 1.

Conclusions: Between 30–50% of patients receiving an OM show poor adherence (except for denosumab, which is <10%), with worse adherence to BF observed in T2DM patients compared to non-diabetics. Poor adherence is associated with a higher incidence of fractures across all time periods, particularly among T2DM patients.

Figure 1:Incidence of fractures (x1,000 person/year) in T2DM and non-diabetic subjects, according to treatment adherence
Green columns = good adherence (MPR ≥0,8); grey columns = poor adherence (MPR <0,8)

P918

ENTHESITIS IN PSORIATIC ARTHRITIS: A MARKER OF INFLAMMATION-DRIVEN BONE REMODELING AND OSTEOPOROSIS RISK

L. Gonta[1], O. Chetrus[2], E. Deseatnicova[2], E. Russu[3]

[1]Republican Diagnostic Centre, Chisinau, Moldova; [2]"Nicolae Testemitanu" State and Pharmaceutical University, Chisinau, Moldova; [3]"Nicolae Testemitanu" State Medical and Pharmaceutical University; "Timofei Mosneaga" Republican Clinical Hospital, Chisinau, Moldova

Objectives:

To evaluate the relationship between entheseal inflammation and markers of bone remodeling in psoriatic arthritis (PsA), and to explore the potential role of enthesitis as a contributor to secondary osteoporosis.

Material and Methods:

A prospective observational study included 70 patients with psoriatic arthritis (23 males, 47 females; mean age 39.4±10.2 years) and a comparison group of 30 patients with rheumatoid arthritis (RA). PsA was diagnosed according to CASPAR criteria. Disease activity ranged from low to high, with early and established forms included.

All patients underwent comprehensive musculoskeletal ultrasound assessment of large and small joints, with special focus on entheses, synovial membrane, tendon–ligament apparatus and adjacent bone structures. Ultrasound was performed using gray-scale and power Doppler techniques. Magnetic resonance imaging (MRI) was applied as a reference method in a subgroup of patients. Clinical activity, inflammatory markers and imaging signs of bone involvement were analyzed. Statistical analysis included group comparisons, correlation analysis and regression models.

Results:

Entheseal involvement was significantly more prevalent and severe in PsA compared with RA, particularly at the patellar ligament and quadriceps tendon insertions (PsA 68.6% vs RA 21.3%, p<0.001). Power Doppler–positive enthesitis was detected in 54.3% of PsA patients versus 13.3% of RA controls (OR 7.65, 95% CI 3.01-19.41, p<0.001), indicating a strong association with active inflammation at the bone–enthesis interface.

Quantitative ultrasound assessment demonstrated significantly higher entheseal thickness and structural damage scores in PsA, which

correlated with synovial vascularization (r=0.59, p<0.001), inflammatory markers (CRP: r=0.46, p=0.002; ESR: r=0.41, p=0.004) and composite disease activity indices.
Entheseal severity, expressed by ultrasound-based enthesitis indices, showed a robust association with imaging markers of bone involvement. MRI-confirmed bone marrow edema adjacent to inflamed entheses was observed in 46.7% of PsA patients with active enthesitis compared with 18.2% without enthesitis (p=0.006). Multivariate regression analysis identified Power Doppler–positive enthesitis as an independent predictor of inflammatory bone involvement (β=0.44, p<0.001), after adjustment for age, sex and disease duration.
Furthermore, higher entheseal inflammatory burden was associated with markers suggestive of increased skeletal fragility. Patients in the upper tertile of entheseal activity demonstrated a significantly higher prevalence of structural bone changes (OR 3.28, 95% CI 1.42-7.58, p=0.005). ROC analysis confirmed good discriminative performance of entheseal ultrasound parameters for identifying patients with bone involvement (AUC 0.86, 95% CI 0.78-0.93), with Power Doppler signal showing the highest predictive accuracy (sensitivity 81.4%, specificity 84.6%).
Conclusions:
Enthesitis is a central feature of psoriatic arthritis and represents a key site of inflammation-driven bone remodeling. Persistent entheseal inflammation is associated with structural bone alterations that may contribute to secondary osteoporosis in PsA. Ultrasound-based assessment of enthesitis provides valuable insight into bone–inflammation interactions and may help identify patients at increased risk of skeletal fragility. Integrating entheseal evaluation into routine PsA assessment could improve early detection of bone involvement and support preventive strategies for osteoporosis.

P919

IS AGE A DIFFERENTIATING FACTOR IN THE RESPONSE TO ROMOSOZUMAB TREATMENT IN WOMEN WITH SEVERE OSTEOPOROSIS? REAL-WORLD DATA

L. Gonzalez Hombrado[1], C. Arconada[2], M. C. Ortega de la O[2], M. Salido Olivares[3], C. Marin Huertas[4], A. Garcia Martos[1], C. Bonilla Gonzalez- Lagana[5], A. Diaz Oca[6], E. M. Andres Esteban[7]

[1]University Hospital of Tajo, Aranjuez (Madrid), Spain; [2]University Hospital of Getafe, Getafe (Madrid), Spain; [3]University Hospital Clinico San Carlos, Madrid, Spain; [4]University Hospital Infanta Leonor, Madrid, Spain; [5]University Hospital Infanta Cristina, Parla (Madrid), Spain; [6]University Hospital of Fuenlabrada, Fuenlabrada (Madrid), Spain; [7]Rey Juan Carlos University, Madrid, Spain

Introduction Romosozumab (RMZ) has demonstrated efficacy in the treatment of severe osteoporosis in clinical trials, although there is limited data on elderly women in real-world clinical practice in Europe.

Objective To evaluate the efficacy of RMZ in women with osteoporosis at high risk of fracture in real-life settings and to analyse possible differences depending on age (<75 years *vs*. ≥75 years).

Materials and methods Multicentre observational study in real clinical practice involving 142 women with severe osteoporosis treated with RMZ. 97 women who completed treatment were analysed. The mean age was 77.8 years (SD: 11.4). 39 patients (27.5%) were ≥75 years old. The mean age of menopause was 47.6 (SD: 5.1). Most patients had previously suffered fractures due to fragility (90.8%). Comorbidities: hypertension (31.7%), dyslipidaemia (29.5%), diabetes mellitus (4.9%), history of smoking (12%). Analytical data was collected before RMZ and after completing treatment (calcaemia, creatinine, PTH, and vitamin D). Changes in bone mineral density (BMD) and TS after treatment were analysed in the lumbar spine, total hip, and femoral neck. Patients were stratified according to age into two groups: <75 years and ≥75 years, analysing the response of each group individually. Differences between pre- and post-treatment data were compared in each group. Likewise, the degree of patient satisfaction with the drug (scale 0-5) and treatment after completing RMZ was collected.

Results Following treatment with RMZ, a statistically significant increase in BMD and TS data was observed in the overall population in the lumbar spine, total hip, and femoral neck (Table 1). The magnitude of the response was comparable between women ≥75 years and <75 years, with no significant differences in densitometric change after treatment between the two age groups. A statistically significant difference was observed only in the increase in total hip BMD, which was not accompanied by a significant difference in T-score. (Table 2).

No analytical alterations were observed before or after treatment. 6 patients reported adverse events, the most common being local reactions at the injection site. Treatment was suspended in 2 patients due to adverse events, one due to a significant reaction at the injection site and the other due to CVA. None of the patients suffered a new fracture during the follow-up period.

The degree of satisfaction with the drug was 4.6 (0-5). Most patients continued treatment with denosumab (65%), followed by oral bisphosphonates (14.5%).

Conclusion In real-world clinical practice, RMZ showed similar efficacy in women with severe osteoporosis regardless of age, including patients aged 75 years or older, supporting its use in elderly women.

THE BURDEN OF VERTEBRAL FRACTURES CAUSED BY FALLS AMONG ELDERLY IN ECUADOR

E. Lopez Gavilanez[1], L. Imaicela Naula[1], M. Navarro Grijalva[1], N. Bautista Litardo[1], M. Hernandez Bonilla[1], R. Cedeño German[1], A. Segura Mestanza[1], M. Navarro Chavez[1]

[1]AECE research Group. The Association of Clinical Endocrinologists of Ecuador. Guayaquil, Ecuador., Guayaquil, Ecuador

Vertebral fractures (VF) are a global health problem. The burden of VF is increasing, especially in older adults.

Objective: To analyze the incidence, prevalence, and years lived with disability (YLD) attributable to vertebral fractures due to falls among people aged 50 years and older between 1990 and 2021 at the national level, and to establish trends stratified by gender and age.

Methods: This study used data from the 2021 Global Burden of Disease (GBD) study, focusing on trend changes and stratified characteristics of the burden of vertebral fractures caused by falls among people aged 50 years and older. We assessed incidence, prevalence, and years lived with disability (YLDs). The projection of epidemiological indicators until 2030 was performed using the method described by Rahib [1].

Results: In 2021, an estimated number of 3,569 new cases of vertebral fractures due to falls in people aged 50 years and older were recorded nationwide, with 3,710 prevalent cases and 371 YLDs. Between 1990 and 2021, the incidence increased from 685.8 to 3,568.5 cases (5.2-fold), the prevalence from 699.4 to 3,709.7 (5.3-fold), and YLDs from 70.4 to 371.4 (5.3-fold). The age-standardized incidence rate (ASIR) in 2021 was 97.4 per 100,000 inhabitants, representing an increase from 1990 with an average annual percentage change (AAPC): 1.05 (p<0.05), the age-standardized prevalence rate (ASPR) AAPC: 1.06 (p<0.05), and the age-standardized years lived with disability (ASYR) AAPC: 1.06 (p<0.05). The projected number of incident cases for 2030, 2040, and 2050 is 3,921, 4,352, and 4,832, respectively; for prevalent cases, 4,079, 4,533, and 5,037, respectively; and for YLDs, 408, 453, and 503, respectively.

Table 1. Age Standardized Rate * of incidence, prevalence, and YLDs of elderly Vertebral Fracture (50+years) from 1990 to 2021.

Year	1990			2021		
	ASIR	ASPR	ASYR	ASIR	ASPR	ASYR
Both	65.8 (94.2–42.3)	28.9 (36.5–22.7)	3.0 (4.6–1.9)	97.4 (141.4–62.7)	43.9 (55.0–35.1)	4.59 (6.8–3.1)
Male	97.1 (138.7–63.2)	40.7 (52.3–31.9)	4.3 (6.4–2.8)	133.9 (190.0–86.7)	56.4 (71.7–44.8)	5.9 (9.0–4.0)
Female	35.4 (54.0–20.5)	17.4 (22.2–13.6)	1.8 (2.6–1.1)	63.0 (94.8–38.2)	32.2 (40.2–25.3)	3.3 (4.8–2.1)

*per 100,000 inhabitants (95 % UI); ASIR, Age-standardized Incidence Rate; ASPR, Age-standardized Prevalence Rate; ASYR, Age-standardized YLDs Rate

Conclusions: The disease burden of vertebral fractures due to falls in people aged 50 and older increased fivefold between 1990 and 2021, and a significant increase is projected in the coming decades. With the aging of the population, vertebral fractures caused by falls require ongoing attention.

RELATIONSHIP BETWEEN LIVER FIBROSIS RISK, BODY MASS INDEX, AND OSTEOPOROSIS IN POSTMENOPAUSAL WOMEN WITH MASH

L. Jashi[1], N. Tsinntsadze[2], T. Peshkova[2], I. Abesadze[1], T. Shervashidze[3], M. Tugushi[1], L. Saginadze[1], R. Kvanchakhadze[4], K. Kamashidze[1]

[1]Avicenna batumi medical university, Batumi, Georgia; [2]Batumi Shota Rustaveli State University, Batumi, Georgia; [3]Avicenna batumi medical university, T'bilisi, Georgia; [4]Batumi Shota Rustaveli State University, Tbilisi, Georgia

Introduction:

Postmenopausal estrogen deficiency significantly accelerates bone loss. Steatohepatitis-related metabolic dysfunction (MASH) and diabetes mellitus may further increase the risk of osteoporosis through insulin resistance, chronic inflammation, and altered bone-liver interaction. Data on impaired bone mineral density in postmenopausal women with MASH remain limited.

Purpose:

To compare the prevalence of osteopenia and osteoporosis based on DXA-derived T-score criteria in postmenopausal women with MASH, with and without diabetes mellitus, and to examine the relationship with liver fibrosis risk and body mass index (BMI).

Methods:

The study included 35 postmenopausal women aged 55-67. 17 patients (48.6%) had diabetes, and 18 (51.4%) did not. All participants had a confirmed diagnosis of MASH. BMI ranged from 25 to 29 kg/m ². FIB-4 index values ranged from 1.3 to 2.67. In patients with diabetes, HbA1c levels ranged from 6.7% to 7.9%. The duration of menopause ranged from 8 to 22 years. Bone mineral density was assessed by dual-energy X-ray absorptiometry (DXA). Osteopenia was defined as a T-score between -1.0 and -2.5, and osteoporosis as a T-score ≤ -2.5.

Results:

Overall, a decrease in bone mineral density (osteopenia or osteoporosis) was observed in 74.3% of study participants. Osteoporosis (T-score ≤ -2.5) was detected in 41.2% of women with diabetes compared to 22.2% of women without diabetes. Osteopenia was observed in 35.3% of patients with diabetes and in 44.4% of patients without diabetes. Higher FIB-4 values (≥ 2.0) were associated with osteoporosis in 57.1% of cases, indicating an association between increased risk of liver fibrosis and lower T-score scores.BMI within overweight limits did not demonstrate a protective effect against osteoporosis, especially among patients with diabetes. Longer duration of menopause (> 15 years) was associated with osteoporosis in 61.5% of women with the condition.

Conclusion:

Postmenopausal women with MASH and diabetes mellitus have a higher prevalence of T-score osteoporosis compared to women without diabetes. Increased risk of liver fibrosis and longer duration of menopause appear to be associated with lower bone mineral density. These data support the need for a comprehensive assessment of liver, metabolism, and skeletal health in postmenopausal women with MASH.

P922

ARTIFICIAL INTELLIGENCE-ASSISTED META-ANALYSIS OF PREVALENCE AND RISK FACTORS FOR VERTEBRAL FRACTURES IN SYSTEMIC LUPUS ERYTHEMATOSUS

L. Jiaxuan[1], D. Jin[1]

[1]Department of Rheumatology and Clinical Immunology, Peking Union Medical College Hospital, Beijing, China

BACKGROUND: Patients with systemic lupus erythematosus (SLE) are at a significantly heightened risk for vertebral fractures (VF), primarily due to chronic inflammation and long-term glucocorticoid exposure. However, VF often remains clinically "silent" or is masked by the routine use of non-steroidal anti-inflammatory drugs (NSAIDs), leading to delayed diagnosis and increased morbidity. This study aims to provide a comprehensive global prevalence estimate and a systematic evaluation of risk factors for VF in SLE patients. Furthermore, it explores a novel multi-model AI workflow to optimize the traditional meta-analysis pipeline.

METHODS: A systematic search was performed across PubMed, Web of Science, Embase, and Cochrane Library to identify relevant observational studies. We implemented a cutting-edge AI-human collaborative framework: **DeepSeek** was utilized for its advanced logic and programming capabilities to generate robust R scripts for automated literature screening and complex statistical pooling. Simultaneously, **Gemini 3.0 Pro** was strategically employed for its superior performance in high-dimensional data extraction and multimodal image recognition, enabling the precise interpretation of forest plots and visual data from published figures. Quality assessment was conducted using the Newcastle-Ottawa Scale (NOS) integrated with Gemini's analytical modules. This dual-AI approach was rigorously validated against manual review by independent researchers to ensure data integrity.

RESULTS: Seventeen high-quality studies met the inclusion criteria. The pooled prevalence of VF among SLE patients was determined to be **23%**. Our analysis identified 18 potential variables, with 7 key factors showing strong statistical significance:

• Advanced age and postmenopausal status;

• Prolonged SLE disease duration;

• Higher cumulative glucocorticoid dosage;

• Elevated SLICC/ACR Damage Index (SDI) scores;

• Personal history of previous fractures and lower bone mineral density (BMD).

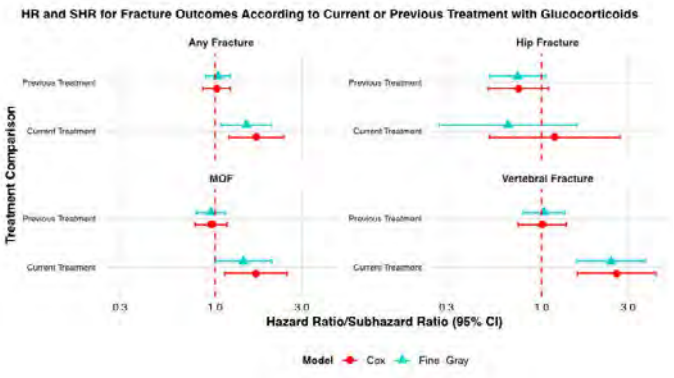
The integrated AI workflow achieved a **94% concordance rate** with traditional manual methods while reducing the total processing time by **90%**, allowing the entire project—from initial search to final manuscript revision—to be completed within just **43 days**.

CONCLUSION: The strategic integration of AI tools—optimizing DeepSeek for computational scripting and Gemini for data synthesis—represents a paradigm shift in evidence-based medicine, significantly accelerating the research cycle without compromising accuracy. Clinicians should maintain a high index of clinical suspicion for VF in SLE patients presenting with the identified risk factors to facilitate early intervention.

P923

CURRENT GLUCOCORTICOID USE IS ASSOCIATED WITH INCREASED CORTICAL POROSITY, REDUCED PHYSICAL PERFORMANCE AND INCREASED FRACTURE RISK IN OLDER WOMEN

M. Zoulakis[1], L. Johansson[2], A. Pihl[1], K. Axelsson[1], M. Lorentzon[2]



[1]University of Gothenburg, Mölndal, Sweden; [2]University of Gothenburg and Sahlgrenska University Hospital, Mölndal, Sweden

Objective(s):
Glucocorticoid (GC)-induced osteoporosis is the most common form of secondary osteoporosis, yet fracture risk frequently remains underestimated. Conventional tools (DXA - BMD, FRAX) fail to capture cortical microarchitectural deterioration and impaired physical function, key contributors to fracture risk. We examined the impact of current and previous oral GC exposure on bone mineral density (BMD), microarchitecture, physical function, and fracture risk in older women.

Material and Methods:
3,028 women aged 75–80 years from the Swedish population based SUPERB cohort were included and followed for 7.3 (4.4-8.4) years (median (IQR). Women were classified as current (n=154), previous (n=728), or never (n=2,146) GC users (≥2 oral GC prescriptions in the last 120 days, Swedish Prescribed Drug Register). Bone health was assessed using DXA, trabecular bone score (TBS), high-resolution peripheral quantitative computed tomography (HR-pQCT) at the tibia. Physical function was evaluated using Timed Up and Go (TUG) and walking speed. Incident fractures were identified via radiology archives and categorized as major osteoporotic (MOF), hip, vertebral, or any fracture. Associations were analyzed using Cox proportional hazards and Fine–Gray models, adjusted for age, BMI, clinical risk factors, and femoral neck BMD.

Results:
Areal BMD did not differ significantly between exposure groups. Compared with GC-naïve women, current GC users had 8.7% higher cortical porosity, 1.6% lower cortical volumetric BMD, and 2.5% lower TBS (all $p < 0.05$). Physical performance was considerably worse in current GC users than in nonusers (13.0% higher TUG, 6.5% slower walking speed, $p<0.05$). Only current, but not previous, GC use was associated with increased risk of MOF (HR 1.68, 95% CI 1.13–2.49), vertebral (HR 2.59, 95% CI 1.58–4.24), and any fracture (HR 1.68, 95% CI 1.19–2.38), but not hip fracture (HR 1.13 95% CI 0.59–2.69)(Figure).

Conclusion(s):
Current, but not previous, GC treatment was associated with increased fracture risk accompanied by substantially increased cortical porosity and impaired physical function. These results indicate that timing of glucocorticoid use, cortical bone microstructure and physical function should be included in fracture risk assessment for GC exposed patients.

P924

EFFICACY AND SAFETY OF CETYLATED FATTY ACIDS IN OSTEOARTHRITIS: A SYSTEMATIC REVIEW AND META-ANALYSIS

L. Kayyal[1], J. O'Logbon[1], A. Viswanath[2], O. Aweid[3]

[1]Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom; [2]Kings College London, London, United Kingdom; [3]Mid and South Essex NHS Trust, Basildon, United Kingdom

Background: Osteoarthritis (OA) is a major cause of pain and disability worldwide. Current management often relies on non-steroidal anti-inflammatory drugs (NSAIDs), which carry long-term safety concerns. Cetylated fatty acids (CFAs) have been proposed as adjunctive therapies due to their purported anti-inflammatory and lubricating properties. This study evaluated the effectiveness of CFAs in reducing pain and improving functional outcomes in adults with osteoarthritis.

Methods: We conducted a systematic review and meta-analysis in accordance with PRISMA and Cochrane guidelines (PROSPERO ID: CRD420251009414). PubMed, EMBASE, and Scopus were searched from inception to March 2025, with an updated search conducted up to September 2025. Eligible studies included randomized controlled trials (RCTs) and observational studies assessing CFAs in adults with OA. The primary outcome was a change in pain scores. Secondary outcomes included physical function, stiffness, and adverse events.

Results: Seven studies (n = 347) met inclusion criteria; five RCTs (n = 277) contributed to quantitative synthesis. The pooled analysis revealed that CFAs resulted in a significant reduction in pain compared to the control group, with a moderate effect size (SMD = −0.68, 95% CI −0.93 to −0.44; $p < 0.00001$). Between-study heterogeneity was negligible ($I^2 = 0\%$), and the direction of effect was consistent across individual comparisons.

Conclusion: CFAs are associated with a statistically significant analgesic benefit in osteoarthritis, with highly consistent effects across trials. While encouraging, these findings derive from a small evidence base, and it is unclear whether this effect is clinically meaningful; larger, rigorously designed, placebo-controlled RCTs with standardized pain and function outcomes and longer follow-up are needed to define optimal formulation, dosing, and durability of benefit.

P925

PREVALENCE OF VITAMIN D DEFICIENCY/ INSUFFICIENCY IN PATIENTS WITH OBESITY AND DIABETES MELLITUS TYPE 2

L. Kezhun[1], L. Yogarathnam[1]

[1]Educational establishment "Grodno State Medical University", Grodno, Belarus

Objective: To assess the prevalence of vitamin D deficiency/insufficiency in patients with obesity and diabetes mellitus (DM) type 2.

Materials and methods: The study involved 32 patients: group 1 – 46,9% (n=15) with obesity and group 2 – 53,1% (n=17) with DM type 2. The average age in this groups were 65 (50; 77) and 68 (63; 71) respectively, (p>0.05). The following parameters were examined: body mass index (BMI), blood pressure (BP), creatinine, triglycerides (TG), cholesterol (CH), glycated hemoglobin (HbA1c), fasting blood glucose (FGL) and vitamin D level (25(OH)D). Statistical processing of the obtained results was carried out using the program "STATISTICA 10.0".

Results: The analyzed groups of patients had not differences in age, BP, creatinine, CH, or TG (p>0,05). BMI was higher in group 1 if compared to group 2 (34,2 kg/m^2 vs 30,1 (28,8; 31,2) kg/m^2, p=0,01). FGL was higher in group 2 if compared to group 1 (7,3 (6,2; 8,3) mmol/l vs 5 (4,7; 5,2) mmol/l, p <0,05). The level of 25(OH)D in the blood plasma of patients in group 1 was 14.2 (10.0; 18.8) ng/ml and corresponded to vitamin D insufficiency in 20% (n=3) and deficiency in 80% (n=12) of those examined.

In group 2, the level of 25(OH)D was 14,3 (11,8; 20,3) ng/ml, which corresponded to insufficiency in 29,4% (n=5) and deficiency in 70,6% (n=12) of patients. The level within the optimal range of 25(OH)D in the blood plasma of patients for these two groups was not revealed. No significant differences were found in the levels of 25(OH)D between those examined, nor was there a significant difference in the ratio of vitamin D deficiency to insufficiency (p>0,05).

In group 2, we found a negative relationship between 25(OH)D levels and HbA1c (R =-0,50, p=0,04), as well as a positive relationship between HbA1c levels and TG (R=0,61, p=0,01), CH (R=0,53, p=0,03) and FGL (R=0,55, p=0.02).

Conclusion. The study revealed a significant prevalence of vitamin D deficiency/insufficiency (100%) among patients with obesity and DM type 2. The level of 25(OH)D had an inverse correlation with HbA1c in patients with type 2 DM.

P926

EFFICACY OF FUNCTIONAL REHABILITATION IN COMMON BACK PAIN: WHEN PERSEVERANCE PAYS OFF

L. Kharrat[1], A. Ben Amou[1], F. Majdoub[1], I. Cherif[1], D. Kaffel[1], H. Ferjani Lassoued[1], K. Maatallah[1], D. Ben Nessib[1], W. Hamdi[1]

[1]Kassab Institute of Orthopedics, Tunis, Tunisia

Introduction: Common back pain is a frequent reason for consultation that significantly impacts patients quality of life. Functional rehabilitation plays a key role in the management of this condition, but its effectiveness may vary depending on various factors.
Objective: The aim of our study was to evaluate the effectiveness of functional rehabilitation in treating common back pain.
Methods: We conducted a cross-sectional study including patients treated for common back pain who underwent functional rehabilitation. Clinical evaluations included pain intensity (visual analog scale for spinal pain [VASBack] and radicular pain [VASRadicular]), spinal mobility measurement (Schöber index [SI]), and sleep quality (evaluated on a scale from 0 [very impaired] to 5 [good]).
Results: We included 42 patients, 35 women and 7 men, with a mean age of 54.69 ± 10.98 years. Twenty-two patients were professionally inactive (52%). Five patients were smokers (12%), and 37 were sedentary (92%). Seventyone percent of patients had comorbidities (n=30). Overweight was noted in 74% of cases (n=31). The most common spinal pathology was lumbosciatica (n=18; 43%), followed by low back pain (n=12; 29%) and cervical radiculopathy (n=9; 21%). The most common radiological abnormalities were lumbar osteoarthritis (29 cases) and posterior facet joint osteoarthritis (17 cases). The mean duration of symptoms was 5.13 ± 4.46 years. Functional rehabilitation was performed in different settings: at the hospital (17 cases) and in a private center (26 cases). The average number of sessions was 12.4 ± 5.1, with an average duration of 53.63 ± 29 minutes per session. Before rehabilitation, the average VASBack and VASRadicular scores were 7 ± 1.87 and 4.4 ± 3.67, respectively. Thirty-six patients presented spinal syndrome (86%) and 21 presented radicular syndrome (48%). The mean SI was 1.87 ± 0.86. Sleep quality was impaired in 69% of patients (n=29), with an average score of 4.83 ± 2.1. After rehabilitation, VASBack and VASRadicular scores decreased to averages of 3.78 ± 2.83 and 3.17 ± 1.14, respectively. Similarly, improvements in SI and sleep quality were noted, with averages of 3.17 ± 1.14 and 6.9 ± 2.26, respectively. Spinal syndrome and radicular syndrome persisted in 16 and 10 patients, respectively. Post-rehabilitation VASBack was negatively correlated with the number of rehabilitation sessions (r=-0.351; p=0.026). Post-rehabilitation SI was correlated with the average duration of sessions (r=0.489 ; p=0.007). Furthermore, post-rehabilitation sleep quality improved with the number of sessions (r=0.390; p=0.011).
Conclusion: Our study showed that physical therapy, depending on the number and duration of sessions, is effective in treating common back pain, with significant improvements in pain and sleep quality.

P927

SCHOOL ABSENTEEISM IN JUVENILE IDIOPATHIC ARTHRITIS: FREQUENCY AND ASSOCIATED FACTORS

A. Fantar[1], L. Kharrat[2], F. Majdoub[2], I. Cherif[2], D. Kaffel[2], H. Ferjani[2], K. Maatallah[2], D. Ben Necib[2], W. Hamdi[2]

[1]Intensive Care Unit, Mongi Slim Hospital, La Marsa, Marsa, Tunisia; [2]Rhumatology Department Mohamed Kassab Institue of Orthopedics, Manouba, Tunisia

Introduction: Juvenile idiopathic arthritis (JIA) can impair a child's quality of life due to joint and extra-articular involvement, leading to a negative impact on school attendance. The aim of our study was to assess the frequency of school absenteeism among children with JIA and to identify associated factors.
Methods: This was a cross-sectional study including school-aged children with JIA fulfilling the ILAR 2010 criteria. The following data were collected: age, sex, erythrocyte sedimentation rate (ESR), and C-reactive protein (CRP) levels. Disease activity was assessed using the JADAS10-ESR and the JSpADA scores. Data related to school absenteeism included its frequency, mean duration, reasons for absenteeism, and patients' perceptions.
Results: Sixty patients were included. The sex ratio was 1. The mean age was 14.88 ± 5.01 years. School absenteeism was reported in 60% of patients, mainly occurring after initiation of therapeutic management (43.3% of patients). The most frequently reported reasons were hospital admissions (36.7%), joint pain (26.7%), and disease flares (25%). The mean duration of absenteeism was 5.5 ± 5 days per month. School absenteeism was significantly associated with the following parameters: later age at disease onset (p=0.03), longer disease duration (p=0.04), enthesitis-related arthritis (ERA) subtype (p=0.024), higher CRP levels (p=0.05), higher JADAS10-ESR and JSpADA activity scores (p=0.05 and p=0.04, respectively), presence of erosions (p=0.03), hip involvement (coxitis) (p=0.001), sacroiliitis (p=0.03), and use of disease-modifying antirheumatic drugs (p=0.02). The duration of absenteeism was positively correlated with disease duration (p=0.007), JADAS10-ESR score (p=0.026), and JSpADA score (p=0.029). In multivariate analysis, the ERA subtype (p=0.035) and hip involvement (p=0.027) were independently associated with school absenteeism.
Conclusion: According to our study, school absenteeism reflects higher disease activity, as evidenced by inflammatory markers, disease activity scores, and structural damage.

P928

FRACTURES IN JUVENILE ARTHRITIS: RACING AGAINST SKELETAL LOSS

L. Kharrat[1], C. Ben Ammar[1], F. Majdoub[1], I. Cherif[1], D. Kaffel[1], H. Ferjani Lassoued[1], K. Maatallah[1], D. Ben Nessib[1], W. Hamdi[1]

[1]Kassab Institute of Orthopedics, Tunis, Tunisia

Introduction: Bone growth is a critical period for achieving optimal skeletal mass. In children with juvenile idiopathic arthritis (JIA), chronic inflammation and corticosteroid intake can be responsible for bone weakening and fracture risk.
Objective: We aimed to identify factors associated with fractures in JIA.

Methods: A retrospective study was conducted including JIA patients diagnosed according to ILAR 2001 criteria. Data collected included demographics, clinical features, laboratory markers, radiographic findings, and treatment history. Disease activity was assessed using JADAS10 (ESR and CRP). Erosive disease was defined as joint space narrowing and/or radiographic/ultrasound erosions. Bone mineral density (BMD) was assessed using a dual-energy X-ray absorptiometry of the entire body and expressed in g/cm ^{2} and Z-score.
Results: Ninety-one patients were included (46 boys, 45 girls). The mean age was 15.9±6 years. The mean age at disease onset was 9.4±4.2 years. The mean disease duration was 6.4±4.6 years. JIA subtypes were ERA 42.9%, systemic 7.7%, oligoarthritis 30.9%, polyarthritis 11.5%. Mean JADAS10-ESR and JADAS10-CRP were 19.6±6.7 and 16± 8.3, respectively. Hip involvement and erosions were noted in 28.6%, and 30.8%, respectively. Treatments included NSAIDs (93.4%), oral corticosteroids (11%), csDMARDs (59.3%), bDMARDs (29.7%), and intra-articular corticosteroid injections (40.7%).
The mean BMD was 0.926±0.123g/cm² with a mean Z-score of -0.7±1.12 SD.
Fractures occurred in 8 patients (8.8%), involving forearm (n=2), ankle (n=2), wrist (n=2), supracondylar humerus (n=1), and basicervical femur (n=1). Patients with fractures were younger (13.1 ± 2 vs 16.1 ± 6.2 years; p=0.006) and had earlier disease onset (6.5 ± 2.8 vs 9.7 ± 4.2 years; p=0.038). No significant associations were found with sex, BMI, bone mineral density, JIA subtype, JADAS, JSpADA, corticosteroid use, intra-articular injections, or BMD.
Conclusion: Younger age and earlier disease onset are associated with fracture risk in JIA. Early and individualized assessment of bone health is essential for optimizing fracture prevention and long-term management.

P929
IMPACT OF HLA-B27 AND HLA-B51 ON CLINICAL AND BIOLOGICAL FEATURES OF JUVENILE IDIOPATHIC ARTHRITIS

L. Kharrat[1], I. Fenniche[1], F. Majdoub[1], I. Cherif[1], D. Kaffel[1], H. Ferjani Lassoued[1], K. Maatallah[1], D. Ben Nessib[1], W. Hamdi[1]

[1]Kassab Institute of Orthopedics, Tunis, Tunisia

Introduction: Juvenile idiopathic arthritis (JIA) prognosis may be influenced by genetic factors. Among these, HLA-B27 and HLA-B51 antigens are of particular interest. However, their role in JIA remains controversial.
Objective: We aimed to analyze the prevalence of HLA-B27 and HLA-B51 in JIA and to identify associated factors.
Methods: A retrospective study was conducted including JIA patients diagnosed according to the 2001 International League of Associations for Rheumatology (ILAR) criteria. The following data were collected: sociodemographic, erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), treatments and disease activity assessed using Disease activity was assessed using the Juvenile Arthritis Disease Activity Score (JADAS) and the Juvenile Spondyloarthritis Disease Activity Index (JSpADA). Only patients who had undergone HLA typing were included.
Results: Fourty-three patients were included (25 boys and 18 girls). The mean age of patients was 16.5 ± 4.3 years. The mean age at disease onset was 3.3±2.1 years. The JIA subtypes were: systemic (n=1), oligoarthritis (n=8), polyarthritis (n=2), enthesitis-related arthritis (ERA) (n=27), psoriatic arthritis (n=4), and undifferentiated JIA (n=1). The mean CRP and ESR levels were 14.5±22.5 mg/L and 26.8±23.9mm/h, respectively. The mean JADAS-CRP and JADAS-ESR scores were 14.7 ± 7.9 and 18.6 ± 6.4, respectively. The mean JSpADA score was 2.9 ± 1.5. Uveitis was reported in 6 patients (14%), and cutaneous psoriasis in 2 patients (4.7%).
HLA typing revealed 8 HLA-B27-positive patients (18.6%) and 7 HLA-B51-positive patients (16.3%). HLA-B27 was significantly associated with male sex (p=0.009), ERA subtype (p=0.019), higher CRP (32.3±33 vs. 10.3±18mg/L; p=0.029), and higher ESR (49.6±37.8 mm/h vs. 21.9±16.3 mm/h; p=0.044).
No significant association was observed between HLA-B27 and the presence of enthesitis (p=0.673), back pain (p=0.508), or sacroiliitis (p=0.304). Similarly, uveitis was not associated with either HLA-B27 (p=0.509) or HLA-B51 (p=0.270).
Conclusion: Our study showed that HLA-B27 was associated with male sex, the ERA subtype, and higher inflammatory activity. Recent studies have shown that HLA-B27 status is linked to more severe disease activity, particularly in ERA, and to lower long-term remission rates [1,2]. These results emphasize the importance of closer monitoring and optimized therapeutic strategies in HLA-B27-positive patients.

SPORTS ACTIVITY AND MEDICAL EXEMPTION IN JUVENILE IDIOPATHIC ARTHRITIS

A. Fantar[1], L. Kharrat[2], F. Majdoub[2], I. Cherif[2], D. Kaffel[2], H. Ferjani[2], K. Maatallah[2], D. Ben Necib[2], W. Hamdi[2]

[1]Intensive Care Unit, Mongi Slim Hospital, La Marsa, Marsa, Tunisia; [2]Rhumatology Department Mohamed Kassab Institue of Orthopedics, Manouba, Tunisia

Introduction: Juvenile idiopathic arthritis (JIA) may be responsible for the alteration of patients' quality of life due to joint and extra-articular involvement, particularly, by limiting participation in sports activities.
Objective: The aim of our study was to assess sports participation among children with JIA.
Methods: A cross-sectional study was conducted including JIA patients fulfilling the ILAR 2010 criteria. The following data were collected: age, sex, visual analogue scale, parent global assessment, disease activity assessed using the JADAS10-ESR and the JSpADA, and structural damage. Data related to sports activity were obtained through patient interviews during pediatric rheumatology consultations.
Results: Sixty patients were included. The sex ratio was 1. The mean age was 14.88 ± 5.01 years. Sports participation was reported in 58.3% of patients, mainly in the school setting (50% of patients), with a mean duration of 4 ± 2.8 hours per week. The most commonly practiced sports were swimming (50%), football (35%), and running (26.7%). A medical exemption from sports was prescribed in 53.3% of patients, mainly indicated by the rheumatologist (36.7%), with a mean duration of 2.89 ± 2 years.
Absence of sports activity was associated with the following parameters: patient VAS (6.56 ± 2.3 vs 3.5 ± 2; p < 0.001), parent global assessment

(6.42 ± 2 vs 4.27 ± 2.18; p < 0.001), physician global assessment (5.16 ± 1.9 vs 3.27 ± 1.97; p = 0.001), JADAS10-ESR (23 ± 5.5 vs 18.3 ± 7.4; p = 0.006), and JSpADA (3.7 ± 1.3 vs 2.67 ± 1.7; p = 0.04). Similarly, hip involvement, radiographic sacroiliitis, and erosive JIA form were more frequently observed in patients with no sports activity (p = 0.008, p = 0.019, and p = 0.023, respectively).

Conclusion: Our study showed that absence of sports activity was associated with higher disease activity, functional impairment, and structural damage. These findings highlight the potential impact of disease severity on sports participation and emphasize the importance of encouraging adapted physical activity in the management of JIA patients, in order to improve quality of life and functional prognosis.

CONTEMPORARY MANAGEMENT OF SPINAL CORD INJURY (SCI)-ASSOCIATED OSTEOPOROSIS: CLINICAL CHALLENGES AND EMERGING STRATEGIES

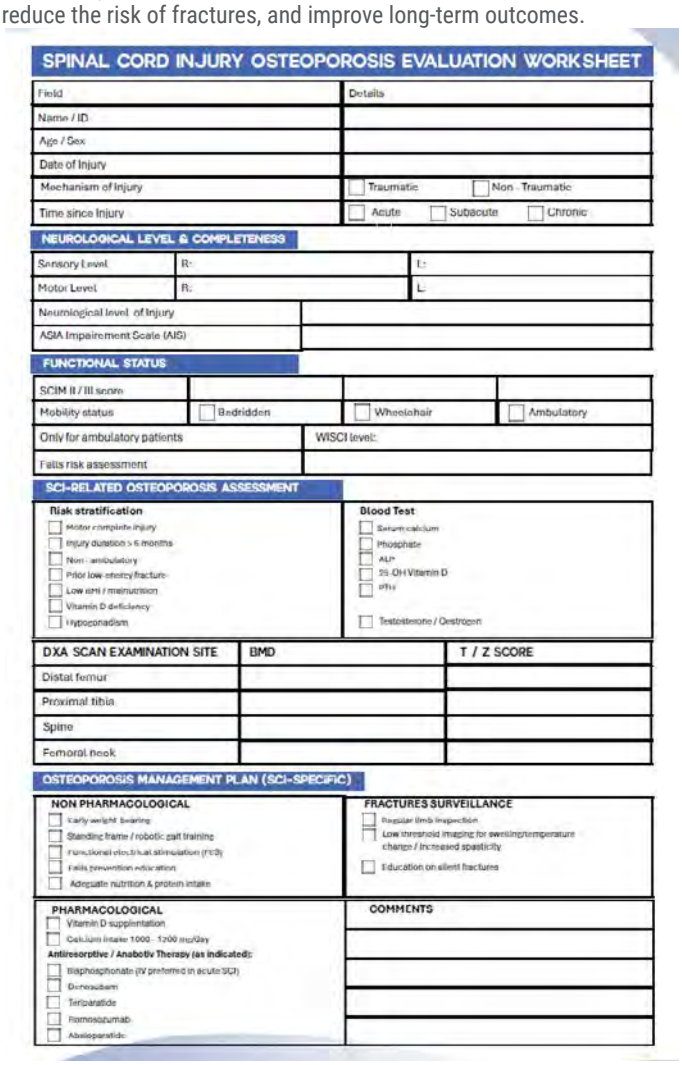
L. L. M. Lapenna[1], S. G. Scivoletto[2], C. C. Coppola[3], A. D. Agnusdei[4]

[1]Rehabilitation Medicine Unit - Ospedale Cristo Re, Italian NHS, Rome, Italy, Roma, Italy; [2]Spinal Unit - Ospedale CTO Andrea Alesini, ASL Roma 2, Italian NHS, Rome, Italy, Roma, Italy; [3]Dept. of Orthopedics & Traumatology, Trauma Center 'Ospedale del Mare' General Hospital, ASL NA1 Center, Italian NHS, Naples, Italy, Napoli, Italy; [4]Indipendent Scientific Consultant, Siena, Italy

Introduction

SCI is complicated by rapid and profound bone loss, resulting in a significantly increased risk of fragility fracture (60% of these patients will suffer a fracture during their lifetime), and a reduction in quality of life. Bone loss after SCI begins within weeks from injury (up to 1% per week in the acute phase), and is more pronounced in the distal femur, proximal tibia and hip. Despite its clinical importance, SCI-associated osteoporosis remains underdiagnosed and undertreated, determining a significant gap in research and clinical practice. The purpose of this study is to highlight these gaps and propose potential solutions.

Methods



The Authors conducted a literature review covering publications from 1953 to present using the keywords spinal cord injury/lesion and osteoporosis. A total of 806 articles were identified; after excluding studies not specifically addressing post-SCI osteoporosis, 396 were included in the analysis.

Results

Advances in the management of SCI have improved survival and neurological outcomes, but long-term skeletal health remains an unmet need. Current diagnostic approaches are inadequate; DXA often produces misleading results because lumbar spine BMD may appear preserved or increased due to sitting-related loading or the presence of degenerative calcifications, while the most affected sites are not assessed by DXA and normative data are not available. From a therapeutic perspective, antiresorptive drugs show limited and often transient efficacy, failing to prevent bone loss around the knee. Anabolic treatments, particularly Teriparatide, appear promising but require further confirmation, while newer agents (Romosozumab and Denosumab) demonstrate potential benefits in preventing or reversing bone loss after spinal cord injury. Non-pharmacological interventions, particularly functional electrical stimulation and loading strategies, play a complementary role in preserving bone mass.

Conclusions

Comprehensive and effective management of patients with SCI requires close coordination between rehabilitation medicine, endocrinology, orthopaedics, and neurosurgery. The use of specific diagnostic tools and the implementation of multimodal treatment strategies for early and proactive management of osteoporosis should be considered an integral part of comprehensive care for patients with spinal cord injury, particularly in order to implement the use of new anabolic therapies, that reduce the risk of fractures, and improve long-term outcomes.

SPINAL CORD INJURY OSTEOPOROSIS EVALUATION WORKSHEET

Field	Details
Name / ID	
Age / Sex	
Date of Injury	
Mechanism of Injury	☐ Traumatic ☐ Non - Traumatic
Time since Injury	☐ Acute ☐ Subacute ☐ Chronic

NEUROLOGICAL LEVEL & COMPLETENESS

Sensory Level	R:	L:

Femoral neck		

OSTEOPOROSIS MANAGEMENT PLAN (SCI-SPECIFIC)

NON PHARMACOLOGICAL
- ☐ Early weight bearing
- ☐ Standing frame / robotic gait training
- ☐ Functional electrical stimulation (FES)
- ☐ Falls prevention education
- ☐ Adequate nutrition & protein intake

FRACTURES SURVEILLANCE
- ☐ Regular limb inspection
- ☐ Low threshold imaging for swelling/temperature change / increased spasticity
- ☐ Education on silent fractures

PHARMACOLOGICAL
- ☐ Vitamin D supplimentation
- ☐ Calcium intake 1000 - 1200 mg/day

Antiresorptive / Anabolic Therapy (as indicated):
- ☐ Bisphosphonate (IV preferred in acute SCI)
- ☐ Denosumab
- ☐ Teriparatide
- ☐ Romosozumab
- ☐ Abaloparatide

SARCOPENIA-DEFINING PARAMETERS CORRELATE WITH SPECIFIC GUT MICROBIOTA: PRELIMINARY FINDINGS FROM THE TEMPUS-FUGIT STUDY

L. Lapauw[1], N. Amini[1], L. Peeters[1], R. Meneses[2,3], J. Dupont[1,4], M. Derrien[2,3], J. Raes[2], E. Gielen[1,4]

[1]KU Leuven, Department of Public Health and Primary Care, division of Gerontology and Geriatrics, Leuven , Belgium; [2]KU Leuven, Rega Institute, Department of Microbiology, Immunology and Transplantation, Laboratory of Molecular Bacteriology, Leuven , Belgium; [3]VIB-KU Leuven Center for Microbiology, Leuven, Belgium, Leuven, Belgium; [4]UZ Leuven, division of Geriatric Medicine, Leuven , Belgium

Objectives

This study aimed to clarify associations between sarcopenia(-defining parameters), gut microbiota (GM), systemic and intestinal inflammation in community-dwelling persons ≥65 years.

Materials and methods

This exploratory, cross-sectional study comprising data from the TEMPUS-FUGIT study (NCT05008770), included 144 community-dwelling persons, of whom 45 had probable, confirmed or severe sarcopenia as per EWGSOP2-criteria. Muscle mass and function were evaluated using Appendicular Lean Mass (ALM), Hand Grip Strength (HGS), 5-time Chair Stand Test (CST), Short Physical Performance Battery (SPPB) and gait speed. Gut microbiota (GM) taxa, enterotypes, and diversity indices were profiled by 16S rRNA sequencing; fecal calprotectin (fCPT), interleukins (IL1β, 4, 6, 8, 10), tumor necrosis factor (TNFα), InterFeroN (IFN)-γ, albumin, highsensitivity Creactive protein (hsCRP), and white blood cell (WBC) counts were measured. Group comparisons and correlations were multiple testing-adjusted. Linear regression analyses were conducted correcting for age, sex, body mass index, steps/day, Bristol Stool Score, intake of statins and proton pump inhibitors, and protein and fiber.

Results

Albumin levels decreased from the lowest to highest tertiles of SMI and ALM. IL-8 increased across HGS tertiles and TNF-α declined from HGS tertile 1 to 2 and rose again in tertile 3. Chao1 richness increased from controls to persons with probable sarcopenia, increased across higher CST tertiles (thus worse muscle strength) and decreased across gait speed tertiles (and thus faster gait). *Eggherthella*, *Eisenbergiella*, *Enterobacter* and *Prevotellaceae* were enriched in controls. A higher CST, associated with lower abundance of *Anaerosporobacter* (β: -0.107; [-0.199; -0.014]) and fCPT associated with *Streptococcus* (β: 0.307[0.108; 0.506]), *Lactobacillus* (β: 0.766 [0.395; 1.137]), *Slackia* (β: 0.465 [0.151; 0.780]) and *Dorea* (β: 0.443[0.174; 0.712]). In persons with any sarcopenia stage, HGS associated with *Mogibacterium* (β: 0.253 [0.062; 0.443]) and fCPT associated with *Acetitomaculum* (β: -0.993 [-1.837; -0.149]). Persons with a *Prevotella*-dominated enterotype walked faster than those with a *Ruminococcus*-dominated enterotype. All findings had a $p_{adj} < 0.05$.

Conclusions

Specific GM taxa were associated with intestinal inflammation in the full cohort and among participants with sarcopenia. Only in those with sarcopenia, GM also associated with muscle strength. GM richness increased with worse lower limb muscle strength and faster gait speed, somewhat contradictory to the expectations. These findings warrant further research in larger, longitudinal cohorts.

Disclosures: all authors have nothing to disclose.

AI-DRIVEN ASMI PREDICTION FROM ROUTINE HIP RADIOGRAPHS FOR OPPORTUNISTIC SARCOPENIA SCREENING

L. Ling[1], C. Shu-Han[2], K. Yi-Jie[3], W. Lien-Chen[3], C. Yu-Pin[3]

[1]School of Medicine, National Defense Medical University, Taipei, Taiwan, R.O.C., Taipei, Taiwan; [2]Department of Ophthalmology, Changhua Christian Hospital, Changhua, Taiwan, R.O.C., Changhua, Taiwan; [3]Department of Orthopedic Surgery, Wan Fang Hospital, Taipei Medical University, Taipei, Taiwan, R.O.C., Taipei, Taiwan

Objectives

To develop and validate a deep learning model predicting DXA-derived Appendicular Skeletal Muscle Mass Index (ASMI) from routine hip radiographs for opportunistic sarcopenia screening.

Material and Methods

This retrospective study included 1,267 patients (development n=1,140, validation n=127). A multimodal deep learning model integrating radiographic images (ResNet-34 backbone) and clinical variables predicted continuous ASMI and classified sarcopenia per AWGS 2019 criteria (<7.0 kg/m² males, <5.4 kg/m² females). Automated implant masking handled orthopedic hardware. Metrics: Pearson r, R^2, mean absolute error (MAE), area under curve (AUC).

Results

On external validation, the model achieved r=0.806, R^2=0.650, MAE=0.414 kg/m², and AUC=0.874 for sarcopenia classification. Applying AWGS diagnostic thresholds yielded sensitivity of 70.5% and specificity of 83.3%. Performance remained consistent across gender subgroups (females AUC=0.854, males AUC=0.864) and age groups (<60 years AUC=0.854, 60-75 years AUC=0.829, >75 years AUC=0.937). Gradient-weighted Class Activation Mapping confirmed anatomically relevant focus on gluteal and proximal thigh musculature. Automated implant masking improved performance (r: 0.78→0.80).

Conclusions

This first hip radiograph-based ASMI prediction model enables automated sarcopenia screening with performance comparable to complex imaging modalities. With 1.6 million hip radiographs performed annually in aging populations, this approach transforms existing workflows into opportunistic screening infrastructure at near-zero marginal cost, particularly valuable for hip fracture patients and fracture liaison services.

Disclosures

The authors declare no conflicts of interest.

P935

PREOPERATIVE STATIN USE AND 1-YEAR SURVIVAL BENEFIT IN GERIATRIC HIP FRACTURE PATIENTS: A REAL-WORLD ANALYSIS

L. Ling[1], C. Shu-Han[2], C. Yu-Pin[3]

[1]School of Medicine, National Defense Medical University, Taipei, Taiwan, R.O.C., Taipei, Taiwan; [2]Department of Ophthalmology, Changhua Christian Hospital, Changhua, Taiwan, R.O.C., Changhua, Taiwan; [3]Department of Orthopedic Surgery, Wan Fang Hospital, Taipei Medical University, Taipei, Taiwan, R.O.C., Taipei, Taiwan

Objective
To investigate the association between preoperative statin exposure and 1 year survival outcomes in geriatric patients undergoing hip fracture surgery, aiming to address the disproportionately high postoperative mortality rates in this vulnerable population.
Material and Methods
This retrospective cohort study utilized the TriNetX US Collaborative Network database to identify patients aged 65 to 85 years diagnosed with hip fracture who underwent surgery within 30 days of diagnosis between January 1, 2013 and December 31, 2024. The exposure cohort comprised patients with at least 3 instances of statin use within 3 months prior to surgery, while the control cohort had no history of statin use within 3 months before surgery. A 1:1 propensity score matching (PSM) was performed based on demographics, comorbidities, medications and laboratory values. The primary outcome was all cause mortality at 1 year. Secondary outcomes included acute myocardial infarction (AMI), cardiac arrest and venous thromboembolism (VTE). Survival probabilities were estimated using Kaplan Meier analysis and hazard ratios (HR) with 95% confidence intervals (CI) were calculated using Cox proportional hazards models. Subgroup analyses were conducted by gender, age and diabetes status, alongside sensitivity analyses across 3, 6 and 12 month exposure windows.
Results
After PSM, 13,222 patients were included (6,611 per group) with a mean age of 76 years. The statin cohort demonstrated a significantly lower risk of 1 year all cause mortality compared to controls (9.3% vs 11.8%; HR 0.78, 95% CI 0.70 to 0.86, p<0.001). This survival benefit was also evident at 1 month post surgery (HR 0.79, p=0.025). Subgroup analyses confirmed consistent protective effects across all stratifications. Sensitivity analyses across varying exposure windows validated these findings. Notably, long term statin users (12 month exposure) maintained a significant survival advantage (mortality HR 0.80, p<0.001) despite presenting with a higher baseline cardiovascular risk profile as reflected by increased AMI incidence (HR 1.38, p=0.001). No significant differences were observed for cardiac arrest or VTE.
Conclusion
Preoperative statin exposure is associated with substantial 1 year survival benefits in geriatric hip fracture patients undergoing surgery, persisting even in those with higher cardiovascular burdens. These findings support maintaining statin therapy to provide crucial perioperative protection for this high risk population.

P936

EFFECT OF LONG TERM CINACALCET THERAPY ON HYPERPARATHYROIDISM IN PATIENTS WITH CHRONIC KIDNEY DISEASE STAGE 5

L. M. Martynyuk[1], T. M. Malska[1]

[1]Ternopil National Medical University, Ternopil, Ukraine

Background. Treatment of the secondary hyperparathyroidism (sHPT) in patients with chronic kidney disease (CKD) G5D remains an actual problem. The ***aim*** was toeveluate the effect of long-term therapy with calcimimetic cinacalcet (LCT) on the course of sHPT in CKD G5D patients. ***Materials and methods.*** The study examined 268 individuals with CKD G5D, who received therapy by program hemodialysis. In all patients, levels of intact parathyroid hormone (iPTH), serum calcium (Ca), phosphorus (P) and alkaline phosphatase (ALP) activity were analyzed before treatment, after one and two years of therapy. The data were analyzed using SPSS, version 21, with statistical significance set at p <0.05. ***Results.*** The single-center cohort prospective study was conducted. SHPT was detected in 33.6 % of patients, whose average age was 52.22±12.9 years. The study group included patients who received LCT and basic sHPT therapy with the use of vitaminD alfacalcidol and calcium-containing/ synthetic phosphate-binder calcium acetate/sevelamer hydrochloride; the control group received long-term basic therapy. LCT contributed to the achievement of the target level of iPTH in 83.3 % of patients with sHPT, which was accompanied by a significant decrease in the frequency of fractures and clinically significant vascular calcification. During LCT there was also significant decrease of P, Ca level and, to a lesser extent, ALP activity in patients with sHPT. ***Conclusion.*** During LCT of sHPT with cinacalcet, there was a significant decrease in the level of iPTH, which was accompanied by a decrease in the level of serum P, Ca and, to a lesser extent, ALP. Cinacalcet can be considered as a safe and effective tool in the treatment of sHPT in CKD G5D patients.

THE IMPACT OF A COMPREHENSIVE REHABILITATION PROGRAM ON BODY COMPOSITION IN POST-MASTECTOMY UPPER LIMB LYMPHEDEMA: A BIOIMPEDANCE ANALYSIS STUDY

V. Vasileva[1], T. Konchugova[1], T. Apkhanova[1], L. Marchenkova[1]

[1]Federal State Budgetary Institution «National Medical Research Center of Rehabilitation and Resort Medicine» of the Ministry of Health of the Russian Federation, Moscow, Russia

INTRODUCTION. Upper limb lymphedema is a common and disabling complication following radical breast cancer treatment, with a prevalence of 20-40%. Although volumetry remains the gold standard for diagnosing limb lymphedema, it cannot differentiate between lymphatic edema and adipose hypertrophy. Bioimpedance analysis (BIA) offers a more comprehensive approach to assessing body composition. However, the impact of complex rehabilitation programs on multi-compartment body composition in postmastectomy upper limb lymphedema has not been sufficiently studied.

Aim. To investigate the effect of a comprehensive medical rehabilitation program—including laser therapy, magnet therapy, therapeutic physical exercises, intermittent pneumatic compression, and workouts on cyclic trainers—on body composition parameters measured by BIA in patients with upper limb lymphedema associated with radical breast cancer treatment.
MATERIAL AND METHODS. A cross-sectional study included 30 women aged 35-75 years with secondary upper limb lymphedema following mastectomy for breast cancer. Over a 10-day period, patients underwent comprehensive rehabilitation while maintaining a high-protein diet. Efficacy was assessed using anthropometry (circumference measurements of upper limb segments) and BIA of body composition before and after the treatment course.
RESULTS. A statistically significant reduction was observed in the circumferences of all upper limb segments on both arms ($p<0.05$), except for the right elbow circumference. The most pronounced dynamics were noted in the proximal segments. BIA revealed a significant decrease in total ($p=0.00035$), extracellular ($p=0.00008$), and intracellular fluid ($p=0.000002$), as well as a reduction in waist ($p=0.00004$) and hip circumference ($p=0.0003$). Changes in lean body mass ($p=0.0018$) and musculoskeletal mass ($p=0.004$), along with an improvement in basal metabolic rate ($p=0.026$), were noted.
CONCLUSION. The comprehensive medical rehabilitation program is an effective means of correcting not only local manifestations of lymphedema but also systemic body composition disorders. The combined use of BIA and traditional anthropometry provides an objective multi-component assessment of rehabilitation efficacy.

P938

NEW OPPORTUNITIES IN REHABILITATION: THE IMPACT OF A SPA RESORT COMPLEX ON METABOLIC PARAMETERS IN DIABETIC ANGIOPATHY (RESULTS OF A RANDOMIZED TRIAL)

V. Vasileva[1], L. Marchenkova[1]

[1]Federal State Budgetary Institution «National Medical Research Center of Rehabilitation and Resort Medicine» of the Ministry of Health of the Russian Federation, Moscow, Russia

Introduction. Diabetes mellitus (DM) is a global non-communicable pandemic, leading to early disability and mortality, primarily due to vascular complications. Diabetic angiopathy of the lower extremities (DALE) is one of the most severe complications, significantly impairing quality of life and increasing the risk of amputations. In this regard, the search for effective rehabilitation methods, including spa and resort treatment (SRT), is of particular importance.
Aim: To study the effect of a comprehensive SRT program on carbohydrate and lipid metabolism parameters in patients with DALE.
Materials and Methods. A randomized prospective study with two parallel groups was conducted. The study included 30 patients with type 1 and type 2 DM and DALE aged 18–70 years. Patients in the main group (n=15) received a 14-day SRT course including carbon dioxide-mineral baths, massage with an elastic pseudo-boiling layer, applications of Ilovo-sulfide mud from Lake Tambukan, intake of mineral water "Essentuki No. 4", and clinical psychological counseling. The comparison group (n=15) received a standard rehabilitation complex (therapeutic exercises, circular shower, vortex foot baths). All patients underwent testing for levels of glucose, total cholesterol (TC), triglycerides (TG), low-density lipoproteins (LDL), and high-density lipoproteins (HDL) before and after the treatment course.
Results. In the main group, after the treatment course, a significant decrease in TC level (from 5.6 [4.9; 6.2] to 5.08 [4.4; 5.6] mmol/l, $p=0.0005$), LDL (from 3.41 [2.73; 3.91] to 3.04 [2.47; 3.54] mmol/l, $p=0.02$), and fasting glucose (from 5.98 [5.3; 6.2] to 5.68 [5.0; 5.8] mmol/l, $p=0.023$) was revealed. In the comparison group, only glucose level decreased significantly (from 6.09 [5.2; 6.15] to 5.54 [5.1; 5.8] mmol/l, $p=0.03$). No significant changes in TG and HDL parameters were noted in either group ($p>0.05$).
Conclusions. The use of a specialized SRT complex, including balneo-, peloido-, and drinking therapy, against the background of a standard diet in patients with DALE leads to a significant improvement in lipid (TC, LDL) and carbohydrate metabolism parameters, surpassing the effect of a standard rehabilitation program.

P939

COMBINING IBANDRONATE WITH MEDICAL REHABILITATION: IMPACT ON TREATMENT OUTCOMES IN POSTMENOPAUSAL OSTEOPOROSIS AT 6 MONTHS

L. Marchenkova[1], V. Vasileva[1]

[1]Federal State Budgetary Institution «National Medical Research Center of Rehabilitation and Resort Medicine» of the Ministry of Health of the Russian Federation, Moscow, Russia

The aim: to evaluate the effect of treatment with oral form of ibandronic acid 150 mg on the duration of maintaining the effect of medical rehabilitation in patients with established postmenopausal osteoporosis undergoing the 2nd stage of medical rehabilitation.
Material and methods. The work included 70 women aged 45 years and older in the postmenopausal period of more than 1 year, admitted to hospital for the 2nd stage of medical rehabilitation for diseases of the musculoskeletal system and diagnosed with postmenopausal osteoporosis. Women were randomized into 2 groups: the main group (n=35), where ibandronic acid, 150 mg tablets for administration once a month, was prescribed, and the comparison group (n=35). All patients in the main and comparison groups received cholecalciferol (vitamin D3) at an average dose of 1500 IU per day. Evaluation of the effectiveness of treatment after 6 months was carried out using a "battery" of functional tests to assess the function of movement, strength of the muscles of the spine and abdomen, static and dynamic balance indicators, as well as by assessing pain on a 5-point VAN scale and quality of life using the SF-36 questionnaire.
Results. After 6 months, in the main group, in contrast to the comparison group, an increase in static endurance of the back muscles ($p=0.017$) and dynamic endurance of the back muscles ($p=0.024$ vs with the initial level; $p=0.030$ vs with the comparison group), an increase in walking speed in the test were noted. 10-meter walk ($p=0.043$) and a decrease in the time to complete the Stand and Go test ($p=0.035$ vs. baseline; $p=0.028$ vs. comparison group). Also, in the main group, a decrease in the degree of forward body displacement in the Fukuda test was observed ($p=0.035$ vs. baseline; $p=0.047$ vs. comparison group) and an increase in the time to maintain balance with eyes open, both on the right ($p=0.018$) and left legs ($p=0.031$). After 6 months, the main group also noted an increase in the score on the SF-36 Physical Functioning ($p=0.040$), Pain Intensity ($p=0.025$ vs. baseline; $p=0.006$ vs. comparison group) and Life Activity ($p=0.024$) scales. The social functioning indicator increased in both groups ($p<0.05$), but the quality of life level in this domain in the main

group was better than in the comparison group (p=0.043). A decrease in the severity of pain syndrome was detected only in the main group (p=0.044).

Conclusion. Preliminary data of the scientific work showed the effectiveness of treatment with oral form of ibandronic acid 150 mg in maintaining the effect of medical rehabilitation in patients with established postmenopausal osteoporosis.

P940

INDIVIDUALIZED FACTOR IX REPLACEMENT AND HEXAPOD EXTERNAL FIXATION IN HEMOPHILIA B PATIENTS WITH OPEN TIBIA AND FIBULA FRACTURES: PERIOPERATIVE SAFETY AND OUTCOMES

L. Meng[1]

[1]Department of Orthopedics, The First Affiliated Hospital of Xi'an Jiaotong University, Xi'an, China

Objective:
To assess the perioperative safety and clinical outcomes of individualized coagulation factor IX (FIX) replacement combined with hexapod external fixation in hemophilia B patients with open tibia and fibula fractures, and to develop a standardized management protocol for high-bleeding-risk cases.

Methods:
A retrospective review was performed on 9 male patients with hemophilia B who sustained open tibia and fibula fractures and were treated at our institution between January 2015 and June 2024 (age range, 19–54 years; mean, 35.7 years). Preoperatively, all patients received FIX replacement therapy under hematology guidance until coagulation targets were achieved. The intraoperative FIX activity target was ≥80%, maintained at 50–70% for the first 3–5 days postoperatively, and adjusted subsequently according to clinical monitoring. All patients underwent fracture reduction and stabilization using a hexapod external fixator (Taylor Spatial Frame / Ortho-SUV). FIX activity and APTT were monitored preoperatively and at 24 and 72 hours postoperatively. Intraoperative blood loss, wound healing, complications, and radiographic bone union were documented.

Results:
All 9 patients underwent successful surgery after achieving target FIX activity. The mean intraoperative blood loss was 220 ± 70 mL, with no major bleeding or reoperation for hemostasis. Postoperative FIX levels remained within the target range, and APTT normalized progressively. Eight wounds healed primarily, while one superficial infection resolved with dressing changes. Soft-tissue recovery was satisfactory, and fixator adjustment proceeded smoothly. At 6-month follow-up, radiographic bone union was achieved in all cases, with no rebleeding, refracture, or inhibitor formation observed.

Conclusion:
In hemophilia B patients with open tibia and fibula fractures, individualized FIX replacement combined with hexapod external fixation is a safe and effective approach. This method provides reliable hemostatic control and stable fracture healing, offering a practical and reproducible perioperative management model for complex high-risk cases.

Keywords: Hemophilia B; Factor IX; Hexapod external fixation; Open tibia and fibula fracture; Perioperative management

P941

CLINICAL APPLICATION OF A PORTABLE FEMORAL TRACTION DEVICE IN ELDERLY PATIENTS WITH OSTEOPOROTIC INTERTROCHANTERIC FRACTURES

L. Meng[1]

[1]Department of Orthopedics, The First Affiliated Hospital of Xi'an Jiaotong University, Xi'an, China

Background
Osteoporotic intertrochanteric femoral fractures are common in the elderly, and PFNA is widely used as a minimally invasive fixation method. However, the traditional supine traction table is bulky, complex to assemble, and provides limited fluoroscopic access, which may prolong operative time and increase complications. This study aimed to evaluate the clinical utility of a newly developed portable lateral-position traction device in PFNA surgery.

Methods
A retrospective analysis was conducted on elderly patients with intertrochanteric fractures who underwent PFNA from January to October 2025. Patients were divided into a control group (traditional supine traction table) and an experimental group (portable traction device). Surgical efficiency and complications were compared. Outcome measures included traction device installation time, reduction time, fluoroscopy frequency, total incision length, device removal time, intraoperative blood loss, and incidence of perineal pressure sores.

Results
A total of 63 patients were enrolled (31 in the control group and 32 in the experimental group), with no significant differences in baseline characteristics such as sex, age, weight, anesthesia type, or Evans classification ($P > 0.05$). Compared with the control group, the experimental group demonstrated significantly improved intraoperative performance: installation time was reduced from 32 to 6 minutes (81% reduction), reduction time decreased by 12 minutes (37 to 25 minutes), fluoroscopy frequency was reduced by approximately 50% (4–5 vs. 8–10 exposures), total incision length shortened by 1.5 cm (5.8 cm vs. 7.3 cm), and device removal time decreased from 8 to 3 minutes (62.5% reduction). In addition, intraoperative blood loss was reduced by about 17% (35 mL vs. 42 mL), and the incidence of perineal pressure sores decreased from 6.5% to 3.1%. These findings indicate that the portable traction device can markedly optimize procedural efficiency and reduce intraoperative risks.

Conclusion
The portable lateral-position traction device significantly enhances surgical efficiency and safety in PFNA procedures for elderly intertrochanteric fractures, reduces complications, and improves the intraoperative experience. Its lightweight structure and ease of use make it suitable for primary hospitals and resource-limited settings, supporting its potential for broader clinical adoption.

P942

ASSOCIATIONS OF FEMORAL NECK COMPOSITE STRENGTH INDICES WITH VITAMIN D AND GLYCATED HEMOGLOBIN IN OLDER SARCOPENIC WOMEN

L. Moussi[1], A. Pinti[2], R. El Hage[3]

[1]Université Polytechnique Haute de France UPHF, Kfarhata el koura north lebanon, Lebanon; [2]Université Polytechnique Haute de France, France , France; [3]University of Balamand El Koura, Lebanon , Lebanon

Background
Bone mineral density does not fully reflect skeletal fragility, particularly in older adults with sarcopenia. Femoral neck composite strength indices like Compression Strength Index (CSI), Bending Strength Index (BSI), and Impact Strength Index (ISI), integrate bone density geometry, and body size to estimate bone mechanical competence. Metabolic factors such as vitamin D status and glycemic control may influence these indices, yet data in sarcopenic older women from Middle Eastern populations are scarce.
Objective
The objective of this study is to examine the associations between total vitamin D, glycated hemoglobin (HbA1c), and femoral neck composite strength indices (CSI, BSI, ISI) in non-diabetic sarcopenic Lebanese women aged 60 years and older.
Methods
58 sarcopenic women (mean age 66.1 ± 5.7 years) underwent dual-energy X-ray absorptiometry for calculation of CSI, BSI, and ISI. Sarcopenia was defined according to EWGSOP criteria using skeletal muscle mass index and handgrip strength. Fasting serum total vitamin D and HbA1c were measured. Associations were assessed using Pearson correlation and multiple linear regression adjusted for age.
Results
Vitamin D levels were positively associated with CSI ($r = 0.301$, $p = 0.0217$) and ISI ($r = 0.296$, $p = 0.0241$). In addition, HbA1c was negatively associated with BSI ($r = -0.270$, $p = 0.0404$), with non-significant negative trends for CSI and ISI. After age adjustment, vitamin D remained an independent positive predictor of CSI ($p = 0.025$) and ISI ($p = 0.028$), while HbA1c remained an independent negative predictor of BSI ($p = 0.030$).
Conclusion
In older sarcopenic women, vitamin D and glycemic status are independently associated with different mechanical components of femoral neck strength. Higher vitamin D is related to greater compression and impact resistance, whereas higher HbA1c is associated with reduced bending strength. Femoral neck composite strength indices may improve fracture-risk assessment by capturing metabolic influences on bone strength beyond BMD.

P943

ASSOCIATIONS BETWEEN FUNCTIONAL PERFORMANCE AND TRABECULAR BONE SCORE IN OLDER WOMEN WITH SARCOPENIA

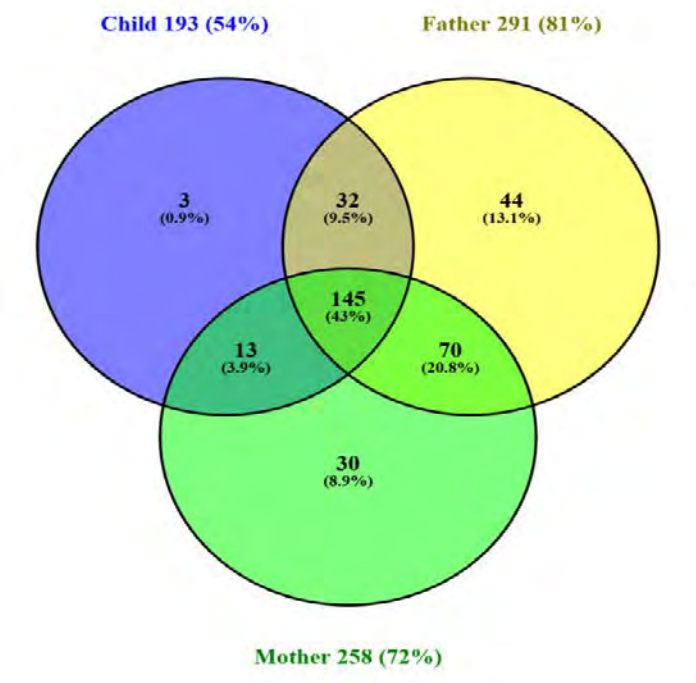
L. Moussi[1], A. Pinti[2], R. El Hage[3]

[1]Université Polytechnique Haute de France UPHF, Kfarhata el koura north lebanon, Lebanon; [2]Université Polytechnique Haute de France, France , France; [3]University of Balamand El Koura, Lebanon , Lebanon

Aim:

This study aimed to explore the association between Six-Minute Walk Test (6MWT), and trabecular bone score (TBS) in a group of older women diagnosed with sarcopenia.
Methods:

36 women aged between 60 and 82 years were enrolled in this study. Participants were recruited from several cities in northern Lebanon. All subjects completed a series of clinical and physical assessments, including dual-energy X-ray absorptiometry (DXA), the 6MWT, handgrip strength testing, and a vertical jump test. Sarcopenia was defined according to EWGSOP criteria using skeletal muscle mass index and handgrip strength.
Results
L1–L4 trabecular bone score (TBS) was positively associated with Six-Minute Walk Test performance and vertical jump height in older sarcopenic women, and these associations remained significant after adjusting for age.
Conclusion:



The findings of this study indicate that performance in the 6MWT and vertical jump test are significant and independent predictors of lumbar spine (L1–L4) trabecular bone score in older women with sarcopenia.

P944

FRAGILITY RUNS IN THE FAMILY: INTERGENERATIONAL CLUSTERING OF OSTEOPOROSIS IN A RURAL INDIAN COHORT

L. Nagendra[1], O. Deshmukh[2], C. Yajnik[2], .. On Behalf Of The Pune Maternal Nutrition Study[2]

[1]Department of Endocrinology/JSS Medical College, Mysore, India; [2]Diabetes Unit, King Edward Memorial Hospital, Pune, Maharashtra, India., Pune, India

Objectives

To study the prevalence of osteopenia and osteoporosis across two generations and to examine the extent and pattern of familial clustering of low bone mass in a well-characterised rural Indian birth cohort.

Material and Methods

The Pune Maternal Nutrition Study (PMNS) is a prospective intergenerational cohort established in 1993 in rural western India. Dual-energy X-ray absorptiometry (DXA) measurements of the lumbar spine and femoral neck were obtained in 558 adult offspring (F1 generation), 392 fathers and 502 mothers (F0 generation). Familial clustering was evaluated among 358 complete parent-offspring trios using Venn-diagram-based visualisation.

Results

In the F1 generation, mean age of males was 26 years and of females was 23 years. Mean age of fathers was 53 years, and of mothers was 46 years. In the F1 generation (children), the prevalence of osteoporosis was 5.3% in males and 3.9% in females while osteopenia was prevalent in 49.8% and 50.3% respectively. In the F0 generation (parents), the prevalence of osteoporosis was 32.6% in fathers and 25.1% in mothers while osteopenia was prevalent in 48.7% of fathers and 48.6% of mothers. There was a strong association between BMD of children and parents, both at AP spine and neck of femur.

Among 358 parent-offspring trios, osteoporosis or osteopenia was present in 81% of fathers and 72% of mothers, with 54% of children affected. Notably, 43% of trios showed clustering of compromised skeletal health in all three family members, indicating strong familial aggregation. In 177 (52%), families there was father-child concordance and in 158 (46%) families, there was mother-child concordance, showing no significant parent-of-origin effect (Figure 1)

Conclusion

Familial clustering of compromised skeletal health in this cohort shows that osteoporosis is a life-course trait shaped by inheritance and shared family environments. Beyond genetics, intergenerational factors such as maternal nutrition, fetal growth, and early-life living conditions appear to program skeletal risk. This makes family-centred, early-life intervention a rational and potentially transformative strategy in prevention of fractures.

GUIDING COST-EFFECTIVE OSTEOPOROSIS CARE IN SOUTH ASIA USING FRAX®-BASED INTERVENTION THRESHOLDS

L. Nagendra[1], A. B. M. Hasan[2], A. Shahin[3], A. Khan[4], C. Minhaj[3], S. Lekamwasam[5], S. Ahmed[6], R. Sahay[7], S. Kalra[8], M. Chandran[9,10], M. Hiligsmann[1]

[1]Department of Health Services Research, Care and Public Health Research Institute, Maastricht University, Maastricht, Netherlands; [2]Department of Endocrinology, Mymensingh Medical College, Mymensingh, Bangladesh; [3]Department Of Rheumatology, Bangladesh Medical University, Dhaka, Bangladesh; [4]Department of Pathology and Laboratory Medicine, Aga Khan University, Karachi, Pakistan; [5]Department of Medicine, Faculty of Medicine, University of Ruhuna, Matara, Sri Lanka; [6]Department of Pathology and Laboratory Medicine,Aga Khan University, Karachi, Pakistan; [7]Department of Endocronology, Osmania Medical College, Hyderabad, India; [8]Department of Endocrinology, Bharti Hospital, Karnal, India; [9]DUKE NUS Medical School, Singapore, Singapore; [10]Osteoporosis and Bone Metabolism Unit, Department of Endocrinology, Singapore General Hospital, Singapore, Singapore

Objectives

Osteoporotic fractures are a growing public health challenge in South Asia, where constrained resources amidst an ageing population necessitate robust economic evaluation of fracture-risk–based intervention strategies to optimize health-care resource utilisation.This study aimed to evaluate the cost-effectiveness of oral bisphosphonate therapy in post-menopausal women at age-dependent FRAX®-based Major Osteoporotic (MOF) and Hip Fracture (HF) intervention thresholds (ITs) in three South-Asian countries - Bangladesh, Sri Lanka, and Pakistan, incorporating country-specific epidemiological and cost inputs.

Methods

Country-specific Markov microsimulation models were adapted to estimate the lifetime healthcare costs and quality-adjusted life years (QALY) of the most commonly used anti-osteoporotic medications (oral risedronate in Bangladesh, oral alendronate in Pakistan and Sri Lanka) compared with no treatment. Cost-effectiveness of age-dependent FRAX®-based MOF and HF ITs was estimated. Cost-effectiveness was evaluated as cost per QALY gained, where one QALY represents one year of life in perfect health. The incremental cost-effectiveness ratio (ICER) reflects the additional cost incurred to gain one additional QALY compared with the alternative. Interventions were considered cost-effective when ICERs were below the country-specific cost-effectiveness

threshold, defined as one-times GDP per capita.
Results
In Bangladesh, treatment with oral risedronate was cost-effective when applied at MOF ITs from 60 years of age and at HF ITs from 55 years under full adherence, and from 70 years for both thresholds under real-world adherence. In Sri Lanka, oral alendronate was cost-effective for both thresholds at 60 and 65 years with full adherence and real-world adherence respectively. In Pakistan, oral alendronate was cost-effective at MOF ITs from 60 and 70 years with full and real-world adherence respectively, and at 70 years for HF ITs with full adherence.
Conclusion
This study suggests that the treatment of South Asian women with oral bisphosphonates is cost-effective at age-dependent FRAX® intervention thresholds from the late 50s to early 70s depending on country, fracture site, and adherence assumptions. Offering cost-effective access to therapy for individuals with high FRAX®-based fracture probabilities, will help guide efficient, equitable osteoporosis treatment strategies in resource-constrained South Asian settings.

P946

AI-DERIVED, DXA-INDEPENDENT PREDICTION OF PREVALENT FRAGILITY FRACTURES: DEVELOPMENT AND VALIDATION OF A CLINICALLY INTERPRETABLE RISK SCORE FOR RESOURCE LIMITED SETTINGS IN INDIA (ASTHI-RISK)

L. Nagendra[1], R. Dasgupta[2,3], G. Banerjee[4], N. Bhavani[5]

[1]Department of Endocrinology/JSS Medical College, Mysore, India; [2]Junior Year, Grade XI, Scarsdale High School, New York, United States; [3]Department of Endocrinology, Sapthagiri Institute of Medical Sciences and Research Centre, Bangalore, India; [4]Director, Artificial Intelligence and Automated Project Management, IBM, New York, United States; [5]Department of Endocrinology and Diabetic Foot Surgery, Amrita Institute of Medical Sciences, Kochi, India

Objectives
DXA-based bone mineral density (BMD) and FRAX are central to fracture risk assessment but are limited by access, cost, and reliance on predefined risk weightings. There is growing interest in explainable artificial intelligence (AI) approaches that can leverage routinely available clinical data to improve fracture case-finding, particularly in resource-constrained settings.
To develop and validate a DXA- and FRAX-independent, clinically interpretable AI-derived risk score (ASTHI-RISK) for identifying individuals with prevalent fragility fractures, using explainable machine learning and penalized regression techniques.
Methods
We analyzed data from 300 adults evaluated for osteoporosis, with prevalent fragility fracture as the primary outcome. Multiple machine-learning models were trained and compared in a stepwise fashion, progressively excluding FRAX variables, BMD, and T-scores. Model performance was assessed using accuracy, precision, recall, F1-score, and ROC–AUC.
To ensure interpretability, SHapley Additive exPlanations (SHAP) were used to quantify the relative contribution and directionality of individual predictors at both global and patient levels. Key features identified through SHAP analysis were subsequently entered into a penalized logistic regression model, enabling derivation of a parsimonious, weighted, point-based clinical risk score.
Results
Among evaluated models, ensemble methods demonstrated superior performance. In a strict DXA- and FRAX-independent setting, XGBoost achieved an accuracy of ~90%, F1-score of 0.94, and ROC–AUC of approximately 0.90. SHAP analysis consistently identified age, body mass index, height, weight, diabetes status, history of falls, glucocorticoid exposure, rheumatoid arthritis, and age at menopause as dominant contributors to fracture risk.
These variables were incorporated into the ASTHI-RISK score (range 0–15), categorizing individuals into low, intermediate, and high-risk groups. A threshold ≥7 demonstrated a sensitivity of ~82% with specificity ~74%, while higher cut-offs achieved specificity >90%, enabling flexible use for screening or confirmatory case-finding.
Conclusions
Explainable AI models can accurately identify prevalent fragility fractures using routinely available clinical data alone, without reliance on DXA or FRAX. By combining SHAP-based feature attribution with penalized regression, ASTHI-RISK translates complex machine-learning outputs into a transparent, clinically actionable risk score. This approach offers a scalable, interpretable strategy for fracture case-finding and prioritization, particularly relevant to low- and middle-income healthcare settings

P947

ATYPICAL SCAPULAR SPINE FRACTURE DURING DENOSUMAB THERAPY: A CASE REPORT

L. Ozgonenel[1]

[1]Department of Physical Medicine and Rehabilitation;Faculty of medicine;Demiroglu Bilim University, Istanbul, Türkiye

Introduction
Antiresorptive therapies effectively reduce osteoporotic fracture risk; however, prolonged suppression of bone turnover may lead to atypical fractures (AFs). Although AFs are predominantly described in the femur, recent evidence indicates that non–weight-bearing sites, including the scapula, may also be affected(1).Several reports link long-term bisphosphonate therapy to atypical scapular or scapular-spine fractures, yet no case has been documented during denosumab monotherapy(2-3). We present what appears to be the first reported case of an atypical scapular spine fracture associated with denosumab use.

Case Report
A 78-year-old woman presented with acute onset of right shoulder pain and restricted range of motion. Her medical history included osteoporosis treated with denosumab for four years (eight doses). She reported no trauma. Physical examination revealed marked tenderness over the scapular spine and painful limitation of shoulder movements. Radiography demonstrated a vertical fracture line at the proximal aspect of acromion, consistent with an atypical scapular spine fracture. An individualized, conservative treatment plan was initiated based on fracture stability and clinical findings.

Conclusion
This case highlights that atypical fractures may occur even at non–weight-bearing sites during denosumab therapy, underscoring the importance of clinical vigilance for unexplained shoulder pain in patients receiving antiresorptive treatment.

IMPACT OF HORMONAL CONTRACEPTIVES ON BONE HEALTH - AN UMBRELLA REVIEW

L. Raskin[1], Y. Malréchauffé[1], J. Douxfils[1], C. Beaudart[1]

[1]University of Namur, Namur, Belgium

Objective This study aims to systematically review and assess evidence from existing systematic reviews on the link between hormonal contraceptive use and bone health outcomes.

Material and Methods A comprehensive literature search was conducted in December 2025 in Medline (Ovid®), Embase, and the Cochrane Database of Systematic Reviews, following the PRISMA guidelines and the Joanna Briggs Institute manual[1], adapted for umbrella reviews. Manual search was also conducted. Systematic reviews and meta-analyses of observational and interventional studies were included if they evaluated hormonal contraceptive use (combined hormonal contraception, CHC; combined oral contraceptives, COC; progestin-only contraceptives, POC) among reproductive-age women and reported fracture risk, bone mineral density (BMD), or bone turnover markers. The risk of bias was assessed using the AMSTAR-2 tool. (PROSPERO CRD420261279749)

Results Of 1,593 screened records, 12 systematic reviews and 2 meta-analyses published between 2006 and 2025 met inclusion criteria. The primary studies included in systematic reviews were highly heterogeneous, limiting synthesis, with moderate overlap across reviews (corrected covered area = 8%). Most reviews focused on CHC (CHC, n=9; COC, n=3), predominantly evaluating ethinyl estradiol-based formulations; only 2 addressed POC (mainly depot medroxyprogesterone acetate (DMPA), with limited data on implants and hormonal intra-uterine device (IUD)), while oral POC were not covered. Outcomes were BMD (n=11); fracture (n=4) and bone turnover markers (n=2). In the general population, CHC use has no significant impact on BMD or fracture risk (n=5). In adolescents, CHC use reduces bone accrual compared to nonusers (n=3), especially with low-dose COC (n=3) (limited evidence). During perimenopause, CHC use may reduce bone turnover and limit BMD loss (n=5). These effects likely depend on different endogenous estradiol level requirements to build or maintain bone health, which differ across adolescence, reproductive years, and perimenopause. DMPA significantly reduces BMD compared to nonusers (n=4), while limited data suggest that POC implants, and hormonal-IUDs may not affect BMD (n=2). The impact of these BMD changes during reproductive years on future fracture risk remains unknown (n=2).

Conclusion Few high-quality systematic reviews exist for assessing bone health in users of hormonal contraceptives. The heterogeneity of the results (for CHC) or the paucity of data (for POC and hormonal-IUD), except for DMPA, suggests the need for further research in this area.

QUALITY OF LIFE AFTER TOTAL HIP ARTHROPLASTY: A CROSS-SECTIONAL STUDY

S. Zanned[1], L. Rouached[1], Y. El Mabrouk[1], S. Ben Dhia[1], S. B. Bouden[1], I. Mahmoud[1], R. Tekaya[1], A. Ben Tekaya[1], M. Ben Salah[2], L. Abdelmoula[1]

[1]Charles Nicolle Hospital, Rheumatology department, Tunis, Tunisia; [2]Charles Nicolle Hospital, Orthopaedics department, Tunis, Tunisia

Background:
Total hip arthroplasty (THA) is a widely performed procedure aimed at restoring function and improving quality of life in patients with advanced hip osteoarthritis. However, postoperative quality of life remains variable and may be influenced by pain-related factors and underlying psychological conditions.
Objectives:
To assess quality of life after THA and to identify factors associated with impaired outcomes.
Methods:
We conducted a cross-sectional study including patients evaluated at least two months after THA. Quality of life was assessed using the

Short Form-36 (SF-36), including its eight domains and the Physical Component Summary (PCS) and Mental Component Summary (MCS). Sociodemographic variables (age, sex, educational level, occupation, living environment) and underlying hip pathology were analysed for their associations with SF-36 scores.

Results:

A total of 51 patients were included (mean age: 51.6 ± 17.6 years; range: 22–85), with a male predominance (male-to-female ratio = 1.55). Most patients lived in urban areas (68.2%), were sedentary (68.6%), and had physically demanding occupations, mainly manual labor (35.5%). The most common comorbidities were hypertension (45.1%) and diabetes mellitus (37.3%). Secondary hip osteoarthritis accounted for 58.8% of surgical indications, primarily related to chronic inflammatory rheumatic diseases and femoral head osteonecrosis. Mean SF-36 physical and mental component scores were 48.9 ± 9.6 (PCS) and 51.7 ± 8.8 (MCS), respectively. The most impaired domains were physical functioning (59.8 ± 23.0), role limitations due to physical health (61.4 ± 25.4), bodily pain (62.6 ± 19.3), and mental health (61.0 ± 20.8). No significant association was found between PCS or MCS scores and age ($p = 0.62$ and $p = 0.67$, respectively) or sex ($p = 0.15$ and $p = 0.07$, respectively). A low educational level was significantly associated with reduced PCS scores ($p = 0.04$). Patients with secondary osteoarthritis related to inflammatory rheumatic diseases had significantly lower physical SF-36 scores compared with those operated on for primary osteoarthritis (235.5 ± 90.5 vs. 248.7 ± 67.1; $p = 0.045$). A strong negative correlation was observed between SF-36 scores and pain intensity measured by the visual analogue scale (VAS) ($r = -0.71$; $p < 0.001$).

Conclusions:

Quality of life after THA is variably affected, with significant impairment in both physical and mental domains. It is strongly correlated with postoperative pain and functional limitation. These factors should be systematically evaluated during follow-up to optimize patient outcomes.

P950

CHRONIC NOCICEPTIVE POSTSURGICAL PAIN FOLLOWING TOTAL HIP ARTHROPLASTY: PREVALENCE AND ASSOCIATED FACTORS

L. Rouached[1], S. Zanned[1], Y. El Mabrouk[1], S. Ben Dhia[1], S. B. Bouden[1], R. Tekaya[1], I. Mahmoud[1], A. Ben Tekaya[1], M. Ben Salah[2], L. Abdelmoula[1]

[1]Charles Nicolle Hospital, Rheumatology department, Tunis, Tunisia; [2]Charles Nicolle Hospital, Orthopaedics department, Tunis, Tunisia

Background :

Total hip arthroplasty (THA) has revolutionized the management of advanced hip osteoarthritis and is now considered the treatment of choice. Despite generally excellent functional outcomes, chronic postsurgical pain (CPSP) persists in a subset of patients and significantly affects postoperative satisfaction and recovery.

Objectives :

To identify factors associated with chronic nociceptive CPSP after THA.

Methods :

We conducted a cross-sectional study including patients evaluated at least two months after THA. Sociodemographic, clinical, and rehabilitation-related variables were analyzed. Nociceptive pain was assessed using the Visual Analogue Scale (VAS). Psychological status was evaluated using the Hospital Anxiety and Depression Scale (HADS)

Results:

Fifty-one patients were included (mean age: 51.6 ± 17.6 years; 38 men and 13 women). Mean postoperative follow-up was 12.7 ± 5.6 months. Most patients lived in urban areas (68.2%), were sedentary (68.6%), and had physically demanding occupations, mainly manual labor (35.5%). The most frequent comorbidities were hypertension (45.1%) and diabetes mellitus (37.3%). Secondary hip osteoarthritis related to chronic inflammatory rheumatic diseases accounted for 58.8% of surgical indications. Chronic nociceptive CPSP was observed in 27.4% of patients, predominantly presenting as mechanical hip pain, with a mean VAS intensity of 45.5 ± 19.4. No significant associations were found between nociceptive CPSP and age, sex, body mass index, socioeconomic status, physical activity, or type of osteoarthritis (primary vs. secondary). Patients with nociceptive CPSP exhibited significantly higher anxiety (HADS-A: 7.3 ± 3.3 vs. 4.6 ± 1.2; $p < 0.001$) and depression scores (HADS-D: 8.2 ± 3.1 vs. 4.7 ± 1.4; $p < 0.001$). Early initiation of postoperative rehabilitation was associated with a reduced risk of developing nociceptive CPSP ($p = 0.024$).

Conclusions:

Chronic nociceptive CPSP after THA is present in approximately one-quarter of our patients and was strongly associated with underlying anxiety and depression. Early functional rehabilitation may decrease the risk of developing nociceptive CPSP. Our results highlight the need for comprehensive perioperative psychological assessment and tailored rehabilitation strategies.

P951

ANXIETY, DEPRESSION AND PAIN CATASTROPHIZING AFTER TOTAL HIP ARTHROPLASTY AND THEIR IMPACT ON QUALITY OF LIFE

L. Rouached[1], S. Zanned[1], Y. El Mabrouk[1], S. Ben Dhia[1], S. Bouden[1], I. Mahmoud[1], R. Tekaya[1], A. Ben Tekaya[1], M. Ben Salah[2], L. Abdelmoula[1]

[1]Charles Nicolle Hospital, Rheumatology department, Tunis, Tunisia; [2]Charles Nicolle Hospital, Orthopaedics department, Tunis, Tunisia

Background :

Psychological factors, such as anxiety, depression, and pain catastrophizing, are recognized contributors to poor postoperative outcomes and reduced quality of life in patients undergoing total hip arthroplasty (THA).

Objectives :

To evaluate the prevalence of anxiety and depressive symptoms after THA, assess their association with pain catastrophizing, and determine their impact on quality of life.

Methods :

A cross-sectional study was conducted including 51 patients who had undergone THA, with a mean postoperative follow-up of 12.7 ± 5.6 months. Anxiety and depression were assessed using the Hospital Anxiety and Depression Scale (HADS), while quality of life was measured using the Short Form-36 (SF-36), including physical (PCS) and mental (MCS) component summary scores. Correlations between HADS scores and SF-36 dimensions were analyzed.

Results:

Probable anxiety was identified in 13.7% of patients (mean HADS-A: 6.0 ± 3.0), and probable depression in 9.8% (mean HADS-D: 6.6 ± 2.8). Patients with higher HADS scores showed significantly lower SF-36

scores, reflecting worse quality of life. The total SF-36 score was reduced in patients with psychological distress (mean 484.9 ± 178.9) compared to those without (496.6 ± 134.8). Significant negative correlations were observed between HADS-A and MCS ($r = 0.63$; $p < 0.001$), HADS-D and MCS ($r = -0.71$; $p < 0.001$), and between combined HADS scores and PCS ($r = -0.42$; $p = 0.003$), indicating an impact on both mental and physical components of quality of life.

Conclusions :

Anxiety, depression, and pain catastrophizing are present in a substantial subset of THA patients and are significantly associated with reduced physical and mental quality of life. These findings highlight the importance of early screening and targeted psychological interventions to optimize postoperative outcomes and patient well-being.

P952

CLINICAL, FUNCTIONAL AND RADIOGRAPHIC PROFILE OF KNEE OSTEOARTHRITIS IN A TERTIARY RHEUMATOLOGY CENTER

L. Rouached[1], W. Khelif[1], S. Ben Dhia[2], S. Bouden[3], I. Mahmoud[3], R. Tekaya[3], A. Ben Takaya[3], L. Abdelmoula[3]

[1]Rheumatology department of Charles Nicolle Hospital, Tunis, Tunisia; [2]Charles Nicoles Hospital, Tunis, Tunisia; [3]Rheumatology department of Charles Nicolle Hospital., Tunis, Tunisia

Background: Knee osteoarthritis (KOA) is a common cause of pain and functional disability. Patients referred to tertiary care centers often present with advanced disease.

Objective: To describe the clinical, functional and radiographic characteristics of patients with knee osteoarthritis followed in a tertiary rheumatology center.

Methods: This descriptive study included 143 patients with knee osteoarthritis followed at the Rheumatology Department of Charles Nicolle Hospital, Tunis. Demographic, anthropometric, clinical and radiographic data were collected. Pain intensity and functional impact were assessed using the visual analog scale (VAS, 0–10), the Lequesne algofunctional index and the Knee injury and Osteoarthritis Outcome Score (KOOS). Radiographic severity was graded according to the Kellgren–Lawrence (KL) classification. Results are expressed as mean ± standard deviation or as numbers and percentages.

Results: The mean age of patients was 61.4 ± 8.9 years (range 42–90), with a marked female predominance (80.4%). The mean body mass index was 31.4 ± 5.3 kg/m², indicating a high prevalence of overweight and obesity. The mean disease duration was 6±6 years.

Baseline pain was moderate to severe, with a mean VAS score of 6.6 ± 1.6. Functional impairment was substantial, with a mean Lequesne index of 9.2 ± 3.6. Mean KOOS scores showed: pain 59.5 ± 16.2, symptoms 60.7 ± 18.9, activities of daily living 62.6 ± 17.3, sport and recreation 45.8 ± 20.4, and knee-related quality of life 48.3 ± 17.

Clinically, axial deformities were observed in 25.3% of patients (genu valgum 14.7%, genu varum 10.5%). Joint motion limitation was found in 29.5% of cases and 12.6% of patients required walking aids. Radiographically, mixed femorotibial and femoro-patellar involvement was the most common pattern (63.4%). Advanced disease predominated, with 68.8% of patients classified as KL grade 3 or 4.

Conclusion: Patients with knee osteoarthritis managed in this tertiary care center present withadvanced disease, characterized by excess body weight, marked pain, significant functional impairment and severe radiographic stages.

P953

EFFECTIVENESS OF PLATELET-RICH PLASMA INJECTIONS IN KNEE OSTEOARTHRITIS: A PROSPECTIVE REAL-WORLD STUDY OF 143 PATIENTS

W. Khelif[1], L. Rouached[1], S. Ben Dhia[2], I. Mahmoud[3], R. Tekaya[3], A. Ben Takaya[3], L. Abdelmoula[3], S. Bouden[3]

[1]Rheumatology department of Charles Nicolle Hospital, Tunis, Tunisia; [2]Charles Nicoles Hospital, Tunis, Tunisia; [3]Rheumatology department of Charles Nicolle Hospital., Tunis, Tunisia

Background

Platelet-rich plasma (PRP) has emerged as a biological treatment option for knee osteoarthritis (KOA), aiming to improve pain and functional impairment. Real-world data evaluating its global effectiveness across different clinical domains remain rare.

Objectives

To evaluate the effectiveness of intra-articular PRP injections on pain, neuropathic pain component, function, and disability in patients with KOA.

Methods

A prospective study was conducted including 143 patients with knee osteoarthritis treated with intra-articular PRP injections at the Rheumatology Department of Charles Nicolle Hospital, Tunis.

Pain was assessed using the visual analogue scale (VAS), neuropathic pain using the DN4 questionnaire, knee-related function using the KOOS score, and disability using the Lequesne algofunctional index. Assessments were performed at baseline (J0), 3 months (M3), and 6 months (M6).

Paired comparisons were performed using paired t-tests, with a significance threshold of $p < 0.05$.

Results

At baseline, mean VAS pain was 6.58 ± 1.69, significantly decreasing to 2.94 ± 2.31 at M3 and 3.51± 2.49 at M6 ($p < 0.001$ for both).

The DN4 score decreased from 1.35 ± 1.61 at baseline to 0.68 ± 1.17 at M3 ($p < 0.001$) and 0.83 ±1.16 at M6 ($p = 0.001$).

Significant functional improvement was observed, with KOOS symptom score increasing from 58.3 ±19.0 at baseline to 71.6 ± 21.9 at M3 and 66.2 ± 21.0 at M6 ($p< 0.001$).

The Lequesne index decreased significantly from 9.4 ± 3.6 at baseline to 6.3 ± 3.5 at M3 and 7.0 ±3.6 at M6 ($p <0.001$).

Conclusion

In this cohort, PRP injections were associated with significant improvements in nociceptive and neuropathic pain, function, and disability at three and six months. These findings support the effectiveness of PRP as a symptomatic treatment option in routine clinical practice.

P954

SAFETY AND ADVERSE EVENTS OF PLATELET-RICH PLASMA INJECTIONS IN KNEE OSTEOARTHRITIS

L. Rouached[1], W. Khelif[1], S. Ben Dhia[2], S. Bouden[3], I. Mahmoud[3], R. Tekaya[3], A. Ben Takaya[3], L. Abdelmoula[3]

[1]Rheumatology department of Charles Nicolle Hospital, Tunis, Tunisia; [2]Charles Nicoles Hospital, Tunis, Tunisia; [3]Rheumatology department of Charles Nicolle Hospital., Tunis, Tunisia

Background
Platelet-rich plasma (PRP) is increasingly used as a biological treatment for knee osteoarthritis. Although its efficacy has been widely studied, real-world data on safety and adverse events remain limited.

Objectives
To describe the frequency and type of adverse events associated with double intra-articular PRP injections in patients with knee osteoarthritis.

Methods
An observational study was conducted including 143 patients with knee osteoarthritis treated with two intra-articular PRP injections in the Rheumatology Department of Charles Nicolle Hospital, Tunis. Adverse events were systematically recorded after the first and second injections and classified according to their type.

Results
After the first PRP injection, adverse events were reported in 45 patients (32.4%). All adverse events were local and transient, with no systemic or serious complications observed. The most frequent manifestation was post-injection pain, followed by local swelling, functional limitation, and joint stiffness, occurring either alone or in combination. After the second injection, the incidence of adverse events decreased substantially, affecting only 12 patients (10.9%). Reported events were limited to localized pain (58.3%) and transient swelling (41.7%). No severe or unexpected adverse events were reported after the second injection.

Conclusion
In this real-world cohort, PRP injections for knee osteoarthritis demonstrated a favorable safety profile. Adverse events were frequent but mild, exclusively local, and transient, with a markedly lower incidence after the second injection. These findings support the good tolerability of PRP in routine clinical practice.

P955

EFFECT OF A PATIENT EDUCATION PROGRAM ON DISEASE ACTIVITY IN RHEUMATOID ARTHRITIS

L. Rouached[1], Y. Tekaya[1], M. Ben Hriz[1], S. Ben Dhia[1], S. Bouden[1], I. Mahmoud[1], R. Tekaya[1], A. Ben Tekaya[1], L. Abdelmoula[1]

[1]Charles Nicolle Hospital, Rheumatology department, Tunis, Tunisia

Introduction:
Rheumatoid arthritis (RA) is a chronic inflammatory disease causing pain, stiffness, and functional impairment. Effective management requires active patient involvement. Therapeutic patient education (TPE) may enhance self-management and improve disease outcomes.

Objective:
To evaluate the impact of a TPE program on disease activity in RA patients.

Material and Methods :
In this prospective longitudinal study, RA patients participated in a 2-month TPE program, consisting of 90-minute face-to-face sessions delivered in small groups of four to six patients by two rheumatologists trained in TPE. Disease activity was assessed before and after the program using the DAS28-CRP score.

Results:
Eighty RA patients were included, 72 women and 8 men, with a mean age of 61.1 ± 8.6 years and a median disease duration of 20 years. Median HAQ score was 1.2, with 66% of patients showing significant functional impairment. Median patient global assessment (EGP) was 70 mm, and median pain VAS was 6.5. Oral corticosteroids were used by 80% of patients (median dose 5 mg/day), csDMARDs by 81%, and bDMARDs by 49%. Mean baseline DAS28-CRP was 4.64 ± 1.27, with 3.8% in remission, 6.3% low, 53.8% moderate, and 36.3% high disease activity.
After the TPE program, mean DAS28-CRP decreased to 3.59 ± 0.73, with a mean reduction of 1.05 ± 0.94 ($p < 0.001$). The proportion of patients in remission increased to 5%, those with low disease activity to 31.3%, while patients with high disease activity decreased significantly to 2.5%.

Conclusion:
Therapeutic patient education may improve self-management and reduce disease activity in patients with rheumatoid arthritis.

IMPACT OF THERAPEUTIC PATIENT EDUCATION ON ANXIETY AND DEPRESSION IN PATIENTS WITH RHEUMATOID ARTHRITIS: A PROSPECTIVE STUDY

L. Rouached[1], Y. Tekaya[1], M. Ben Hriz[1], S. Ben Dhia[1], S. Bouden[1], I. Mahmoud[1], R. Tekaya[1], A. Ben Tekaya[1], L. Abdelmoula[1]

[1]Charles Nicolle Hospital, Rheumatology department, Tunis, Tunisia

Introduction:
Rheumatoid arthritis (RA) is a chronic inflammatory disease frequently associated with anxiety and depression. These psychological comorbidities worsen quality of life and complicate disease management. Therapeutic patient education (TPE) may improve psychological well-being in RA patients.

Objective:
To evaluate the effect of a TPE program on anxiety and depression in patients with RA.

Materials and Methods :
A prospective longitudinal study was conducted in a rheumatology department in Tunisia. RA patients participated in a 2-month TPE program delivered in small groups of 5–6 patients. Anxiety and depression were assessed using the Hospital Anxiety and Depression Scale (HADS) at baseline (T0) and after two months (T1).

Results:
Eighty patients were included, mean age 61.1 ± 8.6 years [40-83], 72 women and 8 men (sex ratio H/F 0.11). Most had low educational levels, and 49% had medium socioeconomic status. Median disease duration was 20 years [1–60], and median HAQ score 1.2 [0.1–3]. At T0, mean HADS scores were 12.88 ± 4.93 for anxiety and 12.04 ± 5.22 for depression; anxiety and depression were present in 86.25% and 80% of patients, respectively. After the TPE program, mean HADS scores decreased to 7.55 ± 2.64 for anxiety (−5.33 ± 3.64, $p < 0.001$) and 7.55 ± 2.96 for depression (−4.49 ± 3.49, $p < 0.001$). Anxiety prevalence decreased to 50% and depression to 48.75%.

Conclusion:
TPE significantly reduced anxiety and depression in RA patients. Structured TPE programs may enhance psychological well-being and support overall disease management.

P957

FUNCTIONAL IMPACT OF FOOT INVOLVEMENT IN SPONDYLOARTHRITIS : A CROSS-SECTIONAL STUDY

L. Rouached[1], Y. Tekaya[1], S. Bouden[1], S. Ben Dhia[1], I. Mahmoud[1], R. Tekaya[1], A. Ben Tekaya[1], L. Abdelmoula[1]

[1]Charles Nicolle Hospital, Rheumatology department, Tunis, Tunisia

Introduction :
Spondyloarthritis (SpA) is a chronic inflammatory disease characterized by axial and peripheral involvement. Foot involvement is frequent, contributes substantially to functional impairment, and remains under-recognized in routine clinical practice.

Patients and Methods :
We conducted a cross-sectional study including patients with SpA fulfilling the ASAS classification criteria. Clinical and podoscopic foot examinations, laboratory parameters, and radiological findings were collected. Foot pain was assessed using a visual analogue scale (VAS, 0–10), and functional impact was evaluated using the validated French version of the Foot Function Index (FFI). Factors associated with functional impairment were analyzed.

Results :
Thirty-two patients were included (17 men and 15 women; male-to-female ratio 1.13), with a mean age of 41.9 ± 13.6 years [20–72]. Eight patients had occupations involving increased foot load, and nine were overweight. Foot pain was reported by 15 patients (46.9%). Podoscopic abnormalities were observed in 12 patients (37.5%), including pes cavus in 5 patients, pes planus in 2, calcaneal valgus in 2, and calcaneal varus in 2 patients (each 6.3%). Radiological foot involvement was present in 7 patients.
Mean BASDAI was 2.2 ± 1.64 [0–5.7], and mean ASDAS-CRP was 2.08 ± 1.24 [0.2–4.85]. The mean total FFI score was 22.0 ± 25.7 [0–74.6]. A significant difference in activity limitation score was observed according to sex ($p = 0.020$). The total FFI score was positively correlated with age ($r = 0.46$, $p = 0.008$), CRP levels ($r = 0.36$, $p = 0.044$), pain intensity (VAS: $r = 0.91$, $p < 0.001$), disease activity (BASDAI: $r = 0.69$, $p < 0.001$), and ASDAS-CRP ($r = 0.67$, $p < 0.001$).
In multivariate analysis, only pain intensity independently predicted functional impairment ($p < 0.001$). No significant associations were found with occupational foot load, physical activity, comorbidities, overweight, positive squeeze test, plantar pathology, radiological involvement, or disease duration.

Conclusion :
Foot involvement is common in spondyloarthritis and is associated with significant functional impairment, predominantly driven by pain. Systematic foot examination and functional assessment should be incorporated into routine patient evaluation to optimize disease management.

P958

IMPACT OF THERAPEUTIC PATIENT EDUCATION ON INTERNALIZED STIGMA IN PATIENTS WITH RHEUMATOID ARTHRITIS

Y. Tekaya[1], L. Rouached[1], M. Ben Hriz[1], S. Ben Dhia[1], S. Bouden[1], I. Mahmoud[1], R. Tekaya[1], A. Ben Tekaya[1], L. Abdelmoula[1]

[1]Charles Nicolle Hospital, Rheumatology department, Tunis, Tunisia

Introduction:
Rheumatoid arthritis (RA) is a chronic inflammatory disease that affects not only physical function but also psychosocial well-being. Internalized stigma, defined as the negative self-perception associated with chronic illness, may adversely affect quality of life, psychological health, and treatment adherence. Therapeutic patient education (TPE) could help patients cope with disease-related stigma, however, its impact in RA remains insufficiently explored.

Objective:
To assess the level of internalized stigma in patients with RA and to evaluate the effect of a structured TPE program on stigma levels.

Methods:
We conducted a prospective longitudinal study over 11 months in a rheumatology department. Internalized stigma was assessed at baseline (T0) and two months after TPE using the Internalized Stigma of Mental Illness scale adapted for RA (ISMI-RA). TPE was delivered by two trained healthcare professionals in small groups of 6–7 patients. Each session lasted 90 minutes and consisted of interactive workshops combining reflection, group discussion, and theoretical input.

Results:
Eighty patients with RA were included (72 women, 8 men; mean age 61.1 ± 8.6 years). At baseline, internalized stigma was severe in 61.3% of patients, moderate in 13.8%, mild in 8.8%, and minimal in 16.3%. Among ISMI-RA subscales, *Alienation* was the most affected domain, followed by "Stereotype Endorsement" and "Social Withdrawal,". "Perceived Discrimination" was less marked and "Resistance to Stigma" was minimally affected.
Two months after TPE, the mean ISMI-RA score decreased significantly from 3.05 ± 0.79 to 2.22 ± 0.52, with a mean reduction of 0.83 ± 0.41 ($p < 0.001$). The proportion of patients with severe stigma declined markedly from 61.3% to 2.5%, whereas minimal and mild stigma increased to 30% and 40%, respectively.
Changes in ISMI-RA scores were significantly associated with socioeconomic status ($p = 0.015$), history of total knee replacement ($p = 0.018$), rheumatoid factor (RF) positivity ($p = 0.018$) and serum RF levels ($r = 0.357$, $p = 0.02$), antinuclear antibody positivity ($p = 0.047$), and serum C-reactive protein levels ($r = 0.223$, $p = 0.047$). Depressive and anxiety symptoms were negatively correlated with ISMI-RA improvement (HADS-depression: $r = -0.396$, $p < 0.001$; HADS-anxiety: $r = -0.337$, $p = 0.002$). No significant associations were found with other sociodemographic, clinical, functional, or treatment-related variables.

Conclusion:
Therapeutic patient education significantly reduced internalized stigma in RA patients, highlighting its value in improving psychosocial well-being and supporting self-management alongside medical treatment.

P959

MOLECULAR PROFILING OF POSTMENOPAUSAL OSTEOPOROTIC VERTEBRAL FRACTURES

L. Sedova[1], J. Vcelak[2], A. Kral[2], B. Chylikova[1], O. Seda[1]

[1]First Faculty of Medicine, Charles University, Prague, Czechia; [2]First Faculty of Medicine, Charles University and Bulovka University Hospital, Prague, Czechia

Objective: Osteoporotic vertebral fractures (OVF) represent a major clinical challenge, yet Bone Mineral Density (BMD) often fails to accurately predict fracture risk. A substantial proportion of fractures occur in individuals with BMD above the osteoporotic threshold, highlighting the need for molecular biomarkers reflecting bone quality beyond simple density measurements.
Material and Methods: We investigated genomic and transcriptomic profiles associated with OVF versus non-osteoporotic controls in postmenopausal women. Intraoperative vertebral bone tissue and peripheral blood were collected from patients undergoing surgery for OVF (n=67) and elective thoracolumbar surgery without osteoporosis (n=48). RNA sequencing was performed using NEBNext Ultra II Directional RNA Library Prep Kit on Illumina NovaSeq6000 platform (150-bp paired-end reads). Differential expression analysis and pathway enrichment were performed comparing osteoporotic and control samples.
Results: Groups were age-matched with similar comorbidity profiles. Controls showed higher BMI and type 2 diabetes prevalence (45.8% vs 19.4%, p=0.004). Mean T-scores were -2.51±0.9 in OVF and -0.7±0.72 in controls. Bone tissue transcriptomic analysis revealed 285 differentially expressed genes (FDR<0.05; >2-fold change): 256 downregulated and 29 upregulated in OVF. The most significantly downregulated genes included *GPR128*, *COL2A1*, and *COL10A1*. Pathway analysis identified significant enrichment in ECM-receptor interaction (p=3.52E-10), focal adhesion (p=6.60E-06), and PI3K-Akt signaling (p=1.83E-04). Gene ontology analysis highlighted skeletal system development (q=1.22E-13), extracellular matrix organization (q=1.20E-10), and collagen fibril organization (q=5.70E-05). Blood transcriptome analysis identified 23 differentially expressed genes (FDR<0.2; >2-fold change): 6 downregulated and 17 upregulated in OVF.
Conclusion: This study establishes a comprehensive transcriptomic signature distinguishing OVF patients from controls, characterized by profound disruption of collagen metabolism, extracellular matrix organization, and skeletal development pathways. Combined genomic and transcriptomic profiling identifies potential non-invasive biomarkers for assessing bone quality and fracture risk beyond conventional BMD measurements, offering promise for improved risk stratification in osteoporotic patients.

IMAGING SPECTRUM OF BONE INVOLVEMENT IN PATIENTS WITH HEMATOLOGICAL DISEASES: A RHEUMATOLOGY PERSPECTIVE

L. Suarez-Zorrilla[1], E. Garmendia-Sanchez[1], C. Modesto-Caballero[1]

[1]Cruces University Hospital, Barakaldo, Spain

INTRODUCTION

Secondary osteoporosis is a frequent complication of various conditions, including hematological diseases. In some cases, the prioritization of hematological disorders may lead to under-recognition and undertreatment of associated bone disease.

MATERIALS AND METHODS

During my one-year rotation in the Rheumatology Department, 338 inpatient consultation requests were assessed, of which 12 originated from Hematology. Three (25%) corresponded to vertebral fractures (VFs) meeting severity criteria.

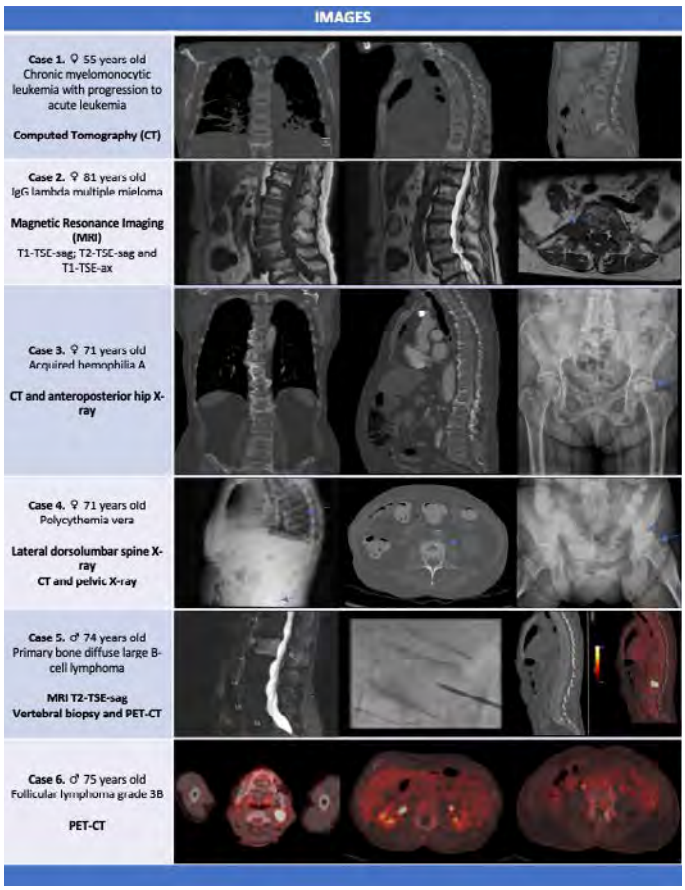
Six illustrated clinical cases are presented, including these three and three additional cases evaluated in outpatient clinics, representing different clinical contexts that encourage multidisciplinary reflection.

RESULTS

1. ♀ **55 years old**, chronic myelomonocytic leukemia, progression to acute leukemia. **13 vertebral fractures (VFs).**

2. ♀ **81 years old**, IgG lambda multiple myeloma. Diffuse bone marrow infiltration with multiple focal lytic lesions, one located in the right L5 pedicle with cortical disruption. **T12 VF.**

3. ♀ **71 years old**, acquired hemophilia A treated 2 years earlier with prednisone 70 mg/day and rituximab.Previous VFs: L2, L5, right humerus and both wrists. Non-adherent to teriparatide.



Current VFs: C7, T2, superior endplate of T4, T5, T7, T9, T12, L1, L2, L3, L4 and L5.

Avascular necrosis (AVN) of the femoral heads and radiolucent images compatible with AVN at T12 and L1.

4. ♀ **71 years old**, polycythemia vera. VFs at T7 and L3, subcapital fracture and AVN of the left hip.

5. ♂ **74 years old**, primary bone diffuse large B-cell lymphoma, and

6. ♂ **75 years old**, follicular lymphoma grade 3B,both treated with R-CHOP + radiotherapy, **without vertebral fractures.**

CONCLUSIONS

Multidisciplinary collaboration, with specific attention to fracture prevention (early diagnosis, lesion stabilization, bone densitometry, trabecular bone score [TBS], nutritional support, mobilization, and management of glucocorticoid-induced osteoporosis), could help improve quality of life and reduce morbidity and mortality in patients with hematological diseases.

TECHNOLOGY TO NOT FORGET THE BONE: THE APP THINKBONE

L. Tafaro[1], A. Santonati[2], A. Spada[2], A. Chiriatti[3], A. Olviero[3], V. Lepidini[4], D. Diacinti[1], R. Pastore[5]

[1]Sapienza University of Rome, ROMA, Italy; [2]S. Giovanni Hospital, Rome, Italy; [3]General Practioner, Rome, Italy; [4]S.Eugenio Hospital, Rome, Italy; [5]Gemelli-Isola, ROMe, Italy

We know that osteoporosis is an often overlooked disease, with a significant gap in secondary prevention, and that a network of different specialists is necessary for proper patient management based on the severity of the osteoporotic disease. Technology is proving increasingly useful for facilitating physicians' clinical work and for creating a communication network, so why not create an app to share information, standardize the management of osteoporosis patients, and facilitate communication between centers at different levels of care? With multidisciplinary support for content entry, an app called ThinkBone was created. It can be downloaded for free from Google Play by clicking

"Search: ThinkBone" and, for iPhone users, from the website: https://www.thinkbone.net

ThinkBone is an app aimed at GPs, non-bone specialists, and bone specialists, and in the near futur, patients as well. The objectives are:

1. To gather all useful information for managing osteoporosis: e.g., links to the DEFRA algorithm for calculating fracture risk, and to Italian guidelines and recommendations.

2. To answer the most frequently asked questions about managing patients with osteoporosis: Vitamin D management, ONJ, etc., in accordance with national and international guidelines.

3. To improve the flow of patients requiring specialist assessment of their bone disease based on geographic area and level of care. The app provides a map of specialist osteoporosis centers. For each center, practical information is provided on how to book, services provided, type of referral, phone number, address, etc.

4. To answer questions interactively using artificial intelligence. This section is under development but should answer questions such as: should I refer my patient to a bone specialist?

The app is currently in Italian and has been downloaded by 81 professionals from 81 different Italian cities. 34% have entered their center, of which 26% can administer monoclonal antibodies. 12% are equipped to administer intravenous zolendronate.

In conclusion, we hope that the treatment gap will be reduced by introducing an additional tool to improve care for patients with osteoporosis

P962

STRONG BONES, STRONG RECOVERY: ENHANCING OSTEOPOROSIS MANAGEMENT POST-HIP FRACTURE SURGERY

L. Vazhayil Joseph[1], A. Frances Yap Hui Wen[1], K. Mamun[1], J. Koh Suang Bee[1], T. S. Howe[1], M. A. Png[1], A. Roy Chowdhury[1], H. Huang[1]

[1]Singapore General Hospital, Singapore, Singapore

Objectives

To improve osteoporosis management in elderly patients with hip fracture surgery through a structured, multidisciplinary approach.

Material and Methods

Hip fractures are a major cause of morbidity, and mortality in the elderly population, and osteoporosis is a key underlying risk factor. Timely identification and treatment of osteoporosis following a fragility fracture is essential to reduce the risk of recurrent fractures and improve patient outcomes. Despite the availability of effective treatment options and evidence-based osteoporosis management guidelines, treatment rates remain suboptimal in many care settings. A study conducted in our setting (Wen et al., 2022) revealed a concerningly low rate of osteoporosis treatment initiation (22.4%), highlighting a significant gap in our current practice. Given the ageing population, high morbidity and mortality of fragility fractures our team aimed to improve osteoporosis management in this vulnerable group.

A pre/post-implementation design was used for this quality improvement initiative. Root cause analysis identified 4 key gaps in care, including absence of structured workflows for osteoporosis treatment, dental clearance, and patient education. A multidisciplinary team developed and implemented a structured osteoporosis management workflow. The interventions included standardised assessments, optimization of calcium and vitamin D, initiation of appropriate osteoporosis treatment, timely dental referrals, scheduled follow ups and targeted patient education by trained nurses.

Results

There was a significant improvement in performing appropriate investigations (75.8% to 100%), calcium and vitamin D optimization (90.3% to 95.8%), dental referrals (53.2% to 95.8%), targeted patient education (89.6%) and scheduled follow up for osteoporosis management (40.3% to 87.5%). A median of 85% of patients received appropriate osteoporosis management.

Conclusion

Implementing a standardized multidisciplinary workflow presents a promising approach to enhancing osteoporosis care following hip fracture surgery. Integration into coordinated clinical pathway, and regular staff orientation will support sustainability and continued improvement.

DURABLE IMMUNOMODULATORY HIERARCHICAL PATCH FOR ROTATOR CUFF REPAIRING

L. Wang[1], J. Jiang[1], X. Ma[1]

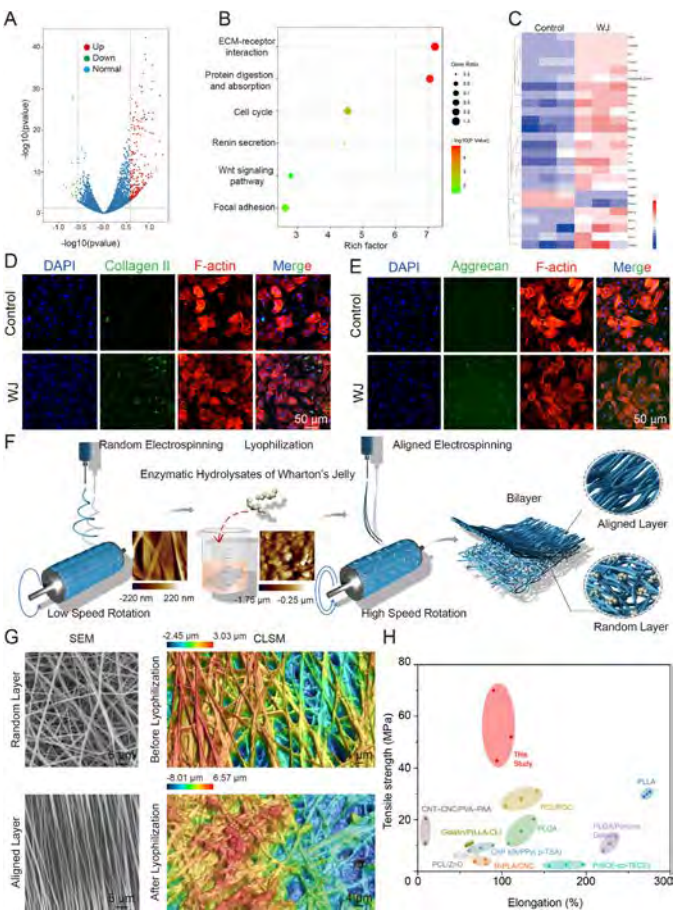
[1]Shanghai Sixth People's Hospital, Shanghai, China

Introduction/Objectives

High re-tear rates exceeding 50% in degradable shoulder cuff patches, observed over a five-year follow-up, are attributed to the failure of degradable polymers alone to restore the inflammatory niche post-rotator cuff injury, hindering tendon-bone interface healing. Theoretically, a degradable polymer with durable immunomodulatory functions throughout its degradation procedure might address this issue.

Methods

Ferulic acid (FA) was introduced into the repeating unit fragments of polyurethane by skeletal copolymerization to construct a biodegradable polymer (poly(ester- ferulic acid-urethane) urea, PEFUU) with long-lasting anti-inflammatory effects. After verifying the anti-inflammatory function of PEFUU in vitro, hierarchical composite nanofiber patch (HCNP) with sustained anti-inflammatory niche was constructed by electrospinning and lyophilization of decellularized Wharton jelly tissue. The HCNP was used for rotator cuff repairing in rat model. The effectiveness of promoting iRCT repairing by the HCNP was also validated by imaging, histology, and molecular biology methods.



Results

Via employing the paradigm of polymer backbone functionalization, a hierarchical composite nanofiber patch

(HCNP) distinguished by its enduring immunomodulatory properties, was fabricated, adept at sustaining a protracted anti-inflammatory microenvironment conducive to fostering tissue regeneration (Scheme 1). The synthesis process by fabricating (PEFUU) was initiated, wherein FA was incorporated as a bioactive constituent. PEFUU stably releases FA in vitro, reversing the inflammatory niche produced by M1 macrophages and restoring the directed differentiation of stem cells. Subsequently, PEFUU was subjected to the electrospinning process, yielding a bipolar fiber patch characterized by an organized, yet partially random, stratified architecture. Within this stratified architecture, the random layer was strategically imbued with the enzymatic hydrolysate derived from decellularized Wharton jelly tissue (HDWJT). In vitro experimentation demonstrated the propensity of FA to undergo a gradual release profile concomitant with the progressive degradation of the HCNP. In a compelling demonstration of the HCNP's therapeutic prowess, this study extended to an in vivo milieu, employing a rat model of tendon-to-bone injury, manifesting as the restoration of the microstructural continuity inherent to the tendon-to-bone interface, coupled with the establishment of a trinomial distribution of collagen ordering.

Conclusions

This study provides an idea for the use of an electrospun nanofiber mat in tissue regeneration. By introducing anti-inflammatory small molecules through copolymerization, the inflammatory niche of the damaged tissue can be altered persistently, effectively inducing tissue regeneration.

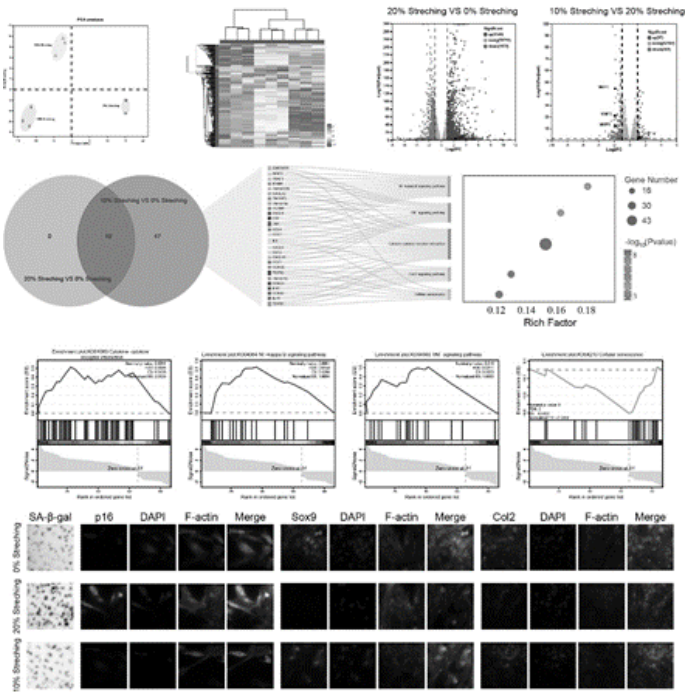
P964

APPROPRIATE MECHANICAL STIMULATION INHIBITS THE SENESCENCE OF CHONDROCYTES

L. Wang[1], J. Jiang[1], X. Ma[1]

[1]Shanghai Sixth People's Hospital, Shanghai, China

Background and aims



Osteoarthritis and related joint diseases are increasingly prevalent, significantly impacting the quality of life globally[1,2]. A critical component in the progression of these diseases is the senescence of chondrocytes, the cells responsible for maintaining healthy cartilage. Recent advancements in biomechanics suggest that controlled mechanical stimulation may retard the senescence process in these cells[3]. This study aims to elucidate the impact of varying degrees of mechanical stimulation on chondrocyte senescence, providing insights potentially transformative for therapeutic approaches in joint disease management.

Methods

We employed an advanced RNA sequencing technique to analyse the genomic expressions of chondrocytes subjected to three different levels of mechanical stimulation: none (0%), mild (10%), and moderate (20%). The mechanical stresses were applied using a custom-designed bioreactor, which allowed precise control over the duration and intensity of the stimuli. This approach enabled a comprehensive comparison of the cellular responses to different mechanical environments.

Results

Our results offer a nuanced view of the chondrocyte response to mechanical stress. In the absence of mechanical stimulation, chondrocytes showed signs consistent with typical senescence processes. Interestingly, under mild mechanical stimulation (10%), there was an upregulation of genes associated with inflammation, paradoxically coupled with a downregulation of senescence markers, suggesting a protective response against cellular senescence. However, increasing the mechanical load to 20% led to a marked increase in stress responses and degenerative markers, indicative of cell damage and accelerated senescence processes. These findings highlight a delicate balance between beneficial and detrimental mechanical forces on chondrocyte health.

Conclusion

The study underscores the critical role of mechanical forces in chondrocyte physiology and senescence. Mild mechanical stimulation appears to confer a protective effect against senescence, while excessive mechanical stress induces cellular damage and degeneration. These insights open avenues for targeted biomechanical therapies in osteoarthritis, where controlled mechanical stimuli could be harnessed to slow down or even reverse cartilage degeneration. Future research should aim to fine-tune these mechanical interventions to optimize therapeutic outcomes in joint disease treatments.

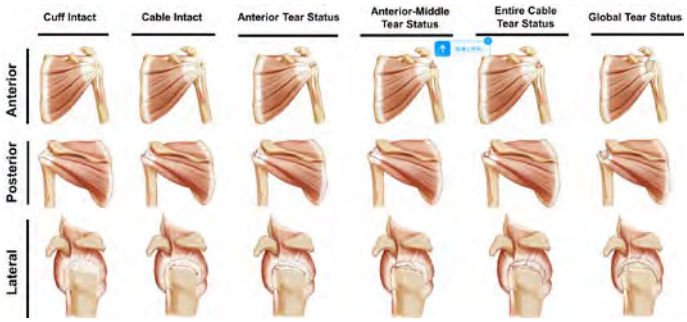
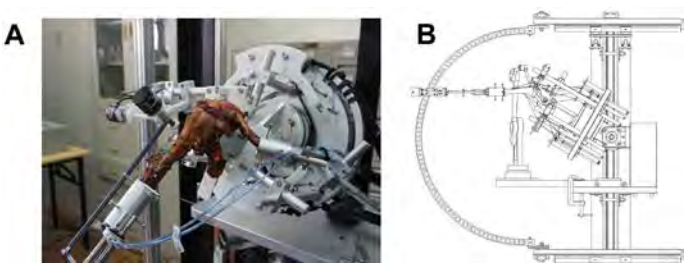
INCOMPLETE ROTATOR CABLE DID NOT CAUSE ROTATOR CUFF DYSFUNCTION IN CASE OF ROTATOR CUFF TEAR: A BIOMECHANICAL STUDY OF THE RELATIONSHIP BETWEEN ROTATOR CABLE INTEGRITY AND ROTATOR CUFF FUNCTION



L. Wang[1], J. Jiang[1], X. Ma[1]

[1]Shanghai Sixth People's Hospital, Shanghai, China

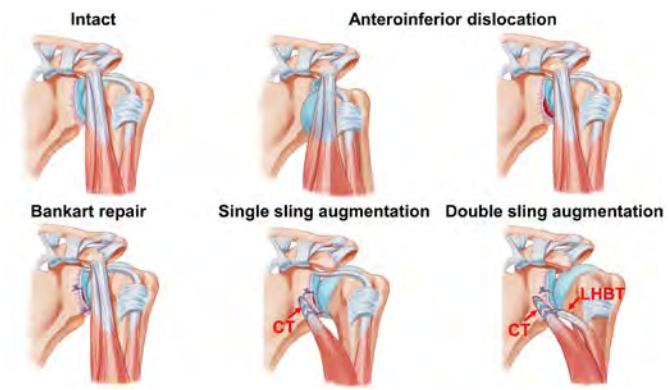


Purpose: This study seeks to evaluate the biomechanical relationship between the severity of rotator cable tears and the function of the rotator cuff.

Methods: Twelve cadaveric shoulders with intact rotator cuff, existing rotator cable and a critical shoulder angle below 35° were included. For each shoulder, a posterosuperior rotator cuff tear (PSRCT) [model 2] in the crescent area was formed. Then anterior insertion detached [model 3], anterior insertion detached together with the middle cable tear [model 4] and the whole rotator cable tear [model 5] were subsequently created. The rotator cuff that lay above the humeral head rotation centre was detached as a global tear control [model 6], along with the primitive status as the intact control [model 1]. Glenohumeral abduction was initiated by simulating deltoid and remaining rotator cuff force. Functioning of the remaining rotator cuff was evaluated using the middle deltoid force (MDF), as required for abduction.

Results: No statistically- significant differences in peak MDF values were seen between the four PSRCT statuses (44.10 ± 7.30 N [model 2], P = 0.96; 45.50 ± 9.55 N [model 3], P = 0.86; 45.90 ± 3.53 N [model 4], P = 0.30; 44.20 ± 8.19N [model 5], P = 0.80) and intact control status (39.79 ± 7.65 N [model 1]). However, significant differences in peak MDF values were found between the four PSRCT statuses and the global tear control status (54.53 ± 7.46 N [model 6], P<0.01).

Conclusion: The PSRCT, regardless of how severe the rotator cable tear, does not induce functionally-significant biomechanical impairment. Tear extension involving all rotator cuff tissue above the geometric rotation centre of the humeral head results in obvious functional impairment.



P966

DYNAMIC DOUBLE-SLING AUGMENTATION PREVENTS ANTEROINFERIOR TRANSLATION FOR RECURRENT ANTEROINFERIOR SHOULDER DISLOCATION WITH 20% GLENOID BONE LOSS: A CADAVERIC BIOMECHANICAL STUDY

L. Wang[1], J. Jiang[1]

[1]Shanghai Sixth People's Hospital, Shanghai, China

Purpose: To biomechanically compare the dynamic double-sling with single-sling augmentation using the conjoined tendon (CT) with 20% of an anteroinferior glenoid bone defect under the high loads in shoulders.
Methods: With the shoulder in 60° of glenohumeral abduction and 60° of external rotation, the 12 shoulders stability was tested sequentially in 5 conditions: intact, 20% glenoid bone loss, Bankart repair, single-sling augmentation with the CT, and double-sling augmentation with both the CT and long head of the biceps tendon (LHBT). The anteroinferior humeral head (HH) translation force of 20N, 30N, 40N, 50N, or 60N was applied to determine the shoulder stability in each condition.
Results: The total HH translation over 8.77 mm represented the anteroinferior shoulder instability (95% CI of bone defect: 7.76 – 8.77 mm). A significant increase in anteroinferior HH translation was demonstrated following the creation of 20% glenoid bone defect under the 20N translational force (10.52 ± 0.71 mm). Structural failure following the Bankart repair and the single-sling augmentation under the 30N (9.84 ± 1.25 mm) and 40N (9.59 ± 0.66 mm) translational forces, respectively, were observed. The double-sling augmentation effectively prevented the anteroinferior HH translation under the translational force of less than 40N, and only half of the augmentation structure (8.25 ± 1.66 mm) had failed under the 50N translational forces.
Conclusion:
In the absence of any Hill-Sachs lesion and when tested at 60° abduction and external rotation in shoulders with 20% glenoid bone defects, at time-zero, the double-sling augmentation strategy could effectively prevent anteroinferior translation when compared with the Bankart repair or the single-sling augmentation technique under all magnitudes of the translational force in biomechanical simulation. Nevertheless, none of the constructs restored the HH translation to the normal intact state.

P967

STRESS FRACTURE IN THE ROYAL NAVY: CAN ROUTINELY COLLECTED ORGANISATIONAL DATA HELP IDENTIFY THOSE AT INCREASED RISK?

G. Bevilacqua[1], L. Westbury[1], J. L. Fallowfield[2], K. Harrison[3], E. M. Dennison[1]

[1]MRC Lifecourse Epidemiology Centre, University of Southampton, Southampton, United Kingdom; [2]Institute of Naval Medicine, Alverstoke, United Kingdom; [3]Defence Statistics (Health), Ministry of Defence, Abbey Wood North, United Kingdom

Objective
Stress fractures (SFs) are overuse musculoskeletal injuries that impact mobility. They occur more frequently in military personnel than in the general population, disrupting occupational training and operational preparedness. We used routinely collected organisational healthcare data to identify characteristics associated with SF in Regular Royal Navy (RN) personnel and evaluated the predictive ability of these characteristics.
Material and Methods
We studied 63,442 Regular RN personnel (90.3% men) who served between 2013 and 2023. SFs were identified from Read codes. Baseline exposures included age, ethnicity, height, weight, body mass index (BMI), smoking status, trained status (untrained or trained), service (RN or Royal Marines [RM]), job role, rank, number of bodily systems medicated in the first year (as a marker of poorer baseline health), and (in women) progestogen contraceptive use. Some variables were incomplete or not concurrent with service entry. Associations with incident SF were examined using sex-stratified univariate and multivariable Cox regression.
Results
Median (lower quartile, upper quartile) baseline age was 25 years in both men (21, 32) and women (21, 30). SF incidence was 1.3% in men and 1.7% in women. In men, RM service was the strongest individual predictor (hazard ratio 8.55, 95% CI 7.25–10.07 versus RN; Harrell's C 0.75), followed by ≥1 medicated system (3.32, 2.42–4.55 versus <1); higher BMI was protective (0.86, 0.84-0.88). In women, trained status (0.11, 0.05–0.24 versus untrained) and higher BMI (0.86, 0.80-0.91) were protective, while ≥1 medicated system increased risk (7.15, 4.67–10.95). Most individual predictors showed modest discrimination (C ≈0.60) but multivariable models, including univariate-significant variables, showed good discrimination (C 0.85 in men; 0.81 in women).
Conclusions
Consistent risk factors for SF were BMI, trained status and poorer baseline health. As all personnel are pre-assessed against service entry medical and fitness standards, higher BMI values may reflect healthier (muscle- vs. fat-mass) body composition rather than obesity per se. Given this pre-assessment—as well as the age-distribution of this military workforce and limitations to data completeness and timeliness—BMI associations should be interpreted cautiously. Improving consistency and quality of service entry and through-career data could improve injury surveillance and prevention.

P968

ANALYTICAL AND CLINICAL PERFORMANCE OF A NOVEL SANDWICH IMMUNOASSAY FOR TOTAL 25-HYDROXYVITAMIN D

L. Wu[1], J. Zeng[2]

[1]Shenzhen Mindray Bio-Medical Electronics Co., Ltd., Shenzhen, China; [2]Department of Clinical Laboratory, Wuhan Fourth Hospital, Wuhan, China

Background-aim: Chemiluminescent immunoassays used for 25(OH)D detection often show inconsistencies with LC-MS/MS in clinical practice, which can lead to misclassification of vitamin D status, impacting patient care. This study assessed the performance of a novel sandwich VD-T immunoassay.

Methods: Analytical performance was evaluated according to CLSI guidelines. A total of 118 selected serum samples, which showed discrepancy results(bias≥20%) on any two immunoassay platforms were also measured with a LC-MS/MS method traceable to the National Institute of Standards and Technology (NIST).

Results: The LoB for the sandwich VD-T assay was ≤2.00 ng/mL, while the LoD and LoQ were both≤3.00 ng/mL. The correlation coefficient (r) is 0.9998 within the linear range of 3.00 to 150.00 ng/mL. The within-run imprecision ranged from 1.64% to 2.36%, and the within-laboratory imprecision from 3.08% to 6.32%, aligning with manufacturer specifications. The cross-reaction rates of the VD-T assay with 1,25-(OH)2 D and 3-epi-25(OH)D3 were 67.00%, and with Vitamin D and 24,25-(OH)2 D were 5.00%. Linear regression analysis between immunoassays and LC-MS/MS showed correlation coefficients(r) and slops(k) of 0.963 and 1.02 for this assay as well as 0.725 and 0.890, 0.762 and 0.78, and 0.792 and 0.790 for other three immunoassays.

Conclusions The novel sandwich VD-T assay demonstrates high analytical sensitivity, specificity, and excellent consistency with LC-MS/MS, making it a reliable tool for clinical measurement of 25(OH)D in routine clinical practice.

P969

QUALITY OF LIFE AND REHABILITATION PROGRAM IN CIRRHOSIS-ASSOCIATED SARCOPENIA PATIENTS

L.-M. Chiritoiu[1], O. Fugaru[2], M. Cealicu[3], R. Traistaru[3]

[1]University of Medicine and Pharmacy , Doctoral School, Craiova, Romania; [2]Filantropia Hospital, Craiova, Romania; [3]University of Medicine and Pharmacy, Craiova, Romania

Background. Sarcopenia is a frequent and clinically relevant complication of liver cirrhosis, characterized by reduced skeletal muscle mass and strength, and is associated with frailty, increased risk of falls, poorer prognosis, and impaired health-related quality of life. Despite increasing awareness, there is still limited consensus regarding standardized rehabilitation protocols in this population, especially considering cirrhosis-related fatigue, malnutrition, and reduced exercise tolerance.

Aim. In this prospective study, we assessed the efficacy of a complex rehabilitation program (TENS, electrostimulation, and an exercise program) on quality of life in patients with cirrhosis-associated sarcopenia.

Methods. We included 26 patients aged 67–73 years diagnosed with liver cirrhosis and sarcopenia. Participants underwent clinical and anthropometric assessment (body mass index - BMI, total body fat - TBF, skeletal muscle - SM, measured by bioelectrical impedance analysis, BF511 - OMRON), laboratory testing (screening tests and leptin), and functional evaluation (Timed Up and Go test - TUG, handgrip strength - HG, and SarQoL quality of life questionnaire). The rehabilitation program included electrotherapy (TENS and electrostimulation) and supervised kinetic training (aerobic and resistance exercises), delivered 5 days/week, structured as 2 weeks inpatient followed by 2 weeks outpatient, with continuation recommendations thereafter. Assessments were performed at baseline (T1) and at 4 weeks (T2) and 12 weeks (T3).

Results. Overall, parameters showed a trend toward improvement, most evident at T3 ($p < 0.05$), particularly for BMI, HG, and TUG. Correlations between baseline and follow-up SarQoL scores were weak, likely due to the limited follow-up interval. In multivariate analysis, SarQoL correlated with performance measures (HG and TUG). At 12 weeks, improvements in functional status were maintained.

Discussions and Conclusions. Our findings highlight that sarcopenia in liver cirrhosis is associated with reduced functional capacity and impaired quality of life, and that a structured rehabilitation approach may improve or maintain functional outcomes over 12 weeks. Rehabilitation interventions should be integrated into a multidisciplinary management strategy addressing the key drivers of cirrhosis-related sarcopenia, including adequate nutrition (especially sufficient protein intake), tailored physical activity, and appropriate medical management, with close monitoring to ensure safety and adherence in this vulnerable population.

P970

FACTORS INFLUENCING QUALITY OF LIFE AMONG SAUDI INDIVIDUALS WITH KNEE OSTEOARTHRITIS: AN ICF-ORIENTED MULTIDIMENSIONAL ANALYSIS

M. A. Albadi[1], H. M. Mirza[1], R. A. Aldhabi[1]

[1]King Abdulaziz University, Jeddah, Saudi Arabia

Purpose: This study aimed to provide a comprehensive, biopsychosocial understanding of factors influencing quality of life (QoL) in individuals with knee osteoarthritis (OA). Specifically, it sought to determine the relative contribution of physical impairments, psychological status, and cognitive-related health perceptions within an International Classification of Functioning (ICF) framework to identify the strongest predictors of QoL.

Methods: A cross-sectional design was employed involving 148 adults aged 40–75 years with clinically diagnosed knee OA. Participants were excluded if they had undergone recent knee surgery, had inflammatory arthritis, severe comorbid medical conditions, or significant language barriers.

QoL was assessed using the **SF-36**. Knee-related symptoms and functional limitations were measured with **WOMAC**. Broader patient-reported outcomes reflecting activities, participation, and environmental influences were recorded using a general PRO measure. Psychological status was evaluated through the **Hospital Anxiety and Depression Scale (HADS)**. Physical performance and impairment measures included the **Timed Up and Go (TUG)**, **Five Times Sit-to-Stand Test (FTSST)**, **Lower Extremity Functional Scale (LEFS)**, **Visual Analog Scale (VAS) for pain**, and knee range of motion (ROM). Pearson correlation analyses and multiple linear regression models were conducted using SPSS to explore associations and identify predictors of QoL.

Results: The SF-36 physical component score demonstrated moderate

associations with physical performance measures, psychological variables, and ICF-related functional indicators. In contrast, correlations with the SF-36 mental component score were not statistically significant, suggesting that mental health-related QoL was not directly linked to physical or functional impairments within this cohort. Consistent with previous literature, higher levels of pain, stiffness, functional restriction, and emotional distress were associated with poorer physical and overall QoL, with WOMAC and HADS scores emerging as important contributors.
Conclusions: In Saudi adults with knee OA, physical aspects of health-related QoL are strongly influenced by pain severity, joint stiffness, limited knee ROM, emotional distress, and ICF-defined functional limitations. Interventions targeting pain management, psychological well-being, and functional capacity may play a critical role in improving QoL outcomes. Longitudinal studies are warranted to determine the impact of multidimensional rehabilitation strategies on HRQoL in this population.
Keywords: Knee osteoarthritis, Quality of life, ICF framework, Disability, Rehabilitation.

P971

OUT-OF-PROPORTION OSTEOPOROSIS AND FRAGILITY HIP FRACTURES IN SAUDI ARABIA: IMPLICATIONS FOR CLINICAL PRACTICE AND HEALTH POLICY

M. A. Ashraf[1], H. A. Harbi[2]

[1]Neom Hospital / King Fahad Armed Forces Hospital, Neom, Saudi Arabia; [2]King Fahad Armed Forces Hospital, Jeddah, Saudi Arabia

Objective(s): To evaluate the epidemiology, fracture patterns, biochemical risk factors, and surgical management of osteoporotic hip fractures in Saudi Arabia, and to identify region-specific implications for prevention, treatment, and healthcare policy.
Material and Methods: A retrospective cohort study was conducted on 247 consecutive patients admitted with osteoporotic hip fractures between 2017 and 2020. Data collected included demographics, fracture type, serum sodium levels, medications affecting sodium balance, and surgical interventions. Descriptive and inferential statistical analyses were performed with significance set at $p < 0.05$.
Results: The cohort comprised 53% males and 47% females, with a mean age of 77.2 ± 9.1 years. The highest incidence occurred in patients aged 71–80 years (42.1%). Intertrochanteric fractures were most frequent (51.8%), followed by intracapsular fractures (42.0%). Hyponatremia was observed in 33.2% of patients, and 83.4% were taking medications known to alter sodium metabolism, most commonly proton pump inhibitors and antihypertensive agents. Surgical management predominantly included short cephalomedullary nailing for extracapsular fractures and uncemented hemiarthroplasty for intracapsular fractures.
Conclusion(s): This study identifies important deviations from global patterns of osteoporotic hip fractures. The male-to-female ratio was nearly equal, highlighting the need for targeted osteoporosis screening in men. Fracture incidence peaked approximately a decade earlier than in Western populations, indicating earlier onset of osteoporosis and the need for earlier preventive interventions. The predominance of intertrochanteric fractures suggests region-specific biomechanical or biological factors. The high prevalence of hyponatremia, largely associated with modifiable medication use, represents an actionable risk factor for falls and fractures. Finally, the widespread use of uncemented hemiarthroplasty warrants reconsideration in light of evidence favoring cemented fixation for improved functional outcomes. These findings support the implementation of national screening programs, standardized fracture care pathways, and evidence-based surgical practices to reduce morbidity, mortality, and economic burden in Middle Eastern populations.
Disclosures: The authors declare no conflicts of interest

P973

DIAGNOSTIC ACCURACY OF ULTRASOUND FOR DETECTING KNEE OSTEOARTHRITIS: A SYSTEMATIC REVIEW AND META-ANALYSIS

M. Abdelsalam[1], M. Lasheen[2], H. Hafez[3], B. Badwy[2], O. El Sedafy[2], M. Mahdy[2], H. Mohammed[2], M. Awad[4]

[1]Rheumatology, Rehabilitation and Physical Medicine Department, Faculty of Medicine, Misr University For Science and Technology, Giza, Egypt, Giza, Egypt; [2]Faculty of Medicine, Misr University For Science and Technology, Giza, Egypt; [3]Faculty of medicine, October 6th University, Giza, Egypt; [4]Faculty of medicine, Al Azhar University., Nasr City, Egypt

Objective: This systematic review and meta-analysis aims to evaluate the diagnostic accuracy of Ultrasound (US) in detecting Knee Osteoarthritis (KOA) and related parameters.
Material and Methods: PubMed, Web of Science, and Scopus were searched from inception to April 4th 2025, for studies evaluating US diagnostic accuracy in detecting KOA. Studies were included if they provided sufficient data to construct 2×2 tables and used a valid reference standard. A meta-analysis estimated pooled sensitivity (Se), specificity (Sp), and the summary receiver operating characteristic (SROC) curve of US for diagnosing KOA and related parameters. All analyses were performed using R software 4.4.2.
Results: 27 studies were included in the qualitative synthesis and 17 in the meta-analysis, encompassing 7,187 and 3,871 knee radiographs, respectively. US achieved a pooled Se of 0.94 (95% CI: 0.71–0.99) and Sp of 0.79 (95% CI: 0.48–0.94) for total KL grading. For KL grade 0, Se was 0.47 (95% CI: 0.12–0.85) and Sp was 0.98 (95% CI: 0.19–1.00). For KL grade 1, Se was 0.95 (95% CI: 0.53–1.00) and Sp was 0.89 (95% CI: 0.44–0.99). For KL grade 2, Se was 0.99 (95% CI: 0.69–1.00) and Sp was 0.86 (95% CI: 0.48–0.97). For KL grade 3, Se was 0.87 (95% CI: 0.82–0.91) and Sp was 0.90 (95% CI: 0.67–0.98). For KL grade 4, Se was 0.94 (95% CI: 0.84–0.98) and Sp was 0.97 (95% CI: 0.42–1.00). For osteophyte detection, Se was 0.86 (95% CI: 0.76–0.92) and Sp was 0.76 (95% CI: 0.65–0.84). For cartilage degeneration, Se was 0.88 (95% CI: 0.71–0.95) and Sp was 0.76 (95% CI: 0.73–0.79). For medial meniscus protrusion (MMP), Se was 0.77 (95% CI: 0.56–0.90) and Sp was 0.70 (95% CI: 0.47–0.86).
Conclusion: This is the first systematic review and meta-analysis to assess US diagnostic accuracy in detecting KOA and KOA-related structural changes, showing high pooled sensitivity and specificity for overall KL grading, individual KL grades, and the detection of osteophytes, cartilage degeneration, and MMP. Future research should focus on enhancing early stage KOA detection for more timely diagnosis and intervention, and explore the link between clinical symptoms and ultrasound findings to better understand how imaging correlates with patient reported outcomes.

P974

DIAGNOSTIC TEST ACCURACY OF ARTIFICIAL INTELLIGENCE IN EARLY DIAGNOSIS OF OSTEOARTHRITIS: A SYSTEMATIC REVIEW AND META-ANALYSIS OF 45,588 KNEES

M. Abdelsalam[1], H. Hafez[2], O. El Sedafy[3], N. Hazem[1], A. Hamza[3], O. El-Sayed[4], H. Mohammed[3], M. Awad[5], G. Omar[1]

[1]Rheumatology, Rehabilitation and Physical Medicine Department, Faculty of Medicine, Misr University For Science and Technology, Giza, Egypt, Giza, Egypt; [2]Faculty of medicine, October 6th University, Giza, Egypt; [3]Faculty of Medicine, Misr University For Science and Technology, Giza, Egypt; [4]Faculty of medicine, Zagazig University, Zagazig, Egypt; [5]Faculty of medicine, Al Azhar University., Nasr City, Egypt

Objective: This study aims to assess the diagnostic accuracy of artificial intelligence (AI) detection and classification of radiographic Kellgren–Lawrence (KL) grades for knee osteoarthritis (KOA).

Material and methods: We conducted a systematic search across PubMed, Web of Science, and Scopus databases, covering all available literature up to March 1st, 2025. We screened and evaluated the methodological quality of the eligible studies, selecting only those deemed to be of high quality and excluding studies without outcome data or insufficient quality. We performed a meta-analysis to estimate pooled sensitivity, pooled specificity, and diagnostic likelihood ratios (LR+/LR-). All analyses were conducted using RStudio version 4.4.2.

Results: A total of 14 studies were included in the systematic review and meta-analysis, encompassing 45588 radiographs. As for KL grading, AI showed robust diagnostic performance across all grades. In KL Grade 0, specificity was 0.954 (95% CI: 0.877–0.984) and sensitivity was 0.829 (95% CI: 0.488–0.961) with Pre Test Probability (PP) of 30%, Post Test Probability +ve (PTP +ve) of 88%, and Post Test Probability -ve (PTP -ve) of 7%. For KL Grade 1, specificity remained high at 0.956 (95% CI: 0.880–0.984), with modest sensitivity of 0.680 (95% CI: 0.392–0.875) and (PP: 20%, PTP +ve: 79%, PTP -ve: 8%). For KL Grade 2, specificity was 0.937 (95% CI: 0.883–0.967), sensitivity was 0.850 (95% CI: 0.733–0.921) and (PP: 25%, PTP +ve: 82%, PTP -ve: 5%). KL Grade 3 yielded a specificity of 0.977 (95% CI: 0.937–0.992), sensitivity of 0.906 (95% CI: 0.793–0.961) and (PP: 15%, PTP +ve: 87%, PTP -ve: 2%). in KL Grade 4, specificity reached 0.995 (95% CI: 0.984–0.999), sensitivity 0.938 (95% CI: 0.800–0.983) and (PP: 10%, PTP +ve: 96%, PTP -ve: 1%).

Conclusion: This is the first systematic review and meta-analysis to evaluate the use of AI in the early diagnosis of KOA. AI demonstrates consistently good sensitivity and specificity across all KL grades. These findings support the use of AI as a valuable assistant for rheumatologists in the early diagnosis of KOA. However, further research is needed to focus on developing, training, and validating of a unified model capable of accurate KOA diagnosis, especially the early stages of the disease.

P975

DIAGNOSTIC DELAY IN PSORIATIC ARTHRITIS AND ITS IMPACT ON RADIOLOGICAL OUTCOMES: A SYSTEMATIC REVIEW AND META-ANALYSIS OF 23,894 PATIENTS

M. Abdelsalam[1], M. Mahdy[2], M. Lasheen[2], N. Hazem[1], A. Moshrif[3], M. Awad[4]

[1]Rheumatology, Rehabilitation and Physical Medicine Department, Faculty of Medicine, Misr University For Science and Technology, Giza, Egypt, Giza, Egypt; [2]Faculty of Medicine, Misr University For Science and Technology, Giza, Egypt; [3]Faculty of medicine, Assiut university, Assiut, Egypt; [4]Faculty of medicine, Al Azhar University., Nasr City, Egypt

Objective: This study aims to examine the extent and consequences of diagnostic and referral delays in Psoriatic arthritis (PsA) and their impact on radiographic outcomes.

Material and methods: PubMed, Web of Science, and Scopus were systematically searched from inception to March 16, 2025 for observational studies reporting diagnostic delay in PsA. Eligible studies included patients diagnosed using CASPAR criteria, rheumatologist-confirmed diagnosis, or self-reported physician diagnosis. Diagnostic and referral delays were extracted as mean (SD) or median (IQR). Meta-analysis was performed using Review Manager (RevMan) 5.4.

Results: Twenty observational studies including 23,894 participants were identified, with 15 studies (22,749 participants) included in the meta-analysis. The pooled mean diagnostic delay was 31.24 months (95% CI: 22.48, 40.00) using a random-effects model, with considerable heterogeneity (I^2 = 100%). The mean referral delay was analyzed using both fixed- and random-effects models, with the random-effects model yielding a pooled mean referral delay of 21.69 months (95% CI: 15.02, 28.35) and the fixed-effects model yielding 15.32 months (95% CI: 13.98, 16.67), with considerable heterogeneity (I^2 = 92%). Patients with prolonged diagnostic delay had significantly increased odds of radiographic damage. The fixed-effects model yielded a pooled OR of 2.80 (95% CI: 2.31, 3.39), while the random-effects model showed an OR of 2.54 (95% CI: 1.58, 4.09). Heterogeneity for both was moderate (I^2 = 49%). geographically, diagnostic delay varied widely ranging from 6.55 months in India to over 62 months in Italy.

Conclusion: This is the first systematic review and meta-analysis that explores diagnostic and referral delays in PsA and their relationship to radiographic joint damage confirming that diagnostic and referral delays in PsA are substantial and clinically significant, with longer delays associated with increased radiographic joint damage. These findings highlight deficiencies in disease recognition and referral pathways, underscoring the need for earlier detection, particularly in primary care and dermatology settings, and more efficient referral to rheumatology to reduce structural damage and improve patient outcomes.

P976

DIAGNOSTIC DELAY IN RHEUMATOID ARTHRITIS AND ITS IMPACT ON RADIOGRAPHIC OUTCOMES: A SYSTEMATIC REVIEW AND META-ANALYSIS OF 100,066 PATIENTS

M. Abdelsalam[1], M. Mahdy[2], B. Badwy[2], M. Lasheen[2], O. El Sedafy[2], H. Hafez[3], M. Awad[4]

[1]Rheumatology, Rehabilitation and Physical Medicine Department, Faculty of Medicine, Misr University For Science and Technology, Giza, Egypt, Giza, Egypt; [2]Faculty of Medicine, Misr University For Science and Technology, Giza, Egypt; [3]Faculty of medicine, October 6th University, Giza, Egypt; [4]Faculty of medicine, Al Azhar University., Nasr City, Egypt

Objective: This study aims to evaluate the extent of diagnostic delay in rheumatoid arthritis (RA) across multiple countries and examine its impact on radiographic joint damage, with emphasis on erosive outcomes.
Material and Methods: We systematically searched PubMed, Web of Science, and Scopus from inception until April 5th, 2025 for observational studies reporting diagnostic delay and radiographic outcomes in RA. Studies were included if RA diagnosis was confirmed by a rheumatologist according to a classification criteria. Diagnostic delays were extracted if reported as mean (SD) or median (IQR). Meta-analyses were conducted for the pooled mean diagnostic delay and prevalence of radiographic damage in delayed diagnosis patients. Heterogeneity was assessed using I^2 statistics following Cochrane guidelines.
Results: A total of 48 studies were identified encompassing 100,066 participants of which 28 were included in the meta-analysis encompassing 15,226 participants. The pooled mean diagnostic delay was 31.92 months (95% CI: 27.48, 36.37) with considerable heterogeneity (I^2 = 100%, τ^2 = 122.29). Radiographic outcomes, primarily bone erosions, were reported in a subset of studies. The pooled proportion of patients with radiographic joint damage was 51.4% (95% CI: 43.3%, 59.5%), with considerable heterogeneity (I^2 = 96.16%). There was marked geographic variation in diagnostic delay, with reported mean delays ranging from 5.47 months in Singapore to 120.5 months in Brazil.
Conclusion: This is the first systematic review and meta-analysis to evaluate diagnostic delay in RA. It revealed a significant mean diagnostic delay, with over half of the patients exhibiting radiographic erosions. These findings highlight critical gaps in early disease recognition, which hinder the implementation of the treat-to-target approach and contribute to irreversible structural damage. The development of clear diagnostic criteria and expansion in the use of diagnostic technologies such as ultrasonography are vital to facilitate earlier detection.

P977

THE ASSOCIATION BETWEEN INSOMNIA AND RHEUMATOID ARTHRITIS: A SYSTEMATIC REVIEW AND META-ANALYSIS OF 546,822 PATIENTS

M. Abdelsalam[1], M. Lasheen[2], M. Mahdy[2], H. Hafez[3], N. Hazem[1], M. Al-Adl[4], M. Awad[4]

[1]Rheumatology, Rehabilitation and Physical Medicine Department, Faculty of Medicine, Misr University For Science and Technology, Giza, Egypt, Giza, Egypt; [2]Faculty of Medicine, Misr University For Science and Technology, Giza, Egypt; [3]Faculty of medicine, October 6th University, Giza, Egypt; [4]Faculty of medicine, Al Azhar University., Nasr City, Egypt

Objective: This study aims to investigate the association between rheumatoid arthritis (RA), disease activity, and insomnia.
Material and Methods: PubMed, Web of Science, and Scopus were systematically searched from inception to March 18, 2025. Eligible studies included case–control, cohort, or cross-sectional designs with RA diagnosed by a rheumatologist, classification criteria, ICD codes, or self-reported physician diagnosis. A meta-analysis estimated the pooled association between insomnia and RA by comparing RA patients with controls, low/remission versus moderate/high disease activity, and rheumatoid factor (RF)–positive versus RF-negative patients. Data were analyzed using Review Manager (RevMan).
Results: Of 1,273 identified records, 25 studies were included in qualitative synthesis and 14 in the meta-analysis, comprising 546,822 and 41,565 participants, respectively. Nine studies explored the association between insomnia and RA. Both fixed- and random-effects models showed significantly higher odds of insomnia in RA patients compared to controls (OR: 2.21; 95% CI 1.85 – 2.64, $p < 0.00001$) and (OR: 3.92; 95% CI 1.59 – 9.7, $p = 0.008$), respectively, with considerable heterogeneity. Sensitivity analysis revealed that RA patients had nearly seven times higher odds of experiencing insomnia (OR: 6.82; 95% CI: 2.32–20.1, $p = 0.006$). Five studies compared insomnia in RA patients based on disease activity. Patients with moderate/high disease activity had higher odds of insomnia (OR: 1.76; 95% CI 1.29–2.39, $p = 0.0004$). RF +ve RA patients had higher but not statistically significant odds of insomnia (OR 1.12; 95% CI 0.74–1.71, $p = 0.59$). Among the countries with insomnia in both the RA and control groups, China had the highest odds of insomnia (OR: 16.48; 95% CI 8.68 – 31.51) and UK had the lowest odds (OR: 1.06; 95% CI 0.73 – 1.54).
Conclusion: This is the first meta-analysis to assess the association between RA, high disease activity, and insomnia, revealing that RA is strongly associated with insomnia, particularly in patients with higher disease activity. These findings highlight the need for increased awareness and targeted interventions to improve sleep and disease management in RA. Further large-scale studies are needed to clarify the relationship between RF and insomnia.

P978

SAFETY AND EFFICACY OF COLCHICINE IN OSTEOARTHRITIS: A SYSTEMATIC REVIEW AND META-ANALYSIS OF 6,965 PATIENTS

M. Abdelsalam[1], B. Badwy[2], M. Mahdy[2], M. Lasheen[2], H. Hafez[3], O. El Sedafy[2], M. Awad[4]

[1]Rheumatology, Rehabilitation and Physical Medicine Department, Faculty of Medicine, Misr University For Science and Technology, Giza, Egypt, Giza, Egypt; [2]Faculty of Medicine, Misr University For Science and Technology, Giza, Egypt; [3]Faculty of medicine, October 6th University, Giza, Egypt; [4]Faculty of medicine, Al Azhar University., Nasr City, Egypt

Objective: Despite growing interest, the evidence regarding colchicine efficacy and safety in osteoarthritis (OA) management remains inconclusive. This study aims to determine the safety and efficacy of colchicine in treating OA.

Material and Methods: A systematic search of PubMed, Web of Science, and Scopus was conducted from inception to April 5, 2025 to identify randomized controlled trials assessing colchicine in OA. Pain assessed by the visual analogue scale (VAS) was the primary outcome. Outcomes were stratified by follow-up duration into short-term (4–8 weeks), medium-term (10–16 weeks), and long-term (≥20 weeks). Meta-analysis was conducted using Review Manager (RevMan) version 5.4.

Results: A total of 21 clinical trials encompassing 6,965 participants were included in this systematic review, with 13 contributing to the meta-analysis including 879 participants. Colchicine significantly improved pain in the short term at week 8 (standardized mean difference [SMD] = -1.03, 95% confidence interval [CI]: -2.01, -0.06, p=0.04), and a non-significant improvement at medium-term follow-up at week 12 (SMD = -0.34, 95% CI: -0.78, 0.10, p=0.75), and a significant long-term improvement at week 20 follow-up (SMD = -1.24, 95% CI: -1.73, -0.76, p< 0.00001), with an overall significant improvement (SMD = -0.73, 95% CI:-1.06, -0.41, p < 0.00001). Similarly, quality of life indicated significant impact of colchicine treatment (SMD = -0.48, 95% CI: -0.83, -0.12, p =0.008). However, for physical dysfunction, the analysis reveals no statistically significant difference (SMD = -0.21, 95% CI: -0.45, 0.04, p=0.09), with significant difference in adverse events (AEs) (risk ratio [RR]: 1.27; 95% CI:1.07, 1.50, p=0.007) between colchicine and control groups.

Conclusion: This is the most recent and comprehensive systematic review and meta-analysis showing that colchicine is an effective therapeutic option for OA, with significant pain relief measured by VAS score. Additionally, it contributes to improved quality of life in patients with OA. However, physical dysfunction did not show significant differences. Future research should focus on optimal dosing, long-term safety, and larger randomized controlled trials to validate these findings.

P979

SHORT- AND LONG-TERM EFFICACY OF METHOTREXATE IN OSTEOARTHRITIS: A SYSTEMATIC REVIEW AND META-ANALYSIS

M. Abdelsalam[1], M. Lasheen[2], H. Hafez[3], B. Badwy[2], O. El Sedafy[2], M. Awad[4]

[1]Rheumatology, Rehabilitation and Physical Medicine Department, Faculty of Medicine, Misr University For Science and Technology, Giza, Egypt, Giza, Egypt; [2]Faculty of Medicine, Misr University For Science and Technology, Giza, Egypt; [3]Faculty of medicine, October 6th University, Giza, Egypt; [4]Faculty of medicine, Al Azhar University., Nasr City, Egypt

Objective: This study aims to evaluate the safety and efficacy of methotrexate (MTX) in reducing osteoarthritis (OA) symptoms in both the short and long term.

Material and methods: PubMed, Web of Science, Embase, Ovid, and Scopus were systematically searched from inception to April 22, 2025 for studies assessing MTX in OA. The primary outcome was pain, measured by the Visual Analogue Scale (VAS) or Numeric Rating Scale (NRS). Outcomes were stratified by follow-up duration: short-term (less than 6 months), medium-term (6 months and 9 months), and long-term (12 months). Data were analyzed using Review Manager (RevMan).

Results: Fourteen studies were included in the qualitative synthesis and 8 in the meta-analysis, with 1,251 and 649 participants, respectively. MTX reduced pain overall (SMD: −0.47; 95% CI: −0.68 to −0.26). with subgroup SMDs of −0.46 (95% CI: −0.75 to −0.17) at <6 months, −0.75 (95% CI: −1.2 to −0.29) at 6 months, −0.42 (95% CI: −1.35 to 0.51) at 9 months, and −0.06 (95% CI: −0.46 to 0.34) at 12 months. For WOMAC, overall effect was (SMD: −0.71; 95% CI: −1.2 to −0.22), with subgroup SMDs of −0.45 (95% CI: −0.88 to −0.01) at <6 months, −1.81 (95% CI: −4.56 to 0.94) at 6 months, −0.37 (95% CI: −0.78 to 0.04) at 9 months, and −0.27 (95% CI: −0.68 to 0.13) at 12 months. Physical function improved overall (SMD: −0.53; 95% CI: −0.84 to −0.23), with subgroup SMDs of −0.46 (95% CI: −0.76 to −0.16) at <6 months, −0.88 (95% CI: −1.73 to −0.03) at 6 months, −0.35 (95% CI: −0.81 to 0.12) at 9 months, and −0.19 (95% CI: −0.58 to 0.19) at 12 months. Stiffness improved overall (SMD: −0.44; 95% CI: −0.65 to −0.23). Subgroup SMDs were −0.33 (95% CI: −0.68 to 0.01) at <6 months, −0.52 (95% CI: −0.81 to −0.24) at 6 months, −0.39 (95% CI: −1.49 to 0.72) at 9 months, and −0.34 (95% CI: −1.43 to 0.75) at 12 months. There was an overall significant difference in adverse events (AEs) (RR, 0.75; 95% CI, 0.60 to 0.94), with a significant difference in mild AEs (RR, 0.77; 95% CI, 0.61 to 0.97) and no significant difference in serious AEs (RR, 0.65; 95% CI, 0.31 to 1.34).

Conclusion: MTX provides significant short- and medium-term improvements in pain, stiffness, and physical function in OA, with maximal effect at 6 months. Long-term efficacy and real-world safety require further investigation. Large-scale randomized trials are needed to confirm these findings.

P980

PREVALENCE OF HYPERMOBILITY SYNDROME AND ASSOCIATED FACTORS IN UNIVERSITY STUDENTS: A CROSS-SECTIONAL STUDY

M. Sayed[1], H. Hosny[1], M. Abdelsalam[2], M. Masoud[1], M. Awad[3], A. Ahmed[1], M. Ahmed[1]

[1]Faculty of Medicine, Misr University For Science and Technology, Giza, Egypt; [2]Rheumatology, Rehabilitation and Physical Medicine Department, Faculty of Medicine, Misr University For Science and Technology, Giza, Egypt, Giza, Egypt; [3]Faculty of medicine, Al Azhar University., Nasr City, Egypt

Objective: Joint hypermobility syndrome (JHS) is characterized by joint hypermobility resulting in musculoskeletal pain, sprains, and poorer quality of life. We aim to assess prevalence and related factors of JHS in University students.

Methods: We conducted a cross-sectional study on a coneonvenient sample of University students, from March 12, 2025 to July 5, 2025. We included students 18 to 29 years old, registered at a university. We excluded staff and faculty members or connective tissue disease patients. We collected demographics, lifestyle characteristics, musculoskeletal complaints, quality of life, and JHS Beighton scoring system. Statistical analyses were done using IBM SPSS v26.0. p value <0.05 was determined as statistically significant.

Results: Out of 493 collected response, 431 fit the inclusion criteria. Age, Height, Weight, BMI, Median (IQR) were 20 (3), 170 (15.50), 70 (20), 24.2 (5.74), respectively and female were 50.1%.Total Beighton score was median (IQR) 4 ± 4 and 55.5% of students had JHS. Age (p=0.001), Gender (P=0.03), Height (P=0.045), Year of study (P=0.012), were all statistically significantly associated with JHS. JHS was statistically significantly with overall health rating of the students (P=0.006). Gender was statistically significantly with total Beighton score (P=0.038) and JHS most affected body part (P=0.043).

Conclusion: Our study showed majority of student had JHS, and associated with risk factors such as age, gender, height and year of study. Gender was associated with JHS and most affected body part of JHS. The high prevalence of JHS may negative affect musculoskeletal health, academic performance, and overall quality of life, highlighting the need for early screening and preventive measures. Further research is recommended to explore gender differences and guide tailored interventions.

Table (1) Prevalence of Hypermobility Syndrome and Associated Factors among the study population

	Hypermobile (N=239)	Not Hypermobile (N=192)	Total (N=431)	p value
How would you rate your overall health?				0.006[1**]
N-Miss	38.0	184.0	222.0	
Excellent	41.0 (20.4%)	3.0 (37.5%)	44.0 (21.1%)

P981

PREVALENCE OF LOW BACK PAIN AND ITS ASSOCIATED RISK FACTORS AMONG UNIVERSITY STUDENTS: A CROSS-SECTIONAL STUDY

B. Mosa[1], D. Mohamed[1], M. Sobh[1], S. Ahmed[1], M. Abbas[1], M. Abdelsalam[2], M. Awad[3]

[1]Faculty of Medicine, Misr University For Science and Technology, Giza, Egypt; [2]Rheumatology, Rehabilitation and Physical Medicine Department, Faculty of Medicine, Misr University For Science and Technology, Giza, Egypt, Giza, Egypt; [3]Faculty of medicine, Al Azhar University., Nasr City, Egypt

Objectives: Low back pain (LBP) is one of the most common musculoskeletal disorders. Although traditionally associated with older adults, recent evidence shows that LBP is increasingly common among university students. Early onset of LBP may increase the risk of chronic pain in adulthood, impair academic performance, and negatively affect social life. We aim to determine the prevalence and risk factors of LBP among university students.

Methods: We conducted a cross-sectional study on a convenient sample of university students from May 26, 2025, to June 30, 2025. We included adults aged 18-30 years and excluded students with conditions causing generalized pain (e.g., rheumatoid arthritis) or sensory loss (e.g., paraplegia) using a validated questionnaire. Statistical analysis was performed using SPSS version 29 (IBM Corp., Armonk, NY, USA). A p-value < 0.05 was considered statistically significant.

Results: We included 1331 students, 57.8% were females, Age median (IQR) was 21 (3). LBP prevalence was 75.7%. Activities like personal care, lifting, walking, sitting, standing, sleeping, social life, and travelling were significantly associated with LBP (p = 0.001). Age, Smoking,

History of smoking, and Drinking alcohol were risk factors significantly interfered with classwork (p = 0.001). Age was a significant predictor (OR = 1.17, 95% CI: 1.04–1.32, p = 0.009). Females had higher odds (OR) of LBP compared to males (OR: 2.3; CI 1.658-3.243, p < 0.001). History of smoking also had higher odds of LBP (OR: 2.67; CI 1.508-4.758, p < 0.001).

Conclusion: Our study showed three out of every four students had LBP which was significantly associated with risk factors like age, gender, smoking history, etc. More studies, awareness campaigns, ergonomic training, and physical activity promotion should all be incorporated into the health programs within universities to establish an early screening and lifestyle modification program to reduce LBP and further complications.

POSTURE AND ASSOCIATED SPINAL MALALIGNMENT AMONG UNIVERSITY STUDENTS: A CROSS-SECTIONAL STUDY

K. Elseiry[1], N. Elezawy[1], E. Zakaria[1], M. Abdelhamid[1], M. Elsayed[1], M. Abdelsalam[2], G. Omar[2]

[1]Faculty of Medicine, Misr University For Science and Technology, Giza, Egypt; [2]Rheumatology, Rehabilitation and Physical Medicine Department, Faculty of Medicine, Misr University For Science and Technology, Giza, Egypt, Giza, Egypt

Objective: To determine the frequency of self-reported spinal malalignment among university students and to identify associated lifestyle and familial risk factors.

Methods: A cross-sectional survey was conducted among 796 university students between March and July 2025. Students completed a structured self-report questionnaire capturing perceived changes in posture, specific spinal deviations, prior diagnoses, musculoskeletal symptoms, and lifestyle factors. Statistical analysis was performed using SPSS version 29 (IBM Corp., Armonk, NY, USA). A p-value < 0.05 was considered statistically significant.

Results: We included 796 students, 61.6% (n=400) of 649 respondents reported that their posture had worsened since starting higher education. The most commonly perceived spinal deviations were forward head tilt (47.8%, n=191) and rounded shoulders (44.5%, n=178), whereas lordosis (4.5%, n=18) and scoliosis (3.3%, n=13) were less frequently reported; only 43% (n=172) of those perceiving malalignment had a formal medical diagnosis. In bivariate analyses, dentistry students were more likely to report worsened posture compared with medicine and pharmacy students (p=0.032), and a positive family history of spinal problems (p=0.035), ≥5 hours/day of sitting (p=0.006), and more slouched sitting postures (p=0.016) were significantly associated with posture deterioration. In multivariable logistic regression, prolonged daily sitting, habitual slouched sitting, positive family history, and being enrolled in dentistry remained significant predictors of perceived postural malalignment (p<0.05), while regular exercise ≥5 times/week was associated with lower odds of deterioration (p=0.018).

Conclusions: Postural malalignment is highly prevalent among MUST students and is associated with extended sitting, slouched sitting habits, family history of spinal disorders, and field of study, particularly dentistry. Regular physical activity appears protective, supporting the need for targeted ergonomic education, promotion of active lifestyles, and early preventive strategies within university settings to mitigate posture-related musculoskeletal problems in young adults.

Table 1 Demographics and lifestyle factors

	Have your posture worsened since starting higher education?			
	Yes (N=400)	No (N=249)	Total (N=649)	p value
Age (in years)				0.824[1]
Median (IQR)	21 (19 — 23)	21 (20 — 22)	21 (20 — 23)

DIAGNOSTIC UTILITY OF SYNOVIAL D-LACTATE FOR PROSTHETIC JOINT INFECTION: A DIAGNOSTIC TEST ACCURACY SYSTEMATIC REVIEW AND META-ANALYSIS

M. El Barbary[1], A. Taha[1], S. Mohamed[1], G. Ahmed[1], M. Abdelsalam[2], K. Sayed[1], M. Sayed[3]

[1]Faculty of Medicine, Misr University For Science and Technology, Giza, Egypt; [2]Rheumatology, Rehabilitation and Physical Medicine Department, Faculty of Medicine, Misr University For Science and Technology, Giza, Egypt, Giza, Egypt; [3]Orthopedic surgery Department, Faculty of Medicine, Misr University for Science and Technology, Giza, Egypt

Objective: To evaluate the diagnostic accuracy of synovial fluid D-lactate for detecting prosthetic joint infection (PJI) and to explore factors influencing its performance across different clinical settings.
Methods: We conducted a diagnostic test accuracy systematic review and meta-analysis according to PRISMA-DTA. PubMed, Scopus, EMBASE, Google Scholar, Cochrane Library, and professional society websites were searched without language or time restrictions for studies assessing synovial D-lactate against established PJI reference standards and reporting data. Two reviewers extracted study characteristics, assay methods, cut-off values, and tables; risk of bias was assessed with QUADAS-2. Pooled sensitivity, specificity, likelihood ratios, diagnostic odds ratio (DOR), and area under the summary ROC curve (AUC) were estimated using random-effects and bivariate models, with subgroup analyses for reference criteria and cut-offs.
Results: Seven studies involving 1,328 patients (413 PJI, 915 aseptic failures) met inclusion criteria. Pooled sensitivity and specificity of synovial D-lactate for PJI were 0.84 (95% CI 0.76–0.90) and 0.85 (95% CI 0.76–0.91), respectively. The pooled positive and negative likelihood ratios were 4.31 (95% CI 3.14–5.92) and 0.20 (95% CI 0.12–0.32), and the DOR was 27.11 (95% CI 11.55–63.63). At the optimal threshold, both sensitivity and specificity were 0.81, and the AUC was 0.90. Subgroup analyses showed sensitivity ranging from 0.81 to 0.92 and specificity up to 1.00 across different definitions and cut-offs. Overall quality was variable, with most studies at low-to-moderate risk of bias.
Conclusions: Synovial fluid D-lactate demonstrates high diagnostic accuracy for PJI, supporting its potential role as a rapid, low-cost adjunctive biomarker and early rule-out tool. Standardized cut-off values and prospective multicenter validation are needed before routine integration into diagnostic algorithms.

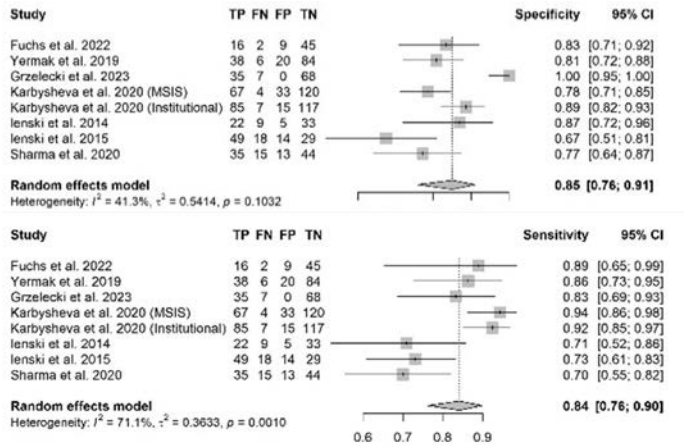

Figure 1: Showing Random-effect model of pooled Sensitivity and Specifity for Synovial fluid D-lactate in included studies

P984

COMPUTED TOMOGRAPHY–DERIVED HOUNSFIELD UNITS FOR OPPORTUNISTIC ASSESSMENT OF BONE MINERAL DENSITY AND PREDICTION OF FRACTURE RISK

M. Alnajjar[1], F. Alqatati[1], M. Alkhanafsa[1], O. Mosleh[1], A. Alwali[1], N. Abdulla[1], S. Al Emadi[1]

[1]hamad medical corporation, Doha, Qatar

Objective: This study evaluated the ability of lumbar HU measurements to predict osteoporotic fractures and compared their performance with conventional DXA parameters.

Materials and Methods: Ninety-six patients who underwent lumbar CT and DXA within one year were analyzed. HU values were recorded from L1–L4 across axial, coronal, and sagittal planes. Fracture status was available in 65 patients. Diagnostic performance for fracture prediction was assessed using ROC analysis, Youden index thresholds, and model quality scoring.

Results: HU demonstrated the strongest predictive performance for osteoporotic fracture risk compared with BMD and T-score. The optimal HU threshold for fracture prediction was 95.9 HU, yielding a sensitivity of 46.7% and a specificity of 88.6%. HU achieved the highest model quality score (0.51), outperforming T-score (0.40) and BMD (0.38).

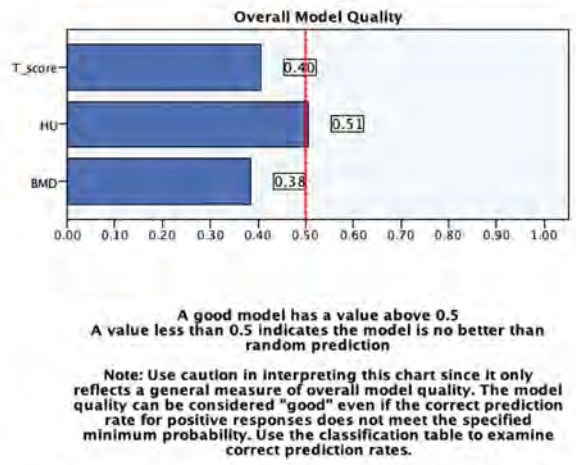

Figure 1: Overall model quality comparison demonstrating the relative predictive performance of HU, T-score, and BMD. HU achieved the highest model quality score (0.51), exceeding T-score (0.40) and BMD (0.38).

Conclusion: Lumbar CT-derived HU values provide a superior predictive signal for osteoporotic fracture risk compared with conventional DXA measures. Opportunistic assessment of HU during routine CT imaging may support early fracture risk stratification and improve screening in populations unlikely to undergo DXA evaluation.

P985

ASSESSMENT OF BRIEF ACTION PLANNING TO PROMOTE PHYSICAL ACTIVITY OVER 4 WEEKS IN ADULTS WITH CHRONIC KNEE SYMPTOMS

M. Alshahrani[1], L. Muhammad[2], K. Haglund[3], P. Papanek[4], P. Semanik[5], R. Chang[6], D. Pinto[4]

[1]Marquette University - Rehabilitation Science/ King Khalid University - Rehabilitation Science, Milwaukee, United States; [2]Preventive Medicine/Northwestern University, Chicago, United States; [3]Marquette University - College of Nursing, Milwukee, United States; [4]Marquette University - Physical Therapy, Milwaukee, United States; [5]Rush University - Adult Health and Gerontological Nursing, Chicago, United States; [6]Nothwestren University - Preventive Medicine (Epidemiology), Medicine (Rheumatology), Physical Medicine and Rehabilitation, Chicago , United States

Background:
Physical inactivity can worsen pain and disability in individuals with chronic knee symptoms. Brief Action Planning (BAP) to increase physical activity (PA) offers promise as a form of health coaching but remains understudied in real-world contexts. This study aimed to (1) assess the impact of coaching metrics on device-tracked physical activity (PA) in participants with chronic knee symptoms; and (2) to monitor the patterns of PA during four weeks' observation based on participants' baseline indicators. Participants (n=18) randomized to the PA coaching arm of a randomized controlled trial.
Materials and Methods:
At baseline, participants completed the Numerical Pain Rating Scale, Self-Efficacy for Exercise Scale, WOMAC osteoarthritis index, and the Tampa Scale of Kinesiophobia. PA was tracked using Fitbit Inspire 3® during a health coaching intervention for four weeks. PA was recorded as the average number of steps per week over 4 weeks. Participants who exceeded 7500 steps/week were categorized as "physically active", and participants with <7,500 steps/week were "insufficiently active". Meaningful improvement in the insufficiently active was defined as 20% increase in average number of steps from baseline. Coaching metrics included the use of behavioral menus, plan changes, plan confidence, and the number and duration of calls. Statistical assumptions including normality were assessed. The statistical tests (X^2 or Fisher's Exact test, independent samples t-test, and Pearson's correlation) were applied accordingly. Binary logistic regression assessed the impact of coaching metrics on the outcome of exceeding 7500 steps/week, and linear regression assessed change in PA trajectories. P<0.05 was considered statistically significant.
Results:
At baseline, six of the 18 participants (33.3%) were physically active, and by week four, ten participants were physically active (55.6%, p=0.125). Four additional participants showed meaningful PA improvements by four weeks. Among the18 participants, average four-week PA was significantly higher among those with lower baseline BMI (p=0.009), and significantly higher among participants who held a college degree or higher (p=0.032). PA did not vary based on coaching metrics. Lower pain levels and higher self-efficacy were associated with higher PA (p=0.006; p=0.028, respectively). Trajectories of PA over four weeks showed that participants with low pain intensity (<4) and low WOMAC scores (<19) experienced higher PA.
Conclusions:
Improved physical activity does not appear to be based on BAP coaching metrics over 4 weeks, but may be affected by demographics, clinical characteristics, disease-related quality of life, and pain values. Further studies with larger sample sizes and longer follow-ups are needed.

P986

BRIEF ACTION PLANNING HEALTH COACHING FOR ADULTS WITH CHRONIC KNEE SYMPTOMS: A QUALITATIVE STUDY

M. Alshahrani[1], K. Haglund[2], P. Papanek[3], L. N. Muhammad[4], M. Miranda[3], D. Pinto[3]

[1]Marquette University - Rehabilitation Science/ King Khalid University - Rehabilitation Science, Milwaukee, United States; [2]Marquette University - College of Nursing, Milwukee, United States; [3]Marquette University - Physical Therapy, Milwaukee, United States; [4]Preventive Medicine/Northwestern University, Chicago, United States

Background:
Physical inactivity worsens pain and disability in individuals with chronic knee symptoms (CKS), yet many interventions are poorly tailored to individual motivation. Brief Action Planning (BAP), a self-management support tool offers promise for supporting health coaching but remains understudied in real-world contexts. This study aimed to explore the feasibility, acceptability, and perceived impact of a computer-supported BAP coaching program on physical activity behavior among employees with CKS. 9 participants were enrolled in a 12-week physical activity coaching program recruited from participating employers in a randomized controlled trial.
Materials and Methods:

The 12-week program consisted of a 30-minute BAP session and four to eleven 10-minute follow-up sessions delivered remotely by trained health coaches. Semi-structured interviews were conducted post-intervention and analyzed using qualitative content analysis. Codes were organized thematically across seven domains: program effectiveness, impact, motivation for participation, opinions of BAP, perceived necessity, personal experience, and sustainability of change. Social Determination Theory's (SDT) three psychological needs autonomy, competence, and relatedness were used to interpret the motivational mechanisms supporting behavior change.

Results:

Three main thematic categories emerged from the data. The first was value and sustainability of the BAP program, including subthemes of acceptability, positive experience with coaching, and anticipated sustainability of behavioral change. The second was active ingredients that facilitated physical activity behavior, including coaching accountability, goalsetting structure, and behavioral monitoring via Fitbit. The third was contextual conditions influencing motivation and program fit, including personal motivation, knee pain management needs, and workplace or lifestyle integration. Participants consistently viewed the coaching relationship as the central driver of behavior change. Coaching enhanced personal accountability, enabled adaptive goal setting, and fostered supportive dialogue. Fitbit use complemented goal adherence but was viewed as secondary to interpersonal support. Mapping to SDT, autonomy was supported by individualized goal-setting, competence through iterative plan refinement and feedback, and relatedness through an empathic, nonjudgmental coaching relationship. Participants reported increased physical activity and most described the changes as sustainable due to internalized motivation and increased self-efficacy.

Conclusions:

BAP coaching was perceived as feasible, highly acceptable, and impactful for promoting physical activity in individuals with CKS. The findings reinforce SDT's utility in understanding how personalized, need-supportive coaching interventions can foster sustained engagement in self-management behaviors.

P987

PATTERNS AND ASSOCIATED FACTORS OF MUSCULOSKELETAL PAIN AMONG HAJJ PILGRIMS

M. Alsobhi[1], R. Aldhabi[1]

[1]Department of Physical Therapy, Faculty of Medical Rehabilitation Sciences, King Abdulaziz University, Jeddah, Saudi Arabia

Background:Every year, the Hajj season brings together approximately two to three million pilgrims from around the world in Mecca, Saudi Arabia, and lasts for about five to seven days.Hajj is a sequence of rituals performed at specific locations and times in Mecca. These rituals require substantial physical exertion, which can lead to musculoskeletal pain (MSP) across various age groups.

Objective:This study aimed to determine the prevalence and distribution of MSP and to identify factors associated with muscular pain among pilgrims during Hajj.

Methods:A web-based questionnaire was administered during the annual Hajj mass gathering, with pilgrims recruited from ritual sites. The questionnaire collected information on demographic characteristics, MSP across ten anatomical body regions, and physical activity (PA) level. Data were analyzed using descriptive and inferential statistical methods, with a significance level of 0.05.

Results:A total of 248 pilgrims participated, with a mean age of 43.49 ±12.70 years. Overall, 78.6% of participants reported experiencing MSP in at least one body region during Hajj. Lower-limb pain was the most commonly reported, particularly in the legs (46%), followed by the lower back (45%), knees (37%), and ankles/feet (30%). No significant associations were found between MSP and age, sex, or PA level; however, body mass index (BMI) was significantly associated with MSP ($p < 0.05$).

Conclusion:A high proportion of pilgrims experienced musculoskeletal pain in one or more body regions during Hajj. Despite of existing physical fitness guidelines from the Saudi Ministry of Health, there is a need for broader dissemination of MSP prevention strategies by relevant organizations worldwide.

P988

POLYOSTOTIC FIBROUS DYSPLASIA REVEALED IN ADULTHOOD ASSOCIATED WITH MCCUNE–ALBRIGHT SYNDROME: A DIAGNOSTIC CHALLENGE

M. Aouchiche[1]

[1]Mouloud Mammeri department of medicine, Tizi ouzou, Algeria

Introduction: Fibrous dysplasia is a rare benign bone disorder in which normal bone is replaced by fibro-osseous tissue. Polyostotic forms in adults are uncommon and may occasionally be associated with McCune–Albright syndrome, which can delay diagnosis due to variable clinical presentation.

Objective: To report a rare adult-onset case of polyostotic fibrous dysplasia and emphasize key clinical and radiological features for timely diagnosis.

Case presentation: A 45-year-old woman with no prior medical history presented with one year of mechanical hip pain and a limp. Examination revealed painful limitation of both hips, scoliosis with restricted anterior trunk flexion, and congenital café-au-lait spots on the left thigh and back. Laboratory tests demonstrated elevated alkaline phosphatase (270 UI/L), hypophosphatemia (2 mg/dL), and normal calcium, vitamin D, PTH, and thyroid function, consistent with active bone remodeling.

Radiographs of the skull, long bones, and pelvis, and CT scans of the spine showed multiple bone lesions with characteristic ground-glass appearance, cortical thinning, and deformities. Diagnosis of polyostotic fibrous dysplasia was made on clinical and radiological grounds without biopsy. The patient was treated with analgesics and bisphosphonates and scheduled for close clinical and radiological follow-up.

Discussion: Adult-onset polyostotic fibrous dysplasia is rare, and its recognition may be delayed, particularly in the absence of endocrine involvement. This case emphasizes the importance of a careful clinical examination, recognition of cutaneous manifestations, and systematic imaging to establish the diagnosis. Laboratory evaluation can provide supportive evidence of active bone remodeling. Early identification allows implementation of appropriate management strategies, including pharmacologic treatment, monitoring for skeletal complications, and planning follow-up to prevent fractures and progressive deformities

Conclusion: Polyostotic fibrous dysplasia in adults remains underdiagnosed. A thorough clinical assessment, supported by imaging and laboratory evaluation, is crucial for timely diagnosis. Early recognition and tailored management are essential to optimize patient

outcomes and prevent complications .

REDUCED QUADRICEPS MUSCLE THICKNESS AND IMPAIRED MUSCLE FUNCTION ARE ASSOCIATED WITH HIGHER FRAX®-PROJECTED HIP FRACTURE RISK IN OLDER ADULTS

M. Arikan Yamaner[1], E. Caran Karabacak[1], B. Gokce[1], Y. Kocaman[1], P. Unsal[2], M. Koca[1], E. Oktay Oguz[1], E. Ceker[1], S. Coteli[1], F. Kaplan Efe[1], G. Sengul Aycicek[1]

[1]Department of Geriatrics,Etlik City Hospital, Ankara, Türkiye; [2]Faculty of Medicine, Ankara Bilkent City Hospital, Department of Geriatrics,Ankara Yıldırım Beyazıt University, Ankara, Türkiye

Objective

Muscle mass and function play a key role in mobility, balance, and fracture prevention. However, their relationship with fracture risk estimation tools remains insufficiently explored. This study aimed to evaluate whether muscle thickness and functional performance differ between older adults with and without elevated FRAX®-projected 10-year hip fracture risk (≥3%).

Material and Methods

Community-dwelling older adults aged ≥65 years were stratified according to FRAX® Turkey–projected 10-year hip fracture risk into Group 1 (no elevated risk) and Group 2 (elevated risk, ≥3%). Quadriceps muscle thickness was measured by ultrasound, while muscle strength and physical performance were assessed using handgrip strength and the chair stand test, respectively. (Figure 1)

Results

A total of 164 older adults were included (Group 1: n=38; Group 2: n=126). Group 2 was significantly older than Group 1 (78.5±6.2 vs 71.2±5.3 years; p<0.001), while the proportion of women was similar between groups (83.3% vs 89.5%; p=0.356). Body mass index did not differ significantly between groups (27.9±5.5 vs 29.5±4.9 kg/m²; p=0.127). Quadriceps muscle thickness was significantly lower in the elevated-risk group (20.4±6.8 vs 22.9±5.6 mm; p=0.045). The prevalence of low handgrip strength was higher in Group 2 (61.6% vs 39.5%; p=0.016). Chair stand test performance indicated poorer lower extremity function in Group 2 (21.9 [17.8–29.6] vs 19.0 [14.9–24.4] s; p=0.012).

Conclusion

Older adults with higher FRAX®-projected hip fracture risk exhibit reduced muscle thickness and functional impairment. These findings highlight the clinical relevance of muscle-related parameters in fracture risk evaluation and support integrating muscle assessment into osteoporosis-focused risk stratification.

VITAMIN D REPLACEMENT IN ADULTS AND ELDERLY IN THE MIDDLE EAST AND NORTH AFRICA REGION: A SYSTEMATIC REVIEW AND META-REGRESSION

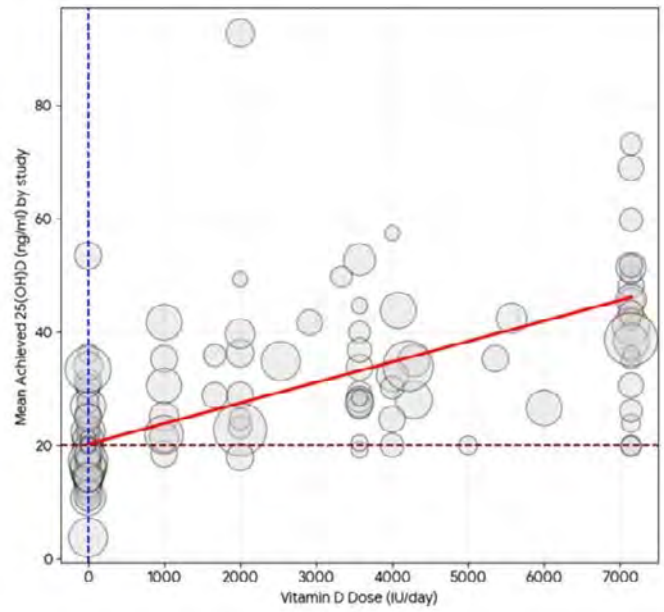
M. Assaad[1], A. Slim[2], B. Sleem[1], V. Ghazi[1], D. Bacha[1], O. Itani[1], A. Bassatne[1], S. Antoune[1], Z. Mahfoud[3], H. Hoballah[1], G. El-Hajj Fuleihan[1], M. Chakhtoura[1]

[1]American university of beirut medical center, Beirut, Lebanon; [2]AUBMC, Beirut, Lebanon; [3]Weill Cornell Medicine, Doha, Qatar

Objective(s):

To update evidence on the impact of vitamin D supplementation on serum 25-hydroxyvitamin D [25(OH)D] levels in adults and elderly populations in the MENA region and investigate the dose-response relationship.

Materials and Methods:



Following PRISMA 2020 guidelines, we searched PubMed, Embase, and Cochrane Library (2015-December 2024) for randomized controlled trials (RCTs) conducted in MENA countries evaluating oral vitamin D for ≥3 months in adults and elderly (>18 years). We assessed the risk of bias (ROB) using the Cochrane RoB 2 tool (2019). We pooled weighted mean differences (WMD) using random-effects models. We conducted a multivariate meta-regression to identify predictors of achieved 25(OH)D levels using STATANow 18 BE. (PROSPERO CRD42014010488)

Results:

From 1,589 citations, 64 trials (61 in adults, 3 in elderly) were included. Weighted mean baseline 25(OH)D was 14.5 ng/mL in elderly and 19.5 ng/mL in adults. Mean age of participants ranged from 21.3 to 73.5 years, and mean BMI ranged from 20.7 to 39.9 kg/m². Gender distribution varied, with the proportion of men ranging from 7.5% to 100% (including 4 studies that enrolled men only). Vitamin D doses ranged from 1,000 to 7,143 IU/day over 3-12 months.

Multivariate meta-regression (R^2=0.737) identified baseline status, dose, and BMI as significant predictors. Achieved 25(OH)D levels increased by 0.79 ng/mL for every 1 ng/mL increase in baseline level (β=0.79; p<0.001)) and by 0.36 ng/mL for every additional 100 IU/day dose (β=0.36, p<0.0001). Conversely, every 1 kg/m² increase in BMI predicted a 0.67 ng/mL decrease in achieved levels (β=-0.67; p=0.002). Participants' age, gender, supplementation duration, vitamin D type (D2

vs. D3), calcium co-administration, latitude, assay method, publication year, or ROB were not significant predictors.
Achieved 25 (OH)D (ng/ml)= 23.46 +0.36* (VitD dose in 100IU) + 0.79* Baseline 25(OH)D (ng/ml) - 0.67 * BMI (kg/m^2)
Conclusion(s):
Vitamin D supplementation response in the MENA region is highly predictable. Baseline status and BMI are critical factors for clinicians when determining the optimal cholecalciferol dose required to reach sufficiency.
No conflicts of interest.
Figure: Impact of daily Vitamin D dosage on mean achieved serum 25(OH)D: A random-effects meta-regression analysis adjusted for baseline status and BMI

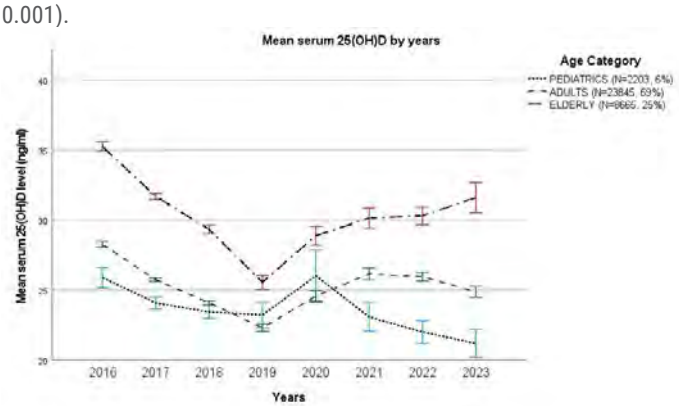
HYPOVITAMINOSIS D: TIME TRENDS AND PREDICTORS ACROSS THE LIFE COURSE: 2016-2023

M. Assaad[1], M. Chakhtoura[1], Z. Mahfoud[2], G. El-Hajj Fuleihan[1]

[1]American university of beirut medical center, Beirut, Lebanon;
[2]Weill Cornell Medicine, Doha, Qatar



Objective: To assess the prevalence, predictors, and secular trends of hypovitaminosis D in a Lebanese cohort.
Materials & Methods: This retrospective study analyzed 34,713 inpatients and outpatients 6% pediatric (0-18 years), 69% adult (19-64 years), 25% elderly (≥65 years)) from the American University of Beirut Medical Center laboratory database (2016–2023). 25(OH)D values were standardized to LC-MS/MS equivalents. Multivariate logistic regression (SPSS 27) identified predictors of deficiency (<12, <15, and <20 ng/ml), evaluating age, sex, BMI, supplementation, inpatient status, and season.
Results: Overall prevalence of hypovitaminosis D was 9.4%, 16.8%, and 31.8% at <12, <15, and <20 ng/ml, respectively.

• **<12 ng/ml**: Pediatric risk increased with older age (6.9% per year) and was 69% lower in summer versus winter. Adults/ elderly: Risk increased with higher BMI (4.4% per kg/m^2) and inpatient status (76% higher). Risk decreased with older age in adults (3% per year), female sex (38% lower in elderly), and summer season (40%–65% lower risk vs. winter, in elderly and adults respectively).

• **<15 ng/ml**: Pediatrics: Risk increased with older age (6.6% per year) and inpatient status (124% higher); risk decreased in summer (65.5% lower vs. winter). Adults: Risk increased with higher BMI (4.4% per kg/m^2) and inpatient status (57% higher); risk decreased with older age (3% per year), female sex (26% lower), and summer (60% lower vs. winter). Elderly: Risk increased with higher BMI (4.4% per kg/m^2); risk decreased with older age (1% per year), female sex (51.5% lower), and summer (28% lower vs. winter).

• **<20 ng/ml**: Pediatrics: Risk increased with older age, winter season, inpatient status, and BMI; risk decreased in summer (65% lower vs. winter). Adult/elderly: Patterns mirrored the <15 threshold. The strongest seasonal effect was at this cutoff, with risk decreasing in summer by 52.7% in adults and 22% in the elderly compared to winter.

Secular trends: levels declined (2016–2019), then increased through 2023. Repeat testing within individuals correlated with increased supplementation and rising 25(OH)D levels.
Conclusions: Hypovitaminosis D remains common, particularly in children and adult men. Levels have been increasing over time, possibly reflecting increased supplementation.
Disclosures: No conflicts of interest.
Figure 1: Annual serum 25(OH)D levels (standardized to LC-MS/MS) were analyzed across pediatric (N=106–678), adult (N=845–8,979), and elderly (N=288–3,304) cohorts. Statistically significant year-to-year variation was observed within each age group (One-Way ANOVA, p < 0.001).

P992

SEQUENTIAL THERAPY WITH DENOSUMAB OR ZOLEDRONIC ACID FOLLOWING ROMOSOZUMAB IN POSTMENOPAUSAL WOMEN WITH SEVERE OSTEOPOROSIS

M. Audisio[1], M. Gonzalez[1], M. S. Gonzalez Pernas[1], F. Jerkovich[1], R. Abdala[1], G. Mumbach[1], V. Longobardi[1], M. B. Zanchetta[1]

[1]IDIM, Buenos Aires, Argentina

Our objective is to compare BMD changes and bone turnover marker profiles in postmenopausal osteoporotic women receiving sequential denosumab (Dmab) or zoledronic acid (Zol) therapy after completing 12 months of romosozumab (Romo) treatment.

Methods

We conducted a prospective study assessing densitometric parameters (lumbar spine (LS), total hip (TH), femoral neck (FN), distal radius), radiographic vertebral fractures, and bone turnover markers. Of 50 enrolled patients, 36 completed Romo therapy. This analysis includes 23 patients who completed 12 months of sequential therapy: 16 received Dmab and 7 received Zol. Sequential treatment selection was based on densitometric response at completion of Romo therapy (Zol: T-Score > -3 and/or BMD gain with Romo ≥ 5%; Dmab: T-Score ≤ -3 and/or BMD gain with Romo < 5%).

Results

Of the 36 patients who completed Romo, median age was 72.6 years (54–89); 69% had a history of fractures (fx) (51% multiple, 57% vertebral, 11% hip, 17% wrist). Recent fx was present in 31%. 14% were treatment-naïve. Baseline BMD data were as follows: LS BMD 0.807 (0.546-0.945), TScore -3 (-5.2 to -2); TH BMD 0.674 (0.540-0.971), TScore -2.6 (-3.8 to -0.3). Dmab group: median age 73 years (61-75); 88% with fx history (69% multiple, 81% vertebral, 19% hip, 19% wrist); 44% recent fx (<24 months); 13% treatment-naïve. Zol group: median age 76 years (70-82); 100% with fx history (71% multiple, 71% vertebral, 14% hip, 14% wrist); 43% recent fx 43% treatment-naïve. Sequential therapy was initiated within 3 months in 91% of patients (range: 1-6 months Dmab, 1-4 months Zol). There were no statistically significant differences between the two groups. In the Dmab group, a final BMD gain of 17% at the LS , 10% at the TH and 6% at the FN was observed. In the ZOL group, a final BMD gain of 9% at the LS, 6% at the TH and 4% at the FN was observed. Baseline characteristics, bone turnover markers, and BMD changes for each group are presented in Table 1.

Discussion

Our real-world cohort demonstrated higher fracture burden than FRAME/ARCH trials yet achieved comparable or superior BMD outcomes. Zol effectively maintained Romo-induced BMD gains, supporting recent meta-analyses validating bisphosphonates as viable alternatives in appropriately selected patients.

IMPACT OF BALNEOTHERAPY AND INDIVIDUALIZED KINESIOTHERAPY ON SARCOPENIA PREVENTION IN PATIENTS AFTER OSTEOPOROTIC FRACTURES

M. B. Bačević[1], S. B. Bačević[2], M. S. Stanković[3]

[1]University Clinical Center Niš, Niš, Serbia; [2]Health Center "Prokuplje", Niš, Serbia; [3]Faculty of Medicine, University of Niš, Niš, Serbia

Background: Osteoporotic fractures are associated with increased risk of sarcopenia and functional decline. Comprehensive rehabilitation strategies are essential to prevent frailty and restore independence.

Objectives: To assess the impact of balneotherapy combined with individualized kinesiotherapy on muscle strength and functional recovery in post-fracture patients at the Clinic for Physical Medicine and Rehabilitation, UKC Niš.

Methods: A cohort of 60 patients (mean age 71 ± 7 years; 45 women, 15 men) with recent osteoporotic fractures underwent a 6-week rehabilitation program including balneotherapy (mineral water baths, 5 sessions/week) and individualized kinesiotherapy tailored to fracture type and baseline muscle strength. Outcomes were assessed using handgrip dynamometry, Short Physical Performance Battery (SPPB), and EuroQol-5D at baseline and after 6 weeks.

Results: Muscle strength improved significantly (handgrip +18%, $p < 0.01$), SPPB scores increased by 2.1 points ($p < 0.05$), and quality of life (EQ-5D index) improved by 22%. Patients reported high satisfaction with balneotherapy as an adjunct to exercise.

Conclusion: The integration of balneotherapy and individualized kinesiotherapy in tertiary rehabilitation settings contributes to prevention of sarcopenia and enhances recovery after osteoporotic fractures, supporting a holistic approach to post-fracture care.

P994

RISK FACTORS FOR OSTEOPOROTIC FRACTURE IN PATIENTS WITH THYROTOXICOSIS: A RETROSPECTIVE OBSERVATIONAL STUDY

S. M. Mahran[1], J. P. Perumbalath[2], M. B. Bukhari[3]

[1]Royal Preston Hospital, Preston , United Kingdom; [2]Royal Blackburn Hospital, Blackburn , United Kingdom; [3]Royal Lancaster infirmary, Lancaster , United Kingdom

Background:

Thyrotoxicosis is a well-recognised cause of secondary osteoporosis and is associated with increase in bone turnover, preferential loss of cortical bone, and an increased risk of fragility fractures. In the presence of excess thyroid hormone, bone remodelling becomes markedly increased, with bone resorption outpacing formation. This imbalance leads to loss of bone mineral density (BMD) and deterioration of bone

microarchitecture, particularly at cortical sites such as the femoral neck.[1] Both overt and subclinical hyperthyroidism have been linked to reduced BMD and a higher incidence of osteoporotic fractures, especially in older individuals and postmenopausal women.[1]

Despite this established association, fracture risk assessment in patients with thyrotoxicosis is largely extrapolated from tools developed for the general population, including FRAX and QFracture. These instruments may not fully capture thyroid-specific skeletal vulnerability. While population-based studies have consistently demonstrated an increased fracture risk in hyperthyroid states,[2] there remains limited evidence defining which clinical and densitometric factors are most predictive of fracture within this group. In particular, the relative contribution of falls risk, previous fracture history, and DXA-derived measures of bone density alongside conventional fracture prediction algorithms has not been clearly delineated.

The aim of this study was therefore to undertake a comprehensive assessment of risk factors for osteoporotic fracture in patients with thyrotoxicosis, incorporating demographic characteristics, lifestyle factors, falls history, fracture prediction scores, and BMD and T-scores.

Methods:

Data were analysed using a retrospective observational approach. Patient characteristics were summarised using means and standard deviations for continuous variables and counts and percentages for categorical variables. Patients with and without osteoporotic fractures were compared using t-tests for continuous variables and chi-square or Fisher's exact tests for categorical variables, as appropriate. Logistic regression was used to examine factors associated with fracture, with adjustment for age, sex, body mass index, and QFracture risk estimates. Other clinical risk factors were assessed individually. Bone mineral density and T-scores at the lumbar spine and femoral neck were compared between groups. Statistical significance was defined as $p < 0.05$.

Results:

A total of 782 patients with thyrotoxicosis were included, of whom 213 (27.2%) had sustained a major osteoporotic fracture. Patients with fracture were more likely to be female and demonstrated higher fracture prevalence despite comparable BMI. In multivariable analysis, female sex and BMI showed borderline associations with fracture risk, while age and QFracture-derived risk estimates were not independently predictive. Lower BMD and T-scores at the femoral neck and lumbar spine were observed in fractured patients. Prior fracture history and recurrent falls emerged as the strongest risk factors.

Conclusion:

In patients with thyrotoxicosis, osteoporotic fracture risk is influenced by a combination of skeletal fragility and non-skeletal factors. Prior fracture history, recurrent falls, female sex, and reduced bone mineral density emerged as the principal determinants of fracture risk in this cohort. These findings are in keeping with established evidence demonstrating accelerated bone turnover, preferential cortical bone loss, and impaired neuromuscular function associated with excess thyroid hormone. [1]

Notably, fracture prediction tools did not adequately identify individuals at highest risk, suggesting that methods developed for the general population may underestimate fracture susceptibility in thyrotoxicosis. As thyroid hormone excess affects both bone strength and neuromuscular function, fracture risk assessment in this population may benefit from a more tailored approach that incorporates falls history, prior fractures, and direct measures of bone density alongside recognition of thyroid-related skeletal and neuromuscular effects.[1,2]

HIGH RATES OF NORMOCALCEMIA AFTER RADIOFREQUENCY ABLATION FOR PRIMARY HYPERPARATHYROIDISM: REAL-WORLD BIOCHEMICAL OUTCOMES FROM A SINGLE-CENTER COHORT

M. B. Miles[1], S. I. Rapp[1], A. M. Begueri[1], M. E. Anselmi[1], M. E. Matsuda[1], M. C. Negueruela[1], J. Guerra[1], A. Voogd[1]

[1]Hospital Universitario Austral, Pilar, Argentina

Objective To evaluate biochemical outcomes and safety of radiofrequency ablation (RFA) in patients with primary hyperparathyroidism (PHPT) who were not candidates for or declined surgery.

Materials and Methods Prospective single-center cohort of patients with PHPT due to single parathyroid adenoma treated with ultrasound-guided RFA between June 2022 and January 2026. All patients had an indication for parathyroidectomy but were either high surgical risk or refused surgery. Serum calcium and parathyroid hormone (PTH) levels were assessed before and after the procedure. Follow-up included biochemical and ultrasound evaluations. Biochemical response was categorized as complete (normal calcium and PTH), normocalcemia with persistent PTH elevation, or persistent hypercalcemia. Complications were recorded.

Results Forty-four patients were treated (mean age 60.4 years, range 38–80; 89% women). Post-procedural PTH <65 pg/mL was observed in 86.4% (38/44), and a ≥50% PTH reduction in 86.4%.

Among patients who had reached 6 months of follow-up (n=36) normocalcemia was achieved in 88.9% (32/36). Complete biochemical response occurred in 72.2% (26/36), while 16.7% (6/36) had normocalcemia with persistent PTH elevation; persistent hypercalcemia was observed in 11.1% (4/36). At 12 months (n=31), normocalcemia was maintained in 83.9% (26/31), with complete biochemical response in 74.2% (23/31).

Ultrasound follow-up at 12 months (n=24) showed a mean adenoma volume reduction of 81%.

Transient dysphonia occurred in 6.8% and transient hypocalcemia in 4.5%. No permanent complications were recorded.

Conclusions In this real-world cohort of patients with PHPT who were not candidates for or declined surgery, RFA was associated with high rates of normocalcemia, effective biochemical control, significant adenoma volume reduction, and a favorable safety profile. RFA may represent a valuable minimally invasive option in carefully selected patients, particularly those at high surgical risk.

CARE GAPS IN HYPOPARATHYROIDISM: PRELIMINARY BASELINE DATA FROM THE HIPOPARARED REGISTRY

M. B. Zanchetta[1], A. Campos Martinez[1], N. Schwartz[2], C. Edber[2], E. Giacoia[3], F. Croce[1], C. Ballarino[4], G. Velez[4]

[1]Institute of Medical Research, Buenos Aires, Argentina; [2]General Acute Hospital "T. Alvarez", Buenos Aires, Argentina; [3]National Hospital "Alejandro Posadas", Buenos Aires, Argentina; [4]Central Military Hospital, Buenos Aires, Argentina

Objective: To describe the preliminary baseline results of a prospective observational registry of patients with hypoparathyroidism in Argentina, and to analyze how many patients would meet the criteria for treatment with PTH according to recent European guidelines[1].

Materials and methods: Adult patients with chronic hypoparathyroidism were enrolled in the prospective observational registry, recruited through a dedicated online platform, and included from multiple healthcare centers across Argentina. Baseline etiology, clinical characteristics, symptom burden, long-term complications, and biochemical parameters were evaluated.

Results: A total of 183 patients were included: 166 women (90.2%) and 17 men (9.8%). The most frequent cause was postsurgical (163/183; 89.1%), with total thyroidectomy for thyroid cancer as the main indication (82/163; 50.3%). Among non-surgical cases (20/183; 10.9%), most were classified as idiopathic or autoimmune. The cohort's mean age was 55 years (range 22–87), with a mean age at diagnosis of 44 years, a mean body mass index (BMI) of 27.8 kg/m², and a mean disease duration of 11.2 ± 8.7 years (median: 9 years). Baseline serum calcium at entry was low-normal (mean 8.37 mg/dL); however, 89 patients (48.6%) had hypocalcemia, and 103 (56.6%) had hyperphosphatemia (mean phosphorus: 4.69 mg/dL). Urinary calcium excretion was assessed in 96 patients, with 18 (18.7%) showing hypercalciuria. Hospitalization was required in 26% of patients, primarily due to hypocalcemia. Sixty-six patients (36.1%) reported at least one complication—renal, cardiovascular, ophthalmologic, and/or neurologic—which were more prevalent among those with disease duration >10 years (44/109, 40%). Although a trend toward a greater burden of complications with longer disease duration was observed, this finding did not reach statistical significance (p = 0.40). According to current international guidelines, 70% of patients (133/183) would meet criteria for PTH treatment. However, 14 patients (7.7%) were receiving off-label PTH (1–34). Palopegteriparatide is not yet available in Argentina.

Conclusions: Our findings are consistent with those reported in other cohorts. A significant care gap was identified, with patients commonly experiencing hypocalcemia, hyperphosphatemia, and other long-term complications. A high proportion of patients would meet international criteria for PTH replacement therapy[1]. This first preliminary report provides relevant data to better understand current therapeutic management and to inform future improvements in care.

P997

EFFECT OF FOUR-WEEK TRAINING SESSION IN NORMOBARIC HYPOXIA ON BONE MINERALISATION INDICES AMONG WOMEN AGED 50-59 YEARS

M. Bagińska[1], M. Morawska-Tota[2], T. Pałka[3], L. Tota[3]

[1]University of Physical Culture in Krakow, Institute of Sport Sciences, Department of Water Sports, Krakow , Poland; [2]University of Physical Culture in Krakow, Institute of Biomedical Sciences, Department of Sports Medicine and Human Nutrition, Krakow , Poland; [3]University of Physical Culture in Krakow, Institute of Biomedical Sciences, Department of Physiology and Biochemistry, Krakow , Poland

Objective

The study aim was to assess the effect of training in normobaric hypoxia on bone mineral density among women aged 50-59 years.

Material and methods

The study group included 57 women aged 50-59 years, who were randomly assigned to one of four groups: HT (n=15, training in normobaric hypoxia), NT (n=13, training in normoxia), B (n=15, passive exposure to normobaric hypoxia), and C (n=14, control group). The intervention comprised 4 weeks of progressive training, performed three times a week, for 60 minutes. The exercise intensity was individualised based on maximum heart rate (HRmax). Each session combined endurance training on a cycle ergometer with resistance training using resistance bands. The simulated altitude was 2,500 m a.s.l. in the HT and B groups, and 223 m a.s.l. in the NT group. The baseline and final values of the following indices: bone mineral content (BMC), bone mineral density (BMD), T-score and Z-score, were determined using Dual Energy X-ray Absorptiometry (DEXA).

Results

Repeated measures ANOVA did not reveal any significant main or interaction effects for any of the analysed bone mineralisation indices. For both BMC and BMD, there was no effect of training condition ($p = 0.937$ and $p = 0.781$), timing of measurement ($p = 0.842$ and $p = 0.298$), or condition × timing of measurement interaction ($p = 0.964$ and $p = 0.601$). Similarly, T- and Z-scores did not change significantly with the intervention; no significant differences were observed for either main effects ($p = 0.748$ and $p = 0.757$, respectively) or interactions (T-score: $p = 0.439$; Z-score: $p = 0.265$).

Conclusion

The planned intervention did not allow us to consider high-altitude conditions or endurance and resistance training in such conditions as an effective approach to osteoporosis prevention. Repeating the protocol at higher altitudes and/or with a longer exposure duration could be contemplated.

P998

STUDY OF BONE ARCHITECTURE IN LUNG TRANSPLANT RECIPIENTS

M. Pascual[1], A. Cabrera[1], N. Boix[1], M. Barceló[1]

[1]Vall d'Hebron University Hospital, Barcelona, Spain

Objectives

To evaluate bone microarchitecture in lung transplant (LT) recipients, analyze post-transplant changes, and assess their relationship with fractures.

Methods

Ambispective study including LT recipients evaluated at Hospital Universitari Vall d'Hebron between 2022 and 2026. Bone mineral density (BMD) was assessed by DXA, bone microarchitecture by trabecular bone score (TBS), and vertebral fractures by dorsolumbar radiography before and within the first year after transplantation.

Results

Seventy-five patients were analyzed (mean age 58.4 ± 9.8 years; 63% men). At follow-up (17.3 ± 8.2 months), 36% had osteoporosis and 40% osteopenia. TBS was normal in 42.7%, partially degraded in 34.7%, and degraded in 20%. A significant decrease was observed only in femoral neck BMD (−3.8%, p<0.001).

Seventy-one patients received anti-osteoporotic treatment, which was associated with higher BMD at all skeletal sites, without significant effects on TBS or post-transplant changes.

Nine patients developed post-transplant fractures, mainly vertebral. Fractured patients showed significantly lower BMD at all sites and lower TBS. Lumbar spine BMD and T-score at follow-up were the best fracture predictors (AUC 0.830 and 0.835). No association was found between glucocorticoid exposure and BMD, TBS, or fractures.

Table 1. Association of Postransplant BMD and TBS with fractures and ROC curve analysis.

	ALL (N=75)	FRACTURED (N=9)	NON-FRACTURED (N=66)	p	AUC (ROC)
BMD (mean (SD))					
. L1-L4 (g/cm²)	1.072 (0.2)	0.869 (0.2)	1.100 (0.2)	**0.001**	**0.830**
. T-score LS	-1.11 (1.6)	- 2.74 (1.2)	-0.89 (1.5)	**0.001**	**0.835**
. Femoral neck(g/cm²)	0.833(0.2)	0.722 (0.1)	0.849 (0.2)	**0.021**	0.743
. T-score FN	-1.62 (1.2)	-2.40 (0.9)	-1.51 (1.2)	**0.032**	0.726
. Total hip(g/cm²)	0.872 (0.2)	0.760 (0.1)	0.888 (0.2)	**0.023**	0.753
T-score TH	-1.47 (1.2)	-2.24 (1.1)	-1.36 (1.1)	**0.033**	0.734
BMD change(%)					
. L1-L4	1.11 (8.8)	-1.94 (10.7)	1.53 (8.5)	0.270	0.562
. Femoral neck	-3.81 (6.0)	-7.28 (4.1)	-3.34 (6.1)	0.067	0.727
. Total hip	-2.60 (5.5)	-4.12 (3.4)	-2.40 (5.7)	0.381	0.609
TBS	1.308 (0.1)	1.188 (0.1)	1.325 (0.1)	**0.003**	0.772
TBS change(%)	1.80 (11.0)	0.65 (10.7)	1.96 (11.1)	0.742	0.530

SD: standard deviation, BMD: bone mineral density, LS: lumbar spine FN: femoral neck, TH: total hip TBS: trabecular bone score

Conclusions

Altered bone microarchitecture is frequent in lung transplant recipients. Despite improvements in BMD with anti-osteoporotic therapy, TBS continues to deteriorate post-transplant. Lumbar spine BMD at follow-up is the most reliable predictor of post-transplant fractures, whereas femoral BMD and TBS changes have limited predictive value. Glucocorticoid exposure was not associated with fracture risk or TBS impairment.

P999

DIAGNOSTIC PERFORMANCE OF AI-SUPPORTED OPPORTUNISTIC DETECTION OF OSTEOPOROTIC VERTEBRAL FRACTURES ON ROUTINE CT SCANS

M. Behanova[1,4], A. Sokhan[1,4], J. Judith[1], S. Zandieh[2], C. H. Salzlechner[3], R. Ljuhar[3], J. Zwerina[1], R. Kocijan[1,4]

[1]Ludwig Boltzmann Institute of Osteology at the Hanusch Hospital of OEGK and AUVA Trauma Centre Meidling, 1st Medical Department, Hanusch Hospital, Vienna, Austria; [2]Department for Radiology and Nuclear Medicine at Hanusch hospital of OEGK, Hanusch Hospital, Vienna, Austria; [3]Department for Research and Development, IB Lab GmbH, Vienna, Austria; [4]Sigmund Freud University Vienna, School of Medicine, Metabolic Bone Diseases Unit, Vienna, Austria

Objectives

Only about 15% of osteoporotic vertebral fractures (VFs) are identified by radiologists in routine computed tomography scans (CT) performed for non-spinal indications. Missed VFs represent a critical diagnostic gap in osteoporosis care. Contributing factors may include high reporting workload, the need for a quick conclusion due to the patient's acute condition, and limited awareness of the prognostic importance of early VFs detection. Artificial intelligence (AI) offers a promising approach to addressing this gap by enabling opportunistic VF detection on routine CT scans.

Material and Methods

We conducted a monocentric, retrospective cross-sectional study at Hanusch hospital (Vienna, Austria) in collaboration with Image Biopsy Lab to evaluate the diagnostic performance of the AI-based software (IB Lab Flamingo) in identifying VFs on CT, using radiologist assessment as the reference standard. Sensitivity, specificity, and accuracy were calculated at the vertebra and patient level.

AI-identified false-positive findings were re-evaluated by radiologists to assess whether they represented overlooked fractures.

Results

Among 205 patients (59% male; mean age 67.9 ± 9.5 years), VFs were initially identified in 11.2% by the radiologist. The AI-software analyzed 190 patients (92.7%), detecting fractures in 24.7%. At the patient level, IB Lab Flamingo showed 81% accuracy, 74% sensitivity and 82% specificity. Vertebra-level performance (N = 3040) demonstrated high accuracy (97%) and specificity (97%). Upon radiologist re-evaluation, fractures were confirmed in 29 of 30 AI-positively flagged patients, increasing sensitivity to 88.5%, specificity to 99.3%, and the overall prevalence of VFs to 25%.

Conclusion

The AI-based IB Lab Flamingo software demonstrated high diagnostic performance in detecting VFs and can markedly increase the detection of vertebral fractures, addressing a persistent diagnostic gap. AI-enhanced diagnostic solutions can reduce the workload on radiologists, enable timely treatment of osteoporosis and secondary prevention of fractures, and improve patient treatment outcomes.

PHYSICAL ACTIVITY AND DAILY FUNCTIONING AND SELF-RATED HEALTH IN OLDER ADULTS

M. Berwecka[1], A. Spannbauer[2], A. Berwecki[3], B. Stach[4]

[1]Jagiellonian University Medical College, Faculty of Health Sciences, Institute of Physiotherapy, Rehabilitation Clinic, Kraków, Poland; [2]Jagiellonian University Medical College, Faculty of Health Sciences, Institute of Physiotherapy, Surgical Clinic St. John the Great Hospital (Order of the Brothers of Mercy) in Krakow, Kraków, Poland; [3]University of Physical Culture in Krakow, Faculty of Rehabilitation, Faculty of Rehabilitation, Department of Kinesiotherapy St. John the Great Hospital (Order of the Brothers of Mercy) in Krakow, Kraków, Poland; [4]Jagiellonian University Medical College, Faculty of Health Sciences, Institute of Physiotherapy, Physiotherapy Department, Kraków, Poland

Objectives

To assess the association between regular physical activity and daily functioning, pain intensity, and self-rated health in older adults.

Material and Methods

The study included 100 participants aged ≥50 years, divided into two groups. The study group consisted of 52 individuals regularly training swimming, while the control group included 48 physically inactive individuals. The mean age of participants was 63.0 ± 7.3 years in the physically active group and 63.0 ± 5.7 years in the control group. Data was collected using an original questionnaire, the Visual Analogue Scale (VAS) for pain intensity, and the WHOQOL-BREF questionnaire for self-rated health. Statistical analysis was performed using non-parametric tests, with statistical significance set at $p < 0.05$.

Results

Self-rated health was significantly higher in the physically active group compared with the control group (mean ± SD: 3.88 ± 0.67 vs. 3.25 ± 0.75; $p < 0.001$). Mean pain intensity assessed using the VAS was significantly lower in physically active participants than in controls (1.92 ± 2.51 vs. 3.00 ± 2.79; $p = 0.045$). In the physically active group, pain was most frequently associated with bending (32.69%), whereas in the control group it was most often related to lifting heavy objects (33.33%). A moderate negative correlation between pain intensity and self-rated health was observed among physically active participants ($\rho = -0.39$; $p = 0.004$).

Conclusions

Regular physical activity is associated with better self-rated health and lower pain intensity in older adults. These findings support the role of physical activity in maintaining daily functioning and functional independence in later life.

Table 1. Pain intensity and self-rated health in study groups

Variable	Physically active group (n = 52) mean ± SD	Control group (n = 48) mean ± SD	*p value*
Pain intensity (VAS)	1.92 ± 2.51	3.00 ± 2.79	0.045
Self-rated health (WHOQOL-BREF item)	3.88 ± 0.67	3.25 ± 0.75	< 0.001

VAS – Visual Analogue Scale; WHOQOL-BREF – World Health Organization Quality of Life Questionnaire (short version)

P1001

OCCUPATIONAL DETERMINANTS OF LOW BACK PAIN AMONG MANUAL WORKERS: A COMPARISON OF CONSTRUCTION WORKERS AND SHOP ASSISTANTS

M. Berwecka[1], B. Latała[1], A. Berwecki[2], M. Jekiełek[3]

[1]Jagiellonian University Medical College, Faculty of Health Sciences, Institute of Physiotherapy, Rehabilitation Clinic, Kraków, Poland; [2]University of Physical Culture in Krakow, Faculty of Rehabilitation, Faculty of Rehabilitation, Department of Kinesiotherapy St. John the Great Hospital (Order of the Brothers of Mercy) in Krakow, Kraków, Poland; [3]Jagiellonian University Medical College, Faculty of Health Sciences, Institute of Physiotherapy, Department of Physiotherapy, Kraków, Poland

Objectives The aim of the study was to evaluate the prevalence and occupational determinants of low back pain among manual workers, with particular emphasis on work ergonomics, work posture, work seniority, and physical activity.

Material and Methods The study included 120 manual workers aged 24–60 years, comprising 60 construction workers and 60 shop assistants. Data was collected using an original questionnaire consisting of 31 items addressing job characteristics, work posture, adherence to ergonomic principles, physical activity, and the occurrence of low back pain. Statistical analysis was performed to assess associations between occupational factors and the prevalence of low back pain, with statistical significance set at $p < 0.05$.

Results Low back pain was reported more frequently by construction workers (73%) than shop assistants (65%), although this difference was not statistically significant ($p = 0.322$). Among shop assistants, work seniority was not significantly associated with pain prevalence ($p = 0.1218$). In contrast, among construction workers, longer work seniority was significantly associated with a higher prevalence of low back pain ($p = 0.0001$).

Failure to adhere to ergonomic principles was strongly associated with pain occurrence, affecting 89% of construction workers and 97% of shop assistants. Work posture and the physical demands of work had a statistically significant impact on pain prevalence ($p < 0.001$). Low back pain was most frequently reported by shop assistants working in a forward-bent standing position (53%), whereas among construction workers it was most common in those working in kneeling or squatting positions (59%). Notably, low back pain was reported by all participants who did not engage in any form of physical activity

Conclusion Work ergonomics, work posture, and physical activity are key determinants of low back pain among manual workers. In contrast, occupation type and work seniority among shop assistants were not

significantly associated with pain prevalence. These findings underscore the importance of ergonomic interventions and regular physical activity in the prevention of occupational low back pain.

P1002

ASSOCIATION OF HBA1C WITH BONE HEALTH IN OLDER ADULTS WITH HIP FRAGILITY FRACTURES IN MALTA.

M. N. Hudson[1], M. Bonnici[2,3,4]

[1]Department of Medicine, Mater Dei Hospital, Msida, Malta; [2]Department of Geriatric Medicine, Mater Dei Hospital, Msida , Malta; [3]Department of Geriatric Medicine, Karin Grech Rehabilitation Hospital, Pieta , Malta; [4]Department of Geriatric Medicine, St. Vincent De Paul, Hal Luqa, Malta

Diabetes mellitus is a growing public health concern in Malta, with 48 thousand adults aged 20–79 years suffering from diabetes in 2024. This number has been projected to increase to 60.1 thousand by 2050 (1).
Objectives
In the Maltese older adult population, diabetes is therefore, not uncommon. The association of glycemic control, as measured by glycated haemoglobin (HbA1c), and bone health, assessed using hip bone mineral density (BMD) and hip T-score, warrants further exploration.
Materials and Methods:
A cross-sectional observational study was conducted among 97 older adults aged over 60 years with hip fragility fractures attending fragility fracture clinics in Malta. Data was collected retrospectively using anonymised clinic documentation. Demographic characteristics were recorded together with measures of bone health; Hip BMD and Hip T-score. Thirteen potential predictors and confounding variables were also collected. Separate general linear models were fitted to relate hip BMD and hip T-score with the explanatory variables, including HbA1c. A backward elimination approach was applied to find the parsimonious model by excluding weak predictors and retaining significant ones.
Results:
Significant predictors of hip BMD included creatinine clearance, HBA1c, and BMI assuming a 0.1 level of significance. Significant predictors of hip T-score included BMI and HBA1c at the same significance threshold. Parameter estimates were carried out and a negative correlation was noted between HbA1c and both BMD and T-score.
Conclusions:
In this cohort of older adults with hip fragility fractures, HbA1c was a significant predictor of bone health, demonstrating a negative correlation with both hip BMD and T-score. These findings contrast with the described "diabetes bone paradox", where individuals with type 2 diabetes mellitus have an increased risk of fractures despite preserved or higher BMD (2). This suggests that poorer glycaemic control may adversely affect bone health in this high risk population and underscores the importance of considering glycaemic status in the assessment and management of fracture risk in older adults with diabetes.

PAIN IN ELDERLY PATIENTS WITH KNEE OSTEOARTHRITIS: ASSESSMENT AND IMPACT

H. Riahi[1], H. Bettaieb[1], M. Boudokhane[1], R. Bourguiba[1], W. Helali[1], C. Besrour[1], S. Bellakhal[1], M. H. Doggui[1]

[1]Internal Security Forces Hospital, La Marsa, Tunisia

Background

Knee osteoarthritis (KOA) is a common degenerative osteoarticular condition in the elderly, and represents a major cause of chronic pain and functional disability. The aim of this study was to assess pain and its impact in the geriatric population and to identify factors associated with moderate to severe pain.
Methods

A cross-sectional study was conducted including patients aged 65 years and older with a confirmed diagnosis of knee osteoarthritis. Pain and functional status were assessed using three validated instruments: The Visual Analog Scale (VAS), the Lequesne Algofunctional Index (AFI) and the Knee Injury and Osteoarthritis Outcome Score-12 (KOOS-12). Our patients were divided into two groups according to VAS scores: G1: patients with mild pain (VAS<40mm) and G2:patients with moderate to severe pain (VAS≥40mm).
Results

Fifty-two patients (40 women and 12 men) were included, with a mean age of 70.2 ± 4.4 years. The median duration of KOA was 10.1 [1–30] years. Knee pain was the main presenting symptom in 85% of patients, and symptoms were bilateral in 72% of cases. The mean VAS pain score was 60.9±21.4mm [20,90mm]. Moderate to severe pain was reported by 79% of patients. Patients aged 75 years and older had significantly higher VAS scores than those under 75 years (75±8.3mm vs 59.1±22mm, p=0.004). The mean AFI pain subscale score was 3.42 ± 2 [0-8], with a statistically significant difference between genders,women reporting higher pain levels than men (3.73 ± 2.0 vs 2.42 ± 1.7; p = 0.048). The mean KOOS-12 pain subscale score was 57.4 ± 20.0 [18.8–100], with no significant difference between genders.
Regarding the groups, patients in G2 showed higher body weight (84.4±14.4 kg vs 75.3±7 kg, p=0.05), higher AFI scores (13.4±3.6 vs 6.5±3.2, p<0.001) and its subscales "Walking Distance" (3.4±1.7 vs 1.5±1.2, p=0.003) and "Activities of Daily Living" (5.9±1 vs 3.9±1.3, p<0.001), as well as lower KOOS-12 scores (44.5±15.2 vs 74±18.9, p<0.001) , particularly in the "Function" (44.2±17.4 vs 76.1±21.6, p<0.001) and "Quality of Life" subscales (37±16.4 vs 70±24, p=0.001) compared with G1 with statistically significant differences.
Conclusions
Knee pain is a common reason for consultation and it can be especially severe in the elderly, affecting activities of daily living and quality of life. Appropriate management is therefore essential.

P1004

PRAYER PRACTICES AMONG ELDERLY PATIENTS WITH KNEE OSTEOARTHRITIS

H. Bettaieb[1], H. Riahi[1], M. Boudokhane[1], W. Helali[1], R. Bourguiba[1], C. Besrour[1], M. H. Doggui[1], S. Bellakhal[1]

[1]Internal Security Forces Hospital, La Marsa, Tunisia

Background

Knee osteoarthritis (KOA) is a common degenerative joint disease, particularly prevalent among the elderly. It can significantly affect activities of daily living, including religious practices such as prayer. The aim of this study was to evaluate the impact of knee osteoarthritis on prayer practices in elderly patients.

Methods

A cross-sectional study was conducted including patients aged 65 years and older with a confirmed diagnosis of knee osteoarthritis. Pain and functional status were assessed using three validated instruments: the Visual Analog Scale (VAS), the Lequesne Algofunctional Index (AFI), and the Knee Injury and Osteoarthritis Outcome Score-12 (KOOS-12).

To assess the impact of KOA on the practice of prayer among elderly individuals, a simple six-item questionnaire was designed. Patients were asked whether they perform prayer, the duration of their practice in years, the position adopted during prayer, the number of bowing movements (Rukū) performed per day, and whether they experience pain during bowing and prostration (Sujūd).

Results

A total of 52 patients (40 women and 12 men) were included, with a mean age of 70.2 ± 4.4 years. The median duration of KOA was 10.6 years [1–30]. Knee pain was the main presenting symptom in 85% of patients, and symptoms were bilateral in 72% of cases.

Fifty-one patients reported performing prayer. Among them, 90.2% adopted a seated position during prayer. The mean number of bowing movements per day was 19.57 ± 2.6 [17–29]. Knee pain was reported by 25.5% of participants during bowing and by 96% during prostration.

The adoption of a seated position during prayer was significantly associated with female gender with 97% of women using this position compared to 66.7% of men (p = 0.009). It was also associated with higher body mass index (32±6.1 kg/m² vs 26±3 kg/m², p=0.039), larger waist circumference (108.1±14.2 cm vs 98.6±4.6 cm, p=0.006), more severe pain assessed by VAS (63.2±20.5 mm vs 36±13.4 mm, p=0,006), higher AFI score (12.6±4 vs 4.8±1.9, p<0.001), and lower KOOS-12 score (48.8±18.9 vs 73.3±16.3 , p=0.008).

Conclusions

Knee pain is a common reason for medical consultation and can be particularly severe in the elderly, affecting activities of daily living, including meaningful routines such as the practice of prayer. Knee osteoarthritis specifically impacts prayer practices, with most patients adopting a seated position to reduce discomfort, particularly women and individuals with obesity.Appropriate management is therefore essential to maintain both mobility and participation in these important daily activities.

P1005

REAL-WORLD PATTERNS OF OSTEOANABOLIC THERAPY AFTER FRAGILITY FRACTURE: PATIENT PROFILES AND TREATMENT SEQUENCING IN A TERTIARY ORTHOPAEDIC CENTRE

D. González-Quevedo[1], M. Bravo-Bardají[1], J. M. Sánchez-Siles[1], E. Díaz-Gálvez[1], D. García-de-Quevedo[1], I. Tamimi[1]

[1]Hospital Regional Universitario de Málaga, Málaga, Spain

• **Objectives:**

To describe the use of osteoanabolic therapies after fragility fracture in routine clinical practice and to characterize patient profiles, previous anti-osteoporotic treatment and subsequent sequential treatment strategies.

• **Material and methods:**

We conducted an observational, descriptive study including consecutive patients treated with osteoanabolic therapy following a recent fragility fracture in a tertiary care centre. Demographic data, comorbidities, fracture history, bone mineral density, laboratory parameters, previous anti-osteoporotic treatment, time to treatment initiation, adherence, adverse events, mortality, subsequent fractures and post-treatment sequential therapy were recorded. Analyses were purely descriptive.

• **Results:**

A total of 117 patients were included (mean age 77.9 ± 10.2 years; 98% women); 86 received abaloparatide and 31 romosozumab. Patients treated with abaloparatide were older and had a higher comorbidity burden (mean age 80.9 vs 69.8 years; ASA 3.0 vs 2.2), whereas those receiving romosozumab presented with more severe baseline osteoporosis based on densitometric values. Previous anti-osteoporotic treatment was common (63% overall) and was more frequent among patients treated with romosozumab (87% vs 62%). Time from index fracture to initiation of osteoanabolic therapy showed wide variability. Adherence to osteoanabolic treatment was high (>94%), adverse events were infrequent (<6%) and predominantly mild. Following completion of osteoanabolic therapy, most patients were transitioned to antiresorptive treatment, mainly oral bisphosphonates or denosumab.

• **Conclusions:**

In routine clinical practice, osteoanabolic therapies are prescribed to patients with distinct clinical profiles after fragility fracture. Previous anti-osteoporotic treatment is frequent, and sequential therapy with antiresorptive drugs is commonly implemented. Despite advanced age, frailty and a high comorbidity burden, osteoanabolic therapies were generally well tolerated, with a low incidence of mostly mild adverse events. These findings provide real-world context on osteoanabolic treatment pathways after fragility fracture.

P1006

TEMPORAL TRENDS IN CARE PROCESSES, OUTCOMES AND SECONDARY FRACTURE PREVENTION AFTER HIP FRACTURE: A REGISTRY-BASED COHORT STUDY (2018–2024)

D. González-Quevedo[1], M. Bravo-Bardají[1], J. M. Sánchez-Siles[1], E. Díaz-Gálvez[1], D. García-de-Quevedo[1], I. Tamimi[1]

[1]Hospital Regional Universitario de Málaga, Málaga, Spain

• **Objectives:**

To analyse year-by-year temporal trends in care processes, early outcomes, functional recovery and secondary fracture prevention after hip fracture between 2018 and 2024.

• **Material and Methods:**

We conducted an observational cohort study including consecutive patients admitted with hip fracture between 2018 and 2024 in a regional tertiary care hospital. Data were obtained from a prospectively maintained institutional hip fracture registry, with systematic data submission to the Spanish National Hip Fracture Registry. Demographic characteristics, fracture type, surgical delay, length of stay, mortality, mobility and residence at 30 days, and osteoporosis treatment initiation at 30 and 120 days were recorded. Temporal trends were analysed using appropriate trend tests for proportions and continuous variables.

• **Results:**

A total of 2,624 patients were included (mean age 83.2 years; 74.6% women). Patient characteristics remained stable throughout the study period. The proportion of patients undergoing surgery within 48 hours declined significantly over time, particularly after the COVID-19 pandemic, from 73.4% in 2018 to 47.2% in 2024 (p for trend <0.001).
Despite this, early outcomes improved. Thirty-day mortality decreased significantly across the study period (from 8.0% in 2018 to 4.1% in 2024; p for trend =0.003). Recovery of ambulation at 30 days also improved over time (p for trend <0.001); however, among patients who were ambulatory before fracture, 70.0% had not recovered their previous ambulatory status at 30 days. In addition, 10.3% of patients who lived at home before fracture had not returned to their previous place of residence at 30 days. Osteoporosis treatment initiation at 30 days declined in recent years; however, treatment uptake at 120 days increased significantly in the post-COVID period (p for trend =0.006), suggesting a delay rather than a loss of secondary fracture prevention.

• **Conclusions:**

In this large registry-based cohort, early mortality and functional outcomes after hip fracture improved significantly over time, particularly in the post-COVID period, despite less favourable trends in surgical timing. Nevertheless, a substantial proportion of patients did not recover ambulation or residential autonomy at 30 days, showing the persistent functional impact of hip fracture. Secondary fracture prevention was largely maintained at mid-term follow-up, although treatment initiation tended to be delayed. These findings highlight the importance of interpreting care process indicators alongside clinical and functional outcomes in hip fracture care.

P1007

REGIONAL ADIPOSITY AND FRACTURE RISK IN INFLAMMATORY BOWEL DISEASE: DIFFERENTIAL EFFECTS OF GLUCOCORTICOID EXPOSURE

W. Donlon[1], H. Amin[2], M. Bukhari[1]

[1]University Hospitals of Morecambe Bay NHS Foundation Trust, Lancaster, United Kingdom, Lancaster, United Kingdom; [2]Lancaster University Medical School, Lancaster, United Kingdom, Lancaster, United Kingdom

Objectives
Patients with Inflammatory Bowel Disease (IBD) are at higher risk of osteoporosis and fractures, potentially mediated by inflammation, body composition changes and glucocorticoid (GC) use. We tested whether regional adiposity predicts fracture risk in IBD and how this is affected by GC exposure.
Materials and Methods
All patients with IBD referred to a regional DEXA scanner in Northern England between 2004 and 2019 were included, stratified by current/previous GC use. Logistic regression analyses were conducted for hip fractures and other major osteoporotic fractures (forearm, spine, humerus) respectively, using DEXA-derived Abdominal Fat Percentage (AFP) and Average Hip Fat Percentage (AHFP) as predictors. Results were adjusted for all FRAX® risk factors.
Results
The study included 1,302 patients including 266 males (20.4%). Mean age was 66.2 years (SD 9.7) and mean BMI 27.6 kg/m² (SD 5.8); 753 (57.8%) had GC exposure. Hip fractures occurred in 65 (5.0%) and other major fractures in 339 (26.0%). Logistic regression outputs are shown in Table 1.

Table 1: Odds Ratio (95% Confidence Interval) for Fracture Type and Regional Body Fat Percentage
Key: (*p<0.05, **p<0.01 ***p<0.001)

	Hip Fractures		Other Major Fractures	
	Abdominal Fat %	Avg Hip Fat %	Abdominal Fat %	Avg Hip Fat %
GC Exposure	0.98 (0.92, 1.03)	1.02 (0.94, 1.10)	*** 0.95 (0.92, 0.98)	1.03 (0.99, 1.08)
No GC Exposure	1.03 (0.98, 1.09)	1.02 (0.93, 1.11)	0.99 (0.96, 1.02)	1.03 (0.98, 1.08)

Conclusion
We found a significant inverse association between non-hip major fractures and AFP only in GC-exposed patients, with no relationship between fractures and AHFP. There was no relationship between hip fractures and AFP or AHFP. Our study demonstrates novel relationships between regional adiposity and fracture risk in IBD that are GC-dependent. Further research is needed to fully understand the role of regional adiposity in IBD fracture risk.

UK ADULT REFERENCE CURVES FOR TRABECULAR BONE SCORE (TBS OSTEO V4)

M. G. Swainson[1], K. Hind[2,3], M. Davies[3], A. Walstra[3], D. Hans[3,4], M. Bukhari[5]

[1]Faculty of Health and Medicine, Lancaster University, UK, Lancaster, United Kingdom; [2]Faculty of Health and Medicine, Lancaster University, Lancaster, UK, Lancaster, United Kingdom; [3]Medimaps Group SA, Geneva, Switzerland; [4]Interdisciplinary Centre of Bone Diseases, Bone and Joint Department, Lausanne University Hospital (CHUV) & University of Lausanne, Switzerland, Lausanne, Switzerland; [5]Royal Lancaster Infirmary, University Hospitals Morecambe Bay Trust, Lancaster, United Kingdom

Trabecular bone score (TBS) is a validated index of bone microarchitecture that can identify more people at risk of fragility fractures than DXA bone mineral density alone. The provision of TBS reference data can support greater clinical utility, but no such data are currently available in the UK.
Objective: To produce the first UK-specific reference curves for TBS in males and females, and using the latest software version, TBS Osteo Advanced (version 4).
Material and Methods: The reference group was from an NHS Trust DXA clinic in Northwest England with scans performed between 2001 and 2024. Lumbar spine L1-L4 scan data were analysed to obtain TBS (TBS iNsight version 4.0 software, Medimaps Group, Switzerland), accounting for soft tissue thickness. TBS reference curves were fitted with the LMS method (*gamlss* package in R, RStudio) to generate age-specific values for males and females with the 50th centile (median) as the reference curve.
Results: 3496 patients (2808 women, 688 men, mean age 68y [22-98y], 99% white, mean BMI 26.7kg/m^2) were included in the study. TBS decreased with age, with marked reduction in women 50-65y, corresponding to the postmenopausal period. In women, median values decreased from a normal TBS (>1.31) at earliest DXA scan to degraded TBS on average (<1.23) at age 80y. In men, median TBS values remained within normal range (>1.31) in the third and fourth decades, but unlike women, TBS did not, on average, reach the degraded range in older age groups (eighth and ninth decades). Age- and sex-specific TBS reference ranges are presented as the 5th, 10th, 25th, 50th, 75th, 90th, and 95th centiles for women and men.
Conclusion: These UK-based TBS v4 reference data enable age- and sex-specific interpretation of TBS, providing assessment of bone microarchitecture in routine practice that may support wider clinical uptake of TBS, demonstrating its capacity to characterise differences in bone microarchitecture between men and women with ageing. By providing population-relevant centiles across the adult lifespan, these data facilitate contextualisation of individual patient results, and complement BMD derived from DXA, without additional patient burden.

P1009

OSTEOGENESIS IMPERFECTA: VARIABLE PHENOTYPIC EXPRESSION IN MEMBERS OF A FAMILY

M. C. Balonga[1], E. C. Authier Cipolla[1], J. I. Zarragoicoechea[1], E. Giacoia[1]

[1]Hospital Nacional Profesor Alejandro Posadas, Buenos Aires , Argentina

Osteogenesis imperfecta (OI) comprises a group of rare connective tissue disorders characterized primarily by increased bone fragility leading to multiple fractures, bone deformity, and disability. Its incidence is estimated at between 1/10,000 and 1/20,000 live births. Clinical severity is variable, with different impacts on quality of life, mobility, and independence. Patients may present with skeletal and extra-skeletal manifestations, including blue sclerae, dentinogenesis imperfecta, hearing loss, and valvular heart disease.[1,2]
Most cases are due to structural or quantitative mutations in the genes encoding type I collagen (COL1A1 and COL1A2). However, up to 25% are associated with alterations in other genes involved in collagen biosynthesis, osteoblast differentiation, or bone mineralization.[1,2]
Diagnosis is clinical and can be confirmed by genetic testing when available. In 1979, Sillence et al. proposed a clinical classification based on specific phenotypes (types I to IV)[3]. With advances in molecular biology and genetic analysis, this classification has been expanded to recognize greater genotypic and phenotypic diversity.
OBJECTIVES: Describe the phenotypic, biochemical, and densitometric characteristics of four patients diagnosed with OI who belong to the same family.
MATERIALS AND METHODS: This was an observational, descriptive, cross-sectional study based on data collected from the electronic medical records of four patients diagnosed with OI who belong to the same family.
RESULTS: A family with a clinical diagnosis of OI is presented, consisting of four members: a 42-year-old mother, two 19-year-old male twins, and a 22-year-old son. The phenotypic characteristics of the four family members are detailed in **Table 1**. All were diagnosed at an early age and suffered multiple fractures throughout their lives. Bone densitometry (Lunar DPX scanner) revealed low bone mass, with greater involvement in the members recently diagnosed with celiac disease. Biochemical evaluation of calcium and phosphorus metabolism showed elevated bone alkaline phosphatase levels in three members (>20 U/L) and vitamin D levels <30 ng/mL. To date, none of the patients have received treatment with antiresorptive or anabolic drugs. Gastroenterology and nutrition evaluations were requested due to celiac disease. Normal levels of calcium, phosphorus, magnesium, PTH, and CTX (<0.5 ng/ml) were found in all four members, and hypogonadism was ruled out. They are currently being followed up and treated with vitamin D in conjunction with dietary and physical activity guidelines. None of them experienced fractures in the last two years.
Table 1.

	Age	Weight Kg	Height Cm	Phenotype OI	Blue sclerae	Fractures	Hearing loss	Dentino-genesis imperfecta	Bone densitometry	Comorbidities
Mother	42	75	150	I	Yes	Wrist Vertebral Clavicle phalanges	Yes	No	LS Z-s -3.1 TH Z-s -0.9	Celiac disease Arterial hypertension
Eldest Son	22	59	162	I	Yes	Ribs Metacarpal metatarsal	No	Yes	LS Z-s -3.4 TH Z-s -2.4	Celiac disease
Twin 1	19	53	163	I	Yes	Tibia Metatarsal Wrist Humerus	Yes	Yes	LS Z-s -1.7 TH Z-s -2.6	Clubfoot Esophageal atresia Genu varum
Twin 2	19	66	172	I	Yes	Olecranon Humerus Metacarpal	No	Yes	LS Z-s -2.4 TH Z-s -2.2	No

LS:Lumbar spine; TH:Total Hip; Z-s: Z-scores

CONCLUSIONS: OI is a rare and heterogeneous condition and should be considered in the differential diagnosis of adult patients with multiple fractures and extra-skeletal manifestations. The knowledge gained from experience, the appropriate transition from childhood to adulthood, and early referral to a specialist are fundamental for multidisciplinary care and improving patients' quality of life. Genetic diagnosis is of great importance for establishing a genotype-phenotype correlation and providing genetic counseling to patients of reproductive age.

BONE MINERAL DENSITY LOSS AND FUNCTIONAL LIMITATIONS AFTER THORACAL SPINAL CORD INJURY IN A 65 YEAR OLD MALE

M. Cevei[1], D. Stoicanescu[2], C. Cseppento Nistor[1], F. Andronie Cioara[1], G. Gherle[1], S. Deac[1], R. Mihut[1], D. Pop[3], C. Moisa[1], V. Sonea[1]

[1]University of Oradea, Faculty of Medicine and Pharmacy, Oradea, Romania; [2]University of Medicine and Pharmacy "Victor Babes", TIMISOARA, Romania; [3]University of Oradea, Faculty of Informatics and Sciences, Department of Biology, Oradea, Romania

Objectives: To evaluate bone mineral density impairment, functional status, and rehabilitation outcomes in an older male patient with chronic thoracolumbar spinal cord injury (SCI) and osteoporosis.

Material and Methods: We report the case of a 65-year-old male patient with spastic paraparesis following traumatic thoracolumbar SCI at T12–L1–L2, initially surgically treated with spinal osteosynthesis in 1997 and reoperated in 2025 for spinal canal stenosis (T9–T10 hemilaminectomy). Neurological status was classified as AIS C, with a neurological level of injury at L1. The patient was admitted for paraparetic motor deficit, impaired standing and gait, limitations in activities of daily living (ADLs), low back pain, and bilateral hip and shoulder pain. Clinical examination revelead that the patient was able to walk for short distances using two Canadian crutches. Motor examination showed preserved active movement in the lower limbs with muscle strength graded 3/5 on the left and 2/5 on the right, and spasticity graded 2 on the Modified Ashworth Scale in the hip adductors and lower-limb extensors. Bone mineral density was assessed using dual-energy X-ray absorptiometry (DXA). Functional mobility was evaluated using the Timed Up and Go (TUG) test. Functional independence was assessed using the Functional Independence Measure (FIM), Barthel Index, and ADL scale. Pain intensity was evaluated using the Visual Analog Scale (VAS). Assessments were performed at admission and discharge. The rehabilitation program included thermal water hydrokinetic therapy (36°C), individualized physiotherapy, occupational therapy, therapeutic massage, electrotherapy for lumbar pain, pneumatic compression therapy, functional electrical stimulation, and LASER therapy.

Results: DXA revealed osteoporosis at the left hip (T-score: −2.5, Z-score: −1.9) and left forearm (T-score: −2.8, Z-score: −1.9). Functional mobility remained severely impaired, with TUG improving from 65 s at admission to 60 s at discharge. Functional scores indicated moderate dependence (FIM 80/126, Barthel Index 50/100, ADL 5/10). Pain intensity decreased from 6/10 to 3/10 on the VAS scale.

Conclusions: Chronic thoracolumbar SCI in older adults is frequently associated with clinically significant osteoporosis and functional limitation. A comprehensive, multimodal rehabilitation program may reduce pain and improve functional capacity, even in the presence of advanced bone loss, highlighting the importance of osteoporosis-oriented assessment and management in SCI rehabilitation.

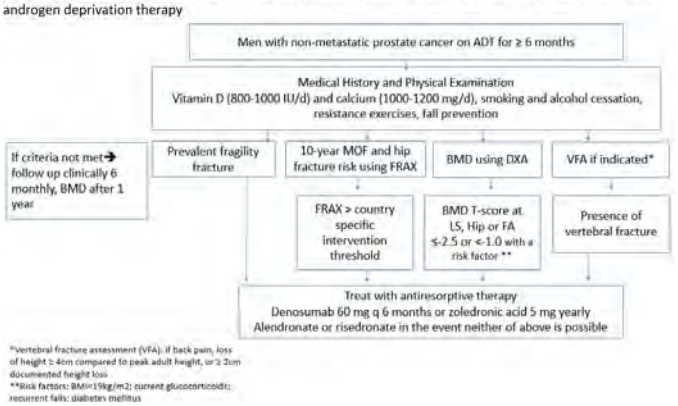
Objective



Androgen deprivation therapy (ADT) induces bone loss and significantly increases fracture risk in non-metastatic prostate cancer (nmPCa). Our aim is to provide physicians an evidence-based and practical guidance on the approach to bone health management in patients with nmPCa on ADT.

Material and Methods

The International Osteoporosis Foundation- Bone and Cancer Working Group (BCWG) members agreed on evaluating a set of 7 clinical questions. We addressed each question based on the evidence retrieved from 2 systematic reviews, including original studies and guidelines that aimed to optimize bone health in patients with nmPCa on ADT (CRD42021225502; CRD420251013073). The BCWG members voted anonymously on each question on answer.forms app, using strongly agree (SA), weakly agree (WA), weakly disagree (WD), strongly disagree (SD), not qualified (NQ).

Results

Figure: Suggested approach to bone health management in patients with non-metastatic prostate cancer on androgen deprivation therapy

Patients with nmPCa on ADT should be assessed for a previous fragility fracture (100%SA), and have a bone mineral density (BMD) and a fracture risk assessment upon the initiation of ADT (87%SA, 13%WA). A calcium intake of 1000-1200 mg/d (86%SA; 14%WA) and vitamin D supplementation of 800-2000 IU/d (71%SA; 29%WA) are required. A bone active agent is recommended for a previous fragility fracture (93%SA; 7%WA), a 10-year fracture risk above the country specific intervention threshold (80%SA;20%WA) or a BMD T-score at the lumbar spine, total hip, femoral neck or forearm ≤ -2.5, or ≤ -1 in the presence of one or more risk factors (53%SA; 34%WA; 13% WD). First line treatment options are Denosumab 60mg every 6 months (as it reduces radiologic vertebral fractures by 85% at 1 year, versus placebo) or Zoledronic acid 5mg yearly (as it increases BMD by 6.9% at lumbar spine, versus placebo) (87%SA; 13%WA) (Figure).

Conclusion

ADT increases osteoporosis risk. Bone health in patients with nmPCa should be prioritized. Screening and early intervention following our simple and practical approach allow to reduce fracture and its related morbidity. Strategies to improve guidelines implementation, increase physician and patient awareness, and investigation of the cost effectiveness of our approach are needed to close the bone health care gap.

Objective: To assess the 12-month effectiveness and safety of romosozumab in Colombian women with postmenopausal Osteoporosis (OP) treated in routine clinical practice.

Methods: We conducted an ambispective, multicenter cohort study of postmenopausal women with very high risk OP who started romosozumab between January 1, 2022, and September 30, 2024. Eligible patients had very high risk OP according to international guidelines Demographics, clinical, radiological and laboratory values were included.

The primary outcome was percent change in lumbar spine BMD at 12 months; secondary outcomes included femoral neck and total hip BMD changes, incident fractures, adverse events

Results: We included 202 women (mean age 71.7 years); 82% were at very high fracture risk. At 12 months, mean BMD increased by 8.1% at the lumbar spine, 5.0% at the femoral neck, and 5.0% at the total hip. During treatment, 6 patients (3.1%) sustained incident fractures and 15 (7.7%) experienced adverse events, including 2 serious events (1.0%). Overall, 75.9% of patients received ≥12 doses, with a mean of 10.5 (SD 3.1) doses.

Conclusions: In a real-world clinical practice setting in Colombia, romosozumab was associated with robust and clinically meaningful gains in BMD, a low incidence of fractures, acceptable safety, and good treatment adherence over 12 months in women with postmenopausal osteoporosis at high or very high fracture risk.

Real-world effectiveness, safety, and adherence of romosozumab: a 12-month ambispective cohort study in Colombian women with postmenopausal osteoporosis

Figure 1. Mean percent change in bone mineral density from baseline to 12 months of romosozumab treatment.

Table 2. Incident fractures, adverse events, treatment discontinuation, and adherence during romosozumab treatment.

Outcome	n with data	n (%) or mean (SD)
Any incident fracture	191	6 (3.1%)
Vertebral fracture	185	3 (1.6%)
Nonvertebral osteoporotic fracture	185	0 (0%)
Any adverse event	194	15 (7.7%)
Serious adverse events	194	2 (1.0%)
Treatment discontinuation	194	28 (14.4%)
Complete adherence (≥12 doses)	191	145 (75.9%)
Number of romosozumab doses received	191	10.5 (3.1)

P1014

CENTRALIZED DXA IMAGING WORKFLOW FOR STANDARDIZED ASSESSMENT IN MULTICENTRE CLINICAL STUDIES

O. Kubassova[1], A. Singareddy[1], M. Clark[1], R. Hagoug[1]

[1]Image Analysis Group, London, United Kingdom

Background
Dual-energy X-ray absorptiometry (DXA) is widely used in clinical research to assess bone mineral density (BMD) and body composition across a range of musculoskeletal and metabolic conditions such as osteoporosis, osteogenesis imperfecta, obesity, and related musculoskeletal disorders. In multicentre clinical studies, variability in DXA acquisition, positioning, artefact management, and analysis across sites can introduce measurement error and limit the reliability of quantitative imaging endpoints used for subject eligibility, baseline characterization and longitudinal follow-up.

Objective
To describe the implementation and performance of a centralized DXA imaging workflow designed to improve data quality and consistency in multicentre clinical research.

Material and Methods
DXA was used to assess bone mineral density at the lumbar spine and hip; spinal radiographs were reviewed in parallel by a radiologist to identify vertebral fractures and to inform exclusion of affected lumbar vertebrae from DXA analysis where required. All DXA scans met quality criteria sufficient to allow subsequent derivation of trabecular bone score (TBS) as an adjunct indicator of trabecular bone microarchitecture, with imaging data transferred and managed using the Dynamika™ cloud-based imaging platform to enable centralized quality control, reader oversight, query management, and harmonized reporting.

Results
Across multiple sites, 930 images were received. Of these, 901 images (97%) passed centralized quality control at first review; 27 images (3%) required re-scan, and 2 images (<1%) failed without the possibility of re-scan due to pre-existing bilateral hip pathology. A total of 271 image-related queries were resolved centrally, with median turnaround times of 1.66 days from image acquisition to upload and 1.38 days from upload to central image reading. Imaging facility qualification timelines were 33 days for DXA and X-ray and 114 days for QCT, enabling standardized acquisition prior to enrolment. These metrics reflect upstream quality control and error interception within a centralized workflow. The centralized imaging workflow, implemented using the Dynamika™ platform, supported timely site activation and completion of subject enrolment, with no enrolment delays attributable to imaging. In contrast, published audits of routine site-level DXA practice report technical and/or interpretative errors in approximately 76–92% of examinations, with 13–42% classified as major, only ~24% judged error-free, and inter-centre coefficients of variation of approximately 2–6% for some DXA measurements [1–4].

Conclusion
Centralized DXA imaging, supported by standardized protocols and centralized quality control implemented using the Dynamika™ platform, reduces variability associated with site-level DXA practice and delivers more consistent, trial-ready quantitative endpoints. This approach supports robust longitudinal assessment, limits avoidable re-scans, and enables integration of complementary DXA-derived measures within a harmonized imaging framework, and supports timely site activation and completion of subject enrolment without imaging-related delays.

BONE FRAGILITY AND AXIAL DEFORMITIES IN ADVANCED PARKINSON'S DISEASE: FUNCTIONAL IMPACT AND REHABILITATION OUTCOMES IN A COMPLEX CASE

M. D. Alexe[1], A. Voicu[1], R. Nartea[1], B. I. Mitoiu[1]

[1]UMF "Carol Davila", Bucharest, Romania

Objectives: The aim of this paper is to highlight the interaction between Parkinson's Disease (PD), bone fragility, and severe postural deformities in the context of increased disability risk in an elderly patient.

Materials and Methods: We present the case of an 82-year-old female patient, known with rigid-akinetic PD diagnosed in 2012, multiple fall-related injuries resulting in L1–L2 compression fractures (2012; 2015),

arterial hypertension, anxiety–depressive disorder, and hiatal hernia. The patient was admitted to the rehabilitation clinic complaining of gait disturbances, especially instability, severe locomotor impairment, and reduced selfcare abilities. The neuromusculoskeletal examination revealed: severe thoracic kyphosis and severe left-convex scoliosis with pelvic rotation and left costo-muscular gibbus, trunk flexion of 90 degrees, severely restricted thoracolumbar mobility in all planes, emotional lability with easy crying, hypomimic facies, global hypobradykinesia, frequent dyskinesias more pronounced cranially, absence of tremor, impaired focusing, diminished amplitude and frequent hesitations in alternating upper-limb movements, limited fine motor control, distal hypoesthesia in the left upper limb and intermediate-to-distal left lower limb, positive Noica sign on the left, and a positive Pull Test. Functionally: during ON periods the patient is able to perform bed transfers with difficulty, stands up with the aid of a cane and upper-limb support, experiences frequent freezing of gait with movement initiation facilitated intermittently by verbal cues. The rehabilitation program included gait and balance training, transfer optimization, postural correction exercises, electrotherapy, and therapeutic massage.
Results: Following multimodal treatment, the patient demonstrated only minor functional improvements, without major benefits on postural stability or global mobility. The limited therapeutic response was significantly influenced by her frail biological status, advanced PD, fluctuating motor phenomena (ON/OFF), and severe structural vertebral deformities.
Conclusions: This case underscores the complexity of managing an elderly patient with advanced PD and vertebral fragility, in whom the risk of falling is substantially increased by severe postural abnormalities, thereby exacerbating disability. Multidisciplinary management is essential to prevent progressive deterioration and to maintain functional independence.

P1016

REHABILITATION CHALLENGES AFTER TOTAL HIP ARTHROPLASTY IN A PATIENT WITH SEVERE NEUROLOGICAL AND MUSCULOSKELETAL SEQUELAE: A CASE REPORT

M. D. Alexe[1], B. G. Ene[1], A. Balasa[1], A. Voicu[1], B. I. Mitoiu[1]

[1]UMF "Carol Davila", Bucharest, Romania

Background: The success of total hip arthroplasty (THA) is often conditioned by the patient's pre-existing neuromotor status. This report analyzes the rehabilitation complexities of a 72-year-old male who underwent left uncemented THA, complicated by severe contralateral neurological deficits and biomechanical misalignments.
Case Presentation: The patient's history was marked by a 2015 L5–S1 laminectomy complicated by a multi-pathogen infection (Acinetobacter, Pseudomonas, Proteus), resulting in permanent right common peroneal nerve palsy, severe muscle atrophy, and a varus equinus deformity. Despite subsequent corrective surgeries (subtalar arthrodesis, tendon lengthening), significant sequelae persisted: a 2 cm limb length discrepancy, marked atrophy (5 cm calf/3 cm thigh differential), and impaired postural control. At presentation for left THA, the patient exhibited a complex gait pattern characterized by right forefoot initial contact, pelvic tilt, and compensatory spinal sagittal imbalances.
Management and Outcomes: Following an uncemented THA via a posterior approach, an individualized rehabilitation program was implemented. This included a dual approach: analgesic physiotherapy (interferential current, laser, ultrasound, and shortwave diathermy) to manage lumbar and bilateral knee pain, combined with a specialized kinesitherapy protocol. The latter focused on strengthening the stabilizers of the hip and cervico-dorso-lumbar spine, alongside intensive proprioceptive and balance re-education to compensate for the contralateral limb's deficits.
Conclusion: Clinical evolution was favorable, achieving significant pain reduction and near-independent ambulation. This case underscores that pre-existing severe neurological sequeale do not preclude successful THA outcomes, provided that the rehabilitation strategy is multidisciplinary and specifically tailored to address the complex biomechanical compensations of the patient.

P1017

MEDICAL REHABILITATION AS A PALLIATIVE–FUNCTIONAL INTERVENTION IN COMPLEX OSTEO-ARTICULAR PATHOLOGY: A CASE REPORT

M. D. Alexe[1], A. Voicu[1], C. Achimescu[1], B. I. Mitoiu[1], R. Nartea[1]

[1]UMF "Carol Davila", Bucharest, Romania

Objective. To evaluate the effectiveness of a short-term medical rehabilitation program on global functional status and associated pain in a patient with severe osteo-articular pathology.
Material and Methods. We report the case of a 68-year-old female patient diagnosed with seropositive rheumatoid arthritis stage III–IV, osteoporosis, arterial hypertension, ischemic heart disease, Graves' disease, Sjögren's syndrome, and extensive infected pseudoarthrosis of the left femur, with a complex surgical history and refusal of limb amputation. At admission, the patient reported severe low back pain, rated 8/10 on the Visual Analog Scale (VAS), with bilateral gluteal radiation, associated with gait disturbance. Neuromusculoskeletal and arthrokinetic (NMAK) examination revealed thoracolumbar dextroconvex scoliosis, loss of lumbar lordosis, reduced spinal mobility, and thoracolumbar paravertebral muscle contractures. Upper limb examination showed bilateral elbow flexion contractures (−15° on the left, −25° on the right), ulnar deviation of the fingers, "swan-neck" deformities, and bilateral impairment of grip function. Lower limb assessment revealed a 25° flexion contracture of the right knee, multiple postoperative scars on the anterior and lateral aspects of the left thigh, muscle strength graded 3/5 proximally and intermediately and 4/5 distally, as well as a left lower limb shortening of approximately 12 cm. The patient underwent a 14-day medical rehabilitation program consisting of individualized physiotherapy, postural re-education exercises, gait training with assistive devices, and analgesic electrotherapy. Clinical evaluation was performed at admission and discharge using the VAS for pain, NMAK clinical examination, and assessment of functional independence.
Results. At discharge, complete resolution of low back pain was observed, with improved postural comfort and increased tolerance to orthostatism. Functional limitations of the lower limbs, particularly involving the left lower limb, remained largely unchanged. Walking ability, dependence on assistive devices, and the level of functional dependency showed no significant improvement. Overall functional status remained stable throughout the rehabilitation program.
Conclusions. Short-term medical rehabilitation is effective in controlling spinal pain in patients with complex osteo-articular pathology; however, its impact on major functional deficits caused by severe and irreversible structural lesions is limited. In such cases, rehabilitation plays a

predominantly palliative role, aimed at symptom relief and preservation of quality of life.

P1018

REHABILITATION CHALLENGES IN A PATIENT WITH THORACIC SPINAL TUBERCULOSIS AND CHRONIC CERVICAL SEQUELAE: A CASE REPORT

M. D. Alexe[1], B. G. Ene[1], M. M. Armeanu[2], B. I. Mitoiu[1]

[1]UMF "Carol Davila", Bucharest, Romania; [2]Spitalul Clinic de Urgenta Oftalmologice, Bucharest, Romania

Background: The functional recovery of patients following surgery for spinal tuberculosis is often complicated by pre-existing degenerative pathologies. This report analyzes the rehabilitation of a 60-year-old female treated for thoracic spondylodiscitis, superimposed on a history of cervical spine surgery.
Case Presentation: The patient's history includes a 2016 cervical spine surgery (C3-C6), which resulted in mild residual motor deficits in the right upper limb. In April 2024, the patient underwent surgery for T11-T12 tubercular osteomyelitis following two months of immobilization due to severe thoracic pain. At presentation, the patient exhibited significant postural deviations, including dextroconvex scoliosis and marked trunk anteversion. Clinical assessment revealed incomplete recovery of the right upper limb strength (wrist flexors 4/5) and C5 hypoesthesia. However, lumbar sequelae were evident, including S1 hypoesthesia and difficulty maintaining orthostatism without support, requiring a cane for ambulation due to incomplete gait rollover.
Management and Outcomes: A multimodal rehabilitation program was implemented alongside Rifampicin therapy. The protocol combined analgesic physiotherapy (TENS, interferential current, laser) to manage diffuse pain, with a specialized kinesitherapy regimen. The latter focused on "back school" education and strengthening the paravertebral and abdominal stabilizers to correct the anteverted trunk posture. The intensity of the exercises was carefully titrated to accommodate the patient's obesity-related limitations and low effort tolerance, while protecting the cervical spine.
Conclusion: Despite an intensive rehabilitation protocol, the clinical outcome remained static regarding mobility and endurance. This underscores the challenge of treating patients with "fragile spines" where systemic factors (obesity, deconditioning) outweigh the benefits of localized physical therapy, limiting the patient's capacity to regain independent ambulation.

P1019

REHABILITATION PROGRAM IMPACT ON MUSCULOSKELETAL ABILITY TO REDUCE THE RISK OF FALLS FOR SENIOR PATIENTS

M. D. Maria Delia[1], B. I. Brindusa Ilinca[1], G. L. Gavril Lucian[1], R. Roxana[1]

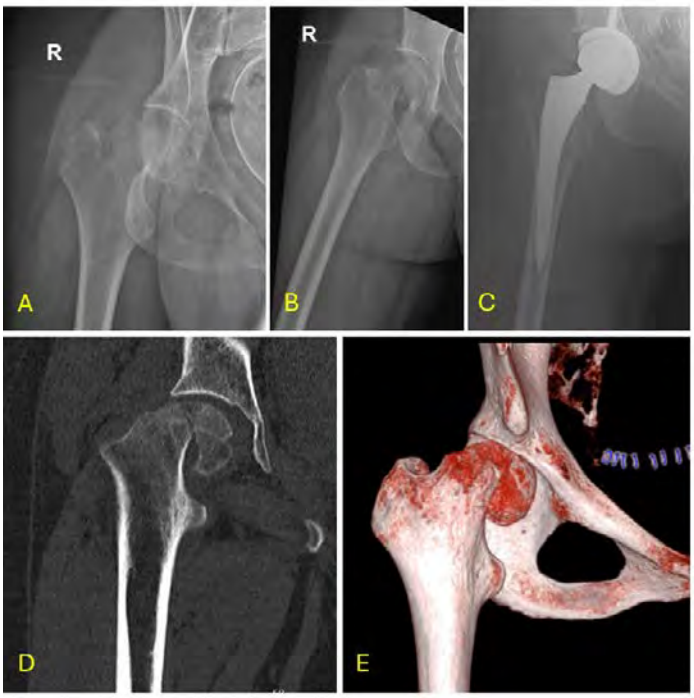
[1]UMF "Carol Davila", Bucharest, Romania

Objective: We intend to determine the impact and role of individualized rehabilitation therapy for elderly patients with a high risk of falls and fall-related injuries. As the world's population ages quickly, there is an increased danger of physical impairments as well as psychological repercussions that further restrict activities and deteriorate general health. Illnesses, including osteoarthritis, sarcopenia, and osteoporosis, result in slower gait, weaker grips, and difficulties carrying out daily duties. Early intervention and diagnosis are essential in order to reduce the complications.
Methods: A multidisciplinary approach helps patients after a fall to restore autonomy and confidence. Personalized rehabilitation treatment includes medical, physical, psychological, and environmental techniques. According to the direction of a multidisciplinary team, rehabilitation programs include physical therapy and exercise programs, occupational therapy aimed at maximizing the capacity to perform daily activities safely and independently, psychological and sensory rehabilitation, and not last, integrating virtual reality programs.
Results: Rehabilitation techniques are essential to this endeavor to improve balance, strength, coordination, and confidence, in addition to restoring physical function for elderly patients. A proactive, multidimensional approach that incorporates environmental, medical, educational, and physical techniques as treatment must be associated with effective prevention focused on risk factors (functional capacity, health status, and living conditions).
Conclusions: We underline the importance of rehabilitation as a key aspect of clinical care and public health for preventing and reducing the number of falls and related repercussions as the world's population ages. Fall prevention is crucial for maintaining independence, functional capacity, and the quality of life in addition to preventing further injuries and complications. By empowering patients to reclaim their independence and enhance their quality of life, the comprehensive approach aids in ending the cycle.

P1020

ANTENATAL FEMORAL NECK FRACTURE AS A COMPLICATION OF TRANSIENT OSTEOPOROSIS OF THE HIP IN PREGNANCY

E. Santos[1], M. D. Pascoal[2], H. Gonçalves[3], N. Borralho[1], D. Pereira[1], M. R. Vaz[1], J. Regino[1]



[1]ULS Viseu Dão-Lafões, Viseu, Portugal; [2]ULS Região de Aveiro, Aveiro, Portugal; [3]ULS Braga, Braga, Portugal

Objective
To highlight the importance of early recognition and appropriate multidisciplinary management of transient osteoporosis of the hip (TOH) during pregnancy in order to prevent severe maternal complications.
Materials and Methods
We present a case of TOH complicated by a displaced femoral neck fracture occurring in the third trimester of pregnancy.
Results
A 36-year-old primigravida at 37+5 weeks of gestation presented at the emergency room with acute right hip pain and inability to bear weight following a low-energy fall. Obstetric assessment, including ultrasound, was unremarkable. She reported a three-week history of progressive mechanical hip pain and functional limitation prior to the trauma, managed conservatively without medical evaluation. The patient had no relevant medical history nor took regular medication, and the pregnancy was uneventful until the present episode.
Due to persistent symptoms, radiographic imaging was performed and revealed a displaced subcapital fracture of the right femoral neck. After multidisciplinary discussion, a cesarean section was performed to achieve pain control and minimize risks associated with vaginal delivery.

Postpartum computerized tomography confirmed the fracture. On the third postdelivery day, the patient underwent a non-cemented total hip arthroplasty. Full weight bearing was allowed immediately. Recovery was uneventful, and the patient was discharged seven days after surgery. At four-week follow-up, she was pain free, ambulating with two crutches, and radiographs showed appropriate implant positioning. Medical anti-osteoporotic treatment was not initiated since this is a transient disease and bone alterations tend to regress spountaneuosly.

Conclusions

Although rare, TOH should be suspected in pregnant women presenting with progressive hip pain, particularly in the third trimester. Early diagnosis with timely imaging and a multidisciplinary approach with institution of fracture-preventing measures such as protected weight bearing, analgesia and schedule delivery by cesarean section may prevent serious complications and ensure optimal maternal and fetal outcomes.

• Panel A and B – Right hip x-rays showing displaced femoral neck fracture

• Panel C – Postoperative hip x-ray showing non-cemented total right hip arthroplasty

• Panel D – CT scan (Coronal) showing femur neck fracture

• Panel E – CT-based 3D reconstruction of the femoral neck fracture

REGIONAL MIGRATORY OSTEOPOROSIS WITH SEQUENTIAL HIP AND KNEE INVOLVEMENT: A CASE REPORT

M. D. Turkoz[1]

[1]Giresun Physical Therapy and Rehabilitation Center, Giresun, Türkiye

Background

Regional migratory osteoporosis (RMO) is a rare, self-limiting condition within the spectrum of transient bone marrow edema syndromes, characterized by sequential involvement of weight-bearing joints, most commonly in the lower extremities. Due to overlapping clinical and imaging features, it is frequently misdiagnosed as avascular necrosis or stress fracture, which may result in unnecessary diagnostic and therapeutic interventions (1,2).

Case Presentation

A 54-year-old male patient initially presented in March 2024 with atraumatic left hip pain. Physical examination revealed preserved but painful range of motion of the hip, without swelling or erythema. Magnetic resonance imaging (MRI) demonstrated diffuse bone marrow edema involving the left femoral head and neck, characterized by hypointense signal on T1-weighted images and hyperintense signal on T2/STIR sequences (Fig1). No evidence of subchondral fracture, femoral head collapse, or serpiginous lines suggestive of osteonecrosis was observed. Conservative treatment consisting of nonsteroidal anti-inflammatory drugs and activity modification was initiated, resulting in complete spontaneous resolution of symptoms.

In August 2025, the patient developed similar atraumatic pain in the right hip. Physical examination again showed preserved but painful range of motion. MRI findings were comparable to the previous episode, revealing bone marrow edema without fracture or osteonecrosis (Fig2). Symptoms resolved spontaneously under conservative management.

In January 2026, the patient presented with severe pain in the right knee, causing functional limitation. Physical examination demonstrated full range of motion of the knee, with no swelling, erythema, or joint effusion. MRI revealed extensive bone marrow edema involving the distal femur and proximal tibia, without evidence of a fracture line, meniscal pathology, ligamentous injury, or history of trauma (Fig3). Laboratory investigations were unremarkable. Based on the characteristic sequential migratory pattern, imaging findings, and spontaneous resolution of previous episodes, a diagnosis of regional migratory osteoporosis was established (Fig4).

Conclusion

This case demonstrates the characteristic migratory pattern of regional migratory osteoporosis with sequential involvement of bilateral hips followed by the knee. Recognition of this rare entity and its benign natural course is essential to avoid misdiagnosis, unnecessary invasive diagnostic procedures, and inappropriate treatment (3). MRI plays a pivotal role in establishing the diagnosis, while conservative management remains effective and is associated with favorable clinical outcomes (4).

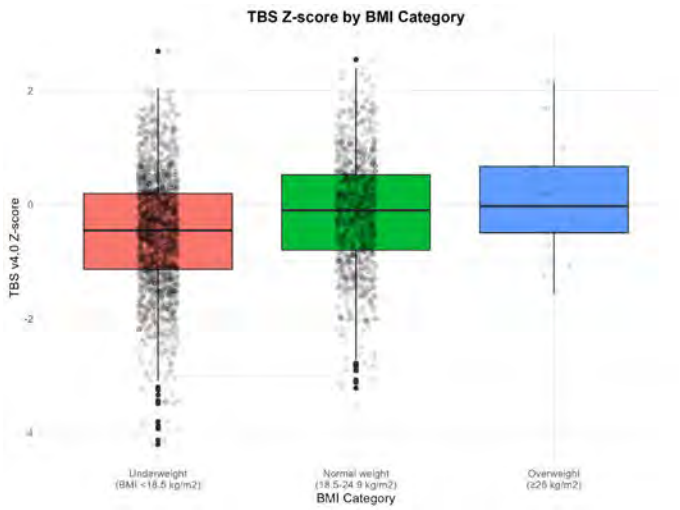
TRABECULAR BONE SCORE (TBS) IN PEDIATRIC FEMALES WITH ANOREXIA NERVOSA

J. Briody[1], K. London[2], A. N. H. Walstra[3], K. Hind[3,4], M. Davies[3], D. Hans[3,5], C. Munns[6]



[1]Children's Hospital at Westmead, Sydney, Australia; [2]University of Sydney, The Children's Hospital at Westmead, Sydney, Australia; [3]Medimaps Group SA, Geneva, Switzerland; [4]Faculty of Health and Medicine, Lancaster University, Lancaster, United Kingdom; [5]Center of Bone Diseases, Rheumatology Unit, Bone and Joint Department, Lausanne University Hospital & University of Lausanne, Lausanne, Switzerland; [6]The University of Queensland, Brisbane, Australia

*Objective:*Anorexia nervosa is characterized by prolonged energy deficiency and low body weight, leading to impaired bone development during critical periods of skeletal growth and an increased risk of fragility fractures. While DXA–derived bone mineral density is commonly used to assess bone health in this population, it does not fully capture alterations in bone microarchitecture. Trabecular bone score (TBS) is a validated, DXA-derived index that provides indirect information on bone microstructure providing insights into skeletal impairment associated with undernutrition. This study aimed to evaluate TBS in a pediatric female cohort with anorexia nervosa and to examine its association with disease severity, as reflected by body mass index (BMI).

*Material and Methods:*DXA scans from female participants aged 5–20 years with anorexia nervosa (AN) were analyzed using TBS Osteo Advanced (version 4), with soft-tissue thickness adjustment. Participants outside the age range and those with abdominal tissue thickness outside the manufacturer-recommended range for TBS v4 (7.0–30.0 cm), were excluded. TBS Z-scores were calculated relative to an age-matched reference population. One-sided statistical testing was performed to assess whether TBS values in AN were lower than reference values. One-way ANOVA was used to compare TBS Z-scores of BMI categories (underweight <18.5, normal weight 18.5-24.9, overweight ≥25 kg/m²), with Tukey post-hoc tests for pairwise comparisons.

*Results:*A total of 2,774 females were included in the final analysis (mean age 15.43 ± 1.77 years; 86.6% White; mean BMI 17.80 ± 2.30 kg/m²). Overall, mean TBS Z-scores were significantly lower than those of the age-matched reference population (−0.36 ± 1.00; $p < 0.001$). Most AN were underweight (64.2%), with 35.2% classified as normal weight and a very small proportion, overweight. Underweight participants demonstrated significantly lower TBS Z-scores compared with the normal-weight group (mean difference −0.35; $p < 0.001$). These findings indicate a graded association between lower BMI and impaired trabecular bone microarchitecture within the cohort.

*Conclusions:*In this large AN cohort, trabecular bone score was significantly reduced compared with age-matched reference values, consistent with compromised trabecular bone microarchitecture. Lower TBS Z-scores in underweight individuals highlight the adverse skeletal effects of low body weight during critical periods of bone development. These findings support the use of TBS as a complementary DXA-derived measure to enhance the assessment of skeletal impairment and disease severity in pediatric patients with anorexia nervosa.

P1023

PHILIPPINE ADULT REFERENCE VALUES FOR TRABECULAR BONE SCORE (TBS OSTEO V3)

J. Li-Yu[1], M. Degruttola[2], M. Davies[2], A. N. H. Walstra[2], K. Hind[2,3], S. Lekamwasam[4], D. Hans[2,5]

[1]University of Santo Tomas Faculty of Medicine and Surgery, Chinese General Hospital and Medical Center, Manila, Philippines; [2]Medimaps Group SA, Geneva, Switzerland; [3]Faculty of Health and Medicine, Lancaster University, Lancaster, United Kingdom; [4]University of Ruhuna, Matara, Sri Lanka; [5]Center of Bone Diseases, Rheumatology Unit, Bone and Joint Department, Lausanne University Hospital & University of Lausanne, Lausanne, Switzerland

Objective: Trabecular bone score (TBS) is a validated index of bone microarchitecture derived from DXA images and used alongside areal bone mineral density (BMD) to improve the identification of individuals at increased risk of fragility fracture. The availability of population-specific TBS reference data supports clinical interpretation; however, such data are limited for some non-Western populations. The purpose of this study was to establish the first age- and sex-specific TBS reference curves for adult men and women in the Philippine population.

Material and Methods: Lumbar spine DXA scans from 1,924 apparently healthy participants were retrospectively analysed to derive mean TBS values from L1–L4 using TBS iNsight version 3 (Medimaps Group, Geneva, Switzerland). Participants younger than 20 years, those with body mass index (BMI) outside the manufacturer-recommended range for TBS v3 (15–37 kg/m²), and statistical outliers were excluded. Reference curves were fitted using the Lambda–Mu–Sigma (LMS) method implemented through Generalized Additive Models for Location, Scale, and Shape (GAMLSS), generating age- and sex-specific estimates for the median and variability, together with ±1 and ±2 standard deviation limits.

*Results:*1,869 DXA scans from healthy adults aged 20–98 years were included (mean age 65.4 ± 12.3 years; BMI 25.1 ± 4.1 kg/m²). For women, 1,473 scans (mean age 66.8 ± 10.6 years; BMI 25.0 ± 4.1 kg/m²) were used to construct reference curves across the age range 25–90 years. Peak median TBS values reached approximately 1.36, followed by a gradual decline beginning at 40–45 years to around 1.21 at 70–75 years, after which values plateaued. For men, 396 scans (mean age 60.1 ± 15.9 years) were analysed across the age range 20–90 years. A more modest decline in TBS was observed, from approximately 1.40 at 20–25 years to 1.35 at 65–70 years, with relative stability at older ages.

Conclusion: This study provides the first age- and sex-specific TBS reference curves for the Philippine population. By enabling population-appropriate interpretation of bone microarchitecture, these data complement BMD derived from routine DXA examinations without additional patient burden. The availability of locally derived reference ranges may enhance the clinical relevance and accessibility of TBS in non-Western settings.

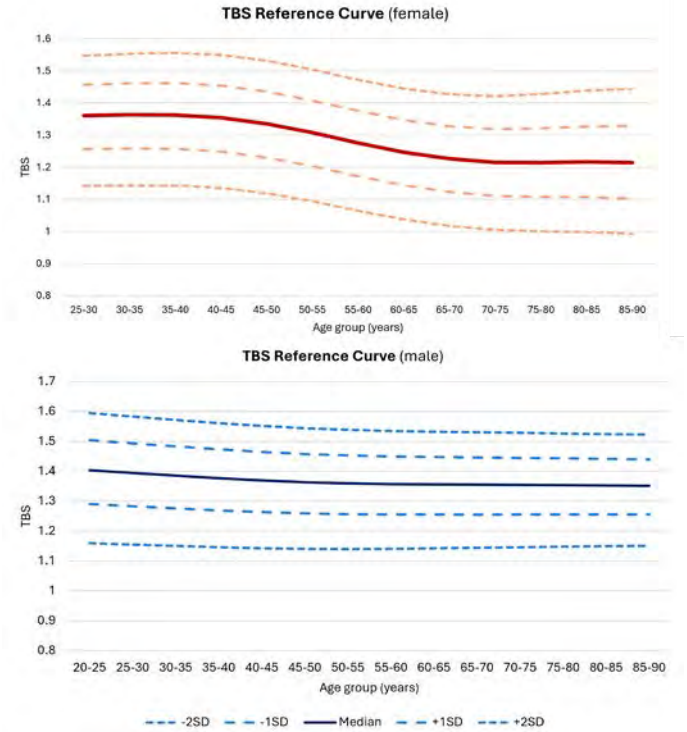


Figure 1. Trabecular Bone Score (TBS) reference curves for Philippine females and males

A CHARACTERISTIC "LINCOLN SIGN" IN MONOSTOTIC PAGET'S DISEASE OF THE MANDIBLE

M. Dhifallah[1], A. Feki[1], Z. Gassara[1], S. Ben Djemaa[1], M. H. Kallel[1], S. Baklouti[1], H. Fourati[1]

[1]Hedi Chaker Hospital, Sfax, Tunisia

A 70-year-old woman with a remote history of breast carcinoma treated ten years earlier by lumpectomy, adjuvant radiochemotherapy, and hormonal therapy was referred for evaluation of an incidental abnormality detected on routine follow-up bone scintigraphy. She was asymptomatic, with no bone pain, facial swelling, deformity, or functional complaints, and her general condition was preserved. Physical examination was unremarkable.

Laboratory investigations revealed an isolated elevation of alkaline phosphatase (214 U/L; 1.6× the upper limit of normal), while serum calcium and phosphate levels were normal. Whole-body bone scintigraphy using ^99mTc-labeled radiotracers demonstrated a focal, intensely increased uptake confined to the mandible **(Figure.1)**. The tracer distribution followed a linear pattern along the mandibular borders,

corresponding to an osteosclerotic area on complementary imaging.
In a patient with a prior history of malignancy, such a finding raises concern for metastatic bone disease. However, the absence of symptoms, the isolated biochemical abnormality, and the highly specific scintigraphic appearance suggested an alternative diagnosis related to focal bone remodeling rather than tumor infiltration. The striking mandibular outline on scintigraphy resembles a dark contour tracing the jaw, prompting recognition of a classic but uncommon imaging sign. What is the diagnosis suggested by this image?
The imaging findings are diagnostic of monostotic Paget's disease of the mandible. The linear, intense uptake outlining the jaw corresponds to the classic "Lincoln sign," also known as the "black beard sign," which reflects increased osteoblastic activity and accelerated bone remodeling along the mandibular cortex.
Paget's disease most commonly involves the pelvis, spine, skull, and long bones, while isolated mandibular involvement is rare. In oncologic patients, this presentation may closely mimic metastatic disease, making recognition of this distinctive scintigraphic pattern essential to avoid misdiagnosis and unnecessary invasive procedures.

Figure 1. Anterior planar image of 99mTc-MDP bone scintigraphy showing an intense, well-defined linear tracer uptake outlining the mandible, producing the characteristic "Lincoln sign" or "Black beard" sign.

WHEN ARTHRITIS TELLS A DIFFERENT STORY: NON-LANGERHANS CELL HISTIOCYTOSIS REVEALED BY SYNOVIAL INVOLVEMENT

M. Dhifallah[1], F. Majdoub[1], L. Kharrat[1], D. Ben Nessib[1], I. Cherif[1], D. Kaffel[1], W. Hamdi[1]

[1]Institut Mohamed Kassab, Mannouba, Tunisia

Introduction
Non-Langerhans cell histiocytoses represent a rare and heterogeneous group of proliferative disorders of the monocyte–macrophage system. Isolated or inaugural articular involvement is exceptional and may mimic chronic inflammatory or infectious rheumatic diseases, leading to significant diagnostic delay.
Case Presentation
We report two cases illustrating atypical rheumatologic presentations of non-Langerhans cell histiocytoses.
The first case involves a 51-year-old man with a three-year history of recurrent oligoarthritis affecting large joints of the lower limbs, associated with biological inflammatory syndrome and microcytic anemia. Synovial fluid analysis was inflammatory, while infectious and immunological investigations were negative. Imaging revealed diffuse joint space narrowing with large geodes. Synovial biopsy demonstrated infiltration by non-Langerhans histiocytes with mild emperipolesis, consistent with Rosai–Dorfman disease. Whole-body positron emission tomography revealed associated skeletal and cardiovascular involvement.
The second case concerns a 35-year-old woman followed for recurrent febrile biarthritis involving the left knee and shoulder, persisting despite prolonged treatment for a previously documented septic arthritis. Given the persistence of fever and inflammatory markers, a synovial biopsy was performed, revealing a dense infiltrate of foamy histiocytes strongly positive for CD68 and negative for CD1a, supporting the diagnosis of Erdheim–Chester disease. Extensive systemic evaluation was unremarkable, leading to the diagnosis of isolated erosive articular involvement.
Discussion
These cases highlight the diagnostic challenge of non-Langerhans cell histiocytoses with predominant articular presentation, frequently misdiagnosed as chronic inflammatory or infectious arthritis. Synovial biopsy with immunohistochemical analysis remains the cornerstone of diagnosis.
Conclusion
Non-Langerhans cell histiocytoses should be considered in cases of atypical or refractory chronic arthritis. Early synovial biopsy is essential to avoid diagnostic and therapeutic delay.

P1026

OPPOSITE DISTRIBUTION OF LOW BONE MINERAL DENSITY AND LOW APPENDICULAR LEAN MASS IN WOMEN AND MEN WITH HIP FRACTURE: A CROSS-SECTIONAL STUDY

M. Di Monaco[1], C. Castiglioni[1], F. Bardesono[1], G. Paglia[1], G. Massazza[2]

[1]Osteoporosis Research Center, Division of Physical and Rehabilitation Medicine, Presidio Sanitario San Camillo, Turin, Italy; [2]Division of Physical and Rehabilitation Medicine, Department of Surgical Sciences, University of Turin, Turin, Italy

Objective. To compare the distribution of low femoral bone mineral density (BMD) and low appendicular lean mass adjusted by height squared (aLM/height^2) in women and men with subacute hip fracture.
Materials and Methods. At a median of 18 days after the occurrence of an original hip fracture due to fragility we measured both BMD at the non-fractured femur and body composition by dual-energy x-ray absorptiometry. Densitometric osteoporosis was diagnosed with a T-score < -2.5 (total proximal femur). The reference population for T-score calculations was derived from the Third National Health and Nutrition Examination Survey (NHANES III) and was sex-specific. Low aLM/height^2 was defined according to the criteria released by the European Working Group on Sarcopenia in Older People in 2019 (EWGSOP2), with cut-off values of 5.5kg/m^2 in women and 7kg/m^2 in men.
Results. We studied 1097 Caucasian patients (953 women and 144 men) with subacute hip fracture. The prevalence of densitometric osteoporosis was significantly higher in women (56%) than in men (26%): c^2=43.3, P<0.001. The association between sex and densitometric osteoporosis persisted after adjustment for age, fat mass, 25-hydroxyvitamin D and PTH (P<0.001). The adjusted odds ratio (women versus men) for having densitometric osteoporosis was 4.87 (95% CI from 3.14 to 7.57). The

prevalence of low aLM/height^2 was significantly lower in women (72%) than in men (90%): c^2=20.6, P<0.001. The association between sex and low aLM/height^2 persisted after adjustment for age, fat mass, 25-hydroxyvitamin D and PTH (P<0.001). The adjusted odds ratio (men versus women) for having low aLM/height^2 was 3.90 (95% CI from 2.2 to 7.0).

Conclusions. Low BMD and low aLM/height^2 had opposite sex-associated distributions in hip-fracture patients: low BMD was more prevalent in women than in men, whereas low aLM/height^2 was more prevalent in men than in women. Data suggests that BMD and muscle mass depletion may have sex-specific roles in the genesis of hip fractures in older people, encouraging sex specific preventive approaches. However, longitudinal studies are needed to validate our cross-sectional results.

P1027

PATIENTS WITH OBESITY AND TYPE 2 DIABETES MELLITUS SUSTAIN HIP FRACTURES AT HIGH LEVELS OF BONE MINERAL DENSITY: A CROSS-SECTIONAL STUDY

M. Di Monaco[1], C. Castiglioni[1], F. Bardesono[1], G. Paglia[1], G. Massazza[2]

[1]Osteoporosis Research Center, Division of Physical and Rehabilitation Medicine, Presidio Sanitario San Camillo, Turin, Italy; [2]Division of Physical and Rehabilitation Medicine, Department of Surgical Sciences, University of Turin, Turin, Italy

Objective. To compare femoral bone mineral density (BMD) in hip-fracture patients categorized into 4 groups depending on the presence of type 2 diabetes mellitus (T2DM), obesity, both the conditions (T2DM and obesity) or absence of both the conditions (controls).

Materials and Methods. At a median of 20 days after the occurrence of an original hip fracture due to fragility we measured BMD by dual-energy x-ray absorptiometry at the non-fractured femur. Densitometric osteoporosis was diagnosed with a T-score < -2.5 (total proximal femur). Obesity was defined with a body mass index ≥ 30kg/m^2.

Results. We studied 964 patients with subacute hip fracture. BMD was significantly different across the 4 categories of patients (F=27.9; P<0.001). Mean (SD) T-score was -2.6 (0.93) in the 754 patients without obesity and T2DM, -2.14 (1.10) in the 128 with T2DM, -1.85 (0.96) in the 60 with obesity and -1.35 (0.93) in the 22 with both T2DM and obesity. The percentage of patients with T-scores below -2.5 also differed across the 4 categories (F=41.8; P<0.001), ranging from 55% (controls) to 14% (concomitant presence of both T2DM and obesity). The significant association between densitometric osteoporosis and the 4 categories of patients persisted after adjustment for age, sex, hip-fracture type, concomitant neurologic impairment, 25-hydroxyvitamin D, PTH and estimated glomerular filtration rate (P<0.001).

Conclusions. Hip fractures occur at high levels of femur BMD in patients with T2DM or obesity and very high levels in the presence of both the conditions. Preserved BMD may not protect patients with T2DM and obesity against hip fractures and may falsely reassure patients and clinicians. To avoid underestimation of hip-fracture risk due to high BMD, we suggest an adjustment of risk calculation based on the T-score differences shown in our sample. Adjustment validation by robust prospective studies is needed.

P1028

PREDICTING A GOOD RESPONSE TO ROMOSOZUMAB IN TERMS OF PERCENTAGE INCREASE IN BONE MINERAL DENSITY IN ROUTINE CLINICAL PRACTICE

M. Dissanayake[1], K. Perera[2], D. Hutchinson[1]

[1]Royal Cornwall Hospital Trust, Rheumatology Department, Truro, United Kingdom, Truro, United Kingdom; [2]University of Sri Jayawardenapura, Colombo, Sri Lanka

Objective: There is a strong relationship between bone mineral density (BMD) and fracture risk. The increase in BMD following treatment with romosozumab is highly variable. Accordingly we have studied a cohort of women treated at the Royal Cornwall Hospital Trust, Truro, UK to determine what factors are associated with a good response to romosozumab in terms of percentage increase in BMD.

Methods: One hundred and twenty women received treatment with romosozumab for one year. A DEXA scan measured the BMD before and after treatment. A good clinical response was deemed to be those women with a percentage increase in BMD at either the lumbar spine and total hip in the upper quartile and a poor response in those women with a percentage increase in BMD at either the lumbar spine and total hip in the lowest quartile.

The age, BMI, baseline BMD at the lumbar spine and total hip, previous osteoporosis treatment, QRISK 3 (UK-developed, validated, clinical algorithm that calculates the percentage of risk of developing heart attack or stroke over the next 10 years), NOGG 10 year risk of major osteoporotic fracture and hip fracture and category of subsequent fracture risk

Participants with missing data exceeding 20% of the total study variables were excluded from the analysis. Consequently the final analytical sample comprised 114 women to determine a good clinical response in terms of an increase in percentage BMD.

Results: The mean age was 69.90±8.05 years, Age >75 years, n=35 (28.9%), mean BMI 24.95±4.54, mean baseline BMD (g/cm^2) at the lumbar spine, total hip and femoral neck 0.73±0.11, 0.66±0.09, 0.55±0.07 respectively. Mean bone mineral density T scores at the lumbar spine, total hip and femoral neck -2.97±1.00, -2.26±0.75 and -2.60±0.86 respectively.

The mean BMD improvement (%) at the lumbar spine was 13.05%±7.65 and total hip 3.23%±4.95. A poor response at the lumbar spine ≤7.4% was oberved in 23 women and at the total hip≤0% in 25 women and a good response at the lumbar spine ≥18.5% in 22 women and at the total hip ≥6.4% in 23 women.

In women with a lumbar spine baseline T score > -3.0 only 6 (31.6%) had a good response to treatment compared to 16 (61.5%) with a T score ≤ -3.0), odds ratio 3.48 (95% CI 0.99- 12.08), P= 0.047. In women with a T score of > -3.0 only 16 women (30.4%) had a good response compared to 7 women (69.6%) with a T score of ≤ -3.0 at the total hip, odds ratio 10.5 (95% CI 1.18-93.69), P= 0.014.

No other factor studied was associated with a good response to romosozumab in terms of percentage increase in BMD at the lumbar spine and total hip.

Conclusion: Baseline BMD was the only factor associated with a good response to romosozumab in terms of percentage increase in BMD. We sugest patients with a T score <-3 should be prioritised for treatment with romosozumab.

P1029

FRACTURE INCIDENCE AND RISK FACTORS IN A PERITONEAL DIALYSIS SETTING

M. Diz Lopes[1], B. Fernandes[2], T. Martins Rocha[3], L. Costa[3], R. Neto[2], J. Frazão[2]

[1]Rheumatology Department, Unidade Local de Saúde de São João, Porto, Portugal; [2]Nephrology Department, Unidade Local de Saúde de São João, Porto, Portugal; [3]Rheumatology Department, Unidade Local de Saúde de São João, Porto, Portugal, Porto, Portugal

Objectives: To evaluate the incidence and determinants of fragility fractures in peritoneal dialysis patients and to assess the performance of the Fracture Risk Assessment Tool (FRAX®).

Materials and Methods: We conducted a retrospective single-center cohort study including adult patients on PD for ≥12 months between 2013 and 2025. Fragility fractures during PD follow-up were identified through clinical records and review of lateral spine radiographs. Clinical and biochemical data were collected. Vascular calcification was assessed using the Adragão vascular calcification score (VCS). FRAX® probabilities were calculated without bone mineral density. Logistic regression identified independent predictors of fractures, and ROC analysis evaluated FRAX® performance.

Results: Among 325 PD patients (mean age 53±8 years; 57.2% male), 32 (9.8%) sustained fragility fractures, corresponding to an incidence of 30.3 per 1,000 patient-years. Most fractures were asymptomatic vertebral fractures (n=23, 7.1%). Patients with fractures were older (p<0.001), more frequently had previous fractures (p<0.001), and were more often diabetic (p=0.05). They also had lower baseline phosphorus (p=0.038) and intact parathyroid hormone (iPTH) levels (p=0.032), although values remained within guideline targets and KDIGO iPTH categories did not differ between groups. There was a trend to higher VCS in the patients with fractures (p=0.064), and mortality was higher (p=0.038). In multivariable analysis, previous fracture history (OR 4.85, 95% CI 1.22–19.27, p=0.025) and higher VCS (OR 2.10, 95% CI 1.10–4.03, p=0.025) were independently associated with fracture occurrence. FRAX® showed modest discriminatory ability for fragility fractures (AUC 0.69, **figure 1**). Using standard intervention thresholds, sensitivity was very low (4.8%), increasing only modestly when CKD was classified as secondary osteoporosis (14.3%).

Conclusions: PD patients experience a high burden of fragility fractures, particularly asymptomatic vertebral fractures. Prior fracture history and vascular calcification are strong predictors of fracture risk. FRAX® underestimates fracture risk in this population, highlighting the need for CKD-specific fracture risk assessment strategies tailored to PD patients.

LONGITUDINAL EVALUATION OF BONE STATUS WITH RADIOFREQUENCY ECHOGRAPHIC MULTI SPECTROMETRY (REMS) TECHNOLOGY IN A PERITONEAL DIALYSIS COHORT

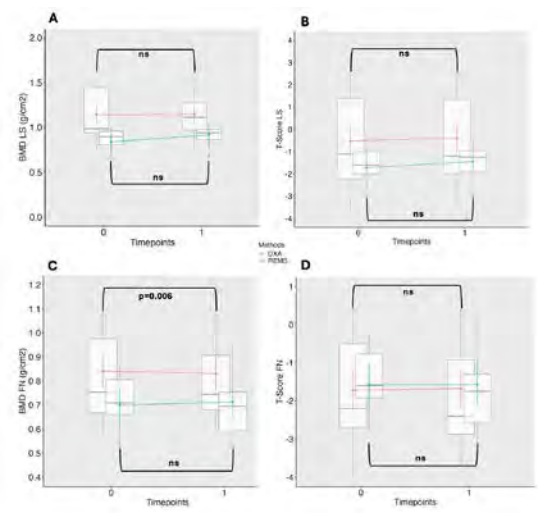
M. Diz Lopes[1], A. Fassio[2], B. Bianco[3], S. Andreola[4], A. Spasiano[4], D. Gatti[2], M. Rossini[2], P. Manuel Ferraro[4], G. Adami[2]

[1]Rheumatololology Section, Department of Medicine, University of Verona, Porto, Portugal; [2]Rheumatology Section, Department of Medicine, University of Verona, Verona, Italy; [3]Nephrology Section, Department of Medicina, University of Verona, Verona, Italy; [4]Nephrology Section, Department of Medicine, University of Verona, Verona, Italy

Objectives: Dual x-ray absorptiometry (DXA) is the gold standard for bone mineral density (BMD) assessment in chronic kidney disease patients, but it can have limited accuracy and radiofrequency echographic multi-spectrometry (REMS) may overcome some of its limitations. We aimed to evaluate and compare longitudinal BMD changes assessed by DXA and REMS in peritoneal dialysis (PD) patients.

Material and Methods: Prospective cohort study including 20 PD patients that underwent two separate DXA and REMS evaluations. Clinical, biochemical, and imaging data, including abdominal aorta calcification (AAC) scores and fracture history were collected. Longitudinal BMD changes were analyzed using linear mixed-effects models.

Results: Over a median follow-up period of 19.8 months, DXA revealed significant BMD declines at the femoral neck (FN) (−3.2%, p=0.039) while REMS showed non-significant numerical declines **(figure 1).** REMS consistently yielded lower BMD values than DXA at both lumbar spine (LS) and FN. Despite these differences, the trajectories over time were similar between DXA and REMS for LS BMD (p=0.806) and FN BMD (p=0.229, **table 1**), regardless of whether patients were receiving anti-osteoporosis treatment and of the presence of fractures. However, there was no correlation of the annualized changes in BMD at the FN and LS between the two methods (r^2=0.001, p=0.905 and r^2=0.001, p=0.928, respectively).



Conclusion: REMS and DXA demonstrated similar longitudinal trends in BMD, but DXA detected a significant decline in BMD at cortical sites, whereas REMS did not. Larger studies are needed to clarify the comparative and complementary roles of REMS and DXA in monitoring bone health in end-stage kidney disease.

Table 1. Comparison of longitudinal changes in BMD over time assessed by REMS (vs. DXA) at the lumbar spine and femoral neck, with and without adjustment for covariates All models included time and methods (REMS vs DXA) as fixed effects, and the other covariates were consecutively included. All presented results are derived from the interaction with time.

ROMOSOZUMAB DOES NOT IMPROVE VOLUMETRIC BONE MINERAL DENSITY AT DISTAL RADIUS BUT INCREASES BONE STRENGTH: A PROSPECTIVE STUDY

M. Diz Lopes[1], F. Pollastri[2], F. Mastropaolo[2], R. Rosanna[2], M. Tugnolli[2], E. Pasetto[2], C. Benini[2], V. Messina[2], A. Fassio[2], D. Gatti[2], O. Viapiana[2], M. Rossini[2], G. Adami[2]

[1]Rheumatolology Section, Department of Medicine, University of Verona, Porto, Portugal; [2]Rheumatology Section, Department of Medicine, University of Verona, Verona, Italy

Objectives:

Romosozumab (ROMO) leads to substantial BMD gains at the lumbar spine and the hip, but its effects on distal radius volumetric BMD (vBMD) remain unclear. High-resolution peripheral Quantitative Computed Tomography (HR-pQCT) allows for detailed assessment of bone microarchitecture and strength at peripheral regions. We aimed to evaluate the effects of 12 months of ROMO on vBMD, microarchitecture and biomechanical properties of the distal radius using HR-pQCT.

Material and Methods:

We did a prospective study on 49 postmenopausal women with osteoporosis treated with ROMO for 12 months who underwent HR-pQCT with microfinite element analysis (uFEA) assessments at baseline, 3, 6 and 12 months. We also performed DXA at lumbar spine, femoral neck and total hip. HR-pQCT parameters trajectories were analyzed using mixed-effects modeling.

Results:

Mean age was 73.4±10.1 years old, mean BMI was 23.1±3.4 kg/m2 and most patients were no smokers (n=45, 91.8%). The majority of the patients had a previous vertebral fracture (n=41, 83.7%) and a smaller percentage had sustained previous hip (n= 9, 18.4%) and wrist fractures (n= 16, 32.7%).

No significant increases were observed in cortical or trabecular vBMD or microarchitectural parameters at the distal radius **(table 1).** On the other hand, uFEA showed early increases in cortical failure load and shear strength, suggesting potentially improved bone mechanical behavior. Cortical failure load increased at both 3 and 6 months (p=0.018 and p=0.049, respectively) but was stable when considering the overall period of treatment (p=0.102). Consistent with these findings, shear strength increased at 3 and 6 months, with significant changes at month 6 (p=0.008). Stiffness remained relatively stable until 12 months (p=0.288). Lumbar spine, femoral neck, and total hip aBMD significantly increased by 11.6%, 8.3%, and 3.1%, respectively (all p<0.001).

Conclusions: ROMO treatment was associated with improved biomechanical properties at the distal radius, despite non-increasing vBMD. ROMO treatment might improve skeletal health beyond BMD gains.

RADIOFREQUENCY ECHOGRAPHIC MULTI SPECTROMETRY (REMS) TECHNOLOGY IN THE EVALUATION OF GLUCOCORTICOID-INDUCED OSTEOPOROSIS IN SYSTEMIC LUPUS ERYTHEMATOUS PATIENTS

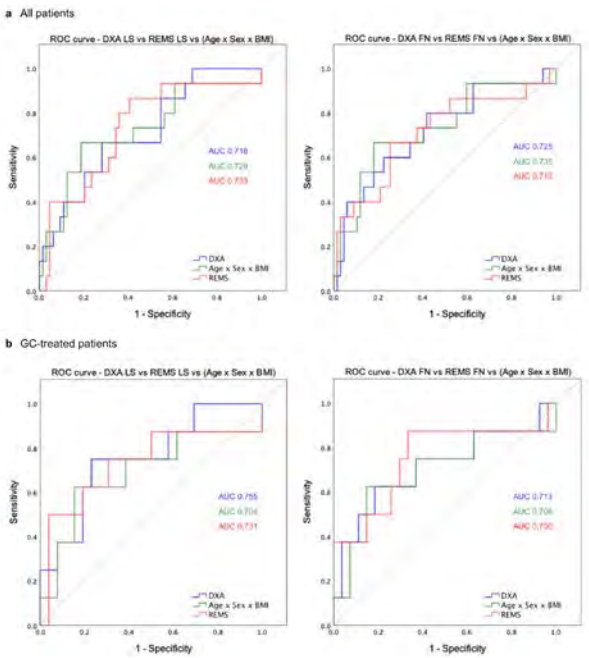
M. Diz Lopes[1], I. Galvagni[2], D. Rotta[2], C. Dartizio[2], G. Orsolini[2], C. Benini[2], A. Fassio[2], D. Gatti[2], O. Viapiana[2], M. Rossini[2], G. Adami[2]

[1]Rheumatolology Section, Department of Medicine, University of Verona, Porto, Portugal; [2]Rheumatology Section, Department of Medicine, University of Verona, Verona, Italy

Objectives: The aim of this study was to assess the diagnostic agreement between Radiofrequency Echographic Multi Spectrometry (REMS) and dual-energy X-ray absorptiometry (DXA) for bone mineral density (BMD) in patients with systemic lupus erythematosus (SLE), particularly those receiving glucocorticoids (GCs).

Material and Methods: 106 SLE patients (44 GC-treated) underwent BMD assessment using both DXA and REMS. We compared BMD and T-scores between methods and analyzed diagnostic agreement using linear regression, Cohen's kappa and Bland-Altman analysis. Receiver operator characteristic (ROC) curves evaluated the ability of REMS and DXA to discriminate fracture status. To assess the predictive performance of both methods relative to patient demographic characteristics, we used FRAX to estimate the 10-year major osteoporotic fracture risk based solely on age, sex, and body mass index (BMI) for each patient.

Results: BMD measurements at all sites were significantly lower with REMS when compared with DXA across all skeletal sites ($p<0.001$). Agreement in osteoporosis classification was slight to moderate (κ ranging from 0.229 at lumbar spine (LS) in all patients to 0.549 at femoral neck (FN) in GC-treated patients, **table 1).** REMS showed moderate correlation with DXA and demonstrated 45% sensitivity and 88.4% specificity for diagnosing osteoporosis. ROC curves in all patients demonstrated that REMS exhibited similar discriminative ability compared to DXA across all skeletal sites evaluated **(Fig.1).** When a clinical predictor model based on age, sex, and BMI was included, its standalone AUC was 0.735 (95% CI 0.582-0.889) at the FN and 0.729 (95% CI 0.574-0.884) at the LS, comparable to REMS and DXA. In a linear regression model, REMS BMD values were more strongly associated with age, sex, and body mass index: r^2 values for REMS LS ($r^2=0.569$), FN ($r^2=0.696$), and total hip ($r^2=0.744$), compared to the corresponding r^2 values for DXA (0.208, 0.489, and 0.429, respectively).



Conclusion: REMS and DXA showed a fair to moderate agreement in osteoporosis diagnosis and in fracture discrimination in SLE patients. REMS measurements showed stronger associations with age, sex, and BMI than DXA.

BEYOND THE POST–ZOLEDRONIC ACID SYNDROME: AN UNEXPECTED FLARE OF ANKYLOSING SPONDYLITIS

D. Lardjani[1], I. Hamdad[1], A. Touche[1], M. Aouchiche[1], M. Djennane[1]

[1]Mouloud Mammeri department of medicine, Tizi ouzou, Algeria

INTRODUCTION:

Zoledronic acid is widely used in the treatment of osteoporosis and is known to induce a transient inflammatory response related to immune system activation. In patients with ankylosing spondylitis, this immune stimulation may potentially contribute to the occurrence of an inflammatory disease flare.

OBJECTIVE:

To report a case of ankylosing spondylitis flare occurring after intravenous zoledronic acid infusion.

CASE REPORT:

A 60-year-old woman, with no significant past medical history, had been followed for more than 20 years for axial and entheseal spondyloarthritis. The disease had remained clinically stable and was well controlled with non-steroidal anti-inflammatory drugs (NSAIDs).

She subsequently developed fracture-related osteoporosis associated with low bone mineral density, which led to the initiation of injectable bisphosphonate therapy with zoledronic acid at a dose of 5 mg.

Clinical course after infusion

Seven days after the infusion, the patient developed a constellation of symptoms including:

• low-grade fever (38 °C),

• diffuse arthralgia and myalgia,

Ten days after the infusion, she presented with inflammatory-type spinal pain that was resistant to her usual NSAID treatment (celecoxib 200 mg/day).

Biology revealed :

• Inflammatory markers: CRP 220 mg/L, elevated ESR

• CBC: within normal limits

• Other biochemistry: unremarkable

Emergency spinal MRI demonstrated multilevel spondylodiscitis extending from T10 to S1, characterized by T1-weighted hypointensity and T2/STIR hyperintensity of the adjacent vertebral endplates and intervertebral discs.

An extensive infectious workup was performed and yielded negative results.

Outcome

Treatment was switched to a maximal dose NSAID from a different pharmacological class (naproxen 1100 mg/day), resulting in rapid clinical and biological improvement. CRP levels decreased from 220 mg/L to 24 mg/L within one week.

Given the presence of inflammatory spinal pain, a marked biological inflammatory syndrome, negative infectious investigations, and a rapid response to NSAIDs, the diagnosis of an inflammatory flare of ankylosing spondylitis was considered the most likely.

DISCUSSION:

The close temporal relationship between the post–zoledronic acid syndrome, which is frequent and well described, and the occurrence of a severe inflammatory flare of ankylosing spondylitis in a patient with long-standing stable disease raises the question of a potential triggering

role of zoledronic acid.

Bisphosphonates, particularly zoledronic acid, are known to induce transient immune activation through stimulation of γδ T lymphocytes and increased production of pro-inflammatory cytokines, mainly interleukin-6 and tumor necrosis factor alpha. This pseudo-infectious inflammatory response may act as a trigger for disease flare in patients with underlying inflammatory conditions.

Although only rare cases of spondyloarthritis flares following zoledronic acid infusion have been reported in the literature, the pathophysiological plausibility exists, and the temporal sequence observed in this patient supports a possible causal relationship.

CONCLUSION:

The occurrence of an inflammatory flare of ankylosing spondylitis following intravenous zoledronic acid infusion remains exceptional. Most published data describe inflammatory articular reactions after bisphosphonate administration.

The plausibility of such an event relies on the known immunomodulatory mechanisms of zoledronic acid, including inhibition of the mevalonate pathway, accumulation of isopentenyl pyrophosphate, and activation of γδ T lymphocytes, leading to increased release of pro-inflammatory cytokines. In patients with stable chronic inflammatory diseases, this acute immune activation may act as a triggering factor for disease flare. This case highlights the importance of increased clinical vigilance and appropriate biological monitoring following zoledronic acid infusion in patients with chronic inflammatory rheumatic diseases, particularly ankylosing spondylitis.

FRACTURES AFTER DENOSUMAB DISCONTINUATION: PRELIMINARY REAL-WORLD EVIDENCE FROM A 60-PATIENT FRACTURE LIAISON SERVICE COHORT

M. Doussiere[1], N. Mousli[2], P. Fardellone[1], V. Goëb[1]

[1]Department of Rheumatology, Amiens University Hospital,, Amiens, France; [2]Faculty of Pharmacy, Amiens University Hospital,, Amiens, France

Objectives

To assess the characteristics of fractures after denosumab in a monocentric Fracture Liaison Service cohort.

Material and methods

We retrospectively included all patients who discontinued denosumab between 2013 and 2023 and had ≥ 12 months of follow-up. Data were extracted from medical records. This abstract reports preliminary analyses from patients with completed follow-up between 2013 and 2016.

Results

Sixty patients were included (83% women; mean age 74 ± 11 years). Before denosumab, 85% had received prior osteoporosis treatment and all had a history of fragility fracture. Comorbidities included diabetes (15%), hypertension (72%), thyroid disorders (30%), chronic kidney disease (17%), and vitamin D insufficiency (41%). Denosumab was given for a median of 5 years; 7 patients had delayed injections and 8 missed at least one dose. Rheumatology follow-up occurred in 43%. Two atypical femoral fractures were reported. After discontinuation, 19% received bisphosphonates. Vitamin D and calcium supplementation continued in 88% and 59%. Three patients (5%) sustained new fractures: one isolated vertebral fracture, one non-vertebral fracture, and one case combining a vertebral and four rib fractures. Median time to fracture was 21 months. All these patients were women, of low weight and short stature, had prior long-term bisphosphonate exposure, excellent adherence to denosumab (no delays or missed injections), and adequate vitamin D and calcium intake. Two received risedronate and one zoledronate after denosumab.

Conclusions

In this preliminary FLS cohort, 5% of patients fractured after denosumab discontinuation. Fractures occurred in women with low body weight and height, prior bisphosphonate exposure, and excellent treatment adherence, despite receiving post-denosumab bisphosphonates, whereas only 19% of the overall cohort received a relay therapy. These findings contrast with classical risk factors such as long injection delays or lack of antiresorptive relay, and highlight the need for larger datasets to better identify fracture-related determinants and support predictive modelling, including AI-based tools.

P1035

IMPACT OF BUROSUMAB ON QUALITY OF LIFE AND BIOLOGICAL PARAMETERS IN ADULTS WITH X-LINKED HYPOPHOSPHATEMIA

M. Pecquet[1], M. Doussiere[2], N. Lakehal[3], P.-A. Bruy[2], P. Fardellone[2], V. Goëb[2]

[1]Department of Rheumatology, Amiens University Hospital, Amiens, France; [2]Department of Rheumatology, Amiens University Hospital,, Amiens, France; [3]Department of General Medicine, Amiens University Hospital,, Amiens, France

Objectives

X-linked hypophosphatemia (XLH) is the most common hereditary form of rickets, caused by mutations in the PHEX gene leading to excess fibroblast growth factor 23 (FGF23), renal phosphate wasting, and chronic osteomalacia. While burosumab, an anti-FGF23 monoclonal antibody, has demonstrated biological efficacy, its impact on quality of life (QoL) in adults has not been well established. This study aimed to evaluate the effects of burosumab on QoL and biological parameters in adults with XLH in a real-world setting.

Material and Methods

This was a prospective, single-center, real-world study. Six adult patients with XLH refractory to conventional therapy received burosumab 1 mg/kg by subcutaneous injection every four weeks. Clinical parameters, biochemical markers, bone mineral density (BMD), and QoL were assessed at baseline, 12 months, and 24 months. QoL was evaluated using six validated questionnaires (FACIT-F, RAPID3, HAQ, SF-36, EQ-5D-5L, WOMAC). Radiographs of non-healed fracture were performed before and after treatment.

Results

All six patients completed 24 months of treatment without serious adverse events or treatment discontinuation. No significant improvement was observed across most QoL questionnaires, except for RAPID3, which showed a trend toward improved QoL at 24 months. Burosumab induced a rapid and significant increase in serum phosphate levels (0.54 mmol/L at baseline vs 0.76 mmol/L at month 3; p = 0.016) and a significant increase in lumbar spine BMD at 24 months (1.084 g/cm² at baseline vs

1.131 g/cm² at month 12; p = 0.028). P1NP levels significantly decreased (301 µg/L at baseline vs 128 µg/L at 24 months; p = 0.028). C-terminal FGF23 levels increased. Three response profiles were identified: improvement in both QoL and biological parameters (50%), biological response without perceived QoL improvement (33%), and biological response with worsening QoL (17%). All patients achieved consolidation of initial fracture sites without recurrence.

Conclusions

Burosumab significantly improves key biochemical and skeletal parameters in adults with XLH and demonstrates a favorable safety profile. However, the impact on quality of life remains heterogeneous, highlighting the need for individualized follow-up and larger studies to better characterize patient-reported outcomes.

P1036

DENOSUMAB THERAPY IN MEN WITH OSTEOPOROSIS: A SINGLE-CENTRE RETROSPECTIVE COHORT STUDY (OSTEOPROM PART 4)

M. Dubovska[1], D. Poksane[2], A. Makarova[1], I. Rasa[2]

[1]Rīga Stradiņš University, RIGA, Latvia; [2]Rīga Stradiņš University, Riga East University Hospital, Latvian Osteoporosis and Bone Metabolic Diseases Association, RIGA, Latvia

Objective: This study aims to evaluate the effects of denosumab therapy on bone mineral density (BMD) and fracture incidence in men with osteoporosis treated in routine clinical practice.

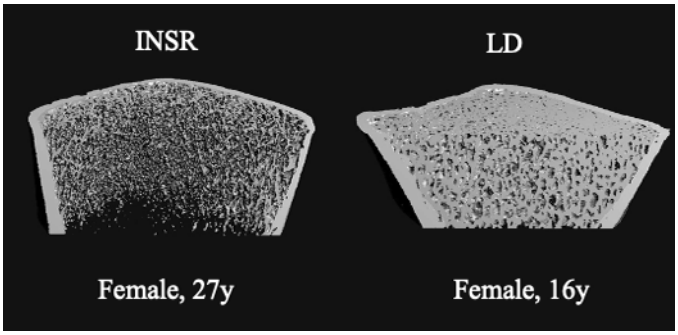
Material and Methods: This study was conducted from 2014 to 2025 (12 years) and included 76 men diagnosed with osteoporosis. We collected REUH Outpatient Clinic data from medical records and then manually analysed it. Demographic and clinical data, including age, body mass index, duration of osteoporosis, prior antiosteoporotic therapy, glucocorticoid use, and fracture history, were collected. BMD at the lumbar spine (L1–L4) and total mean hip was assessed using dual-energy X-ray absorptiometry. Serum cholecalciferol, parathyroid hormone, and calcium levels were evaluated before, during or after denosumab therapy. Fracture incidence was recorded before and during treatment. We performed descriptive statistical analysis.

Results: The mean age of patients was 65.7±14,5SD years (min. 21, max. 89), with 75% aged ≥60 years. The duration of denosumab therapy ranged from 6 months to 7 years; only 10% of patients received denosumab for five years or longer. Among the men with osteoporosis, 26.3% had glucocorticoid-induced osteoporosis, while 73.7% had idiopathic osteoporosis. Prior to denosumab therapy, fractures were documented in 40.8% of patients, including vertebral fractures in 14.5%. During treatment, fractures occurred in 5.3% of patients, of which 75% were non-vertebral. At the lumbar spine, bone mineral density increased by >0.05 g/cm² in 42% of patients and remained stable (±0.05 g/cm²) in 32%. At the total mean hip, a clinically relevant increase in bone mineral density (>0.05g/cm²) was observed in 79% of patients with available paired measurements. The prevalence of cholecalciferol deficiency (≤30ng/mL) decreased from 18.4% before therapy to 4.0% during therapy. A mild increase in PTH levels was noted in 65 patients, while serum calcium levels remained within the normal range in 100%. No significant adverse cardiovascular events, including myocardial infarction or stroke, were observed during denosumab therapy.

Conclusions: This study's findings demonstrate that denosumab can significantly improve patient health by reducing fracture risk and improving bone density. These findings support the effectiveness of denosumab as a therapeutic option for male osteoporosis, a population that remains insufficiently studied, encouraging clinicians to consider it as a reliable treatment option.

P1037

BONE MICROARCHITECTURE IN THE CONTEXT OF INSULIN SIGNALING



M. Dyer[1], M. Jovanovic[2], C. Gordon[2], R. Brown[1]

[1]National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, United States; [2]Eunice Kennedy Shriver National Institute of Child Health and Human Development, Bethesda, United States

Insulin's action on bone is not well understood, especially in insulin resistance (IR). Patients with lipodystrophy (LD) lack adipose tissue and have severe IR, causing hyperinsulinemia and increased insulin signaling. Patients with insulin receptor (INSR) pathogenic variants have hyperinsulinemia, but very low insulin signaling from failure of insulin to stimulate its receptor. To study effects of differential insulin signaling on bone, we performed High Resolution Peripheral Quantitative CT of the diaphyseal and distal radius and tibia in patients with LD (n=9) and INSR (n=3). Measurements included volumetric bone mineral density (vBMD), trabecular bone volume fraction (BV/TV), and trabecular thickness (TT). Micro-finite element analyses evaluated stiffness and failure load (FL).

At the distal radius, LD vs INSR had increased mean total vBMD (354 vs 284 mgHA/cm^3), BV/TV (0.25 vs 0.15), trabecular vBMD (183 vs 115 mgHA/cm^3), TT (0.27 vs 0.21 mm), stiffness (68294 vs 48212 N/mm), and FL (5867 vs 4187 N). At the diaphyseal radius, LD patients had 2.5-fold higher BV/TV and trabecular vBMD, and higher TT (0.18 vs 0.12 mm), stiffness (74771 vs 69538 N/mm), and FL (6607 vs 6263 N). At the distal tibia, LD patients had 2-fold higher BV/TV and trabecular vBMD, and higher total vBMD (378 vs 269 mgHA/cm^3), TT (0.33 vs 0.22 mm), stiffness (209970 vs 127792 N/mm), and FL (17560 vs 10983 N). At the diaphyseal tibia, LD patients had 4-fold higher BV/TV, 10-fold higher trabecular vBMD, 2-fold higher TT, and higher total vBMD (751 vs 714 mgHA/cm^3), stiffness (229949 vs 195003 N/mm), and FL (19785 vs 16717 N). At the distal tibia, those with generalized LD (n=3), who have more severe IR vs partial LD (n=6), had ~2-fold higher total vBMD, trabecular vBMD, BV/TV, TT, stiffness, and FL vs partial LD.

Compared to a database of healthy volunteers, trabecular parameters were ~99th centile for LD and ~1st centile for INSR. These data suggest that excess insulin signaling in LD associates with excess bone mass, especially in trabeculae, while decreased insulin signaling in INSR associates with decreased bone mass. Potential mechanisms include increased osteoblast activity via insulin stimulation of IGF-1 pathways, and differentiation of bone marrow mesenchymal cells into osteoblasts vs adipocytes in patients with LD who cannot produce adipocytes.

P1038

RISK FACTORS FOR OSTEOPOROSIS IN PATIENTS WITH CALCIUM PYROPHOSPHATE DEPOSITION DISEASE

M. Elgendi[1], N. V. Zhuravleva[2], T. L. Smirnova[2], V. N. Diomidova[2]

[1]Global care Hospital, Giza, Egypt; [2]Chuvash State University named after I. N. Ulyanov, Cheboksary, Russia

Objective. To determine the prognostic significance of individual factors in the development of osteoporosis in patients with calcium pyrophosphate deposition disease (CPPD).

Materials and methods. An open prospective study was conducted with the participation of 90 patients. The main group consisted of 61 patients with a verified diagnosis of CPPD (33 men and 28 women). The control group consisted of 28 patients with osteoarthritis (8 men and 20 women). The diagnosis of CPPD was established according to the McCarty criteria, which include the detection of calcium pyrophosphate crystals in the synovial fluid using polarized microscopy and radiological or ultrasound confirmation of chondrocalcinosis. All patients underwent densitometry at the initial stage and at the end of the follow-up.

Results. The initial characteristics of patients by gender, age, and duration of the disease did not reveal statistically significant differences between the groups.

At the end of the follow-up period, osteoporosis was diagnosed in 22 (36%) of the 61 patients with CPPD (13 men and 9 women) and in 8 (28.6%) of the 28 patients with osteoarthritis (2 men and 6 women).

The analysis of risk factors revealed the following associations with the development of osteoporosis in patients with CPPD: age over 55 years in women OR=5.1; 95% CI=1.019-24.29; p=0.047); age over 65 years in men (OR=3.8; 95% CI=1.25-11.5; p=0.013); hyperparathyroidism (OR=14.28; 95% CI=1.65-136.8; p=0.015); increased erythrocyte sedimentation rate (ESR)>20 mm/h (OR=14.37; 95% CI=1.12–10.1; p=0.025); elevated C-reactive protein (CRP) values>5.0 mg/L (OR=5.21; 95% CI=2.03-19.04; p=0.002).

When a multivariate analysis was performed using logistic regression (model sensitivity – 71%, specificity – 82%), the only significant factor associated with the development of osteoporosis in patients with CPPD was hyperparathyroidism (OR=13.64; 95% CI=1.04–193.03; p=0.038). It is important to note that the use of glucocorticoids in this cohort of patients did not show a statistically significant effect on the development of osteoporosis.

Conclusions. In patients with calcium pyrophosphate deposition disease, hyperparathyroidism is associated with the development of osteoporosis.

P1039

RISK FACTORS FOR OSTEOPOROSIS AND OSTEOPOROTIC FRACTURES IN TYPE 2 DIABETES: THE ROLE OF ANTIDIABETIC DRUGS

M. Elgendi[1], N. V. Zhuravleva[2], T. L. Smirnova[2], V. N. Diomidova[2]

[1]Global care Hospital, Giza, Egypt; [2]Chuvash State University named after I. N. Ulyanov, Cheboksary, Russia

Objective. Identification of risk factors for the development of osteoporosis and osteoporotic fractures in patients with type 2 diabetes (T2DM), including taking into account the antidiabetic therapy.

Materials and methods. The study was conducted on the basis of a multidisciplinary hospital. We evaluated the body mass index minus fat, the percentage of adipose tissue using bioimpedansometry, bone mineral density (BMD) in the lumbar spine and proximal femur using dual-energy X-ray absorptiometry, the absolute risk of fractures over 10 years (FRAX) and/or chest and lumbar spine radiography, taking into account the recommendations of the International Osteoporosis Foundation for patients with T2DM.

Results. The study included 35 patients with T2DM and osteoporosis (54% women); the average age was 62.5±9.7 years (group I) and 30 patients with T2DM without osteoporosis, without statistically significant differences in age, gender (group II). The absolute risk of fracture according to the FRAX scale was 22.4±1.2% in group I and 12.9±2.2% in group II. A positive strong association was found between the level of glycated hemoglobin (failure to reach the target level), the presence of microvascular complications, and the FRAX score. Metformin was found to have a protective effect on the development of osteoporosis, especially postmenopausal osteoporosis (OR 3.3; 96% CI=0.001-0.08, p <0.05), indicating its potential bone-protective effect by reducing bone resorption and increasing osteoblast activity. Sodium-glucose cotransporter 2 inhibitors (SGLT-2Is) showed a weak negative association with osteoporosis (OR 2.8; 95% CI=0.81-0.99, p=0.04). Glyclazide demonstrated an increased risk of pathological fractures.

Conclusions. The main risk factors for fractures are poor metabolic control, the presence of nephropathy and retinopathy, and uncontrolled hypertension. The study results indicate the potential ability of metformin to protect bone tissue, which may be beneficial for patients with a high risk of fractures. On the other hand, the use of gliclazide should be approached with caution, especially in individuals with osteoporosis or a high risk of fractures. These results highlight the importance of an individualized approach to the treatment of patients with T2DM to maintain bone health.

P1040

THE EFFECTIVENESS OF DENOSUMAB IN THE TREATMENT OF OSTEOPOROSIS IN PATIENTS WITH RHEUMATOID ARTHRITIS

M. Elgendi[1], N. V. Zhuravleva[2], V. N. Diomidova[2], T. L. Smirnova[2], S. A. Yastrebova[2]

[1]Global care Hospital, Giza, Egypt; [2]Chuvash State University named after I. N. Ulyanov, Cheboksary, Russia

Objective. A comparative study of the antiresorptive efficacy of denosumab and oral bisphosphonates was conducted in patients with rheumatoid arthritis (RA) and osteoporosis (OP).

Materials and methods. 25 patients with RA were included in the study. All participants underwent lumbar spine and proximal femur densitometry using the Lunar Prodigy device. Automatically calculated T- and Z-scores were used to assess bone mineral density (BMD) (WHO, 1994; ISCD, 2007). Osteoporosis (T-score <-2.5 SD) was confirmed in all participants. The diagnosis of osteoporosis (T-score <-2.5 SD) was confirmed in all patients based on DXA data. All patients were in postmenopause. The average age was 60.5±8.5 years, and the average DAS28 activity was 4.17±0.95. The radiological stage of the disease was as follows: stage II in 8 patients, stage III in 10 patients, and stage IV in 7 patients.

14 patients received an injection of denosumab, and 13 patients received alendronate. The control group consisted of 13 patients with RA and OP who did not receive anti-resorptive therapy.

All patients had their serum β-CTX and osteocalcin (OC) levels quantified three times (before treatment and at 1 and 6 months) using a solid-phase enzyme-linked immunosorbent assay. Statistical data processing was carried out using standard methods.

Results. Analysis of bone tissue resorption markers (β-CTX and OC) revealed the following patterns. In the group of patients treated with denosumab, there was a significant decrease in β-CTX levels 1 month after treatment initiation (median 859.3 pg/mL vs. 725.3 pg/mL, p=0.047) and OC levels (median 12.9 vs. 8.39, p=0.045) compared to the group treated with bisphosphonates.

In the group of patients who took bisphosphonates, there was no significant decrease in markers of resorption compared to the denosumab group.

In the control group, there was an increase in the level of β-CTX (median 895.8 pg/ml vs. 915.3 pg/ml, p>0.051) and OC (median 21.8 vs. 26.21, p=0.028), indicating ongoing bone resorption in the absence of therapy.

Conclusions. Denosumab has shown its effectiveness in the treatment of osteoporosis in patients with rheumatoid arthritis, while having a more pronounced antiresorptive effect compared to oral bisphosphonates.

P1041

THE DOSE OF FEBUXOSTAT REQUIRED TO ACHIEVE THE TARGET LEVEL OF URIC ACID IN PATIENTS WITH NORMAL AND IMPAIRED RENAL FUNCTION

M. Chikina[1], M. Eliseev[1], Y. Kuzmina[1]

[1]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia

Objective: to compare the dosage of Febuxostat (FS) required to achieve the target level of uric acid (UA) in blood serum in patients with gout with normal or near normal (glomerular filtration rate (GFR) >60 ml/min/1.73 m2) and moderately impaired (GFR 30–60 ml/min/1.73 m2) renal function.

Material and methods. The study included 159 patients with gout without urate-lowering drugs and MC levels >360 mmol/l. The patients were divided into two groups: GFR >60 ml/min/1.73 m2 (n=123) and GFR 30-60 ml/min/1.73 m2 (n=36). All received febuxostat 80 mg / day, if necessary, the dose was increased to 120 mg / day. The observation lasted 6 months. Changes in the MC level, achievement of the target level (<360 mmol/l) and the required dose of the drug were evaluated.

Results. Data from 152 patients who completed the study were analyzed: 34 of 36 patients with GFR 30–60 ml/min/1.73 m2 and 118 of 123 with GFR >60 ml/min/1.73 m2 . During the observation period, 129 (84.9%) of 152 patients reached the target level of serum UA: 101 (85.6%) of 118 patients with GFR >60 ml/min/1.73 m2 and 28 (82.4%) of 34 with GFR 30–60 ml/min/1.73 m2 (p=0.6). In the GFR >60 ml/min/1.73 m2 group in 68 (67.3%) patients FS dose of 80 mg/day was enough to achieve the target level of UA and in 33 (32.7%) the dose of 120 mg/day was requires, and for the GFR 30–60 ml/min/1.73 m2 group such doses were required in 13 (46.4%) and 15 (53.6%) patients, respectively (p=0.04). The dose of the prescribed drug after the adjustment until the target level of UA was reached was statistically lower in patients with GFR >60 ml/min/1.73 m2 (93.1±18.9 mg/day) than in the group of patients with GFR 30–60 ml/min/1.73 m2 (101.4±20.3 mg/day), p=0.04

Conclusion. The efficacy of FS does not decline in patients with gout and moderate decline in renal function. In more than 80% of cases it is possible to achieve the target level of UA in these patients, but it is associated with the need to use the maximum daily doses of the drug.

P1042

CLINICAL FEATURES IN CALCIUM PYROPHOSPHATE CRYSTAL DEPOSITION DISEASE PATIENTS WITH HYPERURICEMIA (DATA FROM A PILOT STUDY)

M. Eliseev[1], M. Chikina[1], Y. Kuzmina[1]

[1]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia

There are suggestions that Hyperuricemia (HU) can often accompany calcium pyrophosphate deposition (CPPD) disease and affect the clinical manifestations of it. The aim was to determine the frequency of HU and its clinical significance in patients with CPPD.
Materials and Methods. The study included 213 patients with an established diagnosis of CPPD. The serum uric acid (sUA) level was determined in all patients, after which the patients were divided into 2 groups depending on the presence of sUA level (sUA level of ≥360 mmol/l was taken as HU): patients with CPPD and HU (n=75) and with CPPD and without HU (n=138). A comparative characteristic of the groups was carried out according to the clinical manifestations of the disease, comorbidity, therapy taken, and laboratory blood parameters.
Results. The groups did not differ in age. HU was detected in 75 out of 213 patients (35.2 %). The average sUA level in the group with CPPD and HU was 444.6±77.7 mmol/l, in the group with CPPD without HU – 273.2±53.0 mmol/l. In patients with CPPD and HU, chronic kidney disease was more frequently detected (18.7 % vs 8.7 %) and increased parathyroid hormone level (39.0 [29.8; 61.0] pmol/l vs 29.8 [18.4; 41.5] pmol/l). Hypertension, chronic heart failure (CHF), diabetes mellitus (DM) (for all p<0.05), and obesity (p<0,01) were also more frequently detected with CPPD and HU. Among the patients with CPPD and HU there were more people with chronic arthritis (60.0 % vs 45.0 %), and their ankle joints were more often involved (24.0 % vs 13.0 %). The median serum c-reactive protein level was also higher (3.8 [1.7; 6.7] mg/l vs. 2.1 [0.8; 5.9] mg/l).
Conclusion. The high frequency of HU in CPPD (35.2 %) and their combination with each other determines the high probability of comorbidity and metabolic disorders (obesity, hypertension, CHF, DM), and also creates conditions for the development of chronic inflammation.

P1043

COMPARISON OF ANAMNESTIC AND LABORATORY PARAMETERS IN PATIENTS WITH DIFFERENT PHENOTYPES OF HYPERURICEMIA (DATA FROM A PILOT STUDY)

M. Chikina[1], M. Eliseev[1], Y. Kuzmina[1]

[1]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia

Asymptomatic hyperuricemia (AHU) and gout are pathological conditions characterized by elevated uric acid (UA) levels in the blood. Gout is characterized by acute arthritis attacks due to UA crystallization in the joints. Other differences between AHU and gout require further study.
Study objective: To identify key differences between AHU phenotypes.
Materials and methods: 220 patients with HU (UA >360 µmol/L) over 18 years of age were examined and divided into the following phenotypes: AHU; AHU with monosodium urate crystals (verified by ultrasound or synovial fluid analysis) (AHU+crystals); intermittent gout (G); tophaceous gout (G+tophi). Comparative characteristics of the groups included an assessment of the frequency of comorbidities, metabolic disorders, and the main laboratory parameters.
Results: According to phenotyping results, the group of patients with AHU included 40 people (18.2%), AHU+crystals - 26 (11.8%), G - 111 (50.5%), G+tophi - 43 (19.5). The average age in the groups was comparable (p = 0.5). An increase in the frequency of hypertension and nephrolithiasis was revealed in the series AHU without crystals - AHU+crystals - G - G+tophi (p = 0.0006 and p = 0.00006, respectively). Similar patterns were found for the mean serum levels of UA (p=0.00001), creatinine (p=0.0003), and GGT (p=0.0003), the mean values of which increased sequentially from AHU to G+tophi. The maximum mean levels of CRP (4.1 [2.3; 8.4] mg/L) were in patients with G and G+tophi (5.3 [2.3; 12.5] mg/L), which was significantly higher than in AHU patients, but statistically significantly different from the AHU+crystals group (p=0.04). GFR was lower in the G+tophi group compared to AHU (74.7±20.0 ml/min/1.73 m2 vs 86.8±17.9 ml/min/1.73 m2, respectively, p=0.02).
Conclusions: The incidence of hypertension, nephrolithiasis, serum GGT and creatinine levels increases as HU progresses from AGU to G+tophi, which may reflect the intensity of chronic microcrystalline inflammation.

P1044

ULTRASONOGRAPHIC SIGNS OF URATE CRYSTAL DEPOSITION IN THE RENAL PARENCHYMA IN PATIENTS WITH GOUT (PILOT STUDY DATA)

M. Eliseev[1], Y. Kuzmina[1], M. Chikina[1], V. Zelenov[1]

[1]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia

Study objective: to obtain data on the frequency of urate crystal deposition detection in the renal parenchyma using ultrasound (US), and its association with clinical manifestations of the disease in patients with gout.
Materials and methods: the study included 25 patients, 23 (92%) of whom were male. Inclusion criteria were age >18 years and a confirmed diagnosis of gout. All patients underwent evaluation of laboratory blood and urine parameters, calculation of the estimated glomerular filtration rate (eGFR), and renal ultrasound using Doppler mapping.
Results: the mean age of the patients was 48.0±11.4 years. The mean uric acid level was 491.2±120.3 µmol/L. Chronic kidney disease stage >2 was detected in 68% of patients. Ultrasound changes characteristic of urate deposition in the renal medulla were found in 5 (20%) patients. These changes manifested as twinkling artifacts during color Doppler ultrasonography. The presence of urate crystals in the kidneys was associated with a longer disease duration and reduced eGFR.
Conclusion: the preliminary results of this pilot study demonstrate a high (20%) frequency of detecting signs of urate deposition in the renal parenchyma in patients with gout and suggest an association between the identified ultrasound changes and disease duration and decreased eGFR.

P1045

IMPLEMENTATION OF A FRACTURE LIAISON SERVICE REDUCES FRAGILITY FRACTURE RATES IN OLDER ADULTS: A FIVE-YEAR PROSPECTIVE COHORT STUDY

M. Fominykh[1], L. Evstigneeva[1]

[1]Ural State Medical University, Yekaterinburg, Russia

Objective of this study was to evaluate the impact of a fracture liaison service (FLS), integrated into the structure of Trauma Center of Central City Hospital, on the incidence of fragility fractures and overall mortality after 12 months of follow-up.

Materials and Methods. A prospective cohort study with retrospective analysis was conducted among 2,915 patients aged 60 years and older who presented to the Trauma Center of Central City Hospital No.7, Yekaterinburg from January 2019, to December 2023, with diagnoses of hip fracture (ICD-10 S72.0–S72.2), humerus fracture (ICD-10 S42.2), wrist fracture (ICD-10 S52.5–S52.6), thoracic vertebral fracture (ICD-10 S22.0–S22.1), and lumbar vertebra fracture (ICD-10 S32.0, S32.7). An FLS was implemented at the Trauma Center in June 2021. The FLS included a trauma center, rheumatologist consultation office, and nurse coordinator. Data were analyzed to assess the incidence of new fractures and overall mortality after 12 months of follow-up.

Results The study included 2,915 primary patients aged 60 years and older, with a median age of 71[65;79] years. There were 2,507(86%) women, with a median age of 74[65;79], and 408(14%) men, with a median age of 69.5[64;78]. The distribution of fracture locations was as follows: 333 (11.4%) with a hip fracture, 774(26.6%) with humerus fracture, 1,582(54.3%) with wrist fracture, and 226(7.7%) lumbar and/or thoracic vertebrae fracture. In the period before FLS implementation, the annual rates of fragility fractures at 12 months were 5.9%(34/578) in 2019, 6.3%(32/507) in 2020, and 5.7%(31/546) in 2021. The average fragility fracture rate for the entire pre-FLS period was 5.9%(97/1,631). Following the implementation of the FLS in June 2021, annual fragility fracture rates at 12 months decreased to 4.5%(28/620) in 2022 and to 4.1%(27/664) in 2023. The average recurrent fracture rate for the post-FLS period was 4.3%(55/1,284). Implementation of the FLS was associated with a statistically significant reduction in fragility fracture rates (Pearson χ^2 test = 4.03, p = 0.045). The absolute reduction in fragility fracture rates was 1.6% (from 5.9% to 4.3%). The odds ratio (OR) of fragility fracture in the pre-FLS versus post-FLS group was 1.41 (95% CI: 1.01–1.98), indicating a relative risk reduction of approximately 30% compared to the pre-implementation period. Analysis of overall mortality at 12 months revealed no statistically significant differences between periods (Pearson χ^2 test = 0.50, p = 0.48). Mortality rates were: 2019: 5.9% (34/578), 2021: 5.9% (32/546), 2022: 5.3% (33/620), and 2023: 5.1% (34/664). Overall mortality rates at one year remained stable throughout the study period. Mortality data for 2020 were excluded due to the impact of the COVID-19 pandemic.

Conclusions The implementation of an FLS in the fragility resulted in a clinically significant 30% reduction in the annual recurrence rate in older adults with fragility fractures. These real-world results support the rationale for systematically integrating FLS programs in trauma centers as an effective intervention for secondary fracture prevention.

P1046

IMPACT OF ANTIOSTEOPOROTIC THERAPY ON FRAGILITY FRACTURE RATES IN ELDERLY PATIENTS: A 12-MONTH PROSPECTIVE COHORT STUDY FROM THE OUTPATIENT DEPATMENT FRACTURE LIAISON SERVICE

M. Fominykh[1], L. Evstigneeva[1], A. Popov[1]

[1]Ural State Medical University, Yekaterinburg, Russia

Objective: to evaluate the effect of antiosteoporotic therapy on the incidence of fragility fractures after 12 months of follow-up in real clinical practice at the outpatient department of the Central City Hospital of Yekaterinburg.

Materials and Methods. A prospective cohort study was conducted among 564 patients aged 60 years and older who visited the Fracture Liaison Service at the outpatient depatment of the Central City Hospital No. 7, Yekaterinburg from June 2021 to June 2024 with diagnoses of hip fracture (ICD-10 S72.0–S72.2), humerus fracture (ICD-10 S42.2), wrist fracture (ICD-10 S52.5–S52.6), thoracic vertebral fracture (ICD-10 S22.0–S22.1), lumbar vertebral fracture (ICD-10 S32.0, S32.7), and fractures at other locations. Data analysis included an assessment of the incidence of new fractures over 12 months of follow-up and adherence to antiosteoporotic therapy. A comparison was made between two groups of patients who regularly took antiosteoporotic therapy (compliance greater than 80%) and those who did not take them or took them irregularly.

Results. The study included 564 primary patients aged 60 years and older, including 37(6.6%) men, with a median age of 70.8[66;74] years, and 527(93.4%) women, with a median age of 69.7[65;74]. The distribution of patients by fracture location was as follows: 33(5.9%) patients with hip fracture were included in the observation, 120(21.3%) patients with humerus fracture, 308(54.6%) patients with a wrist fracture, 128(22.6%) patients with lumbar and/or thoracic vertebrae fractures, and 8(1.4%) patients with fractures in other locations. At the initial consultation, all patients were recommended additional examination for further diagnosis of osteoporosis, and an appointment was made to start antiosteoporotic therapy.

A total of 318(56.4%) patients attended a follow-up consultation after 12 months, including 18(5.7%) men, median age 70.8[65; 76] years, and 300(94.3%) women, median age 70.2[66; 74]. Treatment adherence was assessed: 316(99.6%) patients regularly took calcium and/or vitamin D3 supplements. 232(72.9%) were taking the recommended antiosteoporotic therapy after 12 months, of which 176(75.9%) were taking it regularly (compliance greater than 80%) and 56(24.1%) were taking it intermittently. Of the 318 patients, 86(27.1%) did not start antiosteoporotic therapy, including 23 who were not prescribed it due to a low 10-year fracture risk, and 63 did not take it for various other reasons, such as not considering it necessary or not having heard of this medication from friends.

During the 12-month follow-up, 14 of the 318 patients experienced fragility fractures. Of these, 9(64.3%) had vertebral and large bone fractures (humerus and hip fracture). An analysis of the causes of fragility fractures was conducted in 14 patients. 12(85.7%) patients did not receive recommended antiosteoporotic therapy; one patient took antiosteoporotic therapy irregularly for less than 3 months during the observation period; and one patient regularly received pathogenetic treatment. A subgroup analysis of patients with fractures not receiving antiosteoporotic therapy revealed that 10(83.3%) patients had a high fracture risk and refused further examination and treatment; 2(16.7%) patients had a moderate risk; densitometry data showed osteopenia and

antiosteoporotic therapy was not indicated for them.
After 12 months, 176(55.3%) patients received regular antiosteoporotic therapy. Of these, only one patient experienced a fragility fracture within the first year after the index fracture. When comparing two groups (Group 1 (n=176): regular antiosteoporotic therapy intake, Group 2 (n=142): irregular intake/no antiosteoporotic therapy intake), statistically significant results were obtained (χ^2=15.2, p<0.001), confirming the effectiveness of antiosteoporotic therapy in preventing recurrent fractures. The relative risk (OR) of fractures without therapy was 17.6 (95% CI 2.3-136.4), with regular treatment 0.057 (95% CI 0.007-0.43).
Conclusions. The fragility fracture rate after 12 months was 4.4%, with 64.3% of these being severe osteoporotic fractures. The main cause of fragility fractures was treatment refusal. Regular antiosteoporotic therapy was associated with a 17-fold reduction in the risk of fragility fractures (0.6% vs. 9.2%, p<0.001). The main problems remain low attendance at follow-up examinations and non-compliance with recommendations in individuals at high risk of fractures.

P1047

ANALYSIS OF A SINGLE CENTRE 20-YEAR SURGICAL MANAGEMENT FOR GIANT CELL TUMOR OF BONE

M. Foteva[1]

[1]University Clinic for Orthopaedic Surgery- Skopje, Skopje, North Macedonia

Giant cell tumor of bone (GCTB) is a locally aggressive and rarely metastasizing neoplasm which is mainly treated with surgery. The main issue with the selection of the most appropriate surgical procedure is its high recurrence rate, possible malignancy and location near the joints which may lead to significant functional impairment. In this retrospective study, we analyze data from patients with GCTB who were treated in the period 2000-2020 at the University Clinic for Orthopaedic Surgery-Skopje. This institution is a tertiary care center and referral center for bone tumors in North Macedonia. The following data of each patient were reviewed: age, sex, location of tumor, type of operative procedure, follow up and recurrence. In the study period, total of 80 patients were treated: 30 male (37,5%), 50 female (62,5%), age : 6-79 (median 35 years). There were total of 108 surgical procedures performed on 80 patients with GCTB. Follow- up 36-144 months (average 84 months), 2 patients lost during follow-up for non-related reasons, 13 patients (16,25%) with 17 local recurrences (21,25%). No metastases during the follow up period. After the initial surgical treatment, 23 patients required a second surgery. Group of 5 patients were treated with additional surgery. There was no significant association between age, sex, location of GCTB and type of operative procedure with local recurrence. There was a statistically significant association between Campanacci staging of tumor and local recurrence. We hope that our study provides useful insights into the management and prognosis of this challenging bone tumor.

P1048

BONE AND WEIGHT OUTCOMES WITH PIOGLITAZONE VS SEMAGLUTIDE IN OBESE POSTMENOPAUSAL WOMEN WITH TYPE 2 DIABETES MELLITUS

M. G. Ghasaboghlyan[1], L. B. Baghdasaryan[2], V. B. Babalyan[3], V. M. Mukuchyan[4], G. S. Shasuvaryan[1]

[1]EcoSence Diagnostic Center, Yerevan, Armenia; [2]Vardanants medical Center, Yerevan, Armenia; [3]Osteoporosis Center, Yerevan, Armenia; [4]National Institute of Health, Yerevan, Armenia

Background: Type 2 diabetes mellitus (T2DM) in older adults is commonly associated with obesity, impaired bone quality, and increased fall risk. Pioglitazone is an insulin sensitizer frequently used in elderly patients due to its low hypoglycemia risk, but long-term use has been associated with decreased bone mineral density (BMD). Conversely, GLP-1 receptor agonists such as semaglutide induce significant weight loss, which may independently worsen BMD through reduced mechanical load. The net skeletal impact of these two agents in osteopenic elderly women remains insufficiently clarified.
Objective: To goal of this study is to compare the effects of pioglitazone and semaglutide on body weight changes and osteoporosis progression risk over 2 years in obese postmenopausal women with T2DM and baseline DEXA-confirmed osteopenia.
Methods: This prospective observational study included 204 postmenopausal women aged 55–75 years with T2DM (HbA1c 7.5–9%) and BMI >35 kg/m², all with osteopenia at baseline. Participants received either pioglitazone (n=103) or semaglutide (n=101), in addition to calcium 1200 mg/day and vitamin D 2000 IU/day. Clinical parameters, HbA1c, and BMI were reassessed every 3 months; vitamin D every 6 months; and DEXA annually. FRAX scores were calculated at baseline and annually.
Results: The pioglitazone group showed a slight increase in BMI (from 37 to 38 kg/m²), while the semaglutide group demonstrated significant weight reduction (from 36 to 29 kg/m²). Osteoporosis developed in 22 of 103 patients (21.4%) in the pioglitazone group versus 14 of 101 (13.9%) in the semaglutide group. No patient in either group progressed to a T-score below −3.0. HbA1c improvement was comparable in both groups, and FRAX risk scores did not meaningfully increase over the 2 year period. The difference in osteoporosis progression represented a trend but did not reach a clinically significant threshold. No severe hypoglycemic events were recorded.
Conclusion: Although osteoporosis progression was slightly higher in the pioglitazone group, the difference was modest and did not result in severe bone loss. Semaglutide was associated with favorable weight reduction, while pioglitazone provided stable glycemic control with minimal hypoglycemia risk, a clinically relevant benefit in elderly patients prone to falls. These findings suggest that pioglitazone remains an appropriate therapeutic option in select obese postmenopausal women with T2DM, particularly those at higher risk of hypoglycemia or falls, where fracture risk from hypoglycemic events may outweigh its modest negative impact on bone density.

P1049

IMMUNE DYSREGULATION IN PATIENTS WITH RADIATION-INDUCED OSTEONECROSIS OF THE JAWS (RONJ)

L. H. Duryagina[1], M. G. Nikolashin[1], G. V. Nikolashin[2], S. Kulanthaivel[3]

[1]V.I. Vernadsky Crimean Federal University, Simferopol, Russia; [2]St. Luka's Clinical Multidisciplinary Medical Center of the Crimean Federal University named after V.I. Vernadsky, Simferopol, Russia; [3]Naarayani Multispeciality Hospital, Erode, India

Objective: The pathogenesis of Radiation-Induced Osteonecrosis of the Jaws (RONJ) involves a complex interplay of hypovascularity, tissue injury, microbial infection, and immune dysregulation. While systemic and local immunodeficiency components are recognized, the specific immunophenotype in RONJ patients requires deeper characterization.
Material and Methods: A comprehensive immunological analysis was performed alongside conservative management in 6 cancer patients with RONJ of the lower jaw. Treatment included oral antiseptic rinses, wound care, and hyperbaric oxygen therapy (as an adjunct). Immune assessment was expanded to include:
Local immunity: Analysis of oral fluid for sIgA, pro-inflammatory cytokines (IL-6, TNF-α), and microbial profiling.
Systemic immunity: Clinical blood count with advanced flow cytometry for T-cell subpopulations (CD4+, CD8+, T-reg, Th17), serum levels of immunoglobulins (IgA, IgG), and inflammatory markers (CRP).
Results:
Local Immunity: Markedly reduced sIgA levels were confirmed, indicating a compromised mucosal barrier. The phagocytic activity of neutrophils was impaired. A significant increase in pro-inflammatory cytokines (IL-6, TNF-α) was observed, confirming a dominant and persistent inflammatory milieu.
Systemic Immunity: Flow cytometry revealed a significant decrease in CD4+ T-helper cell count and an altered CD4+/CD8+ ratio, indicating T-cell dysregulation. Serum IgA was decreased, correlating with low local sIgA. Elevated CRP and IgG levels supported the presence of chronic systemic inflammation and antigenic stimulation.
Conclusions: In patients with RONJ, radiation-induced tissue damage and persistent microbial biofilm lead to a state of chronic non-resolving inflammation and secondary immune dysregulation. This is characterized by impaired mucosal immunity (sIgA deficiency), systemic T-cell dysfunction, and a pronounced humoral inflammatory response. These immunological alterations contribute to impaired bone healing and disease chronicity. Modern management should prioritize surgical removal of necrotic bone combined with targeted anti-inflammatory and antimicrobial strategies, addressing both the cause and the immunological consequences of RONJ.

P1050

ATYPICAL OSTEONECROSIS OF THE JAWS

L. H. Duryagina[1], M. G. Nikolashin[1], G. V. Nikolashin[2], S. Kulanthaivel[3]

[1]V.I. Vernadsky Crimean Federal University, Simferopol, Russia; [2]St. Luka's Clinical Multidisciplinary Medical Center of the Crimean Federal University named after V.I. Vernadsky, Simferopol, Russia; [3]Naarayani Multispeciality Hospital, Erode, India

Objective: Atypical osteonecrosis of the jaws (AONJ) is a severe, treatment-resistant complication, underscoring its high clinical significance. Its relevance is indeed primarily linked to medication-related osteonecrosis of the jaw (MRONJ), which is associated not only with bisphosphonates (BPs) but also with other antiresorptive (denosumab) and antiangiogenic (sunitinib, bevacizumab) drugs, thereby expanding the at-risk population (Ruggiero et al., 2022). The problem of osteonecrosis related to drug abuse (most often associated with inhalational or intravenous use of methamphetamine and cocaine) is indeed recognized as a distinct clinical entity, often termed "drug-induced osteonecrosis of the jaw" or "drug jaw." Its pathogenesis is fundamentally different and involves a combination of severe vasospasm, chemical toxicity, immunosuppression, and poor oral hygiene (Dietrich et al., 2021). Both conditions lead to a similar outcome - exposed necrotic bone - but require fundamentally different approaches to diagnosis and management.
Material and Methods: The study presents data on 10 patients. To enhance scientific rigor, modern publications recommend clearly specifying diagnostic criteria (e.g., the American Association of Oral and Maxillofacial Surgeons criteria for MRONJ), follow-up periods, imaging methods (in addition to MSCT, cone-beam computed tomography [CBCT] is often used for better detail), and specific conservative therapy protocols (e.g., antibiotic regimens, antiseptic use). It is important to note that a comparison of two etiologically distinct groups (n=5 each) is preliminary and descriptive in nature; larger cohorts are required to identify statistically significant differences.
Results: As a result of the study, the following features were identified for bisphosphonate-related osteonecrosis of the jaws: prolonged course, the size of the lesion area depends on the trauma of the preceding extraction, the duration and composition of chemotherapy for the underlying disease, prolonged sequestration formation, and in most cases—a conservative treatment protocol with a positive prognosis upon achievement of sequestration. For jaw osteonecrosis in patients with drug addiction, the following are characteristic: rapidly progressive development of the disease, severe and prolonged course, a hypoergic type of inflammatory reaction, manifested by sluggish clinical progression and absence of a temperature response; in long-term processes, stages of exacerbation and remission alternate.
Conclusions: The assertion regarding the necessity of surgical treatment with primary reconstruction is more applicable to drug-induced osteonecrosis, where the extent of destruction is often significant, or to advanced cases of MRONJ (stage 3). For early-stage MRONJ, international guidelines (Ruggiero et al., 2022) prioritize conservative management. Thus, the key correction is a differentiated approach. The main conclusion from current literature is that the treatment strategy depends not only on the type of osteonecrosis but also on its stage, location, and the patient's overall condition. For MRONJ, the algorithm progresses from conservative to surgical management as the condition advances. For "drug jaw," surgical debridement is often a necessary but insufficient measure without addressing the underlying pathology.

P1051

STIMULATION OF OSTEOINTEGRATION IN THE "BONE-IMPLANT" SYSTEM BY ER:YAG LASER IRRADIATION: AN EXPERIMENTAL STUDY

L. H. Duryagina[1], G. V. Nikolashin[2], M. G. Nikolashin[1], S. Kulanthaivel[3]

[1]V.I. Vernadsky Crimean Federal University, Simferopol, Russia; [2]St. Luka's Clinical Multidisciplinary Medical Center of the Crimean Federal University named after V.I. Vernadsky, Simferopol, Russia; [3]Naarayani Multispeciality Hospital, Erode, India

Objective: Dental implantation is the standard of care for edentulism, whose long-term success directly depends on the speed and quality of osteointegration. A key stage is the preparation of the bone bed, traditionally performed using rotary instruments. However, this method is associated with thermal and mechanical trauma, leading to the formation of a necrosis zone around the implant, which can slow down and impair bone remodeling processes.

In the search for less traumatic techniques, increasing attention is being paid to laser technologies. The Er:YAG laser (wavelength 2940 nm) has a unique property: its radiation is effectively absorbed by water and hydroxyapatite, ensuring precise bone ablation with minimal thermal damage (less than 1-2 μm of coagulation zone). Modern *in vitro* and *in vivo* research demonstrates that irradiation of bone with an Er:YAG laser stimulates the expression of osteogenic factors (BMP-2, RUNX2, type I collagen), increases the proliferative activity and differentiation of osteoblasts, and improves the surface topography of the bone, creating more favorable conditions for cell adhesion and migration. Furthermore, laser treatment (photobiomodulation) at sub-ablative parameters shows a stimulating effect on microcirculation and cellular metabolism.

Thus, the hypothesis of the study is that the use of an Er:YAG laser for preparing a bone bed for a dental implant, both as a standalone method and in combination with classical drilling, will reduce the invasiveness of the procedure, create a more favorable biological environment, and consequently, improve the quality and speed of osteointegration compared to the traditional mechanical technique, provided optimal laser parameters are used (e.g., energy 100-300 mJ/pulse, frequency 10-20 Hz, with water-air cooling).

Material and Methods: In this work, we used 27 non-pedigree female rats weighing 250-300g; an Er:YAG laser with a wavelength of 2940 nm; a physiodispenser; 27 titanium mini-implants; a set of surgical instruments; a microfocus X-ray diagnostic complex "PRDU-02"; and a panoramic digital radiography system Digora PCT. The animals were divided into three groups according to the method of bone bed preparation. In the first group, Er:YAG laser irradiation was used; in the second group, a rotary instrument was used; in the third group, a combination of tools from the first and second groups was used. Animals were euthanized at three time points: 7, 14, and 28 days after implant placement (3 animals from each group at each time point) for histological and histomorphometric analysis. Radiological assessment was performed on all animals prior to sample retrieval.

Results:

1. Histomorphometric analysis revealed statistically significant differences between the groups. On day 28, the percentage of bone-to-implant contact (BIC) was: Group 1 (Er:YAG): 65±5%, Group 2 (rotary instrument): 48±6%, Group 3 (combination): 55±4% ($p<0.05$ between Group 1 and Group 2). The volume of newly formed bone tissue (BV/TV) in the peri-implant area was also higher in Group 1.

2. Radiological assessment (microfocus radiography and panoramic radiography) correlated with histomorphometric data. Group 1 (Er:YAG laser): Radiographs showed the best visualization of bone trabeculae in the peri-implant area. Bone density was homogeneous, with no signs of destruction or sclerotic changes at the edges of the prepared site. The radiolucent zone between the bone and the implant was minimal or absent already at early observation points.

3. Group 2 (Rotary instrument): A zone of moderately increased density around the implant was visualized in the initial stages, possibly corresponding to reactive sclerosis. The trabecular pattern was less clear compared to the laser group. In some cases, a thin, uniform radiolucent line at the contact interface was observed.

4. Group 3 (Combined technique): The findings were similar to Group 1, but there was a tendency for a more rapid disappearance of any potential thin radiolucent zone remaining after mechanical preparation. Trabecular structure was actively and uniformly restored.

5. Dynamics of Bone Remodeling: In groups where the laser was used (1 and 3), signs of more active bone formation were observed: per unit area in the peri-implant zone, a greater number of thin, well-organized bone trabeculae, oriented according to load direction, were visualized compared to control Group 2. In Group 2, the pattern corresponded to a standard reparative process following mechanical trauma.

Conclusions: Based on the histomorphometric data, the use of Er:YAG laser irradiation for preparing the bone bed for an implant results in a statistically significant increase in the percentage of direct bone-to-implant contact (BIC) compared to the classical rotary technique. The combined method shows intermediate results. The qualitative radiological picture in the laser groups corresponds to more active and less traumatic bone remodeling. The use of microfocus radiography with magnification and digital image processing serves as an effective non-invasive screening method for assessing general bone architecture and the formed interface in the "bone-implant" system. Thus, Er:YAG laser treatment can be considered a promising method for improving osteointegration in dental implantology.

P1052

ELECTROMYOGRAPHIC STUDY OF TEMPORAL AND MASTICATORY MUSCLES AFTER BIOFEEDBACK THERAPY IN PATIENTS DURING ORTHODONTIC TREATMENT STAGES

L. H. Duryagina[1], M. G. Nikolashin[1], G. V. Nikolashin[2], S. Kulanthaivel[3]

[1]V.I. Vernadsky Crimean Federal University, Simferopol, Russia; [2]St. Luka's Clinical Multidisciplinary Medical Center of the Crimean Federal University named after V.I. Vernadsky, Simferopol, Russia; [3]Naarayani Multispeciality Hospital, Erode, India

Objective: Contemporary understanding considers hypertonicity and parafunction of the masticatory muscles within the framework of the biopsychosocial model, where central sensitization (increased excitability of neurons in the central nervous system) plays a key role. Central sensitization is often initiated and maintained by peripheral factors, such as occlusal disturbances and stress. Electromyography remains the standard method for the objective assessment of muscle activity. For the treatment of myofascial pain dysfunction associated with hypertonicity, the biofeedback (BFB) method is recommended as

part of complex therapy. Its effectiveness, especially in combination with elements of cognitive-behavioral therapy, is confirmed by a number of randomized controlled trials and systematic reviews (Michelotti et al., 2020). BFB allows the patient to recognize and correct dysfunctional muscle patterns, leading to reduced pain and muscle tension.

Material and Methods: The study involved 22 patients with generalized increased tooth wear (wear index >1 according to Smith & Knight) against the background of diagnosed temporomandibular disorder (TMD) myofascial pain and/or awake bruxism. The patients' ages ranged from 20 to 40 years. They were divided into two groups. The first group underwent 10 training sessions on the "BIOFEEDBACK 2000 x-pert" system - an innovative wireless biofeedback system by "SCHUHFRIED"- during the stages of orthodontic treatment. The second group underwent orthodontic treatment without BFB therapy. For both groups, before and after the intervention, an electromyographic examination was conducted using surface electrodes to study the peripheral innervation of the masticatory muscles. The total interference EMG of the masticatory and temporal muscles on both sides was recorded. The muscles were examined at rest, during inhalation, and under voluntary clenching. The level of statistical significance was set at $p < 0.05$.

Results: The study revealed the greatest decrease in masticatory muscle activity in the group of patients undergoing BFB therapy during orthodontic treatment stages. In the second group, masticatory muscle activity decreased to a lesser extent. A statistically significant ($p<0.01$) greater reduction in the amplitude of bioelectrical activity (BEA) of the masticatory muscles during dental arch clenching was recorded in the BFB group (an average reduction of 35%) compared to the control group (a reduction of 10%). The average BEA of the temporal muscles after BFB therapy was 1070±13 μV; for the masticatory muscles, this indicator was 880±12 μV. These absolute EMG values are specific to the conditions of this study.

Conclusions: The application of the biofeedback method as part of orthodontic treatment for patients with increased generalized tooth wear shows positive results, demonstrating a statistically significant reduction in masticatory muscle hypertonicity compared to the control group. This positive effect on muscle regulation can favorably influence treatment outcomes and long-term stability.

P1053

CLINICAL EFFICACY OF GUIDED TISSUE REGENERATION IN MANAGING CHRONIC PERIODONTITIS

L. H. Duryagina[1], M. G. Nikolashin[1], S. A. Khamidova[2], K. K. Khallaev[3]

[1]V.I. Vernadsky Crimean Federal University, Simferopol, Russia; [2]Tashkent State Pedagogic University named after Nizami, Tashkent, Uzbekistan; [3]Tashkent State Medical University, Tashkent, Uzbekistan

Objective: Achieving bone regeneration in patients diagnosed with periodontitis remains a significant priority in contemporary dental practice. This study aims to evaluate the effectiveness of the Guided Tissue Regeneration (GTR) technique, utilizing the "Bio-Gide" barrier membrane, for the remediation of periodontal bone defects.

Materials and Methods: The study cohort comprised nine individuals with moderate chronic periodontitis. Following a comprehensive diagnostic phase - which included periodontal pocket depth probing and assessment of alveolar bone status via orthopantomography (OPG), along with an initial phase of non-surgical therapy - surgical treatment was performed. Five subjects underwent GTR procedures with the placement of a "Bio-Gide" collagen membrane, while the remaining four received a conventional flap operation supplemented with an osteoplastic graft material.

Results: The investigation findings demonstrated that the GTR protocol yielded a mean bone fill reaching approximately 80% of the original defect volume. In contrast, bone reconstruction following the flap surgery with bone grafting did not exceed 55%.

Conclusions: Therefore, the application of the Guided Tissue Regeneration method facilitates considerable alveolar bone reconstruction, substantially enhancing the overall quality and outcomes of the therapeutic intervention.

P1054

FUNCTIONAL RECOVERY AFTER CONSERVATIVE MANAGEMENT OF A SACRAL FRAGILITY FRACTURE: THE ROLE OF TARGETED LUMBOPELVIC REHABILITATION

M. Gocevska[1], V. Koevska[1], B. Mitrevska[1], C. Gjerakaroska Savevska[1], B. Kalchovska Ivanovska[1], M. Manoleva[1], D. Gechevska[1]

[1]University Clinic of Physical Medicine and Rehabilitation, Medical Faculty, “Ss Ciryl and Methodius” University Skopje, Republic of North Macedonia, Skopje, North Macedonia

Objective To describe functional recovery following a structured, targeted rehabilitation programme in a patient with a **sacral fragility fracture** managed conservatively, with particular emphasis on pain reduction, lumbopelvic stability, and mobility improvement.

Materials and Methods A 72-year-old female presented with severe lumbosacral pain in the absence of trauma and was diagnosed with a sacral fragility fracture. Conservative management included analgesic therapy and temporary reduction of weight-bearing, followed by a four-week physical medicine and rehabilitation programme. The intervention comprised core stabilisation and lumbopelvic control exercises, sacroiliac joint unloading strategies, progressive verticalisation, posture retraining, and graded gait training. Outcomes were assessed using the Visual Analogue Scale (VAS), Oswestry Disability Index (ODI), and the Timed Up and Go (TUG) test.

Results After four weeks of rehabilitation, pain intensity decreased significantly (VAS from 8/10 to 4/10). At ten weeks, functional disability improved from severe to mild (ODI reduced from 56% to 22%), while mobility performance improved, with TUG time decreasing from 24 to 13 seconds. The patient regained the ability to walk continuously for more than 20 minutes. Enhanced lumbopelvic stabilisation played a key role in reducing pain fluctuations and restoring tolerance to functional loading.

Conclusion A structured rehabilitation programme focused on core stabilisation and optimisation of lumbopelvic biomechanics can significantly enhance functional recovery in patients with sacral fragility fractures. Individualised progression under physiatrist supervision is essential for achieving favourable clinical outcomes.

Acknowledgments: None.

Disclosures: The author reports no conflicts of interest.

Keywords: sacral fragility fracture; conservative management; lumbopelvic rehabilitation; functional recovery.

REHABILITATION CHALLENGES IN AN ATYPICAL PROXIMAL HUMERUS FRACTURE ASSOCIATED WITH LONG-TERM BISPHOSPHONATE THERAPY IN A POSTMENOPAUSAL WOMAN

M. Gocevska[1], E. Sulejmani[2], M. Aleksikj[2], C. Gjerakaroska Savevska[1], B. Kalchovska Ivanovska[1], D. Gechevska[1]

[1]University Clinic of Physical Medicine and Rehabilitation; Faculty of Medicine, Ss Cyril and Methodius University, Skopje, Republic of North Macedonia, Skopje, North Macedonia;
[2]University Clinic of Physical Medicine and Rehabilitation;Skopje, Republic of North Macedonia, Skopje, North Macedonia

Objective
To present a rare case of an atypical proximal humerus fracture in a postmenopausal woman receiving long-term bisphosphonate therapy and to highlight rehabilitation-related challenges associated with delayed healing and altered shoulder biomechanics.
Material and Methods
A 67-year-old woman with more than four years of bisphosphonate therapy presented with shoulder pain and functional limitation following a low-energy incident. Imaging revealed an atypical fracture pattern with cortical thickening. Surgical fixation was performed, and an individualised physical medicine and rehabilitation programme was initiated three weeks postoperatively. The programme included gradual shoulder range-of-motion exercises within pain-free or tolerated limits, scapular stabilisation training with emphasis on restoring scapulothoracic rhythm, closed-chain proprioceptive exercises, and a progressive transition from isometric to concentric strengthening. Outcomes were assessed using the Disabilities of the Arm, Shoulder and Hand (DASH) score and active range-of-motion measurements.
Results
Initial rehabilitation progress was limited by signs of delayed fracture healing. After five weeks of rehabilitation, pain intensity decreased significantly (VAS from 7/10 to 3/10). Active shoulder flexion improved from 45° to 110°, and abduction from 40° to 100°. The DASH score improved from 72 to 34 points. Improved scapular stabilisation contributed substantially to enhanced movement control and reduction of secondary pain.
Conclusion
Atypical humeral fractures associated with long-term antiresorptive therapy present significant rehabilitation challenges. An individualised, gradually progressed rehabilitation programme focused on scapulothoracic control and carefully monitored loading can lead to meaningful functional improvement. Early and continuous physiatrist involvement is critical for achieving optimal recovery.
Keywords
atypical humeral fracture; bisphosphonate therapy; rehabilitation; scapular stabilisation.

P1056

COMPREHENSIVE REHABILITATION APPROACH IN A PATIENT WITH SEVERE SARCOPENIA FOLLOWING OSTEOPOROTIC VERTEBRAL COMPRESSION FRACTURES: A 5-WEEK INTENSIVE INTERVENTION PROTOCOL

M. Gocevska[1], E. Nikolikj Dimitrova[1], B. Kalchovska Ivanovska[1], V. Koevska[1], B. Mitrevska[1], C. Gjerakaroska Savevska[1]

[1]University Clinic of Physical Medicine and Rehabilitation; Faculty of Medicine, Ss Cyril and Methodius University, Skopje, Republic of North Macedonia, Skopje, North Macedonia

Objective
To evaluate the effectiveness of a short, intensive, and individualised rehabilitation programme in a patient with severe sarcopenia following osteoporotic vertebral compression fractures, with emphasis on rapid improvement in muscle strength, postural stability, and functional capacity.
Material and Methods
A 74-year-old man with osteoporotic compression fractures at T11–L2 and clinically significant sarcopenia, characterised by reduced muscle strength, impaired posture, balance deficits, and low endurance, participated in a five-week intensive physical medicine and rehabilitation programme. The intervention included targeted strengthening of paravertebral and abdominal muscles, postural exercises aimed at improving thoracic extension and activating trunk stabilisers, progressive core stabilisation training, balance and statodynamic control exercises, and moderate aerobic activity delivered in short, supervised intervals. Functional assessment was performed using the Short Physical Performance Battery, the Timed Up and Go test, and the Five-Times Sit-to-Stand test.
Results
After five weeks of rehabilitation, significant functional improvements were observed. The Short Physical Performance Battery score increased from 4/12 to 7/12 points. Timed Up and Go performance improved from 22 to 16 seconds, while Five-Times Sit-to-Stand time decreased from 23 to 16 seconds. Clinical evaluation confirmed improved postural control, reduced lumbar pain during standing and walking, and increased tolerance to physical activity. The patient regained stable and independent functional mobility in daily activities.
Conclusion
A short but intensive multimodal rehabilitation programme can lead to substantial functional improvement in patients with sarcopenia following osteoporotic vertebral compression fractures. Interventions focused on postural correction, trunk stabilisation, and gradual progression of physical activity enable rapid clinical gains and meaningful improvement in functional independence.
Keywords
sarcopenia; vertebral compression fractures; rehabilitation; functional recovery.

P1057

OBESITY, WEIGHT REDUCTION THERAPY AND BONE MINERAL DENSITY IN PSORIATIC AND RHEUMATOID ARTHRITIS: A COMPLEX INTERPLAY BETWEEN INFLAMMATION AND OSTEOPOROSIS

M. Grosu[1], L. Groppa[1], E. Deseatnicova[1], E. Russu[1]

[1]State University of Medicine and Pharmacy Nicolae Testemitanu, Chișinău, Moldova

Objectives:
To evaluate the impact of obesity and weight reduction therapy on bone mineral density (BMD) in patients with psoriatic arthritis (PsA) and rheumatoid arthritis (RA), and to explore the interaction between adiposity, inflammatory burden and secondary osteoporosis.
Material and Methods:
A cross-sectional observational study included 88 patients with inflammatory arthritis, divided into three groups: PsA with obesity (n=32), RA with obesity (n=30), and PsA/RA patients with prior weight reduction therapy (n=26). Obesity was defined as BMI ≥30 kg/m^2. The cohort comprised 58 women (65.9%) and 30 men (34.1%), with a mean age of 51.8±10.6 years and mean disease duration of 8.1±4.5 years.
Disease activity was assessed using DAPSA (PsA) and DAS28-CRP (RA). Body composition was evaluated by BMI and waist circumference. Bone status was assessed by DXA at the lumbar spine (L1-L4) and femoral neck. Weight reduction therapy included structured hypocaloric diet ± pharmacological anti-obesity treatment for ≥12 months. Multivariate regression models and ROC analyses were applied.
Results:
Reduced BMD (osteopenia or osteoporosis) was identified in 52.3% of the total cohort, with osteoporosis present in 18.2%. Despite higher BMI, obese PsA and RA patients showed lower lumbar spine BMD compared with weight-reduced patients (-0.94±0.12 vs -0.61±0.10 T-score, p=0.004), indicating impaired bone quality.
Weight reduction therapy was independently associated with higher lumbar spine BMD (β=0.38, p=0.002) after adjustment for age, sex, disease duration and glucocorticoid exposure. Obesity was associated with increased inflammatory activity and bone loss (OR for low BMD 2.91, 95% CI 1.32-6.41, p=0.008).
Inflammatory activity correlated negatively with BMD (DAS28/DAPSA vs lumbar spine BMD: r=-0.46, p<0.001). ROC analysis demonstrated good predictive performance of combined BMI and disease activity indices for identifying osteoporosis (AUC 0.83, 95% CI 0.74-0.92).
Conclusions:
In psoriatic and rheumatoid arthritis, obesity is associated with increased inflammatory burden and reduced bone mineral density, despite higher body weight. Weight reduction therapy appears to mitigate inflammation-driven bone loss and is associated with improved BMD. These findings highlight obesity as a modifiable risk factor for secondary osteoporosis in inflammatory arthritis and support integrated strategies targeting both adiposity and inflammation to preserve skeletal health.

P1058

PRESERFLO MICROSHUNT WITH TRIAMCINOLONE SUB-TENON APPLICATION IN MANAGEMENT OF GLAUCOMA PATIENTS

M. H. Aly[1], R. Kashif[1]

[1]Magrabi Eye Hospital, Dubai, United Arab Emirates

Background: Preserflo Microshunt is a recent simple way in glaucoma management but can adding triamcinolone sub-tenon get better results and reduce post operative complications?!
Methods: we did randomized controlled clinical study, eyes with medically uncontrolled or drug intolerant glaucomatous patients, who had Preserflo glaucoma mini-shunt. The eyes were randomly divided to two group. In the first group 3 corneal shield sponges soaked in 0.5 mg Mitomycin C were applied for 3 minutes. In the second group 3 corneal shield sponges soaked in 0.5 mg Mitomycin C were applied for 3 minutes and 10 mg Triamcinolone injected in sub-tenon space. The main outcome was the postoperative intraocular pressure (IOP). Secondary outcomes were, prevalence of complications, number of postoperative glaucoma molecules, and secondary interventions.
Results: A total of 67 patients were included in the final analysis. Mean IOP was lower in the triamcinolone sub-tenon group at most follow-up visits, however, the difference was bigger at 3 months (11.8 mmHg versus 13.6 mmHg) and 9 months (15.5 mmHg versus 20.5 mmHg). Linear mixed model showed that IOP was significantly lower in the triamcinolone sub-tenon group throughout the study period (P = 0.028). Similarly, there was significant less incidence in the post operative complications between the triamcinolone sub-tenon group compared to non-triamcinolone sub-tenon group (P = 0.003).
Conclusions: Triamcinolone sub-tenon application with Preserflo Microshunt surgery is more effective in IOP reduction and decrease the incidence of complications.
Keywords: IOP, MD, Glaucoma, Preserflo Microshunt, triamcinolone sub-tenon.

ASSOCIATIONS BETWEEN CONTROLLING NUTRITIONAL STATUS AND MORTALITY IN OSTEOPOROSIS: EVIDENCE FROM NHANES, 2005-2018

M. H. Hsieh[1], C. C. Yang[1], K. C. Liu[1], J. T. Chien[1]

[1]Department of Orthopedics, Dalin Tzu Chi Hospital, Buddhist Tzu Chi Medical Foundation, Chiayi, Taiwan

Background: Malnutrition and immune dysregulation are common in patients with osteoporosis but are often overlooked and may contribute to poor outcomes. The Controlling Nutritional Status (CONUT) score is a simple instrument reflecting both nutritional and immune status, but its prognostic value in osteoporosis remains unclear.
Methods: This retrospective, observational study included data of adults aged ≥50 years with osteoporosis extracted from three two-year cycles of the National Health and Nutrition Examination Survey (NHANES), 2005–2010, 2013–2014, and 2017–2018. Osteoporosis was defined as femoral neck T-score < −2.5. CONUT scores were calculated from participants' serum albumin, total cholesterol, and total lymphocyte count, and high CONUT was defined as ≥2. All-cause and cardiovascular disease (CVD)-

related mortality through December 31, 2019, was ascertained via the National Death Index. Weighted Cox regression models were used to estimate hazard ratios (HRs) for mortality outcomes.
Results: Among 871 participants representing 5.86 million US adults with osteoporosis, 40.7% had high CONUT scores. During a median follow-up of 9.8 years, high CONUT scores were associated with increased all-cause (53.2% vs 30.9%, p<0.001) and CVD mortality (17.6% vs 8.2%, p<0.001). Multivariable analysis, after adjustments for possible confounders, high CONUT scores were independently associated with higher all-cause (HR 1.64; 95% CI: 1.25–2.14) and CVD mortality (HR 1.91; 95% CI: 1.15–3.19). Associations with all-cause mortality were consistent across sex, diabetes, and CKD subgroups and associations with CVD mortality were most pronounced among females and patients with diabetes.
Conclusion: The CONUT score independently predicts all-cause and CVD mortality in adults with osteoporosis, providing a practical tool for risk stratification and guiding early interventions.

PREVENTIVE DENTAL VISITS AND MEDICATION-RELATED OSTEONECROSIS OF THE JAW IN RHEUMATOID ARTHRITIS PATIENTS RECEIVING OSTEOPOROSIS THERAPY

M. Hanabayashi[1], Y. Yokota[2], H. Watanabe[3]

[1]Department of Orthopedic Surgery / Rheumatology, Ichinomiya Municipal Hospital, Ichinomiya, Japan; [2]Department of Orthopedic Surgery / Rheumatology, Ichinomiya Municipal Hospital, Ichinomiya , Japan; [3]Oral and Maxillofacial Surgery, Ichinomiya Municipal Hospital, Ichinomiya, Japan

Objectives
To investigate the association between dental visit status and medication-related osteonecrosis of the jaw (MRONJ) in rheumatoid arthritis (RA) patients receiving osteoporosis (OP) treatment.
Materials and Methods
We retrospectively studied RA patients receiving OP treatment who visited our outpatient clinic between January and December 2025. Dental visit status was categorized as preventive visits, restorative visits, or no regular visits. MRONJ was defined as stage ≥1 according to AAOMS criteria. In patients with MRONJ, clinical variables—including demographics, RA treatments, glucocorticoid use, disease activity, OP medications, and dental visit status—were assessed at the time of MRONJ onset.
Results
Among 276 RA patients receiving OP treatment (241 women), dental visit status was preventive visits in 59 patients, restorative visits in 54, and no regular visits in 147; status was unknown in 16. MRONJ was identified in 15 patients (13 women), with a mean age of 79.6 years at onset. None of the MRONJ patients had preventive dental visits. Five patients had restorative visits, while ten had no regular visits. Thirteen patients were treated with biologic or targeted synthetic DMARDs, and nine received low-dose glucocorticoids (prednisolone 2–5 mg/day). OP treatments included bisphosphonates, denosumab, and romosozumab, with treatment durations ranging from 3 months to over 10 years.
Conclusions
RA patients are particularly susceptible to infection-related complications, including MRONJ, due to the high prevalence of periodontal disease[1] and the established role of infection in RA pathogenesis[2]. In this cohort of RA patients receiving OP treatment, engagement in preventive dental visits was low, despite infection being the strongest known risk factor for MRONJ[3]. All MRONJ cases occurred exclusively in patients without preventive dental care, indicating that a high-risk population remained clinically unprotected. Insufficient preventive dental management may therefore facilitate infection-driven MRONJ. Systematic integration of preventive dental visits into OP management for RA patients should be prioritized.

MUSCLE WEAKNESS AND BONE MICROARCHITECTURE IN POSTMENOPAUSAL WOMEN

M. D. M. Muñoz-Gomez[1], M. Hayón-Ponce[2], D. Blanquez-Martinez[3]

[1]Reumatology Division, Universitary Hospital Torrecardenas, Almeria, Spain; [2]Endocrinology and Nutrition Division, Universitary Hospital Virgen de las Nieves, Granada, Spain; [3]Department of Hospital Pharmacy, Hospital Santa Ana, Motril, Spain

Objetive: To examine bone health parameters assessed by dual-energy X-ray absorptiometry (DXA) and trabecular bone score (TBS), as well as muscle strength measured by handgrip strength, in postmenopausal women.
Material and methods: Observational cross-sectional study was conducted included 73 postmenopausal women aged 49 to 85 years. Demographic, anthropometric, clinical and biochemical variables were studied. Bone mineral density (BMD) in the lumbar spine (CL), femoral neck and total hip was determined using DXA and TBS iNsight software. Hand grip strength of the dominant hand (kg/cm2) was measured with a Jamar manual hydraulic dynamometer. Hand grip below the age- and sex-specific 5th percentile, according to normative reference values from a Spanish population[1], was defined as low muscle strength. Data were analyzed using SPSS version 25.0.
Results: 73 postmenopausal women were studied. The mean age was 66.6 ± 9.3 years, and the mean body mass index (BMI) was 32.1 ± 5.3 Kg/m2. Low muscle strength was present in 43% of participants. Handgrip strength was positively correlated with TBS (R = 0.321, p < 0.01) and total hip BMD (R = 0.268, p < 0.05).
Conclusion: Reduced muscle strength was significantly associated with decreased bone mass and impaired bone microarchitecture in postmenopausal women.

SIMULTANEOUS MEASUREMENT OF 1-HYDROXYLATED AND 24-HYDROXYLATED VITAMIN D METABOLITES BY LIQUID-CHROMATOGRAPHY TANDEM MASS-SPECTROMETRY – AN INNOVATIVE TOOL IN CHRONIC KIDNEY DISEASE MANAGEMENT

S. Zelzer[1], K. Sobolewska[1], D. Enko[1], P. Kieslinger[1], H. Elsayed[1], S. Zitta[1], M. Herrmann[1]

[1]Medical University of Graz, Graz, Austria

Bone and mineral metabolism is altered in chronic kidney disease (CKD) patients. As kidney function declines, renal 1-alpha- and 24-hydroxylation of vitamin D metabolites decreases thus limiting the utility of 25-hydroxyl-vitamin D (25[OH]D) as a marker for patients vitamin D status. The analysis of additional metabolites could facilitate a functional assessment of vitamin D status that potentially correlates better than 25(OH)D with bone and mineral metabolism in CKD patients. Therefore, we developed and validated a liquid-chromatography tandem mass-spectrometry (LC-MS/MS) method capable of tracking simultaneously 25-hydroxyvitamin D (25[OH]D), 1,25-dihydroxy vitamin D (1,25[OH]2D), 24,25-dihydroxyvitamin D (24,25[OH]2D), and 1,24,25-trihydroxyvitamin D (1,24,25[OH]3D). Sample preparation combined protein precipitation, liquid-liquid-extraction and derivatization. A Nexera UHPLC (SHIMADZU, Kyoto, Japan) with a Kinetex® 5 µm F5 100 Å LC column (150×4.6 mm, Phenomenex, Torrance, CA, USA) coupled to a QTRAP 6500 (SCIEX, Framingham, MA, USA) was used for analysis. Clinical utility was demonstrated analyzing serum from individuals with 24-hydroxlase deficiency, kidney donors and recipients. For all metabolites, linear ranges and limits of quantitation cover the concentrations range physiologically observed in humans. Recovery ranged between 90.8 to 105.5% for all four metabolites. Imprecision was ≤11.5% across the entire analytical range for all metabolites. Analysis of patient samples showed that kidney transplantation and 24-hydroxylase deficiency are associated with profound alterations of 24-hydroxylated, but not 1alpha-hydroxylated, vitamin D metabolites. Hence, the simultaneous measurement 25(OH) D and its 1-alpha and 24-hydroxlated metabolites by LC-MS/MS is a promising tool to identify abnormalities in vitamin D metabolism.

P1063

OPTIMIZING DEEP LEARNING-ENHANCED OPPORTUNISTIC OSTEOPOROSIS SCREENING FROM CHEST X-RAYS IN AUSTRALIA: IMPACT OF FOLLOW-UP AND TREATMENT ADHERENCE ON CLINICAL AND ECONOMIC OUTCOMES

J.-Y. Reginster[1], P. R. Ebeling[2], M. Alokail[1], J. H. Jung[3], M. Hiligsmann[4]

[1]King Saud University, Riyadh, Saudi Arabia; [2]Monash University, Clayton, Victoria, Australia; [3]Promedius Inc. and Chung-Ang University, Seoul, South Korea; [4]Maastricht University, Maastricht, Netherlands

Introduction: Opportunistic osteoporosis screening using artificial intelligence (AI) on routine chest radiographs offers a low-burden way to improve detection and treatment uptake. This study evaluated the cost-effectiveness of AI-enhanced screening versus no screening in Australian women aged ≥50 years, focusing on health outcomes and the added value of improved follow-up and adherence.

Methods: A microsimulation-based Markov model estimated lifetime costs and quality-adjusted life years (QALYs) from the Australian healthcare perspective, expressed in 2025 Australian dollars. The model incorporated AI screening performance on chest radiographs, rates of DXA confirmation, treatment initiation, and real-world medication persistence. Scenario analyses evaluated the potential effect of optimized follow-up pathways and enhanced adherence on clinical and economic outcomes.

Results: AI-enhanced opportunistic screening was associated with better health outcomes (+0.0025 QALYs and −0.0043 fractures per patient) and reduced lifetime costs (−AUD59), making it a dominant strategy compared with no screening. When scaled to 10,000 screened women aged ≥50 years, the model projected prevention of 43 fractures, 25 additional life-years, 25 QALYs gained, and healthcare savings of AUD590,000. Enhanced follow-up and adherence produced four- to five-fold increases in clinical benefit relative to the base-case analysis.

Discussion: AI-enhanced osteoporosis screening using routine chest X-rays appears cost-effective and potentially cost-saving within the Australian healthcare system. Linking AI detection to timely DXA, treatment initiation, and sustained adherence substantially amplifies its clinical value. These findings highlight that follow-up and persistence are not ancillary but essential components for realizing the full potential of AI-driven opportunistic screening programs.

Objectives

Bone compartmental imbalance in the proximal femur may reflect distinct patterns of bone strength not captured by standard DXA metrics, and its assessment may be helpful in the context of clinical fracture risk assessment or treatment decision-making. The aim of the presented analysis was to quantify the prevalence of significant imbalances between cortical and trabecular bone compartments at the proximal femur in a reference population using three-dimensional DXA (3D-DXA).

Materials and methods

Hip DXA scans from 1366 adults (1015 women, 351 men) enrolled in the Spanish multicentre SEIOMM-3D-DXA project were analysed with 3D-Shaper software (v2.14, 3D-Shaper Medical) [1]. Trabecular volumetric (v) bone mineral density (BMD) and cortical surface (s) BMD Z-scores were calculated from age- and sex-specific reference curves. Compartmental imbalance was defined as the absolute difference between trabecular and cortical Z-scores exceeding the least significant change (LSC), calculated using precision data [2].

Results

The LSC for the Z-score difference was 0.397. Overall, 52.0% of females and 48.7% of males had a significant Z-score difference value (**Figure 1**). 26.3% of females and 25.4% of males exhibited a significant positive Z-score difference, indicating trabecular dominance (green bins), while 25.7% of females and 23.4% of males showed a significant negative Z-score difference, indicating cortical dominance (red bins). Both imbalance patterns were observed with similar frequency across age groups.

Conclusions

Nearly half of individuals in a reference population exhibit significant compartmental imbalances at the proximal femur that are not detectable by standard DXA. 3D-DXA enables compartment-specific assessment of bone density and may provide clinically relevant information beyond areal BMD. Further investigations should be undertaken to determine the effect of these differences in bone strength.

EFFECTIVENESS OF ADJUNCTIVE SMALL NEEDLE KNIFE THERAPY FOR FROZEN SHOULDER: A RANDOMIZED CONTROLLED TRIAL

M. J. Wang[1], C. M. Chang[2], C. T. Chen[1]

[1]Department of Chinese medicine, Taipei City Hospital, Renai Branch, Taipei, Taiwan; [2]Center for Traditional Medicine, Taipei Veterans General Hospital, Taipei, Taiwan

Objective

To evaluate the efficacy of adjunctive small needle knife (SNK) therapy combined with rehabilitation on pain, shoulder mobility, and functional outcomes in patients with frozen shoulder.

Material and Methods

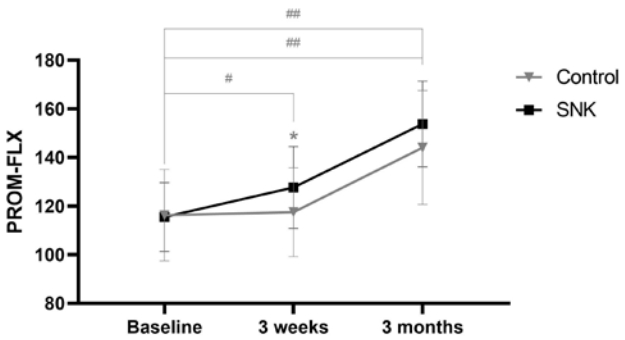
In this prospective randomized controlled trial, 70 patients with idiopathic frozen shoulder were randomized (1:1) to receive either SNK therapy plus rehabilitation or rehabilitation alone. SNK therapy was administered once weekly for three weeks. Rehabilitation included hot-pack thermotherapy and transcutaneous electrical nerve stimulation. Assessments were conducted at baseline, 3 weeks, and 3 months. Primary outcomes were pain score (visual analogue scale, VAS) and shoulder passive range of motion. Secondary outcomes included the Shoulder Pain and Disability

Index (SPADI) and the World Health Organization Quality of Life Brief Version (WHOQOL-BREF).

Results

At 3 weeks, a greater proportion of patients in the SNK group achieved clinically meaningful pain reduction (≥1-point VAS decrease) compared with controls (75.0% vs. 34.5%, *p*=0.001). Pain reduction from baseline to 3 months was greater in the SNK group (−4.13±2.11 vs. −2.33±2.21, *p*=0.012). Passive shoulder flexion range at 3 weeks was significantly higher in the SNK group (127.61±16.81° vs. 117.48±18.32°, *p*=0.029). Total SPADI scores were also lower in the SNK group at 3 weeks (45.48±18.73 vs. 56.21±22.03, *p*=0.044). No significant between-group differences were observed in WHOQOL-BREF scores.

Conclusion



Adjunctive SNK therapy combined with rehabilitation significantly improved pain, shoulder mobility, and functional outcomes in frozen shoulder, with sustained benefits at 3 months.

EVALUATION OF FRAX INDEX FOR EARLY OSTEOPOROSIS RISK ASSESSMENT IN PATIENTS UNDERGOING HAEMODIALYSIS

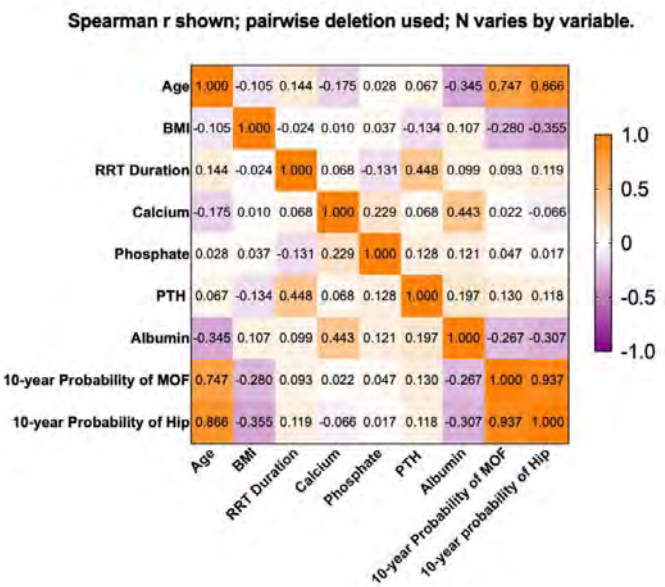
A. Nana[1], B. Yilmaz[2], M. K. I. Jallo[1], R. Jagdale[1]

[1]Thumbay University Hospital, Ajman, United Arab Emirates;
[2]Heidelberg University, Heidelberg, Germany

Objective

To assess the usefulness of FRAX calculated without bone mineral density (BMD) input for early fracture-risk stratification in adults aged ≥40 years on haemodialysis, including estimation of FRAX-defined high-risk prevalence and its associations with demographic, clinical, and laboratory characteristics.

Materials and Methods



This observational cross-sectional study included adults aged ≥40 years receiving haemodialysis at a tertiary care centre. Data on comorbidities, including rheumatoid arthritis, diabetes mellitus, and hypertension, were collected. FRAX 10-year probabilities were calculated without BMD input. High fracture risk was defined as major osteoporotic fracture (MOF) ≥20% and/or hip fracture ≥3%. Statistical analyses were performed in GraphPad Prism.

Results

Among 76 haemodialysis patients, 6 (7.9%) met the FRAX high-risk definition. FRAX-high patients were older than not-high patients (median 70 vs 56 years; p=0.0014). Dialysis vintage and CKD–MBD markers were not significantly different, including RRT duration (median 61.0 vs 30.5 months; p=0.1678), calcium (9.16 vs 9.14 mg/dL; p=0.637), phosphate (6.10 vs 5.05 mg/dL; p=0.476), and PTH (178.7 vs 286.0 pg/mL; p=0.628; PTH available in 55 patients, including 4 FRAX-high). Albumin was borderline lower in FRAX-high patients (3.57 vs 3.84 g/dL; p=0.0535). FRAX correlated strongly with age (MOF r=0.747; hip r=0.866; both p<0.001) and inversely with BMI (MOF r=−0.280, p=0.014; hip r=−0.355, p=0.0017) as well as albumin (MOF r=−0.267, p=0.0206; hip r=−0.307, p=0.0075). FRAX-high status was more frequent in women than men (21.7% vs 1.9%; p=0.0086), and all FRAX-high patients had diabetes (p=0.0265).

Conclusion

FRAX without BMD identified a small high-risk subset in haemodialysis patients. Risk estimates were largely driven by age and showed modest inverse associations with BMI and albumin, whereas dialysis vintage and CKD–MBD biochemistry showed little association. FRAX may support pragmatic first-line fracture-risk stratification when DEXA is unavailable, but validation in larger cohorts with imaging and fracture outcomes is needed.

P1068

TERIPARATIDE BIOSIMILAR IN REAL WORLD - A SINGLE CENTRE EXPERIENCE

J. Begum[1], M. K. Nisar[2]

[1]Luton University HOspital, Luton, United Kingdom; [2]Luton University hospital, Luton, United Kingdom

Teriparatide, a recombinant human parathyroid hormone, significantly reduces the risk of fractures in patients with postmenopausal and glucocorticoid-induced osteoporosis. In the UK, NICE has restricted its use to high-risk patient groups. This project aims to analyse the use of Teriparatide (both originator and biosimilar) at a large University teaching hospital with 55% ethnic catchment population, providing insight into the real-world patient demographic and evaluating the treatment's effectiveness.

A retrospective analysis was conducted to evaluate the use of Teriparatide in patients receiving treatment between 2014-2024 at our unit. Full demographic and clinical data was collected using electronic health records and live multipurpose database. Dual-energy X-ray absorptiometry (DXA) scan results were reviewed to assess bone mineral density (BMD) both before the initiation of Teriparatide treatment and after completion. Data was analysed to provide insights into the demographic characteristics of the treated population, the efficacy of teriparatide based on BMD improvements, treatment adherence, and local compliance with national guidelines.

Over the ten-year study period, a total of 480 patients were prescribed Teriparatide - all women with an average age of 74 years. Alendronate was the most common first-line bisphosphonate. Participants suffered three fractures on average prior to commencing therapy. 224/480 were prescribed teriparatide biosimilar. Pre-treatment, the average T score was -2.7 for the lumbar spine and hip with -2.4 for the femoral neck. Post-treatment, these values improved to -2.2, -2.4 and -2.3 respectively. Treatment was well tolerated with 63.5% completing two years of therapy. During mean follow up of three years, only 10 patients (0.02%) suffered a fragility fracture.

To our knowledge, this is the largest real world study of Teriparatide in nearly 500 patients. Our study demonstrates real world use of Teriparatide in a multi-ethnic diverse setting. It shows that Teriparatide is used predominantly in complex, multi-morbid older individuals with several prior fractures. Despite that, Teriparatide remains effective for a wide range of individuals including those with inflammatory arthritis and/or concurrent steroid use. This is in line with recent meta-analysis of real life Teriparatide use in complex osteoporosis with multimorbidity. Though NICE stipulates minimum two fractures requirement (unless T score <-4.0), in practice patients may have had more suggesting that clinicians are reserving it for high disease burden or there is a delay in diagnosis. We also demonstrate the large scale clinical effectiveness of the biosimilar. Our study should enhance clinicians' confidence in its prescribing. We believe that since the availability of more cost-effective Teriparatide biosimilars, NICE ought to amend its guidance and provide easier access to therapies for better patient outcomes.

P1069

RELIGIOUS AND SPIRITUAL WELL-BEING, BELIEFS, AND PRACTICES IN PATIENTS WITH KNEE OSTEOARTHRITIS: A DESCRIPTIVE STUDY

M. Kaouther[1], O. Rania[1], K. Lobna[1], M. Fatma[1], B. Dorra[1], C. Ines[1], K. Dhia[1], H. Wafa[1]

[1]institut Mohamed Kassab d'orthopédie, Tunis, Tunisia

Objective: To investigate the effects of knee OA on religious and spiritual well-being, beliefs, and practices.

Material and Methods: A cross-sectional study including symptomatic knee OA patients. Spiritual well-being was assessed using Ellison's Spiritual Well-Being Scale (SWBS), a 20-item instrument comprising two subscales: emotional well-being (EWB) and religious well-being (RWB) (10 items each), scored on a 6-point Likert scale. (Total score range: 20–120; subscale range: 10–60). Religious aspects were evaluated using a 25-item self-developed questionnaire to assess four dimensions (religious beliefs, religious and spiritual practices, assistance-seeking, and feelings) 9rated on a 5-point Likert scale (1 = never to 5 = always). Higher scores reflecting greater religious and spiritual engagement.

Results: Forty-one knee OA patients were included. Male-to-female ratio was 6/35. The mean age was 58 ± 10 years [37-78]. Regarding spirituality, the mean SWBS score was 86 ± 27 [36–117]. Nineteen patients had high SWBS, while 20 had moderate levels. Concerning religious practice, 73.2% of patients (n = 30) reported frequent overall religious practice, while 11 practiced occasionally. All patients observed Ramadan fasting, 30 patients prayed regularly. Sixteen patients reported always having difficulties with religious practices. Prayer was the most affected practice, reported by 90% of patients (n = 37). Among these, the most challenging movements were prostration (sujood) for 33 patients and bending the legs during tashahhud for 4 patients. 27 patients reported performing prayers on a chair to avoid knee movement. For ablution, 19 patients reported modifying their practice: 16 using warm water and 3 performing tayammum. Regarding fasting during Ramadan, 11 patients reported difficulties and a reduced ability to fast. These difficulties led to feelings of guilt in 28 patients and shame in 19 patients. To cope, 17 patients asked for help from doctors, 5 from family or friends, and 10 patients chose to remain silent. Regarding beliefs, 17 patients perceived their illness as a punishment from God.

Conclusion: This study revealed a significant divergence in patients' spirituality levels, changes in practice, and coping strategies. Understanding this divergence is crucial for providing more personalized medical, psychosocial, and spiritual care.

P1070

DETERMINANTS OF SPIRITUAL WELL-BEING IN PATIENTS WITH KNEE OSTEOARTHRITIS

M. Kaouther[1], O. Rania[1], K. Lobna[1], M. Fatma[1], B. Dorra[1], C. Ines[1], K. Dhia[1], H. Wafa[1]

[1]institut Mohamed Kassab d'orthopédie, Tunis, Tunisia

Introduction: Knee osteoarthritis (OA) is a common form of OA that requires complex management. Spirituality is increasingly recognized as helping patients cope with chronic illness. Exploring this dimension in knee OA remains largely understudied.

Objective: To identify factors associated with spiritual well-being in patients with knee osteoarthritis.

Methods: A cross-sectional study including symptomatic knee OA patients. Socio-demographic, disease characteristics and imaging data were collected. Health status and psychological impact were assessed using SF-36 and HADS for anxiety and depression. Spiritual well-being was assessed using Ellison's Spiritual Well-Being Scale (SWBS), a 20-item instrument scored on a 6-point Likert scale, higher scores indicating greater well-being.

Results: Forty-one knee OA patients were included. Male-to-female ratio was 6/35. The mean age was 58 ± 10 years [37-78]. Most patients had mild to moderate radiographic changes (Kellgren–Lawrence stage 1–2; 70%).The mean SWBS score was 86 ± 27 [36–117]. Nineteen patients had high overall SWBS, 21 had moderate levels and one with low SWBS. Physically active patients had higher SWBS (15 in the high SWBS group vs. 6 in the low-to-moderate group, **p = 0.004**). Similarly, participation in a functional rehabilitation program was associated with greater spiritual well-being (16 vs. 8, **p = 0.006**). Lower SWBS levels were associated with obesity (**p = 0.005**), smoking (**p = 0.01**), coexisting degenerative low back pain (**p = 0.01**), and limited walking distance (<1000 m; **p = 0.05**). Low SWBS was associated with higher levels of anxiety, depression, and pain catastrophizing: Among the 20 patients with low-to-moderate SWBS, 16 experienced moderate to severe anxiety (**p<0.01**), 25 had moderate depression (**p = 0.003**), and 13 patients showed significant pain catastrophizing (**p = 0.01**). Whereas, high spiritual well-being was associated with higher SF-36 score (**p = 0.01**). Furthermore, SWBS was not associated with sex, age, disease duration, time to diagnosis, patient medical history and radiographic stage of knee OA.

Conclusion: High spirituality was associated with physical activity and linked to lower anxiety, depression, and pain catastrophizing, as well as better quality of life, highlighting the importance of considering spiritual well-being in the management of patients with knee OA.

P1071

DXADERIVED BODY COMPOSITION AND BMD IN PATIENTS WITH T2DM AND MASLD

M. Kasko[1], E. Fraenkel[1], T. Koky[2], S. Pacakova[2], I. Lazurova[1]

[1]1st Department of Internal Medicine, Faculty of Medicine, P. J. Safarik University and University Hospital L. Pasteur, Kosice, Slovakia; [2]2nd Department of Internal Medicine, Faculty of Medicine, P. J. Safarik University and University Hospital L. Pasteur, Kosice, Slovakia

Objectives

This study examined relationships among the extent of hepatic steatosis, DXAderived bodycomposition metrics, bone mineral density (BMD), and boneturnover markers (BTM) in a European cohort with type 2 diabetes (T2DM) and metabolic dysfunctionassociated steatotic liver disease (MASLD), addressing ongoing uncertainty about MASLD's effects on bone metabolism.

Material and Methods

Crosssectional study including 156 T2DM patients with MASLD (95 females, 61 males; mean age 62.9 ± 10.7 years) and 40 T2DM controls without hepatic involvement (mean age 59.13 ± 14.12 years). Hepatic steatosis was quantified using the FibroScan® controlled attenuation parameter (CAP), with steatosis defined as CAP >238 dB/m. DXA assessed TotalBMD, HipBMD, total and regional fat/lean mass, android/gynoid ratio (AGR), and appendicular lean mass index (ALMI). Laboratory panel included HOMAIR, GH/IGF1 axis markers, Osteocalcin, P1NP and bCTX. Correlation analyses and multivariable ROC modelling were used to identify combinations of clinical and DXA metrics that best predict reduced BMD and altered bone turnover.

Results

MASLD patients had significantly higher BMI, visceral adiposity and HOMAIR versus controls. In the full cohort CAP correlated positively with total BMD (r=0.21; p=0.001); stratified analysis showed this association was significant in females (r=0.29; p=0.004) but not in males. In males, CAP correlated negatively with BTM (Osteocalcin r=−0.35; p=0.006; bCTX r=−0.26; p=0.04), suggesting suppressed remodeling. Multivariable ROC models: in females a model combining CAP, age and android fat % achieved AUC 0.746 (sensitivity 76.4%, specificity 71.4%) (Fig 1). The inclusion of AGR (Fig 2) and ALMI (Fig 3) improved the detection of reduced total-BMD and hip-BMD, respectively, in the overall cohort.

Conclusions

In T2DM patients MASLD shows a sexually dimorphic relationship with bone health: in women steatosis associates with higher BMD likely mediated by android fat distribution and mechanical loading; in men steatosis associates with reduced bone turnover. Clinical implication: fracturerisk screening in MASLD should move beyond BMI to include soft tissue metrics (AGR, ALMI) and sexspecific algorithms to better identify secondary osteoporosis and fracture risk.

MICROARCHITECTURAL BONE DEFICITS IN ADULTS WITH HYPOPHOSPHATASIA

M. Kužma[1], J. Payer[1], A. Jančuška[1], V. Zikán[2], H. Resch[3], J. Haschka[4], R. Kocijan[5]

[1]5th department of Internal Medicine, Comenius University Faculty of medicine, University Hospital Bratislava, Bratislava, Slovakia; [2]3rd Department of Internal Medicine – Department of Endocrinology and Metabolism, First Faculty of Medicine, Charles University and General University Hospital, Prague, Czechia; [3]Center of Internal Medicine II, Osteology, Medical Faculty, Sigmund Freud University, Vienna, Austria; [4]Ludwig Boltzmann Institute of Osteology at Hanusch Hospital of OEGK and AUVA Trauma Center Vienna-Meidling, 1st Medical Department, Hanusch Hospital, Vienna Bone and Growth Center, Vienna, Austria; [5]Ludwig Boltzmann Institute of Osteology at Hanusch Hospital .1st Medical Department, Hanusch Hospital. Sigmund Freud University, Vienna, Austria

Background:
Hypophosphatasia (HPP) is rare inherited disorder due to ALPL variants causing deficient tissuenonspecific alkaline phosphatase and impaired skeletal mineralization. Adult HPP often presents with fractures, pseudofractures and delayed fracture healing despite apparently "normal" areal bone mineral denisty (aBMD) on DXA.
Aim: Comparison of conventional (aBMD, TBS) and advanced bone measures (HR-pQCT) between adults with HPP and healthy controls.
Methods:
In a case–control study, from 3 international centres (Austria, Slovakia, Czech republic) adults with clinically/biochemically confirmed HPP (n = 38, mean age 50.3 ± 14.7 years; 14males/24 females) were comapred with age, sex – comaprable controls (n = 24, mean age 45.9 ± 8.6 years; 11 males/13 females). Assessments included anthropometry, biochemistry (ALP, Ca, phosphate, PTH, CTX, P1NP, 25OHvitamin D), aBMD of total hip, femoral neck, and lumbar spine (L1–L4) plus trabecular bone score (TBS). In the subset of 8 HPP subjects and 22 controls a HRpQCT at distal radius and tibia (density, trabecular microarchitecture, cortical parameters) was performed. Fractures (including atypical femoral fractures [AFF]) and delayed healing were recorded.
Results:
HPP participants were shorter (165.9 ± 9.5 vs 171.5 ± 9.7 cm; p = 0.028). Any fracture was recorded in 23 (61%) of HPP subjects vs 0 in control group; p < 0.001). Biochemically, HPP had characteristically low ALP (p < 0.001), higher calcium and phosphate (both p < 0.001), lower PTH (p < 0.001), higher CTX (p = 0.018) and higher 25OHvitamin D (p = 0.0027). No difference in vitamin D and calcium supplementation were observed. DXAderived BMD, T and Zscores at total hip, femoral neck, and L1–L4 and TBS showed no significant betweengroup differences (all p > 0.15). HRpQCT at the radius demonstrated compromised trabecular microarchitecture in HPP: lower metaphyseal density (RadDmeta; p = 0.026), fewer trabeculae (Tb.N; p = 0.001), greater trabecular separation (Tb.Sp; p = 0.006), and higher heterogeneity (Tb.N SD; p = 0.0009); BV/TV was markedly reduced. At the tibia, HPP showed smaller total and cortical areas (TibTotArea p = 0.034; TibCortArea p = 0.014), lower composite density (TibDcomp p = 0.013), and lower BV/TV, with other trabecular indices largely similar.
Conclusions:
Adults with HPP suffer a high fracture burden despite largely normal DXA results. HRpQCT uncovers significant trabecular—plus some cortical—deficits explaining this mismatch. Combining HRpQCT with the characteristic biochemical profile improves detection and phenotyping of adult HPP.

CORRELATION OF NEURO-QOL LOWER EXTREMITY FUNCTION COMPUTER ADAPTIVE TEST SCORES WITH LEGACY SOCRES IN OLDER PATIENTS AFTER HIP FRACTURE: A NEW OPPORTUNITY FOR TECH-BASED ASSESSMENT

M. L. Alvarez-Nebreda[1], J. Corcuera-Catala[1], E. Rodriguez-Espeso[1], L. A. Hernandez-Sanchez[1], P. Gutierrez-Viou[1], A. Jimenez-Martin[2], J. J. Garcia-Dominguez[2]

[1]GERIATRICS DEPARTMENT. HOSPITAL UNIVERSITARIO RAMON Y CAJAL, MADRID, Spain; [2]ELECTRONIC DEPARTMENT. UNIVERSIDAD DE ALCALA DE HENARES, ALCALA DE HENARES, Spain

Objective
In this study, we aimed to use technology to evaluate whether the Neuro-QoL-Lower Extremity Function-Computer Adaptive Test (NQoL-CAT) correlates with traditional functional assessment scales (Barthel Index and Functional Ambulation Classification-FAC) in elderly patients with hip fractures.
Material and Methods
Prospective study that included patients over 69 years admitted to the orthogeriatric unit of a tertiary university hospital for 12 months. Patients were excluded if they had a concomitant fracture, they were not able to walk before the fracture, or they had a terminal illness. Sociodemographic, functional and clinical variables were measured at baseline, 3 months and 12 months by educating patients/proxies in using the MyCap app in their phones, which was connected with a REDCap secured hospital database. The NQoL-CAT was chosen because of its potential advantages: lower limb specific, self-administered by the patient, it is a computer adaptive test scale which reduces application time, and it can be implemented within a technological solution. Non-parametric analysis (Spearman's Rho) was performed to determine the observed correlation between the NQoL-CAT and the functional legacy scores Barthel and FAC at the 3 time points.
Results
105 patients were included, with a mean age of 87 years. Baseline function: Barthel: 79, FAC: 4, NQoL: 42.2. At discharge, 66% received home physiotherapy, 20% rehabilitation in a skilled nursing facility, and 13% were transferred to a hospital for functional recovery. Functional status at 3 months: Barthel: 69, FAC: 3.5, NQoL: 33.2, and 12% were institutionalized. Functional status at 12 months: Barthel: 70, FAC: 3.7, NQoL: 38.5, and 20% of patients were institutionalized. The correlation of NQoL with Barthel and FAC was: 0.61 and 0.65 at baseline, 0.79 and 0.76 at 3 months, and 0.85 and 0.86 at 12 months (p=0.01).
Conclusions
There is a strong correlation between the NQoL-CAT and traditional functional assessment scales in older adults up to 12 months after a hip fracture, suggesting that the use of technology implementing this scale could optimize the measurement of their functional recovery in the future, in order to find predictive models and design potential intervention programs.

P1074

ATTENUATED X-LINKED HYPOPHOSPHATEMIA: LATE DIAGNOSIS IN AN ADULT PATIENT

M. L. Drnovsek[1], E. M. Linari[1], M. G. Poggio[2]

[1]Division of Endocrinology and Metabolism. Dr. J.M. Ramos Mejía General Hospital, Ciudad Autónoma de Buenos Aires, Argentina; [2]Ultragenyx Argentina Laboratory, Ciudad Autónoma de Buenos Aires, Argentina

Introduction: X-linked hypophosphatemia (XLH) is caused by loss-of-function of the PHEX gene. It presents with increased levels of fibroblast growth factor 23 and hypophosphatemia. The phenotypic spectrum ranges from mild hypophosphatemia to severe bowing of lower limbs.
Objective: To describe late onset presentation of XLH in adult patient.
Clinical Case: A 50-year-old woman was referred to endocrinology due to a recent clinical and molecular diagnosis of XLH in her son. Her daughter doesn't exhibit XLH phenotype. She reports loss of some teeth three years ago. Her height: 1.59 m (mother's height 1.57m, father's height 1.78 m), weight: 56 kg.
Radiography: slight valgus curvature of both tibial bones and bilateral coxa vara; the spine, hands, and feet were normal. Renal ultrasound and audiometry were normal Laboratory: hypophosphatemia:2,3mg%, hyperphosphaturia:956mg/24hs, tubular reabsorption of phosphate: 80% Molecular analysis by next-generation sequencing (NGS) of the ALPL, CLCN5, CTNS, CYP27B1, CYP2R1, DMP1, ENPP1, FAH, FAM20C, FGF23, FGFR1,GNAS,KL,OCRL,PHEX,SLC34A1,SLC34A3,andVDRgenesidentified the variant chrX:22.227.584 - 22.227.589 CCAGCT>CATAACTCAG (or c.2044_2048delinsATAACTCAG – ENST00000379374) in heterozygosity in the PHEX gene (p.Gln682Ilefs*36). Panel examination for XLH in the patient's mother and sister by NGS: absence of pathogenic variants.
Conventional treatment was initiated with phosphorus salts, calcitriol and cholecalciferol.
Discussion: The variant identified has not been previously described and is absent in approximately 1.2 million population-based samples. The combination of the molecular mechanism with the early interruption of protein translation, the characteristics of the region where it is located, and the presence of clinical symptoms allow this variant to be classified as pathogenic.
Conclusions: This case illustrates the variability in the XLH phenotype. In this family, the index case was a boy, and the maternal diagnosis occurred in adulthood through a segregation study. Genetic testing is crucial in the diagnosis of cases with attenuated manifestations of the disease, especially when the variant of the index case is known. Furthermore, we underscore its importance for genetic counseling and family planning.

CANCER-TREATMENT-INDUCED BIOLOGICAL AND EPIGENETIC SIGNS OF ACCELERATED AGING IN CANCER SURVIVORS: A SYSTEMATIC REVIEW

A. F. Fastré[1], C. B. Beaudart[1], M. L. Locquet[1]

[1]University of Namur, Department of Biomedical Sciences, Clinical Pharmacology Research Unit, Namur, Belgium

Objective
With growing populations of cancer survivors, late effects of cancer treatments became a major public health burden. Emerging evidence suggests that cancer treatments may induce biological alterations consistent with an accelerated aging hypothesis; however, fragmented. This systematic review (SR) aimed to synthesize biological biomarkers of treatment-induced accelerated aging in cancer survivors (CS) vs. cancer-free individuals.
Material and Methods
The SR was conducted according to PRISMA guidelines. Databases (Scopus, PubMed) were searched (September 2025) to identify observational studies assessing biological or epigenetic aging biomarkers in cancer survivors exposed to cancer treatments. Eligible studies should also include a cancer-free comparison group. Aging biomarkers comprised inflammatory markers, immune cell phenotypes, telomeres, mitochondrial or DNA damages, and epigenetic clocks. Study selection, data extraction, and quality assessment were performed by 2 reviewers. When appropriate, pooled effect estimates were computed, and sensitivity analyses were conducted.
Results
Of the 11,006 screened references, 22 studies were included. The most frequently reported biomarkers were inflammatory markers, immune cell phenotyping, circulating microRNAs, and epigenetic DNA methylation clocks. The included references were mainly cross-sectional or retrospective cohort studies, with sample sizes ranging from 38 to 2,000 CS. Most cohorts included childhood CS (n = 9) and breast CS (n = 8), with sex-specific or mixed populations, depending on cancer type. In pooled analyses, (hs)CRP was significantly higher in CS (k = 7; n = 15,544 individuals; standardized mean difference (SMD) = 1.06, 95% confidence interval (CI): 0.23-1.88; p = 0.012; I^2 = 97.7%), and epigenetic age acceleration was also higher (k = 3 cohorts; 7 effect sizes; n = 2,607 individuals; SMD = 0.31, 95% CI: 0.15-0.48; I^2 = 84.2%) vs. cancer-free controls. Heterogeneity between studies was high. Consistent patterns were observed in subgroup (chemotherapy vs. chemoradiotherapy; childhood vs. adult) and leave-one-out analyses, confirming the robustness of significant pooled effects.
Conclusion
This SR identified biological and epigenetic signs consistent with accelerated aging in CS from clinical studies. Major gaps include limited prospective data, heterogeneous methodologies, and underrepresentation of non-chemotherapy treatments. Standardized biomarkers are needed to support precision oncology, optimize treatment, prevent aging morbidities, and allow healthy aging in CS.

BISPHOSPHONATES OR DENOSUMAB AFTER FRACTURE? REAL-WORLD EVIDENCE FROM A TARGET TRIAL EMULATION IN MULTIMORBID ADULTS

M. Lin[1,2,3], T. Tran[1,4], R. Blank[1,5], J. R. Center[1,2,6], D. Bliuc[1,7]

[1]Bone Epidemiology, Clinical and Translation Science Lab, Garvan Institute of Medical Research, Darlinghurst, Australia; [2]St Vincent's Clinical School, Faculty of Medicine and Health UNSW, Darlinghurst, Australia; [3]Department of Endocrinology, Royal Prince Alfred Hospital, Camperdown, Australia; [4]School of Medical Engineering, University of Technology, Ultimo, Australia; [5]Medical College of Wisconsin, Milwaukee, United States; [6]Department of Endocrinology, St Vincent's Hospital, Camperdown, Australia; [7]North Wales Medical School, Bangor University, Wales, United Kingdom

Objective: Individuals with multimorbidity (MM) are often excluded from randomised trials, limiting evidence on comparative effectiveness of antiresorptive therapies. We implemented target trial emulation (TTE) to compare bisphosphonates (BP) versus denosumab (Dmab) for refracture and all-cause mortality across MM clusters.

Methods: Using whole-population linked administrative data, we identified treatment-naïve adults aged ≥50 years in New South Wales, Australia, who sustained fractures requiring emergency or hospital admission between 2010 and 2018. We excluded individuals with prior osteoporosis treatment, prior fractures, metastatic cancer, or other metabolic bone disorders. A clone-censor-weight approach compared two strategies: initiation of BP (alendronate, risedronate, or zoledronic acid) versus Dmab within 12 months post-fracture (grace period). Time zero was the fracture date, with follow-up of up to 4 years for refracture and mortality. Individuals were cloned, assigned to each strategy, and censored if their observed treatment deviated from the assigned strategy. Inverse probability of censoring weights addressed informative censoring. Latent class analysis (LCA) classified individuals into MM clusters based on comorbidities at time of fracture. Sex-specific weighted pooled logistic regression estimated hazard ratios (HRs) and 4-year risk differences (RDs).

Results: Among 117,031 eligible individuals (mean age 75.7 years; 64% women), 6036 initiated BP and 2611 initiated Dmab within grace period. LCA identified four MM clusters (cardiovascular, cardiometabolic, geriatric, mental health; median comorbidity count: 4-12) and one low MM cluster (median: 0). Compared with Dmab, BP use was associated with lower all-cause mortality in women (HR 0.71, 95% CI 0.67–0.76; RD −26.3%, 95% CI −31.1% to −21.1%) and men (HR 0.79, 95% CI 0.74–0.85; RD −24.4%, 95% CI −30.6% to −17.9%). Mortality reduction was consistent across multimorbidity clusters. Refracture risk was comparable between treatment groups.

Conclusion: In this real-world TTE, initiation of BP after fracture was associated with lower mortality compared to Dmab in both healthy and MM populations, with comparable refracture risk. These findings suggest BP have non-skeletal benefits that warrant further investigation.

P1077

COMPARATIVE CARDIOVASCULAR SAFETY OF BISPHOSPHONATES AND DENOSUMAB AFTER FRACTURE: A SEQUENTIAL TARGET TRIAL EMULATION

M. Lin[1,2,3], T. Tran[1,4], R. Blank[1,5], D. Bliuc[1,6], J. R. Center[1,2,7]

[1]Bone Epidemiology, Clinical and Translation Science Lab, Garvan Institute of Medical Research, Darlinghurst, Australia; [2]St Vincent's Clinical School, Faculty of Medicine and Health UNSW, Darlinghurst, Australia; [3]Department of Endocrinology, Royal Prince Alfred Hospital, Camperdown, Australia; [4]School of Medical Engineering, University of Technology, Ultimo, Australia; [5]Medical College of Wisconsin, Milwaukee, United States; [6]North Wales Medical School, Bangor University, Wales, United Kingdom; [7]Department of Endocrinology, St Vincent's Hospital, Darlinghurst, Australia

Objective

Bisphosphonates (BP) and denosumab (Dmab) are widely used for fracture prevention. Beyond skeletal effects, both agents have been hypothesised to confer potential cardiovascular protection, although evidence remains inconsistent.

Methods

We emulated a sequential target trial using linked, administrative health data from New South Wales, Australia. Adults aged ≥50 years with incident fracture requiring hospitalisation or emergency admission between 1 January 2005 and 30 June 2019, without prior cardiovascular disease (CVD) or antiresorptive therapy, were eligible. New users of BP or Dmab initiating treatment between 1 December 2010 and 30 June 2019 were included. Time zero was treatment initiation, with monthly trial starts. Follow-up was up to 3 years until outcome, death or administrative censoring. Baseline inverse probability of treatment weighting was applied. Outcomes were first hospitalised acute myocardial infarction (AMI), stroke, heart failure (HF) or arrhythmia. Intention-to-treat (ITT) effects were estimated using weighted Cox proportional hazards and Fine–Gray (FG) models accounting for competing risk of death. Per-protocol (PP) analyses used inverse probability of censoring weights.

Results

Baseline characteristics were well balanced (all SMD<0.1). Incidence rates per 1,000 person-years were similar between BP and Dmab for hospitalised AMI (4.71 vs 4.84), stroke (6.77 vs 6.83), HF (5.98 vs 5.88) and arrhythmia (6.05 vs 6.56). In ITT analyses, BP initiation was associated with similar cardiovascular risk compared with Dmab. Weighted Cox hazard ratios (BP vs Dmab) were 1.00 (95% CI 0.80–1.24) for AMI, 1.07 (0.89–1.28) for stroke, 1.14 (0.94–1.38) for HF and 0.98 (0.81–1.19) for arrhythmia; FG estimates accounting for competing risk of death were consistent (HR range 0.92-1.00). PP analyses accounting for treatment non-adherence produced similar estimates. Time-to-event distributions and mortality rates were comparable.

Conclusion

In this large real-world sequential target trial, initiation of BP and Dmab was associated with comparable cardiovascular safety over 3 years of follow-up among fracture patients without prior CVD.

P1078

EXTRASKELETAL EFFECTS OF SCLEROSTIN INHIBITION: ROMOSOZUMAB IMPROVES SARCOPENIA PARAMETERS IN POST-MENOPAUSAL OSTEOPOROSIS

M. Lombini[1], F. Chesini[1], M. Zantedeschi[1], C. Stranieri[1], F. Bertoldo[1]

[1]Unit of Metabolic Bone Diseases, Department of Medicine, University of Verona, Verona, Italy

The Wnt signaling pathway regulates skeletal homeostasis but also drives mesenchymal stem cells differentiation and inhibits adipogenesis. Sclerostin, an endogenous Wnt inhibitor, contributes to osteoporosis, sarcopenia, and ectopic fat accumulation. Romosozumab, an anti-sclerostin monoclonal antibody, enhances bone formation and reduces fracture risk; emerging evidence suggests additional extra-skeletal benefits, including reduced falls.

This real-world prospective study aims to compare the extra-skeletal effects of Romosozumab vs Alendronate on body composition and sarcopenia-related parameters in postmenopausal women with osteoporosis.

45 postmenopausal women with osteoporosis previously treated with alendronate were enrolled: 24 switched to Romosozumab 210mg/month (ROMO) and 21 continued Alendronate (ALN). Exclusion criteria included mobility impairment, advanced CKD, diabetes, chronic corticosteroid use, autoimmune diseases, active cancer, and cirrhosis. Assessments at baseline (T0), 6 months (T1), and 12 months (T2) included DXA (BMD and body composition analysis), handgrip strength (HG), Short Physical Performance Battery (SPPB) and serum cytokines involved in bone-muscle-adipose tissue crosstalk. Appendicular lean soft tissue standardized for weight (appLST/Kg) was derived from DXA.

At T0, ALN showed significant greater HG and appLST/Kg, while ROMO showed lower BMD T-scores at all skeletal sites. Both groups showed increased HG at T2 vs T0 (ROMO: +3.05±3.57 kg, p=0.0012; ALN: +2.71±4.03 kg, p=0.0222), although without significant differences between the two groups. At T2 SPPB improved significantly compared to T0 in both groups, but ROMO showed a greater improvement in SPPB at T1 and T2 compared to ALN (+20.79±17.95 % vs +5.68 ± 9.71 % at T2 respectively, p=0.0036). At T2, myostatin decreased in ROMO and increased in ALN (-3.60±42.35 vs +33.02±44.07; p=0.0045). In ROMO, multiple regression showed an inverse association of myostatin and TNF-α with HG (R^2: 49.09%; p=0.0137).

Romosozumab showed rapid, extra-skeletal effects on muscle strength and physical performance, independent of muscle mass changes, suggesting a potential role in mitigating sarcopenia.

P1079

IMMUNOFIXATION NOT SERUM PROTEIN ELECTROPHORESIS IS THE PREFERRED SCREENING TEST FOR MYELOMA IN PATIENTS PRESENTING WITH VERTEBRAL COMPRESSION FRACTURES (VCF)-3 CASES OF LIGHT CHAIN MYELOMA WITH HYPOGAMMAGLOBULINEMIA PRESENTING WITH VCF

M. Lovy[1]

[1]Desert Oasis Healthcare, Palm Springs, California, United States

OBJECTIVE

Light chain myeloma comprises 10-20% of myeloma cases in large series. This study describes 3 patients presenting with VCF to a fracture clinic diagnosed with light chain myeloma and hypogammaglobulinemia whose diagnosis would have been overlooked if screened with serum protein electrophoresis.

METHODS

Chart review of 3 patients found to have light chain myeloma and hypogammaglobulinemia among a group of 14 patients presenting to a fracture clinic with a VCF who were subsequently diagnosed with myeloma.

RESULTS

All 3 patients were male ages 72 (Patient 1), 75 (Patient 2), and 84 (Patient 3) at the time of diagnosis, with no previous history of fracture, bone or joint pain, or infection. Underlying conditions included diabetes, hypogonadism, and obesity-Patient 1, and kidney stone-Patient 2. Fractures occurred without a fall in all cases at locations T-4, T-12, and T-12, L1 and L2 respectively. All patients had normal CBC, calcium, alkaline phosphatase, creatinine, urinalysis, magnesium, vitamin D, vitamin B-12, TSH, PTH, and total protein levels. An M-spike was not present in any case. Gamma globulin levels were 0.3, 0.4, and 0.5 g/dL (normal 0.4-1.8), A/G ratios 1.6, 1.4, 1.3 (normal 1.2-2.2), total globulin levels 1.8, 2.7, 2.6 g/dL (normal 1.5-4.5) respectively. Low levels of IgG, IgA and IgM were found in all patients. Kappa light chain paraprotein was identified on immunofixation in all patients as well as Bence-Jones protein. Free kappa light chain levels were 1708, 1652, and 1141 (normal 3.3-19.4) with free light chain ratios of 632, 232, 170 (normal 0.26-1.65). Blastic and lytic lesions were found in other locations in all cases. Femoral neck bone density T-score was -3.3 in Patient 1 and -1.7 and -2.3 in Patients 2 and 3. Diagnosis was established by bone marrow biopsy with all patients responding to therapy without further fracture and surviving 8 months, 3 and 5 years from diagnosis.

CONCLUSION

Patients with myeloma can present with VCF without any manifestations of hypercalcemia, renal insufficiency, anemia, previous fracture or other clinical clues to their underlying diagnosis. Serum protein electrophoresis will fail to diagnose patients with light chain myeloma with hypogammaglobulinemia. Therefore, immunofixation is the preferred screening test for myeloma in patients presenting with VCF.

	Adequate vitamin D exposure	0
History of Falls	Two or more falls in the past year	4
	One fall in the past year	2
	No falls	0
Chronic Conditions	Presence of chronic condition affecting bone	3
	No chronic conditions	0
Radiographic Findings		
Vertebral Compression Fractures on X-Ray	Presence of one or more vertebral fractures	6
	No vertebral fractures	0
Generalized Osteopenia on X-Ray	Evidence of cortical thinning/reduced bone	3
	Normal bone appearance	0
Trabecular Bone Loss	Notable loss of trabecular patterns	2
	Normal trabecular patterns	0

Table 1:
The Muzzammil's Osteoporosis Risk Scoring System.
Risk Categories: Low Risk: 0-10 points.
Moderate Risk: 11-20 points.
High Risk: 21-30 points.
Very High Risk: 31+ points.

Background

Osteoporotic fragility fractures represent a growing and under addressed public health problem in low and middle income countries. Limited access to DXA scanning results in delayed diagnosis, missed prevention opportunities, and high fracture related morbidity. A simple community based osteoporosis risk scoring system was previously developed and validated in a single center. This study evaluated its real world performance, scalability, and implementation feasibility across diverse low resource healthcare settings.
Objective

To assess diagnostic accuracy, fracture risk stratification, and feasibility of a low cost osteoporosis risk scoring system when deployed by primary healthcare workers in urban, peri urban, and rural environments.
Methods

This prospective multicenter implementation study enrolled 1,000 adults aged 40 years or older from an urban tertiary hospital, a peri urban health center, and a rural outreach clinic. Participants with known osteoporosis or metabolic bone disease were excluded. Trained primary healthcare workers administered a structured questionnaire and applied the risk score. Lumbar spine and pelvic radiographs were obtained for all participants and independently interpreted by blinded orthopedic radiologists. Fragility fractures were defined as fractures following low energy trauma with radiographic confirmation. Diagnostic performance, fracture prevalence across risk categories, and feasibility metrics were analyzed. Two cutoff strategies were evaluated to reflect screening and referral intent.
Results

The cohort included 57.2% females with a mean age of 59.4 years. Low dietary calcium intake was present in 61.2% and low vitamin D exposure in 68.5%. Radiographic osteoporotic changes were identified in 64.8% of participants, with vertebral compression fractures in 17.3%. Risk stratification classified 36.7% as low risk, 33.2% as moderate risk, 20.8% as high risk, and 9.3% as very high risk. Fragility fracture prevalence increased sharply from 4.9% in the low risk group to 48.4% in the very high risk group. Using a sensitive screening threshold, sensitivity reached 89.2% with a negative predictive value of 95.1%. Using a referral focused threshold, specificity was 75.9% with an area under the ROC curve of 0.80. Primary healthcare workers successfully administered the tool in over 95.0% of encounters, with a mean completion time under seven minutes.
Conclusion

This multicenter study demonstrates that a simple community based osteoporosis risk scoring system can accurately stratify fracture risk and be feasibly implemented at scale in low resource settings. The tool offers a practical pathway for early identification, targeted prevention, and national osteoporosis screening strategies.

P1081

PREDICTING DISABILITY AND HOSPITALIZATION AFTER FRAGILITY FRACTURES IN LOW INCOME SETTINGS. MULTICENTER VALIDATION OF A SIMPLE SCREENING SCALE FOR ELDERLY PATIENTS

M. M. Muzzammil[1]

[1]Sindh Government Services Hospital Karachi, Karachi, Pakistan

Background

Fragility fractures in older adults represent a growing cause of disability and repeated hospitalization in low and middle income countries. Early risk identification remains limited due to the absence of simple, context appropriate screening tools that can be used at the point of care by non specialist providers.
Objective

To develop and externally validate the Low Income Country Simple Comprehensive Screening Scale, LIC SCSS, as a practical tool to predict disability and hospitalization risk in elderly patients presenting with fragility fractures.
Methods

We conducted a multicenter prospective cohort study across three tertiary hospitals in Pakistan, Bangladesh, and Kenya. A total of 300

patients aged 65 years or older with low energy hip, vertebral, or distal radius fractures were enrolled. LIC SCSS is a 13 item score covering physical frailty, psychological health, and socioeconomic vulnerability. The tool was administered at admission and followed at 6 and 12 months. Primary outcomes included functional decline measured by activities of daily living and all cause hospitalization within 12 months. Predictive performance was assessed using logistic regression and receiver operating characteristic analysis. Inter rater reliability was evaluated among trained non specialist healthcare workers.

Results

Median LIC SCSS score was 6. High risk patients showed significantly higher rates of functional decline and hospitalization. At 12 months, high risk patients had a 60 percent rate of three or more ADL decline compared with 7 percent in the low risk group. Hospitalization occurred in 41 percent of high risk patients versus 5 percent of low risk patients. LIC SCSS demonstrated strong predictive accuracy with an AUC of 0.86 for functional decline and 0.84 for hospitalization, outperforming the Clinical Frailty Scale and FRAIL Index. Inter rater reliability was excellent with a Cohen kappa of 0.83. Mean administration time was under five minutes.

Conclusion

LIC SCSS is a rapid, reliable, and highly predictive screening tool for elderly fragility fracture patients in resource limited settings. Its simplicity and strong performance support integration into routine orthopedic and community based care to enable early intervention and reduce avoidable disability and hospitalization.

LIC-SCSS Scoring System

Domain	Dimension	Criteria	Score
Physical Health	Clinical Frailty Scale (CFS)	Mild frailty (CFS 4-5) = 1; Moderate/Severe (CFS 6-7) = 2 = 2	0–2
	Weight Loss	Unintentional weight loss >5% in 6 months	1
	Polypharmacy	≥3 regular medications	1
	Fall History	≥1 fall in the past year	1
	Dizziness/Balance Issues	Frequent dizziness/unsteady gait	1
	Pressure Sores	Present at admission	1
Psychological Health	Insomnia	Difficulty sleeping ≥3 nights/week	1
	Depression (PHQ-2)	Score ≥3 on PHQ-2	1
	Delirium (4AT)	4AT score ≥4	1
Socioeconomic Factors	Living Alone	No primary caregiver/support at home	1
	Elder Neglect/Abuse (EASI)	Positive response on Elder Abuse Suspicion Index	1
	Economic Constraints	Unable to afford medications/home modifications	1
Total Score		Total Score	0–13

Table-1: Risk Stratification Based on LIC-SCSS Score

Total Score	Risk Level	Suggested Intervention
0-3	Low Risk	Routine follow-up, standard post-fracture care
4-7	Moderate Risk	Physiotherapy, nutritional support, home safety assessment
8-13	High Risk	Intensive rehabilitation, social support intervention

Table-1: Risk Stratification Based on LIC-SCSS Score

P1082

A ONE MINUTE BEDSIDE SARCOPENIA RISK MODEL PREDICTS DISABILITY, MORTALITY, AND CARE BURDEN AFTER FRAGILITY FRACTURES IN THE ELDERLY

M. M. Muzzammil[1], A. Q. Qadir[1]

[1]Sindh Government Services Hospital Karachi, Karachi, Pakistan

Background

Muscle and bone form a functional unit that determines fracture risk and recovery in older adults. Sarcopenia worsens outcomes after fragility fractures but is rarely screened in routine care in low resource settings despite availability of simple bedside tools.

Objective

To develop a simple sarcopenia risk stratification model and evaluate its impact on fracture pattern, mortality, functional recovery, and health system burden in elderly fragility fracture patients.

Methods

This prospective cohort study included patients aged 60 years and above presenting with low energy fragility fractures. Sarcopenia was assessed at admission using hand grip strength and calf circumference based on Asian Working Group cutoffs. Patients were classified into low risk, moderate risk, or high risk sarcopenia categories. Primary outcomes were poor functional recovery at three months defined as Modified Barthel Index below 70, loss of independent ambulation, and new caregiver dependence. Secondary outcomes included thirty day mortality, ninety day readmission, length of hospital stay, and institutionalization. Multivariable regression adjusted for age, sex, fracture type, and comorbidities. Interaction analysis assessed combined effects of sarcopenia and hip fracture.

Results

A total of 400 patients were enrolled with a mean age of 71.4 ± 7.2 years. Sarcopenia was present in 47.0 percent, with 28.0 percent classified as high risk. Poor functional recovery increased stepwise across risk categories, occurring in 21.4 percent of low risk, 46.8 percent of moderate risk, and 71.6 percent of high risk patients. Thirty day mortality rose from 2.1 percent in low risk to 11.6 percent in high risk patients. Mean hospital stay increased from 6.1 ± 2.4 days to 10.8 ± 3.6 days. Patients with combined sarcopenia and hip fracture demonstrated the worst outcomes, with poor recovery in 78.9 percent compared to 34.6 percent in non sarcopenic non hip fracture patients. This group showed an adjusted odds ratio of 3.62 for poor recovery with a 95 percent confidence interval of 2.18 to 6.01. Sarcopenia accounted for an excess of 2.8 hospital days per patient and an additional caregiver requirement of 3.4 hours per day at three months. Among sarcopenic patients, early physiotherapy within 48 hours was associated with higher Barthel scores, 69.1 versus 58.4.

Conclusion

A two parameter bedside sarcopenia screen identifies high risk elderly fragility fracture patients within one minute and accurately predicts disability, mortality, and care burden. Sarcopenia markedly amplifies the adverse impact of hip fractures. This zero cost risk model offers an immediately scalable strategy to improve outcomes and optimize resource use in low resource healthcare systems.

P1083

VITAMIN D DEFICIENCY AND FALL RELATED FRAGILITY FRACTURES IN URBAN ELDERLY. PREVALENCE, SEVERITY, FUNCTIONAL AND HEALTH SYSTEM IMPACT

M. M. Muzzammil[1], A. Q. Qadir[1], M. Z. Zubair[1]

[1]Sindh Government Services Hospital Karachi, Karachi, Pakistan

Background

Vitamin D deficiency impairs muscle strength, balance, and mobility and increases fall related fracture risk in elderly populations. Urban elderly in developing countries experience high fracture burden despite abundant sunlight. Data linking vitamin D status with functional outcomes, fracture severity, and early mortality remain limited.

Objective

To determine the prevalence and severity of vitamin D deficiency in elderly patients with fall related fractures and to quantify its association with muscle strength, fall frequency, fracture pattern severity, early mortality, functional recovery, and hospital resource utilization.

Methods

This prospective observational study enrolled 500 adults aged 60.0 years and above presenting with fall related fractures to a public tertiary care hospital. Mean age was 71.6 years with a standard deviation of 7.8 years. Serum 25 hydroxyvitamin D levels were measured at admission. Severe deficiency was defined as less than 10.0 ng per mL, moderate deficiency as 10.0 to 19.9 ng per mL, and sufficient as 20.0 ng per mL or above. Muscle strength was assessed using hand grip strength in kilograms and chair rise test time in seconds. Mobility was evaluated using gait speed in meters per second and Timed Up and Go test time. Fall history over the preceding 12.0 months was recorded. Fractures were classified as hip, vertebral, or peripheral. Outcomes included 30.0 day mortality, length of hospital stay, and 90.0 day functional status assessed by Barthel Index. Multivariable regression analysis adjusted for age, sex, and comorbidities.

Results

Vitamin D deficiency was present in 390 of 500 patients, representing 78.0 percent. Severe deficiency was identified in 215 patients, or 43.0 percent. Mean serum vitamin D level was 13.2 ng per mL with a standard deviation of 6.4. Mean grip strength was 16.1 kg in the severe deficiency group, 18.9 kg in moderate deficiency, and 21.4 kg in sufficient patients. Mean chair rise time was 21.6 seconds, 18.3 seconds, and 14.2 seconds respectively. Mean gait speed was 0.48 m per s in severe deficiency compared to 0.72 m per s in sufficient patients. Recurrent falls occurred in 62.3 percent of severe deficiency patients versus 28.7 percent in sufficient patients. Hip and vertebral fractures accounted for 68.4 percent of fractures in severe deficiency compared to 31.9 percent in sufficient patients. Thirty day mortality was 7.4 percent in severe deficiency versus 2.1 percent in sufficient patients. Mean hospital stay was 9.6 days in severe deficiency and 6.1 days in sufficient patients. Mean Barthel Index at 90.0 days was 55.2 in severe deficiency compared to 72.8 in sufficient patients. Each 5.0 ng per mL decrease in vitamin D level increased odds of recurrent falls by 1.8 times and hip fracture by 2.3 times after adjustment.

Conclusion

Vitamin D deficiency affects more than three quarters of urban elderly patients with fall related fractures and nearly half have severe deficiency. Lower vitamin D levels are independently associated with muscle weakness, impaired mobility, recurrent falls, higher early mortality, prolonged hospitalization, and severe fracture patterns involving the hip and spine. Routine vitamin D screening at first fall or fracture and early supplementation represent a low cost, scalable strategy with potential to reduce fracture severity, disability, and health system burden in urban elderly populations of developing countries.

Fracture Patterns and Outcomes by Vitamin D Status

Variable	Severe Deficiency (<10 ng/mL) N = 215	Moderate Deficiency (10–19.9 ng/mL) N = 175	Sufficient (≥20 ng/mL) N = 110	P Value
Fracture Type

P1084

DELAYED HIP FRACTURE SURGERY IN PUBLIC HOSPITALS. IMPACT ON MORTALITY, MOBILITY, AND SYSTEM LEVEL BARRIERS IN A LOW RESOURCE SETTING

M. M. Muzzammil[1], A. Q. Qadir[1], M. Z. Zubair[1]

[1]Sindh Government Services Hospital Karachi, Karachi, Pakistan

Background

Hip fracture surgery within 48.0 hours reduces mortality, complications, and disability. In public hospitals of low resource settings, most patients experience surgical delay. You evaluated clinical impact, system drivers, and policy relevant consequences of delay.
Objective

You assessed the effect of surgical delay on mortality, mobility, complications, and costs and identified modifiable hospital level barriers.
Methods

You conducted a prospective cohort study including patients aged 60.0 years and above admitted with low energy hip fractures. Time from admission to surgery was recorded. Patients were grouped into early surgery within 48.0 hours and delayed surgery beyond 48.0 hours. You recorded fracture type, procedure, ASA grade, and Charlson Comorbidity Index. Outcomes included 30.0 day mortality, mobility at 3.0 months using Parker Mobility Score, length of stay, complications, readmission, and reoperation. Multivariable regression adjusted for age, sex, fracture type, ASA grade, and comorbidity. You performed process mapping of in hospital delays and estimated excess bed days and cost burden.
Results

You included 420 patients. Mean age was 72.4 years plus minus 7.8 years. Females accounted for 62.1 percent. Mean Charlson Comorbidity Index was 4.1. ASA grade III or IV was present in 58.6 percent. Fracture pattern included intertrochanteric fractures in 56.2 percent and femoral neck fractures in 43.8 percent. Hemiarthroplasty was performed in 44.0 percent and internal fixation in 56.0 percent.
Early surgery occurred in 109 patients, 26.0 percent. Mean time to surgery was 32.6 hours in the early group and 96.8 hours in the delayed group. Thirty day mortality was 6.4 percent versus 14.9 percent. Adjusted odds ratio for mortality with delay beyond 48.0 hours was 2.41. Mortality increased by 3.2 percent for each additional 24.0 hour delay.
At 3.0 months, mean Parker Mobility Score was 6.1 in early surgery patients and 3.9 in delayed patients. Independent or assisted ambulation was achieved in 68.3 percent versus 41.2 percent. Mean hospital stay was 6.2 days versus 11.4 days, adding 5.2 excess bed days per delayed patient. Thirty day readmission was 18.6 percent in delayed cases compared to 9.8 percent in early cases. Chest infection occurred in 23.1 percent versus 9.2 percent. Pressure sores occurred in 16.7 percent versus 4.6 percent.
System related factors accounted for 71.0 percent of delays. Operating room unavailability contributed 34.2 percent. Delayed medical clearance accounted for 18.3 percent. Implant unavailability accounted for 12.1 percent. Financial constraints accounted for 6.4 percent. Weekend admissions had a mean delay of 28.0 additional hours compared to weekday admissions.
Delayed surgery generated an estimated 1617 excess bed days annually, translating into a substantial avoidable cost burden for the public hospital. Modeling showed that achieving surgery within 48.0 hours in 80.0 percent of patients could prevent 8.3 deaths per 100.0 hip fractures.
Conclusion

Delayed hip fracture surgery in public hospitals doubles mortality risk, worsens functional recovery, increases complications, and imposes a major economic burden. You demonstrate that delay is predominantly driven by modifiable system failures. Implementing protected trauma operating time, standardized clearance pathways, assured implant supply, and early geriatric co management can produce immediate survival and mobility gains in low resource healthcare systems.

Fracture Patterns and Outcomes by Vitamin D Status

Variable	Severe Deficiency (<10 ng/mL) N = 215	Moderate Deficiency (10–19.9 ng/mL) N = 175	Sufficient (≥20 ng/mL) N = 110	P Value

P1085

ROUTINE X RAY BASED PREDICTION OF OSTEOPOROSIS IN THE ABSENCE OF DXA. FEMORAL CORTICAL THICKNESS AND SINGH INDEX AS PRACTICAL SCREENING TOOLS

M. M. Muzzammil[1], A. Q. Qadir[1], M. Z. Zubair[1]

[1]Sindh Government Services Hospital Karachi, Karachi, Pakistan

Background

Limited access to DXA in low resource health systems delays osteoporosis diagnosis until after a fragility fracture. Routine plain radiographs are widely available and may provide objective markers for early identification of bone fragility.
Objective

To determine the diagnostic performance of femoral cortical thickness and Singh index measured on routine X rays for predicting osteoporosis and fragility fractures in adults aged fifty years and above.
Methods

This observational study included four hundred adults aged fifty years or older presenting to a public sector hospital with hip, distal radius, or vertebral fractures. Two hundred and sixty patients had fragility fractures and one hundred and forty had non fragility fractures. Standard anteroposterior pelvic and femoral radiographs were obtained in all cases. Femoral cortical thickness was measured bilaterally at a standardized level two centimeters below the lesser trochanter and averaged for analysis. Trabecular bone pattern was graded using the Singh index from grade one to six. DXA scanning was available in one hundred and twenty patients and used for validation. Interobserver reliability was assessed

in fifty randomly selected radiographs following brief focused training. Statistical analysis evaluated associations with fracture type and DXA defined osteoporosis.
Results

Mean femoral cortical thickness was significantly lower in fragility fracture patients compared to non fragility fracture patients, 5.1 ± 0.9 mm versus 6.8 ± 1.1 mm. Mean Singh index grade was also lower in the fragility fracture group, 2.8 ± 0.7 versus 4.1 ± 0.8. A femoral cortical thickness cutoff of less than 6 mm predicted DXA defined osteoporosis with sensitivity of 82 percent and specificity of 74 percent. Singh index grades of three or below showed sensitivity of 76 percent and specificity of 70 percent for osteoporosis. Combined use of cortical thickness and Singh index improved diagnostic accuracy with an area under the curve of 0.85 compared to 0.78 for cortical thickness alone and 0.72 for Singh index alone. Interobserver agreement was good with an intraclass correlation coefficient of 0.81 for cortical thickness and a kappa value of 0.76 for Singh index grading. All measurements were completed within routine radiograph reporting time without additional cost.
Conclusion

Femoral cortical thickness and Singh index derived from routine X rays demonstrate good diagnostic accuracy for identifying osteoporosis and fragility fracture risk in settings without DXA. These simple markers enable early recognition of bone fragility using existing imaging. Their integration into routine radiograph reporting can support timely initiation of osteoporosis treatment and strengthen secondary fracture prevention strategies in resource limited healthcare systems.

P1086

SECONDARY FRACTURE PREVENTION FAILURE AFTER FIRST FRAGILITY FRACTURE IN A LOW RESOURCE SETTING, MAGNITUDE, CONSEQUENCES, AND SYSTEM DETERMINANTS

M. M. Muzzammil[1], A. Q. Qadir[1], M. Z. Zubair[1]

[1]Sindh Government Services Hospital Karachi, Karachi, Pakistan

Background

A first fragility fracture markedly increases the risk of subsequent fractures, disability, and mortality. International guidelines recommend immediate osteoporosis assessment and treatment after the index fracture. In low resource health systems, this step is frequently missed, leading to preventable recurrent fractures and increased healthcare burden.
Objective

To quantify the secondary fracture prevention gap after a first fragility fracture, evaluate clinical and economic consequences, and identify patient and system level predictors of missed osteoporosis care.
Methods

This prospective observational study included adults aged 50.0 years and above presenting with a first low energy fragility fracture involving the hip, distal radius, or spine. Osteoporosis assessment and initiation of calcium, vitamin D, and anti osteoporotic therapy within 3.0 months were recorded. Time to assessment, treatment delays, recurrent fractures, mortality, functional outcomes, and readmissions were documented over 12.0 months. Provider specialty, care setting, and referral patterns were analyzed. Direct hospital costs were estimated. Multivariable regression identified predictors of missed care.
Results

A total of 600.0 patients were enrolled. Mean age was 67.4 ± 8.9 years. Females comprised 406.0 patients, 67.7 percent. Hip fractures accounted for 264.0 patients, 44.0 percent, distal radius fractures for 202.0 patients, 33.7 percent, and vertebral fractures for 134.0 patients, 22.3 percent.
Only 108.0 patients, 18.0 percent, received any osteoporosis assessment within 3.0 months. Dual energy X ray absorptiometry was performed in 46.0 patients, 7.7 percent. Serum vitamin D was measured in 62.0 patients, 10.3 percent. Median time to osteoporosis assessment was 84.0 days. At 12.0 months, 385.0 patients, 64.2 percent, had never undergone any assessment.
Anti osteoporotic therapy was initiated in 84.0 patients, 14.0 percent. Bisphosphonates were prescribed in 61.0 patients, 10.2 percent, denosumab in 15.0 patients, 2.5 percent, and teriparatide in 8.0 patients, 1.3 percent. Calcium and vitamin D supplementation was prescribed in 186.0 patients, 31.0 percent. Median time to treatment initiation was 96.0 days.
Assessment rates were 11.2 percent in emergency or trauma units compared to 31.6 percent in outpatient clinics. Treatment initiation was lowest in hip fracture patients at 9.8 percent, compared to 16.9 percent in vertebral fractures and 19.3 percent in distal radius fractures. Orthopedic services initiated anti osteoporotic therapy in 12.4 percent compared to 26.8 percent in medical clinics.
At 12.0 months, recurrent fragility fractures occurred in 72.0 patients, 12.0 percent. Mean time to second fracture was 7.2 ± 2.1 months. Recurrent fractures occurred in 14.6 percent of untreated patients compared to 4.8 percent of treated patients. One year mortality after hip fracture was 18.9 percent in untreated patients compared to 9.4 percent in treated patients. Loss of independent ambulation occurred in 35.6 percent of untreated patients versus 19.2 percent of treated patients. Fracture related readmissions occurred in 16.3 percent of untreated patients.
Mean hospital cost for index fracture care was 480.0 United States dollars compared to 960.0 United States dollars for recurrent fracture care. Annual cost of calcium, vitamin D, and oral bisphosphonate therapy was 35.0 United States dollars per patient.
On multivariable analysis, management in emergency or trauma units, odds ratio 2.84, lack of outpatient referral, odds ratio 3.12, absence of documented osteoporosis counseling, odds ratio 3.67, and no scheduled follow up appointment, odds ratio 4.01, independently predicted missed osteoporosis care.
Conclusion

Secondary fracture prevention after the first fragility fracture is severely inadequate in this low resource setting. Missed assessment and treatment result in higher fracture recurrence, mortality, disability, and healthcare costs. A simple hospital based fracture liaison pathway could substantially reduce preventable recurrent fractures at minimal cost and should be prioritized in developing health systems.

P1087

REFRACTORY DERMATOMYOSITIS TREATED WITH ANIFROLUMAB: A CASE REPORT AND REVIEW OF THE EVIDENCE

M. M. Muñoz Gómez[1], J. J. López Carvajal[1], A. Almansa Ramírez[1], M. Navidad Fuentes[1]

[1]Rheumatology Department. Torrecárdenas University Hospital., Almería., Spain

Objective.

To describe the clinical course of a patient with dermatomyositis refractory to multiple therapeutic lines and to review the available evidence on the use of anifrolumab in dermatomyositis.
Material and Methods

We report the case of a patient diagnosed in 2024 with dermatomyositis according to the 2017 ACR/EULAR classification criteria. Disease activity was assessed longitudinally using the Myositis Disease Activity Assessment Tool (MDAAT). The patient showed refractoriness to multiple off-label therapeutic targets. A targeted literature search was conducted in updated scientific databases to identify published evidence on anifrolumab in dermatomyositis.
Results

A 65-year-old woman presented in 2024 with extensive cutaneous involvement, dysphagia, weight loss and progressive muscle weakness. She was refractory to high-dose glucocorticoids, methotrexate, mycophenolate mofetil and intravenous immunoglobulins. Due to persistent disease activity, off-label treatment with anifrolumab was initiated. From the first infusion, clinical improvement was observed in myalgias, dysphagia and fatigue, with recovery of independence in basic activities of daily living. Prednisone was progressively tapered until complete withdrawal. MDAAT scores demonstrated sustained improvement across all disease domains. Published literature reports isolated cases of refractory dermatomyositis, including juvenile, paraneoplastic and antisynthetase syndrome-associated forms, showing rapid and sustained response to anifrolumab. Ongoing clinical investigation includes a multicenter phase III trial and the JASMINE study evaluating its use in adult dermatomyositis and polymyositis.
Conclusion.

Anifrolumab is a fully human IgG1 kappa monoclonal antibody that blocks type I interferon signaling, a key pathogenic pathway in dermatomyositis. It has demonstrated efficacy in systemic lupus erythematosus and is currently under investigation for other connective tissue diseases. In our patient, type I interferon blockade resulted in clinically meaningful and sustained improvement, consistent with previously published cases. Although these findings are promising, controlled clinical trials are required to establish the efficacy and safety of anifrolumab in dermatomyositis.

P1088

MAJOR ADVERSE CARDIOVASCULAR EVENTS IN PSORIATIC ARTHRITIS TREATED WITH IL-17 INHIBITORS: ROLE OF HYPERURICEMIA AND CARDIOVASCULAR REFERRAL IN A SOUTHERN SPAIN COHORT

J. J. López Carvajal[1], M. M. Muñoz Gómez[1], M. Navidad Fuentes[1]

[1]Rheumatology Department. Torrecárdenas University Hospital., Almería., Spain

Objective(s):

To determine the incidence of major adverse cardiovascular events (MACEs) in patients with psoriatic arthritis treated with interleukin-17 inhibitors in Almería (southern Spain), and to evaluate cardiovascular risk profile, prevalence and management of hyperuricemia, and referral to specialized cardiovascular risk consultation.
Material and Methods:

Retrospective case series of adult patients (≥18 years) with psoriatic arthritis (CASPAR criteria) receiving IL-17 inhibitors with ≥1 year of follow-up. Patients with previous MACEs, other concomitant biologic DMARDs, severe independent comorbidities, or insufficient follow-up were excluded. Collected variables included demographics, IL-17 inhibitor type, classical and non-classical cardiovascular risk factors (including hyperuricemia defined as uric acid >7 mg/dL), inflammatory activity (DAPSA, CRP, ESR), corticosteroid use, referral to cardiovascular risk clinic, and occurrence of MACEs (myocardial infarction, stroke, cardiovascular death). Descriptive analysis was performed.
Results:

Twenty-nine patients were included (69% male), mean age at IL-17 initiation 51.6 years. Treatments were secukinumab (55.2%), ixekizumab (31%), and bimekizumab (13.8%). Baseline disease activity was moderate-high (mean DAPSA 24.5). The most frequent comorbidities were obesity (65.5%), dyslipidemia (41.4%), hypertension (31%), type 2 diabetes (27.6%), and active smoking (24.1%). Hyperuricemia was present in 20.7%, with no patients receiving urate-lowering therapy. No patients were referred to a specialized cardiovascular risk clinic. Inflammatory activity significantly decreased (final mean DAPSA 4.5), with corticosteroid withdrawal in 57.1% of baseline users. One MACE occurred (3.4%) in a patient with multiple cardiovascular risk factors and untreated hyperuricemia.
Conclusion(s):

IL-17 inhibitors showed a low incidence of MACEs and effective inflammatory control in this real-world cohort. However, the high burden of cardiovascular risk factors, untreated hyperuricemia, and absence of cardiovascular referral highlight a clear need for integrated multidisciplinary cardiovascular assessment in psoriatic arthritis, beyond inflammatory disease control.

P1089

IL-33 PLASMA LEVELS ARE ASSOCIATED WITH MUSCLE MASS AND BODY COMPOSITION IN POSTMENOPAUSAL WOMEN

M. M. Soare[1], A. I. Gasparik[1], I. M. Pascanu[1]

[1]George Emil Palade University of Medicine, Pharmacy, Science and Technology, Targu Mures, Romania

Objective: Interleukin-33 (IL-33) is a pleiotropic cytokine released predominantly by stromal cells and has gained increasing attention in osteoporosis research (1). Experimental and clinical studies suggest that IL-33 may exert protective effects on bone and could play a role in bone–muscle crosstalk (1,2). This study aimed to investigate the relationship between IL-33, bone mineral density, and muscle mass in postmenopausal women with and without osteoporosis.

Materials and Methods: This cross-sectional study included 55 postmenopausal women (30 with osteoporosis undergoing treatment and 25 controls; mean age 66.5 ± 7.4 years). Muscle function was assessed using handgrip strength and gait speed. Muscle mass was evaluated by rectus femoris ultrasonography and bioelectrical impedance analysis, with appendicular skeletal muscle mass estimated using a validated predictive equation. Bone mineral density (BMD) was measured by dual-energy X-ray absorptiometry, and fracture risk was assessed using FRAX. Plasma IL-33 concentrations were measured using a sandwich enzyme-linked immunosorbent assay.

Results: Plasma IL-33 levels differed significantly between postmenopausal women with osteoporosis and controls in unadjusted analyses (21.3 [IQR 45.07] vs 7.99 [IQR 14.3], p=0.038); however, this association was attenuated after adjustment for BMI. IL-33 levels showed significant positive correlations with rectus femoris cross-sectional area (rho=.288, p=0.035) and appendicular skeletal muscle mass (rho=.352, p=0.009). No significant correlations between IL-33 levels and BMD were found. In bootstrapped multivariable linear regression models adjusted for age, BMI, and bone mineral density, higher IL-33 levels (β=0.26, p<0.034) were independently associated with greater muscle mass.

Conclusion: In postmenopausal women, higher circulating IL-33 levels were associated with greater skeletal muscle mass, suggesting a potential role in muscle maintenance and bone–muscle crosstalk.

INFLUENCE OF MACS PROTOCOL ISOLATION TRAITS ON NEUTROPHIL ACTIVATION AND NET FORMATION IN SLE

M. Mamus[1], E. Mozgovaya[1], S. Bedina[1], A. Trofimenko[1]

[1]Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky, Volgograd, Russia

Objective: NET formation is a fairly recently discovered mechanism for elimination of large antigen structures. NETs may also participate in SLE pathogenesis as a target or as a priming factor for antinuclear and antinucleosome antibody formation. Accurate assessment of this phenomenon requires the use of a neutrophil isolation method that minimizes cell activation during isolation.

Methods: We analyzed blood samples from healthy individuals and patients with SLE. Neutrophils were isolated from buffy coats using MACS with in-house synthesized magnetic polyacrylamide beads. Either mixture of mouse monoclonal antibodies for negative selection of neutrophils or mouse monoclonal IgG to human CD16b for the positive selection were immobilized on the particles. Viability was assessed by trypan blue exclusion, and activation was assessed using the standard NBT assay. NETs were induced with PMA and visualized by fluorescence microscopy using SYBR green and RPE conjugated anti- myeloperoxidase antibodies.

Results: 28 healthy volunteers were enrolled in efficiency assessment of neutrophil isolation as a control group. Neutrophil fractions positively selected with immobilized anti-CD16b antibodies from control samples were almost coincided with those purified by negative selection in average yield, average purity, and average viability. Mean non-activated cell fraction was somewhat higher in negatively selected neutrophils (98,9 (94,0-100,0)%) than in positively selected ones (89,6 (81,3-97,9)%), but the difference was not significant. Average spontaneous NET production was 7,8 (3,3-12,3)% for positive selection and 5,0 (3,1-6,9)% for negative selection. PMA induced NET frequency was 28,9 (22,0-35,8)% and 39,3 (31,7-46,9)%, respectively. SLE patients were divided in two consecutively composed groups, 27 patients were applied to positive selection, and 12 patients were applied to negative selection. Average spontaneous NET production was 22,1 (14,6-29,6)% and 11,3 (6,2-16,4)%, respectively. PMA induced NET frequency was 40,4 (27,9-52,9)% and 53,5 (38,2-68,8)%, respectively.

Conclusion: Neutrophil fractions isolated by negative selection using magnetic polyacrylamide beads exhibited a significantly lower proportion of cells with signs of activation compared to fractions isolated by positive selection with immobilized anti-CD16b. Both approaches demonstrated high yield, viability, and purity of neutrophils. We evaluated the feasibility of using the developed isolation methods to study NETs ex vivo. Parameters of NET formation were different for neutrophils obtained using the negative and by positive selection with immobilized anti-CD16b antibodies. In healthy controls neutrophils isolated by negative selection were characterized by a slightly lower proportion of spontaneous NET formation and a somewhat higher proportion of cells with PMA-induced NET formation. Both differences were however not significant. This trend was most pronounced in SLE, where we found statistically significant increase in the proportion of cells with induced NETs in SLE compared to controls using negative selection. We believe these differences may be related to the binding of CD16b to its ligand, monoclonal antibodies immobilized on the beads.

P1091

IMPROVING QUALITY OF LIFE WITH APPLICATION OF RADIAL EXTRACORPOREAL SHOCKWAVE THERAPY IN PATIENTS WITH CALCIFIC TENDINITIS OF THE SHOULDER ROTATOR CUFF

M. Manoleva[1], E. Nikolikj Dimitrova[1], V. Koevska[1], B. Mitrevska[1], M. Gocevska[1], C. Gjerakaroska Savevska[1], B. Kalchovska Ivanovska[1], D. Gecevska[1], T. Jugova[1], L. Malinovska Nikolovska[2]

[1]University Clinic for physical medicine and rehabilitation, Faculty of Medicine, Ss. Cyril and Methodius University in Skopje, R. of North Macedonia, Skopje, North Macedonia; [2]Acibadem Sistina Clinical Hospital, Department of pediatric cardiac surgery, Skopje, R. of North Macedonia, Skopje, North Macedonia

Introduction: Most common disorder of the shoulder is calcific tendinitis of the rotator cuff. It is commonly treated with various physical treatment modalities where extracorporeal shockwave therapy (ECTUB) is emerging as an effective new method.
Objective: The main objective of this clinical study is to evaluate the quality of life of ECTUB treatment in patients with calcific tendinitis of the shoulder rotator cuff.
Material and method: The research was a prospective, monocentric clinical study that included 40 patients who received ECTUB and performed shoulder exercises. The efficacy of the treatment was evaluated using the Questionnaire for quality of life in patients with shoulder rotator cuff disease (RC-QOL). Clinical findings were evaluated at the same time in four time points: before starting physical therapy, immediately after the end of the therapy, after the third month and after the sixth month after starting physical therapy.
Results: After the treatment all patients had statistically significantly better results in the RC-QOL.
Conclusion: Extracorporeal shockwave therapy combined with exercises is a safe and non-invasive treatment that improves quality of life in patients with calcifying tendinitis of the shoulder rotator cuff.
Keywords: extracorporeal shockwave therapy, quality of life, calcifying tendinitis of the shoulder rotator cuff

INTEGRATED ANALYSIS OF GENETIC VARIANTS IN BONE METABOLISM GENES AND BIOCHEMICAL MARKERS IN OSTEOPOROSIS

M. Marozik[1], E. Rudenka[2], A. Rudenka[2], O. Samokhovets[3]

[1]Institute of Genetics and Cytology NAS Belarus, Minsk, Belarus; [2]Belarusian State Medical University, Minsk, Belarus; [3]1st Minsk City Hospital, Minsk, Belarus

Biochemical markers of bone metabolism reflect dynamic processes of bone remodeling and may provide earlier and more sensitive indicators of osteoporosis (OP) progression than densitometric measures. Understanding the genetic determinants underlying inter-individual variation in these biomarkers is therefore essential for improving risk stratification and personalized management of OP.

The aim was to identify associations between polymorphic variants and haplotypes in bone-remodeling genes and key biochemical markers in Belarusian patients with OP and to evaluate whether it enhances biologically and clinically relevant signals.
Material and Methods. A case-control cohort of 456 individuals (251 OP, 205 controls) recruited at the 1st Minsk City Hospital was analysed. Targeted sequencing of 68 bone-metabolism genes was performed on DNA from peripheral blood (Illumina). Association testing with biochemical traits used linear regression models; Benjamini-Hochberg correction was applied for multiple testing. Haplotype and multilocus interaction analyses were performed to increase power and reveal combined effects.
Results. Variants and haplotypes in the *VDR* locus showed the strongest biochemical associations: rs731236 displayed a gene-dose effect on serum 25(OH)D (G/G vs A/A: β = +6.7 ng/mL; P = 0.0016, Figure), while rs11568820 and combined haplotypes (notably A-T-G-C) were significantly associated with increase (haplotype A-T-G-C: β=+4.1 ng/mL; P=0.001), suggesting genotype-dependent vitamin D status and response to supplementation. *VDR* rs7975232 C/C and rs2228570 G/G were associated with modest reductions in total serum calcium in OP (P=0.019 and 0.017).

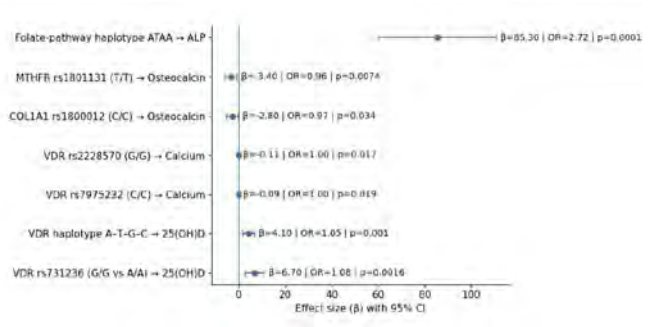

Figure: Forrest plot of revealed genetic associations
COL1A1 rs1800012 C/C and *MTHFR* rs1801131 T/T were linked to lower osteocalcin (P = 0.034 and P = 0.0074). Multilocus folate-pathway haplotypes (e.g., ATAA) associated with markedly increased alkaline phosphatase in OP (difference up to +85.3 U/L vs reference; P < 0.0001), indicating combined genetic influence on bone turnover markers.
Conclusion. Targeted sequencing and integrated haplotype analysis reveal robust, biologically plausible associations. Findings support a model of genotype-dependent vitamin D metabolism and differential biochemical phenotype in OP, with potential implications for genetically informed monitoring and personalized supplementation strategies.

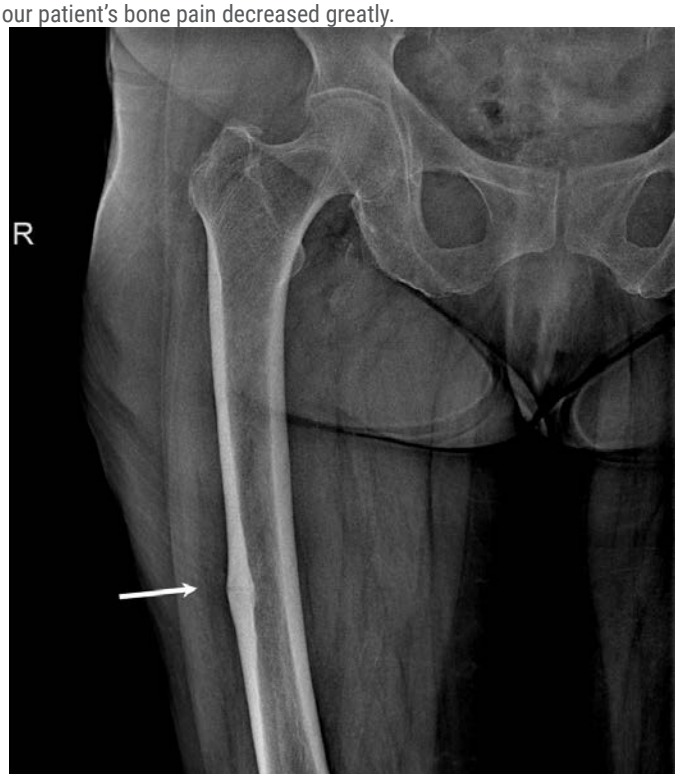
ATYPICAL FEMORAL FRACTURES IN A WOMAN WITH UNTREATED DECOMPENSATED HYPOTHYROIDISM - A CASE REPORT



S. Mazurenko[1], N. Khudyakova[2], M. Mazurenko[1]

[1]Saint Petersburg State University, Russia, Saint Petersburg , Russia; [2]College of Professional Studies – International Center of Professional Studies, Serbia, Belgrade , Serbia

Objective. To present the case of a woman with newly diagnosed hypothyroidism and an atypical femoral fracture who has never received therapy for osteoporosis before the fracture.

Materials and methods. A 86-year-old female patient who had a history of a spontaneous fracture of the left femoral shaft and a Looser zone in the middle of the right femoral shaft

Results. A 86-year-old female patient presented with complaints of pain in her right thigh. X-ray revealed a Looser zone in the lateral cortex in the middle of the right femoral shaft (figure). 6 months earlier, the patient had experienced similar pain in her left thigh, after which she suffered a spontaneous fracture of the left femoral shaft. She underwent internal fixation of fracture with an intramedullary rod. The patient disclosed that she never used glucocorticoids or medications to treat osteoporosis. Laboratory tests showed elevated TSH 25.68 μIU/mL, normal levels of PTH, 25(OH)D, and low levels of serum P1NP and Beta Cross Laps. Hypothyroidism was diagnosed. Therapy with levothyroxine and teriparatide was prescribed. Within 6 weeks of starting teriparatide, our patient's bone pain decreased greatly.

Conclusion. An atypical femoral fracture is an unusual type of fracture that occurs without trauma. This condition usually emerges as a complication of long-term use of antiresorptive therapy for osteoporosis. We presented the case of a woman with newly diagnosed hypothyroidism and an atypical hip fracture who has never received therapy for osteoporosis before the fracture.

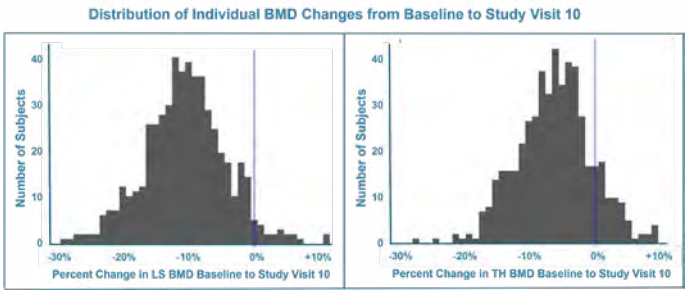
WHAT PROPORTION OF WOMEN EXPERIENCE SIGNIFICANT TRANSMENOPAUSAL BONE LOSS?

M. McClung[1], A. Clark[2]

[1]Oregon Osteoporosis Center, Portland, OR, United States;
[2]Oregon Health & Science University, Portland, OR, United States



The relatively rapid bone loss that occurs during the menopausal transition is an important determinant of the subsequent development of postmenopausal osteoporosis. The Study of Women Across the Nation (SWAN) followed more than 3000 women across the menopausal transition. Reports from SWAN have described the average changes in bone mineral density (BMD) with average losses from 5 years before the final menstrual period (FMP) until 5 years after FMP of 10.6% in the lumbar spine and 9.1% at the femoral neck. Knowing the proportion and characteristics of women who experience significant bone loss during the menopausal transition would aid the development of appropriate strategies to prevent that bone loss in women at high risk for developing osteoporosis.

Objective: To evaluate the distributions of lumbar spine and total hip BMD changes in individual women in SWAN from baseline to Visit 10.

Design: A secondary analysis was conducted using the publicly available SWAN dataset, from baseline through 10 years of annual assessments. The analysis was limited to women undergoing natural menopause without exposure to bone-active drugs (estrogens, osteoporosis medications, tamoxifen, and chemotherapy).

All subjects who had BMD results at baseline and 10 years were evaluated. Menopause status at each visit was categorized as pre-, early peri-, late peri- or post menopause. Percentage change in lumbar spine (LS) and total hip (TH) BMD from baseline to 10 years was calculated. Analyses were conducted in RStudio, version 2024.12.1.

Results: 516 women met inclusion criteria. Mean age was 46.2 years; mean years of menopause 4.5; mean BMI 27.6. Average BMD values at baseline corresponded to T-scores of 0.18 at LS and 0.08 at TH. The average % changes in BMD were 10.4% at LS (almost 1 T-score) and 6.1% at TH. Distributions of individual changes in LS BMD are shown in the Figure. 88% and 72% of women had losses of at least 3% at LS and TH, respectively, while 83% and 57% had losses of 5% or greater. Maximum individual losses exceeded 25% at both the spine and hip.

Conclusion: Almost all women experience significant bone loss during the menopausal transition, and many would benefit from therapy to prevent bone loss and osteoporosis.

COMPARING HYDROTHERAPY AND LAND-BASED EXERCISES ON WALKING PERFORMANCE IN KNEE OSTEOARTHRITIS: A SYSTEMATIC REVIEW OF RANDOMISED CONTROLLED TRIALS

M. Minea[1], D. Oprea[2], L.-E. Stanciu[2], A.-D. Nedelcu[1], B. Georgescu[1], A.-E. Cristea[3], M.-G. Iliescu[3]

[1]Hospital Rehabilitation Unit, Balneal Sanatorium of Techirghiol, Romania. Ovidius University Faculty of Medicine Doctoral School, Constanta, Romania, Constanța, Romania; [2]Hospital Rehabilitation Unit, Balneal Sanatorium of Techirghiol. Department of Medical Rehabilitation, Faculty of Medicine, Ovidius University of Constanța, Constanța, Romania; [3]Hospital Rehabilitation Unit, Balneal Sanatorium of Techirghiol. Ovidius University Faculty of Medicine Doctoral School, Constanța. Department of Medical Rehabilitation, Faculty of Medicine, Ovidius University of Constanța, Constanța, Romania

Objective: This systematic review assessed the impact of aquatic therapy on gait and functional outcomes in knee osteoarthritis (KOA) compared with land-based exercises.

Materials and Methods: Following PRISMA guidelines, electronic databases (PubMed, Scopus, Web of Science, ScienceDirect, SpringerLink, and PEDro) were queried for papers dating from 2015 to 2025, using terms related to KOA, aquatic exercises or hydrotherapy, land-based training, and gait, walking, or functional performance. Randomised controlled trials (RCTs) assessing the effects of aquatic interventions on gait or mobility outcomes such as the 6-minute walking test (6MWT), Time Up and Go (TUG), Five Times Sit to Stand (5TSS) and Stair Climb Test (SCT) or gait kinematics, kinetics or temporo-spatial parameters were searched for inclusion. Studies involving combined treatments, surgical patients or non-human subjects were excluded. Data extraction focused on patients' characteristics, intervention protocols, control groups and walking-related outcomes.

Results: Five RCTs met the inclusion criteria. Both aquatic and land-based programs generated significant within-group improvements, particularly regarding walking distance and 6MWT's speed. However, studies reported no statistically significant differences between groups (1, 2, 3). Kinematic analysis indicated greater increases in knee flexion and range of motion during the early stance phase after hydrotherapy than in the control group (4). Functional mobility outcomes (TUG, 5TSS, SCT) showed significantly better results after 6 weeks of intervention in the study group, whereas the referees (land-based therapy) improved only the 5TSS value (5). Additional observation was the benefits of water walking (2) and dance-based aquatic exercise (3) on functional capacity and gait performance in elderly postmenopausal women with KOA.

Conclusions: Hydrotherapy and land-based exercise are effective treatment options that improve gait in KOA patients, many of whom have comorbid conditions that may restrict other rehabilitation approaches (6).

RELIABILITY OF ULTRASOUND ASSESSMENT OF MEDIAL AND LATERAL MENISCAL EXTRUSION IN SUPINE AND WEIGHT POSITIONS, IN KNEE OSTEOARTHRITIS: A PILOT STUDY

M. Minea[1], G. Nurla[2], A.-E. Minea[3], L. Vlădăreanu[4], D. Oprea[4], E. -V. Ionescu[5], M.-G. Iliescu[5]

[1]Hospital Rehabilitation Unit, Balneal Sanatorium of Techirghiol, Romania. Ovidius University Faculty of Medicine Doctoral School, Constanta, Romania, Constanța, Romania; [2]Hospital Rehabilitation Unit, Balneal Sanatorium of Techirghiol, Romania, Techirghiol, Romania; [3]"Carol Davila" University of Medicine and Pharmacy, Bucharest, Bucharest, Romania; [4]Hospital Rehabilitation Unit, Balneal Sanatorium of Techirghiol, Romania. Department of Medical Rehabilitation, Faculty of Medicine, Ovidius University of Constanța, Constanța, Romania; [5]Hospital Rehabilitation Unit, Balneal Sanatorium of Techirghiol. Ovidius University Faculty of Medicine Doctoral School, Constanța. Department of Medical Rehabilitation, Faculty of Medicine, Ovidius University of Constanța, Constanța, Romania

Objective: This pilot study aimed to assess the validity of musculoskeletal ultrasound (MSUS) for evaluating meniscal extrusion in knee osteoarthritis (KOA), a common disease with a significant impact on quality of life, by quantifying inter- and intra-observer reliability in supine and weight-bearing conditions, given that previous studies have mainly focused on non–weight-bearing assessments (1,2).

Materials and Methods: Twenty patients with KOA (forty knees) underwent MSUS assessment of medial and lateral meniscal extrusion in supine, bilateral, and single-leg standing positions. Two independent evaluators with similar experience performed two measurements 48 hours apart. Statistical analysis was performed using SPSS Statistics 26 software. Inter- and intra-rater reliability were assessed using intraclass correlation coefficients (ICC, two-way random-effects model, absolute agreement). Measurement precision was quantified using the standard error of measurement (SEM) and the minimal detectable change at the 95% confidence level (MDC95). Changes in extrusion from supine to single-leg standing (Δ extrusion) were compared with MDC95 to identify true loading-related changes exceeding measurement error.

Results: Inter-rater reliability was strong to very strong across all positions and both menisci, with ICC values ranging from 0.857 to 0.954. SEM values ranged from 0.176 to 0.346 mm, yielding MDC95 values of 0.49-0.96 mm. The increase in meniscal extrusion from supine to single-leg standing exceeded the MDC95 in 27 (67.5%) knees for the medial meniscus and 19 (47.5%) knees for the lateral meniscus, indicating true loading-related changes in a substantial proportion of cases. Intra-rater reliability for both evaluators was similarly high (ICC range: 0.837–0.962), with higher MDC95 values observed in single-leg standing and for the lateral meniscus.

Conclusions: Ultrasound assessment of medial and lateral meniscal extrusion demonstrates a high inter- and intra-rater reliability and sufficient precision to detect true, load-dependent structural changes in KOA. Weight-bearing ultrasound, particularly in single-leg standing, is a reliable and sensitive method for evaluating meniscal extrusion in both clinical and research settings.

HUMERUS STRENGTH IN WHITE RATS AFTER IMPLANTATION OF HYDROXYLAPATITE SATURATED WITH ZINC IN VARIOUS CONCENTRATIONS INTO THE TIBIA

V. Zaychenko[1], V. Luzin[1], V. Kamlov[1], S. Kovalenko[1], M. Miroshnichenko[1]

[1]FSBEI HI ST. LUKA LSMU of MOH of Russia; Human anatomy department, Lugansk, Russia

Objective of the study is to test the strength of the humerus in rats after implantation of hydroxylapatite material OC-015 saturated with zinc in concentrations of 0.20%, 0.50% and 1.00% into the tibia.
Material and methods. 252 white male rats weighing 135-145 g were used, divided into: group 1 – control, group 2 – rats with tibial defect, in group 3 the defect was filled with OC-015 without zinc. In groups 4-6, the defect was filled with OC-015 saturated with 0.20%, 0.50% and 1.00% zinc. The strength of the humerus was determined when bending at a loading rate of 0.25 mm/min before fracture.
Results. The minimum work of destruction of the humerus (MWD) from 7 to 180 days after surgery was lower in group 2, than in group 1 by 7.22%-14.82%. In group 3 the MWD exceeded the values of group 2 by 7.12% and 9.26%. In group 4 the MWD was higher than the values of group 3 on day 7 by 25.74%. In group 5, the modulus of elasticity was lower than in group 3 from days 15 to 90 by 22.69%, 18.58%, 16.39% and 12.12%. The MWD exceeded the indicators of group 3 from 7 to 90 days by 22.37%, 5.60%, 17.53%, 11.69%, 19.14% and 7.31%. In group 6 the MWD exceeded the values of group 3 from 7 to 180 days by 30.14%, 8.41%, 26.23%, 12.30%, 22.23% and 9.34%.
Conclusion. The implantation of OC-015 into the tibia is accompanied by a decrease in the strength of the humerus; saturation of the OC-015 material with zinc smooths out the negative effect. The optimal zinc concentration is 1.00%.

P1098

HALLUX RIGIDUS IN ATHLETES: BIOMECHANICAL IMPLICATIONS AND THE ROLE OF IMAGING

M. Montatore[1], M. Balbino[1], F. Masino[1], G. Muscatella[1], G. Guglielmi[1]

[1]Department of Clinical and Experimental Medicine, Foggia University School of Medicine, Foggia, Italy

Objective:
To analyze the functional limitations and biomechanical implications of hallux rigidus in athletes, with particular focus on dancers and sports practitioners, for whom first metatarsophalangeal joint mobility is critical. The role of imaging in supporting clinical management and monitoring disease progression is also evaluated.

Material and Methods:
Hallux rigidus, or osteoarthritis of the first metatarsophalangeal joint, leads to progressive reduction of range of motion and pain, impairing athletic performance and increasing compensatory injury risk. Imaging evaluation included conventional radiography to assess joint space narrowing, osteophyte formation, and bone deformities (Fig 1). MRI, both in elective and follow-up settings, was used to detect early inflammatory changes and soft tissue alterations surrounding the joint. Functional limitations and biomechanical impact were correlated with imaging findings.
Results:
Radiographic and MRI assessment allowed precise grading of disease severity and identification of features predictive of progression. Early recognition of hallux rigidus, combined with integrated functional evaluation, informed decisions on conservative versus surgical management and guided adaptation of training programs. In athletes, particularly dancers, imaging findings were essential to prevent secondary biomechanical complications, optimize joint function, and minimize disability risk.
Conclusion:
Management of hallux rigidus in athletes requires a multidisciplinary approach in which imaging plays a central role. Accurate interpretation of radiographic and MRI findings, integrated with clinical and functional assessment, enables tailored treatment strategies, preservation of long-term joint function, and reduction of impact on athletic careers.
Limitations:
The study is limited by its observational design and lack of long-term follow-up. Functional assessment was not quantitatively standardized in all athletes, and imaging results may vary according to technique and operator, potentially affecting generalizability of the findings.

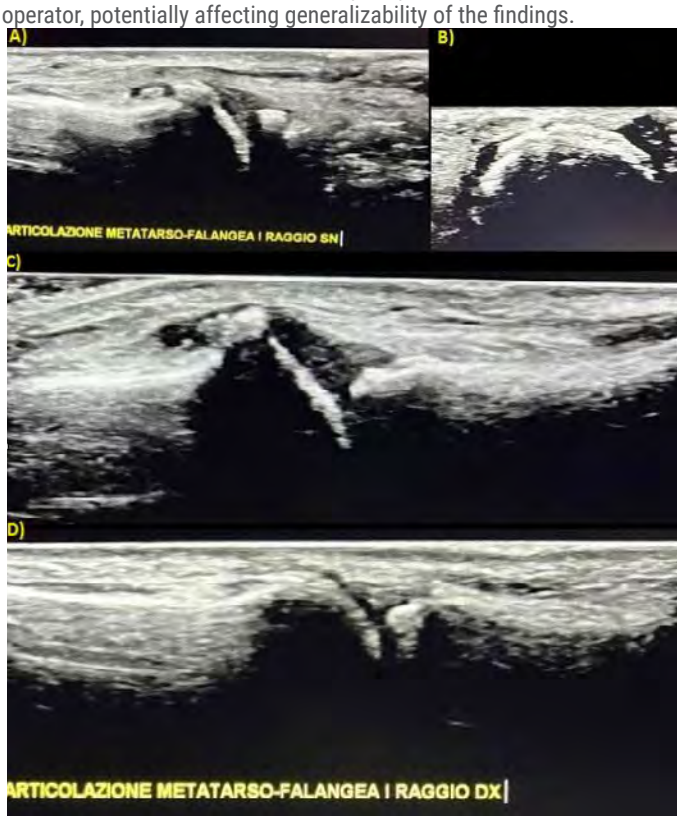

Fig. 1 Ultrasound images of the left first metatarsophalangeal joint (pathologic side):

a) Longitudinal scan showing joint space narrowing, capsular thickening, and osteophytic formation;

b) Transverse scan highlighting osteophytes and signs of periarticular inflammation;
c) Second longitudinal scan demonstrating joint effusion and synovial tissue alterations;
d) Comparative image of the right side (healthy), showing normal joint morphology and preserved joint space.

P1099

PERTHES DISEASE AND SPORTS ACTIVITY: BIOMECHANICAL IMPLICATIONS AND THE ROLE OF IMAGING IN FUNCTIONAL HIP ASSESSMENT

M. Montatore[1], F. Masino[1], R. Gifuni[1], M. Balbino[1], G. Muscatella[1], G. Guglielmi[1]

[1]Department of Clinical and Experimental Medicine, Foggia University School of Medicine, Foggia, Italy

Objective:

To evaluate functional limitations and biomechanical risks in athletes with Perthes disease, emphasizing the predictive role of imaging in guiding clinical management and preserving long-term hip function.

Material and Methods:

Perthes disease, a pediatric avascular necrosis of the femoral head, causes progressive morphological changes that increase susceptibility to deformity and early osteoarthritis. High-impact or unilateral-loading sports (e.g., football, gymnastics) may compromise femoral head remodeling, while low-impact activities (e.g., swimming, cycling) are generally recommended. Radiography and CT assessed femoral head shape, joint congruence, and structural integrity (Fig 1-3). MRI allowed early detection of cartilage lesions, subchondral sclerosis, and subtle soft tissue changes. Imaging findings were integrated with functional evaluation to guide activity modification and anticipate biomechanical complications.

Results:

Multimodal imaging enabled precise characterization of femoral head morphology and early degenerative changes. Patients with early structural alterations were identified for targeted interventions, including training adjustments and rehabilitation. Radiography and CT provided robust bone assessment, while MRI detected predictive markers of unfavorable outcomes, supporting proactive management. Integration with functional evaluation allowed optimization of load, reduction of compensatory stress, and mitigation of long-term hip degeneration.

Conclusion:

Management of Perthes disease in athletes requires a multidisciplinary, imaging-informed approach. Radiologists play a key role in detecting early structural and soft tissue changes predictive of adverse progression, enabling clinicians to define sport-specific activity limits. Accurate interpretation of imaging, contextualized with patient activity, facilitates long-term joint preservation, reduces the risk of degenerative sequelae, and optimizes functional outcomes into adulthood.

Limitations:

Observational design, variable follow-up, and non-standardized functional assessment limit generalizability. Imaging interpretation may vary with operator experience, and results may not extend to older or non-pediatric populations.

Fig. 1.3D Volume Rendering of the pelvis: The left hip demonstrates femoral head flattening and subtle irregularity of the acetabular contour, consistent with sequelae of Perthes disease. The contralateral hip appears normal.

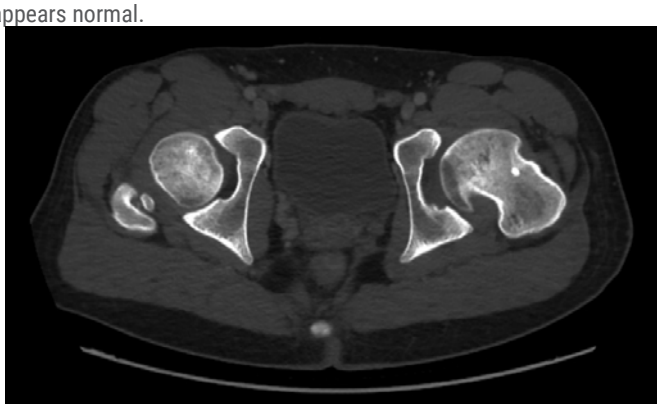

Fig. 2.Axial CT with bone window: The left femoral head shows areas of subchondral sclerosis, reduced sphericity, and early osteophyte formation. Joint space narrowing is more pronounced compared to the right, unaffected hip.

Fig. 3.Coronal CT reconstruction: Morphological assessment highlights lateral and superior flattening of the left femoral head with mild acetabular incongruence. The right hip maintains normal contour and joint congruence, providing an internal control.

P1100

TENNIS ELBOW AND ELBOW KINEMATICS IN TENNIS: COMPARATIVE STUDY WITH BIOMECHANICAL ANALYSIS AND RADIOLOGICAL CORRELATION

M. Montatore[1,2], F. Antonelli[2], R. Gifuni[1], F. Masino[1], G. Guglielmi[1]

[1]Department of Clinical and Experimental Medicine, Foggia University School of Medicine, Foggia, Italy; [2]Department of Electrical and Information Engineering, Polytechnic University of Bari,, Bari, Italy

Objective: To investigate elbow flexion-extension kinematics during the tennis serve in professional and amateur players, identifying patterns associated with increased risk of lateral epicondylitis (1-5). We hypothesize that irregular, low-fluidity movements correlate with overuse injury susceptibility, with radiological correlates in tendon and joint structures.

Material and Methods: Fifty tennis players were divided into four groups: healthy professionals, healthy amateurs, professionals with epicondylitis, and amateurs with epicondylitis. Pathology was confirmed by multimodal imaging, including ultrasound, CT, and MRI. Elbow motion during the serve was captured using OpenCap, a markerless motion capture system. Kinematic data were analyzed with OpenSim and MATLAB, focusing on the jerk index as a quantitative measure of movement smoothness (6-7). Imaging findings were correlated with kinematics to assess structural-functional relationships.

Results: Significant differences in elbow kinematics were observed between professionals and amateurs. Players with epicondylitis showed higher jerk values, indicating abrupt, low-fluidity motion. Flexion-extension velocities exceeding critical thresholds were associated with increased injury incidence. A significant correlation ($p < 0.05$) was found between irregular motion and imaging evidence of tendon overload or early degenerative changes. Subtle biomechanical deviations thus appear predictive of musculoskeletal stress in tennis players (Fig. 1-5).

Conclusion: Markerless motion capture identifies kinematic signatures linked to lateral epicondylitis, with radiological support. Integrating biomechanical analysis and imaging allows early detection of tendon overload, personalized training adaptation, and injury prevention in both elite and recreational athletes (8-10).

Limitations: The sample size limits generalizability. Markerless systems, while practical, have reduced precision for complex joint kinematics and are sensitive to environmental conditions. Long-term imaging follow-up is constrained by ethical and logistical considerations. Alternative systems (inertial sensors or marker-based capture) offer higher accuracy but reduced practicality in dynamic sports settings. Future larger-scale, longitudinal studies are needed to validate predictive kinematic markers.

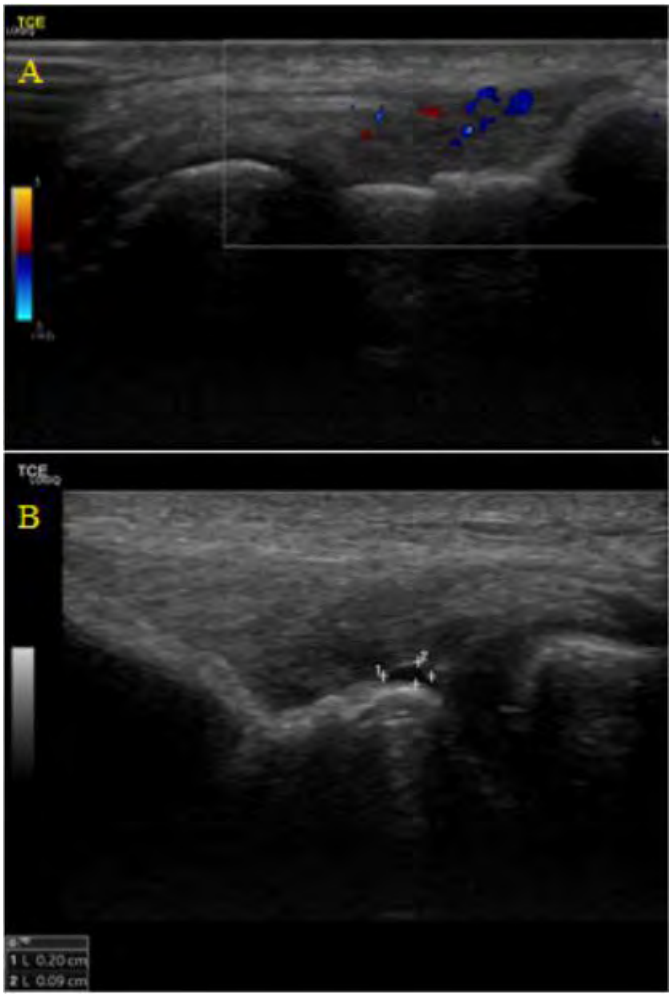

Fig. 1: *Ultrasound images of a patient with lateral epicondylitis. At the lateral epicondyle, the common extensor tendon appears thickened and hypoechoic with heterogeneous texture. Power Doppler shows increased vascularity (A), and tiny calcifications are present. A small anechoic defect (2 × 1 mm) is visible within the deep tendon fibers (B), consistent with a partial-thickness tear.*

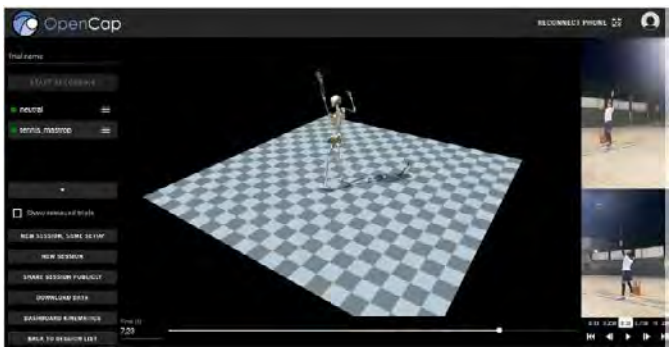

Fig. 2: *OpenCap Data Acquisition Interface After Camera Calibration Once the camera calibration is complete, OpenCap transitions to the data acquisition phase, displaying a real-time preview of the subject's movements. The interface is user-friendly, allowing the operator to monitor camera alignment and ensure optimal positioning of the subject. Key features include:*
1. Real-Time Tracking: Live feedback on the subject's position ensures proper alignment during capture.
2. Positioning Guidelines: Visual cues assist in placing the subject within the camera's view.
3. Motion Capture Monitoring: The system tracks and highlights body parts, ensuring no key movements are missed.
4. Data Visualization: Graphical overlays show the body's movement and joint angles in real time.
5. Calibration Confirmation: The system checks camera alignment and flags errors for correction.
6. Data Storage: Collected data is saved for further analysis in compatible formats.
The interface is designed for efficient and accurate motion capture, streamlining the process and enhancing biomechanical analysis.

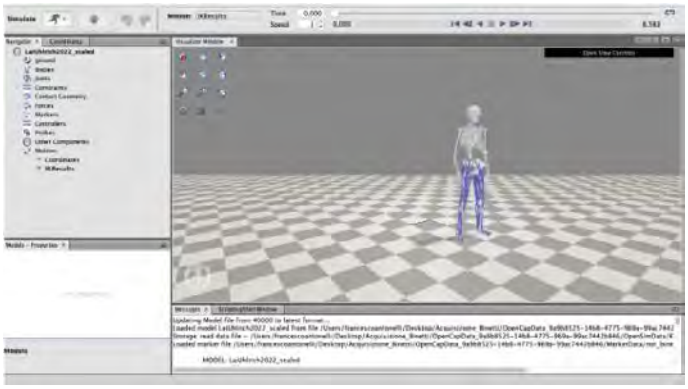

Fig.3: *OpenSim interface with the scaled model obtained from OpenCap, ready for kinematic* analysis.

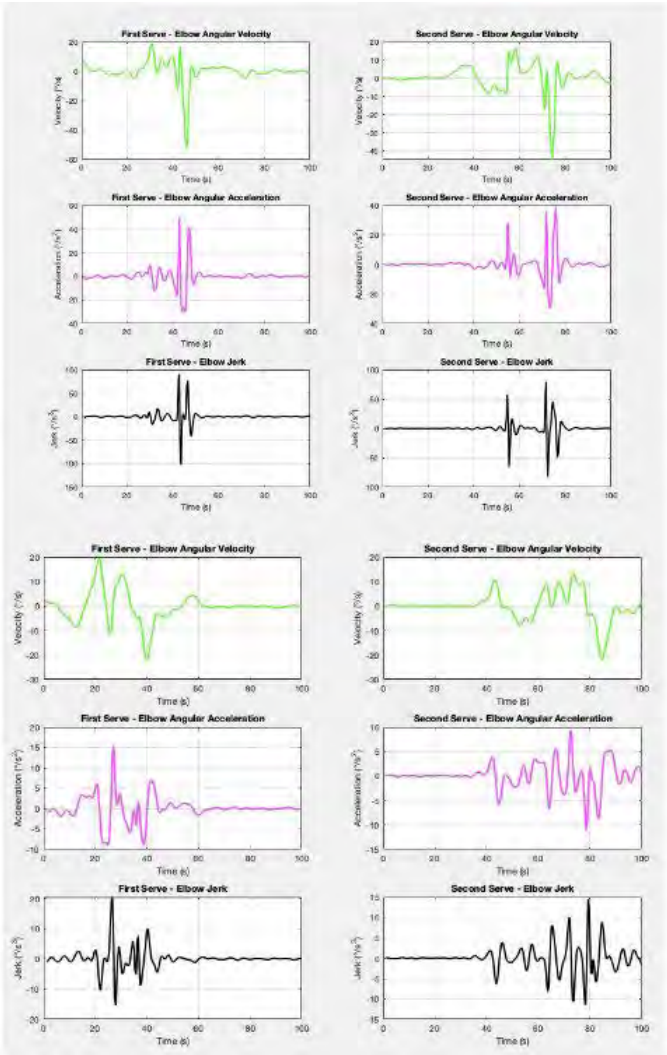

Fig. 4: *a) e b) Comparison of movement fluidity between professional and amateur tennis* players using jerk analysis. Lower jerk values indicate smoother, more continuous movements in professionals.

BONE HEALTH ASSESSMENT IN PATIENTS WITH PROSTATE CANCER: ROLE OF REMS TECHNOLOGY

M. Montatore[1,2], F. Antonelli[2], R. Guglielmi[3], M. G. Capasso[4], A. Issac[5], F. Masino[1], G. Muscatella[1], G. Guglielmi[1]

[1]Department of Clinical and Experimental Medicine, Foggia University School of Medicine, Foggia, Italy; [2]Department of Electrical and Information Engineering, Polytechnic University of Bari,, Bari, Italy; [3]Radiology Unit, Mount Sinai Hospital, 600 University Ave, Toronto, Toronto, Canada; [4]Radiology Unit, "Dimiccoli" Hospital, Viale Ippocrate 15, Barletta, Italy; [5]School of Biomedical Engineering and Imaging Sciences, King's College London, London, United Kingdom

Objective:
Prostate cancer (PCa) and its treatments, particularly androgen deprivation therapy (ADT), accelerate bone loss and increase fracture risk. Early detection of skeletal fragility is crucial. This study evaluates femoral neck bone mineral density (BMD) using Radiofrequency Echographic Multi-Spectrometry (REMS), a non-ionizing, ultrasound-based technique validated for osteoporosis diagnosis and fracture risk prediction (1-6).

Material and Methods:
Fifty-one Caucasian men with PCa and an age-, BMI-, and ethnicity-matched healthy control group underwent REMS scans of the femoral neck to obtain BMD, T- and Z-scores. Statistical differences were evaluated using t-tests. Literature-based evidence was integrated to contextualize REMS findings regarding ADT exposure, fracture risk, and comparison with DXA outcomes.

Results:
Groups were comparable for age (73.5 ± 7.3 vs. 73.4 ± 7.2 years) and BMI (25.3 ± 2.9 vs. 25.3 ± 3.1 kg/m²). PCa patients showed significantly lower femoral neck BMD, T- and Z-scores than controls (BMD reduction: -3.4%, $p < 0.05$). REMS identified early bone deterioration not always detected by DXA, demonstrating high reproducibility and precision. These results corroborate ADT-induced skeletal fragility and suggest REMS as a sensitive tool for fracture risk prediction (7-8) (Table 1).

Conclusion:
REMS enables early detection of bone loss in PCa patients, supporting personalized preventive strategies and monitoring, particularly for those receiving ADT (Fig. 1). Its non-ionizing nature, bedside applicability, and validated predictive accuracy make REMS a valuable addition to routine skeletal assessment, potentially improving long-term outcomes and reducing fracture incidence (9-10).

Limitations:
The study is limited by sample size and single-center design, which may affect generalizability. REMS is operator-dependent, and while reproducibility is high, standardization of scanning technique is crucial. Longitudinal fracture outcome data were not available, and future multicenter, prospective studies are needed to confirm predictive value and cost-effectiveness compared with DXA in PCa populations.

Group	Measurement site	BMI	BMD (g/cm²)	T-score	Z-score
Prostate Cancer	Lumbar Spine	25.6 ± 2.9	0.885 ± 0.08	-1.9 ± 0.8	-0.7 ± 0.7
	Femoral Neck	25.3 ± 2.9	0.691 ± 0.08	-1.8 ± 0.7	-0.7 ± 0.6
Healthy Control	Lumbar Spine	25.7 ± 2.7	0.945 ± 0.11	-1.3 ± 1.0	-0.2 ± 0.9
	Femoral Neck	25.3 ± 3.1	0.715 ± 0.1	-1.5 ± 0.7	-0.2 ± 0.9

Table 1.*Comparison of BMI, Bone Mineral Density (BMD), T-score, and Z-score between Prostate Cancer Group and Healthy Control Group: there is the summarize the BMI, BMD, T-score, and Z-score measurements at the lumbar spine and femoral neck in two groups: PCa patients undergoing ADT and healthy controls. The PCa group shows significantly lower BMD values at both measurement sites compared to the healthy control group, with a more pronounced decrease observed in the femoral neck.*
Additionally, the T-scores for both the lumbar spine and femoral neck in the PCa group indicate lower bone mineral density compared to the average young adult population, reflecting the osteoporotic effects of ADT. Z-scores show that the PCa group has reduced bone density relative to age-matched controls. These differences highlight the impact of ADT on bone health in PCa patients.

Figure 1 .*Acquisition method: REMS technology assesses bone health using a simple ultrasound scan of the spine and femur. The probe is placed on the abdomen to scan the lumbar vertebrae (L1-L4) (A) or on the hip to scan the femoral neck (B). The scans are performed using a dedicated device (EchoStation, Echolight Spa, Lecce, Italy) with a 3.5 MHz convex transducer. For the lumbar spine, the probe is placed in a trans-abdominal position, with each vertebra scan taking 20 seconds, totaling 80 seconds for the entire L1-L4 region. For the femur, the probe is aligned with the femoral head, neck, and trochanter, and the scan lasts 40 seconds.*
After scanning, the data is processed automatically to analyze the bone structure and compare it to reference models based on gender, age, site, and BMI, providing a patient-specific bone health profile (Figures used came from the article: Gifuni R, Montatore M, Et al. Radiofrequency Echographic Multi-Spectrometry in the Diagnosis of Metabolic Bone Disease. Semin Musculoskelet Radiol. 2024 Oct;28(5):547-556. doi: 10.1055/s-0044-1788885).

CASE REPORT OF AN ISOLATED STERNAL FRACTURE AFTER LOW-ENERGY TRAUMA IN A PATIENT

M. Muftić[1], F. Muftić[2], S. Babić[3], M. Zonić[4], R. Alimanović[5]

[1]SSST Sarajevo Medical Faculty, Sarajevo, Bosnia & Herzegovina; [2]Private clinic for Physical Medicine and rehabilitation, Sarajevo, Bosnia & Herzegovina; [3]Veleučilište L. Ružička Vukovar, Vukovar, Croatia; [4]University Clinical Center Tuzla, Tuzla, Bosnia & Herzegovina; [5]University Clinical Center Sarajevo, Sarajevo, Bosnia & Herzegovina

Objectives: The aim of this paper is to present a case of an isolated sternal fracture following minor trauma, with an emphasis on the diagnostic approach and therapeutic modalities.
Material and Methods: A 60-year-old female patient, a pharmacist by profession, experienced sudden severe pain in the sternal region while entering the water prior to swimming. She went to the emergency department due to intense chest pain that worsened with breathing. A chest X-ray and electrocardiogram (ECG) were performed and showed no pathological abnormalities. She was referred to the Department of Thoracic Surgery, where a chest CT scan revealed a fracture of the sternal body. Subsequent examination performed by a physiatrist revealed severe pain on gentle palpation of the sternal region, with exacerbation of pain during both inspiration and expiration. The examination also noted spinal deformities in the form of kyphoscoliosis and an asthenic body constitution, which prompted referral for bone densitometry. Bone densitometry results revealed a T-score of −3.9 in the lumbar spine and −3.0 in the hip, which, together with the sternal fracture, indicated severe osteoporosis. The patient was administered pharmacological therapy for osteoporosis, including subcutaneous denosumab and vitamin D supplementation (4,000 IU). In addition, the patient was enrolled in a physical therapy program, consisting of cryomassage of the painful area, magnetotherapy, laser therapy, and treatment with polarized light.
Results
After 10 days of physical therapy, combined with pharmacological treatment for osteoporosis, the patient reported a significant reduction in sternal pain, with no pain during respiration. Tenderness over the sternal region was minimal on palpation. A follow-up CT scan of the sternum showed findings consistent with a healed fracture, indicating successful bone consolidation.

Conclusion
In cases of low-energy trauma with isolated fractures, after the physical examination of a patient, bone densitometry should be considered to detect osteoporosis. Early initiation of physical therapy is essential to optimize pain control, preserve mobility, and prevent further functional decline.

ESTIMATED MRI-BASED MUSCLE COMPOSITION FROM HIP DXA SCANS IS RELATED TO PHYSICAL ABILITY AND FALL RISK

M. Mundt[1], A. K. Gebre[1], A. Maqsood[1], J. T. Schousboe[2], W. D. Leslie[3], N. Harvey[4], J. R. Lewis[1], M. Sim[1]

[1]Edith Cowan University, Perth, Australia; [2]University of Minnesota, Minneapolis, United States; [3]University of Manitoba, Winnipeg, Canada; [4]University of Southampton, Southampton, United Kingdom

Objective Magnetic Resonance Imaging (MRI)-derived measures of muscle composition including fat free muscle volume (FFMV) and muscle fat infiltration (MFI) may improve fall risk prediction but are rarely used due to high cost. Leveraging routinely captured hip Dual-Energy X-Ray Absorptiometry (DXA) images and machine learning (ML) models we sought to estimate the FFMV and MFI of the thigh muscle measured by MRI and explore associations with physical ability and fall risk in the UK Biobank participants.
Material and Methods A dataset of 34,637 samples containing DXA scans of the right hip from the UK Biobank Imaging Study were used to train and evaluate a Convolutional Neural Network (CNN) to estimate thigh FFMV and MFI measured by MRI. The dataset was split into training, validation, and test set in a five-fold cross-validation. For both MRI- and ML-derived measures, age- and sex-adjusted logistic regression models were used to determine the association with ground truth and ML-derived muscle composition values with weak hand grip strength defined by the European Working Group on Sarcopenia in Older People and self-reported walking pace adjusted by age and sex. Similarly, Cox Proportional-Hazards were used to assess the relationship between ground truth and ML-derived muscle composition values and incident falls.
Results FFMV and MFI were predicted with correlations of r > 0.7 and mean absolute percentage errors of 7.5% and 12.4%, respectively. For each one–standard deviation decrease in FFMV and increase in MFI, the odds of weak grip strength increased by approximately 60% and 30%, whereas only higher MFI was associated with slow walking pace. Similarly, both measures were associated with a higher risk of incident falls (Table 1). ML-derived phenotypes demonstrated similar odds and hazard ratios to traditional MRI measures.
Conclusion Machine learning-derived muscle composition measures estimated from hip DXA scans can be used to estimate thigh muscle quality to identify people with an increased risk for functional decline and falls during routine osteoporosis screening.
Acknowledgments This work has been funded by the Raine Medical Research Foundation (RPG045-2025). The salary of JRL and MM was supported by the Australian Heart Foundation Future Leader Fellowship (107323).

Table 1 Cross-sectional association between muscle composition adjusted by age and sex and odds (OR 95%CI) for weak grip strength, slow walking pace, and hazard ratios (HR 95%CI) for incident falls per standard deviation increase and binary exposure.

Outcome		OR (95%CI) Per SD increase
Low grip strength	Prevalence (%)	3132 (9.2)
	FFMV	**0.37 (0.34, 0.40)**
	MFI	**1.30 (1.26, 1.35)**
	ML-FFMV	**0.41 (0.38, 0.45)**
	ML-MFI	**1.33 (1.28, 1.39)**
Slow walking pace	Prevalence (%)	1482 (4.3)
	FFMV	0.91 (0.82, 1.00)
	MFI	**2.20 (2.11, 2.31)**
	ML-FFMV	1.07 (0.95, 1.20)
	ML-MFI	**2.19 (2.09, 2.30)**
		HR (95%CI) Per SD increase
Falls	Incidence (%)	754 (2.3)
	FFMV	0.89 (0.77, 1.05)
	MFI	**1.13 (1.06, 1.22)**
	ML-FFMV	**0.81 (0.69, 0.96)**
	ML-MFI	**1.14 (1.06, 1.23)**

Fat Free Muscle Volume (FFMV) 1 SD = 2.53 L;
Machine Learning FFMV (ML-FFMV) 1 SD = 2.36 L;
Muscle Fat Infiltration (MFI) 1 SD = 1.85%;
Machine Learning MFI (ML-MFI) 1 SD = 1.37%;
Low grip strength <16kg for females, <27kg for males;
Slow walking pace self-reported "slow pace"

SIMULTANEOUS BILATERAL ATYPICAL FEMORAL FRACTURE FOLLOWING OSTEOPOROSIS TREATMENT WITH DENOSUMAB

M. Munhoz Braz[1], D. Belchior Raimundo[1], S. Falcão[1,2], N. Pina Gonçalves[1], L. Gago[1], F. Araújo[1]

[1]Hospital Beatriz Ângelo - ULS Loures-Odivelas, Lisboa, Portugal; [2]Nova Medical School, Faculdade de Ciências Médicas, Lisboa, Portugal, Lisboa, Portugal

INTRODUCTION: Antiresorptive therapies such as denosumab or bisphosphonates (BPs) reduce the risk of vertebral, non-vertebral and hip fractures, which are major causes of mortality, disability and economic burden.

However, concerns have been raised about rare but potentially severe adverse events such as atypical femoral fractures (AFFs). Some authors report an estimated incidence of 0.8 per 10,000 patient-years of AFFs in patients under denosumab.

CASE REPORT: We present the case of a 67-year-old woman with a medical history of left hip replacement surgery due to osteoarthritis, dyslipidemia, and nephrolithiasis. She had a relevant family history of osteoporosis in both parents and her son was diagnosed with a mild phenotype of osteogenesis imperfecta.

She was referred to our osteoporosis clinic after a 5-year course of IV zoledronic acid (5mg/year) due to vertebral fragility fractures (L1 and L2). Despite bone mineral density (BMD) improvement and no recurrence of fractures, she maintained vertebral osteoporosis and was hence started on denosumab 60mg every 6 months in 2022.

In January 2025 she developed an ill-defined bilateral thigh pain, without reported trauma, with progressive functional impairment requiring the use of a walking aid.

Bilateral hip radiographs, computed tomography, and bone scintigraphy were obtained, confirming bilateral incomplete AFFs (Figure 1). Denosumab was discontinued and a conservative treatment approach with teriparatide was attempted. However, patient ended up needing bilateral fracture fixation.

DISCUSSION: To the best of our knowledge, this is the third reported case of simultaneous bilateral AFF in a patient treated with denosumab. This patient fulfills all criteria (4 major and 6 minor) for AFF established by the 2010 ASBMR Task Force.

The clinical features of the patient described are highly consistent with those reported in the literature. In the two previously reported cases of bilateral AFFs, both patients were women of similar age and had undergone long-term bisphosphonate therapy, such as our patient. One of them was describe with symptomatic recurrent bilateral AFFs. This patient received 18 months of teriparatide to promote remodeling after the first episode of fractures, but experienced recurrent fractures six months after starting denosumab. The remaining reported cases of unilateral AFFs also share key features with our case, including female sex, advanced age, long-standing osteoporosis and previous bisphosphonate use.

While the occurrence of this rare type of fracture does not provide conclusive evidence of a causal relationship between denosumab and AFFs, it seems to be clear that the risk of AFF is higher in patients with prior bisphosphonates use. More research is needed to improve understanding about AFF risk and defining appropriate screening strategies.

CONCLUSIONS: AFFs are a rare adverse event and only a few cases have been reported with the use of denosumab. However, we must keep in mind that prescribing denosumab to a patient previously treated with bisphosphonates may increase such risk.

We emphasize previous guidance which states that the screening of radiographs of femurs should be considered in such cases where the patient has received treatment with multiple antiresorptive drugs.

P1105

EARLY ADULTHOOD BONE MINERAL DENSITY FOLLOWING ATTENDENCE AT SPORTS COMPARED WITH CONVENTIONAL SCHOOLS

M. N. Händel[1], A. K. Pedersen[1], B. L. Heitmann[2], B. Abrahamsen[3], N. Wedderkopp[4]

[1]Research Unit OPEN, Department of Clinical Research, University of Southern Denmark, Odense, Denmark; [2]Research Unit for Diet and Health, Parker Institute, Bispebjerg and Frederiksberg Hospital, Frederiksberg, Denmark; [3]Department of Medicine, Holbæk Hospital, Holbæk, Denmark; [4]Research Unit of Paediatrics, Department of Clinical Research, Faculty of Health Sciences, University of Southern Denmark, Odense, Denmark

Objectives: to evaluate long-term effect of attending sports compared to conventional schools on attained bone mineral density (BMD) in early adulthood.

Material and Methods: In 2008, Svendborg municipality converted 6 primary public schools to be sports schools, while 4 remained conventional schools. All children who went to 0 to 6th grade in one of the involved schools were invited to participate in the study (age 6 to 13 years). More schools joined the sport school program over the study period, as 3 additional schools were included in 2013. The study covers up to 10 comprehensive clinical examinations over a 15-year period, with key data collection periods in 2008 (baseline), 2009, 2010, 2012, 2015 and 2022-2024. The study design is a natural experiment comparing individuals who went to the sports schools with individuals attending the conventional schools using targeted maximum likelihood estimation (TMLE). The treatment model was based on a random forest and included sex, class, school, distance to school, maternal education, and height and the Q-model was a mixed effect model including sex, maternal education and the random slope of the given person. Outcome were Dual-energy X-ray Absorptiometry (DXA) measured BMD at age 18-25 years (total, body, spine and hip). The analysis was conducted in R.

Results: The sample comprised of 2162 individuals. TMLE revealed no difference in the average treatment effect on total body BMD (-0.005 g/cm^2 (95% CI: -0.006; -0.005) between individuals from sports schools when compared to individuals from conventional schools at age 18-25 years. In spine and hip, the average treatment effects on BMD were 0.023 g/cm^2 (95% CI: 0.021; 0.024) and 0.027 g/cm^2 (95% CI: 0.025; 0.029) higher in the individuals from sports schools, which is equivalent to clinical z-scores of 0.23 and 0.25, respectively.

Conclusion: When estimating the effect of attending sports school compared to conventional schools, there were no clinically relevant differences at age 18-25 years on attained total body BMD. The attained BMD at spine and hip in this study population represents an approximately 10–15% relative osteoporotic fracture risk reduction, assuming risk is BMD-mediated.

OSTEOPOROSIS BURDEN AND PREDICTIVE FACTORS IN PRIMARY BILIARY CHOLANGITIS: INSIGHTS FROM A PORTUGUESE COHORT

M. Natal[1], M. J. Almeida[2], G. Terroso[1], B. Fernandes Esteves[1], M. Oliveira[3], L. Costa[1]

[1]Rheumatology Department, Unidade Local de Saúde de São João, Porto, Portugal; [2]Gastroenterology Department, Unidade Local de Saúde de São João, Porto, Portugal; [3]Rheumatology Department, Hospital do Divino Espírito Santo, Ponta Delgada, Portugal

OBJECTIVES: To assess osteoporosis (OP) prevalence in a Portuguese primary biliary cholangitis (PBC) cohort and identify associated factors and predictors.

METHODS: Retrospective observational study including PBC patients with ≥1 DEXA scan. Clinical, demographic and laboratory data at the time of DEXA were analysed. OP was evaluated as a dichotomous outcome (bivariate analyses and multivariate logistic regression). Femoral neck (FN) and lumbar spine (LS) BMD were also analysed as continuous variables using correlations and multiple linear regressions. Significance was set at $p<0.05$.

RESULTS: Sixty-five patients were included (mean age 58±1.6; 90.8% women; 72.2% postmenopausal). Thirty patients (46.2%) had OP, of whom 6 (20.0%) were referred to Rheumatology, and 10 (15.4%) had previous fragility fracture.
OP was more frequent in menopausal women and those with previous fracture, also being associated with older age, longer PBC duration and lower platelets. The multivariate model (including age, PBC duration, and platelets) was significant, with PBC duration as the sole independent predictor (p=0.043; OR=1.11).
Significantly lower FN BMD values were associated with menopause, previous fracture, splenomegaly and cirrhosis, as well as older age, longer PBC duration, lower platelet count, lower albumin and lower BMI; only previous fracture independently predicted LS BMD (β=-0.35; p=0.005).
Significantly lower FN BMD values were associated with menopause, previous fracture, splenomegaly, cirrhosis, older age, PBC duration, lower platelets, lower albumin and lower BMI. Age and cirrhosis remained independent predictors (β=-0.28, p=0.029; β=-0.32, p=0.013, respectively) in the multivariate model.
CONCLUSION: To the best of our knowledge, this is the first study exploring OP in Portuguese PBC patients, revealing a high prevalence in this cohort. Age and PBC duration consistently associated with OP presence and lower BMD, while variables potentially related to more advanced liver disease - such as cirrhosis, platelets and albumin - also showed association with worse bone health. These results emphasize the importance of targeted bone health surveillance in this population (particularly with more severe disease), with early assessment, adequate supplementation and timely OP treatment.

P1107

DENOSUMAB-ASSOCIATED MRONJ IN ADVANCED CKD: CLINICAL CHALLENGES AND THERAPEUTIC LIMITATIONS

M. Natal[1], T. Burnay[2], B. Fernandes Esteves[1], M. Oliveira[3], G. Terroso[1], L. Costa[1]

[1]Rheumatology Department, Unidade Local de Saúde de São João, Porto, Portugal; [2]Pneumology Department, Unidade Local de Saúde de São João, Porto, Portugal; [3]Rheumatology Department, Hospital do Divino Espírito Santo, Ponta Delgada, Portugal

Case Description: A 73-year-old woman with a history of pulmonary lymphangiomatosis, left lung transplantation (2013) and chronic kidney disease (CKD) stage 3b was referred in 2015 for severe osteoporosis (OP) (DEXA showing T-score −4.2 lumbar spine, −3.6 femoral neck). Laboratory studies were normal, and radiography suggested a D7 vertebral fracture. She had been on weekly alendronate for 2 years; given renal deterioration and severe OP, treatment was switched to denosumab.
She maintained regular treatment until 2024, with stable densitometry. After a dental extraction in May 2024, she developed a painful mandibular lesion with swelling and purulent drainage. Evaluation by Maxillofacial Surgery revealed bone exposure, and she was admitted in December 2024 for suspected medication-related osteonecrosis of the jaw (MRONJ). CT and MRI showed extensive mandibular and maxillary involvement compatible with MRONJ, with possible osteomyelitis. Microbiology identified mandibular actinomycosis with *Staphylococcus warneri* superinfection. She completed 14 days of intravenous amoxicillin/clavulanic acid followed by prolonged oral therapy, with favourable evolution.
Denosumab was definitively discontinued, and she remains without pharmacological anti-osteoporotic therapy, given the limitation imposed by CKD, currently at stage 4 (transitioning to stage 5), and the absence of safe pharmacological alternatives available in Portugal.
Discussion/Conclusions: MRONJ is a rare but potentially serious complication described in patients receiving antiresorptive therapy. Denosumab is a key first-line therapeutic option for the treatment of severe OP in patients with contraindications to bisphosphonates, particularly in the presence of advanced CKD. The risk of MRONJ is generally low at doses used for OP, but the presence of multiple predisposing factors (prolonged treatment, renal insufficiency, chronic immunosuppression, and recent dental procedure) seen in this case likely contributed to its development. Definitive discontinuation of denosumab was necessary, leaving the patient without active anti-osteoporotic therapy, highlighting the therapeutic gap existing in this clinical context and the urgent need for safer and effective treatment options for this population.

P1108

TRENDS IN THE BURDEN OF OSTEOPOROTIC HIP FRACTURE, BEFORE, DURING, AND AFTER THE COVID-19 PANDEMIC

M. Navarro Grijalva[1], M. Hernandez Bonilla[1], N. Bautista Litardo[1], R. Cedeño German[1], A. Segura Mestanza[1], M. Navarro Chavez[1], L. Imaicela Naula[1], E. Lopez Gavilanez[1]

[1]AECE research Group. The Association of Clinical Endocrinologists of Ecuador. Guayaquil, Ecuador., Guayaquil, Ecuador

Summary: Globally, the incidence of hip fractures (HF) has declined in recent decades. The impact of the COVID-19 pandemic on HF continues to be actively evaluated in literature.
Objective: We analyzed and compared the incidence, prevalence, and years lived with disability (YLDs) attributable to HFs before, during, and after the COVID-19 pandemic in adults of both sexes aged 50 years and older in the period 2010–2023.
Methods: We used data from the 2023 Global Burden of Disease (GBD) study, focusing on trend changes and stratified characteristics of the HF burden. We assessed incidence, prevalence, and years lived with disability (YLDs), as well as the corresponding crude and age-standardized rates of incidence (ASIR), prevalence (ASPR), and YLDs (ASYR).
Results: In 2023, there were 19,274 incident cases of HF, 36,850 prevalent cases, and 5,202 YLDs. Between 2010 and 2023, the incidence increased from 5,207 to 7,178 cases (1.4 times), the prevalence from 9,977 to 13,286 (1.3 times), and the YLDs from 1,664 to 1,855 (1.1 times). The age-standardized incidence rate (ASIR) in 2023 was 138.1 per 100,000 population, representing an increase (1.2 times) from 2010 (Average annual percentage change, AAPC 0.23; p<0.05), the ASPR was 230 (AAPC 0.22; p<0.05), and the ASYR was 32 (AAPC −1.15; p<0.05). Table 1.

Table 1. Age Standardized Rate * of incidence, prevalence, and YLDs of Hip Fracture (50+years) from 2010 to 2023.

Year	2010			2023		
	ASIR	ASPR	ASYR	ASIR	ASPR	ASYR
Both	111.8 (153–77.9)	189.0 (210.1–168.1)	32.6 (43.4–22.3)	138.1 (187.9–97.1)	230.3 (260.6–202.6)	33.2 (45.2–23.2)
Male	114.5 (159.9–78.1)	176.2 (197.7–156.8)	31.0 (41.8–21.1)	118.2 (166–82.3)	177.5 (199.6–157.5)	26.3 (35.8–18.5)
Female	106.5 (146.2–73.7)	196.7 (220.5–170.6)	33.3 (44.1–23.2)	151.8 (204.9–106.4)	271.6 (306.9–234.9)	38.5 (53.4–26.9)

*per 100,000 inhabitants (95 % UI); ASIR, Age-standardized Incidence Rate; ASPR, Age-standardized Prevalence Rate; ASYR, Age-standardized YLDs Rate

Conclusion: Between 2010 and 2023, the disease burden of HF increased significantly before, during, and after the COVID-19 pandemic, at the expense of older adults and women. In contrast to the global trend, the incidence has been steadily increasing in Ecuador over the last decade.

P1109

ARTIFICIAL INTELLIGENCE FOR SARCOPENIA ASSESSMENT IN ADULTS: A SYSTEMATIC REVIEW OF MULTIMODAL APPROACHES AND VALIDATION GAPS

M. O'Riordan[1], P. Kartik[2], J. Rosen[3], N. Al-Saffar[4], N. R. Fuggle[1]

[1]Univeristy of Southampton, Southampton, United Kingdom; [2]Kettering General Hospital NHS Foundation Trust, Kettering, United Kingdom; [3]University of Warwick, Coventry, United Kingdom; [4]Bolton NHS Foundation Trust, Bolton, United Kingdom

Objectives: To synthesise evidence on artificial intelligence (AI) approaches for adult sarcopenia assessment across imaging, routinely collected clinical and laboratory data, ultrasound and wearable/sensor modalities, and to summarise performance, validation strategies and translational evidence gaps.

Materials and Methods: PubMed, Embase, Scopus and IEEE Xplore were searched (2015–2026). We screened 2,970 records; 1,814 remained after deduplication. Eligible studies applied AI or machine learning to explicitly defined/classified sarcopenia in adults. Ninety-six papers proceeded to full-text screening. We extracted modality, model type, sarcopenia reference standard, validation approach and performance metrics, with synthesis by modality and use-case.

Results: AI approaches clustered into assessment using routinely acquired imaging, structured clinical and laboratory data, ultrasound-based classification and wearable/sensor-enabled functional assessment. Imaging deep learning most frequently targeted automated muscle segmentation/quantification with high agreement against manual labels (e.g., Dice 0.95 for skeletal muscle in CT, reflecting near-complete overlap between automated and reference segmentations). Clinical models commonly used readily available features and achieved good discrimination in representative studies (area under the receiver operating characteristic curve (AUC) 0.94). Where independent external validation was performed, performance often attenuated (e.g., AUC 0.862 internally vs 0.785 externally), highlighting generalisability as a key barrier alongside heterogeneous sarcopenia reference standards.

Conclusions: AI methods for sarcopenia assessment demonstrate strong technical performance for imaging-based assessment using routinely acquired scans and promising discrimination for scalable screening using routinely collected clinical data. The key gap is robust, multi-site external validation against harmonised reference standards, supported by prospective evaluation and transparent reporting, to enable safe clinical implementation.

SYSTEMIC MASTOCYTOSIS PRESENTING AS OSTEOPOROSIS WITH FRAGILITY FRACTURES

M. Oliveira[1,2], L. Costa[2], D. Oliveira[3,4,5]

[1]Rheumatology Department, Hospital do Divino Espírito Santo, Ponta Delgada, Portugal; [2]Rheumatology Department, Unidade Local de Saúde São João, Porto, Portugal; [3]Rheumatology Department, Unidade Local de Saúde Entre Douro e Vouga, Santa Maria da Feira, Portugal; [4]Department of Medicine of Faculty of Medicine, University of Porto, Porto, Portugal; [5]RISE-Health, Porto, Portugal

INTRODUCTION

Systemic mastocytosis (SM) is characterised by abnormal proliferation of neoplastic mast cells. Bone involvement is common and may manifest as reduced bone mineral density (BMD) and fragility fractures, particularly vertebral fractures.

CLINICAL CASE

A 59-year-old woman with SM was referred to the Rheumatology Department for evaluation of vertebral pain and fragility fractures. Osteoporosis (OP) risk factors included smoking (20 pack-years) and a maternal history of proximal femur fracture. She reported pruritic maculopapular skin lesions with a positive Darier's sign and flushing episodes. The diagnosis of SM was confirmed by bone marrow biopsy, showing hypercellular marrow with mast cell infiltration, increased CD25 expression, KIT D816V mutation and elevated serum tryptase levels (>20 ng/mL). Physical examination revealed a 4 cm height loss and dorsal hyperkyphosis. Calcium–phosphate metabolism was normal. Radiography showed fragility fractures, including bilateral humeral head, ischiopubic rami and vertebral fractures (D3, D6, D10–D12, L2, L4 and L5) (Figure 1). Dual-energy X-ray absorptiometry showed osteopenia, with a lumbar spine T-score −2.1 and a femoral neck T-score −2.3. Despite six monthly doses of intravenous zoledronate (5 mg) combined with calcium and vitamin D, an additional left humeral head fracture occurred. Treatment was switched to denosumab (60 mg every 6 months) and midostaurin (50 mg twice daily), after which no further fragility fractures have occurred to date.

CONCLUSION

Bone fragility in SM results from mast cell-mediated disruption of bone metabolism, preferentially affecting trabecular bone. SM should be considered in the differential diagnosis of OP, as early recognition is crucial to optimise treatment and reduce fracture-related morbidity.

ACETABULAR PROTRUSION AS DIAGNOSTIC CLUE TO OSTEOGENESIS IMPERFECTA TYPE V

M. Oliveira[1,2], L. Costa[2], M. Rato[2]

[1]Rheumatology Department, Hospital do Divino Espírito Santo, Ponta Delgada, Portugal; [2]Rheumatology Department, Unidade Local de Saúde São João, Porto, Portugal

Introduction

Osteogenesis imperfecta type V (OI type V) is defined by characteristic radiological and histological findings and the absence of typical extraskeletal manifestations such as blue sclerae and dentinogenesis imperfecta. These atypical features may contribute to delayed recognition, underscoring the diagnostic value of specific radiological patterns.

Case Report

A 42-year-old woman was referred to the Rheumatology Department after pelvic radiography revealed marked bilateral acetabular protrusion. As advanced degenerative joint disease was absent, this finding raised suspicion of an underlying systemic bone disorder. The patient reported a history of bone fragility with multiple low-impact fractures in childhood involving the elbows, tibia, left ankle and vertebrae. No further fractures occurred in adulthood and there was no family history of fragility fractures. Physical examination showed short stature (153 cm), pectus carinatum, dorsal hyperkyphosis, limited elbow flexion, brittle nails and severe restriction of hip mobility. There was no evidence of scleral discoloration or dentinogenesis imperfecta. Biochemical assessment of bone metabolism, including calcium, phosphate, parathyroid hormone, vitamin D, osteocalcin, and beta-crosslaps, was normal. Dual-energy X-ray absorptiometry revealed a lumbar spine Z-score of −2.1 SD, below the expected range for age. Radiographic review demonstrated previous fractures, fish-shaped vertebrae, calcification of interosseous membranes, radial head dislocation and marked bilateral acetabular protrusion. The coexistence of these findings strongly suggested OI type V. Molecular analysis identified a heterozygous pathogenic IFITM5 variant (c.−14C>T) confirming the diagnosis. Calcium and vitamin D supplementation was initiated and no new fractures occurred during follow-up.

Conclusion

Diagnosis of OI type V relies on clinical and radiological evaluation, with genetic testing providing definitive confirmation. In this patient, acetabular protrusion was a valuable radiological clue for OI type V. Awareness of this finding, particularly alongside interosseous membrane calcification and fracture history, may facilitate earlier diagnosis and appropriate management in adults without classical extraskeletal signs.

P1112

DENOSUMAB-INDUCED SEVERE HYPOCALCAEMIA IN OSTEOPOROSIS

M. Oliveira[1], T. Nóvoa[1], C. Furtado[1]

[1]Rheumatology Department, Hospital do Divino Espírito Santo, Ponta Delgada, Portugal

Introduction

Denosumab is used in the treatment of osteoporosis (OP) in postmenopausal women and reduces vertebral, non-vertebral and hip fractures. Although generally well tolerated, hypocalcaemia is a potentially serious adverse effect.

Clinical cases

Case 1: A 65-year-old woman with stage 3a chronic kidney disease (CKD), secondary hyperparathyroidism and premature menopause was referred to the Rheumatology Department for the management of OP after sustaining a femoral neck fragility fracture (FF) while receiving zoledronic acid with calcium and vitamin D supplementation. Therapy was switched to denosumab 60 mg every six months. One month later the first administration, she presented to the emergency department (ED) with a generalised tonic–clonic seizure. Laboratory evaluation revealed severe hypocalcaemia (6.6 mg/dL; previously 8.6 mg/dL), hypophosphataemia (1.7 mg/dL; previously 3.5 mg/dL), vitamin D deficiency (7.52 ng/mL; previously 21.8 ng/mL) and elevated parathyroid hormone (PTH) levels (630 pg/mL; previously 287 pg/mL). She was admitted an treated with intravenous calcium gluconate, oral calcium carbonate and vitamin D. After nine days, biochemical parameters normalised (calcium 9.4 mg/dL and phosphate 4.0 mg/dL) and she was discharged.

Case 2: A 76-year-old woman with stage 5 CKD and secondary hyperparathyroidism was referred for OP management following a femoral neck FF. Denosumab 60 mg every six months was initiated with calcium and vitamin D supplementation, although adherence was suboptimal. Two days after the first administration, she developed

generalised polyarthralgia and profound weakness, presenting to the ED approximately one month later. Investigations showed severe hypocalcaemia (4.9 mg/dL; previously 9.2 mg/dL), hypomagnesaemia (0.9 mg/dL; previously 1.6 mg/dL), vitamin D level of 39.7 ng/mL (previously stable), and markedly elevated PTH (633 pg/mL; previously 266 pg/mL). She was hospitalised for three weeks, with correction of electrolyte disturbances.

Conclusion

Denosumab-associated hypocalcaemia may be more prevalent than previously recognised, particularly in patients with CKD. Optimisation of calcium and vitamin D supplementation and regular biochemical monitoring are essential to prevent serious adverse effects.

P1113

HOW DOES NUTRITION AFFECT THE COURSE OF RHEUMATOID ARTHRITIS?

S. Lezhenina[1], M. Osman[2], N. Shuvalova[3], E. Guryanova[1,4]

[1]Federal State Budgetary Educational Institution of Higher Education "I.N. Ulyanov Chuvash State University", Cheboksary, Russia; [2]El galaa hospital, Cairo, Egypt; [3]Chuvash State Pedagogical University named after I. Ya. Yakovlev, Cheboksary, Russia; [4]State Autonomous Institution of the Chuvash Republic of Additional Professional Education "Institute of Advanced Medical Training" of the Ministry of Health of the Chuvash Republic, Cheboksary, Russia

Objectives. The objective of this study was to analyze whether nutrition can affect the level of inflammatory markers and subjective symptoms in people with rheumatoid arthritis, as well as the frequency of exacerbations.

Materials and methods. A double-blind study was conducted in Egypt, it consisted of compliance with the protocol on nutrition (anti-RA). Neither the participants nor the researchers knew which of the 60 people were in the main group of "anti-RA" nutrition, and who was in the control group, until the results of the study came in. All 60 patients aged 25-55 years had a history of rheumatoid arthritis from 2 to 15 years. The study was conducted between December 2024 and March 2025. During the experiment, all patients filled out a food diary that recorded each meal, in addition, venous blood was taken from patients before and after the experiment for: C-reactive protein (CRP), interleukin-6 (IL-6), tumor necrosis factor (TNF-α), rheumatoid factor (RF) . The VAS scale (a visual analog scale of joint pain from 0 to 10) was used for the subjective assessment of pain syndrome. All patients were divided into two groups of 30 people (main and control). In the main group, patients ate a daily menu according to the "anti-RA" model (fish 3 ×/week, vegetables >400 g, nuts 30 g, olive oil 1 tbsp. l., kefir 200 ml, turmeric /ginger). prohibited: red meat, sugar > 20 g/day, trans fats. In the control group, patients followed their usual diet, and all foods in normal quantities were allowed without recommendations. Both groups continued to lead their usual lifestyle, vitamins were not added. In addition, all patients during the experiment noted the frequency of taking nonsteroidal anti-inflammatory drugs (NSAIDs).

Results. At the end of the study: in the main group, the average C-reactive protein decreased from 5.8 to 3.2 mg/l, while in the control it remained at 5.7 mg/l. Interleukin-6 decreased by 22% in the main group (from 4.1 to 3.2 pg/ml), while in the control group the decrease was only 3%. TNF-α levels in the main group decreased by 19% (from 8.3 to 6.7 pg/ml), while in the control group there was an increase of 2%. Rheumatoid factor decreased in 18 (60%, 18/30) participants of the main group (by an average of 28%), no changes were recorded in the control group. Subjective pain on a 10-point scale decreased from 4.2 to 2.1 points, morning stiffness decreased from 42 to 19 minutes. The control group showed only a slight improvement in pain (by 0.3 points) and an increase in stiffness for 3 minutes. 24 subjects (80%, 24/30) from the main group noted a decrease in the frequency of taking nonsteroidal anti-inflammatory drugs, while in the control group only 5 (16%, 5/30) of the subjects revealed this fact.

Conclusion. A 16-week anti-inflammatory diet significantly reduced systemic inflammation and clinical symptoms (pain) in people with rheumatoid arthritis. The decrease in CRP, IL-6, and TNF-α confirms that nutritional factors modulate the immune response. The data obtained support the concept of "food as medicine" and allow us to recommend the described diet as a safe, affordable and effective strategy for secondary prevention of RA. 24 subjects (80%, 24/30) from the main group noted a decrease in the frequency of taking nonsteroidal anti-inflammatory drugs, while in the control group only 5 (16%, 5/30) of the subjects revealed this fact. Therefore, the authors of the article believe that following a diet (anti-RA) can be used as a secondary prevention method that has a positive effect on the course of this disease. This is evidenced by the results obtained.

P1114

SHOULD I USE ANTIDEPRESSANTS FOR RHEUMATOID ARTHRITIS?

M. Osman[1], N. Shuvalova[2], S. Lezhenina[3], E. Guryanova[3,4]

[1]El galaa hospital, Cairo, Egypt; [2]Chuvash State Pedagogical University named after I. Ya. Yakovlev, Cheboksary, Russia; [3]Federal State Budgetary Educational Institution of Higher Education "I.N. Ulyanov Chuvash State University", Cheboksary, Russia; [4]State Autonomous Institution of the Chuvash Republic of Additional Professional Education "Institute of Advanced Medical Training" of the Ministry of Health of the Chuvash Republic, Cheboksary, Russia

Objective. Rheumatoid arthritis (RA) is a chronic autoimmune inflammatory disease characterized not only by pain, but also by progressive functional loss. Also, a significant proportion of patients suffer from depression, which can exacerbate the perception of pain, reduce drug adherence and worsen the quality of life. Traditionally, antidepressants are prescribed to treat depression in patients with RA along with nonsteroidal anti-inflammatory drugs (NSAIDs). However, the extent to which the use of antidepressants affects the quality of life of patients with RA remains a matter of debate. The objective was to evaluate the effect of antidepressants on the quality of life of patients with rheumatoid arthritis.

Methods and materials. The study was conducted in Egypt, from November 2023 to April 2024. All patients were at the outpatient stage of treatment. The patient group consisted of 100 people with a verified diagnosis of rheumatoid arthritis (RA) lasting more than five years. The gender distribution showed the predominance of women, characteristic of this pathology: 72 patients (72%, 72/100) and 28 male patients (28%, 28/100) participated in the study. The average age of the patients was 49 [47;51] years. The exclusion criteria were acute mental disorders, severe uncompensated somatic diseases, as well as intolerance to prescribed medications.

All subjects were divided into two groups: experimental and control, with 50 patients in each group. The groups were comparable in terms of basic demographic and clinical indicators. Patients from the experimental group, along with basic antirheumatic therapy (HDL), received antidepressants according to an individual regimen: sertraline at a dose of 50-100 mg /day or venlafaxine at a dose of 75-150 mg / day. The choice of the drug and its dosage depended on the profile of side effects, concomitant diseases, and patient preferences. Patients from the control group received only standard basic therapy without the appointment of psychotropic drugs. The duration of the follow-up and treatment period was six months.

To assess the effectiveness of the intervention, all patients underwent a comprehensive psychometric examination before the start of the study and six months later using the SF-36 quality of life assessment questionnaire (The Short Form-36 Health Survey). This tool provides an integrated picture of physical and mental well-being across eight main domains.

Statistical processing of the obtained quantitative data was carried out in Statistical Analysis Software 17.0 using analysis of variance (ANOVA) to compare intergroup differences and dynamics of indicators. The level of statistical significance was set at $p<0.05$.

Resuts. The most pronounced positive dynamics in the experimental group was observed in the field of mental health. The indicator "Role functioning due to emotional state" (RE) increased from 34.8 [22.4; 47.2] to 69.0 [57.2; 80.8] points. The Mental Health (MH) scale, which reflects the level of anxiety and depression, improved from 40.9 [31.3; 50.5] to 66.1 [57.2; 75.0] points. A significant increase was also noted on the scale of "Vital activity" (VT) — from 39.1 [29.0; 49.2] to 61.0 [51.5; 70.5] points, which indicates a decrease in asthenia and an improvement in energy tone.

Positive dynamics was also recorded in the field of physical health, although less pronounced than in the mental components. The General Health index (GH) increased from 46.2 [37.5; 54.9] to 59.5 [50.3; 68.7] points. The "Physical pain" (BP) scale, despite the persistence of the underlying disease, improved from 29.8 [18.5; 41.1] to 43.2 [32.6; 53.8] points, which may indirectly indicate a change in pain perception. "Physical functioning" (PF) increased from 39.7 [29.9; 49.5] to 50.5 [41.8; 59.2] points.

In the control group, where patients received only basic antirheumatic therapy, the results of the six-month follow-up showed no significant changes in quality of life. The SF-36 assessment revealed the absence of statistically significant dynamics in both mental and physical well-being. In particular, the key parameters of the mental component of health remained almost at the initial level. The Psychological Health Scale (MH) showed a slight increase from 41.8 [32.9; 50.7] to 44.2 [34.9; 53.5] points, which did not reach the threshold of statistical significance ($p=0.205$). A similar situation was observed in the field of role functioning due to emotional state (RE), where values ranged from 35.8 [22.6; 49.0] to 37.5 [24.8; 50.2] points ($p=0.325$), as well as on the scale of vital activity (VT), which increased from 40.1 [29.6; 50.6] to only 41.0 [30.9; 51.1] points ($p=0.395$). These minimal changes, which fit within the standard measurement error, indicate the persistence of psychoemotional distress, fatigue, and related limitations in everyday life.

Indicators reflecting physical health also showed no clinically significant improvements. The functional capabilities assessed on the physical functioning scale (PF) remained virtually unchanged, demonstrating an increase from 42.4 [33.9; 50.9] to 43.9 [35.8; 52.0] points ($p=0.165$). Pain intensity perception (BP) remained at a comparable level, slightly shifting from 32.0 [21.2; 42.8] to 33.2 [22.8; 43.6] points ($p=0.285$).

Conclusion. The authors of the article believe that antidepressants should be used for rheumatoid arthritis, as this leads to a reduction in pain and an improvement in the quality of life of patients. Thus, in the experiment, it was shown that the 24-week use of antidepressants for rheumatoid arthritis led to an improvement in the quality of life of patients (questionnaire SF-36), namely, the changes were in the following sections: Physical Functioning (PF), pain (Body Pain, BP), general health (General Health Perceptions, GH), mental Health (MH). It is also necessary to systematize data on the effectiveness and safety of antidepressants and integrate psychological support and rehabilitation into routine clinical practice.

P1115

HOW TO REDUCE THE PAIN OF RHEUMATOID ARTHRITIS AT HOME?

M. Osman[1], N. Shuvalova[2], S. Lezhenina[3], E. Guryanova[3,4]

[1]El galaa hospital, Cairo, Egypt; [2]Chuvash State Pedagogical University named after I. Ya. Yakovlev, Cheboksary, Russia; [3]Federal State Budgetary Educational Institution of Higher Education "I.N. Ulyanov Chuvash State University", Cheboksary, Russia; [4]State Autonomous Institution of the Chuvash Republic of Additional Professional Education "Institute of Advanced Medical Training" of the Ministry of Health of the Chuvash Republic, Cheboksary, Russia

Objective. Rheumatoid arthritis (RA) is a chronic autoimmune inflammatory disease characterized by polyarthritis and systemic manifestations. Pain is a leading symptom that significantly reduces the quality of life and functionality of patients. Modern RA therapy includes pharmacological (nonsteroidal anti-inflammatory drugs, biological replacement agents, DMARDs) and non-pharmacological approaches. In recent years, there has been increasing interest in self-management of pain and self-management of symptoms at home, which can reduce the need for medications, reduce the risk of side effects, and increase satisfaction with treatment. The objective was to analyze the effectiveness of rheumatoid arthritis pain treatment at home.

Materials and methods. The study was conducted on the basis of outpatient facilities in Egypt in the period from October 2024 to January 2025. The study included a group of 90 patients with a diagnosis of rheumatoid arthritis that meets the modern ACR/EULAR classification criteria, aged 30 to 75 years. The gender distribution in the general sample showed the predominance of women, characteristic of this pathology: 62 patients (69%, 62/90) versus 28 male patients (31%, 28/90). Age characteristics revealed that the average age of patients was 52.4 [48.1; 56.7] years old. The group distribution was comparable: in the experimental group, the average age was 51.8 [47.3; 56.3] years, in the control group — 53.0 [48.9; 57.1] years. All patients were randomly divided into two groups: experimental and control, with 45 people each. The patients of the experimental group, along with standard pharmacotherapy (basic anti-inflammatory drugs), used a set of non-medicinal methods: individual breathing exercises during episodes of pain syndrome (5-6 times a week for 5-7 minutes) and local heat therapy to reduce pain (thermal compresses at home for 15-20 minutes, 3-4 times a week). Patients in the control group received only standard pharmacotherapy and were instructed to lead a normal lifestyle without additional non-drug interventions. The duration of the observation period and the application of the techniques was 16 weeks. A Visual Analog Scale (VAS) of joint pain from 0 to 10 points was used to subjectively assess the dynamics of pain syndrome. Statistical processing of the obtained quantitative data was carried out in Statistical Analysis Software 17.0 using Analysis of Variance (ANOVA) to compare intergroup differences and dynamics of indicators. The level of statistical significance was set at $p<0.05$.

Results. At the end of the 16-week study, the subjective pain assessment

on a 10-point VAS scale in the experimental group showed a statistically significant decrease from 4.7 [4.1; 5.3] to 2.5 [2.0; 3.0] points (p<0.001). An analysis of the distribution of patients by total pain scores showed that 38 patients (84%, 38/45) in this group achieved a minimal clinically significant difference (improvement of ≥2 points according to VAS), and in 15 of them (33%, 15/45) pain decreased to a level of < 2 points. Gender dynamics analysis revealed that marked improvement (pain reduction by ≥3 points) was more often observed in women: 18 patients (64%, 18/28) versus 5 male patients (29%, 5/17) in this group. In parallel, a reduction in the average duration of morning stiffness was recorded in the experimental group from 45 [38; 52] to 20 [15; 25] minutes (p<0.001). In the control group, which received only standard therapy, the dynamics were minimal and statistically insignificant. The subjective assessment of pain by VAS decreased by only 0.2 points: from 4.5 [3.9; 5.1] to 4.3 [3.7; 4.9] points (p=0.325). Morning stiffness did not decrease, but increased slightly by 2 minutes: from 43 [36; 50] to 45 [38; 52] minutes (p=0.285). A clinically significant improvement in pain (≥2 points) in the control group was observed in only 3 patients (7%, 3/45).

Conclusion. The results of this study showed that at home, the pain of rheumatoid arthritis can be reduced using breathing exercises and heat therapy. They are an effective addition to pharmacotherapy to reduce pain and improve functional status in patients with rheumatoid arthritis. This approach is easily scaled and available outside the clinic, which increases its practical value. The authors of this article aim to conduct further research with a long follow-up period and an assessment of the long-term stability of the analgesic effect.

P1116

CHANGES IN BODY COMPOSITION AND MUSCLE STRENGTH WITH A HIGH-PROTEIN NUTRITIONAL PLAN IN PATIENTS WITH OSTEOPOROSIS AND FRAGILITY FRACTURES AT A HOSPITAL IN BOGOTÁ

L. Ely[1], A. Medina[2], M. Ospino[2]

[1]Hospital San José, Bogotá, Colombia; [2]Fundación Universitaria de Ciencias de la Salud, Bogotá, Colombia

Objective: To evaluate changes in body composition and muscle strength following a three-month high-protein nutritional intervention in patients with osteoporosis and fragility fractures enrolled in the Fracture Liaison Services (FLS) program at Hospital Universitario de San José, Bogotá, Colombia.

Materials and Methods: A quasi-experimental study was conducted including 36 patients over 50 years of age with fragility fractures. Each participant received an individualized nutritional plan with a protein intake of 1.2 g/kg/day, evenly distributed across three main meals for three months. Body composition was assessed using bioelectrical impedance analysis, and handgrip strength was measured with dynamometry before and after the intervention. The Shapiro–Wilk test was applied to assess normality, and paired Student's t-tests were used for pre–post comparisons. Statistical significance was set at $p < 0.05$.

Results: Thirty-six patients were analyzed, with a mean age of 81.5 ± 6.74 years; 72.2% were women, and the mean BMI was 23.1 ± 4.2 kg/m². After the intervention, a significant increase was observed in muscle mass percentage (28.9 ± 4.2 vs. 29.4 ± 4.1; $p = 0.03$) and handgrip strength (13.2 ± 5.1 kg vs. 14.8 ± 5.3 kg; $p = 0.004$), along with a trend toward reduced body fat percentage. Body weight and BMI remained stable.

Conclusions: The high-protein nutritional intervention improved muscle mass and handgrip strength in older adults with osteoporosis. Previous studies have highlighted that the combination of protein intake and exercise enhances bone and muscle health, thereby reducing the risk of falls and fractures (1). These findings are consistent with international literature supporting nutrition as a cornerstone in the management of osteoporosis.

IMPACT OF A HIGH-PROTEIN NUTRITIONAL PLAN ON FRAILTY AND FUNCTIONALITY SCALES IN PATIENTS WITH OSTEOPOROSIS AT A HOSPITAL IN BOGOTÁ

L. Ely[1], A. Medina[2], M. Ospino[2]

[1]Hospital San José, Bogotá, Colombia; [2]Fundación Universitaria de Ciencias de la Salud, Bogotá, Colombia

Objective: To evaluate changes in frailty and functionality following a three-month high-protein nutritional intervention in patients with osteoporosis and fragility fractures enrolled in the Fracture Liaison Services (FLS) program at Hospital Universitario de San José, Bogotá, Colombia.

Materials and Methods: A quasi-experimental study was conducted including 36 patients over 50 years of age with fragility fractures. Each participant received an individualized nutritional plan with a protein intake of 1.2 g/kg/day, evenly distributed across three main meals for three months. Frailty was assessed using the FRAIL scale, and functional independence was evaluated with the Barthel Index before and after the intervention. Normality was tested with the Shapiro–Wilk test; the Wilcoxon test was applied to non-normally distributed variables (FRAIL), and paired Student's t-tests were used for normally distributed variables (Barthel). Statistical significance was set at $p < 0.05$.

Results: Thirty-six patients were analyzed, with a mean age of 81.5 ± 6.74 years; 26 were women (72.2%). The mean T-score was −2.6 ± 0.8 SD at the femoral neck and −3.18 ± 0.6 SD at the lumbar spine. FRAIL scores decreased from 2.24 ± 1.65 to 1.88 ± 1.56, with the median shifting from 2 to 1 ($p = 0.014$; $r = 0.40$), indicating a statistically significant reduction in frailty with a moderate effect size. The Barthel Index showed improved functionality, with the mean increasing from 81.86 ± 14.98 to 89.03 ± 13.83 and the median from 85 to 95 ($p < 0.001$; $d = 0.82$), reflecting a moderate-to-large effect size.

Conclusions: Recent studies have confirmed that targeted nutritional programs can improve frailty status in older adults, reducing the risk of disability and dependence (1). Our findings, which demonstrate a significant improvement in the Barthel Index, reinforce this evidence and suggest that nutrition may be a key component in functional rehabilitation.

SEVERE PRIMARY HYPERPARATHYROIDISM WITH MISDIAGNOSIS AS FIBROUS DYSPLASIA: A CASE REPORT

A. Peña[1], S. Henriquez[1], L. Kuang[1], A. Medina[1], M. Ospino[1], J. Benavides[1]

[1]Fundación Universitaria de Ciencias de la Salud, Bogotá, Colombia

Objective. The objective was to report a case of severe primary hyperparathyroidism in a young patient, initially misdiagnosed as polyostotic fibrous dysplasia.

Case Description

A 21-year-old male with normal growth and development until age 17 presented with a pathological fracture of the right femur. Over the following years, he sustained additional fractures of the right tibia, right humerus, and left femur, requiring multiple orthopedic surgeries and resulting in progressive skeletal deformities and functional impairment. Histopathological evaluation of femoral and tibial lesions was initially interpreted as polyostotic fibrous dysplasia.

Two years later, metabolic evaluation revealed markedly elevated parathyroid hormone levels (>3000 pg/mL), increased alkaline phosphatase, mild intermittent hypercalcemia, low–normal phosphorus levels, and severe vitamin D deficiency. Lumbar spine assessment by radiofrequency echographic multi-spectrometry showed preserved bone mineral density, while magnetic resonance imaging demonstrated multiple lytic vertebral lesions with compression fractures. Bone scintigraphy revealed diffuse increased skeletal uptake.

Parathyroid scintigraphy identified a focal hyperfunctioning lesion at the left superior thyroid pole, consistent with a parathyroid adenoma, confirming the diagnosis of severe primary hyperparathyroidism. Next-generation sequencing for genes associated with hereditary hyperparathyroidism showed no pathogenic variants. In the absence of syndromic features, the skeletal lesions were retrospectively reinterpreted as brown tumors.

Discussion. This case illustrates a severe and atypical presentation of primary hyperparathyroidism in a young patient with extensive skeletal involvement and recurrent pathological fractures, initially misdiagnosed as fibrous dysplasia. Sustained parathyroid hormone excess leads to high bone turnover and brown tumor formation, which can mimic other fibro-osseous lesions and delay diagnosis.[1] The discordance between preserved bone mineral density and marked skeletal fragility highlights the limitations of densitometric techniques in high-turnover metabolic bone diseases.[1,2]

Conclusion. Primary hyperparathyroidism should be considered in young patients presenting with pathological fractures or lytic bone lesions, even when bone mineral density appears preserved. Early biochemical evaluation is essential to prevent misdiagnosis and irreversible skeletal damage.2

CORRELATION BETWEEN BONE MINERAL DENSITY AND PARASPINAL MUSCLE THICKNESS IN POSTMENOPAUSAL PATIENTS WITH AND WITHOUT VERTEBRAL FRACTURES

U. Akarırmak[1], M. Ozturk[1]

[1]Istanbul University-Cerrahpaşa, Cerrahpaşa Faculty of Medicine, PM&R Department, Istanbul, Türkiye

Objective

To investigate the relationship between paraspinal muscle thickness and lumbar total bone mineral density (BMD) in patients with and without vertebral fractures, and to evaluate the influence of lumbar degenerative changes on this relationship.

Material and Methods

This cross-sectional study included 65 postmenopausal women aged 51–88 years (mean age 68,45±8,78 years). Participants were classified into three groups: patients with vertebral fractures (n = 24), patients without vertebral fractures (n = 24), and controls without osteoporosis or vertebral fractures (n = 17). Total lumbar spine and proximal femur BMD were measured by dual-energy X-ray absorptiometry (DXA; Hologic QDR 4500SL). Bilateral paraspinal muscle thickness was measured by ultrasonography transversely, at L3 vertebral level. Paraspinal muscle strength was measured using a hand-held dynamometer. Lumbar degenerative changes (osteophyte formation, endplate sclerosis, aortic calcification, facet sclerosis) were recorded based on x-ray findings. Statistical analyses were performed to assess the relationships between paraspinal muscle parameters and BMD.

Results

Mean right and left paraspinal muscle thicknesses were 40.94 ± 5.48 mm and 41.34 ± 5.23 mm, respectively. Lumbar degenerative changes were present in 75.4% of patients. No significant correlation was found between lumbar BMD and paraspinal muscle thickness ($p>0.05$). Paraspinal muscle thickness did not differ significantly between vertebral fracture, non-fracture, and control groups ($p>0.05$). In contrast, paraspinal muscle strength differed significantly between groups, with lower values observed in patients with vertebral fractures ($p=0.002$).

Conclusion

Paraspinal muscle thickness was not associated with lumbar BMD, regardless of the presence of lumbar degenerative changes. These findings suggest that ultrasonographic muscle thickness alone may be insufficient to reflect musculoskeletal function, highlighting the importance of functional muscle assessment in elderly populations.

P1120

STUDY OF BONE MICROARCHITECTURE IN LUNG TRANSPLANT PATIENTS: PRE-TRANSPLANT ANALYSIS

M. Pascual-Pastor[1], A. Cabrera[1], N. Boix Martí[1], M. Barceló Bru[1]

[1]Rheumatology Department, Vall d'Hebron University Hospital. Barcelona. Spain, Barcelona, Spain

Objectives: To evaluate bone microarchitecture using Trabecular Bone Score (TBS) in lung transplant (LT) candidates and assess its relationship with fracture risk.

Material and methods: Retrospective study of 250 patients evaluated for LT between 2022-2025. Bone mineral density (BMD) was assessed by DXA and microarchitecture by TBS. All patients underwent a standardized clinical history and spinal radiography. Glucocorticoid therapy was defined as a dose ≥ 5mg for more than 3 months or more than three courses/year.

Results: The cohort included 154 men and 96 women (mean age 57.9±8.2 years). Degraded bone microarchitecture was found in 28.4% of patients, partially degraded in 36.8%, and normal in 34.8%. Osteoporosis prevalence was 31.2%, and 30 patients (12%) presented at least one fracture, 14 of which were thoracic vertebral fractures. Patients with fractures had a higher prevalence of family history of femoral fracture (23.3% vs 7.3%; p=0.004). Furthermore, fractured patients showed lower performance in the walking test (277.4 vs 339.0 meters; p=0.017).

No significant differences were observed in absolute TBS values between patients with and without fractures (1.26±0.19 vs 1.28±0.14; p=0.51). However, patients receiving glucocorticoids showed a significantly higher proportion of degraded TBS (<1.200) compared to those untreated (34.0% vs 19.1%; p=0.034), and glucocorticoid therapy itself was associated with a higher risk of fracture (OR=2.6; p=0.03). Fractured patients had significantly lower BMD at the lumbar spine (0.98 vs 1.08 g/cm²; p=0.020), femoral neck (0.76 vs 0.88 g/cm²; p<0.001), and total femur (0.80 vs 0.91 g/cm²; p=0.005). FRAX scores (major and hip), both with and without TBS, were significantly higher in the fractured group (p<0.001).

Conclusions: Impaired bone microarchitecture is highly prevalent in LT candidates, particularly those receiving glucocorticoid therapy. Although BMD and FRAX effectively identified patients with fractures, TBS did not show a significant association with fracture risk in this specific population.

CLINICAL PROFILE OF EARLY-ONSET OSTEOPOROSIS: INSIGHTS FROM A PORTUGUESE TERTIARY CENTER

M. Patela[1], T. Beirão[1], C. Rua[1], C. Silva[1], A. S. Pinto[1], T. Meirinhos[1], R. Vieira[1]

[1]Unidade Local de Saúde Gaia de Espinho, Vila Nova de Gaia, Portugal

Objective

To describe the clinical characteristics of patients with early-onset osteoporosis (EOOP) followed at a Portuguese tertiary center and compare primary and secondary EOOP.

Materials and Methods

A retrospective study including patients diagnosed with osteoporosis before age 50 at a Rheumatology Unit. Data comprised demographics, etiology, bone mineral density (BMD), fracture history, treatments, lifestyle factors, laboratory parameters, and genetic findings.

Results

Thirty-nine patients were included (70% female), with a mean age at diagnosis of 37.7 ± 9.4 years. EOOP was secondary in 64% (n=25). Drug-induced osteoporosis accounted for 26% (n=10), mainly due to corticosteroids (n=7) and cancer-related hormone therapy (n=3). Other secondary causes (38%, n=15) included gastrointestinal disease (n=3), premature menopause (n=3), genetic disorders (n=3), primary hyperparathyroidism (n=2), low body weight (n=2), and rheumatic disease (n=1). Primary EOOP represented 36% (n=14), including one case of osteogenesis imperfecta.

Mean lumbar spine T-scores were −2.98 ± 1.07 (primary) vs. −2.69 ± 0.70 (secondary); femoral neck T-scores −1.96 ± 0.91 vs. −2.14 ± 1.09; and total femur T-scores −2.16 ± 0.62 vs. −1.94 ± 0.71. Before treatment, fifteen patients (38%) sustained low-impact fractures (10 primary, 5 secondary), with seven experiencing multiple fractures. Two patients (5%) had fractures during or after treatment, both in the secondary group. Pharmacological therapy was initiated in 51% of patients: bisphosphonates (28%), denosumab (8%), teriparatide (5%), and sequential therapy (10%). Bisphosphonates were first-line in 71% of primary vs. 20% of secondary EOOP. Treatment changes were driven by reproductive planning, adverse events, or insufficient response. E18% were active smokers, and 41% reported adequate calcium intake. Routine laboratory parameters, including calcium, phosphate, vitamin D, parathyroid hormone, and magnesium, were within normal ranges. Genetic testing (n=8) identified Turner syndrome, CHARGE syndrome, osteogenesis imperfecta, and an X chromosome anomaly.

Conclusion

EOOP is frequently secondary. Fractures before diagnosis were common, supporting the need for earlier recognition and individualized management in younger patients.

Variable	Primary	Secondary
Number of Patients	14	25
Mean Age at Diagnosis (years)	38.85 ± 9.57	37.04 ± 9.40
Lumbar Spine BMD (g/cm²)	0.82 ± 0.15	0.83 ± 0.10
Femoral Neck BMD (g/cm²)	0.76 ± 0.13	0.68 ± 0.16
Total Femur BMD (g/cm²)	0.75 ± 0.08	0.77 ± 0.09
Lumbar Spine T-score	-2.98 ± 1.07	-2.69 ± 0.70
Femoral Neck T-score	-1.96 ± 0.91	-2.14 ± 1.09
Total Femur T-score	-2.16 ± 0.62	-1.94 ± 0.71
Smokers (n, %)	4 (29%)	3 (12%)
Adequate Calcium Intake	4 (29%)	12 (48%)

Table 1. Baseline characteristics of Primary/ Idiopathic EOOP and Secondary EOOP groups

Variable	Primary	Secondary
Patients with fractures during treatment (n, %)	0 (0%)	2 (8%)
≥1 fracture before treatment (n, %)	10 (70%)	5 (20%)
>1 fracture before treatment (n, %)	6 (43%)	1 (4%)
First line treatment with:		
Bisphosphonates (n, %)	10 (71%)	5 (20%)
Denosumab (n, %)	1 (7%)	4 (16%)
Teriparatide (n, %)	1 (7%)	1 (4%)
>1 treatment (n, %)	4 (29%)	0 (0%)

Objectives

The association of obesity- related markers such as Visceral Adiposity Index (VAI) and Lipid Accumulation Product (LAP) with bone health is controversial (1,2). This study aimed to evaluate this association among men using data from the second recruitment of the Bushehr Elderly Health (BEH) program.

Methods

A cross-sectional analysis was conducted on 851 men aged 50 years and older on the data from BEH program (3). Demographic information, laboratory data, bone mineral density (BMD) and trabecular bone score (TBS) were collected. Participants with a T-score ≤ −2.5 at the lumbar spine, total hip, or femoral neck were classified as having osteoporosis, while others were not. Low BMD (osteopenia/osteoporosis), was defined as a T-score ≤ −1 at any of these sites. Associations of adiposity measures and bone health were investigated using linear and logistic regression analyses.

Results

The mean age of the participants was 62.9± 0.2 years and 151 (17.7%) were diagnosed with osteoporosis. Compared to individuals without osteoporosis, those with osteoporosis had lower mean of VAI (2.3 vs. 2.7, p=0.001) and LAP (44.5 vs. 61.6, p< 0.001). After adjusting for known and measured confounders, VAI exhibited a positive association with BMD at total hip and LAP exhibited a negative association with TBS. Each one unit increases in VAI was associated with 0.0192 gr/cm^2 increase in lumbar spine BMD, while one-unit increase in LAP was associated with 0.0011 gr/cm^2 decrease in TBS (Table 1). Moreover, in logistic regression analysis, VAI was related with lower odds of having low BMD (odds ratio = 0.725, p = 0.041) (Table 2).

Conclusion

These findings highlighted that some adiposity parameters may serve as valuable markers in evaluating bone health in older adult men. A deeper understanding of these associations may improve clinical approaches for the prevention and management of osteoporosis in this population.

THE ASSOCIATION OF THE TYG INDEX-RELATED PARAMETERS AND BONE HEALTH STATUS IN MEN AGED 50 AND OVER: A CROSS-SECTIONAL ANALYSIS OF BUSHEHR ELDERLY HEALTH (BEH) PROGRAM

S. Mohseni[1], K. Khalagi[2], A. Amanollahi[3], N. Fahimfar[4], M. Pejman Sani[5], B. Larijani[6], I. Nabipour[7], A. Ostovar[4]

[1]Osteoporosis Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran., Tehran, Iran; [2]Obesity and Eating Habits Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran., Tehran, Iran; [3]Trauma and Injury Research Center, Iran University of Medical Sciences, Tehran, Iran., Tehran, Iran; [4]Department of Epidemiology and Biostatistics, School of Public Health, Tehran University of Medical Sciences, Tehran, Iran, Tehran, Iran; [5]Endocrinology and Metabolism Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran, Tehran, Iran; [6]Endocrinology and Metabolism Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran., Tehran, Iran; [7]The Persian Gulf Marine Biotechnology Research Center, The Persian Gulf Biomedical Sciences Research Institute, Bushehr University of Medical Sciences, Bushehr, Iran, Tehran, Iran

Objectives

The triglyceride-glucose (TyG) index and its related parameters (TyG-BMI, TyG-WC, and TyG-WHtR) have emerged as sensitive and cost-effective markers of insulin resistance (1). However, limited research has investigated the association between these parameters with bone health with controversial findings (2,3). This study aimed to evaluate the association between TyG and its related parameters with bone mineral density (BMD), as surrogate markers of IR and bone health among men over 50 years living in Bushehr, Iran, utilizing data from the Bushehr Elderly Health (BEH) program (4).

Methods

This cross-sectional analysis utilized data from the BEH Program involving 851 older adult men aged 50 years or more. Bone health was assessed using BMD measurements at the lumbar spine, total hip, and femoral neck, and trabecular bone score (TBS). Low BMD (osteopenia/osteoporosis) and osteoporosis were defined as a T-score lower than 1 SD below the reference mean (−1 or lower) and 2.5 SD or more below reference mean (−2.5 and lower) in at least one site, respectively.

Results

The mean age of the study participants was 62.9 ± 0.2 years, of whom 151 (17.74%) had osteoporosis. Through multivariate linear and logistic regression analysis, TyG and its related parameters (except TyG-WHtR) exhibited a significant positive association with BMD and a negative association with osteoporosis/ low BMD at each bone site. Conversely, TyG-BMI and TyG-WHtR showed negative associations with TBS ($p< 0.001$) after adjustment for confounding factors (Table 1 and Table 2).

Conclusions

These findings highlighted that TyG index-related parameters may serve as valuable markers in evaluating bone health in older adult men.

P1124

CAN MASS SPECTROMETRY ELUCIDATE THE ROLE OF PTH PEPTIDES IN SKELETAL HYPORESPONSIVENESS TO PTH IN CHRONIC KIDNEY DISEASE?

M. Piette[1], P. Massonnet[2], E. Cavalier[1,2]

[1]University of Liège, Liège , Belgium; [2]CHU of Liège, Liège , Belgium

Objective: This research project aims to develop a liquid chromatography-tandem mass spectrometry (LC-MS/MS) method for quantifying parathyroid hormone (PTH) fragments and to use this approach to investigate their role in skeletal hyporesponsiveness to PTH in patients with chronic kidney disease (CKD).

Material and Methods: We developed an LC-MS/MS method to quantify four of the eight currently identified PTH fragments (PTH (38-77), PTH (38-84), PTH (37-84), and PTH (34-84)). A proof-of-concept study was then conducted by quantifying these four fragments in pooled serum samples from patients stratified according to estimated glomerular filtration rate (eGFR: <15, 15-30, 30-45, and 45-60 mL/min/1.73 m²).

Results: As reported by Kritmetapak et al.[1], serum concentrations of C-terminal PTH fragments increased as eGFR decreased. However, substantial interindividual variability was observed among patients with similar eGFR values. For example, the highest concentration of PTH (34-84) was up to 13-fold higher than the lowest observed concentration, whereas the concentration of PTH (1–84) in the same patient was only threefold higher at maximum. These findings suggest that PTH fragments concentrations depend not only on eGFR but may also reflect varying degrees of skeletal resistance to PTH. This observation indicates that PTH (1-84) alone lacks sufficient precision for reliable monitoring, as no correlation was observed between PTH fragments and PTH (1–84).

Conclusion: In conclusion, thanks to our LC–MS/MS method, we were able to observe large variability in PTH peptides concentrations in CKD patients across different eGFR levels. This research project paves the way for elucidating the mechanisms underlying skeletal resistance to PTH, which may ultimately lead to more effective patient care, help prevent fractures that are often fatal, and significantly reduce associated healthcare costs.

COMPARATIVE ASSESSMENT OF VITAMIN D STATUS IN PREGNANT WOMEN AND NEONATES USING LC-MS/MS AND ROCHE TOTAL II ASSAY: INSIGHTS FROM THE PREG-D TRIAL

M. Rahme[1], M. Chakhtoura[1], A. Nassar[2], E. Cavalier[3], C. Sempos[4], S. Ajjour[1], M. Assaad[1], V. Hubert[5], G. El-Hajj Fuleihan[1]

[1]American University of Beirut /Department of Internal Medicine/ Calcium Metabolism Osteoporosis Program, Beirut, Lebanon; [2]American University of Beirut/Department of Department of Obstetrics and Gynecology, American University of Beirut Medical Center, Beirut, Lebanon., Beirut, Lebanon; [3]CHU de Liège/Department of Clinical Chemistry/CIRM, University of Liège, Liège, Belgium., Liege, Belgium; [4]Vitamin D Standardization Program, Havre de Grace, MD, USA., Maryland, United States; [5]Centers for Disease Control and Prevention, Atlanta, GA., Atlanta, United States

Objective:
We compared the performance of Roche Elecsys Vitamin D Total II immunoassay with a CDC standardized liquid chromatography–tandem mass spectrometry (LC–MS/MS) assay, for 25(OH)D concentrations, in maternal-neonatal dyads from the Preg-D trial.

Methods:
We measured 25(OH)D in serum from 199 pregnant women and 170 cord blood samples collected at early second-trimester (10–14 weeks), and at delivery (37–41 weeks) after vitamin D supplementation, using both assays. We evaluated agreement using paired t-tests, linear regression, Bland–Altman plots, and Cohen's κ for vitamin D status classification. We assessed analytical accuracy through comparison with CDC reference materials and NIST SRM 1949 samples.

Results:
The two assays correlated strongly (R^2 = 0.65–0.73) but demonstrated systematic differences. LC–MS/MS reported higher maternal 25(OH)D values at delivery (mean bias +6 ± 6 ng/mL, p < 0.001)s,), whereas the Roche assay yielded higher cord blood values (mean bias −8 ± 6 ng/mL, p < 0.001 relative to LC–MS/MS). Classification concordance declined across time points substantial at baseline (κ = 0.66), moderate at delivery (κ = 0.56), and fair in cord blood (κ = 0.26). Against CDC and NIST reference materials, LC–MS/MS displayed minimal proportional bias, while the Roche assay underestimated 25(OH)D, with concentration-dependent deviations.

Conclusions:
Our study underscores LC–MS/MS superior accuracy, and the pressing need for vitamin D immunoassay standardization, particularly in pregnancy and early life, to ensure appropriate clinical management.

P1126

BIOFEEDBACK TRAINING IN PATIENTS WITH SYSTEMIC SCLEROSIS

R. Grekhov[1,2], A. Aleksandrov[1,2], M. Raza[3]

[1]Zborovsky Research Institute for clinical anf experimental rheumatology, Volgograd, Russia; [2]Volgograd State Medical University, Volgograd, Russia; [3]Riga Stradins University, Riga, Latvia

Background

Microcirculation disorders are the most important sign of Systemic Sclerosis (SS) and can be used to assess the effectiveness of therapy for this disease based on nail plate capillaroscopy. Our attention was drawn to the possibilities of using temperature biofeedback training for therapeutic effects on Raynaud's syndrome in patients with SS.

Objectives

The aim of our study was to evaluate the possibility of using temperature biofeedback training to treat Raynaud's syndrome in patients with SS.

Methods

The study population consisted of 70 SS patients. Patients were randomly divided into two groups: a control group (n = 30) and a main group (n = 40), whose patients received additional biofeedback procedures in addition to conventional therapy. The aim of the temperature-myographic biofeedback was to normalize blood flow in the peripheral vessels by teaching relaxation skills. Wide-field capillaroscopy of the nail bed of SS patients was performed. A qualitative (capillary shape, tortuosity, kinks, blood filling completeness, etc.) and quantitative assessment (capillary length and diameter, density per unit area, capillary network volume, etc.) of the detected changes were performed.

Results

The effectiveness of biofeedback was analyzed based on the dynamics of nail capillaroscopy parameters by comparing the data obtained from patients in the main and control groups.

Table 1. Dynamics of capillaroscopy signs in SS patients with Raynaud's syndrome

Signs	Main group (n = 40)		Control group (n = 30)	
	Before treatment	After treatment	Before treatment	After treatment
Skin count, M±SD	22.56 ± 10.24	14.98 ± 9.45*	21.05 ± 12.02	20.02 ± 9.89
Active type of capillaroscopy pattern, %	28 (70)	21 (52.5)	20 (66.7)	16 (53,3)
Capillary dilation, %	34 (85)	16 (40)*	24 (80)	17 (56.7)
Morphological changes in capillaries, %	36 (90)	22 (55)*	22 (73,33)	10 (33.33)*
Haemorrhages, %	25 (62.5)	10 (25)*	12 (40)	7 (23.33)
Avascular fields, %	26 (65)	24 (60)	13 (43.33)	13 (43.33)

Note: M – mean value, SD – standard deviation, (*) – p < 0.05.

The results indicate that the positive effect of therapy was higher in the main group of SS patients. Successful attempts at self-regulation contribute to improved well-being and mood, and reduced hypochondria and depression.

Conclusions

Thus, biofeedback is a complex, multi-component therapeutic method that combines physiological, psychological and behavioral mechanisms. The use of temperature-based biofeedback in patients with SS and Raynaud's syndrome leads to an improvement in microcirculation and capillary blood flow, which has a positive effect on the results of conventional pharmacotherapy.

P1127

THE EFFECTIVENESS OF USING TWO-COMPONENT INDICES OBTAINED FROM A COMPLETE BLOOD COUNT TO MONITOR INFLAMMATION IN PATIENTS WITH ANKYLOSING SPONDYLITIS AND RHEUMATOID ARTHRITIS

A. Aleksandrov[1,2], R. Grekhov[1,2], V. Aleksandrov[1,2], M. Raza[3]

[1]Zborovsky Research Institute for clinical anf experimental rheumatology, Volgograd, Russia; [2]Volgograd State Medical University, Volgograd, Russia; [3]Riga Stradins University, Riga, Latvia

Objectives

Accurate monitoring of inflammation intensity and disease status is important for patients with ankylosing spondylitis (AS) and rheumatoid arthritis (RA). Various indices obtained from complete blood counts (CBC) can be added to the list of non-invasive markers for use in various inflammatory and autoimmune diseases. The aim of the study was to investigate the dynamics of integral markers of inflammation obtained from CBC during inpatient treatment of these patients.

Methods

Data from standard clinical and laboratory examinations of 48 AS patients and 52 patients with RA were supplemented with the results of single-component and integral index assessments obtained using automated hematological analyzers. The analysis of biomarkers from CBC included the determination of the number of leukocytes, neutrophil granulocytes, lymphocytes, monocytes, and platelets. Standard methods were used to calculate the neutrophil-to-lymphocyte ratio (NLR), platelet-to-lymphocyte ratio (PLR), and monocyte-to-lymphocyte ratio (MLR).

Results

In AS patients, a positive correlation was found between NLR and age ($p=0.036$) and between MLR and ASDAS scores ($p=0.006$). No statistically significant correlation was found between ESR, CRP and two-component inflammatory markers obtained from CBC ($p>0.05$). In group with moderate AS activity, ASDAS scores correlated positively with MLR and monocytes ($p=0.037$ and $p=0.042$, respectively), and in group with high AS activity – only with MLR ($p=0.03$). Only MLR showed a significant decrease during treatment in the general group of AS patients ($p=0.011$). In patients with RA, markers obtained from CBC were not associated with either age or gender of the subjects ($p>0.05$), in contrast to commonly accepted markers of inflammation (ESR and CRP), for which a positive correlation with patient age was established. Of all the indices studied, only TLR correlated significantly with ESR and CRP ($p<0.05$). The TLR index should be considered as an additional (to CRP) marker when assessing the effectiveness of therapeutic interventions in patients with highly active RA in a hospital setting.

Conclusions

Biomarkers obtained from clinical blood tests may be useful for monitoring inflammation in AS patients (MLR) and in patients with highly active RA (TLR in conjunction with ESR and CRP).

P1128

VITAMIN D LEVELS AND DEXA SCAN FINDINGS IN PATIENTS WITH RHEUMATOID ARTHRITIS

M. Rexhepi[1], B. Rexhepi-Kelmendi[2], A. Gashi[2], S. Boja-Dashevci[2], B. Krasniqi[3], S. Krasniqi[4]

[1]University of Prishtina, Rheumatology Clinic-University Clinical Center of Kosova, PRISHTINA, Albania; [2]Rhematology Clinic, University Clinical Center of Kosova, PRISHTINA, Albania; [3]University of Tirana, Faculty of Medicine, Prishtina, Albania; [4]University of Prishtina, Faculty of Medicine, Institute of Clinical Pharmacology, Prishtina, Albania

Objective:

Patients with rheumatoid arthritis exhibit significantly lower bone mineral density compared with the healthy population. Vitamin D deficiency is highly prevalent in this group of patients and is associated with lower bone mineral density and higher disease activity. Vitamin D supplementation, particularly when combined with anti-osteoporotic therapy, has been associated with improvement in BMD values measured by DEXA. The objective was to evaluate the relationship between vitamin D levels and DEXA scan findings in patients with rheumatoid arthritis, as well as their clinical significance.

Materials and Methods:

This was a cross-sectional study that included 100 patients with rheumatoid arthritis treated at a tertiary care level. Bone mineral density was assessed using DEXA scan at the lumbar spine and femoral neck and was compared with serum levels of 25-hydroxyvitamin D.

Results:

In our study, among analyzed patients with rheumatoid arthritis, with the average age 50.94±5.7, the mean serum vitamin D level was 15.86±3.4. Using Pearson correlation analysis, a positive correlation was found between vitamin D levels and metabolic bone disorder derived by T-score values at the lumbar spine ($r = 0.28$) and the femoral neck ($r = 0.33$). A strong positive correlation ($r = 0.7$) was observed between bone mineral density values of the lumbar spine and the femoral neck regions.

Conclusions:

Regular assessment of bone mineral density using DEXA scan and monitoring of vitamin D levels are important components of the long-term management of patients with rheumatoid arthritis. Identification and correction of vitamin D deficiency may contribute to reducing the risk of osteoporosis and fractures in this population.

P1129

CHARACTERISTICS AND TREATMENT OPTIONS OF 272,152 GERIATRIC PATIENTS WITH VERY HIGH AND HIGH FRACTURE RISK

M. Rippl[1], P. Grupp[1], S. Martini[1], K. Mueller[1], S. Schluessel[1], R. Schmidmaier[1], O. Tausendfreund[1], T. Tuemena[2], M. Drey[1]

[1]LMU Hospital, Munich, Germany; [2]Geriatrics in Bavaria Database, Nuremberg, Germany

Objective: The German osteoporosis guideline defines high and very high fracture-risk based on quantifiable evidence-based risk-factors, recommending bone anabolic treatment as first-line therapy for the latter. Given age as a major risk factor, we investigated the proportion of geriatric patients with very high fracture risk, their characteristics, and the percentage suitable for bone anabolic treatment considering contraindications.

Material and Methods: Data from the Geriatrics in Bavaria-Database (GiB-DAT, Geriatrie in Bayern Datenbank) included 272,152 participants (mean age 82±7 years) between 2013 and 2023. Risk-factors and contraindications were evaluated using ICD-10- (International Statistical Classification of Diseases) and ATC-codes (Anatomical Therapeutical Chemical Classification). We analyzed the proportion in the high-risk and very high-risk group, their characteristics, and the share with a contraindication for specific anti-osteoporotic treatments.

Results: >75% of the patients qualified for specific anti-osteoporotic treatment, with the majority (54%) at very high-risk equiring bone anabolic treatment. Patients in the very high-risk group had the lowest mini mental status examination (MMSE) (23±5 points) and activities of daily living (ADL) scores (45±20 points). Contraindications for bone anabolic treatments were found in 20% of women and 8% of all very high-risk patients. 70% of the total study population had no contraindication for any specific anti-osteoporotic medications.

Conclusion: The majority of geriatric patients is at a very high-risk for osteoporotic fractures, characterized by cognitive impairment, ADL limitations, and increased vulnerability. While some patients had contraindications, most were eligible for anti-osteoporotic and particularly bone anabolic treatments. Timely risk-assessment and treatment initiation is crucial and barriers need to be addressed.

P1130

EVALUATING CHATGPT FOR OSTEOPOROSIS PATIENT EDUCATION IN GERIATRIC MEDICINE

S. Martini[1], S. Schluessel[1], M. Rippl[1], L. Deissler[1], O. Tausendfreund[1], D. Nuebler[1], K. Mueller[1], U. Aghamaliyev[1], R. Schmidmaier[1], M. Drey[1]

[1]LMU Hospital, Munich, Germany

Objective: Large language models (LLMs) such as ChatGPT are increasingly used by patients and caregivers to obtain medical information, particularly for chronic conditions in older adults such as osteoporosis. The aim of this study was to systematically evaluate the quality of AI-generated responses to frequently asked patient questions on osteoporosis. Beyond assessing absolute ratings of accuracy, relevance, and potential harm, this study specifically examined uncertainty in expert judgments and agreement regarding the clinical prioritization of osteoporosis-related information.

Materials and Methods: In this cross-sectional expert evaluation study, ten geriatricians independently assessed ten ChatGPT-generated responses to common patient questions addressing key aspects of osteoporosis, including diagnostic, etiologic, therapeutic, risk-related, and prognostic domains. Accuracy, relevance, and potential harm were rated using a 5-point Likert scale. Non-parametric comparisons were performed across content domains. Uncertainty in expert ratings was quantified using interquartile ranges (IQR), while agreement on relative prioritization of statements was assessed using Kendall's coefficient of concordance (W).

Results: No statistically significant differences were observed between content domains in absolute ratings, indicating a high degree of consistency in expert evaluations across osteoporosis-related topics. Overall uncertainty was low to moderate. The highest IQR values were found for therapeutic statements related to osteoporosis with respect to potential harm, as well as for risk-related osteoporosis statements. The lowest levels of agreement (lowest Kendall's W) were observed in risk-related domains pertaining to osteoporosis. These findings suggest that expert disagreement was primarily driven by differences in clinical prioritization rather than by fundamental disagreement regarding the correctness or relevance of the AI-generated statements.

Conclusion: The increased variability observed in therapeutic and risk-related osteoporosis statements is clinically plausible, reflecting areas characterized by heterogeneous evidence, diverse patient populations, and nuanced risk–benefit considerations. The combination of low uncertainty in absolute ratings and low agreement in relative prioritization suggests that AI-generated information on osteoporosis is generally accurate and acceptable but lacks sufficient differentiation to support consistent expert prioritization. From a clinical and patient education perspective, these findings highlight the importance of clearer contextualization and prioritization of osteoporosis-related information when AI-generated content is used.

P1131

ROMOSOZUMAB AND MICROARCHITECTURE: TBS LUMBAR T-SCORE DETECTS CHANGE BEYOND BMD

A. Zúñiga-Vera[1], M. Sanabria-Hernández[1], M. Robustillo-Villarino[1]

[1]HOSPITAL UNIVERSITARIO DE LA PLANA, VILA-REAL, Spain

Objective: Trabecular Bone Score (TBS) provides microarchitectural information complementary to bone mineral density (BMD). However, evidence on the responsiveness of TBS to romosozumab in real-world clinical settings remains limited. The objective was to evaluate and compare the sensitivity to change of TBS (index and lumbar T-score) and lumbar BMD after 12 months of romosozumab in a real-life cohort.

Methods: Postmenopausal women with osteoporosis who completed 12 months of romosozumab and underwent paired baseline and annual DXA scans were included. Outcomes were absolute and percentage changes in: (1) TBS index, (2) TBS lumbar T-score, and (3) lumbar BMD. Responsiveness was assessed using paired t-tests and Standardized Response Means (SRM). Correlations between change in TBS and change in BMD were evaluated using Pearson's r. Ethical approval and written informed consent were obtained.

Results: A total of 47 participants had paired TBS index values, 48 had paired TBS T-scores and 45 had paired lumbar BMD measurements. TBS index increased modestly (+0.016; +1.7%), without statistical significance (p=0.295) and with low responsiveness (SRM=0.15). TBS lumbar

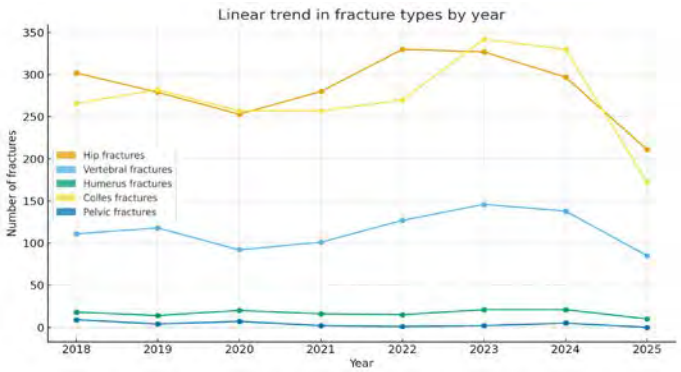
T-score showed a markedly greater improvement (+1.03), reaching high responsiveness (SRM=1.43, p<0.001). Lumbar BMD increased by +0.070 g/cm² (+10.5%), demonstrating strong responsiveness (SRM=1.34, p<0.001). Correlation between change in TBS index and change in lumbar BMD was minimal (r≈0.01), whereas change in TBS T-score correlated moderately with BMD improvement (r≈0.53). A summary table with descriptive changes are provided.

Metric	Absolute change	Percent change	SRM
TBS index change	0,016	0,017	0,15
TBS T-score change	1,03		1,43
BMD lumbar change	0,07	0,105	1,34

Conclusions: In this real-world analysis, romosozumab produced robust increases in lumbar BMD and TBS lumbar T-score, while the TBS index showed limited sensitivity to change. TBS lumbar T-score exhibited strong responsiveness and appears to be a more reliable parameter for monitoring microarchitectural effects of romosozumab in clinical practice.

P1132

TRANSFORMING OSTEOPOROSIS CARE: MEASURABLE BENEFITS OF IMPLEMENTING A FRACTURE LIAISON SERVICE IN A REGIONAL HOSPITAL



M. Robustillo-Villarino[1], A. Zúñiga-Vera[1], M. Sanabria-Hernández[1]

[1]HOSPITAL UNIVERSITARIO DE LA PLANA, VILA-REAL, Spain

Objectives: Fracture Liaison Services (FLS) have demonstrated effectiveness in reducing secondary fractures, improving treatment initiation, and optimizing follow-up of patients at high fracture risk. The FLS of Hospital Universitario de la Plana was implemented 18 months ago, providing an opportunity to evaluate early changes in fracture epidemiology and osteoporosis-related risk profiles. The objective was to describe temporal trends in patient characteristics, fracture types, and clinical risk factors before and after FLS implementation, using a stratified analysis by year in patients who presented and osteoporotic fracture.

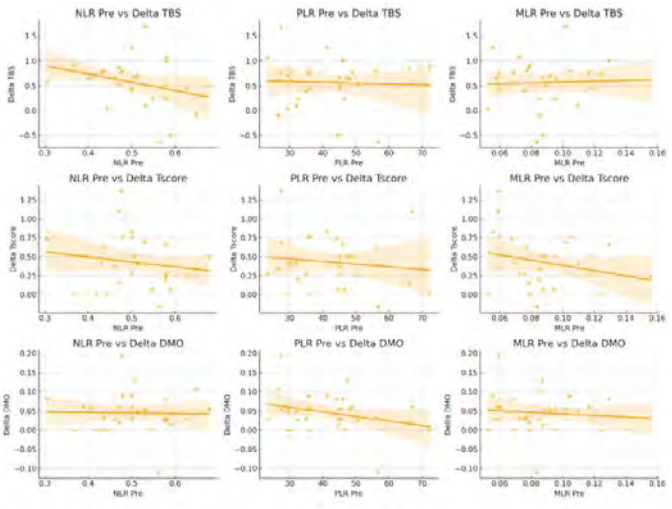
Methods: A retrospective cohort was constructed from the hospital emergency registry covering **2018–2025**. **Only patients presenting with a clinical osteoporotic fracture** (hip, vertebral, humeral, Colles, or pelvic) were included. Patients <45 years were excluded. Annual strata were analyzed using descriptive statistics for continuous and dichotomous variables. Fracture incidence patterns were compared across years, with specific assessment of trends during the **18-month post-FLS period** (June 2024–December 2025).

Results: A total of **5,538 patients** were evaluated (4,602 pre-FLS; 936 post-FLS). Demographic and functional profiles remained stable across years. Documentation of classical osteoporosis risk factors improved after FLS implementation. Fracture distributions showed a relative reduction in hip and vertebral fractures post-FLS, alongside increased detection of peripheral fractures. Early indicators suggested lower-severity presentations and shorter hospital stays, consistent with strengthened secondary prevention pathways.

Conclusions: Introducing an FLS in June 2024 was associated with better risk-factor documentation, shifts in fracture patterns, and early signals of reduced major osteoporotic fractures. These findings support the positive early impact of the FLS and reinforce the need for continued long-term monitoring.

P1133

INTEGRATING BONE QUALITY AND SYSTEMIC HEALTH: ROMOSOZUMAB-DRIVEN MICROARCHITECTURAL GAINS AND THEIR RELATIONSHIP WITH INFLAMMATION AND CARDIOVASCULAR RISK



M. Robustillo-Villarino[1], A. Zúñiga-Vera[1], M. Sanabria-Hernández[1]

[1]HOSPITAL UNIVERSITARIO DE LA PLANA, VILA-REAL, Spain

Objective Trabecular Bone Score (TBS) provides complementary information on trabecular microarchitecture, whereas bone mineral density (BMD) reflects bone quantity. Inflammatory ratios such as neutrophil-to-lymphocyte (NLR), platelet-to-lymphocyte (PLR), and monocyte-to-lymphocyte (MLR) are recognised biomarkers of subclinical inflammation and surrogate indicators of cardiovascular risk (CVR). Given ongoing debate about the cardiovascular safety of romosozumab, it is relevant to determine whether this anabolic agent modifies inflammatory markers linked to vascular risk. No previous real-world study has evaluated changes in these biomarkers under romosozumab. The objective was to assess changes in TBS, BMD, densitometric T-scores and inflammatory ratios after 12 months of romosozumab, and to determine whether treatment influences markers of subclinical inflammation associated with CVR.

Methods: A total of 60 postmenopausal women with paired baseline and 12-month DXA scans were included. Mean age was 66.6 ± 9.5 years. Comorbidities included hypertension (43%), dyslipidaemia (38%), diabetes mellitus (3%) and inflammatory diseases (17%). Previous fractures were present in 42%. Prior osteoporosis treatments included bisphosphonates (52%), denosumab (23%), and teriparatide (8%). Outcomes were changes in TBS index, lumbar TBS T-score, lumbar and femoral BMD, and corresponding T-scores; NLR, PLR and MLR were assessed at baseline and at 12 months.

Results: Lumbar BMD increased from 0.699 to 0.771 g/cm² (+10.2%), lumbar TBS T-score improved by +1.04, and TBS index increased by +1.7%. Baseline inflammatory ratios did not showed associations with ΔT-score or ΔBMD but baselina NLR moderately correlated with ΔTBS (r≈−0.63). Importantly, inflammatory ratios remained stable over 12 months, showing no evidence of systemic inflammatory activation.

Linear regression models showed **low predictive capacity** of NLR, PLR, or MLR on changes in TBS, T-score, or BMD ($R^2 < 0.1$ in all models)

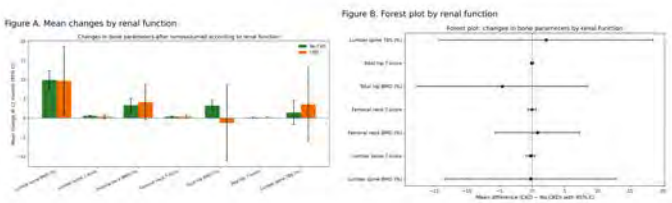
Conclusions: Romosozumab produced substantial anabolic effects on bone without altering inflammatory ratios linked to CVR. These findings support that romosozumab exerts a purely anabolic mechanism, maintains stable subclinical inflammation, and shows a neutral cardiovascular profile in real-world practice.

P1134

ROMOSOZUMAB IN PATIENTS WITH CHRONIC KIDNEY DISEASE AND VERY HIGH FRACTURE RISK: REAL-WORLD EVIDENCE TO GUIDE THERAPEUTIC DECISION-MAKING

M. Robustillo-Villarino[1], A. Zúñiga-Vera[1], M. Sanabria-Hernández[1]

[1]HOSPITAL UNIVERSITARIO DE LA PLANA, VILA-REAL, Spain



Objective: Chronic kidney disease (CKD) is associated with a markedly increased fracture risk, particularly vertebral fractures, which are frequently underdiagnosed and contribute to increased morbidity and mortality. Bone fragility in CKD results from the coexistence of traditional osteoporosis risk factors and CKD-related disturbances in bone and mineral metabolism, with predominant involvement of cortical bone. Although the predictive value of bone mineral density (BMD) in CKD was previously debated, recent evidence supports the use of BMD and Trabecular Bone Score (TBS) for fracture risk assessment and therapeutic decision-making. Nevertheless, concerns regarding efficacy and safety contribute to persistent undertreatment. Real-world data on the skeletal response to romosozumab according to renal function remain scarce. The objective was to evaluate the impact of baseline renal function on densitometric response, changes in T-score, and TBS after 12 months of romosozumab treatment in patients with osteoporosis at very high fracture risk.

Methods: Longitudinal observational real-world study including patients who completed 12 months of romosozumab and had baseline and follow-up densitometry. CKD was defined as estimated glomerular filtration rate <60 mL/min/1.73 m². Absolute and percentage changes in BMD at the lumbar spine, femoral neck, and total hip were analysed, together with changes in T-score and TBS. Comparisons between patients with and without CKD were adjusted for age, baseline densitometric values, vitamin D levels, baseline parathyroid hormone, and prior bisphosphonate exposure.

Results: Fifty patients were included, of whom 12% had CKD. Baseline parathyroid hormone levels were similar between groups, with a non-significant trend toward higher values at 12 months in CKD patients. After treatment, significant BMD increases were observed at all skeletal sites, particularly at the lumbar spine. Changes in BMD, T-score, and TBS were comparable between patients with and without CKD, with no significant between-group differences.

Descriptive analysis of clinical and analytical variables

Variable	Result
Age (years)	66.2 ± 7.9
Early menopause	9/51 (17.6%)
Diabetes mellitus	2/51 (3.9%)
Current smoking	6/51 (11.8%)
Alcohol consumption	1/51 (2.0%)
Family history of hip fracture	5/49 (10.2%)
History of vertebral fracture	14/51 (27.5%)
History of hip fracture	5/49 (10.2%)
History of proximal humerus fracture	4/51 (7.8%)
History of Colles' fracture	10/51 (19.6%)
Glucocorticoid therapy	4/51 (7.8%)
Inflammatory disease	8/51 (15.7%)
Previous bisphosphonate treatment	28/51 (54.9%)
Baseline 25(OH)D (ng/mL)	28.9 ± 9.3
Baseline calcium (mg/dL)	9.47 ± 0.44
Calcium at 12 months (mg/dL)	9.45 ± 0.44
eGFR <60 mL/min/1.73 m²	6/51 (11.8%)
eGFR 30–59 mL/min/1.73 m²	6/51 (11.8%)

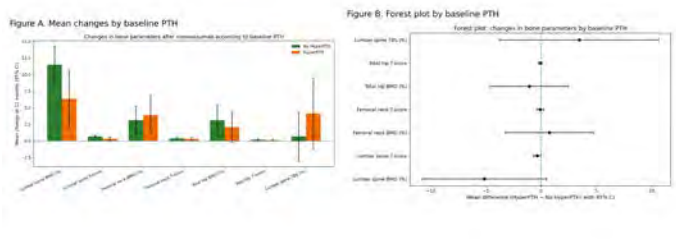
BASELINE HYPERPARATHYROIDISM AND PRIOR BISPHOSPHONATE EXPOSURE IDENTIFY A CLINICAL PROFILE ASSOCIATED WITH RESPONSE TO ROMOSOZUMAB IN PATIENTS AT VERY HIGH FRACTURE RISK

M. Robustillo-Villarino[1], A. Zúñiga-Vera[1], M. Sanabria-Hernández[1], P. Martínez-Fernández[1]

[1]HOSPITAL UNIVERSITARIO DE LA PLANA, VILA-REAL, Spain

Objective: Romosozumab (ROMO) is an anabolic therapy with a dual mechanism of action, with beneficial effects on both trabecular and cortical bone and proven antifracture efficacy. In contrast, hyperparathyroidism (hyperPTH) is associated with cortical bone deterioration (reduced cortical thickness and strength), while its effects on trabecular bone are more variable. It is clinically relevant to assess

whether hyperPTH modulates the skeletal response to ROMO in patients with osteoporosis (OP). The objective was to evaluate the influence of hyperPTH on changes in bone mineral density (BMD), T-score, and Trabecular Bone Score (TBS) after 12 months of ROMO treatment, and to explore the modulatory role of prior bisphosphonate (BP) therapy in real-world practice.



Methods: This longitudinal observational real-world study included patients with OP at very high fracture risk who completed 12 months of ROMO treatment. HyperPTH was defined as baseline parathyroid hormone (PTH) >65 pg/mL. Absolute and percentage changes in BMD at the lumbar spine (LS), femoral neck (FN), and total hip (TH), as well as changes in T-score and TBS, were analysed. Unadjusted comparisons and multivariable linear regression models adjusted for age, baseline densitometric values, renal function, vitamin D levels, and prior BP treatment were performed, including interaction terms.

Results: Fifty women were included. In unadjusted analyses, patients with hyperPTH showed lower gains in LS BMD and T-score compared with those with normal PTH levels, while differences at FN, TH, and in TBS were smaller and not significant. In adjusted models, hyperPTH remained associated with a reduced LS response, although this effect was attenuated after accounting for prior BP treatment. Interaction analyses suggested a greater negative impact of hyperPTH in BP-naïve patients, without reaching statistical significance.

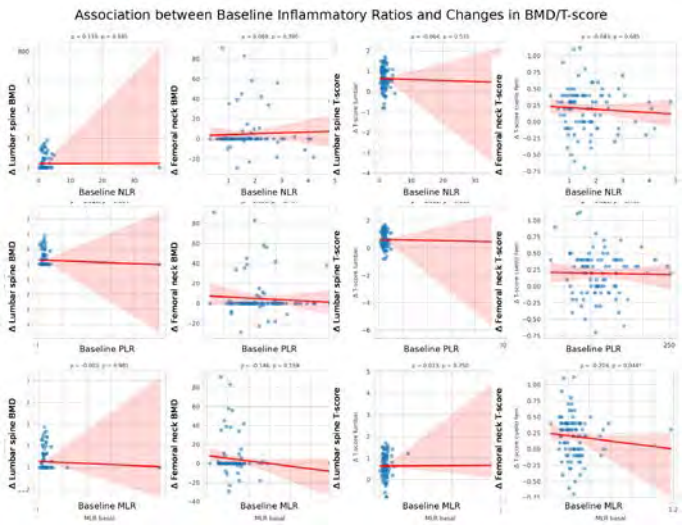
Conclusions: In patients with OP treated with romosozumab, BMD gains are observed, but their magnitude is modulated by the presence of hyperPTH compared with patients without this condition, particularly at LS. Prior BP treatment appears to attenuate this effect. Assessment of baseline PTH status and treatment history may help identify patients with complex OP in whom romosozumab represents an appropriate therapeutic option.

Descriptive analysis of clinical and analytical variables

Variable	Result
Age (years)	66.2 ± 7.9
Early menopause	9/51 (17.6%)
Diabetes mellitus	2/51 (3.9%)
Current smoking	6/51 (11.8%)
Alcohol consumption	1/51 (2.0%)
Family history of hip fracture	5/49 (10.2%)
History of vertebral fracture	14/51 (27.5%)
History of hip fracture	5/49 (10.2%)
History of proximal humerus fracture	4/51 (7.8%)
History of Colles' fracture	10/51 (19.6%)
Glucocorticoid therapy	4/51 (7.8%)
Inflammatory disease	8/51 (15.7%)
Previous bisphosphonate treatment	28/51 (54.9%)
Baseline 25(OH)D (ng/mL)	28.9 ± 9.3
Baseline calcium (mg/dL)	9.47 ± 0.44
Calcium at 12 months (mg/dL)	9.45 ± 0.44
eGFR <60 mL/min/1.73 m²	6/51 (11.8%)
eGFR 30–59 mL/min/1.73 m²	6/51 (11.8%)
eGFR 15–29 mL/min/1.73 m²	0/51 (0.0%)
PTH ≤65 pg/mL	51/51 (100.0%)
PTH >65 pg/mL	0/51 (0.0%)
FRAX major osteoporotic fracture risk (%)	8.66 ± 4.78
FRAX hip fracture risk (%)	3.05 ± 2.81

P1136

BLOOD CELL COUNT–DERIVED INFLAMMATORY RATIOS AND SKELETAL RESPONSE TO ROMOSOZUMAB: A MULTICENTER REALWORLD COHORT



A. Zúñiga-Vera[1], M. Sanabria-Hernández[1], L. Gifre-Sala[2], A. Naranjo-Hernández[3], S. Ojeda[3], E. Naveda[3], R. Durán-Rodríguez[2], M. Robustillo-Villarino[1]

[1]HOSPITAL UNIVERSITARIO DE LA PLANA, VILA-REAL, Spain; [2]Hospital Universitari Trias i Pujol, Badalona, Spain; [3]Hospital universitario de Gran Canaria Dr Negrín, Gran Canaria, Spain

Objectives:
To assess whether baseline complete blood count (CBC)–derived inflammatory ratios—neutrophiltolymphocyte ratio (NLR), platelettolymphocyte ratio (PLR), and monocytetolymphocyte ratio (MLR)—are associated with 12month changes in bone parameters (BMD, Tscore and trabecular bone score [TBS]) in patients treated with romosozumab.

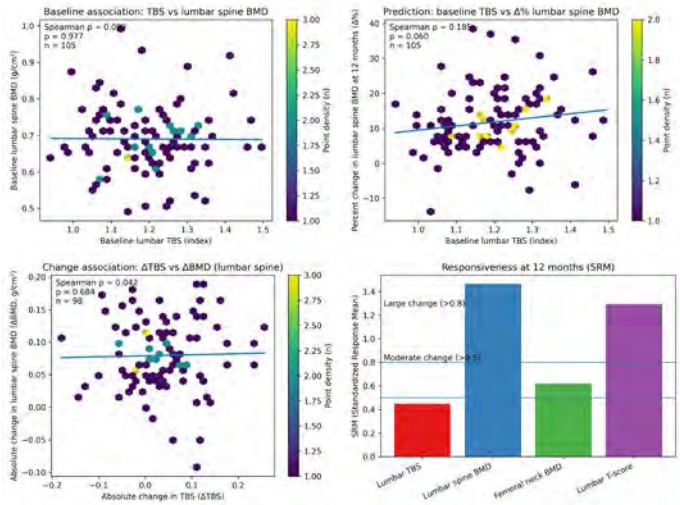
Material and Methods:
Retrospective, multicenter observational study including osteoporotic patients treated with romosozumab 210 mg monthly for 12 months at three Spanish hospitals. CBCderived ratios (NLR, PLR, MLR) were calculated at baseline and month 12. DXA outcomes included lumbar spine (LS), femoral neck (FN) and total hip (TH) BMD (g/cm²) and Tscores; lumbar TBS was analyzed when available. Pre–post changes were evaluated with paired Wilcoxon tests. Associations between baseline ratios and changes in bone outcomes were tested using Spearman correlation. Subgroups were explored by NLR tertiles and by NLR >3 vs ≤3.

Results:
A total of 154 patients were included (98.7% women; mean age 65.9±8.8 years). Baseline ratios were: median NLR 1.42 (IQR 1.05–1.87), PLR 113.6 (87.7–147.7) and MLR 0.24 (0.18–0.30). At 12 months, significant gains were observed in LS BMD (+11.5±8.7%, p<0.001), LS Tscore (+0.64±0.54, p<0.001) and FN Tscore (+0.23±0.42, p<0.001). Lumbar TBS increased modestly and did not reach conventional significance (+0.016±0.10, p=0.055). No significant correlations were found between baseline inflammatory ratios and changes in BMD, Tscore or TBS (Spearman ρ −0.04 to 0.14; all p>0.05). Bone responses did not differ across NLR tertiles or by NLR >3 (all p>0.05). CBCderived ratios did not change significantly over 12 months (all p>0.05).

Conclusions:
Baseline CBCderived inflammatory ratios (NLR, PLR, MLR) did not predict the magnitude of skeletal response to romosozumab in this realworld cohort. These findings support a predominantly direct anabolic effect of romosozumab on bone, consistent with the rapid BMD gains reported in pivotal trials, with no measurable modulation by lowgrade systemic inflammation.

P1137

TBS FOR MONITORING OSTEOPOROSIS DURING ROMOSOZUMAB: FEASIBILITY, RESPONSIVENESS AND LEAST SIGNIFICANT CHANGE IN A MULTICENTER COHORT



M. Robustillo-Villarino[1], A. Zúñiga-Vera[1], M. Sanabria-Hernández[1], A. Naranjo-Hernández[2], L. Gifre-Sala[3], R. Durán-Rodríguez[3], E. Naveda[2], S. Ojeda[2]

[1]HOSPITAL UNIVERSITARIO DE LA PLANA, VILA-REAL, Spain; [2]Hospital universitario de Gran Canaria Dr Negrín, Gran Canaria, Spain; [3]Hospital Universitari Trias i Pujol, Badalona, Spain

Objectives:
To evaluate the feasibility and longitudinal performance of lumbar trabecular bone score (TBS) versus BMD and Tscores during 12 months of romosozumab, using an individuallevel interpretation based on the least significant change (LSC).

Material and Methods:
Retrospective, multicenter study of women treated with romosozumab for 12 months. DXA was performed at baseline and followup to obtain lumbar spine (LS; L1–L4) and proximal femur outcomes, including LS, femoral neck (FN) and total hip (TH) BMD (g/cm²) and Tscores. Lumbar TBS was derived from LS DXA images using dedicated software (TBS iNsight®). Changes were expressed as absolute (Δ) and percent (Δ%) change, and responsiveness was quantified by the standardized response mean (SRM = mean change/SD of the change). Using a "detectable change" approach, TBS response was categorized by whether changes exceeded the 95% LSC, and the proportions with |Δ%| ≥3.0% and ≥5.8% were estimated. Bone turnover markers (BTM) P1NP and βCTX were analyzed when available. Spearman correlations assessed relationships between baseline TBS and baseline LS BMD, between baseline TBS and %Δ LS BMD, and between ΔTBS and ΔLS BMD.

Results:
One hundred eleven women were included (mean age 68.4±8.6 years); 4.5% had diabetes, 40.5% hypertension, and 87.4% prior fracture. At 12 months, LS BMD increased by 11.5% (SRM 1.47; p<0.001), FN BMD by 3.7% (SRM 0.62; p<0.001) and TH BMD by 4.0% (SRM 0.58; p<0.001). LS Tscore improved by +0.67 (SRM 1.29; p<0.001). Lumbar TBS increased by +0.035 (Δ% 3.10; SRM 0.45; p<0.001). TBSadjusted LS Tscore increased by +0.81 (SRM 1.00; p<0.001). P1NP showed no significant change (p=0.837) and βCTX tended to decrease (p=0.142). No correlation was observed between baseline TBS and baseline LS BMD (ρ=0.003; p=0.977) or between ΔTBS and ΔLS BMD (ρ=0.042; p=0.684). Baseline TBS showed a nonsignificant trend with %Δ LS BMD (ρ=0.185; p=0.060).

Conclusion:
In routine clinical practice, lumbar TBS is feasible and demonstrates modest but statistically robust responsiveness to romosozumab (SRM 0.45 at 12 months). While BMD remains the primary monitoring parameter, TBS may provide complementary information for individual followup when interpreted against LSC thresholds, consistent with an anabolic treatment profile as shown in pivotal romosozumab trials.

P1138

POSTMENOPAUSAL OSTEOPOROSIS AND COMORBID PATHOLOGY

M. Rostom[1], N. V. Zhuravleva[2], T. L. Smirnova[2], V. N. Diomidova[2]

[1]Beni-Suef Hospital, Beni-Suef, Egypt; [2]Chuvash State University named after I. N. Ulyanov, Cheboksary, Russia

Objective. When treating patients with postmenopausal osteoporosis, it is important to assess the impact of comorbid pathology on the progression of the disease.
Material and methods. A retrospective analysis of the management of 86 women with primary osteoporosis and a history of one or more fractures was conducted. An analysis of the medical documentation of outpatient patients at the rheumatologist's office at the Osteoporosis Prevention Center, and outpatient and inpatient patients at the city rheumatology center was performed.
Results. In first place (72.5%) in frequency in patients with osteoporosis, concomitant cardiovascular pathology was identified, its nosological distribution is as follows: arterial hypertension - 41%; coronary heart

disease – 26%, a combination of hypertension and coronary heart disease – 27%, other diseases (congenital or acquired heart disease, myocarditis, rhythm and conduction disorders) – 6%. At the same time, of the patients with cardiovascular pathology, the number of patients with CHF was 83%.
In second place is osteoarthritis with predominant damage to the joints of the lower extremities – 68%. Damage to the joints of the lower extremities leads to loss of stability when walking; degenerative changes in the ligamentous apparatus and muscles contribute to loss of balance and increase susceptibility to falls, which are an independent risk factor for osteoporotic fractures. Moreover, 73% of patients with a combination of osteoarthritis and osteoporosis belong to the age group over 70 years.
The third most common nosology is bronchial asthma and/or chronic obstructive pulmonary disease (COPD) – 17.5%.
Other comorbid conditions in patients with postmenopausal osteoporosis amounted to 13.5%. Combinations of major comorbid diseases were distributed as follows: hypertension and osteoarthritis is 53.6%, ischemic heart disease and hypertension in combination with osteoarthritis is 21.3%, ischemic heart disease and asthma is 2.8%, osteoarthritis and asthma are 6.1%, respectively, osteoarthritis and in combination with ischemic heart disease is 18.9%.
Conclusions. Patients with complicated osteoporosis are characterized by polymorbidity. The most common are osteoarthritis and diseases of the cardiovascular system, complicated by chronic heart failure.

P1139

ADHERENCE TO THERAPY IN PATIENTS WITH OSTEOPOROSIS: ANALYSIS OF FACTORS AND DYNAMICS

M. Rostom[1], N. V. Zhuravleva[2], T. L. Smirnova[2], V. N. Diomidova[2]

[1]Beni-Suef Hospital, Beni-Suef, Egypt; [2]Chuvash State University named after I. N. Ulyanov, Cheboksary, Russia

Objective. Assessment of treatment adherence in patients with osteoporosis and identification of associated factors determine prognosis and quality of life.
Materials and methods. The prospective study included 94 patients with a verified diagnosis of osteoporosis. Patients were stratified into two groups: 32 patients without a history of fractures and 62 patients with a history of low-energy fractures.
The last group included patients with fractures: Collis (n=30), ribs (n=3), proximal femur (n=8), sternum (n=2), vertebral compression fractures (n=17) and ankle (n=2). The following number of patients were prescribed oral bisphosphonates as primary therapy: weekly oral bisphosphonates - 36, monthly - 24, quarterly intravenous - 15, intravenous annual - 9, strontium ranelate - 2, denosumab - 7. Treatment adherence was assessed at 12 and 24 months from the start of therapy.
Results. Dynamics of adherence after 12 months: among patients without anamnestic fractures, 14 people (34.4%) stopped therapy. In the group of patients who suffered fractures, refusal of treatment was noted in 12 people (24.1%).
Dynamics of adherence after 24 months: the proportion of patients who stopped treatment increased: among patients without fractures - up to 17 people (53.1%), among patients with fractures - up to 21 people (65.6%). It is important to note that among the patients who discontinued therapy, there were no patients with a history of femur or ankle fractures.
Analysis of the dynamics of therapy discontinuation in the period from 12 to 24 months: the largest increase in the number of patients who stopped therapy was observed in the groups receiving oral bisphosphonates. In the group of monthly administration of bisphosphonates, the proportion of those who stopped treatment increased from 12.5% to 41.6% (10 people), and in the group of weekly administration of bisphosphonates - from 13.8% to 58.3% (21 people).
The reasons for discontinuing medications include inconvenience of administration, poor tolerability, high cost.
Conclusions. Adherence to therapy was statistically significantly higher in patients with a history of fractures, especially fractures of the lower extremities. Discontinuation of intravenous bisphosphonates during the first year of therapy was associated with high drug costs and adverse events.

P1140

MENTAL DISORDERS IN GERIATRIC PATIENTS WITH SARCOPENIA AND SARCOPENIC OBESITY

M. Rostom[1], N. V. Zhuravleva[2], T. L. Smirnova[2], V. N. Diomidova[2]

[1]Beni-Suef Hospital, Beni-Suef, Egypt; [2]Chuvash State University named after I. N. Ulyanov, Cheboksary, Russia

Objective. To study the incidence of depression, sleep disorders, fatigue and loneliness in geriatric patients with sarcopenia and sarcopenic obesity.
Materials and methods. 73 patients took part in the study. The level of depression, loneliness, fatigue and sleep disturbances was assessed using standardized instruments. Diagnosis of sarcopenic syndromes was carried out in accordance with the criteria of EWGSOP (2018) and ESPEN and EASO (2022). Depression was assessed using the Geriatric Depression Scale (GDS-15). The level of loneliness was determined using the UCLA Loneliness Scale. Clinically significant fatigue was defined as 36 or more points on the FSS (Fatigue Severity Scale).
Results. The average age of the patients was 77.51±5.31 years, women predominated (71.46%). Various NS sleep disorders were observed in 72.65% of respondents, high and average levels of loneliness – in 57.54%. Clinically significant fatigue was detected in 68.15%, increased levels of depression – in 48.29% of patients. Direct statistically significant correlations were established between fatigue and depression ($r=0.41$, $p<0.001$), as well as loneliness and depression ($r=0.45$, $p<0.001$).
After additional examination, the patients were divided into three groups: with sarcopenia (n=13), with sarcopenic obesity (n=41) and a control group (without signs of sarcopenia) (n=19). Fatigue was most pronounced in patients with sarcopenia (56 (36.25; 62) points) and sarcopenic obesity (50 (37.75; 54.25) points), $p=0.32$, compared with the control group (31 (27.5; 51.25) points), $p<0.05$. The largest number of patients with clinically significant fatigue belonged to the sarcopenic obesity group (79.49%). In the same group, a moderate direct correlation between fatigue and depression was revealed ($r=0.37$, $p=0.01$).
Conclusions. The high incidence of mental disorders in patients with sarcopenic syndromes indicates the need for early diagnosis and timely correction of these conditions in geriatric practice. The findings highlight the importance of a comprehensive approach to the management of geriatric patients, including assessment of both physical and mental health.

P1141

RISK FACTORS FOR OSTEOPOROSIS IN PATIENTS WITH CALCIUM PYROPHOSPHATE DEPOSITION DISEASE

M. Rostom[1], N. V. Zhuravleva[2], T. L. Smirnova[2], V. N. Diomidova[2]

[1]Beni-Suef Hospital, Beni-Suef, Egypt; [2]Chuvash State University named after I. N. Ulyanov, Cheboksary, Russia

Objective. To determine the prognostic significance of individual factors in the development of osteoporosis in patients with calcium pyrophosphate deposition disease (CPDD).

Materials and methods. An open prospective study was conducted with the participation of 90 patients. The main group consisted of 61 patients with a verified diagnosis of calcium pyrophosphate deposition disease (CPDD) (33 men and 28 women). The control group consisted of 28 patients with osteoarthritis (8 men and 20 women). The diagnosis of calcium pyrophosphate deposition disease (CPDD) was established according to the McCarty criteria. All study participants underwent densitometry at the initial stage and at the end of the study to assess bone mineral density (BMD) in the lumbar spine, femoral neck, and forearm bones.

Results and discussion. The baseline characteristics of the patients in terms of gender, age and disease duration did not reveal statistically significant differences between the groups. At the end of the follow-up period, osteoporosis was diagnosed in 22 (36%) of 61 patients with calcium pyrophosphate deposition disease (CPPD) (13 men and 9 women) and in 8 (28.6%) of 28 patients with osteoarthritis (2 men and 6 women).

The analysis of risk factors revealed the following associations with the development of osteoporosis in patients with calcium pyrophosphate crystal deposition disease (CDPC): age over 55 years in women RR=5.1; 95% CI=1.019–24.29; p=0.047); age over 65 years in men (RR=3.8; 95% CI=1.25–11.5; p=0.013); hyperparathyroidism (RR=14.28; 95% CI=1.65–136.8; p=0.015); increased erythrocyte sedimentation rate (ESR) > 20 mm/h (RR=3.37; 95% CI=1.12–10.1; p=0.025); elevated C-reactive protein (CRP) values > 5.0 mg/L (RR=5.21; 95% CI=2.03–19.04; p=0.002).

In a multivariate analysis using logistic regression (model sensitivity of 71%, specificity of 82%), the only significant factor associated with the development of osteoporosis in patients with calcium pyrophosphate deposition disease (CPDD) was hyperparathyroidism (RR=13.64; 95% CI=1.04–193.03; p=0.038).

Conclusions. Hyperparathyroidism is associated with the development of osteoporosis in patients with calcium pyrophosphate crystal deposition disease.

P1142

VERTEBRAL FRACTURE MORTALITY: AN OVERLOOKED HIGH-RISK ENTITY IN A MIDDLE EASTERN FRAGILITY FRACTURE COHORT

A. Alamri[1], K. Alamri[1], Y. Alhakami[1], O. Almohareb[1], M. Almehthel[1], M. S. Almohaya[1]

[1]Obesity, Endocrine & Metabolism Center / King Fahad Medical City, Riyadh, Saudi Arabia

Objective:

Fragility fractures, particularly of the hip, are known predictors of excess mortality. However, mortality data specifically for vertebral fractures remains scarce in the Middle East. This study evaluated mortality across fragility fracture types, focusing on vertebral fractures, and assessed current gaps in osteoporosis assessment and treatment.

Methods:

We conducted a retrospective cohort study of adults presenting with fragility fractures to a tertiary care center between February 2021 and July 2025. Fractures were categorized as hip, vertebral, femoral shaft, or others. Outcomes included all-cause mortality, bone mineral density (BMD) testing, and initiation of osteoporosis therapy. Mortality rates were compared using Fisher's exact test. Multivariable logistic regression was performed to identify predictors of treatment initiation.

Results:

Among 227 patients, overall mortality was 11.0% (n=25). Mortality following vertebral fractures was 17.3% (9/52), with no significant difference observed compared to hip fracture mortality at 14.1% (13/92; p=0.64) and substantially higher than femoral shaft fractures (3.8%; 3/79). Our observed vertebral fracture mortality rates were aligned with those reported in international cohort studies. Despite this risk, major care gaps were identified. Among patients with hip or vertebral fractures, 71.5% (103/144) did not receive osteoporosis therapy. Furthermore, 89.3% (92/103) of untreated hip or vertebral fracture patients lacked BMD testing following fracture. Female sex was the strongest independent predictor of treatment initiation (OR 8.58, 95% CI 2.4–37.0; p=0.0017), indicating marked undertreatment of men independent of age, fracture type, and endocrine follow-up.

Conclusions:

In this Middle Eastern cohort, vertebral fractures were associated with a mortality burden statistically equivalent to hip fractures, challenging their perception as lower-risk events. Despite this, over two-thirds of patients with hip or vertebral fractures remained untreated, with major diagnostic and therapeutic gaps, particularly among men. These findings highlight vertebral fractures as a an improtant yet under-recognized target for Fracture Liaison Services to reduce post-fracture mortality.

P1143

GYNECOLOGICAL PROFILE OF NON-MENOPAUSAL WOMEN WITH RHEUMATOID ARTHRITIS

M. S. Mahjoub[1], R. L. Rouached[1], G. M. Garci[1], B. D. S. Ben Dhia[1], B. S. Bouden[1], M. I. Mahmoud[1], R. T. Tekaya[1], B. T. A. Ben Tekaya[1], A. L. Abdelmoula[1], M. N. Mathlouthi[1]

[1]Rheumatology department, Charles Nicolle Hospital, Tunsiia, Tunis, Tunisia

Objective: Rheumatoid arthritis (RA) is the most common chronic inflammatory rheumatism and predominantly affects women of childbearing age. Despite the stakes in reproductive health, the gynecological profile of patients with RA remains understudied.
Our objective was to evaluate the prevalence of fertility disorders, vaginal dryness, and endometriosis in this population and to study their associations with the characteristics of RA.

Methods: A cross-sectional, descriptive, and observational study, including women aged 18 years or older, non-menopausal, diagnosed with RA according to the ACR 1987 or ACR/EULAR 2010 criteria.
The socio-demographic, clinical, and biological data were collected in a standardized manner. The gynecological profile was evaluated by searching for fertility issues, vaginal dryness, and endometriosis.
Endometriosis was screened by the ENDOL4D score and pelvic ultrasound.

Results: Fifty patients were included, with an average age of 39 years, and an average duration of RA evolution of 8.5 years. RA was immuno-positive in 27% of cases.
A fertility disorder was observed in 31% of the patients, including subfertility in 19% and infertility in 12%. Vaginal dryness was reported by 22%, associated with dyspareunia in 9%. A high probability of endometriosis was identified in 20%.
The duration of RA evolution was significantly longer in patients with fertility issues, with an optimal predictive threshold of 6 years (Se 84.2%, Sp 55.2%).
Vaginal dryness was associated with VAS pain scores >5, EGP >7, and high activity according to CDAI.
ACPA was significantly more frequent in patients with a high probability of endometriosis (p=0.02).

Conclusion: Fertility issues, vaginal dryness, and endometriosis are common among non-menopausal women with RA. Their screening should be systematic, especially if the RA has been evolving for more than six years for fertility issues, high activity for vaginal dryness, and ACPA positivity for

P1144

RHEUMATOID ARTHRITIS AND FEMALE FERTILITY: WHAT IS THE IMPACT OF THE DISEASE?

M. S. Mahjoub[1], R. L. Rouached[1], G. M. Garci[2], B. D. S. Ben Dhia[1], M. I. Mahmoud[1], R. T. Tekaya[1], B. T. A. Ben Tekaya[1], A. L. Abdelmoula[1], M. N. Mathlouthi[2], B. S. Bouden[1]

[1]Rheumatology department, Charles Nicolle Hospital, Tunsiia, Tunis, Tunisia; [2]Gyneacology department, Charles Nicolle Hospital, Tunis, Tunisia, Tunis, Tunisia

Objective. Infertility is defined as the absence of conception after 12 months of unprotected sexual intercourse. It may be primary or secondary. Its prevalence in the general population is estimated between 16.5% and 17.8% [1]. Subfertility is defined either as a conception delay exceeding 12 months or a history of at least one unsuccessful pregnancy in a nulliparous woman. The objective was to determine the frequency and type of fertility disorders (infertility or subfertility) among women with RA of reproductive age, and to identify associated factors.

Methods. A cross-sectional study was conducted including women aged ≥18 years with RA according to the ACR/EULAR 2010 classification criteria. A fertility disorder was defined as the presence of infertility or subfertility. The population was divided into two groups:
• Group A: patients with a fertility disorder
• Group B: patients without a fertility disorder
A comparison of sociodemographic and RA-related characteristics was performed between the two groups.
Results. Forty-two patients were included. The mean age was 39 ± 5.6 years, the median RA duration was 8 years [8–14], and the median age at RA diagnosis was 33 years [25.75–37.25]. Fertility disorder was identified in 31% of patients: subfertility in 19% (conception delay >12 months: 10%; unsuccessful pregnancy: 9%) and infertility in 12% (80% of which was primary).
Comparative analysis showed that disease duration was significantly longer in patients with a fertility disorder (11 years [8–19] vs 5 years [4–13], p=0.04). ROC analysis confirmed its predictive role: AUC = 0.7 (p=0.049), with an optimal threshold >6 years (Se = 84.2%, Sp = 55.2%, PPV = 45.8%, NPV = 88.9%). No significant differences were found regarding age, RA serology, erosive status, disease activity, or composite scores (CDAI, SDAI, DAS28-CRP).

Conclusions. In women with RA, screening for fertility disorders is recommended, especially when disease duration exceeds 6 years.

ENDOMETRIOSIS AND RHEUMATOID ARTHRITIS: EXPLORING POSSIBLE LINKS

R. L. Rouached[1], M. S. Mahjoub[1], G. M. Garci[2], B. D. S. Ben Dhia[1], B. S. Bouden[1], M. I. Mahmoud[1], R. T. Tekaya[1], B. T. A. Ben Tekaya[1], A. L. Abdelmoula[1], M. N. Mathlouthi[2]

[1]Rheumatology department, Charles Nicolle Hospital, Tunsiia, Tunis, Tunisia; [2]Gyneacology department, Charles Nicolle Hospital, Tunis, Tunisia, Tunis, Tunisia

Background
Current literature suggests a potential association between endometriosis and rheumatoid arthritis (RA), possibly through immune dysregulation or a shared genetic susceptibility.

Objectives
To identify patient-related or RA-related factors associated with endometriosis among women with RA.

Methods
This was a cross-sectional study including women with RA (according to ACR/EULAR 2010 classification criteria) aged ≥18 years. Endometriosis was screened using the ENDOL4D score, which estimates the probability of the disease (low, moderate, or high), and by transvaginal and/or pelvic ultrasound. The population was divided into two groups (A and B). Group A included patients considered potentially affected by endometriosis, defined by at least one of the following criteria: high probability on ENDOL4D score, ultrasound signs of external endometriosis (sliding sign or endometrioma) or adenomyosis (globular adenomyotic uterus).

Results
Fifty patients were included. The mean age was 39 ± 7 years. Regarding marital status, 64% were married, 16% divorced, 16% single, and 2% widowed. The most frequent educational level was primary school (38%). More than half were unemployed (62%), and 66% had a middle socioeconomic status. Only 4% were smokers. The mean BMI was 26.78 ± 5.56kg/m². RA was diagnosed at 31 ± 9 years, with a median disease duration of 8 [4–14] years. It was seropositive in 70.7%, immunopositive in 27%, and erosive in 80% of cases, with moderate mean disease activity. DMARDs were prescribed in 90% of cases (80% conventional, 24% biologics), and corticosteroids in 76%.
The median ENDOL4D score was 2 [1–61], indicating a low probability in 74% and moderate in 26%. Ultrasound signs of endometriosis or adenomyosis were identified in 20% of patients. Thus, 20% were classified as potentially affected by endometriosis.
Comparison between groups A and B showed no significant sociodemographic differences.Regarding RA-related factors, only anti–citrullinated peptide antibody (ACPA) positivity was significantly associated with potential endometriosis (p=0.02).

Conclusions
Among women with RA, endometriosis appears to be associated with ACPA positivity, suggesting a possible immunological contribution to its pathophysiology.

P1146

GYNECOLOGIC AND OBSTETRIC PROFILE OF WOMEN WITH RHEUMATOID ARTHRITIS

M. S. Mahjoub[1], R. L. Rouached[1], G. M. Garci[2], B. D. S. Ben Dhia[1], B. S. Bouden[1], M. I. Mahmoud[1], R. T. Tekaya[1], B. T. A. Ben Tekaya[1], A. L. Abdelmoula[1], M. N. Mathlouthi[2]

[1]Rheumatology department, Charles Nicolle Hospital, Tunsiia, Tunis, Tunisia; [2]Gyneacology department, Charles Nicolle Hospital, Tunis, Tunisia, Tunis, Tunisia

Objective. Rheumatoid arthritis (RA) is a chronic inflammatory rheumatic disease that predominantly affects women between 40 and 60 years of age. Gynecologic and obstetric manifestations in these patients remain poorly studied. The objective was to describe the gynecologic and obstetric profile of women with RA during reproductive age.
Methods. This was a cross-sectional study including non-menopausal women aged over 18 years who met the ACR/EULAR 2010 classification criteria. Gynecologic and obstetric data were collected using a standardized questionnaire.
Results. The mean age was 39 ± 7 years, and the median RA duration was 8.5 years [4–14]. The median age at menarche was 12 years [12–14]. Most patients had regular menstrual cycles (94%), normal menstrual flow (66%), and a mean duration of menstruation of 5 days [2–8]. Short cycles were rare (2%), and 4% presented with oligomenorrhea. Regarding menstrual flow, oligomenorrhea was observed in 6% and polymenorrhea in 28%. Duration of menstruation was mostly normal; hypomenorrhea was found in 4%, with no cases of hypermenorrhea reported. Excluding single women (8%), 57% used contraception: oral hormonal contraception (42%), condoms (33%), intrauterine device (42%), or natural methods (13%). Infertility was identified in 12% of patients, and 19% were nulliparous. The median gravidity was 2.5 [0.75–4], with a median number of living children of 2 [0–3]. Spontaneous miscarriages or early pregnancy losses were reported in 48% of cases. No cases of elective termination or ectopic pregnancy were noted. Among women who had delivered, 2% reported preterm birth, 5% gestational hypertension, and 17% gestational diabetes.
Conclusions. Women with RA of reproductive age show a higher rate of spontaneous miscarriages compared with the general population, highlighting the need for close gynecologic and obstetric monitoring, particularly during the peri-conceptional period.

P1147

OBSTETRICAL OUTCOMES IN WOMEN WITH RHEUMATOID ARTHRITIS: A CROSS-SECTIONAL STUDYC

R. L. Rouached[1], M. S. Mahjoub[1], G. M. Garci[2], B. D. S. Ben Dhia[1], B. S. Bouden[1], M. I. Mahmoud[1], R. T. Tekaya[1], B. T. A. Ben Tekaya[1], M. N. Mathlouthi[2], A. L. Abdelmoula[1]

[1]Rheumatology department, Charles Nicolle Hospital, Tunsiia, Tunis, Tunisia; [2]Gyneacology department, Charles Nicolle Hospital, Tunis, Tunisia, Tunis, Tunisia

Objective. Rheumatoid arthritis (RA) predominantly affects women during their reproductive years. Beyond fertility impairment, pregnancy outcomes in women with RA may be influenced by chronic systemic inflammation, immune dysregulation, and long-term exposure to disease-modifying treatments. The objective was to describe obstetrical outcomes and pregnancy-related complications in women with RA of reproductive age.

Methods. We conducted a cross-sectional study including non-menopausal women with RA. Obstetrical outcomes were analyzed in 37 women with a history of at least one pregnancy. Pregnancy history and obstetrical complications were collected through standardized interviews and medical records when available.

Results. Among the 37 women with prior pregnancies, a history of pregnancy loss was reported in 20 patients (54.1%), including spontaneous miscarriage or arrested pregnancy. Intrauterine fetal death occurred in 2 patients (5.4%), while voluntary pregnancy termination was reported in 8 patients (21.6%). No cases of ectopic pregnancy or therapeutic termination were observed.

Regarding obstetrical complications, preterm delivery was reported in 1 patient (2.7%), hypertensive disorders of pregnancy in 2 patients (5.4%), and gestational diabetes in 7 patients (18.9%).

Conclusion. Women with RA who achieved pregnancy exhibited a substantial burden of adverse obstetrical outcomes, particularly pregnancy loss and gestational complications. These findings underscore the need for early reproductive counseling and close multidisciplinary collaboration between rheumatologists and obstetricians to optimize pregnancy outcomes in women with RA.

P1148

DISCONNECT BETWEEN CLINICAL SCREENING TOOLS AND ULTRASOUND FINDINGS FOR GYNECOLOGICAL ABNORMALITIES IN RHEUMATOID ARTHRITIS

M. S. Mahjoub[1], R. L. Rouached[1], G. M. Garci[2], B. D. S. Ben Dhia[1], B. S. Bouden[1], M. I. Mahmoud[1], R. T. Tekaya[1], B. T. A. Ben Tekaya[1], M. N. Mathlouthi[2], A. L. Abdelmoula[1]

[1]Rheumatology department, Charles Nicolle Hospital, Tunsiia, Tunis, Tunisia; [2]Gyneacology department, Charles Nicolle Hospital, Tunis, Tunisia, Tunis, Tunisia

Objective. Rheumatoid arthritis (RA) is a systemic inflammatory disease predominantly affecting women of reproductive age. Gynecological involvement may remain clinically silent, and screening often relies on symptom-based questionnaires. However, the concordance between clinical screening tools and imaging findings in this population remains uncertain. The objective was to evaluate the agreement between clinical screening tools and pelvic ultrasonography in detecting gynecological abnormalities in women with RA of reproductive age.

Methods. We conducted a cross-sectional study including non-menopausal women with RA. All participants underwent standardized gynecological assessment, including clinical examination and symptom-based screening using the ENDOL4D questionnaire, followed by pelvic ultrasonography (endovaginal or suprapubic as appropriate). Ultrasound abnormalities suggestive of endometriosis or adenomyosis were systematically recorded. Clinical, reproductive, and RA-related characteristics were collected.

Results. Fifty women with RA were included (mean age 39.1 ± 6.9 years). According to the ENDOL4D questionnaire, no patient had a high probability of endometriosis, while 1 patient (2%) had a previously known diagnosis. Clinical gynecological examination revealed no deep bluish nodules suggestive of endometriosis.

In contrast, pelvic ultrasonography identified gynecological abnormalities in 10 patients (20%), including ultrasound features suggestive of adenomyosis in 6 patients (12%), positive sliding sign in 3 patients (6%), and ovarian endometrioma in 1 patient (2%). Importantly, all patients classified as having potential gynecological involvement were detected exclusively by ultrasonography, with no overlap with clinical screening tools or symptom-based assessment.

Conclusion. A marked disconnect exists between clinical screening tools and pelvic ultrasound findings in women with RA of reproductive age. Symptom-based questionnaires and clinical examination alone failed to identify a substantial proportion of patients with ultrasound-detected gynecological abnormalities. These findings highlight the added value of pelvic ultrasonography as a complementary tool in the comprehensive assessment of women with RA.

P1149

ENDOMETRIOSIS-LIKE ULTRASOUND FEATURES IN WOMEN WITH RHEUMATOID ARTHRITIS

R. L. Rouached[1], M. S. Mahjoub[1], G. M. Garci[2], B. D. S. Ben Dhia[1], M. I. Mahmoud[1], R. T. Tekaya[1], B. T. A. Ben Tekaya[1], M. N. Mathlouthi[2], A. L. Abdelmoula[1], B. S. Bouden[1]

[1]Rheumatology department, Charles Nicolle Hospital, Tunsiia, Tunis, Tunisia; [2]Gyneacology department, Charles Nicolle Hospital, Tunis, Tunisia, Tunis, Tunisia

Objective. Rheumatoid arthritis (RA) is a systemic immune-mediated inflammatory disease predominantly affecting women of reproductive age. Chronic inflammation and immune dysregulation may influence hormonally responsive pelvic connective tissues, potentially promoting endometriosis-related structural changes. Pelvic ultrasonography may detect such abnormalities, even in the absence of overt gynecological symptoms. The objective was to assess the prevalence of endometriosis-like ultrasound features in women with RA of reproductive age and to describe their clinical context.

Methods. We conducted a cross-sectional study including non-menopausal women with RA. All patients underwent standardized gynecological evaluation and pelvic ultrasonography (endovaginal or suprapubic, according to sexual status). Ultrasound features suggestive of endometriosis or adenomyosis were systematically recorded. Clinical, reproductive, and disease-related characteristics were collected.

Results. Fifty women with RA were included, with a mean age of 39.1 ± 6.9 years. A previous diagnosis of endometriosis was reported in 1 patient (2%). Pelvic ultrasonography revealed endometriosis-like abnormalities in 10 patients (20%),despite the absence of high clinical suspicion in most cases. Ultrasound findings included signs of adenomyosis in 6 patients (12%), a positive sliding sign in 3 patients (6%), and ovarian endometrioma in 1 patient (2%). Notably, none of

the patients had a high probability of endometriosis according to the ENDOL4D questionnaire, and no deep bluish nodules were detected on clinical gynecological examination. Thus, all patients classified as having potential endometriosis were identified exclusively through ultrasonographic findings. These women were subsequently referred for specialized gynecological assessment, highlighting the ability of ultrasound to detect subclinical pelvic involvement.
Conclusion. Endometriosis-like ultrasound features are frequently detected in women with RA of reproductive age, affecting one in five patients, often in the absence of suggestive symptoms or positive clinical screening tools. Pelvic ultrasonography may represent a valuable adjunct in the systemic assessment of women with RA, supporting the concept of shared immuno-inflammatory connective tissue vulnerability.

P1150

DO FEMALE DOCTORS ADOPT A DIFFERENT DIAGNOSTIC APPROACH TO LOW BACK PAIN AND SCIATICA?

S. R. Safa[1], M. S. Mahjoub[2], B. M. F. Ben Massoud[1], B. S. S. Boussaid[1], R. S. Rekik[1], S. H. Sehli[1]

[1]Rhuematology department, Hopital La Rabta, Tunis, Tunis, Tunisia; [2]Rheumatology department, Charles Nicolle Hospital, Tunsiia, Tunis, Tunisia

Background

Low back pain (LBP), with or without sciatica, is one of the most common reasons for consultation in primary care and represents a major public health concern. Despite the availability of evidence-based guidelines, considerable variability persists in diagnostic practices. Physician-related factors, including sex, may influence clinical decision-making and contribute to these variations.

Objectives

To compare diagnostic management strategies for LBP and sciatica between male and female primary care physicians.

Methods

A national cross-sectional study was conducted among primary care physicians using a self-administered online questionnaire. The survey assessed diagnostic practices, including screening for red flags and signs of severity, imaging prescriptions, laboratory investigations, and referral criteria. Diagnostic practices for LBP and sciatica, including screening for red flags and signs of severity, imaging prescription, and laboratory testing, were compared according to physician sex, with reference to the 2019 French National Authority for Health (HAS) recommendations [1].

Results

A total of 252 primary care physicians were included, of whom 72.6% were women. No significant differences were observed between male and female physicians with regard to age, professional status, or practice setting.

Screening practices differed significantly according to physician sex. Male physicians more frequently screened for red flags than female physicians (78.3% vs 51.4%, p = 0.001). In contrast, female physicians more often assessed signs of severity requiring surgical management compared with male physicians (84.2% vs 68.1%, p = 0.009).

Sex-related differences in imaging prescription were observed only in specific clinical contexts. In acute LBP, female physicians prescribed lumbar spine imaging less frequently than male physicians (41% vs 56.5%, p = 0.027), whereas no difference was found for pelvic radiography prescription. In chronic LBP, imaging practices did not differ significantly between male and female physicians for either lumbar spine or pelvic radiographs (all p > 0.05).

Laboratory testing practices differed only in specific clinical situations. Women were more likely than men to request laboratory investigations at initial presentation (6% vs 0%, p = 0.037). In contrast, laboratory tests prompted by the presence of red flags were more frequently prescribed by male physicians compared with female physicians (88.4% vs 71%, p = 0.04). No significant sex-related differences were observed for laboratory testing in cases of resistance to medical treatment, severe pain, neurological signs, patient request, prior to referral to a specialist, or before epidural infiltration (all p > 0.05).

Conclusion

Sex-related differences were observed in selected aspects of diagnostic management of LBPsciatica, indicating that physician characteristics may influence clinical decision-making in primary care.

[1] Prise en charge du patient présentant une lombalgie commune. Haute Aut Santé n.d. https://www.has-sante.fr/jcms/c_2961499/fr/prise-en-charge-du-patient-presentant-une-lombalgie-commune (accessed April 14, 2025).

P1151

SEX-RELATED DIFFERENCES IN THERAPEUTIC APPROACH TO LOW BACK PAIN AND SCIATICA AMONG PRIMARY CARE PHYSICIANS

S. R. Safa[1], M. S. Mahjoub[1], B. M. F. Ben Massoud[1], B. S. S. Boussaid[1], R. S. Rekik[1], S. H. Sehli[1]

[1]Rhuematology department, Hopital La Rabta, Tunis, Tunis, Tunisia

Objective

Optimal therapeutic management of LBP and sciatica relies on a combination of pharmacological and non-pharmacological approaches, as recommended by international guidelines. However, real-world practice often diverges from these recommendations. The influence of physician sex on therapeutic decision-making in primary care remains insufficiently explored. The objective is to evaluate differences in therapeutic management of LBP and sciatica between male and female primary care physicians.

Methods

This national cross-sectional survey included primary care physicians who completed an online questionnaire evaluating their therapeutic practices for LBP and sciatica. Assessed outcomes included pharmacological prescriptions (analgesics, NSAIDs, opioids, corticosteroids, muscle relaxants), non-pharmacological management (physiotherapy, physical activity advice, lumbar brace use), sick leave prescription, and screening for psychosocial risk factors (yellow flags). Therapeutic strategies were compared according to physician sex.

Results

The study included 252 primary care physicians, of whom 72.6% were women. No significant differences were observed between male and female physicians with regard to age, professional status, or practice setting.

Therapeutic practices differed between male and female physicians in selected aspects of management. Male physicians prescribed sick leave less frequently than female physicians (30.4% vs 72.7%, p < 0.001). They were also more likely to recommend physical therapy (69.6% vs 47.5%, p < 0.001) and to screen for psychosocial risk factors associated with chronicity (yellow flags) (33.3% vs 23%, p < 0.001).
In contrast, no significant sex-related differences were observed in the prescription of analgesics, NSAIDs, muscle relaxants, corticosteroids, lumbar bracing, or advice on physical activity (all p > 0.05).

Conclusion

While pharmacological treatment strategies for low back pain and sciatica appear broadly comparable between male and female physicians, differences emerge in work-related decisions, physical therapy referral, and screening for chronicity risk factors. These findings suggest selective rather than global sex-related variations in therapeutic practice.

P1152

ECOSYSTEM DESIGN FOR THE PREVENTION OF FRACTURES CAUSED BY OSTEOPOROSIS IN SMART HEALTH BASED ON ONTOLOGY

Z. Abdollahzade[1], M. Sanjari[2], A. Mohammadian[1], A. Moini[3]

[1]Department of Information Technology Management, Faculty of Industrial and Technology Management, School of Management, University of Tehran, Tehran, Iran; [2]Osteoporosis Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran; [3]Department of Algorithms and Calculations, Faculty of Engineering Sciences, University of Tehran, Tehran, Iran

Objective: Smart health, due to its capacity in disease prevention, is a suitable solution for providing osteoporosis fracture prevention services. Also, the existence of close relationships between active organizations for the prevention of this disease requires this area to be examined from the perspective of the ecosystem. Therefore, the purpose of this study is to identify the elements and players of the ecosystem for preventing osteoporosis-related fractures in smart health, and then to outline the ontology of this ecosystem and the relationship between its players and to determine the key players.
Materials and Methods: A grounded theory guided method that includes three sources of literature review, interviews, and document review was used to identify elements and players. Interviews were conducted with 31 people active in the management and operational levels of osteoporosis prevention and treatment in the health and other fields (social, cultural, and educational) as well as people with fractures or at risk of fractures; at this stage, the documents and agreements concluded were also reviewed to identify elements and players; data analysis was performed using open, axial, and selective coding. The ontology was also drawn based on the data obtained from the grounded theory guided using Protege software. Subsequently, social network analysis was performed using Gephi software and key players were determined.
Results: Based on the findings from the guided database, 38 final codes, 13 sub-concepts for elements and 50 final codes and 11 sub-concepts for players were identified. Elements were classified into four categories: lifestyle modification, clinical, technological, and contextual; players were also classified into three layers: core, complementary, and facilitator based on the Moor model. By drawing an ontology, elements were identified and players and the relationships between them were depicted. The Ministry of Health and the Osteoporosis Research Center were identified as two key players in the ecosystem.
Conclusion: This study showed that the fracture prevention ecosystem in smart health, in addition to technological and clinical elements, requires lifestyle and contextual factors for fracture prevention. Also, in order to prevent fractures, it is necessary to cooperate with players from other fields, including cultural, social, economic, educational, and political, in addition to the health sector, and the relationship between health sector players and these fields should be strengthened.

P1153

FALL PREVALENCE IN THE EASTERN MEDITERRANEAN REGION (EMRO): A SYSTEMATIC REVIEW AND META-ANALYSIS

E. Hesari[1], M. Sanjari[1], S. Abdollahi[2], V. Mohseni[1], P. Zarepour[3], N. Malekraisi[1], N. Fahimfar[1], K. Khalagi[4], M. J. Mansourzadeh[5], S. Salehi Nezamabadi[1], R. Kalantar Mehrjerdi[6], A. Ostovar[1]

[1]Osteoporosis Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran; [2]Metabolic Disorders Research Center, Endocrinology and Metabolism Molecular -Cellular Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran; [3]School of Public Health, Department of Epidemiology and Biostatistics, Tehran University of Medical Sciences, Tehran, Iran; [4]Obesity and Eating Habits Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran; [5]Prevention of Metabolic Disorders Research Center, Research Institute for Metabolic and Obesity Disorders, Research Institute for Endocrine Sciences, Shahid Beheshti University of Medical Sciences, Tehran, Iran; [6]Endocrinology and Metabolism Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran

Objectives

Falls are a leading cause of fractures, disability, and mortality among older adults worldwide. As the population ages, the burden of falls is expected to rise. In the Eastern Mediterranean Region (EMRO), data on fall prevalence are fragmented and methodologically heterogeneous, which makes regional comparisons and policy planning challenging. We performed a systematic review and meta-analysis to estimate the prevalence of falls in EMRO countries.

Methods

This systematic review and meta-analysis were performed in accordance with PRISMA guidelines. PubMed, Scopus, and Web of Science were searched from inception to 2025. Population-based observational studies reporting fall prevalence among adults in EMRO countries were included. Study quality was assessed using the Newcastle Ottawa Scale. Pooled estimates were calculated using a random effects model. Heterogeneity was assessed with the I^2 statistic, and publication bias was evaluated through funnel plots and Egger's test.

Results

A total of 73 studies from 10 EMRO countries were included. The pooled prevalence of falls was 31% (95% CI: 27-34%, P<0.001). Considerable heterogeneity was observed across studies (I^2 =99.54%). Subgroup analyses revealed higher fall prevalence among adults aged ≥70 years (32%, 95% CI: 31-43%, P<0.001) and among females (37%, 95% CI: 31-

43%, P<0.001). Several EMRO countries lacked nationally representative data, highlighting critical gaps in regional fall surveillance.

Conclusion

Falls reflect a major public health challenge in the EMRO region. These findings emphasize the need for standardized epidemiological studies, improved regional surveillance, targeted fall prevention strategies integrated with aging, osteoporosis care, and fracture prevention programs.

P1154

ASSOCIATION BETWEEN THE TREATMENT-RELATED CHANGE IN BONE MINERAL DENSITY AND FRACTURE RISK REDUCTION ACCORDING TO THE PRE-TREATMENT BMD: ANALYSIS FROM THE FNIH-ASBMR SABRE PROJECT

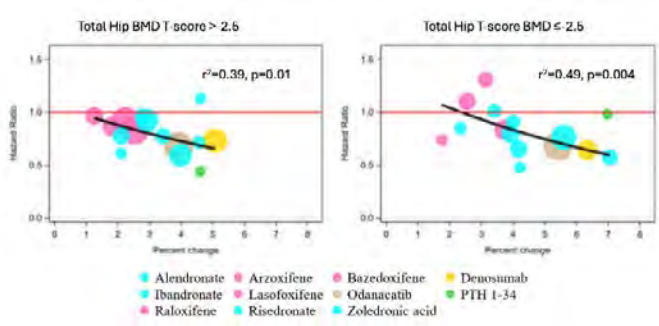
M. Schini[1], L. Lui[2], T. Vilaca[3], S. K. Ewing[4], A. Thompson[4], B. L. Langdahl[5], D. M. Black[4], M. L. Bouxsein[6], R. Eastell[1]

[1]The University of Sheffield, SHEFFIELD, United Kingdom; [2]Research Institute, California Pacific Medical Center, San Francisco, United States; [3]The University of Sheffield, Sheffield, United Kingdom; [4]Department of Epidemiology & Biostatistics, University of California, San Francisco, United States; [5]Department of Clinical Medicine, Department of Endocrinology and Internal Medicine, Aarhus University, Aarhus, Denmark; [6]Center for Advanced Orthopedic Studies, Beth Israel Deaconess Medical Center and Department of Orthopedic Surgery, Harvard Medical School, Boston, United States

Objective

In December 2025, the FDA has qualified the use of total hip BMD (TH BMD) as a surrogate endpoint for future trials of anti-osteoporosis therapies. This was based on analyses and evidence from the FNIH-ASBMR SABRE (Study to Advance BMD as a Regulatory Endpoint) project. However, if future trials do not have to demonstrate anti-fracture efficacy, they may enrol lower-risk subjects. Thus, it is essential to determine whether baseline BMD levels affect the relationship between changes in TH BMD and fracture risk reduction.

Methods



Using the SABRE database, we separated participants into those with a TH BMD T-score ≤ -2.5 and those with a TH BMD T-score> -2.5. We performed trial-level meta-regressions comparing the association between the 24-month between-treatment difference in TH BMD per cent change and clinical fracture risk reduction across baseline TH BMD T-score subgroups. We calculated the r^2 (95% CI) for each group. The clinical fracture category was defined as non-vertebral + clinical vertebral fractures.

Results

Data from 15 trials were included in the meta-regression. There were 20,474 participants in the T-score ≤ -2.5 group and 54,196 in the T-score > -2.5 group. The meta-regression results were similar across groups, with r^2 (95% CI) for the T-score ≤ -2.5 group of 0.49 (0.08 to 0.70), p = 0.004, and for the T-score > -2.5 group, r^2 = 0.39 (0.02 to 0.64), p = 0.01. The p value for the r^2 interaction term was 0.66.

Conclusion

Notably, the range of BMD per cent change was greater in the low-BMD group. This was because the results were expressed as a percentage, however, the absolute changes in BMD were similar. The higher BMD group had more trials from less potent medications. These findings suggest that, in future trials of new osteoporosis treatments where efficacy will be judged by total hip BMD change, participants can be included independently of their baseline total hip T-score, as the association between bone mineral density per cent change and fracture risk reduction is similar.

P1155

INFLUENCE OF LIVING ENVIRONMENT STIMULATION ON KEY COMPONENTS OF AUTONOMY IN OLDER ADULTS

M. Scouvemont[1], C. Schmidt[1], C. Dautremont[1], V. Tannoia[1], G. Schaff[1], N. Beliy[1], C. Elsen[1], S. Adam[1], O. Bruyère[1]

[1]University of Liège, Liège, Belgium

Objective : (1) To examine whether the stimulating nature of the living environment (home and neighborhood) is associated with two key predictors of autonomy in older adults: physical activity and sleep, and (2) to test whether physical activity mediates the association between environmental stimulation and sleep.

Material and Methods: We conducted a cross-sectional study among community-dwelling adults aged 75 years and over. Auto-administered questionnaires collected data on socio-demographic, general health, quality of life (SF-12), risk of sarcopenia (SARC-F), physical activity (PASE), sleep quality, timing and sleepiness (PSQI, µMCTQ, and ESS). The stimulating nature of the living environment was measured using a weighted questionnaire developed by the HabitAge team (ULiège). Regarding the analyses, multiple logistic regressions are currently being conducted. In addition, given the potential mediating role of physical activity in the relationship between living environment's stimulation and sleep, mediation analyses are being realized.

Results : A total of 150 older participants completed the auto-administered questionnaires. Analyses are currently ongoing, and results will be presented at the conference. We hypothesize that higher living environment's stimulation score will be positively associated with better levels of physical activity and sleep. We further hypothesize that physical activity will mediate the relationship between living environment's stimulation and sleep quality.

Conclusion : These findings will highlight how the stimulating nature of the living environment can support autonomy among older adults, addressing an aspect that has received little attention compared to the influence of safety-related housing factors on health.

P1156

IMPACT OF PHARMACOTHERAPY NON-PERSISTENCE ON OSTEOPOROTIC FRACTURE RISK IN OSTEOPOROSIS: LANDMARK ANALYSIS OF 20,940 PATIENTS FROM REAL-WORLD DATABASE

L. Kovacova[1], S. Dubecka[2,3], M. Selvek[1], D. Kubek[1], R. Muzik[1], P. Vanuga[3,4], P. Jackuliak[2,3], M. Kuzma[2,3], J. Payer[2,3]

[1]Dovera Health Insurance Company, Bratislava, Slovakia; [2]University Hospital, Bratislava, Slovakia; [3]5th department of Internal Medicine, Comenius University Faculty of Medicine, Bratislava, Slovakia; [4]National Institute of Endocrinology and Diabetology, Lubochna, Slovakia

Objective
Longterm treatment persistence is essential for achieving optimal outcomes in chronic diseases, particularly asymptomatic conditions such as osteoporosis. The aim of this study was to evaluate the impact of non-persistence on subsequent fracture risk using a large real-world administrative database.

Methods
From the administrative database of a health insurance company in Slovakia (1.77 million insurees in 2024), all patients initiating osteoporosis pharmacotherapy between 2018 and 2023 were retrospectively identified. A 1year landmark analysis was applied, excluding patients who experienced an osteoporotic fracture within the first year. Persistence at 1 year was assessed based on missing prescription for more than 60 days, and subsequent fracture incidence was analysed using Cox regression. The effects of age, sex, initial medication, and 1year persistence were evaluated.

Results
A total of 20,940 patients initiated osteoporosis treatment and were fracture-free at landmark. During a mean followup of 3.6 years (SD 1.9), 3,051 patients experienced an osteoporotic fracture. Fracture rates were independent of sex, and initial medication. Compared to patients aged 40–64 years, older patients had 58% higher fracture risk (95% CI: 1.47–1.70, p<0.001). Oneyear treatment persistence was associated with a 16% lower fracture risk (95% CI: 0.78–0.90, p<0.001). The 5year postlandmark fracture rate was 17.1% (95% CI: 16.3–18.0) in persistent patients and 19.8% (95% CI: 18.8–20.8) in nonpersistent patients. Persistence rates varied substantially across medications ranging from 32% (SD 0.7) on risedronate to 65% (SD 0.4) on denosumab (Figure 1).

Conclusion
Oneyear treatment persistence was significantly associated with a lower subsequent fracture risk. While fracture incidence did not differ by sex or initial drug, persistence rates varied substantially across medications, highlighting opportunities to optimize treatment selection and improve longterm adherence in osteoporosis management.

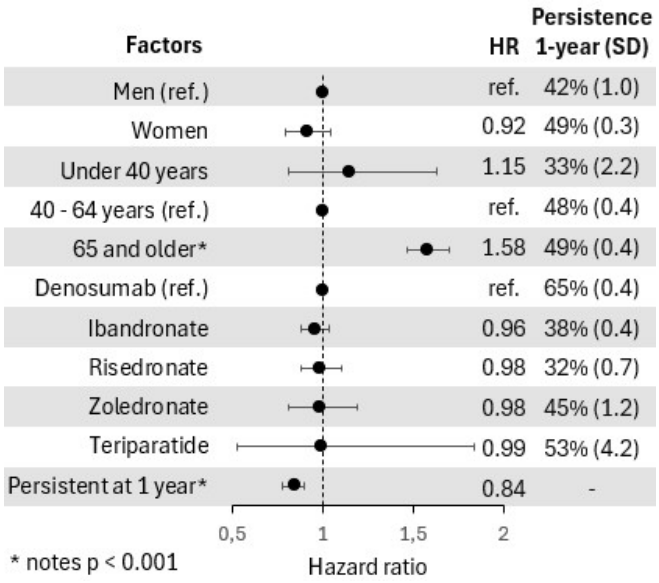


Figure 1 Osteoporotic fracture-free survival analysis results and 1-year persistence rates

P1157

REIMAGINING ROUTINE HEALTH INFORMATION SYSTEMS TO DETECT FRACTURE RISK AND OSTEOPOROSIS: A POLICY BRIEF PREPARED FOR THE WORLD HEALTH ORGANISATION (WHO)

Introduction: Fragility fractures impose major economic and social burdens, yet wide global variation in health data systems limits the

translation of data into actionable insights and a global fracture risk registry. This policy brief was commissioned and prepared for WHO to advise Ministries of Health on leveraging health data to improve osteoporosis screening, monitoring, diagnosis and prevention, to reduce fracture-related morbidity and mortality.

Methods: Twenty-five global experts were identified with 21 invitations from 16 countries accepted. A total of 11 x one-hour virtual interviews were conducted in October-November 2025. A thematic analysis was conducted, beginning with 15 initial codes derived from the WHO Building Blocks and the PRISM framework, with four additional codes added as new themes emerged. Findings were synthesised into barriers and mutually reinforcing policy opportunities.

Results: Five key barriers consistently identified included (1) low public awareness and competing health priorities, gaps in (2) diagnosis and clinical care, and (3) workforce capability, (4) fragmented and low-quality data, and (5) implementation complexity and sustainability constraints. To address these barriers and challenges, four mutually reinforcing policy opportunities were presented to increase the profile of osteoporosis and fragility fractures (Figure). Experts provided recommendations around (1) importance of local osteoporosis management guidelines, (2) minimum dataset and principles needed for local fracture risk registries, and (3) facilitation and integration of resources including digital solutions (e.g., AI, risk prediction algorithms) to bridge workforce and health equity gaps, including opportunistic case finding.

Conclusion: Findings provide practical, feasible, equitable and scalable recommendations to strengthen data systems, workforce capability and governance for Ministries of Health and stakeholders. Emphasising local context-appropriate guidelines, registries and digital solutions appear key to improving awareness of bone health to prevent fragility fractures.

Figure. Four mutually reinforcing policy opportunities to improve data generation, quality and use for the prevention and earlier detection of osteoporosis and fragility fractures, as well as patient risk assessment. These recommendations are designed to collectively work towards increasing the global profile of osteoporosis and fragility fracture, which is ultimately required for sustainable improvements in patient outcomes.

P1158

THE DUAL EFFECT OF HIGH-DOSE GLUCOCORTICOIDS AND TYROSINE KINASE INHIBITORS ON BONE FRAGILITY AND FRACTURE RISK

R. P. Ristea[1], M. Stanciu[1], C. I. Lebădă[1]

[1]Lucian Blaga University of Sibiu, Sibiu, Romania

Objective: To illustrate the severe skeletal consequences of combined high-dose glucocorticoids, active rheumatoid arthritis (RA), and Tyrosine Kinase Inhibitor (TKI) therapy for metastatic gastrointestinal stromal tumor (GIST). While glucocorticoids are known to induce osteoblast apoptosis, Imatinib targets c-KIT and PDGFR—signaling pathways crucial for mesenchymal stem cell differentiation and osteoblast proliferation. We present a clinical case where this "double hit" mechanism led to severe bone loss and very high fracture risk.

Case Presentation: A 54-year-old male (BMI 18.9 kg/m², active smoker) referred for skeletal assessment due to acute back pain. Medical history included stage III seropositive RA (on Methylprednisolone 16 mg/day>1 year) and small bowel GIST with resected hepatic metastasis, currently under Imatinib therapy. Phenotypic evaluation revealed sarcopenia, significant dorsal kyphosis, and pallor. Imaging confirmed multiple prevalent vertebral fractures (T5-T12 mild compressions; L1, L2 severe compressions). Dual-energy X-ray absorptiometry (DXA) showed very low bone density: lumbar spine (L1-L3) T-score -3.1 SD, and left femoral neck T-score -4.5 SD (Z-score -3.9), confirming the very high fracture risk. Laboratory assessment revealed iatrogenic adrenal suppression (serum cortisol 37 nmol/L), consequent to chronic exogenous glucocorticoid exposure, suppressed bone formation (osteocalcin 6.2 ng/mL; ref: 14-46), normocalcemia (8.6 mg/dL), normal PTH levels (65.3 pg/ml), hypophosphatemia (2.3 mg/dL), with optimal Vitamin D status (39.8 ng/mL). This profile suggests a dual suppression of osteoblast function mediated by both glucocorticoids and TKI therapy. While current guidelines advocate for anabolic treatment given the severe fracture profile, the recent history of metastatic GIST represented a major contraindication. Therefore, management prioritized oncologic safety, and intravenous Zoledronic Acid was initiated.

Conclusion: Osteoporosis management in oncologic patients with comorbid autoimmune diseases represents a major clinical challenge. This case highlights a drug-drug interaction with a significant impact on bone metabolism. Clinicians must recognize that Imatinib can potentiate glucocorticoid-induced osteoporosis by blocking compensatory osteoblast recovery and causing hypophosphatemia. Therefore, fracture risk stratification must be implemented at the very onset of oncologic and antirheumatic therapy. In such "double-hit" patients, early skeletal protection is mandatory to prevent bone decay.

P1159

SEVERE BONE FRAGILITY AND HIGH FRACTURE RISK ASSOCIATED WITH LONG-STANDING UNTREATED HYPOGONADISM IN JUVENILE PANHYPOPITUITARISM

C. I. Lebădă[1], M. Stanciu[1], R. P. Ristea[1]

[1]Lucian Blaga University of Sibiu, Sibiu, Romania

Objective: Male hypogonadism is associated with low bone mass and fragility fractures. Panhypopituitarism is a rare cause of hypogonadotropic hypogonadism that requires early evaluation of bone density by Dual-energy X-ray absorptiometry (DXA) and adequate testosterone replacement therapy.

Case Presentation: We report the case of a 57-year-old man diagnosed in another endocrinology department with Panhypopituitarism at the age of 7. Despite the early diagnosis, the patient did not receive androgen replacement therapy or skeletal evaluation until the age of 47. In the last

decade, he reported chronic mechanical pain in the lumbar spine and hip region. DXA revealed very low bone density: Lumbar Spine (L1-L3) T-score -4.3 SD, Left Femoral Neck T-score -4.7 SD (Z-score -3.8), and Right Femoral Neck T-score -4.2 SD (Z-score -3.6), confirming the very high fracture risk. Laboratory analysis showed osteocalcin 10.2 ng/mL (ref: 14-46), hypocalcemia (8.2 mg/dL), normal PTH levels (55.2 pg/mL), and elevated alkaline phosphatase (231 U/L), with low Vitamin D (19.8 ng/mL). Hormonal profile confirmed hypogonadism: Testosterone level at 5.2 pg/ml (ref: 6.3 – 17.8), FSH 2,1 mUI/mL (ref: 1.5 – 12.4), and LH 1,9 mUI/mL (ref: 1.7 – 8.6). Pituitary MRI confirmed Empty Sella, stable over a 20-year follow-up. We decided to treat our patient with transdermal Testosterone 16,2 mg/g and Risedronic acid 35 mg/ week. At the 6-month follow-up, the patient reported significant alleviation of bone pain.

Conclusion: Osteoporosis management in hypopituitarism is complex and should be performed as early as possible. The role of androgens in the acquisition of peak bone mass during puberty and its maintenance thereafter is of high importance for patients with hypogonadism and high risk for fragility fractures.

THE ASSOCIATION BETWEEN SERUM URIC ACID AND BONE MINERAL DENSITY ACROSS MENOPAUSAL STATUS IN WOMEN: A CROSS-SECTIONAL STUDY USING THE TAIWAN BIOBANK

S. C. Liu[1], C. Y. Lai[2], M. T. Hsieh[3]

[1]Department of Radiology, Taitung Mackay Memorial Hospital, Taiwan, Taitung, Taiwan; [2]Assistant Professor, Master Program in Biomedicine, National Taitung University, Taitung, Taiwan, Taitung, Taiwan; [3]Department of Radiology, Taitung Branch, Taipei Veterans General Hospital, Taiwan, Taitung, Taiwan

Objective: Uric acid, the end product of purine metabolism, has both antioxidant and pro- inflammatory properties. Although moderate serum uric acid (SUA) levels may benefit bone health, the point at which SUA becomes harmful remains unclear, especially in postmenopausal women who face higher osteoporosis risk. This study used data from the Taiwan Biobank to examine the relationship between SUA levels and bone mineral density (T-score) in Asian women, and to clarify how this association differs between premenopausal and postmenopausal groups.

Methods: This study utilized data from the Taiwan Biobank, including 103,090 Asian female participants. We conducted a cross-sectional analysis to evaluate the association between SUA and BMD, as measured by T-scores obtained via quantitative ultrasound (QUS). Subgroup analyses were performed for premenopausal and postmenopausal women. Multiple linear and logistic regression models were used to assess the relationship between SUA and BMD, adjusting for age, BMI, comorbidities, relevant blood test parameters, and lifestyle factors.

Results: A significant positive association was found between SUA and BMD. Each 1 mg/dL increase in SUA was associated with a 0.030 increase in T-score ($p < 0.001$) in all women. This effect was stronger in postmenopausal women ($\beta = 0.159$, $p < 0.001$) than in premenopausal women ($\beta = 0.067$, $p = 0.003$). Logistic regression indicated that women with SUA levels between 4.2 and 8.0 mg/dL had significantly lower odds of osteoporosis, with the strongest protective effect observed at 7.0–8.0 mg/dL (OR = 0.652). However, SUA levels above 8.0 mg/dL showed no further benefit.

Conclusion: Moderate SUA levels (4.2–8.0 mg/dL) appear to be associated with increased BMD and reduced risk of osteoporosis in women, particularly after menopause. Excessively high SUA levels may attenuate this protective effect. These findings highlight the need for nuanced clinical management of SUA levels, especially among postmenopausal women at high risk of bone loss.

P1161

COMPARISON OF PHYSICAL PERFORMANCE AND EMOTION REGULATION SKILLS IN OBESE INDIVIDUALS WITH AND WITHOUT KNEE OSTEOARTHRITIS

M. T. Yıldız[1], O. U. Ülger[2]

[1]Burdur Central Healthy Life Center, Ministry of Health, Burdur, Türkiye; [2]Hacettepe University, Faculty of Physical Therapy and Rehabilitation, Ankara, Türkiye

Objective(s): Knee osteoarthritis is a common degenerative joint disease, and obesity is a major risk factor that increases mechanical load and inflammatory processes, affecting physical and emotional functioning. This study aimed to compare physical performance and emotion regulation skills in obese individuals with and without knee osteoarthritis.

Material and Methods: A total of 118 obese individuals participated in the study. 78 participants were diagnosed with knee osteoarthritis according to the Kellgren–Lawrence grading scale (stages 2–3), while 40 participants had no knee osteoarthritis. Sociodemographic and clinical characteristics were recorded. Knee pain severity was assessed using the Visual Analog Scale. Physical performance was evaluated using the Timed Up and Go Test, 5-Repetition Sit-to-Stand Test, Weighted Forward Reach Test, and 10-Repetition Trunk Flexion Test. Emotion regulation skills were assessed using the Emotion Regulation Skills Questionnaire. Group comparisons and correlation analyses were performed using appropriate statistical methods.

Results: Obese individuals with knee osteoarthritis demonstrated poorer performance in the Timed Up and Go Test and the 5-Repetition Sit-to-Stand Test compared to those without osteoarthritis ($p<0.05$). Knee pain severity was higher in the osteoarthritis group ($p<0.01$). Participants with knee osteoarthritis showed lower scores in the emotion regulation subdimensions of attending to emotions, bodily perception of emotions, and modification ($p<0.05$). A moderate negative correlation was observed between bodily perception of emotions and Timed Up and Go Test performance, while a weak negative correlation was found between attending to emotions and the 5-Repetition Sit-to-Stand Test ($p<0.05$).

Conclusion(s): Obese individuals with knee osteoarthritis exhibit impairments in physical performance and emotion regulation skills compared to obese individuals without osteoarthritis. Reduced awareness of emotions is associated with poorer physical performance. These findings highlight the importance of biopsychosocial approaches, including emotion regulation interventions, in managing knee osteoarthritis.

P1162

THE UTILITY OF DXA ASSESSMENT FOLLOWING INCIDENT VERTEBRAL FRACTURE

A. Al Kaddah[1], I. Sharif[1], P. Connelly[1], M. Talla[1]

[1]Department of Endocrinology, Queen Elizabeth University Hospital, NHS Greater Glasgow & Clyde, Glasgow, United Kingdom

Objectives
Those with incident vertebral fractures may be recommended a DXA (dual-energy X-ray absorptiometry) scan as part of fracture risk assessment. Although DXA is the gold standard in determining bone mineral density (BMD), it may give spuriously high BMD results. Our aim is to assess the utility of DXA in BMD assessment following incident vertebral fracture.
Methods
We identified patients who had an incident vertebral fracture between January and July 2023. Patients were identified through a digital automated fracture liaison service tool. We retrospectively reviewed demographic data and DXA results. T-scores were classified as normal (≥ −1.0), osteopenia (−2.5 to −1.0) or osteoporosis (≤ −2.5). Bone density was measured at three sites: lumbar spine, femoral neck and total hip.
Results
Of 322 patients, DXA was undertaken in 200. Lumbar spine measurements were available in all individuals. Femoral neck T-scores were missing in 4.0% of cases and total hip T-scores in 5.0%.
Of these 200 patients, 44.5% met densitometric criteria for osteoporosis at one or more skeletal sites, while 55.5% did not have a T-score ≤ −2.5 at any site.
By skeletal site, osteoporosis was present in 31.5% of patients at the femoral neck, 26.0% at the total hip and 30.5% at the lumbar spine. When hip sites were considered together, 35.5% met densitometric criteria for osteoporosis.
Among females (n = 144), 49.3% met densitometric criteria for osteoporosis at at least one skeletal site, compared with 18 of 56 males (32.1%). Females had significantly higher odds of densitometric osteoporosis than males (Fisher's exact p=0.039; odds ratio 0.49, 95% CI 0.24, 0.97).
Conclusions
In this audit of patients with incident vertebral fracture, hip and lumbar spine measurements detected unique subsets of patients, with neither site demonstrating statistical superiority, supporting the continued use of multi-site DXA assessment in this population.
However, more than half of patients with vertebral fracture did not meet densitometric criteria for osteoporosis at any site. Females were significantly more likely than males to meet densitometric criteria for osteoporosis, while age was not independently associated with osteoporosis prevalence in this cohort.

P1163

THE STRUCTURE OF THE ALVEOLAR BONE OF THE MAXILLA IN RATS DURING THE ADMINISTRATION OF ALLOGENEIC MESENCHYMAL STEM CELLS INTO THE TIBIAL DEFECT AFTER SURGERY

M. Trufanova[1], I. Soloviova[2], V. Ryabkov[2], T. Gorbatykh[2], D. Voropaev[1]

[1]FSBEI HI ST. LUKA LSMU of MOH of Russia; Human anatomy department, Lugansk, Russia; [2]FSBEI HI ST. LUKA LSMU of MOH of Russia, Department of medical chemistry, Lugansk, Russia

Objective of the study is to test the structure of the interradicular alveolar bone of the maxilla (IAB) in white rats after the administration of allogeneic mesenchymal stem cells (allo-MSCs) into the tibial defect at different times after surgery.
Material and methods. 162 white rats weighing 190-225 g were divided: 1 group – control, in group 2 rats suffered a defect in both tibiae, in groups 3-7 5 million allo-MSCs were injected into the defect on days 3, 10, 15, 24, and 45 after surgery. Histological sections of the region of the first upper molar with a thickness of 6-8 microns were stained with hematoxylin-eosin.
Results. In group 2 the bone volume fraction (BVF) was lower than the values of group 1 from 15 to 90 days after surgery by 4.95-7.43%, and the trabecular thickness (Tb.Th.) from 7 to 90 days – by 4.48-8.33%; the width of the intertrabecular spaces (WITS) increased by 5.57-9.58% from days 7 to 90. In group 3, compared with group 2, the BVF and the Tb.Th. by 60 and 90 days after surgery were higher by 5.31% and 4.98% and by 5.48% and 5.69. In group 4, compared with group 2, the Tb.Th. from days 15 to 90 was 4.26%, 4.77%, 6.05% and 5.32% higher, and the BVF from days 30 to 90 was 5.60%, 5.80% and 5.21%. In group 5, the BVF by 30 and 60 days was 4.87% and 5.31% larger, and the Tb.Th. by 60 days was 5.67%.
Conclusion. The administration of allo-MSCs into the tibial defect is accompanied by the restoration of the structure of the IAB. The most effective is the administration of allo-MSCs on the 10th day after tibia injury.

P1164

EARLY MOBILIZATION AFTER HIP SURGERY: PRELIMINARY DATA FROM THE ORTHOPAEDIC CLINIC OF THE GENERAL UNIVERSITY HOSPITAL OF PATRAS IN GREECE

M. Tsekoura[1], I. Tatani[2], V. Giannatos[2], A. Charbi[2], G. Sinos[2], C. Matzaroglou[2], J. Gliatis[3]

[1]Department of Physiotherapy, University of Patras, Rio, Greece; [2]Department of Medicine, University of Patras, Rio, Greece; [3]Orthopaedic Clinic, General University Hospital of Patras, Rio, Greece

Objective. The aim of this study was to record data regarding early mobilization (within 24 hours) after hip fracture surgery of Greek patients.
Material and Methods. The study contains data on all hospitalizations following hip fracture surgeries within Orthopedic Clinic of the University

Hospital of Patras in Greece, including admission and discharge dates, fracture type, surgical procedure, cognitive function, ongoing medications for bone treatment, and early mobilization for each admission. Data from 2022 to 2024 were collected and analyzed.

Results. 367 patients (mean age: 79.8±13.1 years) with hip fractures were recorded. Of these, 228 (62.1%) were female. The largest proportion was treated with intramedullary nail and spinal anesthesia was most used. The average waiting time for surgery was 5±2.7 days (ranging 1-19 days). 192 (52.3%) patients did not receive physiotherapy or mobilization the first 24 hours post-surgery. Regression analysis showed that early mobilization was associated with better cognitive status, better mobility before surgery, less days of hospitalization and waiting until surgery and increased likelihood of post-operative death.

Conclusions. Despite early mobilization being suggested as a key component of enhanced recovery after hip surgery, only one out of two Greek patients received mobilization the first post-operative day. Further work on the factors underlying delayed mobilization and post-operative outcomes is required.

SARCOPENIA PREVALENCE AND ASSOCIATED FACTORS IN PATIENTS WITH HYPERTENSION: A CROSS SECTIONAL STUDY

M. Tsekoura[1], P. Angelopoulos[1], E. Billis[1], G. Tsigkas[2], K. Fousekis[1], J. Gliatis[3]

[1]Department of Physiotherapy, University of Patras, Rio, Greece; [2]Department of Pathology, University of Patras, Rio, Greece; [3]Orthopaedic Clinic, General University Hospital of Patras, Rio, Greece

Objective: The aim of this study is to investigate the prevalence rate of sarcopenia and associated factors associated among older adults with hypertension.

Material and Methods: This was a cross-sectional study of 102 older patients with hypertension aged ≥60 years. Hypertension was defined by self-reporting of a physician diagnosis or the use of antihypertensive medication. All participants were evaluated for sarcopenia using the European Working Group on Sarcopenia in Older People 2 (EWGSOP2) criteria. Sociodemographic characteristic, of the participants were obtained through a questionnaire. Anthropometric assessments were performed to measure the patients' weight, height and body mass index (BMI). Body composition was evaluated by bioimpedance analysis (Tanita BC-601). Handgrip strength was assessed via a hand held dynamometer (Saehan, Seoul, Korea). Gait speed, and chair stand test were evaluated also. The association between variables was calculated using Pearson-r correlation coefficients. A logistic regression analysis was performed in order to determine associated risk factors. The research study was approved by the committee for Ethics in Research at the University of Patras.

Results: The overall prevalence of sarcopenia among older adults with hypertension was 24.5% (n=25). The mean age of the study population was 70.2 ± 5.6 years (age range, 60–93 years). Patients with sarcopenia were older than those without sarcopenia. Patients with concurrent hypertension and sarcopenia had a significantly lower SMMI, handgrip strength, walking speed and a higher incidence of osteoporosis, and fall history ($p < 0.05$) compared to non sarcopenic older adults. The following factors were associated with a greater risk of sarcopenia: age of ≥70 years (OR, 5.65; 95% CI, 2.38–13.39; $p < 0.001$), osteoporosis, BMI.

Conclusions: This study revealed a high prevalence of sarcopenia among older adults with hypertension (22.4%). Current research confirms that sarcopenia is associated with hypertension. These results may have significant impact in both prevention and treatment techniques for older adults with sarcopenia and hypertension. Future studies should investigate more factors that could influence older adults with hypertension and sarcopenia.

PHYSIOTHERAPY STUDENTS' ATTITUDES TOWARDS AND KNOWLEDGE OF OLDER PEOPLE

M. Papakostopoulou[1], E. Billis[1], C. Koutserimpas[1], C. Matzaroglou[1], S. Lampropoulou[1], S. Xergia[1], E. Tsepis[1], M. Tsekoura[1]

[1]Department of Physiotherapy, University of Patras, Rio, Greece

Objective: To evaluate the knowledge and attitudes of Greek physiotherapy students regarding knowledge and geriatric rehabilitation of older patients.

Material and Methods: The present cross-sectional study was carried out on a sample of 243 undergraduate physiotherapy students attending the Department of Physiotherapy, University of Patras, Greece. Students, were recruited during the academic year 2024–2025. Three tools were used to collect data. I) A list of demographic characteristics; age, gender, level of education, ii) Kogan's attitude towards old people scale (KAOP) and iii) Facts of ageing quiz (FAQ1). The research study was approved by the committee for Ethics in Research at the University of Patras. Informed consent was obtained from all participants. To assure anonymity, students were asked not to place their names on the questionnaire.

Results: Two hundred and forty-three (243) physiotherapy students with a mean age of 20.5±4.4 years (164 women, 79 men) participated in this study. The largest number of students were in their first year (n=134,55.1%). and second year (n = 38, 15.6%) of studies. The KAOP mean attitude score of the students was 124.8 ± 8, indicating a neutral score. More than one third (32%) of respondents had poor to average knowledge. The majority of students believe they will work with older adults in the future. Significant statistical differences in negative attitudes were found between first and fourth year students ($p \leq 0.05$).

Conclusions: In general, physical therapist students in this study showed slightly positive attitudes and beliefs about older adults as measured by total positive Kogan score. Further investigation is needed to identify the level of knowledge on ageing and attitudes toward older people,

in larger samples. The number of fourth-year students was small and future research should investigate whether students' attitudes towards and knowledge of older people changes throughout the physiotherapy undergraduate programme.

P1167

TRANSLATION AND CROSS-CULTURAL ADAPTATION OF THE GERIATRIC PAIN MEASURE IN GREEK OLDER ADULTS

E. Chalari[1], E. Billis[1], E. Kapreli[2], M. Tsekoura[1]

[1]Department of Physiotherapy, University of Patras, Rio, Greece; [2]Department of Physiotherapy, University of Thessaly, Lamia, Greece

Objective: This study aimed to translate, culturally adapt, and evaluate the psychometric properties of the Greek version of the Geriatric Pain Measure (GPM) in Greek older adults.

Materials and Methods: The cross-cultural adaptation was carried out according to internationally recognized guidelines to ensure both linguistic accuracy and cultural appropriateness. The translation and adaptation of the questionnaire was carried out in five stages: (a) forward translation by two professionals with excellent knowledge of English. b) Synthesis, c) Back-translation into English, d) Creation of the pre-final version of the instrument, e) Pilot testing of the instrument. Then, a reliability (test-retest reliability) and validity check was performed in older adults. For the purposes of the study, a demographic questionnaire, the McGill Pain Questionnaire, and the Numerical Rating Scale (NRS) were used. The sample consisted of 20 Greek participants (aged > 60). Participation was voluntary, and participants had the option to withdraw at any time. The research study was approved by the Research Ethics Committee of the University of Patras.

Results: The translation was completed without any difficulties. The questionnaire was found to be user-friendly and easy to administer. Twenty (20) individuals (mean age: 76.05 years,17 women, 3 men) participated in this research study. The Greek version of the GPM had excellent reliability of repeat measurements (ICC = 0.9) and high internal consistency (Cronbach alpha = 0.91). Significant correlations between GPM scores, McGill (r=0.8;p≤0.001)), NRS (r=0.82; p≤0.001) showed good convergent validity.

Conclusions: The Greek version of the Geriatric Pain Measure is available and can be used for both clinical and research purposes in Greek-speaking individuals. Further research is needed to investigate the psychometric characteristics of the GPM in a larger sample.

THE RELATIONSHIP AND THE DIFFERENCES OF KINESIOPHOBIA AND PAIN BETWEEN REHABILTATION PHASES IN PATIENTS AFTER TOTAL KNEE REPLACEMENT

D. Georgitsi[1], M. Tsekoura[2], M. Papadopoulos[3,4], N. Zacharakis[5], P. Papagelopoulos[6], A. Christakou[7]

[1]Physiotherapy Department, University of Peloponnese, Sparta, Greece; [2]Department of Physiotherapy, University of Patra, Patra, Greece; [3]Department of Physiotherapy, Evangelismos General Hospital, Athens, Greece; [4]Frederick University, Limassol, Cyprus; [5]2nd Department of Othopedics & Traumatology Athens General Hospital G. Gennimatas, Athens, Greece; [6]1st Department of Orthopedic Surgery, School of Medicine, National & Kapodistrian University of Athens, Attikon University General Hospital, Athens, Greece; [7]Department of Physiotherapy, Laboratory of Biomechanics, University of Peloponnese, Sparta, Greece

Objectives

To examine (a) the relationship between kinesiophobia and pain and (b) the differences in kinesiophobia and pain between (a) the 1st postsurgical day, (b) the day of hospital discharge, (c) the 15th day of hospital discharge day and (d) the 4 weeks of the hospital discharge.

Material and Methods

The sample was consisted of 41 patients (8 men, 33 women), aged 65 to 85 years (M=70,66 SD=5.60), with knee osteoarthritis diagnosed in the mean of the 7,8 years (SD=5,4) with symptoms of pain, stiffness and oedema. After the Total Knee Replacement (TKR), the participants completed two validated instruments: (a) the Greek version of Tampa Scale of Kinesiophobia, (b) the VAS of pain in the 4 aforementioned phases. The participants followed the standard physiotherapy session from the 1st surgical day until the hospital discharge. The data were non parametric; thus, we performed (a) a Friedman test with Kendall W for effect size, (b) a Wilcoxon post hoc analysis with Bonferroni correction, (c) a Spearman r to assess correlation between the 2 aforementioned variables in the 4 phases by a SPSS 30.00 (α=0.05).

Results

Spearman r showed positive significant correlations between kineshiophobia and pain in all the phases (r=0,27; p=0,09, r=0,56; p=0,001, r=0,56; p=0,001, r=0,47; p=0,002), respectively. The Friedman test showed significant differences in kinesiophobia between all the phases $\chi^2(3) = 76,40$, $p < 0,001$, with an average effect size (Kendall's W = 0,62). Regarding pain, Friedman test showed similar reduction in all the phases $\chi^2 (3) = 89,60$; $p <0,001$, with large effect size (Kendall's W = 0,73). The Wilcoxon post hoc analysis with Bonferroni correction showed significant results in all the phases (p<0,001) confirming the reduction of kinesiophobia and pain 4 weeks after the hospital discharge day after a TKR.

Conclusions

Kineshiophobia correlated with pain in all the phases. The kinesiophobia and pain had reductions until the 4th week of hospital discharge after TKR. No other studies had been conducted with the present aim of the study. More research should verify the present results with larger sample

of men. Further studies should correlate range of motion, strength and patient satisfaction after TKR.

P1169

FRAILTY AND MENOPAUSE: A SCOPING REVIEW

M. Tsekoura[1], C. Koutserimpas[2], C. Matzaroglou[3], E. Billis[1]

[1]Department of Physiotherapy, Laboratory of Clinical Physiotherapy and Research, University of Patras, Rio, Greece; [2]Department of Physiotherapy, University of Patras, Rio, Greece; [3]Department of Medicine, University of Patras, Rio, Greece

Objective: The aim of this scoping review was to explore existing literature on menopause and frailty, identify key concepts and evidence gaps, and summarize findings related to prevalence, determinants, biological mechanisms, and health outcomes in women.

Materials and Methods: Web of Science, PubMed, EMBASE, and the Cochrane Library were searched. Two reviewers independently screened records and extracted data on study characteristics, menopausal assessment, frailty operationalization, main findings, and research gaps. Findings were synthesized descriptively. Hormonal changes—particularly reductions in estrogen—were linked to alterations in body composition, bone health, inflammation, and mitochondrial function, which may underlie increased vulnerability. Longitudinal data indicate that early menopause and longer duration of postmenopausal life are associated with higher frailty risk later in life. However, studies varied widely in design, frailty definitions, and adjustment for confounders, limiting comparability.

Results. The review included 16 studies. Existing studies suggest that menopause is associated with frailty. Evidence suggests that postmenopausal status is associated with higher prevalence of frailty and accelerated decline in muscle strength, physical function, and metabolic health compared to premenopausal women. Early menopause, hysterectomy, hormonal changes, low-free testosterone levels, and high Creactive protein levels may increase the likelihood of frailty among postmenopausal women

Conclusions: Current evidence highlights a potentially important relationship between menopause and frailty, with hormonal and physiological changes contributing to vulnerability in later life. Standardization of frailty assessment tools and menopausal status definitions is essential to improve comparability across studies. Future studies are required to adopt longitudinal and mechanistic designs to elucidate causal pathways linking menopausal transition to frailty trajectories in later life.

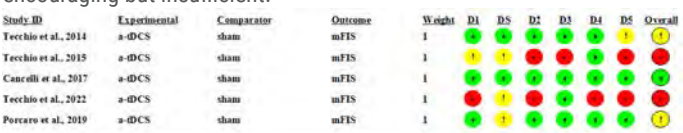
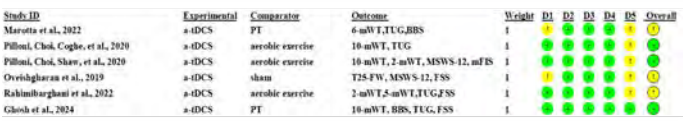
NON-INVASIVE BRAIN STIMULATION METHODS FOR THE MANAGEMENT OF MOTOR DYSFUNCTION AND FATIGUE IN INDIVIDUALS WITH MULTIPLE SCLEROSIS: A SYSTEMATIC REVIEW



S. Tsioranou[1], E. Papadimitriou[1], M. Tsekoura[1], E. Trachani[1], E. Nastou[1], A. Gotsopoulou[1], S. Lampropoulou[1]

[1]University of Patras, Patras, Greece

Objective: Motor dysfunctions and fatigue are among the most frequently reported symptoms in individuals with Multiple Sclerosis (MS) (1)(2). In recent years, interest in non- invasive brain stimulation methods has increased due to the need for non-pharmacological interventions (3). The purpose of the present study is the systematic presentation of non-invasive brain stimulation methods—repetitive transcranial magnetic stimulation (rTMS), intermittent theta burst stimulation (iTBS), transcranial random noise stimulation (tRNS), and transcranial direct current stimulation (tDCS) in the management of motor dysfunctions and fatigue in individuals with MS.



Materials and Methods: A systematic review of the literature was conducted in the PubMed, EBSCO, Web of Science, ScienceDirect, and Cochrane Library databases from 2000 to October 2024. A total of thirty-three (33) randomized clinical trials including 812 individuals with MS of any type and regardless of sex were included, in which brain stimulation was applied either as a stand alone intervention or in combination with exercise and physiotherapy programs. Methodological quality was assessed by two independent reviewers using the Cochrane Risk of Bias 2 (RoB 2) tool, and data synthesis was performed based on the Best Evidence Synthesis approach.

Results: Bilateral tDCS applied to the somatosensory cortex (S1) demonstrated the most consistent positive effects on fatigue, while targeting the left dorsolateral prefrontal cortex (F3) was also effective, particularly when combined with physiotherapy. Stimulation of the primary motor cortex (M1) with tDCS showed consistent benefits for gait and balance when combined with exercise or rehabilitation. Cerebellar tDCS improved balance with a more long-lasting effect when combined with exercise or physiotherapy. HF-rTMS demonstrated positive effects on fatigue, showing superiority over iTBS, while data regarding gait and balance were limited. Evidence for cerebellar iTBS and for tRNS was encouraging but insufficient.

Conclusions: Non-invasive brain stimulation constitutes a promising intervention for individuals with MS, particularly when combined with physiotherapy. However, the strength of the conclusions remains limited due to protocol heterogeneity and the limited number of high-quality

studies. Further standardized and methodologically rigorous research is required to document the clinical effectiveness of these interventions.

CORRELATIONS BETWEEN KINETIC AND KINEMATIC GAIT PARAMETERS AND MINI-BESTEST PERFORMANCE IN ADULTS AGED ≥50 YEARS DURING OBSTACLE CROSSING

S. Pappas[1], E. Nastou[1], E. Papakosta[1], V. Donta[1], E. Forliaka[1], S. Xergia[1], M. Tsekoura[1], S. Lampropoulou[1]

[1]University of Patras, Physiotherapy Department, Rio, Greece

Objective

Timely and valid assessment of balance and gait in adults aged ≥50 years is critical for fall prevention, particularly under challenging walking tasks such as obstacle negotiation (3). The mini Balance Evaluation Systems Test (mini-BESTest) is widely used to clinically assess dynamic balance and has demonstrated reliability across different populations (1). The present study aims to examine the concurrent clinical validity of the mini-BESTest by investigating its correlations with kinetic and kinematic gait parameters recorded with reliable three-dimensional motion analysis during obstacle crossing in adults aged ≥50 years (2).

Materials and Methods

Ten healthy adults participated (8 women, 2 men; 59 ± 5 years). Biomechanical data were collected using a Vicon Nexus 2.16 motion capture system (8 cameras, 200 Hz) and AMTI/Bertec force plates (2000 Hz) under two conditions: (a) level walking and (b) obstacle crossing (23 cm), with the dominant limb leading, along a 12 m walkway. Three trials were performed per condition. Kinematic variables included single-support time, step length, and step width. Kinetic variables included peak vertical ground reaction force (GRF) at initial contact (landing) and at push-off during obstacle crossing for the dominant limb (Figure 1). The mini-BESTest was administered in the same session according to standard procedures. The mean of three trials per condition was used for analysis. Correlation coefficients (r) were computed in IBM SPSS Statistics 29.0.1, with statistical significance set at $p<0.05$.

Results

Higher mini-BESTest total scores were significantly associated with lower peak vertical GRF during obstacle crossing, both at landing ($r=-0.68$, $p=0.03$) and at push-off ($r=-0.65$, $p=0.04$). The Anticipatory Postural Control subscore was also negatively correlated with step width ($r=-0.76$, $p=0.01$) and with push-off force ($r=-0.63$, $p=0.05$). Overall, these findings support the hypothesis that better clinical performance in dynamic balance is accompanied by lower loading peaks and distinct lateral stability control during obstacle negotiation.

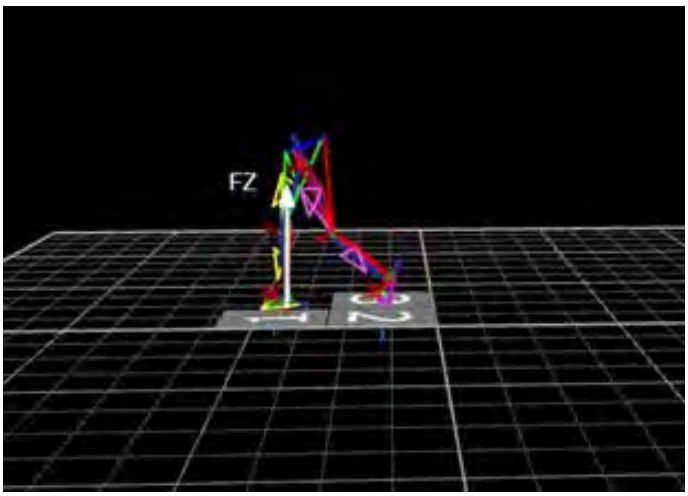

Figure 1. *3D kinematic model immediately after obstacle clearance, during landing (initial contact) of the leading/dominant limb on the force plate. The label FZ denotes the vertical ground reaction force (GRF) component recorded at landing (white arrow indicates the direction of the vertical loading peak).*

Conclusion

Correlations between the mini-BESTest and kinetic and kinematic gait parameters during obstacle crossing provide evidence of concurrent clinical validity in adults aged ≥50 years. However, the small sample size underscores the need for confirmation in larger cohorts.

COMPARISON OF THE MINI BALANCE EVALUATION SYSTEM TEST (MINI-BESTEST) WITH THE SHORT PHYSICAL PERFORMANCE BATTERY IN RELATION TO WALKING SPEEDAND FEAR OF FALLING IN COMMUNITY-DWELLING OLDER ADULTS

A. Konstanti[1], S. Pappas[1], E. Papakosta[1], E. Forliaka[1], P. Chatziioannou[1], M. Tsekoura[1], S. Lampropoulou[1]

[1]University of Patras, Physiotherapy Department, Rio, Greece

Objective

In recent years, a growing body of research has focused on the effects of aging, with most studies addressing impairments in balance (1), reductions in physical activity (2), decreased gait speed (3), and fear of falling. However, the combined assessment of these parameters with the aim of deriving prognostic value appears to be limited within the scientific community. The purpose of the study is to investigate the relationship between balance and physical performance with walking speed in community-dwelling older adults.

Materials and Methods

A cross-sectional study was conducted with a sample of elderly individuals (≥60 years old) without significant pathology or neurological deficits. Balance was assessed using the mini-Balance Evaluation

System Test (mini-BESTest) scale, physical performance using the Short Physical Performance Battery (SPPB) scale, and walking speed using the 10-meter walk test (10mWT). Statistical analysis was performed using IBM SPSS Statistics software, with a statistical significance level of p< 0.05.

Results

Thirty-two healthy elderly individuals (25 women, 7 men) aged 69±5 years participated in the study. Normal walking speed was found to be lower than expected normal values in both women (1.09±0.3 m/s vs. 1.13 m/s) and men (1.14±0.3 m/s vs. 1.26 m/s). Both the total mini-BESTest and SPPB scores were statistically significantly correlated with normal walking speed in the 10mWT (r=0.51 and r=0.56, respectively, p<0.05) (Fig. 1). In addition, the compensatory control of the mini-BESTest was significantly correlated with normal speed (r=0.46, p<0.05) and walking time (r=-0.38, p<0.05) in the 10mWT. The SPPB test of 5 repeated chair rises was also significantly correlated with walking speed (r=0.44, p<0.05). The comparison of independent samples between slow and fast walkers revealed statistically significant differences in the preparatory and somatosensory control scores of the mini-BESTest (p<0.05), as well as in the total score, balance activities, and repeated sit-to-stand tests of the SPPB (p<0.05).

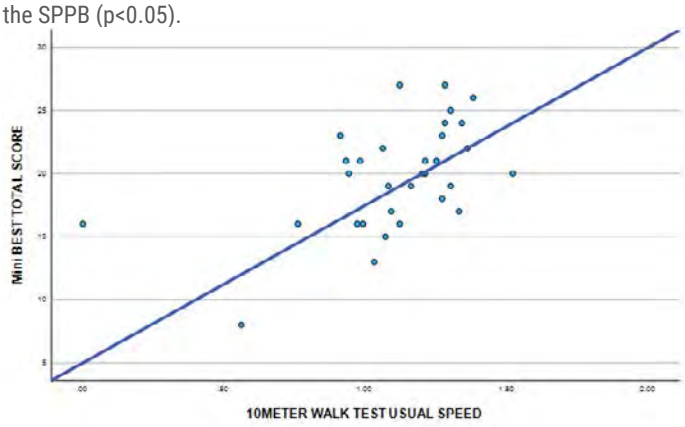

Figure 1. Correlation between the mini-Balanace Evaluation Systems Test (mini-BESTest) and the normal speed at the 10 meters walking test

Conclusions

The results suggest that mini-BESTest shows a comparable correlation with SPPB in terms of speed and walking time over 10 meters. Reduced balance and physical performance are associated with slower walking speed in older adults, highlighting the importance of using these two tools in combination in clinical assessment.

DEVELOPMENT AND VALIDATION OF A DIAGNOSTIC TOOL FOR PREDICTING OSTEOPOROSIS USING KNEE RADIOGRAPH AND PATIENT CHARACTERISTICS

M. Tunsiri[1], A. Laoruengthana[1], S. Tananoo[1], A. Hinphet[1], N. Kongsawadsrisuk[1], A. Sriling[1], P. Sinlapachai[1]

[1]Naresuan University, Phisanulok , Thailand

Objective: Advanced-stage knee osteoarthritis (KOA) may comorbid with osteoporosis, and increase the risk of fragility fracture and complicating patients who undergoing total knee arthroplasty (TKA) such as periprosthetic fracture or aseptic loosening. Although Dual-energy X-ray absorptiometry is the gold diagnostic standard, its accessibility is still limited in some clinical settings. The previous study showed a significant correlation between bone thickness of distal femur in knee radiographic and bone mineral density. To develop and validate a diagnostic tool for predicting osteoporosis based on knee radiograph and clinical characteristics.

Material and Methods: In a retrospective observational cohort study, data of 385 women aged ≥60 years with knee osteoarthritis (Kellgren-Lawrence classification grade 2–4) were retrieved. Diagnostic determinants included the distal femoral cortical index (DFCI), age, body mass index (BMI), and menopausal age. The primary outcome was an osteoporosis diagnosis based on criteria that was T score of hip or spine ≤-2.5 or FRAX scores ≥ 3%. A multivariable logistic regression model was developed, from which an integer-based clinical risk score was derived. Model performance was assessed for discrimination, calibration, and internal validity.

Results: Of 385 participants, 200 (52%) were diagnosed with osteoporosis, and 185 (48%) had non-osteoporosis. The model included 1. DFCI <0.65, 0.65-0.75, and ≥0.75; 2. age <65, 65-70, and >70 years; 3. BMI <25 and ≥25 kg/m²; 4. menopause age ≤45 and >45. Discrimination was good (AuROC 76.5; 95% CI: 71.9 to 81.2), and calibration was excellent (calibration-in-the-large 0.00, 95% CI: -0.23 to 0.23; slope 1.00, 95% CI: 0.77 to 1.23). Internal validation with bootstrap replications yielded AuROC 76.7, calibration-in-the-large -0.00, and slope 1.01 with a bootstrap shrinkage of 1.009. Risk scores were categorized as low (<3.5), moderate (3.5 to 11), and high (>11), with corresponding positive likelihood ratios of 0.16, 0.90, and 4.08, respectively.

Conclusion: The knee radiograph and clinical characteristics can be applied as a risk-stratified diagnostic approach for osteoporosis. This diagnostic prediction model shows good discrimination and calibration for osteoporosis in elderly women with KOA.

THE ASSOCIATION BETWEEN SOLUBLE TOLL-LIKE RECEPTOR 2 (STLR2) LEVELS AND VITAMIN D STATUS IN PATIENTS WITH JOINT AND EXTRA-ARTICULAR MANIFESTATIONS OF RHEUMATOID ARTHRITIS

O. P. Galkina[1], M. V. Dovbnya[1]

[1]V.I. Vernadsky Crimean Federal University, Medical Academy named after S.I. Georgievsky, Simferopol, Russia

Objective: Toll-like receptor 2 (TLR2) is a key component of innate immunity, recognizing both pathogen-associated and endogenous (damage-associated) molecular patterns. In rheumatoid arthritis (RA), increased TLR2 expression in the synovium and immune cells promotes pro-inflammatory pathway activation (NF-κB), which is associated with disease severity. Vitamin D has immunomodulatory properties, suppressing Th1/Th17 differentiation and pro-inflammatory cytokine production. Research suggests vitamin D may inhibit TLR expression. Vitamin D deficiency is a common comorbidity in RA and correlates with disease activity. Aim: To study the relationship between serum levels of soluble TLR2 (sTLR2) and 25(OH)D in patients with joint and extra-articular forms of RA.

Material and Methods: A single-center study included 94 RA patients meeting the ACR/EULAR 2010 criteria. Patients were divided into 2 groups: 1) with joint form (n=53) and 2) with extra-articular manifestations (nodulosis, vasculitis, Felty's syndrome; n=41). The control group consisted of 30 age- and sex-matched healthy donors. Serum concentrations of sTLR2 and 25(OH)D were measured by ELISA using commercial kits (specify manufacturer, e.g., R&D Systems, USA for sTLR2 and Dia-Service, Russia for 25(OH)D). Statistical analysis was performed using SPSS 23.0. The Mann-Whitney U test was used for group comparisons, and Spearman's rank correlation coefficient was used for correlation analysis. Data are presented as median (Me) and interquartile range (Q1-Q3). Differences were considered statistically significant at $p<0.05$.

Results: Patients with extra-articular RA had significantly lower vitamin D levels [16.3 (12.1–20.8) ng/ml] ($p=0.032$) than those with the joint form [19.8 (15.9–23.1) ng/ml], and in both groups levels were below the optimal threshold (>30 ng/ml). The sTLR2 concentration was significantly higher ($p=0.008$) in the extra-articular group [35.4 (18.2–59.1) ng/ml] compared to the joint form group [15.8 (9.4–24.7) ng/ml]. In the total RA cohort, a moderate negative correlation was found between 25(OH)D and sTLR2 levels ($r = -0.41$; $p<0.001$).

Conclusions: 1. Patients with extra-articular RA exhibit more severe vitamin D deficiency and statistically significant higher serum sTLR2 levels compared to patients with only joint involvement. 2. The identified inverse correlation between 25(OH)D and sTLR2 concentrations suggests that vitamin D deficiency may be associated with the activation of TLR2-dependent pro-inflammatory pathways, potentially contributing to systemic manifestations of RA. 3. These findings justify further research to evaluate the impact of vitamin D deficiency correction on TLR2 pathway activity and the clinical course of extra-articular RA forms.

P1176

CONTRIBUTION OF INFECTIONS AND ORAL MICROBIOME TO THE DEVELOPMENT OF RHEUMATOID ARTHRITIS

O. P. Galkina[1], M. V. Dovbnya[1], J. A. Dovbnya[1]

[1]V.I. Vernadsky Crimean Federal University, Medical Academy named after S.I. Georgievsky, Simferopol, Russia

Objective: Rheumatoid arthritis (RA) is an immune-inflammatory disease resulting from a dysregulated response in genetically predisposed individuals to environmental triggers. The role of infections and microbiome dysbiosis in RA pathogenesis is of considerable interest, with oral pathogens like Porphyromonas gingivalis implicated in breaking immune tolerance via citrullination.

Material and Methods:

Study Cohorts: We analyzed 461 patients with early RA (ERA, DMARD-naïve), 247 individuals at pre-RA stages (at-risk individuals with arthralgia but no clinical arthritis), and 398 healthy controls (HC) without family history of RA.

Infection Assessment: Data on the frequency and duration of common infections (respiratory tract infections, herpes simplex virus (HSV) reactivations, etc.) in the year preceding enrollment were collected. All participants were examined in an infection-free state and were not receiving immunomodulatory therapy.

Microbiome Analysis: Oral microbiome profiling via 16S rRNA gene sequencing (NGS platform) was performed in subgroups: ERA (n=14), established RA (n=45), pre-RA (n=52), and HC (n=26). Alpha-diversity was assessed using the Shannon Index (SI) and Operational Taxonomic Unit (OTU) count.

Laboratory Tests: Standard inflammatory markers, anti-citrullinated protein antibody (ACPA) status, and serum cytokine levels (multiplex Luminex assay) were evaluated.

Results:

1. Infections: Approximately 15% of patients linked RA onset/pre-RA symptoms to a specific infection. The ERA group had a higher frequency/duration of infections vs. HC.

ACPA-positive RA was associated with exacerbations of chronic tonsillitis and HSV infection. HSV reactivations influenced the course of tonsillitis.

ACPA-negative RA was characterized by bacterial upper respiratory tract infections (URTI), acute/chronic bronchitis, and combinations of viral and bacterial URTI.

A history of active tuberculosis (TB) was more frequent in RA. Prior TB was associated with longer exacerbations of chronic tonsillitis.

2. Oral Microbiome: Common infections increased oral bacterial alpha-diversity. SI correlated with the total number of annual infection episodes ($\rho=0.32$, $p<0.01$). A strong positive correlation was found between SI/OTU and the cumulative duration of episodes in the "viral + bacterial URTI" cluster ($\rho=0.41$, $p<0.001$).

Individuals with a history of TB had significantly higher SI and OTU values ($p<0.05$, Mann-Whitney U test).

Both SI and OTU showed a weak but highly significant inverse correlation with serum IL-4 levels ($\rho=-0.28$, $p<0.01$).

Alpha-diversity indices (SI and OTU) were significantly elevated in the established RA and pre-RA groups compared to HC ($p<0.05$). A similar trend was observed in the ERA group.

Conclusions:

1. The development of RA is preceded by frequent and prolonged common infections. Specific patterns are associated with ACPA status: HSV/tonsillitis in ACPA-positive RA and respiratory tract infections in

ACPA-negative RA.
2. These infections are associated with increased alpha-diversity of the oral microbiome.
3. A history of tuberculosis is more common in RA and is linked to altered infection course and increased oral microbiome diversity.
4. Elevated oral microbiome alpha-diversity in pre-RA and RA stages, along with its inverse correlation with IL-4, suggests a shift in microbial community structure potentially relevant to early disease mechanisms.

P1177

SERUM LEPTIN IS ASSOCIATED WITH PAIN AND RADIOGRAPHIC SEVERITY IN KNEE OSTEOARTHRITIS: EVIDENCE FOR A METABOLIC PHENOTYPE

M. V. Vu[1], M. N. Nguyen Thi Thanh[2]

[1]Phenikaa University Hospital, Hanoi, Vietnam; [2]Bach Mai Hospital, Hanoi, Vietnam

Objectives: 1. Measurement and analysis of serum levels of leptin in healthy people and knee osteoarthritis (KOA) patients with different BMIs. 2. To determine the relationship between serum leptin levels and the severity of clinical symptoms and radiographic findings in KOA patients.
Methods: Cross-sectional study conducted on 242 subjects, including 164 KOA patients (case group) and 78 healthy people (control group). Demographic data, Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) scores, radiographic findings, and serum leptin levels were collected. Serum leptin concentrations were measured using an enzyme-linked immunosorbent assay (ELISA) with monoclonal human antibodies.
Results: 59 (36%) obese KOA patients and 105 (64%) non-obese KOA patients. Mean serum leptin level in the obese KOA group (15.6 ng/mL ± 10.6) and the non-obese KOA group (9.3 ng/mL ± 7.6) was significantly higher than that in the control group (0.54 ng/mL ± 0.37) ($p<0.05$). There was a statistically significant positive correlation between leptin level and pain severity, with a correlation coefficient of 0.22 – 0.24 ($p<0.05$). Leptin levels were highest in patients with grade 4 KOA. Across all radiographic grades, obese KOA patients had higher leptin levels than non-obese patients.
Conclusion: Serum leptin levels were significantly elevated in patients with KOA compared to healthy controls. Higher leptin levels were associated with increased pain severity and more advanced radiographic stages of KOA, suggesting a potential role of leptin in disease severity and progression.

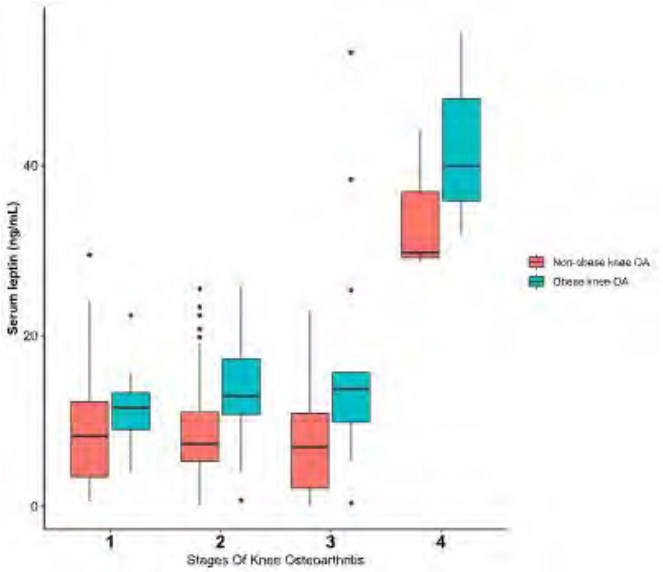

Figure 1. Mean serum leptin levels across radiographic stages of knee osteoarthritis in obese and non-obese patients.

P1178

ULTRASOUND-DERIVED RECTUS FEMORIS MUSCLE THICKNESS IDENTIFIES SARCOPENIA IN PATIENTS WITH KNEE OSTEOARTHRITIS

M. V. Vu[1], H. N. Nguyen Duy[2], H. H. Ho Duc[3]

[1]Phenikaa University Hospital, Hanoi, Vietnam; [2]Phenikaa University, Hanoi, Vietnam; [3]Yen Bai Provincial General Hospital, Yen Bai, Vietnam

Objectives: 1. To compare ultrasonographic characteristics of the rectus femoris muscle in patients with primary knee osteoarthritis (KOA) with and without sarcopenia. 2. To determine cut-off values of rectus femoris ultrasound parameters for sarcopenia screening in patients with primary KOA.

Methods: This cross-sectional study was conducted at Bach Mai Hospital and included 95 patients with primary KOA. Sarcopenia was diagnosed according to the Asian Working Group for Sarcopenia (AWGS) 2019 criteria. Sixty-eight patients (71.6%) had sarcopenia and 27 patients (28.4%) served as the non-sarcopenic control group. Bilateral ultrasound examination of the rectus femoris muscle was performed. Skeletal muscle mass index (SMI) and ultrasonographic parameters—including muscle thickness, cross-sectional area, fascicle length, and pennation angle—were recorded.

Results: The mean SMI in KOA patients with sarcopenia was significantly lower than in controls (4.8 ± 0.6 vs. 6.4 ± 0.5 kg/m², $p < 0.05$). Ultrasonographic parameters of the rectus femoris muscle in the sarcopenia group were significantly reduced compared with the control group: muscle thickness (11.6 ± 2.7 mm), cross-sectional area (3.4 ± 1.0 cm²), fascicle length (16.7 ± 3.8 mm), and pennation angle (12.9 ± 2.4°) (all $p < 0.05$). Receiver operating characteristic (ROC) curve analysis demonstrated that muscle thickness had the highest diagnostic accuracy for sarcopenia (AUC = 0.946), whereas fascicle length showed the lowest (AUC = 0.794). Using a muscle thickness cut-off value of 15.1

mm, sensitivity and specificity for sarcopenia screening were 86.8% and 96.3%, respectively.

Conclusion: KOA patients with sarcopenia exhibit significantly reduced ultrasonographic parameters of the rectus femoris muscle compared with non-sarcopenic patients. Rectus femoris muscle thickness showed a strong association with sarcopenia and demonstrated excellent diagnostic performance, suggesting its potential utility as a simple and non-invasive screening tool for sarcopenia in patients with KOA.

Table 1. Summary receiver operating characteristic curves (ROC) of different ultrasound measurements for diagnosing sarcopenia

Parameter	Cut-off	AUC	Sensitivity %	Specificity %
Thickness (mm)	15.1	0.946	86.8	96.3
Cross-sectional area (cm^2)	3.6	0.901	67.6	99.4
Fascicle length (mm)	18.8	0.794	61.8	98.9
Pennation angle	16.0	0.903	88.2	92.6

AUC: the area under the curve

P1179

REPRODUCTIVE HEALTH CHALLENGES AND THEIR IMPACT ON BONE METABOLISM IN GENETICALLY CONFIRMED COL1A1 OSTEOGENESIS IMPERFECTA: A CASE-BASED MULTIDISCIPLINARY FRAMEWORK

M. Velinovic[1], D. Vasovic[1], V. Jovanovic[1], B. Petrovic[1]

[1]Institute for Orthopaedics Banjica, Belgrade, Serbia

Objective

Osteogenesis imperfecta (OI) is a systemic collagen type I disorder. Beyond skeletal fragility, collagen type I is a key structural component of the endometrial stromal matrix and uteroplacental vasculature. Reproductive challenges in women with OI become increasingly clinically relevant in late reproductive age, when lactation-associated prolactin–PTHrP-mediated bone loss and declining bone remodeling capacity may converge. Data addressing reproductive outcomes and postpartum skeletal protection in this population remain limited.

Case presentation

We report a 36-year-old woman with childhood-onset OI who sustained a left tibial plateau fracture treated by Ilizarov circular external fixation on 17 July 2023. Genetic testing confirmed a heterozygous pathogenic COL1A1 frameshift variant (c.274del; p.Cys92ValfsTer173), consistent with autosomal dominant OI. Longitudinal densitometry documented severe bone material deficit from childhood (L1–L4 Z-score −4.2 at 12 years; −2.8 at 14 years) with persistent low bone mass in adulthood (L1–L4 Z-score −2.5 at 28 years; −3.3 at 37 years).

The patient had received oral alendronate (70 mg weekly) between 2014 and 2019. During bisphosphonate treatment in 2018, bone turnover markers demonstrated markedly suppressed bone formation (P1NP 8.6 ng/mL) and low resorption (CTX 76 pg/mL), consistent with a low-turnover collagen phenotype. She delivered a healthy child on 20 September 2022 and was actively breastfeeding at the time of fracture, corresponding to the highest physiological prolactin–PTHrP-mediated bone resorption window. The external fixator was removed on 21 December 2023. She is currently 38 years old and experienced two consecutive spontaneous miscarriages within the last year, and now expresses a desire for further conception. Targeted testing of her child did not detect the familial COL1A1 variant.

Management and proposal

Given the systemic collagen deficiency and low-turnover phenotype, a multidisciplinary reproductive–endocrine pathway was proposed before assisted reproduction, integrating metabolic priming, skeletal risk stratification, and genetic counseling with preimplantation genetic testing (PGT-M). A postpartum bone-protection plan was emphasized to address lactation-associated skeletal vulnerability.

Conclusion

This case highlights OI as a systemic reproductive collagen disorder with a distinct lactation-associated fracture-risk window. Proactive endocrine optimization, genetic guidance, and structured postpartum bone protection may improve both reproductive and skeletal outcomes in women with COL1A1-related OI.

P1180

SEVERE JUVENILE-ONSET CORTICAL OSTEOPOROSIS ASSOCIATED WITH A DE NOVO COPB2 VARIANT MIMICKING INFLAMMATORY BONE DISEASE: A CASE REPORT

M. Velinovic[1], I. Seslija[1]

[1]Institute for Orthopaedics Banjica, Belgrade, Serbia

Objective(s)

To describe a diagnostic challenge in a child with severe juvenile-onset osteoporosis mimicking inflammatory bone disease and to highlight the role of integrated densitometric and genetic assessment in guiding therapy.

Material and Methods

We report the clinical course of a 9-year-old girl presenting with chronic lower limb pain, gait impairment and recurrent low-trauma fractures. The patient underwent comprehensive clinical evaluation, laboratory assessment of mineral metabolism, imaging including magnetic resonance imaging, dual-energy X-ray absorptiometry (DXA), and whole genome sequencing.

Results

DXA demonstrated severe reduction in bone mineral density predominantly affecting cortical bone, with a femoral neck Z-score of −4.4 and total hip Z-score of −2.6, while lumbar spine Z-score was −1.3. Laboratory parameters of calcium-phosphate metabolism were within age-adjusted reference ranges, with adequate vitamin D levels and mildly elevated parathyroid hormone. Inflammatory markers were normal. Magnetic resonance imaging showed bone marrow edema without signs of active inflammation. Genetic analysis identified a heterozygous de novo nonsense variant in the COPB2 gene (c.10C>T; p.Arg4*), classified as a variant of uncertain significance. The clinical and densitometric phenotype strongly overlapped with recently described COPB2-associated childhood-onset osteoporosis. Based on the severity of bone loss and fragility fractures, intravenous bisphosphonate therapy was initiated.

Conclusion(s)
This case emphasizes that COPB2-associated juvenile osteoporosis may closely resemble inflammatory bone disorders, leading to misdiagnosis and delayed appropriate treatment. Severe cortical bone involvement on DXA should prompt consideration of primary bone fragility disorders. Therapeutic decisions should rely on clinical severity rather than genetic classification alone, with intravenous bisphosphonates representing an effective treatment strategy.

P1181

GLUCOCORTICOID IMPACT ON BONE DENSITY IN INFLAMMATORY BOWEL DISEASE PATIENTS

M. Vuksanovic[1], M. Marjanovic Petkovic[1], A. Cvetkov Grujanac[2], D. Stankovic[2], D. Trailov[2], M. Andjelic Jelic[3]

[1]University of Belgrade, Faculty of Medicine, Clinical University Hospital Zvezdara, Belgrade, Serbia; [2]Clinical University Hospital Zvezdara, Belgrade, Serbia; [3]Universiy of Belgrade, Faculty of Dental Medicine, Clinical University Hospital Zvezdara, Belgrade, Serbia

Objective: Inflammatory bowel diseases (IBD) are chronic diseases of the intestines, etiologically unclear, with complications such as osteoporosis. A lot of factors can cause osteoporosis in IBD patients, but one of the most significant ones is glucocorticoid (GC) therapy application. The aim was to determine bone density in IBD patients, as well as what effect glucocorticoid therapy has on bone density in these patients.
Material and methods: This retrospective study involved 60 patients who have IBD or other diseases of the intestines. Bone mineral density (BMD) was measured via DXA in the lumbar spine and the hip. Diagnosis was based on T and Z scores, depending on age. Height, weight and body mass index were measured. Data about the type of IBD, duration of the disease, application of GC, duration of menopause, presence of fractures and life habits such as smoking were taken.
Results: In IBD patients, 63% had osteoporosis and 20% had osteopenia. In postmenopausal women with IBD, 77% had osteoporosis and 18% had osteopenia. Among the premenopausal women, each third had normal bone density, osteopenia or osteoporosis, respectively. Menopause is a significant factor for low BMD in IBD women (p=0.036). Bone density deficit was noticed in 90% of IBD patients on GC (n=35). Among the patients who were not on GC (n=10), 50% had low BMD. A significant difference in BMD was noticed in patients who were on GC therapy (p=0.04). Average BMD of femoral neck of IBD patients who were on GC therapy was lower compared to patients who were not on GC (p=0.031). Patients who had been ill for 12 months or longer had a significantly lower BMD (p=0.02).
Conclusion: The application of GC in IBD patients reduces BMD, particularly in the femoral neck. Postmenopausal women and patients who have been ill for 12 months or longer are at higher risk.

P1182

GENTAMICIN-COATED TIBIAL NAILS IN REDUCING FRACTURE-RELATED INFECTIONS AND NON-UNION RATES: A SYSTEMATIC REVIEW OF OUTCOMES IN LOWER LEG TRAUMA

M. Z. Zarif[1]

[1]University of Buckingham, Buckingham, United Kingdom

Objective
Open tibial fractures remain at high risk of fracture-related infection (FRI) and impaired healing despite advances in fixation and systemic antibiotic therapy. Biofilm formation on implant surfaces is a key contributor to infection and non-union. Gentamicin-coated intramedullary nails have been introduced to provide local antimicrobial protection; however, comparative clinical evidence remains limited and fragmented. The aim was to evaluate whether gentamicin-coated intramedullary tibial nails are associated with reduced infection rates and improved bone healing compared with uncoated implants in adult patients with fresh open or revision tibial fractures.
Methods
A systematic review was conducted in accordance with PRISMA 2020 guidelines. PubMed, ScienceDirect, and the Cochrane Library were searched (January 2010–August 2025). Eligible studies included adults (≥18 years) undergoing fixation with gentamicin-coated tibial nails for fresh open fractures (FF) or revision surgery (RS). Outcomes included infection, union, delayed union, and non-union. Study quality was assessed using the Newcastle-Ottawa Scale and MINORS criteria. Due to heterogeneity, data were synthesised descriptively.
Results
Across included studies, infection rates in FF averaged approximately 5%, with union rates exceeding 80% and non-union rates around 10%. In RS for aseptic non-union or previous infection, union rates similarly exceeded 80%, with reinfection rates of approximately 10%. No statistically significant differences were observed between FF and RS groups for infection or healing outcomes ($p > 0.05$). Reoperation rates were approximately 18%, reflecting predominantly planned procedures in FF and complication-related interventions in RS. Overall, gentamicin-coated nails were consistently associated with favourable infection and healing outcomes, particularly in high-grade open fractures.
Conclusions
Gentamicin-coated intramedullary nails appear to reduce fracture-related infection and support bone healing in both primary and revision tibial fracture management. However, heterogeneity in study design, follow-up duration, and sample size limits definitive conclusions. Large, multicentre randomised trials using standardised FRI and union criteria are required to confirm clinical benefit.

P1183

FROM HOSPITAL TO THE PUBLIC: THE FIRST INTEGRATED OSTEOPOROSIS AND SARCOPENIA CARE NETWORK PROGRAM IN TAIWAN

M.-H. Hsieh[1], W.-H. Wen-Hua[2], L.-C. Li-Chi[2], J.-L. Jiun-Liang[3], Y.-Y. Ya-Yun[2]

[1]Department of Orthopedics, Dalin Tzu Chi Hospital, Buddhist Tzu Chi Medical Foundation, Chiayi, Taiwan; [2]Chiayi County Public Health Bureau, Chiayi, Taiwan; [3]Department of Orthopedics, Chiayi Chang Gung Memorial Hospital, Chiayi, Taiwan

Objective: Osteoporosis and sarcopenia are prevalent age-related conditions in Taiwan, driven by rapid population aging. Both disorders contribute to increased risks of fractures, disability, falls, and mortality. Integrated prevention and management strategies focusing on early screening, nutrition, exercise, and multidisciplinary care are essential to reduce healthcare burden and improve healthy aging outcomes. As one of the most rapidly aging areas in Taiwan with relatively limited healthcare resources, Chiayi County has an even greater need for an integrated prevention and care program.
Methods: Over the past two years, two FLS hospital cooperated with Chiayi County public health bureau and has expanded community health screening through mobile healthcare services. By integrating AI-assisted DXA screening with fracture liaison services, the county is establishing Taiwan's first integrated osteoporosis and sarcopenia care network linking public health centers and hospitals to enhance early detection, prevention, and long-term care.
Results: Sixteen of 18 local public health centers have been evaluated by the Capture the Fracture® Governance and been rated as Bronze in the map of the best practice. From April 2023 to December 2025, a total of 28,670 participants were screened. Approximately over 76% of participants were assessed as having osteopenia or worse. The proportion of individuals with a major osteoporotic fracture risk >20% was 8.4%. The proportion with a hip fracture risk >3% was 41.8%. About 7.7% of participants had experienced a low-energy fracture. The proportion with a STEADI fall risk score >4 was 10.7%. 7.7% participants had SARC-F questionnaire ≥4 and 18.9% had an abnormal response in one SARC-F item. Individuals identified with abnormalities were enrolled by trained professionals, provided with relevant information, and referred to appropriate hospitals for further evaluation and treatments.
Conclusion: These findings highlight the high prevalence of bone fragility, fall risk, and sarcopenia indicators in this population, emphasizing the need for early identification, preventive strategies, and targeted interventions to reduce fracture risk, falls, and functional decline. Through this integrated program, we are confident that implementing a similar initiative in other public agencies can enable more comprehensive and effective screening of local residents.

P1184

FRACTURE RISK PREDICTION IN DIALYSIS PATIENTS: A SYSTEMATIC REVIEW

M.-J. Bégin[1], A. Hang[2], A. Bergeron[3], A. Rakel[1], L.-G. Ste-Marie[1], F. Mac-Way[4], H. Cardinal[5], M. Chassé[6]

[1]Division of Endocrinology, Department of Medicine, Centre hospitalier de l'Université de Montréal (CHUM), Montréal, Canada; [2]Department of Social and Preventative Medicine, École de santé publique de l'Université de Montréal (ESPUM), Montréal, Canada; [3]Medical Libraries, Université de Montréal, Montréal, Canada; [4]Division of Nephrology, Department of Medicine, Centre hospitalier universitaire de Québec (CHU de Québec), Hôtel-Dieu de Québec, Québec, Canada; [5]Division of Nephrology, Department of Medicine, Centre hospitalier de l'Université de Montréal (CHUM), Montréal, Canada; [6]Division of Intensive Care, Department of Medicine, Centre hospitalier de l'Université de Montréal (CHUM), Montréal, Canada

Objective: The primary objective is to investigate the accuracy of available models and variables predicting fracture risk among chronic kidney disease stage 5D (CKD5D) patients. **Material and Methods:** This systematic review was conducted in accordance with methodological standards, and the protocol was registered in PROSPERO (CRD42024503688). A systematic search was conducted in MEDLINE, EMBASE, Cochrane Central, Cochrane Database of Systematic Reviews, CINHAL, the Web of Science Core Collection, IEEE Xplore, and in gray literature sources. Prospective and retrospective observational studies were included. The target population was adults with CKD stage 5 receiving dialysis (5D: hemodialysis (HD) or peritoneal dialysis (PD)). Studies addressing fracture prediction (discrimination or calibration) were included. Eligibility assessment (first and second screening) as well as extraction of articles were performed independently by two authors (MJB, AH) in a standardized manner (κ = 0.82). PROBAST was used to assess the risk of bias. Descriptive statistics were used to report and discuss results. **Results:** From the 6427 citations retrieved from literature search, 24 addressed fracture prediction in CKD5D and were included: 8 cross-sectional, 8 retrospective cohort and 8 prospective cohort studies. Several studies have examined the performance of bone mineral density (BMD) in predicting fracture risk or fracture status in patients undergoing chronic HD, no data specific to PD patients is available. Reported AUC for BMD in HD patients varies considerably from 0.50-0.85 in the literature included. Discrimination ability of FRAX with and without BMD for major osteoporotic fracture is reported to be fairly good in HD and PD patients (Table 1). In CKD5D population, the HRpQCT appears to have good discrimination ability for fracture status with AUCs of 0.66-0.90 depending on the parameter used. Different serum biomarkers have been studied with variable performance, particularly good AUC are reported for alkaline phosphatase and FGF-23. Most studies had a high or unclear risk of bias. **Conclusion:** This analysis highlights the potential gap in the evidence regarding fracture prediction tools in CKD5D population. FRAX score appears to have greater discriminatory potential than BMD alone.

Table 1. Discrimination (AUC) of FRAX for fracture prediction in dialysis patients

Population	Study	FRAX, outcome	AUC (95% CI)
Hemodialysis	Chang 2016, n=136	FRAX without BMD, MOF FRAX with BMD, MOF	0.715 (0.631-0.789) 0.697 (0.613-0.773)
	Przedlacki 2018, n=718	FRAX without BMD, hip fx FRAX without BMD, MOF	0.70 (0.563–0.832) 0.76 (0.69-0.84)
	Jafari 2021, n=109	FRAX with BMD, MOF + FN T-score FRAX with BMD, hip fx + FN T-score	0.73 (0.63-0.83) 0.78 (0.69-0.88)
	Jirasirirak 2022, n=80	FRAX without BMD, MOF FRAX without BMD, hip fx	0.64 (0.47-0.81) 0.62 (0.46-0.79)
Peritoneal dialysis	Diz Lopez 2025, n= 184	FRAX without BMD, MOF	0.755 (0.651-0.858)

AUC: area under the curve (Receiver Operating Characteristic analysis), BMD: bone mineral density, CI: confidence intervals, FN: femoral neck, hip fx: hip fracture, MOF: major osteoporotic fracture

WHOLE SLIDE IMAGING USED FOR HISTOMORPHOMETRIC ANALYSIS OF BONE BIOPSY: DIGITAL TRANSITION AND EXPLORATION OF ARTIFICIAL INTELLIGENCE APPLICATION

M.-J. Bégin[1], N. Dion[2], B.-N. Nguyen[2], L.-G. Ste-Marie[1]

[1]Division of Endocrinology, Department of Medicine, Centre hospitalier de l'Université de Montréal (CHUM), Montréal, Canada; [2]Division of Pathology, Centre Hospitalier de l'Université de Montréal (CHUM), Montréal, Canada

Histomorphometric analysis (HA) of undecalcified bone biopsies is the gold standard for diagnosing complex bone disorders. Traditionally, HA is performed through microscopic observation of glass slides and computerized semi-automated image analysis systems (SAIAS). Advances in digital pathology and artificial intelligence (AI) have expanded slide evaluation. Since 2019, our center has adopted whole slide imaging (WSI)-based digital pathology, initiating the digital transition of HA.

Objectives: To report our experience with the digital transition of HA and to explore the use of AI-based tools.

Material and Methods: Goldner's trichrome slides were digitalized with a Hamamatsu NanoZoomer XR brightfield scanner (226 nm/pixel) and unstained slides were digitalized by a Leica Aperio Versa fluorescent scanner (446 nm/pixel). Digital HA validation was performed through comparison with a standard microscope-based method. Eight patients with bone fragility were included in the exploratory AI analysis. Bone volume (BV/TV) and osteoid volume (OV/BV) values measured by AI-based tools (CaloPix®) were compared with two SAIAS (OsteoMetrics® and Bioquant®).

Results: The use of WSI for HA provides a seamless digital workflow that enables efficient navigation across multiple magnifications. This enhances visualization, improves tissue and cellular assessment, and supports more precise, reproducible measurements. WSI offers key advantages, including facilitating expert collaboration through highresolution image sharing, supporting remote mentoring, and promoting research and education. Digital archiving, particularly for fluorescent labeling, ensures longterm preservation. AI-based tools refine tissue segmentation by combining color information with pixel-level features such as texture and edges, enabling accurate differentiation of bone, osteoid, and marrow. Repeated-measures ANOVA and Friedman test revealed a non-significant difference (p>0.05) between the two SAIAS and AI tools for BV/TV and OV/BV.

Conclusions: The adoption of digital pathology is a paradigm shift in HA and should be encouraged. It will facilitate collaboration, teaching and research. Furthermore, it will help development of AI-based tools to support analysis and improve phenotyping of complex bone disorders.

P1186

FRACTURE RISK PREDICTION IN KIDNEY TRANSPLANT RECIPIENTS: A SYSTEMATIC REVIEW

M.-J. Bégin[1], A. Hang[2], A. Bergeron[3], A. Rakel[1], L.-G. Ste-Marie[1], F. Mac-Way[4], H. Cardinal[5], M. Chassé[6]

[1]Division of Endocrinology, Department of Medicine, Centre hospitalier de l'Université de Montréal (CHUM), Montréal, Canada; [2]Department of Social and Preventative Medicine, École de santé publique de l'Université de Montréal (ESPUM), Montréal, Canada; [3]Medical Libraries, Université de Montréal, Montréal, Canada; [4]Division of Nephrology, Department of Medicine, Centre hospitalier universitaire de Québec (CHU de Québec), Hôtel-Dieu de Québec, Québec, Canada; [5]Division of Nephrology, Department of Medicine, Centre hospitalier de l'Université de Montréal (CHUM), Montréal, Canada; [6]Division of Intensive Care, Department of Medicine, Centre hospitalier de l'Université de Montréal (CHUM), Montréal, Canada

Objective: The primary objective is to investigate the accuracy of available models and variables predicting fracture risk among kidney transplant recipients (KTR). **Material and Methods:** A systematic search was conducted in MEDLINE, EMBASE, Cochrane Central, the Cochrane Database of Systematic Reviews, CINHAL, the Web of Science Core Collection, IEEE Xplore, and in gray literature sources, in accordance with methodological standards, until November 2025. The protocol was registered in PROSPERO (CRD42024503688). Prospective and retrospective observational studies addressing fracture prediction (discrimination or calibration) were included. The target population was adults with chronic kidney disease; this subgroup analysis included only KTR. Eligibility assessment (first and second screening) as well as

extraction of articles were performed independently by two authors (MJB, AH) in a standardized manner (κ = 0.82). PROBAST was used to assess the risk of bias. Descriptive statistics were used to report and discuss results. **Results:** From the 6427 citations retrieved from literature search, four studies involving KTR were included. Two retrospective population-based Canadian studies evaluated bone mineral density (BMD), FRAX and trabecular bone score (TBS) (n=458/327), one retrospective cohort study assessed the impact of BMD on incident fractures (n=48), and finally one study analyzed BMD and Calcaneal Trabecular Bone Structure (CTBS) predicting fracture in a cross-sectional design (n=357). The mean time elapsed since KT was 0.3, 1.1, 4.3 and 12.6 years and weighted average age was 47.1 years. Discrimination capacity of BMD in KTR seems poor to moderate, with AUC varying between 0.541 and 0.680. FRAX with or without BMD for major osteoporotic fracture, as well as TBS, had moderate predictive value (AUC 0.62-0.64). CTBS seems to have interesting discrimination ability (AUC 0.87) (Table 1). Most studies had a high risk or unclear risk of bias. **Conclusion:** Limited data are available in KTR to stratify high fracture risk patients after transplant. Discrimination capacity of BMD and FRAX appears to be lower than in the general population. In KTR, development and validation of fracture prediction models specific to their risk factors are needed to better guide fracture prevention management.

Table 1. Discrimination (AUC) of different variables/models for fracture prediction in kidney transplant recipients

Variable	Study	BMD site	AUC (95% CI)
BMD	Naylor 2014 n=458	Lumbar spine (T-score) Femoral neck (T-score) Total hip (T-score)	0.60 (0.49-0.71) 0.64 (0.53-0.75) 0.58 (0.47-0.68)
	Link 2002 n=48	Femoral neck (g/cm^2)	0.64

SEX-SPECIFIC ASSOCIATIONS OF GRIP STRENGTH WITH LONG-TERM CARDIOVASCULAR AND CEREBROVASCULAR OUTCOMES: FINDINGS FROM THE 16-YEAR KOREAN LONGITUDINAL STUDY OF AGING

E.-J. Jung[1,2,3], M.-R. Lee[4]

[1]Department of Public Healthcare Center, Seoul National University Hospital, Seoul, South Korea; [2]Department of Public Health and Medical Services, Seoul National University Hospital, Seoul, South Korea; [3]Department of Preventive Medicine, Seoul National University College of Medicine, Seoul, South Korea; [4]Department of Preventive Medicine, Soonchunhyang University College of Medicine, Cheonan, South Korea

OBJECTIVE(S)
Handgrip strength is a simple measure of muscle function linked to health outcomes in older adults. This study investigated whether higher grip strength is associated with a lower risk of cardiovascular (CVD) and cerebrovascular (CeVD) disease in middle-aged and older adults, focusing on sex-specific associations and the potential protective role of grip strength in women.
MATERIAL AND METHODS
We analyzed data on approximately 9,500 participants of the Korean Longitudinal Study of Aging (aged ≥45 years, free of CVD/CeVD at baseline). Grip strength was measured in multiple waves and treated as a time-varying exposure. Cross-sectional logistic regression was used to evaluate baseline associations, and Cox regression models with time-varying grip strength were used to assess the 16-year incidences of CVD and CeVD after adjusting for major confounders. The analyses were stratified according to sex.
RESULTS
Higher handgrip strength was inversely associated with prevalent CVD and CeVD at baseline (p<0.001). Over a 16-year follow-up, each 1-kg grip strength increase predicted a lower hazard of CeVD (hazard ratio [HR] ~0.98), driven by a significant protective effect in women (HR ~0.95), with no association in men. Similarly, higher grip strength predicted a lower CVD risk in women (HR ~0.97), but not in men.
CONCLUSION(S)
Greater grip strength is associated with reduced risks of CVD and CeVD later in life, with particularly pronounced benefits in older women. These findings suggest that preserving muscle strength may help reduce the risk of cardiovascular and cerebrovascular disease in this population.

P1188

ASSOCIATION OF ANTHROPOMETRIC FACTORS AND BONE MINERAL DENSITY WITH KNEE OSTEOARTHRITIS IN HAKKA WOMEN AGED 50 YEARS AND OLDER: A COMMUNITY-BASED STUDY

Y.-C. Huang[1], S.-W. Kao[1], Y.-C. Chen[1], M.-T. Cheng[1]

[1]Taoyuan General Hospital, Taoyuan, Taiwan

Objective
This study aimed to investigate the risk factors and relationship between osteoporosis and osteoarthritis (OA) in ethnic-specific Hakka women.
Materials and Methods
We conducted a retrospective study of community-dwelling Hakka women aged ≥50 years in Northwest Taiwan. Anthropometric data (age, height, weight, BMI) and bone mineral density (BMD) using dual-energy X-ray absorptiometry (DXA) were obtained. Radiographic knee OA was defined by Kellgren–Lawrence grade ≥3.
Results
1,429 participants with available radiographic knee OA status were analyzed. In the multivariable logistic regression model adjusting for all anthropometric factors, age and body weight are significant risk factors, while greater height showed a protective effect of knee OA. Specifically, each additional year of age increased the odds of knee OA by 6% (OR 1.06, 95% CI 1.05–1.08), and each kilogram of weight increased the odds by 8% (OR 1.08, 95% CI 1.06–1.09). Conversely, each centimeter increase in height reduced the odds of knee OA by approximately 5% (OR 0.95, 95% CI 0.93–0.98). In addition, BMI was strongly correlated with knee OA ($r = 0.263$, $p < 0.001$), each 1 kg/m² increase in BMI was associated with a 19% higher odds of knee OA (OR 1.19, 95% CI 1.14–1.23, $p < 0.001$). BMD at the lumbar spine and hips was further examined. In the multivariable logistic regression model, lumbar spine BMD was significantly associated with increased risk of knee OA (OR 1.25, 95% CI 1.11–1.42, $p < 0.001$). In contrast, BMD at the hip showed no significant associations with knee OA. When age was included as a covariate, lumbar spine BMD remained independently associated with knee OA. In the multivariable logistic regression model, each 1-unit decrease in lumbar spine T-score increased the odds of knee OA by 31% (OR 1.31, 95% CI 1.19–1.43, $p < 0.001$).
Conclusions
In this study of 1,429 Hakka women, knee osteoarthritis was strongly influenced by age, body weight, and BMI, whereas greater height was protective. Lumbar spine BMD, but not hip BMD, remained independently associated with knee OA even after adjusting for age, with lower T-scores markedly increasing risk. These findings highlight age, body composition, and lumbar spine bone loss as key determinants of knee OA in this ethnic-specific population.

P1189

ACCURACY OF A TAIWAN-SPECIFIC DEMOGRAPHIC MODEL FOR PREDICTING FEMORAL AND TIBIAL COMPONENT SIZES IN TOTAL KNEE ARTHROPLASTY

Y.-C. Huang[1], S.-W. Kao[1], Y.-C. Chen[1], M.-T. Cheng[1]

[1]Taoyuan General Hospital, Taoyuan, Taiwan

Objective
Total knee arthroplasty (TKA) demand is increasing rapidly in aging Asian populations. Accurate implant sizing is essential to optimize surgical efficiency and outcomes, yet conventional radiographic templating shows limited exact-size accuracy and may not adequately account for ethnic and anthropometric differences. Demography-based prediction models have shown promise, but population-specific validation remains limited in East Asian cohorts.
Methods
We conducted a retrospective study of consecutive patients aged ≥40 years who underwent primary TKA at a single institution between January 2022 and December 2024. Demographic variables (age, sex, height, weight, body mass index) and implanted femoral and tibial component sizes were collected. All patients received the same implant system. Univariable and multivariable linear regression analyses were performed to identify predictors of component size. Model performance was evaluated using exact match and ±1 size accuracy, calibration analyses, and sex-stratified assessments. Predicted sizes were converted to discrete implant sizes using a standardized clinical rounding rule.
Results
A total of 633 patients (461 females, 172 males) were included. Height, weight, and sex were the strongest independent predictors of both femoral and tibial component sizes. Multivariable models explained approximately two-thirds of the variance in implanted sizes (femur: $R^2 = 0.666$; tibia: $R^2 = 0.689$). Exact match accuracy was 69.2% for femoral and 52.9% for tibial components, while ±1 size accuracy exceeded 95% for both. Calibration analyses demonstrated good agreement between predicted and actual sizes. Sex-stratified analyses showed consistent performance in female and male patients, with no clinically meaningful sex-related bias.
Conclusions
A demography-based prediction model tailored to Taiwanese patients can accurately estimate femoral and tibial component sizes in TKA. Although exact match accuracy was moderate, high ±1 size accuracy better reflects clinically acceptable performance. This population-specific approach may enhance preoperative planning, optimize implant inventory management, and improve workflow efficiency in Asian arthroplasty practice.

P1190

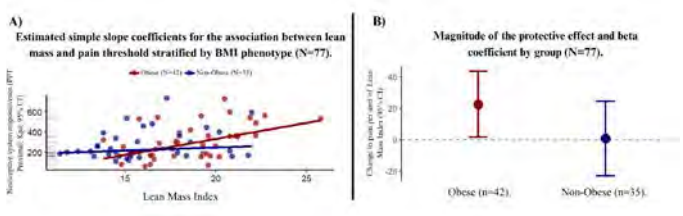
RADIOGRAPHIC KNEE OSTEOARTHRITIS IS ASSOCIATED WITH HIGHER LUMBAR SPINE BONE MINERAL DENSITY BUT NOT REDUCED FRACTURE RISK IN OLDER WOMEN

Y.-C. Huang[1], M.-T. Cheng[1]

[1]Taoyuan General Hospital, Taoyuan, Taiwan

Objective
Osteoarthritis and osteoporosis commonly coexist in older adults, yet the relationship between radiographic knee osteoarthritis, site-specific bone mineral density, and fracture risk remains controversial. Degenerative changes associated with osteoarthritis may influence dual-energy X-ray absorptiometry measurements, particularly at the lumbar spine, potentially obscuring true skeletal fragility.
Methods
This retrospective cross-sectional study included community-dwelling women aged 50 years and older who underwent knee radiography and bone mineral density assessment. Radiographic knee osteoarthritis was defined as Kellgren–Lawrence grade ≥2. Bone mineral density T-scores at the lumbar spine and hip were measured using dual-energy X-ray absorptiometry. Vertebral, hip, and distal radius fractures were identified using radiographic and clinical records. Multivariable logistic regression models were applied to evaluate independent associations between knee osteoarthritis, bone mineral density, and fracture outcomes after adjustment for age and body mass index.
Results
A total of 2,036 women were included, of whom 27.0% had radiographic knee osteoarthritis. Women with knee osteoarthritis were older and had higher body mass index than those without osteoarthritis. Lumbar spine bone mineral density T-scores were significantly higher in women with knee osteoarthritis, whereas hip bone mineral density showed no independent association after adjustment. Vertebral fractures were more prevalent among women with knee osteoarthritis in unadjusted analyses; however, this association was fully attenuated after adjustment for age and body mass index. No independent associations were observed between knee osteoarthritis and hip or distal radius fractures.
Conclusions
Radiographic knee osteoarthritis is independently associated with higher lumbar spine bone mineral density but does not confer protection against vertebral or non-vertebral fractures. These findings suggest that elevated spine bone mineral density in individuals with knee osteoarthritis likely reflects degenerative artifacts rather than improved bone strength. Emphasizing hip bone mineral density and clinical fracture history may provide a more reliable assessment of skeletal health in osteoarthritic populations.

P1191



THE PROTECTIVE EFFECT OF LEAN MASS ON NOCICEPTIVE SYSTEM RESPONSIVENESS IN KNEE OSTEOARTHRITIS IS RESTRICTED TO OBESITY: A MODERATION ANALYSIS.

F. E. S. Sette[1], N. A. C. Casonato[1], S. M. M. Mattiello[1]

[1]Department of Physical Therapy, Federal University of São Carlos (UFSCar), São Carlos, Brazil

Objective: Obesity appears to negatively influence nociceptive modulation in individuals with Knee Osteoarthritis (KOA). However, the protective role of lean mass regarding pain in obese and non-obese subjects with KOA remains uncertain in the literature. We hypothesized that the Lean Mass Index would exert a more effective protective role against knee pain in obese individuals with KOA. The aim of this study was to investigate the interaction between obesity and Lean Mass Index on nociceptive system responsiveness in obese and non-obese individuals with KOA
Materials and Methods: Seventy-seven participants aged >40 years, of both sexes, with a clinical diagnosis of KOA according to the American College of Rheumatology criteria, were selected and divided into two groups based on Body Mass Index (BMI): (1) non-obese or overweight KOA and (2) obese KOA. Nociceptive system responsiveness was assessed based on the stimulus-response function, obtained via a psychophysical direct scaling protocol using a pressure algometer. A moderation analysis was performed using quantile regression with simple slopes decomposition to investigate the interaction between obesity and Lean Mass Index.
Results: Our results indicate a significant interaction between obesity and Lean Mass Index on nociceptive system responsiveness. Simple slopes analysis revealed that in the obese group, lean mass acted as a strong protective factor (β = 22.5; p = 0.034). For every unit increase in Lean Mass Index, the pain threshold significantly increased. Conversely, in the non-obese group, lean mass showed no protective effect (β = 0.68; p = 0.95) regarding pain in KOA.
Conclusion: Our results indicated that lean mass exhibited a protective effect on nociceptive pain in obese individuals with KOA, but not among non-obese subjects. These findings highlight the importance of muscle mass gain for obese individuals with KOA as part of the treatment for this condition.

Figure *1* - Quantile Regression Estimates of Lean Mass and Pain Threshold by BMI Phenotype (N=*77*).
Figure 1 – (A) Quantile regression demonstrating divergent slopes: lean mass increases the pain threshold in the obese, but not in the non-obese. (B) Magnitude of effects (simple slopes) confirming significant protection only under the condition of obesity.

P1192

DIVERGENT EFFECTS OF BODY COMPOSITION ON BONE MASS IN KNEE OSTEOARTHRITIS: A PRELIMINARY 8-MONTH LONGITUDINAL STUDY

N. A. Casonato[1], F. E. Sette[1], M. G. Silva[1], R. F. Tizzioti[1], J. B. Aily[1], S. M. Mattiello[1]

[1]Federal University of São Carlos, São Carlos, Brazil

Objective: Knee osteoarthritis (KOA) is frequently accompanied by alterations in body composition that may influence bone health; however, longitudinal evidence remains limited. This preliminary study aimed to evaluate 8-month trajectories of bone mineral density (BMD) and examine their associations with body mass index (BMI), body fat percentage (PFAT), pain catastrophizing (PCS), and clinical variables in adults with KOA.

Material and methods: Adults aged ≥40 years with clinically diagnosed KOA underwent assessments including BMI, PFAT and BMD via dual-energy X-ray absorptiometry (Hologic DEXA). Demographic variables (age, sex) and PCS were also collected. BMD was repeatedly measured across several time points over an 8-month follow-up. Linear mixed-effects models were used to examine associations between BMD and BMI, PFAT, PCS, age, sex, and time. Statistical analyses were performed in RStudio, with significance set at $p < 0.05$.

Results: Forty-two participants were included (40.5% obese; 64.3% women; mean age 58 years). Overall, BMD remained stable over time, with no significant monthly change (β = 0.006 g/month; p = 0.408), despite substantial interindividual variability (ICC ≈ 0.94). Higher BMI was significantly associated with greater BMD (β = 0.109 g; p = 0.038), consistent with a potential osteoprotective effect of mechanical loading. In contrast, higher PFAT showed a nonsignificant inverse trend with BMD (β = −0.082 g; p = 0.114), suggesting a possible adverse metabolic influence. Age, sex, and PCS were not associated with BMD. Predicted trajectories (Fig. 1) indicated overall BMD stability while reinforcing the divergent associations of BMI and PFAT.

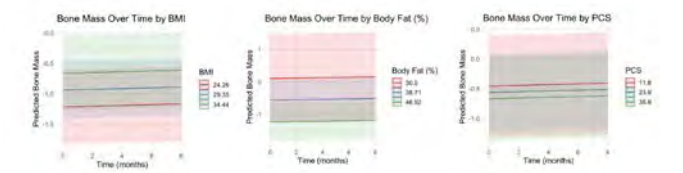


Figure 1 - Predicted bone mass trajectories over 8 months according to BMI, body fat percentage, and pain catastrophizing (PCS). Each panel displays the estimated bone mass over time derived from the linear mixed-effects model. Colored lines represent predicted trajectories for representative values of each variable.

Conclusion: In this preliminary longitudinal cohort of individuals with KOA, BMD remained stable over 8 months. BMI was positively associated with bone mass, whereas PFAT showed an opposite tendency, highlighting divergent effects of body composition components on bone health in KOA.

P1193

ADIPOSITY IS ASSOCIATED WITH PERIPHERAL PAIN SENSITIVITY IN INDIVIDUALS WITH KNEE OSTEOARTHRITIS - COMPARISON BETWEEN APPENDICULAR FAT MASS AND THE KNEE REGION OF INTEREST

N. A. Casonato[1], Y. A. De Miranda[1], I. L. Nobrega[1], F. E. Sette[1], J. B. Aily[1], S. M. Mattiello[1]

[1]Federal University of São Carlos, São Carlos, Brazil

Objective: Obesity contributes to knee osteoarthritis (KOA) pain through mechanical and metabolic–inflammatory pathways; however, the role of regional fat distribution in peripheral and central pain sensitization remains unclear. This study investigated associations between regional adiposity and peripheral and central pressure pain thresholds (PPT) in obese and non-obese individuals with KOA.

Material and methods: Thirty-six individuals with clinically and radiographically confirmed KOA (Kellgren & Lawrence grades II–IV) were categorized as obese or non-obese. Peripheral and central PPT were assessed using a digital algometer (Algomed, Medoc) at the medial joint line of the most painful knee and at the contralateral thenar eminence, respectively. Total body and appendicular fat percentages were assessed by dual-energy X-ray absorptiometry (DXA; Hologic). Periarticular knee fat mass was quantified using a predefined region-of-interest (ROI). Multivariable linear regression models were applied to examine associations between adiposity measures and PPT outcomes, adjusting for relevant covariates ($p < 0.05$).

Results: The sample included 20 obese and 16 non-obese participants (mean age 60.1 years; mean BMI 30.5 kg/m²). Mean peripheral and central PPT values were 199.1 kPa and 249.9 kPa, respectively. Participants exhibited marked regional adiposity (mean quadriceps fat area 1618.4 mm²; thigh fat percentage 46.1%). In adjusted models, central PPT was not associated with systemic or regional adiposity (adjusted $R^2 = 0.004$; p = 0.439). Conversely, peripheral PPT showed a modest but significant association with periarticular knee fat (β = 0.19; p = 0.036), whereas BMI and total body fat percentage were not associated with PPT. Predicted plots indicated weak inverse trends between systemic adiposity and PPT, while local adiposity showed a site-specific relationship restricted to peripheral pain sensitivity (Fig. 1).

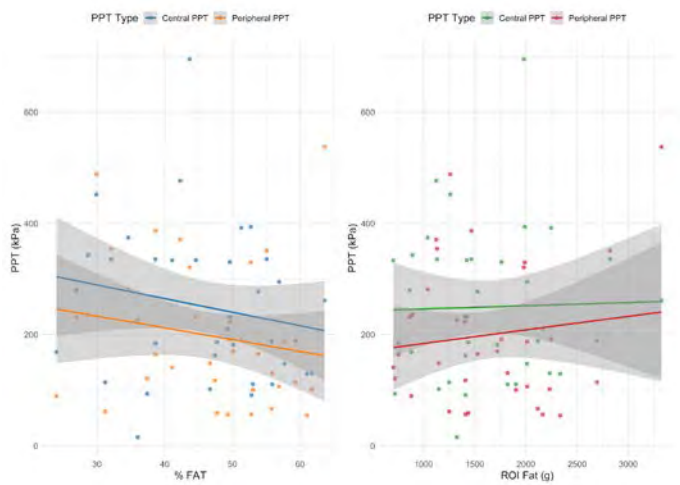

Figure 1. Associations between body fat measures and PPTs

Conclusion: In KOA, systemic adiposity does not appear to meaningfully

influence pressure pain sensitivity or central sensitization. In contrast, periarticular knee fat shows a modest, site-specific association with peripheral PPT, suggesting a localized influence of fat accumulation on nociceptive processing.

P1194

TRENDS IN ALCOHOL-ATTRIBUTABLE FALL-RELATED INJURY BURDEN IN THE NORTH AFRICA AND MIDDLE EAST REGION, 1990–2023

M. Dehghani[1], N. Zareshahi[1], N. Behgam[2], S. Akbarpour[3]

[1]Non-Communicable Diseases Research Center, Endocrinology and Metabolism Population Sciences Institute , Tehran University of Medical Sciences, Tehran, Iran; [2]Endocrinology and Metabolism Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran; [3]Non-Communicable Diseases Research Center, Endocrinology and Metabolism Population Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran

Objective: To assess trends in the burden of fall-related injuries attributable to alcohol use in the North Africa and Middle East region between 1990 and 2023.

Material and Methods: Age-standardized DALY and mortality rates for falls attributable to alcohol use were extracted from Global Burden of Disease 2023 estimates for 1990–2023 in the region, stratified by sex.

Results: The alcohol-attributable falls burden showed a steady decline over the study period. The total age-standardized DALY rate dropped from 1.44 per 100,000 in 1990 to 1.01 in 2023. This burden was predominantly shouldered by men, whose DALY rates fell from 2.62 to 1.82 (with fall-related deaths decreasing from 0.023 to 0.014 per 100,000), whereas women's rates remained minimal, declining from 0.19 to 0.12 (deaths from 0.0011 to 0.000054).

Conclusions: The marked reduction in alcohol-related fall injuries indicates progress in mitigating this risk, likely reflecting effective public health policies or changing alcohol use patterns. However, the persistent male predominance in this burden highlights a need for targeted interventions focusing on men. Strengthening alcohol control measures and fall-prevention strategies — especially among high-risk male populations — should remain a priority to further reduce this preventable injury burden.

P1195

BURDEN OF FALLS ATTRIBUTABLE TO LOW BONE MINERAL DENSITY IN THE NORTH AFRICA AND MIDDLE EAST REGION, 1990–2023

N. Behgam[1], A. Dashti[2], S. Akbarpour[3]

[1]Non-Communicable Diseases Research Center, Endocrinology and Metabolism Population Sciences Institute , Tehran University of Medical Sciences, Tehran, Iran; [2]Endocrinology and Metabolism Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran; [3]Non-Communicable Diseases Research Center, Endocrinology and Metabolism Population Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran

Objective: To evaluate the burden and temporal trends of fall-related injuries attributable to low bone mineral density (BMD) in the North Africa and Middle East region from 1990 to 2023.

Material and Methods: Age-standardized DALY and mortality rates for falls due to low BMD were obtained from Global Burden of Disease 2023 data for 1990–2023 in the region, with stratification by sex.

Results: The overall falls burden attributable to low BMD remained largely stable over the study period. Total age-standardized DALY rates plateaued, changing only slightly from 85.62 to 83.50 per 100,000. Women consistently experienced a higher DALY burden (maintaining ~88 per 100,000) than men (~79–83 per 100,000) throughout 1990–2023. Meanwhile, fall-related mortality due to low BMD showed a modest decline: the combined death rate fell from 2.87 to 2.39 per 100,000 (men from 2.99 to 2.60; women from 2.78 to 2.24).

Conclusions: The persistently high burden of falls linked to low BMD — especially among women — emphasizes the ongoing need for robust osteoporosis prevention and bone health strategies in the region. Despite a slight improvement in mortality, the stable disability rates suggest that current efforts in fracture prevention and osteoporosis management have plateaued. Policymakers should bolster initiatives (e.g., wider bone density screening, calcium/vitamin D supplementation, fall prevention programs) to reduce BMD-related fall injuries and address the gender gap in bone health.

P1196

TOBACCO USE AS A DETERMINANT OF LOW BACK PAIN BURDEN IN THE NORTH AFRICA AND MIDDLE EAST REGION, 1990–2023

N. Behgam[1], G. Shakibamaram[2], M. Dolikhani[2], S. Akbarpour[3]

[1]Non-Communicable Diseases Research Center, Endocrinology and Metabolism Population Sciences Institute , Tehran University of Medical Sciences, Tehran, Iran; [2]Department of Orthopedic Surgery and Traumatology, School of Medicine, Shahid Beheshti University of Medical Sciences, Tehran, Iran; [3]Endocrinology and Metabolism Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran

Objective: To examine the long-term trends in low back pain attributable to tobacco consumption across the North Africa and Middle East region from 1990 to 2023.
Material and Methods: Age-standardized disability-adjusted life years (DALYs) for low back pain linked to tobacco use were obtained from the Global Burden of Disease 2023 dataset. Data were stratified by sex and analyzed over the 1990–2023 period to assess temporal and gender-specific patterns.
Results: The total regional burden of tobacco-related low back pain showed a gradual reduction. DALY rates declined from 122.41 to 107.49 per 100,000 over the study period. This burden was consistently higher in men, with DALYs dropping from 195.68 to 167.51 per 100,000, while women exhibited a significantly lower and more stable trend (from 45.43 to 42.53 per 100,000)
Conclusions: Tobacco use remains a modifiable contributor to the musculoskeletal disease burden in the region, particularly among men. Despite a modest decline, the persistently high burden in males calls for strengthened tobacco cessation policies integrated with musculoskeletal health initiatives. Policymakers should consider embedding spine health messages into smoking cessation campaigns and enhancing gender-sensitive interventions to reduce the disability impact of smoking-related low back pain.

P1197

RELATIONSHIP BETWEEN BODY MASS INDEX AND SARCOPENIA RISK IN THE BIRJAND LONGITUDINAL AGING COHORT IN IRAN

N. Behgam[1], B. Mohammadi[2], M. Mohammadi[1], S. Akbarpour[3]

[1]Non-Communicable Diseases Research Center, Endocrinology and Metabolism Population Sciences Institute , Tehran University of Medical Sciences, Tehran, Iran; [2]Endocrinology and Metabolism Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran; [3]Non-Communicable Diseases Research Center, Endocrinology and Metabolism Population Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran

Objective: To investigate the relationship between body mass index (BMI) and sarcopenia risk among older participants in the Birjand Longitudinal Aging Cohort.

Material and Methods: This analysis included 1,348 elderly participants from the Birjand Longitudinal Aging Study (BLAS). Body Mass Index (BMI) was categorized into three groups: Normal/Underweight (<25 kg/m²), Overweight (25–29.9 kg/m²), and Obese (≥30 kg/m²). Sarcopenia status was classified as either 'Robust'; or 'Probable Sarcopenia' based on muscle strength criteria. The association between BMI categories and sarcopenia risk was evaluated using chi-square tests, while mean BMI differences between robust and sarcopenic groups were compared using independent sample t- tests in Stata.

Results: BMI was significantly associated with sarcopenia in this cohort (P=0.001). Older adults with a normal or underweight BMI (<25 kg/m²) had the highest prevalence of probable sarcopenia (47.5%), whereas those in the overweight range (25–29.9) exhibited the lowest prevalence (36.5%). Obese participants (BMI ≥30) had a similarly lower prevalence (38.3%), suggesting that higher body mass might confer some protection against sarcopenia in late life. Consistently, the mean BMI of non-sarcopenic individuals was slightly higher than that of those with sarcopenia (26.71 vs 26.02, respectively; P=0.020).

Conclusions: In this elderly population, lower BMI was associated with greater sarcopenia risk, while being overweight (or mildly obese) appeared to be protective against muscle loss. This paradoxical finding highlights the importance of avoiding undernutrition in older adults: maintaining an adequate BMI and muscle mass is crucial for healthy aging. Geriatric care strategies should carefully balance weight management goals with the need to preserve muscle, rather than promoting weight loss indiscriminately in all seniors. Public health programs must focus on nutritional support and resistance training for at-risk, lean older individuals to reduce sarcopenia and its associated adverse outcomes.

P1198

REVISITING THE ADFR CONCEPT: CLINICAL USE OF CYCLIC ROMOSOZUMAB

N. Binkley[1], S. Wheeler[1], C. Morganti[1], D. Krueger[1], K. Hare[1]

[1]University of Wisconsin-Madison, Madison, Wisconsin, United States

Objective: Evaluation of novel osteoporosis medication approaches to maximize BMD is reasonable. A bone remodeling-based approach, i.e., activate, depress, free and repeat (ADFR) has been proposed. We hypothesized that short course romosozumab (Romo) followed by denosumab (Dmab) may be an advantageous ADFR strategy. Here we report data from a clinical cohort treated with monthly Romo for six months followed by a Dmab dose, then repeated. FRAME data were used as a BMD change referent.
Methods: Women at very high fracture risk were offered cyclic therapy by bone health practitioners. DXA was obtained at baseline, 1 and 2 years. Data from 41 women treated for 1, and 11 for 2, years are reported. BMD change from baseline was evaluated by ANOVA.
Results: Cyclic (C) patient demographics were similar to FRAME (F) subjects; mean age 68.8 C/70.9 F years, BMI 25.6 C/24.7 F kg/m², FN T-score -2.6 C/-2.8 F; 90% of C patients had prior fractures. After one cycle, mean (SD) % BMD increase (all p < 0.001) from baseline at LS, TH and FN was 12.6 (6.6), 5.9 (5.3) and 4.4 (5.9) respectively, similar to 12 months of Romo in FRAME (Figure 1a). After two years of cyclic

treatment BMD mean (SD) increase from baseline was LS 17.5% (6.5), TH 9.0% (5.9) and FN 5.5% (4.2) also similar to FRAME (Figure 1b). In a subset (n = 6) CTX was suppressed (all ≤ 80 pg/mL) prior to the second Romo course. No major adverse cardiac events occurred.

Conclusion: At one year, six doses of Romo then one Dmab dose increased BMD comparably to 12 months of Romo in FRAME. A second Romo/Dmab course further increased BMD, but the response was blunted perhaps reflecting persistent turnover suppression. Evaluation of novel Romo dosing approaches is indicated.

HEMOPHILIC ARTHROPATHY: A REPORT OF FOUR CASES

N. Boulemani[1]

[1]El Harrouch, Constantine, Algeria

Introduction: In major hemophilia, chronic arthropathy is responsible for severe functional disability.

Case Reports: We describe the cases of four men who have suffered from hemophilic arthropathy for several years. For each patient, various epidemiological, clinical, radiological, and management aspects were investigated.

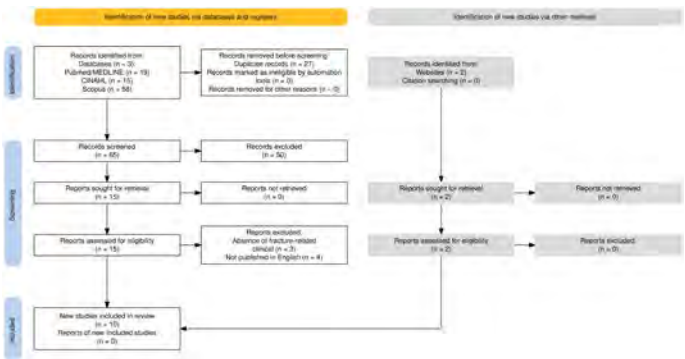
Discussion: The results show that severe hemophilia patients on prophylaxis, even in the absence of clinical hemarthrosis, can develop arthropathy, primarily affecting the ankles. Furthermore, patients who have developed aloimmunization against their replacement factor are particularly at risk of hemophilic arthropathy, especially in cases of immune tolerance failure.

Conclusion: Although replacement prophylaxis with coagulation factors helps limit the risk of spontaneous hemarthrosis in hemophilia patients, hemophilic arthropathy remains a significant concern and can be disabling for many.

P1201

FRACTURE MANAGEMENT AND HEALING OUTCOMES IN OSTEOPOIKILOSIS: A SYSTEMATIC REVIEW AND SYNTHESIS WITHOUT META-ANALYSIS (SWIM)

N. Chanalithichai[1], R. Suwanaratana[1]



[1]Princess Srisavangavadhana Faculty of Medicine, Chulabhorn Royal Academy, Bangkok, Thailand

Objective(s): Fractures in patients with Osteopoikilosis (OPK) pose a unique challenge due to the unknown biomechanical quality of the sclerotic bone islands. Surgeons often face uncertainty regarding implant anchorage and healing potential. This study aims to synthesize current evidence on fracture characteristics, management strategies, and healing outcomes in OPK patients to provide clinical recommendations.

Material and Methods: This systematic review was conducted in accordance with PRISMA 2020 and Synthesis Without Meta-analysis (SWiM) guidelines. The protocol was registered with PROSPERO. We searched PubMed/MEDLINE, CINAHL, and Scopus for studies reporting fractures in OPK patients up to December 2025. Data on patient demographics, fracture sites, fixation methods, and healing complications were extracted and synthesized qualitatively.

Results: A total of 10 studies were included in the review, representing 9 unique cases from the literature. There was a male predominance (78%), with ages ranging from 17 to 37 years. Fractures involved both the appendicular skeleton (femur, tibia, humerus, radius, hand) and the axial skeleton (cervical spine). Management strategies included surgical fixation (intramedullary nailing, plating, tension band wiring) and conservative care (traction, casting). Fracture union was consistently achieved in all reported cases. Time to union (8–26 weeks) was comparable to the general population. No instances of delayed union, nonunion, implant failure, or difficulty in drilling/screw insertion through sclerotic lesions were reported.

Conclusion(s): Despite the radiographically alarming appearance of "spotted bones," the literature confirms that biological healing potential in OPK is preserved. The sclerotic lesions do not compromise implant stability or impede callus formation. Orthopedic surgeons can confidently apply standard surgical principles and fixation techniques, as outcomes are consistently excellent without the need for modified protocols.

P1202

MICROSTRUCTURAL DEFECTS IN BONE TRABECULAE OF GENETICALLY HYDRONEPHOTIC MICE: A NANOSCALE X-RAY MICROSCOPY STUDY

N. Charoenphandhu[1], P. Suntornsaratoon[1], W. Tiyasatkulkovit[2], N. Panupinthu[1], K. Wongdee[3]

[1]Department of Physiology, Faculty of Science, Mahidol University, Bangkok, Thailand; [2]Department of Biology, Faculty of Science, Chulalongkorn University, Bangkok, Thailand; [3]Faculty of Allied Health Sciences, Burapha University, Chonburi, Thailand

Massive dilation of the renal pelvis and calyces, as observed in bilateral hydronephrosis, profoundly deteriorates renal function, including calcium and phosphate handling and 1,25-dihydroxyvitamin D production. Herein, we aimed to investigate bone microarchitecture in a genetically hydronephrotic Imprinting Control Region (ICR) mouse strain, namely ICR/Mlac-*hydro* mice (Hydro), to elucidate how bilateral hydronephrosis is associated with osteopenia and trabecular fragility. Histopathological analyses revealed that Hydro mice exhibited marked enlargement of the renal pelvicalyceal system and distortion of Bowman's capsule and tubular architecture, accompanied by an elevated serum blood urea nitrogen-to-creatinine ratio. Volumetric bone mineral density (vBMD) was significantly lower in Hydro mice compared with age-matched wild-type controls, presumably due to the presence of adynamic bone disease characterized by reduced activities of both osteoblasts and osteoclasts. Ultra-high-resolution E-Class VECTor6 micro-computed tomography demonstrated a reduction in trabecular thickness and increased trabecular separation in the femora of Hydro mice, which in turn resulted in a decreased bone volume fraction. Nanoscale X-ray microscopy using a Bruker Skyscan 2214 revealed multiple losses of trabecular connectivity, suggesting microstructural defects or trabecular microfractures on the order of several micrometers. In addition, tibial mineral apposition and bone formation rates in Hydro mice were reduced by more than 60% compared with wild-type mice, as determined by dynamic bone histomorphometry. In conclusion, bilateral hydronephrosis in Hydro mice is apparently associated with trabecular microstructural defects in long bones, characterized by pronounced trabecular separation and impaired bone formation, ultimately leading to reduced vBMD and osteopenia.

P1203

HIGH HEMOGLOBIN LEVELS AS AN INDEPENDENT PREDICTOR OF OSTEOPOROSIS IN POSTMENOPAUSAL WOMEN

N. Doganyigit Kuzan[1], T. Tiftik[1], C. Mülkoğlu[1]

[1]ANKARA TRAINING AND RESEARCH HOSPITAL, ANKARA, Türkiye

Introduction: Emerging evidence suggests a complex interplay between erythropoiesis and bone remodeling within the bone marrow niche. While anemia is a known risk factor for fractures, the impact of high-normal hemoglobin (HGB) levels on bone health remains less clear. This study aimed to evaluate whether HGB levels are independently associated with osteoporosis (OP) in postmenopausal women, regardless of conventional risk factors.

Methods: This cross-sectional study included 438 postmenopausal women. Osteoporosis was defined by a T-score ≤ -2.5 at the lumbar spine or hip via dual-Xray absorptiometry (DXA). HGB levels were analyzed as a continuous variable, in tertiles, and using a clinical cut-off of >14 g/dL. Multivariate logistic regression models adjusted for age, body mass index (BMI), smoking status, and metabolic comorbidities to isolate the specific impact of HGB.

Results: Out of 438 participants, 197 (45%) were diagnosed with osteoporosis. In the multivariate logistic regression analysis, after adjusting for all potential confounders, HGB was identified as a significant independent predictor of OP. Specifically, each 1 g/dL increase in HGB level was associated with a 23.4% increase in the risk of developing osteoporosis (OR: 1.234, 95% CI: 1.016–1.500, p=0.034).

The study demonstrated a clear dose-response relationship; women in the highest HGB tertile exhibited a 2.16-fold higher risk of OP compared to those in the lowest tertile (OR: 2.160, p=0.024). Threshold analysis reinforced these findings, showing that women with HGB levels >14 g/dL had an 1.82-fold increased risk of OP (OR: 1.821, p=0.009) compared to those below this cutoff. Regarding other covariates, advanced age significantly increased risk (OR: 1.071, p<0.001), while higher body weight remained a protective factor (OR: 0.959, p<0.001).

Conclusion: Our results demonstrate that higher hemoglobin levels are robustly and independently associated with an increased risk of osteoporosis in postmenopausal women. This positive correlation suggests that the "EPO-bone axis" or iron-mediated oxidative stress may play a dominant role in accelerated bone resorption. The persistence of HGB as a risk factor highlights its potential utility as a novel clinical biomarker. Clinicians should consider high-normal HGB levels in postmenopausal women as a potential indicator of bone density deterioration.

THE ASSESSMENT OF KINESIOPHOBIA AND RELATING FACTORS IN OFFICE WORKERS WITH CHRONIC SHOULDER PAIN

N. Doganyigit Kuzan[1], C. Mülkoğlu[1], I. Ciftci Yol[1], N. Koca[1], T. Tiftik[1]

[1]ANKARA TRAINING AND RESEARCH HOSPITAL, ANKARA, Türkiye

Objective: To determine the level of kinesiophobia in office workers with chronic shoulder pain and to analyze its relationship with pain intensity, functional disability, handgrip strength, depression, and job satisfaction in comparison with a healthy control group.

Methods: This cross-sectional study included 55 office workers with shoulder pain lasting >3 months and 56 age- and sex-matched healthy controls. Assessments included the Tampa Scale for Kinesiophobia (TSK), Visual Analog Scale (VAS), Leeds Assessment of Neuropathic Symptoms and Signs (LANNS), Shoulder Pain and Disability Index (SPADI), Beck Depression Inventory (BDI), and Minnesota Satisfaction Questionnaire (MSQ). Physical examination and MRI findings were recorded. Handgrip strength was measured using a hydraulic dynamometer. Statistical analysis was performed using Student's t-test, Pearson correlation, and logistic regression (Kolmogorov-Smirnov for normality).

Results: No significant differences were found between groups regarding age, sex, and BMI (p>0.05) (Table 1). In the patient group, shoulder range of motion (ROM) was restricted at mid-range in 45% and at end-range in 55% of participants. Patients exhibited significantly lower handgrip strength (26.2±8.1 vs 33.5±9.7 kg, p=0.001) and higher BDI scores (10.0±3.8 vs 5.2±1.9, p<0.001) compared to controls. TSK scores correlated positively with VAS (p=0.018), all SPADI subscales (p<0.01), and BDI scores (p<0.05). No significant correlation was found between MSQ scores and kinesiophobia (p>0.05). Although a negative trend was observed between handgrip strength and TSK scores, it did not reach statistical significance (p>0.05). In the logistic regression analysis, no single independent factor was identified as a unique predictor of high kinesiophobia (p>0.05), suggesting a multifactorial etiology.

Conclusion: Kinesiophobia in office workers with chronic shoulder pain emerges as a complex interaction of pain intensity, functional impairment, and depressive symptoms. The significant reduction in handgrip strength suggests that shoulder-related kinesiophobia may impact distal upper extremity performance. The absence of a single dominant predictor in regression analysis supports the multidimensional nature of movement fear. Rehabilitation programs should integrate functional restoration with psychosocial strategies to optimize clinical outcomes.

Keywords: Chronic shoulder pain, TAMPA, SPADI, Handgrip strength, Office workers.

ANTHROPOMETRIC AND MORPHOLOGICAL ALTERATIONS PRECEDE FUNCTIONAL IMPAIRMENT IN POSTMENOPAUSAL OSTEOPOROSIS

T. Tiftik[1], N. Doganyigit Kuzan[1], C. Mülkoğlu[1], H. Genc[1]

[1]ANKARA TRAINING AND RESEARCH HOSPITAL, ANKARA, Türkiye

Objective: To investigate whether alterations in body composition and muscle morphology occur before the onset of functional and strength deficits in postmenopausal women with osteoporosis (OP).

Material and Methods: This cross-sectional study included 441 postmenopausal women (OP+: n=203, OP−: n=238). Anthropometric measures (BMI, waist/hip circumference) and ultrasound-based morphological assessments (abdominal fat, abdominal muscle, and quadriceps muscle thickness) were obtained. Functional performance was evaluated using the chair stand test (CST), six-minute walk test (6MWT), and balance tests, while strength was measured via handgrip dynamometry.

Results: Despite being older (62.1 vs 59.5 years, p=0.002), the OP+ group exhibited significantly lower BMI (28.3 vs 30.4 kg/m², p<0.001) and abdominal fat thickness (40.0 vs 42.9 mm, p=0.02) compared to the OP− group. Notably, a selective thinning was observed in the quadriceps muscle of OP+ patients (32.3 vs 33.6 mm, p=0.02), while trunk muscle (abdominal) thickness remained preserved (p=0.09). Crucially, these morphological changes did not translate into functional deficits, as no significant differences were found in handgrip strength (p=0.93), CST (p=0.08), 6MWT (p=0.94), or balance performance between groups.

Conclusion: Our findings suggest that postmenopausal osteoporosis is characterized by an early body composition phenotype where peripheral muscle thinning and reduced adiposity precede measurable declines in physical function or strength. The significant reduction in quadriceps thickness despite preserved abdominal muscle morphology and physical performance indicates a selective, compartmental deterioration. This "morphology-first" decline highlights the importance of early screening for muscle and fat distribution changes, even in patients who appear functionally intact, to allow for early intervention before overt musculoskeletal failure occurs.

Keywords: Postmenopausal osteoporosis, Muscle morphology, Body composition, Physical performance, Ultrasonography

Table 1. Comparison of Body Composition, Muscle Architecture, and Physical Function According to Osteoporosis Status

Parameter	Osteoporosis (OP+) (n=203)	Control (OP-) (n=238)	p
Age (Years)	62.1 ± 7.4	59.5 ±8.0	0.002
Body Mass Index (BMI) (kg/m²)	28.3 ±4.6	30.4 ±4.8	<0.001
Waist Circumference (cm)	93.1 ±11.5	96.0 ±11.4	0.300
Hip Circumference (cm)	108.4 ±10.3	112.7 ±10.8	0.030
Abdominal Fat Thickness (mm)	40.0 ±13.8	42.9 ±13.5	0.020
Abdominal Muscle Thickness (mm)	6.9 ±1.8	7.2 ±2.0	0.090
Thigh Muscle Thickness (mm)	32.3 ±6.1	33.6 ±6.0	0.020

PREVALENCE OF SARCOPENIA IN RURAL COMMUNITY-DWELLING MEXICAN OLDER ADULTS

H. Rangel Flores[1], A. L. Rivera Almaraz[1], C. A. Martinez Rangel[1], J. L. Delgado Gallegos[1], C. M. Flores Quiñones[2], M. M. Olascoaga Valdez[1], Y. E. Dominguez Diaz[2], G. Angeles Chimal[3], N. Escalona Poblete[3]

[1]Instituto nacional de salud publica, Cuernavaca, Mexico; [2]universidad latinoamericana, Cuernavaca , Mexico; [3]universidad del valle de cuernavaca, Cuernavaca , Mexico

Introduction: Sarcopenia, defined as the loss of muscle mass, strength, and function, is a global health issue with significant implications for older adults.

Material and Methods: A cross-sectional study involving 306 participants aged 60 and above was conducted in Xochitepec, Morelos, Mexico. The survey included: demographics, chronic diseases, quality of life, nutritional status, mental status, dependence in activities of daily living, disability, physical measurements, health behaviors. Sarcopenia was defined using the SARC-F questionnaire. The instrument includes 5 components: Strength, Assistance in walking, Rising from a chair, Climbing stairs, and Falls.

Results: The median age of the participants was 62.6 years (SD 18.2), and 206 (67.3%) were women. Sarcopenia was identified in 79 individuals (25.8%), while 227 (74.2%) did not present this condition. The prevalence of sarcopenia was significantly higher in women (29.6%) compared to men (18%) (p < 0.05). Older age, female sex, and potential interactions with other geriatric syndromes, such as frailty and disability, were observed in those with sarcopenia.

Conclusion: These results align with prevalence rates reported in similar studies across Asia, Europe, and North America, these findings underscore the importance of early prevention strategies, can and should be addressed prior to the sixth decade of life.

Objective: Using data from a population-based cohort of Iranian adults aged ≥50 years, this study aimed to assess fall occurrence, identify associated risk factors, and evaluate fear of falling post-fall.
Material and Methods: In this prospective cohort study, 1,410 adults were followed for one year. Data were collected on fall incidents, including their causes, complications, and subsequent fear of falling. We evaluated associated factors such as demographics, BMI, osteoporosis, dizziness, visual impairment, gait speed, and history of falls. Cox proportional hazards models were employed to identify determinants of falls.
Results: During follow-up, 265 participants (18.7%) experienced at least one fall. Most falls were person-related (54.3%), 32.5% were attributed to extrinsic factors, and 13.2% involved a combination of both. Complications occurred in 75% of fallers, and 57.7% reported fear of falling after the event. Nearly half of falls occurred inside the home. Fallers were more often female (64.1% vs. 35.9%, p = 0.001), had higher BMI (29.0 vs. 28.2 kg/m², p = 0.024), and showed a higher prevalence of osteoporosis (35.6% vs. 28.9%, p = 0.034), dizziness (18.5% vs. 11.6%, p = 0.003), visual impairment (27.9% vs. 18.3%, p < 0.001), and previous fall history compared with non-fallers. Lifetime history of falls was strongly associated with subsequent falls (HR = 2.32; 95% CI: 1.74–3.11; p < 0.001). Low gait speed and dizziness showed borderline significance in multivariable analyses.
Conclusions: This study indicated that Falls affect a substantial portion of adults (nearly one in five) and often lead to complications and post-fall fear. Regular screening for key risk factors may help identify high-risk individuals and guide preventive health policies.

Objective(s)
To evaluate the association between osteoporosis (overall and site-specific) and trabecular bone score (TBS) with Rose Angina Questionnaire (RAQ)–defined angina pectoris in an elderly population.
Material and Methods
This cross-sectional study included 2,001 community-dwelling adults aged ≥50 years from the Bushehr Elderly Health (BEH) Study. Angina was assessed using the Rose Angina Questionnaire. Lumbar spine, total hip, and femoral neck bone mineral density (BMD) along with TBS were measured by dual-energy X-ray absorptiometry. Osteoporosis was defined according to World Health Organization criteria; a T-score ≤ -2.5 at any of the aforementioned sites. Multivariable logistic regression, adjusted for potential confounders, was used to investigate the associations between osteoporosis and TBS with RAQ-defined angina.

Results
The mean age of participants was 62.1±8.1 years, and 57.1% were women. RAQ positivity was observed in 10.2% of participants, while the overall prevalence of osteoporosis was 27.5%. After multivariable adjustment, RAQ-defined angina was not independently associated with overall osteoporosis.(p=0.932) An inverse association between RAQ positivity and lumbar spine osteoporosis observed in crude analyses was attenuated after adjustment.(p=0.354) Participants diagnosed with angina (RAQ-positive) had a significantly higher mean lumbar spine BMD compared to angina negative participants (p < 0.001); no significant differences were found at the total hip or femoral neck. In sex-stratified multivariable analyses, RAQ positivity was independently associated with higher odds of femoral neck osteoporosis among men (OR=2.17; 95% CI 1.07–4.38; p=0.032), whereas no such association was observed among women. RAQ-defined angina was not associated with TBS across crude, stratified, interaction, or stepwise multivariable models (adjusted OR=0.86; 95% CI 0.61–1.19; p=0.36). Across all analyses, age, sex, BMI, smoking, and SES were the dominant determinants of skeletal outcomes.
Conclusion(s)
RAQ-defined angina was not independently associated with overall osteoporosis or trabecular bone score in this elderly population; nevertheless, a site- and sex-specific significant positive association was observed between femoral neck osteoporosis and angina among men only.
These findings indicate heterogeneity in the relationship between cardiovascular symptoms and bone health, highlight the importance of skeletal site-specific and sex-specific analyses and suggest that RAQ, as a symptom-based cardiovascular instrument, does not adequately capture the complexity of generalized bone loss or compromised bone quality.

P1209

THE OSTEOPOROSIS DIAGNOSIS AND TREATMENT GAPS IN IRANIAN OLDER ADULTS: BUSHEHR ELDERLY HEALTH (BEH) PROGRAM

M. Sanjari[1], N. Fahimfar[1], E. Hesari[1], H. Yarmohammadi[1], S. Shahrousvand[2], K. Khalagi[3], P. Zarepour[2], S. Gharibzadeh[4], M. J. Mansourzadeh[5], G. Sahafiei[6], I. Nabipour[7], B. Larijani[8], A. Ostovar[1]

[1]Osteoporosis Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran; [2]School of Public Health, Department of Epidemiology and Biostatistics, Tehran University of Medical Sciences, Tehran, Iran; [3]Obesity and Eating Habits Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran; [4]Leicester Real World Evidence Unit, Diabetes Research Centre, Leicester General Hospital, University of Leicester, Leicester, LE5 4PW, UK, Leicester, United Kingdom; [5]Prevention of Metabolic Disorders Research Center, Research Institute for Metabolic and Obesity Disorders, Research Institute for Endocrine Sciences, Shahid Beheshti University of Medical Sciences, Tehran, Iran; [6]Chronic Diseases Research Center, Endocrinology and Metabolism Population Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran; [7]The Persian Gulf Marine Biotechnology Research Center, the Persian Gulf Biomedical Sciences Research Institute, Bushehr University of Medical Sciences, Bushehr, Iran; [8]Endocrinology and Metabolism Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran

Objective Despite the availability of diagnostic and therapeutic facilities for osteoporosis, a significant proportion of older adults remain undiagnosed and untreated. This care gap may stem from various barriers and understanding the underlying reasons for these disparities is crucial for developing targeted interventions. This study aimed to investigate the gaps in osteoporosis diagnosis and treatment among older adults in Iran and to identify the key factors contributing to these gaps. Methods This cross-sectional study analyzed data from two phases of the Bushehr Elderly Health (BEH) Program. Participants were selected using multistage cluster random sampling. The first phase, conducted between 2015 and 2017, included 2,424 residents aged 60 and above. The second phase, from 2018 to 2021, involved 1,721 residents aged 50 and above. Bone mineral density (BMD) was measured using the Dual-energy X-ray absorptiometry method and T-score≤-2.5 in either of the femoral neck, total hip, or spinal sites was defined as osteoporosis. Participants reported whether a doctor had diagnosed them with osteoporosis and if they received treatment. Those diagnosed via bone densitometry but unaware of their condition were considered underdiagnosed. Those diagnosed through BMD tests but not on osteoporosis medication were considered undertreated. Multiple logistic regression was used to identify determinant factors of the underdiagnosis and undertreatment of osteoporosis. Results A total of 4145 elder adults with a mean age of 65.5 (54.40% female) participated in this study. Underdiagnosis and undertreatment in the participants who underwent DXA were estimated at 1050 (73.06% (and 1328 (92.41), respectively. The undertreatment rate was 666 (91.98%), 836(90.96%) and 868 (92.53%) based on the intervention thresholds of FRAX without BMD, MOF-FRAX with BMD and FRAX with TBS for MOF, respectively. A statistically significant association was found between osteoporosis underdiagnosis and variables including male (OR=0.57, P<0.001), age (OR:1.05, P<0.001), asset in quartile 4 (OR=0.79, P=0.028), and years of education (OR:0.96, P<0.001). Male sex (OR:0.37, P<0.001), age (OR:1.07, P<0.001), years of education (OR:0.95, P<0.001), marital status (OR:0.78, P:0.013), and being disable in IADL (OR:1.28, P:0.003) were significantly associated with undertreatment. Conclusion This study highlights significant gaps in the diagnosis and treatment of osteoporosis among participants, with significant disparities linked to demographic and socioeconomic factors. Further research is needed to investigate the causes and extensive interventions at the population level should be taken to fill the gap and raise awareness on osteoporosis as a growing public health concern and provide access to the treatment of the disease. Key words: osteoporosis, diagnosis, treatment, care gap, older adults, Iran

OSTEOPOROSIS DIAGNOSIS AND TREATMENT GAP IN THE EASTERN MEDITERRANEAN REGION (EMRO): A SYSTEMATIC REVIEW AND META-ANALYSIS

M. Sanjari[1], S. Abdollahi[2], E. Hesari[1], V. Mohseni[1], P. Zarepour[3], N. Malekraise[1], N. Fahimfar[1], K. Khalagi[4], M. J. Mansourzadeh[5], S. Salehi Nezamabadi[1], A. Ostovar[1]

[1]Osteoporosis Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran; [2]Metabolic Disorders Research Center, Endocrinology and Metabolism Molecular -Cellular Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran; [3]School of Public Health, Department of Epidemiology and Biostatistics, Tehran University of Medical Sciences, Tehran, Iran; [4]Obesity and Eating Habits Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran; [5]Prevention of Metabolic Disorders Research Center, Research Institute for Metabolic and Obesity Disorders, Research Institute for Endocrine Sciences, Shahid Beheshti University of Medical Sciences, Tehran, Iran

Objective: Osteoporosis is highly prevalent in the EMRO region. Fractures contribute to hospitalization, disability, and mortality, driving substantial costs for patients and health systems. Early diagnosis and timely treatment are critical to prevent these adverse outcomes. This study synthesizes EMRO-region evidence to estimate the prevalence of underdiagnosis and undertreatment rate of osteoporosis.

Material and Method: A comprehensive search of PubMed, Scopus, and Web of Science was conducted through January 2025 to identify relevant studies from EMRO. Eligible study designs included observational studies and randomized controlled trials that addressed diagnosis or treatment gaps in osteoporosis care. Data were extracted by a single reviewer using a pre-piloted form, capturing study characteristics and outcomes. Methodological quality was appraised with the Newcastle–Ottawa Scale (NOS). A meta-analysis estimating underdiagnosis and undertreatment rates was performed using metaprop in Stata 17.0 under a random-effects model, with meta-regression to explore heterogeneity sources. Publication bias was evaluated with funnel plots and tests for asymmetry (Egger's and Begg's), with a two-sided p-value < 0.05 considered significant; results were presented with 95% prediction intervals.

Results: This meta-analysis identified 89 articles, of which 7 studies (2019–2025) from Iran, Saudi Arabia, Egypt, and Kuwait met criteria for analysis. Study quality (NOS) was generally good for sample selection and outcome assessment, though comparability was suboptimal in several studies. Substantial between-study heterogeneity was observed ($p < 0.001$; $I^2 = 99.6\%$). Meta-regression identified age, sex, year of sampling, and study design as significant predictors of heterogeneity in underdiagnosis ($p < 0.05$). mPooled estimates showed an underdiagnosis rate of 53% (95% CI, 28%–80%; $p < 0.001$) and an undertreatment rate of 75% (95% CI, 65%–86%; $p < 0.001$). Assessments for publication bias found no evidence of bias (Begg's: underdiagnosis $p = 0.2673$, undertreatment $p = 0.4694$; Egger's: underdiagnosis $p = 0.9950$, undertreatment $p = 0.8567$).

Conclusion: Our findings indicate a significant gap in osteoporosis care across EMRO countries. Policy-level actions are essential to embed osteoporosis care into national health strategies and to identify and target high-risk populations.

Objective(s): This study was conducted to examine the association between sarcopenia and its components with angina pectoris in an elderly Iranian population.

Material and Methods: This descriptive-analytical cross-sectional study included 1088 adults aged≥60 years from the Bushehr Elderly Health (BEH) program. Using European working group on sarcopenia in older people (EWGSOP-2) criteria, sarcopenia was defined by low skeletal muscle index (SMI) plus either reduced muscle strength (hand grip) or slowed gait speed. Low SMI cut-offs were 7.0 kg/m² for men and 5.4 kg/m² for women. Low muscle strength was defined as hand grip <26 kg in men and <18 kg in women. A low physical performance threshold was gait speed <0.8 m/s for both sexes, based on Iranian cut-off points. SMI was measured using dual-energy X-ray absorptiometry (DXA). Muscle strength and gait speed were measured using digital dynamometer and chronometer respectively. Angina was assessed using the Rose angina questionnaire (RAQ). All analyses were conducted using Stata statistical software (Release 14; StataCorp LP). A p-value of less than 0.05 was considered significant.

Results: 1088 participants with a mean age of 68.07 ± 5.93 years and a male-to-female ratio of 0.81:1 were included. Angina was observed in 12.2% of participants. Total prevalence of sarcopenia was 20.37%. Crude analyses revealed that RAQ positivity was not associated with overall sarcopenia or low SMI but was more frequent among participants with low gait speed (13.97% of participants with low gait speed vs 9.11% of

those not in the low gait speed group) (p=0.015).
Furthermore, sex-stratified analyses demonstrated consistent female-specific functional associations. In multivariable models adjusted for age, body mass index (BMI), hypertension, diabetes, physical activity, protein intake adequacy, and adiposity measures, RAQ positivity remained independently associated with low gait speed (OR: 2.04, 95% CI: [1.06-3.92]; p=0.032) and low hand grip strength (OR: 1.70, 95% CI: [1.02-2.85]; p=0.043) among women only. RAQ was not independently associated with SMI or overall sarcopenia.
Conclusion(s): The study found that RAQ positivity is independently linked to low gait speed and reduced hand grip strength in women, with no association with SMI or overall sarcopenia. These sex-specific functional associations highlight a need for targeted attention to RAQ-positive women to mitigate functional decline.

P1212

ASSOCIATION BETWEEN BREASTFEEDING DURATION AND BONE MINERAL DENSITY AND OSTEOPOROSIS IN IRANIAN POSTMENOPAUSAL WOMEN: RESULTS FROM THE IRANIAN MULTICENTER OSTEOPOROSIS STUDY (IMOS)

N. Panahi[1], S. Rashidi[1], K. Khalagi[2], N. Fahimfar[3], M. Sanjari[3], N. Rezaei[4]

[1]Metabolic Disorders Research Center, Endocrinology and Metabolism Molecular-Cellular Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran, Tehran, Iran; [2]Obesity and Eating Habits Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran, Tehran, Iran; [3]Osteoporosis Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran, Tehran, Iran; [4]Non-Communicable Diseases Research Center, Endocrinology and Metabolism Population Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran, Tehran, Iran

Objective. The long-term relationship between breastfeeding and postmenopausal bone health remains uncertain. This study examined the association between breastfeeding duration and bone mineral density (BMD), as well as osteoporosis, among Iranian postmenopausal women using data from the Iranian Multicenter Osteoporosis Study (IMOS).
Methods. This cross-sectional analysis included women aged ≥50 years recruited between January 2021 and December 2022. BMD at the lumbar spine (LS), total hip (TH), and femoral neck (FN) was measured using dual-energy X-ray absorptiometry (DEXA). Osteoporosis was defined as a T-score ≤−2.5. Participants were categorized according to cumulative breastfeeding duration into ≥5 years (study group) and <5 years (control group). Univariable and multivariable logistic regression models (backward stepwise model) were used to assess associations between breastfeeding duration and BMD as well as osteoporosis, adjusting for relevant confounders.
Results. A total of 781 postmenopausal women (mean age 61.8 ± 7.7 years) were included; 381 had breastfed for ≥5 years and 400 for <5 years. BMD at the LS, TH, and FN was significantly lower among women with prolonged breastfeeding. Osteoporosis was more prevalent in the prolonged breastfeeding group compared with controls (44.5% vs 29.5%, p<0.001). In univariable analysis, breastfeeding duration ≥5 years was associated with higher odds of osteoporosis (OR 2.41, 95% CI 1.73–3.37). After adjustment for age, time since menopause, vitamin D status, kidney function, BMI, calcium intake, physical activity, and socioeconomic status, this association remained significant (adjusted OR 1.88, 95% CI 1.26–2.80).
Conclusion. In this national cohort of Iranian postmenopausal women, longer breastfeeding duration was associated with lower BMD at the lumbar spine, total hip, and femoral neck, as well as higher odds of osteoporosis. These findings underscore the importance of incorporating reproductive history into osteoporosis risk assessment. Prospective studies are warranted to further clarify these associations.

P1213

FREQUENCY AND SEVERITY OF RADIOGRAPHIC COXITIS IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS: COMPARATIVE ANALYSIS OF ANKYLOSING SPONDYLITIS AND AXIAL PSORIATIC ARTHRITIS

N. A. Zakharova[1], N. G. Nikolashina[1], S. A. Khamidova[2], K. K. Khallaev[3]

[1]V.I. Vernadsky Crimean Federal University, Simferopol, Russia; [2]Tashkent State Pedagogic University named after Nizami, Tashkent, Uzbekistan; [3]Tashkent State Medical University, Tashkent, Uzbekistan

Objective: Hip involvement (coxitis) is a common and disabling manifestation of spondyloarthritis (SpA). In ankylosing spondylitis (AS), radiographic coxitis is reported in up to 40% of cases. However, robust epidemiological data on its frequency in patients with axial psoriatic arthritis (axPsA) are scarce. This study aimed to assess and compare the prevalence, radiographic severity, and associated clinical features of coxitis in patients with AS and axPsA.
Material and Methods: We conducted a cross-sectional study of 222 patients with axial SpA.
Group 1 (AS): 108 patients meeting the modified New York criteria (1984) for AS or the ASAS classification criteria for axial SpA (2009).
Group 2 (axPsA): 114 patients satisfying the CASPAR criteria for PsA with confirmed axial involvement (radiography/MRI).
The mean age at disease onset was 26.3±20.3 years; 54% were HLA-B27 positive. Radiographic coxitis was assessed using the BASRI-hip index. Disease activity was evaluated by BASDAI and ASDAS-CRP, functional status by BASFI. Statistical analysis was performed using Mann-Whitney U and Chi-square tests (p<0.05 significant).
Results: Radiographic coxitis was detected in 52 of 222 patients (overall prevalence 23.4%): in 22/108 (20.4%) AS patients and in 30/114 (26.3%) axPsA patients.
Comparative analysis of these 52 patients revealed significant intergroup differences. Patients with axPsA and coxitis were older than AS patients (45.0 ± 10.3 vs. 32.0 ± 8.1 years, p<0.05), had a higher prevalence of BMI >25 kg/m² (73.3% vs. 36.4%, p<0.05), and a more even gender distribution (50.0% vs. 81.8% males, p<0.05).
Disease activity was significantly higher in the axPsA group, as measured by BASDAI (6.1 ± 2.0 vs. 4.5 ± 1.8, p<0.05) and ASDAS-CRP (3.2 ± 0.9 vs. 2.1 ± 0.7, p<0.05). Functional impairment (BASFI) was also more severe in axPsA (5.2 ± 2.4 vs. 3.8 ± 2.1, p<0.05). No significant differences were found in acute-phase reactants (CRP, ESR) or the prevalence of peripheral

arthritis between the groups (p>0.05).
Conclusions: In our cohort, radiographic coxitis was present in about a quarter of patients with axial SpA, being more frequent in axPsA (26.3%) than in AS (20.4%). These rates exceed previously reported averages, likely reflecting a referral bias towards more severe cases in a tertiary center. Coxitis in axPsA is associated with a distinct phenotype (older age, higher BMI, balanced gender ratio), significantly higher disease activity, and greater functional disability compared to AS. These findings underscore the clinical importance of systematic hip assessment in axPsA.

P1214

FREQUENCY AND SEVERITY OF RADIOGRAPHIC COXITIS IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS: COMPARATIVE ANALYSIS OF ANKYLOSING SPONDYLITIS AND AXIAL PSORIATIC ARTHRITIS

A. N. Zakharova[1], N. G. Nikolashina[1], S. A. Khamidova[2], K. K. Khallaev[3]

[1]V.I. Vernadsky Crimean Federal University, Simferopol, Russia; [2]Tashkent State Pedagogic University named after Nizami, Tashkent, Uzbekistan; [3]Tashkent State Medical University, Tashkent, Uzbekistan

Objective: Hip involvement (coxitis) is a common and disabling manifestation of spondyloarthritis (SpA). In ankylosing spondylitis (AS), radiographic coxitis is reported in up to 40% of cases. However, robust epidemiological data on its frequency in patients with axial psoriatic arthritis (axPsA) are scarce. This study aimed to assess and compare the prevalence, radiographic severity, and associated clinical features of coxitis in patients with AS and axPsA.
Material and Methods: We conducted a cross-sectional study of 222 patients with axial SpA from a tertiary rheumatology center. The study was approved by the local Ethics Committee.
Group 1 (AS): 108 patients meeting the modified New York criteria (1984) for AS or the ASAS classification criteria for axial SpA (2009).
Group 2 (axPsA): 114 patients satisfying the CASPAR criteria for PsA with confirmed axial involvement (radiography/MRI).
The mean age at disease onset was 26.3±20.3 years; 54% were HLA-B27 positive. Radiographic coxitis was assessed using the BASRI-hip index. Disease activity was evaluated by BASDAI and ASDAS-CRP, functional status by BASFI. Statistical analysis was performed using Mann-Whitney U and Chi-square tests (p<0.05 significant).
Results: Radiographic coxitis was detected in 52 of 222 patients (overall prevalence 23.4%): in 22/108 (20.4%) AS patients and in 30/114 (26.3%) axPsA patients.
Comparative analysis of these 52 patients revealed significant intergroup differences. Patients with axPsA and coxitis were older than AS patients (45.0 ± 10.3 vs. 32.0 ± 8.1 years, p<0.05), had a higher prevalence of BMI >25 kg/m² (73.3% vs. 36.4%, p<0.05), and a more even gender distribution (50.0% vs. 81.8% males, p<0.05).
Disease activity was significantly higher in the axPsA group, as measured by BASDAI (6.1 ± 2.0 vs. 4.5 ± 1.8, p<0.05) and ASDAS-CRP (3.2 ± 0.9 vs. 2.1 ± 0.7, p<0.05). Functional impairment (BASFI) was also more severe in axPsA (5.2 ± 2.4 vs. 3.8 ± 2.1, p<0.05). No significant differences were found in acute-phase reactants (CRP, ESR) or the prevalence of peripheral arthritis between the groups (p>0.05).
Conclusions: In our cohort, radiographic coxitis was present in about a quarter of patients with axial SpA, being more frequent in axPsA (26.3%) than in AS (20.4%). These rates exceed previously reported averages, likely reflecting a referral bias towards more severe cases in a tertiary center. Coxitis in axPsA is associated with a distinct phenotype (older age, higher BMI, balanced gender ratio), significantly higher disease activity, and greater functional disability compared to AS. These findings underscore the clinical importance of systematic hip assessment in axPsA.

NUTRITIONAL STATUS IN GERIATRIC PATIENTS WITH AND WITHOUT OSTEOPOROSIS: A COMPARATIVE STUDY

N. G. Somak[1], S. Avci[1], P. Degirmenci[2]

[1]Istanbul University, Cerrahpasa Faculty of Medicine, Department of Internal Medicine Geriatrics Division, Istanbul, Turkiye, Istanbul, Türkiye; [2]University of Health Sciences, Şişli Hamidiye Etfal Training and Research Hospital, Department of Geriatrics, Istanbul, Turkiye, Istanbul, Türkiye

Objective: This study aimed to compare the nutritional status of geriatric patients with and without osteoporosis using GNRI, CONUT, MNA scores, and laboratory parameters.
Material/Methods: A cross-sectional study was conducted including 120 geriatric outpatients (60 with osteoporosis and 60 without). Patients with active infection, malignancy, or advanced dementia were excluded; demographic and clinical characteristics, laboratory parameters, and nutritional status assessed by GNRI, CONUT and MNA were evaluated.
Results: Female sex was significantly more frequent in the osteoporosis group compared to non-osteoporotic patients, whereas mean age, number of comorbidities, and history of falls did not differ between groups. The number of medications was significantly higher in osteoporotic patients. Serum folate, vitamin B12, and vitamin D levels were significantly higher in the osteoporosis group, while other parameters showed no significant differences. In the osteoporosis group, the majority of patients were receiving antiresorptive therapy (96.7%). Anabolic therapy was administered in 3.3% of the patients, and antiresorptive treatment modification was implemented in 16.7%. A history of fragility fracture was present in 26.7% of osteoporotic patients. GNRI, CONUT, MNA scores and their categorical classifications did not differ significantly between groups; however, osteoporotic patients tended to have lower MNA scores and a higher risk of malnutrition. Within the osteoporosis group, CONUT scores ≥2were observed in 16.7% of patients, GNRI values ≤98 in 11.7%, and 35.0% were classified as being at risk of malnutrition or malnourished according to the total MNA score. In multivariable logistic regression analyses, female sex remained the strongest independent predictor of osteoporosis across all models, while only MNA showed an independent association when nutritional scores were evaluated simultaneously.
Conclusions: In this population, nutritional status assessed by GNRI, CONUT, and MNA did not differ significantly between patients with and without osteoporosis; however MNA demonstrated a relatively stronger and independent association with osteoporosis, while female sex remained the most consistent determinant.
Disclosures: The authors declare no conflicts of interest.

P1217

HISTOMORPHOMETRIC INDICATORS OF TIBIA IN INFANTILE RATS DURING 90-DAY CAFFEINE OVERCONSUMPTION AND CORRECTION WITH MEXIDOL

A. Movenko[1], Y. Trishchenkova[1], I. Belik[1], N. Gal'Chenko[1], D. Vailenko[1]

[1]FSBEI HI ST. LUKA LSMU of MOH of Russia; Human anatomy department, Lugansk, Russia

Objective of the study is to investigate changes in the structure of the proximal epiphyseal cartilage (PEC) of tibiae in infantile male rats during 90-day excessive caffeine administration and correction with Mexidol.
Material and methods. The experiment was conducted on 72 male rats weighing 70-75 g. Intact animals were in group 1 (K-90). In group 2 (C-90), animals received caffeine intragastrically at a dose of 120 mg/kg/day. In group 3 (CM-90) animals received caffeine in the same manner as animals from the second group and additionally subcutaneously injected Mexidol at a dose of 50 mg/kg/day. The histomorphometric study was performed on a morphometric complex.
Results. The C-90 group showed 8.37%, 9.63% and 9.09% narrowing of the PEC, width of the proliferating cartilage and tibial osteogenesis zone when compared to group K-90 at 90 days. The width of the indifferent, definitive cartilage zone decreased by 8.39%, and 7.18%, and the width of the destruction zone decreased by 7.36%. Also, the specific number of primary spongiosa and osteoblasts decreased by 8.50% and 10.66% in the osteogenesis zone. Total PEC width and osteogenesis zone width increased by 6.55% and 7.91% at 90 days of experiment in CM-90 group when compared with C-90. The width of the zone of indifferent, proliferating and definitive cartilage was increased by 7.11%, 7.55% and 5.53% and the width of the zone of destruction by 4.89%. In the osteogenesis zone, the proportion of primary spongiosa and the number of osteoblasts were increased by 7.51% and 9.79%.
Conclusion. In infantile male rats, excessive caffeine administration depressed bone-forming function of the PEC of tibiae. When Mexidol was administered, the detected changes were restored.

P1218

BONE MINERAL DENSITY, VITAMIN D STATUS, AND BONE TURNOVER MARKERS IN WAR VETERANS AFTER LOWER LIMB AMPUTATION

N. Grygorieva[1], A. Vilenskyi[2], O. Stefiuk[3], I. Kaut[2], D. Kurylo[1], A. Iniushyna[1], T. Solonenko[1]

[1]D.F. Chebotarev Institute of Gerontology of the NAMS of Ukraine, Kyiv, Ukraine; [2]Charitable Organisation “Charitable Fund”Superhumans”, Lviv, Ukraine; [3]Danylo Halytsky Lviv National Medical University, Lviv, Ukraine

Objective: The study aimed to evaluate bone mineral density (BMD), vitamin D status, and bone turnover markers in war male veterans with unilateral lower limb amputation caused by mine-blast injuries.
Methods: This study included 64 men aged 20–54 years, divided into two groups: 32 healthy controls and 32 patients with transfemoral (TF) or transtibial (TT) amputations. The median post-amputation period (PAP) was 5.0 [4.0–7.0] months. BMD was measured by dual-energy X-ray absorptiometry (Hologic). Laboratory assessments included calcium–phosphorus metabolism parameters, bone turnover markers, and the serum 25-hydroxyvitamin D (25(OH)D) level.
Results: BMD at the hip and femoral neck on the amputated side was significantly lower than in controls (hip: 0.78±0.22 vs. 1.00±0.20 g/cm², p=0.0002, respectively), whereas no significant differences were observed between the contralateral limb and controls. Low BMD (Z-score ≤ −2 SD) on the amputated side was confirmed in 39–42% of patients. Bone loss in the amputated limb increased with longer PAP and was more pronounced in TF than in TT amputations. Vitamin D deficiency or insufficiency was present in 81% of amputees. Serum P1NP levels were higher in amputees than in controls, and β-CTX levels were significantly elevated only in the TF amputations group.
Conclusions: War veterans with traumatic unilateral lower limb amputations exhibit significantly reduced BMD in the amputated limb, while the contralateral limb remains comparable to controls. Bone loss is greater after TF than TT amputations and progresses with time since amputation. The high prevalence of vitamin D deficiency or insufficiency, along with elevated bone turnover markers, underscores the importance of bone health assessment and management in rehabilitation programs for this population.
Disclosures: The authors declared no competing interests.

P1219

BONE MINERAL DENSITY AND DXA-BASED 3D ANALYSIS OF THE HIP CORTICAL AND TRABECULAR BONE IN POSTMENOPAUSAL WOMEN WITH OSTEOSARCOPENIA

N. Grygorieva[1], M. Bracco[2], N. Zaverukha[1], L. Humbert[2], D. Kurylo[1], A. Iniushyna[1]

[1]State Institution "Institute of Gerontology NAMS of Ukraine", Kyiv, Ukraine; [2]3D-Shaper Medical, Barcelona, Spain

Objective: The study aimed to assess the bone mineral density (BMD), Trabecular Bone Score (TBS), and DXA-derived 3D hip cortical and trabecular bone indices in postmenopausal women with osteosarcopenia (OSP).
Methods: In a case-control study, 60 postmenopausal women aged 60-89 years were examined and divided into two groups: the first group consisted of 30 females with OSP, and the second group consisted of 30 patients with osteoporosis (OP). OSP was defined as a combination of sarcopenia (SP, confirmed by EWGSOP2 criteria) and OP (BMD T-score < -2.5 SD, confirmed by dual-energy X-ray absorptiometry [DXA]). Anthropometric measurements were performed using standard clinical methods. Muscle strength was determined using hand dynamometry and the "sit-to-stand" test. BMD of the lumbar spine (LS), total hip (TH), and femoral neck (FN), appendicular lean mass, TBS, and 3D hip cortical and trabecular bone indices were evaluated by DXA (Hologic). The 3D-Shaper Research software (v2.14, 3D-Shaper Medical, Barcelona, Spain) was used to derive 3D analysis from hip DXA scans.
Results. Women did not differ in age and menopausal status. However, subjects with OSP had significantly lower height, body mass, and body mass index (BMI) than the OP group (p<0.05 for all indices). Additionally, their BMD indices were lower than in subjects with OP (p<0.001 for all indices), but TBS did not differ between groups. Women with OSP have significantly lower total cortical sBMD index than women with OP (124.48±15.87 vs. 133.94±14.41 mg/cm2, p<0.05), whereas no significant difference was observed in total trabecular vBMD, suggesting that BMD in patients with OSP is mainly driven by the cortical compartment.

Conclusion. To our knowledge, this is the first study to assess DXA-derived 3D hip parameters in postmenopausal women with OSP. Analysis of large cohorts using DXA-derived 3D measurements could confirm our results and establish the negative impact of SP on bone density and microarchitecture in patients with OP.
Disclosures: The authors declared no competing interests.

PARADOXICAL INCREASES IN BONE RESORPTION AFTER ROMOSOZUMAB IN BARIATRIC SURGERY PATIENTS

N. Holanda[1], R. Brito[2], M. Cavalcanti[2], J. Silva[1], F. C. C. Carneiro[1], C. Limeira[3], M. D'Oliveira[1], F. Bandeira[2]

[1]Federal University of Paraiba, Department of Endocrinology and Metabolism, João Pessoa, Brazil; [2]Agamenon Magalhães Hospital, Department of Diabetes and Endocrinology (UED_HAM), Recife, Brazil; [3]Nova Esperança School of Medicine, Internal Medicine Residency Program, João Pessoa, Brazil

Objective: Bariatric surgery is associated with accelerated bone remodeling and increased fracture risk. Romosozumab (RMZ), a monoclonal antibody against sclerostin, typically induces a marked increase in bone formation markers and suppression of bone resorption in postmenopausal osteoporosis. However, its bone biochemical effects in post-bariatric patients remain unknown. The objective was to describe bone mineral density (BMD) and bone turnover marker responses to RMZ in patients with osteoporosis after Roux-en-Y gastric bypass (RYGB).
Methods: We report a case series of six patients (4 women, 2 men; age range 39–77 years) with prior RYGB and densitometric osteoporosis treated with RMZ. Serial measurements of BMD and bone turnover markers (CTX and P1NP) were analyzed. Data were analyzed descriptively (mean ± SD) and Spearman correlation was used to assess associations between early marker changes and BMD response. Due to the small sample size and non-normal distribution, nonparametric methods were used and no inferential hypothesis testing was performed.
Results: Baseline CTX levels were elevated, with a mean of 487.5 ± 210.2 pg/mL. After romosozumab initiation, a paradoxical increase in bone resorption was observed, with mean CTX values of 947.7 ± 829.1 pg/mL at 1 month and 1,721.7 ± 1,552.6 pg/mL at 3 months. When early post-treatment values (1–3 months) were combined, mean CTX was 1,334.7 ± 1,191.2 pg/mL. P1NP increased consistently in all patients during the first three months (mean increase +115.5%). Spearman correlation between early P1NP increase and final lumbar spine BMD gain (12 months) was moderate, although statistical significance was not achieved ($r = 0.400$, $p = 0.600$). At the total hip, no significant correlations were observed between changes in P1NP ($r = -0.300$, $p = 0.624$) or CTX ($r = 0.738$, $p = 0.262$) and densitometric response. Early changes in CTX showed a strong positive correlation with lumbar spine BMD gain ($r = 0.949$, $p = 0.051$), suggesting that, in this cohort, greater early increases in CTX were paradoxically associated with a more robust anabolic response.
Conclusions: In post-bariatric patients, RMZ induces significant gains in BMD despite an atypical biochemical response characterized by persistent elevation of bone resorption markers. These findings suggest that conventional bone turnover markers may not reliably reflect anabolic response in this population. Prospective studies are needed to clarify bone remodeling dynamics and optimize monitoring strategies in patients with osteoporosis after bariatric surgery.

P1221

BRIDGING THE "KNOWLEDGE GAP" IN OSTEOPOROSIS: THE CRUCIAL ROLE OF OSTEOPOROSIS MANAGERS IN ENHANCING PATIENT ADHERENCE AT A PRIMARY CARE CLINIC

N. Ikuyo[1], O. Kosaku[2]

[1]Oda Orthopedic and Rheumatology Clinic, Nishinomiya, Japan; [2]Oda Orhopedic and Rheumatology Clinic, Nishinomiya, Japan

. Introduction

• **The Global Challenge:** One-year drop-out rates for osteoporosis medication reach ~50%.

• **The "Liaison Gap":** Despite ICT systems (e.g., "VitalLink"), treatment often stops when patients transition to primary care.

• **Objective:** To identify barriers to treatment persistence and evaluate the impact of Osteoporosis Manager (OM) interventions.

1. **Methods**

• **Analysis:** Retrospective study of 80 patients at Oda Orthopedic Rheumatology Clinic.

• **Key Metrics:** * Comparison of Lumbar BMD change rates across treatment groups.

• Patient knowledge survey using the McNemar test.

• Patient satisfaction via Net Promoter Score® (NPS®).

1. **Results (Main Data)**

2. **The "Knowledge Doughnut" Phenomenon**

Knowledge Category	Awareness Rate (%)
Disease Name Recognition	**85.0%**
Dietary Knowledge (Calcium)	76.3%
Necessity of Testing	**55.0%***
($p < 0.001$ compared to Disease Recognition)	

• **Insight:** Patients "know" the disease name but lack "core" understanding of diagnosis and long-term risk.

1. **BMD Change Rates (Average %)**

• **Romosozumab:** +22.56%

• **Teriparatide (PTH):** +18.06%

• **Denosumab:** +9.77%

• Untreated/Vit.D only: -1.55%

(Significant gains observed with anabolic agents)

1. **Patient Satisfaction**

• **NPS® Score: 82.5%**

• **OM Guidance:** 85% of patients desired continued support from an OM.

1. **Discussion**

• **Barriers in the 50s-60s:** High dropout rates due to work-life balance and the misconception that "healing of a fracture" equals "cure of osteoporosis."

• **Role of OM:** Bridging the gap by shifting the focus from "doctor's orders" to "patient's personal health priority."

• **Multidisciplinary Collaboration:** Collaboration with dentists is crucial for total patient care (e.g., prevention of ONJ).

1. **Conclusion**

To prevent secondary fractures, we must foster a **"Community Culture of Support."** The personalized approach of Osteoporosis Managers is essential for bridging the "Knowledge Gap" and ensuring long-term treatment success in primary care.

CHARACTERISTICS AND CIRCUMSTANCES LEADING TO FRAGILITY FRACTURES – A MULTICENTER CROSS-SECTIONAL STUDY FROM INDIA

N. Kapoor[1], L. Nagendra[2], A. Bhandarkar[3], A. Joseph[4], A. Agarwal[5], A. Jose[6], D. Arjunan[7], R. Dasgupta[8], S. Bhattacharya[9], S. Patra[10], R. Banarase[2], S. Sankrityayan[2], S. Jajodia[2], A. Mithal[11]

[1]Christian Medical College, Vellore, Vellore, India; [2]JSS Medical college, Mysore, Mysore, India; [3]KS Hegde Medical College, Managalore, India; [4]MOSC medical college, Kolencherry, India; [5]ABVIMS & Dr. RML Hospital, New Delhi, India; [6]St Gregorious Mission Hospital, Parumala, India; [7]KMC Hospital, Coimbatore, India; [8]apthagiri Institute of Medical Sciences and Research Centre, Bengaluru, India; [9]Indraprastha Apollo Hospital, New Delhi, India; [10]AIIMS, Kalyani, Kalyani, India; [11]Institute of Endocrinology and Diabetes, Max Healthcare, New Delhi, India

Objective
Several factors beyond osteoporosis may lead to the development of a fragility fracture. Identification of these region-specific circumstances may help develop policies and practices that reduce fracture risk in high-risk individuals, in addition to treating underlying osteoporosis. This study describes where, when, and how fractures occurred in Indian adults across different centers.
Material and Methods
This study characterized the types and circumstances of fractures among individuals recruited from 10 centers in India. Details of fracture characteristics and circumstances were recorded by the treating endocrinologist using a standardized questionnaire. Medical and lifestyle history, including self-reported physical activity, was also obtained. The study was approved by a central ethics committee, and informed consent was taken from each individual.
Results
214 adults with a median age of 67.4 years and a recent history of fragility fracture were included. Hip fractures were the most commonly reported fragility fractures in this population. Most fractures occurred following a fall (74.9%), at home (54%), in the evening/nighttime (57%), and during the winter season(63%). Although 15% were known to have osteoporosis and only 11% were on anti-osteoporotic agents, about a third were on calcium and vitamin D supplementation. Descriptive analyses revealed usage of long traditional clothes, poor choice of footwear, dim lighting, walking in haste, lack of rails and physical support systems, were the key circumstances cited as a reason for sustaining a fragility fracture
Conclusion
Falls are a leading cause of fractures among Indian adults. Guidelines to prevent fractures need to include population-specific strategies to reduce the risk of falls and subsequent fragility fractures during activities of daily living.

P1223

PREVALENCE AND DETERMINANTS OF SARCOPENIA IN GYNAECOLOGICAL MALIGNANCY SURVIVORS FROM A TERTIARY CARE CENTRE IN SOUTH INDIA- A CROSS-SECTIONAL STUDY

N. Kapoor[1], F. Manoharan[1], K. E. Cherian[1], P. Biradar[1], A. Thomas[1], V. Thomas[1]

[1]Christian Medical College, Vellore, Vellore, India

Objective Gynecological malignancies are among the most common neoplasms affecting women, and the co-presence of osteoporosis and sarcopenia in them has been shown to have a lower progression-free survival and poor quality of life. The aim of the study was to investigate the prevalence of sarcopenia in patients with gynecological cancer in accordance with the current diagnostic criteria of sarcopenia.
Methods A series of patients with gynecological cancer who came for follow-up after surgery were recruited in this study. Eligible patients underwent dual-energy X-ray absorptiometry and a handgrip strength test, and a gait speed evaluation. Furthermore, we also evaluated metabolic parameters and their relation to sarcopenia in this cohort.
Results 50 Individuals with different gynecological malignancies were recruited. The mean (SD) age was 41.9 (6.1) years. 22% had osteoporosis at any DXA site (neck, hip, lumbar spine/LS, forearm).
The frequencies of patients with low skeletal muscle mass index, low hand grip strength, and low gate speed were 24%, 14%, and 14%, respectively. Sarcopenia was identified in 12% of individuals. Furthermore, sarcopenia was more prevalent among older individuals (≥55 years), those with a lower BMI level (<23 kg/m2), lower physical activity, or those with diabetes mellitus.
Discussion Our study is the first prevalence study using DXA analysis in Indian patients with gynecological cancers. Sarcopenia was detected to be notably prevalent in 12% of individuals. Given the likely negative outcomes of sarcopenia reported in the literature (treatment failure, increased complications, and impaired survival), it is important to know the presence of sarcopenia in these individuals. such that appropriate measures can be initiated,

P1224

A NEW DIGITAL THORACIC KYPHOSIS–BASED APPROACH FOR VERTEBRAL FRACTURE ASSESSMENT (VFA) IN WOMEN WITH OSTEOPOROSIS

N. Kirilov[1], F. Bischoff[2], S. Vladeva[3], E. Bischoff[4]

[1]Department of Orthopedics and Traumatology, University Hospital UMBAL Dr. Georgi Stranski, 5803, Pleven, Bulgaria, Pleven, Bulgaria; [2]IPSMP Rheumatology, Stara Zagora, Stara Zagora, Bulgaria; [3]Trakia University, Department of Health Care, Faculty of Medicine, Stara Zagora, Stara Zagora, Bulgaria; [4]Burgas State University "Prof. Dr. Assen Zlatarov" Burgas, Burgas, Bulgaria

Objective:
Thoracic kyphosis is an important feature of osteoporosis and can be assessed using vertebral fracture assessment (VFA) imaging, typically via standard radiography or lateral Dual-Energy X-ray Absorptiometry (DEXA) scans. VFA is recommended for individuals with a T-score below −1.0 SD and at least one risk factor (age ≥70 years for women or ≥80 years for men, height loss >4 cm, self-reported vertebral fracture or prolonged glucocorticoid therapy). This study aimed to develop and validate an automated method for measuring thoracic kyphosis using a You Only Look Once (YOLO) deep learning model applied to lateral DEXA images.
Material and Methods:
A total of 116 women with a T-score < −1.0 SD and at least one additional risk factor (age ≥70 years, height loss >4 cm, self-reported vertebral fracture or long-term glucocorticoid therapy) were included to develop an automated thoracic kyphosis measurement method using a YOLO deep learning model on lateral scans. The YOLO–based artificial intelligence model automatically identified thoracic vertebrae on morphometric images. The kyphosis angle was calculated using a circular fitting method between the centroids of thoracic vertebrae 4 to 12. Lumbar spine bone mineral density and T-scores were recorded.
Results:
The mean age was 54.3 ± 10.7 years and mean body mass index (BMI) was 27.1 ± 4.5 kg/m². Mean lumbar T-score was −1.5 ± 0.9 SD. Among the participants, 70% had osteopenia and 30% had osteoporosis. The AI-derived mean kyphosis angle was 46.2° ± 8.0°, showing strong agreement with manual Cobb measurements (Pearson r = 0.89, p < 0.001; MSE = 3.8°). Clinically relevant kyphosis (≥40°) was detected with 0.90 sensitivity and 0.92 specificity. Over two years, 7% of patients exhibited kyphosis progression ≥5°, often accompanied by a parallel decline in T-scores, indicating coupled deterioration of spinal alignment and bone density.
Conclusion:
Thoracic kyphosis can be readily assessed using VFA imaging. The YOLO-based approach reliably measures thoracic kyphosis on DEXA VFA scans and correlates strongly with manual Cobb angles. This method enables efficient evaluation of kyphosis progression over time and holds potential as a practical digital biomarker for osteoporosis monitoring and management.

P1225

SKELETAL STEM AND PROGENITOR SPECIFIC DELETION OF BASIGIN AUGMENTS BONE MASS AND RESCUES STEROID-INDUCED OSTEOPOROSIS

D. Morales[1], C. Kun[1], T. Ambrosi[1], N. Lane[1]

[1]U.C. Davis Health, Sacramento, United States

Glucocorticoids (GCs) are widely used to treat autoimmune diseases but come at the expense of noticeable side effects, in particular significant deterioration of skeletal health. GC supplementation has been linked to muscle wasting, reduced mineral bone density, and increased bone-marrow adipose tissue. There is an estimated 30 – 50% of patients receiving GCs that experience osteoporotic fractures. GC-supplemented mouse models have demonstrated impaired bone formation and pathological alterations in bone vasculature. We demonstrated that Basigin, a transmembrane glycoprotein, is markedly upregulated in skeletal stem cells (SSCs) upon GC treatment. We also observed an age-related increase of Basigin in the bone marrow space with a more pronounced phenotype in female mice. In vitro, studies showed that overexpression of Basigin significantly hinders osteogenic differentiation and compromises endothelial cell function. Monoclonal antibody-treatment against Basigin prevented GC-induced osteoporosis (GIOP) and reversed age-related bone loss. Here, we generated an inducible conditional knockout mouse for Basigin in *Col2a1* expressing cells (Col2a1-Cre^{ERT} x Bsg$^{fl/fl}$; Bsg-iKO), targeting the mesenchymal lineage which includes SSCs and progenitors. While young adult mice displayed low baseline levels of Basigin, a significant reduction of Basigin expression could be observed in heterozygous and homozygous Bsg-iKO mice. Both, heterozygous and homozygous Bsg-iKO mice doubled volumetric trabecular bone mass 4 weeks after induction compared to Cre-negative controls as determined by DEXA and microCT measurements. Accordingly, when Basigin expression was removed immediately before administration of methylprednisolone (MP) slow-release pellets, Bsg-iKO mice exhibited resistance to steroid-mediated bone loss after 4 weeks of GC exposure with trabecular bone volume comparable to placebo treated controls. Intriguingly, bone marrow adipogenic progenitor cell populations assessed via FACS and bona marrow fat measured by histology were also significantly diminished in Bsg-iKO mice indicating potential protection from GIOP-associated osteonecrosis. Preliminary studies additionally found that aged mice are significantly more sensitive to GC-induced skeletal changes. Future studies will explore if pharmacological and genetic interventions mitigating high Basigin levels are sufficient to prevent these phenotypes. These findings support Basigin as a promising therapeutic target for counteracting GC- and age-induced skeletal deterioration.

P1226

LIGAND-ENGINEERED M-CSF AND SCLEROSTIN VARIANTS AS BALANCED BONE REMODELING THERAPEUTICS

Y. Zur[1], S. Katchkovsky[1], B. Chatterjee[1], G. Gozlan[1], C.-V. Abramovitch-Dahan[1], N. Papo[2], N. Levaot[1]

[1]Ben-Gurion University of the Negev/Department of Physiology and Cell Biology, Beer-Sheva, Israel; [2]Ben-Gurion University of the Negev/Department of Biotechnology engineering, Beer-Sheva, Israel

Objective: Macrophage colony-stimulating factor (M-CSF)/c-FMS, αvβ3 integrin, and sclerostin–LRP4/5/6 pathways are central regulators of bone remodeling, yet current osteoporosis therapies mainly suppress bone turnover rather than restoring balanced coupling between resorption and formation. In a series of experimental studies, our group engineered and validated ligand-based protein antagonists that selectively modulate these pathways to prevent osteoporotic bone loss while preserving or enhancing bone formation.

Materials and methods : Using structure-guided design and combinatorial yeast display, we converted human M-CSF into a monomeric high-affinity c-FMS antagonist and into bispecific variants ($MCSF_{RGD}$, $MCSF_{RGD}$–HSA) targeting both c-FMS and αvβ3, followed by biophysical characterization, osteoclast/osteoblast assays, pharmacokinetic profiling, and efficacy testing in mouse models of osteoporosis. In parallel, we mapped the sclerostin–LRP4 interface and engineered a competitive LRP4selective mutant (ScIN93AFc) that antagonizes sclerostin-mediated inhibition of Wnt signaling and was evaluated in vivo in developing mice.

Results: Experimentally, monomeric MCSF (MCSFC31S,M27R) retained nanomolar c-FMS binding but failed to dimerize, converted c-FMS signaling into potent antagonism, and dosedependently inhibited osteoclast differentiation in murine bone marrow macrophages and human CD14+ monocytes. Bispecific MCSFRGD variants bound c-FMS and αvβ3 with nanomolar–submicromolar affinity, disrupted osteoclast actin organization, and strongly suppressed differentiation and resorptive function, while HSA fusion markedly prolonged halflife, enhanced bone targeting, and prevented ovariectomyinduced trabecular bone loss without suppressing the bone formation marker PINP compared with alendronate. ScIN93AFc bound LRP4 but not LRP6 with high affinity, relieved sclerostin-mediated inhibition of Wnt3a signaling in osteoblasts, and increased trabecular bone volume, trabecular number, bone formation rate, and femur length while reducing osteoclast surface in vivo.

Conclusion: Collectively, we demonstrate that ligandengineered MCSF and sclerostin variants constitute experimentally validated, highly specific antiresorptive and anabolic biologics that restore balanced bone remodeling and provide modular scaffolds for targeting additional osteoclast and Wnt coreceptor axes in skeletal disease.

ORAL MANIFESTATIONS AS DIAGNOSTIC INDICATORS OF ADDISON'S DISEASE

M. Imre[1], A. M. Țâncu[2], S. M. Pițuru[3], A. Camen[4], A. N. Căpitănescu[5], C. M. Comănescu[6], N. M. Bugălă[7]

Objective: Addison's disease, or primary adrenocortical insufficiency, is a rare endocrine disorder characterized by the inadequate production of cortisol and aldosterone. While the systemic symptoms - such as fatigue, hypotension, and weight loss - are often non-specific and insidious, oral manifestations frequently serve as the first clinical sign of the disease, providing a critical window for early diagnosis. The most salient oral feature is mucocutaneous hyperpigmentation, presenting as solitary or confluent bluish-brown to black macules and patches, most commonly on the buccal mucosa, gingiva, lips, and lateral borders of the tongue. This pigmentation results from elevated levels of adrenocorticotropic hormone (ACTH) and its precursor pro-opiomelanocortin (POMC), which stimulate melanocytes in basal epithelial layers. This abstract explores the prevalence, pathophysiology, and clinical significance of oral lesions associated with Addison's disease, emphasizing the role of the dental professional in the multidisciplinary management of the condition.

Methods: A review of current clinical literature and case studies was conducted to identify the most common oral presentations and the biochemical pathways leading to their development.

Results:

- Hyperpigmentation: The hallmark oral sign is diffuse or focal hyperpigmentation of the mucous membranes, most commonly affecting the buccal mucosa, gingiva, tongue, and lips.
- Pathophysiology: This occurs due to the loss of negative feedback on the pituitary gland, leading to excess secretion of Adrenocorticotropic Hormone (ACTH) and Melanocyte-Stimulating Hormone (MSH), which share a precursor molecule (POMC).
- Clinical Presentation: These "bronzing" or "smoky" patches often appear prior to systemic crisis and do not disappear with local treatment.
- Secondary Effects: Patients may also present with delayed wound healing or an increased susceptibility to oral infections due to impaired immune response and metabolic imbalances.

Conclusion: Oral hyperpigmentation is a sensitive, though not exclusive, marker for Addison's disease. Because these changes often precede severe systemic failure (Addisonian crisis), dentists and oral health professionals play a vital role beeing uniquely positioned to identify these early signs, facilitating timely referral for endocrine evaluation and potentially preventing life-threatening adrenal crises. Recognition of these signs, followed by prompt referral for endocrine evaluation, is essential for reducing morbidity and mortality. This review underscores

the essential role of the dentist and periodontist as frontline observers in the healthcare system, capable of identifying these systemic sentinel signs. In conclusion, oral manifestations, particularly mucosal hyperpigmentation, serve as valuable diagnostic clues in Addison disease. An awareness of this oral-systemic link is essential for comprehensive patient care, reinforcing the dentist's role within the interdisciplinary diagnostic team.

BONY LANDMARKS AND ORAL SIGNS: A REVIEW OF THE ORAL MANIFESTATIONS OF HYPERPARATHYROIDISM

M. Imre[1], A. M. Țîncu[2], S. M. Pițuru[3], A. Camen[4], A. N. Căpitănescu[5], C. M. Comănescu[6], N. M. Bugălă[7], S. A. Bugălă[8]

Objective: Hyperparathyroidism (HPT) is a clinical disorder characterized by the excessive secretion of parathyroid hormone (PTH), leading to significant disruptions in calcium and phosphate homeostasis. While the systemic effects on the renal and skeletal systems are well-documented, the oral cavity often serves as a critical site for the early detection and diagnosis of the disease. This article explores the diverse spectrum of oral manifestations associated with primary, secondary, and tertiary hyperparathyroidism.

Methods: A review of current clinical literature and case studies was conducted to identify the most relevant issues concerning the oral manifestations that can be encountered in hyperparathyroidism .

Results. Key clinical and radiographic findings include:

- The central giant cell granuloma historically termed a "brown tumor": giant cell lesions that appear as expansive, non-neoplastic radiolucencies in the mandible or maxilla, representing the "terminal" stage of HPT-related bone remodeling.
- Loss of Lamina Dura: A classic early radiographic sign characterized by the disappearance of the cortical bone lining the tooth sockets.
- "Ground-Glass" Bone Pattern: A generalized demineralization of the alveolar bone, resulting in a granular, trabecular appearance similar to fibrous dysplasia.
- Dental Abnormalities: Including tooth mobility, drifting, and, in chronic cases, pulp calcifications or root resorption, as well as delayed healing of extraction sockets due to altered bone metabolism.
- Soft Tissue Changes: Vague symptoms such as xerostomia (dry mouth) or paresthesia may also be reported.
- While primary HPT is the most common etiology, secondary HPT related to chronic kidney disease presents a more complex picture, often compounded by renal osteodystrophy and metastatic soft tissue calcifications, which can appear as firm, yellow-white nodules on the tongue or buccal mucosa.

Conclusion: Because these oral markers often precede systemic symptoms, dental professionals play a pivotal role in the multidisciplinary management of HPT. Early recognition of these "silent" skeletal changes through routine dental radiography can facilitate timely biochemical screening and prevent severe systemic complications such as pathological fractures or renal failure.

Objective: Periodontitis is a chronic inflammatory disease characterized by the destruction of the tooth-supporting structures. Emerging evidence suggests a bidirectional relationship between periodontal health and systemic metabolic conditions, with insulin levels—specifically hyperinsulinemia and insulin resistance—serving as a critical mechanistic link. This paper examines the physiological and molecular pathways through which fluctuations in serum insulin levels influence the onset, severity, and progression of periodontal disease.
Pathophysiology: Elevated insulin levels, often associated with Type 2 Diabetes Mellitus and Metabolic Syndrome, promote a systemic pro-inflammatory state. This environment exacerbates the host immune response to dental plaque biofilms. High insulin concentrations are linked to the overproduction of pro-inflammatory cytokines (such as TNF-α IL-6, and IL-1β) and the activation of oxidative stress pathways, which accelerate alveolar bone resorption and collagen degradation.
Clinical Implications: Conversely, periodontitis-induced systemic inflammation can impair insulin signaling, creating a feedback loop that worsens glycemic control.4 Clinical data indicate that patients with hyperinsulinemia exhibit deeper periodontal pockets and greater clinical attachment loss compared to normo-insulinemic individuals.
Conclusion: Insulin levels are a potent modulator of the periodontal inflammatory landscape. Understanding this relationship is vital for integrated medical-dental care, suggesting that managing insulin sensitivity may be a requisite component for successful long-term periodontal therapy.

THE STRESS-PERIODONTIUM AXIS: A REVIEW OF THE ASSOCIATION BETWEEN CORTISOL LEVELS AND PERIODONTITIS

M. Imre[1], A. M. Țîncu[2], S. M. Pițuru[3], A. N. Căpitănescu[4], C. M. Comănescu[5], A. Camen[6], N. M. Bugălă[7], S. A. Bugălă[8]

[1]Department of Prosthodontics, Faculty of Dentistry, Carol Davila University of Medicine and Pharmacy, București, Romania; [2]Department of Prosthodontics, Faculty of Dentistry, Carol Davila University of Medicine and Pharmacy, Bucharest, Romania; [3]Department of Organization, Professional Legislation and Management of the Dental Office, Faculty of Dentistry, "Carol Davila" University of Medicine and Pharmacy,, Bucharest, Romania; [4]Department of ORL, University of Medicine and Pharmacy, Craiova, Romania; [5]Department of Anatomy, University of Medicine and Pharmacy, Craiova, Romania; [6]Univ Med & Pharm Craiova, Dept Occupat Med & Profess Dis,, Craiova, Romania; [7]University of Medicine and Pharmacy, Faculty of Medicine and Pharmacy, CRAIOVA, Romania; [8]Univ Med & Pharm Craiova, Fac Dent Med, Dept Endodont, Craiova, CRAIOVA, Romania

Objective: Periodontitis is a chronic inflammatory disease characterized by the destruction of the tooth-supporting structures. While bacterial biofilm is the primary etiological factor, host response modifiers - specifically psychological stress - have been increasingly implicated in disease progression. Chronic psychological stress activates the hypothalamic-pituitary-adrenal (HPA) axis, leading to sustained elevation of serum and salivary cortisol. This hypercortisolemia exerts potent immunomodulatory effects, including the suppression of neutrophil and lymphocyte function and the upregulation of pro-inflammatory cytokines (e.g., IL-1β, TNF-α, PGE2), which synergistically amplify the local inflammatory response to periodontal biofilm. Furthermore, cortisol can directly influence bone metabolism by altering the RANKL/OPG balance, thereby promoting osteoclastic alveolar bone resorption. This study investigates the correlation between cortisol, a primary glucocorticoid biomarker of the hypothalamic-pituitary-adrenal (HPA) axis, and clinical periodontal parameters. The objective was to evaluate whether elevated levels of cortisol in saliva and serum correlate with the severity of chronic periodontitis and to determine if stress-induced cortisol secretion serves as a reliable systemic indicator of periodontal tissue destruction.
Methods: A cross-sectional analysis was conducted on patients categorized into three groups: healthy periodontium, mild-to-moderate periodontitis, and severe periodontitis. Clinical measurements included Probing Depth (PD), Clinical Attachment Loss (CAL), and Gingival Index (GI). Cortisol levels were measured using Enzyme-Linked Immunosorbent Assay (ELISA) from morning saliva samples collected under standardized conditions to account for diurnal variations.
Results: Data indicated a statistically significant positive correlation between elevated cortisol levels and increased PD and CAL ($p < 0.05$). Patients in the severe periodontitis group exhibited significantly higher mean salivary cortisol concentrations compared to the healthy control

group. These findings suggest that hypercortisolemia may suppress the immune response, leading to increased susceptibility to pathogenic bacteria and impaired wound healing in the periodontium.
Conclusion: The findings support the hypothesis that cortisol is a biological link between psychological stress and periodontal breakdown. Elevated cortisol levels may serve as a potential biochemical marker for identifying individuals at higher risk for aggressive periodontal disease. Cortisol acts as a key biological mediator translating psychosocial stress into a heightened risk for periodontal tissue destruction. Integrating stress management into periodontal therapy may be beneficial for long-term clinical outcomes. This underscores the importance of a holistic, biopsychosocial approach to periodontal management, where stress assessment and coping strategies may be considered adjunctive components of therapy for susceptible patients.

THE INFLUENCE OF HYPOTHYROIDISM PHARMACOTHERAPY ON ORAL HEALTH OUTCOMES: A REVIEW OF CLINICAL MANIFESTATIONS AND MANAGEMENT STRATEGIES

M. Imre[1], A. M. Țîncu[2], S. M. Pițuru[3], A. Camen[4], A. N. Căpitănescu[5], C. M. Comănescu[6], N. M. Bugălă[7], S. A. Bugălă[8]

Objective: Hypothyroidism manifests with systemic symptoms that extend significantly into the oral cavity, affecting tissues from the mucosa to the alveolar bone. While the disorder itself poses challenges to oral health, the pharmacological management of hypothyroidism - primarily with thyroid hormone replacement therapy - plays a decisive role in modulating these outcomes. This medication exerts a profound influence on oral health, creating a complex clinical landscape where both the drug itself and the physiological state it targets interact with the oral cavity. Achieving and maintaining a euthyroid state is not merely an endocrinological goal but a foundational prerequisite for optimal oral health. This review examines the impact of thyroid replacement therapy on the oral cavity, distinguishing between the effects of the disease state and the consequences of its treatment.
Methods: This article synthesizes current clinical perspectives on oral manifestations associated with hypothyroidism pharmacotherapy, including salivary gland function, periodontal integrity, and drug-drug interactions relevant to dental practice.
Results : The influence of hypothyroidism medication on oral health is largely dependent on the accuracy of the dosage. Optimal titration is essential; however, iatrogenic fluctuations frequently occur. Supra-therapeutic doses (over-medication) can induce a state of artificial hyperthyroidism, which is linked to accelerated bone turnover, potentially leading to mandibular osteoporosis and increased susceptibility to periodontal bone loss. Conversely, sub-therapeutic levels maintain hypothyroid symptoms such as macroglossia, delayed wound healing, and dysgeusia. Furthermore, Levothyroxine therapy is frequently associated with xerostomia (dry mouth), which significantly elevates the risk of dental caries and oral candidiasis. Clinical management is further complicated by significant drug interactions, particularly with calcium and iron supplements commonly used in dental or nutritional contexts, which can inhibit the absorption of thyroid hormones.
Conclusion: Hypothyroidism pharmacotherapy plays a dual role in oral health, acting as both a restorative agent for oral homeostasis and a potential source of secondary oral complications. Effective clinical outcomes require an interdisciplinary approach between endocrinologists and dental professionals to monitor salivary flow, bone density, and precise medication adherence to mitigate adverse oral effects.

Objective: Periodontitis is a chronic inflammatory condition characterized by the destruction of supporting periodontal tissues. Emerging evidence suggests a bidirectional relationship between systemic endocrine disorders and oral health. Hypothyroidism, primarily managed through Levothyroxine (a synthetic form of thyroxine) replacement therapy, has been implicated in altered bone metabolism and immune dysfunction. However, the specific impact of hypothyroidism medication on the prevalence and severity of periodontitis remains a subject of clinical debate. The objective was to evaluate the association between hypothyroidism medication (Levothyroxine) and periodontal health status, including its influence on disease severity, clinical attachment loss (CAL), and pocket probing depth (PPD).
Methods: This review synthesizes findings from recent cross-sectional and case-control studies examining hypothyroid patients on hormone replacement therapy. Clinical parameters such as PPD, CAL, and bleeding on probing (BoP) were compared between medicated hypothyroid subjects and euthyroid controls. Additionally, the effects of medication dosage and duration of therapy on periodontal destruction were analyzed.
Results: Current literature indicates that patients with hypothyroidism, even those undergoing hormone replacement therapy, exhibit a significantly higher prevalence of moderate-to-severe periodontitis compared to healthy controls.
Results. Key findings include:
- Disease Severity: Patients on levothyroxine often present with deeper periodontal pockets and greater clinical attachment loss.
- Dose-Response Relationship: Recent data suggest a significant correlation between higher medication doses, longer duration of therapy, and increased periodontal tissue destruction. This may reflect the severity of the underlying hormonal deficiency or the impact of subclinical hormonal fluctuations on bone remodeling.
- Inflammatory Synergy: Hypothyroidism appears to amplify the systemic inflammatory cascade, which, when combined with microbial plaque, accelerates the breakdown of the periodontium through increased matrix metalloproteinase activity.
