Conclusion: The relationship between hypothyroidism medication and periodontitis is fundamentally one of systemic management influencing local inflammatory disease. Hypothyroidism and its pharmacological management are significantly associated with increased periodontitis severity. While hormone replacement therapy is essential for systemic homeostasis, it may not fully mitigate - and in high doses may correlate with - periodontal bone loss. These findings underscore the necessity for interdisciplinary collaboration between endocrinologists and dental professionals. Routine periodontal screening should be integrated into the standard of care for patients receiving hypothyroidism medication to preserve oral and systemic health.

Objective: Periodontal disease is a chronic inflammatory condition characterized by the destruction of the tooth-supporting tissues. While its primary etiology is microbial, systemic health significantly modulates its progression. Hypothyroidism, an endocrine disorder resulting from a deficiency in thyroid hormones (T_3 and T_4), has been increasingly linked to oral health complications, yet the specific association with periodontitis remains an emerging area of clinical interest. Hypothyroidism induces systemic effects - including metabolic slowdown, microvascular alterations, and impaired fibroblast function - that can compromise the periodontium's health and healing capacity. This paper evaluates the clinical and biological relationship between hypothyroidism and periodontal status, focusing on how thyroid hormone deficiency

influences periodontal tissue destruction and treatment outcomes.
Methods: A review of cross-sectional and case-control studies was conducted to analyze periodontal parameters - including Probing Pocket Depth (PPD), Clinical Attachment Level (CAL), and bone mineral density - in patients with varying degrees of thyroid dysfunction compared to euthyroid controls.
Results. Key Findings
- Increased Disease Severity: Clinical data indicates that patients with hypothyroidism exhibit a higher prevalence of moderate-to-severe periodontitis. Specifically, hypothyroid individuals often present with significantly higher mean PPD and CAL values, even after adjusting for age and oral hygiene.
- Bone Remodeling & Metabolism: Thyroid hormones are essential for bone homeostasis. A deficiency leads to decreased bone turnover and may exacerbate alveolar bone loss by increasing the activity of tartrate-resistant acid phosphatase (TRAP)-positive cells, which are markers of bone resorption.
- Systemic Inflammation & Immune Response: Hypothyroidism is associated with an elevated systemic pro-inflammatory state (increased IL-1β, TNF-α and IL-6) and impaired wound healing. This compromised immune response facilitates the progression of subgingival dysbiosis and limits the tissue's capacity for repair.
- Treatment Correlation: Emerging evidence suggests a correlation between the dose and duration of hormone replacement therapy (levothyroxine) and periodontal health, highlighting the importance of metabolic stability in managing oral disease.
Conclusion: There is a significant positive association between hypothyroidism and the complexity of periodontal diseases. The deficiency in thyroid hormones acts as a systemic modifier that accelerates periodontal destruction. These findings suggest that dentists should consider thyroid screening for patients with recalcitrant periodontitis, while endocrinologists should prioritize periodontal evaluations as part of standard care for hypothyroid patients. Further research is needed to elucidate causal pathways and explore the impact of thyroid hormone replacement therapy on periodontal outcomes.

THE SYSTEMIC-INFLAMMATORY NEXUS: A REVIEW OF THE ASSOCIATION BETWEEN PERIODONTAL DISEASES, METABOLIC SYNDROME, AND OBESITY

M. Imre[1], A. M. Țâncu[2], S. M. Pițuru[3], C. M. Comănescu[4], A. N. Căpitănescu[5], A. Camen[6], N. M. Bugălă[7], S. A. Bugălă[8]

[1]Department of Prosthodontics, Faculty of Dentistry, Carol Davila University of Medicine and Pharmacy, București, Romania; [2]Department of Prosthodontics, Faculty of Dentistry, Carol Davila University of Medicine and Pharmacy, Bucharest, Romania; [3]Department of Organization, Professional Legislation and Management of the Dental Office, Faculty of Dentistry, "Carol Davila" University of Medicine and Pharmacy,, Bucharest, Romania; [4]Department of Anatomy, University of Medicine and Pharmacy, Craiova, Romania; [5]Department of ORL, University of Medicine and Pharmacy, Craiova, Romania; [6]Univ Med & Pharm Craiova, Dept Occupat Med & Profess Dis,, Craiova, Romania; [7]University of Medicine and Pharmacy, Faculty of Medicine and Pharmacy, CRAIOVA, Romania; [8]Univ Med & Pharm Craiova, Fac Dent Med, Dept Endodont, Craiova, CRAIOVA, Romania

Objective: Periodontal disease, a chronic inflammatory condition of the supporting structures of the teeth, has increasingly been recognized as more than a localized oral health issue. Emerging evidence suggests a bidirectional and complex relationship between periodontal health and systemic metabolic disorders, specifically obesity and metabolic syndrome (MetS). This association is primarily driven by systemic inflammation and the dysregulation of metabolic pathways. This paper examines the clinical and biological links between periodontal diseases and the cluster of conditions defining metabolic syndrome, with a specific focus on the role of adipose tissue-derived inflammation in the progression of oral bone loss.
Methods: A comprehensive review of recent epidemiological studies, longitudinal cohorts, and mechanistic research was conducted to evaluate how obesity-induced systemic changes influence the risk and severity of periodontitis, and conversely, how periodontal pathogens contribute to metabolic dysfunction.
Results. Key Findings:
- Systemic Inflammation: Obesity functions as a pro-inflammatory state where adipose tissue, particularly visceral fat, acting as an active endocrine organ, releases excess cytokines (e.g., TNF-α, IL-6) and adipokines. These mediators exacerbate the inflammatory response in the gingival tissues, accelerating periodontal destruction.
- Metabolic Synergy: Individual components of MetS - including hyperglycemia, dyslipidemia, and hypertension - show a dose-response relationship with periodontal pocket depth and clinical attachment loss. Insulin resistance, in particular, acts as a primary mediator in this tripartite association. Epidemiological studies consistently demonstrate a significant association, with individuals with obesity or MetS having a higher prevalence and greater severity of periodontitis. Conversely, the chronic inflammatory burden of periodontitis contributes to systemic inflammation and oxidative stress, which can exacerbate insulin resistance, dyslipidemia, and endothelial dysfunction, perpetuating the cycle of MetS.
- Microbial Alterations: Evidence suggests that metabolic changes may alter the subgingival microbiome, favoring the growth of virulent periodontopathogens that further fuel systemic low-grade inflammation.

Conclusion: The association between periodontal disease, obesity, and metabolic syndrome underscores the need for an integrated approach to patient care. Managing periodontal inflammation through professional care and improved oral hygiene may serve as a critical adjunct in improving metabolic profiles, while weight management and metabolic control are essential for successful periodontal therapy outcomes. Conversely, medical strategies for weight loss and MetS control, including dietary modification and exercise, may positively influence periodontal status. Recognition of this bidirectional link is essential for developing comprehensive, patient-centered prevention and treatment strategies.

PATHOPHYSIOLOGICAL INTERCONNECTIVITY BETWEEN METABOLIC SYNDROME AND ENDODONTIC PATHOLOGY: A COMPREHENSIVE ANALYSIS OF SYSTEMIC INFLAMMATORY CASCADES AND CLINICAL OUTCOMES

M. Imre[1], A. M. Țâncu[2], S. M. Pițuru[3], A. Camen[4], C. M. Comănescu[5], A. N. Căpitănescu[6], N. M. Bugălă[7], S. A. Bugălă[8]

[1]Department of Prosthodontics, Faculty of Dentistry, Carol Davila University of Medicine and Pharmacy, București, Romania; [2]Department of Prosthodontics, Faculty of Dentistry, Carol Davila University of Medicine and Pharmacy, Bucharest, Romania; [3]Department of Organization, Professional Legislation and Management of the Dental Office, Faculty of Dentistry, "Carol Davila" University of Medicine and Pharmacy,, Bucharest, Romania; [4]Univ Med & Pharm Craiova, Dept Occupat Med & Profess Dis,, Craiova, Romania; [5]Department of Anatomy, University of Medicine and Pharmacy, Craiova, Romania; [6]Department of ORL, University of Medicine and Pharmacy, Craiova, Romania; [7]University of Medicine and Pharmacy, Faculty of Medicine and Pharmacy, CRAIOVA, Romania; [8]Univ Med & Pharm Craiova, Fac Dent Med, Dept Endodont, Craiova, CRAIOVA, Romania

Background: Metabolic Syndrome (MetS) - a cluster of conditions including obesity, insulin resistance, hypertension, and dyslipidemia - is increasingly recognized as a systemic determinant of oral health. While the link between MetS and periodontal disease is well-established, emerging evidence suggests a profound pathophysiological interconnectivity between systemic metabolic dysfunction and endodontic outcomes, specifically chronic apical periodontitis and pulp vitality.

Pathophysiological Mechanisms: The nexus between MetS and endodontic pathology is primarily mediated by low-grade systemic inflammation and oxidative stress. Hyperglycemia and visceral adiposity trigger the release of pro-inflammatory adipose-derived cytokines, such as TNF-α, IL-6, and CRP, which prime the dental pulp's immune response and the host's immunoinflammatory response to endodontic infection. This systemic "priming" can exacerbate the inflammatory cascade within the endodontic system when challenged by microbial biofilms.

Furthermore, MetS-induced microvascular changes - including atherosclerosis and impaired vasodilation - compromise the terminal circulation of the dental pulp. Reduced blood flow limits the delivery of immune cells and nutrients, potentially accelerating pulp necrosis and impairing the periapical healing process following endodontic therapy.

Clinical Implications: patients with MetS frequently exhibit:

- increased prevalence and size of periapical lesions.
- reduced success rates in conventional root canal treatments.
- a heightened risk of systemic inflammatory "spillover" from untreated endodontic infections, further aggravating insulin resistance.

Successful endodontic treatment of chronic apical periodontitis has been shown to reduce systemic inflammatory markers and improve key metabolic indicators, such as HbA1c and lipid profiles, suggesting that clearing local infection helps improve systemic metabolic health. Dentists are increasingly advised to consider screening for HbA1c during oral exams, while physicians are encouraged to check for periodontal and endodontic infections when treating MetS.

Conclusion: The relationship between MetS and endodontic pathology is bidirectional. Integrating metabolic screening into endodontic assessment is essential for managing patient expectations and improving clinical outcomes. Understanding these molecular pathways allows for a more holistic approach to endodontic medicine, treating the tooth not as an isolated entity, but as part of a complex, metabolically integrated system.

A SYSTEMATIC REVIEW OF OSTEOPOROSIS AS A MODIFYING FACTOR IN PERIAPICAL LESION PREVALENCE AND HEALING

M. Imre[1], A. M. Țîncu[2], S. M. Pițuru[3], C. M. Comănescu[4], A. N. Căpitănescu[5], A. Camen[6], N. M. Bugălă[7], S. A. Bugălă[8]

[1]Department of Prosthodontics, Faculty of Dentistry, Carol Davila University of Medicine and Pharmacy, București, Romania; [2]Department of Prosthodontics, Faculty of Dentistry, Carol Davila University of Medicine and Pharmacy, Bucharest, Romania; [3]Department of Organization, Professional Legislation and Management of the Dental Office, Faculty of Dentistry, "Carol Davila" University of Medicine and Pharmacy,, Bucharest, Romania; [4]Department of Anatomy, University of Medicine and Pharmacy, Craiova, Romania; [5]Department of ORL, University of Medicine and Pharmacy, Craiova, Romania; [6]Univ Med & Pharm Craiova, Dept Occupat Med & Profess Dis,, Craiova, Romania; [7]University of Medicine and Pharmacy, Faculty of Medicine and Pharmacy, CRAIOVA, Romania; [8]Univ Med & Pharm Craiova, Fac Dent Med, Dept Endodont, Craiova, CRAIOVA, Romania

Objective:
Osteoporosis is a systemic skeletal disorder characterized by decreased bone mass and the deterioration of bone microstructure, leading to increased fragility. Apical periodontitis (AP), manifests as periapical lesions, is a chronic inflammatory response to microbial infection within the root canal system, resulting in localized alveolar bone resorption. While the relationship between osteoporosis and marginal periodontitis is well-documented, the impact of systemic bone mineral density (BMD) on the prevalence and progression of periapical pathology remains a subject of emerging clinical interest. The objective was to evaluate the association between osteoporosis and the prevalence, severity, and healing of periapical lesions in adult populations.
Methods: A systematic review of literature was conducted across major databases (PubMed, EMBASE, Cochrane Library). Studies were included if they utilized dual-energy X-ray absorptiometry (DXA) for osteoporosis diagnosis and radiographic indices (such as the Periapical Index) to assess periapical status.
Results: Current evidence suggests a positive correlation between systemic osteoporosis and the prevalence of periapical lesions. Large-scale hospital-based studies have indicated that osteoporotic patients may have a significantly higher risk (OR ≈ 3.36) of presenting with periapical lesions compared to non-osteoporotic controls. Mechanistically, estrogen deficiency - a primary driver of osteoporosis - is associated with increased levels of pro-inflammatory cytokines (e.g., IL-1β, TNF-α) and higher expression of the RANKL/OPG ratio, which may accelerate periapical bone destruction. Furthermore, while endodontic treatment remains the standard of care, evidence suggests that systemic bone loss may impair or delay the quality of newly formed bone during the healing phase. Notably, the use of bisphosphonates for osteoporosis treatment appears to modulate this risk, with some studies showing a reduction in periapical lesion prevalence among patients on antiresorptive therapy, though clinicians must remain vigilant regarding the risk of medication-related osteonecrosis of the jaw (MRONJ).
Conclusion: Osteoporosis appears to be a significant systemic modifier that may increase the prevalence and severity of periapical lesions. While further high-quality longitudinal studies are required to establish definitive causality, the current data underscores the importance of a multidisciplinary approach. Dentists should consider a patient's systemic bone health when planning endodontic treatments and assessing long-term periapical healing prognoses.

THE IMPACT OF ANTIDIABETIC AGENTS ON PERIAPICAL TISSUE HOMEOSTASIS AND REPAIR

A. M. Țâncu[1], M. Imre[2], S. M. Pițuru[3], L. E. Stoica[4], F. L. Gherghina[5], N. M. Bugălă[6], S. A. Bugălă[7]

[1]Department of Prosthodontics, Faculty of Dentistry, Carol Davila University of Medicine and Pharmacy, Bucharest, Romania; [2]Department of Prosthodontics, Faculty of Dentistry, Carol Davila University of Medicine and Pharmacy, București, Romania; [3]Department of Organization, Professional Legislation and Management of the Dental Office, Faculty of Dentistry, "Carol Davila" University of Medicine and Pharmacy,, Bucharest, Romania; [4]University of Medicine and Pharmacy of Craiova Faculty of Medicine, Craiova, Romania; [5]Department of Medical Rehabilitation, University of Medicine and Pharmacy of Craiova, CRAIOVA, Romania; [6]University of Medicine and Pharmacy, Faculty of Medicine and Pharmacy, CRAIOVA, Romania; [7]Univ Med & Pharm Craiova, Fac Dent Med, Dept Endodont, Craiova, CRAIOVA, Romania

Background: Diabetes mellitus is a systemic metabolic disorder characterized by chronic hyperglycemia, which significantly impairs the healing of periapical lesions and increases the prevalence of apical periodontitis (AP). While the bidirectional relationship between diabetes and oral inflammation is well-documented, recent evidence suggests that specific antidiabetic medications may exert pleiotropic effects on periapical pathology independent of their glucose-lowering capabilities. This study evaluates the influence of primary diabetes medications - Metformin, GLP-1 receptor agonists (GLP-1RAs), and Insulin - on the evolution and resolution of apical pathology.
Pathophysiological Mechanisms: Hyperglycemia promotes the formation of Advanced Glycation End-products (AGEs), increases oxidative stress, and upregulates pro-inflammatory cytokines such as TNF-α and IL-1β. In the periapical environment, these factors increase the RANKL / OPG ratio, thereby accelerating osteoclastogenesis and alveolar bone resorption.
Impact of Medications:
- Metformin: Research indicates that metformin may attenuate periapical bone destruction. Its mechanism involves the activation of the AMPK signaling pathway, which inhibits the NF - kB and mTOR pathways in macrophages, effectively reducing the synthesis of pro-inflammatory

cytokines and suppressing monocyte recruitment to the lesion site.
- GLP-1 Receptor Agonists (e.g., Liraglutide): Emerging data suggest these agents promote the osteogenic differentiation of periodontal ligament stem cells (PDLSCs) via the Wnt/β - catenin pathway. They demonstrate potent anti-inflammatory effects that may limit the expansion of periapical lesions even in poorly controlled glycemic states
- Insulin Therapy: While essential for systemic control, the direct impact of insulin on apical healing is complex. While it can mitigate the detrimental effects of hyperglycemia on bone, some clinical studies show a slightly higher persistence of apical lesions in insulin-dependent patients, likely reflecting the increased severity and longer duration of the underlying disease rather than a negative drug effect
- DPP-4 Inhibitors: These agents appear to inhibit osteoclast formation by suppressing TNF-α expression, potentially slowing the rate of periapical bone loss.
Conclusion: Antidiabetic medications, particularly metformin and GLP-1RAs, show promise in shifting the periapical environment from a pro-inflammatory, resorptive state toward one that favors tissue repair. Understanding these drug-specific influences is crucial for dental clinicians to establish more accurate prognoses and tailored treatment plans for diabetic patients undergoing endodontic therapy.

Objective: The management of gingival inflammation in individuals with diabetes presents a significant clinical challenge, necessitating strategies that address both localized infection and systemic metabolic dysregulation. This review examines the emerging rationale for utilizing newer classes of antidiabetic medications - particularly Glucagon-Like Peptide-1 Receptor Agonists (GLP-1 RAs) and Sodium-Glucose Cotransporter-2 (SGLT2) inhibitors - as potential adjuvant agents in the control of gingivitis in diabetic patients.
Results: Beyond their primary glycemic and cardiovascular benefits, these drugs demonstrate significant pleiotropic effects, including systemic anti-inflammatory, anti-oxidative, and endothelial function-improving properties. By mitigating the hyperinflammatory state characteristic of diabetes, these medications may effectively downregulate the exaggerated gingival inflammatory response to plaque biofilm, thereby reducing clinical signs of gingivitis such as bleeding on probing and gingival index scores. This review synthesizes current evidence from mechanistic studies and preliminary clinical observations, proposing a shift towards a more integrated treatment model. In this model, systemic pharmacotherapy for diabetes concurrently supports periodontal health by modifying the host's inflammatory milieu, potentially preventing the progression of gingivitis to periodontitis.
Conclusion: While direct clinical evidence in gingivitis is still evolving, the profound systemic impact of these medications positions them as promising tools in a comprehensive oral-systemic healthcare approach for the diabetic population.

Objective. Osteoporosis is a systemic skeletal disorder marked by reduced bone mineral density (BMD) and microarchitectural deterioration, while periapical lesions are localized inflammatory responses to endodontic infection. Emerging evidence suggests a bidirectional or synergistic relationship where systemic bone metabolism significantly influences the progression and healing of periapical disease. This study aims to synthesize current research regarding the impact of systemic osteoporosis on the prevalence, severity, and healing potential of periapical lesions, as well as the underlying biological mechanisms linking the two conditions.

Methods: A comprehensive review of recent observational studies, systematic reviews, and meta-analyses (2013–2025) was conducted. Key focus areas included the correlation between DEXA-measured T-scores and periapical radiolucencies, the role of pro-inflammatory cytokines, and the influence of anti-resorptive medications (e.g., bisphosphonates) on endodontic outcomes.

Results: Evidence indicates that patients with osteoporosis exhibit a significantly higher prevalence of periapical lesions compared to normodense individuals (Odds Ratios ranging from 1.9 to 4.2). The systemic "hyper-resorptive" state associated with estrogen deficiency appears to accelerate periapical bone destruction through the up-regulation of the RANKL/OPG signaling pathway and elevated levels of pro-inflammatory cytokines. Furthermore, osteoporotic patients may experience delayed or lower-quality periapical bone repair following endodontic therapy. Conversely, dental radiographs - specifically indices like the Mandibular Cortical Index (MCI) - demonstrate potential as screening tools for identifying undiagnosed systemic bone loss.

Conclusion: Osteoporosis is a significant modifying factor in the course of periapical disease. Clinicians should consider systemic bone health when assessing endodontic prognosis and lesion progression. Integrating dental radiomorphometric analysis into routine care may facilitate earlier detection of osteoporosis, particularly in postmenopausal populations.

Objective: Osteoporosis and periodontitis are prevalent chronic diseases characterized by bone resorption. While osteoporosis is a systemic skeletal disorder resulting in compromised bone strength, periodontitis is a localized inflammatory condition leading to the destruction of the tooth-supporting apparatus. Osteoporosis has been widely investigated as a potential risk factor for periodontal disease. Emerging evidence suggests a bidirectional relationship between these two conditions, mediated by shared risk factors and biological pathways. This study aims to evaluate the extent to which systemic bone mineral density (BMD) affects periodontal status, specifically examining whether osteoporosis exacerbates the progression of alveolar bone loss and attachment level changes.

Methods: A comprehensive review of clinical and radiographic parameters was conducted, comparing postmenopausal women with diagnosed osteoporosis to a control group with normal BMD. Key indicators of periodontal health - including Probing Depth (PD), Clinical Attachment Level (CAL), and Radiographic Alveolar Bone Loss (ABL) - were assessed alongside systemic Dual-energy X-ray Absorptiometry (DEXA) scores.

Results: The analysis indicates a significant correlation between low systemic BMD and increased severity of periodontal destruction. Patients with osteoporosis exhibited higher rates of clinical attachment loss compared to healthy counterparts and reduced alveolar bone density, suggesting that systemic skeletal weakness may predispose the mandibular and maxillary bone to more rapid resorption during inflammatory insults. Increased Pro-inflammatory Cytokines (such as IL-1, IL-6, and TNF-α) in the gingival crevicular fluid, which may be exacerbated

by estrogen deficiency. Clinical and radiographic studies also indicate that individuals with osteoporosis, especially postmenopausal women, tend to exhibit deeper periodontal pockets, and increased alveolar bone loss compared to those with normal bone mineral density. This association appears to be independent of traditional local risk factors, though its strength is modulated by the severity of osteoporosis and the presence of other comorbidities. Furthermore, the systemic inflammation associated with periodontitis may, in turn, negatively impact bone metabolism, potentially creating a deleterious cycle.

Conclusion: Osteoporosis is a significant risk factor for the progression of periodontal disease. While a direct causal link remains complex, substantial evidence supports osteoporosis as a modifying factor that can accelerate periodontal tissue destruction. The systemic reduction in bone mass appears to lower the threshold for periodontal bone loss, particularly in postmenopausal populations. These findings underscore the importance of an interdisciplinary approach, where dental professionals and primary care physicians collaborate to monitor the oral health of patients with diagnosed metabolic bone diseases.

THE RELATIONSHIP BETWEEN CHRONIC GINGIVITIS AND DIABETES MELLITUS: A REVIEW OF PATHOPHYSIOLOGICAL MECHANISMS AND CLINICAL IMPLICATIONS

A. M. Țâncu[1], M. Imre[2], S. M. Pițuru[3], F. L. Gherghina[4], L. E. Stoica[5], N. M. Bugălă[6], S. A. Bugălă[7]

[1]Department of Prosthodontics, Faculty of Dentistry, Carol Davila University of Medicine and Pharmacy, Bucharest, Romania; [2]Department of Prosthodontics, Faculty of Dentistry, Carol Davila University of Medicine and Pharmacy, București, Romania; [3]Department of Organization, Professional Legislation and Management of the Dental Office, Faculty of Dentistry, "Carol Davila" University of Medicine and Pharmacy,, Bucharest, Romania; [4]Department of Medical Rehabilitation, University of Medicine and Pharmacy of Craiova, CRAIOVA, Romania; [5]University of Medicine and Pharmacy of Craiova Faculty of Medicine, Craiova, Romania; [6]University of Medicine and Pharmacy, Faculty of Medicine and Pharmacy, CRAIOVA, Romania; [7]Univ Med & Pharm Craiova, Fac Dent Med, Dept Endodont, Craiova, CRAIOVA, Romania

Objective: The association between periodontal health and systemic metabolic disorders has become a focal point of integrated medicine. Chronic gingivitis, characterized by persistent inflammation of the gingival tissues, is increasingly recognized not merely as a localized oral ailment but as a significant contributor to systemic inflammatory burden. This abstract explores the correlation between chronic gingivitis and diabetes mellitus, emphasizing the "two-way street" relationship that defines their interaction. The objective was to analyze the physiological and immunological links between gingival inflammation and glycemic control, and to evaluate how each condition exacerbates the progression of the other.

Methods: A comprehensive review of current clinical literature and longitudinal studies was conducted, focusing on biomarkers of inflammation, such as C-reactive protein (CRP) and Interleukin-6 (IL-6), and clinical markers of diabetes, specifically HbA1c levels.

Results: The correlation is underpinned by a synergistic inflammatory cycle. Persistent hyperglycemia in diabetic patients drives a state of systemic inflammation and immune dysfunction. Diabetes increases the risk and severity of gingivitis through the accumulation of Advanced Glycation End-products (AGEs), which induce oxidative stress and impair the regenerative capacity of oral tissues. Conversely, chronic gingivitis introduces periodontal pathogens and pro-inflammatory cytokines into the systemic circulation. This systemic "leakage" promotes insulin resistance by interfering with insulin receptor signaling, thereby making blood glucose levels more difficult to regulate in diabetic patients. Clinical evidence suggests that the effective treatment of gingival inflammation can lead to a statistically significant reduction in HbA1c levels.

Conclusion: There is a robust, positive correlation between chronic gingivitis and diabetes mellitus. This study consistently reports a higher prevalence and greater severity of gingival inflammation in individuals with poorly controlled diabetes compared to those without diabetes or with well-controlled disease. This correlation underscores the importance of integrated patient care. Chronic oral inflammation serves as both a complication of and a risk factor for poor glycemic control. These findings underscore the necessity for a multidisciplinary approach to patient care, where dental professionals and endocrinologists collaborate to manage systemic inflammation.

THE INFLUENCE OF OSTEOPOROSIS PHARMACOTHERAPY ON THE CLINICAL PROGRESSION AND MANAGEMENT OF CHRONIC GINGIVITIS: A REVIEW

S. M. Pițuru[1], M. Imre[2], A. M. Țâncu[3], F. L. Gherghina[4], L. E. Stoica[5], N. M. Bugălă[6], S. A. Bugălă[7]

[1]Department of Organization, Professional Legislation and Management of the Dental Office, Faculty of Dentistry, "Carol Davila" University of Medicine and Pharmacy,, Bucharest, Romania; [2]Department of Prosthodontics, Faculty of Dentistry, Carol Davila University of Medicine and Pharmacy, București, Romania; [3]Department of Prosthodontics, Faculty of Dentistry, Carol Davila University of Medicine and Pharmacy, Bucharest, Romania; [4]Department of Medical Rehabilitation, University of Medicine and Pharmacy of Craiova, CRAIOVA, Romania; [5]University of Medicine and Pharmacy of Craiova Faculty of Medicine, Craiova, Romania; [6]University of Medicine and Pharmacy, Faculty of Medicine and Pharmacy, CRAIOVA, Romania; [7]Univ Med & Pharm Craiova, Fac Dent Med, Dept Endodont, Craiova, CRAIOVA, Romania

Objective: Osteoporosis and chronic gingivitis are highly prevalent conditions that frequently co-occur in aging populations. The inflammatory bone resorption in gingivitis is primarily driven by local biofilm, but systemic medications have been proven to significantly modify the host response and tissue homeostasis. While the systemic impact of bone mineral density (BMD) loss on alveolar bone is well-documented, the specific influence of osteoporosis medications - particularly bisphosphonates and RANKL inhibitors - on the inflammatory dynamics of chronic gingivitis remains a subject of clinical scrutiny. This abstract explores the bidirectional relationship between osteoporosis pharmacotherapy and gingival inflammation, evaluating how systemic bone-modifying agents alter the clinical presentation and treatment response of chronic gingivitis.

Methodq: A review of current clinical trials and observational studies was conducted to assess parameters such as Gingival Index (GI), Bleeding on Probing (BOP), and crevicular fluid cytokine levels in patients receiving antiresorptive or anabolic osteoporosis treatments.

Results:

- anti-inflammatory potential: evidence suggests that nitrogen-containing bisphosphonates may exert a protective effect on the periodontium by inhibiting pro-inflammatory mediators and matrix metalloproteinases (MMPs), potentially reducing the clinical severity of gingival inflammation.
- alveolar integrity: improved systemic BMD correlates with enhanced alveolar bone density, which may indirectly stabilize the gingival attachment apparatus and modify the host response to dental plaque.
- clinical complications: antiresorptive drugs, notably Bisphosphonates and Denosumab, may attenuate alveolar bone loss secondary to inflammation by suppressing osteoclastic activity; conversely, the risk of Medication-Related Osteonecrosis of the Jaw (MRONJ), although primarily associated with invasive procedures, necessitates a cautious approach to managing chronic gingivitis to prevent progression to more severe periodontal disease.

Conclusion: Osteoporosis medication significantly influences the oral microenvironment. While these agents may mitigate some inflammatory markers of gingivitis, they also necessitate specialized dental monitoring. Understanding this interplay is vital for developing integrated treatment protocols that optimize both systemic bone health and oral inflammatory control.

Objective. Diabetes mellitus (DM) is a systemic metabolic disorder characterized by chronic hyperglycemia, which significantly impacts oral health. While the relationship between diabetes and periodontal disease is well-established, its influence on endodontic pathology - specifically the health of the dental pulp and the periradicular tissues - has emerged as a critical area of clinical concern. This paper explores the pathophysiological mechanisms by which diabetes affects the initiation, progression, and healing of endodontic lesions, while evaluating the clinical success rates of root canal treatments in diabetic patients.

Methods: A comprehensive review of current literature was conducted, focusing on the immune response alterations, vascular changes, and inflammatory markers present in diabetic individuals with apical periodontitis.

Results:

- enhanced Inflammation: hyperglycemia leads to the accumulation of Advanced Glycation End-products (AGEs), which trigger a pro-inflammatory state. This results in an exaggerated immune response within the dental pulp.
- impaired healing: diabetes impairs the function of neutrophils and fibroblasts, leading to a reduced capacity for periapical bone healing following endodontic intervention.
- prevalence: diabetic patients exhibit a higher prevalence of periapical

radiolucencies and a greater likelihood of asymptomatic infections compared to non-diabetic controls.
- success rates: while endodontic therapy is generally successful in controlled diabetics, patients with poor glycemic control show a significantly higher risk of endodontic failure and post-operative complications.
Conclusions: Diabetes mellitus serves as a significant modifier of endodontic disease. The systemic environment in diabetic patients not only predisposes the dental pulp to infection but also complicates the resolution of periapical lesions. For the clinician, strict glycemic monitoring and tailored treatment protocols are essential to optimize outcomes and prevent tooth loss in this high-risk population.

THE INFLUENCE OF HYPERTHYROIDISM ON THE PROGRESSION AND HEALING OF APICAL PERIODONTITIS: A REVIEW OF PATHOPHYSIOLOGICAL MECHANISMS AND CLINICAL IMPLICATIONS

A. M. Țâncu[1], M. Imre[2], S. M. Pițuru[3], F. L. Gherghina[4], L. E. Stoica[5], N. M. Bugălă[6], S. A. Bugălă[7]

[1]Department of Prosthodontics, Faculty of Dentistry, Carol Davila University of Medicine and Pharmacy, Bucharest, Romania; [2]Department of Prosthodontics, Faculty of Dentistry, Carol Davila University of Medicine and Pharmacy, București, Romania; [3]Department of Organization, Professional Legislation and Management of the Dental Office, Faculty of Dentistry, "Carol Davila" University of Medicine and Pharmacy,, Bucharest, Romania; [4]Department of Medical Rehabilitation, University of Medicine and Pharmacy of Craiova, CRAIOVA, Romania; [5]University of Medicine and Pharmacy of Craiova Faculty of Medicine, Craiova, Romania; [6]University of Medicine and Pharmacy, Faculty of Medicine and Pharmacy, CRAIOVA, Romania; [7]Univ Med & Pharm Craiova, Fac Dent Med, Dept Endodont, Craiova, CRAIOVA, Romania

Objective: Hyperthyroidism, characterized by the excessive production of thyroxine (T_4) and triiodothyronine (T_3), significantly alters systemic metabolism and immune regulation. While its impact on marginal periodontitis is well-documented, its specific influence on apical periodontitis (AP) - a chronic inflammatory disease of the periradicular tissues - is an emerging area of clinical interest. This study examines how elevated thyroid hormones modulate the pathogenesis, bone destruction, and healing potential of periapical lesions.

Methods: A review of current literature and clinical data was conducted to evaluate the relationship between thyroid dysfunction and periapical health. Key parameters included the expression of pro-inflammatory cytokines, bone turnover markers (RANKL/OPG), and the rate of periapical bone resorption in hyperthyroid versus euthyroid states.
Results: Hyperthyroidism appears to exacerbate the progression of apical periodontitis through several mechanisms:
- Accelerated Bone Resorption: Excess thyroid hormones stimulate osteoclast activity, leading to faster expansion of periapical radiolucencies.
- Immunological Dysregulation: Elevated levels of pro-inflammatory cytokines and mediators associated with hyperthyroidism, alongside a potential dysregulation of the RANKL/OPG pathway, could synergistically amplify the local inflammatory and osteoclastogenic response to pulpal pathogens, potentially leading to more extensive periapical lesions.
- Impaired Healing: Despite a high metabolic rate, the "high-turnover" state often results in poor quality of bone repair, potentially leading to delayed healing or persistent lesions following endodontic treatment. The implied pathophysiological mechanisms suggest that hyperthyroidism may act as a modifying factor, aggravating the bony destruction of apical periodontitis and possibly impairing post-treatment healing.
- Microbiological Shifts: Some evidence suggests hyperthyroidism may alter oral microbiome diversity, potentially increasing the virulence of endodontic pathogens.
Conclusion: Hyperthyroidism acts as a systemic modifier that may increase the prevalence and severity of apical periodontitis. The hypermetabolic state and cytokine imbalance favor bone catabolism over repair in the periradicular region. Clinicians should consider a patient's thyroid status as a risk factor for endodontic treatment prognosis and emphasize the importance of hormonal stabilization to improve healing outcomes.

THE INFLUENCE OF ANTI-DIABETIC MEDICATION ON THE EVOLUTION OF APICAL PERIODONTITIS: A SCOPING REVIEW OF PATHOPHYSIOLOGICAL INTERACTIONS AND CLINICAL IMPLICATIONS

M. Imre[1], A. M. Țâncu[2], S. M. Pițuru[3], F. L. Gherghina[4], L. E. Stoica[5], N. M. Bugălă[6], S. A. Bugălă[7]

[1]Department of Prosthodontics, Faculty of Dentistry, Carol Davila University of Medicine and Pharmacy, București, Romania; [2]Department of Prosthodontics, Faculty of Dentistry, Carol Davila University of Medicine and Pharmacy, Bucharest, Romania; [3]Department of Organization, Professional Legislation and Management of the Dental Office, Faculty of Dentistry, "Carol Davila" University of Medicine and Pharmacy,, Bucharest, Romania; [4]Department of Medical Rehabilitation, University of Medicine and Pharmacy of Craiova, CRAIOVA, Romania; [5]University of Medicine and Pharmacy of Craiova Faculty of Medicine, Craiova, Romania; [6]University of Medicine and Pharmacy, Faculty of Medicine and Pharmacy, CRAIOVA, Romania; [7]Univ Med & Pharm Craiova, Fac Dent Med, Dept Endodont, Craiova, CRAIOVA, Romania

Objective: Apical periodontitis (AP) is an inflammatory disease of periradicular tissues primarily caused by bacterial infection of the root canal system. Diabetes mellitus (DM), particularly when poorly controlled, is a well-established risk factor for increased prevalence, severity, and delayed healing of AP due to hyperglycemia-induced impaired immune response, microangiopathy, and chronic inflammation. The widespread use of anti-diabetic medications necessitates an understanding of their specific impact on AP pathogenesis beyond glycemic control alone. This review synthesizes current evidence on how anti-diabetic medications modulate the evolution of apical periodontitis, focusing on pleiotropic drug effects on bone metabolism, immune cell function, and the inflammatory milieu.
Results: Emerging evidence suggests that anti-diabetic agents exert divergent effects on AP evolution. Metformin, beyond hypoglycemia, demonstrates anti-inflammatory and osteo-protective properties, potentially attenuating periapical bone destruction and promoting healing. Incretin-based therapies (GLP-1 agonists, DPP-4 inhibitors) may reduce pro-inflammatory cytokine production (e.g., TNF-α, IL-6) in the periapical lesion. Conversely, sodium-glucose cotransporter-2 (SGLT2) inhibitors have been associated with potential risks, such as a higher incidence of diabetic ketoacidosis and related acidosis, which could theoretically exacerbate osteoclast activity and bone resorption. Insulin therapy, while crucial for glycemic normalization, may have complex site-specific immunomodulatory effects. The overall impact appears contingent on achieving glycemic control, but direct pharmacologic actions are increasingly recognized.
Conclusion: The progression and resolution of apical periodontitis in diabetic patients are not solely dictated by glycemic levels but are also influenced by the specific anti-diabetic pharmacotherapy. A paradigm shift is emerging from viewing DM as a monolithic risk factor towards a nuanced understanding where medication choice may actively shape the host response to endodontic infection. Further clinical and translational research is essential to guide integrated treatment planning between endodontists and physicians, optimizing both diabetic and periapical health outcomes.

Objective: Osteoporosis is a systemic skeletal disorder characterized by reduced bone mineral density and microarchitectural deterioration. Osteoporosis medications and apical periodontitis (AP) have a complex relationship, as these drugs primarily target bone remodeling processes that are also central to the development and healing of periapical periodontitis. Emerging evidence suggests a bidirectional link between systemic bone health and inflammatory periapical pathology (apical periodontitis). While the microbial etiology of periapical lesions is well-established, host systemic factors - specifically the use of antiresorptive medications such as Bisphosphonates (BPs) and Denosumab - significantly modulate the inflammatory bone remodeling process. This review aims to evaluate the impact of common osteoporosis medications on the prevalence, progression, and healing dynamics of periapical lesions in patients undergoing endodontic therapy.
Methods: A comprehensive review of clinical trials, systematic reviews, and retrospective studies (up to 2024-2025) was conducted. Key focus areas included the pharmacological mechanisms of Bisphosphonates and RANKL inhibitors – Denosumab - on osteoclast activity within the periapical microenvironment.

Results: Current data indicate that osteoporosis itself may predispose patients to more rapid progression of periapical bone destruction. However, the administration of antiresorptive drugs presents a dual-natured impact:
- healing dynamics: bisphosphonates may paradoxically support the reduction of periapical lesion size by suppressing osteoclast-mediated bone resorption. Some studies report a lower prevalence of periapical lesions in osteoporotic patients taking oral BPs compared to those untreated.
- treatment outcomes: conversely, long-term use of high-potency antiresorptives (especially intravenous formulations) is associated with delayed healing of periapical tissues post-endodontic treatment. In some cases, persistent periapical infections serve as a localized "trigger" for Medication-Related Osteonecrosis of the Jaw (MRONJ), particularly if surgical intervention is pursued.
- success rates: while overall endodontic success remains high, patients on denosumab or long-term BP therapy may exhibit lower radiographic healing scores in root-canal-treated teeth compared to healthy controls.
Conclusions: Osteoporosis medications significantly alter the periapical host response. While they may limit the expansion of inflammatory lesions by inhibiting bone turnover, they also necessitate a cautious, non-surgical approach to endodontic treatment to minimize MRONJ risks. Clinicians must prioritize the elimination of periapical infections in these patients to maintain systemic and localized bone stability.

DIABETES MELLITUS AND ENDO-PERIODONTAL LESIONS: FROM NECROSIS TO APICAL PERIODONTITIS

I. T. Dascălu[1], A. Camen[1], N. M. Bugălă[2], A. N. Căpitănescu[3], C. M. Comănescu[4]

[1]Faculty of Dentistry, University of Medicine and Pharmacy of Craiova, CRAIOVA, Romania; [2]University of Medicine and Pharmacy, Faculty of Medicine and Pharmacy, CRAIOVA, Romania; [3]Department of ORL, University of Medicine and Pharmacy, Craiova, Romania; [4]Department of Anatomy, University of Medicine and Pharmacy, Craiova, Romania

Introduction: Diabetes mellitus and periodontitis have a bidirectional relationship, with reciprocal effects on inflammation and metabolic control. In the endodontic field, the main concern is whether hyperglycemia increases the risk of apical periodontitis and delays periapical healing after root canal treatment.

Objective: To provide a clinical synthesis of the associations between type 2 diabetes mellitus (T2DM), glycemic status, and endodontic pathology (apical periodontitis), within the framework of the endo-periodontal continuum.

Methods:A narrative synthesis of recent clinical studies and meta-analyses evaluating the association between T2DM, HbA1c levels, and apical periodontitis, integrated into the inflammatory endo-periodontal model.

Results: In a hospital-based case–control study, T2DM was independently associated with a higher prevalence of apical periodontitis (OR 2.05), while HbA1c levels above 8.0% were associated with an even higher prevalence (OR 2.46). The use of metformin (OR 0.82) and statins (OR 0.70) was associated with a lower prevalence of apical periodontitis. A meta-analysis cited in the same context reported a higher prevalence of apical periodontitis after endodontic treatment in diabetic patients compared with controls, both at the tooth level (OR 1.51) and at the patient level (OR 3.38). These findings support the hypothesis that metabolic dysregulation may amplify chronic inflammation within the endo-periodontal unit.

Conclusions: In patients with T2DM, HbA1c represents a clinically useful marker for endodontic and periodontal risk stratification. Collaboration between the endocrinologist, endodontist, and periodontist is particularly relevant when HbA1c levels exceed 8%.

PERIODONTAL THERAPY AS AN ADJUNCTIVE INTERVENTION FOR GLYCEMIC CONTROL: IMPLICATIONS FOR ENDOCRINOLOGY

I. T. Dascălu[1], A. Camen[1], C. M. Comănescu[2], N. M. Bugălă[3]

[1]Faculty of Dentistry, University of Medicine and Pharmacy of Craiova, CRAIOVA, Romania; [2]Department of Anatomy, University of Medicine and Pharmacy, Craiova, Romania; [3]University of Medicine and Pharmacy, Faculty of Medicine and Pharmacy, CRAIOVA, Romania

Introduction: Periodontitis is associated with low-grade systemic inflammation and impaired glycemic control in patients with diabetes, within a bidirectional relationship. From this perspective, periodontal treatment emerges as a potential adjunctive intervention in metabolic management.

Objective: To assess the effect of periodontal therapy on HbA1c levels, with a focus on the magnitude of the effect and the clinical factors that may modify it.

Methods: Comparison of HbA1c values in patients with diabetes and periodontitis who received periodontal treatment versus control groups.

Results: One meta-analysis (11 studies) demonstrated significant reductions in HbA1c at 3 months (−0.64%) and at 6 months (−0.33%), accompanied by decreases in C-reactive protein (CRP), suggesting a reduction in systemic inflammation. Another meta-analysis (23 randomized controlled trials) reported reductions in HbA1c at 3 months (weighted mean difference [WMD] −0.514%) and at 6 months (WMD −0.548%), with substantial heterogeneity, partially explained by baseline HbA1c levels. The effect tended to be more pronounced in patients with poorer initial glycemic control.

Conclusions: The integration of periodontal evaluation into the clinical pathway of patients with diabetes is supported by meta-analytic evidence, showing a modest but clinically relevant average effect, particularly in subgroups with elevated baseline HbA1c levels

THYROID DYSFUNCTION AND PERIODONTAL DISEASE: SYNTHESIZED EVIDENCE AND CLINICAL RELEVANCE

A. Camen[1], I. T. Dascălu[1], C. Bănică[1], L. Gheorghiță[1], N. M. Bugălă[2]

[1]Faculty of Dentistry, University of Medicine and Pharmacy of Craiova, CRAIOVA, Romania; [2]University of Medicine and Pharmacy, Faculty of Medicine and Pharmacy, CRAIOVA, Romania

Introduction: Thyroid dysfunction may alter immune responses and bone metabolism, representing plausible mechanisms for the exacerbation of periodontal inflammation. Clinical evidence addressing this association has recently been evaluated in meta-analyses.

Objective: To synthesize the association between thyroid dysfunction (hypothyroidism or hyperthyroidism) and clinical periodontal indices, with an emphasis on relevance for endocrinology practice.

Methods:A summary of findings from recent meta-analyses and systematic reviews assessing periodontal status in patients with thyroid diseases.

Results: One meta-analysis identified significantly higher periodontal indices in patients with thyroid dysfunction compared with controls (standardized mean difference [SMD] 0.369; 95% confidence interval [CI] 0.194–0.545), with effects reported mainly for clinical attachment loss (CAL) and probing pocket depth (PPD). In a systematic review with meta-analysis, patients with thyroid diseases—particularly hypothyroidism—exhibited poorer periodontal status than controls, and in cross-sectional studies, 5.74% of patients with periodontitis reported thyroid comorbidity.

Conclusions: The available data support an association between thyroid dysfunction and periodontal impairment, with implications for bidirectional clinical screening. Standardization of disease definitions and improved control of confounding factors remain necessary to obtain more robust estimates.

BONE METABOLISM, VITAMIN D, AND PARATHYROID HORMONE: ENDOCRINE INTERSECTIONS RELEVANT TO PERIODONTAL ATTACHMENT LOSS

M. C. Beznă[1], A. Camen[1], L. Gheorghiță[1], N. M. Bugălă[2]

[1]Faculty of Dentistry, University of Medicine and Pharmacy of Craiova, CRAIOVA, Romania; [2]University of Medicine and Pharmacy, Faculty of Medicine and Pharmacy, CRAIOVA, Romania

Introduction: Periodontal bone loss is influenced by systemic bone status and by the endocrine axes that regulate bone metabolism (estrogen, vitamin D, parathyroid hormone [PTH], glucocorticoids). Within this framework, periodontitis can be interpreted as a local disease with important systemic determinants.

Objective: To synthesize the relationship between postmenopausal osteoporosis, vitamin D status, hyperparathyroidism, and clinical periodontal parameters, with reference to endo-periapical involvement where data are available.

Results: In postmenopausal osteoporosis, a meta-analysis reported lower bone mineral density (BMD) compared with non-osteoporotic individuals (mean difference [MD] −0.41), with the overall conclusion that women with postmenopausal osteoporosis are more prone to periodontitis and disease progression. Regarding vitamin D, a meta-analysis concluded that patients with periodontitis have lower serum concentrations, and that the combination of scaling and root planing (SRP) with vitamin D supplementation resulted in greater reductions in clinical attachment loss (CAL) compared with SRP alone (weighted mean difference [WMD] −0.13).In primary hyperparathyroidism, patients with the highest preoperative ionized calcium levels had an increased risk of tooth extractions (incidence rate ratio [IRR] 1.85). In an observational study, certain subgroups of patients with primary hyperparathyroidism exhibited higher probing depth, greater clinical attachment loss, and increased gingival bleeding. In states of glucocorticoid excess (Cushing syndrome), the literature describes maxillary bone loss, tooth loss, and periodontal disease as potential manifestations.

Conclusions: Endocrine markers of bone metabolism, including vitamin D and PTH, may support periodontal risk stratification and guide integrated management strategies. With respect to the association between osteoporosis and endodontic pathology, systematic reviews are available; however, the direction and magnitude of the effect cannot be confirmed here due to the lack of full access to the underlying data in those studies.

POLYCYSTIC OVARY SYNDROME AND PERIODONTITIS: A BIDIRECTIONAL INFLAMMATORY MODEL

L. Gheorghiță[1], A. Camen[2], M. C. Beznă[1], C. Bănică[1], N. M. Bugălă[3]

[1]Faculty of Dentistry, University of Medicine and Pharmacy of Craiova, CRAIOVA, Romania; [2]Univ Med & Pharm Craiova, Dept Occupat Med & Profess Dis,, Craiova, Romania; [3]University of Medicine and Pharmacy, Faculty of Medicine and Pharmacy, CRAIOVA, Romania

Introduction: Polycystic ovary syndrome (PCOS) is associated with low-grade chronic inflammation and metabolic disturbances that may influence the gingival–periodontal response. Conversely, periodontitis may amplify systemic inflammatory burden, which is relevant to the PCOS phenotype.

Objective: To present the available evidence regarding the bidirectional association between PCOS, periodontitis, and the severity of clinical periodontal parameters.

Results:A meta-analysis indicated that women with PCOS have a 28% higher risk of periodontal disease, while women with periodontitis have a 46% higher risk of having PCOS. In addition, women with both PCOS and periodontitis exhibited greater gingival bleeding, increased probing pocket depths, and more severe clinical attachment loss compared with women without PCOS but with periodontitis. The authors emphasized the need for prospective and interventional studies to clarify causality and to evaluate the impact of periodontal therapy on PCOS-related markers.

Conclusions: In clinical practice, the association between PCOS and periodontitis supports the implementation of periodontal screening in patients with PCOS, particularly in the presence of metabolic phenotypes. From a periodontal perspective, PCOS may be considered a potential systemic risk factor for increased inflammatory severity and periodontal attachment loss.

ENDODONTIC TREATMENT OF APICAL PERIODONTITIS AND METABOLIC MARKERS: LONGITUDINAL METABOLOMIC DATA

A. Camen[1], I. T. Dascălu[1], L. Gheorghiță[1], C. Bănică[1], N. M. Bugălă[2]

[1]Faculty of Dentistry, University of Medicine and Pharmacy of Craiova, CRAIOVA, Romania; [2]University of Medicine and Pharmacy, Faculty of Medicine and Pharmacy, CRAIOVA, Romania

Introduction: Apical periodontitis (AP) is a chronic periradicular inflammatory disease associated with systemic inflammatory burden and increased cardiometabolic risk.

Objective: To evaluate systemic metabolic changes associated with successful endodontic treatment in patients with apical periodontitis.

Methods:A longitudinal, self-controlled cohort study conducted over 2 years in 65 patients with apical periodontitis. Serum metabolomic analysis was performed using nuclear magnetic resonance (NMR) spectroscopy at five time points: preoperative, 3 months, 6 months, 1 year, and 2 years post-treatment.

Results: Significant postoperative changes were identified in 24 of the 44 analyzed metabolites (54.5%). The metabolic profile suggested improvements in glucose and lipid metabolism and a reduction in inflammatory burden. These changes included a reduction in branched-chain amino acids at 3 months, decreased glucose and pyruvate levels at 2 years, short-term reductions in cholesterol, choline, and fatty acids, and a progressive increase in tryptophan levels. Associations were observed between the metabolic profile, clinical indicators of metabolic syndrome, inflammatory markers, and preoperative microbiome data. Dynamic Bayesian modeling identified tricarboxylic acid (TCA) cycle metabolites as key regulators of longitudinal metabolic changes.

Conclusions: Successful endodontic treatment of apical periodontitis is associated with favorable systemic metabolic changes and reduced inflammation, supporting the inclusion of chronic endodontic infections in cardiometabolic risk assessment.

HYPOESTROGENISM AND THE ENDO-PERIODONTAL UNIT: THE ROLE OF THE NLRP3 INFLAMMASOME IN APICAL PERIODONTITIS AND PERIODONTAL IMPLICATIONS

M. C. Beznă[1], A. Camen[1], I. T. Dascălu[1], C. Bănică[1], N. M. Bugălă[2]

[1]Faculty of Dentistry, University of Medicine and Pharmacy of Craiova, CRAIOVA, Romania; [2]University of Medicine and Pharmacy, Faculty of Medicine and Pharmacy, CRAIOVA, Romania

Introduction: The physiological decline in estrogen levels after menopause may alter inflammatory responses and bone remodeling, with potential effects on both periodontal tissues and periapical lesions.

Objective: To evaluate the association between estrogen deficiency and the progression of apical periodontitis as well as periodontal pathology, from an odontogenic–endo-periodontal perspective.

Results: In a clinical study, infected apical tissues from postmenopausal women showed increased expression of the NLRP3/caspase-1/IL-1β axis compared with tissues from premenopausal patients, suggesting involvement of this pathway in apical periodontitis under conditions of estrogen deficiency. An ovariectomized animal model confirmed upregulation of the same pathway in infected areas, along with aggravated bone loss as lesion progression advanced. A preclinical systematic review including 12 studies reported that estrogen deficiency consistently increased the progression of apical periodontitis lesions in animal models (moderate certainty of evidence according to GRADE).

Regarding periodontal tissues, a systematic review concluded that reduced estrogen levels are associated with increased periodontal pathology, although more robust clinical studies are required. At the odontogenic level, a meta-analysis reported a higher DMFT index in postmenopausal women (mean difference 3.13; 95% confidence interval 2.12–4.15).

Conclusions: Menopausal status may be clinically relevant in assessing the risk of apical periodontitis and periodontal disease. Inflammatory markers such as IL-1β and the NLRP3 inflammasome may represent a biological link between endocrinology and endo-periodontal pathology.

PERIODONTITIS AND GESTATIONAL DIABETES MELLITUS: RISK ESTIMATION FROM META-ANALYSES AND PRACTICAL IMPLICATIONS

A. Camen[1], I. T. Dascălu[1], M. C. Beznă[1], C. Bănică[1], L. Gheorghiță[1], N. M. Bugălă[2]

[1]Faculty of Dentistry, University of Medicine and Pharmacy of Craiova, CRAIOVA, Romania; [2]University of Medicine and Pharmacy, Faculty of Medicine and Pharmacy, CRAIOVA, Romania

Introduction: Chronic periodontal inflammation may amplify systemic inflammatory responses during pregnancy, a physiological state already characterized by increased insulin resistance.

Objective: To synthesize quantitative evidence on the association between periodontitis and gestational diabetes mellitus (GDM), with relevance for integrated dentistry–endocrinology–obstetrics screening strategies.

Methods: Comparison of the risk of GDM in pregnant women with and without periodontitis, including analyses adjusted for potential confounders.

Results:A meta-analysis reported that, in studies adjusted for confounders, the odds of GDM were more than twofold higher in women with periodontitis (adjusted odds ratio [aOR] 2.08; 95% confidence interval [CI] 1.21–3.58), with evidence of heterogeneity across studies and recommendations for standardized definitions and prospective study designs. A more recent analysis reported an odds ratio of 1.83 (95% CI 1.25–2.69) for the association between periodontal disease and GDM, confirming the signal of increased risk. Consensus-type evidence indicates that non-surgical periodontal therapy during the second trimester is considered safe, although its effect on pregnancy outcomes remains variable across studies.

Conclusions: Periodontitis is associated with an increased risk of gestational diabetes mellitus in meta-analyses. Periodontal evaluation during pregnancy and early interventions may therefore be justified as part of a multidisciplinary care pathway.

OSTEOPOROSIS TREATED WITH BISPHOSPHONATES OR DENOSUMAB: MRONJ RISK AND ENDODONTIC/PERIODONTAL DECISION-MAKING TO AVOID SURGICAL INTERVENTION

M. C. Beznă[1], A. Camen[1], L. Gheorghiță[1], I. T. Dascălu[1], N. M. Bugălă[2]

[1]Faculty of Dentistry, University of Medicine and Pharmacy of Craiova, CRAIOVA, Romania; [2]University of Medicine and Pharmacy, Faculty of Medicine and Pharmacy, CRAIOVA, Romania

Introduction: Antiresorptive therapy for osteoporosis raises concerns regarding medication-related osteonecrosis of the jaw (MRONJ), a rare but clinically significant adverse event in dental practice.

Objective: To provide a pragmatic synthesis of MRONJ risk estimates and relevant recommendations guiding endodontic and periodontal treatment choices in patients with osteoporosis receiving bisphosphonates or denosumab.

Results: The American Association of Oral and Maxillofacial Surgeons (AAOMS) reports that, in patients treated for osteoporosis, the risk of MRONJ ranges from 0.02–0.05% for bisphosphonates and from 0.04–0.3% for denosumab. Following tooth extraction, estimated risks are 0–0.15% for bisphosphonates and approximately 1% for denosumab. For procedures such as endodontic or periodontal treatment, AAOMS states that the risk remains unknown due to insufficient data.

The American Association of Endodontists (AAE) notes that there are no reports directly implicating non-surgical endodontic treatment in the development of MRONJ. Accordingly, it recommends caries control, conservative periodontal and restorative treatments, and appropriate endodontic therapy to avoid extractions whenever possible. Surgical procedures, including extractions and endodontic surgery, should be avoided if feasible.

Conclusions: In patients with osteoporosis receiving antiresorptive therapy, tooth-preserving strategies—including non-surgical endodontic treatment—may reduce the need for extractions, the primary reported trigger for MRONJ. Such approaches should be implemented within a framework of coordinated dental–endocrinological care.

OBESITY AND THE ODONTO-PERIODONTAL BURDEN: QUANTITATIVE SYNTHESIS OF PERIODONTAL RISK AND RADIOLOGICAL DATA ON CARIES AND TOOTH LOSS

I. T. Dascălu[1], A. Camen[1], M. C. Beznă[1], C. Bănică[1], L. Gheorghiță[1], N. M. Bugălă[2]

[1]Faculty of Dentistry, University of Medicine and Pharmacy of Craiova, CRAIOVA, Romania; [2]University of Medicine and Pharmacy, Faculty of Medicine and Pharmacy, CRAIOVA, Romania

Introduction: Obesity is associated with low-grade chronic inflammation and has been investigated as a risk factor for periodontal disease and deterioration of oral health.

Objective: To assess the association between obesity and periodontal disease, as well as odontogenic parameters (dental caries and tooth loss) relevant to the continuity of the odonto-endo-periodontal unit.

Methods:A synthesis of an updated meta-analysis on obesity and periodontitis, complemented by a comparative radiological study across body mass index (BMI) groups.

Results: In the updated meta-analysis, obesity was associated with increased odds of periodontal disease (odds ratio [OR] 1.35; 95%

confidence interval [CI] 1.05–1.75), with heterogeneity across studies and subgroup-specific variations. In the radiological study involving 352 patients, BMI groups differed significantly with respect to dental caries, alveolar bone loss, and tooth loss, whereas the incidence of periapical lesions did not differ significantly between groups.

Conclusions: The data support obesity as a factor associated with periodontal disease and with odontogenic indicators such as caries, edentulism, and alveolar bone loss. Integrating the assessment of body weight status into dental anamnesis may aid risk stratification and facilitate bidirectional referral for metabolic management.

A TRAIN MAY HIDE ANOTHER: A CASE OF PANCOAST-TOBIAS SYNDROME ASSOCIATED WITH A BLADDER TUMOR

S. Boussaid[1], N. Mabrouk[1], S. Rahmouni[1], K. Zouaoui[1], S. Rekik[1], H. Sahli[1]

[1]Rheumatology Department, La Rabta Hospital, Beb Saadoun, Tunisia

Objective

Chronic neck pain is a common reason for consultation in rheumatology and is often attributed to chronic inflammatory rheumatic diseases. However, neoplastic processes may mimic inflammatory presentations and lead to diagnostic delay. Pancoast-Tobias syndrome is a rare entity characterized by an apical lung lesion with locoregional extension, sometimes responsible for Horner's syndrome. Its association with a synchronous tumor, particularly of the bladder, remains exceptional. This report describes a case of Pancoast-Tobias syndrome associated with synchronous urothelial carcinoma.

Material and methods

77-year-old man, chronic smoker with a history of hypertension, was admitted in January 2025 for right inflammatory cervicobrachial neuralgia evolving over six weeks. The symptoms were associated with fatigue, anorexia, weight loss, and were refractory to conventional analgesics. On clinical examination, there was cervical stiffness, right-sided ptosis, miosis and enophthalmos consistent with Horner's syndrome, as well as mild motor weakness of the right upper limb. Laboratory tests revealed an inflammatory syndrome with a C-reactive protein level of 45 mg/L, and microscopic hematuria. Standard radiography demonstrated an osteolytic lesion of the posterior arch of T1. Cervical MRI confirmed the diagnosis of Pancoast-Tobias syndrome. Thoraco-abdomino-pelvic CT scan showed a T4N1M1a stage with a right adrenal metastasis, and a focal thickening of the bladder wall consistent with synchronous urothelial carcinoma. The patient received multimodal analgesic treatment including morphine, tramadol and pregabalin, and was referred to pulmonology and urology for further work-up and multidisciplinary management.

Results

Pancoast-Tobias syndrome is a rare condition, accounting for 3 to 5% of lung tumors (1), and is most often related to non-small cell lung carcinoma. It is underdiagnosed because of its misleading presentation mimicking rheumatologic disease, with a reported mean diagnostic delay of up to 18 months (2). Horner's triad, present in only 18 to 27% of cases, represents an important warning sign (3,4). MRI is the imaging modality of choice, as it accurately delineates locoregional extension and provides better prognostic assessment (5,6). In the present case, the synchronous bladder involvement illustrates the possibility of dual primary malignancies. This situation is reported in less than 1% of bladder cancers and is probably explained by the shared carcinogenic effect of tobacco smoking, which is implicated in more than 90% of Pancoast tumors and in about 60% of bladder tumors (7,8). The advanced T4N1M1a stage conferred a poor prognosis, justifying a palliative therapeutic approach. Pain management was a major issue, as neuropathic pain is frequent in this syndrome; the pregabalin–tramadol combination has shown synergistic analgesic benefit in some studies, supporting its use in this context (9,10).

Conclusions

Pancoast-Tobias syndrome, although rare, is a severe condition that requires a high level of diagnostic vigilance in order to avoid therapeutic wandering. Its unprecedented association with a synchronous

bladder tumor underlines the importance of a comprehensive and multidisciplinary approach.

CARBOXYMETHYL-CHITOSAN FOR MODERATE-ADVANCED HIP OSTEOARTHRITIS: CASE SERIES OF 12 PATIENTS NON-RESPONDERS TO HYALURONIC ACID

N. Manocchio[1], A. Sorbino[1], M. Massafra[2], F. Giovannangeli[2], A. Paglionico[2], A. Migliore[2], C. Foti[1]

[1]Physical and Rehabilitation Medicine, Tor Vergata University, Rome, Italy, Rome, Italy; [2]Rheumatology, S. Pietro Fatebenefratelli Hospital, 00189 Rome, Italy, Rome, Italy

Objectives: Hip OA non-responsive to intra-articular hyaluronic acid (HA) and conventional treatments often necessitates surgical intervention. Carboxymethyl-chitosan (CM-C), an emerging compound with lubricating and anti-inflammatory properties, has already shown promise for refractory knee OA. This study aimed to evaluate the efficacy of a single intra-articular CM-C injection associated with 40 mg triamcinolone acetonide (TAA) in patients with hip OA non-responsive to HA.

Material and Methods: Retrospective study of 12 patients (mean age 68.0 ± 11.64 years, range 56–82) with symptomatic hip OA and radiographic Kellgren–Lawrence grade III–IV, previously unsuccessfully treated with intra-articular HA, who received a single injection of CM-C (60 mg/3 mL) associated with 40 mg TAA from November 2022 to March 2025. Pain and functional outcomes were assessed using the Visual Analogue Scale (VAS) and Oxford Hip Score (OHS) at baseline (T0), one month (T1), three months (T2), and six months (T3) post-injection. Changes over time are described in terms of percentage improvement from baseline.
Results: A single CM-C injection produced heterogeneous clinical responses in this cohort. In 2 out of 12 patients no relevant improvement in pain or hip function was observed. In 4 out of 12 patients, pain and function improved by approximately 40% at T1 from baseline, but this benefit was limited to T2. In the remaining 6 out of 12 patients, pain and functional scores improved by around 60% at T1 compared with baseline, with a perceived benefit persisting at T3. No serious adverse events were reported; mild transient arthralgia was observed in 3 patients.
Conclusions: A single CM-C injection showed early and sustained pain relief and functional improvement in moderate-advanced hip OA for non-responders to HA. Although the small sample size, these preliminary findings suggest CM-C may represent an additional conservative therapeutic option to improve quality of life before recommending surgery. Larger prospective randomized controlled trials are warranted to confirm these results and to better identify patients who are most likely to benefit from this approach.

P1259

RETROSPECTIVE ANALYSIS OF THE RESULTS OF PERCUTANEOUS VERTEBROPLASTY OF COMPRESSION FRACTURES OF BODIES ON THE BACKGROUND OF OSTEOPOROSIS

A. Popov[1], N. Moloduk[1]

[1]Sytenko Institute of Spine and Joint Pathology National Academy of Medical Sciences of Ukraine, Kharkiv, Ukraine

Objective. Analyzing the condition of spines of the patients suffering from compression fractures of vertebral bodies on the background of osteoporosis after the performed Percutaneous vertebroplasty (PVP).
Material and Methods. 553 patients who underwent hospital treatment at the spine pathology clinic of the Sytenko Institute of Spine and Joint Pathology (2005–2022) and underwent PVP were examined. The patients were divided into three groups depending on the number of damaged vertebrae. The 1st group included the patients with compression fractures of one vertebra (185 — 33.4 %); the 2nd group included the patients having 2 or 3 deformed vertebrae (216 — 39 %); and the 3rd group included the patients with 4–5 damaged vertebrae (152 — 27.4 %). Stages of compression of vertebral bodies during the X-ray morphometry was as follows before the surgery: I — 349 (24 %) vertebrae; II — 494 (34 %); III — 552 (38 %); and IV — 58 (4 %)
Results. We achieved the reduction of the level of compression of vertebral bodies as a result of PVP in 20 % of cases (patients who noticed the manifestation of the pain syndrome within 2 weeks mostly suffered from these deformations). Additionally, we achieved a reduction in pain syndrome in 90% of patients in the first group, 74% in the second group, and 48% in the third group. The analysis of PVP of 553 patients with composite material and bone cement in the near and far future provide us an opportunity to state that this surgical treatment is an efficient and safe treatment method (despite the materials used). 40 (24 %) patients out of 165 patients of the group I, 52 (33 %) patients out of 157 patients

of the group II and 54 (44 %) patients our of 133 patients of the group III were diagnosed with repeated compression fractures.
Conclusions. Summarizing all the above, we should note that the more compression fractures the patient has, the higher the risk of further augmentation of other deformations of vertebral bodies is.
Conflict of interest. The authors declare that there is no con-flict of interest.

P1260

TOPOGRAPHIC PREDICTION OF REPEATED OSTEOPOROTIC FRACTURES OF THE THORACIC AND LUMBAR VERTEBRAE

A. Popov[1], V. Kutsenko[1], N. Moloduk[1]

[1]Sytenko Institute of Spine and Joint Pathology National Academy of Medical Sciences of Ukraine, Kharkiv, Ukraine

Objective. To analyze the topographic patterns of occurrence of postoperative recurrent vertebral compression fractures (RVCF) depending on the location of the primary fracture after percutaneus vertebroplasty (PVP).
Materials and Methods. 520 case histories of patients with osteoporotic fractures of the thoracic and lumbar spine of various locations were analyzed. The total number of treated vertebral bodies was 1,458 (thoracic 596 — 40.88 %, lumbar 862 — 59.12 %). Most often, compression fractures of the spine occurred in the thoracolumbar junction (784 — 53.77 %). RVCF was diagnosed in 64 (12.31 %) people (95 % CI: 9.94–14.68 %) during follow-up examinations, after 1, 3, 6 or 12 months. since the operation. The study was carried out by 3 methods of forecasting: assessment of conditional probabilities, study of the significance of a primary fracture as a predictor of repeated fracture in a specific vertebra, analysis of associative rules and relationships
Results. According to the 1st method, all conditional probabilities do not exceed 0.4 and the highest of them are the probabilities LI and LIV RVCF (0.39) with a primary ThVI fracture, and the probability of ThVIII RVCF (0.38) with a ThV primary fracture. Method II found only two regularities that allow an interpretation that corresponds to the purpose of our research. The third method revealed the associative rules and connections of the primary fracture of ThV with RVCF LI, ThXII; according to ThVI with RVCF LI, LII; in the case of ThVIII with RVCF LI, ThXII; ThX fracture with ThX, ThXI, ThXII, LII RVCF; under ThXI conditions with ThV, ThVII, ThVIII, ThIX, ThX, ThXII RVCF; for ThX with RVCF ThIX, ThXI, ThXII, LII; ThX fracture with ThX, ThXI, ThXII, LII RVCF.
Conclusions.The prediction of recurrent osteoporotic fractures remains one of the most relevant challenges in modern vertebrology. The conducted study identified the most distinct patterns characteristic of the general patient sample: with a primary fracture at ThXI, a new deformation of ThVIII may occur; with ThVII injury, new fractures of ThIX, ThXII, and LI are possible; with ThXII — damage to ThXI; and with a primary fracture of LI — new deformations of ThXII, LIV, and LV.
We believe that in the future, larger-scale studies involving a greater number of patients and extended follow-up periods will be conducted, which will allow the identification of new and more detailed regularities in the development of recurrent vertebral compression fractures. Such research will provide a foundation for the further advancement of preventive and predictive medicine in vertebrology, aimed at individualized risk forecasting, early intervention, and reduction of complication rates in patients with osteoporosis.
Conflict of interest. The authors declare that there is no con-flict of interest.

P1261

RECURRENT VERTEBRAL COMPRESSION FRACTURES AFTER PERCUTANEOUS VERTEBROPLASTY IN OSTEOPOROTIC PATIENTS: RISK FACTORS AND CLINICAL OUTCOMES — A SYSTEMATIC REVIEW AND META-ANALYSIS

N. Moloduk[1], A. Popov[1], M. Nessonova[1], V. Kutsenko[1]

[1]Sytenko Institute of Spine and Joint Pathology National Academy of Medical Sciences of Ukraine, Kharkiv, Ukraine

Objective. To synthesize clinical data and quantitatively assess the impact of demographic, morphometric, and technical factors on recurrent vertebral compression fractures (RVCF) incidence post percutaneus vertebroplasty.
Methods. A search was conducted in PubMed, Scopus, Medline, and Google Scholar (2010–2024) using MeSH terms: «vertebroplasty», «compression fractures», «osteoporosis», «risk factors», «recurrence». Twenty cohort studies (7,923 patients) were included. Continuous variables were pooled using the Sidik–Jonkman random-effects model (Cohen's d), and categorical variables using the Paule–Mandel model (odds ratio, OR). Heterogeneity was assessed with I^2 and prediction intervals; sensitivity analyses were performed. Evidence certainty was evaluated using GRADE.
Results. Significant risk factors for rVCFs included absence of anti-osteoporotic therapy (AOT) (OR = 1.97, I^2 = 40 %), cement leakage (OR = 1.92, I^2 = 68 %), and low bone mineral density (BMD) (d = −0.55, I^2 = 72 %), with moderate GRADE certainty. Female sex (OR = 1.30, I^2 = 39 %) and older age (d = 0.24, I^2 = 62 %) showed weaker associations with low certainty. Cement volume, body mass index, kyphotic angle, its correction, vertebral height restoration, and thoracolumbar junction involvement were not associated with rVCFs.
Conclusions. The most significant RVCF risk factors are absence of AOT, cement leakage, and low BMD, nearly doubling the risk. Female sex increases risk by approximately one-third, and older age has a minor effect. These findings highlight the importance of AOT and technical precision in PVP to prevent rVCFs.
Conflict of interest. The authors declare that there is no con-flict of interest.

P1262

BIOCHEMICAL CHANGES IN BLOOD AND URINE IN OSTEOPOROTIC PATIENTS WITH RECURRENT VERTEBRAL COMPRESSION FRACTURES

A. Popov[1], I. Korzh[1], D. Morozenko[1], N. Moloduk[1]

[1]Sytenko Institute of Spine and Joint Pathology National Academy of Medical Sciences of Ukraine, Kharkiv, Ukraine

Objective
To determine the biochemical parameters of blood and urine in patients with new vertebral compression fractures in adjacent and distant spinal segments.
Materials and Methods
The study was conducted at the State Institution "Sytenko Institute of Spine and Joint Pathology of the National Academy of Medical Sciences of Ukraine" during 2023–2025. The diagnosis of osteoporosis was confirmed by densitometry. The age of patients in Group I ranged from 55 to 72 years, in Group II from 55 to 73 years, and in Group III from 56 to 72 years. The T-score values for the groups were as follows: Group I — −0.8 ± 0.2; Group II — −2.63 ± 0.3; Group III — −2.8 ± 0.26. Statistical analysis of the data was performed using Microsoft Excel XP and StatSoft Statistica 6.0 software packages.
Results
In patients of Group II, who, compared with Group I, had concomitant osteoporosis, new vertebral compression fractures developed after spinal surgery on the background of osteoporosis. These changes were reflected in biochemical markers of bone and cartilage metabolism. Specifically, there was an increase in the blood levels of glycoproteins (markers of systemic inflammation) and chondroitin sulfates (indicators of bone and cartilage tissue destruction); an increase in the activity of alkaline phosphatase (due to its bone isoenzyme) and acid phosphatase (markers of bone metabolism); an elevation in ionized calcium levels (a marker of mineral matrix degradation); and increased urinary excretion of hydroxyproline (a marker of collagen catabolism) and uronic acids (metabolites of proteoglycans in bone and cartilage tissues).
Conclusions
The conducted laboratory studies indicate the potential use of a complex of biochemical markers for assessing the risks of progressive bone and cartilage tissue destruction after fractures in osteoporotic patients. Such markers may serve as valuable predictors for identifying patients at increased risk of recurrent vertebral fractures and the possible need for repeated surgical interventions.
Conflict of interest. The authors declare that there is no con-flict of interest.

P1263

PREDICTIVE MODEL FOR NEW VERTEBRAL COMPRESSION FRACTURES AFTER PERCUTANEOUS VERTEBROPLASTY USING RADIOGRAPHIC MORPHOMETRY

A. Popov[1], V. Kutsenko[1], R. Zlatnik[1], N. Moloduk[1]

[1]Sytenko Institute of Spine and Joint Pathology National Academy of Medical Sciences of Ukraine, Kharkiv, Ukraine

Objective: To identify prognostic radiographic morphometric parameters of vertebrae following percutaneous vertebroplasty (PVP) that may be associated with the risk of developing new vertebral compression fractures (NVCF) after the PVP, and to develop a mathematical model for predicting such fractures.
Material and Methods: A retrospective cohort study (2023–2025) was conducted at the Institute of Spine and Joint Pathology, Ukraine, involving 26 patients (24 females, 2 males; mean age 69.04 ± 2.04 years) with osteoporotic vertebral compression fractures treated with PVP. Morphometric parameters of 99 vertebrae were assessed on digital radiographs (frontal/sagittal, RadiAnt DICOM Viewer, precision 0.1 mm/0.1°): anterior (Ha), middle (Hm), posterior (Hp) heights, relative compression (%), wedge index, local kyphotic angle, thoracic kyphosis, lumbar lordosis, and scoliosis (Cobb's angles). Statistical analysis (Statistica 13, easyROC) included Shapiro–Wilk's normality test, Mann–Whitney's test for comparisons, multivariate discriminant analysis (backward stepwise), and ROC analysis.
Results: NVCF occurred in 46.2% of cases (45 fractures in 12 patients). Significant differences between NVCF and non-NVCF groups were observed for Ha compression (20.69 ± 1.16 mm vs. 23.89 ± 0.78 mm, p=0.0338), Hm (17.84 ± 1 mm vs. 21.31 ± 0.61 mm, p=0.0021), Hp (26.97 ± 0.81 mm vs. 29.61 ± 0.51 mm, p=0.0073), lumbar lordosis (44.4 ± 1.52° vs. 38.28 ± 1.46°, p=0.01), and scoliosis (7.53 ± 0.56° vs. 5.90 ± 0.48°, p=0.022). The linear discriminant functions model, based on Hm (canonical correlation = −0.863) and relative Ha compression (canonical correlation = 0.139), achieved Wilks' Λ = 0.8 (χ^2 = 15.77, p=0.000376), classification accuracy of 76.25% (sensitivity 76.9%, specificity 75.9%), and AUC = 0.754 ± 0.058. Adjusted function: D = −2.197 * Hm + 0.095 * Ha(%) − 17.133; D > −1.955 indicates NVCF risk. Other parameters were excluded due to low discriminatory power or collinearity.
Conclusion: This two-parameter model, using Hm and relative Ha compression, offers moderate predictive accuracy for NVCF post-PVP. Its simplicity suits resource-limited Ukrainian clinics. External validation and inclusion of confounders (e.g., BMD, therapy) are required for broader adoption.

Conflict of interest. The authors declare that there is no con-flict of interest.

P1264

AGE-RELATED FEATURES OF GROWTH AND SHAPING OF THE MANDIBLE IN WHITE RATS UNDER CONDITIONS OF CHRONIC RENAL FAILURE

A. Kiselev[1], N. Mosyagina[2], V. Luzin[2], A. Razaryonova[2], D. Shcherbakov[2]

[1]FSBEI HI ST. LUKA LSMU of MOH of Russia, Department of hospital surgery- urology- and oncology, Lugansk, Russia; [2]FSBEI HI ST. LUKA LSMU of MOH of Russia; Human anatomy department, Lugansk, Russia

Objective of the study was to establish age-related features of growth and shaping of the mandible in white rats under conditions of chronic renal failure.
Material and methods. The experiment included 144 white male rats. CRF was modeled using subtotal nephrectomy. The mandibles were isolated and their osteometry was performed.
Results. Under conditions of CRF in infantile rats, the height of the mandibular ramus from day 15 to day 90 of the experiment lagged behind the values of the Int group by 5.80%, 8.65% and 7.86%, and the maximum length of the mandible by days 30 and 90 – by 6.59% and 4.45%. The height of the alveolar process from day 15 to day 90 was less than the values of the Int group by 5.38%, 7.67% and 8.86%. In sexually mature animals, the height of the mandibular ramus by 30 and 90 days after the operation lagged behind the values of the Int group by 6.44% and 6.34%, and the maximum length of the mandible - by 5.33% and 6.70%. The height of the alveolar process by 30 and 90 days was less than the values of the Int group - by 7.85% and 6.03%. In old rats with CRF, the height of the mandibular ramus by 90 days after the operation lagged behind the values of the Int group by 3.19%. The height of the alveolar process of the mandible with CRF from the 15th to the 90th day was less than the values of the Int group by 6.37%, 8.01% and 8.12%.
Conclusion. CRF is accompanied by inhibition of growth processes in the mandible. These changes are observed earlier in senile rats on the 7th day after surgery, and later in sexually mature rats on the 30th day.

P1265

MANGANESE DISTRIBUTION TO THE UNDAMAGED BONES AFTER IMPLANTATION OF MANGANESE-ENHANCED HYDROXYAPATITE IMPLANTS INTO THE DEFECTS OF THE TIBIAE

D. Astrakhantsev[1], N. Mosyagina[1]

[1]FSBEI HI ST. LUKA LSMU of MOH of Russia; Human anatomy department, Lugansk, Russia

Objective of the study is to test manganese distribution in the undamaged skeletal bones after implantation of manganese-enhanced hydroxyapatite implants into the tibia.
Material and methods. In the study we used grounded bone ash taken from the mandibular rami of the rats with the defects in the tibiae filled with manganese-enhanced hydroxyapatite material. Manganese shares in the implants were 0.1%, 0.25%, and 0.5%. Intact animals, animals with empty defects, and animals with pure HA implants were added for comparison purposes. Observation terms were 7, 15, 30, 60, 90, and 180 days. Manganese levels in ash were detected by atomic emission spectroscopy. The data were analyzed by ANOVA methods.
Results. In animals with 0.1% share of manganese in the implants as compared to the animals with pure HA implants, manganese levels significantly increased by the 15th and the 30th days of the experiment – by 11.36% and 8.35% respectively. With manganese share in the implants increase to 0.25%, manganese levels growth was observed in the period from the 7th to the 90th day – by 4.63%, 9.55%, 9.37%, 6.35%, and 4.04% respectively. After implantation of 0.5% manganese implants, manganese levels began increasing from the 15th day of the experiment and lasted up to the 180th day. Manganese levels in this group increased by 11.36%, 11.61%, 7.50%, 5.32%, and 5.74% respectively.
Conclusion. During resorption of manganese containing bone implants manganese is likely to spread to undamaged bones and thus improve bone structure restoration after systemic bone loss that follows fracture or bone tissue removal. Its effects depend on manganese concentration in the implants. 0.25% share of manganese is optimal for concentration maintenance.

P1266

MAGNESIUM CONTENT OF BONE REGENERATE MINERAL IN DIABETIC RATS WITH INTACT BONES AND AFTER SECONDARY FRACTURE OF THE TIBIA

D. Astrakhantsev[1], N. Mosyagina[1], N. Gal'Cenko[2]

[1]FSBEI HI ST. LUKA LSMU of MOH of Russia; Human anatomy department, Lugansk, Russia; [2]Lugansk city polyclinic № 11, LPR, Lugansk, Russia

Objective of the study is to test magnesium levels in rats with type 2 diabetes (T2D) with intact bones and after modeling of secondary fracture in the tibia after healing of fracture the femur.
Material and methods. Bone samples were collected from 72 female rats. Group 1 (n=24) comprised intact animals, group 2 (n=24) comprised rats with T2D modeled by means of 60-day high-fat and saccharose diet, and group 3 (n=24) comprised animals with secondary fracture modeled as consecutive openings in the femur and the tibia separated by 60-day period assigned for femur healing. Observation terms were 7, 15, 30, and 60 days after tibia surgery. Ashed and grounded specimens collected from callus area were used for measuring of magnesium level in bone mineral. In animals without fractures, bone specimens were collected from the area corresponding to fracture area in operated animals.
Results. Diabetic animals without fractures as compared to the intact ones exhibited magnesium level increase in the period from the 15th to the 60th day of the experiment – by 6.54%, 6.53%, and 7.03% respectively. In diabetic animals with secondary fracture of the tibia also in comparison with the intact animals, magnesium level increase was more pronounced. In the period from the 7th to the 30th day magnesium level increased by 8.61%, 12.01%, and 12.44%.
Conclusion. It is known that in T2D serum magnesium levels decrease. In our study magnesium release from the bone mineral in diabetic animals suggest that low serum magnesium does not significantly affect magnesium stored in apatite crystals. Such a release is possibly caused by impaired apatite crystal formation in diabetes accompanied by increased bone resorption. As far as in fracture bone resorption becomes more intense, combined action of diabetes and fracture may affect bone formation by derangement of magnesium content in bone mineral.

P1267

ASSOCIATION BETWEEN DIABETES AND BONE MINERAL DENSITY IN PATIENTS WITH HIP FRACTURES

N. Nagatani[1], K. Yamazaki[2]

[1]Department of Pharmacy, Iwata City Hospital, Iwata City, Japan; [2]Department of Orthopedic Surgery, Iwata City Hospital, Iwata City, Japan

Objective:Although diabetes mellitus increases fracture risk, bone mineral density (BMD) in patients with diabetes has been reported to be preserved or even increased, and the relationship between the two remains unclear.
Methods:We conducted an observational study of patients admitted with hip fractures between November 2024 and October 2025. Diabetes was defined as the use of antidiabetic medications or an HbA1c level ≥6.5%. Patients were classified into diabetes and non-diabetes groups. Lumbar spine and femoral neck BMD were measured by dual-energy X-ray absorptiometry. Multivariable linear regression analyses were performed adjusting for age, sex, body mass index (BMI), steroid use, use of osteoporosis medications, use of anticonvulsants, and estimated glomerular filtration rate (eGFR). Additional analyses were conducted among patients with diabetes to evaluate the association between HbA1c and BMD.
Result:The study included 75 patients with diabetes (mean age 86 years) and 171 patients without diabetes (mean age 85 years); 63 women in the diabetes group and 131 women in the non-diabetes group. Lumbar spine BMD was higher in patients with diabetes than in those without diabetes (0.82 ± 0.069 vs. 0.74 ± 0.20 g/cm²), while femoral neck BMD was 0.46 ± 0.038 and 0.43 ± 0.066 g/cm², respectively. Multivariable analysis showed that diabetes was significantly associated with higher lumbar spine BMD (β = 0.058, p = 0.013), but not with femoral neck BMD (β = 0.017, p = 0.19). Among patients with diabetes, HbA1c was not associated with lumbar spine BMD (β = −0.01, p = 0.64), whereas higher HbA1c was significantly associated with lower femoral neck BMD (β = −0.03, p = 0.048).
Conclusions:In patients with hip fractures, diabetes was associated with higher lumbar spine BMD but not with femoral neck BMD. In contrast, in analyses restricted to patients with diabetes, HbA1c showed a negative association with femoral neck BMD, suggesting that the effects of diabetes and glycemic control on bone mineral density may differ by skeletal site.

P1268

BONE TISSUE STATUS IN ADOLESCENTS DEPENDING ON GROWTH INTENSITY AND BSML POLYMORPHISM OF THE VDR GENE

T. Frolova[1], N. Osman[1], N. Stenkova[1], I. Siniaieva[1], O. Ashcheulov[1]

[1]Kharkiv National Medical University, Kharkiv, Ukraine

Objective: To determine the characteristics of the bone tissue condition of adolescents based on the study of densitometry indicators, BSML polymorphism of the VDR gene, and growth intensity.
Materials and methods: 292 children aged 10-17 years were examined. They were divided into two groups depending on gender: 159 boys and 133 girls. Criteria of inclusion: absence of chronic somatic and endocrine pathology, genetic diseases. Adolescent presented to University Pediatric Clinic for general clinical examination, ultrasound densitometry (QUS) (Sonost-2000, Korea) and dual-energy X-ray absorptiometry (DXA) (HOLOGIC QDR W Explorer, USA) were performed according to indications, molecular diagnostics - BSML polymorphism of the VDR gene. The criterion for reducing bone mineral density according to the recommendations of The International Society For Clinical Dencitometry, 2019, was considered to be BMD Z-score ≤ -2.
Results: Low bone mineral density was diagnosed in 66 boys (41.5%) and 52 girls (39.1%) according to the results of QUS and confirmed by DXA. The average Z-score in boys was -2.28±0.302, in girls – -2.41±0.291. In children with a growth spurt, a decrease in BMD was diagnosed in 50.3% of boys and 60.2% of girls, which is significantly higher than the average indicators for the groups. Pathological mutations (heterozygous and homozygous) of the BSML polymorphism of the VDR gene were detected in 47.2% of boys and 57.1% of girls. In children with a growth spurt, pathological mutations (heterozygous and homozygous) of the BSML polymorphism of the VDR gene were found in 47.8% of boys and 58.3% of girls, which does not significantly differ from the general group of children.
Conclusion: Decreased of bone mineral density was shown in 41.5% of the examined boys and 39.1% of the girls, while in girls in the group with a growth spurt, low bone mineral density was detected more often (60.2%) than in boys (50.3%). Also, pathological mutations of the BSML polymorphism of the VDR gene dominate in the examined children, which lead to a violation of mineral metabolism and requires preventive measures to maintain the health of the bone tissue. But at the same time, during the period of intensive growth, pathological mutations of the BSML polymorphism of the VDR gene did not affect the level of bone mineralization and the percentage of children with low BMD did not become significantly higher, which affects other mechanisms of the formation of a transient decrease in BMD during the growth spurt.

SECONDARY HYPERPARATHYROIDISM AND BONE HEALTH *BMD AND TBS)): BUSHEHR ELDERLY HEALTH PROGRAM

N. Panahi[1], F. Sehatpour[2], Y. Waladi[1], K. Khalagi[3], N. Noushin[2], I. Nabipour[4]

[1]Metabolic Disorders Research Center, Endocrinology and Metabolism Molecular-Cellular Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran, Tehran, Iran; [2]Osteoporosis Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran, Tehran, Iran; [3]Obesity and Eating Habits Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran, Tehran, Iran; [4]The Persian Gulf Marine Biotechnology Research Center, The Persian Gulf Biomedical Sciences Research Institute, Bushehr University of Medical Sciences, Bushehr, Iran, Bushehr, Iran

Objective: Although the adverse skeletal effects of prolonged, untreated primary hyperparathyroidism (PHPT) are well established, data on the impact of secondary hyperparathyroidism (SHPT) on skeletal health in the general population remain limited. This study investigated the

associations between SHPT and bone mineral density (BMD) as well as trabecular bone score (TBS) in adults aged ≥50 years from a population-based cohort in southern Iran.
Methods: This cross-sectional population-based study used data from the second recruitment phase of the Bushehr Elderly Health Program (BEHP). Participants with low parathyroid hormone (PTH) levels or elevated PTH accompanied by hypercalcemia were excluded. The final analysis included 1,774 individuals, comprising 425 (24%) with SHPT and 1,349 with normal PTH levels. Associations between SHPT and BMD or TBS were assessed using univariable and multivariable linear and logistic regression models, adjusting for relevant confounders.
Results: SHPT was independently associated with lower BMD at predominantly cortical skeletal sites, including the femoral neck (FN; adjusted β = −0.021, 95% CI: −0.034 to −0.009, p = 0.001) and total hip (TH; adjusted β = −0.020, 95% CI: −0.033 to −0.006, p = 0.003). No significant association was observed between SHPT and lumbar spine (LS) BMD. While SHPT was significantly associated with lower TBS in crude analyses (β = −0.023, 95% CI: −0.035 to −0.011, p < 0.001), this relationship attenuated to borderline significance after multivariable adjustment (β = −0.009, 95% CI: −0.020 to 0.001, p = 0.08).
Conclusion: In this population-based cohort, SHPT was associated with reduced BMD at cortical bone sites (FN and TH), whereas LS BMD appeared relatively preserved. However, the observed decline in TBS suggests potential impairment of trabecular bone microarchitecture. Reliance on BMD alone may therefore underestimate skeletal fragility in individuals with SHPT. Integrating TBS with BMD may provide a more comprehensive evaluation of bone health and fracture risk. Early detection and management of SHPT may play an important role in preserving skeletal integrity.

P1271
HYPERURICEMIA IN KNEE OSTEOARTHRITIS

N. Savushkina[1], E. Taskina[1], E. Strebkova[1], N. Kashevarova[1], A. Khalmetova[1], D. Kudinskii[1], K. Mikhailov[1], L. Alekseeva[1], A. Lila[1]

[1]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia

Purpose: to study the relationship between hyperuricemia (HU) and clinical and laboratory parameters in patients with osteoarthritis (OA) of the knee joint (KJ).

Methods. The study included 255 patients aged 40–75 years with a reliable diagnosis of knee OA, stages I–III according to Kellgren-Lawrence, who signed informed consent. The mean age was 53.0±10.5 years, body mass index (BMI) was 28.8±6.7 kg/m2, and the median disease duration was 2 [0.8; 7] years. An individual card was completed for each patient. All patients underwent standard radiography and laboratory examination.

Results: GU was detected in 16.9% of cases. Patients were divided into two groups based on the presence of GU. However, the group of patients with HU had a higher BMI and waist circumference (WC). In this regard, an adjustment for BMI and WC was made, after which the difference in the group of patients with HU, higher medians of the following parameters were still recorded: triglycerides (TG), creatinine, ALP, 25-OH vitamin D, and lower HDL (Table 1).

Table 1 – Comparative clinical, instrumental, and laboratory characteristics of patients with OA with and without HU

Indicator	Patients with OA and HU (n=42)	Patients with OA without HU (n=109)	p
TG, mmol/L, Me	1.59 [1,26; 2,23]	1.14 [0.86; 1.71]	**0.001**
HDL, mmol/L, Me	1.3 [1.17; 1.62]	1.63 [1.29; 1.89]	**0.003**
Creatinine, μmol/l, Me	71.6 [64,4; 82]	65 [56; 71.1]	**<0.0001**
ALP, ед/л, Me	84.2 [73.8; 94.2]	75 [63.4; 89.4]	**0.02**
25-OH vitamin D, ng/ml, Me	22 [16.8; 28.3]	28.1 [22.1; 35.4]	**0.05**
CRP, mg/l, Me	3.1 [1.6; 5.4]	2 [0.9; 4]	**0.001**

Subsequently, during a simple regression analysis, the relationships between HU and TG (β = 0.13, p = 0.0003), HDL (β = -0.11, p < 0.0001), ALP (β = 0.16, p < 0.0001), and creatinine (β = 0.12, p < 0.0001) were confirmed; at the same time, no relationship was observed between HU and CRP (p > 0.05).

Conclusions. This study provides new insights into the relationship between HU and knee OA, demonstrating that the negative impact of the former is mediated by the patient's metabolic status, thereby integrating HU into the context of metabolic syndrome.

P1272
HYPERURICEMIA AND MRI-DETECTED STRUCTURAL CHANGES IN KNEE OSTEOARTHRITIS

A. Lila[1], N. Savushkina[1], E. Taskina[1], E. Strebkova[1], N. Kashevarova[1], A. Khalmetova[1], D. Kudinskii[1], K. Mikhailov[1], L. Alekseeva[1]

[1]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia

Purpose: To investigate the associations between hyperuricemia (HU) and structural changes in MRI in patients with knee osteoarthritis (OA).

Methods. The study included 255 patients aged 40–75 years with a confirmed diagnosis of knee OA (ACR) stage I–III according to Kellgren-Lawrence radiographic classification and who signed informed consent. The mean age was 53.0±10.5 years, body mass index (BMI) – 28.8±6.7 kg/m2, median disease duration – 2 [0.8; 7] years. All patients underwent standard radiography, ultrasound of the knee joints, and MRI of the target joint.

Results: HU was detected in 43 patients (16.9%). Depending on the presence of HU, patients were divided into two groups. The group of patients with HU was characterized by more pronounced changes in instrumental examination: an advanced radiographic stage was detected more often (III - 13.95 versus 7.08, II - 53.49 versus 38.68, I - 32.56 versus 54.25%, p < 0.05), thicker synovial membrane dimensions according to ultrasound (3.0 [2.5; 3.3] versus 2.7 [2.0; 3.1] mm, p = 0.008). According to MRI of the knee (WORMS system), patients with HU were significantly more likely to have osteitis in the medial condyle and central tibia (TC), osteophytes in the femur (FC) and TC, and collateral ligament damage

(Table 1). However, the group of patients with HU had a higher BMI and WC. Therefore, after adjustment for BMI and WC, the differences in radiographic stage, ultrasound, and MRI parameters were eliminated (p>0.05).

Table 1. Comparative characteristics of MRI data of knee joints in patients with OA depending on the presence/ absence of HU

Indicator	Patients with OA and HU (n=43)	Patients with OA without HU (n=212)	p
Osteitis in the medial condyle TC, %	31.3	10.6	**0.031**
Osteitis in the central sections TC, %	31.25	7.5	**0.004**
Osteophytes in the medial condyle FC, %	56.25	30.1	**0.009**
Osteophytes in the lateral condyle FC, %	56.25	27.5	**0.011**
Osteophytes in the medial condyle TC, %	56.25	33	**0.01**
Osteophytes in the lateral condyle TC, %	56.25	31	**0.007**
Medial collateral ligament injury, %	25	7	**0.033**
Lateral collateral ligament injury, %	18.57	5	**0.03**

Conclusions. The identified relationship between HU and the severity of structural changes in joints in OA is not independent and is due to the influence of concomitant abdominal obesity and excess body weight.

P1273

ASSOCIATION OF MR T2 RELAXATION TIMES IN DIFFERENT CARTILAGE LAYERS WITH CLINICAL, LABORATORY, AND IMAGING PARAMETERS IN KNEE OSTEOARTHRITIS

N. Savushkina[1], E. Taskina[1], E. Strebkova[1], N. Kashevarova[1], A. Khalmetova[1], D. Kudinskii[1], L. Alekseeva[1], A. Lila[1]

[1]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia

Purpose: to study the relationship between MR T2 cartilage relaxation time and clinical, laboratory and instrumental parameters in patients with osteoarthritis (OA) of the knee joint (KJ).

Methods. A prospective study included 96 patients aged 40–75 years with a confirmed diagnosis of knee OA, stages I–III according to Kellgren-Lawrence, who signed informed consent. The average age was 52.7±10.5 years, body mass index (BMI) was 29.0±6.5 kg/m². Each patient underwent MRI of the target knee with determination of T2 cartilage relaxation time (T2) in the total, deep, and superficial layers.

Results: The T2 value in the total cartilage layer was 36.05 [34.2; 39.45] ms, in the deep layer – 35.4 [33.35; 38.45] ms, in the superficial layer – 39.3 [35.6; 43.6] ms. Spearman's rank correlation analysis revealed statistically significant positive relationships ($p < 0.05$) between T2 in various cartilage layers and body weight, BMI, synovitis (clinical), radiographic stage, synovial thickness by ultrasound, and the level of C-terminal telopeptide of type I collagen (CTX-I) (Table 1).

Table 1 – Correlation coefficients between T2 and various clinical, instrumental, and laboratory parameters

Indicator	r	p
Total cartilage layer		
Radiographic stage	0.42	<0.0001
Body weight, kg	0.33	0.007
BMI, kg/m2	0.24	0.049
Synovial thickness on ultrasound, mm	0.29	0.045
CTX-I, ng/ml	0.45	0.047
Deep cartilage layer		
Radiographic stage	0.28	0.022
Body weight, kg	0.26	0.039
Superficial cartilage layer		
Radiographic stage	0.44	<0.0001
Body weight, kg	0.31	0.013
Synovitis (clinically)	0.25	0.047
CTX-I, ng/ml	0.48	0.033

Conclusions. The established positive correlations between T2 in different layers of cartilage and anthropometric (body weight, BMI), clinical (synovitis), instrumental (radiographic stage, synovial thickness according to ultrasound) parameters and the bone resorption marker CTX-I confirm the relationship between the structural degradation of the cartilage matrix with metabolic factors, inflammatory activity and the intensity of bone resorption.

P1274

COMPARATIVE ASSESSMENT OF THE EFFICACY AND SAFETY OF TOPICAL TENOXICAM AND DICLOFENAC THERAPY IN PATIENTS WITH KNEE OSTEOARTHRITIS

N. Kashevarova[1], E. Taskina[1], E. Strebkova[1], E. Sharapova[1], N. Savushkina[1], T. Korotkova[1], L. Alekseeva[1], A. Lila[1]

[1]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia

OBJECTIVE: To evaluate the efficacy and safety of tenoxicam 1% gel compared with diclofenac 1% gel in patients with knee osteoarthritis (OA) in a prospective randomized comparative study.
MATERIALS AND METHODS: The study included 60 patients (91.7% women) with knee OA, Kellgren–Lawrence grade II–III. Mean age was 62.5±8.0 years, mean body mass index (BMI) 24.9±4.7 kg/m², and disease duration 5.7 (3–15) years. Patients were randomly assigned to two groups: Group 1 received tenoxicam 1% gel (5 cm twice daily for 14 days), and Group 2 received diclofenac 1% gel using the same regimen.
Pain intensity (VAS), WOMAC index, quality of life (EQ-5D), and time to onset of effect were assessed. Three visits were performed: baseline (V1), day 7 (V2), and day 14 (V3).
RESULTS: At baseline, groups were comparable in age (63.2±7.6 vs 61.8±8.5 years), BMI (24.8±4.1 vs 25.0±5.2 kg/m²), OA duration (8.5 [3;17] vs 6.5 [3;10] years), and pain VAS (60.1±11.7 vs 57.3±11.4 mm; p>0.05).
After 7 days, both treatments significantly reduced pain (Figure 1). In Group 1, pain decreased by 23.2% at V2 (to 45.7±14.7 mm; p<0.0001) and by 32.5% at V3 (to 40.2±15.8 mm; p<0.0001). In Group 2, pain reduction was 19.2% at V2 (46.3±17.0 mm; p=0.0008) and 28.0% at V3 (41.1±17.1 mm; p<0.0001). Similar trends were observed for WOMAC total score and subscales (pain, stiffness, physical function).
EQ-5D significantly improved in Group 1 (V1: 0.52 [0.52;0.59], mean 0.47; V2: 0.52 [0.52;0.59], mean 0.55; p=0.04; V3: 0.59 [0.52;0.69], mean 0.59; p=0.01 vs baseline), while no significant changes were observed in Group 2. No serious adverse events were reported.

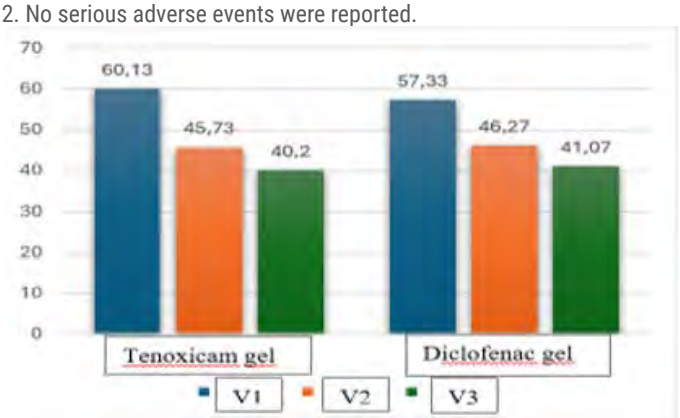

Figure 1. Changes in knee pain intensity (VAS) during walking during topical therapy.

CONCLUSIONS:The study demonstrated high clinical efficacy and a favorable safety profile of topical tenoxicam and diclofenac in patients with knee OA.

P1275

KEY FACTORS OF KNEE OSTEOARTHRITIS PROGRESSION: INSTRUMENTAL CHARACTERISTICS (RESULTS OF A LONG-TERM PROSPECTIVE STUDY)

N. Kashevarova[1], E. Taskina[1], E. Strebkova[1], N. Savushkina[1], N. Demin[1], L. Alekseeva[1]

[1]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia

OBJECTIVE: To identify risk factors for radiographic progression of knee osteoarthritis (KOA) based on instrumental imaging findings.
MATERIALS AND METHODS: The study included 110 women with KOA, Kellgren–Lawrence grade I–III, who provided informed consent. Mean age was 59.1±9.0 years, body mass index 31.5±5.9 kg/m², and disease duration 8 [3;20] years. Individual case records included anthropometric data, medical history, clinical examination, standard radiography, ultrasound (US), magnetic resonance imaging (MRI) of the knee joints, and densitometry of subchondral regions of the femur and tibia.
RESULTS: After 5 years of follow-up, radiographic progression (increase in Kellgren–Lawrence grade) was observed in 40 patients (Group 1), while 70 patients (Group 2) showed no progression. The groups were comparable in age (59.2±9.5 vs 59.0±8.1 years) and disease duration (11.1±10.6 vs 13.7±9.9 years).
Compared with Group 2, patients in Group 1 more frequently had synovitis on US (62.5% vs 34.3%; p=0.004). MRI revealed a higher prevalence of bone marrow edema in the medial femoral and tibial compartments (70% vs 20% and 80% vs 24.3%, respectively; p=0.001), subchondral cysts in the medial femur and tibia (52.5% vs 12.9% and 55.5% vs 18.6%, respectively; p=0.001), and severe medial meniscal damage with displaced tears or complete destruction (55% vs 24.3%; p=0.003).
Densitometry showed higher bone mineral density (BMD) in the medial tibial condyle (0.90 [0.69–1.10] vs 0.78 [0.69–0.86]; p=0.003) and across subchondral tibial regions (0.82 [0.66–0.97] vs 0.74 [0.66–0.83]; p=0.013) in Group 1.
Spearman correlation analysis confirmed significant associations between OA progression and synovitis on US (R=0.49), bone marrow edema in medial compartments (R=0.38), and medial meniscal damage on MRI (R=0.34; p<0.05 for all). Additional associations were found with BMD of subchondral tibial regions overall and the medial tibial condyle (R=0.28 and R=0.37, respectively; p<0.05).
CONCLUSIONS: Synovitis, bone marrow edema, severe medial meniscal damage, and higher BMD of the medial tibial condyle and subchondral tibial regions are associated with radiographic progression of knee osteoarthritis.

P1276

EFFECT OF COMBINATION THERAPY WITH GLUCOSAMINE HYDROCHLORIDE AND CHONDROITIN SULFATE ON MARKERS OF SYSTEMIC INFLAMMATION IN PATIENTS WITH KNEE OSTEOARTHRITIS

A. Lila[1], E. Taskina[1], N. Savushkina[1], E. Strebkova[1], N. Kashevarova[1], T. Korotkova[1], A. Khalmetova[1], A. Avdeeva[1], E. Samarkina[1], M. Diatroptov[1], L. Alekseeva[1]

[1]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia

Objective: To study the effect of combination therapy of glucosamine hydrochloride (500 mg) and chondroitin sulfate (500 mg) on markers of systemic inflammation in patients with knee osteoarthritis (OA).
Methods. The study included 70 patients aged 41 to 74 years with a confirmed diagnosis of Kellgren–Lawrence stage II-III OA of the knee joint and a walking pain level of ≥4 points on the Numerical Rating Scale (NRS). The duration of the disease ranged from 1 to 25 years. All patients gave informed consent.
Results: During the three-month study, statistically significant positive dynamics of clinical indicators were recorded: the median pain intensity according to the NRS decreased from 5 [5; 6] to 3 [2; 4] points ($p < 0.0001$); according to the WOMAC index: pain - from 9 [7; 11] to 5 [3; 8] points, stiffness - from 4 [3; 5] to 3 [1; 4] points, functional impairment - from 36 [24; 41] to 23.5 [12; 32] points ($p < 0.0001$ for all indicators); 3) the general assessment of patient health (GAHP) increased from 50 [50; 70] to 65 [58; 75] mm ($p<0.0001$) (Figure 1). In addition, a decrease in the proportion of patients with clinically detectable synovitis ($p=0.04$) and limited knee motion ($p<0.0001$) was noted. A significant result was a decrease in tumor necrosis factor-α (TNF-α) levels (0.5 [0.1; 0.9] at baseline and 0.3 [0; 0.8] pg/ml at the end of the study, $p=0.04$), confirming the anti-inflammatory effect of the combination of chondroitin sulfate and glucosamine hydrochloride.

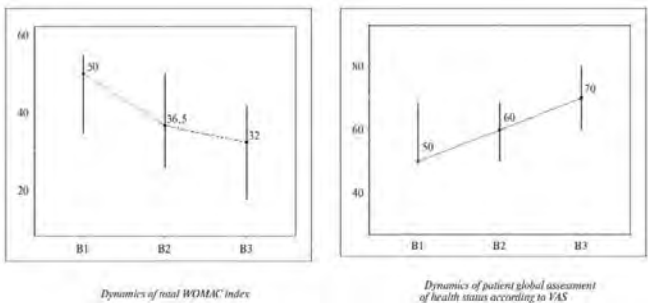

Figure 1. Dynamics of total WOMAC and GAHP indicators during the use of combination therapy with glucosamine hydrochloride and chondroitin sulfate.

Conclusions. A single-center study demonstrated that combination therapy with glucosamine hydrochloride and chondroitin sulfate in patients with knee OA resulted not only in rapid symptomatic improvement but also in a consistent increase in clinical efficacy throughout the entire observation period. This study expands our understanding of the molecular pathways underlying the efficacy of the chondroitin sulfate and glucosamine hydrochloride combination, focusing on the reduction of TNF-α levels.

P1277

MR T2 RELAXATION TIME IN PATIENTS WITH METABOLIC PHENOTYPE OF OSTEOARTHRITIS

N. Savushkina[1], E. Taskina[1], E. Strebkova[1], N. Kashevarova[1], A. Khalmetova[1], D. Kudinskii[1], L. Alekseeva[1], A. Lila[1]

[1]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia

Purpose: To study MR T2 relaxation time of cartilage in patients with metabolic phenotype (MP) of osteoarthritis (OA).
Methods. The prospective study included 96 patients aged 40–75 years with a confirmed diagnosis of knee OA, stages I–III according to Kellgren-Lawrence, who signed informed consent. The mean age was 52.7±10.5 years, body mass index (BMI) was 29.0±6.5 kg/m2. Each patient underwent MRI of the target knee with determination of T2 cartilage relaxation time (T2) in the total, deep, and superficial layers. MP was established if the patient had a waist circumference > 80 cm and two or more of the following symptoms: hypertension/elevated triglyceride levels over 1.7 mmol/l/decreased HDL levels — less than 1.0 mmol/l in men and less than 1.2 mmol/l in women/fasting hyperglycemia/impaired glucose tolerance.
Results: MP OA was detected in 41% of cases. Depending on the presence of MP, patients were divided into two groups. No differences in T2 values were found in the total and deep layers: (36.5 [34.1; 43.3] vs. 35.7 [34.5; 38.6] ms, $p=0.07$) and 35.5 [33.7; 38.5] vs. 35.3 [32.9; 38.0] ms, $p=0.28$), respectively. However, patients with MP had significantly higher T2 levels in the superficial cartilage layer (40.7 [36.0; 43.3] vs. 38.9 [35.3; 41.3] ms, $p=0.04$) (Figure 1). Spearman's correlation analysis also demonstrated a positive relationship between these indicators ($r=0.23$, $p<0.04$).

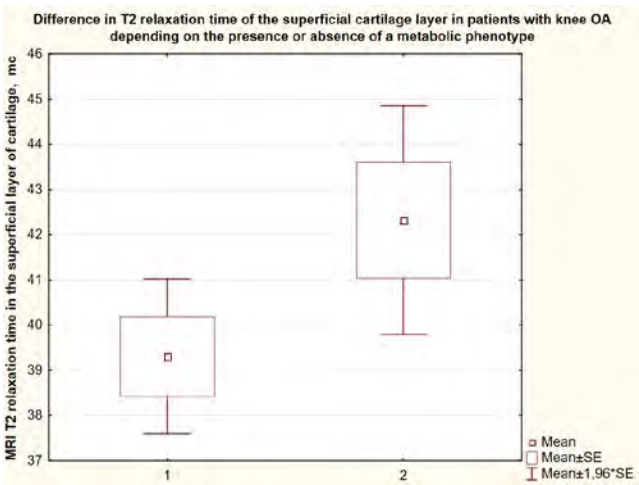

Figure 1. Difference in T2 relaxation time of the superficial cartilage layer in patients with knee OA depending on the presence or absence of a metabolic phenotype

Conclusions. The results of the study may indicate a significant influence of metabolic disorders on the processes of degradation of the cartilage matrix, mainly in its superficial layer.

P1278

A COMPARATIVE STUDY OF THE PREVALENCE OF ABNORMAL LOW MUSCLE MASS BETWEEN THAI OLDER ADULTS WHO CONSUME A PLANT-BASED DIET AND MEAT-INCLUSIVE DIET

N. Sithiwichankit[1], E. Vanitcharoenkul[1], A. Unnanuntana[1], P. Chotiyarnwong[1]

[1]Department of Orthopaedic Surgery, Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkok, Thailand

Objective: Sarcopenia involves the age-related loss of muscle mass and strength, increasing mortality and injury risks. While animal proteins support muscle synthesis, the rising popularity of plant-based diet for chronic disease prevention raises concern of potential muscle wasting. This study investigates the concern by comparing the prevalence of low muscle mass and sarcopenia, muscle strength and physical performance between Thai elderly following plant-based versus meat-inclusive diet.
Material & methods: This cross-sectional study, conducted from October to December 2025, compares low muscle mass between Thai elderly individuals following plant-based versus meat-inclusive diet. Participants, age > 60 years, maintained same dietary pattern for at least 2 years. We recruited plant-based subjects from dhamma retreats and meat-inclusive subjects from the prior study[1]. Data collection involved appendicular skeletal muscle mass (ASM) measurement, muscle strength and physical performance assessments. Low muscle mass and sarcopenia were diagnosed under both criteria from Asian Working Group for Sarcopenia (AWGS) 2019 and 2025.
Results: A total of 198 plant-based and 301 meat-inclusive participants were included. Although higher ASM was found in meat-inclusive group, prevalence of low muscle mass under AWGS 2019 criteria between groups were not significantly different (17.2% in plant-based group and 17.3% in meat-inclusive group, p=0.976). According to the new cut-off for low muscle mass in AWGS 2025, prevalence of low muscle mass increased and were still not significantly different. In contrast, plant-based participants performed better in physical performance tests. Prevalence of sarcopenia and muscle strength were the same in both groups.
Conclusion: From this study, same prevalence of low muscle mass between groups according to both criteria were found. Also, sarcopenia prevalence and muscle strength were similar. However, plant-based group performed better in physical performance assessments.

DEFINITION OF THE JOINT AS AN ORGAN OF THE MUSCULOSKELETAL SYSTEM

N. Tkachenko[1], V. Deev[2], L. Urazovskaya[1], A. Vorokov[1], V. Miroevskiy[3], A. Ostapchenko[3]

[1]North-Western State Medical University named after I.I. Mechnikov, Saint-Petersburg, Russia; [2]Avtsyn Research Institute of Human Morphology of Federal state budgetary scientific institution "Petrovsky National Research Centre of Surgery", Moscow, Russia; [3]The V. A. Almazov National Medical Research Center, Saint-Petersburg, Russia

Introduction.
The majority of anatomy and orthopaedic textbooks, both in Russia and internationally, define a joint as a “movable connection between bones,” thereby excluding soft tissues as integral components. The concept of the joint as an independent hollow organ composed predominantly of soft tissues remains largely overlooked in clinical practice, where an outdated, bone structures -centred definition is still widely used.
Objective.
To elucidate the developmental process of the joint and to characterize its morphology as an independent organ based on embryological and anatomical investigations.
Materials and Methods.
A morphological study was conducted using aborted human fetal material. Preparations of 36 joints (20 knee and 18 hip joints) from embryos at gestational ages of 5–20 weeks were examined. Staining was performed with hematoxylin and eosin. Anatomical dissection was carried out on cadaveric material (3 knee and 3 hip joints). The joints were isolated from surrounding bone and muscle tissue and tendons using blunt and sharp dissection techniques, including rotary instruments.
Results and Discussion.
A joint is defined as a hollow connective tissue organ, the obligatory components of which are the capsule, articular cartilage, and synovial membrane. Optional components include ligaments, articular discs, menisci, and bursae. The primary functions of the joint are the connection of bones and facilitation of mobility; additional functions include load bearing, shock absorption, congruence, and wear resistance.
Integrated embryological, molecular, and biomechanical data demonstrate that the joint forms as a distinct organ, developing prior to and independently of adjacent bones. Its cells possess a unique molecular profile, distinct from growth plate chondrocytes, and are governed by specific regulatory mechanisms. This fundamental concept has direct clinical implications: joint pathologies (including osteoarthritis) should be regarded not as “bone wear,” but as primary disorders of an independent organ, requiring appropriate diagnostic and therapeutic strategies.
Conclusions.
The joint develops as an independent organ, the primordium of which arises prior to and outside the bone anlagen. Its components have a unique cellular origin, molecular profile, and dependence on external signals. Recognition of this independence is fundamental for understanding the pathogenesis of osteoarthritis and for developing organ-preserving treatment strategies. Dissection and isolation of the joint constitute a labor-intensive process even in vitro.
In this context, experimental research aimed at developing methods for isolating and mobilizing joints in vitro and in vivo, as well as designing joint-preserving surgical procedures with conservation of bone tissue, appears promising.

P1280

SKELETAL MUSCLE STRENGTH AND ASSOCIATED FACTORS IN FEMALE RHEUMATOID ARTHRITIS PATIENTS

O. Dobrovolskaya[1], M. Kozyreva[1], A. Sorokina[1], N. Demin[1], N. Toroptsova[1]

[1]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia

Objective: To estimate the skeletal muscle strength and determine the factors affecting it in women with rheumatoid arthritis (RA).
Materials and methods. 202 people with rheumatoid arthritis were included in the study. The mean age was 59.3±9.1 years. Clinical and laboratory studies were conducted, among them an assessment of muscle strength. Using dual-energy X-ray absorptiometry (DXA), the appendicular lean mass (ALM) was evaluated, followed by the calculation of the appendicular lean mass index (ALMI).
Results. Among the patients with RA 28.7 % had low ALM and 19.3 % - low ALMI. The frequency of low muscle strength and physical performance was 76.2% and 45.5% accordingly. Univariate logistic regression revealed an association between low hand grip strength and low muscle strength of the legs with DAS28 (OR 1.66; 95% CI 1.21-2.28, p=0.002 and OR 1.66; 95% CI 1.24-2.22, p=0.001 accordingly) and DAS28-based RA activity level (OR 1.99; 95% CI 1.12-3.56, p=0.020 and OR 2.11; 95% CI 1.24-3.60, p=0.006 accordingly). Hand grip strength also associated with CRP (OR 1.04; 95% CI 1.01-1.07, p=0.018), ALM and ALMI (OR 0.84; 95% CI 0.75-0.94, p=0.003 and OR 0.65; 95% CI 0.48-0.89, p=0.007 accordingly) and presence of erosive arthritis (OR 4.75; 95% CI 1.99-11.36, p=0.001). Limb muscle strength was associated with the use of proton pump inhibitors (OR 3.56; 95% CI 1.85-6.84, p<0.001).
Conclusion. The frequency of sarcopenia in women with RA was 30.7%. Low muscle strength associated with the activity of the disease, assessed by DAS 28, the presence of erosive arthritis and muscle mass.

P1281

OSTEOSARCOPENIA: FOCUS ON BIOMARKERS OF MUSCLE, BONE, AND FAT TISSUES

O. Dobrovolskaya[1], M. Kozyreva[1], E. Samarkina[1], M. Diatroptova[1], N. Toroptsova[1]

[1]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia

Objective: to determine the association of muscle, fat, and bone tissue markers with osteosarcopenia versus normal body composition in women with rheumatoid arthritis (RA).
Materials and Methods. 102 women with RA (aged 40-75 years) enrolled in the study, including 45 women with osteosarcopenia and 57 with normal body composition. Osteosarcopenia was diagnosed by osteopenia/osteoporosis or low bone mineral density (WHO criteria) and sarcopenic phenotype (appendicular muscle mass or index < 15 kg or <5.5 kg/m2 respectively). Dual-energy X-ray absorptiometry (Lunar prodigy, GE, USA) was performed to assess the body composition. Serum levels of myostatin, insulin-like growth factor 1(IGF-1), leptin, adiponectin, resistin, interleukin 6, irisin, and sclerostin were measured using Enzyme linked immuno sorbent assay (ELISA). The sensitivity and specificity of biomarkers for osteosarcopenia diagnostics were determined using ROC-analysis. The cut-off-points were determined by the Youden index.
Results. The levels of IGF-1, leptin, resistin, sclerostin were less and adiponectin levels were more in patients with osteosarcopenia than in women with normal body composition (p<0.05). In logistic regression, the following markers are significantly associated with osteosarcopenia: IGF-1 (OR 0.97 [95% CI 0.95; 0.99]), adiponectin (OR 1.23 [95% CI 1.02; 1.48]), and sclerostin (OR 0.92 [95% CI 0.87; 0.96]. IGF-1 showed the best result in ROC-analysis: the area under the curve (AUC) was 0.850 (95% confidence interval (CI) 0.733-0.929, p<0.001). The cut-off-point was ≤38,4 ng/ml with sensitivity of 53.5%, specificity of 100.0%, and positive predictive value 100.0%.
Conclusion. Associations of osteosarcopenia with IGF-1, adiponectin, and sclerostin levels have been determined. For IGF-1, the positive prognostic value was 100% at the found cut-off point. This biomarker can be considered as a diagnostic (confirming) test of osteosarcopenia in women with RA.

P1282

SARCOPENIA AND BIOMARKERS OF MUSCLE, BONE, AND FAT TISSUES

O. Dobrovolskaya[1], M. Kozyreva[1], E. Samarkina[1], N. Toroptsova[1]

[1]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia

Objective: to study the association of muscle, fat, and bone tissue markers with sarcopenia in women with rheumatoid arthritis (RA).
Materials and Methods. 163 women were examined with confirmed RA. All patients underwent dual-energy X-ray absorptiometry (Lunar prodigy, GE, USA) to assess the body composition. Serum levels of myostatin, insulin-like growth factor (IGF) 1, leptin, adiponectin, resistin, interleukin 6, irisin, and sclerostin were measured using ELISA method. The cut-off-points in ROC-analysis were determined by the Youden index.
Results. Only 12 women had isolated sarcopenia according to EWGSOP 2 criteria, 49 patients had osteoporosis, 45 – osteosarcopenia and 57 persons had normal body composition. Median age in women with sarcopenia and normal body composition was 49.0 [47.0; 56.5] and 56.0 [50.0; 62.0] years (p>0.05). IGF-1 level in persons with normal body composition (81.9 [45.0; 122.3] ng/ml) was more than in women with SP (17.0 [15.5; 18.0] ng/ml), p=0.001. Other marker's levels did not significantly differ between these groups. In univariate logistic regression IGF-1 level were associated with SP (OR 0.94 [95% CI 0.89- 0.99], p<0.05). The area under the curve in ROC-analysis was 0.914 (95% CI 0.727-0.989, p<0.001). The cut-off-point was ≤18.0 ng/ml with sensitivity of 87.5%, specificity of 100%, and positive predictive value 100%.
Conclusion. Among the studied markers, only IGF-1 was associated with sarcopenia. Sensitivity, specificity and positive predictive value at the found cut-off point was 87.5%, 100% and 100% respectively. IGF-1 can be considered as a prognostic marker of sarcopenia.

P1283

MID-UPPER ARM CIRCUMFERENCE AS A SCREENING TOOL FOR LOW MUSCLE MASS IN WOMEN WITH RHEUMATOID ARTHRITIS

O. Dobrovolskaya[1], M. Kozyreva[1], A. Sorokina[1], N. Demin[1], N. Toroptsova[1]

[1]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia

Objective: To re-evaluate the suitability of mid-upper arm circumference (MUAC) as a screening marker of low muscle mass in women with rheumatoid arthritis (RA). The impact of obesity and age on the screening efficacy of MUAC for low muscle mass was also evaluated.
Materials and Methods. The study included 205 women (mean age 59.2±9.1 years) with confirmed RA. All patients underwent a routine clinical examination, as well as MUAC measurements and dual-energy X-ray absorptiometry (Lunar Prodigy, GE, USA) to analyze body composition. The sensitivity and specificity of MUAC for screening low muscle mass were determined using ROC analysis.
Results. The appendicular muscle index (AMI) <5.5 kg/m2 was determined in 39 (19.0%) patients. MUAC had a direct correlation with AMI (r=0.60, p<0.001). The correlation depending on age (<65 and ≥65 years) was 0.62 and 0.45 respectively, p<0.001. The correlation depending on overfat (<35% and ≥35%) was 0.73 and 0.55 respectively, p<0.001. The cut-off-point for MUAC was ≤26.0 cm, it was detected according to the Jouden index (sensitivity and specificity were 64.1% and 84.3%, respectively). The area under the curve (AUC) was 0.809 (95% confidence interval (CI) 0.748-0.860, p<0.001). At the specified cut-off-point depending on age (<65 and ≥65 years) sensitivity was 85,7% and 81.8% respectively, depending on overfat (<35% and ≥35%) – 92.1% and 94.1% respectively.
Conclusion. MUAC demonstrated high sensitivity, independent of age and overfat status. Therefore, it may be considered a potential screening tool for low muscle mass in women with with RA.

P1284

ASSOCIATION OF TRABECULAR BONE SCORE WITH IMMUNOLOGICAL PARAMETERS IN WOMEN WITH RHEUMATOID ARTHRITIS

M. Kozyreva[1], N. Demin[1], N. Toroptsova[1]

[1]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia

Objective: to establish the frequency of damaged bone microarchitecture according to trabecular bone score (TBS) and to evaluate the relationship with immunological parameters in postmenopausal women with rheumatoid arthritis (RA).
Material and methods: 124 women with a confirmed RA (mean age 60.3±10.0 years) were included. Questionnaires, dual-energy X-ray absorptiometry (DXA) of the lumbar spine were performed. TBS calculation of was done using TBS iNsight software, version 3.0. Laboratory assessments included serum rheumatoid factor (RF), antibodies to cyclic citrullated peptide (ACCP) and serum C-reactive protein (CRP) all using the nephelometric method on the Atellica® NEPH 630 system analyzer (Siemens Healthineers, Germany).The study was approved by the local ethics committee.
Results: Median duration of RA was 8 [3,2; 13,0] years. 95 (76.6%) patients were RF seropositive, and 90 (72.6%) women were ACCP positive. Median RF serum level was 50.6 [9.6; 197.5] IU/ml, ACCP - 72.7 [7.3; 218.1] U/ml, and CRP -5.5 [1.3; 12.5] mg/l. According to TBS data, vertebral microarchitecture was normal in 44.3% women, partially degraded in 21.8%, and degraded in 33.9% individuals. Negative associations were found between TBS and RF (r=-0.20, p=0.001), ACCP (r=-0.22, p=0.020). No association between TBS and CRP was found. Univariate linear regression analysis confirmed the relationship between TBS and ACCP (β = -0.19, p=0.037), at the same time, the association with the RF value was not confirmed (p>0.05).
Conclusion. Normal microarchitecture was found only in 44.3% RA patients. Bone microarchitecture as measured by TBS was negatively associated with ACCP.

P1285

URIC ACID LEVEL, BONE MINERAL DENSITY AND TRABECULAR BONE SCORE IN RHEUMATOID ARTHRITIS PATIENTS

M. Kozyreva[1], N. Demin[1], N. Toroptsova[1]

[1]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia

Objective: to study the relationship of uric acid (UA) level with bone mineral density (BMD) and trabecular bone score (TBS) in postmenopausal women with rheumatoid arthritis (RA).
Material and methods: 140 women (mean age 65,0±10.2 years) with a confirmed RA were included. All patients were interviewed and laboratory examination, dual-energy X-ray absorptiometry (DXA) of femur and lumbar spine (L1-L4) with determination of TBS were done. The bone microarchitecture was assessed depending on TBS: degraded - TBS ≤1.23, partially degraded – TBS 1.23 - <1.31, normal microarchitecture - TBS≥1.31. The study was approved by the local ethics committee.
Results: mean level UA was 273.9±73.7 mkmol/L and hyperuricemia (UA level≥360 mkmol/L) was diagnosed in 13.6% of persons. Mean BMD L1-L4 was 0,998±0,206 g/cm2, total hip (TH) - 0,832±0,149 g/cm2, femoral neck (FN) - 0,783±0,132 g/cm2. Osteoporosis (OP) was detected in 47.9% of women. Low TBS was detected in 40.7% patients, partially degraded microarchitecture had 24.3% and normal - 35% of the examined women. A positive association was established between UA level and BMD L1-L4 (r=0.025, p=0.003), BMD TH (r=0.23, p=0.007), as well as an inverse association with TBS (r=-0.18, p=0.035). Univariate linear regression analysis an independent association between UA level and BMD L1-L4, TH and TBS were found (β=0.18, p=0.021; β=0.19, p=0.016; β=-0.19, p=0.027, respectively), while with BMD FN it was not detected (p>0.05).
Conclusion. Hyperuricemia was diagnosed in 13.6% of persons. Osteoporosis was detected in 47.9% of women. Degraded bone microarchitecture was found in 40.7% of patients with RA. Our study showed that in postmenopausal women with RA, UA level was positively correlated with BMD L1-L4 and TH, but negatively with TBS.

P1286

SYSTEMIC SCLEROSIS IN POSTMENOPAUSAL WOMEN: FOCUS ON BONE MINERAL DENSITY

A. Sorokina[1], N. Demin[1], O. Dobrovolskaya[1], N. Toroptsova[1]

[1]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia

Objective: to study the frequency of low bone mineral density (BMD) and factors affecting it in postmenopausal women with systemic sclerosis (SSc)

Material and Methods: 125 postmenopausal women with SSc (median age –60,0 [54,0; 64,0] years) according to the criteria of ACR/EULAR criteria (2013) were included. All women were interviewed; a laboratory and instrumental examination was conducted. BMD of lumbar spine (LS), femoral neck (FN) and total hip (TH) was measured by dual energy X-ray absorptiometry (DXA). To identify the factors associated with low BMD, linear regression analysis was performed.

Results: 113 (90,4%) patients had OP or osteopenia in at least one of measurement area (59 (47.2%) and 54 (43.2%) women, respectively). Univariate linear regression revealed a negative association between BMD LS and daily dose of glucocorticoids (GCs) (b= -0,19; p=0,04) and a positive with 25-hydroxy calciferol level (25(OH)D) (b=0,28; p=0,01). Body mass index (BMI) (b=0,38; p<0,001), glomerular filtration rate (b=0.31; p<0.001), 25(OH)D level (b=0,23, p=0,04) positively and the duration of postmenopause (b=-0,25; p=0,005), duration of SSc (b=-0,28; p=0,002), GCs cumulative dose (b=-0,33, p<0,001), the duration of proton pump inhibitors using (b=-0,25, p=0,04) negatively affected the BMD FN. BMD TH positively associated with BMI (b=0.26; p=0,04), 25(OH)D (b=0,24, p=0,04) and negatively with duration of SSc (b=-0,21; p=0,02) and GCs cumulative dose (b= -0,24, p<0,001).

Conclusion: 90,4% of postmenopausal women with SSc had low BMD. Associations between BMD and both traditional and SSc-related factors have been identified.

P1287

MUSCLE MASS IN WOMEN WITH SYSTEMIC SCLEROSIS: FOCUS ON SARCOPENIA

A. Sorokina[1], N. Demin[1], N. Toroptsova[1]

[1]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia

Objective: to study the frequency of sarcopenia (SP) and factors affecting appendicular lean mass (ALM) in women with systemic sclerosis (SSc)

Material and Methods: The study included 64 women with SSc: 20 (31,2 %) fertile and 44 (68,8%) in postmenopause. All women were interviewed; Mini Nutritional assessment (MNA), laboratory and instrumental examination were conducted. BMD of lumbar spine, femoral neck (FN), total hip (TH) and whole-body was measured using dual-energy X-ray absorptiometry. The appendicular muscle index (AMI) was calculated (ALM)/height, kg/m2). SP was defended according to EWGSOP2 criteria: both low muscle quantity (ALM <15 kg or AMI <5.5 kg/m2) and low muscle strength (handgrip strength <16 kg or chair stand test >15 s for five rises). Linear regression analysis was performed to identify factors associated with ALM.

Results: 24 (37.5%) women had low grip strength and 25 (39.1%) had low lower limb muscle strength. The low ALM/AMI had 27 (42.2%) patients: 13 (32.5%) women with a limited form of SSc and 14 (58.3%) patients with a diffuse form (p = 0.043). The frequency of confirmed SP according to EWGSOP2 was 34,4 %, with no differences depending on the form of the disease. Univariate linear regression revealed a relationship between ALM and BMI (b= 0.77; p<0.001), MNA (b=0.51; p<0.001), BMD FN and BMD TH (b=0.52; p<0.001 and b=0.50; p<0.001, respectively), the Rodnan skin score (b=-0.40; p=0.005) and the cumulative dose of glucocorticoid (GC) (b=-0,39; p=0,001).There was no association with the age of the women. Multivariate linear regression revealed a negative relationship between ALM and the Rodnan skin score (b=-0.19; p=0.047), GC cumulative dose (b= -0.22; p=0.021), and a positive relationship with BMI (b=0.65; p<0.001).
Conclusion: 1/3 observed women with SSc had SP. ALM depended on BMI, Rodnan skin score and GC cumulative dose.

P1288

VITAMIN D STATUS IN YOUNG PATIENTS WITH SYSTEMIC SCLEROSIS

A. Sorokina[1], E. Samarkina[1], N. Toroptsova[1]

[1]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia

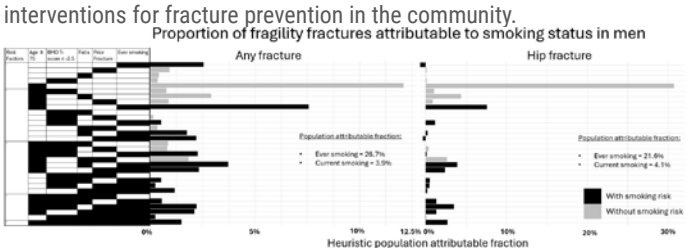
The processes of absorption and metabolism of vitamin D in patients with systemic sclerosis (SSc) are often disrupted due to the clinical features of the disease.

Objective: to assess the level of vitamin D (25(OH)D) in fertile women and men <50 years of age with SSc.

Material and Methods: 84 patients with SSc according to the 2013 ACR/EULAR criteria were included: 69 (82.2%) fertile women and 15 (17.9%) men < 50 years. The median age of the patients was 36.5 [31.5; 44.5] years. The level of 25(OH)D was determined in all patients by immunochemiluminescence method.

Results: The median 25(OH)D level was 13.4 [13.9; 22.6] ng/ml. 25(OH) D adequate level (≥30 ng/ml) was found in 6 (7.1%) patients, insufficient (20-29 ng/ml) - in 20(23.8%), deficiency (<20 ng/ml) - in 47 (56.0%), and a severe deficiency (<10 ng/ml) – in 11 (13.1%) persons. 25 (OH)D level was comparable among women and men (p>0.05). Among patients with inadequate levels of 25(OH)D, only 11 (14.1%) people received vitamin D supplements at a dose of 800 IU, among them hypovitaminosis was detected in 3 (27.3%), and deficiency in 8 (72.7%) patients.

Conclusion: Among the examined men under 50 years of age and fertile women with SSc, adequate vitamin D level was diagnosed in only 7.1% of patients. Thus, 92.9% of patients needed additional intake of supplements of cholecalciferol, while the dose of 800 IU was insufficient to maintain a level of more than 30 ng/ml.



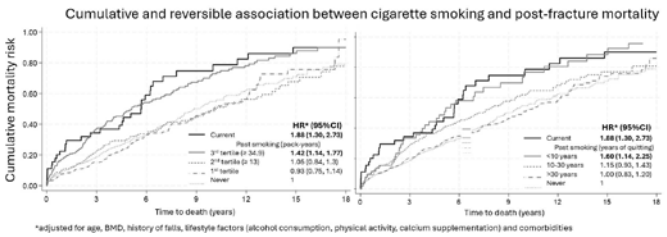
P1289

REVERSIBLE IMPACT OF CIGARETTE SMOKING ON FRAGILITY FRACTURES

N. Tran[1], D. T. Nguyen[1], T. S. Tran[1], T. V. Nguyen[1]

[1]University of Technology Sydney, Sydney, Australia

Objectives: To investigate the reversible effect of cigarette smoking on fracture risk and quantify the proportion of fractures preventable in a population via smoking cessation.
Materials and Methods: We analysed online data of 5992 men from the Osteoporotic Fractures in Men Study in the USA. Smoking status (current, past, or never smoking), cumulative smoking exposure (tertiles of pack-years) and time since smoking cessation (<10, 10-30, >30 years) were self-reported, and fractures were confirmed via medical records. A cause-specific Cox regression was used to quantify the association between smoking conditions and fracture risk, adjusted for competing risk of death and confounders (age, BMD, history of falls or prior fractures and lifestyle factors). We calculated the heuristic population-attributable fraction to quantify the proportion of fractures preventable if smoking was eliminated.
Results: Over a median follow-up of 12.4 (IQR: 7.0-18.2) years, 1084 participants sustained a fragility fracture, including 237 hip fractures, yielding the incidence of 14.5 fractures (95% CI: 13.7-15.4) and 3.2 hip fractures (2.8-3.6) per 1000 person-years. Cigarette smoking had a dose-response association with fracture risk. Compared to nonsmokers, current smokers were independently associated with two-fold greater fracture risk (adjusted hazard ratio: 1.85, 95% CI: 1.35-2.54), whereas past smokers within the highest tertile of smoking exposure or less than 10 years of smoking cessation tended to have a 20-30% greater fracture risk (1.17, 0.90-1.39, and 1.29, 0.96-1.74, respectively). Past smokers who had smoked less or quit for more than 10 years were not associated with fracture risk. A similar dose-response relationship was found between smoking conditions and hip fractures. Importantly, if current smokers quit, future fractures would be reduced by 4%; and a quarter of fractures would have been prevented had no individuals ever smoked.
Conclusions: The effect of cigarette smoking on bone fragility is reversible, suggesting that quitting smoking could substantially lower fracture risk. This emphasizes the importance of smoking cessation interventions for fracture prevention in the community.



P1290

"SKELETAL AGE" FOR CUMULATIVE IMPACT OF CIGARETTE SMOKING ON POST-FRACTURE MORTALITY

N. Tran[1], D. T. Nguyen[1], T. S. Tran[1], T. V. Nguyen[1]

[1]University of Technology Sydney, Sydney, Australia

Objectives: To quantify the cumulative and reversible effect of cigarette smoking on post-fracture mortality risk and communicate this effect using "Skeletal Age" to improve doctor-patient risk communication.
Material and Methods: We analysed online prospective data of 1084 individuals who had fractured at an average age of 82.6±6.6 years from the Osteoporotic Fractures in Men Study in the USA. Smoking status (current, past or never), cumulative smoking exposure (tertiles of pack-years) and time since smoking cessation (<10, 10-30 or >30 years) were self-reported close to fracture time, and deaths were confirmed via death certificates. We quantified the association between smoking conditions and post-fracture mortality, using Cox regression, adjusted for known confounders. *"Skeletal Age"* is defined as the age of an individual's skeleton resulting from a fracture and/or fracture risk factor, computed as chronological age plus the estimated years of life lost associated with that risk factor.
Results: Over a median follow-up of 5.1 years (IQR: 2.1-9.3), 639 fracture patients died, yielding the rate of 10.2 deaths/100 person-years (95% CI: 9.5-11.0). We found a dose-response association between cigarette smoking and post-fracture mortality. Current smokers and past smokers within the highest tertiles of smoking exposure or less than 10 years of smoking cessation were independently associated with 90%, 42% and 60%-greater risk of post-fracture mortality than non-smokers, respectively. Past smokers who had smoked less or quit for over 10 years were not associated with mortality risk, suggesting that smoking's impact on post-fracture mortality is reversible. Additionally, a 60-year-old fracture patient who was currently smoking had a *"Skeletal Age"* of 65.1 years, suggesting 5 years of life lost related to current smoking. Similarly, past smokers who had either smoked heavily or quit within 10 years would lose 3 and 4 years of life, ~ *"Skeletal Age"* of 62.9 and 63.8 years old, respectively.
Conclusion: Cigarette smoking-associated risk of post-fracture mortality is reversible. *"Skeletal Age"* provides a novel metric that facilitates risk communication between doctors and patients.

P1291

IMPACT OF SARCOPENIC OBESITY ON THE CLINICAL COURSE OF KNEE OSTEOARTHRITIS IN POSTMENOPAUSAL WOMEN

N. Zaverukha[1], N. Grygorieva[1]

[1]State Institution "Institute of Gerontology NAMS of Ukraine", Kyiv, Ukraine

Aim

The study aimed to determine whether knee pain intensity and quality of life differ between postmenopausal women with knee osteoarthritis (KOA) with sarcopenic obesity (SPO) and those with KOA and obesity (OB) without sarcopenia (SP).

Methods

The study included 68 women (mean age 65.2±7.3 years) with Kellgren–Lawrence grade 2–3 KOA, who were stratified into two groups. Group I consisted of 21 women with SPO (mean age 64.4±8.2 years) (cut-off values for the Ukrainian female population, 2023), and group II – 47 participants (mean age 65.5±6.9 years) with OB (WHO criteria 1998) without SP (EWGSOP2, 2019). Height, weight and body mass index (BMI) were measured using standardized procedures. Muscle strength was assessed by handgrip dynamometry and the five-times sit-to-stand test. Body composition (used for SPO diagnosis) was determined by dual-energy X-ray absorptiometry. Pain intensity and quality of life were assessed using the KOOS-12 questionnaire.

Results

Women in Groups I and II did not differ significantly in age, height, weight or BMI. Pain intensity was significantly higher in women with SPO (40 [30.0–50.0] points) compared to women with OB without SP (50 [40.0–60.0] points) (p=0.004). Quality of life scores were also significantly lower in women with SPO (40 [30.0–47.5] points) than in those with OB without SP (50 [40.0–52.5] points, p=0.04). Handgrip strength of both dominant and nondominant hands was lower in patients with KOA and SPO (13.5 [10.0-23.0] vs 20.0 [17.5-26.0] kg and 10.0 [9.5-15.0] vs 22.0 [19.0-26.5] kg, respectively, p<0.001 for both parameters). However, no statistically significant difference was observed in the sit-to-stand test results between the two groups (15 [13.5-16.0] vs 13.5 [12.0-15.0] sec., respectively; p=0.07).

Conclusion

Women with KOA and SPO exhibited significantly higher knee pain intensity, poorer quality of life, and reduced muscle strength as measured by handgrip dynamometry.

Disclosures: The authors declared no competing interests.

P1292

PREVENTION OF OSTEOPOROSIS CANCER PATIENTS ON THE BACKGROUND OF HORMONE THERAPY

V. Diomidova[1], E. Guryanova[1,2], N. Zhuravleva[1]

[1]Federal State Budgetary Educational Institution of Higher Education "I.N. Ulianov Chuvash State University", Cheboksary, Russia;

[2]The State Autonomus Institution of the Chuvash Republic Supplementary Vocational Education "Postgraduate Doctors Training Institute" of Health Care Ministry of the Chuvash Republic, Cheboksary, Russia

Relevance. Hormone therapy for breast cancer reduces estrogen levels and increases the risk of bone loss and osteoporosis with subsequent fractures. Bisphosphonates can limit bone resorption and reduce the incidence of fractures. Given the insufficient monitoring of bone mineral density in oncological practice, the study of the effectiveness of bisphosphonates in patients receiving hormone therapy is of great clinical importance.

The aim is to evaluate the effect of taking bisphosphonates on the prevention of osteoporosis in breast cancer patients receiving hormone therapy.

Materials and methods. The study was performed at the Cheboksary Republican Clinical Oncology Hospital from April to November 2025. The study included 72 patients of reproductive age 29-43 years (mean age 35.9±4.8) with a verified diagnosis of stage I–IIIa breast cancer after radical surgical treatment, radiation and systemic therapy, who were on hormone therapy. The participants were randomized into four groups of 18 people: Group A received anastrozole, group B received tamoxifen, group C received tamoxifen + zoledronate, and group D received anastrozole + zoledronate. All patients underwent osteoscintigraphy to exclude bone metastases. Primary multiple tumors, a history of fractures, confirmed bone metastases, and prolonged use of glucocorticosteroids (>90 days) were excluded. Examinations were performed before the start of therapy and after 6 months. The statistical significance of the differences in the mean values was determined using a ttest; for nonparametric data, the Wilcoxon criterion was used for dynamic observation. The significance level was taken at p<0.05. Data processing was performed in Statistica 10.0.

Results and discussion. After 6 months, generalized grade 2-3 osteoporosis was detected in 15 patients in group A (83%, 15/18) according to densitometry. Grade 2-3 focal/regional osteoporosis was detected in group B in 13 patients (72%, 13/18). The incidence of severe bone loss in groups with the addition of zoledronate was lower: in group C, 6 patients (33%, 6/18) had grade 1-2 osteoporosis; in group D, 5 patients (28%, 5/18) — grade 1-2 osteoporosis; no significant joint dysfunction was detected.

Conclusions. The results of the study confirm the effectiveness of bisphosphonates in the prevention of bone mineral density loss in patients on hormone therapy and indicate a reduction in the risk of fractures with combination therapy.

P1293

A MIMIC OF ANKYLOSING SPONDYLITIS, OCHRONOSIS: CASE REPORT

N. Şen[1], C. B. Önder[2]

[1]Kartal Dr Lütfi Kırdar City Hospital, Department of Rheumatology, İstanbul, Türkiye; [2]Kartal Dr Lütfi Kırdar City Hospital, Department of Physical Medicine and Rehabilitation, İstanbul, Türkiye

Ochronosis is a rare hereditary autosomal recessive dis order and generally presents after the fourth decade, although alkaptonuria may be identified in childhood. The disorder is caused by a deficiency of homogentisate 1,2-dioxygenaze, an enzyme which catalyzes the conver sion of homogentisic acid (HGA)tomaleylacetoacetic acid. Renal clearance of HGA is maintained very effectively in youth. With aging, the efficiency of the process decreases and the steady level of plasma HGA slowly increases. High levels of HGA lead to deposition in effected joints in articular cartilage as well as in periarticular, collagen-rich ligaments and menisci. Wereport herein a detailed description of a disease of the spine in a woman with late onset ochronosis.

A 50-year-old woman presented to the rheumatology outpatient clinic with a complaint of low back pain. Her rheumatologic review of systems was unremarkable. Physical examination revealed bluish-black pigmentation of the ear cartilage (Figure 1). Laboratory findings showed that erythrocyte sedimentation rate and C-reactive protein levels were within normal limits. Liver function tests demonstrated elevated transaminases: AST 72 U/L (0–35), ALT 92 U/L (0–35), GGT 50 U/L (0–38), while alkaline phosphatase was within the normal range at 76 U/L (33–88). Her x-ray findings also revealed typical wafer-like cal cifications and radiolucent spaces in the vertebral discs, which can be seen definitely in the presence of ochronotic arthropathy (Figure 2).

X-ray features of spinal ochronosis resemble ankylosing spondylitis; therefore, SpA is considered as one of the differentials in the diagnosis.

A BODY SHAPE INDEX AS A SURROGATE MARKER FOR SARCOPENIA RISK IN POSTMENOPAUSAL WOMEN: A CROSS-SECTIONAL ANALYSIS

N. Şentürk Durmuş[1], A. Yılmaz[2], E. D. Özüdoğru[3], Y. Yıldız[4], Z. Beşışık Yılmaz[4], C. Alkaç[4], B. Can[4], A. Tufan[4]

[1]MD, Geriatrician, Independent Investigator, İstanbul, Türkiye; [2]MD Department of Internal Medicine, Marmara School of Medicine, Istanbul, Türkiye; [3]MD Department of Internal Medicine, Division of Geriatrics, Marmara University Medical School, Istanbul, Türkiye; [4]MD, Department of Internal Medicine, Division of Geriatrics, Marmara University Medical School, Istanbul, Türkiye

Background: Hormonal changes and increased central adiposity in postmenopausal women contribute to a disproportionately higher rate of sarcopenia, a condition characterized by the progressive loss of skeletal muscle mass (SMM) and function. Primary care requires simpler screening methods, despite the availability of standard diagnostic tools like imaging and functional testing. A Body Shape Index (ABSI), which uses waist, height, and body mass index (BMI), might reflect central fat accumulation and mortality risk, but its role in sarcopenia prediction remains unclear. To analyze the connection between ABSI and sarcopenia in postmenopausal women, using demographic, metabolic, and body composition data categorized by ABSI quartiles.

Methods: A total of 296 postmenopausal women participated in this cross-sectional study. Sarcopenia was defined according to the EWGSOP2 definition. ABSI was calculated and analyzed in quartiles. Logistic regression identified predictors of high ABSI.

Results: The prevalence of sarcopenia was 43.9% among participants. Participants in the highest ABSI quartile showed significantly older, slower gait speed, and higher rates of osteoporosis and sarcopenia (all $p<0.05$). In the total sample, older age, lower SMMI and slower gait speed were associated with the probability of being Q4 ABSI group ($p<0.05$). In addition, lower SMM and slower gait speed were independent predictors of higher ABSI in women over 65.

Conclusion: Postmenopausal women with high ABSI show a significant association with poor musculoskeletal and metabolic health. In clinical and community settings, ABSI may offer a cost-effective and simple anthropometric marker for early sarcopenia risk assessment.

P1295

ORAL FRAILTY AND OROPHARYNGEAL DYSPHAGIA IN COMMUNITY-DWELLING OLDER ADULTS: EVIDENCE FROM EAT-10 AND OFI-8

N. Şentürk Durmuş[1], N. Turkoglu[2], A. Şeker[3], F. Sevilmis[4], H. Usta Atmaca[4], O. Yılmaz[5]

[1]MD, Geriatrician, Independent Investigator, İstanbul, Türkiye; [2]Gerontology, Health Science University Istanbul Training and Research Hospital, İstanbul, Türkiye; [3]MD, Department of Internal Medicine Kartal Dr. Lütfi Kırdar City Hospital, İstanbul, Türkiye; [4]MD, Department of Internal Medicine, Health Science University, Istanbul Training and Research Hospital, Istanbul, Türkiye; [5]MD, Geriatrician, Department of Internal Medicine, Division of Geriatrics, Health Science University, Istanbul Training and Research Hospital, Istanbul, Türkiye

Background: Frailty, a multidimensional geriatric syndrome, is related to adverse health outcomes. Declining chewing, swallowing, and tongue function, termed oral frailty, is now recognized as a factor in systemic vulnerability. Oropharyngeal dysphagia (OD) represents a major pathway linking oral decline to frailty, yet evidence from non-Asian populations remains limited. This study aimed to examine the relationship between OD risk, oral frailty, and systemic frailty in older adults.

Methods: A cross-sectional study was conducted among 447 individuals aged ≥65 years recruited from geriatric outpatient clinics. The Eating Assessment Tool-10 (EAT-10) was used to evaluate swallowing function; a score of ≥3 indicating OD risk. Oral frailty was identified by the Oral Frailty Index-8 (OFI-8), where scores ≥4 defined oral frailty. Independent frailty predictors were identified using multivariate logistic regression.

Results: The mean age was 73.6 ± 7.8 years; 75.6% were female. OFI-8 classified 56.6% as frail and 31.3% as OD risk based on EAT-10. Individuals at risk of OD had significantly lower handgrip strength, lower albumin and vitamin D levels, and more cases of osteoporosis (all p<0.05). Frail individuals had higher FRAIL scores and a greater prevalence of osteoporosis (all p<0.05). Logistic regression revealed that OD risk independently predicted frailty, increasing odds nearly sixfold (Odds ratio [OR] range 5.83–6.34, all p<0.001), even after adjusting for age, sex, FRAIL score, and osteoporosis.

Conclusions: OD risk, as assessed by the EAT-10, is a robust predictor of frailty in older adults. Incorporating the EAT-10 and OFI-8 in complete geriatric assessments may enable early detection of vulnerable individuals and inform multidisciplinary.

Table 1. Multivariate logistic regression models for factors associated with frailty based on OFI-8

Variable	Model 1		Model 2		Model 3	
	OR (95% CI)	p-value	OR (95% CI)	p-value	OR (95% CI)	p-value
Oropharyngeal dysphagia risk (based on EAT-10)	6.19 (3.96–9.70)	**<0.001**	6.34 (4.03–9.98)	**<0.001**	5.83 (3.68–9.25)	**<0.001**
Age	0.98 (0.96–1.01)	0.179	0.97 (0.94–0.998)	**0.033**	0.98 (0.95–1.01)	0.107
Sex (male)	1.33 (0.83–2.13)	0.243	1.12 (0.68–1.83)	0.663	1.34 (0.80–2.23)	0.266
FRAIL score			1.31 (1.07–1.61)	**0.009**	1.32 (1.08–1.63)	**0.008**
Osteoporosis					2.44 (1.56–3.81)	**<0.001**

Notes: CI: Confidence Interval, EAT-10: Eating Assessment Tool-10, FRAIL: Fatigue, Resistance, Ambulation, Illnesses, Loss of weight (frailty score), OR: Odds Ratio.

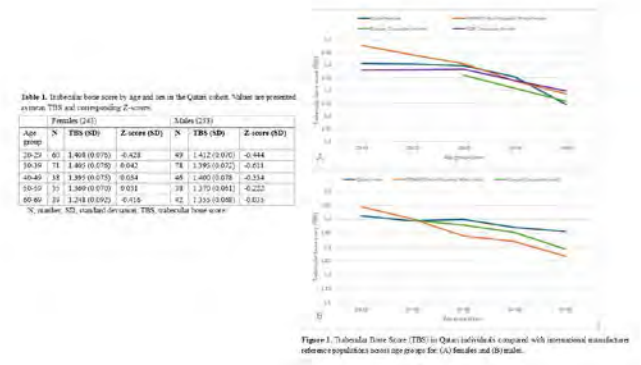
POPULATION-SPECIFIC REFERENCE DATA FOR BONE MINERAL DENSITY AND TRABECULAR BONE SCORE (TBS V4) IN HEALTHY QATARI ADULTS

O. Alsaed[1], F. Alam[1], A. Lutf[1], I. Abdulla[1], K. Hind[2,3], M. De Gruttola[3], M. Davies[3], S. Al Emadi[1], D. Hans[3,4]



[1]Department of Medicine (Rheumatology Division), Hamad Medical Corporation, Doha, Qatar; [2]Lancaster University, Lancaster, United Kingdom; [3]Medimaps Group SA, Geneva, Switzerland; [4]Center of Bone Diseases, Rheumatology Unit, Bone and Joint Department, Lausanne University Hospital & University of Lausanne, Lausanne, Switzerland

Objectives: Bone mineral density (BMD) and trabecular bone score (TBS) provide complementary assessments of bone mass and microarchitecture for osteoporosis and fracture risk assessment within the same DXA scan. However, reference data for both measures are largely derived from Western populations, and their applicability to Middle Eastern populations remains uncertain. This study aimed to establish normative BMD and TBS version 4 reference data in healthy Qatari adults and to compare these values with manufacturer-provided US NHANES reference standards.

Materials and Methods: This analysis included healthy Qatari men and women aged 20–69 years selected from the Qatar Biobank. Participants with medical conditions or medication use known to affect bone metabolism were excluded. BMD at the lumbar spine, femoral neck, and total hip was measured using GE Lunar iDXA systems and interpreted by ISCD-certified clinicians. TBS was derived from lumbar spine DXA using TBS Osteo Advanced version 4.0, incorporating correction for soft-tissue thickness. Mean BMD and TBS values were compared with US NHANES reference data using two-tailed t-tests.

Results: 477 lumbar spine scans and 497 hip scans were analysed. Lumbar spine BMD did not differ significantly between sexes across age groups, whereas hip BMD was consistently lower in women than men, particularly after age 50. Compared with NHANES, Qatari women aged 20–29 years exhibited significantly lower BMD with site- and age-specific differences persisting in older female age groups. In contrast, BMD in Qatari men was largely comparable to NHANES, with significantly higher total hip BMD observed in those aged 50–69 years. Mean BMD T-scores were predominantly within the normal range, with osteopenic mean values observed only at the femoral neck in women aged 60–69 years. TBS was generally within the normal range across all groups. Relative to NHANES, Qatari women demonstrated lower TBS at younger and older ages, while Qatari men showed higher TBS values in older age groups (40–69 years).

Conclusions: This study provides normative BMD and TBS v4 reference data for a healthy adult Qatari population. These data describe age- and sex-specific patterns of bone density and trabecular microarchitecture and may serve as a population-specific reference for future clinical and research applications.

P1297

LIPID-MUSCLE INTERACTIONS IN AGING: THE RELATIONSHIP BETWEEN TOTAL CHOLESTEROL AND PROBABLE SARCOPENIA

O. Can Ceylan[1], E. Ascı Civelek[1], E. Pinar[1], Z. Fetullahoglu Durmus[2], Z. Sahin Tirnova[1], T. Erdogan[1], S. Ozkok[1], G. Bahat[1], M. A. Karan[1]

[1]Istanbul University Istanbul Medical School, Department of Internal Medicine, Division of Geriatrics, Istanbul, Türkiye; [2]Sinop Atatürk State Hospital, Sinop, Türkiye

INTRODUCTION: Sarcopenia is a significant health issue that occurs as a result of the decrease in skeletal muscle mass and function with aging and increases the risk of frailty, falls and mortality in elderly individuals. The effects of lipid metabolism on muscle health are increasingly being investigated . It has been suggested that low cholesterol levels may be associated with the development of sarcopenia.
OBJECTIVES: This study aimed to investigate the relationship between total cholesterol levels and probable sarcopenia, as well as the effects of lipid metabolism on muscle health.
METHODS: Data from 328 patients aged ≥60 years who applied to a university geriatrics outpatient clinic between March 2018 and October 2023 were retrospectively analyzed. Demographic characteristics, history of chronic diseases, frailty status, probable sarcopenia assessment, and total cholesterol levels were obtained from patient records. Basic activities of daily living (ADL) were assessed using the KATZ Index, and instrumental ADL were evaluated using the LAWTON-BRODY scale. Frailty was assessed with the FRAIL scale, and nutritional status was evaluated with the Mini Nutritional Assessment–Short Form (MNA-SF). Body mass index (BMI) was calculated by dividing body weight (kg) by the square of height (m²). Handgrip strength was measured using a hand dynamometer, and low values were defined as probable sarcopenia. Low handgrip strength was determined according to cut-off values specific to the Turkish population (35 kg for men / 20 kg for women) . The association was evaluated using multivariable logistic regression analysis. The cholesterol level predicting probable sarcopenia was calculated via ROC analysis, and patients were divided into two groups based on the determined threshold value.
RESULTS: The mean age of the participants was 74.5 ± 6.8 years, and among the 147 patients (44.8%) identified with probable sarcopenia, 55.8% were women. In univariate analyses, male sex, frailty, malnutrition, dependence in instrumental activities of daily living (IADL), low BMI, and low cholesterol levels were significantly associated with probable sarcopenia ($p < 0.001$). In ROC analysis, the area under the curve (AUC) was 0.617 (95% CI: 0.562–0.670, $p = 0.0002$), with a sensitivity of 70.5% and specificity of 49.7%. The optimal cut-off value was determined as 216 mg/dL. In multivariable analyses including age, sex, BMI, and frailty, low cholesterol levels (≤216 mg/dL) remained an independent risk factor for probable sarcopenia [OR: 1.729, 95% CI (1.017–2.939), $p = 0.043$].
CONCLUSİON: Low total cholesterol levels were independently associated with probable sarcopenia. The findings support the role of lipid metabolism in muscle health and suggest that low cholesterol levels may be an important risk factor for probable sarcopenia.
Keywords: Sarcopenia, cholesterol, older adults

P1298

A SIMULTANEOUS EVALUATION OF MUSCLE AND BONE HEALTH IN PATIENTS WITH OBESITY USING REMS TECHNOLOGY

O. Di Vincenzo[1], M. C. Massari[1], E. Poggiogalle[1], L. M. Donini[1], S. Migliaccio[1]

[1]Department of Experimental Medicine, Food Science and Human Nutrition Unit, Sapienza University, Roma, Italy

Objective(s): Muscle and bone are closely interconnected tissues that ensure structural integrity, mobility and functional capacity. Alterations in this interplay contribute to musculoskeletal disorders, such as osteoporosis and sarcopenia, which often coexist, increasing frailty and fracture risk. In patients affected by obesity, bone mineral density (BMD) may appear preserved or increased, while bone quality is often compromised, contributing to increased fracture risk. Early assessment of musculoskeletal health is therefore crucial. This study aimed to evaluate bone and muscle health in patients with obesity using Radiofrequency Echographic Multi-Spectrometry (REMS), a non-invasive, radiation-free technology.
Materials and Methods: Caucasian individuals of both sexes, with a diagnosis of obesity (BMI ≥30 kg/m²) were enrolled and underwent REMS evaluation to assess both bone and muscle. Bone status at femoral site was assessed by the evaluation of bone density (BMD, T-score and Z-score) and quality (Fragility Score (FS), a dimensionless parameter ranging from 0 to 100 reflecting microarchitecture and skeletal fragility) parameters. Muscle status was evaluated at thigh through the REMS-Muscle Quality Index (MQI), which increases with muscle impairment.
Results: A total of $n = 38$ patients with obesity was included (mean age = 50.6 ± 13.4 years, BMI 33.19 ± 6.89 kg/m²). Patients with obesity showed higher BMD at femoral neck in comparison to controls (0.890 ± 0.120 g/cm²*vs*. 0.850 ± 0.100 g/cm²; $p < 0.05$). Although not statistically significant, a trend toward increased FS values was observed, suggesting worse bone quality in the obese group (31.84 ± 11.22 *vs*. 29.30 ± 10.66; $p = 0.3$). Interestingly, patients with obesity also showed higher MQI value at both the right (67.29 ± 14.13) and left thigh (65.5 ± 15.79), strongly suggesting impaired muscle quality.
Conclusion(s): These preliminary results suggest that REMS enables simultaneous assessment of bone and muscle using a single device, providing an integrated evaluation of musculoskeletal health. The presence of impaired muscle quality together with a trend toward reduced bone quality supports the concept of a coupled muscle-bone unit, with clinical relevance for early diagnosis and management.

P1299

VITAMIN D SUPPLY IN REHABILITATION AFTER TOTAL JOINT REPLACEMENT AND REVISION SURGERY

O. Döring[1]

[1]Rehabilitation Clinic Birkental, Bad Wildungen, Germany

It is well known that vitamin D deficiency can have a negative impact on bone metabolism, bone healing, bone quality, and thus also on the healing of an endoprosthesis.
In cases of deficiency, infections are more common and rehabilitation is delayed due to impaired strength and coordination, an increased risk of falls, higher levels of pain, and thus poorer function.
Materials and methods:
In an orthopedic rehabilitation clinic, vitamin D levels were determined 1-3 days after admission for follow-up treatment after total joint replacement over a period of 1 year.
Throughout 2025, the vitamin D levels of 1027 patients were recorded after primary total joint replacement and implant revision surgery procedures. The average age was 67.3 years. Vitamin D levels were measured on average 12 days postoperatively for hip and knee surgeries and 36.7 days for shoulder and ankle surgeries. Thirty-nine percent of all rehabilitation patients were taking a vitamin D supplement at the time of admission.
Results:
Male Female
< 12 ng/ml 16,3% 11,8%
12 bis <20 ng/ml 31,4% 19,4%
20 bis <30 ng/ml 33,6% 33,2%
30 - 51 ng/ml 18,7% 35,0%
>50 ng/ml 4,1%
Conclusion: Despite the known negative effect of vitamin D deficiency on outcomes after joint replacement surgery, in 2025, 394 of 1,027 patients (38.4%) still had vitamin D deficiency (values < 20 ng/ml) for postoperative rehabilitation, 144 (14.0%) of whom had severe deficiency (below 12 ng/ml). Taking 30 ng/ml as the threshold value (insufficient <30), 81.3% of men and 64.4% of women were affected.
Based on the study results presented, a recommendation for preoperative vitamin D supplementation must be made. Vitamin D levels should be determined 4-6 weeks prior to surgery (especially in the case of revision surgery) and supplementation should be initiated if necessary. Vitamin D monitoring during postoperative rehabilitation is also advisable. In addition, all patients who have to undergo bone surgery should have their levels determined and balanced at the hospital where they are being treated.

P1300

EFFECT OF ENZYME ANTIBODIES ON ENZYMATIC ACTIVITY IN PATIENTS WITH RHEUMATOID ARTHRITIS

O. Emelianova[1], A. Trofimenko[1], O. Rusanova[1], S. Spicina[1]

[1]FSBI"RICER"named after A. B. Zborovskiy", Volgograd, Russia

Autoantibodies to enzymes are detected in rheumatic diseases, but their pathological significance is unclear. Antibody formation to superoxide dismutase (SOD), glutathione reductase (GR), and catalase (CAT) in RA is currently a poorly understood problem. Considering the hyperproduction of reactive oxygen species in RD, one can expect a compensatory increase in the synthesis of antioxidants, which should lead to the inhibition of free radicals. However, in RA, there is an accumulation of secondary toxic products of free radical reactions, thus an imbalance between the production and utilization of oxygen is noted. The causes of this imbalance are unclear. One of the causes of this functional deficiency of enzymes is believed to be the formation of antibodies (AT) to them.
Objective: to study the effect of antibodies to superoxide dismutase, glutathione reductase and catalase on enzymatic activity in RA.
Materials and methods: The serum of 30 practically healthy individuals and 84 patients with RA undergoing inpatient treatment was studied. The activity was determined (according to the method of E. Dubinina, 1983) of SOD, GR and CAT, the level of antibodies (AT) to the enzymes was determined by the enzyme immunoassay method using magnetosorbents, which are granules of polyacrylamide gel with the inclusion of magnetic material and the corresponding antigen.
Results: SOD activity in the blood of donors was 40±2.5 units, GR - 115±3.9 units, CAT - 22.6±1.6 units. The level of AT to SOD in the serum of donors was 0.06±0.004 units, AT to GR - 0.055±0.004 units and AT to CAT - 0.048±0.003 units. It was found that in patients with stage I RA activity, there is a slight increase in the activity of SOD and GR ($p<0.05$), and CAT ($p<0.01$), as well as an increase in the content of AT to SOD and GR (p<and a decrease in the activity of CAT ($p<0.05$). In patients with stage II disease activity, a decrease in the activity of SOD, GR and CAT ($p<0.05$) and an increase in the number of AT to them ($p<0.01$) are observed. At stage III RA activity, compared with the parameters of patients with stage II RA activity, an increase in AT to SOD ($p<0.01$), GR ($p<0.05$), CAT ($p<0.05$) was noted, against the background of an increase in the activity of GR ($p<0.01$), SOD ($p<0.05$) and a decrease in the activity of CAT ($p<0.01$).
Conclusion: The activity of SOD, GR and CAT and the level of antibodies to them can serve as an additional criterion for expressing the degree of disease activity, reflecting the state of oxidative stress in rheumatoid arthritis.

P1301

COMPARISON OF PAIN, CENTRAL SENSITIZATION, FUNCTIONAL STATUS, AND QUALITY OF LIFE ACCORDING TO STENOSIS SEVERITY IN INDIVIDUALS WITH CHRONIC NECK PAIN

M. Sevgili[1], F. Taşpınar[2], O. Engin[3], B. Taşpınar[2]

[1]Izmir Democracy University, Institute of Health Sciences, Physiotherapy and Rehabilitation, Izmir, Türkiye; [2]Izmir Democracy University, Faculty of Health Sciences, Physiotherapy and Rehabilitation, Izmir, Türkiye; [3]Izmir Democracy University, Faculty of Medicine, Physical Medicine and Rehabilitation, Izmir, Türkiye

Objective:
This study aimed to evaluate central sensitization, functional status, proprioception, sensory function, and quality of life according to the severity of cervical spinal stenosis in individuals with chronic neck pain.
Materials and Methods:
This study included patients with chronic neck pain who attended the Physical Medicine and Rehabilitation Clinic and had undergone cervical MRI. Pain intensity was assessed using the Visual Analog Scale (VAS),

pressure pain threshold was measured with an algometer, and cervical range of motion was evaluated using a CROM device. Sensory function was assessed with the Semmes–Weinstein Monofilament Test, and proprioception was evaluated using the CROM device by measuring joint position error during target head position and neutral head position tests. Cervical stenosis severity was classified using the Kang grading system. Central sensitization was evaluated using the Central Sensitization Inventory, functional status with the Copenhagen Neck Functional Disability Scale, and quality of life with the SF-36 questionnaire.

Results:

Eighty-nine patients were included (mean age 49.7±14.1 years; 86.4% female). Increasing cervical stenosis severity was associated with reduced cervical rotation range of motion ($p<0.05$) and impaired proprioception, reflected by increased joint position error in flexion ($p=0.032$) and in the total joint position error calculated as the sum of errors across all movement directions ($p=0.030$). Sensory impairment was observed in the right C8 ($p=0.006$) and left C7 ($p=0.033$) dermatomes. Quality-of-life scores deteriorated with stenosis severity in the SF-36 energy/fatigue ($p=0.024$), emotional role limitations ($p=0.014$), general health ($p=0.012$), and emotional well-being ($p=0.037$) domains. No significant differences were observed between stenosis groups for the remaining clinical and functional parameters (all $p>0.05$).

Conclusion:

Greater severity of cervical spinal stenosis is associated with worsening sensorimotor function, reduced cervical mobility, and impaired quality of life in patients with chronic neck pain, highlighting the need for multidimensional assessment and rehabilitation strategies beyond structural imaging findings alone.

P1305

STRUCTURAL AND FUNCTIONAL STATUS OF PERIODONTAL TISSUES IN ADOLSCENTS WITH IDIOPATHIC SCOLIOSIS

O. Galkina[1]

[1]V.I. Vernadsky Crimean Federal University, Simferopol, Russia, Simferopol, Russia

Introduction. Osteoporosis is a systemic skeletal disease characterized by a reduction in bone mass per unit volume and disruption of bone microarchitecture. For a long time, osteoporosis was regarded as a disease of older age groups. It is now known that the origins of this condition lie in childhood and adolescence. Therefore, monitoring bone mass accumulation during childhood, adolescence, and the teenage years is of critical importance. Osteoporosis of the alveolar process is one of the many factors contributing to the development of periodontal diseases. Changes in periodontal tissues occur as a result of biochemical, endocrine, and immunological reactions. These same reactions underlie the pathogenesis of idiopathic scoliosis (IS). According to the literature, an increase in periodontal tissue diseases is observed during puberty. The World Health Organization reports that 100% of children at the age of 14 have gingivitis. The prevalence of localized and generalized periodontitis at the age of 15 is reported in 5–20% of cases and reaches 45% by the age of 19–20 years. During adolescence, idiopathic scoliosis also progresses (by 4–5 times). This age period corresponds to the main increase in bone mass (the final growth spurt) in both females and males. Therefore, this age interval is crucial for the prevention and treatment of inflammatory and dystrophic periodontal diseases.

Aim of the study. To investigate the condition of periodontal tissues in adolescents with grade I idiopathic scoliosis.

Materials and methods. A clinical and radiographic examination was performed in 38 adolescents aged 15–16 years (34 females and 14 males). Periodontal tissue status was assessed based on clinical findings and radiographic evaluation.

Results. An intact periodontium was identified in 3 individuals (7.89%). Chronic catarrhal gingivitis of varying severity was diagnosed in 27 individuals (71.05%). Chronic hypertrophic gingivitis, granulating form, was detected in 3 individuals (7.89%). Generalized chronic periodontitis, stage I severity, was found in 5 individuals (13.18%). Radiographic examination in cases of gingivitis revealed indistinct contours of the cortical plate of the interalveolar septa and, in some cases, osteoporosis of the cancellous bone at the apices of the interdental septa. In generalized periodontitis of stage I severity, osteoporotic changes of the interalveolar septa were observed, along with widening of the periodontal ligament space at the cervical regions of the teeth, indistinct contours of the compact bone plate, destruction of the cortical plate at the apices of the interalveolar septa, and destruction of the interalveolar septa up to one quarter of their height.

Conclusion. Adolescents aged 15–16 years with grade I idiopathic scoliosis require comprehensive diagnostic evaluation of periodontal tissue status. Timely preventive and therapeutic dental measures can help prevent the progression of periodontal diseases.

P1306

PREVALENCE OF DENTOFACIAL ANOMALIES IN ADOLESCENTS WITH GENERALIZED PERIODONTITIS ASSOCIATED WITH IDIOPATHIC SCOLIOSIS

O. Galkina[1]

[1]V.I. Vernadsky Crimean Federal University, Simferopol, Russia, Simferopol, Russia

Introduction. Contemporary scientific studies demonstrate a structural and functional interrelationship between the condition of the maxillofacial skeletal tissues and the axial skeletal system. It is well established that during childhood and adolescence approximately 45% of genetically determined bone mass is accumulated. By the end of puberty, this accounts for about 86% of total adult bone mass. During the same age period, 17-21% of genetically determined dentofacial anomalies are recorded, as well as up to 40% of cases of idiopathic scoliosis (IS).

Aim of the study. To investigate the prevalence of dentofacial anomalies in adolescents with generalized periodontitis of initial to stage I severity, depending on the degree of spinal deformity.

Materials and methods. A total of 152 adolescents (mean age 15.26 ± 0.04 years) with generalized periodontitis were examined and classified according to posture disorders: IS-0 (spinal curvature angle up to 5°, n = 44), IS grade I (curvature angle 5-10°, n = 69), IS grade II (curvature angle 11-30°, n = 25), and IS grade III (curvature angle 31–60°, n = 14). Dental status was assessed in all participants.

Results. The prevalence of soft tissue attachment anomalies was as follows: IS-0 – 34.09% (n = 15), IS-I – 46.38% (n = 32), IS-II – 72% (n = 18), IS-III – 78.57% (n = 11), overall – 50% (n = 76). A shallow oral vestibule

was identified in: IS-0 – 31.82% (n = 14), IS-I – 40.58% (n = 28), IS-II – 60% (n = 15), IS-III – 71.43% (n = 10), overall – 44.08% (n = 67). Tooth position anomalies were detected in: IS-0 – 68.18% (n = 30), IS-I – 82.61% (n = 57), IS-II – 92% (n = 23), IS-III – 100% (n = 14), overall – 81.58% (n = 124).

Conclusion. The prevalence of dentofacial anomalies in adolescents increases with the severity of spinal deformity. The findings indicate a predominant role of dentofacial anomalies and anatomical-topographical disturbances in the development of generalized periodontitis in adolescents with idiopathic scoliosis. This patient population requires an orthodontic component as part of comprehensive dental treatment.

P1307

LEVELS OF MOLECULAR REGULATORS OF BONE METABOLISM (OPG/RANKL) IN PATIENTS WITH JUVENILE RHEUMATOID ARTHRITIS

O. Galkina[1]

[1]V.I. Vernadsky Crimean Federal University, Simferopol, Russia, Simferopol, Russia

Introduction. In modern medicine, prevention, early diagnosis, and treatment of childhood diseases remain important priorities. Autoimmune diseases in children present particularly challenging problems. Over recent decades, there has been an increase in cases of juvenile rheumatoid arthritis (JRA). This disease is difficult to treat, tends to worsen over time, and can lead to disability. Therefore, once diagnosed, it's crucial to predict how the disease will progress – both overall and specifically regarding bone health. Two key factors that control the breakdown of bone cells are OPG and RANKL.

Objective. To study how bone metabolism is regulated by measuring OPG and RANKL levels.

Materials and methods. We examined 307 patients with JRA (average age: 11.09±3.08 years) using clinical and X-ray assessments. We measured OPG concentration in blood serum using a laboratory technique called enzyme-linked immunosorbent assay (ELISA), specifically using the "Human Osteoprotegerin Instant ELISA" test kit (eBioscience, Austria). RANKL levels in blood serum were determined using the "ampli-s-RANKL" reagent kit (Biomedica, Germany).

Results. The measurements of signaling mechanisms that regulate bone breakdown at the system level in JRA patients showed reduced normal bone formation activity. Specifically, we found decreased concentrations of OPG (43% lower, statistically significant) and RANKL (9.89% lower, not statistically significant), as well as a reduced OPG/RANKL ratio (41.7% lower, not statistically significant).

Conclusion. The imbalance we found in molecular regulators of bone metabolism indicates a disruption in the RANK/RANKL/OPG system. The sharp decrease in OPG reflected weak activity of this regulatory protein in eliminating mature bone-breakdown cells and reduced blocking of the connection between RANK and RANK-ligand. These negative changes in the natural bone remodeling process suggest a tendency toward osteoporosis (bone weakening) development in JRA patients.

P1308

CASE REPORT: STATIN-INDUCED NECROTIZING AUTOIMMUNE MYOPATHY(SINAM) IN A PATIENT WITH OSTEOPOROSIS

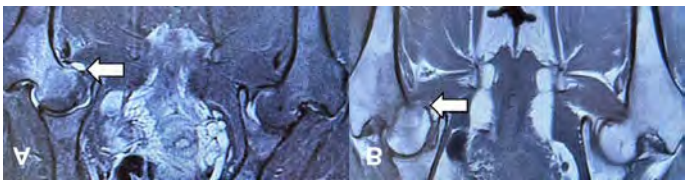
O. Gelaj[1], V. Duraj[2], C. Todhe[3]

[1]Department of Rheumatology,Italian Salus Hospital, Tirana, Albania; [2]Department of Rheumatology,Mother Theresa University Hospital Center, Tirana, Albania; [3]Department of Rheumatology,Regional Shkodra Hospital, Shkodra, Albania

Introduction: Statins are widely prescribed for the prevention of cardiovascular disease and are generally well tolerated. However, rare immune-mediated adverse effects such as statin-induced necrotizing autoimmune myopathy have been increasingly recognized. SINAM is associated with anti–HMG-CoA reductase antibodies and requires immunosuppressive treatment. The coexistence of osteoporosis complicates management due to the risks associated with long-term corticosteroid therapy.

Case Report: In this case report, we present a 68-year-old female patient with with a history of hyperlipidemia She had been receiving atorvastatin 20 mg daily for the past 3 years.She presented diffuse musculoskeletal pain for approximately two years, associated with poor nocturnal rest, which significantly limited her ability to perform normal daily activities. The patient reported progressive difficulty swallowing, noted over the recent period .Past medical history was notable for a previous right humeral fracture treated surgically, thyroid nodules, and left parathyroid hyperplasia. Surgical history included tonsillectomy and appendectomy. Thyroid and major salivary gland ultrasonography showed normal glandular architecture, with no locoregional macroadenopathy. There was a family history of autoimmune diseases (HSP) .Laboratory investigations revealed a significant rise in creatinine kinase (CK) 9872 IU (normal <170 IU/L), aspartate aminotransferase (AST) 75 U/L, alanine aminotransferase (ALT) 61 U/L, lactic dehydrogenase (LDH) 416 U/L. Inflammatory markers were mildly elevated. Despite discontinuation of statin therapy, CK levels and muscle weakness persisted. Densitometry: T-Score L1-L4 -3.2 T-Score neck f -3.2 T-Score tot -2.3. Physical examination revealed symmetric proximal muscle weakness in both upper and lower limbs, without sensory deficits. Electromyography demonstrated a myopathic pattern. Muscle biopsy revealed necrotic muscle fibers with minimal inflammatory infiltrates. Serological testing was positive for anti–HMG-CoA reductase antibodies,Ab anti-HMGCR (287),confirming the diagnosis of statin-induced necrotizing autoimmune myopathy.The patient was started on high-dose oral corticosteroids (prednisone 1 mg/kg/day) followed by intravenous immunoglobulin (IVIG) at 0.4 gm/kg daily for 5 days. She showed significant improvement of muscle strength. It was also,decided to initiate therapy with Denosumab, for osteoporosis, with careful monitoring and to continue vitamin D supplementation at 25,000 IU every two weeks.Over the following months, the patient showed significant improvement in muscle strength and gradual normalization of CK levels.

Conclusion:This case underscores the importance of considering statin-induced necrotizing autoimmune myopathy in patients with persistent muscle weakness and elevated CK levels despite statin cessation. Special attention should be given to comorbid conditions such as osteoporosis when planning long-term immunosuppressive therapy.



P1309

TRANSIENT OSTEOPOROSIS OF THE HIP COMPLICATED BY FEMORAL NECK FRACTURE DURING LACTATION: A CASE REPORT

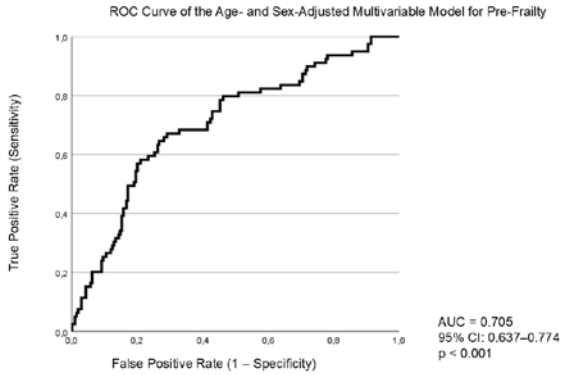
N. Yilmaz Cakmak[1], Y. Kinaci Gumuscubuk[2], O. Gumuscubuk[3]

[1]Ankara Bilkent City Hospital, Department of Internal Medicine, Palliative Care Center, Ankara, Türkiye; [2]Hacettepe University, Faculty of Medicine, Division of Occupational Medicine, Ankara, Türkiye; [3]Ankara University, Faculty of Medicine, Department of Geriatrics, Ankara, Türkiye

Objective(s):
Transient osteoporosis of the hip (TOH) is a rare, self-limiting disorder that typically occurs during late pregnancy or the early postpartum period. It presents with acute hip pain, functional limitation, and characteristic diffuse bone marrow edema on magnetic resonance imaging (MRI). The risk of insufficiency fracture may increase when lactation is accompanied by vitamin D deficiency.
Material and Methods:
We present the case of a 38-year-old woman who developed sudden inability to walk and severe right hip pain 11 months after her second delivery while actively breastfeeding. The patient reported no history of trauma or fall. She had no chronic illnesses and was not taking any medication. Written informed consent was obtained from the patient.
Results:
At presentation, her body mass index was 27 kg/m² and serum 25(OH) vitamin D level was 11.4 ng/mL. MRI revealed a nondisplaced femoral neck fracture with diffuse bone marrow edema involving the femoral head and neck, without subchondral collapse, findings highly suggestive of transient osteoporosis of the hip. Dual-energy X-ray absorptiometry (DEXA), performed 11 months after the fracture, showed preserved lumbar spine bone mineral density (L2-L4 Z-score: +1.2) but relatively lower femoral neck BMD (Z-score: −0.6) compared with lumbar spine, supporting a regional rather than systemic process. Serum calcium, phosphorus, alkaline phosphatase, and parathyroid hormone levels were within normal limits. The patient was managed conservatively with vitamin D supplementation and hip-protective exercises without antiresorptive therapy. After two months of supplementation, serum 25(OH) vitamin D level increased to 37 ng/mL. At 10-year follow-up, she remained asymptomatic with no additional fractures.
Conclusion(s):
This rare case illustrates transient osteoporosis of the hip during lactation complicated by femoral neck fracture and vitamin D deficiency. The regional pattern of bone involvement, characteristic MRI findings, absence of trauma, and benign long-term clinical course support the diagnosis of TOH rather than pregnancy- and lactation-associated osteoporosis. Selected patients may be successfully managed conservatively. Clinicians should consider TOH in lactating women presenting with acute hip pain and evaluate for modifiable risk factors such as vitamin D deficiency.
Figure 1 (A) Coronal T2-weighted fat-suppressed MRI showing diffuse hyperintense bone marrow edema involving the right femoral head and neck, without subchondral collapse. (B) Coronal T1-weighted MRI of the pelvis demonstrating diffuse hypointense signal in the right femoral head and neck, consistent with bone marrow edema.

P1310

CALF CIRCUMFERENCE IS INDEPENDENTLY ASSOCIATED WITH PRE-FRAILTY IN NON-SARCOPENIC, NON-MALNOURISHED OLDER ADULTS



O. Gumuscubuk[1], Y. Kinaci Gumuscubuk[2], H. Yesin[1], V. Atmis[1], M. Varli[1]

[1]Ankara University, Faculty of Medicine, Department of Geriatrics, Ankara, Türkiye; [2]Hacettepe University, Faculty of Medicine, Division of Occupational Medicine, Ankara, Türkiye

Objective
To evaluate the independent associations between anthropometric measures (peripheral and central) and pre-frailty among older adults without sarcopenia or malnutrition.
Materials and Methods
This is a retrospective observational study conducted in a community-dwelling older adult population. Individuals with sarcopenia (defined according to EWGSOP2 criteria) and malnutrition (based on the Mini Nutritional Assessment) were excluded.
Frailty status was assessed using the Turkish-validated version of the FRAIL Scale. Participants were categorized as robust (score = 0), pre-frail (score = 1–2), or frail (score ≥3), and individuals classified as frail were excluded from the analysis.
Data on age, sex, Charlson Comorbidity Index, waist-to-height ratio (as a marker of central adiposity), handgrip strength, arm circumference, and calf circumference were collected. A total of 600 individuals were screened. After applying exclusion criteria, 296 participants with complete data were included in the final analysis. Multivariable logistic regression analysis was used to identify independent associations, and the discriminative performance of the final model was evaluated using ROC curve analysis.
Results
Calf circumference was significantly higher in pre-frail participants compared with robust individuals (37.8 ± 4.6 cm vs 36.4 ± 3.3 cm, p = 0.011), whereas the difference in arm circumference was smaller and did not remain significant in multivariable analysis (31.2 ± 5.4 cm vs 29.7 ± 6.2 cm, p = 0.041).
In a multivariable logistic regression model including age, sex, comorbidity burden, central adiposity, muscle strength, and peripheral anthropometric measures, only calf circumference was independently associated with pre-frailty (OR 1.07 per cm, 95% CI 1.00–1.15, p = 0.046). ROC curve analysis showed acceptable discriminative performance (AUC = 0.705, 95% CI 0.637–0.774, p < 0.001).
Conclusion
Our findings suggest that the independent association between increased calf circumference and pre-frailty may not reflect preserved muscle mass, but rather early qualitative alterations in body composition, such as peripheral fat accumulation or reduced muscle quality.
Calf circumference is a simple, objective bedside measurement that may complement subjective frailty tools such as the FRAIL Scale and

help identify early vulnerability. Prospective studies which incorporate objective body composition methods are needed.

Figure 1. ROC curve of the age- and sex-adjusted multivariable model for predicting pre-frailty (AUC = 0.705).

P1311

CLINICAL AND ELECTROPHYSIOLOGICAL EFFECTS OF DOWNHILL TREADMILL WALKING IN PATIENTS WITH ISCHEMIC STROKE: A RANDOMIZED CONTROLLED STUDY

B. Yildiz[1], I. Midi[2], N. Karadağ Saygi[3], O. Keniş Coşkun[2]

[1]Emet state hospital, Kütahya, Türkiye; [2]marmara university, İstanbul, Türkiye; [3]Marmara University, İstanbul, Türkiye

ABSTRACT

Objective: Downhill walking on the treadmill has been shown to reduce the excitability of the spinal reflex arc. This study aimed to investigate the clinical and electrophysiological effects of downhill treadmill walking at different inclines in patients with ischemic stroke.

Material and Methods: This single-center, randomized, controlled, prospective, and single-blind study included 35 stroke patients, who were able to ambulate independently and had ankle flexor muscle spasticity levels between 1 and 3 according to the Modified Ashworth Scale (MAS). Participants were randomized into three groups: without inclination (control) group, a 7.5% incline group, and a 15% incline group . The intervention program consisted of a total of five rehabilitation sessions, administered five days a week. Clinical assessments (MAS, Fugl-Meyer Lower Extremity Scale, 2-Minute Walk Test, Timed Sit-to-Stand Test, Berg Balance Scale) were performed before and after five sessions. Electrophysiological measurements (Hmax/Mmax) were evaluated before, after one session, and after five sessions. The study has been registered at the ClinicalTrials.gov with the number NCT05833295.

Results: A total of 30 patients with a mean age of 50.3 ± 9.8 were included in the final analyses. After a single session of walking, a significant depression in the Hmax/Mmax ratio was observed only in the paretic lower extremities of patients walking on a -15% incline. Following the five-session intervention, statistically significant depression in the Hmax/Mmax ratios was observed in the paretic legs of patients in both the -7.5% and -15% incline groups, while no significant change was observed in the control group. Statistically significant improvements were observed in the 2-MWT and TUG scores in all groups, but this improvement was more pronounced in the -15% incline group compared to the control group.

Conclusion: Walking at a -15% incline stands out as an effective neurorehabilitation approach for modulating spasticity secondary to upper motor neuron damage after stroke.

P1312

SARCOPENIA AND PELVIC FLOOR DYSFUNCTION IN ELDERLY WOMEN: THE RELATIONSHIP AND IMPACT ON SEVERITY

F. Koman[1], S. Kanyılmaz[1], N. Bademler[2], O. Kuru[1]

[1]Department of Physical Medicine and Rehabilitation, Prof. Dr. Cemil Taşcıoğlu State Hospital, Istanbul, Türkiye; [2]Department of Obstetrics and Gynecology, Prof. Dr. Cemil Taşcıoğlu State Hospital, Istanbul, Türkiye

Objective: Sarcopenia, characterized by loss of muscle mass and strength, may be linked to pelvic floor dysfunction, yet few studies have investigated this association. This study aimed to evaluate the relationship between sarcopenia and pelvic floor dysfunctions (PFD), including urinary incontinence (UI), pelvic organ prolapse (POP), fecal incontinence (FI), and constipation in elderly women.

Materials and Methods: This cross-sectional observational study included 182 female patients aged ≥65 years. Risk of sarcopenia (SARC-F), muscle strength (grip strength), muscle mass (dual-energy X-ray absorptiometry), physical activity levels (Short Physical Performance Battery [SPPB] and gait speed) and presence of sarcopenia were compared between participants with and without urinary incontinence (self-report and ICIQ-SF), pelvic organ prolapse (POP-Q), fecal incontinence (self-report) and constipation (Rome IV).

Results: UI was present in 132 women. Among participants, 73.1% had probable sarcopenia and 5.4% had sarcopenia (2.7% confirmed, 2.7% severe). No significant association was found between sarcopenia and UI or its subtypes. Reduced muscle strength, gait speed, and SPPB scores were significantly associated with UI, and regression analysis identified lower muscle strength as an independent risk factor. Lower gait speed, SPPB scores, and appendicular skeletal muscle mass (ASM) were associated with UI severity. No relationship was observed between sarcopenia or its markers and POP, FI, or constipation. SARC-F scores were significantly associated with UI and showed a low positive correlation with UI severity (ICIQ-SF).

Table 1: Sarcopenia and related parameters according to urinary incontinence status

	Elder Women With UI (n=132)	Elder Women Without UI (n=50)	p
SARC-F score	3.53 ± 1.93	2.44 ± 1.79	0.001
Handgrip strength (kg)	17.06 ± 5.15	19.64 ± 5.34	0.004
Gait speed (m/s)	1.01 ± 0.26	1.10 ± 0.24	0.036
SPPB score	9.91 ± 2.08	10.76 ± 1.44	0.003
Sarcopenia	6 (4.5%)	4 (8%)	0.361

Conclusion: Sarcopenia markers may be valuable clinical indicators of UI and PFD in elderly women. Low hand grip strength appears to be a significant indicator for UI, suggesting that screening may be clinically useful. Muscle strength and physical performance may decline before muscle mass and could play a greater role in the development of UI and PFD. The SARC-F questionnaire also shows potential to predict UI, PFD, and UI severity.

Keywords: sarcopenia, pelvic floor dysfunction, urinary incontinence, pelvic organ prolapse

CALCIFICATION MARKERS, FGF23 AND SALT TRANSPORT: COMMON PATHWAYS IN NEPHROLITHIASIS, CRYSTALLURIA AND BONE METABOLISM

O. Nikitin[1], I. Kordubailo[1], O. Nishkumay[1], M. K.S. Chan[2], M. B.F. Wong[2]

[1]Bogomolets National Medical University, Kyiv, Ukraine;
[2]European Wellness Academy, Kota Kinabalu, Malaysia

Objectives

Nephrolithiasis (NL) is a common polyetiological urological disease that is frequently associated with reduced bone mineral density (BMD). One of the shared key factors contributing to both osteoporosis (OP) and NL is the activation of calcification factors, including osteopontin (OPN), osteocalcin (OC), and fibroblast growth factor 23 (FGF23). The aim was evaluating indices of salt transport, calcification markers (OPN, OC), and FGF23 in patients with nephrolithiasis and crystalluria.

Materials and Methods: The study was conducted at the Department of Urology, Bogomolets National Medical University. The assessment of salt transport, osteopontin, and FGF23 was carried out in a certified laboratory (Medical Laboratory "DILA," Kyiv, Ukraine). Osteocalcin measurement was carried out based on the Ukrainian Osteoporosis Center of the State Institution "Institute of Gerontology named after D.F. Chebotarev of the National Academy of Medical Sciences of Ukraine", Kyiv, Ukraine (Chief of the Center Prof. N.V. Grygorieva).

A total of 104 patients were enrolled: 21 men (20.19%) and 83 women (79.81%), with a mean age of 57 years [23–83]. Patients were divided into three groups: Group I: 41 participants without NL or crystalluria (28 women [68.3%], 13 men [31.7%]); mean age 58 years [50–65]. Group II: 39 participants with NL (22 women [56.4%], 17 men [43.6%]); mean age 55 years [52–61.5]. Group III: 24 participants with crystalluria (20 women [83.3%], 4 men [16.7%]); mean age 57.5 years [52.5–63.75].

Data processing was carried out using MS Excel and Statistica EZR version 1.62-2023 statistical programs.

Results: Higher rates of oxaluria were observed in patients with NL and crystalluria, which was predominant in the study groups compared to other indicators studied. The levels of calcification markers (OPN, OC) and FGF23 were significantly lower in patients Group I compared with those with NL and crystalluria. The level of FGF23 showed a positive association with serum phosphate levels, which is consistent with its physiological mechanism of action.

Conclusion: rising calcification markers (OPN, OC) and FGF23 might contribute to the mechanism of stone formation. Further study is needed to determine the specific changes these markers undergo in relation to changes in BMD.

P1314

BONE METABOLISM MARKER LEVELS IN ADOLESCENTS WITH IDIOPATHIC SCOLIOSIS, DEPENDING ON THE SEVERITY OF SPINAL CURVATION

O. P. Galkina[1], J. A. Dovbnya[1], V. B. Kaliberdenko[1], O. Y. Poleshchuk[1], M. V. Dovbnya[1]

[1]V.I. Vernadsky Crimean Federal University, Medical Academy named after S.I. Georgievsky, Simferopol, Russia

Objective: Early prevention of idiopathic scoliosis (IS) requires a thorough understanding of the disease's pathogenesis. Modern bone metabolism diagnostic methods offer the potential for predicting the development and progression of IS and for tailoring treatment and prevention to an individualized approach.

Material and Methods: We observed 152 adolescents aged 15-16 years (62 boys and 90 girls) with varying degrees of spinal deformity, including poor posture, grade 1 scoliosis, grade 2 scoliosis, and grade 3 scoliosis. The average age was 15.26±0.04 years. Levels of bone metabolism markers were measured: serum osteocalcin (OC) (an indicator of osteosynthesis) and urinary deoxypyridinoline (DPD) (an indicator of osteoresorption). The control group (CG) consisted of 20 apparently healthy peers.

Results: Depending on the degree of IS in the group of subjects, the level of OKC gradually decreased in comparison with the age norm (93.4 ± 14.1 ng / ml) and with the CG (96.66 ± 2.17 ng / ml) ($p < 0.001$) and was: with NO - 81.41 ± 0.98 ng / ml, scoliosis of the first degree - 77.34 ± 0.98 ng / ml, scoliosis of the second degree - 70.84 ± 0.82 ng / ml, scoliosis of the third degree - 66.41 ± 0.69 ng / ml When assessing bone resorption depending on the degree of IS, the level of DPD in case of posture disorders was within the age norm (41.55 ± 1.78 nmol DPD / mmol Cr), but higher in comparison with the CG ($p < 0.05$). In grades I and II scoliosis, the values approached the normal range (53.21 ± 1.08 nmolDPD/mmolCr and 58.55 ± 2.61 nmolDPD/mmolCr, respectively), but were also significantly higher compared to the control group ($p < 0.001$). In grade III scoliosis, the DPD concentration was 64.74 ± 4.21 nmolDPD/mmolCr, which is significantly higher than the age-appropriate norm and the control group ($p < 0.001$).

Conclusions: Biochemical indicators of bone remodeling, osteocalcin and deoxypyridinoline, are early markers of processes occurring in bone tissue. Studying their levels can be used in a differentiated approach to developing treatment and preventive programs for idiopathic scoliosis, as well as for comorbid conditions.

P1315

PERIODONTAL TISSUE CONDITION IN HIV-INFECTED PATIENTS AFTER COVID-19

O. P. Galkina[1], A. V. Grokhotova[1], V. B. Kaliberdenko[1], M. V. Dovbnya[1]

[1]V.I. Vernadsky Crimean Federal University, Medical Academy named after S.I. Georgievsky, Simferopol, Russia

Objective: Processes occurring in bone tissue are reflected in the condition of dental hard tissues and periodontal tissues. A strong correlation between laboratory parameters of bone metabolism and paraclinical periodontal indices has been repeatedly described in scientific studies. Currently, periodontal pathology is considered by authors to be a comorbid condition associated with arthropathies, dorsopathies, and other musculoskeletal disorders. Furthermore, studying the condition of periodontal tissues in HIV-infected patients is relevant. This category of patients has varying degrees of impaired bone remodeling. These changes are undoubtedly characteristic of both the musculoskeletal system in general and periodontal tissues in particular. Osteoclast activity and osteoblast apoptosis are known to increase with prolonged infection and viremia.

Material and Methods: A dental examination was conducted on 103 HIV-infected patients aged 35-44 years who had recovered from COVID-19 (the study group). The comparison group (CG) consisted of 27 HIV-infected patients with no history of coronavirus infection. The community periodontal index (CPI) was used in accordance with WHO recommendations.

Results: The prevalence of periodontal pathology in both study groups was 100%. In the primary group, the following were recorded: codes 1 and 2 (gingival bleeding, tartar, and periodontal pocket up to 3 mm) – in 7.77% of cases (n=8); code 3 (periodontal pocket up to 4-5 mm deep) – 23.3% (n=24); code 4 (periodontal pocket more than 6 mm) – 68.93% (n=71). In the primary group, the following were noted: codes 1 and 2 – in 14.81% of cases (n=4); code 3 – in 70.38% (n=19); code 4 – in 14.81% (n=4).

Conclusions: HIV-infected patients who recovered from COVID-19 show progression of periodontal pathology, which is registered by an increase in the depth of periodontal pockets. This is a direct sign of a decrease in the height of the interalveolar septum of the jaw bone. This category of patients requires a differentiated approach in the treatment of periodontal tissue pathology, taking into account the underlying pathology, secondary and opportunistic infections.

P1316

INFLUENCE OF LUMBAR SPINAL STENOSIS ON FUNCTIONAL RECOVERY AFTER HIP FRACTURE SURGERY

K. Mokmongkolkul[1], P. Sarasombath[1], C. Chaichankul[1], P. Gajaseni[1], O. P. Phruetthiphat[1]

[1]Phramongkutkalo Hospital, Bangkok, Thailand

Background

Fragility hip fractures in the elderly are associated with high mortality and a decline in functional outcome. Vertebral fractures are the most common osteoporotic fractures in the elderly population. Many previous studies identified the association of hip fracture and osteoporotic vertebral compression fracture (OVCF), particularly regarding recovery and functional outcomes. Generally, the umbar spinal stenosis (LSS) frequently coexists with hip fractures in older adults and may impair postoperative recovery. However, data is lacking on the functional outcome in those patients with hip fracture and LSS. We evaluated whether concomitant LSS adversely affects functional outcomes after hip fracture surgery and explored LSS-related subgroups.

Methods

We retrospectively analyzed 270 patients undergoing hip fracture surgery (Non-LSS=184; LSS=86). Outcomes included Harris Hip Score (HHS) at 3, 6, and 12 months; Timed Up and Go (TUG) at 2 weeks, 6 months, and 12 months; and Oswestry Disability Index (ODI) at preoperative, 3, 6, and 12 months. Group comparisons used Welch's t-tests. Subgroup analyses within LSS evaluated stenosis level (single vs multi-level) and severity (Lee grade 1-3).

Results

Compared with Non-LSS, the LSS group had significantly lower HHS at 3 and 6 months [70.8 ± 9.6 vs 75.9 ± 8.8 (p = 0.0004), 79.9 ± 8.9 vs 83.7 ± 8.3 (p = 0.0011), respectively] and higher ODI at 6 months [28.4 ± 7.9 vs 24.3 ± 6.8 (p = 0.0001)], while differences attenuated by 12 months [88.4 ± 8.1 vs 89.6 ± 7.5 (p = 0.282)]. TUG at 6 months was significantly slower in LSS [17.2 ± 3.8 vs 15.1 ± 3.5, p = 0.002)], with no significant difference at 2 weeks or 12 months. Within LSS, multi-level stenosis showed poorer HHS at 6 months versus single-level, and higher Lee grade was associated with worse HHS, indicating a dose–response pattern. Age and ASA classification were comparable between groups.

Conclusions

The presence of coexisting Lumbar Spinal Stenosis (LSS) in hip fracture patients was associated with significantly poorer functional recovery in the early to-mid-term following hip fracture surgery, particularly noted between 3 and 6 months post-operation. Crucially, this difference was not sustained at the 12-month follow-up. Furthermore, factors such as multi-level spinal involvement and a higher Lee grade served to identify patients at greatest risk, underscoring the necessity for early recognition and tailored rehabilitation strategies.

P1317

RELIGIOUS PRACTICES IN PATIENTS WITH KNEE OSTEOARTHRITIS: ASSOCIATED FACTORS AND IMPACT ON PATIENT OUTCOMES

O. Rania[1], M. Kaouther[1], K. Lobna[1], M. Fatma[1], B. Dorra[1], C. Ines[1], K. Dhia[1], H. Wafa[1]

[1]institut Mohamed Kassab d'orthopédie, Tunis, Tunisia

Introduction: Knee osteoarthritis (OA) is a chronic condition with diverse therapeutic strategies. Since spirituality and religion contribute to psychological resilience in chronic diseases, examining factors associated with religious practices among knee OA patients remains important.

Objective: To evaluate the impact of knee OA on religious practices and beliefs, and to identify the main associated factors.

Material and Methods: A cross-sectional study including symptomatic knee OA patients. Socio-demographic, disease characteristics and imaging data were collected. Health status and psychological impact were assessed using SF-36 and HADS for anxiety and depression. Religious aspects were evaluated using a 25-item self-developed questionnaire assessing four dimensions: religious beliefs, religious and spiritual practices, assistance-seeking, and feelings.

Results: Forty-one knee OA patients were included. Male-to-female ratio was 6/35. The mean age was 58 ± 10 years [37-78].Most patients had mild to moderate radiographic changes. Regarding religious practices, 30 patients reported frequent practice. Thirty five experienced difficulties. The most affected practice was prayer, 27 patients reported praying while seating. During Ramadan, 11 patients reported difficulty to fast. To cope with these difficulties, 17 patients asked for help from doctors, 5 turned to family or friends, and 10 remained silent. Patients who practiced religion more frequently had lower pain intensity and Patient Global Assessment scores (**p = 0.001 and 0.01**), as well as lower anxiety, depression, and pain PCS scores (**p = 0.003, 0.002, and 0.005**, respectively). No significant associations were found between frequency of religious practice and age, sex, time to diagnosis, disease duration, or radiographic stage of knee OA. Functional rehabilitation was linked to fewer changes in religious practices (**p = 0.04**), particularly with fewer difficulties in performing prayer (**p = 0.05**). Radiographic stage of knee OA was not associated with difficulties in performing prayer. Difficulties in religious practices were associated with poorer quality of life assessed with SF-36 scores < 50; (**p = 0.01**) and higher HADS anxiety (**p = 0.05**) and PCS scores (**p = 0.04**).
Conclusion: Difficulties in religious practices were related to psychological distress more than to structural joint damage itself, so that considering spiritual dimensions is crucial for optimal care.

P1318

AUTOIMMUNITY TO CERULOPLASMIN IN PATIENTS WITH RHEUMATOID ARTHRITIS AND SYSTEMIC LUPUS ERYTHEMATOSUS

O. Rusanova[1], A. Trofimenko[1], O. Emelianova[1]

[1]FSBI"RICER"named after A. B. Zborovskiy", Volgograd, Russia

The primary role of free radicals in rheumatoid arthritis is their ability to damage proteins, lipids, and DNA, imparting autoantigen properties to them and triggering antibody production. This is achieved by increasing the production of reactive oxygen species (ROS), which, in turn, oxidize proteins, cause lipid peroxidation, stimulate the release of proteolytic enzymes and vasoactive amines, and are responsible for enzyme inactivation and transformation, as well as suppression of the functional activity of immune cells. The body's antioxidant system (AOS), which includes enzymatic and non-enzymatic components, naturally prevents the pathological effects of ROS on its own tissues. The main enzymatic components of the AOS are glutathione peroxidase (GP), superoxide dismutase (SOD), glutathione reductase (GR), catalase (CAT), and ceruloplasmin (CP). They neutralize highly active superoxide anions, hydrogen peroxide, and fatty acid hydroperoxides, preventing the accumulation of particularly toxic secondary lipid peroxidation products. The formation of antibodies to these enzymes is believed to be one of the causes of antioxidant enzyme deficiency in rheumatoid arthritis and systemic lupus erythematosus.
OBJECTIVE: To study the formation of autoantibodies to antioxidant defense system enzymes and ceruloplasmin in rheumatoid arthritis and systemic lupus erythematosus.
MATERIALS AND METHODS: The serum of 75 patients with RA and 68 patients with systemic lupus erythematosus (SLE) treated in the rheumatology department of Volgograd City Clinical Hospital No. 25 served as a control. Thirty apparently healthy individuals, donors from the blood transfusion center, served as a control. Commercially available antigens were used: CP- "Diagnostic Purified Liquid Human Ceruloplasmin," St. Petersburg, Russia. Antibodies to the enzymes were determined by enzyme immunoassay with antigen fixation in magnetically controlled sorbents using the Gontar method. Resultswere expressed as optical density units (ODU).
RESULTS: In the sera of 75 patients with RA, elevated levels of antibodies to CP were found in 74.6% (56 patients). In patients with grade I activity, 11 patients (68.7%) had an elevated level of AT to CP. With grade II, in 36 people (75%). In the third group, in 9 people (81.8%). In patients of the first group, the antibody level was 0.097±0.014 U.O.P., in group II 0.139±0.011 U.O.P., in group III 0.182±0.02 U.O.P. The antibody level in the control group was 0.02±0.06 U.O.P. Out of 68 patients with SLE, 32 patients had an elevated level of antibodies to ceruloplasmin. Of the 14 patients with minimal activity, two (14.3%) had a significant increase in the level of antibodies to CP. With a moderate activity, 10 out of 21 patients (47.6%) had a moderate activity. Of the 33 patients with a high activity, 20 (60.6) had an increased level of antibodies to CP. The level of AB to CP in the first group was 0.389±0.432 U.O.P., in the second group 0.705±0.596 U.O.P., in the third group 0.886±0.556 U.O.P.
CONCLUSIONS: In RA and SLE, the formation of antibodies to antioxidant enzymes is observed, depending on disease activity. Detection of antibodies can serve as an additional criterion for expressing the degree of disease activity.
CONCLUSION: The study revealed elevated levels of antibodies to ceruloplasmin, which significantly differed from those in healthy individuals. A statistically significant relationship was found between the level of antibodies to enzymes and disease activity

P1319

VDMT FOR NEUROMA PREVENTION IN TRANSTIBIAL AMPUTATION AFTER MINE-BLAST INJURY

O. Smyk[1], O. Buryanov[2]

[1]Military Medical Clinical Treatment and Rehabilitation Center, Irpin, Ukraine; [2]Bogomolets National Medical University, Kyiv, Ukraine

Background: Mine-blast injuries often result in the destruction of the distal parts of the lower extremity and are among the most common causes of below-knee amputations (BKA) in combat-related trauma. Such amputations are associated with a high risk of both early and late complications. One of the most frequent late complications is the formation of symptomatic neuromas, which may lead to PLP and RLP. According to current data, the incidence of symptomatic neuromas following BKA ranges from 14% to 35%. The superficial peroneal nerve (SPN) is most commonly affected (up to 89.7% of cases). Reinnervation techniques such as RPNI, VDMT, and TMR have demonstrated high efficacy in both the treatment and prevention of neuroma formation.
Material and methods: From 2022 to 2023, 64 patients with mine-explosive injuries underwent transtibial amputations. All patients were divided into two equal groups (32 patients each). In the main group, traction neurectomy was performed on the tibial, deep peroneal, sural, and saphenous nerves, while the SPN was treated using the VDMT method. A muscle flap from the anterior tibial muscle, excised below the level of amputation and raised on the anterior tibial vessels, was used to envelop the cut end of the SPN and placed in the deep, non-load-bearing surface of the residual limb. In the control group, traction neurectomy was performed on all listed nerves without the VDMT technique. Outcomes were assessed at 12 and 24 months postoperatively.
Results: Pain levels in both groups were assessed using the Visual Analog Scale (VAS). At 12 months, the mean VAS score in the main group was 2.12 ± 0.60, compared to 3.94 ± 0.82 in the control group. At 24 months,

the scores were 1.68 ± 0.41 and 5.74 ± 0.96, respectively. Ultrasound examination of the residual limbs at 24 months revealed no neuromas of the SPN in the main group, whereas 15 patients (48.0%) in the control group had such neuromas, 9 of whom (28.1%) had symptomatic neuromas requiring surgical intervention.
Conclusion: The VDMT technique is an effective method for preventing the formation of symptomatic neuromas of the SPN during transtibial amputation. Its application significantly reduces pain intensity, improves limb function and quality of life, and decreases the need for reoperations.

P1320

VITAMIN D AND BONE METABOLISM IN NON-ALCOHOLIC, NON-VIRAL LIVER CIRRHOSIS

O. Spasskaya[1], A. Gorbacheva[1], I. Tikhonov[2], A. Kairieva[1], E. Litvinova[1], H. Bagirova[1], A. Eremkina[1], N. Mokrysheva[1]

[1]Endocrinology Research Centre, Moscow, Russia; [2]Sechenov University, Moscow, Russia

Background.
Chronic liver diseases and liver cirrhosis (LC) are associated with an increased risk of mineral and bone disorders, including hepatic osteodystrophy, impaired bone quality, and fractures. The liver plays a central role in vitamin D metabolism, protein synthesis, and calcium homeostasis, and disruption of these functions may contribute to skeletal complications. Although reduced bone mineral density (BMD) has traditionally been used to assess bone involvement in LC, accumulating evidence suggests that alterations in bone microarchitecture may occur early and are not always accompanied by a decrease in BMD. Data on vitamin D metabolism, parathyroid hormone (PTH), and bone microarchitecture assessed by trabecular bone score (TBS) in patients with non-alcoholic, non-viral LC remain limited, particularly in relatively young patients without classical osteoporosis risk factors.
Aim.
To evaluate mineral metabolism, vitamin D metabolism, and bone tissue characteristics in patients with non-alcoholic, non-viral liver cirrhosis and to identify clinically relevant markers of bone impairment in this population.
Materials and Methods.
This cross-sectional pilot study included 45 patients with liver cirrhosis and 20 age- and sex-matched healthy volunteers. All participants underwent anthropometric assessment and comprehensive laboratory evaluation of mineral and bone metabolism, including measurements of total and ionized calcium, phosphate, magnesium, PTH, and insulin-like growth factor-1 (IGF-1). A detailed panel of vitamin D metabolites, including 25-hydroxyvitamin D and its downstream metabolites, was measured using liquid chromatography–tandem mass spectrometry. Bone mineral density was assessed by dual-energy X-ray absorptiometry at the lumbar spine, proximal femur, and distal radius. Bone microarchitecture was evaluated using trabecular bone score (TBS), and screening for vertebral compression fractures was performed using spinal radiography.
Results.
Patients with LC demonstrated significant disturbances of mineral metabolism compared with healthy controls, including lower levels of total and ionized calcium, PTH, and IGF-1. A pronounced deficiency of 25-hydroxyvitamin D was observed in the LC group, accompanied by significantly reduced concentrations of 24,25-dihydroxyvitamin D, while levels of 1,25-dihydroxyvitamin D were comparable between groups. Despite the absence of significant differences in absolute BMD values, patients with LC exhibited a markedly lower TBS, indicating impaired bone microarchitecture. Correlation analysis revealed positive associations between TBS and several vitamin D metabolites, whereas no significant correlations were identified between BMD and PTH levels.
Conclusion.
Non-alcoholic, non-viral liver cirrhosis is associated with complex disturbances of mineral metabolism, including vitamin D deficiency, hypocalcemia, reduced PTH and IGF-1 levels, and deterioration of bone microarchitecture despite preserved BMD. Trabecular bone score appears to be a sensitive marker of early bone involvement in this population and may complement standard BMD assessment in patients with liver cirrhosis.
Funding.
This work was supported by the Russian Science Foundation (RSF), grant number 24-25-00348, "Disorders of vitamin D metabolism and features of bone remodeling in patients with liver cirrhosis of various etiologies."

P1321

A BIBLIOMETRIC ANALYSIS OF THE TOP 100 MOST-CITED ARTICLES IN FIELD OF MACHINE LEARNING AND BONE FRACTURE DETECTION

M. Golabchi[1], M. Dehghanpour Abyaneh[2], O. Tabatabaei-Malazy[3], B. Larijani[4]

[1]Department of Energy (DENERG), Politechnico Di Torino, 10129 Torino,, Torino, Italy; [2]Department of Mechanical and Aerospace Engineering (DIMEAS), Politechnico Di Torino, 10129 Torino,, Torino, Italy; [3]Non-Communicable Diseases Research Center, Endocrinology and Metabolism Population Sciences Institute, Tehran University of Medical Sciences,, Tehran, Iran; [4]Endocrinology and Metabolism Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences,, Tehran, Iran

Objective: Recently, it has more emphasis on the role of artificial intelligence in early detection of bone fractures. We aimed in current bibliometric study to analysis the top 100 most-cited published papers on this topic to map the field's structure and influence. We especially want to identify subject area of these papers, the most productive countries, institutions, the first top cited paper and its citation number, and main journals.
Material and Methods: We performed a comprehensive search in the Scopus database up to 4 Nov 2025. After excluding book chapters, and non-English language papers, we assessed the top 100 most-cited papers. The bibliometric metrics were analyzed using the "analyze results" tool in Scopus.
Results: Among, 100 top-cited papers, the first top-cited study was published in 2018, with 751 citations out of a total 29284 citation number (2.56%). This paper entitled "Deep learning algorithms for detection of critical findings in head CT scans: a retrospective study" was an original study published in "The Lancet", impact factor (IF): 88.50, and CiteScore 87.60. Research articles were the most common type of publications (n=81, 81.0%). The main subject area of the papers was medicine (n=84, 84.0%). The US was the most productive country (n=35, 35.0%), followed by China (n=13, 13.0%). The main journals were "Radiology" (IF: 15.2), "European Radiology" (IF: 4.7), "Scientific Reports" (IF: 3.9), and "Acta Orthopaedica" (IF: 2.4), each contributing 6 papers. The top three affiliations were from US; "Massachusetts General Hospital" (5 papers), followed by "Harvard Medical School", and "NYU Grossman School of Medicine", each contributing 4 studies.

Conclusions: Our results showed the US and China as the top-ranked countries in terms of publications, but the US as top-institutions in affiliations of the researchers. Moreover, "The Lancet" was the main journal for publishing top-cited paper in this field.
Keywords: Artificial intelligence, Fracture, Bibliometric

P1322

IMPACT OF STATINS ON BONE HEALTH; A BIBLIOMETRIC ANALYSIS OF THE SCIENTIFIC PUBLICATIONS OF MENA COUNTRIES

S. Akbarpour[1], O. Tabatabaei-Malazy[2], B. Larijani[3]

[1]Non-Communicable Diseases Research Center, Endocrinology and Metabolism Population Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran; [2]Non-Communicable Diseases Research Center, Endocrinology and Metabolism Population Sciences Institute, Tehran University of Medical Sciences,, Tehran, Iran; [3]Endocrinology and Metabolism Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences,, Tehran, Iran

Objective: It is shown beneficial effects of statins on bone health. We aimed to conduct a bibliometric analysis of scientific publications from countries in the Middle East and North Africa (MENA) region over the past 15 years in this field.
Material and Methods: We carried out a bibliometric study through a comprehensive search of Scopus database up to 12 Nov. 2025. We identified publication trend, the most productive countries and institutions, main journals, and the most prominent research topics in the field. Bibliometric analysis was conducted by "analyze results" tool available in Scopus, and VOSviewer 1.6.20.
Results: After assessing 169 records, 80 relevant studies were included in the analysis. A time trend in publications was shown with the highest number in 2025 (n=13, 16.25%). Main type of the papers was original articles (n=62, 77.5%). Top three productive countries were Iran (n=38, 47.5%), Egypt (n=21, 26.25%), and Saudi Arabia (n=15, 18.75%). The majority of the published papers appeared in dental and pharmacology-related journals (n=27, 33.75%). The total citation number was 1,163. The highest cited paper (138) was a review article entitled "Potential mechanisms and applications of statins on osteogenesis: Current modalities, conflicts and future directions", published in "J Control Release", impact factor: 11.5. Top three ranked institutes in producing these documents were "Tehran University of Medical Sciences", Iran (n=10, 12.5%), followed by "Ain Shams University" (n=7, 8.75%) Egypt, and then "Cairo University" (n=6, 7.5%) Egypt. Top keywords included "bone density", "bone regeneration", "osteoporosis", "osteoblast", "bone development", and "bone metabolism".
Conclusions: There is a large research output in field of impact of statins on bone health among MENA countries. We found a leading position for Iran as top productive country, supported by its prominent institutes. Pharmacology- and dental-related journals were the main sources for disseminating of influential publications in the studied field.
Keywords: Statin, Bone, Bibliometric.

ARTIFICIAL INTELLIGENCE–BASED DETECTION OF BONE BIOMARKERS IN OSTEOARTHRITIS: A BIBLIOMETRIC ANALYSIS

M. Dehghanpour Abyaneh[1], M. Golabchi[2], O. Tabatabaei-Malazy[3], B. Larijani[4]

[1]Department of Mechanical and Aerospace Engineering (DIMEAS), Politechnico Di Torino, 10129 Torino,, Torino, Italy; [2]Department of Energy (DENERG), Politechnico Di Torino, 10129 Torino,, Torino, Italy; [3]Non-Communicable Diseases Research Center, Endocrinology and Metabolism Population Sciences Institute, Tehran University of Medical Sciences,, Tehran, Iran; [4]Endocrinology and Metabolism Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences,, Tehran, Iran

Objective: Currently, it has shown the role of artificial intelligence in diagnosis of osteoarthritis. We assessed in current study the bibliometric status of the published scientific papers in this topic to identify their subject areas, the most productive countries/institutions, total citation number of the studies, the highest-cited paper, and main journal for dissemination of the studies.
Material and Methods: We conducted a comprehensive search in the Scopus database up to 20 Dec. 2025. After excluding book chapters, non-related subject area, and non-English language published papers, we assessed the bibliometric characteristics of the remaining papers using the Scopus "analyze results" tool.
Results: Out of the 127 records retrieved, 60 documents were relevant to our topic. The highest-cited paper was published in 2022, and had 100 citation number of the 769 total citations (13.0%). This was an observational study entitled "Osteoarthritis endotype discovery via clustering of biochemical marker data", published in "Annals of the Rheumatic Diseases", with an impact factor: 20.6, and CiteScore: 33.20. The majority of the papers was published in 2025 (n=17, 28.3%), indicating with an increasing time trend in publications. Research and review articles were the most common type of publications, respectively (n=37, and 12). The main subject area was "Medicine" (n=44, 73.3%), followed by "Biochemistry, Genetics and Molecular Biology" (n=14, 23.3%). The top three productive countries were the US (n=20, 33.3%), China (n=13, 21.7%), and UK (n=9, 15.0%). The main journal was " Osteoarthritis and Cartilage " (impact factor: 9.0), contributing 4 papers. The top three affiliations were from the US: "The University of North Carolina at Chapel Hill" (5 papers), "Harvard Medical School" (4 papers), and "UNC School of Medicine" (4 papers).
Conclusions: Our results showed that the US, China, and UK were as the top-ranked countries in terms of publications, and the US institutions also dominated researcher affiliations. Moreover, "Annals of the Rheumatic Diseases" was the main journal for publishing the highest-cited paper in this field.

CARDIOVASCULAR DISEASE AND RISK OF FALLS AMONG IRANIAN ADULTS: EVIDENCE FROM A NATIONAL FOLLOW-UP COHORT STUDY

H. Ataei-Goujani[1], M. Khojasteh[1], Y. Azizpour[2], O. Tabatabaei-Malazy[3]

[1]Non-Communicable Diseases Research Center, Endocrinology and Metabolism Population Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran; [2]Endocrinology and Metabolism Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences,, Tehran, Iran; [3]Non-Communicable Diseases Research Center, Endocrinology and Metabolism Population Sciences Institute, Tehran University of Medical Sciences,, Tehran, Iran

Objective(s): Assessment the association between cardiovascular disease and the risk of falls among Iranian adults.
Method: This study used data from the STEPS follow-up study, a nationally representative longitudinal prospective cohort established four years after the 2021 STEPwise Approach to Noncommunicable Disease Risk Factor Surveillance. Participants aged 18 years and older who completed both baseline and follow-up assessments were included. Cardiovascular disease at baseline was defined based on self-reported physician diagnosis of heart attack, angina (chest pain from heart disease), or stroke (cerebrovascular accident). History of falls outcome on the follow-up study during the preceding four years was assessed through standardized telephone interviews. Incidence of falls was estimated separately for participants with and without cardiovascular disease. Group differences were examined using the chi-square test. Statistical analyses were conducted using Stata version 17.
Results: Among 8,655 eligible participants, 637 reported a history of cardiovascular disease. The study population consisted of 55.10% females (95% confidence interval [CI]: 53.93–56.27) and 44.90% males (95% CI: 43.73–46.07). Overall, the incidence of falls was higher among individuals with cardiovascular disease compared with those without. The incidence of falls among individuals with cardiovascular disease was 7.21% (95% CI: 5.25–9.83), whereas the corresponding estimate among participants without cardiovascular disease was 4.08% (95% CI: 3.62–4.60). This difference was statistically significant (P value < 0.001), indicating a higher risk of falls in the cardiovascular disease group.
Conclusion: Cardiovascular disease is associated with a significantly increased risk of falls among Iranian adults. Given the clinical and public health consequences of falls, particularly in ageing populations, these findings underscore the importance of integrating fall risk assessment and prevention strategies into the management of individuals with cardiovascular disease.

P1325

A CROSS-SECTIONAL STUDY OF DAIRY CONSUMPTION AMONG NEWLY ADMITTED STUDENTS AT TEHRAN UNIVERSITY OF MEDICAL SCIENCES

Y. Azizpour[1], A. Gharajeh[1], H. Ataei-Goujani[2], P. Zarepour[2], O. Tabatabaei-Malazy[3]

[1]Non-Communicable Diseases Research Center, Endocrinology and Metabolism Population Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran; [2]Endocrinology and Metabolism Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences,, Tehran, Iran; [3]Non-Communicable Diseases Research Center, Endocrinology and Metabolism Population Sciences Institute, Tehran University of Medical Sciences,, Tehran, Iran

Objective(s): This study aimed to evaluate dairy consumption status and its sociodemographic and lifestyle association among newly admitted students at Tehran University of Medical Sciences. Methods: This secondary analysis included 391 newly admitted students of Tehran University of Medical Sciences, from an initial sample of 422 after excluding those with missing outcome data. Mean ± standard deviation (SD) daily dairy intake (servings/day) was evaluated as a continuous variable and as a binary outcome, defined as adequate (≥2 servings/day) versus inadequate (<2 servings/day). Sociodemographic characteristics included sex, self-reported socioeconomic status (SES), and living status (home vs. dormitory). Leisure-time physical activity (LPA) was also assessed. Descriptive statistics were calculated, and group comparisons were performed using independent t-tests, one-way ANOVA, and chi-square tests, as appropriate. Results: The mean ±SD daily dairy intake was 1.52 ±1.29 servings. Overall, only 119 of the students (30.4%) achieved adequate dairy consumption. Mean ± SD dairy intake was higher in males than females (1.64±1.40 vs. 1.40±1.19 servings/day), although the difference was not statistically significant (p=0.07). Significant differences in mean dairy intake were observed across self-reported SES levels (3rd tertile: 1.71 ±1.37, 2nd tertile: 1.52 ±1.34, and 1st tertile: 1.11 ±0.69; p=0.022). Students with higher levels of LPA had significantly greater mean of dairy intake compared with those with low LPA (1.67 ±1.31 vs. 1.31±1.24 servings/day; p=0.006) and higher proportion of them meet adequacy criteria (81 (36.3%) vs. 37 (22.8%), p=0.005). Students living at home tended to have higher mean of dairy intake than those residing in dormitories (1.58 ± 0.10 vs. 1.43 ± 0.10), although this difference did not reach statistical significance (p=0.25). Conclusion: Dairy consumption among newly admitted medical sciences students was suboptimal, with fewer than one-third meeting recommended intake levels. Targeted nutrition promotion strategies focusing on physically inactive and socioeconomically disadvantaged students may contribute to improved bone health during early adulthood.

P1326

ANTIDIABETIC MEDICATIONS AND FALL RISK IN PATIENTS WITH DIABETES: A PROSPECTIVE NATIONAL COHORT STUDY

A. Gharajeh[1], Y. Azizpour[2], S. Salehi[1], O. Tabatabaei-Malazy[3]

[1]Non-Communicable Diseases Research Center, Endocrinology and Metabolism Population Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran; [2]Endocrinology and Metabolism Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences,, Tehran, Iran; [3]Non-Communicable Diseases Research Center, Endocrinology and Metabolism Population Sciences Institute, Tehran University of Medical Sciences,, Tehran, Iran

Objective(s): This study aimed to examine the association between anti-diabetes medication use and fall risk among adults with diabetes in a prospective national cohort.
Methods: This analysis included 1,128 adults with diabetes, which are subpopulation of STEPS 2021 survey, identified using standard clinical criteria (HbA1c ≥6.5% or fasting plasma glucose ≥126 mg/dL, or self-reported use of anti-diabetic medication). Participants were classified based on current use of anti-diabetes medications, including oral agents and insulin. Incidence of falling was assessed by self-report of at least one fall within the previous four years (STEPS 2021 follow-up). Fall incidence with 95% confidence intervals (CI) were calculated, and differences between medication users and non-users were evaluated using chi-square.
Results: Among the total diabetic population, 647 (57.1%) were female, and 481 (42.9%) were male. Overall, 71 (6.92%) participants reported a fall in the past four years. Anti-diabetes medication use was reported by 549 (48.7%) participants. The incidence of falls was 7.36% among medication users and 6.42% among non-users. No statistically significant difference in fall incidence was observed between the two groups (p = 0.63).
Conclusion: In this national cohort study, the incidence of falls did not differ significantly between adults with diabetes using anti-diabetic medications and those not using them. These findings highlight that fall occurrence in this population may be multifactorial, emphasizing the need to consider comorbidities, functional status, and other non-pharmacologic factors in prevention strategies.

P1327

HYPERTENSION AND RISK OF FALLS AMONG IRANIAN ADULTS: FINDINGS FROM A NATIONAL FOLLOW-UP COHORT STUDY

Y. Azizpour[1], H. Ataei-Goujani[2], S. Salehi[1], O. Tabatabaei-Malazy[3]

[1]Non-Communicable Diseases Research Center, Endocrinology and Metabolism Population Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran; [2]Endocrinology and Metabolism Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences,, Tehran, Iran; [3]Non-Communicable Diseases Research Center, Endocrinology and Metabolism Population Sciences Institute, Tehran University of Medical Sciences,, Tehran, Iran

Objective(s): Determination the risk of falls among Iranian adults with hypertension. Method: This study utilized data from the Iran STEPS follow-up study, a nationally representative, prospective cohort initiated four years after the 2021 STEPwise Approach to Noncommunicable Disease Risk Factor Surveillance. The analysis included adults aged 18 years and older who completed both baseline and follow-up evaluations. Hypertension at baseline study was defined as a systolic blood pressure of at least 140 mmHg, a diastolic blood pressure of at least 90 mmHg, or self-reported use of antihypertensive medications. Information on history of falls during the four-year follow-up was collected through standardized telephone interviews. Fall incidence was estimated separately for participants with and without hypertension, and between-group differences were assessed using the chi-square test. All statistical analyses were performed using Stata version 17. Results: A total of 8,626 individuals were included in the analysis, of whom 2,889 met the criteria for hypertension. Females comprised 55.12% of the study population (95% confidence interval [CI]: 53.95–56.30), while males accounted for 44.88% (95% CI: 43.70–46.05). The incidence of falls was higher among participants with hypertension compared to those without. Specifically, the fall incidence was 6.36% (95% CI: 5.42–7.45) in the hypertensive group, versus 3.29% (95% CI: 2.81–3.84) in the non-hypertensive group. This difference was statistically significant (P < 0.001), indicating a substantially increased risk of falls associated with hypertension Conclusion: Hypertension is significantly associated with an increased risk of falls among Iranian adults. These findings underscore the importance of integrating fall risk assessment and prevention strategies into hypertension management and support the need for targeted interventions, particularly in ageing populations.

P1328

PREVALENCE OF PHYSICAL ACTIVITY AND ITS ASSOCIATED FACTORS AMONG NEWLY ADMITTED MEDICAL SCIENCES STUDENTS: A SEX-SPECIFIC ANALYSIS IN TEHRAN, IRAN

A. Gharajeh[1], Y. Azizpour[2], S. Salehi[1], P. Zarepour[1], O. Tabatabaei-Malazy[3]

[1]Non-Communicable Diseases Research Center, Endocrinology and Metabolism Population Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran; [2]Endocrinology and Metabolism Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences,, Tehran, Iran; [3]Non-Communicable Diseases Research Center, Endocrinology and Metabolism Population Sciences Institute, Tehran University of Medical Sciences,, Tehran, Iran

Objective(s): This study aimed to assess the prevalence of sufficient physical activity (PA) among newly admitted medical sciences students and to examine sex-specific associations with selected sociodemographic factors and dairy intake. Methods: This study is a secondary analysis of cross-sectional data collected from 422 newly admitted students at Tehran University of Medical Sciences. After excluding 18 students due to missing outcome data, 404 participants were included in the analysis. Total weekly PA was calculated in minutes and classified as insufficient (<150 min/week) or sufficient (≥150 min/week) based on WHO recommendations. Data on sex, living status (home vs. dormitory), socioeconomic status (SES), and dairy intake were assessed. Daily dairy intake was categorized as adequate (≥2 servings/day) or inadequate

(<2 servings/day). Descriptive analyses, sex-stratified cross-tabulations, and chi-square tests were conducted using Stata version 17. Results: Of the 404 students included, 217 (53.8%) were female. Overall, 58.7% of students met the recommended level of PA, while only 30.4% reported adequate dairy intake. Among females, 114 of 217 (48.1%) achieved sufficient PA. The prevalence of sufficient PA was higher among females living at home compared with those residing in dormitories (59.4% vs. 42.7%; $\chi^2 = 5.86$, p= 0.016). Similarly, a higher prevalence of sufficient PA was observed among females with adequate dairy intake compared to those with inadequate intake (59.0% vs. 46.9%) (p=0.112). Among males, 123 of 187 (51.9%) achieved sufficient PA. Males living in dormitories showed higher prevalence of PA than those living at home (70.0% vs. 61.9%), although this difference was not statistically significant (p= 0.241). Among males, the prevalence of sufficient PA was higher in those with adequate dairy intake (78.9%) compared with those with inadequate intake (60.5%) (p=0.015). Differences in the prevalence of sufficient PA were observed across SES groups in both females and males, but these differences were not statistically significant. Conclusion: Many newly admitted medical sciences students, particularly females, had insufficient PA and inadequate dairy intake, highlighting the need for early sex-sensitive preventive interventions.

P1329

THE BURDEN OF FALLS IN IRAN: TRENDS, AGE-SEX DISPARITIES, AND RISK FACTORS (GBD 2023)

M. Mirzad[1], S. Akbarpour[2], O. Tabatabaei-Malazy[3]

[1]Non-Communicable Diseases Research Center, Endocrinology and Metabolism Population Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran; [2]Endocrinology and Metabolism Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences,, Tehran, Iran; [3]Non-Communicable Diseases Research Center, Endocrinology and Metabolism Population Sciences Institute, Tehran University of Medical Sciences,, Tehran, Iran

Background: Falls represent a significant, yet often preventable, cause of morbidity and mortality globally. Understanding the burden of falls, stratified by age, sex, and over time, is crucial for targeted public health interventions in the Islamic Republic of Iran.
Methods: This study analyzed data from the Global Burden of Disease (GBD) 2023 study for the location "Iran (Islamic Republic of)". We examined trends in age-specific incidence, prevalence, Deaths, and Disability-Adjusted Life Years (DALYs) rates, and the contribution of major risk factors for falls between 1990 and 2023. Age-standardized rates were used to compare overall burden across the study period.
Results: In Iran, the age-specific incidence rate of falls was notably higher in young males, peaking in the 20-24 years age group (Figure 1). A distinct sex divergence was observed in older age: incidence rates in females surpassed those in males starting in the 70-74 years age group, peaking in the 90-94 years category. DALY rates increased with advancing age in both sexes, with higher rates observed in males in age groups below 80-84 years, after which the burden became female-dominant. Overall, the age-standardized DALY rate exhibited a decreasing trend from 1990 to 2023 for both sexes (Figure 2). This overall reduction was largely attributable to a significant decrease in the burden driven by occupational injuries, especially among males. Major risk factors contributing to the remaining burden included low bone mineral density, occupational injuries, smoking, and high alcohol use.
Conclusion: While Iran has successfully reduced the age-standardized DALY rate due to falls since 1990, particularly by addressing occupational hazards, significant disparities remain across the life course. Public health strategies should maintain a dual focus: preventing occupational falls in young males and implementing comprehensive strategies—targeting low bone mineral density—to mitigate the disproportionately rising burden in the oldest populations, predominantly affecting females.

P1330

COMPERISON OF THE EFFECTIVENESS OF SELECTIVE NERVE ROOT INJECTION UNDER X-RAY AND ULTRASOUND CONTROL IN PATIENTS WITH NEUROCOMPRESSIVE PAIN SYNDROMES IN THE LUMBAR SPINE

O. Tarasenko[1], T. Tarasenko[1]

[1]Kherson State University, Dnipro, Ukraine

Objective: Considering the extreme prevalence of pain syndromes in the back, doctors of many specialties face this problem every day. Most often, such patients turn to a family doctor, neurologist, neurosurgeon, rheumatologist, so doctors must differentiate radiculopathy, inflammatory back pain, mechanical and reflex pain syndromes. Radicular pain syndrome is characterized by symptoms that spread to the innervation zone of the affected root, the innervation zones of which are well known. Recently, pain medicine (pain management) has been actively developing, especially considering the fact that no more than 1-3% of patients with neurocompressive pain syndromes are subject to surgical treatment. The effectiveness of selective root injection under X-ray control is generally recognized, but recently such manipulations are performed under ultrasound control, especially with the advent of portable ultrasound devices.
We aimed to determine the effectiveness of selective root injection guided by ultrasound in patients with radicular neurocompressive pain syndromes in the lumbar spine.
Methods: A study was conducted of patients in whom clinical manifestations of radicular neurocompressive pain syndromes in the lumbar spine were confirmed using radiological examination methods (CT, MRI). The level of pain syndrome was assessed on the VAS scale before the start of treatment, one day after the manipulation, one week and 1 month after the start of treatment. Along with traditional treatment (NSAIDs, muscle relaxants, etc.), selective root injection was performed under X-ray or ultrasound control.
Results: 50 patients (22 women and 28 men) were included. The average age was 43.54±0.65 years. 38% of patients were overweight. 86% of patients had L5 or S1 radiculopathy. Patients were divided into 2 groups of 25 people. Patients of both groups were prescribed drug therapy with NSAIDs and muscle relaxants. A solution of corticosteroid and local anesthetic was injected into the affected areas in the patients of the first group under X-ray, the patients of the second group - under ultrasound control. Before the procedure, the average pain level according to VAS in patients of the 1st group was 88±1.5 mm, in the 2nd group - 85±2.7 mm. After 1 day, the level of pain in patients of the 1st group was 31±4.3 mm, and in the 2nd group - 35±3.7 mm. 7 days after the start of treatment and manipulation, the level of pain was 27±2.5 mm in the 1st group and 32±3.5 mm in the second group of patients. After 30 days, the level of pain in patients of the 1st group was 30±3.4 mm, and in the 2nd group - 37±3.8 mm.
Conclusion: despite the increasing popularity of ultrasound-guided

injections, the X-ray-guided blockades method shows better results, which are achieved due to better visualization and more accurate targeting.

P1331

CALF CIRCUMFERENCE PERCENTILES ARE ASSOCIATED WITH GASTROCNEMIUS MUSCLE ARCHITECTURE IN OLDER ADULTS

O. Turhan[1], C. Kayabaşı[1], M. Pehlivan[1], O. Özgün[1], I. A. Nacar[1], D. Cengiz[1,2], M. Eşme[1], B. B. Doğu[1], M. G. Halil[1], M. Cankurtaran[1], C. Balcı[1]

[1]Hacettepe University, Faculty of Medicine, Division of Geriatric Medicine, Ankara, Türkiye; [2]St.George's University Hospitals, London, United Kingdom

Objective(s)
Calf circumference (CC) is widely used as a simple screening tool for sarcopenia; however, its association with underlying muscle architectural characteristics is not well established. This study aimed to evaluate the relationship between CC percentile categories and gastrocnemius muscle thickness, fascicle length, and pennation angle in older adults.
Material and Methods
This cross-sectional study included 152 community-dwelling older adults (mean age 74.1 ± 5.7 years; 61.2% women). CC was categorized into four percentile groups: >50th, 25–50th, 5–25th, and <5th percentile. Gastrocnemius muscle thickness, fascicle length, and pennation angle were assessed using B-mode ultrasonography. Differences and ordered trends across CC categories were analyzed using the Jonckheere–Terpstra test. Additionally, logistic regression models adjusted for age and sex were used to examine the independent association between ultrasound-derived muscle parameters and low CC status.
Results
Median gastrocnemius muscle thickness progressively decreased across descending CC categories (13.9 mm in >50th percentile vs. 10.6 mm in <5th percentile). Similarly, median pennation angle declined from 26.2° to 21.3° across the same categories. Jonckheere–Terpstra analysis demonstrated a significant negative trend between CC categories and gastrocnemius muscle thickness (standardized J-T = 3.915, $p < 0.001$) as well as pennation angle (standardized J-T = 3.060, $p = 0.002$). No significant ordered trend was observed for fascicle length (standardized J-T = 0.553, $p = 0.580$). In multivariable logistic regression analyses adjusted for age and sex, lower gastrocnemius muscle thickness (OR 0.78, 95% CI 0.68–0.90, $p = 0.001$) and lower pennation angle (OR 0.92, 95% CI 0.86–0.99, $p = 0.023$) were independently associated with low CC (<5th percentile).
Conclusion(s)
Lower calf circumference percentiles are significantly associated with reduced gastrocnemius muscle thickness and pennation angle in older adults, reflecting unfavorable muscle architectural characteristics. These findings indicate that declining calf circumference percentiles are associated with unfavorable changes in gastrocnemius muscle architecture, supporting the use of calf circumference percentiles as a clinically meaningful indicator of muscle structural deterioration in older adults.

P1332

STRUCTURAL AND FUNCTIONAL STATE OF BONE TISSUE IN CHILDREN WITH BRONCHIAL ASTHMA DEPENDING ON AGE

O. Y. Poleshchuk[1], O. P. Galkina[1], J. A. Dovbnya[1], V. B. Kaliberdenko[1], K. K. Kaladze[1]

[1]V.I. Vernadsky Crimean Federal University, Simferopol, Russia

Objective: The aim is to study the structural and functional state of bone tissue in children with bronchial asthma depending on the age of the children.
Material and Methods: 103 children observed (aged 7 to 15 years) with remitted bronchial asthma and manifestations of osteopenic syndrome, diagnosed by ultrasound osteodensitometry using the "Achilles+" diagnostic device. The average age of the patients was 11.70 ± 0.15. The study population included 63 (61.1%) boys and 40 (38.9%) girls.
Results: In children with bronchial asthma, ultrasound parameters with age do not reach those of healthy children in any age group, and the greatest lag in bone tissue condition (decreased elasticity and strength) was found in boys aged 9, 12, and 14 years, and in girls aged 8, 9, and 14 years. The greatest changes were detected during periods of intensive growth and development of the child, as well as during puberty. Before entering puberty, bone tissue had the worst characteristics: in the group of 7-10-year-old boys, density index was reduced by 20% of the norm, and in girls by 16%. In the group of children aged 11-14 years, density index was reduced by 17% in boys, and by 12% in girls. A study of other ultrasound densitometry parameters revealed a uniform decrease with a persistent difference in accordance with the age-related trend by gender (by 18% in girls and 17% in boys). Thus, in children with bronchial asthma, both boys and girls, the formation of peak bone mass is critically impaired.
Conclusions: According to the final examination of the structural and functional state of bone tissue in children with bronchial asthma, a decrease in the formation of peak bone mass was noted.

P1333

ISOLATED LOW LUMBAR SPINE BONE MINERAL DENSITY: FRACTURE RISK AND THERAPEUTIC EFFECTS IN A MONOCENTRIC COHORT

O. Zhesan[1], K. Scheidhauer[2], V. R. Seifert-Klauss[3]

[1]Interdisciplinary Osteoporosis Center, Department of Gynecology, University Hospital Rechts der Isar, School of Medicine and Health, Technical University of Munich(TUM), Munich, Germany; [2]Department of Nuclear Medicine, University Hospital Rechts der Isar, School of Medicine and Health, Technical University of Munich(TUM), Munich, Germany; [3]Interdisciplinary Osteoporosis Center, Department of Gynecology, University Hospital Rechts der Isar, School of Medicine and Health,Technical University of Munich(TUM), Munich, Germany

Objectives:
Current guideline-based osteoporosis risk assessment mainly focuses on hip BMD, potentially underestimating risk in (predominantly female) patients with isolated low lumbar spine (LS) BMD. We aimed to assess the clinical relevance of isolated LS osteoporosis by analyzing fracture outcomes in a real-world cohort.
Material and Methods:
This retrospective cohort study included 169 patients selected from over 1000 individuals, meeting criteria for osteoporosis on lumbar spine and hip DXA and a minimum follow-up of 5 years (IOZ, 2014–2024). Patients received basic therapy (vitamin D/calcium) with or without specific anti-osteoporotic medication. Descriptive statistics and logistic regression were applied.
Results:
Isolated LS BMD was present in 105 of 169 patients (62.1%). The cohort was predominantly female (159/169); sex-specific analyses were not performed due to the small number of men (n=10). Patients with isolated LS osteoporosis were significantly less likely to receive current specific anti-osteoporotic therapy than those with combined LS and hip involvement (74.0% vs. 90.7%; p=0.014). Mean age was comparable between groups (64 vs. 63 years). Patients with at least one fracture prior to DXA (n=112) showed a higher cumulative incidence of ≥1 fracture during the entire follow-up period (mean 8.6 years) compared with patients without baseline fractures (n=50): 42.0% vs. 28.0% . Baseline fractures were independently associated with major osteoporotic fractures (vertebral, femoral, or humeral) after adjustment for age and follow-up duration (OR 3.82, 95% CI 1.25–11.69), whereas age showed no independent association (OR 0.98, p=0.54). Median per-patient fracture rates (fractures/patient-year) were higher in patients with prior fractures (0.091 vs. 0.000; p=0.033).
Conclusions:
Isolated low lumbar spine osteoporosis was common and associated with lower use of specific therapy despite a clinically relevant fracture risk. Baseline fractures were the strongest independent predictor of future and major osteoporotic fractures. These findings were observed in a real-world cohort with a high proportion of patients receiving basic and/or specific anti-osteoporotic therapy. Fracture risk in patients with isolated LS BMD may be underestimated in routine clinical practice.

LONG-TERM SKELETAL CONSEQUENCES OF THYROID STIMULATING HORMONE SUPPRESSIVE THERAPY FOR DIFFERENTIATED THYROID CANCER

O.-C. Sima[1], A.-M. Gheorghe[2], M. Costachescu[3], A.-I. Trandafir[2], A. Dumitrascu[4], E. Petrova[5]

[1]PhD Doctoral School of "Carol Davila" University of Medicine and Pharmacy, 020021 Bucharest, Romania & Department of Endocrinology V, "C.I. Parhon" National Institute of Endocrinology, 011863, Bucharest, Romania; [2]Department of Endocrinology V, "C.I. Parhon" National Institute of Endocrinology, 011863 Bucharest, Romania & Department of Endocrinology, PhD Doctoral School of "Carol Davila" University of Medicine and Pharmacy, 020021, Bucharest, Romania; [3]Department of Radiology and Medical Imaging, "Dr. Carol Davila" Central Military University Emergency Hospital & Department of Radiology, PhD Doctoral School of "Carol Davila" University of Medicine and Pharmacy, 020021, Bucharest, Romania; [4]Department of Radiology and Medical Imaging, "C.I. Parhon" National Institute of Endocrinology, 011863, Bucharest, Romania; [5]Department of Endocrinology, "Carol Davila" University of Medicine and Pharmacy, 020021, Bucharest, Romania

Background/Objective: Postmenopausal patients under Thyroid Stimulating Hormone suppressive therapy (TSH-ST) have a higher fracture risk related to thyroxine-induced bone loss [1-10]. We aim to introduce such case.
Method: case report. Ethical approval: no. 33 from 22/09/2025.
Results: A 75-year-old female with a history of total thyroidectomy for papillary thyroid carcinoma at age 42, followed by radioiodine therapy (75 mCi), and TSH-ST, entered menopause at 50. Osteopenia was found at DXA at 65: femoral neck bone mineral density (BMD) 0.899 g/sqcm, T-score -1.1; lumbar BMD 1.087 g/sqcm, T-score -0.8; total hip BMD 0.978 g/sqcm, T-score -0.2. One decade later, under TSH-ST (with negative thyroglobulin), she presented normal 25-hydroxyitamin D 41.73 ng/mL (Normal>30) under cholecalciferol 1000 IU/day and parathormone 53.94 pg/mL (Normal: 17.3-74.1). DXA showed a small BMD decrease at lumbar BMD 1.034 g/sqcm, T-score -1.2 and stationary femoral neck BMD 0.896 g/sqcm, T-score -0.7, total hip BMD 0.957 g/sqcm, T-sore -0.4 and an incidental asymptomatic vertebral fracture at spine X-Ray. 10-year fracture risk assessment was 5.2%, respectively, 1.1% for major osteoporotic fractures, respectively, hip fracture. She continued TST-ST, vitamin D replacement and started oral risendronate.
Conclusion: Long-term surveillance of skeletal health is essential under TSH-ST, noting the age and hypo-estrogenic-related influence over time.

Parhon" National Institute of Endocrinology, 011863, Bucharest, Romania

Background: Bisphosphonates holiday requires a close surveillance of bone turnover markers (BTM), bone mineral density (BMD) and incidental fractures [1-10].
Objective: We aim to introduce a tailored decision in a patient with drug holiday-related bone loss.
Method: case report. Ethical approval: no. 33 from 22/09/2025.
Results: This is 79-year-old female with osteoporosis diagnosed at 65 due a left forearm fracture. After two years of IV ibandronate, and another two of annual zoledronate 5 mg (ZOL), BTMs were suppressed [osteocalcin 6.9 ng/mL (Normal: 15-46), P1NP 22 ng/mL (Normal: 20.25-76.31), CrossLaps 0.1 ng/mL (Normal: 0.152-0.858)]. DXA showed lumbar BMD 0.934g/sqcm, T-score -2.2; femoral neck BMD 0.729 g/sqcm, T-score -2.2, and total hip BMD 0.738 g/sqcm, T-score -2.1. A delay of next ZOL was recommended, then a drug holiday was decided for 6 years, until a femoral neck BMD loss was registered (not at lumbar spine): 0.667 g/sqcm, T-score -2.6, associated with a reduced TBS 1.187, without incidental fractures. BTMs remained suppressed (osteocalcin 11.4 ng/mL) or normal (P1NP 32.1 ng/mL, CrossLaps 0.2 ng/mL). High 25-hydroxyvitamin D of 61 ng/mL (Normal >30) under daily cholecalciferol 2000 UI associated a suppressed parathormone (PTH) 13.4 pg/mL (Normal: 17.3-74.1) with normal blood calcium and phosphorus levels. ZOL was re-administered with an initial reduction of cholecalciferol doses to 1000 UI/day due to PTH values.
Conclusion: Drug holiday helps postponing bisphosphonates re-administration even in cases with a history of fracture and stationary BTMs profile. An optimum vitamin D replacement ensures a better outcome. Over-supplementation might be reflected by PTH suppression.

Background/Objective: Uncontrolled hyperthyroidism is associated with an accelerated bone loss even in males and additional contributors may be co-found (e.g. diabetes) [1-10]. We aim to introduce such case.
Method: case presentation. Ethical approval no. 33 from 09/22/2025.
Results: A 68-year-old male with a history of total gastrectomy for gastric adenocarcinoma at age of 55 and type 2 diabetes mellitus under diet was admitted for neck compressive symptoms and recent weight loss. Basedow disease-related hyperthyroidism is confirmed by low Thyroid Stimulating Hormone (TSH) 0.003 µIU/mL (Normal: 0.35-4.94), high

free levothyroxine 26.16 pmol/L (Normal: 9-19) and positive anti-TSH receptor antibodies 2.08 IU/L (Normal <1.75). A 4-cm nodule is detected in the left thyroid lobe at ultrasound. Lab findings showed normal glycated hemoglobin A1, low 25-hydroxyvitamin D 11.7 ng/mL (Normal <30) and normal parathormone 26.94 pg/mL (Normal: 15-65); abnormally high bone turnover markers P1NP 140.4 ng/mL (Normal: 20.25-76.31), and CrossLaps 0.83 ng/mL (Normal: 0.104-0.504); osteopenia at DXA: L1-L4 lumbar BMD 1.119 g/sqcm, T-score -0.9; femoral neck BMD 0.871 g/sqcm, T-score -1.7, normal TBS (1.355) and a L2 vertebral fracture at X-Ray. He underwent methimazol 20 mg/day to control the thyroid function, followed by successful total thyroidectomy, in addition to zoledronate 5 mg/day and vitamin D replacement.

Conclusion: This case highlights the interplay between thyrotoxicosis, type 2 diabetes, gastric surgery-related malabsorption and hypovitaminosis D to potentially impact the skeletal health.

Objective: Premature ovarian insufficiency leads to loss of the protective effect that estrogens have on the skeletal health, being associated with an increased fracture risk. Non-adherence to the hormonal replacement therapy (HRT) enhances these bone health consequences [1-10]. We aim to introduce such a case.

Method: case report. Retrospective data collection was approved by the university hospital no. 33 from 22/09/2025.

Results: A 53-year-old female with premature ovarian insufficiency since the age of 38 refused HRT and was confirmed with osteoporosis since the age of 52: L1-4 lumbar DXA-based BMD 0.879 g/sqcm, T-score -2.5; femoral neck BMD 0.806 g/sqcm, T-score -1.7; total hip BMD 0.907 g/sqcm, T-score -0.8. Oral bisphosphonates (ibandronate 150 mg/month) was initiated and immediately stopped due to gastrointestinal complains, and she further refused other anti-osteoporotic medication. 18 months later, she presented a normal 25-hydroxyvitamin D level 31.1 ng/mL (Normal >30) under daily cholecalciferol 2000 UI with normal parathormone 28.59 pg/mL (Normal: 17.3-74.1), serum bone formation markers [osteocalcin 20.97 ng/mL (Normal: 15-46), P1NP 52.28 ng/mL (Normal: 20.25-76.31)], and bone resorption marker CrossLaps 0.49 ng/mL (Normal: 0.33-0.782). No incidental fracture was detected, despite decreasing BMD at lumbar site 0.871 g/sqcm (T-score -2.6) and total hip 0.872 g/sqcm (T-score -1.1). Bone microarchitecture was partially degraded (TBS 1.272). The patient agreed for IV medication (zoledronate 5 mg/year) plus vitamin D supplements.

Conclusion: Periodic bone quantity and quality assessment is mandatory for patients with early untreated estrogen deficiency.

Parhon" National Institute of Endocrinology, 011863, Bucharest, Romania; [2]Department of Family Medicine, State "Nicolae Testemiţanu" University of Medicine and Pharmacy, 2004, Chisinau, Moldova; [3]Department of Endocrinology V, "C.I. Parhon" National Institute of Endocrinology, 011863 Bucharest, Romania & Department of Endocrinology, PhD Doctoral School of "Carol Davila" University of Medicine and Pharmacy, 020021, Bucharest, Romania; [4]Department of Radiology and Medical Imaging, "Dr. Carol Davila" Central Military University Emergency Hospital & Department of Radiology, PhD Doctoral School of "Carol Davila" University of Medicine and Pharmacy, 020021, Bucharest, Romania

Objective: Drug holiday is recommended in selected patients with improved bone mineral density (BMD) after prolonged bisphosphonates exposure, depending on the overall fracture risk profile, which should be carefully followed. [1-10].
Method: case presentation (ethical approval no. 33, date 22/092025).
Results: This was a 77-year-old female with surgically-induced menopause at age 45 for a uterine leiomyoma (she received no estrogens replacement). She underwent a total thyroidectomy for toxic multinodular goiter at age 66, after experiencing thyrotoxicosis for a few years. Osteoporosis was confirmed at 70 years: lumbar DXA-BMD 0.864 g/sqcm, T-score -2.5; femoral neck BMD 0.753 g/sqcm, T-score -2.1. After 4 years of oral risedronate, BMD increased: lumbar BMD 0.949 g/sqcm (T-score -1.9), femoral neck BMD 0.752 g/sqcm (T-score -2.1). No prevalent fractures were found and drug holiday was initiated. After 2 years, an asymptomatic single thoracic vertebral fracture at X-Ray associated stationary BMD: lumbar BMD 0.955 g/sqcm, T-score -1.9, femoral neck BMD 0.764 g/sqcm, T-score -1.8; total hip BMD 0.967 g/sqcm, T-score -0.3 and low TBS 1.199. Vitamin D was normal: 25-hydroxyvitamin D 35.88 ng/mL (Normal >30). Bone formation markers were normal [osteocalcin 15.11 ng/mL (Normal: 15-46), P1NP 35.9 ng/mL (Normal: 20.25-76.31)]. Despite suppressed bone resorption marker CrossLaps 0.31 ng/mL (Normal: 0.33-0.782), bisphosphonates re-initiation was decided (zoledronate 5 mg/year).
Conclusion: The decision to resume anti-osteoporotic treatment should be tailored to each patient's fracture risk status, taking into consideration the incidental fractures, DXA-BMD changes, and bone turnover markers dynamics.

INTERVENTIONAL STRATEGY AGAINST MENOPAUSAL OSTEOPOROSIS: DOES THE CO-PRESENCE OF AN APPARENTLY NON-FUNCTIONAL ADRENAL TUMOUR MATTER?

O.-C. Sima[1], V. Salaru[2], A.-M. Gheorghe[3], A.-I. Trandafir[3], M. Costachescu[4], L. Suveica[2]

[1]PhD Doctoral School of "Carol Davila" University of Medicine and Pharmacy, 020021 Bucharest, Romania & Department of Endocrinology V, "C.I. Parhon" National Institute of Endocrinology, 011863, Bucharest, Romania; [2]Department of Family Medicine, State "Nicolae Testemiţanu" University of Medicine and Pharmacy, 2004, Chisinau, Moldova; [3]Department of Endocrinology V, "C.I. Parhon" National Institute of Endocrinology, 011863 Bucharest, Romania & Department of Endocrinology, PhD Doctoral School of "Carol Davila" University of Medicine and Pharmacy, 020021, Bucharest, Romania; [4]Department of Radiology and Medical Imaging, "Dr. Carol Davila" Central Military University Emergency Hospital & Department of Radiology, PhD Doctoral School of "Carol Davila" University of Medicine and Pharmacy, 020021, Bucharest, Romania

Background/Objective: Osteoporosis in menopausal women confirmed with non-functional adrenal tumors (NFATs) might represent a complication of mild cortisol secretion impairment (either an intermittent excess or the current suboptimal diagnosis criteria do not accurately reflect the hormonal imbalance across lifespan) in addition to age and hypo-estrogenic status [1-10].
Method: case presentation (ethical approval no. 33 from 22/09/2025).
Results: A 78-year-old female (menopause duration of 32 years) was confirmed 3 years prior with a right NFAT of 1.8 cm and osteoporosis at DXA: lumbar BMD 0.906 g/sqcm, T-score -2.3; femoral neck BMD 0.681 g/sqcm, T-score -2.5; total hip BMD 0.724 g/sqcm, T-score -2.3. She had a L2 lumbar vertebral fracture. The tumor was conservatively managed. After 3 years of risendronate, she experienced a novel thoracic vertebral fracture, and lumbar BMD decreased to 0.763 g/sqcm (T-score -3.5); femoral neck 0.703 g/sqcm (T-score -2.4); total hip 0.695 g/sqcm (T-score -2.5). 25-hydroxyvitamin D was normal (33.83 ng/mL), and serum bone turnover markers. The tumor was stationary at computed tomography, so was post-1 mg dexamethasone suppression test cortisol 1.03 µg/dL (Normal <1.8), with low-normal ACTH 14.66 pg/mL (Normal: 7.2-63.3). Adrenalectomy was postponed, and the anti-osteoporotic medication was switched to IV zoledronate 5 mg/year.
Conclusion: In NFATs, adrenalectomy might be an alternative to a

suboptimal response to anti-osteoporotic strategy, which is not guideline-based so far. A non-secretor adrenal profile was found to associate a higher cardio-metabolic risk, and even a higher fracture risk in certain population groups, such as menopausal females and elderly.

MUSCULOSKELETAL INVOLVEMENT IN A MALE WITH ACROMEGALY: THE RELATIONSHIP WITH THE PITUITARY DISEASE CONTROL

O.-C. Sima[1], V. Salaru[2], A.-M. Gheorghe[3], A.-I. Trandafir[3], M. Costachescu[4], L. Suveica[2]

[1]PhD Doctoral School of "Carol Davila" University of Medicine and Pharmacy, 020021 Bucharest, Romania & Department of Endocrinology V, "C.I. Parhon" National Institute of Endocrinology, 011863, Bucharest, Romania; [2]Department of Family Medicine, State "Nicolae Testemiţanu" University of Medicine and Pharmacy, 2004, Chisinau, Moldova; [3]Department of Endocrinology V, "C.I. Parhon" National Institute of Endocrinology, 011863 Bucharest, Romania & Department of Endocrinology, PhD Doctoral School of "Carol Davila" University of Medicine and Pharmacy, 020021, Bucharest, Romania; [4]Department of Radiology and Medical Imaging, "Dr. Carol Davila" Central Military University Emergency Hospital & Department of Radiology, PhD Doctoral School of "Carol Davila" University of Medicine and Pharmacy, 020021, Bucharest, Romania

Objective: Acromegaly is associated with bone microarchitecture, joints anomalies and increased fracture-risk underlying multiple mechanisms, thus they are not directly correlated with IGF1-GH normalization. We aim to introduce such a case [1-10].

Method: case presentation.

Results: A 68-year-old male was diagnosed with pituitary macroadenoma-related acromegaly at 59, which was controlled after hypophysectomy, gammaknife, and 3-year octreotide LAR 30 mg/month plus cabergoline 1 mg/week until present. At 61, osteoporosis complicated with lumbar vertebral fractures required zoledronate 5 mg/year after 6 years of risedronate 75 mg/bimonthly. Currently, 25-hydroxyvitamin D and parathormone are normal, with suppressed bone biomarkers [osteocalcin 11.66 ng/mL (Normal: 15-46), P1NP 19.89 ng/mL (Normal: 20.25-76.31), CrossLaps 0.09 ng/mL (Normal: 0.33-0.782)]. DXA-BMD improved: lumbar 0.983 g/sqcm, T-score -1.9; femoral neck 0.891 g/sqcm, T-score -1.4; total hip 0.98 g/sqcm, T-score -0.8 with low TBS 1.225 and no incidental fracture. Despite disease control [IGF1 209 ng/mL (Normal: 31-243)], he developed acromioclavicular osteoarthritis and supraspinatus tendinopathy (MRI aspect) causing pain; a right posterior cervical lump (1.8 cm-lipoma at ultrasound); multiple lipomas adjacent to parietal, occipital bone and within subscapular muscle (CT aspect). Zoledronate 5 mg/year, cholecalciferol 2000 IU/day, cabergoline were continued adding a rehabilitation program.

Conclusion: Osteoarthritis, lipomas, osteoporosis might not be the hallmark of acromegaly, especially in well-controlled disease, but they belong to the overall disease burden.

PITFALLS OF ADHERENCE TO THE ANTI-OSTEOPOROSIS MEDICATION ACROSS REAL-LIFE SETTING

O.-C. Sima[1], L. Gitu[2], A.-I. Trandafir[3], A.-M. Gheorghe[3], M. Costachescu[4], L. Suveica[2]

[1]PhD Doctoral School of "Carol Davila" University of Medicine and Pharmacy, 020021 Bucharest, Romania & Department of Endocrinology V, "C.I. Parhon" National Institute of Endocrinology, 011863, Bucharest, Romania; [2]Department of Family Medicine, State "Nicolae Testemiţanu" University of Medicine and Pharmacy, 2004, Chisinau, Moldova; [3]Department of Endocrinology V, "C.I. Parhon" National Institute of Endocrinology, 011863 Bucharest, Romania & Department of Endocrinology, PhD Doctoral School of "Carol Davila" University of Medicine and Pharmacy, 020021, Bucharest, Romania; [4]Department of Radiology and Medical Imaging, "Dr. Carol Davila" Central Military University Emergency Hospital & Department of Radiology, PhD Doctoral School of "Carol Davila" University of Medicine and Pharmacy, 020021, Bucharest, Romania

Background/Objective: Delayed osteoporosis diagnosis and lack of compliance/adherence to anti-osteoporotic therapy represents significant aspects of real-life settings in the field of menopausal osteoporosis [1-10]. We aim to introduce such a case.
Method: case report.
Results: A 70-year-old female suffered a low-trauma right knee fracture at the age of 46 that was treated surgically (she entered menopause at 45). At 63, DXA highlighted osteoporosis: lumbar BMD 0.743 g/sqcm, T-score -2.7; femoral neck BMD 0.734 g/sqcm, T-score -1.6; total hip BMD 0.794 g/sqcm, T-score -1.6. She still refused anti-osteoporotic treatment and presented for a check-up only 6 years later. Low 25-hydroxyvitamin D 21 ng/mL (Normal >30), normal PTH and bone markers [osteocalcin 21.33 ng/mL (Normal: 15-46), P1NP 49.82 ng/mL (Normal: 20.25-76.31), CrossLaps 0.429 ng/mL (Normal: 0.33-0.782)] were pointed out. DXA revealed BMD loss at lumbar spine 0.852 g/sqcm (T-score -2.8); femoral neck 0.756 g/sqcm (T-score -1.9), and total hip 0.76 g/sqcm (T-score -2) with reduced TBS 1.316. No incidental fracture was detected. FRAX showed a 10-year probability of major osteoporotic fractures 10% and hip fracture 2.7% that increased to 11%, respectively, 2.9% after adjusting for lumbar BMD (FRAXplus). IV zoledronate 5 mg /year was administered and supplementation with cholecalciferol 2000 IU/day.
Conclusion: Early intervention against osteoporosis prevents further bone mass loss. However, the medication is limited to the patient's compliance and decision to start and follow the medication.

PELVIC FRACTURES AFTER LOSS TO FOLLOW-UP IN A PATIENT WITH LONG-TERM HISTORY OF OSTEOPOROSIS

O.-C. Sima[1], L. Gitu[2], A.-M. Gheorghe[3], A.-I. Trandafir[3], M. Costachescu[4], L. Suveica[2]

[1]PhD Doctoral School of "Carol Davila" University of Medicine and Pharmacy, 020021 Bucharest, Romania & Department of Endocrinology V, "C.I. Parhon" National Institute of Endocrinology, 011863, Bucharest, Romania; [2]Department of Family Medicine, State "Nicolae Testemiţanu" University of Medicine and Pharmacy, 2004, Chisinau, Moldova; [3]Department of Endocrinology V, "C.I. Parhon" National Institute of Endocrinology, 011863 Bucharest, Romania & Department of Endocrinology, PhD Doctoral School of "Carol Davila" University of Medicine and Pharmacy, 020021, Bucharest, Romania; [4]Department of Radiology and Medical Imaging, "Dr. Carol Davila" Central Military University Emergency Hospital & Department of Radiology, PhD Doctoral School of "Carol Davila" University of Medicine and Pharmacy, 020021, Bucharest, Romania

Background/Objective: Close surveillance is essential in the management of patients with long-standing menopausal osteoporosis and loss to follow-up represents an important challenge to solve the risk fracture assessment and medication strategy [1-10]. We aim to introduce such a case.
Method: case report.
Results: A 70-year-old female with premature menopause at 43 years was diagnosed with osteoporosis since the age of 52. After 2 years of raloxifene followed by another 5 years of risedronate 35 mg/week, she was lost to follow-up for the next 5 years. Then, DXA showed a bone mineral density (BMD) improvement: L1-L4 lumbar BMD 0.892 g/sqcm, T-score -2.4; femoral neck BMD 0.741 g/sqcm, T-score -2.1; total hip BMD 0.729 g/sqcm, T-score -2.2. She presented low-normal osteocalcin 18 ng/mL (Normal: 15-46), normal P1NP 37.02 ng/mL (Normal: 20.25-76.31). Suppressed CrossLaps 0.287 ng/mL (Normal: 0.33-0.782) and lack of incidental fractures were adequate for a drug holiday. The subject was again lost to follow-up for 7 years. Recently, risedronate 35 mg/week was re-initiated by her primary care physician after suffering fractures of ilio-ischiopubic ramus and sacrum. DXA-BMD decreased only at femoral neck 0.674 g/sqcm (T-score -2.5) and remained stationary at the other central sites, associating a partially degraded microarchitecture based on low DXA-derived trabecular bone score 1.236. Bone turnover markers and 25-hydroxyvitamin D were normal. Noting a low compliance to endocrine check-up over time, IV zoledronate 5 mg/year was administered.
Conclusion: In patients with a long history of poor compliance to annual check-ups, IV medication addresses this issue and the high fracture risk amid real-life practice.

RECURRENT RIB FRACTURES UNDER SUBCUTANEOUS MEDICATION AGAINST OSTEOPOROSIS IN A PATIENT WITH SYSTEMIC SCLEROSIS: THE ISSUES OF SEVERE CALCINOSIS CUTIS

O.-C. Sima[1], L. Suveica[2], A.-I. Trandafir[3], M. Costachescu[4], A.-M. Gheorghe[3], A. Topa[2]

[1]PhD Doctoral School of "Carol Davila" University of Medicine and Pharmacy, 020021 Bucharest, Romania & Department of Endocrinology V, "C.I. Parhon" National Institute of Endocrinology, 011863, Bucharest, Romania; [2]Department of Family Medicine, State "Nicolae Testemiţanu" University of Medicine and Pharmacy, 2004, Chisinau, Moldova; [3]Department of Endocrinology V, "C.I. Parhon" National Institute of Endocrinology, 011863 Bucharest, Romania & Department of Endocrinology, PhD Doctoral School of "Carol Davila" University of Medicine and Pharmacy, 020021, Bucharest, Romania; [4]Department of Radiology and Medical Imaging, "Dr. Carol Davila" Central Military University Emergency Hospital & Department of Radiology, PhD Doctoral School of "Carol Davila" University of Medicine and Pharmacy, 020021, Bucharest, Romania

Objective: Patients with systemic sclerosis/scleroderma present major challenges in the management of osteoporosis, especially when skin and gastrointestinal involvements are co-present. We aim to introduce such a case [1-10].
Method: case report.
Results: This was a 57-year-old female with severe systemic sclerosis affecting the skin (calcinosis cutis), blood vessels, lung and esophagus. She had premature ovarian failure since the age of 39 (no hormone replacement therapy) and was diagnosed with osteoporosis at 44 when anti-resorptive treatment was initiated (sequential therapy with risedronate, IV ibandronate, followed by teriparatide with premature dropout due to recurrent rib fractures and no response as a consequence to ineffective subcutaneous administration in relationship with calcinosis cutis). She started denosumab 60 mg/6 months, but experienced recurrent rib fractures and further BMD loss. Subsequently, zoledronate 5 mg/year (ZOL) was initiated at a lumbar DXA-BMD 0.95 g/sqcm (T-score -1.9), femoral neck BMD 0.643 g/sqcm (T-score -2.8), total hip BMD 0.756 g/sqcm (T-score -2). After 3 years, no incidental fracture was detected and DXA-BMD showed a mild decrease: lumbar 0.906 g/sqcm (T-score -2.3), femoral neck 0.618 g/sqcm (T-score -3), total hip 0.772 g/sqcm (T-score -1.9), associated with a normal TBS 1.403. Suppressed bone turnover markers [osteocalcin 11.69 ng/mL (Normal: 15-46), P1NP 18.77 ng/mL (Normal: 20.25-76.31), and CrossLaps 0.187 ng/mL (Normal: 0.183-1.06)] reflected ZOL effects, which was further continued.
Conclusion: In this particular instance of severe skin ailments, subcutaneous anti-osteoporotic medication did not prove to be an adequate strategy.

OSTEOPOROSIS IN PATIENTS WITH PSORIATIC ARTHRITIS: A CLINICAL ASSESSMENT IN A RHEUMATOLOGY UNIT

P. Abreu[1,2], A. Rocha[2,3]

[1]Rheumatology Unit, ULS Castelo Branco, Portugal, Castelo Branco, Portugal; [2]Faculty of Health Sciences, University of Beira Interior, Portugal, Covilhã, Portugal; [3]Anesthesiology Department, ULS Castelo Branco, Portugal, Castelo Branco, Portugal

Introduction: Psoriatic arthritis (PsA) is a chronic inflammatory disease that affects the joints and skin, occurring in individuals with psoriasis. Osteoporosis (OP), on the other hand, is characterized by decreased bone mineral density, increasing the risk of fractures. Recent studies suggest that PsA patients have an increased risk of developing OP due to chronic inflammation and prolonged corticosteroid use.
Objective: This study aims to analyze the prevalence of OP in patients with PsA followed in a Rheumatology Unit, in Beira Interior (Portugal).
Methods: Observational, cross-sectional, retrospective, and monocentric study conducted with 36 patients diagnosed with PsA using CASPAR criteria and followed in the Rheumatology outpatient clinic of the Local Health Unit of Castelo Branco (ULSCB). Variables such as age, sex, comorbidities, smoking habits, treatments, laboratory parameters, and dual-energy X-ray absorptiometry (DEXA) results were analyzed. Statistical analysis was performed using descriptive statistics with Microsoft Excel.
Discussion: The results showed a low prevalence of OP (8,33%) and

osteopenia (11,11%) in the sample, values lower than those reported in the literature. The low rate of DEXA screening (27,78%) suggests a possible underdiagnosis of the disease. Corticosteroid (PDN<10mg/day) use was high (63,89%), which may negatively impact bone density. Additionally, biological therapy, used by 66.67% of patients, may have protective effects on bone mass, requiring further studies. The presence of only one patient identified with fractures contrasts with studies indicating a higher risk of fractures in PsA, highlighting the need for improved imaging screening.
Conclusion: OP may be underdiagnosed in patients with PsA, reinforcing the need for early screening with DEXA. The high rate of corticosteroid use may negatively impact bone density, while biological therapy may act as a protective factor. Future studies should explore the influence of disease activity and therapy on boné remodeling, allowing for the implementation of more effective preventive strategies.

P1345

OSTEOARTICULAR MANIFESTATIONS IN TYPE 2 DIABETIC PATIENTS: A CLINICAL STUDY

P. Abreu[1,2], J. Gonzalez[3], A. M. Monteiro[1], A. Rocha[2,4]

[1]Rheumatology Unit, ULS Castelo Branco, Portugal, Castelo Branco, Portugal; [2]Faculty of Health Sciences, University of Beira Interior, Portugal, Covilhã, Portugal; [3]ULS Castelo Branco, Portugal, Castelo Branco, Portugal; [4]Anesthesiology Department, ULS Castelo Branco, Portugal, Castelo Branco, Portugal

Introduction: Rheumatic complaints are common in patients with diabetes. Type 2 generally occurs in people over 40 and is characterised by insulin resistance. Maintaining good glycaemic control with non-pharmacologic and pharmacologic treatments improves or prevents the development of rheumatic conditions.
Objectives: Evaluate the prevalence of MSK manifestations in patients with type 2 diabetes (T2D)
Materials and Methods: Retrospective, transversal and descriptive study carried out in 2025 involving all patients with documented T2D, adults (age 18 and above), searching for MSK manifestations. Demographics, diabetes history, glycated haemoglobin (HbA1c), treatment modalities were collected.
Results: Of 85 patients with T2D, MSK manifestations were observed in 74,12%. 50.6% were men and 49.4% women. Mean age: 72.25 years (ranging from 50-92). Mean IMC 29.1Kg/m2. Mean reading of Hb A1C was 7.21%. Osteoarthritis (OA) of vertebral column (38.82%) was the common manifestation, followed OA of the knee (23.53%), osteoporosis (12.94%) and shoulder tendinopathy (11.76%). Carpal tunnel syndrome and Dupuytren's contracture were found only in 1 patient, each.
Conclusions: This study reported a higher prevalence of MSK manifestations among people with T2D. Clinical findings may be associated with overweight, advanced age, longer duration of disease and poor metabolic control (high HbA1c levels). For prevention and management of chronic disabilities due to these disorders, it would help a regular examination of the musculoskeletal system and better glycemic control of diabetes.

P1346

DIABETES AND THE SKELETON: EXPLORING BONE AND JOINT COMPLICATIONS – STUDY IN A FAMILY HEALTH UNIT

J. Gonzalez[1], I. Correia[1], A. Freitas[1], M. Barata[1], P. Água[1], C. Pires[1], L. Pacheco[1], S. Simões[1], A. M. Monteiro[2], P. Abreu[2,3]

[1]ULS Castelo Branco, Portugal, Castelo Branco, Portugal; [2]Rheumatology Unit, ULS Castelo Branco, Portugal, Castelo Branco, Portugal; [3]Faculty of Health Sciences, University of Beira Interior, Portugal, Covilhã, Portugal

Introduction: Diabetes mellitus (DM) is one of the most common diseases worldwide. Patients with DM are prone to develop multiple musculoskeletal (MSK) manifestations, which may lead to disability and an impact on patient's quality of life.
Objective: Assess the prevalence of MSK disorders in diabetic patients in a Family Health Unit (FHU) of Beira Interior-Portugal.
Materials and Methods: This is a retrospective, transversal and descriptive study carried out between 2023 and 2024 involving all patients with DM (type I, type II and LADA), between the age of 10 and 93, looking for those who were diagnosed with MSK manifestations.
Results: A total of 518 patients were found to have DM but only 482 were included int the study (476 type II, 5 type I and 1 LADA). 54.1% were men and 45.9% women. In this group, 65.4% had MSK manifestations. The average age of patients was 70.5 years old ranging from (10-93). 80.3% had IMC≥25 (2.9% with obesity grade III). The mean reading of A1C was 7.14%. Axial and peripheral osteoarthritis (OA) were the most prevalent pathologies, followed by periarticular pathology (shoulder tendinopathy). Carpal tunnel syndrome was found only in 8 patients (1.7%). Clinical findings may be more associated with excess weight, the time of disease progression and poor metabolic control.
Conclusions: MSK manifestations are common among diabetic patients. OA was the most frequently seen disorder. Physicians should be aware of the high prevalence and the huge impact on patients when treating patients with type II DM. The early recognition and management can improve quality of life and physical function.

P1347

THE RISK OF PERONEAL NERVE INJURY IN ALL-INSIDE LATERAL MENISCAL REPAIR THROUGH THE POPLITEUS TENDON USING FIVE DIFFERENT CURVATURES OF ALL-INSIDE MENISCAL REPAIR DEVICES: A CADAVERIC STUDY

P. Asavanapakas[1], T. Boonriong[1]

[1]Prince of Sonkla University, Songkhla, Thailand

Background: All-inside meniscal repair through the popliteus tendon (PT) has been proposed to enhance fixation of posterior horn tears of the lateral meniscus. However, the proximity of the common peroneal nerve (PN) raises concerns regarding potential iatrogenic injury during suture placement.
Objectives: To assess the risk of PN injury and to evaluate the effectiveness of different needle curvatures and lengths in safely achieving capsular penetration during all-inside lateral meniscal repair

through the PT.

Methods: Twenty-six knees from 13 cadaveric specimens underwent simulated arthroscopic meniscal repair using TrueSpan devices with five needle curvatures (straight, 12°-curved, 24°- curved, 12°-reverse-curved, 24°-reverse-curved) and three lengths (14 mm, 18 mm, 20 mm). Suture deployment was performed at both the upper and lower thirds of the lateral meniscus. Key outcomes included incidence of PN injury, incidence of capsular underpenetration, distances from the needle tip to the PN, and excess needle lengths beyond the capsule.
Results: No PN injury was observed in any of the repair attempts. Needle tip distances to the PN were not significantly different among all the devices. The 20-mm straight needle achieved 100% capsular penetration at the upper third of the meniscus, while the other needle types showed variable degrees of underpenetration.

Conclusion: All-inside lateral meniscal repair through the PT appeared safe with no risk of PN injury in the cadaveric specimens. A 20-mm straight needle offered the most reliable capsular penetration at the upper third of the meniscus.

P1348

COMPARATIVE EFFECTS AND MECHANISMS OF BOTULINUM TOXIN TYPE A VERSUS HYALURONIC ACID ON CHONDROCYTES

P. C. Hsieh[1], P. Y. Liu[2,4], T. S. Kuan[1,3]

[1]Department of Physical Medicine and Rehabilitation, National Cheng Kung University Hospital, Tainan, Taiwan; [2]Institute of Clinical Medicine, National Cheng Kung University, Tainan, Taiwan; [3]Department of Physical Medicine and Rehabilitation, College of Medicine, National Cheng Kung University, Tainan, Taiwan; [4]Division of Cardiology, Internal Medicine, National Cheng Kung University Hospital, Tainan, Taiwan

Objective: This study aimed to investigate the signaling pathways underlying the effects of botulinum toxin type A (BTXA) on chondrocytes and compare its chondrogenic potential with hyaluronic acid (HA).
Material and methods: Following dosage optimization via cell death ELISA, the ATDC5 chondrocytes were treated with or without BTXA, or with HA. The expression of Matrix metallopeptidases (MMPs), SOX9, and ROCK I & II was evaluated using RT-PCR and Western blot analysis.
Results: Western blot analysis revealed that BTXA treatment reduced ROCK I & II in a dose-dependent manner and reduced MMP-9. RT-PCR showed that HA treatment induced higher SOX9 mRNA levels than BTXA. Notably, BTXA decreased while HA increased MMP-3 expression, both in a dose-dependent manner.
Conclusion: BTXA exerts potential chondroprotective effect via inhibition of Rho-signaling pathway, a mechanism distinct from that of HA.

P1349

KNOWLEDGE, LIFESTYLE HABITS, AND PERCEPTIONS ABOUT BONE HEALTH AMONG MEXICAN LATE ADOLESCENTS AND YOUNG ADULTS ENTERING HEALTH CAREERS

D. Montiel-Ojeda[1], M. Calo[2], B. Araiza[3], V. Barrachina[2], P. Clark[1]

[1]Unidad de Investigación en Epidemiología Clínica, Hospital Infantil de México Federico Gómez - UNAM, Mexico City, Mexico; [2]International Osteoporosis Foundation, Mexico City, Mexico; [3]Facultad de Medicina, Universidad Nacional Autónoma de México, Mexico City, Mexico

Objective: To explore the knowledge and perspectives about bone health in late adolescent/young Mexican adults.
Material and Methods: A transversal survey to explore knowledge about bone health. The survey was conducted during the "2° Feria de Salud Integral" at the Universidad Nacional Autónoma de México (UNAM) School of Medicine, an event that gathered new information on science and medicine careers of individuals aged 17 to 40.
Results: The survey gathered responses from 1,292 students, of whom 66.6% were women. Nearly half of the respondents (49.8%) were aged 18–20 years. Most students (94.7%) considered it important to take care of their bone health at their age, and 87.6% had heard about the relationship between bone health and osteoporosis. Regarding physical activity, 68.1% reported engaging in moderate-to-vigorous exercise at least twice per week, and 75.7% reported engaging in strength- or impact-based activities. Regarding nutrition, 69.7% reported consuming calcium-rich foods at least once daily. More than half of the students reported sun exposure without sunscreen for over 15 minutes per day. Caffeine intake was relatively low (15.2%), while 32.4% reported consuming carbonated beverages, mainly soft drinks. Smoking and vaping use were uncommon (5.4% and 2.9%, respectively).
Conclusion: Medical sciences students showed a high awareness of bone health and generally favorable lifestyle habits. Despite potential response bias, these findings provide a baseline for understanding perceptions regarding bone health among future health professionals.
Acknowledgments: The authors thank the students for their collaboration. We thank the IOF for its support in the application of the survey, as well as the students of the Clinical Epidemiology Research Unit for their support on-site. The intervention was a result of a collaboration between IOF and UNAM School of Medicine within the framework of IOF University Network.
Disclosures: M.C. and V.B. are IOF employees. D.MO., P.C., and B.A. report no conflict of interest.

P1350

TRABECULAR BONE SCORE AND AREAL BONE MINERAL DENSITY ACCRUAL IN RELATION TO PEAK BONE MASS IN CHILDREN AND ADOLESCENTS FROM MEXICO CITY

M. A. Guagnelli[1], D. Lopez-González[1], A. N. H. Walstra[2], K. Hind[2,3], D. Hans[2,4], P. Clark[1]

[1]Clinical Epidemiology Unit, Hospital Infantil de México Federico Gomez – Facultad de Medicina, Universidad Nacional Autónoma de México, Mexico City, Mexico; [2]Medimaps Group SA, Geneva, Switzerland; [3]Faculty of Health and Medicine, Lancaster University, Lancaster, United Kingdom; [4]Center of Bone Diseases, Rheumatology Unit, Bone and Joint Department, Lausanne University Hospital & University of Lausanne, Lausanne, Switzerland

Objective: Peak bone mass acquisition is a key determinant of lifelong skeletal health. Bone mineral accumulation and trabecular microarchitectural development may follow different biological patterns during growth. Trabecular bone score (TBS) is a DXA-derived index reflecting trabecular bone microarchitecture and provides information complementary to areal bone mineral density (BMD). This study compared age- and sex-specific patterns of lumbar spine TBS and BMD in a healthy pediatric population from Mexico City within the context of peak bone mass development.
Material and Methods: This cross-sectional analysis included lumbar spine DXA scans from 1,552 healthy participants aged 5–18 years. Scans were acquired using a GE Lunar iDXA system. TBS was derived using TBS Osteo Advanced (version 4), incorporating correction for soft-tissue thickness. BMD and TBS values were stratified by sex and analysed across the age range.
Results: A total of 1,533 participants (781 females, 752 males) were included. Both BMD and TBS were higher at older ages; however, distinct age-related patterns were observed. BMD showed a pronounced pubertal pattern, with the steepest age-associated differences at approximately 12–13 years in females and 13–14 years in males, followed by attenuation toward late adolescence. In contrast, TBS demonstrated smaller age-associated differences and greater variability across age groups. In females, higher TBS values were observed at younger ages relative to the age at which BMD values were highest, whereas in males, higher TBS values were observed at older ages relative to BMD. A moderate positive association between BMD and TBS was observed in females (Spearman r = 0.651) and males (r = 0.644).
Conclusion: TBS and areal BMD exhibited age- and sex-dependent patterns consistent with different components of skeletal development relevant to peak bone mass. While BMD primarily reflects mineral accumulation, TBS provides complementary information on bone microarchitectural status. Sex-specific differences in the timing of higher TBS values align with known patterns of pubertal maturation and underscore the importance of age- and sex-appropriate reference data. Together, these findings support the combined use of TBS and BMD to improve characterization of bone health during the critical period of peak bone mass development.

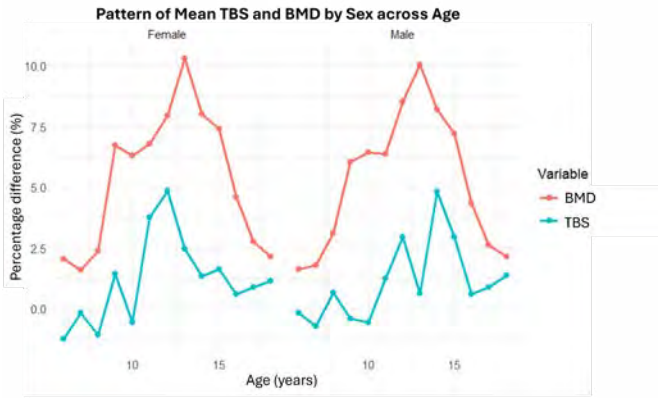

Figure 1 Sex-specific mean trabecular bone score (TBS; blue) and areal bone mineral density (BMD; red) across ages 5 to 18

P1351

TRABECULAR BONE SCORE BY TANNER STAGE IN CHILDREN AND ADOLESCENTS FROM MEXICO CITY

M. A. Guagnelli[1], D. Lopez-González[1], A. N. H. Walstra[2], K. Hind[2,3], D. Hans[2,4], P. Clark[1]

[1]Clinical Epidemiology Unit, Hospital Infantil de México Federico Gomez – Facultad de Medicina, Universidad Nacional Autónoma de México, Mexico City, Mexico; [2]Medimaps Group SA, Geneva, Switzerland; [3]Faculty of Health and Medicine, Lancaster University, Lancaster, United Kingdom; [4]Center of Bone Diseases, Rheumatology Unit, Bone and Joint Department, Lausanne University Hospital & University of Lausanne, Lausanne, Switzerland

Objective: Trabecular bone score (TBS) is a DXA-derived index reflecting trabecular bone microarchitecture and may provide complementary information to bone mineral density during growth. Skeletal development during childhood and adolescence is strongly influenced by pubertal maturation, yet pediatric TBS reference data stratified by pubertal stage are limited. This study aimed to establish sex-specific TBS reference curves in Mexican children and adolescents and to evaluate the influence of pubertal development, defined by Tanner stage, on TBS.
Material and Methods: Lumbar spine DXA scans (GE Lunar iDXA) from 1,552 healthy participants (age 5–18 years, 781 females, 752 males) were analysed using TBS Osteo Advanced (version 4), incorporating correction for abdominal soft-tissue thickness. TBS values were stratified by sex and Tanner stage (Sexual Maturity Rating 1–5). Smoothed Tanner stage and age-specific percentile curves were generated using Generalized Additive Models for Location, Scale, and Shape (GAMLSS).
Results: TBS increased significantly across pubertal development in both sexes, with the most pronounced gains observed between Tanner stages 2 and 3 (13.2% in girls and 9.9% in boys). Females demonstrated an earlier and steeper rise in TBS beginning at Tanner stage 2–3, with peak values reached by stage 4 (mean TBS 1.28), whereas males exhibited a more gradual increase extending from Tanner stages 3 to 5. Sex- and Tanner stage–specific TBS percentile curves and corresponding age-based reference curves were established.
Conclusion: Trabecular bone score shows clear, sex-specific pubertal trajectories in Mexican children and adolescents, with marked increases during mid-puberty. These findings underscore the value of considering

pubertal stage, in addition to chronological age, when interpreting TBS in young people. The provision of Tanner stage–specific reference data supports the use of TBS as a complementary tool for assessing bone microarchitecture during growth and skeletal maturation.

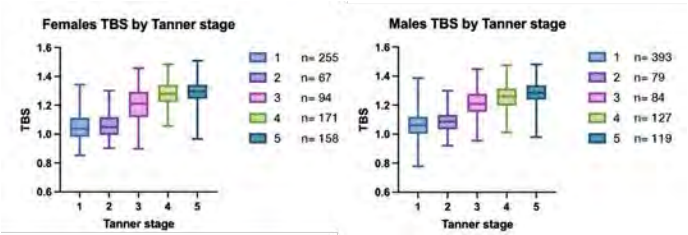

Figure 1 Boxplot representing TBS distributions by Tanner stage for males and females.

TRABECULAR BONE SCORE (TBS) AT THE HIP REFLECTS 3D BONE MICROARCHITECTURE: A MICRO-CT VALIDATION STUDY

P. Eghbalishamsabadi[1], G. Gatineau[1,2], M. De Gruttola[1], M. Swainson[3], M. Davies[1], A. Walstra[1], K. Hind[1,3], D. Hans[1,2]

[1]Medimaps Group, Plan-les-Ouates, Switzerland; [2]Center of Bone Diseases, Rheumatology Unit, Bone and Joint Department, Lausanne University Hospital & University of Lausanne, Lausanne, Switzerland; [3]Faculty of Health and Medicine, Lancaster University, Lancaster, United Kingdom

Objectives: Hip fractures are the most burdensome osteoporotic fracture, associated with significant morbidity and a 20-30% mortality rate within one year post fracture. Resilience to fracture depends on both density and microarchitecture. Trabecular bone score (TBS) provides an established surrogate of bone microarchitecture at the lumbar spine and predicts fracture independent of bone mineral density (BMD). The aim of this study was to validate TBS Hip with micro-computed tomography (micro-CT)-derived 3D bone microarchitecture.
Methods: Thirty dry human cadaveric proximal femurs were imaged using micro-CT (42 µm isotropic voxel size). A standardized trabecular region within the femoral neck was segmented (Figure 1), and microarchitectural parameters were quantified: bone volume fraction (BV/TV), connectivity density (Conn.D), trabecular thickness (Tb.Th), trabecular separation (Tb.Sp), and trabecular number (Tb.N). Specimens then underwent DXA scanning with TBS analysis. A femoral neck mask was registered to ensure anatomical correspondence between modalities (Figure 1). To account for soft tissue, additional DXA scans were acquired with simulated tissue (16 cm high-density polyethylene and 9 mm polyvinyl chloride).
Results: TBS of the femoral neck showed strong correlations with all micro-CT parameters, including BV/TV ($r = 0.86$), Tb.N ($r = 0.85$), Tb.Sp ($r = -0.87$), Tb.Th ($r = 0.70$), and Conn.D ($r = 0.62$; all $p < 0.001$). When simulated soft tissue was applied, TBS maintained significant positive correlations with BV/TV ($r = 0.66$), Tb.N ($r = 0.66$), Tb.Th ($r = 0.57$), and Conn.D ($r = 0.53$), as well as a negative correlation with Tb.Sp ($r = -0.68$; all $p < 0.001$). After adjusting for BMD, correlations remained moderate and significant for Conn.D ($r = 0.53$, $p = 0.003$), Tb.N ($r = 0.51$, $p = 0.004$), BV/TV ($r = 0.43$, $p < 0.001$), and Tb.Sp ($r = -0.66$, $p < 0.001$).
Conclusions: TBS at the hip demonstrates strong associations with three-dimensional trabecular microarchitecture. Correlations remained moderate and significant after adjustment for BMD, indicating that TBS captures bone microarchitecture independent of density. These findings validate TBS as a measure of bone quality at the hip, a critical osteoporotic fracture site.

Figure 1. TBS Hip region of interest (ROI)

P1353

TRABECULAR BONE SCORE (TBS) AT THE HIP DEMONSTRATES HIGH EX-VIVO AND IN-VIVO REPRODUCIBILITY

P. Eghbalishamsabadi[1], G. Gatineau[1,2], M. De Gruttola[1], M. Swainson[3], M. Davies[1], A. Walstra[1], K. Hind[1,3], D. Hans[1,2]

[1]Medimaps Group, Plan-les-Ouates, Switzerland; [2]Center of Bone Diseases, Rheumatology Unit, Bone and Joint Department, Lausanne University Hospital & University of Lausanne, Lausanne, Switzerland; [3]Faculty of Health and Medicine, Lancaster University, Lancaster, United Kingdom

Objectives: Trabecular bone score (TBS) at the hip has the potential to extend assessment of bone microarchitecture beyond the lumbar spine. Clinical implementation requires robust reproducibility within International Society for Clinical Densitometry (ISCD) standards. This study aimed to evaluate the ex-vivo and in-vivo reproducibility of DXA-derived TBS Hip, and to define precision error and least significant change (LSC) thresholds relevant for clinical and longitudinal use.
Methods: Reproducibility of TBS Hip was assessed in both ex-vivo and in-vivo settings. For ex-vivo analysis, 30 proximal femur bone specimens underwent two repeated DXA acquisitions to evaluate measurement stability under controlled conditions. In-vivo reproducibility was assessed in 30 individuals, each undergoing two repeated DXA scans with bilateral hip acquisitions (120 acquisitions in total). TBS Hip values were analysed using a defined femoral neck mask to ensure consistent anatomical localisation of the trabecular region of interest. Measurement precision was quantified using the root mean square (RMS) coefficient of variation (CV) in accordance with ISCD recommendations. LSC was calculated at the 95% confidence level ($2.77 \times CV$).
Results: Ex-vivo analysis demonstrated high measurement stability, with an RMS-CV of 0.58% and a corresponding 95% LSC of 1.60%. In the clinical cohort, in-vivo reproducibility remained robust, with an RMS-CV of 1.73% and a 95% LSC of 4.79%. Although in-vivo precision was reduced compared with ex-vivo conditions, values remained within the ISCD-recommended LSC threshold of 5.1% for clinical applicability.
Conclusions: TBS Hip demonstrates high reproducibility in both ex-vivo and clinical settings. Precision and LSC values meet established ISCD

criteria, supporting the technical robustness of the algorithm. These findings confirm that TBS Hip is suitable for longitudinal assessment of bone microarchitecture at the proximal femur.

P1354

A NOVEL PHEX VARIANT UNDERLYING X-LINKED HYPOPHOSPHATEMIC RICKETS

P. Ferreira[1], S. Ribeiro[1], R. Quental[2], A. Varela[1]

[1]Serviço de Endocrinologia, Diabetes e Metabolismo, ULS São João, Porto, Portugal; [2]Serviço de Genético, ULS São João, Porto, Portugal

Background: X-linked hypophosphatemic rickets (XLH) is a rare inherited disorder of phosphate metabolism, characterized by renal phosphate wasting, impaired bone mineralization, and variable skeletal involvement. Although usually diagnosed in childhood, XLH can show clinical heterogeneity, even within the same family. We report a family in which evaluation of an affected proband led to the identification of a previously unreported PHEX variant.
Case presentation: The index case is a male patient, currently 20 years old, followed for XLH diagnosed in childhood. Genetic testing performed early in the evaluation identified a hemizygous PHEX variant, c.2039A>C (p.Asn680Thr), classified as a variant of uncertain significance and not previously reported in the literature. He initially presented with recurrent knee pain and progressive genu valgum, requiring corrective orthopedic surgery. Dental involvement was also documented, with multiple devitalized teeth. Biochemical evaluation consistently demonstrated hypophosphatemia. The patient has been managed with conventional therapy and is currently with oral phosphate supplementation (six tablets per day) and calcitriol 0.5 µg daily. During follow-up, mild medullary nephrocalcinosis and a small non-obstructive renal calculus were identified, without impairment of renal function. At present, he is asymptomatic, with normal final height and no musculoskeletal pain. Family evaluation revealed the same variant in his mother, sister, and maternal uncle. The mother is asymptomatic. The sister presents persistent hypophosphatemia but no overt musculoskeletal manifestations. In contrast, the maternal uncle exhibits a more severe phenotype, with short stature and significant skeletal deformities, having undergone multiple orthopedic surgeries.
Conclusion: This family illustrates a broad clinical spectrum associated with a novel PHEX gene variant, ranging from asymptomatic or biochemically mild disease to clinically significant XLH. These findings emphasize the need for high clinical suspicion to identify affected individuals, and the reporting of novel variants in international databases. Such vigilance is crucial to enhance understanding of this rare disorder, refine genotype–phenotype correlations, and optimize patient management.

P1355

FULLY DIGITAL PLATFORM FOR FRACTURE LIAISON SERVICE AND OSTEOLOGY - A PILOT PROJECT

P. Hasler[1]

[1]aarReha, Schinznach Bad, Switzerland

Objective: Solutions to identify, investigate and treat patients after an osteoporotic fracture have been locally successful in significantly reducing the rate of new fractures in the first two years after a major osteoporotic fracture. However, broader use and meaningful improvement have failed despite information campaigns and promotion. In Switzerland there remains an overall treatment gap of 83 % according to the SCOPE 2019 analysis. The consequences are persisting high suffering and costs to society. Because the adoption of fracture liaison service (FLS) standards has been shown to be effective, the aim of the current project is to study the impact of a fully digital program to identify, investigate and to include patients in an FLS that complies with the International Osteoporosis Foundation (IOF) standards and to document their treatment.
Methods: At aarReha, discharge reports from referring institutions for in-house or ambulatory care are scanned for entry into the clinical information system as an electronic PDF file with optical character recognition. Potential fracture cases will be ranked according to the number of fracture-related terms recognized. Identified cases will be flagged for inclusion in an FLS or at a specialist osteology care facility for investigation and treatment. A list of items according to the IOF FLS specifications and for routine osteology care will be implemented in a structured data entry format and tested in a clinical routine setting. A real-time, automated report generator will compile the entered clinical data, osteodensitometry values and lab results in a patient report as the basis for standardized communication to patients and their basic and specialist health care providers. The FLS follow-ups will be documented likewise. All data points will be stored in an addressable format for continuous statistical evaluation and monitoring.
Results and Conclusions: Broad implementation of FLSs and achieving its benefits has been elusive. With the described system we aim to assess the practicability and performance of an innovative, comprehensive and scalable digital approach to FLS and post-fracture care.
Acknowledgments: This project is funded as a Pilot Project by the Health Department of the Canton Aargau, Aarau, Switzerland.

P1356

BEFORE AND AFTER A HIP FRACTURE: ARE WE PROPERLY MANAGING OSTEOPOROSIS?

P. J. Manuel Hernandez[1], E. Monleon Acosta[1], J. A. Rodríguez Fernández[1], A. López Lisón[1], M. R. Oliva Ruiz[1], J. M. Andreu Ubero[1], A. Pérez González[1], G. Albaladejo Paredes[1], P. V. Castillo Dayer[1], C. Fernández Díaz[1], A. Egea Fuentes[1], M. Fernández Salamanca.[1], V. Cogolludo Campillo[1]

[1]Hospital Universitario Santa Lucía, Cartagena, Spain

Objectives:
To evaluate the therapeutic management following osteoporotic hip fractures, as well as associated mortality and subsequent fracture rates, in order to determine whether establishing a fracture unit coordinated by a specialist in bone metabolism could offer a clinical benefit for these patients.
Methods:
A retrospective observational study was conducted at a tertiary care center (Hospital Santa Lucía, Cartagena) including patients with osteoporotic hip fracture. Data were systematically collected between January 2017 and January 2023.
Results:
We collected 1,068 patients with a mean age of 81.4 ± 10.5 years.
The 22.3% of patients had a history of previous osteoporotic fracture, being hip fracture the most frequent (9.2%), followed by vertebral fractures (4.6%). Despite this, only 2.6% of individuals in our sample had received anti-osteoporotic treatment and just the 10.5% of individuals had been treated with calcium and vitamin D supplements prior to sustaining the hip fracture.
After the fracture, 20.4% of patients received osteoporosis treatment, and among these, denosumab was the most frequently prescribed drug (12.2%), followed by bisphosphonates (2.25%). Calcium and vitamin D supplementation was prescribed in 41.3% of patients.
At 5 years of follow-up, the mortality rate was 45% (23.1% within the first year, 18.1% at 3 years, and 3.8% at 5 years), and 9.4% experienced a new fragility fracture, being hip fracture the most common.
Only 4.5% of these individuals were followed after the fracture by a rheumatology service, 23.8% were followed by a rehabilitation specialist service, and 18.1% by a geriatrics service.
Conclusions:
Our study shows a high mortality rate after suffering an osteoporotic hip fracture. Despite a substantial proportion of patients having a history of prior osteoporotic fractures, the vast majority was not receiving anti-osteoporotics. Although the proportion of patients receiving anti-osteoporotic treatment increased following the fracture, it remained suboptimal. Moreover, less than half of the patients were followed by a specialist in bone disease after the event.
These findings underscore the need of implementing a fracture liaison service (FLS) led by an expert in bone metabolism, aiming to increase the specialist follow-up rates and enhance the proportion of patients receiving osteoporosis treatment.

P1357

DESIGN AND CHARACTERIZATION OF LUMINESCENT NANOPARTICLES FOR THEIR APPLICATION IN BONE REGENERATION AND ANGIOGENESIS

L. Lozano-Barajas[1], R. Sanchez[1], P. Sengar[2], M. Marsal[3], P. Loza[3], G. Hirata[2], P. Juarez[4]

[1]CICESE, Ensenada, Mexico; [2]UNAM, Ensenada, Mexico; [3]ICFO, Barcelona, Spain; [4]CICESE- AMMOM, Ensenada, Mexico

Objective: Bone tissue is a dynamic and highly vascularized structure with an inorganic matrix composed primarily of hydroxyapatite (HAp) crystals, Ca5(PO4)3OH. Synthetic Hap is osteoconductive, facilitating cartilage formation, hard tissue deposition, and blood vessel proliferation. These properties make it useful in nanomedicine for treating musculoskeletal disorders resulting from imbalances in the bone remodeling process, such as those caused by mechanical stress. The Eu3+ ion is a particularly promising activator for the apatite family due to its stable luminescence, high thermal and chemical stability, biocompatibility, and applications in bioimaging. The purpose of this work was the synthesis and biological characterization of calcium phosphates doped with europium ions (Eu3+) using hydrothermal and combustion methods, selected for their efficiency in obtaining particles with controlled structural and optical properties, as well as biocompatibility.
Materials & Methods: Physicochemical characterization was carried out using techniques such as scanning electron microscopy (SEM), transmission electron microscopy (TEM), X-ray diffraction (XRD), Fourier transform infrared spectroscopy (FTIR), energy-dispersive X-ray spectroscopy (EDS), photoluminescence (PL) and cathodoluminescence (CL) spectroscopy. For biological evaluation, *in vitro* assays were performed on different cell lines, including osteoblasts, using colorimetric cell viability tests, cellular internalization observed by confocal microscopy, and measurement of reactive oxygen species (ROS). Additionally, live studies were done using zebrafish (Danio rerio) at early stages of development, using both wild type and Fli strains.
Results: Luminescent nanoparticles presented the expected physicochemical characteristics, including size and luminescence. They were safe to use in vitro, got internalized in the cells, and induced ROS. They were detected in Fli-zebra fish, and at low doses, they did not induce mortality and malformations in embryonic development, as demonstrated by the internalization of the nanomaterials using confocal microscopy. The materials did not generate significant toxic effects, supporting their potential use in biomedical applications.
Conclusion: the synthesized luminescent materials exhibited optimal structural and optical properties, as well as biocompatibility in both *in vitro* and *in vivo* models. These results suggest that the developed materials are promising candidates for applications in regenerative medicine, particularly in bone tissue engineering (BTE) and angiogenesis promotion.

P1358

CARDIAC TROPONINS, PROGNOSTIC BIOMARKERS FOR AFTER-FALL MORTALITY IN OLDER ADULTS

P. Khashayar[1,2]

[1]University of Hertfordshire/School of Life and Medical Sciences, Hertfordshire, United Kingdom; [2]University of Minnesota/ International Institute for Biosensing, Minneapolis, United States

Osteoporosis and cardiovascular disease (CVD) are highly prevalent age-related conditions that share overlapping risk factors and frequently coexist. Their concurrence substantially increases the risk of falls and fall-related fractures in older adults. Despite this, falls remain an underrecognized clinical consequence of CVD, with reported rates approaching 60% in hospitalized patients and 25–40% among those with stroke or heart failure.

Cardiac biomarkers, particularly high-sensitivity cardiac troponins, are routinely measured in older adults, yet their clinical significance in the context of falls is not well established. We performed a systematic review of PubMed using the terms "high-sensitivity cardiac troponin T (hs-cTnT) or I (hs-cTnI)," "falls, fall-related hospitalization, functional performance, and mortality," and "older adults or the elderly." Of 90 identified articles, 60 met inclusion criteria. Outcomes of interest included myocardial infarction, mortality, and fall-related clinical outcomes.

Across studies, elevations in cardiac troponins following falls were frequently reported and consistently associated with increased short- and long-term mortality. Importantly, elevated hs-cTnT and hs-cTnI levels were often observed following falls in the absence of acute myocardial infarction or other overt cardiovascular events. Mortality within one year after a fall was significantly higher in individuals with elevated troponin levels, independent of underlying cardiovascular disease. In addition, a community-based cohort study of 1,179 women aged over 70 years demonstrated that higher subclinical hs-cTnI levels were independently associated with increased fall-related hospitalizations over 14.5 years (hazard ratio 1.46, 95% CI 1.08–1.98) and impaired functional performance, as assessed by the Timed Up-and-Go test.

Overall, the available evidence suggests that elevated cardiac troponins in older adults presenting after falls are rarely indicative of acute coronary syndromes. Instead, they appear to function as prognostic biomarkers of increased mortality, frailty, functional decline, and fall-related hospitalization. Incorporating high-sensitivity troponin measurements into clinical assessment may enhance risk stratification and inform management strategies for older adults at risk of falls and adverse outcomes.

P1359

INCREASED BONE MINERAL DENSITY IN THE LUMBAR SPINE IN PATIENTS WITH RHEUMATOID ARTHRITIS DURING LONG-TERM OBSERVATION

P. Kovalenko[1], I. Dydykina[1], A. Smirnov[1], S. Glukhova[1], E. Nasonov[1]

[1]V.A.Nasonova Research Institute of Rheumatology, Moscow, Russia

Introduction. Chronic inflammation in rheumatoid arthritis (RA) is one of the causes of activation of bone resorption, occurrence of erosive changes, disruption of microarchitecture, bone mineral density (BMD) decrease and increased risk of vertebral and peripheral bone fractures.

The aim – to study the dynamics of bone mineral density, vertebral deformations and degenerative changes in the lumbar spine in patients with rheumatoid arthritis during long-term prospective observation.

Materials and methods. A prospective multi-year cohort study, the duration of which was 9.7 ± 1.7 years, included 151 women with RA aged 53.9 ± 9.2 years with a reliable diagnosis established at the age of 41.9 ± 12.5 years. All patients underwent clinical, laboratory and radiological examination (X-ray densitometry of the lumbar spine (L1–L4), femoral neck (FN) and total hip (TH), X-ray morphometry of the spine using the Genant method, assessment of degenerative changes in the lumbar spine) in dynamics.

Results. A BMD decrease in FN and TH and stabilization in L1–L4 were established; in patients over 55 years of age it was an increase in BMD in L1–L4 and a decrease in FN and TH; a decrease in BMD in all studied skeletal regions in patients under 55 years of age. The appearance or increase in deformations (fractures) of the vertebrae in the thoracic spine was observed in 50 (33%) patients, in the lumbar spine –in 4 (2.6%) patients; a relationship between deformations (fractures) of the vertebrae and an increase in BMD was not established. An increase in degenerative changes in all segments of the lumbar spine was established in patients with pain and a significant increase in L1–L4 BMD. Long-term monotherapy with DMARDs, as well as with biologics, did not have a positive effect on the BMD.

Conclusions. A long-term prospective cohort study revealed stabilization of the BMD in L1–L4; its increase in the group of patients with RA over 55 years of age against the background of the appearance or intensification of the initial deformation (fractures) of the vertebrae; and an increase in degenerative changes in all segments of the lumbar spine.

P1360

RATE OF RADIOGRAPHIC PROGRESSION OF RHEUMATOID ARTHRITIS. RESULTS OF LONG-TERM OBSERVATION

P. Kovalenko[1], I. Dydykina[1], A. Smirnov[1], S. Glukhova[1], E. Nasonov[1]

[1]V.A.Nasonova Research Institute of Rheumatology, Moscow, Russia

Introduction. Radiographic progression (RP) of rheumatoid arthritis (RA) is one of the main signs of the disease and a key factor in assessing the effectiveness of therapy. RP is accompanied by an increase in the number of erosions, narrowed joint spaces, and radiographic stage (Rg stage).
Objective. To compare the characteristics of RA patients with rapid and slow rates of radiographic progression during long-term follow-up.
Materials and Methods. A prospective cohort study lasting 9.7 ± 1.7 years included 151 women with RA, aged 53.9 ± 9.2 years. All patients underwent clinical, laboratory, and radiographic examinations. RP was analyzed consideringchanges in the Steinbrocker RA stage, the number of erosions, and the degree of joint space narrowing using the Sharp method.
Results. An increase in the erosion count according to SVH was detected in 66 (53%) patients, and narrowed clefts – in 81 (65%) patients. The number of patients with Rg1, Rg2, and Rg3 decreased; those with Rg4 increased from 29 (19%) to 54 (36%) people ($p<0.05$). Slow RP (Rg1-Rg2 in dynamics) was observed in 63 (42%) patients, and rapid RP (increase in Rg stage) – in 32 (21%) patients. In 56 (37%) patients, the Rg stage did not change. Rapid RP is associated with a younger age at RA onset and inclusion in the study, with a longer duration of RA, with a higher MMP-3 index and IL-6 level above normal in dynamics, with a lower dose of methotrexate both in monotherapy and in combination with other agents; with a higher average daily and cumulative dose of GC.
Conclusions. A long-term prospective study demonstrated RP despite achieving remission and decreasing activity in the majority of RA patients. The rate of RP depends on many factors, both RA-related and non-RA-related. Distinguishing phenotypes of RA patients with rapid and slow RP will enable a personalized approach to patient management.

P1361

EFFICACY AND SAFETY OF INJECTION THERAPY WITH A DOMESTIC BIOPOLYMER MICROHETEROGENEOUS COLLAGEN-CONTAINING HYDROGEL OF LOW, MEDIUM, AND HIGH DENSITY IN PATIENTS WITH KNEE OSTEOARTHRITIS

P. Kovalenko[1], I. Dydykina[1], E. Shakhramanova[1], D. Gukasyan[1], V. Zelenov[1], O. Alekseeva[1], S. Shkireeva[1], E. Zotkin[1]

[1]V.A.Nasonova Research Institute of Rheumatology, Moscow, Russia

Introduction. Orthobiology (OB) is a new approach to osteoarthritis (OA) treatment. OB promotes natural restoration of joint structures without surgical intervention.
Objective. To present a comparative assessment of the efficacy and safety of therapy with a domestic biopolymer microheterogeneous collagen-containing hydrogel of low, medium, and high density in patients with knee OA.
Materials and Methods. This open-label, post-registration, randomized, observational, prospective, comparative, single-center study in three groups using a low, medium, and high-density hydrogel included 60 women and men aged 40 to 75 years diagnosed with knee OA stages II-III according to Kellgren and Lowrence. Pain and patient condition were assessed using a visual analog scale (VAS), the Lequesnealgofunctional index, and the WOMAC, KOOS, and EQ-5D-3L questionnaires. Statistical analysis was performed using Statistika 10 for Windows.
Results. Three treatment groups were formed: low-, medium-, and high-density hydrogel. After one month of therapy, all studied parameters improved: the proportion of patients with a pain VAS score <40 mm increased to 63%, 95%, and 58%, respectively. The EQ-5D-3L score, compared with baseline, improved by 81%, 35%, and 37%, respectively. The need for NSAIDs decreased in all groups. After 6 months of follow-up, there were no differences between the groups in VAS pain scores, WOMAC, KOOS, and EQ-5D-3L scales.
Conclusions. Comparable efficacy and safety of low-, medium-, and high-density hydrogels were established after 6 months of follow-up. There were no serious adverse reactions. Joint pain and stiffness after intravenous injection, primarily of high-density hydrogel, were relieved with nonsteroidal anti-inflammatory drugs. The use of hydrogel is a promising method of orthobiological therapy of OA.

P1362

A COMPARATIVE STUDY OF PREVALENCE OF ANTERIOR KNEE PAIN AND FUNCTIONAL OUTCOME BETWEEN TOTAL KNEE REPLACEMENT WITH PATELLAR RESURFACING, WITH OR WITHOUT CIRCUMFERENTIAL PATELLAR DENERVATION: A RANDOMIZED CONTROLLED TRIAL

P. Limpanapittayatorn[1], P. Pinijprapa[1], O. P. Phruetthiphat[1]

[1]Phramongkutkalo Hospital, Bangkok, Thailand

Objective(s):
To compare the incidence and severity of anterior knee pain and functional outcomes between total knee arthroplasty with patellar resurfacing with or without circumferential patellar denervation.

Material and Methods:
This double blinded, randomized controlled trial studied patients with knee osteoarthritis who underwent total knee arthroplasty with patellar resurfacing. Knees were randomized to receive circumferential patellar denervation or no denervation. Denervation was done by using a monopolar coagulation diathermy set to 45 W to a depth of no more than 1 mm around the patellar rim. Baseline patient data were collected. Outcomes included the incidence of anterior knee pain, anterior knee pain score, and Knee Society Score. Clinical assessment was performed at 6 weeks, 3 months, and 6 months after surgery.

Results:
A total of 102 knees were analyzed, with 51 knees in each group. Baseline demographic characteristics were similar between groups. At 3 months postoperatively, the incidence of anterior knee pain was identical

between the denervation and non-denervation groups (15/51 [29.41%] vs 15/51 [29.41%], p=0.999). The mean anterior knee pain score did not differ between the denervation and non denervation groups (0.63±1.33 vs 0.61±1.30, p=0.821). Knee Society Score improved significantly from the preoperative period in both groups across all follow up visits. No significant difference in functional outcome was observed between groups at any time point.

Discussion:
These findings indicate that circumferential patellar denervation does not add measurable benefit when patellar resurfacing is already performed. Pain related to the patellofemoral joint may be adequately addressed by resurfacing alone, reducing the potential impact of additional nerve ablation. The neutral effect observed in this trial aligns with previous randomized studies reporting limited or inconsistent benefit of patellar denervation when combined with patellar resurfacing.

Conclusion(s):
Circumferential patellar denervation in total knee arthroplasty with patellar resurfacing did not reduce anterior knee pain or improve knee function compared with no denervation.

P1363

RENAL SAFETY OF ZOLEDRONIC ACID IN ELDERLY PATIENTS WITH OSTEOPOROSIS AND CHRONIC KIDNEY DISEASE

P. M. Negrão[1], F. A. A. Uechi[1], H. F. Kroes[1], D. S. Domiciano[1], A. S. Franco[1]

[1]Division of Rheumatology, Hospital das Clinicas HCFMUSP, Faculdade de Medicina, Universidade de Sao Paulo, São Paulo, Brazil

Objective: Osteoporosis (OP) and chronic kidney disease (CKD) frequently coexist in the elderly, creating uncertainty regarding the safety of zoledronic acid (ZA). This study aimed to evaluate renal safety and the risk of hypocalcemia following ZA infusion in elderly patients with CKD stages 3b and 4.
Materials and methods:
Patients receiving ZA for OP were identified at a tertiary referral hospital through a retrospective review of electronic medical records from January 2022 to December 2024. Eligible patients were aged ≥ 60 years with CKD stages 3b and 4, defined as an eGFR (CKD-EPI) or CrCl (Cockcroft–Gault) < 45 mL/min. Renal function parameters and serum calcium levels were obtained before and after ZA infusion. Continuous variables were expressed as mean ± standard deviation (SD) and compared using the Wilcoxon signed-rank test. Statistical analyses were performed using R software, with a significance level of $p < 0.05$.
Results:
Of 1,080 ZA infusions screened, 145 met inclusion criteria, comprising 110 patients with CKD stage 3b and 35 with stage 4. The population had a mean age of 78.4 ± 9.0 years, was 94.5% female, and 85% white. Fragility fractures were present in 92 (63%) patients. Mean BMI was 23.3 ± 4.2 kg/m², and baseline 25-hydroxyvitamin D was 39.3 ± 13.7 ng/mL. Renal function and calcium levels remained clinically stable during a mean follow-up of 174.7 days between pre- and post-infusion assessments. Serum creatinine showed no significant variation (1.09 ± 0.3 vs. 1.09 ± 0.36 mg/dL; p = 0.35). Similarly, eGFR was preserved using both CKD-EPI (56.7 ± 15.2 vs. 58.3 ± 17.9 mL/min/1.73 m²; p = 0.15) and Cockcroft–Gault equations (35.9 ± 6.8 vs. 37.1 ± 9.5 mL/min; p = 0.62). Total serum calcium levels were also maintained (9.53 ± 0.51 vs. 9.34 ± 0.50 mg/dL; $p < 0.01$).
Conclusion:
Zoledronic acid infusion demonstrated a favorable safety profile in elderly patients with CKD stages 3b and 4. Renal function remained stable and no clinically significant hypocalcemia was observed, supporting the use of ZA as a therapeutic option in this high-risk population.
Keywords: Osteoporosis; Chronic Kidney Disease; Elderly; Zoledronate-aqqg.

ARTIFICIAL INTELLIGENCE VS HUMAN INTERPRETATION FOR OPPORTUNISTIC DETECTION OF VERTEBRAL FRACTURES IN ROUTINE CT IMAGING: RESULTS OF A 2-MONTHS PILOT STUDY

P. Makras[1,2], M. Yavropoulou[2,3], E. Chatzellis[1], C. Gravvanis[1], G. Kanti[1], K. Papadimitropoulos[4], N. Kyriakopoulos[5]

[1]Department of Endocrinology and Diabetes, 251 Hellenic Air Force & VA General Hospital, Athens , Greece; [2]Department of Medical Research, 251 Hellenic Air Force & VA General Hospital, Athens, Greece; [3]Endocrinology Unit, First Department of Propaedeutic and Internal Medicine, Medical School, National and Kapodistrian University of Athens, Athens, Greece; [4]Hospital Command, 251 Hellenic Air Force & VA General Hospital, Athens, Greece; [5]Department of Radiology, MRI Section, 251 Hellenic Air Force & VA General Hospital, Athens, Greece

Objective:
To evaluate the diagnostic performance of an artificial intelligence (AI) system for detecting vertebral fractures (VFs) opportunistically in routine chest and abdominal CT scans compared with human readers in a real-world hospital setting during a single-center pilot study.
Material and Methods:
All thoracic and abdominal CT scans performed over two months in patients aged ≥50 years at a tertiary hospital were prospectively analyzed using the HealthOST AI platform (Nanox AI Ltd.). Routine radiology reports and targeted endocrinologist reviews were compared to AI findings. A gold-standard adjudication panel confirmed VF presence or absence. Statistical comparisons of sensitivity, specificity, predictive values, and odds ratios (OR) were performed using χ^2 tests ($p<0.05$).
Results:
Among 427 scans, AI achieved a sensitivity of 86.3% in the discrimination of CT scans with or without VFs, outperforming radiologists (50.0%) and endocrinologists (68.8%) ($p\leq0.01$). In addition, AI demonstrated significantly higher odds of correctly flagging VFs leading to case finding: OR=14.23 (95% CI 4.7–43.1, p<0.000001) compared to radiologists, and OR=4.77 (95% CI 1.6–13.6, p=0.001) compared to endocrinologists. Extrapolated annually, the integration of this system in the hospital's radiology setting could identify approximately 150 otherwise undiagnosed patients needing osteoporosis therapy.
Conclusion:
AI-driven VF detection in routine CT scans offers significantly higher diagnostic accuracy than human interpretation. Its integration into clinical workflows can enhance early osteoporosis diagnosis and optimize treatment strategies without added imaging or cost.

P1365

EFFICIENT MANAGEMENT OF AN HISTIOCYTIC JAW LESION AND SUBSEQUENT BONE FORMATION FOLLOWING DENOSUMAB TREATMENT

P. Makras[1,2], A. D. Anastasilakis[3], M. Kouveletsou[2], I. Siska[4], D. Kalkanis[5], M. P. Yavropoulou[2,6], S. Papapoulos[2,7]

[1]251 Hellenic Air Force & VA General Hospital, Department of Endocrinology and Diabetes, Athens, Greece; [2]251 Hellenic Air Force & VA General Hospital, Dpt of Medical Research and LCH Adult Clinic, Athens, Greece; [3]424 Military General Hospital, Department of Endocrinology, Thessaloniki, Greece; [4]251 Hellenic Air Force & VA General Hospital, Department of Dental Radiology, Athens , Greece; [5]251 Hellenic Air Force & VA General Hospital, Department of Nuclear Medicine, Athens, Greece; [6]Medical School, National and Kapodistrian University of Athens,Endocrinology Unit, First Department of Propaedeutic and Internal Medicine, Athens, Greece; [7]Leiden University Medical Center, Leiden,Department of Internal Medicine, Division of Endocrinology; Center for Bone Quality, Leiden, Netherlands

Objectives: Medication Related Osteonecrosis of the Jaw (MRONJ) is associated with antiresorptive treatments, including denosumab (Dmab). The reported incidence of MRONJ of patients with cancer treated with high dose Dmab is about 2% the first year, is much lower in patients with osteoporosis (5.2/10.000 yrs) and occurs mainly after an invasive oral procedure. We report here the effects of Dmab treatment on the jaw of a patient with Langerhans Cell Histiocytosis (LCH) following extensive oral surgery

Patient and Methods: A 41-year-old man presented with multiple painful, non-healing, teeth extractions of the right lower jaw associated with progressive osteolytic lesions of the maxilla and the mandible. Conservative treatment had no effect, and he also sustained a low impact fracture of the right clavicle with osteolytic lesions. A whole-body FDG PET/CT scan revealed increased metabolic activity in the mandible, the right clavicle, and pulmonary nodular lesions. Following the initial inconclusive mandibular and clavicular biopsies showing nonspecific inflammatory changes, a third biopsy of the mandible confirmed LCH and a consistent p.K57N (c.171G>C) mutation in exons 2 and 3 of the *MAP2K1* gene.

Results: He was treated with Dmab 120 mg/2 months for 6 months (4 doses), an efficacious off-label therapy of patients with LCH, and reported an early, dramatic decrease of the jaw pain associated with progressive decrease of serum CTX and P1NP values which stabilized at 6 months. A PET/CT scan 2 months after the last Dmab administration (8 mo follow-up) showed reduction of the extent of the mandibular lesions, decreased FDG avidity in the right clavicle, and stable low-grade metabolic activity in the pulmonary nodules. There was marked radiologic improvement of mandibular bone integrity, including formation of new bone matrix, and restoration of both lingual and buccal cortical plates at the site of posterior tooth loss.

Conclusion: The remarkable response of the operated jaw to Dmab is difficult to be explained and raises questions about the pathogenesis of MRONJ associated with Dmab use.

P1366

SITE CHARACTERISTICS AND PATIENT SELECTION CRITERIA FOR ROMOSOZUMAB IN ROUTINE CLINICAL PRACTICE: INSIGHTS FROM THE PRIME EUROPEAN MULTI-COUNTRY STUDY

A. Moayerri[1], M. Langlois[2], P. Öhagen[3], P. Makras[4], M. R. Laurent[5,6], C. Bullmann[7], E. Toniolo[8]

[1]UCB, Slough, United Kingdom; [2]UCB, Paris, France; [3]UCB, Uppsala, Sweden; [4]251 Hellenic Air Force and VA General Hospital, Department of Endocrinology and Diabetes and Department of Medical Research, Athens, Greece; [5]KU Leuven, Department of Cellular and Molecular Medicine, Leuven, Belgium; [6]Imelda Hospital, Geriatrics Department, Bonheiden, Belgium; [7]Amedes MVZ Hamburg GmbH, Hamburg, Germany; [8]UCB, Madrid, Spain

Objective: Romosozumab (Romo) is indicated for postmenopausal women with severe osteoporosis (OP) at high risk of fracture. We describe site characteristics, real-world prescribing and patient selection practices for Romo in the Prospective Romosozumab Investigation in Multiple European countries (PRIME).

Materials/Methods: PRIME is a non-interventional, primary data-collection study conducted in 8 European countries (final results expected Sept 2026), collecting patient-/site-/country-level data to describe patient characteristics, treatment patterns, persistence with and transition from Romo. To assess site characteristics, principal investigators completed a questionnaire.

Results: As of Nov 2025, all 99 currently enrolled centres, across 8 countries, completed the survey; 83% were outpatient clinics. Prescribing specialty varied: the most frequently reported specialties were rheumatology, endocrinology and multidisciplinary teams (26% of centres reported ≥2 specialties for OP care).

Self-injection at home was most common (83%), except Switzerland where in-clinic administration was preferred (5/6 centres). Across sites, patient follow-up typically occurred every 3–6 months (75%). 44% of centres were associated with a fracture liaison service (range: 10% [Greece] to 67% [Switzerland]).

Respondents cited that when a bone mineral density (BMD) T-score threshold was considered for starting Romo, it fell between ≤−2.5 and ≤−3.5; centres in Spain often used a lower threshold (≤−3.0). Most respondents rated recent (≤24 months; 75%), major osteoporotic (68%) and multiple fractures (78%) as being of high-to-very-high importance for consideration of Romo initiation.

Variability was observed in willingness to prescribe in the presence of comorbidities, reflecting differences in local healthcare systems. Interpretation and extrapolation is limited by responses representing only the opinion of the principal investigator at each centre and the possibility of recall bias.

Conclusion: Preliminary results from the PRIME study provide real-world insights into Romo use in routine OP care in Europe. Findings show cross-country variation in care, Romo administration and patient selection, underscoring the influence of healthcare systems and policies.

CORTICAL AND TRABECULAR DXA-DERIVED 3D BONE PARAMETERS IN DIABETIC AND NON-DIABETIC WOMEN WITH FRACTURES: AN EXPLORATORY ANALYSIS

P. Mashru[1], M. Chandran[2], L. Humbert[3], M. Bracco[3]

[1]Advanced Mumbai Osteoporosis Rheumatology and Arthritis Centre, MUMBAI, India; [2]singapore general hospital, Singapore , Singapore; [3]3D-Shaper Medical, Greater Barcelona, Spain

Introduction
Individuals with diabetes mellitus experience increased fracture risk. DXA-based 3D modeling techniques such as 3D-Shaper allow separate estimation of trabecular volumetric BMD (vBMD) and cortical surface BMD (sBMD), potentially offering insight into compartment-specific skeletal deficits. Whether fracture-associated cortical and trabecular bone alterations differ between diabetic and non-diabetic individuals remains incompletely understood.
Methods
We performed a retrospective case–control analysis of women undergoing DXA with 3D-Shaper (3D-Shaper Medical, Barcelona, Spain). Corticosteroid users were excluded. Participants were stratified by diabetes status. Fracture status was defined as a history of fracture recorded in the clinical dataset. Standard hip aBMD T-scores, trabecular vBMD, and cortical sBMD were compared between fracture and non-fracture groups within diabetic and non-diabetic strata. Discriminative performance was assessed using univariate logistic regression and area under the receiver operating characteristic curve (AUC).
Results
Among diabetic women (fracture n=12; controls n=67), fracture cases demonstrated lower cortical sBMD and trabecular vBMD compared with controls. Cortical sBMD showed a numerically higher discriminative performance (AUC 0.67) than trabecular vBMD (AUC 0.62), though differences were modest and did not reach statistical significance. In non-diabetic women (fracture n=34; controls n=192), all measures were lower in fracture cases, with standard hip aBMD showing the highest discrimination (AUC 0.75), while trabecular and cortical parameters demonstrated similar performance (AUCs ~0.73).
Conclusion
In this exploratory analysis, both cortical and trabecular DXA-derived 3D parameters were associated with fracture status. In diabetic women, cortical measures showed a trend toward stronger association with fracture than trabecular measures, whereas in non-diabetic women, discriminative performance was comparable across compartments. Given the retrospective design and small number of diabetic fracture cases, these findings should be considered hypothesis-generating and warrant confirmation in larger, prospectively phenotyped cohorts.

P1368

PREDICTING OSTEOPOROSIS RISK IN CARDIOVASCULAR DISEASES USING THE FRAX SCORE.

P. Mathew[1], M. Islam[2], J. Fleming[1], Y. Ahmed[1], B. Qureshi[1], Z. Diwan[1], S. Patel[1], D. Harvey[1], A. Sikandar[1]

[1]MfOP department, Royal Blackburn Teaching Hospital, East Lancashire NHS Trust, Blackburn, United Kingdom; [2]Cardiology, Royal Blackburn Teaching Hospital, East Lancashire NHS Trust, Blackburn, United Kingdom

Introduction: Many journals and articles have mentioned the correlation between bone health and cardiovascular health. There are several overlapping risk factors in lifestyles and multiple comorbidities. We are using the FRAX score as we use it in patients presenting with falls risk and fractures to assess osteoporosis risk in patients with cardiovascular disease.

Aims and objectives: To assess osteoporosis risk in patients aged 75 years and above admitted to cardiology, using the FRAX score.

1. Osteoporosis risk using the FRAX score.

2. Correlation of FRAX score with coronary artery disease, heart failure, and similar conditions.

Methods This was a retrospective study involving 143 patients admitted to the cardiovascular care unit from April 2024 to March 2025. We used ICD codes to identify these cases: I11.0 Hypertensive heart disease with (congestive) heart failure; I25.5 Ischaemic cardiomyopathy; I42.0 Dilated cardiomyopathy; I42.9 Cardiomyopathy, unspecified; I50.0 Congestive heart failure; I50.1 Left ventricular failure; I50.9 Heart failure, unspecified; I24.9 Acute ischaemic heart disease, unspecified.

The data was collected using CERNER and LPRES records. Data collected for age, ethnicity, lifestyle (smoking, alcohol), body weight, BMI low/ high, family history of fracture, previous fracture(s), comorbidities; Type 1 or 2 diabetes mellitus, secondary causes for osteoporosis, rheumatological conditions, use of steroids, chemotherapy.

Once this data was collected, the online FRAX score calculator was used to determine the percentages for 10-year probability of fracture risk for major osteoporotic fracture < 20% or > 20%, and hip fracture risk of <3% or > 3% and NOGG advice on lifestyle vs. bone mineral density vs treatment for osteoporosis were captured.

Inclusion criteria Patients admitted to the CCU who were 75 years and above, male or female, with ICD codes as mentioned in the methods and excluded anyone below 75 years.

Results The majority of cases were male, admitted under the cardiac care unit of white British ethnicity. The lifestyle and co-morbidity history revealed 45.6% were smokers or ex-smokers, with alcohol consumption of around 14%, many had high BMI (41.2%), cases with a history of diabetes mellitus were 26.5%, only a fraction had previous fragility fractures (11.8%), very small number had rheumatological conditions.

On performing the FRAX score, the 10-year fracture probability of:

- Major Osteoporosis risk of <20% in 72% and > 20 % in 23.5%
- Hip fracture risk of <3 % in 21.7% and > 3% in 76.9%

FRAX score advice:

- 41.3% lifestyle advice
- 42% Measure BMD
- 13.3% to treat
- Not applicable to a small percentage

Discussion

- Is the FRAX score useful to predict fracture and osteoporosis risk in patients with cardiovascular conditions?
- Can this be used as a preventative measure to reduce fracture risk and improve bone health?

Plans: Train to use the FRAX score and use it regularly in our services, MfOP and cardiology.

Educating the team on the importance of preventing osteoporosis in cardiovascular diseases with shared risk factors.

Conclusion: FRAX score is a useful tool to identify osteoporosis risk in medical conditions with overlapping risk factors (lifestyles and multiple comorbidities). The advice for BMD scan on the FRAX score suggests that we need to consider bone health in this group of patients.

The FRAX score can be embedded as a part of holistic assessment by the primary, secondary, or tertiary care services, and if the BMD scans suggest a T-score in the osteoporosis range, to refer to the appropriate bone health clinic for further advice, treatment and management.

HANDGRIP STRENGTH AND BONE HEALTH IN CHILDHOOD: A 5-YEAR POPULATION-BASED PROSPECTIVE STUDY

P. N. C. Che[1], M. B. Breslin[1], M. T. Thompson[2], B. F. Fraser[1], N. C. H. Harvey[3], S. C. R. Crozier[3], R. J. M. Moon[3], L. S. Lieke[1]

[1]Menzies Institute for Medical Research, University of Tasmania, Hobart, Australia; [2]Department of Endocrinology, Royal Hobart Hospital, Hobart, Australia; [3]MRC Lifecourse Epidemiology Centre, University of Southampton, Southampton General Hospital, Southampton, United Kingdom

Objective
As longitudinal data on the handgrip–bone relationship in early childhood are limited, we aimed to determine whether handgrip strength predicts bone health from early childhood to preadolescence.
Materials and Methods
Data were obtained from 1,312 children in the Southampton Women's Survey (SWS), a UK population-based birth cohort. Handgrip strength was assessed using a Jamar dynamometer, and bone health was measured by total-body-less-head dual-energy X-ray absorptiometry (DXA) scans at ages 4, 6–7, and 8–9 years. Primary and secondary bone outcomes were area-adjusted bone mineral content (aBMC) and bone mineral apparent density (BMAD), respectively. Linear mixed-effects models with age interaction were fitted to multiply imputed and inverse probability-weighted data, adjusting for sex, socioeconomic status, height, and fat mass.
Results

At age 4, handgrip strength was not associated with bone outcomes. Across follow-up, greater handgrip strength predicted higher bone accrual (aBMC: 0.97 g/year per 1 kg increase, 95% CI: 0.71–1.22; BMAD: 0.00010 g/cm³/year per 1 kg, 95% CI: 0.00001–0.00019). Associations strengthened with age as seen for aBMC: 4 years (−1.02 g, 95% CI: −2.54–0.50), 6–7 years (0.91 g, 95% CI: −0.22–2.04), and 8–9 years (2.84 g, 95% CI: 1.97–3.72). A 1 SD higher grip strength at age 4 corresponded to approximately 2% greater aBMC accrual from ages 4 to 8. Findings were robust after adjustment for fat mass and consistent across sex and BMI categories.
Conclusion

This study provides the first longitudinal evidence linking handgrip strength with bone accrual in later childhood. Findings highlight muscular strength as a modifiable determinant of bone development in early childhood and underscore the potential for early-life interventions promoting muscle function to optimize peak bone mass and mitigate future osteoporosis risk.

P1370

MATERNAL DIABETES IN PREGNANCY AND FRACTURE RISK IN OFFSPRING: A VICTORIA STATE-WIDE DATA LINKAGE STUDY

P. N. Che[1], M. Breslin[1], M. Thompson[2], M. Dalton[1], F. Johnston[1], L. S. Lieke[1]

[1]Menzies Institute for Medical Research, University of Tasmania, Hobart, Australia; [2]Department of Endocrinology, Royal Hobart Hospital, Hobart, Australia

Objective
Maternal diabetes in pregnancy may influence fetal skeletal development; therefore, this study examined the association between maternal diabetes subtype and hazard of first long-bone fracture in offspring during the first nine years of life.
Materials and Methods
We conducted a population-based cohort study using linked administrative health data for singleton births in Victoria, Australia. Maternal gestational diabetes (GDM), type 1 diabetes (T1DM), or type 2 diabetes (T2DM) status was identified from the Victorian Perinatal Data Collection (2012–2015) using ICD-10-AM codes. Offspring time to first long-bone fracture and censoring was ascertained from emergency department records between 2013 and 2021 and modelled using Cox proportional hazards regression, with maternal diabetes subtype as the exposure. Models were adjusted for offspring sex, index of relative socioeconomic disadvantage, and maternal smoking during pregnancy.
Results
Among 279,067 mother–offspring pairs, 22,153 (8.0%) mothers had GDM, 998 (0.4%) had T1DM, and 885 (0.3%) had T2DM. A total of 15,275 (5.7%) offspring sustained at least one incident long-bone fracture during follow-up. Compared with offspring of mothers without diabetes, fracture hazard ratio was lower among offspring exposed to GDM (hazard ratio [HR] 0.90; 95% confidence interval [CI] 0.84–0.96), higher among those exposed to T1DM (HR 1.28; 95% CI 1.00–1.64), and not significantly different for T2DM (HR 0.92; 95% CI 0.68–1.25).
Conclusion
Offspring fracture hazard differed by maternal diabetes subtype, with higher hazard following T1DM and lower hazard following GDM, the latter likely reflecting behavioural rather than skeletal factors. Early monitoring and targeted injury-prevention strategies may benefit offspring exposed to maternal T1DM.

P1371

BİLATERAL ATYPİCAL FEMORAL FRACTURES FOLLOWİNG LONG-TERM DENOSUMAB THERAPY: A CASE REPORT AND LİTERATURE REVİEW

P. O. Başaran[1], S. Güzel Esen[2], Y. O. Akcan[2]

[1]Hitit University, Çorum, Türkiye; [2]Erol Olçok Research Hospital, Çorum, Türkiye

Introduction
Denosumab is generally used for 5–10 years to treat postmenopausal osteoporosis. Atypical femoral fractures (AFFs) are rare complications classically associated with long-term bisphosphonate therapy. Emerging evidence suggests that denosumab, a potent RANKL inhibitor, may also be implicated, particularly with prolonged use.
Case Report
We report the case of a 73-year-old woman with postmenopausal osteoporosis who had been treated with denosumab for approximately 10 years. One day after her most recent injection, she sustained a low-energy fall resulting in a displaced fracture of the distal third of the right femoral shaft and a non-displaced fracture of the left femoral shaft. She had no prior exposure to bisphosphonates. Her medical history included type 2 diabetes mellitus, hypertension, and hyperlipidemia. Radiographic and clinical findings met all major and minor criteria for atypical femoral fractures as defined by the American Society for Bone and Mineral Research (ASBMR). No evidence of malignancy, metabolic bone disease, high-energy trauma, periprosthetic fracture, or other pathological conditions was identified, and all ASBMR exclusion criteria were ruled out. Despite long-term antiresorptive therapy, she had persistent osteoporosis and a recent severe vertebral compression fracture.
This case highlights the potential association between prolonged denosumab therapy and atypical femoral fractures, independent of bisphosphonate use. Long-term suppression of bone remodeling may impair microdamage repair, leading to compromised bone quality despite improvements in bone mineral density.
Conclusion
This case adds to the growing body of evidence that long-term denosumab therapy may be associated with atypical femoral fractures, even in bisphosphonate-naive patients. Clinicians should maintain a high index of suspicion for prodromal symptoms and consider individualized treatment duration and monitoring strategies in patients receiving prolonged denosumab therapy.
Keywords: Denosumab, atypical femoral fracture, osteoporosis, antiresorptive therapy

P1372

NON-ENDEMIC SKELETAL FLUOROSIS: ATYPICAL FEMORAL FRACTURE AS A MANIFESTATION OF EXCESSIVE TOOTHPASTE INGESTION

P. Padam[1], R. Chandra[1], N. Rao[1]

[1]King's College Hospital, London , United Kingdom

Introduction: Skeletal fluorosis (SF) is a rare metabolic bone disorder caused by excessive fluoride accumulation, leading to osteosclerosis, altered bone architecture, and increased fracture risk. While endemic fluorosis is well described in regions with high natural fluoride exposure, non-endemic cases due to unusual sources are uncommon.
Case Report: We present a 54-year-old man who sustained an atypical fracture of the left femoral mid-diaphysis following a forward fall whilst reaching into a low kitchen cabinet. Radiographs demonstrated a grossly displaced fracture with diffusely sclerotic bone. A FDG-PET scan revealed diffuse osteosclerosis with no metabolically active lesions. Biochemical evaluation showed markedly elevated urinary fluoride 24 mg/L (reference range <1mg/L).
Bone mineral density was profoundly increased: lumbar spine BMD 3.324 g/cm² (T-score 16.9), right femoral neck BMD 1.718 g/cm² (T-score 5.0), and right total femur BMD 2.061 g/cm² (T-score 7.5). On further history, the patient reported ingestion of toothpaste after every episode of brushing (3 times a day) throughout life. The patient also reported chronically coating teeth in toothpaste multiple times a day as a chewing-gum substitute to freshen his mouth. He would consume approximately

1.5 tubes of toothpaste per week. This excessive fluoride exposure established the diagnosis of skeletal fluorosis. He was counselled to stop excessive consumption of toothpaste. On review in metabolic bone clinic 6 months after presentation, urinary fluoride was 10.81 mg/L

Discussion: This case highlights an unusual iatrogenic source of fluoride exposure leading to severe skeletal fluorosis and pathological fracture. The paradox of increased bone density and compromised bone quality is characteristic of fluorosis and highlights the importance of considering fluoride toxicity in the differential diagnosis of unexplained osteosclerosis.

Conclusion: SF though rare in non-endemic regions, can occur due to excessive ingestion of fluoride-containing products. Clinicians should maintain a high index of suspicion when encountering unexplained osteosclerosis and pathological fractures, as early recognition and elimination of the fluoride source are essential to prevent further morbidity.

P1373

ANTIGEN PRESENTATION OF CHONDROCYTES IN KNEE OSTEOARTHRITIS

P. Pentrakulchai[1], P. Sengprasert[2], S. Pimthanom[3], C. Amarase[4], S. Ngarmukos[4], A. Tanavalee[4], R. Reantragoon[5]

[1]Pink Diamond Project, Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand; [2]Immunology Division, Department of Microbiology, Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand; [3]Medical Microbiology Interdisciplinary Program, Graduate School, Chulalongkorn University, Bangkok, Thailand; [4]Department of Orthopedics, Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand; [5]Immunology Division, Department of Microbiology, Faculty of Medicine, Chulalongkorn University, and Center of Excellence in Immunology and Immune-mediated Diseases, Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand

Osteoarthritis (OA) is characterized by cartilage degeneration. Within the cartilage, chondrocytes support joint structure, maintain joint homeostasis, and also have antigen presentation functions. As a non-immune cell, chondrocytes upregulate MHC class II in the OA setting. To date, an understanding of APC function in chondrocytes is lacking. Thus, this research aimed to study drivers that regulate APC function in chondrocytes. Primary chondrocytes were isolated from knee OA patients and evaluated for levels of cell surface molecule expression related to antigen presentation (CD40, CD80, CD86, HLA-ABC, HLA-DR) via flow cytometry. Our results show positive correlations between HLA-ABC and HLA-DR, CD86 and HLA-DR, and also CD40 and CD80. However, the expression of the cell surface molecules was not dependent upon body mass index (BMI), despite obesity being a risk factor of OA. Further research is needed to identify factors driving enhanced antigen presentation potential of chondrocytes.

P1375

ECOLOGICAL ANALYSIS OF LATITUDE AS A DETERMINANT OF OSTEOPOROSIS HEALTH-ADJUSTED LIFE EXPECTANCY

G. Harewood[1], P. Ramdass[1]

[1]St. George's University School of Medicine, St. George, Grenada

Objective

To examine the ecological association between geographic latitude and osteoporosis-related Health-Adjusted Life Expectancy (HALE) in women across populations.

Material and Methods

Data on osteoporosis Health-Adjusted Life Expectancy (HALE), latitude, and covariates were obtained from the World Health Organization Global Health Observatory, the Global Health Data Exchange, and geographic coordinates from a validated GitHub repository. All analyses were conducted in RStudio (version 4.4.1). Descriptive statistics were computed for all variables, including normality assessment using Shapiro-Wilk tests. Regression analysis was employed to examine the association between latitude and osteoporosis HALE, adjusting for ecological covariates such as median age, and prevalence of underweight, alcohol consumption, etc.

Results

Descriptive analysis revealed considerable variability across all variables, with osteoporosis ranging from 16.97 to 898.31, median age spanning 15.20 to 56.90 years, and latitude extending from -41.00 to 72.00 degrees, indicating substantial geographic diversity in the sample. Spearman correlation analysis revealed a strong, statistically significant positive association between latitude and osteoporosis HALE (ρ = 0.526, $p < 0.01$). The rank-based regression analysis revealed significant ecological associations between latitude and osteoporosis HALE. Age demonstrated the strongest positive association with osteoporosis ranks (β = 10.999, $p < 0.001$), followed by latitude (β = 1.193, $p < 0.001$), indicating higher osteoporosis burden at more northern latitudes. DM showed a significant negative association (β = -7.682, $p < 0.001$). Health Expenditure approached significance with a negative trend (β = -0.827, p = 0.062), while Underweight, Cigarettes, and Alcohol consumption were not statistically significant. The model explained 72.25% of the variability in osteoporosis ranks (Robust R^2 = 0.7225).

Conclusion

This ecological analysis demonstrates that geographic latitude is significantly associated with osteoporosis HALE in women, with populations at higher latitudes experiencing greater osteoporosis-related health burden. Age was also a significant contributor, whereas higher health expenditure had a protective effect.

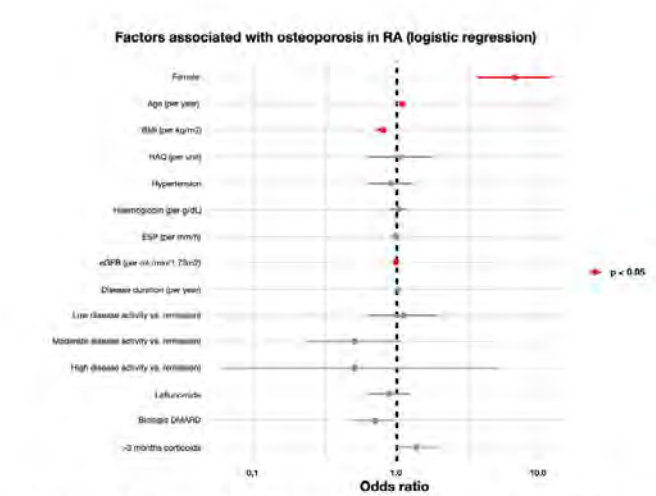
PREVALENCE AND DETERMINANTS OF OSTEOPOROSIS IN PATIENTS WITH RHEUMATOID ARTHRITIS USING EMERGING REMS TECHNOLOGY - EVIDENCE FROM A REAL-WORLD COHORT

P. Santos-Moreno[1], J. Arias-Aponte[1], A. Riobó-Santamaría[1], J. Villamarin-Rojas[1], F. Rodríguez-Florido[1], P. Rodríguez-Linares[1], L. Villarreal[1], N. Gutiérrez-Gaitán[1], A. Rojas-Villarraga[2]



[1]Biomab - Center for rheumatoid arthritis, Bogotá, Colombia; [2]Fundación Universitaria de Ciencias de la Salud FUCS, Bogotá, Colombia

Background/Objective: Rheumatoid arthritis (RA) is a chronic autoimmune disease characterised by persistent inflammation and progressive joint damage. Osteoporosis (OP) is one of its most consequential systemic complications. Individuals with RA have nearly twice the risk of OP compared with the general population due to the combined effects of inflammation, sarcopenia, reduced mobility and glucocorticoid exposure. Radiofrequency Echographic Multi-Spectrometry (REMS) has emerged as a valuable alternative, demonstrating diagnostic equivalence to DXA and greater accuracy. Some guidelines now endorse REMS when DXA is unavailable or unreliable. The aim of the study was to estimate the prevalence of OP and identify associated factors in a real-world RA cohort assessed with REMS.

Methods: A retrospective cross-sectional study included 1,290 adults with RA from a rheumatology centre. Only patients with a last year REMS of lumbar spine and/or femoral neck assessment were analysed. Sociodemographic data, comorbidities, disease activity, laboratory parameters and treatments were extracted from electronic records. OP was defined as a T-score ≤ −2.5. Bivariate analyses compared OP vs non-OP groups; multivariable logistic regression identified independent predictors.

Results: OP was present in 985 individuals (76%). Patients with OP were older (73 ± 8 vs 67 ± 6 years; p < 0.001), had lower BMI, lower haemoglobin and markedly reduced eGFR (63 vs 84 mL/min/1.73 m²; p < 0.001). Comorbid hypertension and cardiovascular disease were more frequent in the OP group. Disease activity did not differ between groups. Biologic DMARDs were more common in non-OP patients (30% vs 23%; p = 0.016). In adjusted models, female sex (OR 6.79; 95% CI 3.74–12.4), age (OR 1.10 per year; 95% CI 1.07–1.13), lower BMI (OR 0.80; 95% CI 0.76–0.84) and reduced eGFR (OR 0.99; 95% CI 0.98–1.00) were independently associated with OP. Biologic therapy showed a non-significant protective trend; glucocorticoid exposure was not independently associated.

Conclusions: OP was very common in this large Latin American RA cohort. Classic risk factors, older age, female sex and low BMI, were strongly associated with OP. Biologic therapy may offer protection, though further study is needed. REMS proved feasible and clinically informative in a population with limited DXA access.

OR: odds ratio; CI: confidence interval; BMI: body mass index; CVD: cardiovascular disease; Hb: haemoglobin; eGFR: estimated glomerular filtration rate; HAQ: Health Assessment Questionnaire; yrs: years.

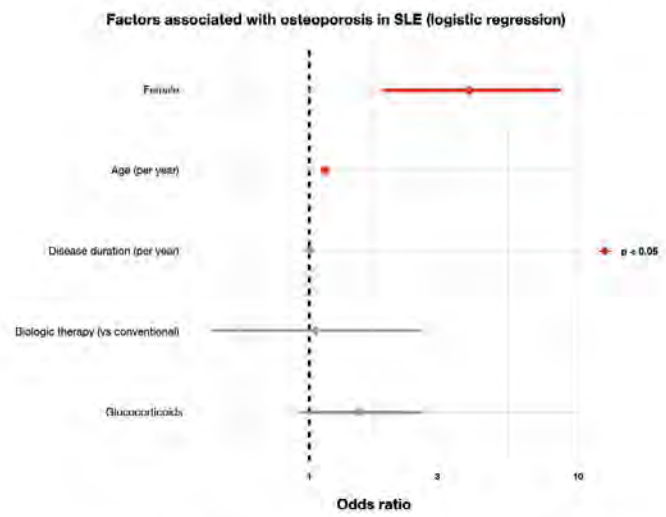
Figure 1. Multivariable logistic regression of demographic, clinical, and therapeutic factors in rheumatoid arthritis patients on associated osteoporosis factors

P1377

PREVALENCE AND DETERMINANTS OF OSTEOPOROSIS IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS USING EMERGING REMS TECHNOLOGY - EVIDENCE FROM A REAL-WORLD COHORT

P. Santos-Moreno[1], J. Arias-Aponte[1], A. Riobó-Santamaría[1], J. Villamarin-Rojas[1], F. Rodríguez-Florido[1], P. Rodríguez-Linares[1], L. Villarreal[1], N. Gutiérrez-Gaitán[1], A. Rojas-Villarraga[2]

[1]Biomab - Center for rheumatoid arthritis, Bogotá, Colombia; [2]Fundación Universitaria de Ciencias de la Salud FUCS, Bogotá, Colombia



Background/Objective: Osteoporosis (OP) is a common comorbidity in systemic lupus erythematosus (SLE), driven by chronic inflammation, prolonged glucocorticoid exposure, hormonal influences, and reduced physical activity. In Latin America, evidence about OP is scarce and assessment often limited by restricted access to DXA the gold-standard examination. Radiofrequency Echographic Multi-Spectrometry (REMS), a portable and radiation-free ultrasound-based technology, offers an alternative, and its clinical relevance has been highlighted by ESCEO. The aim of the study was to estimate the prevalence of OP and identify associated factors in Colombian SLE patients assessed with REMS in routine practice.

Methods: A retrospective cross-sectional study of 385 adults with SLE from a rheumatology referral center. Lumbar spine and/or femoral neck Bone Mineral Density (BMD) was measured using REMS (ECHOLIGHT®). OP was defined using age-specific thresholds: T-score ≤ −2.5 in individuals ≥50 years, and Z-score ≤ −2.0 in those <50 years. Group comparisons used t-tests and Chi-square/Fisher tests; multivariable logistic regression identified independent predictors.

Results: OP prevalence was 55.6 %. Patients with OP were more often

female (92 % vs 81 %; p = 0.002), had slightly longer disease duration (17 ± 10 vs 15 ± 10 years; p = 0.019) and more frequent glucocorticoid use (71 % vs 60 %; p = 0.025). Age and SLEDAI activity scores were similar between groups. Lumbar spine T-scores were consistently lower than femoral neck values. In adjusted analyses, age (OR 1.15; 95 % CI 1.11–1.18) and female sex (OR 4.00; 95 % CI 1.91–8.85) remained independent predictors; glucocorticoids showed a non-significant trend (OR 1.54; p = 0.10) (Figure 1). The age-specific T/Z-score approach identified a clinically relevant subgroup of younger, steroid-exposed patients with low Z-scores.

Conclusions: OP was highly prevalent in this Colombian SLE cohort assessed with REMS. Age and female sex were the main determinants, while age-specific densitometric thresholds enabled the detection of younger, glucocorticoid-exposed patients who may be overlooked. REMS proved feasible and clinically valuable in a setting with limited DXA availability, supporting its role in improving OP detection and guiding targeted bone-health surveillance in SLE.

Multivariable logistic regression of demographic, clinical, and therapeutic factors in Lupus patients on associated Osteoporosis factors

P1378

TRAJECTORY ANALYSIS OF MEDICATION ADHERENCE IN A RURAL CHINESE COHORT WITH OSTEOPOROTIC FRACTURES

P. She[1], J. Yang[2], S. Deng[3]

[1]Xiangya Hospital of Central South University, Changsha , China; [2]Xiangya Hospital of Central South University, Changsha, China; [3]General Hospital of Hunan Medical University, Huaihua, China

Objective

To identify longitudinal medication adherence trajectories and associated factors among elderly patients with osteoporotic fractures in Huaihua, Hunan, China.

Material and Methods

A 12-month prospective observational study was conducted at two orthopedic centers in Huaihua. A total of 130 patients aged ≥65 years with fragility fractures were included. Medication adherence was assessed using the Morisky Medication Adherence Scale (MMAS-8) at baseline, 3, 6, and 12 months. Group-based trajectory modeling (GBTM) was used to classify adherence patterns. Data on socio-demographic, clinical, and psychosocial variables were collected via structured questionnaires and medical records. Multivariate logistic regression was performed to identify predictors of trajectory groups.

Results

Four distinct adherence trajectories were identified: "Stable High Adherence" (38.5%), "Progressive Decline" (26.9%), "Variable Adherence" (20.0%), and "Consistently Low Adherence" (14.6%). Lower health literacy (OR=3.12, p<0.01), polypharmacy (OR=2.34, p<0.05), lack of social support (OR=2.01, p<0.05), and limited access to healthcare services (OR=1.95, p<0.05) were significantly associated with belonging to the declining or low-adherence trajectories.

Conclusions

Medication adherence among elderly osteoporotic fracture patients in rural China follows distinct and often suboptimal trajectories, driven largely by patient-level and systemic barriers. These findings highlight the need for targeted adherence support strategies in similar populations, focusing on health education, medication management, and access to care. Future interventions should consider these predictors in design and implementation.

P1379

PREDICTORS FOR GOOD OUTCOME AFTER HIP REPLACEMENT FOR ELDERLY FEMORAL NECK FRACTURE

A. P. Phruetthiphat[1], P. Siriamornthep[1], R. Suwanaratana[2], S. Tatiyaworakulwong[1], P. Woratanarat[3]

[1]Phramongkutkalo Hospital, Bangkok, Thailand; [2]Chulabhorn Hospital, Bangkok, Thailand; [3]Ramathibodi Hospital, Bangkok, Thailand

Introduction

Elderly patients with hip fractures often face severe complications, reduced quality of life, and increased mortality. Hemiarthroplasty and total hip arthroplasty are the primary treatments for displaced intracapsular femoral neck fractures. However, patients with significant comorbidities may not qualify for total hip arthroplasty, making hemiarthroplasty a suitable alternative with comparable midterm outcomes. While previous studies have examined surgical and medical factors impacting outcomes, there is a gap in understanding how these parameters interact to predict recovery. This study aims to identify predictive factors for successful outcomes and develop a scoring system for elderly patients with femoral neck fractures.

Materials and Methods

Study Design and Subjects: This retrospective study, conducted from January 2015 to December 2021, included elderly patients with low-energy femoral neck fractures who underwent bipolar hemiarthroplasty (BHA) with at least two years of follow-up. Exclusion criteria included pathological fractures, primary tumors, high-energy trauma, and insufficient data, resulting in a final cohort of 427 patients.

Data Collection: Demographic information, comorbidities (e.g., diabetes, hypertension), surgical parameters, and functional outcomes were analyzed. The Charlson Comorbidity Index and American Society of Anesthesiologists classifications assessed preoperative physical conditions. Cognitive impairment was evaluated using the Mini-Mental State Examination (MMSE).

Surgical Procedure: Bipolar hemiarthroplasty was performed via the piriformis sparing approach, which preserves key muscles while exposing the joint. Standard postoperative pain management protocols were implemented for all patients.
Outcome Measurements: Patients were followed up at various intervals, with functional outcomes assessed using the Harris Hip Score (HHS). Scores were categorized into good (80-89) and non-good outcomes (<80), with any patient who died within two years classified as non-good.
Statistical Analysis: STATA version 14.0 was used for statistical analyses, employing descriptive statistics for demographic data and multivariate logistic regression to identify predictors of outcomes.
Development of the Scoring System: The Integrated Scoring System in Elderly Patients with Isolated Femoral Neck Fracture (ISSIFN) was developed from the patient data. Logistic regression identified predictors, and a scoring model was created based on regression coefficients. ROC curve analysis determined the optimal cut-off score for predicting good outcomes.

Results
The demographic and clinical characteristics of the study cohort are summarized in Table 1. The mean age of the participants was 80.6 ± 7.7 years (range, 60–96), with a predominance of females (76.4%). Over half of the patients (58.6%) were aged 80 years or older, and the mean body mass index was 22.0 ± 3.5 kg/m².
Comorbidities were prevalent, with 52.2% classified as ASA class III and a mean Charlson Comorbidity Index (CCI) of 4.37 ± 1.27. Cognitive impairment was observed in 12.4% of patients. The mean serum vitamin D level was 26.2 ± 12.9 ng/mL, while the mean hip bone mineral density (BMD) T-score was −2.39 ± 1.21.
Functional status prior to injury indicated that 66.5% of patients were independently ambulatory, whereas 32.1% required walking aids. Only 15.7% underwent surgery within three days of admission; however, 86.7% initiated rehabilitation within three days post-surgery.
In the regression analysis involving 427 elderly patients who underwent bipolar hemiarthroplasty (BHA), significant factors associated with favorable outcomes included: age <80 years, CCI ≤5, GFR ≥45 mL/min, hip BMD >-2.5, independent ambulation prior to fracture, normal cognitive function, vitamin D levels ≥20 ng/mL, and timely surgery and rehabilitation (≤3 days). The Integrated Scoring System in Elderly Patients with Isolated Femoral Neck Fracture (ISSIFN) score ranged from 0 to 21, with a cut-off score of at least 12 demonstrating optimal discriminatory power (AUC = 0.804), sensitivity of 70%, and specificity of 75%.

Discussion
restore hip function and enhance quality of life in elderly patients, early rehabilitation following bipolar hemiarthroplasty (BHA) for displaced femoral neck fractures is crucial. This study identifies significant non-surgical factors linked to functional outcomes, including patient comorbidities. Key indicators associated with favorable outcomes post-BHA include age <80 years, Charlson Comorbidity Index (CCI) ≤5, absence of cognitive impairment, estimated glomerular filtration rate (eGFR) ≥45 mL/min, serum vitamin D levels ≥20 ng/mL, hip bone mineral density (BMD) T-score >−2.5, independent ambulation prior to fracture, and timely intervention (surgery and rehabilitation within three days).
Previous research has similarly identified that vitamin D levels, renal function, pre-fracture ambulation, and age are critical predictors of recovery. Vitamin D deficiency, prevalent among elderly patients, contributes to sarcopenia and muscle weakness, adversely affecting rehabilitation. Impaired renal function is associated with poor bone quality and limited physiological reserves, complicating surgical recovery.

Surgical factors, including operative timing and rehabilitation protocols, also significantly influence recovery. Although the statistical significance of timing diminished in multivariate analyses, early surgery and rehabilitation remain essential. Delayed intervention has been linked to higher complication rates, while early ambulation mitigates the risks of immobilization.
This study is notable for integrating both surgical and comprehensive medical parameters, including bone health indicators, into the Integrated Scoring System in Elderly Patients with Isolated Femoral Neck Fracture (ISSIFN). The ISSIFN score, ranging from 0 to 21, identifies patients with a score of ≥12 as having a higher likelihood of achieving good outcomes, achieving an area under the ROC curve of 0.804.
While the study's strengths lie in its comprehensive approach, limitations include potential selection bias due to its retrospective design and the need for external validation across diverse populations. Despite these limitations, the ISSIFN score offers orthopedic surgeons a practical tool for evaluating and managing patients holistically, emphasizing the importance of addressing modifiable factors to enhance functional recovery in elderly patients with femoral neck fractures.

Conclusion
The Integrated Scoring System in Elderly Patients with Isolated Femoral Neck Fracture (ISSIFN) is a novel and effective tool that combines medical comorbidities—particularly vitamin D status and renal function—with surgical parameters to predict functional outcomes following bipolar hemiarthroplasty. This scoring system demonstrates high discriminatory power, enabling orthopedic surgeons to stratify patients early in the postoperative period. Beyond mere prognostication, the ISSIFN score promotes a proactive approach, allowing clinicians to address modifiable risk factors through targeted supplementation and intensive rehabilitation, thereby enhancing recovery in the geriatric population.

ISORHYNCHOPHYLLINE MITIGATES BONE LOSS IN OVX MICE BY MODULATING INFLAMMATORY RESPONSES, OXIDATIVE STRESS, GUT MICROBIOTA COMPOSITION AND SCFAS PRODUCTION

Y. Lei[1], P. Sun[1]

[1]The First Affiliated Hospital of Guangdong Pharmaceutical University, Guangzhou, China

Objective: This study examines the protective effects of IRN against bone loss in ovariectomized (OVX) mice, with a focus on its regulation of inflammatory responses, oxidative stress, gut microbiota composition, the production of short-chain fatty acids (SCFAs) and the intestinal barrier.
Methods: The potential core targets and mechanisms of action of IRN in the treatment of OP were investigated through network pharmacology and molecular docking, following by *in vivo* validation on OVX mice treated with 8-week IRN. The *in vivo* study included Micro-CT analysis, measurement of serum biomarkers for inflammation, oxidative stress and bone remodeling, gut microbiome profiling, SCFAs quantification, and immunohistochemical analysis of intestine.
Results: Network pharmacology analysis identified 50 intersecting targets between IRN and OP, with molecular docking demonstrating strong binding affinities of IRN to EGFR and GSK3B. GO and KEGG enrichment analyses revealed that IRN is involved in many key pathways related to cell survival, inflammation, and oxidative stress, with the PI3K-Akt signaling

pathway being notably prominent. *In vivo* assessment showed that IRN treatment reduced serum levels of the pro-inflammatory cytokines, such as tumor necrosis factor-alpha (TNF-α), interleukin-1 beta (IL-1β) and interleukin-6 (IL-6), while increasing serum levels of the anti-inflammatory cytokine interleukin-10 (IL-10) in OVX mice and reversed the excessive bone loss caused by estrogen deficiency. IRN also effectively managed the oxidative stress in OVX model, characterized by lowered serum levels of nitric oxide (NO), inducible nitric oxide synthase (iNOS) and reactive oxygen species (ROS). Combination of 16S rRNA sequencing and GC-MS analysis found that IRN modulated the gut microbiota composition, reducing the abundance of *Helicobacter* and increasing the level of butanoic acid, a type of SCFAs. Additionally, immunohistochemical analysis indicate that IRN repaired the compromised intestinal barrier in OVX mice by upregulating the expression of tight junction proteins, including Zonula Occludens-1(ZO-1), Claudin-1 and Occludin.
Conclusions: IRN effectively alleviates OVX-induced bone loss through its anti-inflammatory and antioxidant properties, modulation of gut microbiota composition, enhancement of short-chain fatty acid (SCFAs) production, and protection of the intestinal barrier.

P1381

TARAXASTEROL AMELIORATES OVX MICE BONE LOSS BY SUPPRESSING NLRP3 INFLAMMASOME AND MODULATING GUT MICROBIOTA

Y. Liu[1], P. Sun[1]

[1]The First Affiliated Hospital of Guangdong Pharmaceutical University, Guangzhou, China

Background: Postmenopausal osteoporosis (PMOP) is a prevalent skeletal disorder associated with menopause-related estrogen withdrawal. Taraxasterol (Tara), a pentacyclic-triterpene isolated from Taraxacum officinale, has been shown to have anti-inflammatory and anti-rheumatic effects. However, its efficacy against PMOP remains unclear. The purpose of this research is to investigate Tara's anti-osteoporotic effects.
Methods: In this study, the ovariectomized (OVX) mouse model is a well-established surrogate for PMOP, recapitulating the bone loss observed in humans following menopause. After 8 weeks of intervention, the mice were euthanized, and samples from their femur, serum, colon and feces were collected, then bone microstructure parameter, NLRP3 inflammasome, inflammatory cytokines, intestinal barrier and gut microbiota (GM) were assessed. Network pharmacology and molecular docking approach were employed to predict and validate its anti-osteoporosis-related molecular targets and pathways.
Results: The results revealed that Tara lowered proinflammatory cytokine levels (IL-6, TNF-α), suppressing NLRP3 inflammasome (caspase-1, IL-1β and IL-18) and affected adipokines content (decrease leptin and visfatin, increases adiponectin), which cloud enhance bone strength and prevent OVX-induced bone loss. Moreover, it restored the abundance of GM and increased the expression of Occludin and ZO-1 proteins in the colon. Network pharmacology identified a total of 75 core anti-osteoporosis targets. Of these, ALB, PPARG, IGF1, EGFR, ESR1, CASP3, HSP90AA1, SRC, GSK3B, MMP2 were successfully docked with the Tara and showed excellent binding ability.
Conclusions: The present study suggests that Tara alleviated inflammatory cytokines, NLRP3 inflammasome and intervened GM, representing that Tara is a novel, promising therapeutic candidate for PMOP.

P1383

PHENOTYPIC STRATIFICATION OF RESIDUAL PAIN AFTER OSTEOPOROTIC VERTEBRAL COMPRESSION FRACTURES USING SHEAR-WAVE ELASTOGRAPHY: A PROSPECTIVE COHORT STUDY

P. W. Liao[1]

[1]Orthopedics and Traumatology/Chongqing Liangping Hospital of Traditional Chinese Medicine, Chongqing, China

Objective: To determine whether stiffness patterns measured by shear-wave elastography (SWE) can identify residual pain phenotypes after osteoporotic vertebral compression fractures (OVCF) and to examine their association with 6-month recovery.
Methods: This prospective cohort enrolled adults aged 55 years or older with acute OVCF within 4 weeks of onset. Baseline SWE assessed stiffness of the multifidus, erector spinae, and posterior vertebral soft tissues. Phenotypes were generated using unsupervised clustering based on stiffness level, asymmetry, and tissue uniformity. Outcomes included 6-month pain, Oswestry Disability Index (ODI), vertebral height change, EQ-5D-5L, and analgesic use. Analyses were adjusted for demographics, bone mineral density, fracture level, muscle quality, and treatment strategy.
Results: A total of 189 patients were enrolled and 172 completed follow-up. Three SWE phenotypes were identified: a high-stiffness pattern, a moderate-stiffness pattern with marked asymmetry, and a low-stiffness pattern with reduced muscle integrity. Residual pain at 6 months differed across phenotypes (26.2%, 44.7%, and 61.3%; $p < 0.01$). ODI improvement was greatest in the high-stiffness phenotype (−19.8 points) and lowest in the low-stiffness phenotype (−8.9 points). Neuropathic pain features were most prominent in the low-stiffness phenotype (mean PainDETECT 18.4), which also showed the greatest progression of anterior height loss (mean 6.1%). Stiffness asymmetry and reduced tissue uniformity independently predicted persistent pain (adjusted OR 1.31; 95% CI 1.12–1.54).
Conclusions: SWE-based phenotyping can stratify residual pain risk after OVCF. Early identification of unfavorable stiffness patterns may support targeted rehabilitation and improve long-term outcomes.

P1384

CHONDROITIN SULFATE IN KNEE OSTEOARTHRITIS: REAL-WORLD EVIDENCE FROM POST-MARKETING CLINICAL FOLLOW-UP

P. Wiland[1], M. Rell-Bakalarska[2], V. Eid[3], A. I. S. Sobczak[4], R. Niarra[3], M. Adjibade[4], C. Hauville[3], S. Degroote[4], E. J. Kucharz[5]

[1]Department of Rheumatology and Internal Diseases, Wroclaw Medical University, Wroclaw, Poland; [2]Interdisciplinary Academy of Practical Medicine, Warsaw, Poland; [3]Pierre Fabre Médicament, Boulogne-Billancourt, France; [4]ClinSearch, Malakoff, France; [5]Department of Internal Medicine, Rheumatology and Clinical Immunology, Medical University of Silesia, University Hospital No 7, Katowice, Poland

Objectives: European guidelines now recommend chondroitin sulfate (CS) as first-line osteoarthritis (OA) treatment, but real-world evidence remains limited. TRUST was a study conducted in patients with knee OA treated with pharmaceutical-grade CS. It aimed to describe: 1) their baseline clinical profile and OA symptom severity, as assessed by the Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC); 2) changes in OA symptom severity and health-related quality of life over 6 months (6M), as respectively assessed by the WOMAC and Short Form 12-item (SF12) questionnaire; 3) changes in concomitant use of non-steroidal anti-inflammatory drugs (NSAIDs) and analgesics during the 6M follow-up compared to the 6M prior to study inclusion.
Material and Methods: This prospective, multicentre, observational study included patients aged 50–85 years with a confirmed diagnosis of knee OA and a new CS prescription, treated at 11 Polish centers and followed for 6M (JUL2023–OCT2024). Collected data included demographics, clinical characteristics, prior OA treatments, CS treatment details, patient-reported outcomes at baseline, 3M and 6M (WOMAC, SF12 and treatment satisfaction questionnaire), and adverse events.
Results: Among 136 eligible patients (68% women; mean age 65 years; with severe physical impairment), 124 (91%) remained on CS by 6M. CS treatment was associated with a reduction in OA symptoms as measured by the WOMAC (mean decrease 54 ± 34%), improved quality of life according to SF-12 (mean increase 24 ± 27% in physical component and 20 ± 34% in mental component) and decreased use of NSAIDs and analgesics (36% of patients stopped these medications and 15% reduced their dosage). Few adverse events (10), all non-serious, occurred in 9 patients (7%), and 97% of patients gave CS a positive assessment at 6M.
Conclusion: This real-world study supports the clinical effectiveness, favourable benefit-risk profile and high treatment satisfaction associated with pharmaceutical-grade CS in knee OA management.

DEVELOPMENT OF AN OVERLOAD RESISTANCE TRAINING CURRICULUM USING PORTABLE EQUIPMENT TO IMPROVE OSTEOPOROSIS AND SARCOPENIA IN RURAL TAIWAN

P.-Y. Hsu[1], W.-H. Chao[2], L.-C. Chang[2], Y.-Y. Hsiao[2]

[1]Nanhua University, Chiayi County, Taiwan; [2]Chiayi County Public Health Bureau, Chiayi County, Taiwan

Objective
The study aims to address the lack of specialized equipment in rural Taiwan and provide effective strength training for individuals at high risk of osteoporosis and sarcopenia.
Materials and Methods

1. Participants: 345 participants from the 2025 Exercise and Nutrition Curriculum for Osteoporosis and Sarcopenia High-Risk Groups in Chiayi, Taiwan.

2. Curriculum Design: Based on the ACSM (GETP12) FITT-VP principle, the curriculum focuses on strength enhancement, three times a week for two hours each time, for a total of 12 weeks.

3. Course Content: Resistance training courses include " Front-Loaded Carries", "long bar midsection pull-up" and "1/4 squat quick pull-up", while other courses include Cross-walking and Self-practice courses.

4. Intelligent Resistance Training Machine: A portable, compact device utilizing a motor-driven cable and pulley system to generate resistance. It supports multi-angle training with a maximum pull force of 120 kg, making it suitable for training in rural areas.

5. Assessment: Pre- and Post-assessment of the 12-week exercise curriculum, including body composition analysis and upper and lower limb muscle strength tests.

Results
Muscle Mass Index (SMI) increased in 162 participants (47%); Total Muscle Mass (SMM) increased in 227 participants (65.8%), total increase of 73.2 kg. Maximum grip strength increased in 272 participants (78.8%), average increase of 2.25 kg; Peak Force(PF) increased in 320 participants (92.8%), average increase of 133.45 N ($kg \cdot m/s^2$); and Rate of Force Development (RFD) increased in 190 participants (55.1%), average increase of 226.99 N/s. The t-test showed that SMI, SMM, grip strength, PF, and RFD were all reached statistical significance ($p^* < .05$).
Conclusion
After 12-week progressive overload resistance training curriculum using intelligent resistance training machine, 345 participants achieved effective improvements in both muscle quality and quantity, confirming that developing overload resistance training curriculum using portable resistance training equipment can improve the symptoms of osteoporosis and sarcopenia patients in rural Taiwan.

P1386

IMPROVING CORE STABILITY THROUGH BADUANJIN EXERCISE TO OPTIMIZE MUSCLE TRAINING QUALITY FOR SARCOPENIA PATIENTS IN TAIWAN FEMALE

P.-Y. Hsu[1], W.-H. Chao[2], L.-C. Chang[2], Y.-Y. Hsiao[2]

[1]Nanhua University, Chiayi County, Taiwan; [2]Chiayi County Public Health Bureau, Chiayi County, Taiwan

Objective

This study aims to investigate whether Baduanjin, a traditional Oriental exercise combining precise stretching with rhythmic breathing, can enhance body stability and core strength in individuals at sarcopenia patients. Furthermore, the study evaluates whether these improvements increase the efficiency of overload resistance training in enhancing muscle quality.

Materials and Methods

1. **Participants:**A total of 195 Taiwan female patients with sarcopenia were recruited and assigned to either **Experimental group** (overload resistance training , Baduanjin and self-practice, n = 97) and **Control group** (overload resistance training, cross walking and self-practice, n = 98).

2. **Course Design**:The intervention lasted 12 weeks, with training conducted three times per week for two hours per session, following the ACSM FITT-VP exercise prescription guidelines.

3. **Experimental Design**: Pre- and post-intervention assessments included muscle mass (InBody 270), upper limb strength (handgrip strength), flexibility (sit-and-reach test), cardiorespiratory endurance (3-minute step test), balance ability (eyes-closed double-leg stance, COP path length), and lower limb strength (isometric mid-thigh pull).

4. **Statistical Analysis**: Multivariate and univariate analyses of covariance (MANCOVA and ANCOVA) were performed with baseline values as covariates.

Results

After adjusting for baseline measurements, a significant overall group effect was observed ($p < .001$). The experimental group demonstrated significantly greater improvements in muscle mass, upper and lower limb strength, flexibility, and postural stability compared with the control group ($p < .05$). Notably, the center of pressure(COP) path length was significantly reduced in the experimental group, indicating enhanced balance and core stability. The control group showed slightly superior performance in step counts, reflecting greater cardiorespiratory adaptation.

Conclusion

Combining Baduanjin with overload resistance training effectively enhances core stability, neuromuscular control, and muscle training quality in individuals with sarcopenia. This integrative exercise approach appears to be safe, practical, and beneficial, supporting its application as an adjunct training strategy in clinical and community-based sarcopenia interventions.

P1387

SEX DIFFERENCES IN CANNABINOID-MEDIATED ANALGESIA IN AN OSTEOARTHRITIS MOUSE MODEL: ROLE OF CAMKIIA NEURONS IN THE MEDIAL PREFRONTAL CORTEX

Z. H. Jiang[1], Q. Wang[2], W. T. Wang[1], Z. H. Zheng[1]

[1]Department of Clinical Immunology, Xijing Hospital, Fourth Military Medical University, Xi'an, Shaanxi Province, China; [2]a Department of Anesthesiology and Perioperative Medicine, Department of Pain Medicine, Xijing Hospital, The Fourth Military Medical University, Xi'an, Shaanxi Province, China

Objective: This study aimed to identify CaMKIIα neurons in the upstream mPFC that control vlPAG activity and to determine if CB1R signaling in this circuit mediates sex-specific antinociception in an OA mouse model.
Material and Methods: We utilized the monosodium iodoacetate (MIA) model to induce knee osteoarthritis in male and female C57BL/6J wild-type and CB1R-floxed mice. To map the mPFC-vlPAG circuitry, we employed retrograde viral tracing combined with RNAscope in situ hybridization and immunohistochemistry. To investigate the functional role of CB1R, we used a Cre-loxP system to selectively knockout CB1R in mPFC CaMKIIα neurons. Furthermore, optogenetics and whole-cell patch-clamp recordings were performed to evaluate changes in synaptic transmission (oEPSCs and sIPSCs) within the vlPAG in response to specific activation of mPFC terminals.
Results: Viral tracing revealed that the mPFC-vlPAG projection is predominantly composed of CaMKIIα excitatory neurons. Under naive conditions, these neurons exhibited significantly higher CB1R expression in females compared to males. Following OA induction, CB1R mRNA levels were downregulated in both sexes, but the reduction was significantly more pronounced in female mice. Behavioral testing showed that specific ablation of CB1R in this pathway exacerbated OA-induced mechanical allodynia, particularly in females. Conversely, specific optogenetic activation of CB1R on mPFC terminals produced robust analgesia that was more effective in female mice. Electrophysiological analysis demonstrated that CB1R activation inhibits glutamatergic drive onto vlPAG GABAergic neurons, thereby disinhibiting the descending analgesic output—a mechanism that is compromised in female OA mice due to receptor downregulation.
Conclusion: These results clarify the function of CB1R in the mPFC-CaMKIIα-vlPAG circuit. We demonstrate that the sex-specific distribution and pathological downregulation of CB1R in this cortical-subcortical pathway underlie the differential pain sensitivity and analgesic responses observed in OA. These findings shed light on sex-specific cannabinoid analgesia and provide a theoretical basis for developing more potent, sex-tailored therapeutics for osteoarthritis pain management.

P1388

HIGH-VELOCITY STRENGTH TRAINING FOR ENHANCING BONE MINERAL DENSITY IN WOMEN OVER 45: SAFETY AND ACCEPTABILITY OF THE OSTEOVELOCITY TRIAL

R. A. Quattlaender[1], P. Rothmore[1], M. R. Hutchinson[1], T. J. H. Lathlean[1]

[1]Adelaide University, Adelaide, Australia

Objective: To determine the safety and acceptability of high-velocity strength training designed to enhance bone mineral density (BMD).
Materials and Methods: The OsteoVelocity trial (ACTRN12624001276549) is a pilot RCT to enhance strength training (ST) for increasing BMD. Healthy untrained women over 45 with osteopenia or normal BMD were included. 51 women were randomly assigned to one of two ST intervention groups or control. Both intervention groups engaged in ST, incorporating an explosive concentric phase, twice weekly over a 6-month period. The high strain rate group (HST) performed the eccentric phase at a moderate pace (2 s), while the low strain rate group (LST) implemented a prolonged eccentric phase (4 s). Adverse events were recorded. After 6 months, surveys and group interviews were administered. Survey questions utilized a 5-point Likert scale (1 = "strongly agree"; 5 = "strongly disagree").
Results: There were 3 minor adverse events in the LST and 1 in the HST group. 50 % were deemed "unlikely related." Participants reported no pain beyond muscle soreness [1.5 (0.79)]. Soreness did not impede their activities of daily living (ADLs) [1.28 (0.46)]. All stated that they would participate in the study again [1.07 (0.26)]. They expressed enjoyment of the training program [1.23 (0.51)] and looked forward to the training sessions [1.5 (0.75)]. They enjoyed training with free weights [1.35 (0.73)], pin-loaded machines [1.32 (0.67)], and the cable pulley [1.5 (0.79)]. Qualitative data indicated a particular preference for compound exercises. Additionally, most favoured performing exercises with eight repetitions or fewer. Preferences regarding exercise pace varied. Most expressed an intention to continue ST in future [1.39 (0.57)]. They noticed favourable changes in their body [1.54 (0.79)] and feel fitter for ADL's [1.36 (0.62)]. All participants reported experiencing benefits from the program, with increases in strength and confidence being frequently highlighted. Furthermore, many participants noted improvements in well-being, such as reduced pain during ADLs and alleviation of menopausal symptoms.
Conclusion: High-velocity strength training is safe and accepted for non-osteoporotic women over 45.

P1389

OSTEOMETABOLIC BASELINE CHARACTERISTICS OF YOUNG ADULTS AT THE BEGINNING OF GENDER AFFIRMING HORMONAL TREATMENT

R. A. Russo[1], V. F. Valsecchi[2], A. P. Amadori[3], R. V. Racanelli[4]

[1]Azienda Sanitaria Universitaria Integrata del Trentino (ASUIT), Internal Medicine Division, Santa Chiara Hospital, TRENTO, Italy; [2]Institute of Endocrine and Metabolic Sciences, Università Vita Salute San Raffaele, IRCCS Ospedale San Raffaele, Milano, Italy; [3]Azienda Sanitaria Universitaria Integrata del Trentino (ASUIT), Department of Primary Care, Trento, Italy; [4]Azienda Sanitaria Universitaria Integrata del Trentino (ASUIT), Internal Medicine Division, Santa Chiara Hospital, Trento, Italy

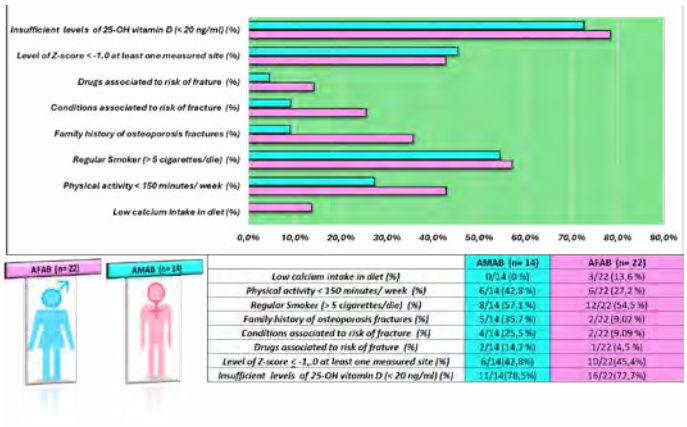
INTRODUCTION

Nowadays, the number of transgender people undergoing gender-affirming hormone therapy (GAHT) is increasing, and they are getting younger and younger. Since GAHT has a significant impact on bone, osteometabolic assessment is essential both at the start of treatment and during follow-up.

OBJECTIVE

Describe the osteometabolic profile of transgender patients at the start of GAHT.

METHODS



36 transgender individuals (Mean Age 22.2 ± 3.73 years) were enrolled at the start of the GAHT. Of these, 14 were AMAB (Assigned Male At Birth, Mean Age 22.3 ± 3.78 years) and 22 were AFAB (Assigned Female At Birth, Mean Age 22.2 ± 3.79 years). Demographic characteristics, osteometabolic risk factors, bone mineral density obtained by DXA (Dual X-ray Absorptiometry), and laboratory data are summarised in Table 1.

	AMAB (n= 14)	AFAB (n= 22)
Demographic characteristics	Mean + SD	
Age at first evaluation (years)	22,32 + 3,78	22,22 + 3,79
BMI (kg/m2)	26,58 + 5,65	22,74 + 3,79
Waist circumference (cm)	89,5 + 14,5	73,7 + 10
Hip circumference (cm)	99,8 + 11,45	95,6 + 12,6
DXA results	Mean + SD	
Lumbar BMD (g/cm2)	1,13 + 0,12	1,14 + 0,13
Lumbar Z-score	-0,74 ± 1,19	-0,21 ± 1,10
Total femur BMD (g/cm2)	1,06 + 0,14	0,99 + 0,10
Total Femur Z-score	-0,23 ± 1,17	-0,09 ± 0,89
Femoral Neck BMD (g/cm2)	1,02 + 0,14	0,93 + 0,12
Femoral Neck Z-score	-0,41 ± 0,93	-0,43 ± 0,85
Laboratory results	Mean + SD	
Creatinine (mg/dl)	0,85 + 0,10	0,74 + 0,11
eGFR (ml/min)	123,9 + 9,46	117 + 11,1
Total calcium (mg/dl)	9,71 + 0,06	9,38 + 0,33

Phosphate (mg/dl)	3,89 + 0,83	3,75 + 0,56
Alcaline Phosphatase (U/L)	18,2 + 7,43	7,2 + 24,7
25OH-vit D (ng/ml)	14,7 + 5,38	18,31 + 7,55
TSH (mU/L)	2,70 + 1,95	2,09 + 0,98
LH (mIU/ml)	5,79 + 2,47	11,71 + 13,38
FSH (mIU/ml)	4,02 + 3,23	6,38 + 3,31
Estradiol (pg/ml)	32,6 + 12,64	81,74 + 51,3
Total Testosterone (ng/ml)	5,18 + 1,90	0,33 + 0,16
Prolactin(ng/ml)	16,7 + 10,17	22,08 + 14,90

RESULTS

A level of physical activity below 150 minutes per week (AMAB 42.8%, AFAB 27.2%), smoking more than 5 cigarettes per day (AMAB 57.1%, AFAB 54.5%), a Z-score level < -1.0 at least one measured site (AMAB 42.8%, AFAB 45.2%) and levels of 25-OH vitamin D < 20 ng/ml (AMAB 78.5%, AFAB 72.7%) emerged as the main risk factors for fractures at the initial assessment in our population study (figure 1).

CONCLUSIONS

Osteometabolic assessment at the start of GAHT is extremely important due to its impact on fracture risk. Smoking, lack of physical activity and hypovitaminosis D are prevalent risk factors in this population, and correcting them can help to improve the long-term bone health of transgender patients.

P1390

DIGITAL VERSUS PAPER-BASED RESISTANCE EXERCISE FOR INDIVIDUALS WITH KNEE OSTEOARTHRITIS: A RANDOMIZED CONTROLLED STUDY

R. Aldhabi[1], M. Albadi[1], A. Shuruq[1]

[1]Department of Physical Therapy, Faculty of Medical Rehabilitation Sciences, King Abdulaziz University, Jeddah, Saudi Arabia, Jeddah, Saudi Arabia

Background and Objective:
Digital health tools are increasingly used to support rehabilitation programs; however, evidence comparing app-guided exercise to conventional formats remains limited in knee osteoarthritis (KOA). This study aimed to compare the effects of a smartphone-delivered resistance training program with a paper-based exercise protocol on pain, lower-limb strength, functional performance, and exercise adherence in individuals with KOA.

Methods:
A single-blind randomized controlled trial was conducted in which participants with KOA completed a 6-week resistance training program delivered either through a mobile application or printed exercise materials. Outcome measures were collected at baseline and after the intervention and included pain intensity (Numeric Pain Rating Scale), knee-related symptoms and function (WOMAC), functional mobility (Timed Up and Go), lower-extremity performance (Five-Times Sit-to-Stand Test), muscle strength, and self-reported adherence. Mixed-model ANOVA was used to examine within- and between-group effects.

Results:
Forty participants were randomly allocated to the app-guided group (n = 20) or the paper-based group (n = 20). Significant improvements over time were observed in both groups across pain, muscle strength, functional performance, and adherence outcomes ($p < 0.05$). No statistically significant differences were identified between groups for any outcome measure ($p > 0.05$).

Conclusion:
An app-guided resistance training program produces comparable clinical and functional benefits to traditional paper-based exercise instruction in individuals with knee osteoarthritis. These findings support the use of mobile applications as an effective and practical alternative for delivering resistance exercise interventions in this population.

P1391

THE THAI ICOAP-HIP: CROSS-CULTURAL ADAPTATION AND VALIDATION FOR ASSESSING INTERMITTENT AND CONSTANT PAIN IN HIP OSTEOARTHRITIS

W. Witayakom[1], N. Chuenta[1], K. Sukhonthamarn[1], W. Kosuwon[1], R. Apinyankul[1]

[1]Department of Orthopaedics, Faculty of Medicine, Khon Kaen University, Khon Kaen, Thailand

Objective: The Intermittent and Constant Osteoarthritis Pain (ICOAP) questionnaire, developed by the OARSI/OMERACT initiative, is a tool for assessing pain in hip and knee osteoarthritis patients. This study aimed to develop a Thai version of the ICOAP for hip through standardized translation and cross-cultural adaptation and to evaluate its reliability and validity.
Material and Methods: In this prospective descriptive study, patients aged ≥18 years with hip osteoarthritis were enrolled. Thai Intermittent and Constant Osteoarthritis Pain for hip (ICOAP-Hip) was developed using a multi-language translation and adaptation process. Forty-eight patients (24 males) completed the Thai ICOAP-Hip, pain subscale of the Thai Hip Osteoarthritis Outcome Score (HOOS), a Visual Analog Scale (VAS) for pain, and Thai Short Form-36 Health Survey version 2 (SF-36v2) during outpatient visits. Test-retest reliability was assessed by readministering ICOAP-Hip via telephone 48 hours later. Reliability was evaluated using intraclass correlation coefficient (ICC) and Cronbach's alpha, while construct validity was examined via Pearson's correlation with comparator instruments.
Results: Thai ICOAP-Hip total score showed excellent test-retest

reliability (ICC = 0.988) and high internal consistency (Cronbach's α = 0.941). Construct validity was supported by strong negative correlations with the HOOS pain subscale (r = -0.737, p < 0.001) and SF-36v2 bodily pain subscale (r = -0.737, p < 0.001), as well as a strong positive correlation with VAS pain (r = 0.796, p < 0.001).
Conclusion: The Thai ICOAP-Hip is a reliable and valid instrument for evaluating pain in Thai patients with hip osteoarthritis.

P1393

SPORT-SPECIFIC VARIATION OF TIBIAL AND FIBULAR SAFETY FACTOR PROXIES IN YOUNG MALE ATHLETES

G. Cointry[1], L. Pisani[2], L. Intelagelo[3], C. Mildenberger[2], M. Lutterotti[2], L. Aloni[2], P. Costamagna[2], S. Luscher[1], R. Capozza[1]

[1]Center for Studies of Phosphocalcium Metabolism, CONICET, Faculty of Medicine, National University of Rosario, Santa Fe, Argentina, Rosario, Argentina; [2]Biomechanical Osteomuscular Studies Unit (UDEBOM), University Center for Assistance, Teaching and Research (CUADI), University of Gran Rosario, Rosario, Argentina, Rosario, Argentina; [3]Unidad de Investigación Musculoesquelética (UIM), University Center for Assistance, Teaching and Research (CUADI), University of Gran Rosario, Rosario, Argentina, Rosario, Argentina

Objectives
To characterise sportspecific differences in tibial and fibular safety factor (SF) proxies and to determine whether these adaptations are sitespecific along the shaft and differ between axial (jump) and lateral (eversion) loading.

Material and Methods
Crosssectional study in men aged 25–35 years: semiprofessional basketball, rugby, football, tennis, gymtrained athletes and sedentary controls (≈10–15/group). Peripheral QCT of tibia and fibula was obtained at 14 sites between 10–80% of tibial length. At each site we computed polar bone strength index (pBSI). Two SF proxies were defined: pBSI_Fvec = pBSI/Fjump (vertical countermovementjump force) and pBSI_Frot = pBSI/Fever (maximal rotationaleversion force measured with a loadcell device). Linear mixedeffects models (random intercept for subject) included sport, site, sport×site, body mass and tibial length.

Results
In tibia, pBSI_Fvec showed a strong site effect (p<0.0001) but no sport or sport×site effect, indicating similar longitudinal SF patterns across groups. Tibial pBSI_Frot showed a marked site effect (p<0.0001) and a significant sport×site interaction (p<0.0001), without a global sport effect. Posthoc comparisons revealed higher distal (≈65–80%) tibial pBSI_Frot in basketball and rugby versus sedentary, with football intermediate and gym/tennis similar to controls. In fibula, pBSI_Fvec depended only on site (p<0.0001). Fibular pBSI_Frot showed significant site (p<0.0001) and sport×site effects (p<0.001); only rugby presented higher midshaft (≈35–55%) values than sedentary. Covariates were not independent predictors.

Conclusions
SF proxies vary strongly along tibia and fibula. Jumpbased SF does not discriminate sports at any level, whereas eversionbased SF reveals localised advantages in regions relevant to lateral ankle loading in basketball and especially rugby. These findings support a bone and sitespecific mechanostat rather than a uniform SF along the leg.

P1394

PHARMACOKINETICS, PHARMACODYNAMICS, SAFETY AND IMMUNOGENICITY OF BP16 (PROPOSED DENOSUMAB BIOSIMILAR) COMPARED TO EU- PROLIA® AND US- PROLIA®

R. Eastell[1], A. Prajapati[2], P. Ryan[3], C. Schwabe[4], D. Dadke[2]

[1]University of Sheffield Medical School, Sheffield , United Kingdom; [2]Curateq Biologics Pvt Ltd, Hyderabad, India; [3]Nucleus Network Melbourne, Melbourne, Australia; [4]New Zealand Clinical Research-Auckland, Auckland, New Zealand

Objective(s)
To evaluate the pharmacokinetic (PK) similarity along with pharmacodynamic (PD), safety, and immunogenicity of BP16 with the US-Prolia® and EU-Prolia® following a single SC administration in healthy male subjects.
Material and Methods
In this phase 1, double-blind, parallel group study, 204 healthy male subjects were randomized 1:1:1 and treated to receive a single 60 mg/mL SC administration of BP16, EU-Prolia® or US-Prolia®, and evaluated for 253 days. The primary objective was to demonstrate PK similarity by evaluation of AUC0-inf, AUC0-t, and Cmax. between BP16 and the reference products, using the standard 80–125% bioequivalence criteria.
Results
Demographics and baseline demographics for the 204 subjects were comparable across all treatment groups. Of the 204 subjects who received treatment, 185 subjects completed the study: 60 subjects (88.2%) from BP16 arm, 62 subjects (88.6%) from EU-Prolia® arm, and 63 subjects (91.3%) from US-Prolia® arm.
PK profile of denosumab serum concentrations in terms of primary PK parameters (AUC0-inf, AUC0-t, and Cmax) were similar between the three products. The 90% CIs for the ratios of PK parameters were within 80% to 125% for all three pairwise comparisons. PD profiles of sCTX using percent change from baseline evaluated in terms of Emax and AUEC0-t was found to be comparable between the three treatment arms.
Treatment-emergent adverse events (TEAEs) were reported by 86.8%, 88.4% and 89.6% subjects in the BP16, EU- Prolia®, and US- Prolia® groups, respectively. The most common TEAEs were vitamin D decreased, upper respiratory tract infection, COVID-19, headache, and arthralgia. In all the treatment groups, immunogenicity profile was comparable with majority of subjects having positive ADA responses. Majority of ADA response were transient in nature with negative neutralizing antibodies. The ADA positive rate was comparable among the treatment arms with no impact on the safety, PK, or PD profile.
Conclusion(s)
This study demonstrated 3-way PK similarity between BP16, EU-Prolia® and US-Prolia®. All three treatments had a similar PD, safety, and immunogenicity profile and were well tolerated.

P1395

REAL WORLD COMPARISON BETWEEN THE HEALTHVCF AND HEALTHOST AI MODELS FOR DETECTION OF VERTEBRAL FRACTURES FROM EXISTING CT SCANS

R. Eckert[1], M. K. Javaid[2]

[1]Oxford Fracture Prevention Service, Oxford University Hospitals NHS Foundation Trust, Oxford, United Kingdom; [2]NDORMS, University of Oxford, Oxford, United Kingdom

Objectives

A number of different AI models have been developed to identify vertebral fractures (VFs) from existing CT scans to increase the case identification of adults at high fracture risk for fracture liaison services (FLS). We aimed to compare the test performance of AI detected vertebral fractures (moderate/ severe deformity or clear endplate fractures) between the commercially available Nanox-AI HealthVCF (VCF) and HealthOST (OST) models.

Material and Methods

A consecutive series of CT scans from 1st to 3rd October 2025 were analyzed using the VCF and OST models using the balanced sensitivity equivalent settings. While VCF analyzes axial images to generate a sagittal image output, HealthOST is a measurement tool of vertebral height loss on primary sagittal images. An FLS nurse with experience in identifying vertebral fractures read the AI outputs from both models blinded to order. We used descriptive statistics to test agreement and describe differences between the two AI models.

Results

431 consecutive CT scans were analysed by both VCF and OST, 24 (5.6%) only by VCF and 43 (10.0%) only by OST. In the 364 scans analysed by both models, the clinician VF prevalence was 9.6% with VCF and higher at 12.7% with OST (p<0.001) with 94.5% agreement (kappa 0.74, p<0.001; Gwet's AC 0.93). The improvement in performance characteristics from VCF to OST are shown in Table 1. 10.1% of OST AI scans were also identified as low BMD, with higher rates of low BMD in scans that were clinically confirmed VFs (23.9% vs 8.2%, p=0.001).

Conclusion

The HealthOST system improved the clinician detection of VF as well as test performance with fewer scans flagged requiring clinical confirmation and fewer VF missed. The addition of low BMD detection identified almost a quarter of VF patients who could be prioritised for FLS assessment.

Table: Comparison between HealthVCF and HealthOST AI vs clinician reading for Vertebral Fracture (VF) detection and estimated impact per 1000 CT scans

	AI VF flag rate	Sensitivity	Specificity	% clinician agreement	NPV	PPV	Estimated impact per 1000 scans using 12.7% VF prevalence			
							AI-flagged scans (n)	AI-flagged scans with VF (n)	AI-flagged Scans without VF (n)	VF missed (n)
HealthVCF	32.7%	88.6%	73.3%	74.7%	98.4%	26.1%	327	112	215	14.5
HealthOST	28.0%	95.7%	81.7%	83.5%	99.2%	43.1%	280	121	159	5.4

P1396

BENCH PRESS PERFORMANCE IS ANOTHER INDICATOR OF BONE MINERAL DENSITY IN MIDDLE-AGED MEN

I. Fayad[1], A. Pinti[1], H. Zouhal[2], R. El Hage[3]

[1]Université Polytechnique Hauts-de-France, INSA Hauts-de-France, LARSH - Laboratoire de Recherche, Sociétés & Humanités, Valenciennes F-59313, France., Valenciennes, France; [2]Institut International des Sciences du Sport (2IS), Irodouer, 35850, Irodouer, France; [3]University of Balamand/ Department of Physical Education, Kelhat, Lebanon

Objective: The main aim of the current study was to explore the relationships between bench press performance and bone health variables in a group of middle-aged active men. Because the bench press primarily reflects absolute strength rather than relative strength, we hypothesized that bench press performance would show a stronger correlation with whole-body bone mineral content (BMC) and bone mineral density (BMD) compared to the squat or deadlift.
Methods: A total of 50 physically active men in middle adulthood voluntarily took part in this study. The participants had a mean age of 45 ± 8.6 years and were randomly selected from the northern region of Lebanon. All individuals were in good health, with no history of significant orthopedic conditions or other medical issues known to impact bone metabolism. Bone mineral density (BMD) measurements were obtained using dual-energy X-ray absorptiometry (DXA; GE Lunar, Madison, WI, USA).
Results: 1-RM bench press was positively correlated with WB BMC (r = 0.66; p < 0.001), WB BMD (r = 0.59; p < 0.001), L1-L4 BMD (r = 0.38; p < 0.01), TH BMD (r = 0.40; p < 0.01), FN BMD (r = 0.39; p < 0.01), CSA (r = 0.57; p < 0.001), CSMI (r = 0.50; p < 0.001) and Z (r = 0.34; p < 0.05). These positive correlations remained significant after controlling for age. 1-RM squat was positively correlated with WB BMC (r = 0.56; p < 0.001), WB BMD (r = 0.40; p < 0.01), L1-L4 BMD (r = 0.29; p < 0.05), CSA (r = 0.48; p < 0.001), CSMI (r = 0.58; p < 0.001) and Z (r = 0.45; p < 0.01). 1-RM deadlift was positively correlated with WB BMC (r = 0.43; p < 0.01), WB BMD (r = 0.36; p < 0.01), CSA (r = 0.38; p < 0.01), CSMI (r = 0.40; p < 0.01) and Z (r = 0.37; p < 0.01).
Conclusion: The current study suggests that bench press performance is a positive predictor of whole-body BMC and BMD in middle-aged men. It also showed moderate associations with regional BMD and bone strength indicators.

P1397

BONE HEALTH PARAMETERS IN MIDDLE-AGED FORMER VOLLEYBALL PLAYERS COMPARED WITH MIDDLE-AGED ACTIVE MEN

I. Fayad[1], A. Pinti[1], R. El Hage[2]

[1]Université Polytechnique Hauts-de-France, INSA Hauts-de-France, LARSH - Laboratoire de Recherche, Sociétés & Humanités, Valenciennes F-59313, France., Valenciennes, France; [2]University of Balamand/Department of Physical Education, Kelhat, Lebanon

Objective: The purpose of this study was to compare bone health parameters (bone mineral content (BMC), bone mineral density (BMD), geometric indices of femoral neck (FN) strength (cross-sectional area [CSA], cross-sectional moment of inertia [CSMI], section modulus [Z], and strength index [SI]), and composite indices of FN strength (compression strength index [CSI], bending strength index [BSI], and impact strength index [ISI])) between middle-aged active men (n = 24) and middle-aged former volleyball players (n = 26).
Methods: Fifty middle-aged men aged 35–60 years participated in the study. Dual-energy X-ray absorptiometry (DXA) was used to assess body composition, BMD, and geometric indices of FN strength. Composite indices of FN strength (CSI, BSI, and ISI) were calculated using established formulas. Physical performance was evaluated through tests assessing vertical jump (VJ), horizontal jump (HJ), triple jump (TJ), lower-limb maximal power (MP, watts), maximal squat strength, maximal bench press strength, maximal leg extension strength, maximal barbell curl strength, maximal triceps extension strength, sprint performance over 10 m, and maximal oxygen consumption (VO max, L/min).
Results: After adjusting for body weight using one-way analysis of covariance (ANCOVA), no significant differences were observed between the two groups in bone health parameters, including BMC, BMD, and hip geometry indices.
Conclusion: The findings of the present study suggest that former volleyball participation is not associated with superior bone health parameters in middle-aged men compared with age-matched active men.

P1398

IMPACT OF VITAMIN D LEVELS ON FUNCTIONAL PERFORMANCE AND JOINT SYMPTOMATOLOGY: IMPLICATIONS FOR OSTEOMETABOLIC HEALTH

R. F. Tizziotti[1], I. L. Nóbrega[1], N. A. Casonato[1], M. G. Da Silva[1], L. V. Almeida[1], S. M. Mattiello[1]

[1]Federal University of São Carlos, São Carlos, Brazil

Objective: Osteometabolic homeostasis is highly dependent on adequate vitamin D levels. In knee osteoarthritis (KOA), the complex interaction with bone metabolism often results in increased pain and functional impairment. Given that vitamin D is a key determinant of musculoskeletal health, this study aims to evaluate the association between serum vitamin D levels and clinical symptoms, as measured by the WOMAC score and its subscales, in individuals with KOA.
Material and Methods: Seventy-two individuals of both sexes with a clinical and radiographic diagnosis of KOA (according to the ACR criteria) were evaluated. A multiple linear regression analysis was performed, adjusted for sex and age. The Bootstrap resampling technique (1000 replications) was applied to ensure the robustness of the total WOMAC score estimates. Statistical analyses were performed in RStudio, with significance set at $p < 0.05$.
Results: The sample consisted of 72 individuals with a mean age of 58.3 years (SD = 9.37), predominantly female (63.9%). The regression model for Total WOMAC was statistically significant (P = 0.0042). Vitamin D demonstrated a protective effect with beta = -5.259. Although the nominal p-value was marginal (P = 0.0512), Bootstrap analysis confirmed the association (95% CI: -11.15 to -0.544). In domain-specific analysis, vitamin D was an independent and significant factor for physical function (beta = -4.195; P = 0.0351), showing no direct association with pain (P = 0.3307) or stiffness (P = 0.6625). Sex significantly influenced pain (P = 0.0148) and function (P = 0.0006), while age was not a significant predictor.
Conclusion: Vitamin D levels are essential determinants of functional performance in KOA. The clinical benefit focuses on physical activity and mobility, independent of age or direct pain relief. These findings suggest that vitamin D sufficiency helps preserve mechanical competence, serving as a key strategy for maintaining functional independence.

P1399

INTEGRATIVE TRANSCRIPTOMICS AND MACHINE LEARNING IDENTIFY OSTEOBLAST IMMUNOLOGY DYSREGULATION IN STAT3-LOF HYPER-IGE SYNDROME

R. Garg[1], H. Choudhary[1], R. Kaur[1], A. Tiwari[1], D. Suri[2], A. Rawat[2], Y. Kumar[1], B. Saikia[1]

[1]Department of Immunopathology, PGIMER, Chandigarh, India; [2]Department of Advanced Paediatrics Center, PGIMER, Chandigarh, India

Aim:
To identify molecular mechanisms underlying bone–immune dysregulation in STAT3-LOF HIES using an AI-driven transcriptomic approach.
Methods:
Four STAT3-LOF HIES patients (mutations spanning DNA-binding, coiled-coil, and linker domains; NIH score ≥20; Th17 ≤0.5%; pSTAT3 <30%) and four healthy controls were studied. PBMC-derived mesenchymal stromal cells were differentiated into osteoblasts and assessed for alkaline phosphatase (ALP) activity and mineralization. Bulk RNA-sequencing was performed followed by differential expression analysis. To move beyond static DEG analysis, we implemented a multi-layer AI pipeline comprising:(i) trajectory-based pseudotime inference to reconstruct osteoblast maturation dynamics, (ii) WGCNA with cross-power robustness assessment to identify stable co-expression modules, (iii) machine-learning feature prioritization using Elastic Net, Random Forest, and ReliefF with bootstrap stability and consensus ranking, (iv) STAT3 transcription factor activity inference using DoRothEA-VIPER, (v) pathway activity inference using PROGENy, and (vi) image-anchored pseudo-spatial analysis integrating immunofluorescence-derived ALP and OCN signals with transcriptomic maturation scores. Key genes were validated by qRT-PCR, and discriminative performance was assessed using ROC analysis.
Results: Patient-derived osteoblasts exhibited impaired mineralization and reduced ALP activity compared with controls. RNA-seq identified **529 downregulated and 769 upregulated genes** (≥1.5-fold). AI-guided

enrichment analyses highlighted pathways central to **extracellular matrix organization, skeletal system development, osteoblast differentiation, immune cell signaling, and cytokine-mediated regulation of bone remodeling**. WGCNA revealed distinct modules enriched in skeletal and immune programs: the **turquoise module** (836 DEGs) was dominated by skeletal morphogenesis genes (HOX cluster, **TBX15, ALPL, ID4, EFEMP1**); the **yellow module** (197 DEGs) contained immune regulators (**CYBB, ITGAX, TLR4, MMP9, SPP1, SPI1, TREM2**); and the **blue/red modules** were enriched for ECM remodeling and signaling mediators (**POSTN, BMP4, FOS, NFATC2, WNT9A**). Integrated ML feature selection and DEG overlap prioritized a compact **bone–immune signature** consisting of **BGN, EFEMP1, HOXA11, SULF1, IGFBP3, ID4, ADRB2** (skeletal) and **TLR4, MMP9, SPP1, TREM2, SPI1** (immune). ROC analyses confirmed excellent discriminative performance for this signature (Random Forest AUC ≈ 1.0), and qRT-PCR validation confirmed altered expression (**p = 0.0286**). Together, these findings support the potential of these hub genes as **robust biomarkers linking immune dysfunction to skeletal pathology in STAT3-LOF HIES**.

Conclusions: Our integrative transcriptomic and AI-based analysis reveals profound dysregulation of bone–immune regulatory networks especially in osteoblast formation in STAT3-LOF HIES. These findings provide new insights into the molecular basis of skeletal abnormalities in primary immunodeficiency and highlight potential biomarkers linking immune dysfunction to bone pathology.

P1400

COMPARATIVE EFFECTS OF ANTIDIABETIC DRUGS ON LEAN BODY MASS AND FAT MASS: A SYSTEMATIC REVIEW AND NETWORK META-ANALYSIS

S. Rakhsha[1], H. Shahinfar[2], G. Shafiee[1], R. Heshmat[1]

[1]Chronic Diseases Research Center, Endocrinology and Metabolism Population Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran, Tehran, Iran; [2]Nutritional Health Research Center, School of Health and Nutrition, Lorestan University of Medical Sciences, Khorramabad, Iran., Khorramabad, Iran

Objective : his systematic review and network meta-analysis aimed to quantify and compare the effects of major antidiabetic agents on key body composition parameters.

Methods: We systematically searched PubMed, Web of Science, and Scopus databases from inception to March 2025 for randomized controlled trials assessing the effects of major antidiabetic drugs on body composition outcomes in adults. Network meta-analyses were performed within a frequentist random-effects framework to estimate mean differences (MDs) and 95% confidence intervals (CIs) for changes fat mass (FM) and lean body mass (LBM).

Results: A total of 41 randomized trials (n = 2,906) were included. For LBM, tirzepatide (MD = -4.40 kg; 95% CI -7.58 to -1.22; low certainty) and liraglutide (MD = -1.54 kg; 95% CI -2.55 to -0.52; moderate certainty) significantly reduced LBM versus placebo. SGLT2 inhibitors caused minor reductions, while metformin, insulin regimens, and DPP-4 inhibitors showed neutral effects. Compared with placebo, tirzepatide showed the greatest reduction in FM (MD = -10.70 kg; 95% CI -13.42 to -7.99; moderate certainty), followed by liraglutide combined with exercise and beinaglutide. Semaglutide and liraglutide produced moderate FM decreases. In contrast, glargine (MD = +2.60 kg; 95% CI 1.24 to 3.97; low certainty) and alogliptin (MD = +1.89 kg; 95% CI 0.26 to 3.52; very low certainty) increased FM compared with metformin.

Conclusion: GLP-1 receptor agonists and dual GIP/GLP-1 agonists, particularly tirzepatide, liraglutide, semaglutide, and beinaglutide, significantly reduce both LBM and FM. Liraglutide combined with exercise showed the most pronounced FM reduction, except for tirzepatide, which had the greatest overall reduction in FM but also caused a significant decrease in LBM. Among SGLT2 inhibitors, canagliflozin and empagliflozin led to modest reductions in LBM, while alogliptin as a DPP-4 inhibitor slightly increased FM without affecting LBM. In contrast, metformin, insulin, and sulfonylureas had no meaningful impact on either FM or LBM. These findings underscore the varied effects of antidiabetic drugs on body composition and highlight the need for further research into the role of dosage and treatment duration.

P1401

COMPARATIVE INCIDENCE OF SUBSEQUENT FRACTURES FOLLOWING ANTIRESORPTIVE VERSUS OSTEOANABOLIC THERAPY IN A FRACTURE LIAISON SERVICE IN SPAIN

R. Izquierdo-Aviño[1], D. García-Aguilera[2]

[1]Hospital Nuestra Señora de Gracia, Zaragoza, Spain; [2]Hospital Royo Villanova, Zaragoza, Spain

OBJECTIVE

The objective of this study was to analyze and compare the incidence of subsequent fractures in patients treated with antiresorptive drugs (ARs) versus those treated with osteoanabolic drugs (OAs) among patients enrolled in an FLS, where standardized follow-up is implemented to monitor treatment adherence.

MATERIAL AND METHODS

- Retrospective observational cohort study
- Patients aged ≥50 years with fragility fractures enrolled in a FLS between 2017 and 2025
- Comparative descriptive statistical analysis of subsequent fracture incidence between treatment groups (AR versus OA) over a follow-up period of up to 8 years, stratified by treatment type and adherence

RESULTS

A total of 2,322 patients included in the FLS initiated treatment (either AR or OA), with a mean follow-up of 2.2 years (range: 0.5–8.7 years). In the overall cohort, 386 subsequent fractures occurred, corresponding to an incidence rate of 6.67 fractures per 100 person-years (95% CI: 6.0–7.3). In the AR group, 303 fractures occurred (6.4 per 100 person-years) compared with 83 fractures in the OA group (13.3 per 100 person-years). Patients treated with ARs demonstrated a significantly lower re-fracture rate (incidence rate ratio [IRR] 0.48, 95% CI: 0.38–0.61; p<0.001)

The most frequent site of re-fracture in the overall cohort was the hip (24.6%), followed by the forearm (17.6%). After an index hip fracture, the most common subsequent fracture was the hip (37.4%). Similarly, following an index vertebral fracture, the most frequent subsequent fracture was vertebral (26.4%)

Following the index fracture, 86.1% of patients initiated ARs while 13.9% received OAs. The rate of good adherence to treatment (>80% of prescribed doses) at 2 years was similar in both groups (80.5% in the OA group and 79.5% in the AR group). Similarly, good adherence was observed among re-fractured patients (84.3% in the AR group and 79.5% in the OA group)

CONCLUSION
A rate of re-fracture of 6.67 fractures per 100 person-years was recorded in our FLS. The proportion of high/very high-risk patients receiving OA therapy was low. The higher re-fracture rate observed in the OA group likely reflects the very high baseline fracture risk in this population. The hip was the most common site of re-fracture, emphasizing the importance of effective secondary fracture prevention strategies.

P1402

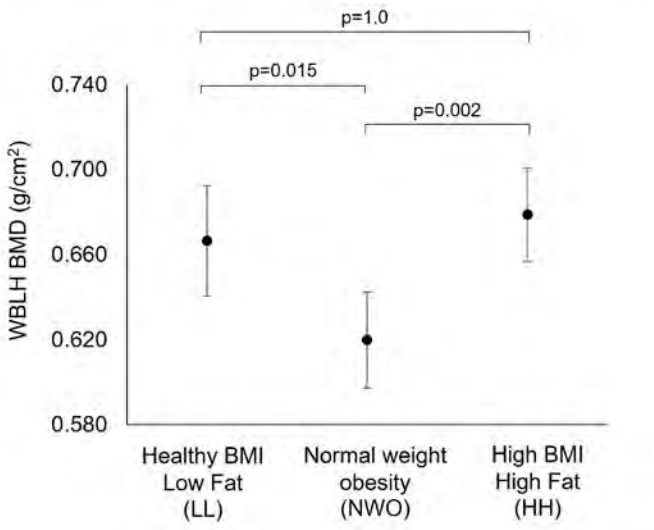
MORTALITY AFTER PROXIMAL HUMERUS FRAGILITY FRACTURES IN A FRACTURE LIAISON SERVICE COHORT: BEYOND TREATMENT STRATEGY

D. García-Aguilera[1], R. Izquierdo-Aviño[2]

[1]Hospital Royo Villanova, Zaragoza, Spain; [2]Hospital Nuestra Señora de Gracia, Zaragoza, Spain

Objectives
To analyze mortality after proximal humerus fragility fractures in a Fracture Liaison Service (FLS) cohort and to evaluate the impact of treatment strategy, comorbidity burden, and anti-osteoporotic treatment on survival.
Material and Methods
A retrospective observational study was conducted including patients aged ≥50 years with proximal humerus fragility fractures enrolled in a Fracture Liaison Service between 2017 and 2025. Patients were classified according to treatment strategy (conservative or surgical). Demographic data, baseline functional status, comorbidity burden assessed using the age-adjusted Charlson Comorbidity Index (ACCI), anti-osteoporotic treatment, and follow-up were recorded. The primary outcome was all-cause mortality during follow-up. Multivariate logistic regression analysis was performed.
Results
A total of 121 patients were included, with a mean age of 77.1 ± 10.3 years and a mean follow-up of 22.8 ± 14.7 months. Patients treated conservatively were significantly older than those treated surgically (80.7 ± 9.4 vs 72.0 ± 9.7 years) and had a higher comorbidity burden. Mortality was 33.3% in the conservative group and 20.4% in the surgical group (p = 0.18). In multivariate analysis, treatment strategy and type of anti-osteoporotic treatment (bisphosphonate, denosumab, or teriparatide) were not independently associated with mortality. Higher ACCI scores, male sex, and loss of pre-fracture autonomy were independent predictors of mortality.
Conclusions
In a Fracture Liaison Service cohort, mortality after proximal humerus fragility fractures is primarily driven by patient-related factors rather than treatment strategy or anti-osteoporotic therapy. The higher mortality observed in conservatively treated patients appears to reflect older age, greater comorbidity burden, and poorer baseline clinical status. These findings highlight the importance of comprehensive patient assessment and multidisciplinary management within FLS programs.

P1403



NORMAL WEIGHT OBESITY: A THREAT TO BONE HEALTH IN CHILDHOOD?

R. J. Moon[1,2,3], S. D'Angelo[1], S. R. Crozier[1,2,4], K. M. Godfrey[1,2], N. C. Harvey[1,2]

[1]MRC Lifecourse Epidemiology Centre, University of Southampton, Southampton, United Kingdom; [2]NIHR Southampton Biomedical Research Centre, University of Southampton and University Hospital Southampton NHS Foundation Trust, Southampton General Hospital, Southampton, United Kingdom; [3]Regional Centre for Paediatric Endocrinology, Southampton Children's Hospital, University Hospital Southampton NHS Foundation Trust, Southampton, United Kingdom; [4]NIHR Applied Research Collaboration Wessex, Southampton, United Kingdom

Objectives
Normal weight obesity (NWO) describes a healthy body mass index (BMI) but high body fat percentage (%BF). It is associated with increased cardiovascular risk. The effect on bone health is poorly described, particularly in childhood when high BMI is associated with higher bone mineral density (BMD) compared to peers with healthy BMI. We compared BMD in children with NWO to those with a healthy BMI and %BF (LL) and a high BMI and %BF (HH).
Materials and Methods
In the Southampton Women's Survey cohort study, children aged 8-9y had anthropometry measurements and whole body (WB) and lumbar spine (LS) DXA (Hologic Discovery). BMI z-score (BMIz) for age and sex was calculated using British reference data; overweight/obese was defined as ≥1. DXA WB %BF adjusted for age and sex was standardised within the cohort and ≥1 was classed as high.
For each sex, propensity score matching was used to match 1:1 NWO (BMIz<1 & %BFz≥1) to LL (BMIz<1 & %BFz<1) by BMIz and age, and to HH (BMIz≥1 & %BFz≥1) by %BFz and age.
Whole body less head (WBLH) and LS bone mineral content (BMC), BMD and bone mineral apparent density (BMAD) were compared across groups (ANOVA). Results are shown as mean (SD).
Results
Of 807 participants, 24 (3%) had NWO (9 male, mean BMIz 0.55 (0.36), %BF 34.2 (2.6)). The 24 matched LL had similar BMIz (0.63 (0.29) p=1.0) but lower %BF (25.2 (3.2) p<0.001); HH had higher BMIz (1.65 (0.51), p<0.001) but similar %BF (34.5 (2.7) p=1.0).
WBLH BMC was similar for each group (p=0.92). WBLH BMD was lowest in NWO and similar in LL and HH (Fig 1). WBLH BMAD was also lower in NWO (0.018 g/cm^3 (0.002), LL 0.020 (SD 0.002), HH 0.020 (SD 0.002), p<0.001 across groups). LS BMD and BMAD showed similar trends (p>0.05).

Fig 1: Whole body less head (WBLH) bone mineral density (BMD) in children grouped by BMI and body fat percentage
Shown as mean (95% CI)

Conclusions
Children with NWO have a lower BMD, suggesting that excess adiposity without loading weight may impair bone mineral accrual. Consideration of how to identify children with NWO and promote bone health is needed.

P1404

EXPANDING ACCESS TO EVIDENCE-BASED BONE HEALTH TRAINING: COLLABORATIVE GROWTH OF THE BONE FIT™ PROGRAM

R. Monzer[1], R. Jain[1], J. Laprade[2], C. Mcarthur[3], A. Medeiros[4], C. Gill[5]

[1]Osteoporosis Canada, Toronto, Canada; [2]Division of Anatomy, Department of Surgery, Faculty of Medicine, University of Toronto, Toronto, Canada; [3]School of Physiotherapy, Faculty of Health, Dalhousie University, Halifax, Canada; [4]MPH, Bone Health & Osteoporosis Foundation, Arlington, United States; [5]CEO, Bone Health & Osteoporosis Foundation and Founder & President of National menopause foundation, Arlington, United States

Objectives:

To successfully adapt Bone Fit™ program, developed by the Ontario Osteoporosis Strategy (OOS), to the requirements of the U.S. audience and train healthcare professionals in the clinical and fitness fields on how to administer safe, effective and evidence-based exercises to patients with osteoporosis.

Material & Methods:

The Bone Fit™ program provides safe, effective, evidence-based training for rehabilitation and exercise professionals to better support patients with osteoporosis or those who have recently fractured. It was developed in conjunction with an advisory committee of expert clinicians and academics in the field of osteoporosis and exercise and launched in 2010. The curriculum was adapted to a hybrid delivery post COVID-19 and was updated based on the Canadian Osteoporosis Guideline published in 2023.

In 2019, OOS and the Bone Health and Osteoporosis Foundation (BHOF) collaborated to bring Bone Fit™ to the United States to address the growing population of osteoporosis patients who would benefit from exercise intervention. OOS shared Bone Fit™ program's content, background materials and research with the BHOF to use and adapt to their own clinical guidance and develop a similar program. OOS and BHOF have established an Advisory Council consisting of researchers, experts and Bone Fit™ trainers that meet bi-annually to review and update the training curriculum to ensure Bone Fit™ workshops provide continued value to rehabilitation and exercise practitioners.

Results:

Program launch	Organization	Workshops	Trainees	Method of Learning
2010	OOS	128	3004	Virtual & In-Person
2019	BHOF	15	424	Virtual & In-Person

The program has been very well received, prompting both organizations to expand in response to strong demand, with BHOF maintaining a waitlist of over 100 professionals and increasing to four annual workshops, while OOS has already opened three workshops for 2026 and plans to schedule them monthly. The OOS has also received interest from healthcare professionals in the United Kingdom, Australia, Hungary and New Zealand.

Conclusions:

The Bone Fit™ program was established to serve Canadian rehabilitation and exercise professionals. The OOS has successfully collaborated with the U.S. and adapted the educational content for its use. This collaboration can serve as a model for adapting Bone Fit™ for other countries.

P1405

DENOSUMAB-INDUCED HYPOCALCAEMIA IN PATIENTS WITH LOW EGFR: A CASE SERIES

R. Jarmal[1], S. Donnelly[1], V. Ramasamy[1], L. D. Williamson[1]

[1]Barts Health NHS Trust/Rheumatology Department/Whipps Cross Hospital, London, United Kingdom

Objective: There are limited therapeutic options for treating patients with severe osteoporosis and chronic kidney disease, especially those with an estimated glomerular filtration rate (eGFR) of <30ml/min/1.73^2. These patients often have a very high risk of morbidity and mortality associated with a major osteoporotic fracture. Denosumab is effective at reducing the risk of osteoporotic fractures, however is associated with a risk of hypocalcaemia [1]. We audited the risk of developing significant hypocalcaemia in patients with low eGFR taking denosumab for osteoporosis.
Material and Methods: We present a small retrospective case series on patients with eGFR <30ml/min/1.73^2 who received denosumab 60mg by subcutaneous (SC) injection. Prior to administration, initial bloods including bone profile, urea and electrolytes and vitamin D were normal or corrected (vitamin D>50nmol/L). Blood monitoring of serum corrected calcium (cCa2+) was completed every 2 weeks for 6 weeks post Denosumab injection (2,4 and 6 weeks). All patients received high dose Vitamin D3 as colecalciferol 20,000iu for 6 weeks (week 2,4 and 6).

Results: We terminated the audit after treating seven female patients (age 74-95 years). There were six Caucasian and one South Asian patient. Six patients had a history of multiple fractures and one patient had been taking letrozole. The median baseline eGFR was 24 (4-31) ml/min/1.73^2 and mean baseline serum cCa2+ (at time of 1st injection) was 2.44 mmol/l (2.22-2.65). At 2 weeks, the mean serum cCa2+ was 2.14 mmol/l (1.54-2.51), at week 4, 2.24 mmol/l (1.90.2.51) and at week 6, 2.25 mmol/l (1.94-1.41). Two out of seven patients developed severe hypocalcaemia in week 2 (1.54 mmol/l and 1.62 mmol/l) with emergency hospitalisation to correct this. These patients had eGFR 4 ml/min/1.73^2 and eGFR 19ml/min/1.73^2 respectively. Both were asymptomatic and corrected with IV therapy. Two patients developed mild-moderate hypocalcaemia (1.90-2.10 mmol/l), in week 4 and week 6. There was no discernible trend between decreasing eGFR and decreasing serum cCa2+ levels across all weeks.

Conclusion: Treating elderly females with a low eGFR for osteoporosis with denosumab carries a significant risk of severe hypocalcaemia, which in turn can be life-threatening. The hypocalcaemia may be asymptomatic and based on this audit the risk is highest in patients with an eGFR <20ml/min/1.73^2.

Objective:
This study examined the association between ultra-processed food intake and bone mineral density among Iranian adults participating in the Iranian Multicenter Osteoporosis Study (IMOS).
Materials and Methods:
This cross-sectional study included 1,365 adults aged 50 years and older from the Iranian Multicenter Osteoporosis Study (IMOS), a nationwide population-based study conducted in Iran. Dietary intake was assessed using a validated food frequency questionnaire, and participants were categorized into tertiles of ultra-processed food intake. Bone mineral density at the total hip, lumbar spine, and femoral neck was measured using dual-energy X-ray absorptiometry (DXA). Baseline characteristics across UPF tertiles were compared using analysis of variance and chi-square tests. Logistic regression models were used to examine associations between UPF intake and BMD. Model 1 was adjusted for age and sex, while Model 2 further adjusted for education level, smoking status, diabetes, body mass index, physical activity, and total energy intake.
Results:
The mean age of participants was 59.6 ± 7.2 years, and 55.4% were women. In age and sex-adjusted analyses, participants in the highest tertile of UPF intake had higher odds of lower femoral neck BMD (OR = 1.42; 95% CI: 1.05–1.93) compared with those in the lowest tertile. A similar but non-significant trend was observed for total hip BMD, while no significant association was found for lumbar spine BMD. After further adjustment for lifestyle and clinical factors, the observed associations were attenuated and did not remain statistically significant.
Conclusions:
Higher consumption of ultra-processed foods was associated with lower femoral neck BMD in minimally adjusted models, but no independent associations were observed after comprehensive adjustment. These findings suggest that the relationship between UPF intake and bone health may be influenced by confounding lifestyle and clinical factors. Prospective studies are needed to clarify the potential role of ultra-processed food consumption in osteoporosis risk.

[1]Osteoporosis Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran, Tehran, Iran; [2]Obesity and Eating Habits Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran, Tehran, Iran; [3]Endocrinology and Metabolism Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran, Tehran, Iran; [4]Prevention of Metabolic Disorders Research Center, Research Institute for Metabolic and Obesity Disorders, Research Institute for Endocrine Sciences, Shahid Beheshti University of Medical Sciences, Tehran, Iran, Tehran, Iran; [5]Chronic Diseases Research Center, Endocrinology and Metabolism Population Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran, Tehran, Iran; [6]Center for Non-Communicable Disease Control & Prevention, Deputy of Public Health, Ministry of Health and Medical Education, Tehran, Iran, Tehran, Iran

Objective:
Phytochemical-rich foods may support musculoskeletal health, especially in postmenopausal women. The phytochemical index (PI) reflects dietary phytochemical intake, but evidence linking PI to site-specific bone mineral density (BMD) and muscle outcomes is limited. This study examined associations between PI and musculoskeletal problems in general population.
Materials and Methods:
This cross-sectional analysis included 1,365 adults aged ≥50 years from Round 4 of the Iranian Multicenter Osteoporosis Study (IMOS), recruited via multi-stage random sampling. Participants with implausible energy intake (<800 or >4,200 kcal/day), secondary osteoporosis, or missing data were excluded. Dietary intake was assessed using a validated food frequency questionnaire, and PI calculated as the percentage of energy from phytochemical-rich foods. Hip, spine, and femoral neck BMDs were measured by dual-energy X-ray absorptiometry. Baseline characteristics across PI tertiles were compared using ANOVA and chi-square tests. Associations with BMD were assessed by Pearson correlations, and logistic regression estimated odds ratios (ORs) for abnormal BMD, sarcopenia, and osteosarcopenia, adjusting for demographic, lifestyle, and clinical factors ($P < 0.05$).
Results:
Participants (mean age 59.6 ± 7.2 years; 55.4% women) showed differences across PI tertiles in education, BMI, smoking, vitamin D deficiency (all $P \leq 0.01$), and marital status ($P = 0.012$). Spine BMD ($P = 0.011$) and T-scores ($P = 0.009$) increased across PI tertiles, while hip and femoral neck BMD did not. PI showed weak positive correlations with hip ($r = 0.082$), spine ($r = 0.101$), and femoral neck ($r = 0.108$) BMD (all $P \leq 0.003$). Higher PI tertiles were linked to lower odds of abnormal spine BMD in crude and partially adjusted models (Model 1, third vs. first tertile: OR 0.65; $P = 0.003$; P-trend = 0.035), but not after full adjustment. No significant associations were observed for other outcomes.
Conclusions:
Higher PI was associated with better spine BMD in unadjusted analyses, but not independently after adjustment. Our findings suggest potential benefits of phytochemical-rich diets on spine health, although residual confounding and dietary complexity may influence these findings, highlighting the need for intervention studies to clarify the role of dietary phytochemicals in bone and muscle health.

P1408

TARGETING IMMUNOPOROTIC PTREGS AS A NOVEL STRATEGY IN MITIGATING INFLAMMATORY BONE LOSS IN POST-MENOPAUSAL OSTEOPOROSIS

R. K. Srivastava[1], A. Asha[1], L. Leena[1]

[1]All India Institute of Medical Sciences (AIIMS), Delhi, India

Introduction: Osteoporosis, particularly post-menopausal osteoporosis (PMO), is increasingly recognised as an immune-mediated skeletal disorder ***(Immunoporosis)***. The gut represents the largest immune compartment, and emerging evidence indicates that gut-resident regulatory T cells (GTregs) critically regulate bone remodeling and inflammation-driven bone loss. However, the functional dichotomy between thymus-derived Tregs (tTregs) and peripherally induced Tregs (pTregs), including RORγT$^-$ and RORγT$^+$ subsets, in PMO-associated bone deterioration remains unresolved.
Materials & Methods: Female C57BL/6 mice were divided into Sham and ovariectomized (ovx) groups. After 45 days, mice were euthanised, intestine and bone marrow were harvested for various analyses using SEM, µCT, FACS, and ELISA. HPLC was performed on collected faecal samples to determine the effect of ovx on SCFA production. Additionally, *in vitro* assays were conducted to investigate the potential of SCFAs in promoting the differentiation of Treg cells and influencing osteoclastogenic/osteoblastogenic pathways. Furthermore, ovx mice were supplemented with probiotic strains (*Lactobacillus rhamnosus, Bifidobacterium longum,* and *Lactobacillus acidophilus*) and butyrate to evaluate restoration of GTreg homeostasis.
Results: We observed that GTregs are depleted in PMO and are functionally critical in maintaining bone homeostasis. GTregs significantly promoted osteoblast differentiation while suppressing osteoclastogenesis in a ratio-dependent manner. SCFAs deficiency under PMO conditions disrupts the balance of tTregs and pTregs. Interestingly, within pTregs, the population of RORγT$^-$ pTregs and RORγT$^+$ pTregs is further altered, along with simultaneous expansion of Th17 cells-likely through the conversion of RORγT$^-$ pTregs into Th17 cells. Notably, probiotic supplementation restores the homeostasis of RORγT$^-$ pTregs and Th17 cells in a butyrate-mediated manner. Moreover, it was observed that butyrate-primed RORγT$^-$ pTregs have reduced osteoclastogenic potential. Collectively, our findings for the first time reveal the pivotal role of gut resident RORγT$^-$ pTregs-Th17 cell axis in the pathophysiology of PMO. Notably, GTreg dysregulation was also evident in osteopenic and osteoporotic patients, underscoring their clinical relevance as regulators of bone integrity.
Conclusion: These findings establish GTregs, especially RORγT$^-$ pTregs, as central modulators of bone-immune homeostasis in PMO. The SCFA-dependent restoration of GTreg composition by targeted probiotics

highlights a promising immunomoporotic approach to mitigate inflammatory bone loss and offers translational potential for future therapeutics.

P1409

LATE-DIAGNOSED JUVENILE IDIOPATHIC ARTHRITIS OF THE HIP PRESENTING AS COXA MAGNA AND LIMB-LENGTH DISCREPANCY

R. M. Runcheva[1], M. B. Markoski[2]

[1]Private orthopedic practice Ortomedik Dr. Mirjana Runcheva, Shtip, North Macedonia; [2]Private orthopedic practice Ortomed, Kumanovo, Kumanovo, North Macedonia

Objective

To present a rare case of late-diagnosed juvenile idiopathic arthritis (JIA) of the hip leading to severe structural deformity, limb-length discrepancy and the need for surgical treatment.

Methods (Case presentation)

A 16-year-old male presented with a two-year history of progressive right hip pain, limp, and limitation of motion, without previous trauma. Initial evaluation elsewhere raised suspicion of osteoid osteoma. Pelvic MRI demonstrated marked synovial hypertrophy, joint effusion, cartilage loss, and secondary degenerative changes of the right hip.

Open biopsy revealed chronic synovitis. Laboratory testing showed elevated C-reactive protein (21.2 mg/L) with negative rheumatoid factor and antinuclear antibodies. Based on clinical, radiological and histological findings, a diagnosis of juvenile idiopathic arthritis with isolated hip involvement was made.

Because symptoms started during skeletal growth, progressive deformity developed, including coxa magna, femoral neck widening, limb-length discrepancy of approximately 2 cm, and significant atrophy of the pelvitrochanteric and thigh muscles.

Results

The patient was treated with systemic corticosteroids and sulfasalazine, resulting in partial inflammatory control (CRP decreased to 8.45 mg/L), but persistent pain, stiffness, and progressive deformity remained. Due to ongoing symptoms and structural deterioration, surgical treatment was indicated. The patient underwent open hip synovectomy combined with soft-tissue release.

Despite medical therapy, the disease progressed, confirming that delayed diagnosis of JIA affecting the hip can lead to irreversible joint destruction and major functional impairment.

Conclusion
Hip involvement in juvenile idiopathic arthritis is a major predictor of poor functional outcome. Late diagnosis during growth may result in coxa magna, limb-length discrepancy, muscle atrophy, and early joint destruction. Early recognition and aggressive medical treatment are essential to prevent irreversible damage. Synovectomy and soft-tissue release may be beneficial in early stages, whereas advanced disease often requires reconstructive surgery or total hip arthroplasty.

P1410

THE USE OF P1NP IN A NON-TERTIARY CENTRE

R. Mcvittie[1], C. Rosa[1], R. D'Silva[1], B. Bharj[1], K. Chaudhuri[1]

[1]University Hospitals Coventry and Warwickshire, Coventry, United Kingdom

Objectives
Procollagen type 1 N-terminal propeptide (P1NP) is increasingly used in osteoporosis management, with suppression indicating effective antiresorptive therapy and elevation representing successful anabolic therapy or inadequate antiresorptive effect. No formal guidelines exist for its use in clinical practice. Our objective was to evaluate P1NP utilisation and its impact on management in a non-tertiary rheumatology centre.

Methods
P1NP requests between March 2025 - August 2025 were extracted and case notes reviewed. Historic P1NP results were included when found. Data collected included indication, frequency of repeat testing and resulting change in management. If reasoning was not explicitly stated but could be inferred from treatment, this was recorded. Dual-energy X-ray absorptiometry (DEXA) results were reviewed when available.

Results
138 patients had P1NP measured in the study period. 9 cases were excluded due to absent documentation.
Indications are summarised in table 1:

Reasoning	Numbers
Drug Holiday	72
Baseline (no specific reasoning, done at initial assessment)	17
Justify switch to parenteral or anabolic	9
Baseline (specific reasoning, e.g. fractures with normal BMD)	8
Assess drug response (no specific indication)	6
Denosumab cessation	5
Metabolic bone MDT advice	5
Pre-anabolic	4
Treatment restart after complication (ONJ/ AFF)	3

Other findings of note included repeat tests during drug holidays. In some cases 35 µg/L was noted to rise as early as six months after treatment cessation. In most cases, P1NP trends were concordant with DEXA findings. Where results were discordant, clinicians favoured DEXA results.
Baseline P1NP testing changed management only when performed for a specific indication, indiscriminate baseline testing did not alter treatment decisions.
P1NP measurement to assess therapy response did not result in treatment changes.

Conclusions
These results support targeted use of P1NP to guide drug holidays, parenteral/anabolic escalation, denosumab cessation and selected baseline assessments. Routine baseline testing did not provide clinical benefit, but conclusions are possibly limited by the short study duration. Similarly, using P1NP to assess treatment response in the absence of clinical change or planned treatment change did not influence management.

P1411

MALE PATIENT WITH PSORIATIC ARTHROPATHY AND OSTEOPOROSIS

R. Mihut[1], S. Deac[1], G. Gherle[1], D. Pop[2], M. Cevei[1], C. Cseppento Nistor[1], F. Andronie Cioara[1]

[1]University of Oradea, Faculty of Medicine and Pharmacy, Oradea, Romania; [2]University of Oradea, Faculty of Informatics and Sciences, Department of Biology, Oradea, Romania

Osteoporosis is a systemic skeletal disorder characterized by reduced bone mineral density and an increased risk of fractures, resulting from an imbalance between bone formation and bone resorption. In inflammatory rheumatic diseases, chronic inflammation and glucocorticoid therapy promote bone loss, contributing to the development of secondary osteoporosis and to the worsening of functional disability.
A 67-year-old male patient, with a medical history significant for renal tuberculosis (1998), psoriatic polyarthritis (2024), hyperuricemia (2024), chronic kidney disease (2024), and mixed peripheral neuropathy (2024), presented with mechanical pain in the left ankle, cramp-like pain in the left calf and low back pain.
Clinical musculoskeletal examination revealed lumbar spine involvement with bilateral paravertebral muscle contracture, decreased lumbar mobility (finger-to-shin distance of ½ calf), and painful limitation of extension and lateral flexion.
Fall risk assessment using the Johns Hopkins Health System Corporation Fall Risk Assessment Tool yielded a score of 17 points, indicating a high risk of falls.
Dual-energy X-ray absorptiometry (DXA) performed during hospitalization revealed the following values: right femoral neck – T-score −1.4 (−22%), Z-score −0.9 (−15%); lumbar spine – T-score −2.8 (−35%), Z-score −2.1 (−27%). These findings are consistent with a diagnosis of osteoporosis.
Anti-osteoporotic pharmacological treatment and a daily individualized physical therapy program were recommended.
Secondary osteoporosis associated with inflammatory rheumatic diseases represents a clinically significant issue in rehabilitation medicine, requiring an integrated approach focused on optimal control of inflammation, as well as prevention and treatment of bone loss, in order to reduce fracture risk and improve long-term functional outcomes.

SEVERE NUTRITIONAL POLYNEUROPATHY WITH FLACCID TETRAPARESIS FOLLOWING BARIATRIC SURGERY: A CASE REPORT

I. Ghiorghiu[1], D. Avramescu[1], R. Nartea[1,2], L. Meiu[1], G. Gheorghievici[1], M. Pentiuc[1]

[1]National Institute of Recovery, Physical Medicine and Balneoclimatology, Bucharest, Romania; [2]Carol Davila University of Medicine and Pharmacy, Bucharest, Romania

Background:
Bariatric surgery is an effective treatment for morbid obesity, but it may be complicated by nutritional, metabolic, and neurological disorders. [1,2] Neurological complications occur in up to 16% of patients, most commonly as peripheral neuropathies related to malabsorption, persistent vomiting, and rapid weight loss. [3,4] Severe flaccid tetraparesis remains a rare but disabling manifestation.[4]

Case Presentation:
We report the case of a 42-year-old woman with class III obesity (BMI 41 kg/m²) who underwent laparoscopic sleeve gastrectomy in January 2023, followed by two reinterventions, including gastro-jejunal anastomosis, due to persistent vomiting and feeding intolerance. During the third intervention, she developed acute flaccid tetraparesis with progressive sensorimotor deficits, predominantly affecting the left hemibody. By December 2023, she presented with cachexia, recurrent hematemesis, and severe malnutrition (BMI 16.1 kg/m²), secondary to a giant ischemic gastric ulcer with mediogastric stenosis. Neurological examination revealed areflexic flaccid tetraparesis, marked sensory loss, gait impairment, and mild cognitive decline. Laboratory investigations showed normocytic anemia, hypoproteinemia, hypoalbuminemia, vitamin D deficiency, and persistent hypocalcemia, with normal vitamin B12 levels.

Management:
A multidisciplinary rehabilitation program was initiated, combining nutritional and metabolic stabilization, pharmacological therapy, intensive physical and occupational rehabilitation, orthotic support, and psychological counselling. Differential diagnoses, including Guillain–Barré syndrome, multiple sclerosis, diabetic and toxic neuropathies, were excluded, supporting the diagnosis of nutritional axonal sensorimotor polyneuropathy secondary to bariatric surgery complications.

Outcomes:
During hospitalization, gradual motor and functional improvement was observed, with partial recovery of ambulation and activities of daily living, though residual left lower limb deficits persisted.

Conclusions:
This case highlights a rare but severe neurological complication of bariatric surgery and underscores the importance of early recognition, nutritional surveillance, and interdisciplinary rehabilitation to optimize functional outcomes and prevent irreversible disability.

ROSAH SYNDROME DUE TO A RARE P.TYR254CYS VARIANT IN THE ALPK1 GENE: ATYPICAL PRESENTATION WITH EROSIVE ARTHRITIS AND UVEITIS IN THE ABSENCE OF SPLENOMEGALY

R. O. Mnevets[1], K. Ostrovskyy[2], I. Ostrovska[3]

[1]Educational and Scientific Center "Institute of Biology and Medicine", Taras Shevchenko National University of Kyiv. State Institution "Ukrainian Center of Maternity and Childhood of the National Academy of Medical Sciences of Ukraine", Kyiv, Ukraine; [2]Pharmaceutical Product Development, Warsaw, Poland; [3]Dept. of Therapy, Shevchenkivskyi District Outpatient Dept. #2, Kyiv, Ukraine

Objective: ROSAH syndrome (Retinal dystrophy, Optic nerve edema, Splenomegaly, Anhidrosis, Headache) is an autosomal dominant autoinflammatory disorder caused by heterozygous pathogenic variants in the *ALPK1* gene. Typical manifestations include ocular involvement (retinal dystrophy, optic disc edema), splenomegaly, anhidrosis, and headache. However, the phenotypic spectrum may be broader, encompassing arthritis, fever, and elevated acute-phase reactants. The p.Thr237Met variant is the most frequently reported. We present a case with the rare p.Tyr254Cys variant and an atypical phenotype.
Material and Methods: A male patient was observed from birth due to congenital ichthyosis and cheek erythema. At 4 months of age, painless swelling of the wrist and knee joints was noted. By 1 year of age, flexion contractures of the fingers, multiple caries, recurrent fever episodes, and anhidrosis had developed. At 3 years, he was hospitalized at a pediatric rheumatology department for evaluation. The workup included: clinical examination, radiography and MRI of the joints, laboratory tests (rheumatoid factor, anti-CCP, ANA, HLA-B27, CRP), and ophthalmological examination. Whole-exome sequencing was performed, with Sanger sequencing confirmation.
Results: Examination at age 3 revealed severe deformities and limited range of motion in the wrist joints (swan-neck deformity). Chronic erosive arthritis of the hand and foot joints was verified instrumentally. Rheumatic serology was negative, and CRP was normal. Ophthalmological examination diagnosed acute bilateral anterior uveitis. Splenomegaly and cytopenia were absent. Based on the atypical course (early onset, erosive arthritis without pain or systemic inflammation, ichthyosis, anhidrosis), a monogenic disorder was suspected. Genetic analysis identified a heterozygous c.761A>G (p.Tyr254Cys) mutation in the *ALPK1* gene. The mutation was not found in the parents (de novo). The diagnosis of ROSAH syndrome was established despite the absence of key features (splenomegaly, cytopenia). Due to active polyarthritis, therapy with the JAK inhibitor tofacitinib (0.2 mg/kg/day) was initiated. Uveitis was controlled with topical corticosteroids, which were subsequently discontinued. After 6 months of tofacitinib therapy, positive dynamics were observed: no uveitis flares, reduced arthritis activity, and slowed progression of joint deformities.
Conclusions: This case expands the phenotypic spectrum of ROSAH syndrome, demonstrating a presentation with isolated arthritis mimicking JIA and uveitis, lacking classical signs (splenomegaly, cytopenia). The presence of congenital ichthyosis and anhidrosis should raise suspicion for autoinflammatory syndromes. The use of tofacitinib showed preliminary efficacy in controlling articular and ocular manifestations, warranting further investigation in larger studies. ROSAH syndrome should be included in the differential diagnosis of atypical juvenile arthritis, especially when combined with skin and eye involvement.

P1414

FEATURES OF THE HYPOTHALAMIC-PITUITARY-GONADAL AXIS IN WOMEN OF REPRODUCTIVE AGE WITH SYSTEMIC LUPUS ERYTHEMATOSUS AT EARLY AND ADVANCED DISEASE STAGES

R. O. Mnevets[1]

[1]Educational and Scientific Center "Institute of Biology and Medicine", Taras Shevchenko National University of Kyiv. State Institution "Ukrainian Center of Maternity and Childhood of the National Academy of Medical Sciences of Ukraine", Kyiv, Ukraine

Objective: Systemic lupus erythematosus (SLE) exhibits a marked sexual dimorphism, with a predominance of incidence among women of reproductive age, indicating a significant role of sex hormones in its pathogenesis. According to current data, estrogens and prolactin can modulate the immune response, potentiating humoral reactions and the survival of autoreactive lymphocytes, while androgens often possess immunosuppressive properties. Investigating the state of the hypothalamic-pituitary-gonadal (HPG) axis at different stages of SLE remains relevant for understanding the mechanisms of disease onset and progression, as well as for developing personalized therapeutic strategies.
Material and Methods: The study included 64 women of reproductive age diagnosed with SLE according to the SLICC 2012 classification criteria. Patients were divided into two groups: Group 1 (n=32) – with early-stage SLE (disease duration ≤ 6 months, no prior glucocorticoid or cytostatic therapy); Group 2 (n=32) – with advanced-stage SLE (disease duration ≥ 2 years, receiving standard immunosuppressive therapy). The control group consisted of 24 healthy women of comparable age. Disease activity was assessed using the SLEDAI-2K index. On days 5–8 of the menstrual cycle, serum levels of luteinizing hormone (LH), follicle-stimulating hormone (FSH), prolactin, estradiol, and total testosterone were determined by enzyme-linked immunosorbent assay. Statistical analysis was performed using Student's t-test and Pearson's correlation analysis (data presented as M ± SD, $p < 0.05$ considered significant).
Results:

Hormonal Status: Patients in Group 1 showed a significant increase in estradiol (119.95 ± 48.80 pg/ml vs. 55.43 ± 13.16 pg/ml in controls, $p<0.001$) and prolactin levels (32.28 ± 21.7 ng/ml vs. 16.20 ± 8.58 ng/ml, $p<0.05$). Testosterone concentration was decreased (0.38 ± 0.09 ng/ml vs. 0.58 ± 0.12 ng/ml, $p<0.05$). In Group 2, levels of estradiol (70.19 ± 31.61 pg/ml) and prolactin (22.20 ± 8.24 ng/ml) remained above control values but were lower than in Group 1. Hypoandrogenemia persisted (0.42 ± 0.11 ng/ml, $p<0.05$). LH and FSH levels did not differ significantly from controls.

Clinical Correlations: A direct correlation was found between disease activity (SLEDAI-2K) and levels of prolactin ($r=0.52$, $p<0.05$) and estradiol ($r=0.47$, $p<0.05$) in Group 1.
Conclusions: Women with SLE at the early disease stage exhibit a pronounced HPG axis imbalance characterized by hyperestrogenemia, hyperprolactinemia, and relative hypoandrogenemia. These changes are most significant at disease onset and are associated with its activity. The

obtained results support the hypothesis of neuroendocrine mechanisms' involvement in SLE immunopathogenesis and justify the feasibility of assessing the hormonal profile as a potential marker of disease activity and prognosis.

P1415

COMPARATIVE ANALYSIS OF CLINICAL AND LABORATORY PROFILES IN WOMEN WITH EARLY AND ESTABLISHED SYSTEMIC LUPUS ERYTHEMATOSUS

R. O. Mnevets[1]

[1]Educational and Scientific Center "Institute of Biology and Medicine", Taras Shevchenko National University of Kyiv. State Institution "Ukrainian Center of Maternity and Childhood of the National Academy of Medical Sciences of Ukraine", Kyiv, Ukraine

Objective: To conduct a comparative analysis of the spectrum and severity of clinical symptoms and laboratory markers in women with early and established stages of SLE.
Material and Methods: A single-center cross-sectional study included 64 women of reproductive age with SLE (mean age 27.1 ± 8.6 years). The diagnosis was verified according to the 1997 ACR criteria. Patients were divided into 2 groups: Group 1 (n=32) – early stage (disease duration < 6 months, no prior immunosuppressive/glucocorticoid therapy); Group 2 (n=32) – established stage (disease duration ≥ 2 years, receiving standard therapy). Disease activity was assessed using the SLEDAI-2K index. A comprehensive laboratory workup was performed: complete blood count, ESR, CRP, creatinine, total protein, and enzyme-linked immunosorbent assay for antinuclear antibodies (ANA), anti-double-stranded DNA (anti-dsDNA), and anti-Sm antibodies. Statistical analysis employed the Mann-Whitney U test and the χ^2 test.
Results: Patients with early-stage SLE had significantly higher disease activity by SLEDAI-2K (14.5 ± 4.2 vs. 6.8 ± 3.1 in Group 2; p<0.001). This group also showed a significantly higher frequency of fever (69% vs. 28%; p<0.01), lymphadenopathy (53% vs. 16%; p<0.01), and markedly elevated ESR (39.2 ± 11.5 mm/h vs. 24.1 ± 10.8 mm/h; p<0.05). The frequency of arthralgia (75% vs. 58%) and skin manifestations (76% vs. 53%) was higher in Group 1, but the differences did not reach statistical significance (p>0.05). Mild anemia was noted in both groups without a significant difference (hemoglobin 109.4 ± 12.7 g/L vs. 114.2 ± 11.9 g/L; p>0.05). The immunological profile was characterized by a high frequency of ANA (>90% in both groups), anti-dsDNA (74% vs. 71%), and anti-Sm antibodies (42% vs. 38%) with no intergroup differences (p>0.05), indicating their stable diagnostic value regardless of disease stage or therapy.
Conclusions: 1. The early stage of SLE in women is characterized by higher immunoinflammatory activity, manifested by a significantly higher frequency of constitutional symptoms (fever, lymphadenopathy) and an acute-phase laboratory response (ESR). 2. The frequency of specific immunological markers (ANA, anti-dsDNA, anti-Sm) is independent of disease stage, confirming their fundamental role in diagnosis. 3. The obtained data emphasize that the diagnostic algorithm for suspected SLE should be uniform and include comprehensive immunological screening even at early stages, while the reduction of general symptoms under therapy with persistent serological abnormalities requires constant monitoring.

P1416

PATIENT INVOLVEMENT IN DISEASE MANAGEMENT AS A FACTOR IN TREATMENT EFFICACY FOR KNEE OSTEOARTHRITIS

R. O. Mnevets[1], K. Ostrovskyy[2], I. Ostrovska[3]

[1]Educational and Scientific Center "Institute of Biology and Medicine", Taras Shevchenko National University of Kyiv. State Institution "Ukrainian Center of Maternity and Childhood of the National Academy of Medical Sciences of Ukraine", Kyiv, Ukraine; [2]Pharmaceutical Product Development, Warsaw, Poland; [3]Dept. of Therapy, Shevchenkivskyi District Outpatient Dept. #2, Kyiv, Ukraine

Objectives: Osteoarthritis (OA) is a prevalent chronic degenerative joint disease leading to pain, functional impairment, and reduced quality of life. Current guidelines emphasize the importance of a comprehensive approach, where the patient's active role (disease self-management) is considered a key component alongside pharmacotherapy. The study aimed to evaluate the impact of a structured patient involvement program in OA management on pain dynamics.
Material and Methods: The study included 44 patients (24 women, 20 men) with radiographically confirmed knee OA (Kellgren-Lawrence grade II) and obesity (BMI 32±3). All patients received standard therapy with diacerein for 30 days. Patients were divided into two groups. The intervention group (n=22) participated in a structured disease management program alongside medication. This program included an educational module on OA pathogenesis and treatment mechanisms, training in medication self-monitoring, dietary counseling for weight control, and a course of supervised physical exercises in the rehabilitation department. The control group (n=22) received only pharmacological treatment. Pain intensity was assessed using a Visual Analogue Scale (VAS, 0-3 points) at baseline and after 30 days. Statistical analysis was performed using Student's t-test in Statistica 11.0; differences were considered significant at p<0.05.
Results: Before treatment, the mean pain VAS scores showed no significant difference between groups (2.89±0.12). After 30 days, a significant reduction in pain intensity to 1.36±0.04 was recorded in the intervention group (p<0.05). A positive trend was also observed in the control group (2.18±0.09), but it did not reach statistical significance (p>0.05). The intergroup difference after treatment was significant (p<0.05).
Conclusions: The obtained data demonstrate that integrating a structured patient involvement program for osteoarthritis management - based on education, lifestyle modification, and physical rehabilitation - combined with standard pharmacotherapy (diacerein) leads to a statistically significant and clinically more pronounced reduction in pain compared to isolated drug therapy. This supports the feasibility of implementing disease self-management strategies into the clinical practice of managing OA patients.

P1417

THE INFLUENCE OF AGE AT DISEASE ONSET ON THE EFFICACY OF ANTI-B-CELL THERAPY IN SYSTEMIC SCLEROSIS: A PROSPECTIVE COHORT STUDY

R. O. Mnevets[1], K. Ostrovskyy[2], I. Ostrovska[3]

[1]Educational and Scientific Center "Institute of Biology and Medicine", Taras Shevchenko National University of Kyiv. State Institution "Ukrainian Center of Maternity and Childhood of the National Academy of Medical Sciences of Ukraine", Kyiv, Ukraine; [2]Pharmaceutical Product Development, Warsaw, Poland; [3]Dept. of Therapy, Shevchenkivskyi District Outpatient Dept. #2, Kyiv, Ukraine

Objectives: Late-onset systemic sclerosis (SSc) is often associated with a more severe disease course and poorer prognosis. The impact of age at onset on therapeutic response, particularly to B-cell depletion therapy with rituximab (RTX), remains underexplored. We aimed to assess the dynamics of skin fibrosis, measured by the modified Rodnan Skin Score (mRSS), in response to RTX in SSc patients stratified by age at disease onset.

Material and Methods: In this prospective cohort study, 151 patients with a confirmed SSc diagnosis (according to ACR/EULAR 2013 criteria) were included. Patients were stratified into three groups based on age at onset: Group 1 - <30 years (n=40, 26%), Group 2 - 31-59 years (n=90, 60%), and Group 3 - ≥60 years (n=21, 14%). The mean follow-up period was 13±2.3 months. All patients received RTX (cumulative dose 1.5±0.6 g) along with stable low-dose glucocorticoids (prednisone 11.6±4.8 mg/day); 48% received concomitant immunosuppressants without dose changes during the observation period. Disease activity was assessed using the European Scleroderma Study Group Activity Index (EScSG-AI). Skin involvement was evaluated by mRSS at baseline and follow-up. Statistical analysis employed the Wilcoxon signed-rank test for intra-group dynamics and ANOVA/Kruskal-Wallis test for inter-group comparisons.

Results: The mean patient age was 48±13 years, 83% were female. Diffuse cutaneous SSc was present in 52%. Baseline mRSS and disease activity were significantly higher in Group 3 (p<0.001). A significant reduction in mRSS was observed in all groups: Group 1 – from 10.2±8.0 to 7.7±6.5 (p=0.01); Group 2 – from 9.0±7.2 to 6.2±4.7 (p=0.0001); Group 3 – from 20.5±14.1 to 10.8±9.4 (p=0.001). The absolute reduction in mRSS was greatest in Group 3 (-9.7±5.8 points vs. -2.8±3.2 in G1 and -2.8±4.1 in G2, p<0.01), while the relative reduction was comparable (≈47% in all groups, p=0.85). The EScSG-AI also decreased significantly in all groups (p<0.01 for each), with the most pronounced drop in Group 3 (from 4.2±2.1 to 1.3±1.0).

Conclusions: Anti-B-cell therapy with rituximab led to a significant improvement in skin fibrosis and overall disease activity in systemic sclerosis patients regardless of age at onset. Notably, patients with late-onset disease (≥60 years), despite having more severe skin involvement initially, demonstrated a comparable or even greater absolute response to therapy. Therefore, older age at SSc onset should not be considered a limiting factor for prescribing rituximab.

P1418

EFFICACY OF RITUXIMAB IN SYSTEMIC SCLEROSIS PATIENTS: A COMPARATIVE ANALYSIS BASED ON THE PRESENCE OF ASSOCIATED MYOPATHY

R. O. Mnevets[1], K. Ostrovskyy[2], I. Ostrovska[3]

[1]Educational and Scientific Center "Institute of Biology and Medicine", Taras Shevchenko National University of Kyiv. State Institution "Ukrainian Center of Maternity and Childhood of the National Academy of Medical Sciences of Ukraine", Kyiv, Ukraine; [2]Pharmaceutical Product Development, Warsaw, Poland; [3]Dept. of Therapy, Shevchenkivskyi District Outpatient Dept. #2, Kyiv, Ukraine

Objectives: Systemic sclerosis (SSc) is a multysystem disorder where skeletal muscle involvement (scleroderma myopathy) is a poor prognostic marker, associated with more severe disease and significant visceral organ involvement, particularly interstitial lung disease (ILD) and cardiomyopathy. Rituximab (RTX) has shown efficacy in SSc-associated ILD and skin disease, yet data on its effect on the myopathic component are limited.

Material and Methods: A prospective single-center observational study included 151 patients with confirmed SSc (mean age 48±13 years, 83% female). Myopathy was diagnosed based on the presence of proximal muscle weakness (≥3 on the MRC scale) combined with pathological needle electromyography findings and/or elevated creatine phosphokinase (CPK) levels. Patients were divided into two groups: Group 1 (n=22) with myopathy and Group 2 (n=129) without myopathy. All patients received RTX therapy (mean cumulative dose 1.5±0.6 g) in addition to standard care. Assessments were performed at baseline and after 13±2.3 months and included the modified Rodnan skin score (mRSS), pulmonary function tests (FVC and DLCO, % predicted), CRP, CPK levels, and the European Scleroderma Study Group (EScSG) activity index. Statistical analysis employed the Mann-Whitney U test, Wilcoxon signed-rank test, and Spearman's correlation.

Results: Myopathy was detected in 15% of patients. Group 1 patients had a significantly shorter disease duration (3.8 [1.5; 6.0] vs. 6.0 [2.0; 10.0] years, p=0.003), higher mRSS (12.0 [6.0; 18.0] vs. 8.0 [4.0; 14.0], p=0.004), higher EScSG activity index (3.9±1.7 vs. 3.1±1.8, p=0.03), and elevated CRP (9.3 [3.8; 20.6] vs. 5.2 [1.7; 11.5] mg/L, p=0.04) and CPK levels (458 [240; 639] vs. 243 [225; 261] U/L, p<0.001). Baseline FVC did not differ, but DLCO was higher in Group 1 (55.7±16.4% vs. 46.1±20.1%, p=0.0001). Following RTX therapy, Group 1 demonstrated significantly greater improvement: increase in FVC (+4.3% [0.1; 12.2] vs. +2.4% [-1.8; 9.4], p=0.04), decrease in CRP (-3.8 [0.1; 8.9] vs. -0.9 [-1.0; 4.2] mg/L, p=0.01) and activity index (-2.2±1.6 vs. -1.6±1.5 points, p=0.02), as well as a more pronounced reduction in prednisone dose. A strong negative correlation was found between baseline muscle weakness and change in DLCO (r=-0.656; p=0.002).

Discussion: Our data confirm that myopathy in SSc is a marker of more active and aggressive disease. The more pronounced response to RTX in patients with myopathy, particularly regarding lung function and inflammatory markers, may be related to its effect on a common immunopathological mechanism underlying both myopathy and ILD progression. The identified correlation suggests that assessment of the muscular component may be relevant for predicting pulmonary response to therapy. A limitation of the study is the relatively short follow-up period.

Conclusions: SSc-associated myopathy (15% in our cohort) is

characterized by higher overall inflammatory and skin activity. Patients with myopathy demonstrate a significantly better response to rituximab therapy across multiple parameters (FVC, inflammatory markers, disease activity) compared to patients without myopathy. The presence of myopathy may serve as a predictor of a more pronounced positive effect of rituximab on lung function, warranting further investigation in randomized controlled trials.

P1419

CLINICAL AND GENETIC PREDICTORS OF TREATMENT FAILURE IN PATIENTS WITH RHEUMATOID ARTHRITIS

R. O. Mnevets[1]

[1]Educational and Scientific Center "Institute of Biology and Medicine", Taras Shevchenko National University of Kyiv. State Institution "Ukrainian Center of Maternity and Childhood of the National Academy of Medical Sciences of Ukraine", Kyiv, Ukraine

Objective: Despite advances in therapy with biologic (bDMARDs) and targeted synthetic disease-modifying antirheumatic drugs (tsDMARDs), a significant proportion of patients with rheumatoid arthritis (RA) do not achieve low disease activity or remission. Primary and secondary treatment failures necessitate switching between these agents. However, reliable predictors of response to a subsequent line of targeted therapy remain largely unidentified, leading to a "trial-and-error" approach.
Material and Methods: The study included 174 patients (86.6% female, mean age 46.9±13.9 years) with established RA and moderate/high disease activity (DAS28-CRP 5.4±0.9) despite current bDMARD/tsDMARD therapy. All patients were switched to a drug with a different mechanism of action: TNF inhibitors (17.8%), IL-6 inhibitors (25%), rituximab (45.6%), abatacept (1.1%), JAK inhibitors (10.6%). Clinical response was assessed after 6 months using DAS28-CRP. Responders (n=75) were defined as achieving remission or low disease activity (DAS28-CRP ≤3.2), while non-responders (n=71) did not. Thirty-four patients discontinued the study. For the 146 patients who completed the 6-month follow-up, genotyping of 10 single nucleotide polymorphisms (SNPs) was performed using real-time PCR: IL6 (rs1800795), IL6R (rs2228145), TNFAIP3 (rs10499194, rs6920220), TNFα (rs1800629), CTLA4 (rs231775), TNFSF13B (BAFF) (rs9514828), KCNS1 (rs734784), IL10 (rs1800872), STAT4 (rs7574865). SNP selection was based on prior evidence of association with RA pathogenesis or treatment response. Hardy-Weinberg equilibrium was assessed. Baseline clinical, immunological, and genetic parameters were compared between groups using comparative, correlational, and binary logistic regression analysis (intention-to-treat principle applied).
Results: Multivariate logistic regression identified independent predictors of treatment failure after switching.
Factors increasing the risk of failure:
* Overweight/obesity (BMI ≥25 kg/m²): OR=2.4, 95% CI 1.0–5.7, p=0.048.
* Higher baseline pain VAS (per 1 mm increase): OR=1.04, 95% CI 1.00–1.08, p=0.042.
* Higher tender joint count (per joint): OR=1.12, 95% CI 1.04–1.21, p=0.004.
* Higher PainDetect questionnaire score (neuropathic pain component): OR=1.07, 95% CI 1.01–1.13, p=0.032.
* Concomitant glucocorticoid use at baseline: OR=2.75, 95% CI 1.20–6.30, p=0.017.
* IL10 rs1800872 AA genotype: OR=12.81, 95% CI 1.25–131.73, p=0.031.
Factors associated with a lower risk of failure (protective):
* Seropositivity for rheumatoid factor: OR=0.33, 95% CI 0.11–0.96, p=0.043.
* Presence of rheumatoid nodules: OR=0.34, 95% CI 0.12–0.94, p=0.038.
* TNFSF13B (BAFF) rs9514828 T allele: OR=0.27, 95% CI 0.11–0.67, p=0.005.
* KCNS1 rs734784 G allele: OR=0.41, 95% CI 0.17–0.97, p=0.044.
Conclusions: This study reveals that the likelihood of a second-line bDMARD/tsDMARD failure is influenced by a combination of heterogeneous factors. Alongside known clinical factors (BMI, GC use, pain severity), the presence of a neuropathic pain component and specific genetic polymorphisms (IL10, BAFF, KCNS1) are significant independent predictors. The strong protective association of seropositivity and rheumatoid nodules warrants further investigation. These findings highlight the potential for developing a predictive model to guide personalized treatment selection after an initial targeted therapy failure in RA.

P1420

THE EFFECT OF TOCILIZUMAB ON CARDIOVASCULAR PARAMETERS IN SYSTEMIC SCLEROSIS PATIENTS WITH DIFFERENT DISEASE COURSE VARIANTS

R. O. Mnevets[1], K. Ostrovskyy[2], I. Ostrovska[3]

[1]Educational and Scientific Center "Institute of Biology and Medicine", Taras Shevchenko National University of Kyiv. State Institution "Ukrainian Center of Maternity and Childhood of the National Academy of Medical Sciences of Ukraine", Kyiv, Ukraine; [2]Pharmaceutical Product Development, Warsaw, Poland; [3]Dept. of Therapy, Shevchenkivskyi District Outpatient Dept. #2, Kyiv, Ukraine

Objectives: To study the impact of the inhibition of the IL-6 signaling pathway with the monoclonal antibody tocilizumab on the cardiovascular profile in SSc patients, with the effect potentially varying depending on disease activity (course variant).
Material and Methods: A prospective observational study included 79 SSc patients (mean age 38.5±7.8 years, 92.4% female, disease duration 6.2±3.8 years). All patients, alongside standard therapy, received tocilizumab (8 mg/kg IV every 4 weeks) based on indications (active disease refractory to standard treatment). A comprehensive assessment was performed at baseline and after 6 months: disease activity index (EDAI), levels of C-reactive protein (CRP) and IL-6, echocardiography (EchoCG) with assessment of systolic (left ventricular ejection fraction – LVEF) and diastolic (E/A, e') function, end-systolic and end-diastolic volumes (ESV, EDV), left ventricular mass (LVM), as well as 24-hour ECG and BP monitoring. Statistical analysis used the paired Student's t-test and χ^2 test; data are presented as M±SD; differences were considered significant at $p<0.05$.
Results: After 6 months of therapy, a significant reduction in SSc activity (EDAI) and inflammatory markers was observed: CRP in 60 patients (75.9%, $p<0.01$), IL-6 in 57 (72.2%, $p<0.01$). BP stabilization was achieved in 55 patients (69.6%). EchoCG in the total group showed: a significant 8.3% decrease in LV ESV (from 72.4±5.1 ml to 66.4±4.7 ml; $p<0.05$) and a 6.5% decrease in LV EDV (from 138.7±7.2 ml to 129.7±6.8 ml; $p<0.05$). The increase in LVM in the tocilizumab group was only 3.2% (from 143.5±10.4 g to 148.0±9.7 g), which was significantly less than in a historical control group (standard therapy, +9.7%; $p<0.05$). LVEF significantly increased by 6.0% (from 51.5±4.2% to 54.6±3.8%; $p<0.01$). Positive dynamics on Holter monitoring (reduction in ventricular extrasystoles and episodes

of silent ischemia) were registered in 46 patients (58.2%). The most pronounced comprehensive clinical and instrumental response was noted in the subacute course group: improvement was recorded in 24 of 28 patients (85.7%).
Conclusions: The addition of tocilizumab to standard SSc therapy is associated with reduced inflammatory activity, positive cardiac remodeling (decreased LV volumes, slowed progression of myocardial hypertrophy), and improved systolic function. Positive dynamics regarding BP stabilization and reduced arrhythmia frequency were observed. The greatest therapeutic efficacy was demonstrated in patients with the subacute variant of SSc, likely due to a more pronounced inflammatory component in the pathogenesis at this stage.

P1421

PREVALENCE OF FIBROMYALGIA IN PATIENTS WITH PSORIATIC ARTHRITIS AND ITS IMPACT ON DISEASE ACTIVITY AND PATIENT-REPORTED OUTCOMES

R. O. Mnevets[1]

[1]Educational and Scientific Center "Institute of Biology and Medicine", Taras Shevchenko National University of Kyiv. State Institution "Ukrainian Center of Maternity and Childhood of the National Academy of Medical Sciences of Ukraine", Kyiv, Ukraine

Objectives: The prevalence of fibromyalgia (FM) in psoriatic arthritis (PsA) cohorts, according to contemporary research, ranges from 17.2% to 53.3%, significantly exceeding population levels. The presence of FM in PsA patients is associated with a more severe subjective disease burden, which can complicate the assessment of objective inflammatory activity. Established risk factors for developing or exacerbating FM symptoms in these patients include female sex, older age, high PsA activity, presence of enthesitis, as well as comorbid anxiety disorders and impaired quality of life (QoL). Importantly, a substantial proportion of patients with PsA and FM (reported up to 28.5%) show a lower response to standard therapy, necessitating special consideration in treatment strategy.
Material and Methods: A single-center cross-sectional study included 114 consecutive patients with a verified PsA diagnosis according to the CASPAR criteria (2006). The cohort comprised 58 male (50.9%) and 56 female (49.1%). PsA activity was evaluated using DAPSA, ASDAS-CRP, and BASDAI indices, while functional capacity was assessed using the BASFI index. Patient-reported outcomes (PROs) were collected using the Visual Analogue Scale (VAS) for pain, VAS for disease activity, PsAID-12, FACIT-F (fatigue), and HADS (anxiety and depression) questionnaires. FM was screened using the validated Fibromyalgia Rapid Screening Tool (FiRST). Patients providing 5 or 6 positive answers on FiRST were allocated to the PsA+FM group (n=19, 16.7%), others to the PsA without FM group (n=95, 83.3%). The groups were comparable in age (median 46 [38;55] years) and PsA duration (median 36 [12;96] months). Statistical analysis utilized the χ^2 test for qualitative variables and the Mann-Whitney U test for quantitative variables, presented as median with interquartile range [Q25; Q75] or mean ± standard deviation (M±SD). The significance level was set at $p < 0.05$.
Results: FM was diagnosed significantly more often in women (13.2% of the cohort) than in men (3.3%, p=0.002). The PsA+FM group had a statistically significantly higher number of tender joints compared to the PsA without FM group (p=0.01). However, the number of swollen joints (p=0.05) and enthesitis sites (p=0.26) did not differ significantly. PROs were significantly worse in the PsA+FM group: pain VAS (68.8±12.1 mm vs. 54.2±20.9 mm, p=0.007), disease activity by BASDAI (6.68±1.39 vs. 5.50±2.0, p=0.02), functional impairment by BASFI (6.02±1.96 vs. 3.71±2.62, p=0.0006), fatigue level by FACIT-F (23.5±7.71 vs. 30.2±9.78, p=0.02), and disease impact on QoL by PsAID-12 (6.38±1.5 vs. 4.18±2.33, p=0.007). Anxiety levels (HADS) were higher in the PsA+FM group (10.6±2.91 vs. 6.22±3.51, p=0.00001), while depression scores, although higher in the FM group, also showed a statistically significant difference (p=0.005).
Conclusions: The study confirms that patients with PsA and comorbid FM, despite comparable objective inflammatory activity (number of swollen joints, enthesitis), experience a significantly more severe subjective disease burden. This manifests as greater pain intensity, higher patient-reported disease activity (BASDAI), pronounced functional impairment (BASFI), increased fatigue, reduced QoL (PsAID-12), and higher anxiety levels. Identifying FM in PsA patients is clinically crucial, as it necessitates a comprehensive treatment approach addressing both inflammatory and central (nociplastic) pain components.

P1422

EVALUATION OF THE EFFICACY OF LOCAL INJECTION THERAPY FOR THE CONTRALATERAL KNEE JOINT AFTER UNILATERAL TOTAL KNEE ARTHROPLASTY

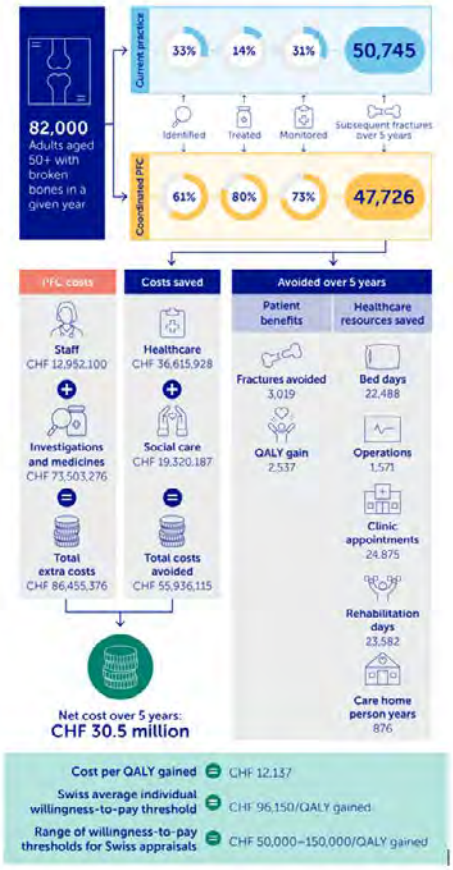
R. O. Mnevets[1], K. Ostrovskyy[2], S. A. Khamidova[3], K. K. Khallaev[4]

[1]Educational and Scientific Center "Institute of Biology and Medicine", Taras Shevchenko National University of Kyiv. State Institution "Ukrainian Center of Maternity and Childhood of the National Academy of Medical Sciences of Ukraine", Kyiv, Ukraine; [2]Pharmaceutical Product Development, Warsaw, Poland; [3]Tashkent State Pedagogic University named after Nizami, Tashkent, Uzbekistan; [4]Tashkent State Medical University, Tashkent, Uzbekistan

Objectives: Patients after unilateral total knee arthroplasty (TKA) experience increased biomechanical load on the contralateral knee, which can exacerbate pre-existing osteoarthritis (OA) symptoms. Effective management of pain and function in the non-operated knee is crucial for patient rehabilitation and quality of life.
Material and Methods: A prospective, single-center, randomized controlled study included 88 patients with bilateral post-traumatic knee OA (Kellgren-Lawrence grade III) after unilateral TKA. Patients were comparable in age, sex, and comorbidities. They were randomized into three groups (n=30 each): Group 1 received a single 3 ml injection of HA+CS into the contralateral knee; Group 2 received a single 6 ml injection of HA+CS; Control Group received no injection therapy. Pain intensity was assessed using a Visual Analog Scale (VAS) at rest and during movement at 3 and 6 months post-TKA. The monthly consumption of lornoxicam tablets (NSAID) was recorded.
Results: At the 3-month follow-up, VAS pain scores in the non-operated knee were significantly lower in Groups 1 and 2 compared to the Control Group ($p<0.05$). At 6 months, a more substantial and statistically significant reduction in pain was observed only in Group 2 compared to both its 3-month score and the other groups ($p\leq0.01$). NSAID consumption significantly decreased from 8.93±3.27 to 6.13±3.19 tablets/month between 3 and 6 months in Group 2 ($p\leq0.01$). In Group 1, consumption remained higher (11.1±3.44 to 9.9±3.44 tablets/month, $p>0.05$). The Control Group maintained the highest consumption level (>14 tablets/month) throughout the period, correlating with significantly

higher pain scores (p≤0.01 vs. intervention groups).
Conclusion: A single 6 ml intra-articular injection of a combined hyaluronic acid and chondroitin sulfate preparation into the contralateral knee joint after unilateral TKA provides effective pain relief and significantly reduces the need for NSAIDs over a 6-month period, demonstrating its utility as an adjunct therapy in postoperative rehabilitation.

P1423



EVALUATING THE CLINICAL AND ECONOMIC IMPACT OF COORDINATED POST-FRACTURE CARE IN OSTEOPOROSIS MANAGEMENT IN SWITZERLAND

J. Everts-Graber[1], S. Ferrari[2], R. Pinedo-Villanueva[3]

[1]Inselspital, Universitätsspital Bern, Bern, Switzerland; [2]Hôpitaux Universitaires Genève, Geneva, Switzerland; [3]University of Oxford, Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, Oxford, United Kingdom

Objective(s): Despite osteoporotic fractures accounting for 4.5% of Swiss healthcare spending, an estimated 684,000 women in Switzerland remain untreated, highlighting a substantial care gap.[1] Coordinated post-fracture care (PFC) is designed to identify, treat and monitor patients with fragility fractures, to reduce the risk of re-fracture. We sought to assess the cost-effectiveness of implementing PFC in Switzerland.
Materials and Methods: An established state-based microsimulation model was used to estimate the impact of PFC compared with current practice over 5 years, for people aged 50 years or older with a fragility fracture.[2] Model input parameters, including estimated PFC efficiency and fracture costs, were sourced from published literature, Swiss insurer data, the Swiss Osteoporosis Registry, extrapolated Dutch data, and Swiss expert elicitation. Outcomes estimated included number of re-fractures, hospital admissions, operations, bed days, clinical appointments, rehabilitation needs, care home admissions, costs averted and associated costs of PFC. Indirect costs were not included. The model predicted fractures avoided, quality-adjusted life years (QALYs) gained, and net economic outcomes over 5 years.
Results: Compared with current practice, PFC was associated with avoidance of 3,019 fractures, 1,571 operations and 22,488 bed days over 5 years (**Figure**). Costs saved over 5 years totalled CHF 55,936,115, including CHF 36,615,928 in healthcare and CHF 19,320,187 in social care. A net cost of CHF 30.5 million was estimated for PFC implementation, resulting in 2,537 QALYs gained and an incremental cost-effectiveness ratio of CHF 12,137/QALY. Thus, PFC was likely costeffective at an average Swiss willingness-to-pay threshold of ~CHF 96,150/QALY.[3]
Conclusions: PFC was likely cost-effective compared with current practice over 5 years in Switzerland using a microsimulation model. The results demonstrate the value of PFC in closing the osteoporosis care gap for patients at very high risk of fracture, supporting policy and clinical decisions.

Figure. Expected overall impact of PFC implementation in Switzerland over 5 years

CHF: Swiss Franc; PFC: coordinated post-fracture care; QALY: quality-adjusted life year.

P1424

ADULTS WITH XLH WHO LOOK AFTER RELATIVES WITH XLH: QUALITY OF LIFE PROFILES FROM THE RUDY STUDY

R. Pinedo-Villanueva[1], M. K. Javaid[1], C. Cai[2]

[1]University of Oxford, Oxford, United Kingdom; [2]University of South Carolina, Columbia, United States

Objective

To identify distinct groups of adults living with XLH, who act as carers of relatives with XLH, based on their quality of life.

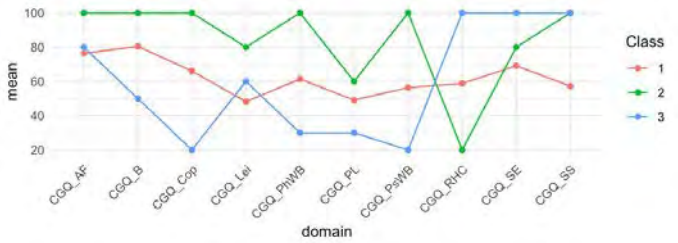
Methods

Adults with XLH reporting to act as carers of relatives with XLH who completed the CarGOQol carer quality of life questionnaire as participants in the Rare and Diagnosed Study (RUDY) were included. Self-reported patient-level data were extracted in October of 2025. The CarGOQol consists of 29 questions covering 10 domains: Psychological well-being, Burden, Relationship with health care, Administration and finances, Coping, Physical well-being, Self-Esteem, Leisure, Social support, and Private Life. Latent profile analysis was conducted to identify unobserved groups of carers based on the 10 unweighted CarGOQol domain scores. Different numbers of profiles were tested and the solution with the lowest BIC/AIC was selected. Model fit was assessed by interpretability and mean posterior probabilities with >0.79 indicating good separation.

Results

Currently, 13 participants from various regions in the UK met the inclusion criteria, mean age 42.5 years and 85% female. They looked after one to three people with XLH (mean 1.5), either children only (46.2%), adult only (46.2%), or a mix (1/13).

One to four possible profiles were tested and a three-profile solution was selected based on BIC/AIC and interpretability (Figure 1). Class sizes (11, 1, 1) were unsatisfactory though likely due to reduced sample size. Profiles: (1) Average QoL domains; (2) Very good QoL, poor relationship with the health care system; (3) Mixed levels of QoL across domains, good relationship with the health care system, self-esteem and social support but poor psychological and physical wellbeing, coping and private life. Mean posterior probabilities indicate good class separation for profile 1 (0.85) but poor for profiles 2 and 3 (0.08 each).



Conclusions

There are distinct hidden groups within people with XLH who care after relatives with XLH. Future analysis with larger sample size is needed. Understanding carer profile characteristics can help support care givers and the relatives they care for.

Acknowledgment

Funding for this study was provided by Kyowa Kirin. We acknowledge all RUDY participants, the team, and funders that support it.

Objectives: Dyslipidemia is characterized by an abnormal lipid profile, including hypercholesterolemia and hypertriglyceridemia. Oxidized LDL (Ox-LDL), play a key role in joint inflammation and cartilage degeneration. Although serum lipids are routinely investigated, similar studies on synovial fluid (SF) are limited. As a dynamic interface among various tissues within the knee joint, the lipid profiling of SF is a promising approach to track dynamic changes in lipid signatures, including OxLDL, during OA progression.

Material and Methods: Lipid analysis of 34 SF samples from patients with OA across the Kellgren–Lawrence (KL) grades was performed using an automated enzymatic analysis. Ox-LDL levels in SF were measured using a commercial ELISA kit. Synovitis and cartilage damage were assessed by estimation of Interleukin-1β (IL-1β) and glycosaminoglycan (GAG) levels respectively in SF samples. This data was compared with the proteomic data available from our previous study.

Results: IL-1β levels increased with OA severity, except for a non-specific significant decline in KL grade-II SF samples, whereas GAG levels showed a constant grade-wise increase. Significantly higher levels of triglycerides, total cholesterol, LDL, and VLDL were noted in all SF samples but declined gradually with advanced OA grades. The HDL/LDL ratio showed significant decline with increasing KL grade, particularly in advanced OA. Ox-LDL levels increased progressively with OA severity and were significantly elevated in grade-IV **(Figure 1a, b, c, d, e)**. Proteome analysis revealed upregulation of LPA and down-regulation in apolipoproteins (APOB-100, APOA1, APOA2, APOA4, APOC4, and APOE) in advanced OA grades **(Table 1)**.

Conclusions: This is the first report on grade-wise lipid profile analysis in OA-SF. Elevated triglycerides, total cholesterol, LDL, and VLDL levels in SF confirm lipid infiltration and oxidative stress, with notable elevation of Ox-LDL in advanced OA. SF triglycerides and total cholesterol levels parallelly increased with IL-1β levels across the grade, supporting an association between lipid dysregulation and chronic synovial inflammation. IL-1β levels are positively correlated with glycosaminoglycan (GAG) release and KL grade, linking lipid dysregulation with cartilage degradation. A declined HDL/LDL ratio indicates a shift toward pro-inflammatory lipid milieu within the SF reflects impaired lipid homeostasis, favoring LDL dominance and oxidative modification. Further, this data aligns with downregulation of APO-lipoproteins, that are major carriers of triglycerides, total cholesterol and their derivatives. Altogether, these findings highlights changes in lipid imbalance and Ox-LDL as key contributors to OA associated inflammation and cartilage damage.

SYNOVIAL FLUID-CELL TRANSCRIPTOME ACROSS THE KL-GRADES IN KNEE OSTEOARTHRITIS REVEALED ALTERED LIPID METABOLIC NETWORK AND ACTIVATION SIGNATURE OF IMMUNE CELLS

R. Raj[1], S. Pawar[2], A. Harsulkar[1,2], A. Electricwala[3]

[1]Poona College of Pharmacy, Bharati Vidyapeeth (Deemed to be) University, Erandwane, Pune, 411038, India, Pune, India; [2]School of Bioengineering Sciences and Research, MIT ADT University, Loni Kalbhor, Pune, 412201, India, Pune, India; [3]Electricwala Hospital, A 4/1, Pleasant Park, Fatima Nagar, Wanowrie, Pune 411013, India, Pune, India

Objective

We have shown that synovial fluid (SF) serves as a niche for differentiation of immune cells like monocytes and haematopoietic stem cells into effector cells. SF is known to contain several types of cells including macrophages, neutrophils and mast cells (MCs) which drive inflammation and disease progression. We have performed transcriptomic analysis of osteoarthritis (OA) SF-cells across the grades and correlate transcript abundance with OA severity. This would provide us with a comprehensive understanding of molecular mechanism and diversity of immune cells in OA.

Materials and Methods

The SF samples were collected from clinically and radiographically confirmed OA (age group – 40 to 75 years, ethnicity – Indian Asian, exclusion – rheumatic, gouty and infective arthritis), with severity graded by the Kellgren–Lawrence (KL) scale. A subset of SF samples (n = 20; 5 × 4 grades) was used for grade-wise transcriptomic analysis. Total RNA was extracted and purified by phenol–chloroform extraction followed by TapeStation. rRNA depleted samples were used for strand-specific library preparation using the KAPA RNA HyperPrep Kit. Final libraries were purified, quantified, pooled, and sequenced on a NovaSeq X Plus (150 bp paired end; ~40 million reads/sample). FASTQ files were processed and aligned using Strand NGS v4.1. Differential gene expression was analysed using Strand NGS, with KL grade-I as the control.

Results

Transcriptomic profiling of SF across KL grades revealed extensive molecular alterations involving lipid metabolism, apolipoprotein signaling, and MCs associated pathways. Multiple apolipoproteins (ApoA-I, ApoC-III, ApoA-IV, ApoM, PLTP, FABP5, etc.) were differentially expressed, highlighting dysfunctional lipoprotein remodelling involving significant alterations in lipid and fatty acid transport, handling indicating a progressive shift toward a dyslipidemic and inflammatory microenvironment. Importantly, MCs associated genes including FCER1A (high-affinity IgE receptor α-chain) and c-KIT (MCs survival and maturation receptor) were consistently upregulated. This suggest a close link between MCs activation within SF-dyslipidaemia in shaping the inflammatory landscape reflecting a metabolically stressed and immunologically active synovial milieu in OA progression.

Conclusion

This study demonstrates that OA severity is marked by progressive alterations in SF lipid pathways, apolipoprotein networks, and MCs related transcriptional signatures. Our grade-wise SF analysis reveals that OA progression is accompanied by dysregulation of apolipoproteins, lipid handling pathways, and MCs associated genes. Upregulation of FCER1A and c-KIT, together with a dyslipidemic SF profile, suggests that MCs activation and abnormal lipid remodeling are integral to the inflammatory progression of OA.

P1427

REAL-WORLD TREATMENT DURATION WITH ROMOSOZUMAB IN CONTEXT OF OTHER OSTEOANABOLIC/ANTIRESORPTIVE TREATMENTS - DATA FROM GERMAN CLAIMS DATABASE

R. Schmidmaier[1], L. Seefried[2], G. Schildgen[3], H. D. Pannen[4], C. Schiener[3], L. Möckel[4]

[1]LMU University Hospital, Department of Medicine IV, Endocrinology and Geriatrics, Munich, Germany; [2]Orthopedic Hospital, König-Ludwig Haus, Julius-Maximilians-Universität Würzburg, Department of Osteology and Clinical Trial Unit, Würzburg, Germany; [3]Insight Health GmbH, Waldems-Esch, Germany; [4]UCB, Monheim am Rhein, Germany

Objective

We analyzed treatment duration by estimating the time to discontinuation of romosozumab (ROMO), abaloparatide (ABALO), teriparatide (TERI) and alendronate (ALN), including subgroup analyses with ROMO treated patients by prior osteoporosis treatment and co-medications.

Materials and Methods

This retrospective study used a German claims database of 64 million insured individuals. It included women newly initiated on ROMO, ABALO, TERI or ALN (Jan 2022–Oct 2025) with ≥12 months pre-index data; combination therapy was excluded. Time until 25%, 50%, and 75% of patients discontinued treatment was estimated via Kaplan–Meier method. Discontinuation was defined as no refill within package duration plus 60 days grace period; ongoing treatments were censored at database end.

Results

A total of 10,651 female patients treated with ROMO (mean age 73.7 ± SD 9.4 years), 895 with ABALO (74.0±9.2 years), 9,171 with TERI (72.5±12.6 years) and 250,510 with ALN (75.1±9.4 years) were included.

Median time to discontinuation for each drug – when 50% of the cohort have stopped the medication (25%; 75%) – were: ROMO 12.1 (6.8; 12.8), ABALO 11.0 (3.1; 17.9), TPTD 12.4 (3.5; 23.6) and ALN 4.8 (2.8; 15.2) months (see figure), respectively.

Among ROMO treated patients there was no difference in the discontinuation rate with respect to 50% and 75% threshold between patients pretreated with bisphosphonates (BP) and those without osteoporosis pre-treatment (see table). However, 25% of BP pre-treated patients discontinued ROMO after 10.1 months compared to 5.5 months among patients without pre-treatment (see table).

In subgroup analyses based on the number of concomitant medications, 25% of patients with 0-1 co-medication discontinued ROMO after 2.0 months. For patients with 2-3, 4-5, or 6+ co-medications, the corresponding durations were 4.7, 8.4, and 11.0 months, respectively. However, there was no difference regarding the type of co-medication (Tab. 1).

Conclusion

This real-world evidence shows that most patients completed the full recommended treatment duration (12 months) for ROMO, while the real-world treatment duration with ALN, ABALO and TERI are all shorter than recommended, which is consistent with known adherence issues in osteoporosis.

Figure: Persistence in patients treated with ROMO, ABALO, TERI or ALN

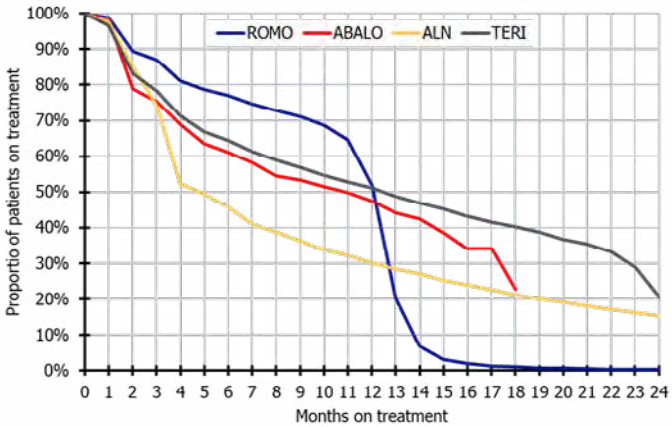

Table: Time in months until 25%, 50% and 75% of romosozumab treated patients discontinued treatment stratified by subgroups

Subgroups		25%	50%	75%
Osteoporosis pre-treatment	Bisphosphonates (n=2,456)	10.1	12.3	12.9
	Denosumab (n=844)	8.0	12.1	13.0
	Estrogens/SERMs (n=239)	9.4	12.2	12.8

REAL-WORLD EFFECTIVENESS OF ANTIRESORPTIVE THERAPY ON BONE DENSITY IN THAI BREAST CANCER PATIENTS RECEIVING LETROZOLE

R. Suwanaratana[1], N. Chanalithichai[1], P. Thanindratarn[1], T. Chobpenthai[2]

[1]Princess Srisavangavadhana Faculty of Medicine, Chulabhorn Royal Academy, Bangkok, Thailand; [2]Princess Srisavangavadhana Faculty of Medicine, Chulabhorn Royal Academy, Bangkok, Thailand

Objective(s): To evaluate the real-world effectiveness of bisphosphonates and denosumab in preventing bone loss among Thai postmenopausal women receiving letrozole and to compare site-specific skeletal responses.

Material and Methods: This retrospective study evaluated 369 Thai postmenopausal women receiving adjuvant letrozole (2016-2020). Bone mineral density (BMD) at the lumbar spine, total hip, and distal radius was assessed using DXA. Patients were grouped into no antiresorptive, bisphosphonate, or denosumab. Percentage annualized BMD change was compared using ANCOVA adjusted for age, BMI, baseline BMD, fracture history, and years since menopause. Longitudinal analysis included 178 patients with follow-up data (N varied slightly by site).

Results: Among 178 patients (mean follow-up 16.3 months), antiresorptive therapy significantly preserved total hip BMD compared with no treatment (adjusted mean change: -1.90%/year vs. +0.02%/year with bisphosphonates and +1.14%/year with denosumab; $p < 0.001$). At the lumbar spine, adjusted differences were not statistically significant (no treatment: -1.59%, bisphosphonates: -0.37%, denosumab: -0.17%; $p = 0.284$). However, bone loss persisted at the distal radius across all

groups (no treatment: -2.25%, bisphosphonates: -0.86%, denosumab: -2.93%; p = 0.308).
Conclusion(s): In real-world practice, antiresorptive therapy effectively preserves hip BMD in Thai women receiving letrozole. The persistent bone loss at the distal radius suggests a therapeutic gap for cortical bone, highlighting the need for site-specific monitoring.

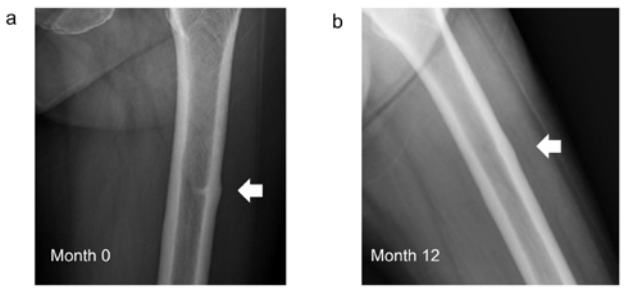
P1429

HIGH ANTICIPATORY ANXIETY VERSUS LOW CLINICAL NECESSITY FOR DRUG HOLIDAYS: REAL-WORLD INSIGHTS FROM A DIGITAL DENTAL DECISION AID IN OSTEOPOROTIC PATIENTS

R. Suwanaratana[1], T. Rujiraphan[2], P. Wiphakphongpakorn[2]

[1]Princess Srisavangavadhana Faculty of Medicine, Chulabhorn Royal Academy, Bangkok, Thailand; [2]Chulabhorn Hospital, Chulabhorn Royal Academy, Bangkok, Thailand

OBJECTIVE(S) To compare patient-perceived anticipatory anxiety regarding medication-related osteonecrosis of the jaw (MRONJ) against the actual clinical necessity for drug holidays determined by a digital decision aid.
MATERIAL AND METHODS We analyzed two datasets from a tertiary osteoporosis center (Jan–Aug 2025). First, a prospective cohort of 51 osteoporotic patients (mean age 70.3 years) on antiresorptive therapy assessed dental anxiety using the Visual Analog Scale (VAS) before and after using "Dental Confidence," a web-based decision aid (AAOMS 2022 guidelines). Second, we performed an aggregate analysis of 109 system usage logs to characterize the real-world risk profile. Subjective fear was contrasted with objective clinical recommendations.
RESULTS Patients exhibited high baseline anticipatory anxiety (mean Pre-VAS = 51.38 ± 32.91). However, risk stratification revealed that clinical necessity for discontinuation was rare. Among 109 assessments, 98.2% did not require a drug holiday. Specifically, 69.7% were low risk (proceed immediately), while 19.3%—predominantly Denosumab users—were guided to schedule procedures during the optimal window (3-4 months post-injection). Only 1.8% (n=2) met criteria for a drug holiday (>4 years oral bisphosphonates or concomitant risk factors). Following this risk contextualization, patient anxiety significantly decreased (Post-VAS = 41.49 ± 32.30, p=0.0002).
CONCLUSION(S) A disconnect exists between high anxiety and low necessity for drug holidays (<2%). Digital aids bridge this gap by distinguishing "high risk" requiring discontinuation and "manageable risk" requiring only schedule optimization. This guidance reassures patients, reducing anxiety and supporting adherence without compromising safety.



P1430

SUCCESSFUL HEALING OF AN INCOMPLETE ATYPICAL FEMORAL FRACTURE AFTER BISPHOSPHONATE DISCONTINUATION AND ROMOSOZUMAB THERAPY: A CASE REPORT AND LITERATURE REVIEW

R. Suwanaratana[1], N. Chanalithichai[1]

[1]Princess Srisavangavadhana Faculty of Medicine, Chulabhorn Royal Academy, Bangkok, Thailand

Objective(s): To report a case of successful non-operative management of an incomplete atypical femoral fracture (AFF) using romosozumab following denosumab discontinuation and to review the potential role of anabolic therapy in this clinical scenario.
Material and Methods: A 70-year-old woman with rheumatoid arthritis on long-term immunosuppressants presented with an asymptomatic incomplete AFF after ten years of sequential antiresorptive therapy (bisphosphonate followed by denosumab). DXA showed osteoporosis with high fracture risk and significant bone mineral density (BMD) decline (-10% at the total hip) despite denosumab treatment. Denosumab was discontinued, and romosozumab (210 mg monthly) was initiated along with protective weight-bearing and close radiographic monitoring.
Results Radiographs: at six months demonstrated progressive cortical healing. After 12 months of romosozumab therapy, complete radiographic union and callus remodeling were achieved. Follow-up DXA demonstrated substantial BMD improvement: +15.5% at the lumbar spine, +6.2% at the femoral neck, and +3.6% at the total hip. The patient remained asymptomatic, ambulated normally, and successfully transitioned to oral alendronate for maintenance.
Conclusion(s): Incomplete AFF can heal with non-operative management after antiresorptive discontinuation. In this case, romosozumab therapy supported complete radiographic union and substantial BMD gain, suggesting its potential value for patients at high fracture risk transitioning from denosumab.
Disclosures: None

(a) Initial presentation showing a transverse radiolucent line (arrow). (b) Complete cortical union and remodeling after 12 months of romosozumab.

P1431

BONE HEALTH OPTIMIZATION IN REVERSE SHOULDER ARTHROPLASTY: FROM OPPORTUNISTIC SCREENING TO SURGICAL MITIGATION

R. Suwanaratana[1], N. Chanalithichai[1], S. Aimprasittichai[2], W. Suphakitchanusan[2]

[1]Princess Srisavangavadhana Faculty of Medicine, Chulabhorn Royal Academy, Bangkok, Thailand; [2]Chulabhorn Hospital, Chulabhorn Royal Academy, Bangkok, Thailand

Objective(s): Reverse shoulder arthroplasty (RSA) in patients with severe osteoporosis carries significant risks of fixation failure, periprosthetic fracture, and acromial stress fracture. While mechanical solutions exist, a comprehensive strategy integrating surgical precision with systemic Bone Health Optimization (BHO) is often lacking. We propose a quantitative, algorithmic approach to bridge this gap.
Material and Methods: Based on a comprehensive review of current evidence, we describe the "Red Zone" management algorithm utilizing preoperative quantitative computed tomography (CT) analysis. Local bone density is measured in Hounsfield Units (HU) to identify critical deficits in three structural pillars: the proximal humerus (<50 HU), glenoid vault (<200 HU), and acromion (<100 HU). This objective classification dictates zone-specific reconstruction strategies.
Results: The algorithm mandates a shift from standard techniques to targeted solutions for the "Red Zone" patient. For the "stovepipe" humerus, cemented fixation with undersized broaching relative to the canal is utilized to mitigate fracture risk. Glenoid management prioritizes augmented baseplates or specific screw trajectories to engage higher-density columns. For the fragile acromion, implant geometry is optimized alongside "deltoid-protective" tensioning. Crucially, these mechanical constructs are coupled with aggressive pharmacological optimization, prioritizing anabolic therapy (e.g., teriparatide, romosozumab) via pre-operative optimization for elective cases and immediate initiation for fractures, to accelerate osseointegration and fracture healing, alongside a load-managing rehabilitation protocol.
Conclusion(s): The "Red Zone" algorithm serves as a practical execution tool within the broader context of BHO. By combining objective density metrics with synergistic surgical and biological interventions, surgeons can transform a catastrophic risk into a durable reconstruction for the fragility patient.

P1432

TRAUMATIC TIBIAL PLATEAU FRACTURE IN A PATIENT WITH OSTEOPOIKILOSIS: UNVEILING THE BONE QUANTITY-QUALITY PARADOX AND METABOLIC ACTIVITY - A CASE REPORT

R. Suwanaratana[1], N. Chanalithichai[1], P. Thanindratarn[1]

[1]Princess Srisavangavadhana Faculty of Medicine, Chulabhorn Royal Academy, Bangkok, Thailand

Objective(s): Osteopoikilosis (OPK) is a rare sclerosing bone dysplasia that radiographically mimics osteoblastic metastases. While often considered incidental, the biological quality of the bone remains poorly understood. We report a rare case of a tibial plateau fracture in OPK to characterize the "quantity-quality paradox" between Bone Mineral Density (BMD) and Trabecular Bone Score (TBS), and to investigate the metabolic activity of the lesions.
Material and Methods: A 66-year-old female sustained a Schatzker type II tibial plateau fracture following a simple mechanical fall. Radiographs revealed multiple symmetric sclerotic spots. To differentiate from malignancy, a comprehensive evaluation including tumor markers (CEA, CA 15-3, CA 125, CA 19-9) and whole-body computed tomography was performed. Biologic bone assessment included serum bone turnover markers (CTX, P1NP), DXA-derived BMD and TBS, and metabolic imaging via 18F-Sodium Fluoride (18F-NaF) PET/CT. The fracture was managed with standard Open Reduction and Internal Fixation (ORIF).
Results: Malignancy was ruled out. Bone turnover markers were within normal limits, yet 18F-NaF PET/CT demonstrated intense focal tracer uptake within the sclerotic lesions, indicating active bone remodeling rather than inert islands. DXA revealed a "bone paradox": lumbar spine BMD and hip BMD were normal (T-score -0.2 and 0.5), whereas TBS indicated degraded microarchitecture (score 1.173). Despite the compromised trabecular texture and altered metabolic signal, the fracture achieved solid union at 2 months with full weight-bearing recovery.
Conclusion(s): In OPK, normal BMD is misleading due to sclerotic artifacts. This case highlights the biological complexity of OPK: lesions are metabolically active on 18F-NaF PET/CT and exist alongside degraded microarchitecture (low TBS). TBS may serve as a valuable adjunctive tool to provide better insight into bone quality. Despite these biologic abnormalities, the bone retains its healing potential, confirming that standard fixation remains the treatment of choice.

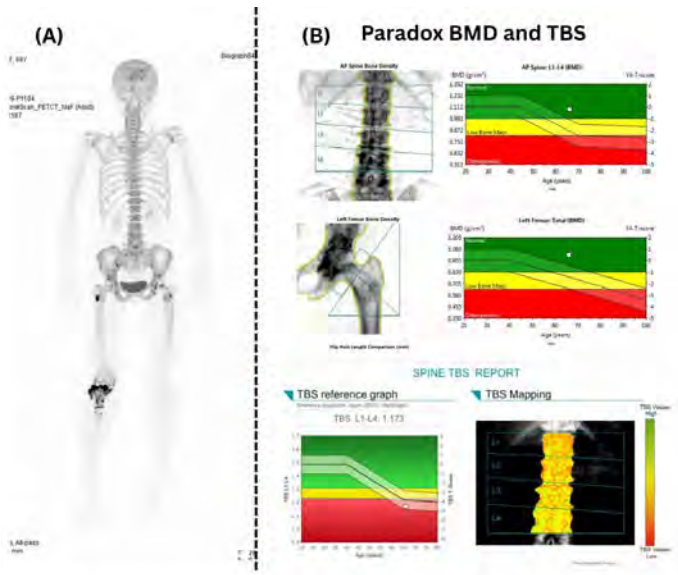


Figure 1: (A) 18F-NaF PET/CT showing active metabolic uptake in sclerotic lesions. (B) DXA Paradox: normal BMD T-score (-0.2 and 0.5) due to sclerosis (top), contrasted with Degraded Microarchitecture (TBS 1.173) (bottom).

P1433

UNMASKING HIDDEN OSTEOPOROSIS RISKS AND REACTIVE HEALTH BEHAVIORS USING A GAMIFIED WEB-BASED SCREENING TOOL: A CROSS-SECTIONAL STUDY IN THAILAND

R. Suwanaratana[1], T. Rujiraphan[2], N. Lordkaew[2]

[1]Princess Srisavangavadhana Faculty of Medicine, Chulabhorn Royal Academy, Bangkok, Thailand; [2]Chulabhorn Hospital, Chulabhorn Royal Academy, Bangkok, Thailand

Objective(s): To evaluate a web-based gamified tool in characterizing osteoporosis risk profiles and identifying "hidden risk" populations among Thai adults.
Material and Methods: A descriptive and analytic cross-sectional study evaluated the "Bone Score Challenge," a responsive web application designed for smartphone and desktop accessibility. The tool utilized a weighted scoring algorithm, with a baseline of 100 points, derived from Thai Osteoporosis Foundation (TOPF) guidelines and international standards. To enhance user engagement, the application integrated gamification mechanics, including instant visual feedback via a color-coded traffic light system (Green for Excellent, Orange for Improvement Needed, Red for High Risk) and a social percentile ranking system that compares users against the aggregate database. Logistic regression and chi-square tests analyzed associations between lifestyle factors and fracture history, with the multivariate model adjusted for age.
Results: The algorithm demonstrated internal validity with significantly lower mean scores in the fracture group compared to the non-fracture group ($p < 0.001$). Multivariate analysis (Table 1) identified history of falls as the strongest independent predictor of fracture history (aOR 6.13, 95% CI: 2.92–12.85, $p < 0.001$). A synergistic protective effect was observed: combined adequate calcium and vitamin D exposure was associated with 60% lower odds of fracture history (aOR 0.40, $p = 0.013$). The tool identified a "hidden risk" cohort among participants aged <60 years (41.5%) who exhibited high-risk lifestyle scores despite being asymptomatic. Additionally, an inverse association between exercise and fracture history suggested a pattern of reactive behavioral modification post-diagnosis.
Conclusion(s): The "Bone Score Challenge" effectively unmasks hidden risks and identifies reactive health behaviors. This digital platform serves as a scalable pre-screening mechanism to bridge the gap between community awareness and clinical diagnosis.

Table 1: Clinical characteristics and risk factors associated with fracture history (N=261)

Variable	Fracture (n=43)	No Fracture (n=218)	aOR (95% CI)*	P-value
Age (years), Mean ± SD	57.2 ± 13.9	50.8 ± 13.2	1.06 (1.03–1.09)	<0.001
History of Falls, n (%)	19 (44.2)	31 (14.2)	6.13 (2.92–12.85)	<0.001
Parental Fracture, n (%)	13 (30.2)	30 (13.8)	-	0.011
Very Active Exercise†, n (%)	15 (34.9)	40 (18.3)	-	0.024
Nutrient Synergy‡, n (%)	14 (32.6)	104 (47.7)	0.40 (0.19–0.82)	0.013

*Adjusted for age. †Exercise frequency ≥3 times/week. ‡Concurrent adequate calcium and vitamin D.

OPPORTUNISTIC SCREENING FOR OSTEOPOROTIC VERTEBRAL COMPRESSION FRACTURES USING STANDARD AP DENSITOMETRY REPORT IMAGES: A DEEP LEARNING-BASED COMPARATIVE STUDY AGAINST ORTHOPEDIC SPECIALISTS

R. Suwanaratana[1], N. Chanalithichai[1], A. Lawanprasert[2]

[1]Princess Srisavangavadhana Faculty of Medicine, Chulabhorn Royal Academy, Bangkok, Thailand; [2]Chulabhorn Hospital, Chulabhorn Royal Academy, Bangkok, Thailand

Objective(s): Osteoporotic vertebral compression fractures (OVCFs) are frequently underdiagnosed. While lateral imaging is standard, Bone Mineral Density (BMD) reports routinely utilize Anteroposterior (AP) spine images, which are overlooked for screening. This study investigated the clinical utility of a deep learning model to opportunistically screen for OVCFs using these standard AP report images, comparing performance against orthopedic surgeons and residents.
Material and Methods: A YOLO-based model was developed using 513 AP spine images extracted from BMD reports, utilizing data augmentation. Following internal validation (mAP@0.5 = 91.0%), the model was evaluated on an external set of 60 patients (30 fractures, 30 controls). Diagnostic performance was compared with (1) three board-certified orthopedic surgeons and (2) three orthopedic residents. We analyzed performance against both the pooled average of individual readers and their majority vote consensus.
Results: Patient-level AI sensitivity was 93.3% (95% CI: 74.4-96.5), significantly superior to the pooled average of surgeons (68.9%, $p<0.001$) and residents (81.1%, $p=0.003$). Against expert consensus, AI sensitivity remained significantly higher than surgeons (93.3% vs 70.0%, $p=0.016$) and comparable to resident consensus (86.7%, $p=0.50$). While surgeons showed superior specificity (100%), AI maintained robust specificity (83.3%). At the vertebral level, AI significantly outperformed surgeon consensus in sensitivity (78.0% vs 51.2%, $p=0.003$), highlighting superior detection of subtle fractures in AP images.
Conclusion(s): Deep learning transforms standard AP BMD report images into an opportunistic screening tool. The AI demonstrated significantly higher sensitivity than both average and consensus orthopedic surgeons, serving as an automated second reader to enhance detection in routine reports without additional cost or radiation.

P1435

CLOSING THE EXPERTISE GAP IN OSTEOPOROSIS MANAGEMENT: AN EQUALIZING EFFECT OF A GUIDELINE-BASED CLINICAL DECISION SUPPORT SYSTEM AMONG JUNIOR AND SENIOR PHYSICIANS

R. Suwanaratana[1], A. Lawanprasert[2], C. Wuthikraikun[2], T. Amphansap[3]

[1]Princess Srisavangavadhana Faculty of Medicine, Chulabhorn Royal Academy, Bangkok, Thailand; [2]Chulabhorn Hospital, Chulabhorn Royal Academy, Bangkok, Thailand; [3]Police General Hospital, Bangkok, Thailand

Objective(s): To evaluate the impact of a clinical decision support system (CDSS) on the accuracy of osteoporosis risk assessment and treatment selection, and to examine its role in standardizing care across different levels of clinical experience.
Material and Methods: A within-subject randomized experimental study was conducted with 65 physicians (56 orthopedists, 5 general practitioners, 4 internal medicine). Participants were divided into Junior (GP/R1, n=22) and Senior (R2-Staff, n=43) groups. Each evaluated 20 randomized clinical vignettes derived from real-world data, comparing manual assessment against CDSS-supported assessment. The CDSS utilized a deterministic logic engine based on the 2021 Thai Osteoporosis Foundation (TOPF) guidelines. Accuracy and error patterns (under/over-treatment) were analyzed against an expert-validated gold standard.
Results: CDSS support significantly improved risk classification accuracy from 70.3% to 84.8% (absolute gain +14.5%, p<0.001) and treatment selection concordance from 78.5% to 85.4% (gain +6.9%, p=0.003). A marked "equalizing effect" was observed: Junior physicians achieved a 22.3% accuracy gain (62.7% to 85.0%), effectively eliminating the performance gap with Senior physicians (84.7% with support). Furthermore, CDSS use reduced under-treatment in high-risk cases from 17.3% to 12.8% and nearly halved over-treatment (8.9% to 4.5%). System usability was rated as "good" (SUS: 69.1 ± 17.0).
Conclusion(s): The guideline-based CDSS facilitates high-fidelity adherence to osteoporosis management protocols. By mitigating clinical errors and equalizing performance between junior and senior clinicians, the system serves as a powerful tool for standardizing patient safety and optimizing musculoskeletal care delivery.

P1436

COMPARISON OF ULTRASONOGRAPHICALLY MEASURED NAIL PLATE THICKNESS IN PATIENTS WITH OSTEOPOROTIC FRACTURES, OSTEOPENIC FRACTURES, AND HEALTHY CONTROLS

R. Terlemez[1], E. Aygun[1], B. U. Cetin[1], S. T. Tuzun[1]

[1]Istanbul University-Cerrahpaşa, Istanbul, Türkiye

Objective:
This study aimed to compare ultrasonographically measured nail plate thickness in patients with osteoporotic fractures, patients with osteopenic fractures, and healthy controls, and to evaluate its potential association with bone quality.
Methods:
A total of 69 participants were included and categorized into three groups: patients with osteopenic fractures (n=25), patients with osteoporotic fractures (n=24), and healthy controls without fractures (n=20). Nail plate thickness was measured using ultrasonography from the first to fifth digits. Group comparisons were performed to assess differences in ultrasonographic nail plate thickness among the three groups.
Results:
Patients with osteoporotic fractures demonstrated significantly lower nail plate thickness in the second through fifth digits compared with healthy controls (p<0.01 for all), while no significant difference was observed for the first digit (p=0.64). Patients with osteopenic fractures also exhibited reduced nail plate thickness compared with controls, particularly in digits 2–5 (p<0.01). Post-hoc analysis revealed that differences were mainly driven by comparisons between fracture groups and controls, whereas nail plate thickness was largely comparable between osteoporotic and osteopenic fracture groups, except for the fifth digit (p=0.04). Patients with osteoporotic fractures had lower BMD values and higher FRAX-derived major osteoporotic and hip fracture risks compared with osteopenic fracture patients.
Conclusion:
Ultrasonographically measured nail plate thickness, particularly in the second to fifth digits, was reduced in patients with osteoporotic and osteopenic fractures compared with healthy controls. These findings suggest that nail plate thickness assessment by ultrasonography may reflect underlying bone quality and fracture risk, supporting its potential role as a simple, non-invasive imaging biomarker.

P1437

LONG-TERM QUALITY OF LIFE TRAJECTORIES IN FIBROUS DYSPLASIA AND MCCUNE-ALBRIGHT SYNDROME

R. Vijjhalwar[1], F. Clemeno[1], M. A. Legrand[1], R. Pinedo-Villanueva[1], M. K. Javaid[1]

[1]Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, Oxford, United Kingdom

Objectives: Fibrous dysplasia and McCune-Albright syndrome (FD/MAS) are associated with substantial morbidity, yet long-term patient-reported outcomes remain poorly characterised. We describe longitudinal health-related quality of life (HRQoL) trajectories in FD/MAS and identify clinically meaningful subgroups at differential risk of deterioration using generic HRQoL (EQ-5D) data.
Material and Methods: We analysed longitudinal EQ-5D-5L data from 74 adults with participant-reported FD/MAS contributing 509 HRQoL observations (median follow-up 6.5 years) from the UK-based RUDY research database (www.rudystudy.org). Linear mixed-effects models estimated annual changes across EQ-5D domains and VAS, adjusting for age, sex, and year of entry. EQ-5D index scores were derived using validated algorithms. Patients with ≥2 measurements underwent unsupervised clustering of baseline-to-follow-up EQ-5D index change. K-means clustering (k=2) was compared with Gaussian mixture modelling (GMM). Baseline associations with cluster membership were tested using Fisher's exact tests.
Results: Population-level analyses showed overall significant annual worsening in mobility, self-care, and anxiety/depression, with declining EQ-5D VAS scores, while pain/discomfort and usual activities remained stable. Clustering identified two distinct trajectories. A high-risk

"decliner" group (≈30%) had poor baseline HRQoL (mean EQ-5D index 0.33) with marked deterioration over time (mean change -0.23), while a second majority group remained stable or slightly improved (Figure 1). Baseline EQ-5D index <0.5 was strongly associated with high-risk cluster membership (p=0.0005), whereas age and sex showed no association.
Conclusions: FD/MAS patients demonstrate heterogeneous long-term HRQoL trajectories. A substantial subgroup experiences a severe, progressive decline that may be identified at first assessment using baseline EQ-5D index scores. Early recognition may support targeted monitoring, multidisciplinary intervention, and future trials in this rare disease population.
Declarations: RV, FC, MAL, RPV nothing to declare. MKJ received paid consultancy or sponsorship for external talks from Amgen, UCB, Sanofi, Kyowa Kirin, Nanox-AI, Native Technologies, Thornton Ross and Theramex

P1439

CLINICAL OUTCOMES OF A COMBINED THERAPEUTIC APPROACH IN PATIENTS WITH SYSTEMIC OSTEOPOROSIS AND FIXED LUMBAR VERTEBRAL COMPRESSION FRACTURES

R. Zhurayev[1], T. Solomenchuk[1]

[1]Danylo Halytskyy Lviv National Medical University, Lviv, Ukraine

Objective**:** Vertebral compression fractures are often the initial sign of systemic osteoporosis. Early detection and targeted treatment are crucial to prevent additional skeletal damage.
Methods: Ten patients with systemic osteoporosis and confirmed lumbar compression fractures were examined (mean age 63 ± 2 years; 8 women, two men). All fractures occurred before patients were aware of their osteoporosis. Laboratory tests included 25(OH)D, CRP, calcium, ionized calcium, and phosphorus. DXA scans were performed at the hip and lumbar spine. Initial results showed vitamin D levels at 18.7 ± 1.3 ng/mL (normal 30), CRP at 7.25 ± 1.1 mg/L (normal <5), phosphorus at 0.65 ± 0.07 mmol/L (normal 0.81), and ionized calcium at 0.81 ± 1.1 mmol/L (normal 1.1). Femoral neck T-score was −2.2 ± 0.1, Z-score −2.3 ± 0.1; lumbar spine T-score +2.5 ± 0.1 and Z-score +2.8 ± 0.1, reflecting degenerative artifacts. All patients received vitamin D 5600 IU, ibandronic acid 150 mg monthly, and Osteogenon two tablets twice daily for 60 days.
Results. After six months, improvements were observed in clinical, laboratory, and densitometric assessments. Vitamin D levels normalized in 9 patients (33.2 ± 2.3 ng/mL). DXA showed positive changes: hip T-score increased to −1.9 ± 0.1 and Z-score to −1.8 ± 0.1; lumbar spine T-score rose to −1.7 ± 0.1 and Z-score to −1.6 ± 0.1.
Conclusion: The combined therapeutic approach of vitamin D repletion, anabolic vitamin D repletion, anti-resorptive therapy with ibandronic acid, and adjunctive Osteogenon recting metabolic abnormalities and enhancing bone mineral density. These findings support the importance of comprehensive, multimodal management in patients with systemic osteoporosis and vertebral compression fractures.

P1440

METHOTREXATE INTOLERANCE: AN UNFORTUNATE REALITY!

S. Abdellaoui[1], B. Bengana[1]

[1]Issad Hassani Beni messous hospital, Algiers, Algeria

Introduction: Methotrexate (MTX) is gold standard disease-modifying antirheumatic drug (DMARD) treatment in rheumatoid arthritis (RA). While effective, it is often poorly tolerated by patients. Consequently, this lack of adherence can be an obstacle to achieving remission. The objective of this study was to evaluate MTX tolerance through the frequency of adverse effects and across MISS score evaluation, and to determine the factors associated with the disease itself and/or the drug that predict poor tolerance.
Patients and Methods: This was a cross-sectional study including RA patients meeting the 2010 ACR/EULAR criteria while taking MTX. Intolerance to this treatment was assessed using the "MISS" (Methotrexate Intolerance Severity Score), and logistic regression was used to determine predictive factors. SPSS 26 was used for statistical analysis.
Results: 57 patients were collected: 53 women and 4 men with a mean age of 51.53 ± 10.58 [29–72 years]. The mean disease duration was 12.11 years ± 6.12 [3–30 years], with 73.7% of patients being immunopositive. The DAS28-ESR showed remission in 10.5%, low disease activity in 70.2%, moderate disease activity in 17.5%, and high disease activity in 1.8%. HAQ score was <0.5 in 54.4%, between 0.5 and 1 in 28.1%, and between 1 and 3 in 17.5%. All patients were receiving methotrexate (MTX): the mean dose was 19.3 mg/week for 7.47 ± 3.16 [2–15 years], administered orally in 40.4% and by injection in 59.6%, combined with folic acid in isodose form in 94.7%. The mean time to switch to injectable was 2.57± 3.02. Patients were simultaneously receiving corticosteroids in 49.1%, NSAIDs in 24.6% and biologics in 36.8%. The MISS score was 6.53 ± 4.83 [0–20], indicating good tolerance (score=0) in 17.5%, mild intolerance (score 1–5) in 26.7%, moderate intolerance (score 6–10) in 36.8%, and severe intolerance (score 11–36) in 19.3% of patients. Severe intolerance was characterized by abdominal pain in 21.1%, nausea in 56.1%, fatigue in 52.6%, crying spells in 15.8%, and irritability and/or aversion to the drug in 54.4%. Liver function tests were abnormal in 7% and hematological function tests in 24.6%. A statistically significant relationship was found between a MISS score ≥ 6 and sex (p = 0.05), age (p = 0.02), HAQ score (p = 0.011), route of administration (p = 0.003) favoring the oral intake (34% vs. 66%), duration of use (p = 0.025), and use of biologics (p = 0.017). In contrast, disease duration, DAS28 score, MTX and/or folic acid dose, and use of corticosteroids and/or NSAIDs did not appear to be predictive factors for intolerance.
Conclusion: MTX intolerance is a fact, with the psycho-behavioral component playing the dominant role. MISS should be used more frequently in consultations to predict individuals likely to experience intolerance and thus identify candidates eligible for therapeutic education sessions. The association with bDMARD use likely suggested an easy recourse to biologics due to poor adherence to maintenance therapy.

P1441

IS LOW APPENDICULAR LEAN MASS A FRAX-INDEPENDENT PREDICTOR FOR FRACTURE AFTER ACCOUNTING FOR PRIOR FALLS AND COMPETING MORTALITY?

S. Aftabi[1,2], M. R. Alexiuk[3,4], N. Tangri[3,4], E. V. McCloskey[5], H. Johansson[6], N. C. Harvey[7,8], J. A. Kanis[5,9], W. D. Leslie[4]

[1]Department of Physics and Astronomy, University of Manitoba, Winnipeg, Canada; [2]Division of Medical Physics, CancerCare Manitoba, Winnipeg, Canada; [3]Chronic Disease Innovation Centre, Winnipeg, Canada; [4]University of Manitoba, Winnipeg, Canada; [5]Centre for Metabolic Bone Diseases, University of Sheffield Medical School, Sheffield, United Kingdom; [6]Sahlgrenska Osteoporosis Centre, Institute of Medicine, University of Gothenburg, Gothenburg, Sweden; [7]MRC Lifecourse Epidemiology Centre, University of Southampton, Southampton, United Kingdom; [8]NIHR Southampton Biomedical Research Centre, University of Southampton and University Hospital Southampton NHS Foundation Trust, Southampton, United Kingdom; [9]Department of Medicine, School of Clinical Sciences, Monash University, Clayton, Australia

Objective: To determine whether low appendicular lean mass (ALM) consistent with sarcopenia (EWGSOP2) predicts major osteoporotic fracture (MOF), hip fracture, and any clinical fracture independently from FRAX-derived fracture probability.
Methods: We conducted a population-based retrospective cohort study of adults aged ≥50 years undergoing dual-energy X-ray absorptiometry (DXA) in Manitoba, Canada (1999–2017). ALM was estimated from spine and hip DXA using a validated algorithm, and categorized as low or normal according to EWGSOP2 criteria. We estimated hazard ratios (HR) for low (versus normal) ALM from Cox models, sequentially adjusting for FRAX probability with bone mineral density (BMD) and self-reported prior-year falls. Competing mortality was considered using Fine-Gray subdistribution hazard regression (SHR). FRAX calibration was assessed by comparing predicted and observed 10-year fracture probabilities across risk quintiles, accounting for competing mortality.
Results The cohort included 69,554 individuals (mean age 65.6 years; 89.9% women), of whom 10.9% had low ALM. After adjustment for FRAX probability, low ALM was associated with higher risk for MOF (HR 1.31), hip fracture (HR 1.27), any clinical fracture (HR 1.29) and even more strongly with death (HR 1.66), without significant sex differences (all p-interaction >0.1). The effect of low ALM was similar when further adjusted for fall history (HR MOF 1.39, hip 1.32, any fracture 1.36, death 1.97, respectively) but was attenuated after accounting for competing mortality (Fine-Gray SHR MOF 1.18, hip 1.11, any fracture 1.16, respectively). FRAX demonstrated good calibration in individuals with and without low ALM for MOF (both slopes 0.95) and hip fracture (slopes 1.00 and 1.14, respectively), although predicted and observed fracture probabilities were higher in those with low ALM within all risk quintiles.
Conclusion: Low ALM consistent with sarcopenia is a FRAX-independent risk factor for fracture independent of self-reported falls, but observed associations are attenuated after accounting for competing mortality. FRAX showed good calibration across risk strata in those with and without low ALM.

P1442

SPINE AGE DERIVED FROM DXA VFA IMAGES PREDICTS FALL-ASSOCIATED HOSPITALIZATION: THE MANITOBA BONE MINERAL DENSITY REGISTRY

S. Aftabi[1,2], S. Cho[3,4], S. N. Morin[5], C. Ye[6], B. A. Monchka[7], D. Kimelman[8], N. Hong[4,9], W. D. Leslie[10]

[1]Department of Physics and Astronomy, University of Manitoba, Winnipeg, Canada; [2]Division of Medical Physics, CancerCare Manitoba, Winnipeg, Canada; [3]Department of Biomedical Systems Informatics, Yonsei University College of Medicine, Seoul, South Korea; [4]Institute for Innovation in Digital Healthcare (IIDH), Yonsei University Health System, Seoul, South Korea; [5]McGill University, Montreal, Canada; [6]University of Alberta, Edmonton, Canada; [7]George & Fay Yee Centre for Healthcare Innovation, University of Manitoba, Winnipeg, Canada; [8]Department of Radiology, University of Manitoba, Winnipeg, Canada; [9]Department of Internal Medicine, Endocrine Research Institute, Severance Hospital, Yonsei University College of Medicine, Seoul, South Korea; [10]Department of Internal Medicine, University of Manitoba, Winnipeg, Canada

Objective: Biological age, which reflects heterogeneity in the aging process, may offer greater predictive value for health outcomes than chronological age. We investigated whether accelerated spine aging, estimated from dual-energy x-ray absorptiometry (DXA) vertebral fracture assessment (VFA) using deep learning, predicts fall-related hospitalization independently of chronological age and other covariates.
Methods: Among 27,601 adults aged ≥50 years who underwent DXA VFA in Manitoba, Canada (2010–2023), a pre-trained model was fine-tuned using 20% randomly sampled scans. Predicted spine age difference (PAD) was defined as predicted spine age minus chronological age. Among the remaining 80%, 8,810 individuals completed DXA VFA before 2018 and had linkage with population-based administrative data including hospital records for ascertaining any fall-associated hospitalization during follow-up through 2018.
Results: During a mean follow-up of 3.9 years, 758 fall-associated hospitalizations were identified. Spine age positively correlated with chronological age (r=0.89), with a mean difference of 0.0 years (SD=3.4). Spine age was more strongly associated with fall-associated hospitalizations than chronological age (area under the curve 0.693 versus 0.657, respectively; difference = 0.026, p<0.001). Individuals with PAD greater than 1 SD (accelerated spine age) had a 2-fold higher risk of outcome compared to those with PAD < 1 SD, after adjustment for chronological age and sex (adjusted hazard ratio [aHR] 2.04, p<0.001). Each SD increase in PAD was associated with increased risk of fall-associated hospitalization (HR 1.28, 95% CI 1.19 to 1.37, p<0.001), which was independent of age, sex, body mass index, radiographically confirmed vertebral fracture, nonvertebral fracture history, spine degenerative/structural artifact, and femoral neck BMD (aHR 1.17, 95% CI 1.09 to 1.27, p<0.001). The association remained robust after excluding individuals with fall-associated hospitalization in the last 3 years or self-reported fall within the last year (aHR 1.24, p=0.005) and when death was considered as a competing risk (Fine-Gray HR 1.14, p=0.001).
Conclusion: Accelerated spine aging detected from DXA VFA predicts fall-associated hospitalization independently of chronological age, multiple covariates and previous falls, supporting its potential to both enhance fracture risk assessment and identify additional aging-related health outcomes.

P1443

DEEP LEARNING-BASED FRACTURE RISK PREDICTION USING ONLY DXA HIP IMAGES: COMPARISON WITH FRAX

S. Aftabi[1,2], D. Kimelman[3], B. A. Monchka[4], S. Pistorius[1,3], W. D. Leslie[5]

[1]Department of Physics and Astronomy, University of Manitoba, Winnipeg, Canada; [2]Division of Medical Physics, CancerCare Manitoba, Winnipeg, Canada; [3]Department of Radiology, University of Manitoba, Winnipeg, Canada; [4]College of Community and Global Health, University of Manitoba, Winnipeg, Canada; [5]Department of Internal Medicine, University of Manitoba, Winnipeg, Canada

Objectives: Can deep learning (DL) models trained exclusively on Dual-Energy X-ray Absorptiometry (DXA) hip images achieve fracture risk prediction comparable to FRAX™ with Bone Mineral Density (BMD)?
Methods: We conducted a population-based retrospective cohort study of adults aged 40-90 years undergoing baseline hip DXA on GE Healthcare systems in Manitoba, Canada (1999-2018). Data were split into training (70%), validation (10%), and test (20%) cohorts with similar event rates (hip 2.8%, major osteoporotic fracture [MOF] 9.3%, any fracture 12.5%). Seven DL models (convolutional neural networks and transformers) were trained on hip DXA images, using a Cox proportional hazards loss and patient-level ensembling across 5 random seeds. Sampling and model selections were performed on the validation set using a hierarchical framework based on integrated Brier score adjusted for inverse probability of censoring weighting (IBS-IPCW), 10-year calibration error, and 10-year discrimination. Test set performance was compared with FRAX™+BMD using paired bootstrap analyses.
Results: The cohort included 79,748 adults (mean age 64.7 years; 90.2% women; mean follow-up 8.65 years). For hip fracture prediction, the DL model achieved a 10-year time-dependent area under the curve (tAUC) of 0.809 (95% CI 0.786:0.831), comparable to FRAX™+BMD (0.806, 95% CI 0.784:0.826; ΔtAUC 0.003, 95% CI −0.013:0.020). For MOF, the DL model outperformed FRAX™+BMD at 10 years (0.717 [0.702:0.732] vs 0.698 [0.683:0.713]; ΔtAUC 0.019, 95% CI 0.006:0.032) and at 5 years (ΔtAUC 0.038). For any fracture, the DL model exceeded FRAX™+BMD at 10 years (0.706 [0.691–0.719] vs 0.684 [0.669–0.699]; ΔtAUC 0.022, 95% CI 0.010–0.034) and at 5 years (ΔtAUC 0.034). At 2 years, differences were not statistically significant. Calibration plots showed agreement between predicted and observed risk at 2, 5, and 10 years, with acceptable 10-year calibration (mean absolute error ≈ 0.011 hip, 0.038 MOF, 0.045 any fracture). Kaplan-Meier curves demonstrated clear risk-stratified separation.
Conclusions: DL models trained solely on baseline hip DXA images matched FRAX™+BMD for hip fracture prediction and significantly outperformed FRAX™+BMD for predicting MOF and any fracture. These findings highlight the prognostic value of DXA images beyond BMD and support image-based DL approaches for fracture risk prediction. Independent external validation is ongoing.

P1444

TEMPORAL PATTERNS IN LABORATORY-MEASURED TESTOSTERONE LEVELS IN ADULT MEN: IMPLICATIONS FOR MALE SKELETAL HEALTH

S. Ahmed[1], M. Imran[2], I. Siddiqui[1]

[1]Section of Chemical Pathology, Department of Pathology and Laboratory Medicine, Aga Khan University, Karachi, Pakistan, Karachi, Pakistan; [2]Aga Khan University, Karachi, Pakistan, Karachi, Pakistan

Aim:
This study examines temporal trends in laboratory-measured testosterone test results in adult men and explores their relevance to bone health and fracture risk.
Methods:
A retrospective, repeated cross-sectional analysis was conducted using a large clinical laboratory database comprising 104,559 serum testosterone test results from adult men aged ≥18 years, collected between 2008 and 2025. Annual distributions were evaluated using descriptive statistics. Lower-quantile exposure (10th and 25th percentiles), the prevalence of testosterone levels <300 ng/dL, and age-by-year heatmap analyses were used to identify bone-relevant hormonal vulnerability across the adult life course.
Results:
Mean serum testosterone levels demonstrated marked inter-year variability rather than a monotonic decline, with calendar year explaining minimal overall variance. However, lower-quantile testosterone values remained persistently low across the study period, indicating sustained exposure to bone-adverse hormonal ranges in a substantial subgroup of men. Approximately 35–40% of adult men consistently exhibited testosterone levels <300 ng/dL across multiple years. Age-by-year heatmap analysis revealed considerable overlap in testosterone distributions between younger and older men, suggesting that hormonal vulnerability relevant to bone health is not confined to advanced age.
Conclusion:
Despite apparent stability in population mean testosterone levels, a large proportion of adult men experience chronic exposure to testosterone concentrations associated with impaired bone health and increased fracture risk. These findings highlight laboratory testosterone testing as an underutilized marker for identifying male skeletal risk and support a life-course approach to fracture prevention in men.

P1445

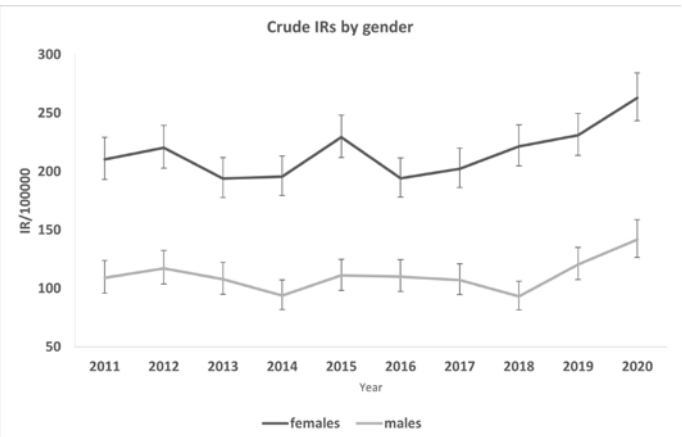
OCCULT MONOCLONAL GAMMOPATHY IN MEN: IMPLICATIONS FOR SECONDARY OSTEOPOROSIS FROM A 15-YEAR REAL-WORLD LABORATORY COHORT

S. Ahmed[1], S. B. Hashmi[1], I. Siddiqui[1]

[1]Section of Chemical Pathology, Department of Pathology and Laboratory Medicine, Aga Khan University, Karachi, Pakistan, Karachi, Pakistan

Background: Male osteoporosis is frequently underdiagnosed and often attributed to primary or age-related bone loss. Plasma cell dyscrasias, including monoclonal gammopathy of undetermined significance and early multiple myeloma, are increasingly recognized contributors to skeletal fragility in men. However, subtle laboratory abnormalities on protein electrophoresis may delay recognition.
Objective: To evaluate the burden and diagnostic patterns of monoclonal gammopathy in men undergoing serum and urine protein electrophoresis and to explore their relevance to male bone health.
Methods: We conducted a retrospective laboratory-based analysis of serum and urine protein electrophoresis data collected between 2008 and 2023, comprising 29,448 unique diagnostic episodes. Monoclonal gammopathy was identified based on electrophoretic patterns and confirmed by immunofixation. Age- and sex-stratified analyses were performed, and multivariable logistic regression was used to identify predictors of monoclonal detection, with emphasis on subtle findings.
Results: Monoclonal gammopathy was identified in 32.7% of diagnostic episodes. Men had a significantly higher likelihood of monoclonal protein detection compared with women. Among 1,445 episodes reporting a faint band on electrophoresis, 712 (49.3%) were confirmed as true monoclonal gammopathy on immunofixation. Light-chain–only disease constituted a disproportionate share of these subtle findings.
Conclusion: Nearly half of faint monoclonal bands represent true clonal disease, with clear male predominance. These findings have important implications for male bone health, suggesting that occult monoclonal gammopathy may represent an underrecognized cause of secondary osteoporosis. Screening strategies for men with unexplained low bone mass or fragility fractures should include protein electrophoresis, supported by reflex immunofixation and urine studies when abnormalities are detected.

P1446



SECULAR TRENDS IN HIP FRACTURE INCIDENCE RATES IN LEBANON, 2011-2020

S. Ajjour[1], Z. Mahfoud[2], J. Makouk[3], A. Sibai[1], G. El-Hajj Fuleihan[1]

[1]American University of Beirut, Beirut, Lebanon; [2]Weill Cornell, Doha, Qatar; [3]Ministry of Public Health, Beirut, Lebanon

Objectives: To estimate national hip fracture incidence rates (IRs) in Lebanon from 2011–2020 using Ministry of Public Health data and to standardize rates to United Nations (UN) world population estimates.
Methods: We analyzed data from the Ministry of Public Health hip fracture registry, using combined ICD diagnosis codes and CPT procedure codes for case identification and confirmation. We calculated age- and sex-specific hip fracture IRs among adults aged ≥50 years. We assessed secular trends using Kendall's tau-b (τb) test correlation between year and annual IRs, and estimated the annual percent change (APC) using log-linear regression. Age-standardized rates were calculated using direct standardization to the UN 2020 world estimates.
Results: Between 2011 and 2020, we identified 8,189 hip fractures among Lebanese adults aged ≥50 years, with women accounting for approximately two-thirds of cases. Annual crude hip IRs per 100,000 ranged from 194 (95% CI [178-212]) to 263 [244-284] in women and from 93 [82-106] to 142 [127-159] in men. Incidence increased steeply with advancing age in both sexes and was highest in individuals aged ≥80 years, with higher rates in women. UN age-standardized rates ranged from 197 [179-214] to 267 [246-288] per 100,000 in women and 62 [54-70] to 94 [83-105] per 100,000 in men. The women-to-men incidence rate ratio averaged 1.4 (range 1.2-1.5) for crude rates and 2.9 (range 2.3–3.4) for age-standardized rates. Kendall's tau analysis showed no statistically significant monotonic secular trend in hip fracture incidence over time in either sex, with a weak positive association in women ($\tau = 0.47$, $p = 0.06$) and men ($\tau = 0.11$, $p = 0.66$). However, a significant short-term increase in incidence was observed among women during 2017–2020 while no significant trends were detected among men.
Conclusion: Hip fracture incidence in Lebanon remains relatively stable, consistently greater in women than men, with a steep age-related increase in both sexes. Compared with international data, Lebanese rates were in the upper-middle global range for women and the lower-middle range for men, with sex differences consistent with global patterns. These updated, national estimates provide essential evidence to support calibration of the FRAX Lebanon calculator and guide national osteoporosis guidelines.

Figure: Crude IRs by gender and year 2011-2020

P1447

FRACTURE LIAISON SERVICE AND BONE HEALTH; A SCIENTOMETRIC STUDY

O. Tabatabaei-Malazy[1], S. Akbarpour[2], B. Larijani[3]

[1]Non-Communicable Diseases Research Center, Endocrinology and Metabolism Population Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran; [2]Non-Communicable Diseases Research Center, Endocrinology and Metabolism Population Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran; [3]Endocrinology and Metabolism Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran

Objective: Fractures have become huge public health burden and mortality rate. Fracture Liaison Service (FLS) is established to prevent future fractures and mortality rate following the fracture. We conducted a scientometric analysis of scholarly publications over the past 15 years in field of FLS and its impact on bone health.
Material and Methods: We carried out a bibliometric study through a comprehensive search of Scopus database up to 20 Dec. 2025. We identified publication trend, the most productive countries and University, main journals, and the most prominent subject areas in the field. Bibliometric analysis was conducted by "analyze results" tool available in Scopus.
Results: After assessing 165 records, 93 relevant studies were included in the analysis. The highest number of publications was in 2025 (n=15, 16.13%). Main type of the papers was original articles (n=78, 83.9%). Netherlands (n=16, 17.20%), UK (n=15, 16.13%), and the US (n=14, 15.05%) were ranked as top three productive countries. The main subject area of the published papers was "medicine" (n=90, 96.77%), followed by " Biochemistry, Genetics and Molecular Biology" area (n=12, 12.90%). Among total citation number (1,903), the highest cited paper (222, 11.66%) was a research article entitled “Fracture liaison services for the evaluation and management of patients with osteoporotic fracture: A cost-effectiveness evaluation based on data collected over 8 years of service provision", published in “Osteoporosis International", 2011, with an impact factor: 3.1. Top ranked University in producing the related documents was different institutes from “Maastricht University”, Netherlands.
Conclusions: There is a large research output in field of FLS and bone health with a leading position for Netherlands as top productive country. Medicine-related journals were the main source which published the scientific papers in the studied field.

A DOSE–RESPONSE RELATIONSHIP BETWEEN BODY MASS INDEX AND FALL RISK: EVIDENCE FROM A NATIONALLY REPRESENTATIVE IRANIAN COHORT STUDY

M. Khojasteh[1], P. Zarepour[2], Y. Azizpour[3], S. Akbarpour[1]

[1]Non-Communicable Diseases Research Center, Endocrinology and Metabolism Population Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran; [2]Epidemiology and Biostatistics Department, School of Public Health, Tehran University of Medical Sciences, Tehran, Iran; [3]Endocrinology and Metabolism Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran

Background: Falls are a major contributor to injury and disability and may be influenced by body composition and excess body weight. While obesity has been linked to impaired balance and mobility, evidence on the dose–response relationship between body mass index (BMI) and fall risk in nationally representative populations is limited.
Methods: This prospective cohort study utilized nationally representative data from the STEPS 2021 survey in Iran with a four-year follow-up. A total of 8,625 adults were included in the analysis. BMI was measured at baseline and calculated as weight in kilograms divided by height in meters squared (kg/m²). Participants were categorized as underweight (<18.5), normal weight (≥18.5 to <25), overweight (≥25 to <30), or obese (≥30), based on World Health Organization criteria. Incident falls were assessed using a self-reported history of falls within the previous year at follow-up. Weighted analyses were conducted to ensure national representativeness. The association between BMI categories and fall occurrence was evaluated using the chi-square test, and 95% confidence intervals (CIs) were reported. All analyses were performed using Stata software.
Results: Overall, 55.13% of participants were female. The prevalence of falls increased progressively across BMI categories, from 1.42% (95% CI: 0.57–3.52) among underweight individuals to 3.84% (95% CI: 3.12–4.72) in normal-weight, 4.47% (95% CI: 3.73–5.34) in overweight, and 5.10% (95% CI: 4.17–6.22) in obese participants. A statistically significant association was observed between BMI category and fall occurrence (P = 0.022), indicating a dose–response pattern.
Conclusion: Higher BMI was associated with an increased risk of falls in a graded manner at the population level. These findings highlight excess body weight as a potential modifiable risk factor for falls and support the inclusion of weight management strategies in fall prevention programs.
Keywords: BMI, Obesity, Osteoporosis, Fall Risk, Iran

KIDNEY FUNCTION DECLINE AND INCIDENT FALLS: A LINEAR DOSE-RESPONSE ANALYSIS IN A NATIONAL POPULATION

S. Salehi[1], A. Gharajeh[2], Y. Azizpour[3], S. Akbarpour[1]

[1]Non-Communicable Diseases Research Center, Endocrinology and Metabolism Population Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran; [2]Epidemiology and Biostatistics Department, School of Public Health, Tehran University of Medical Sciences, Tehran, Iran; [3]Endocrinology and Metabolism Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran

Background: Falls are a significant public health problem and are influenced by chronic conditions that impair physical function. Chronic kidney disease (CKD) may increase fall risk through progressive decline in kidney function; however, evidence on the linear relationship between estimated glomerular filtration rate (eGFR) and falls in nationally representative populations is limited.
Methods: This prospective cohort study used nationally representative data from the STEPS 2021 survey in Iran with a four-year follow-up. A total of 6,219 adults were included. CKD was defined as an eGFR < 60 mL/min/1.73 m² using the 2021 CKD-EPI creatinine equation and/or a urinary albumin-to-creatinine ratio (UACR) ≥ 30 mg/g. Incident falls were assessed using a self-reported history of falls within the previous year at follow-up. Weighted analyses were conducted to ensure national representativeness. The association between CKD status and falls was assessed using the chi-square test, while the linear relationship between eGFR and falls was examined using Pearson correlation. All analyses were performed using Stata, and 95% confidence intervals (CIs) were reported.
Results: Overall, 55.26% of participants were female. A weak but statistically significant inverse linear correlation was observed between eGFR and incident falls (r = −0.0699, P < 0.001), indicating a lower fall risk with higher kidney function. Among participants with CKD at baseline (n = 728), 6.46% (95% CI: 4.51–9.17) reported falls, compared with 4.52% (95% CI: 3.92–5.21) among those without CKD (P = 0.069).
Conclusion: Higher kidney function was linearly associated with a lower risk of falls at the population level, despite the modest strength of the association. These findings suggest that even mild reductions in eGFR may contribute to fall risk and should be considered in population-based fall prevention strategies.

P1450

THE IMPACT OF CARDIOMETABOLIC MULTIMORBIDITY ON FALL RISK: A PROSPECTIVE NATIONAL INVESTIGATION

P. Zarepour[1], M. Khojasteh[2], H. Ataei-Goujani[1], S. Akbarpour[1]

[1]Non-Communicable Diseases Research Center, Endocrinology and Metabolism Population Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran; [2]Endocrinology and Metabolism Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran

Introduction: Cardiometabolic multimorbidity—the co-occurrence of two or more conditions such as cardiovascular disease, diabetes, chronic kidney disease, hypertension, or cancer—is a growing public health challenge in Iran. Despite its clinical significance, the association with functional outcomes, such as fall risk, remains underexplored in nationally representative cohorts. This study investigates the prospective relationship between cardiometabolic multimorbidity and falls using the national IRAN-STEPS Follow-Up Cohort (ISFUC). Method: This is a prospective longitudinal analysis embedded within the ISFUC. The baseline population consists of adults aged 18 years or older who participated in the 2021 national STEPS survey, which collected comprehensive data on demographics, behavioral risk factors, medical history, anthropometrics, and laboratory biomarkers (e.g., fasting glucose, HbA1c, creatinine, blood pressure). From this cohort, we included 5,937 participants with complete data on the conditions of interest and follow-up. Cardiometabolic multimorbidity was defined as the presence of two or more of the following physician-diagnosed conditions: CVD, diabetes, CKD, HTN, or any cancer. Fall incidence in the three past years was assessed via follow-up interviews. The association was evaluated using chi-square tests. Analyses were performed in STATA 18, with a p-value <0.05 considered statistically significant. Results: From a total of 5,937 participants, 56.84% (95% CI: 54.32, 57.36) were female, and 44.16% (95% CI: 42.64, 45.68) were male. Among the participants, 3,461 (58.3%) had no cardiometabolic conditions, 1,508 (25.4%) had one condition, and 968 (16.3%) had multimorbidity (≥2 conditions). The incidence of falls increased progressively with the number of cardiometabolic conditions: 3.39% (95% CI: 2.76, 4.16) among those with no conditions, 5.98% (95% CI: 4.69, 7.60) among those with one condition, and 8.72% (95% CI: 6.80, 11.12) among those with multimorbidity (≥2 conditions). The association between multimorbidity and fall occurrence was statistically significant (p-value <0.001). Conclusion: Cardiometabolic multimorbidity is significantly associated with an increased risk of falls in the Iranian adult population. These findings underscore the importance of integrating fall risk assessment and prevention strategies into the clinical management of individuals with multiple chronic cardiometabolic conditions.
Keywords: Multimorbidity, Diabetes, Osteoporosis, Fall Risk, Iran

CURRENT SMOKING AND EXPOSURE TO SECONDHAND SMOKE IN RELATION TO INCIDENT FALLS: EVIDENCE FROM A NATIONALLY REPRESENTATIVE PROSPECTIVE STUDY IN IRAN

S. Salehi[1], P. Zarepour[2], M. Khojasteh[3], S. Akbarpour[1]

[1]Non-Communicable Diseases Research Center, Endocrinology and Metabolism Population Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran; [2]Epidemiology and Biostatistics Department, School of Public Health, Tehran University of Medical Sciences, Tehran, Iran; [3]Endocrinology and Metabolism Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran

Background: Falls represent an important public health issue and are influenced by behavioral and environmental risk factors. Tobacco use and exposure to secondhand smoke may affect neuromuscular function and balance; however, population-based evidence on their association with falls remains limited, particularly in nationally representative settings. **Methods**: This prospective cohort study used nationally representative data from the STEPS 2021 survey in Iran with a four-year follow-up. A total of 8,648 adults were included. Current smoking status was assessed by self-report at baseline. Exposure to secondhand smoke was defined as reported exposure within the past 30 days at home and/or workplace, with exposure in at least one setting considered positive. Incident falls were assessed using a self-reported history of falls within the previous year at follow-up. Weighted analyses were performed to ensure national representativeness. Associations between smoking status, secondhand smoke exposure, and falls were evaluated using the chi-square test. All analyses were conducted using Stata, and 95% confidence intervals (CIs) were reported. **Results**: Among participants, 55.12% were female. The prevalence of falls was 3.59% (95% CI: 2.59–4.96) among current smokers and 4.42% (95% CI: 3.92–4.98) among non-smokers, with no statistically significant association observed (P = 0.238). Similarly, participants exposed to secondhand smoke had a fall prevalence of 5.90% (95% CI: 4.26–8.11), compared with 4.73% (95% CI: 4.14–5.41) among those without exposure (P = 0.217). No significant differences in fall occurrence were detected across exposure groups. **Conclusion**: In this nationally representative cohort, neither current smoking nor exposure to secondhand smoke was significantly associated with incident falls. These findings suggest that tobacco-related exposures may not play a major role in fall risk at the population level, although further studies using objective exposure measures and longer follow-up periods are warranted. **Keywords**: Smoking, Passive Smoke, Cigarette, Hookah, Osteoporosis, Iran.

TEMPORAL PATTERNS IN OBESITY-ATTRIBUTABLE MUSCULOSKELETAL DISABILITY AND MORTALITY ACROSS THE NORTH AFRICA AND MIDDLE EAST REGION, 1990–2023

N. Behgam[1], S. Badamchizadeh[2], A. Emami Far[3], S. Akbarpour[4]

[1]Non-Communicable Diseases Research Center, Endocrinology and Metabolism Population Sciences Institute , Tehran University of Medical Sciences, Tehran, Iran; [2]Non-Communicable Diseases Research Center, Endocrinology and Metabolism Population Sciences Institute , Tehran University of Medical Sciences, Tehran, Iran, Tehran, Iran; [3]Endocrinology and Metabolism Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran; [4]Non-Communicable Diseases Research Center, Endocrinology and Metabolism Population Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran

Objective: To analyze trends in obesity-attributable disability and mortality for osteoarthritis and low back pain in the North Africa and Middle East region from 1990 to 2023.

Material and Methods: Age-standardized disability-adjusted life year (DALY) and mortality data for osteoarthritis and low back pain attributable to high body mass index (BMI) were obtained from the Global Burden of Disease 2023 study for the region, stratified by year and sex.

Results: The obesity-related musculoskeletal disease burden increased substantially over the study period. The age-standardized DALY rate for osteoarthritis rose from 42.93 to 62.20 per 100,000, with women experiencing higher rates (50.85 to 70.87) than men (35.26 to 53.74). Similarly, low back pain showed a sharp linear increase in DALY rate from 114.37 to 185.55, again disproportionately affecting women (rising from 155.01 to 241.04) compared to men (75.52 to 134.11).

Conclusions: The substantial rise in obesity-related musculoskeletal burden — particularly among women — signals a growing public health challenge for the region. These findings underscore the urgent need for strengthened obesity prevention and management strategies aimed at reducing osteoarthritis and back pain disabilities. Health authorities should prioritize resources and targeted interventions (especially for women) to curb this trend and mitigate future disability and healthcare costs.

P1453

ASYMPTOMATIC MULTIFOCAL OSSEOUS SARCOIDOSIS: THE DIAGNOSTIC VALUE OF PET AND MRI

S. Almeida[1], M. Pontes Ferreira[1], A. Cunha[1], B. D. Carneiro[1], J. Tavares-Costa[1], A. R. Gigante[2], F. Teixeira[1], S. Azevedo[1]

[1]Unidade Local de Saúde do Alto Minho, Ponte de Lima, Portugal; [2]Unidade Local de Saúde do Alto Minho, Viana do Castelo, Portugal

Introduction: Osseous sarcoidosis is a rare manifestation of sarcoidosis, and most patients are asymptomatic. Its reported prevalence ranges from 0.5-30% according to the sensitivity of the imaging modalities used.[1, 2]
Case report: A 47-year-old male with known pulmonary and lymph node sarcoidosis, without musculoskeletal symptoms, was referred to the Rheumatology department due to imaging abnormalities. PET revealed multiple areas of increased uptake, including bone involvement, despite normal findings on plain radiographs and CT. T1-weighted modified Dixon MRI (Fig. 1A–D) showed sacral, iliac, and peritrochanteric lesions with enhancement on fat-suppressed sequences. Calcium-phosphate metabolism was unremarkable. An extensive evaluation to exclude malignancy, including bone biopsy, showed no evidence of neoplasia; however, biopsy of the lesions was not feasible due to technical inaccessibility. In the context of established systemic sarcoidosis, the imaging findings supported the diagnosis of osseous sarcoidosis. The patient will started treatment with prednisolone.
Discussion: Osseous sarcoidosis may affect any bone, most commonly the metacarpals and phalanges of the hands and feet, typically with bilateral distribution. Lesions affecting the spine and pelvis are particularly challenging, as they may mimic metastatic disease and require careful differential diagnosis. Imaging plays a central role in the detection of osseous sarcoidosis. More sensitive imaging techniques, such as MRI and 18F-FDG PET, have been shown to detect bone involvement not identified by conventional radiography or CT. Accurate diagnosis relies on correlation between imaging findings and clinical and laboratory data. Bone biopsy may be required in atypical cases or in the absence of typical extraosseous manifestations.[1,2] Bone involvement in sarcoidosis is most commonly observed in advanced, chronic multiorgan disease. Although osseous lesions are frequently asymptomatic, many patients with bone sarcoidosis receive systemic therapy due to concomitant active involvement of other organs, particularly pulmonary disease. [1] This case highlights the importance of considering osseous sarcoidosis in the differential diagnosis of multifocal bone lesions, particularly in patients with known systemic sarcoidosis.

METHOTREXATE AND BONE HEALTH: WHEN COMMON THERAPY TURNS INTO A RISK

S. Almeida[1], M. Pontes Ferreira[1], A. Cunha[1], B. D. Carneiro[1], J. Tavares-Costa[1], S. Azevedo[1], F. Teixeira[1]

[1]Unidade Local de Saúde do Alto Minho, Ponte de Lima, Portugal

Introduction: Methotrexate (MTX) at doses ≤ 25 mg/week is commonly used as first-line disease-modifying antirheumatic drug in rheumatic diseases such as peripheral psoriatic arthritis.[1,2] MTX osteopathy is a rare adverse effect characterized by the triad of bone pain, osteopenia/osteoporosis, and stress fractures.[3]
Clinical case: A 51-year-old woman presented to the rheumatology department with mechanical bilateral knee pain without trauma. She had been diagnosed with psoriatic arthritis in 2019 and treated with MTX 20 mg/week for four years, with good disease control. Physical examination showed significant tenderness over both tibial plateaus, without visible abnormalities. Radiographs showed bilateral tibial plateau fractures, and magnetic resonance imaging (MRI) confirmed stress fractures in the tibial metaphysis (Figs. 1 and 2). Calcium-phosphate metabolism was normal. Dual-energy X-ray absorptiometry (DXA) demonstrated osteopenia (femoral neck T-score of -2.3, lumbar spine T-score of -1.8). Based on these findings, a diagnosis of MTX osteopathy was established. MTX was discontinued, and treatment with denosumab was initiated. The patient showed marked improvement, with no psoriatic arthritis relapse. Follow-up computed tomography after one year demonstrated near-complete bone healing.
Discussion: Stress fractures due to MTX osteopathy most commonly involve the tibia, followed by the calcaneus.[4] Patients usually present with multiple, bilateral, and sometimes recurrent stress fractures.[5] While DXA frequently shows osteopenia or osteoporosis, typical osteoporotic fractures are rare.[4] MRI is the preferred diagnostic tool due to its high

sensitivity for early and subtle bone changes.[3,5] Characteristic band- or meander-shaped stress fractures along the growth plate (epimetaphyseal osteolysis and band-like sclerosis) are considered pathognomonic.[5] Prognosis is generally favorable after MTX withdrawal. In some cases, anti-osteoporotic drugs, including antiresorptive and osteoanabolic agents, may be used to promote bone healing and improve bone density.[4] This case illustrates MTX osteopathy with bilateral tibial stress fractures, osteopenia, and improvement after MTX discontinuation and anti-osteoporotic treatment.

Conclusion: MTX osteopathy should be considered in patients with unexplained lower limb pain, particularly with no trauma and atypical sites of osteoporotic fractures. Early recognition is essential to prevent complications and guide therapy.

UNEXPECTED DIAGNOSIS OF METASTATIC MELANOMA IN A RHEUMATOID ARTHRITIS PATIENT PRESENTING WITH HIP PAIN

A. Cunha[1], M. P. Ferreira[1], S. Almeida[1], B. D. Carneiro[1], J. Tavares-Costa[1], D. Peixoto[1]

[1]Rheumatology Department, Unidade Local de Saúde do Alto Minho, Ponte de Lima, Portugal

Objective: To present a case in which hip pain in a patient with rheumatoid arthritis led to the diagnosis of metastatic melanoma.

Methods: Clinical, imaging and histopathology data were retrospectively reviewed.

Results: A 76-year-old male with a previous diagnosis of rheumatoid arthritis was referred to our rheumatology department for evaluation He was treated with methotrexate 10 mg/week, with inflammatory disease control. At first evaluation, he reported persistent bilateral nocturnal hip pain for the past three months, with only partial response to analgesic therapy. Physical examination showed good general condition, absence of arthritis or deformities, and painless limitation of left hip rotation. Laboratory evaluation was unremarkable. Baseline radiographs revealed a discontinuity of the right ischiopubic ramus, not present on previous imaging (Figure 1). Subsequent bone scintigraphy and pelvic magnetic resonance imaging (MRI) identified a large pelvic mass with bone involvement and additional hypermetabolic skeletal lesions (Figure 2 and 3). Positron emission tomography (PET) demonstrated intense metabolic activity in the pelvic lesion and distant skeletal sites (Figure 4). Biopsy of the pelvic mass revealed histological and molecular features consistent with melanoma, and a BRAF V600E mutation was identified. A diagnosis of metastatic melanoma was established and palliative therapy with encorafenib and binimetinib initiated, resulting in mild metabolic response on recent follow-up PET. The patient remains in good general condition.

Conclusion: This case demonstrates that serious underlying conditions can present with minimal warning or nonspecific musculoskeletal symptoms. In patients with pre-existing rheumatic disease, pain is often attributed to the chronic condition, so maintaining a low threshold for further investigation is essential for timely diagnosis and may be, in some cases, lifesaving.

Figure 1. Pelvic radiograph: discontinuity of the right ischiopubic ramus.

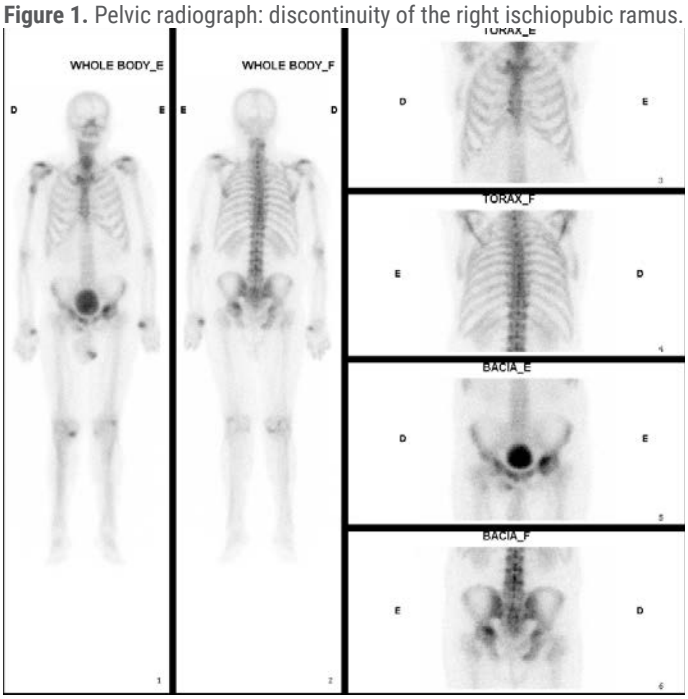

Figure 2. Bone scintigraphy: increased uptake in the ischial and pubic bones, acetabulum, and left humerus.

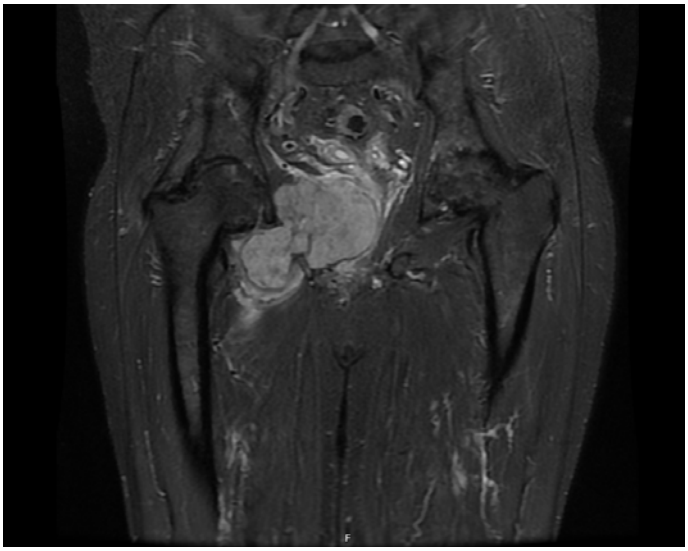

Figure 3. Pelvic MRI: lobulated mass extending into the pelvic cavity and thigh with bone marrow and soft tissue oedema.

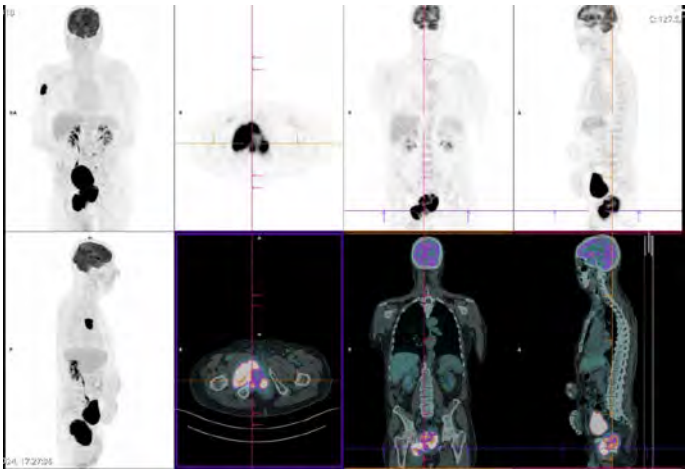

Figure 4. PET scan: intense metabolic activity in the pelvic mass, proximal right humerus and right femoral condyle.

CHRONIC RECURRENT MULTIFOCAL OSTEOMYELITIS: REPORT OF TWO SISTERS

A. Cunha[1], M. P. Ferreira[1], B. D. Carneiro[1], S. Almeida[1], J. Tavares-Costa[1], D. Roriz[2], D. Peixoto[1]

[1]Rheumatology Department, Unidade Local de Saúde do Alto Minho, Ponte de Lima, Portugal; [2]Radiology Department, Unidade Local de Saúde do Alto Minho, Viana do Castelo, Portugal

Objective:
To describe the clinical and imaging features of Chronic Recurrent Multifocal Osteomyelitis (CRMO) in two sisters and discuss potential genetic predisposition in this rare autoinflammatory bone disease.
Methods:
We report two paediatric CRMO cases in siblings followed at a tertiary rheumatology center.
Results:
Case 1: An 11-year-old girl presented with bilateral hip pain of insidious onset and elevated inflammatory markers. Magnetic resonance imaging (MRI) revealed multifocal bone marrow oedema in sacroiliac joints and acetabula with joint effusion (figure 1). CRMO was diagnosed after exclusion of other aetiologies. Nonsteroidal anti-inflammatory drug (NSAID) therapy led to clinical, laboratory, and imaging improvement. Methotrexate was added due to difficulty tapering NSAIDs and later discontinued after stable disease. At 15 years, she remains clinically stable, with follow-up MRI showing decreased oedema.

Case 2: An 8-year-old sister developed acute inflammatory pain in the dorsal right foot, pubic symphysis, and left ankle, partially responsive to NSAIDs. Examination showed localized swelling and tenderness; labs revealed raised inflammatory markers. Whole-body MRI (WB-MRI) demonstrated bone marrow oedema in pubic rami, first right metatarsal, and distal left tibia, with surrounding soft tissue oedema (Figure 2). A concomitant diagnosis of psoriasis was established by Dermatology. Methotrexate resulted in clinical and imaging improvement. At 11 years, she remains stable, with follow-up WB-MRI showing lesion regression and no new foci.

Both sisters were referred for genetic evaluation, which is pending.
Conclusion:
The occurrence of CRMO in two sisters with similar clinical and imaging patterns supports a genetic predisposition. Although most cases are not monogenic, familial aggregation suggests an underlying genetic susceptibility, including non-syndromic forms. Genetic evaluation may contribute to improved understanding of disease mechanisms and support earlier diagnosis and targeted therapeutic strategies.

Fig.1 Multifocal bone marrow oedema in sacroiliac joints and acetabula.

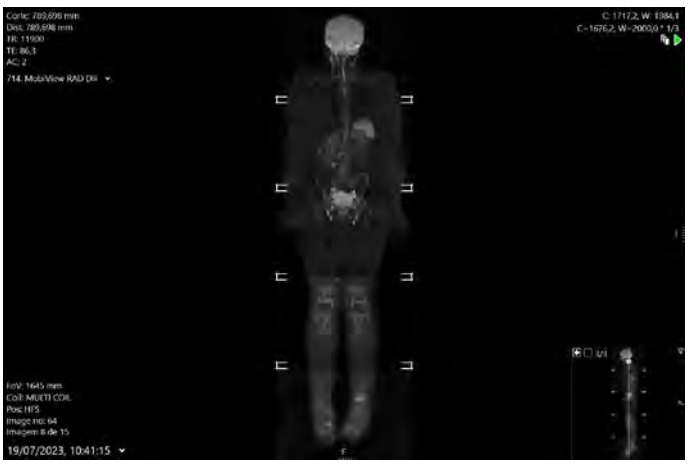

Fig.2 Bone marrow oedema in pubic symphysis, adductor insertions, pubic rami, first right metatarsal, and distal third of the left tibia, associated with soft tissue oedema.

OSTEOPOROSIS AND FRAGILITY FRACTURES IN SYSTEMIC SCLEROSIS: INSIGHTS FROM A SINGLE-CENTER COHORT

S. Amaro Lopes[1], B. M. Fernandes[1], L. Costa[1], R. M. Ferreira[1], G. Terroso[1]

[1]Department of Rheumatology, ULS São João, Porto, Portugal, Porto, Portugal

Objectives: Given the increased susceptibility of systemic sclerosis (SSc) patients to osteoporosis (OP), this study aimed to investigate the clinical determinants and risk factors involved.
Material and methods: This retrospective monocentric study included 144 patients (133 women)- mean age 67.7±12.9years, from the Reuma.pt database. Associations between clinical variables (SSc subtype, overlap syndromes, organ involvement, autoantibodies, treatments) and OP and fractures (overall, fragility, atypical, other sites) were analyzed using SPSS v30 ($p < 0.05$).
Results: OP prevalence was 40.7% (mean age at diagnosis 64.8±8.8years). Among patients with OP, fracture distribution was 32.2% vertebral, 6.8% hip, 3.4% wrist, 1.7% atypical, and 11.9% at other locations.

Anti-topoisomerase I (ATA) was the most robust and consistent independent predictor of bone-related outcomes, significantly increasing the risk of osteoporosis (RR=2.83;95%CI 2.09-3.84,p<0.001), overall fracture (RR=4.76;95%CI: 2.77-8.19,p<0.001) and vertebral fractures (RR=7.08; 95%CI:3.23-15.50,p<0.001).
Furthermore, the use of antidiabetic agents was independently associated with vertebral involvement (RR=7.44; 95%CI: 1.69-32.70,p=0.003), whereas antihypertensive therapy was independentlyassociated with osteoporosis (RR=2.343; 95%CI: 1.11-4.96, p=0.024). Pentoxifylline was associated with increased risk in bivariate analysis, but not after adjustment for serological markers.
Corticosteroid use was not associated with OP or fractures. Most patients received low doses, with 95.8% exposed to ≤ 5 mg/day.
Multivariate analysis confirmed ATA as the strongest independent predictor after adjustment for pharmacological factors (β = −0.39; p < 0.001)
OP was associated with adverse outcomes and reduced survival (RR=1.60; 95%CI:1.09–2.34, p=0.024)
Conclusion: Patients with SSc have a substantially higher OP risk than the general population (40.7% vs. 5.6%). ATA positivity and selected cardiovascular risk factors may support tailored risk stratification.

P1458

WILLINGNESS TO TAKE ANTI-OSTEOPOROSIS MEDICATIONS (AOM) IS VERY HIGH AFTER DOING DEXA SCAN AMONGST THE OLDER ADULTS (OA)

S. B. Bajaj[1]

[1]KEDARMAL BAJAJ FALLS INSTITUTE OF INDIA (KBFII), Nagpur , India

OBJECTIVES : To explain that older adults suffering from osteoporosis , after diagnosis by doing DEXA or after calculating FRAX Plus scores (SOS) , are highly interested in taking AOM . Materials and Methods : The PI at Kedarmal Bajaj Falls Institute of India (KBFII) , have analysed retrospectively the willingness to take Anti -Osteoporosis Medication (AOM), specifically after doing DEXA Scan . The beneficiaries were chosen from 1 Jan 2025 to 31 Dec 2025 from the KBFII registered members . Total 51 people had done the DEXA Scan .
After studying their T-Scores & taking FRAX Plus Scores (SOS) into consideration each one was advised the AOM or no medications etc , as follows :

1. Zoledronic Acid = 12
2. Denosumab (DMAB) = 16
3. Teriparatide (TPTD) = 2
4. TPTD and DMAB (Both) = 1 (Here the T Score was -10.5 at Left Wrist)
5. Oral AOM = 2
6. Refused to take any medication = 9
7. Within normal limits = 8 (No Medications)
8. Lost to follow up = 1

Total = 51 .
RESULTS : Out of total 51 members studied , 33 started taking the advised AOM , which is approximately 65% . In this study 8 members had reports within normal limits and 9 refused to take any treatment . Here the willingness to start AOM , after doing DEXA Scan , was significantly high .

CONCLUSIONS : After doing DEXA Scan and calculating FRAX Plus scores (SOS) , if appropriate advice is given, older adults listen and initiat the AOM .

EFFECTIVENESS OF COMBINED PHYSICAL THERAPY IN IMPROVING FUNCTIONAL STATUS IN PATIENTS WITH KNEE OSTEOARTHRITIS IN A HEALTH CENTER "PROKUPLJE"

S. B. Bačević[1], M. B. Bačević[2]

[1]Health Center "Prokuplje", Niš, Serbia; [2]University Clinical Center Niš, Niš, Serbia

Background: Osteoarthritis of the knee is a leading cause of disability among older adults. Rehabilitation programs in regional centers play a crucial role in improving mobility and reducing pain.

Objectives: To evaluate the effectiveness of a combined rehabilitation protocol (kinesiotherapy + electrotherapy + patient education) in patients with knee osteoarthritis treated at ZC Prokuplje.

Methods: A prospective study included 52 patients (mean age 67 ± 8 years; 38 women, 14 men). All underwent a 4-week program consisting of daily kinesiotherapy sessions, low-frequency electrotherapy, and structured education on joint protection. Outcomes were measured using WOMAC, Timed Up and Go (TUG), and Visual Analogue Scale (VAS) at baseline and post-intervention.

Results: Significant improvements were observed in pain reduction (VAS decreased by 35%, p < 0.01), functional mobility (TUG improved by 2.4 seconds, p < 0.05), and overall WOMAC score (improvement of 28%). Patient-reported adherence to home exercises was 82%.

Conclusion: A structured rehabilitation program in a regional setting significantly improves pain and mobility in knee osteoarthritis patients, highlighting the importance of accessible multidisciplinary care outside tertiary centers.

P1460

QUANTITATIVE PROFILE OF NEUTROPHIL EXTRACELLULAR TRAP FORMATION: ASSOCIATION WITH CLINICAL ACTIVITY IN RHEUMATOID ARTHRITIS

S. Bedina[1], E. Mozgovaya[2], S. Spitsina[1], M. Mamus[2], A. Trofimenko[2], E. Zagorodneva[3], N. Krayushkina[3]

[1]Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky, Volgograd State Medical University, Volgograd, Russia; [2]Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky, Volgograd, Russia; [3]Volgograd State Medical University, Volgograd, Russia

Introduction: Emerging evidence points to neutrophil dysregulation in the immunopathogenesis of rheumatoid arthritis (RA), where neutrophil extracellular traps (NETs) serve as a critical link between innate immunity and autoimmune tissue damage. NETs provide a scaffold for citrullinated autoantigens and sustain inflammation.
Objective: To perform a quantitative analysis of NET generation by assessing both the basal (spontaneous) and inducible (PMA-stimulated) capacity of neutrophils across the clinical activity continuum of RA, from remission to high disease activity.
Materials and Methods: A cohort of 49 RA patients (mean age 44.5 years, disease duration ≤2 years) and 35 demographically matched healthy donors (control group) were enrolled. Clinical phenotyping was performed using the DAS28 index. Peripheral blood neutrophils were isolated by density gradient centrifugation [1, 2]. A standardized fluorescence microscopy assay with dual staining was employed using SYBR Green (nucleic acid) and antibodies against myeloperoxidase (MPO) conjugated with R-phycoerythrin for specific NET identification. NETs were defined as extracellular MPO-positive DNA structures exceeding cell size [3, 4]. The primary assessed parameters were the proportion of neutrophils demonstrating spontaneous NETosis and the proportion of cells responding with NET formation to *in vitro* stimulation with 100 nM PMA.
Results: RA patients exhibited a pronounced, statistically significant ($p<0.0001$) increase in NET formation compared to the control group, indicating a state of neutrophil hyperactivation. NET levels correlated with clinical status. Compared to controls [Spontaneous: 3.9% (95% CI 2.7–5.1); Induced: 12.4% (9.2–15.6)], patients with inactive disease (DAS28<2.6) showed an intermediate increase [6.2% (5.9–6.5) and 27.3% (24.4–30.2), corresponding to a 1.6- and 2.2-fold rise, respectively]. The most pronounced dysregulation was observed in active RA (DAS28>3.2), where spontaneous NET formation increased to 16.9% (16.7–17.1; a 4.3-fold increase) and induced formation to 38.4% (38.1–38.7; a 3.1-fold increase).
Conclusion: This study identifies a profile of NET formation in RA that is linked to clinical activity. The results demonstrate not only elevated basal neutrophil activity but also a significant reserve potential for NET generation. Critically, the persistence of neutrophil hyperactivation even during remission indicates an ongoing subclinical immunopathological process. These findings justify the integration of quantitative NET parameters into the biomarker panel for RA as a novel cell-oriented indicator. Its use may enable a deeper assessment of immunological activity, refine therapeutic targets, and monitor treatment efficacy, complementing traditional clinical scales.

MONOCYTE EXTRACELLULAR TRAPS IN RHEUMATOID ARTHRITIS: FROM REMISSION TO CLINICAL EXACERBATION

S. Bedina[1], E. Mozgovaya[2], S. Spitsina[1], E. Zagorodneva[3], N. Krayushkina[3], M. Mamus[2], A. Trofimenko[2]

[1]Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky, Volgograd State Medical University, Volgograd, Russia; [2]Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky, Volgograd, Russia; [3]Volgograd State Medical University, Volgograd, Russia

Introduction. Chronic inflammation in rheumatoid arthritis (RA) is characterized by a dissociation between clinical remission and the persistent risk of structural progression. The role of monocytes, capable of forming extracellular traps (METs), in maintaining the subclinical immune response is insufficiently studied. We hypothesized that quantitative parameters of MET formation could serve as an indicator of immunological activity, retaining informativeness even upon achieving clinical well-being.
Objective. To conduct a quantitative assessment of spontaneous and induced formation of monocyte extracellular traps (METs) in RA patients to determine their association with clinical disease activity.
Methods. A prospective study included 49 patients with early RA (disease duration ≤2 years, DAS28<2.6 at baseline) and 35 healthy donors as a control group. Monocytes were isolated by centrifugation in an iohexol gradient [1, 2, 3]. The ability to form extracellular traps was assessed using fluorescence microscopy by measuring the proportion of cells forming METs spontaneously and in response to stimulation with PMA (100 nM) [4, 5, 6].
Results. At baseline, all RA patients (n=49) showed a significant ($p<0.0001$) increase in MET formation compared to controls: a 1.6-fold increase in spontaneous formation (8.9% [8.5–9.3] vs. 5.6% [4.4–6.8]) and a 1.5-fold increase in induced formation (26.6% [24.9–28.3] vs. 18.3% [15.6–21.0]). In patients who experienced an exacerbation during follow-up (DAS28>3.2), the values reached a maximum: 18.4% [18.1–18.7] for spontaneous formation (3.3-fold higher than control) and 38.6% [38.4–38.8] for induced formation (2.1-fold higher). In patients who achieved stable clinical remission by the 12th month (DAS28<2.6, n=21) and normalization of CRP (median 3.2 mg/L), MET levels remained stably elevated, practically unchanged from baseline values (spontaneous: 8.4–8.7%, induced: 26.8–27.3%).
Conclusions. Thus, METs represent a novel potential quantitative biomarker reflecting RA activity. The persistence of METs during clinical remission despite normal systemic inflammatory markers indicates sustained subclinical activation of the monocyte compartment and incomplete immunological recovery. Monitoring METs could become an important addition to standard clinical and laboratory criteria, enabling the identification of patients in "immunological" remission versus those with ongoing hidden immune activation and, presumably, a higher risk of progression. This opens prospects for a personalized approach to

assessing therapy efficacy and long-term prognosis in RA.

LEVERAGING ARTIFICIAL INTELLIGENCE AND DIGITAL TOOLS FOR PERSONALIZED PROGNOSIS AND MANAGEMENT IN OSTEOARTHRITIS AND RHEUMATOID ARTHRITIS

S. Bedina[1], E. Zagorodneva[2], N. Krayushkina[2], T. Kvlividze[2], E. Mozgovaya[3], S. Spitsina[1]

[1]Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky, Volgograd State Medical University, Volgograd, Russia; [2]Volgograd State Medical University, Volgograd, Russia; [3]Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky, Volgograd, Russia

Introduction: The transition to precision medicine in rheumatology is underpinned by digital technologies: artificial intelligence (AI), machine learning (ML), and telemedicine. These innovations are fundamentally reshaping diagnostic and therapeutic strategies through their capacity to process multidimensional data, thereby facilitating truly individualized patient management.
Objective: to systematize current evidence on how digital technologies can enhance early diagnosis, predict treatment outcomes, and facilitate dynamic monitoring in osteoarthritis (OA) and rheumatoid arthritis (RA).
Materials and Methods: A comprehensive literature review was conducted using major scientific databases (PubMed, Scopus, Web of Science) for studies published between 2018 and 2025. The search focused on keywords including "artificial intelligence," "machine learning," "digital biomarkers," "wearable devices," "telemedicine," "rheumatoid arthritis," and "osteoarthritis." The review analyzed data from retrospective and prospective cohort studies, clinical trials, and proof-of-concept studies.
Results: The analysis revealed several key findings:

1. Artificial intelligence-based automated analysis of medical imaging is used for early diagnosis and progression assessment. It automatically detects and classifies radiographic features of osteoarthritis (using the Kellgren-Lawrence scale), as well as quantitatively measures synovitis activity and the degree of bone erosions in rheumatoid arthritis on MRI and ultrasound scans. Modern algorithms are capable of solving key diagnostic tasks with accuracy comparable to that of an expert rheumatologist, and in some parameters, even surpassing it.

2. Predictive modeling and algorithm development utilizing big data (from registries and genomic databases) for forecasting individual therapeutic response and complication risk in rheumatoid arthritis (RA), aimed at optimizing the choice of first-line treatment.

3. Remote monitoring technologies, including electronic patient-reported outcomes (ePRO) and wearable devices, provide continuous collection of objective data on disease activity (joint mobility, step count, morning stiffness) in real time. This enables the physician to dynamically assess the patient's condition and manage care beyond the clinical setting.

At the same time, implementation is hindered by a complex of challenges: methodological (validation on quality data), legal (data protection), and organizational (integration into practice).
Conclusion: Personalized treatment of OA and RA is becoming possible thanks to digital technologies: AI for accurate diagnosis and wearables for monitoring. The key remaining tasks are the validation, regulation, and clinical implementation of these tools.

AN EXAMINATION OF PATIENT KNOWLEDGE AND EDUCATION IN PATIENTS WITH OSTEOPOROSIS, OSTEOPENIA, AND NORMAL BONE DENSITY

S. Beg[1], A. Ziyar[2]

[1]University of Central Florida College of Medicine, Rheumatology and Internal Medicine, Orlando, United States; [2]UCF, Orlando, United States

Introduction: Osteoporosis represents a preventable and often treatable condition that is responsible for 1.5 million fractures annually in the United States. Proper patient knowledge represents a crucial aspect of disease management and has potential implications in treatment adherence and lifestyle modification. By examining how much patients know about their own diagnosis, their disease knowledge, and what resources they would like to use, we aim to lay the groundwork for developing efficient patient education resources.
Methods: We surveyed 52 individuals and collected data on demographics, bone density test results, disease knowledge, and educational sources both used and preferred. This was done to learn how much patients know about their condition on a fundamental level.
Results: 50% of participants diagnosed with osteoporosis correctly self-reported their condition, as did 21.1% diagnosed with osteopenia. Between the normal, osteopenia, and osteoporosis groups there were no significant differences between participants' scores on the patient knowledge questionnaire. The resources most used by patients were handouts/brochures and internet/personal research, and patients reported a preference for learning directly from their doctor/nurse.
Conclusion: Most fractures occur in patients with osteopenia because they have not yet been treated or diagnosed. Our study confirms the lack of disease awareness in patients with osteopenia. The observed discrepancy poses a serious health threat since such patients are at risk for disease progression. We confirmed the invaluable role of medical personnel in teaching patients about bone density loss. It is through efficient learning that patients can be empowered to take charge of their health.

P1464

TUBERCULOSIS INFECTION IN CHRONIC INFLAMMATORY RHEUMATIC DISEASES: FREQUENCY AND REACTIVATION UNDER BIOLOGICS

Y. Makhlouf[1], S. Ben Hamouda[1], H. Boussaa[1], S. Miladi[1], A. Fazaa[1], K. Ben Abdelghani[1], A. Laatar[1]

[1]Hôpital Mongi Slim Marsa, Marsa, Tunisia

Introduction :
Biotherapy has revolutionized the management of chronic inflammatory rheumatic diseases (CIRD) by reducing inflammation and structural damage [1]. However, these therapies increase the risk of serious infections, particularly tuberculosis, due to the reactivation of latent infections.

Objective:
The aim of our study was to determine the frequency of tuberculosis in patients with CIRD and to assess the rate of tuberculosis reactivation on biologic therapy.

Methods:
We conducted an 11-year retrospective study of patients with CIRD recruited from the rheumatology department of Mongi Slim Hospital. Sociodemographic and disease activity data were collected. We also collected data related to tuberculosis infection (latent or active) and its management. Additional details such as imaging findings (e.g., CT scans) and microbiological data (e.g., BK testing, interferon-gamma release assay (IGRA)) were also documented.

Results:
The study included 50 patients with CIRD : rheumatoid arthritis (RA) (40%), and spondyloarthritis (60%), with a male-to-female ratio of 1.08. The mean age at diagnosis was 38 years [11-63], with a mean disease duration of 10.7 years [3-24]. The patients' current mean age was 48.8 years [19-77]. The main comorbidities were high blood pressure (14%), diabetes (4%), dyslipidaemia (2%), progressive neoplasia (4%) and inflammatory bowel disease (10%). In terms of therapy, 60% of patients had received treatment with CsDMARDs distributed as follows: Methotrexate (MTX) (12%), MTX and Sulfasalazine (SLZ) (22%), SLZ (8%) and a combination of MTX and leflunomide (10%). The majority of patients (80%) had more than 2 Csdmards. Twenty-four per cent of the patients were on corticosteroids, with a mean dose of 7.95 mg/d [5-15] of prednisone equivalent. The average duration of corticosteroids was 44.6 months [7-84]. The distribution of the different biologics was as follows : Anti-TNFα (62%) : Adalimumab (35.4%), Etanercept (29%), Certolizumab (29%), Golimumab (6.4%), Anti-IL6 (24%), Rituximab (10%), and Jak inihibitors (4%). Prior to initiating biologics, 22% of patients had a positive IGRA. Among these, 27% were diagnosed with tuberculosis, all of which were pulmonary, as confirmed by the presence of BK in sputum samples and thoracic CT scans, and 54.5% had latent tuberculosis treated by chemoprophylaxis. During follow-up, no tuberculosis reactivation was observed. However, 2% of the patients developed peritoneal tuberculosis, which was successfully treated with a 9-month anti-tuberculosis treatment.

Conclusion:
Our study showed a high frequency of latent or active tuberculosis in patients with CIRD, with no reactivation on biologics. However, 2% of them developed tuberculosis while on biotherapy.
This underlines the importance of ongoing monitoring, even after a negative pre-therapy work-up.

[1] Quartuccio L, Zabotti A, Del Zotto S, Zanier L, De Vita S, Valent F. Risk of serious infection among patients receiving biologics for chronic inflammatory diseases: Usefulness of administrative data. J Adv Res. 2018 Sep 19;15:87-93.

P1465

ASSOCIATION BETWEEN SYSTEMIC IMMUNE-INFLAMMATION INDEX AND BONE MINERAL DENSITY IN PATIENTS WITH RHEUMATOID ARTHRITIS

Y. Makhlouf[1], S. Ben Hamouda[1], H. Boussaa[1], S. Miladi[1], A. Fazaa[1], K. Ben Abdelghani[1], A. Laatar[1]

[1]Hôpital Mongi Slim Marsa, Marsa, Tunisia

Introduction Rheumatoid arthritis (RA) is associated with an increased risk of osteoporosis (OP) due to chronic systemic inflammation, disease activity, and prolonged exposure to glucocorticoids (GCs). Identifying simple inflammatory markers reflecting bone involvement may help improve early risk stratification. The systemic immune-inflammation index (SII), derived from routine blood counts, reflects systemic inflammatory burden, but its association with bone mineral density (BMD) in RA remains insufficiently explored.
Objective The objective of this study was to evaluate the association between the systemic immune-inflammation index and bone mineral density in patients with rheumatoid arthritis.
Methods We conducted a cross-sectional study including patients with RA. BMD was assessed by dual-energy X-ray absorptiometry (DXA) at the femoral neck and lumbar spine, and results were expressed as T-scores. OP was defined according to World Health Organization (WHO) criteria (T-score ≤ −2.5).
SII was calculated as (neutrophil count × platelet count) / lymphocyte count. Demographic, clinical, biological, and therapeutic data were collected. Associations between SII and BMD parameters were evaluated using Spearman's rank correlation, and SII values were compared across bone status categories using the Kruskal–Wallis test.
Results The study included 48 patients, with a mean age of 59.5 ± 11.0 years and a marked female predominance (85.4%). The mean disease duration was 10.4 ± 8.5 years. The majority of patients were seropositive (85.4%), with anti-citrullinated protein antibodies (ACPA) and rheumatoid factor (RF) positivity observed in 77.1% and 72.9% of cases, respectively. Structural joint deformities were present in 48.9% of patients. RA was classified as active in 72.9% of patients, , with a mean DAS28-erythrocyte sedimentation rate (DAS28-ESR) of 4.07 ± 1.41, and 72.9% of patients had active disease. Inflammatory markers were elevated, with mean C-reactive protein (CRP) and erythrocyte sedimentation rate (ESR) values of 18.6 ± 22.5 mg/L and 49.9 ± 33.1 mm, respectively.
Regarding treatment, 72.9% of patients were receiving methotrexate (MTX), and 25% were treated with biologic disease-modifying antirheumatic drugs (bDMARDs). GC therapy was used in 75% of patients, most frequently at a daily dose of 5 mg, and 35.7% had received GC bolus therapy. BMD assessment revealed a high prevalence of bone involvement. Mean femoral and vertebral T-scores were −2.13 ± 1.30 and −1.90 ± 1.36, respectively. OP was identified in 57.4% of patients, while 21.3% had osteopenia and 21.3% had normal BMD. The mean SII value was 703,3 ± 474,8. SII was significantly and inversely correlated with femoral T-score (Spearman's ρ = −0.436, p = 0.002) and vertebral T-score (ρ = −0.334, p = 0.022).
Patients with OP tended to have higher SII values compared to those with osteopenia, although the difference did not reach statistical significance (p = 0.077).

Conclusion
In patients with RA, higher SII values are associated with lower BMD at both femoral and vertebral sites. As a simple and low-cost biomarker, SII may help identify RA patients at increased risk of OP, particularly in settings where access to advanced investigations is limited. Prospective studies are needed to confirm its role in clinical practice.

P1466

IS THE NUTRITION–INFLAMMATION INDEX A PREDICTOR OF BONE HEALTH IN RHEUMATOID ARTHRITIS?

Y. Makhlouf[1], S. Ben Hamouda[1], H. Boussaa[1], S. Miladi[1], A. Fazaa[1], A. Laatar[1]

[1]Hôpital Mongi Slim Marsa, Marsa, Tunisia

Introduction
Rheumatoid arthritis (RA) is a chronic inflammatory disease associated with systemic complications, including anemia and bone loss. Conventional inflammatory markers may not fully reflect the combined impact of inflammation and nutritional status. The C-reactive protein to albumin ratio (CAR) has emerged as a practical composite marker of systemic inflammation. Its relationship with disease activity and bone health in patients with RA remains insufficiently characterized.
Objective
To evaluate the association between CAR, disease activity, and bone health in patients with rheumatoid arthritis.
Methods
We conducted a cross-sectional study including patients with established RA. Clinical, biological, and densitometric data were collected. Disease activity was assessed using DAS28-ESR. Bone mineral density (BMD) was measured at the femoral and vertebral sites by DXA and categorized as normal, osteopenia, or osteoporosis. Fragility fractures were recorded. The CAR index was calculated as CRP (mg/L) divided by serum albumin (g/L). Correlations were assessed using Spearman's rank correlation coefficient. Comparisons between groups were performed using Mann–Whitney or Fisher's exact test, as appropriate.
Results
The study population consisted of 48 patients, predominantly postmenopausal women (85.4%), with a mean age of 59.5 ± 11.0 years and a mean disease duration of 124.8 ± 101.5 months. Eighty-five percent of patients were seropositive for rheumatoid factor and/or ACPA. Mean DAS28-ESR was 4.07 ± 1.41, indicating moderate to high disease activity. Osteoporosis was present in 56.3% of patients, osteopenia in 21.3%, and normal BMD in 21.3%. Fragility fractures were observed in 26.8% of patients.The mean CAR was 0.72 ± 0.90. CAR showed a significant positive correlation with disease activity (DAS28-ESR: r = 0.524, p = 0.001). However, The CAR index was not significantly correlated with femoral BMD (r = −0.158, p = 0.366) or vertebral BMD (r = −0.207, p = 0.232). Similarly, there were no differences between CAR in patients with and without fractures (Mann–Whitney test, p = 0.617).
Conclusion
The CAR index was strongly associated with disease activity but not with BMD or fragility fractures. These findings suggest that CAR primarily reflects systemic inflammatory burden rather than bone involvement.

P1467

ANEMIA IN RA : A CAUSE OR CONSEQUENCE OF INFLAMMATION ?

Y. Makhlouf[1], S. Ben Hamouda[1], H. Boussaa[1], S. Miladi[1], A. Fazaa[1], K. Ben Abdelghani[1], A. Laatar[1]

[1]Hôpital Mongi Slim Marsa, Marsa, Tunisia

Introduction
Anemia is a frequent extra-articular manifestation of rheumatoid arthritis (RA) and is mainly driven by chronic inflammation. However, the relationship between hemoglobin (Hb) levels, inflammatory markers, and disease activity remains incompletely characterized in routine clinical practice.
Objectives
To evaluate the association between Hb levels, inflammatory markers, disease activity, and serum albumin in patients with RA, and to identify independent predictors of anemia.
Methods
We conducted a cross-sectional observational study including patients with established RA. Clinical, immunological, and biological data were collected. Disease activity was assessed using the 28-joint Disease Activity Score with erythrocyte sedimentation rate (DAS28-ESR). Nutritional status was assessed using serum albumin and Hb levels. Correlations were assessed using Spearman's rank test. Linear regression analyses were performed to identify predictors of Hb levels.
Results
Forty-eight patients were included. They were predominantly female (85.4%), with a mean age of 59.5 ± 11 years. The mean disease duration was 124.8 ± 101.5 months. Most patients were seropositive for rheumatoid factor (RF) and/or anti-citrullinated protein antibodies (ACPA) (85.4%). The mean DAS28-ESR was 4.07 ± 1.41, reflecting moderate to high disease activity in the majority of patients. The mean Hb level was 12.1 ± 1.8 g/dL.
Hb levels were negatively correlated with C-reactive protein (CRP) (ρ = −0.495, p < 0.001), ESR (ρ = −0.435, p = 0.002), and DAS28-ESR (ρ = −0.352, p = 0.014), and positively correlated with serum albumin (ρ = 0.482, p = 0.003).
In univariate linear regression analysis, ESR was a significant predictor of Hb levels (β = −0.398, p = 0.005), explaining 15.9% of Hb variability. In multivariate analysis, only serum albumin remained independently associated with Hb levels (β = 0.371, p = 0.028), while inflammatory markers and disease activity were no longer significant.
Conclusion
Hb levels in RA are closely associated with inflammatory burden and disease activity, supporting the concept of inflammation-related anemia. Serum albumin was an independent predictor of Hb levels, highlighting the combined role of chronic inflammation and nutritional status in the pathophysiology of anemia in RA. These findings emphasize the importance of comprehensive inflammatory control and nutritional assessment in the management of anemia in RA.

PREVALENCE AND DETERMINANTS OF FRAGILITY FRACTURES IN PATIENTS WITH RHEUMATOID ARTHRITIS

Y. Makhlouf[1], S. Ben Hamouda[1], H. Boussaa[1], S. Miladi[1], A. Fazaa[1], K. Ben Abdelghani[1], A. Laatar[1]

[1]Hôpital Mongi Slim Marsa, Marsa, Tunisia

Introduction:
Rheumatoid arthritis (RA) is associated with an increased risk of osteoporosis and fragility fractures due to chronic inflammation, autoimmune mechanisms, and exposure to glucocorticoids. Data on fracture prevalence and associated factors in RA in Tunisia remain limited.
Objective:
To assess the prevalence of fragility fractures in Tunisian patients with RA and to analyze their association with bone mineral density (BMD), immunological status, treatments, and clinical characteristics.
Methods:
We conducted a cross-sectional study including patients with established RA. Demographic data (age, sex, menopausal status), disease characteristics (serological status, disease duration), treatments , and BMD assessed by dual-energy X-ray absorptiometry were collected. Osteoporosis was defined according to WHO criteria. Fragility fractures were identified clinically and radiologically. Categorical variables were compared using chi-square or Fisher's exact test, and quantitative variables using non-parametric tests. A p-value <0.05 was considered statistically significant.
Results:
The study population included 48 patients, of whom 85.4% were postmenopausal women, with a mean age of 59.5 ± 11.0 years. Eighty-five percent of the patients were seropositive for rheumatoid factor and/or ACPA. Osteoporosis was present in 56.3% of patients, osteopenia in 21.3%, and normal BMD in 21.3%. Regarding bone-protective treatments, bisphosphonates were prescribed in 28.2% of patients.
Fragility fractures were observed in 26.8% of patients with available data. Among fractured patients, 90.9% had osteoporosis and 9.1% had osteopenia, with no fractures occurring in patients with normal BMD. Vertebral fractures were the most frequent (14.6%), followed by wrist fractures (7.3%) and hip fractures (4.9%). Fractures were significantly more frequent in patients with osteoporosis compared to those without osteoporosis (90.9% vs 9.1%, Fisher's exact test p = 0.042).
In the osteopenic patient, the femoral neck T-score was −2.0 SD with a corresponding BMD of 0.773 g/cm², and the lumbar spine T-score was −2.1 SD with a BMD of 0.901 g/cm². Among patients with both osteoporosis and fragility fractures, the mean femoral neck T-score was −3.19 ± 0.60 SD, corresponding to a mean femoral BMD of 0.67 ± 0.13 g/cm². The mean lumbar spine T-score was −2.76 ± 1.22 SD, with a corresponding mean BMD of 0.75 ± 0.12 g/cm².
No significant association was found between fragility fractures and current glucocorticoid use, although most fractured patients were receiving corticosteroids.
Conclusion:
Fragility fractures are frequent in patients with rheumatoid arthritis and are strongly associated with BMD levels.

P1469

MANAGING THE GAP OF OSTEOPOROSIS IN PATIENTS WITH RHEUMATOID ARTHRITIS

Y. Makhlouf[1], S. Ben Hamouda[1], H. Boussaa[1], S. Miladi[1], A. Fazaa[1], K. Ben Abdelghani[1], A. Laatar[1]

[1]Hôpital Mongi Slim Marsa, Marsa, Tunisia

Background
Patients with rheumatoid arthritis (RA) are at increased risk of osteoporosis (OP) and fragility fractures due to chronic inflammation, glucocorticoid exposure, and hormonal factors. International guidelines recommend systematic screening and appropriate anti-osteoporotic treatment in high-risk patients. However, real-life adherence to these recommendations remains uncertain.
Objective
To evaluate the management OP in patients with RA and to identify potential gaps between bone health status and therapeutic interventions.
Methods
We conducted a cross-sectional study including patients with RA. Demographic data (age, sex, menopausal status), disease characteristics, bone mineral density (BMD) assessed by dual-energy X-ray absorptiometry (DEXA), and history of fragility fractures were collected. OP and osteopenia were defined according to WHO criteria. Data on OP management, including bisphosphonate therapy and calcium–vitamin D supplementation were recorded.
Results
The study population included 48 patients, predominantly postmenopausal women (85.4%), with a mean age of 59.5 ± 11.0 years. OP was diagnosed in 56.3% of patients, while 21.3% had osteopenia and 21.3% had normal BMD. Fragility fractures (FF) were identified in 26.8% of patients with available data, mainly vertebral fractures. Calcium and vitamin D supplementation was prescribed at a mean daily dose of 1000 mg and 800 IU, respectively, but use was inconsistent, even among patients with low BMD.Despite the high prevalence of OP and fractures, only 28.2% of patients were receiving bisphosphonate therapy.
Notably, 45.5% of patients with documented FF were not receiving any specific anti-osteoporotic treatment at the time of evaluation.
Conclusion
Our study highlighted the gap in the management of OP among patients with RA . Despite a high prevalence of OP and FF , anti-osteoporotic therapies remain underutilized. These findings emphasize the need for improved implementation of OP screening and treatment strategies in RA, to reduce fracture risk and long-term morbidity.

P1470

PREDICTORS OF OSTEOPOROSIS IN PATIENTS WITH RHEUMATOID ARTHRITIS

Y. Makhlouf[1], S. Ben Hamouda[1], H. Boussaa[1], S. Miladi[1], A. Fazaa[1], K. Ben Abdelghani[1], A. Laatar[1]

[1]Hôpital Mongi Slim Marsa, Marsa, Tunisia

Introduction
Osteoporosis (OP) is a common complication of rheumatoid arthritis (RA), resulting from the combined effects of chronic inflammation, disease activity, hormonal status, and long-term treatments, particularly corticosteroids. Identifying factors associated with OP in RA remains essential for early prevention and optimized management.
Objectives:
To identify clinical, biological, and therapeutic factors associated with OP in patients with RA.
Methods
We conducted a cross-sectional study including 48 patients with RA . Demographic characteristics, disease-related variables, biological parameters, and therapeutic data were collected. Disease activity was assessed using DAS28-VS. Bone mineral density (BMD) was measured at femoral and vertebral sites by dual-energy X-ray absorptiometry, and OM was defined according to WHO criteria. Associations between OM and clinical, biological, and therapeutic variables were evaluated using non-parametric tests. A multivariable logistic regression model was performed to identify independent predictors of OP.
Results
The study population was predominantly female (85.4%), with a mean age of 59.5 ± 11.0 years. Most women were postmenopausal (85.4%). Disease activity was moderate, with a mean DAS28-VS of 4.07 ± 1.41. Corticosteroids were used in 75% of patients, with a mean daily dose of 5 mg, and 35.7% had received corticosteroid boluses. Biologic therapy was prescribed in 25% of patients. Calcium and vitamin D supplementation were administered in 69% and 74% of cases, respectively, while 28.2% received anti-osteoporotic treatment. OP was diagnosed in 56.3% of patients, osteopenia in 20.8%, and normal BMD in 20.8%. The mean femoral and vertebral T-scores were −2.13 ± 1.30 and −1.90 ± 1.36, respectively. In multivariable logistic regression analysis including age, menopausal status, and corticosteroid use, no factor was independently associated with OP. Corticosteroid use showed a trend toward increased risk (OR 3.4, p = 0.14).
Conclusion
In our study OP was highly prevalent despite relatively young age and moderate disease activity. No clinical or therapeutic factor was independently associated with OP in multivariable analysis, although corticosteroid exposure tended to increase the risk.

P1471

PAIN SEVERITY AND INFLAMMATORY MARKERS IN RHEUMATOID ARTHRITIS

Y. Makhlouf[1], S. Ben Hamouda[1], H. Boussaa[1], S. Miladi[1], A. Fazaa[1], K. Ben Abdelghani[1], A. Laatar[1]

[1]Hôpital Mongi Slim Marsa, Marsa, Tunisia

Background
Pain is a major contributor to disability in rheumatoid arthritis (RA) and reflects both inflammatory activity and clinical disease burden. The relationship between pain intensity, inflammatory markers, and disease activity remains complex.
Objectives
To assess the association between pain severity, inflammatory markers, and disease activity in patients with RA.
Methods
We conducted a cross-sectional study including patients with established RA. Pain severity was evaluated using a visual analog scale (VAS). Disease activity was assessed using DAS28-ESR, while inflammatory markers included C-reactive protein (CRP) and erythrocyte sedimentation rate (ESR). Correlations were analyzed using Spearman's rank test, and pain severity was compared between active and inactive disease using the Mann–Whitney U test.
Results
The study population included 48 patients, predominantly female (85.4%), with a mean age of 59.5 ± 11.0 years and a mean disease duration of 124.8 ± 101.5 months. Most patients were seropositive for rheumatoid factor and/or anti-citrullinated protein antibodies (85.4%). The mean DAS28-ESR was 4.07 ± 1.41, indicating moderate to high disease activity. Mean VAS pain score was 4.7 ± 2.3. The mean number of tender joints (NAD) was 5.9 ± 5.1, while the mean number of swollen joints (NAT) was 2.2 ± 3.1. The mean patient global assessment (EGP) was 4.7 ± 2.4. Pain severity was strongly correlated with disease activity assessed by DAS28-ESR ($\rho = 0.539$, $p < 0.001$). In contrast, no significant correlation was observed between pain severity and CRP ($\rho = 0.122$, $p = 0.408$) or ESR ($\rho = 0.108$, $p = 0.465$). Patients with active disease reported significantly higher pain scores compared to those with inactive disease ($p = 0.001$).
Conclusion
Pain severity in RA is strongly associated with clinical disease activity but not with isolated biological inflammatory markers. These findings highlight the importance of comprehensive clinical assessment, beyond laboratory parameters, to adequately evaluate pain and disease burden in RA.

P1472

IMPACT OF SEROLOGICAL STATUS ON DISEASE ACTIVITY IN RHEUMATOID ARTHRITIS

Y. Makhlouf[1], S. Ben Hamouda[1], H. Boussaa[1], S. Miladi[1], A. Fazaa[1], K. Ben Abdelghani[1], A. Laatar[1]

[1]Hôpital Mongi Slim Marsa, Marsa, Tunisia

Introduction
Rheumatoid arthritis (RA) is a chronic inflammatory disease with heterogeneous clinical severity and outcomes. Serological markers such as rheumatoid factor (RF) and anti-citrullinated protein antibodies (ACPA) are key elements in disease classification and prognosis. However, the association between serological status and the clinical phenotype of RA, including disease activity, functional impairment, and structural damage, remains incompletely defined.
Objective
To evaluate the impact of serological status on the clinical phenotype of rheumatoid arthritis.
Patients and Methods
We conducted a cross-sectional study including 48 patients with rheumatoid arthritis. Serological status was assessed using RF and ACPA, and patients were classified as seropositive or seronegative. Disease activity, functional impairment, and structural severity were evaluated using the Disease Activity Score in 28 joints (DAS28-ESR), the Health Assessment Questionnaire (HAQ), and the presence of joint

deformities, respectively.
Comparisons between ACPA status and RA clinical phenotype were performed using non-parametric tests (Mann–Whitney U test) for quantitative variables and Chi-square or Fisher's exact test for qualitative variables. Statistical significance was set at $p < 0.05$.

Results

The study population was predominantly female (85.4%) with a mean age of 59.5 ± 11.0 years. The mean disease duration was 124.8 ± 101.5 months. Seropositivity was observed in 85.4% of patients; ACPA positivity was present in 77.1%, and RF positivity in 72.9%. Regarding treatment, 75.0% of patients were receiving corticosteroid therapy, with a mean daily dose of approximately 5 mg of prednisone equivalent. Methotrexate was used in 72.9% of patients, leflunomide in 16.7%, sulfasalazine in 29.2%, and hydroxychloroquine in 8.3%. Biologic therapy was prescribed in 25.0% of cases, mainly anti-TNF agents. RA was classified as active in 72.9% of patients with a mean DAS28-VS of 4.07 ± 1.41, and a mean HAQ score of 0.96 ± 0.68. Joint deformities were observed in 48.9% of patients.
Disease activity assessed by DAS28 did not differ significantly between seropositive and seronegative patients ($p = 0.942$). Similarly, no significant difference was observed in HAQ scores between the two groups ($p = 0.941$). Joint deformities were more frequent in seropositive patients (52.6%) compared to seronegative patients (28.6%), although this difference did not reach statistical significance ($p = 0.242$).

Conclusion

Seropositive status was associated with a tendency toward higher disease activity and greater structural damage, although no statistically significant differences were observed. Larger studies are needed to better delineate its prognostic value.

P1473

BODY COMPOSITION AND BONE IMPAIRMENT IN AXIAL SPONDYLOARTHRITIS: A CROSS-SECTIONAL STUDY

Y. Makhlouf[1], S. Ben Hamouda[1], O. Haj Ahmed[1], H. Boussaa[1], S. Miladi[1], A. Fazaa[1], K. Ben Abdelghani[1], A. Laatar[1]

[1]Hôpital Mongi Slim Marsa, Marsa, Tunisia

Introduction

Axial spondyloarthritis (axSpA) is a chronic inflammatory disease frequently complicated by alterations in bone health, including osteopenia and osteoporosis (OP), which contribute to increased morbidity and fracture risk. While systemic inflammation is known to affect both muscle and bone, the relationship between body composition and bone impairment in axSpA remains insufficiently explored.

Objective

The objective of this study was to assess the association between body composition parameters (lean and fat mass indices) and bone impairment

Patients and Methods

A cross-sectional study was conducted including patients with axSpA. Demographic, clinical and biological data were collected, including age, sex, disease duration, body mass index (BMI), disease activity scores (Ankylosing Spondylitis Disease Activity Score based on C-reactive protein and erythrocyte sedimentation rate : ASDAS-CRP and ASDAS-ESR), Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) and functional status assessed using the Bath Ankylosing Spondylitis Functional Index (BASFI). Body composition parameters were assessed using lean mass index (LMI) and fat mass index (FMI). Bone impairment was defined as the presence of either osteopenia or OP .

Results

The study population of 129 patients had a mean age of 40.7 ± 12.9 years and included 61% women. The mean BMI was 26.9 ± 5.0 kg/m². The mean FMI was 0.068 ± 0.041, and the mean LMI was 26.9 ± 4.9 kg/m².
OP was observed in 17 patients (13.2%) and osteopenia in 8 patients (6.2%), resulting in an overall prevalence of bone impairment of 19.4%. Patients with bone impairment tended to have a lower LMI compared to those without bone impairment (25.9 ± 5.5 vs 27.2 ± 4.8 kg/m²), although this difference did not reach statistical significance. FMI did not differ significantly between groups (0.078 ± 0.050 vs 0.065 ± 0.038). No significant differences were observed between patients with and without bone impairment regarding disease activity or functional scores, including ASDAS-CRP, ASDAS-ESR, BASDAI and BASFI. In multivariable logistic regression analysis adjusting for age, sex, BMI, disease duration and disease activity, neither LMI nor FMI was independently associated with bone impairment.

Conclusion

Our study showed that bone impairment affects nearly one-fifth of patients with axSpA and does not appear to be adequately explained by standard body composition parameters. These findings suggest that the muscle–bone interaction in axSpA is complex and multifactorial, highlighting the need for a more comprehensive approach to bone health assessment beyond conventional clinical and biological markers.

P1474

INFLUENCE OF BODY MASS COMPOSITION ON DISEASE ACTIVITY IN AXIAL SPONDYLOARTHRITIS

Y. Makhlouf[1], S. Ben Hamouda[1], O. Haj Ahmed[1], H. Boussaa[1], S. Miladi[1], A. Fazaa[1], K. Ben Abdelghani[1], A. Laatar[1]

[1]Hôpital Mongi Slim Marsa, Marsa, Tunisia

Introduction

Alterations in body composition, including increased fat mass and reduced muscle mass, have been described in chronic inflammatory diseases and may contribute to functional impairment and symptom burden. In axial spondyloarthritis (axSpA), the relative contributions of fat and lean compartments to disease activity remain insufficiently explored.

Objective

The objective of this study was to assess the associations between body composition parameters and disease activity and functional outcomes in patients with axSpA .

Patients and Methods

We conducted a cross-sectional study including patients diagnosed with axSpA. Demographic and clinical data were collected, including age, sex, anthropometric measurements, and disease characteristics. Body composition was assessed using bioimpedance-derived parameters, including fat mass percentage (FM%), fat mass index (FMI), and lean mass index (LMI). Disease activity was evaluated using the Ankylosing Spondylitis Disease Activity Score based on erythrocyte sedimentation rate (ASDAS-ESR) and C-reactive protein (ASDAS-CRP), as well as the Bath Ankylosing Spondylitis Disease Activity Index (BASDAI). Functional status was assessed using the Bath Ankylosing Spondylitis Functional Index (BASFI).

Results

A total of 129 patients were included. The mean age was 40.7 ± 12.9 years, and 61.2% were women. The mean body mass index (BMI) was

26.9 ± 5.0 kg/m², and 29.9% of patients were classified as obese. Mean disease activity and functional scores were 2.29 ± 0.93 for ASDAS-ESR, 1.94 ± 0.97 for ASDAS-CRP, 2.43 ± 1.65 for BASDAI, and 2.08 ± 2.32 for BASFI. The mean FM% was 18.5 ± 10.1%, the mean FMI was 0.068 ± 0.041, and the mean LMI was 26.9 ± 4.9 kg/m².

LMI was inversely correlated with BASDAI (ρ = −0.24, p = 0.045), while no significant correlations were observed between FMI and disease activity or functional indices. Neither FMI nor LMI correlated with ASDAS-ESR, ASDAS-CRP, or BASFI.

In multivariable linear regression analyses adjusted for age and sex, LMI showed a non-significant trend toward an inverse association with BASDAI (β = −0.16, p = 0.08), whereas FMI was not independently associated with any disease activity or functional outcome. BASDAI did not differ significantly between obese and non-obese patients (2.13 ± 1.83 vs 2.50 ± 1.58, p = 0.41).

Conclusion

Lean mass was more strongly associated to disease activity than fat mass in axSpA. These findings suggest that muscle depletion may contribute to symptom burden independently of overall adiposity, highlighting sarcopenia as a potential therapeutic and rehabilitation target in this population.

CLINICAL PHENOTYPES AND BONE HEALTH IN AXIAL SPONDYLOARTHRITIS: INSIGHTS FROM BODY COMPOSITION ANALYSIS

Y. Makhlouf[1], S. Ben Hamouda[1], O. Haj Ahmed[1], H. Boussaa[1], S. Miladi[1], A. Fazaa[1], K. Ben Abdelghani[1], A. Laatar[1]

[1]Hôpital Mongi Slim Marsa, Marsa, Tunisia

Introduction

Bone loss is a frequent and under-recognized complication of axial spondyloarthritis (axSpA), resulting from a complex interplay between systemic inflammation, mechanical factors, and body composition. While the muscle–bone axis has emerged as a key determinant of skeletal health, the influence of clinical phenotypes and body composition on bone impairment in axSpA remains insufficiently characterized.

Objective:

The objective of this study was to assess the association between clinical phenotypes and bone impairment in patients with axial spondyloarthritis.

Patients and Methods

We conducted a cross-sectional study including patients fulfilling the Assessment of SpondyloArthritis International Society (ASAS) criteria for axSpA. Clinical phenotypes were classified according to ASAS definitions. Disease activity was assessed using the Ankylosing Spondylitis Disease Activity Score (ASDAS), the Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), and functional status using the Bath Ankylosing Spondylitis Functional Index (BASFI). Bone impairment was defined as the presence of osteoporosis (OP) or osteopenia based on dual-energy X-ray absorptiometry (DXA). Body composition parameters included fat mass index (FMI) and lean mass index (LMI). Associations between clinical phenotypes, body composition, and bone impairment were analyzed using multivariable models adjusted for age, sex, body mass index (BMI), and disease duration.

Results

The study included 129 patients with a mean age of 49.2 ± 13.3 years, and a female predominance (61.2%). The mean disease duration was 4.25 ± 2.14 years. The distribution of clinical phenotypes was as follows: pure axial SpA (25.4%), peripheral articular SpA (12.7%), peripheral enthesitic SpA (6.3%), peripheral articular and enthesitic SpA (14.3%), axial with peripheral articular involvement (19.8%), axial with peripheral enthesitic involvement (6.3%), and axial with combined peripheral involvement (15.1%). Regarding treatments, 60.5% of patients received conventional synthetic DMARDs (csDMARDs), 55.8% had been treated with biologic DMARDs (bDMARDs), and 27.1% had a history of methotrexate (MTX) use, while no patient received targeted synthetic DMARDs (tsDMARDs). Among the 129 patients, OP was present in 13.2% and osteopenia in 6.2%, resulting in an overall bone impairment prevalence of 19.4%. Bone impairment significantly differed across clinical phenotypes, with the highest prevalence observed in patients with peripheral involvement (44% in axial–peripheral articular phenotype), compared with pure axial disease (12.5%).

FMI significantly varied across phenotypes, with higher FMI values observed in patients with combined axial and peripheral involvement, particularly those with both articular and enthesitic features, whereas patients with pure axial disease showed the lowest FMI values. In contrast, LMI did not significantly differ between phenotypes (p = 0.45). Similarly, no significant differences in disease activity or functional scores (ASDAS, BASDAI, BASFI) were observed between patients with and without bone impairment. In multivariable logistic regression, clinical phenotype showed a borderline association with bone impairment (OR 1.36, p = 0.093), while age, sex, BMI, disease activity indices, and disease duration were not independently associated.

Conclusion

Bone impairment in axSpA is significantly influenced by clinical phenotype, with peripheral forms showing the highest risk. Fat mass, rather than lean mass, appears to be associated with unfavorable bone profiles, highlighting the importance of body composition in skeletal vulnerability. These results emphasize the need for phenotype-driven strategies for bone health screening and

P1476

CLINICAL CHARACTERISTICS OF PATIENTS WITH TYPE 2 OSTEOPOROSIS RECEIVING PROTON PUMP INHIBITORS: AN OBSERVATIONAL STUDY

S. Birsan[1]

[1]Faculty of Medicine and Pharmacy, University of Oradea, Oradea, Romania

Background:

Type 2 osteoporosis is a major public health concern, associated with increased fracture risk and morbidity. Several studies have suggested a potential association between long-term use of proton pump inhibitors (PPIs) and impaired bone metabolism; however, available evidence remains inconsistent.

Objective:

To evaluate clinical characteristics and potential differences between patients with type 2 osteoporosis using proton pump inhibitors and those not receiving PPIs.

Materials and Methods:

This observational study included 32 female patients diagnosed with type 2 osteoporosis. Among them, 14 patients were receiving concomitant treatment with proton pump inhibitors, while 18 patients were not using PPIs. Relevant clinical and paraclinical data related to bone health were analyzed and compared between the two subgroups.

Results:
Patients receiving proton pump inhibitors accounted for 43.75% of the study population. Differences were observed between the two groups in the evaluated parameters; however, the small sample size limited the statistical power of the analysis. No definitive causal relationship between PPI use and osteoporosis severity could be established.

P1477
THE IMPORTANCE OF EARLY DIAGNOSIS AND PREVENTION OF MORTON'S NEUROMA

S. Birsan[1]

[1]Faculty of Medicine and Pharmacy, University of Oradea, Oradea, Romania

Background:
Morton's neuroma is a common cause of metatarsalgia, characterized by fibrotic thickening of the interdigital nerve, most frequently located in the third intermetatarsal space. Diagnosis is often delayed, as early symptoms are nonspecific and frequently attributed to other forefoot disorders.
Objective:
To highlight the importance of early diagnosis and preventive measures in limiting the clinical progression of Morton's neuroma and reducing the need for invasive treatments.
Materials and Methods:
This paper is based on the analysis of clinical data and a review of the relevant literature regarding the biomechanical mechanisms involved in the development of Morton's neuroma, associated musculoskeletal risk factors, and strategies for prevention and early diagnosis.
Results:
The reviewed data suggest that early recognition of suggestive symptoms (intermetatarsal pain, burning sensation, or paresthesia) and correction of predisposing biomechanical factors (metatarsalgia, forefoot deformities, inappropriate footwear) may limit the progression of nerve damage. Preventive measures, including patient education, use of plantar orthoses, and footwear modification, are associated with symptom relief and a reduced risk of recurrence.
Conclusions:
Early diagnosis and prevention are essential components in the management of Morton's neuroma. A preventive and multidisciplinary approach may limit disease progression, reduce the need for invasive interventions, and improve patients' quality of life.

P1478
ANALYSIS OF COMORBIDITY SCORES IN PATIENTS WITH DXA-CONFIRMED OSTEOPOROSIS

S. Birsan[1]

[1]Faculty of Medicine and Pharmacy, University of Oradea, Oradea, Romania

Background:
Osteoporosis is a chronic condition frequently associated with multiple comorbidities, which may influence disease progression, fracture risk, and therapeutic strategies. Standardized assessment of comorbidities allows an objective evaluation of the clinical complexity of patients with osteoporosis.
Objective:
To analyze comorbidity scores assessed using the Charlson Comorbidity Index in patients with DXA-confirmed osteoporosis.
Materials and Methods:
This observational study included 25 female patients diagnosed with osteoporosis according to DXA criteria. Comorbidities were assessed using the **Charlson Comorbidity Index (CCI)**. Data were analyzed descriptively, focusing on the distribution of CCI scores and their relationships within the study cohort.
Results:
Charlson Comorbidity Index scores demonstrated considerable variability in comorbidity burden among the included patients. The observed interindividual differences reflect the clinical heterogeneity of the study population. The small sample size limits the statistical power of the analysis and the interpretation of the observed relationships.
Conclusions:
Assessment of comorbidities using the Charlson Comorbidity Index provides relevant information regarding the clinical profile of patients with DXA-confirmed osteoporosis. Integrating CCI into routine evaluation may contribute to individualized osteoporosis management. Larger, prospective studies are needed to validate these findings.

P1479
EMOTIONAL DETERMINANTS OF MUSCULOSKELETAL PAIN IN CHRONIC ARTHRITIS

S. Bogdanova[1], S. Dimitrov[1,2], S. Hristova[1], G. Gerganov[1], R. Moraliyska[1], Z. Zhaklin[1], D. Simeonova[1], M. Markov[1], P. Kabakchieva[3], T. Shivacheva[1], T. S. Georgiev[1]

[1]Medical University Varna, UMPHAT "St.Marina", Varna, Bulgaria; [2]UMPHAT"St.Marina", Varna, Bulgaria; [3]Medical University Varna, Military Hospital Varna, Varna, Bulgaria

Background: Chronic inflammatory joint diseases such as rheumatoid arthritis (RA), ankylosing spondylitis (AS), and psoriatic arthritis (PsA) are among the most prevalent rheumatic conditions and are frequently associated with persistent musculoskeletal pain. Pain pathogenesis is multifactorial, involving inflammatory, neurobiological, and psychosocial mechanisms. While inflammatory activity plays a central role, psychoemotional factors may significantly influence patients' perceptions and reporting of pain.
Objectives: To evaluate the intensity of musculoskeletal pain (arthralgia and myalgia) and its association with anxiety and depressive symptoms in a Bulgarian cohort of patients with chronic inflammatory joint diseases.
Methods: This single-center observational study included patients with RA, AS, and PsA followed at the Rheumatology Clinic of St. Marina University Hospital, Varna. All patients fulfilled established classification criteria for the respective disease and were receiving biological therapy. Pain intensity (joint and muscle) was assessed using visual analogue scales (VAS). Anxiety and depressive symptoms were evaluated using the Zung Self-Rating Anxiety Scale (SAS) and Self-Rating Depression Scale (SDS). Laboratory markers of inflammation were recorded. Statistical analyses included descriptive statistics, one-sample t-tests, correlation, and linear regression analyses, with a significance level set at $p<0.01$.
Results: A total of 130 patients were included (mean age 56.37± years, range 21–76); 41.5% were women and 58.5% men. No significant sex differences were observed in joint or muscle pain intensity ($p=0.177$ and $p=0.717$, respectively). Women demonstrated significantly higher anxiety

and depression scores compared to men (p<0.001 for SDS; p=0.001 for SAS). Depressive symptoms showed a strong positive correlation with both muscle and joint pain (SDS–VASm r=0.666, p<0.001; SDS–VASj r=0.644, p<0.001). Anxiety symptoms correlated significantly with joint pain and muscle pain (SAS–VASj r=0.680, p<0.001; SAS–VASm r=0.698, p<0.001). Inflammatory markers explained approximately 8% of the variance in pain intensity (R^2=7.8% for joint pain; R^2=8.1% for muscle pain).

Conclusion: Musculoskeletal pain in chronic inflammatory joint diseases is influenced not only by inflammatory activity but also by psychoemotional factors. Anxiety and depressive symptoms are significantly associated with higher pain intensity, underscoring the importance of integrated biopsychosocial assessment and management in patients with inflammatory rheumatic diseases.

P1480

MEDICAL EDUCATION IN HYPOPHOSPHATASIA SIGNIFICANTLY IMPROVES COMPETENCE IN DIFFERENTIAL DIAGNOSIS

S. C. Rohani-Montez[1], R. Moreira da Silva[1], K. Reid[1]

[1]Medscape Education Global, London, United Kingdom

Objectives

Hypophosphatasia (HPP) is often missed or misdiagnosed by pediatric endocrinologists as a) it is rare; b) its clinical presentation overlaps with more common metabolic bone diseases. The critical diagnostic marker of low serum alkaline phosphatase is often overlooked. We sought to improve physician competence in recognizing possible HPP by providing expert-led accredited education.

Material and Methods

Physicians were targeted based on their specialty, learning habits, and interest, to participate in a 40-minute, video-based, online CME activity delivered by experts, with synchronized slides (available at https://www.medscape.org/viewarticle/1001401). The effects of the education were assessed using a 3-question, repeated pairs, pre-assessment/post-assessment study design. One question assessed confidence. Differences from pre- to post-assessment were evaluated using the McNemar's test. P ≤ 05 is the significance level.

Results

Overall significant improvements were seen after participation for both endocrinologists (correct response rate of 49% at pre-assessment vs 68% at post-assessment; P<.001, Cohen's d= 0.96, N=57), and pediatricians (correct response rate of 48% at pre-assessment vs 65% at post-assessment; P<.001, Cohen's d= 0.74, N=82). Specifically, significant improvements were observed in clinicians' ability to identify differential labs & symptoms between HPP and rickets, and in their understanding of how to correctly quantify ALP levels.

After participating in the activity, 60% of endocrinologists and 51% of pediatricians had measurable improved confidence related to differentially diagnosing hypophosphatasia from other rare metabolic diseases. In addition, 62% of endocrinologists and 54% of pediatricians said they intend to "always request ALP levels in heparin test tubes when HPP is part of my differential diagnosis."

Conclusions

This study demonstrates the success of online, expert-led, video-based education in improving competence and confidence in differentially diagnosing HPP when the right target audiences are identified, reached, and engaged at addressable learning moments.

P1481

FLUOROSCOPY-GUIDED LUMBAR FACET JOINT INFILTRATION WITH HYDROLYZED COLLAGEN PEPTIDES IN CHRONIC FACET SYNDROME: A PROSPECTIVE COMPARATIVE COHORT

S. Carlucci[1], L. Scialpi[1]

[1]SS annunziata, Taranto, Italy

Objective(s): To explore short-term pain and disability outcomes of fluoroscopy-guided lumbar facet joint infiltration with low molecular weight collagen peptides (LWPs) compared with standard approaches in chronic low back pain due to facet syndrome.

Material and Methods: Single-centre prospective cohort at the Orthopaedics and Traumatology Department, "SS. Annunziata" Hospital (Taranto, Italy). Forty patients (mean age 68.6 years; range 64–73) were treated in four groups (n=10 each): corticosteroid injection, corticosteroid+LWPs, LWPs alone, or corticosteroid+radiofrequency (RF) procedure. Outcomes were numeric rating scale (NRS) pain and Oswestry Disability Index (ODI) at baseline, 1 month and 3 months.

Results: Mean NRS pain scores at baseline, 1 month and 3 months were: corticosteroid 7.9, 5.0, 3.0; corticosteroid+LWPs 8.0, 4.0, 2.0; LWPs 8.0, 5.0, 3.0; corticosteroid+radiofrequency (RF) 8.0, 3.0, 1.0. Mean ODI (mean ± SE, %) improved: corticosteroid 26.5±5.44, 20.5±3.50, 15.2±4.80; corticosteroid+LWPs 25.7±6.31, 16.0±4.85, 16.3±5.25; LWPs 23.5±6.31, 18.0±6.55, 14.7±3.77; corticosteroid+RF 27.6±7.03, 17.7±5.52, 14.6±3.37. No adverse events were reported. The cohort was clinically homogeneous in terms of diagnosis and age range; however, variability measures for NRS could not be derived from the available dataset.

Conclusion(s): All treatment strategies were associated with reduced pain and disability at 3 months, with the greatest mean pain improvement observed in the corticosteroid+RF group. The addition of LWPs to corticosteroid appeared to be associated with lower NRS scores compared with corticosteroid alone, while disability improvements were similar across groups. Although preliminary and limited by sample size and incomplete NRS variance reporting, these findings suggest that fluoroscopy-guided LWPs infiltration may represent a feasible adjunct or alternative option to conventional corticosteroid injections and RF procedures in chronic facet syndrome.

P1482

RARE CAUSE OF PRIMARY OSTEOPOROSIS DUE TO MUTATION IN LRP5 GENE AND RESPONSE TO BISPHOSPHONATE THERAPY

S. Chirayath[1], S. Abdulwahhab[1], M. Mahjoub[1], M. Ibrahim[1], K. Bureshad[1], T. Omran[1], M. Sunni[1], K. Hussain[1]

[1]Sidra Medicine, Doha, Qatar

Introduction: Low-density lipoprotein receptor-related protein 5 is a protein encoded by the *LRP5* gene.LRP5 has an essential role in the Wnt signaling pathway, since it acts as a co-receptor that binds Wnt proteins with Frizzled-receptors. Gain-of-function mutations in the *LRP5* gene can cause high-bone-mass phenotypes in humans, whereas homozygous loss-of-function mutations cause osteoporosis-pseudoglioma syndrome (OPPG) which is characterized by early-onset osteoporosis and complications in eye development (1,2). Mutations in this gene also cause exudative viteroretinopathy (EVR). Osteoporosis-pseudoglioma syndrome (OPPG) is a rare autosomal recessive syndrome of juvenile-onset osteoporosis and ocular abnormalities described first by Saraux in 1967. To date, approximately 50 cases have been reported, most with onset of fractures after age 2 years and congenital blindness, the latter due to persistence of the fetal ocular fibrovascular system and failure of retinal development (3). Familial exudative vitreoretinopathy (FEVR) is a rare childhood hereditary eye disorder that affects both the retina and the vitreous body. It is clinically similar to advanced retinopathy of prematurity, but the affected individuals do not have a history of premature birth and oxygen therapy (4).
Objective: We report 2 cases of pediatric primary osteoporosis due to LRP5 mutation. Both of them were managed with bisphosphonate therapy
Case discussion: Case 1: A 13-year-old boy, first born of consanguineous parentage, presented with spontaneous low back ache. Evaluation of his back ache revealed multilevel vertebral compression fractures. The causes of secondary osteoporosis were ruled out after which whole exome sequencing (WES) was done. WES reveled a missense variant p. Arg1036Trp in the homozygous state in *LRP5* gene. His ocular examination was within normal limits. Following the diagnosis of osteoporosis, he was initiated on bisphosphonate therapy (Zoledronic acid). He received 2 doses of Zoledronic acid and has not had any further osteoporotic fractures. He will be maintained on Zoledronic acid for 2 years.
Case 2: A 14-year -old girl, second born of consanguineous parentage, had spontaneous blurring of vision at 9 years of age. Simultaneously she had spontaneous low back ache. She was investigated for the visual blurring and diagnosed to have right posterior subcapsular cataract and straightening of bilateral retinal vessels all quadrants with areas of capillary dropout noted in temporal peripheries. Evaluation of the back ache revealed multilevel vertebral compression fractures. The causes of secondary osteoporosis were ruled out after which whole exome sequencing was done and she was found to have homozygous missense variant of uncertain significance in the *LRP5* gene. The amino acid change detected was p.(Arg399Ser). Her phenotype and genotype were suggestive of exudative vitreoretinopathy. Along with the ocular findings, she had osteoporosis. In view of the osteoporosis, she has been on bisphosphonate therapy from the age of 11 years. During the course of bisphosphonate therapy, she has not developed further osteoporosis fractures.
Conclusion: We report 2 cases of primary osteoporosis which outlines a rare cause of pediatric primary osteoporosis due to mutation in *LRP5* gene. LRP5 protein affects bone accrual and eye development. Mutation of the *LRP5* gene is associated with osteoporosis and ocular abnormalities. Both the cases had good response to bisphosphonate therapy.

SINGLE CENTER EXPERIENCE OF PEDIATRIC OSTEOPOROSIS

S. Chirayath[1], M. Ibrahim[1], K. Bureshad[1], S. Taha[1], A. Saif[1], H. Yaseen[1], H. Dauleh[1], E. Hamdoun[1], A. Khalifa[1], M. Sunni[1], K. Hussain[1]

[1]Sidra Medicine, Doha, Qatar

Introduction : The practice of our institution is to diagnose and treat cases of pediatric osteoporosis is based on the following 3 phases:

• (1) **Bone health monitoring**, which is used to identify early signs of compromised bone health

• (2) **Osteoporosis stabilization**, which is aimed to mitigate back pain and interrupt the fracture–re fracture cycle through bone-targeted therapy

• (3) **Bone health maintenance**, which has the goal to preserve the clinical gains realized during the stabilization phase through ongoing bone-targeted therapy

• (4) **Osteoporosis therapy discontinuation**, which places those who are eligible for discontinuation of osteoporosis treatment back on a health monitoring program.

Objective : The aim of this study is to describe the cases of pediatric osteoporosis being managed (from 2024) in the bone clinic under the Division of Endocrinology and Diabetes at our institution.
Methodology: The cases of suspected pediatric osteoporosis are referred to the bone clinic for establishment of care and further follow-up. The bone clinic has been functional once a month from 2025. As per ***The International Society of Clinical Densitometry (ISCD) 2019 official position statement for pediatrics***, the diagnostic criteria for osteoporosis is as follows :

• The finding of >/= 1 vertebral compression fractures (VF) is indicative of osteoporosis , in the absence of local disease or high energy trauma.

• In the absence of VF , diagnosis of osteoporosis is indicated by presence of both

• **Clinically significant fracture history**

• **BMD score </= -2.0**

• **BMD Z-score >-2.0 does not preclude the possibility of skeletal fragility and increased fracture risk**

• Clinically significant fractures (one or more):

• 2 or more long bone fractures by the age of 10 years or

• 3 or more long bone fractures at any age till 19 years of age

• 2 or more long bone fractures of the upper limbs

Results :

A total of 26 patients have established care in the bone clinic for management of osteoporosis. 7 of them had primary osteoporosis, the etiology being osteogenesis imperfecta, Bruck syndrome, Winchester syndrome,osteoporosis pseudoglioma syndrome. All of them are on bisphosphonate therapy (intravenous Zoledronic acid) and have showed improvement in BMD Z-score and vertebral morphology with therapy. The remaining 19 had osteoporosis secondary to Duchenne muscular dystrophy, spinal muscular atrophy, hereditary spastic paraplegia, steroid dependent nephrotic c syndrome , juvenile dermatomyositis, Marfan syndrome, Sjogren's syndrome. The modified criteria for osteoporosis in DMD (Duchenne muscular dystrophy) (***as per Diagnosis and management of Duchenne muscular dystrophy, part 2: respiratory, cardiac, bone health, and orthopedic management 2018***):Osteoporosis is diagnosed once a child with DMD demonstrates at least 1 clinically significant fracture (i.e., a long-bone fracture or vertebral fracture) , multiple fractures are not required.

Conclusion: We are adhering to the diagnostic criteria of osteoporosis before considering bisphosphonate therapy.In terms of secondary osteoporosis the currents standard of care is in line with secondary prevention i.e to identify and treat early instead of late signs of bone fragility, including timely identification of VF through periodic spine imaging.The protocol for initiation of bisphosphonate therapy is in accordance with the Hospital clinical guidelines. The bisphosphonate of choice are Pamidronate (less than 2 years of age) and Zoledronic acid (2 years and above)

P1484

CHANGES IN BONE STRENGTH WITH ROMOSOZUMAB AFTER LONG-TERM DENOSUMAB USE IN WOMEN WITH POSTMENOPAUSAL OSTEOPOROSIS: A REAL-WORLD STUDY

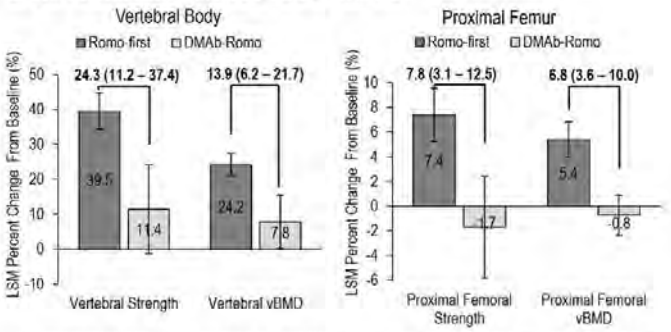
K. Ishikawa[1,2], T. Keaveny[3,4], X. Li[5], Y. Shi[5], D. Lee[3], S. Tani[2], T. Towatari[2], B. Elder[6], P. Passias[1], S. Colgan[5], M. Oates[5]

[1]Duke University, Durham, United States; [2]Showa Medical University, Tokyo, Japan; [3]O.N. Diagnostics, Berkeley, United States; [4]University of California Berkely, Berkeley, United States; [5]Amgen Inc., Thousand Oaks, United States; [6]Mayo Clinic, Rochester, United States

Objectives: Treatment with a potent anti-resorptive agent like denosumab (DMAb) can provide large gains in bone mineral density (BMD) over time in women with postmenopausal osteoporosis (PMO). However, in patients who remain at very high risk of fracture, switching to a bone-forming agent may help in achieving greater and more rapid gains in BMD and bone strength to reduce fracture risk. This study evaluated the real-world effectiveness of romosozumab (Romo) after DMAb treatment (DMAb-Romo) on bone strength in Japanese women with PMO using biomechanical computed tomography (BCT; VirtuOst®, FDA-cleared).

Materials and methods: Women with PMO aged ≥55 years either received Romo as initial therapy (Romo-first, n=57) or switched to Romo after prior DMAb (DMAb-Romo, n=9). Women in the Romo-first group had not received osteoporosis medication within the 36 months before Romo initiation, whereas women in the DMAb–Romo group had received DMAb for an average of 43 months prior to switching. Vertebral and proximal femoral bone strength and volumetric BMD (vBMD) were assessed at baseline and after 12 months of treatment. The primary endpoint was percentage change in vertebral strength at 12 months. Secondary endpoints included percentage changes in vertebral vBMD and proximal femoral strength and vBMD.

Results: At baseline, vertebral strength was lower in the Romo-first group than in the DMAb-Romo group, whereas differences in vertebral vBMD and proximal femoral strength and vBMD were minimal between groups (Fig A). After 12 months of treatment, percent increase in vertebral strength from baseline was 39.5% in Romo-first and 11.4% with DMAb-Romo group, with the group difference of 24.3% (Fig B). Similar changes were observed for vertebral vBMD (Fig B). Percent increase in proximal femoral strength was 7.4% in Romo-first group, and 1.7% decrease in DMAb-Romo group. Similar trends were observed for proximal femoral vBMD (Fig B).



Conclusion: In this real-world BCT study, Romo further increased vertebral strength and vBMD in women with prior DMAb treatment, and changes in proximal femoral strength and vBMD were minimal. Romo-first provides greater gains in vertebral strength and vBMD, while switching to Romo after DMAb may still offer additional benefits when further improvement is needed at the vertebrae.

Figure: Baseline characteristics and endpoints in Romo-first and DMAb-Romo cohorts

A. Baseline Characteristics

	Romo-first (N = 57)	DMAb-Romo (N = 9)
Age, mean (SD) years	73.8 (7.9)	78.6 (6.5)
Fracture history, n (%)	45 (79)	8 (89)
Vertebral strength, Newton	3680 (840)	4360 (1410)
Vertebral vBMD, mg/cm^3	132 (20)	145 (36)
Proximal Femoral strength, Newton	2440 (600)	2620 (620)
Proximal Femoral vBMD, mg/cm^3	201 (43)	207 (48)

B. LSM Percent Change From Baseline at Month 12

LSM percent change (mean, 95% CI) was determined using generalized linear models adjusted for the patients age at the index date, baseline value of the parameter, and fracture history. Numbers above the bar graphs represent the group difference of LSM percent change from baseline with lower and upper bound 95% CI in the parenthesis. CI, confidence interval; LSM, least square mean; Romo romosozumab; DMAb, denosumab; vBMD, volumetric bone mineral density.

P1485

THE EFFECT OF PREGNANCY VITAMIN D SUPPLEMENTATION ON OFFSPRING BONE MINERAL DENSITY IS NOT AFFECTED BY MATERNAL AND CHILD GENETIC VARIATION IN THE VITAMIN D METABOLISM PATHWAY

S. D'Angelo[1], C. Maden[1,2], L. Westbury[1], E. M. Curtis[1,2], S. R. Crozier[1,2,3], K. M. Godfrey[1,2], K. A. Ward[1,2], C. Cooper[1,2], N. C. Harvey[1,2], R. J. Moon[1,2,4]

[1]MRC Lifecourse Epidemiology Centre, University of Southampton, Southampton, United Kingdom; [2]NIHR Southampton Biomedical Research Centre, University of Southampton and University Hospital Southampton NHS Foundation Trust, Southampton General Hospital, Southampton, United Kingdom; [3]NIHR Applied Research Collaboration Wessex, Southampton, United Kingdom; [4]Regional Centre for Paediatric Endocrinology, Southampton Children's Hospital, University Hospital Southampton NHS Foundation Trust, Southampton, United Kingdom

Objectives Post-hoc analysis of the MAVIDOS trial showed that pregnancy vitamin D supplementation is associated with higher offspring bone mineral density (BMD) at age 6-7 years. In this analysis, we assessed whether genetic variation (single nucleotide polymorphisms (SNP)) related to vitamin D metabolism modifies this effect.

Material and Methods MAVIDOS was a randomised placebo-controlled trial of 1000 IU/day cholecalciferol (vitD) from 11-14 weeks gestation until delivery. Offspring follow-up at age 6-7 years included whole-body-less-head (WBLH) dual-energy X-ray absorptiometry (DXA; Hologic Discovery) to assess BMD and, in a subset, tibia high resolution peripheral quantitative computed tomography (HR-pQCT, Scanco XTremeCTII) to assess bone microarchitecture.

Maternal and child genotype at four SNPs [rs12785878 (*DHCR7*), rs10741657 (*CYP2R1*), rs6013897 (*CYP24A1*), rs2282679 (GC)] was determined from blood samples. Statistical interactions between genotype and randomisation group (placebo or vitD) were assessed for standardised BMD and HRpQCT outcomes (bone cross-sectional area, cortical thickness, cortical porosity, trabecular number, trabecular thickness, cortical volumetric BMD, trabecular volumetric BMD) using additive linear regression models with adjustment for the child's age and sex.

Results WBLH DXA and SNP data were available for 466 children (228 placebo; 238 vitD), and HRpQCT for 170 children. WBLH BMD was greater in the vitD group (β=0.15 SD, 95%CI -0.02, 0.32), but tibia microarchitecture was similar in both groups. There was no evidence of a significant interaction between maternal or child genotype in the SNPs and intervention for any bone outcome.

Conclusions The beneficial effect of maternal vitamin D supplementation in pregnancy on offspring BMD at 6-7 years was not modified by maternal or child SNPs. These findings point away from the use of personalised genotype directed vitamin D supplementation in pregnancy to optimise offspring bone health.

P1486

THE INFLUENCE OF THE MUSCULAR SYSTEM ON BONE MINERAL DENSITY IN WOMEN OF THE OLDER AGE GROUP WITH OSTEOARTHRITIS OF THE KNEE JOINT

S. Dahmani[1], N. V. Zhuravleva[2], T. L. Smirnova[2], V. N. Diomidova[2]

[1]"Rahmani" Pharmacy, Casablanca, Morocco; [2]Chuvash State University named after I. N. Ulyanov, Cheboksary, Russia

Objective. Sarcopenia is a complex multifactorial condition, the clinical picture of which is determined not only by muscle mass, but also by muscle strength and functional abilities.

Purpose of the study: to evaluate bone mineral density in women of the older age group with osteoarthritis of the knee joint depending on the condition of the muscular system.

Materials and methods. The study included 64 patients with diagnosed osteoarthritis of the knee joint. The median age of patients was 68.7 years (interquartile range: 66.1–71.3 years). The diagnosis of osteoarthritis of the knee was made according to the diagnostic criteria of the American College of Rheumatology (ACR, 1991).

To conduct a comparative analysis, all patients with knee osteoarthritis were stratified into three groups depending on the state of the muscular system, according to the recommendations of the European Working Group on Sarcopenia in Older People (EWGSOP, 2010). Group 1: 19 patients without signs of sarcopenia; Group 2: 21 patients with presarcopenia; Group 3: 26 patients with sarcopenia.

Assessment of the state of the muscular system was carried out using the following methods: muscle mass; multislice computed tomography.

Bone mineral density was assessed by dual-energy X-ray absorptiometry in the following areas: femoral neck and proximal femur (total), as well as the lumbar spine.

Results. Osteopenic syndrome was diagnosed in 46 (71.9%) patients: osteopenia was detected in 38 (59.4%) patients, osteoporosis - in 8 (12.5%). Normal bone mineral density values were recorded in 18 (28.1%) patients.

The frequency of detection of osteopenic syndrome in patients with sarcopenia was statistically significantly higher compared to patients without sarcopenia (p=0.031) and with presarcopenia (p=0.042).

Indicators of bone mineral density in the neck and proximal femur (total) in patients with sarcopenia were statistically significantly lower than in patients without sarcopenia and with presarcopenia (p = 0.021).

A direct correlation has been established between the total area of skeletal muscles at level LIII and densitometric parameters of the femoral neck.

Conclusions. Sarcopenia is associated with a decrease in bone mineral density in the neck and proximal femur in elderly and senile women with osteoarthritis of the knee.

P1487

STUDY OF BIOCHEMICAL MARKERS OF BONE TISSUE IN THE EARLY STAGES OF OSTEOARTHRITIS

S. Dahmani[1], N. V. Zhuravleva[2], T. L. Smirnova[2], V. N. Diomidova[2]

[1]"Rahmani" Pharmacy, Casablanca, Morocco; [2]Chuvash State University named after I. N. Ulyanov, Cheboksary, Russia

Objective. The relationship between changes in bone tissue and the dynamics of bone remodeling markers in the early stages of knee osteoarthritis was studied. Understanding these processes is key to developing strategies for early diagnosis and pathogenetic therapy.

Materials and methods. The study included 78 patients with a verified diagnosis of osteoarthritis of the knee joint of radiographic stages I and II. The average age of the sample was 54.68±13.97 years, the ratio of men to women was 1:4.7. The average duration of the disease in history was 5.37±3.92 years.

All participants underwent a comprehensive clinical, laboratory and instrumental examination. Determination of the levels of osteocalcin and C-terminal telopeptides of type I collagen (b-CrossLaps, β-CTX) was carried out by immunochemiluminescence using an automatic analyzer.

Exclusion criteria from the study included: secondary forms of osteoarthritis, diabetes mellitus, cancer, pathology of the parathyroid glands, osteoporosis, as well as a history of taking symptom-modifying drugs, systemic glucocorticoid therapy and drugs that affect bone mineral density.

Results and discussion. The average values of biochemical markers of bone remodeling were: osteocalcin – 25.90±10.47 ng/ml; b-CrossLaps – 0.33±0.18 ng/ml. It is important to note that the obtained indicators did not go beyond the reference values for a healthy population. However, a number of statistically significant correlations were identified. The b-CrossLaps level showed a positive correlation with the radiographic stage of knee osteoarthritis ($r=0.74$, $p<0.045$). There was a strong positive correlation between b-CrossLaps levels and the presence of osteophytes ($r=0.78$, $p<0.045$). Osteocalcin content correlated with the severity of subchondral sclerosis in the femur ($r=0.68$, $p<0.045$) and tibia ($r=0.82$, $p<0.05$).

A direct correlation was revealed between the level of osteocalcin and b-CrossLaps ($r=0.68$, $p<0.05$), which indicates a parallel change in the processes of bone formation and bone resorption.

Conclusions. In the early stages of osteoarthritis, there is a relationship between an increase in bone resorption markers and the formation of osteophytes, as well as bone formation markers and the development of subchondral sclerosis.

P1488

ASSESSMENT OF CARDIOMETABOLIC RISK IN WOMEN WITH NEWLY DIAGNOSED POSTMENOPAUSAL OSTEOPOROSIS

S. Dahmani[1], N. V. Zhuravleva[2], T. L. Smirnova[2], V. N. Diomidova[2]

[1]"Rahmani" Pharmacy, Casablanca, Morocco; [2]Chuvash State University named after I. N. Ulyanov, Cheboksary, Russia

Objective. Postmenopausal osteoporosis is a severe progressive disease with high social significance. The development of postmenopausal osteoporosis in patients with cardiovascular pathology and type 2 diabetes mellitus has not been sufficiently studied.

Purpose of the study. To assess the severity of cardiometabolic risk in women with newly diagnosed postmenopausal osteoporosis.

Materials and methods. The study included 59 women with newly diagnosed postmenopausal osteoporosis (average age 64.27±4.29 years). All patients underwent a comprehensive examination: To assess cardiometabolic risk, the CMDS (Cardiometabolic Disease Staging) scale was used.

Results. The average age of patients at the time of diagnosis of postmenopausal osteoporosis was 63.43±4.55 years. The average age of onset of natural menopause was 47.58±6.14 years (n=34), surgical menopause – 45.3±1.41 years (n=25). Menopausal hormone therapy was not administered in any case. Excess body weight was detected in 32.2% of those examined: overnutrition - 9 cases, obesity of 1st degree - 7 cases, obesity of 2nd and 3rd degrees - one case each. The average values of systolic and diastolic blood pressure were 145/87±6.71 mm Hg. Art. 52.1% of patients had a history of prolonged arterial hypertension. There was no history of cardiovascular events in all subjects. The glomerular filtration rate calculated using the CKD-EPI formula was 82±9.5 ml/min/1.73 m². The average fasting glucose level was 5.31±0.54 mmol/l; in three cases, impaired fasting glucose was detected. The average level of glycated hemoglobin (HbA1c) is 5.51±0.24%. The average values of total cholesterol were 6.11±1.19 mmol/l, triglycerides - 1.01±0.38 mmol/l, low-density lipoproteins - 3.9±1.3 mmol/l, high-density lipoproteins - 1.74±1.26 mmol/l. Dyslipidemia requiring drug correction was detected in 27% of cases. Distribution of cardiometabolic risk stages according to the CMDS (Cardiometabolic Disease Staging) scale: stage 1 – 25.6%, stage 2 – 20.5%, stage 3 – 12.8%, stage 4 – 2.6%. 38.5% of those examined were considered metabolically healthy.

Conclusions. 1. Women with newly diagnosed postmenopausal osteoporosis have a cardiometabolic risk corresponding to stages 1-4 on the CMDS scale.

2. Patients are shown dynamic monitoring by specialized specialists and treatment.

P1489

ASSESSMENT OF 25(OH)D LEVELS IN PATIENTS WITH OSTEOPOROSIS AND OSTEOARTHRITIS

S. Dahmani[1], N. V. Zhuravleva[2], T. L. Smirnova[2], V. N. Diomidova[2]

[1]"Rahmani" Pharmacy, Casablanca, Morocco; [2]Chuvash State University named after I. N. Ulyanov, Cheboksary, Russia

Objective. In clinical practice, it is important to assess the level of 25(OH)D in patients with osteoporosis and osteoarthritis in order to timely correct the disorders.

Materials and methods. The study involved 54 people aged from 47 to 75 years. Of these, 30 patients suffered from osteoporosis (27 women, 3 men), and 24 from osteoarthritis (17 women, 7 men). Total calcium and 25(OH)D levels were determined in all participants. Interpretation of 25(OH)D results was carried out as follows: severe deficiency <10 ng/ml; deficiency <20 ng/ml; deficiency 20-30 ng/ml; adequate level 30-100 ng/ml (target values for correction of vitamin D deficiency 30–60 ng/ml). The reference values for total calcium in the blood for the age group 12-60 years were 2.10-2.55 mmol/l, for the age group 60-90 years 2.2-2.55 mmol/l.

Results. In patients with osteoporosis: severe 25(OH)D deficiency (<10 ng/ml) was detected in one case (3.3%) in a smoking woman with type 2 diabetes mellitus requiring insulin therapy and a combination of AP with osteomalacia. Deficiency (<20 ng/ml) was found in 7 patients (23.3%), including 2 men and 5 women. It was noted that vitamin D deficiency was identified in men who abuse alcohol. Insufficiency (20-30 ng/ml) was detected in 20 patients (67%), of whom 2 were men and 18 women. Adequate levels (30-100 ng/ml) were recorded in 2 patients (6.31%).

The level of total calcium in the blood serum was reduced only in 4 (37.5%) patients with 25(OH)D deficiency and in 13 (52%) patients with its deficiency. In the remaining patients, calcium levels were normal.

In patients with osteoarthritis: adequate levels of 25(OH)D (30-100 ng/ml) were detected in 5 patients (20.83%), including 3 men and 2 women; deficiency (<20 ng/ml) was found in 6 patients (25%); deficiency (20-30 ng/ml) was detected in 13 patients (54.16%), of whom 5 were men and 9 women.

In the group of patients with osteoarthritis, total calcium levels were reduced in all patients with vitamin D deficiency and in 3 patients with normal 25(OH)D levels.

Conclusions. Vitamin D metabolism is impaired in patients with osteoarthritis and osteoporosis. In both groups, vitamin D insufficiency prevailed over its deficiency. No direct correlation was found between a decrease in total serum calcium levels and 25(OH)D deficiency.

P1490

SECONDARY OSTEOPOROSIS IN NEUROLOGICAL DISORDERS: A FUNCTIONAL AND OSTEODENSITOMETRIC ANALYSIS

S. Deac[1], M. Cevei[1], G. Gherle[1], R. Mihut[1], D. Stoicanescu[2], C. Cseppento Nistor[1], F. Andronie Cioara[1], D. Pop[3]

[1]University of Oradea, Faculty of Medicine and Pharmacy, Oradea, Romania; [2]University of Medicine and Pharmacy "Victor Babes", TIMISOARA, Romania; [3]University of Oradea, Faculty of Informatics and Sciences, Department of Biology, Oradea, Romania

Introduction

Secondary osteoporosis frequently complicates neurological disorders due to immobilization and motor deficits, leading to decreased bone mineral density and increased fracture risk, even in young patients experiencing prolonged motor impairment and reduced mechanical loading.

Objectives

This study aimed to examine clinical, functional, and bone health characteristics in young neurological patients with secondary osteoporosis and their association with motor deficits and fall risk.

Materials and Methods

From an initial cohort of 54 patients with neurological disorders and osteoporosis, 19 with secondary osteoporosis due to immobilization were selected. The group included patients with stroke, multiple sclerosis, spinal cord injury, traumatic brain injury, ALS, Charcot–Marie–Tooth neuropathy, muscular dystrophy, Guillain–Barré syndrome, Stiff Person syndrome, bulbar cavernoma, and paraparesis. Patients were hospitalized at the Clinical Rehabilitation Hospital Băile Felix between May 2025 and January 2026. Bone mineral density was assessed by DXA (Medix 90), functional status by FIM, Barthel Index, and FAC, and fall risk by the Johns Hopkins tool. All patients received personalized rehabilitation based on their neurological condition and comorbidities.

Results

The study included 19 patients (36.8% men, 63.2% women) with a mean age of 43.8 ± 2.1 years, all presenting chronic neurological conditions with significant functional impairment. Patients exhibited high fall risk (mean score 18.8 ± 3.6) and moderate functional dependence, with reduced independence in daily activities (mean FIM 77.7 ± 15.3; Barthel Index 55.3 ± 20.1). Gait was limited (FAC 2.0 ± 1.6), requiring physical assistance. Bone mineral density assessment revealed reduced values, with mean hip Z and T scores of −2.06 ± 0.68 and −2.4 ± 0.63, and lumbar spine Z and T scores of −2.4 ± 0.69 and −2.64 ± 0.87, consistent with secondary osteoporosis in this young patient population.

Discussion

Relatively young neurological patients exhibit secondary osteoporosis characterized by reduced bone mineral density, functional impairment, limited mobility, and increased fall risk.

Conclusions

Neurological patients with secondary osteoporosis require a multidisciplinary approach integrating rehabilitation, fall prevention strategies and appropriate antiosteoporotic treatment.

P1491

EFFECTS OF SELECTIVE CANNABINOID RECEPTOR TYPE 2 (CBR2) ANTAGONIST ON OSTEOGENIC DIFFERENTIATION AND BONE-RELATED GENE REGULATION IN HUMAN ADIPOSEDERIVED STEM CELLS: A PRELIMINARY STUDY

S. Donati[1], G. Palmini[2], I. Falsetti[1], R. Zonefrati[2], T. Iantomasi[1], L. Margheriti[3], A. Moro[3], M. L. Brandi[2]

[1]Department of Experimental and Clinical Biomedical Sciences, University of Florence, Florence, Italy; [2]Fondazione Italiana Ricerca sulle Malattie dell'Osso (F.I.R.M.O. Onlus), Florence, Italy; [3]Stabilimento Chimico Farmaceutico Militare (SCFM)_ Agenzia Industrie Difesa (AID), Florence, Italy

Objectives: The endocannabinoid system (ECS) has emerged as an important regulator of bone remodeling, with activation of the cannabinoid receptor type 2 (CBR2) reported to promote osteoblast maturation and reduce bone loss. However, the effects of CBR2 inhibition on osteogenic differentiation remain poorly defined. This study aimed to investigate the *in vitro* effects of the selective CBR2 antagonist SR144528 on the osteogenic differentiation of human adipose-derived mesenchymal stem cells (hADMSCs) and on the expression of osteogenic markers and bone-metabolism-related microRNAs.
Methods: hAMSCs were isolated from subcutaneous adipose tissue of healthy donors and induced toward osteogenic differentiation in the presence of SR144528 (i.e., 300nM, 1μM, and 3μM) for up to 35 days. Alkaline phosphatase (ALP) activity and calcium-phosphate deposition were quantified by fluorometric assay and laser-scanning confocal microscopy, respectively. Furthermore, qPCR was performed to evaluate the expression of early and late osteogenic marker genes, as well as selected microRNAs closely related to bone metabolism.
Results: Treatment with SR144528 at 3 μM and 1 μM significantly reduced ALP activity and HA deposition at day 28 compared to control. At day 7, 3μM and 1μM SR144528 downregulated early osteogenic markers (*ALP*, *RUNX2*, *COL1A1*) and reduced *OPG* expression at day 21, while *OCN* levels remained unchanged. Moreover, qPCR analysis revealed a significant upregulation of miR-23a and miR-21, whose overexpression has been associated with the inhibition of osteogenic differentiation. In parallel, a marked downregulation of miR-29b was detected, whose increased expression correlates with enhanced ALP activity and extracellular matrix mineralization.
Conclusions: Collectively, these findings indicate that CBR2 activity contributes to osteogenic mineralization and bone matrix formation. Pharmacological CBR2 activation could therefore represent a promising therapeutic strategy for osteoporosis and other lowbonemass conditions, whereas CB2R inhibition could be relevant in pathological conditions characterized by excessive mineral deposition, such as tumoral calcinosis.
Acknowledgments: Supported by Fondazione Ente Cassa di Risparmio di Firenze (FCRF) and F.I.R.M.O. Onlus Foundation.

P1492

STUDY OF THE IN VITRO EFFECT OF PHOSPHATE ON OSTEOGENIC DIFFERENTIATION AND MINERALIZATION IN HUMAN ADIPOSE-DERIVED MESENCHYMAL STEM CELLS

S. Donati[1], G. Palmini[2], I. Falsetti[1], F. Marini[2], R. Zonefrati[2], T. Iantomasi[1], L. Margheriti[3], A. Moro[3], M. L. Brandi[2]

[1]Department of Experimental and Clinical Biomedical Sciences, University of Florence, Florence, Italy; [2]Fondazione Italiana Ricerca sulle Malattie dell'Osso (F.I.R.M.O. Onlus), Florence, Italy; [3]Stabilimento Chimico Farmaceutico Militare (SCFM)_ Agenzia Industrie Difesa (AID), Florence, Italy

Objectives: Inorganic phosphate (Pi) is essential in mammals, supporting key metabolic activities such as intracellular signaling and ATP-dependent energy production. Pi also contributes structurally by enabling hydroxyapatite formation in bone tissue, while reduced Pi levels are linked to impaired bone metabolism and mineralization defects. This study aimed to investigate for the first time how phosphate exposure influences calcification and osteogenic differentiation in human adipose-derived mesenchymal stem cells (hADMSCs).
Methods: hADMSCs were isolated from subcutaneous adipose tissue of healthy donors and cultured in 24-well plates. Cells were exposed to 2, 3, or 4mM Pi for up to 35 days, either in standard growth medium or in osteogenic differentiation medium. Alkaline phosphatase (ALP) activity and hydroxyapatite (HA) deposits were quantified by fluorometric assay during osteogenic differentiation (from day 0 to day 35). In addition, qPCR using TaqMan technology was performed to evaluate the expression of early- and late-stage osteogenic marker genes, including *ALP*, *COL1A1*, *OPG*, and *OCN*.
Results: Our data showed a significant increase in ALP activity in hADMSCs induced toward the osteogenic phenotype and treated with 4mM Pi at day 28 compared with control cells. Regarding mineralization, 4mM Pi significantly enhanced HA deposition both in standard growth medium and in osteogenic differentiation medium. Gene expression analysis revealed a significant upregulation of early (*ALP* and *COL1A1*) and late (*OCN* and *OPG*) osteogenic markers in cells induced to differentiate toward the osteogenic phenotype in the presence of 4mM Pi.
Conclusions: Overall, exposure to high Pi concentration (4mM) significantly enhanced osteogenic differentiation by increasing ALP activity, promoting HA deposition, and upregulating both early and late osteogenic markers in hADMSCs, thereby supporting the pro-osteogenic activity of phosphate *in vitro*. Based on these findings, investigating the role of Pi in osteoblastic cell differentiation may contribute to a better understanding of metabolic bone disease.
Acknowledgments: Supported by F.I.R.M.O. Onlus Foundation.

A STRANGE CASE OF HYPERPARATHYROIDISM

S. E. Oros[1], A. I. Caragheorgheopol[2], R. Boanta[2], G. Voicu[2], R. S. Cismasiu[3], D. Grigorie[2]

[1]Carol Davila University of Medicine and Pharmacy, Bucharest, Romania; [2]C.I. Parhon National Institute of Endocrinology Bucharest, Bucharest, Romania; [3]Clinical Hospital for Orthopedics, Traumatology and Osteoarticular TB "Foisor", Bucharest, Romania

Coeliac disease (CD) affects 1-2% of the population, diagnosed in early childhood but also in the second or third decade of life.
It has chameleonic clinical presentation, ranging from severe malabsorption to minimally symptomatic to osteomalacia and high fracture risk. Hypocalcaemia is a common finding in CD, however hypercalcemia has been also reported either due to primary hyperparathyroidism (PHPT) or tertiary hyperparathyroidism (THPT). Bone turnover is enhanced in several metabolic bone diseases, but there is no statement regarding cut-off values, nor national standardization of bone turnover markers (BTM) especially in premenopausal patients with CD.
We present the case of a 33-year-old patient with CD, high BTM probably due to mixed hyperparathyroidism (bone THPT).

DETERMINANTS OF SUBOPTIMAL BONE MINERAL DENSITY RESPONSE TO ROMOSOZUMAB: A PROSPECTIVE MULTICENTER SWISS COHORT STUDY

S. Ferrari[1], M. Hars[1], J. Falciola[2], O. Lamy[3], C. Meier[4], S. Jehle-Kunz[5], B. Aubry-Rozier[6], E. Biver[1], E. Gonzalez Rodriguez[3]

[1]Division of Bone Diseases, Geneva University Hospitals and Faculty of Medicine, University of Geneva, Geneva, Switzerland; [2]Division of Rehabilitation and Geriatrics, Geneva University Hospitals and Faculty of Medicine, University of Geneva, Geneva, Switzerland; [3]Interdisciplinary Center of Bone Diseases, Lausanne University Hospital and University of Lausanne, Lausanne, Switzerland; [4]Division of Endocrinology, Diabetology and Metabolism, University Hospital and University of Basel, Basel, Switzerland; [5]Center for Osteoporosis Lucerne, Lucerne, Switzerland; [6]FMH Rheumatology and Bone Diseases, Lausanne, Switzerland

Objective: Thanks to its dual anabolic and antiresorptive effects, romosozumab (Romo) substantially increases bone mineral density (BMD). In the FRAME trial, 1-year Romo BMD gains <3% were observed in only 4% of subjects at spine and 22% at hip. However, prior anti-resorptive (AR) therapy attenuates Romo effects on BMD. We assessed the proportion and determinants of suboptimal BMD response to Romo in real-world practice.
Materials and Methods: This prospective multicenter study included osteoporosis patients (70% with recent and/or multiple fractures) treated with Romo (210mg s.c. monthly for 12 months) across five centers in Switzerland between 2021 and 2025. Non-responders (NR) were defined as patients with <3% BMD gain at spine and/or hip after one year. Determinants of NR were analyzed using multivariable logistic regression models including baseline clinical characteristics, prior treatment exposure, and bone turnover markers (CTx, P1NP).
Results: A total of 496 patients (89.7% women; mean age 70.4 ± 10.3 years) were included, of whom 51% were treatment-naïve and 49% previously exposed to AR (mainly bisphosphonates). At 12 months, 10.7% were NR at spine and 47.9% at hip. Among spine responders, 41.7% were NR at hip, whereas 90.2% of hip NR responded at spine. In treatment-naïve patients, 7.1% were NR at spine and 39.0% at hip, whereas among pre-treated patients the proportion of NR reached 14.6% at spine and 57.7% at hip ($p < 0.001$ vs. naïve). In multivariable logistic regression models, prior AR treatment (OR 1.98, 95%CI 1.07–3.65), age (OR 1.03, 95%CI 1.00–1.05) and higher baseline hip BMD (OR 1.75, 95%CI 1.35–2.34), but not BMI nor baseline CTx / P1NP, were the strongest determinants of NR at one year. Moreover, lower P1NP levels at 3 months were associated with BMD non-response at spine but not at the hip.
Conclusion: In real-world practice, the vast majority of Romo-treated subjects gains >3% BMD at spine, yet suboptimal hip BMD response is commonly observed, even among treatment-naïve patients. Although prior AR use, age, and baseline hip BMD contributed, a substantial proportion of variability remained unexplained, underscoring the incomplete understanding of hip-specific anabolic response and the need for optimized treatment sequencing.

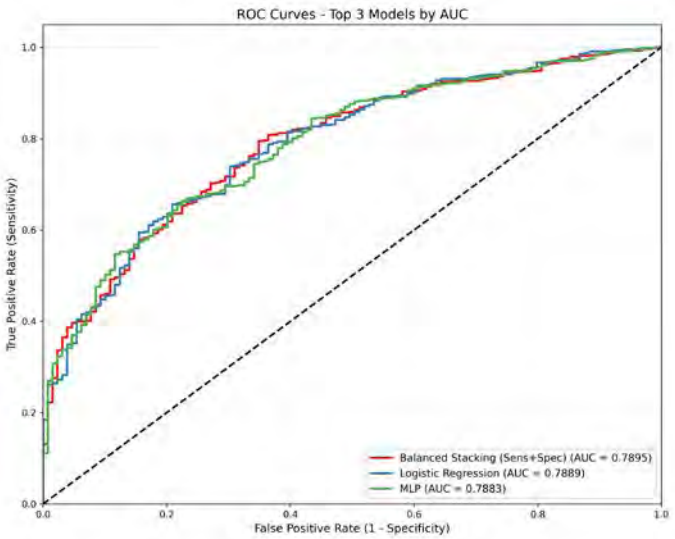
Research Center, Tehran University of Medical Sciences, Tehran, Iran, Tehran, Iran

Objective: To develop and validate supervised machine learning models for the screening of low bone mass using demographic and clinical data from the Bushehr elderly health (BEH) program.

Material and Methods: We partitioned BEH baseline data into training (80%) and independent test (20%) sets. Low bone mass was defined by DXA T-score ≤ −1.0 (lumbar spine, femoral neck, or total hip). We trained 15 machine learning algorithms including linear classifiers, neural networks, and ensembles. Top predictors were selected via recursive feature elimination with logistic regression and XGBoost. Random undersampling within stratified 5-fold nested cross-validation addressed class imbalance. Decision thresholds prioritized sensitivity. Performance metrics included AUC, sensitivity, specificity, and F1-score.

Results: 4,110 participants (median age 66, 54.2% female, 84% low bone mass prevalence) were analyzed. In the test set, balanced stacking ensemble and logistic regression yielded identical AUC (0.79), sensitivity (87.3%), specificity (47.3%), and F1-score (0.89). Standard stacking ensemble demonstrated a comparable AUC of 0.79 and F1-score of 0.89, with slightly higher sensitivity (87.7%) and lower specificity (45.0%). Conversely, the multi-layer perceptron classifier exhibited an AUC of 0.79, a sensitivity of 84.0%, a specificity of 56.6%, and an F1-score of 0.87 (Table & Figure).

Conclusion: Stacking ensemble models demonstrate utility as non-invasive screening tools, effectively triaging high-risk individuals for confirmatory DXA. This approach optimizes resource allocation for early fracture prevention. We developed an online risk calculator based on these models.



https://osteosarcopenia-risk-calculator-u9pvs4ecg7euxryfcec3mc.streamlit.app/

Table: Performance of the top five models for low bone mass screening using 11 features.

Model	F1-Score	Sensitivity	Specificity	ROC-AUC

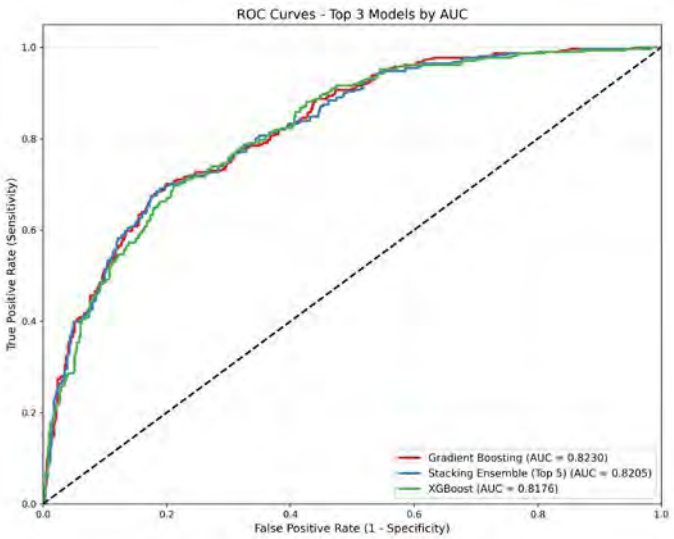
Objective: To design and evaluate machine learning approaches for osteoporosis screening.

Material and Methods: Using baseline data from the Bushehr Elderly Health (BEH) program, we developed screening tools defining osteoporosis as bone mineral density T-score ≤ -2.5 (lumbar spine, femoral neck, or total hip) by dual-energy X-ray absorptiometry. Data were partitioned into training (80%) and independent test (20%) sets. Fifteen algorithms were trained using hybrid feature selection (recursive elimination with logistic regression and XGBoost). We addressed class imbalance via SMOTEENN resampling within stratified cross-validation. Decision thresholds were constrained to maximize F2-score. Model performance was evaluated on the test set using AUC, sensitivity, specificity, and F2-score.

Results: Among 4,110 participants (median age: 66 years; 54.2% female; 37.8% osteoporosis prevalence), key predictors included weight, height, age, parity, and fracture cause. The voting ensemble achieved the highest screening performance (AUC 0.82, sensitivity 95.2%, specificity 39.3%, F2-score 0.80). Gradient boosting demonstrated balanced discrimination (AUC 0.82, sensitivity 90.7%, specificity 52.1%, F2-score 0.80), while LightGBM offered higher specificity (AUC 0.82, sensitivity 82.6%, specificity 60.7%, F2-score 0.75) (Table & Figure).



Conclusion: Machine learning enables effective osteoporosis screening; the voting ensemble excels at exclusion, while Gradient boosting optimizes discriminative balance. This allows tool selection based on surveillance goals and resource constraints. An online risk calculator was developed.

THE ASSOCIATION OF 25(OH)D3 CONCENTRATION WITH BONE MINERAL DENSITY, BONE TURNOVER MARKERS AND BIOCHEMICAL PARAMETERS IN PSORIATIC ARTHRITIS

S. Grazio[1], A. Vrtarić[2], N. Nikolac Gabaj[2], F. Grubisic[1], M. Bozovic[2], M. Punda[3], H. Skala Kavanagh[1], I. Doko Vajdic[1], L. Prtenjaca[1]

[1]Department of Rheumatology, Physical and Rehabilitation Medicine, Sestre milosrdnice University Hospital Center, Zagreb, Croatia; [2]Department of Clinical Chemistry, Sestre milosrdnice University Hospital Center, Zagreb, Croatia; [3]Department of Oncology and Nuclear Medicine, University Hospital Center Sestre Milosrdnice, Zagreb, Croatia

Objective: Psoriatic arthritis (PsA) is an inflammatory rheumatic disease characterized by inflammation of joints and entheses, and may be associated with osteoporosis. Although the role of vitamin D in bone health is well documented, its effects in PsA remain unclear. The aim of this study was to elucidate the association of vitamin D concentration with bone mineral density (BMD), trabecular bone score (TBS), and bone turnover markers (BTM) in PsA patients.

Materials and Methods: This was a cross-sectional study with 68 patients diagnosed with PsA. Participants were divided into two groups based on their 25(OH)D3 concentrations (<75 nmol/L and >75 nmol/L). BMD and TBS were measured using dual-energy X-ray absorptiometry (DXA), while serum samples were analyzed for calcium, phosphorus, osteocalcin, CTX-I, and parathyroid hormone (PTH) concentrations. (Table 1)

Results: Patients with 25(OH)D3 levels >75 nmol/L had a significantly lower BMD at the lumbar spine compared to those with levels <75 nmol/L (P = 0.020), which was not shown for hip or femoral neck. Additionally, significant differences were observed in BTM, with higher concentrations of osteocalcin and CTX-I in patients with 25(OH)D3 levels exceeding 75 nmol/L. There were no significant differences regarding TBS, as well as alkaline phosphatase or other biochemical parameters.

Conclusion: Our study suggests that higher vitamin D levels in PsA patients may be associated with lower lumbar spine BMD and altered bone turnover markers. These findings highlight the complexity of bone metabolism in PsA and suggest that vitamin D supplementation may have a nuanced impact on bone health. Further studies are needed to confirm these results and explore their clinical implications.

Table 1. Bone and biochemical parameters according to the concentration of 25(OH)D3.

Parameter	25(OH)D3 <75 nmol/L	25(OH)D3 >75nmol/L	P
Hip BMD	0.50 (-0.53-0.90)	-0.40 (-0.83-0.90)	0.110
Femur BMD	-0.75 (-1.30-0.30)	-0.80 (-1.75-0.03)	0.418
Spine BMD	0.25 (-1.50-1.30)	-1.20 (-2.20-0.15)	0.020*
TBS	1.41 (1.34-1.48)	1.39 (1.22-1.43)	0.095
ALP (U/L)	73 (57-92)	76 (57-95)	0.806
Ca (mmol/L)	2.38 (2.30-2.45)	2.35 (2.30-2.41)	0.712
iCa (mmol/L)	1.24 (1.22-1.28)	1.25 (1.23-1.28)	0.642
Phos (mmol/L)	1.04 (0.86-1.56)	1.19 (1.07-1.28)	<0.001*
PTH (pmol/L)	4.35 (3.49-5.06)	3.85 (3.28-4.96)	0.231
Osteocalcin (µg/L)	18 (14-23)	23 (18-30)	<0.001*
CTX-I (µg/L)	0.329 (0.240-0.465)	0.459 (0.345-0.576)	<0.001*

BMD - bone mineral density, TBS- trabecular bone score, ALP- alkaline phosphatase, Ca- total calcium, iCa- ionized calcium, Phos- inorganic phosphates, PTH- parathyroid hormone, CTX-I- C-terminal telopeptides of type I collagen, 25(OH)D3- 25-hydroxy vitamin D3. Data are presented as median and interquartile range.

P1498

DOES THE FRACTURE LIAISON SERVICE MODEL REDUCE MORTALITY AFTER A FRAGILITY FRACTURE? A SYSTEMATIC REVIEW AND META-ANALYSIS OF THE LITERATURE

S. Grignaschi[1], L. Solimando[2], G. Voltan[3], N. Veronese[2]

[1]ASST Pavia, Pavia, Italy; [2]Saint Camillus University, Rome, Italy; [3]Unità Locale Socio Sanitaria 3, Distretto 3 Mirano-Dolo, Venice, Italy

Background: The first Fracture Liaison Service (FLS) model was born in 2003. Since then it has spread all over the world, improving fragility fractures (FF) management, pharmacological treatment and reducing re-fracture rates. However, FFs carry an increased risk of death within 2 years of the fracture. Although the effectiveness of FLS in reducing re-fractures rates has been proved, its effect on FF-related mortality could not be more blurry. The purpose of this systematic review is to answer its impact on mortality using meta-analysis.

Methods: A literature search was performed within several databases to identify original articles published until 15 September 2025, reporting the effect of FLS on mortality versus a control group. A meta-analysis using random-effects models was conducted summarising the data as risk ratio (RR) and correspondent 95% confidence intervals (CIs). The quality of studies was appraised after combining and modifying criteria of existing quality assessment tools.

Results: Among the 331 works initially examined, we included 21 observational studies (mainly pre/post studies) for a total of 146,453 patients (73,331 in FLS vs. 73,122 controls). During a mean follow-up period of 2.4 years, 12,329 in the FLS group vs. 18,602 in the control group died (16.8% FLS vs. 25.4% in control group). The meta-analysis of the raw data showed a significant reduction of 17% of FLS compared to the control group (RR=0.83; 95%CI: 0.75-0.92; figure 1), even if this outcome was characterized by a high heterogeneity (I^2=87.4%). Conversely, in 13 studies giving data for the adjusted analyses, after correcting for a mean of 5 potential confounders, the adjusted RR was 0.80 (95%CI: 0.70-0.91; I^2=91.8%; figure 2).

Stratifying the data for the type of fracture, FLS was more effective in preventing mortality for any fracture (RR= 0.78; 95%CI: 0.69-0.89; I^2=91%) compared to hip fracture (RR= 0.92; 95%CI: 0.85-1.00; I^2=0%) (p for interaction<0.0001).

Conclusions: FLS care is associated with a significantly lower probability of mortality, even after adjusting for potential confounders and, particularly, when considering hip fracture as type of fracture.

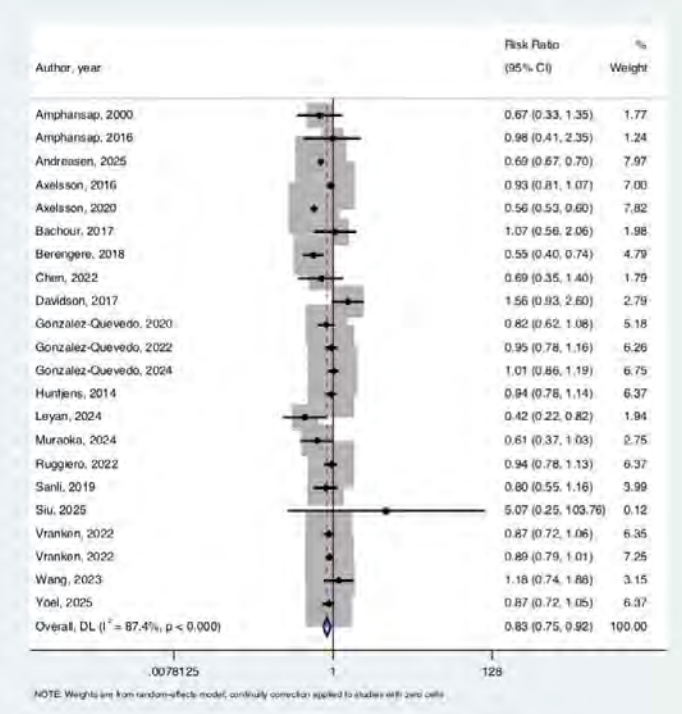

Figure 1. Meta-analysis of the raw data.

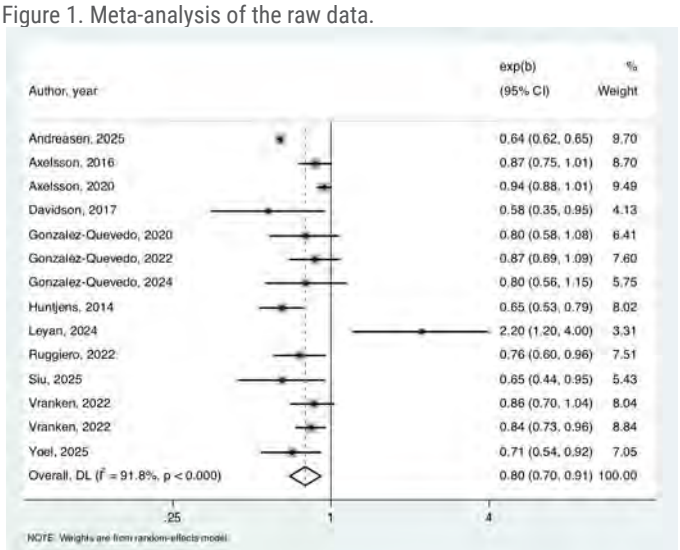

Figure 2: meta-analysis of the adjusted data.

P1499

CLINICAL PREDICTORS OF REHABILITATION OUTCOMES AFTER FRAGILITY HIP FRACTURE IN PATIENTS AGED ≤75 YEARS: A RETROSPECTIVE COHORT STUDY

M. Pastrano[1], M. C. Caffetti[1], A. Sozzi[1], S. Balduzzi[1], A. Nardone[2], S. Grignaschi[1]

[1]ASST Pavia, Pavia, Italy; [2]ICS Maugeri, Pavia, Italy

Objective

To investigate clinical, functional and metabolic determinants of rehabilitation outcomes in patients aged ≤75 years with fragility hip fractures, a population underrepresented in current literature and potentially highly responsive to targeted interventions.

Material and Methods

This retrospective observational study included 84 consecutive patients aged ≤75 years admitted to a specialist rehabilitation unit after surgically treated fragility hip fracture (January 2023–August 2025). Demographic characteristics, comorbidities, bone mineral density (DXA), laboratory parameters (including 25-hydroxyvitamin D), surgical timing, and rehabilitation data were collected. Functional outcome was assessed using the Barthel Index (BI) at admission and discharge. Multivariable linear regression analyses were performed to identify independent predictors of functional outcome and rehabilitation length of stay.

Results

The cohort had a mean age of 69.2 ± 5.7 years and was predominantly female (75%). Functional autonomy improved markedly during rehabilitation, with BI increasing from 50.9 ± 18.2 at admission to 90.4 ± 15.7 at discharge ($p < 0.001$). In multivariable models, BI at admission emerged as the strongest independent predictor of BI at discharge ($\beta = 0.38$; $p < 0.001$) and shorter rehabilitation stay ($\beta = -0.16$; $p < 0.001$, figure 1). Vitamin D deficiency (<20 ng/mL), observed in 40% of patients, was independently associated with longer rehabilitation stay ($\beta = -0.12$; $p = 0.028$, figure 2). Neither osteoporosis diagnosis, sex, type of surgical procedure nor DXA T-scores significantly influenced functional outcome.

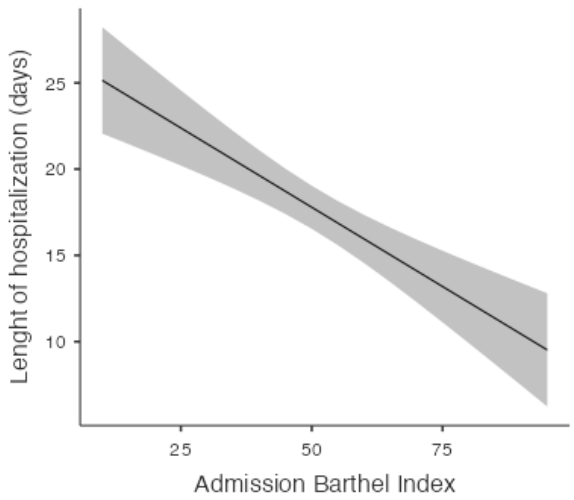

Figure 1: linear regression plot with 95% confidence interval demonstrating a negative relationship between Barthel Index at admission and lenght of hospital stay.

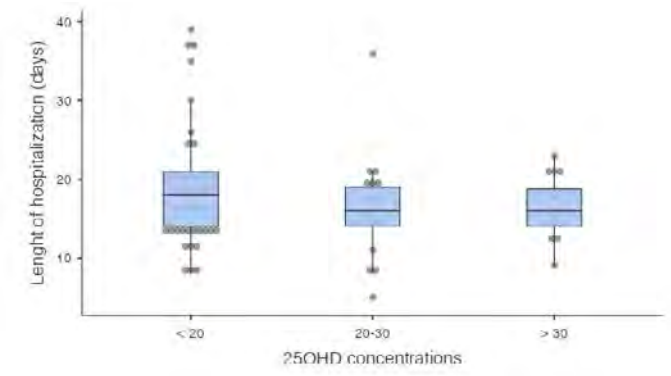

Figure 2: box-and-whisker plot demonstrating the relationship between vitamin D concentration and lenght of hospitalization.

Conclusion

In younger-old patients with fragility hip fracture, baseline functional status is the strongest predictor of rehabilitation success, surpassing traditional structural bone parameters and comorbidities. Vitamin D deficiency represents a modifiable factor associated with delayed recovery. These findings support a shift toward early functional stratification and metabolic optimization to improve rehabilitation efficiency and outcomes in this clinically and socially active population.

P1500

MUTATIONS IN THE GENE FOR LRP5 AS CAUSE FOR MALE JUVENILE OSTEOPOROSIS

S. H. J. Scharla[1], U. G. Lempert[1]

[1]Endocrine Practice, Bad Reichenhall , Germany

Osteoporosis in juvenile age may result from genetic causes. The availability of genetic panel analyses allows the use of genetic diagnostic investigations also in routine medical care, because samples can be send to specialized laboratories accredited for health care. Diagnostic procedures often reveal genetic variants, which have low pathogenetic significance. However, the combination of two mutations (compound mutation) might nevertheless result in severe osteoporosis, as is demonstrated in the following case report:

The patient (46 years) presented with a history of multiple fractures: ribs, clavicula, vertebral fractures. The areal bone mineral density (BMD, DXA) measurement showed a T-Score of -3.2 at the proximal femur. Except for an eating disorder in the past there were no risk factors. The actual body mass index was 21 kg/m2. The physical examination showed no blue sclerae and no increased mobility of the joints. Endocrine disorders, osteomalacia, hypophosphatasia, or hematologic disease were excluded by laboratory diagnostics.

Treatment was initiated with 5 mg of intravenous zoledronate. After 6 months, the patient presented again with a fracture of the right humerus and multiple rib fractures on the right side without adequate trauma. Genetic panel screening was then performed (Laboratory Heidrich and colleagues, Hamburg, Germany). Within the LRP5-Gen (LDL receptor related protein 5) two heterozygous variants were found: c.1999G>A p.(Val667Met) and c.3989C>T p.(Ala1330Val).

Both variants are described as low grade pathogenic, but show a high prevalence in patients with juvenile osteoporosis (Collet et al. *JBMR1 Plus, Vol. 2, No. 1, pp 12–21*).

Treatment was switched to teriparatide. Thereafter, the patient suffered one fracture of the clavicula after trauma, but there were no further vertebral fractures and no fractures of the extremities. Moreover, the pain symptoms improved significantly.

Conclusion: functional variants of the LRP5-gene can cause severe osteoporosis provided they present as a compound mutation. Teriparatide appears as an successful treatment.

P1501

ROMOSOZUMAB VERSUS TERIPARATIDE AND RISK OFALL-CAUSE MORTALITY IN PATIENTS WITH OSTEOPOROSIS: A REAL-WORLD PROPENSITY SCORE-MATCHED COHORT STUDY

S. H. L. Tsai[1]

[1]Taipei Medical University Hospital, Taipei, Taiwan

Background

Osteoporosis is a prevalent condition among older adults and significantly increases the risk of fragility fractures,particularly affecting the hip and vertebrae. Pharmacologictherapy remains central to osteoporosis management, with anabolic agents such as Romosozumab and Teriparatide demonstrating efficacy in increasing bone mineral density andreducing fracture risk. However, direct comparative evidenceregarding their impact on mortality is limited. This studyaimed to evaluate the differences in all-cause mortality between Romosozumab and Teriparatide in patients with osteoporosis, utilizing a large real-world dataset.

Methods

We conducted a retrospective cohort study using electronic medical records from the TriNetX US Collaborative Network, comprising data from over 120 healthcare organizations. Patients aged ≥20 years diagnosed with osteoporosis betweenJanuary 1, 2016, and December 31, 2023, initiating either Romosozumab or Teriparatide were included. Individuals with malignancies, bone neoplasms, multiple myeloma, parathyroid disorders, or cerebrovascular accidents were excluded. Propensity score matching (1:1) balanced demographic, clinical, and laboratory characteristics between cohorts. The primary outcome was all-cause mortality, with subgroup analyses performed based on age, sex, comorbidities, and treatment settings.

Findings

Each treatment group included 2470 matched patients. Overthe follow-up period, Romosozumab was associated with significantly lower all-cause mortality compared to Teriparatide (hazard ratio [HR] 0.68, 95% CI: 0.49–0.94). This survival advantage was particularly evident in patients aged ≥60 years (HR 0.65, 95% CI: 0.47–0.88). Subgroup analyses consistently favored Romosozumab across multiple comorbid conditions, including diabetes mellitus and chronic kidney disease, although these subgroup results did not reach statistical significance. Importantly, no increased mortality risk was observed in patients with hypertension or coronaryheart disease, indicating a favorable cardiovascular safety profile in these populations.

Interpretation

In this extensive real-world analysis, Romosozumab was associated with a significantly lower risk of all-causemortality compared to Teriparatide among patients withosteoporosis. These findings support the preferential consideration of Romosozumab, particularly for older adults and patients at elevated fracture risk, while highlighting the necessity of careful cardiovascular risk assessment.

P1502

LONG-TERM EFFICACY AND SAFETY OF DENOSUMAB IN PATIENTS WITH ANKYLOSING SPONDYLITIS AND LUMBAR OSTEOPOROSIS

S. H. Lee[1], S. H. Kim[1], H. I. Yang[1]

[1]Department of Rheumatology, Kyung Hee University hospital at Gandong, Seoul, South Korea

Objective

Ankylosing spondylitis (AS) is a chronic inflammatory disease characterized by inflammation of the axial skeleton, which can lead to structural damage and ankylosis. Chronic spinal inflammation has been associated with reduced vertebral bone mineral density (BMD). We previously reported the 1-year efficacy of denosumab in patients with AS and osteoporosis. This study aimed to evaluate the long-term efficacy and safety of denosumab with follow-up of up to 7 years in this population.

Methods

Between 2018 and 2020, patients with AS were assessed for osteoporosis using dual-energy X-ray absorptiometry (BMD) or quantitative computed tomography (qCT). Patients diagnosed with osteoporosis were treated with denosumab and followed longitudinally.

Results

Of the 26 patients initially followed for 1 year, 24 patients were followed for at least 2 years; two patients discontinued treatment after 1 year due to improvement in osteoporosis. Among the 24 patients, 9 were male and 15 were female. The mean age was 54.0 ± 6.7 years, and the mean disease duration was 16.7 ± 10.6 years. Seventeen patients were evaluated using BMD and seven using qCT. The mean follow-up duration was 4.7 ± 1.5 years. At the final follow-up, increased bone density was observed in 19 patients (79.1%). The mean change in BMD T-score was +0.4 ± 0.5, and the mean change in qCT was +6.1 ± 13.2. No serious adverse events related to denosumab were observed during the follow-up period.

Conclusion

Long-term treatment with denosumab in patients with ankylosing spondylitis and osteoporosis was effective and well tolerated, with sustained improvements in bone density and no significant safety concerns.

CONTRIBUTION OF OSTEOBLAST AND OSTEOCLAST SUPERNATANTS TO BONE FORMATION: DETERMINATION USING A NOVEL MICROFLUIDIC CHIP

S. H. Park[1], S. C. Lee[2]

[1]Soonchunhyang university Bucheon hospital, Bucheon, South Korea; [2]Cha university Bundang medical center, Seongnam, South Korea

We fabricated a microfluidic chip (osteoblast [OB]-osteoclast [OC] chip) that could regulate the mixture amounts of OB and OC supernatants to investigate the effect of different supernatant distributions on osteogenesis or osteoclastogenesis. Computer-aided design was used to produce an OB-OC chip from polydimethylsiloxane. A pressure controller was assembled and different blends of OB and OC supernatants were correctly determined. OB and OC supernatants were placed on the upper panels of the OB-OC chip after differentiation for an in vitro evaluation. We then tested the changes in osteogenesis using MC3T3-E1 cells in the middle chambers. We observed that a 75:25 distribution of OB and OC supernatants was the most potent in osteogenesis. We then primed the osteogenic differentiation of MC3T3-E1 cells using an OB-OC mixed supernatant or an OB supernatant alone (supernatant ratios of 75:25 or 100:0, respectively). These cells were placed on the calvarial defect sites of rats. Microcomputed tomography and histological analyses determined a significantly higher bone formation in the group exposed to the OB-OC supernatant at a ratio of 75:25. In this study, we demonstrate the applicability of an OB-OC chip to evaluate the effect of different supernatant distributions of OB and OC. We observed that the highest bone-forming potential was in MC3T3-E1 cells treated with conditioned media, specifically the OB-OC supernatant at a ratio of 75:25.

Objectives: To investigate the fracture type distribution across T-score ranges in elderly hip fracture patients and to identify spatial differences in bone mineral density(BMD) and cortical thickness between femoral neck fractures (FNF) and intertrochanteric fractures (ITF).

Material and Methods: In this retrospective, cross-sectional analysis, elderly patients (≥65 years, N=1993) with first-time, non-violent unilateral hip fractures (2019-2024) were reviewed; those receiving contralateral DXA within one month from the injury were included (N=380). Selection bias related to age, sex, and fracture type was addressed using inverse probability weighting. Fracture type proportions across T-score ranges were calculated, with the T-score taken as the minimum T-score between the femoral neck and total hip. Region-specific BMD and cortical parameters were analyzed using a DXA-based 3D modeling software (3D-SHAPER), with comparisons between FNF and ITF groups adjusted for age, sex, and height.

Results: Among hip fracture patients, 40% (42% after weighting) were non-osteoporotic, of whom 74% (64% after weighting) had FNF—a proportion increasing with T-score. Total hip BMD was higher in FNF versus ITF patients (P=0.005), while femoral neck BMD was similar (P=0.588). Lateral cortical deficits were fracture-site specific: at the femoral neck in FNF patients (P<0.001 for thickness, P=0.016 for surface BMD) and at the intertrochanteric region in ITF patients (P<0.001 for both parameters). Medial cortical parameters, except intertrochanteric surface BMD, did not differ. Differences in lateral cortical thickness at both sites persisted when comparing FNF and ITF patients within the same T-score ranges.

Conclusions: T-score-based assessment fails to accurately capture the fracture risk associated with FNF. Specific lateral cortical deficits are associated with different hip fracture types, highlighting the need to further investigate the role of lateral cortical parameters in fracture risk stratification.

P1505

TWELVE-MONTH REAL-WORLD SAFETY OUTCOMES FOR BIOSIMILAR DENOSUMAB IN CLINICAL PRACTICE IN CANADA

D. Z. Zampatis[1], C. G. Godefroy[2], N. N. Nasseri[2], S. J. Jagodic[3], S. H. Howe[4]

[1]Sandoz International GmbH, Holzkirchen, Germany; [2]Sandoz Canada Inc., Saint-Hubert, Canada; [3]Lek d.d. (Sandoz group), Ljubljana, Slovenia; [4]Hexal AG, Holzkirchen, Germany

Objective

Biosimilar denosumab (Jubbonti® for treatment of osteoporosis and increasing bone mass, and Wyost® for bone giant cell tumors and prevention of bone fractures in metastatic cancers; Sandoz) was approved by Health Canada in 2024. As of August 2025, its estimated cumulative exposure in Canada was 118,544 (osteoporosis) and 17,540 (oncology) patient treatment years. Here, we describe the first Canadian post-marketing safety experience for this biosimilar denosumab.

Material and Methods

Post-marketing safety reports received by Sandoz during the first 12 months following product launch in Canada and coded under 'denosumab' were assessed using MedDRA v28.0, classified by causal association to biosimilar denosumab by event-level assessment, and categorized by seriousness.

Results

A total of 97 reports were received (38 oncology dose; 9 osteoporosis dose; 5 'other'; 45 'unknown') describing 213 events, with 80 events determined as 'suspected', 15 'not suspected', and 118 'not assessable' for causal association with denosumab; 72/213 events were characterized as 'serious'. The most reported event was arthralgia (12/213).

Severe hypocalcemia was reported in two cases, with one requiring hospitalization. No serious infections were reported. No skin infections or hypersensitivity/anaphylaxis were identified. Two cases describing malignancies were retrieved (no new malignancies) and assessed as 'not related' to denosumab treatment.

Treatment interruption was reported in five cases, and treatment discontinuation occurred in six cases, with no specific event predisposition. No occurrences of osteonecrosis of the jaw and atypical femoral fractures were reported. Twelve deaths were reported, all 'not assessable' for causality, with 11/12 in patients treated for oncologic indications (one 'unknown').

Conclusions

Initial 12-month Canadian post-marketing safety reporting for this biosimilar denosumab observed predominantly non-serious adverse drug reactions, consistent with the established safety profile of denosumab, identifying no new or unexpected safety signals and risks.

Disclosures

CASE OF SCLERODERMA CALCINOSIS AND VITAMIN D POISONING

S. Jasqui[1], A. De la Pena[1], A. Jasqui[1]

[1]Hospital Angeles Lomas, Mexico State, Mexico

This is a 66-year-old female patient with a 16-year history of scleroderma and Raynaud's phenomenon. She was prescribed 5,000 units of vitamin D daily. Due to an error in interpretation, the patient took 50,000 units of vitamin D daily for 5 years. Multiple calcium deposits were found in her right elbow, causing skin breakdown and infection. As well extraosseous calcifications in the right axillary región, abdomen and lower limbs

Preoperative tests from October 14, 2025, showed the following: blood chemistry: glucose 74 mg/dL, BUN 20.23, creatinine 0.80 mg/dL, calcium 9.8, albumin 4.04, phosphorus 3.4; normal thyroid function tests; PTH 26.4; vitamin D 25-hydroxylase > 210 ng/mL; DEXA T score: lumbar spine -3.1, femoral neck -2, total hip -1.9

She underwent surgery to remove calcifications from his elbow and resolve the infection.

Vitamin D was discontinued, 5 mg of zoledronic acid was applied.

There are some x-ray images

pictures pre and post-operative

RISK OF IMMINENT OSTEOPOROTIC FRACTURES AND MORTALITY FOLLOWING SURGICAL TREATMENT OF PROXIMAL FEMUR FRACTURES IN ELDERLY INDIAN WOMEN: A PROSPECTIVE COHORT STUDY

S. Jeevannavar[1], S. Pruthvi[1], S. Shenoy[2], P. Baindoor[2], S. Fernandes[2], R. Gurudev[2]

[1]Shri Dharmasthala Manjunatheshwara University/Department of Orthopaedics /SDM College of Medical Sciences and Hospital, Dharwad , India; [2]Shri Dharmasthala Manjunatheshwara University/Department of Orthopaedics /SDM College of Medical Sciences and Hospital, Dharwad, India

Objectives: The concept of "imminent fractures," defined as fractures occurring within 2 years of an initial osteoporotic fracture, aims to improve bone quality and reduce mortality and morbidity associated with major osteoporotic fractures. This study's objective was to assess the risk of subsequent (imminent) fractures and mortality following operative treatment of fragility fractures of proximal femur in elderly Indian women. **Materials and methods:** In this 2-year prospective cohort study, 176 female patients over 60 years with low-energy proximal femur fractures treated surgically were included. Patients were followed up at 3,6, 12, and 24 months and assessed. The primary outcomes were mortality and occurrence of imminent fractures (new major osteoporotic fractures at the hip, vertebrae, distal radius, or proximal humerus within 24 months of the initial fracture). Secondary outcomes included time to refracture, site of refracture, comorbidities, osteoporosis treatment, and mobility. Clinical and patient characteristics at baseline and cumulative fracture incidences at 12 and 24 months were analyzed. Risk factors for subsequent fractures were identified using multivariate regression analysis, considering fracture as the outcome and death as a competing event. **Results:** Among the 176 elderly women followed over two years, the incidence of refracture was 8.4% at one year and 14.5% at two years. During follow-up, 32 patients (18.2%) died, including 14 with refracture and 18 without. Mortality was significantly higher in patients with refracture (53.8%) compared to those without (12.0%) ($p < 0.001$). Patients with refracture were significantly older . Cox proportional hazards regression analysis showed that refracture independently increased mortality risk (HR 3.02, 95% CI 1.55–5.88, $p = 0.001$). Kaplan–Meier analysis revealed a gradual decline in overall survival, with estimated survival probabilities of 86% at 12 months, and 81.8% at 24 months, corresponding to an overall 2-year mortality rate of 18.2%.**Conclusions:**This study underscores the significance of "imminent" fractures, declining bone quality, and increased mortality following primary hip fractures in elderly Indian women. The perioperative period is a critical window to aggressively address osteoporosis and general health , ideally through establishing fracture liaison services. Preventing imminent fractures may indirectly reduce mortality and enhance quality of life in this population.

P1508

A NOVEL TECHNIQUE FOR BUNIONETTE DEFORMITY - FIRST PRESENTATION

S. Koliatzakis[1], C. Rossas[1], A. Therapos[1], A. Garoufis[1], L. Tsiopos[1], D. Pafilas[1]

[1]Orthopaedic Department / General Hospital of Agrinio, Agrinio, Greece

Background

The bunionette, also known as a tailor's bunion, can be a painful deformity causing excessive pressures to the lateral and plantar fifth metatarsal head. Clinically it is a lateral deviation of the fifth metatarsal head and adduction of the fifth digit at the metatarsophalangeal joint. Its etiology is multifactorial, being associated with both anatomical and structural factors.

The purpose of this study is to present a novel, first attempted at our institution, minimal invasion technique to correct this deformity with the use of a non-absorbable suture with a fixation button (tight rope by Arthrex).

Case Presentation

A female 27 years old came to our outpatient clinic presenting a painful prominence on the lateral aspect of the 5th metatarsal head and a callus formation of her right foot. The radiographic imaging depicted increased 4-5 IMA and increased width of MT head, characteristic findings of tailor's bunion. An operation was decided and the patient admitted to our clinic a few weeks later.

Under general anesthesia a incision was performed at the lateral side of the head of the 5th metatarsal and we resected the lateral exostosis of the fifth metatarsal head. A second approximately 2 cm longitudinal incision was made between the 3rd and 4th metatarsals proximal their heads at the level of the proximal extent of the lateral resection. The medial aspect of the 4th metatarsal shaft was exposed and a tunnel was performed with a 1,3 or 1,1 K-wire through the 4th metatarsal and then through the 5th metatarsal, exiting through the lateral diaphysis just proximal to the 5th metatarsal head. The suture button construct was then inserted. It was very important for the fore foot to be supple enough so as the correction of the IMA was possible without major forces being exerted on the metatarsal. The incisions are closed, and soft sterile dressings are applied to the foot and ankle.

The patient discharged from hospital the next day and the patient is allowed to weightbear as tolerated without the use of a special shoe or boot.

Clinical Outcomes
After six months the correction of the IMA is stable and no pain or lateral hyperkeratosis on the skin has been reported from the patient. So and the cosmetic and the functional deformity is considered treated.

Discussion
To our knowledge this is the first case of bunionnete treated this way. This novel technique described provides a stable method for correcting bunionettes with minimal violation to the soft tissue. This allows for a reduction through the center of angular rotation as well as fixation with the tight rope to allow for maintained reduction. This minimal invasion technique not only benefits in maintaining reduction and healing but allows for early weightbearing from the time of surgery. The use of a soft tissue procedure combined with tight rope IMA correction is a safe and effective treatment of bunionette. Our results show that this technique can achieve correction of the IMA without the need for osteotomy.

P1509

CLINICAL EFFICACY OF GUIDED TISSUE REGENERATION IN MANAGING OF CHRONIC PERIODONTITIS

L. H. Duryagina[1], M. G. Nikolashin[1], N. G. Nikolashina[1], G. V. Nikolashin[2], S. Kulanthaivel[3]

[1]V.I. Vernadsky Crimean Federal University, Simferopol, Russia; [2]St. Luka's Clinical Multidisciplinary Medical Center of the Crimean Federal University named after V.I. Vernadsky, Simferopol, Russia; [3]Naarayani Multispeciality Hospital, Erode, India

Objective: Achieving bone regeneration in patients diagnosed with periodontitis remains a significant priority in contemporary dental practice. This study aims to evaluate the effectiveness of the Guided Tissue Regeneration (GTR) technique, utilizing the "Bio-Gide" barrier membrane, for the remediation of periodontal bone defects.
Material and Methods: The study cohort comprised nine individuals with moderate chronic periodontitis. Following a comprehensive diagnostic phase—which included periodontal pocket depth probing and assessment of alveolar bone status via orthopantomography (OPG), along with an initial phase of non-surgical therapy—surgical treatment was performed. Five subjects underwent GTR procedures with the placement of a "Bio-Gide" collagen membrane, while the remaining four received a conventional flap operation supplemented with an osteoplastic graft material.
Results: The investigation findings demonstrated that the GTR protocol yielded a mean bone fill reaching approximately 80% of the original defect volume. In contrast, bone reconstruction following the flap surgery with bone grafting did not exceed 55%.
Conclusions: Therefore, the application of the Guided Tissue Regeneration method facilitates considerable alveolar bone reconstruction, substantially enhancing the overall quality and outcomes of the therapeutic intervention.

JUVENILE OSTEOPOROSIS CAUSED BY LRP 5 GENE MUTATION

S. Kutilek[1], R. Pikner[2], O. Sluneckova[3], F. Losan[3]

[1]Department of Pediatrics, Klatovy Hospital, Klatovy, Czechia; [2]Department of Clinical Biochemistry and Bone Disease Center, Klatovy Hospital, Klatovy, Czechia; [3]Department of Medical Genetics Ltd, Pilsen, Czechia

Low-density lipoprotein receptor-related protein 5 (LRP5; OMIM: 603506) is encoded by the ***LRP5*** gene (11q13.2). This gene encodes a transmembrane low-density lipoprotein receptor that binds and internalizes ligands in the process of receptor-mediated endocytosis. LRP5 acts as a co-receptor with Frizzled protein family members for transducing signals by Wnt proteins. LRP5 gene mutations can lead to changes in bone mineral density (BMD): Inactivating mutations lead to osteoporosis (with pseudoglioma). Activating LRP 5 mutations result in excessively high BMD, even to osteopetrosis. We report a patient carrying LRP 5 mutation with osteoporosis.15-year old boy with uneventful personal and family history suffered two low-energy trauma fractures (L2-L3 vertebral compression fractures and a distal radius fracture) within six months.His anthropometric parameters were normal. Blood count and biochemical parameters (incl. S-creatinine, AST, ALT, Ca, P, Mg, ALP, PTH) were also within reference range, with the sole exception of lower 25OH-D vitamin. Bone densitometry performed by dual-X-ray absorptiometry (DXA) revealed low BMD : L1-L4 -3.3 SD Z-score. Therefore, oral ibandronate 150 mg once -a-month was started at the age of 16 years, together with calcium (1000 mg daily) and cholecalciferol (1000 IU/day). After two years of therapy, a significant increase in L1-L4 BMD (+70%) up to -1.9 SD Z-score was apparent. After these two years we proceeded to drug holiday and terminated the ibandronate treatment. Periodic controls (blood count, S-Ca,P, PTH, ALP, ALT, AST) were performed throughout the treatment and the results were always within relevant reference ranges. The genetic examination revealed interesting results: Firstly, LRP5 heterozygous sequential variant c.4087G>A,p.(Asp1363Asn). This causes exsudative vitreoretinopathy, osteoporosis and liver polycystosis type 4. The result of the genetic analysis is related to patient´s bone fragility. Fortunately, no liver cysts were detected by abdominal ultrasonography. The magnetic resonance imaging of the brain is normal, same as the ophthalmology examination. The patient is also a healthy carrier of heterozygous sequential variant c.1213+6T>C,p in arylsulphatase B (ARSB) gene, causative for mucopolysacharidosis type VI (Maroteaux-Lamy syndrome) and a heterozygous sequential variant c.100del,p.(His34ThrfsTer14) in the dedicator of cytokinesis 6 (DOCK6) gene , causative for autosomal recessive Adams-Oliver syndrome type 2 (skin and central nervous system defects, limb

malformations). The patient is currently 22 years old. He is in good state of health. At the age of 19 years he suffered a high-energy fracture of the left olecranone, otherwise he is free of fractures since the ibandronate treatment. He survived several injuries, always without fracture. The BMD measurement by DXA is repeated every two years, and remains stable (cca -2 SD). His basic biochemistry and bone turnover markers are within normal reference ranges. In conclusion, orally adminstered ibandronate improved BMD and quality of life in a patient with juvenile osteoporosis. Genetic assessment revealed LRP 5 mutation in a young man with bone fragility.

P1511

EFFECTS OF A 12-WEEK MULTIMODAL EXERCISE INTERVENTION ON BONE HEALTH IN POSTMENOPAUSAL WOMEN – PILOT STUDY

S. Liu[1], K. Daďová[1]

[1]Charles University, Praha, Czechia

Objective The aim of this pilot study was to investigate the effects of a 12-week multimodal exercise intervention on bone mineral density and physical function in postmenopausal women with osteopenia, and to evaluate its potential role in attenuating menopause-related functional decline.

Material and Methods Fifteen postmenopausal women aged 55–75 years with osteopenia or osteoporosis participated in a single-group pre–post study. Participants completed a 12-week multimodal exercise intervention focusing on lower-limb function, incorporating weight-bearing activities, resistance training, and traditional Chinese exercise (Baduanjin). Whole-body bone mineral density and functional outcomes were assessed before and after the intervention using dual-energy X-ray absorptiometry (DEXA). Statistical analyses were performed using SPSS software. Normality was assessed using the Shapiro–Wilk test, and paired t-tests or Wilcoxon signed-rank tests were applied as appropriate, with significance set at $P < 0.05$

Results Following the intervention, Tscores changed from −1.80 (IQR: −2.40 to −0.30) to −1.10 (IQR: −2.20 to −0.70), with no statistically significant difference ($P = 0.440$). Wholebody bone mineral content (BMC) changed from 1870.35 g (IQR: 1823.26–2084.42) to 1875.92 g (IQR: 1776.28–2051.70), showing no significant difference ($P = 0.307$). The agematched percentage (AM%) decreased from 97.40 ± 7.52 to 96.80 ± 6.92 after the intervention, with no statistically significant difference ($P = 0.436$). Bone mineral density (BMD) values changed from 0.987 ± 0.081 g/cm² to 0.981 ± 0.076 g/cm², and the difference was not statistically significant ($P = 0.383$).

Conclusion: This study found that a 12-week multimodal exercise intervention incorporating weight-bearing activities, resistance training, and Baduanjin did not result in statistically significant changes in whole-body bone mineral density, bone mineral content, or T-scores in postmenopausal women with osteopenia or osteoporosis. On the other hand, all bone-related outcomes were maintained over the intervention period, with no statistically significant declines. These findings suggest that this exercise program may help attenuate postmenopausal bone loss and contribute to the preservation of bone health.

P1512

CLINICAL EFFICACY AND SAFETY OF INTRA-ARTICULAR ALLOGENIC MESENCHYMAL STEM CELL THERAPY IN KELLGREN-LAWRENCE GRADE 2 & 3 KNEE OSTEOARTHRITIS

S. Londhe[1], G. Baranwal[2], I. Londhe[3]

[1]Department of Ortrhopaedics, Holy Spirit hospital, Criticare Asia hospital, Mumbai, India; [2]Department of Orthopaedics, Criticare Asia hospital., Mumbai, India; [3]Department of Electrical engineering, IIT Madras, Chennai, India

Objective: Incidence of osteoarthritis (OA) is rising with increased life expectancy of the population. OA is a degenerative joint disease primarily affecting the older population. Unfortunately, till to date, no medical treatment can reverse/ stop the articular cartilage degeneration eventually necessitating surgical procedure like Total Knee Arthroplasty. Allogenic mesenchymal stem cells (AMSC) have been shown to be a promising candidate to treat grade 2 and 3 Kellgren Lawrence (KL) OA due to their anti-inflammatory, immunomodulatory and chondrocyte differentiating properties potentially leading to cartilage regeneration. Aim of the study is to evaluate the safety and efficacy of the AMSC in treating grade 2 &3 KL OA.

Methods: A retrospective analysis of a prospectively collected data of 8 knees treated with intra articular AMSC plus hyaluronic acid injection from June 2023 to August 2024. Inclusion criteria were patients having grade 2&3 KL OA refractory to medical treatment. Patient having inflammatory arthritis, grade 3 meniscal tears and varus/ valgus deformity of > 5 degrees were excluded. Patients were evaluated by an independent observer with Visual analogue score (VAS) and Oxford Knee Score (OKS) at baseline and at 3,6 & 12-months post injection. Statistical analysis was carried out with student's t - test. P value < 0.05 was considered statistically significant.

Results:

The study group had 6 patients (M: F, 3:3). In 2 patients both knee joints were injected (Total 8 knees). The mean age of the study group was 54.38 ± 18.39 years (Range 35-80). The pre procedure VAS score was 6.5±0.92 which improved to 3.25±0.71 at 12 months follow up (p value<0.0001) The pre procedure OKS was 25.13±2.80, which improved to 37.25±3.65 at 12 months follow up (p value<0.0001). No patient in the study group experienced any local or systemic adverse effects.

Conclusion: The intra articular injection AMSC is safe and effective in reducing pain (as judged by VAS score) and improving the knee function as analysed by OKS in grade 2&3 KL OA patients. Small sample size being the limitation of the current study, further research is warranted with larger sample size, comparative group and longer follow up of the study cohort.

P1513

REALWORLD PRESCRIBING PATTERNS OF COMBINATION THERAPY WITH DENOSUMAB AND TERIPARATIDE (COMBIDATA) AMONG INDIAN ORTHOPAEDICIANS: A CROSSSECTIONAL SURVEY

S. Londhe[1], K. Shriram Dhanasekaran[2], P. Palkar[2], S. Mehta[2]

[1]Criticare Asia Hospital, Mumbai, India; [2]Medical Affairs, Cipla, Mumbai, India

Introduction

Combination therapy with denosumab and teriparatide (COMBI-DATA) has emerged as a strategy for managing patients with severe or complex osteoporosis, particularly those at very high fracture risk. Despite growing clinical interest, realworld patient selection, prescribing and monitoring patterns remain less documented in Indian Orthopaedic practice. The COMBIDATA survey aimed to capture perspectives and prescribing trends relating to this combination therapy among Indian Orthopaedicians.

Materials and Methods

A crosssectional, questionnairebased survey was conducted among practising Orthopaedicians across India. The validated digital questionnaire consisted of 22 items covering prescribing frequency, patient profiles, fracture indications, agegroup preferences, timing of denosumab initiation, DXA monitoring practices, safety, reasons for treatment discontinuation, comorbidityrelated avoidance, and alternative choices for patients with severe renal impairment. A total of 66 fully validated responses were analysed descriptively.

Results

Among 66 respondents, 92.4% reported having prescribed the denosumab–teriparatide combination. Most clinicians use the combination in 1–10% (33.3%) or 11–25% (31.8%) of their osteoporotic patients. Severe osteoporosis with fractures (72.7%) was the most frequent indication (Figure 1). Vertebral (81.8%) and hip (74.2%) fractures being the predominant sites treated. Patients aged 61–70 years were most prescribed with the combination. Denosumab was mostly added at 3 months (34.8%) or at the initiation of teriparatide (30.3%). DXA evaluation was repeated at 12 months (37.9%). The common adverse effects reported were musculoskeletal pain (59.1%) and muscle cramps (57.6%), whereas osteonecrosis of the jaw was reported as uncommon (4.5%). Cost (86.4%) and hesitation toward daily injections (54.5%) constituted the primary reasons for discontinuation. Severe renal impairment (83.3%) was the most strongly associated with avoidance of the combination; in such cases, denosumab monotherapy (54.5%) and calcitonin nasal spray (39.4%) were the preferred alternatives.

Conclusion

The COMBIDATA survey highlights the prescribing patterns of denosumab–teriparatide combination therapy in India. While the combination is widely adopted for highrisk fracture phenotypes of osteoporosis, variability exists in frequencies and monitoring approaches. Economic concerns and injectionrelated barriers remain factors influencing adherence. This underscores the need for clearer clinician and patienteducation strategies to optimise combinationtherapy outcomes in routine orthopaedic practice.

PERCEIVED BARRIERS TO PHYSICAL ACTIVITY IN PATIENTS WITH RHEUMATOID ARTHRITIS AND SPONDYLOARTHRITIS

S. Loukil[1], A. Fazaa[1], S. Miladi[1], Y. Makhlouf[1], H. Boussaa[1], K. Ben Abdelghani[1], A. Laatar[1]

[1]Monji Slim Hospital, Tunis, Tunisia

Introduction : Physical activity (PA) is a cornerstone in the management of inflammatory rheumatic diseases especially Rheumatoid arthritis (RA) and spondyloarthritis (SpA). However, many patients do not achieve recommended levels of PA. This situation may be partly explained by patients' perceived barriers.

AIM : This study aimed to identify the perceived barriers to physical activity within patients with rheumatoid arthritis (RA) and spondyloarthritis (SpA).

Methods : We conducted a cross-sectional study that included patients with RA recruited from the rheumatology department of Mongi Slim Hospital. Sociodemographic data as well as those related to the disease were transcribed.

Perceived barriers were assessed using the Exercise Barriers Scale (EBBS), which comprises four subscales. Statistical significance was fixed for $p<0.05$.

Results : In total, 100 patients were included (60 RA and 40 SpA). The mean age was 51 ± 14 years old. There was a female predominance (sex ratio F/M =1.85). The mean disease duration was 11.8 ± 7,2 years. RA was immunopositive in 83% and erosive in 77% of cases. Twenty patients had axial and peripheral spondyloarthritis (SpA) (50%). SpA was primary in 28 patients (70%), associated with inflammatory bowel disease (IBD) in 9 patients (23%), and with psoriasis in 3 patients (8%).

The mean EBBS "barriers" subscore was 31.8 ± 9.9. This mean was 32.6 ± 10.2 [14–55] in patients with rheumatoid arthritis (RA) and 30.4 ± 9.2 [14–52] in patients with spondyloarthritis (SpA). The main barrier to physical activity reported by patients was: "I am too fatigued to exercise." The EBBS "barriers" subscore was significantly associated with female gender ($p = 0.007$), low educational level ($p = 0.01$), occupational status, particularly manual labor ($p = 0.02$), rural living environment ($p = 0.01$), and the presence of psoriasis ($p = 0.02$).

Conclusion : Our study revealed that higher perceived barriers were linked to greater disease impact, emphasizing the need for tailored interventions, to encourage physical activity among patients with RA and SpA.

P1515

ASSESSMENT OF PHYSICAL ACTIVITY IN CHRONIC INFLAMMATORY RHEUMATIC DISEASES

S. Loukil[1], A. Fazaa[1], S. Miladi[1], Y. Makhlouf[1], H. Boussaa[1], K. Ben Abdelghani[1], A. Laatar[1]

[1]Monji Slim Hospital, Tunis, Tunisia

Introduction :
Physical activity (PA) is recognized as a key component for the management of Chronic Inflammatory Rheumatic Diseases (CIRD) such as Rheumatoid arthritis (RA) and spondyloarthritis (SpA), contributing to improved disease outcomes, physical function, and quality of life. Despite this fact, previous studies have shown lower levels of PA compared with the general population.
AIM :
This study aims to assess the level of PA in patients with RA and SpA and to identify factors associated with active engagement.
Methods :
We conducted a cross-sectional study involving patients diagnosed with CIRD, recruited from the rheumatology department of Monji Slim Hospital. Sociodemographic data as well as disease-related characteristics were transcribed (medical history, educational level, occupation, marital status, living setting). The level of PA was assessed using the Global Physical Activity Questionnaire (GPAQ). Statistical significance was fixed for $p<0.05$.
Results :
The study included 100 patients 60 with RA and 40 with SpA, with a female predominance (sex ratio F/M =1.85). The mean age was of 51 ± 14 years old.
Regarding educational levels, 25% had a university level or higher, 30% had a secondary level, 26% had a primary level, and 19% were illiterate. In terms of occupation, 37% were employed, 43% were unemployed, and 20% were retired.
As for marital status, 69% were maried, 4% were single, 28% were widowed, and 8% were divorced. Seventy-six percent of patients lived in urban areas, while 24% resided in rural settings.
The mean disease duration was 11.8 ± 7,2 years. RA was immunopositive and erosive in the majority of cases (83 % and 77%). The mean erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP) were 28,5 ± 24 and 17,2 ± 32, respectively.
The mean Disease Activity Score (DAS28-ESR) was 3.6 ± 1.2, and the mean ASDAS-CRP was 2.3 ± 1.1.
The median total PA was 6840 MET-minutes/week [2175–12390].
Physical activity was negatively correlated with ESR ($p = 0.048$), ASDAS-CRP ($p = 0.029$), and BASFI ($p = 0.026$).
Conclusion :
Our study showed that Physical activity was inversely associated with inflammatory markers, disease activity, and functional impairment. Based on these findings, it appears essential to highlighting its potential role as an important component of disease management.

P1516

PERCEIVED BENEFITS OF PHYSICAL ACTIVITY IN CHRONIC INFLAMMATORY RHEUMATIC DISEASES

S. Loukil[1], A. Fazaa[1], S. Miladi[1], Y. Makhlouf[1], H. Boussaa[1], K. Ben Abdelghani[1], A. Laatar[1]

[1]Monji Slim Hospital, Tunis, Tunisia

Introduction :
Physical activity (PA) is a key determinant of health in patients with chronic inflammatory rheumatic diseases (CIRD), particularly rheumatoid arthritis (RA) and spondyloarthritis (SpA). These include improved physical function, reduced disease-related symptoms, and enhanced quality of life. Exploring patients' perceptions of these benefits can help tailor interventions to increase PA participation.
AIM :
The objectives of this study were to assess patients' perceptions of PA-related benefits among patients with CIRDs and to identify associated factors.
Methods :
This was a cross-sectional study including patients followed for RA or SpA. Sociodemographic data and disease-specific characteristics were collected. The level of PA was assessed using the Global Physical Activity Questionnaire (GPAQ). Perceptions of PA benefits were explored using the Exercise Benefits Scale (EBBS), which includes five subscales for benefits, with a score ranging from 28 to 112.
Results :
A total of 100 patients were included, 60 with RA and 40 with SpA, comprising 65 women and 35 men, with a mean age of 51 ± 14 years.
The median total PA was 6840 MET-minutes/week [2175–12390]. The mean EBBS "benefits" subscore was 96.4 ± 15.3 (94.2 ± 14.8 in RA vs. 99.7 ± 15.5 in SpA; $p=0.07$). The most strongly perceived benefit of PA was mental health improvement (3,68±0,6).
(2,88±1,14). A favorable perception of PA was independently associated with male gender ($p = 0.001$; $\beta = 15.364$ [6.892; 23.836]), higher educational level ($p = 0.006$; $\beta = 5.777$ [1.661; 9.893]), urban living environment ($p = 0.001$; $\beta = -17.032$ [−26.998; −7.066]), marital status ($p = 0.014$; $\beta = 4.380$ [0.912; 7.849]), SpA diagnosis ($p = 0.02$; $\beta= 4.994$ [0.818; 9.170]), and lower erythrocyte sedimentation rate ($p = 0.019$; $\beta= -0.279$ [−0.511; −0.047]).
Conclusion:
Integrating the assessment of PA perceptions into the management of patients with CIRDs appears essential to identify barriers and to tailor interventions accordingly.

SPECIFIC FEATURES OF PHYSICAL ACTIVITY IN PATIENTS WITH SPONDYLOARTHRITIS (SPA)

S. Loukil[1], A. Fazaa[1], S. Miladi[1], Y. Makhlouf[1], H. Boussaa[1], K. Ben Abdelghani[1], A. Laatar[1]

[1]Monji Slim Hospital, Tunis, Tunisia

Introduction :
Spondyloarthritis (SpA) is a chronic inflammatory rheumatic disease associated with significant functional impairment which negatively affects patients' quality of life. A major consequence of this condition is reduced physical activity (PA).
AIM :
The aim of this study is to investigate the impact of spondyloarthritis on physical activity.
Methods :
We conducted a cross-sectional study including patients diagnosed with spondyloarthritis according to the [ASAS] classification criteria recruited from the rheumatology department of Mongi Slim Hospital. Sociodemographic and clinical data were collected. Patients also completed a self-administered questionnaire to assess their global physical activity questionnaire (GPAQ) scores. Statistical significance was fixed for $p<0.05$.
Results :
The study included 40 patients with SpA :sixteen women (40%) and twenty-four men (60%), with a gender ratio of 1.5. The mean age was 44.5 ± 13.1 years. Eight patients (20%) had office jobs, 11 (27%) performed manual labor, six patients (15%) were retired, and 15 (38%) were unemployed.
Twenty patients had both axial and peripheral articular SpA (50%). SpA was primary in 28 patients (70%), associated with IBD in nine patients (23%), and with psoriasis in three patients (8%). The mean disease duration of SpA was 11.8 ± 7.2 years. In terms of disease activity, the mean erythrocyte sedimentation rate (ESR) was 28.5 ± 24 mm, and the mean C-reactive protein (CRP) level was 17.2 ± 32 mg/L. The mean BASDAI score was 2.4 ± 1.7, with 75% of patients in remission. The mean ASDAS-CRP score was 2.3 ± 1.1, with 18% of patients exhibiting low disease activity. The mean LEI score was 2.3 ± 1.6. and the mean BASFI score was 3.5 ± 2.3.
Twenty-one patients (53%) had hip involvement (coxitis), which required surgery in 13% of cases. In patients with SpA (n = 40), the median total physical activity was 6860 MET-min/week. Regarding activity levels, 8% had low, 23% moderate, and 70% high total physical activity. The median daily duration of total physical activity was 244 minutes, including 111 minutes of work-related activity, 45 minutes of transport-related activity, and 30 minutes of leisure-time activity. The median percentage of total daily activity attributable to work, transport, and leisure was 53.3%, 18.7%, and 15.9%, respectively. Median daily sedentary time was 105 minutes .
Conclusion :
Patients with spondyloarthritis exhibit moderate to high levels of physical activity despite functional limitations, with work-related activity contributing most to total daily activity. Sedentary time remains relatively low, highlighting the potential for maintaining an active lifestyle. Targeted interventions could further promote leisure-time physical activity to improve overall health and quality of life in this population.

P1518

PASSIVE HIP STIFFNESS AND MEDIAL KNEE PAIN SENSITIVITY: A PRELIMINAR CROSS-SECTIONAL STUDY

I. L. Nóbrega[1], M. G. Da Silva[1], R. F. Tizziotti[1], N. A. Casonato[1], F. E. Sette[1], S. M. Mattiello[1]

[1]Federal University of São Carlos, São Carlos, Brazil

Objectives: Knee Osteoarthritis (KOA) pain involves biomechanical mechanisms and sensitization. While hip strength is well-studied, the influence of passive stiffness on pain sensitivity remains underexplored. This preliminary study analyzed the association between passive hip stiffness and pressure pain threshold (PPT), investigating whether KOA modifies this relationship.
Methods: This preliminary cross-sectional analysis included 25 participants (20 with KOA and 5 without KOA). Separate multiple linear regression models were used to examine the association between PPT and passive hip joint stiffness (measured in degrees, where higher values indicate lower stiffness), adjusting for age. PPT was assessed at three sites: 3 cm medial to the knee joint line, the ipsilateral tibialis anterior muscle, and the contralateral forearm. Knee pain status was included as a categorical variable (0 = no osteoarthritis, 1 = osteoarthritis). An interaction term between hip stiffness and knee pain status was included to assess whether the association between stiffness and PPT was modified by the presence of osteoarthritis. Statistical analyses were performed in RStudio, with significance set at $p < 0.05$.
Results: Participants (mean age 58.6±9.6; 68% female) had a mean pain intensity of 5.0±2.8. For medial knee PPT, the model explained 44.1% of the variance (R^2=0.44, p=0.005). A significant interaction was found (p=0.007): greater hip flexibility correlated with higher pain thresholds in controls, but with lower thresholds (increased pain responsiveness) in the KOA group (Figure 1). No significant associations were found for secondary sites, indicating the effect was specific to the medial knee.
Conclusion: These preliminary findings suggest that passive hip stiffness is differentially associated with local pain sensitivity depending on the presence of knee osteoarthritis. While greater hip flexibility appears to be associated with reduced pain sensitivity in individuals without KOA, the opposite pattern was observed in those with KOA, indicating a potential maladaptive biomechanical–sensory interaction in this population. Further studies with larger samples and longitudinal designs are needed to confirm these associations and to clarify their clinical relevance.

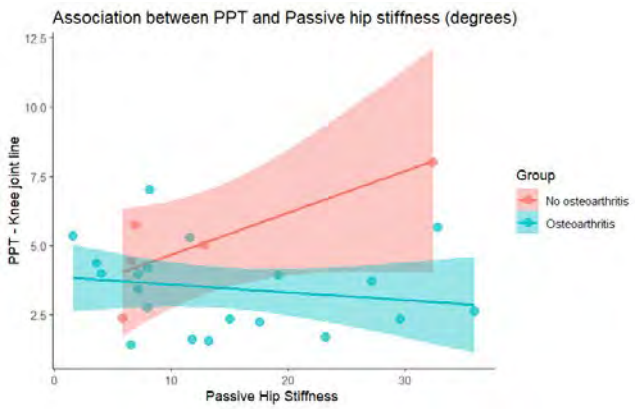

Figure 1 - Interaction effect of passive hip stiffness on medial knee pressure pain threshold (PPT) stratified by group.

P1519

THE MODERATING ROLE OF PHYSICAL ACTIVITY IN THE RELATIONSHIP BETWEEN METABOLIC MARKERS AND CARDIOVASCULAR RISK IN OSTEOARTHRITIS: OBESE VS. NON-OBESE

L. V. Almeida[1], M. Gyaraki[1], R. F. Tizziotti[1], S. M. Mattiello[1]

[1]Department of Physiotherapy, Federal University of São Carlos-SP, São Carlos, Brazil

Objective: To compare the association between cardiometabolic markers and cardiovascular risk in obese versus non-obese individuals with osteoarthritis and assess moderation by physical activity. **Methods**: Blood samples were collected after a 12-hour fast for analysis of lipid and glycemic profiles. Muscle function was assessed with the 30-second Chair Stand Test using an armless chair. Physical activity was measured objectively using an activPAL accelerometer (right thigh, 7 days), with valid data defined as ≥10 hours/day for ≥5 days, providing measures of sitting time, sit-to-stand transitions, step count, and stair use. **Results**: The study included 61 individuals with osteoarthritis, divided into obese (n=30; age: 59.3±9.7 years; 64.5% female, 35.5% male) and non-obese (n=31; age: 60.3±9.7 years; 63.3% female, 36.7% male) groups. Obese participants showed significantly higher weight, waist and hip circumference, and BMI (all p<0.001). Borderline differences were observed for fasting glucose and visceral adipose tissue area, whereas height, waisttohip ratio, HDL, triglycerides, sittostand performance, and daily step count did not differ between groups.In multiple linear regression analysis (predictors: VAT area, BMI, waist-to-hip ratio), predictive patterns differed according to nutritional status. For fasting glucose, the model was significant only in the non-obese group (p=0.040), with waist-to-hip ratio as a positive predictor. For triglycerides, no model was significant. For HDL, the model fit was excellent in the non-obese group (p=0.0003), with BMI as a negative predictor, and marginal in the obese group (p=0.099). Additional models incorporating functional variables (sittostand and steps/day) showed no significant associations with metabolic markers, suggesting that adipositymetabolic relationships are linear only in nonobese individuals, whereas more complex, nonlinear mechanisms likely dominate in obesity. **Conclusion**: The association between adiposity and metabolic markers in osteoarthritis differs by obesity status. In non-obese individuals, waist-to-hip ratio was linearly related to fasting glucose, and BMI to HDL levels. These linear associations were absent in obese individuals, suggesting the predominance of alternative pathways, such as inflammation and insulin resistance. The lack of correlation with functional measures underscores the complex, multifactorial nature of metabolic regulation in this population, highlighting the need to investigate nonlinear pathways for targeted management.

P1520

ASSOCIATION OF SARCOPENIA-RELATED INDICES WITH SELF-REPORTED PAIN, STIFFNESS, AND PHYSICAL FUNCTION IN KNEE OSTEOARTHRITIS

M. Gyaraki[1], L. Almeida[1], I. Nóbrega[1], N. Casonato[1], S. M. Mattiello[1]

[1]University of São Carlos, São Carlos, Brazil

Objective

To investigate the association between sarcopenia-related indices, represented by muscle function and appendicular lean mass, and pain, stiffness, and perceived physical function in individuals with knee osteoarthritis (KOA).

Methods

This cross-sectional study included individuals of both sexes, aged 40–80 years, diagnosed with KOA according to the American College of Rheumatology criteria. Muscle function was assessed using the 30-Second Chair Stand Test (30s-CST). Body composition was evaluated by dual-energy X-ray absorptiometry, and appendicular lean mass was adjusted for body size. Pain sensitivity was assessed by pressure pain threshold at the medial joint line of the symptomatic knee using digital algometry. Pain, stiffness, and physical function were assessed using the Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC). Associations were examined using multiple linear regression models adjusted for age, sex, and pain sensitivity.

Results

Seventy-seven participants were included (mean age 58.2 ± 9.4 years; 64.9% women). Mean performance on the 30s-CST was 9.7 ± 2.8 repetitions, and the mean WOMAC total score was 37.6 ± 18.5 points. Appendicular lean mass showed a mean value of 7.39 ± 2.07, while pressure pain threshold demonstrated high variability (246 ± 145 kPa). Muscle function was inversely and independently associated with WOMAC scores (β = −2.36; p = 0.0011*; 95% CI: −11.22 to −2.93), as was appendicular lean mass (β = 3.44; p = 0.0027*; 95% CI: 2.21 to 10.15), jointly explaining 27% of the outcome variability. Age (p = 0.298; 95% CI: −2.52 to 8.11) and pressure pain threshold (p = 0.713; 95% CI: −6.82 to 4.69) were not significantly associated with WOMAC scores.

Conclusions

Sarcopenia-related indices, represented by muscle function and appendicular lean mass, were associated with the severity of pain, stiffness, and perceived disability in individuals with knee osteoarthritis, even after adjustment for age, sex, and pain sensitivity. In contrast, age and pain sensitivity did not significantly contribute to the explanation of WOMAC scores.

Disclosure of Conflict of Interest

DIVERGENT MUSCLE–METABOLIC AGING TRAJECTORIES IN OLDER WOMEN WITH BREAST CANCER TREATED WITH AROMATASE INHIBITORS VERSUS SELECTIVE ESTROGEN RECEPTOR MODULATORS: A REAL-WORLD LONGITUDINAL STUDY

O. Regev[1], S. Matzri[2], E. Izkhakov[2], T. Kolitz[2], Y. Marcus[2], Y. Greenman[2], V. Rouach[3,4]

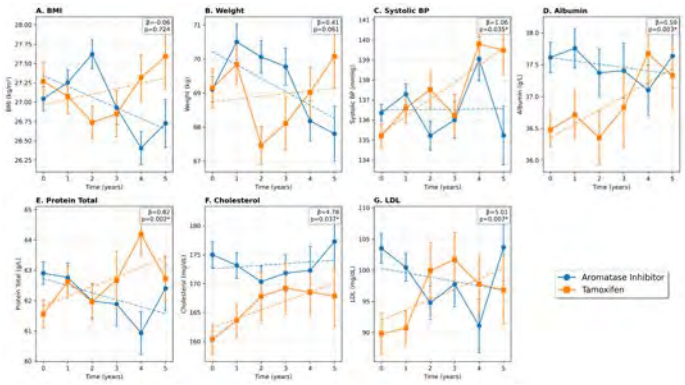
[1]Department of Public Health, Faculty of Health Sciences, Ben-Gurion University of the Negev, Beer Sheva ., Israel; [2]Institute of Endocrinology, Metabolism and Hypertension, Tel Aviv Sourasky Medical Center, Israel, Tel Aviv, Israel; [3]The Dr. Miriam and Sheldon G. Adelson School of Medicine (The Gray School), Tel Aviv University, Israel, Tel Aviv, Israel; [4]Tel Aviv Sourasky Medical Center, Institute of Endocrinology, Metabolism and Hypertension, Tel Aviv, Israel

Background: Endocrine therapy in older women with hormone receptor–positive breast cancer may substantially influence aging-related outcomes beyond cancer control. While Aromatase Inhibitors (AI) and Selective Estrogen Receptor Modulators (SERM) differ in their estrogenic effects, their comparative impact on muscle integrity, metabolic stability, and downstream fall and fracture risk remains insufficiently characterized. Sarcopenia is a key determinant of frailty and skeletal outcomes, yet objective muscle measures are rarely available in routine oncology care.

Methods: We conducted a large population-based longitudinal cohort study of women aged ≥50 years with breast cancer treated with AI or SERM. Propensity score matching balanced baseline demographic, clinical, and metabolic characteristics. Longitudinal changes in anthropometric, cardiometabolic, and nutritional biomarkers serving as proxies of muscle health (serum albumin and total protein) were assessed using linear mixed-effects models. Lipid trajectories, including LDL variability, were evaluated descriptively. Falls and fractures were assessed using Kaplan–Meier analyses. Mean follow-up was approximately 3 years.

Results: Among 4,987 women treated with endocrine therapy, 1,632 (1,040 AI users and 592 SERM users) were included in the propensity score–matched longitudinal analysis. BMI trajectories did not differ significantly between treatment groups, although modestly greater weight loss was observed among AI users. Markers relevant to sarcopenia risk showed significantly different longitudinal patterns: AI therapy was associated with greater declines in serum albumin and total protein over time, particularly among women aged 70–79 years ($p<0.01$). SERMs were associated with less favorable cardiometabolic trajectories, including greater increases in systolic blood pressure and progressive elevations in total and LDL cholesterol. LDL trajectories under AI therapy demonstrated greater dispersion over time, indicating increased LDL variability despite similar mean changes. No significant differences were observed in fall or fracture incidence between groups.

Figure 1: Treatment Effects Over Time on Clinical Parameters
Longitudinal trajectories of (A) BMI, (B) Weight, (C) Systolic Blood Preassure, (D) Albumin, (E) Total protein, (F) Total cholesterol, and (G) LDL, comparing Aromatase Inhibitors (blue circles) versus SERM=Tamoxifen (orange squares) over 5 years. Data points represent means within 6-month time bins with 95% confidence intervals. Solid lines connect observed means; dashed lines show linear trends. The β coefficient represents the treatment-by-time interaction, indicating the difference in annual rate of change (SERM=Tamoxifen minus Aromatase Inhibitor). Positive β indicates SERM=Tamoxifen increases more (or decreases less) per year than Aromatase Inhibitors. P-values from linear mixed models.



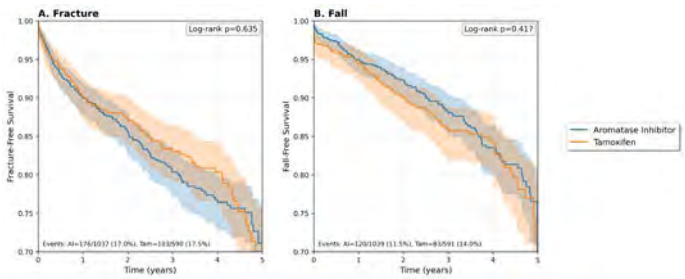


Figure 2. Kaplan–Meier estimates of fracture-free (A) and fall-free (B) survival according to endocrine therapy (aromatase inhibitors vs tamoxifen). Shaded areas indicate 95% confidence intervals.

Conclusions: Endocrine therapy in older women with breast cancer is associated with distinct aging-related trade-offs. Aromatase inhibitors are linked to nutritional biomarker decline suggestive of early sarcopenic vulnerability, whereas SERMs are associated with adverse cardiometabolic changes. These findings highlight the importance of integrated bone–muscle–metabolic assessment and geriatric-informed monitoring in aging cancer survivors.

DOES EXCESSIVE SUGAR INTAKE CONTRIBUTE TO SARCOPENIA IN RHEUMATOID ARTHRITIS?

K. Zouaoui[1], S. Mhamdi[1], R. Ben Othmane[2], A. Krir[3], S. Rahmouni[1], S. Rekik[1], S. Boussaid[1], H. Sahli[1]

[1]Rheumatology department, La Rabta Hospital, Tunis, Tunisia; [2]National Institute of Nutrition, Tunis, Tunisia; [3]Biochemistry Department, Pasteur Institute, Tunis, Tunisia

Objective: To examine the association between dietary sugar intake and sarcopenia in female patients with rheumatoid arthritis (RA).
Material and Methods: A monocentric cross-sectional study was conducted over a 6-month period, including female patients with RA who met the 2010 ACR-EULAR criteria. Demographic, clinical, and paraclinical

data related to RA were collected.
Muscle mass and strength were measured to assess sarcopenia. Appendicular skeletal muscle mass index (ASMI) was assessed using both bioelectrical impedance analysis (BIA) and dual-energy X-ray absorptiometry (DEXA). ASMI was obtained by dividing appendicular muscle mass by height squared. Muscle strength was evaluated with a handgrip dynamometer. Sarcopenia was defined as an ASMI ≤ 5.5 kg/m² and a handgrip strength <16 kg.
Dietary sugar intake was assessed using a 24-hour dietary recall. Intake was evaluated according to World Health Organization recommendations, with consumption exceeding 100 g/day considered excessive.
Results: A total of 52 women were enrolled in the study. The mean age was 58 ± 8 years [40–76], and the mean duration of rheumatoid arthritis was 9 ± 6 years [1–30]. RA was seropositive in 90% and erosive in 90% of patients. The mean DAS28-CRP score was 4 ± 2 [1.5–6.5]. All patients received at least one conventional DMARD, and 40% had been switched to biologic therapy.
Mean handgrip strength was 9 ± 6 kg [2–26], and mean ASMI was 7 ± 1 kg/m² [5–11] by BIA and 6 ± 1 kg/m² [4–9] by DEXA. Sarcopenia was identified in 19% of patients (n = 10).
Mean daily sugar intake was 99 ± 33 g [58–161] in sarcopenic patients and 100 ± 34 g [39–182] in non-sarcopenic patients. Excessive intake was noted in 50% of sarcopenic and 40% of non-sarcopenic patients. This difference did not reach statistical significance (p = 0.698).
Conclusion: No significant association was found between dietary sugar intake and sarcopenia in this female RA patients' cohort.

P1523

IS SERUM MYOSTATIN ASSOCIATED WITH SARCOPENIA IN KNEE OSTEOARTHRITIS?

S. Mhamdi[1], K. Zouaoui[1], R. Ben Othmane[2], A. Krir[3], S. Rahmouni[1], S. Rekik[1], S. Boussaid[1], H. Sahli[1]

[1]Rheumatology department, La Rabta Hospital, Tunis, Tunisia; [2]National Institute of Nutrition, Tunis, Tunisia; [3]Biochemistry Department, Pasteur Institute, Tunis, Tunisia

Objective: To investigate the association between serum myostatin levels and sarcopenia in female patients with knee osteoarthritis (OA).
Material and Methods: Female patients with knee osteoarthritis (OA) fulfilling the ACR classification criteria were enrolled. We collected demographic, clinical, and paraclinical data.

The severity of knee OA was graded according to the Kellgren–Lawrence (KL) scale, from 0 (no radiographic OA) to 4 (severe OA), based on joint space narrowing, osteophyte formation, subchondral sclerosis, and bone deformities.

Sarcopenia was assessed through both muscle strength and muscle mass. Handgrip strength was measured using a dynamometer, and muscle mass was evaluated via bioelectrical impedance analysis (BIA) and dual-energy X-ray absorptiometry (DEXA). The appendicular skeletal muscle mass index (ASMI) was calculated by dividing appendicular lean mass by the square of the patient's height. Sarcopenia was defined by an ASMI ≤ 5.5 kg/m² and a handgrip strength <16 kg.
Venous blood samples were obtained from all participants to determine serum myostatin levels using an ELISA kit. Reference values ranged from 1,264 to 8,588 pg/mL.
Results: Thirty female patients were included, with a mean age of 62±8 years [48-74]. The mean knee OA duration was 40±28 months [8-120]. Fifty percent of patient had stage II knee OA according the KL grading. Sarcopenia was diagnosed in 10% (n=3) of patients.

Mean serum myostatin levels were 1400±443pg/mL [1136-1912] in sarcopenic patients versus 1738±829 pg/mL [149-3859] in non-sarcopenic patients.
Correlation analysis revealed no significant association between serum myostatin and sarcopenia (p=0.207).
Conclusion: Serum myostatin levels were not associated with sarcopenia in female patients with knee osteoarthritis. These results suggest that myostatin has limited value as a biomarker for early muscle loss in knee OA, and larger studies are needed to further explore this association.

P1524

CORTICOSTEROID USE AND SARCOPENIA IN RHEUMATOID ARTHRITIS: IS THERE A LINK?

K. Zouaoui[1], S. Mhamdi[1], R. Ben Othmane[2], A. Krir[3], S. Rahmouni[1], S. Rekik[1], S. Boussaid[1], H. Sahli[1]

[1]Rheumatology department, La Rabta Hospital, Tunis, Tunisia; [2]National Institute of Nutrition, Tunis, Tunisia; [3]Biochemistry Department, Pasteur Institute, Tunis, Tunisia

Objective: To assess the association between corticosteroid use and sarcopenia in patients with rheumatoid arthritis (RA).
Material and Methods: A cross-sectional study included female patients with RA meeting the ACR/EULAR 2010 criteria. Demographic, clinical, paraclinical and therapeutic data of participants were collected. Corticosteroid use and the prednisone-equivalent dose in milligrams (mg) were recorded.
Muscle mass was assessed by both bioelectrical impedance analysis (BIA) and dual-energy X-ray absorptiometry (DEXA). The appendicular skeletal muscle mass index (ASMI) was calculated as appendicular muscle mass divided by height squared.
Muscle strength was determined by a handgrip test using a dynamometer. Sarcopenia was diagnosed if ASMI was ≤ 5.5 kg/m² combined with a handgrip strength < 16 kg.
Results: Fifty-two female patients were included. The average age was 58±8 years [40-76]. The mean duration of RA progression was 9±6 years [1-30]. The mean DAS28-CRP was 4±2 [1.5-6.5]. Active disease with a DAS28-CRP > 3.2 was noted in 92% (n=48) of patients. All our patients have had at least one conventional synthetic disease-modifying antirheumatic drug. Biologics were used in 40% of patients. Corticosteroids were still ongoing in 77% of patients at the study time with an average dose of 6.3±2 mg of prednisone per day [2.5-10]. Sarcopenia was detected in 19% (n=10) of patients with a mean hand grip test of 9±6 kg [2-26]. The mean ASMI was 7±1 kg/m² [5-11] by BIA and 6±1 kg/m² [4-9] by DEXA.
When comparing sarcopenic and non-sarcopenic patients, corticosteroids were used in 100% and 98% of cases, respectively, with respective mean daily prednisone doses of 6.0 ± 2.4 mg and 6.1 ± 2 mg. No significant association was found between sarcopenia and corticosteroid use (p = 1) or corticosteroid dose (p = 0.663).
Conclusion: In this female RA cohort, no association was found between corticosteroid use or dose and sarcopenia.

P1525

IS SERUM BDNF A POTENTIAL BIOMARKER OF SARCOPENIA IN RHEUMATOID ARTHRITIS?

S. Mhamdi[1], K. Zouaoui[1], R. Ben Othmane[2], A. Krir[3], S. Rahmouni[1], S. Rekik[1], S. Boussaid[1], H. Sahli[1]

[1]Rheumatology department, La Rabta Hospital, Tunis, Tunisia; [2]National Institute of Nutrition, Tunis, Tunisia; [3]Biochemistry Department, Pasteur Institute, Tunis, Tunisia

Objective: To explore the association between serum brain-derived neurotrophic factor (BDNF) and sarcopenia in patients with rheumatoid arthritis (RA).
Material and Methods: Female patients with RA fulfilling the 2010 ACR–EULAR classification criteria were included. Demogr aphic data as well as clinical and paraclinical RA parameters were collected.

Sarcopenia was assessed based on its two domains: muscle strength and muscle mass. Muscle strength was evaluated using a handgrip strength test performed with a dynamometer. Muscle mass was assessed by bioelectrical impedance analysis (BIA) and dual-energy X-ray absorptiometry (DEXA). The appendicular skeletal muscle mass index (ASMI) was calculated by dividing appendicular muscle mass by height squared.

Sarcopenia was defined as an ASMI ≤ 5.5 kg/m² combined with a handgrip strength < 16 kg.

Serum BDNF levels were measured in 29 patients using venous blood samples and analyzed by ELISA. Normal reference values ranged from 6,186 to 42,580 pg/mL.
Results: Fifty-two female patients were included. The mean age was 58 ± 8 years [40–76]. RA was seropositive in 90% and erosive in 90% of patients. The mean disease duration was 9 ± 6 years [1–30]. Ninety-two percent of patients (n=48) had active disease with a DAS28-CRP > 3.2. All patients received at least one conventional synthetic DMARD, and 40% (n=21) were treated with biologics.
The mean handgrip strength was 9 ± 6 kg [2–26]. The mean ASMI was 7 ± 1 kg/m² [5–11] by BIA and 6 ± 1 kg/m² [4–9] by DEXA. Sarcopenia was diagnosed in 19% of patients (n=10).
The mean serum BDNF level was 184.8 ± 119.9 pg/mL in sarcopenic patients versus 136.1 ± 50 pg/mL in non-sarcopenic patients, with no statistically significant difference (p=0.258).
Moreover, only one non-sarcopenic patient had a low BDNF level, while all sarcopenic patients had BDNF levels within the normal range, with no significant difference between groups (p=1).
Conclusion: In this cohort, serum BDNF levels were not associated with sarcopenia in RA patients.

P1526

DO SOCIODEMOGRAPHIC FACTORS CONTRIBUTE TO SARCOPENIA IN RHEUMATOID ARTHRITIS PATIENTS?

K. Zouaoui[1], S. Mhamdi[1], R. Ben Othmane[2], A. Krir[3], S. Rahmouni[1], S. Rekik[1], S. Boussaid[1], H. Sahli[1]

[1]Rheumatology department, La Rabta Hospital, Tunis, Tunisia; [2]National Institute of Nutrition, Tunis, Tunisia; [3]Biochemistry Department, Pasteur Institute, Tunis, Tunisia

Objective: To investigate the association between sociodemographic factors and sarcopenia in patients with rheumatoid arthritis (RA).
Material and Methods: Female patients with RA who met the 2010 ACR-EULAR criteria were enrolled in this study. We collected sociodemographic, clinical, and paraclinical data.
Sarcopenia was assessed by measuring both muscle strength and muscle mass. Muscle strength was evaluated using a handgrip test with a dynamometer, while muscle mass was determined through bioelectrical impedance analysis (BIA) and dual-energy X-ray absorptiometry (DEXA). The appendicular skeletal muscle mass index (ASMI) was calculated as appendicular muscle mass divided by height squared. Sarcopenia was defined as an ASMI ≤ 5.5 kg/m² combined with handgrip strength < 16 kg.
Results: Fifty-two female patients were included in this study, with a mean age of 58 ± 8 years [40–76]. Among the participants, 35% (n = 18) lived in rural areas. Most patients were married (88%, n = 46), while 4% (n = 2) were single and 8% (n = 4) were widowed. Regarding educational level, 46% (n = 24) had primary school education, and 36% (n = 19) were illiterate. Forty-six percent (n = 24) were unemployed.
The mean disease duration was 9 ± 6 years [1–30]. RA was seropositive and erosive in 90% of cases. The mean DAS28-CRP score was 4 ± 2 [1.5–6.5], with active disease (DAS28-CRP > 3.2) observed in 92% (n = 48) of patients. Mean handgrip strength was 9 ± 6 kg [2–26]. Mean ASMI was 7 ± 1 kg/m² [5–11] by BIA and 6 ± 1 kg/m² [4–9] by DEXA. Sarcopenia was present in 19% of patients (n = 10).
No significant association was observed between sarcopenia and sociodemographic factors, including age (p = 0.368), living area (p = 1), marital status (p = 0.360), educational level (p = 0.468), or professional status (p = 1).
Conclusion: In this cohort, sarcopenia occurred independently of sociodemographic factors in female patients with RA.

P1527

IS PAIN RELATED TO SARCOPENIA IN KNEE OSTEOARTHRITIS?

S. Mhamdi[1], K. Zouaoui[1], R. Ben Othmane[2], A. Krir[3], S. Rahmouni[1], S. Rekik[1], S. Boussaid[1], H. Sahli[1]

[1]Rheumatology department, La Rabta Hospital, Tunis, Tunisia; [2]National Institute of Nutrition, Tunis, Tunisia; [3]Biochemistry Department, Pasteur Institute, Tunis, Tunisia

Objective: To investigate the link between pain and sarcopenia in patients with knee osteoarthritis (OA).
Material and Methods: A cross-sectional study included female patients with knee osteoarthritis (OA) fulfilling the ACR classification criteria. Demographic, clinical, and paraclinical data were collected.
Radiographic severity of knee OA was assessed using the Kellgren–

Lawrence (KL) grading system, ranging from grade 0 (no radiographic OA) to grade 4 (severe OA), based on joint space narrowing, osteophyte formation, subchondral sclerosis, and bone deformities.
Sarcopenia was evaluated by the assessment of muscle strength and muscle mass. Muscle strength was measured by handgrip testing with a dynamometer, while muscle mass was assessed using bioelectrical impedance analysis (BIA) and dual-energy X-ray absorptiometry (DEXA). The appendicular skeletal muscle mass index (ASMI) was calculated as appendicular lean mass divided by height squared. Sarcopenia was defined by an ASMI ≤ 5.5 kg/m² combined with handgrip strength < 16 kg. Pain intensity was assessed using a visual analog scale (VAS) ranging from 0 (no pain) to 10 (worst imaginable pain).
Results: Thirty female patients were enrolled. The mean age was 62 ± 8 years [48–74], and the mean duration of knee OA was 40 ± 28 months [8–120]. According to the KL grading, 50% of patients had stage II knee OA and 37% had stage III knee OA.
The mean handgrip strength was 11±4 kg [6-23]. The mean ASMI was 8±1 kg/m² [5-9] by BIA and 7±1 [4-9] kg/m² by DEXA. Sarcopenic was present in 10% (n=3) of patients.
The mean VAS pain score was 4.2 ± 1.8 [2–6]. No significant association was found between sarcopenia and pain assessed by VAS (p = 0.276).
Conclusion: No association was found between sarcopenia and knee pain in this female OA cohort.

P1528

JOINT DEFORMITIES AND SARCOPENIA IN RHEUMATOID ARTHRITIS: INSIGHTS INTO THEIR ASSOCIATION

S. Mhamdi[1], K. Zouaoui[1], R. Ben Othmane[2], A. Krir[3], S. Rahmouni[1], S. Rekik[1], S. Boussaid[1], H. Sahli[1]

[1]Rheumatology department, La Rabta Hospital, Tunis, Tunisia; [2]National Institute of Nutrition, Tunis, Tunisia; [3]Biochemistry Department, Pasteur Institute, Tunis, Tunisia

Objective: To investigate a potential association between joint deformities and sarcopenia in woman with rheumatoid arthritis (RA).
Material and Methods: We conducted a monocentric cross-sectional. Female patients with RA meeting the 2010 ACR-EULAR criteria were enrolled. Demographic, clinical, and paraclinical data related to RA were collected. Sarcopenia was assessed based on both muscle strength and muscle mass. Muscle strength was measured using a handgrip dynamometer, while muscle mass was determined via the appendicular skeletal muscle index (ASMI), calculated as appendicular muscle mass divided by height squared. Appendicular muscle mass was obtained using bioelectrical impedance analysis (BIA) and dual-energy X-ray absorptiometry (DEXA). Sarcopenia was defined by an ASMI ≤ 5.5 kg/m² and a handgrip strength < 16 kg.
Results: Fifty-two women were enrolled, with a mean age of 58±8 years [40-76]. The mean disease duration was 9±6 years [1-30]. RA was seropositive and erosive in 90% of patients, respectively. The mean DAS28-CRP score was 4±2 [1.5-6.5] and 92% (n=48) of patients had active disease (DAS28-CRP > 3.2). The mean Health Assessment Questionnaire (HAQ) was 1.1±0.6 [0.1-2.5].
All participants had received at least one conventional treatment and 40% were treated with biologics.
The mean handgrip strength was 9±6 kg [2-26]. The mean ASMI was 7±1 kg/m² [5-11] by BIA and 6±1 [4-9] kg/m² by DEXA. Nineteen percent (n=10) of patients were sarcopenic.
Joint deformities were observed in 80% (n = 8) of sarcopenic patients compared with 36% (n = 15) of non-sarcopenic patients, with a statistically significant difference (p = 0.015).
Conclusion: In this cohort, joint deformities were associated with sarcopenia in female patients with RA.

P1529

ARE SARCOPENIA AND FUNCTIONAL IMPAIRMENT ASSOCIATED IN KNEE OSTEOARTHRITIS?

K. Zouaoui[1], S. Mhamdi[1], R. Ben Othmane[2], A. Krir[3], S. Rahmouni[1], S. Rekik[1], S. Boussaid[1], H. Sahli[1]

[1]Rheumatology department, La Rabta Hospital, Tunis, Tunisia; [2]National Institute of Nutrition, Tunis, Tunisia; [3]Biochemistry Department, Pasteur Institute, Tunis, Tunisia

Objective: To explore a potential association between sarcopenia and the Lequesne algofunctional index (AFI) in patients with knee osteoarthritis.
Material and Methods: Female patients with knee osteoarthritis (OA) fulfilling the ACR classification criteria were included. Demographic, clinical, and paraclinical data were collected.
Radiographic severity of knee OA was evaluated using the Kellgren–Lawrence (KL) grading system, ranging from grade 0 (no radiographic OA) to grade 4 (severe OA), based on joint space narrowing, osteophyte formation, subchondral sclerosis, and bone deformities.
Sarcopenia was assessed through the evaluation of muscle strength and muscle mass. Muscle strength was measured using a handgrip test with a dynamometer, while muscle mass was assessed by bioelectrical impedance analysis (BIA) and dual-energy X-ray absorptiometry (DEXA). The appendicular skeletal muscle mass index (ASMI) was calculated as appendicular lean mass divided by height squared. Sarcopenia was defined as an ASMI ≤ 5.5 kg/m² combined with handgrip strength < 16 kg. Functional impairment related to knee OA was assessed using the Lequesne AFI, which includes three domains: pain, walking distance, and difficulties in daily activities. A score > 8 indicates major to extreme disability.
Results: This study included 30 female patients with a mean age of 62 ± 8 years [48–74]. The mean disease duration was 40 ± 28 months [8–120], and 50% of participants had stage II knee OA according to the KL grading system.
Mean handgrip strength was 11 ± 4 kg [6–23]. The mean ASMI was 8 ± 1 kg/m² [5–9] by BIA and 7 ± 1 kg/m² [4–9] by DEXA. Sarcopenia was identified in 10% of patients (n = 3).
The mean Lequesne algofunctional index (AFI) was 8.7 ± 3.3 [5.5–12] in sarcopenic patients versus 9.4 ± 3.7 [3.5–17.5] in non-sarcopenic patients, with no statistically significant difference (p = 0.753).
Major to extreme disability was observed in two sarcopenic patients and seventeen non-sarcopenic patients, with no significant difference between groups (p = 1).
Conclusion: No significant association was observed between sarcopenia and Lequesne AFI score in female patients with knee OA.

P1530

DETERMINANTS OF AVASCULAR NECROSIS AND ASSOCIATED OUTCOMES IN SYSTEMIC LUPUS ERYTHEMATOSUS: A PROPENSITY-MATCHED ANALYSIS FROM A MULTI-CENTER DATABASE

O. Pamuk[1], S. Mistry[1]

[1]University Hospitals/Rheumatology, Cleveland, United States

Background: Avascular necrosis (AVN) is a serious and potentially disabling complication of systemic lupus erythematosus (SLE), often resulting from vascular injury, immune-mediated inflammation, and corticosteroid exposure. The condition contributes substantially to morbidity in SLE through pain, reduced mobility, and need for surgical intervention. While corticosteroid use is a recognized risk factor, the relative influence of demographic, clinical, and treatment-related factors remains unclear. Prior studies have been limited by small sample sizes and single-center data.

Objectives: To identify demographic, clinical, and therapeutic factors associated with avascular necrosis in patients with systemic lupus erythematosus using a large, real-world multicenter database.

Methods: We conducted a multi-center, retrospective cohort analysis using the TriNetX research platform. Two cohorts were defined based on ICD-10 coding: SLE patients with AVN of the hips, shoulders, knees, or ankles after diagnosis of SLE and those without AVN. Patients with confounding autoimmune conditions such as rheumatoid arthritis, systemic sclerosis, dermatomyositis, polymyositis were excluded. Propensity score matching (1:1) was performed across 61 demographic, diagnostic, procedural, and medication variables to balance baseline characteristics. Outcomes assessed within one year after index included SLE flare (defined by flare-related medication use), emergency visits, hospitalizations, and all-cause mortality. Risk differences, risk ratios, and hazard ratios were calculated using TriNetX analytic tools with a significance threshold of $p<0.05$.

Results: A total of 3,852 patients with SLE and AVN and 142,731 SLE patients without AVN met inclusion criteria. After 1:1 propensity score matching across 61 demographic, clinical, and treatment variables, 3,532 patients remained in each cohort. Before matching, patients with AVN were younger ($p<0.001$), more often Black or African American ($p<0.001$), and had higher rates of comorbidities including hypertension, chronic kidney disease, and end-stage renal disease ($p<0.001$). Glucocorticoid and immunosuppressant use was also more common in the AVN cohort ($p<0.001$). After matching, baseline characteristics were well balanced between groups (all $p>0.05$). Patients with AVN experienced higher 1-year rates of ER visits (23.6% vs. 21.1%; $p=0.046$) and hospitalizations (29.5% vs. 22.6%; $p<0.001$).

In the matched analysis, flare rates (defined by belimumab, rituximab, or mycophenolate use) were similar between cohorts ($p=0.719$). Kaplan–Meier analysis demonstrated no difference in 1-year flare-free survival ($p=0.36$). No significant differences were observed in cardiovascular, infectious, or renal complications. All-cause mortality was comparable ($p=0.118$).

Conclusion: Overall, SLE patients with AVN exhibited greater healthcare utilization, but similar flare and mortality outcomes compared to matched SLE patients without AVN.

P1531

FACTORS ASSOCIATED WITH FRACTURE RISK IN SYSTEMIC LUPUS ERYTHEMATOSUS: A REAL-WORLD PROPENSITY-MATCHED COHORT STUDY

S. Mistry[1], O. Pamuk[1]

[1]University Hospitals/Rheumatology, Cleveland, United States

Background: Fractures are a common but often overlooked complication of systemic lupus erythematosus (SLE). Chronic inflammation, corticosteroid exposure, and premature osteoporosis contribute to skeletal fragility, yet the long-term systemic consequences of fractures in SLE remain poorly defined. Understanding these associations could inform preventive and therapeutic strategies to reduce morbidity and mortality in this high-risk population.

Objectives: To determine whether fractures are associated with increased cardiovascular, infectious, and mortality outcomes in patients with SLE using a large, real-world electronic health record dataset.

Methods: This retrospective study utilized the TriNetX global federated research network, which includes data from 110 healthcare organizations. Adults (≥ 18 years) with an SLE diagnosis were divided into two cohorts: those with any fracture after SLE diagnosis (n = 6,878) and those without fracture (n = 142,276). Patients with overlapping autoimmune diseases were excluded. Propensity score matching (1:1) was performed across 72 demographic, clinical, and treatment variables, yielding two balanced groups of 6,673 patients each. Outcomes were analyzed using risk difference, risk ratio, odds ratio, and Kaplan–Meier survival analyses. Outcomes included heart failure, myocardial infarction, stroke, urinary tract infection (UTI), sepsis, mortality, and avascular necrosis (AVN) surgery.

Results: Before matching, patients with SLE + fracture were older (60.7 ± 14.5 vs 47.0 ± 15.6 years, p<0.001) and had higher rates of hypertension (65% vs 32%), diabetes (25% vs 11%), CKD (28% vs 11%), hypocalcemia (4.1% vs 1.1%), and corticosteroid use (prednisone 51% vs 31%, p<0.001). After matching, all baseline characteristics were well balanced. Compared with matched SLE patients without fractures, those with fractures had higher risks of heart failure (13.3% vs 10.1%; RR 1.32, p<0.001), myocardial infarction (5.8% vs 4.4%; RR 1.31, p=0.001), stroke (5.5% vs 4.1%; RR 1.34, p<0.001), UTI (18.0% vs 13.8%; RR 1.30, p<0.001), sepsis (12.0% vs 7.3%; RR 1.64, p<0.001), mortality (19.0% vs 13.3%; RR 1.44, p<0.001), and surgery for AVN (2.6% vs 0.7%; RR 3.58, p<0.001). Kaplan–Meier curves demonstrated significantly lower survival in the fracture group (HR 1.43, 95% CI 1.31–1.56, p<0.001).

Conclusion: In this large, propensity-matched cohort, fractures in patients with SLE were independently associated with increased cardiovascular events, infections, and mortality. These findings underscore the systemic impact of skeletal fragility and highlight the importance of early bone health assessment and fracture prevention in the comprehensive management of SLE.

P1532

CLINICAL OUTCOMES AND COMORBIDITY BURDEN AFTER HIP FRACTURE IN SYSTEMIC LUPUS ERYTHEMATOSUS: A PROPENSITY-MATCHED COHORT STUDY

S. Mistry[1], O. Pamuk[1]

[1]University Hospitals/Rheumatology, Cleveland, United States

Background: Patients with systemic lupus erythematosus (SLE) are at increased risk of osteoporosis and fragility fractures due to disease-related inflammation, corticosteroid use, and comorbid conditions. However, the long-term outcomes and comorbid burden of SLE patients who sustain hip fractures remain poorly defined.

Objectives: To compare demographic, clinical, and outcome characteristics of SLE patients with versus without hip fracture, and to identify comorbid and treatment factors associated with adverse outcomes.

Methods: Data were obtained from the TriNetX Research Network (110 healthcare organizations). Two cohorts of adults with SLE (≥18 years) were identified: (1) SLE with hip fracture after SLE diagnosis (n=1,788) and (2) SLE without hip fracture (n=148,398). Patients with other autoimmune diseases (e.g., RA, systemic sclerosis, myositis) were excluded. Propensity score matching (1:1) was performed across 72 demographic, clinical, and medication covariates, resulting in 1,735 patients per group. Outcomes including cardiovascular events, infections, mortality, and hospitalization were compared using risk and Kaplan–Meier survival analyses.

Results: Before matching, SLE patients with hip fractures were significantly older (mean 63.5 vs. 47.4 years, $p<0.001$) and had higher prevalence of hypertension, chronic kidney disease, vitamin D deficiency, and hypocalcemia (all $p<0.001$). They were more likely to use corticosteroids, diuretics, bisphosphonates, and biologic or immunosuppressive agents including tacrolimus and rituximab (all $p<0.001$). After matching, demographic and comorbidity profiles were balanced.

In outcome analyses, SLE patients with hip fractures had significantly higher risks of sepsis ($p<0.001$), urinary tract infection ($p=0.007$), mortality ($p<0.001$), hospitalization ($p<0.001$), and emergency visits ($p<0.001$). Surgery for avascular necrosis was nearly tenfold more frequent among those with prior hip fracture ($p<0.001$).

Patients with a hip fracture demonstrated significantly worse Kaplan–Meier survival curves for multiple outcomes, including UTI, sepsis, mortality, ER visits, hospitalizations, and surgery for AVN. In contrast, no significant survival differences were observed for cardiovascular outcomes (heart failure, myocardial infarction, stroke) or herpes zoster.

Conclusion:

Among patients with SLE, those who experienced hip fractures demonstrated markedly greater comorbid burden and worse clinical outcomes, including higher infection rates, mortality, and hospitalization risk. Despite adjustment for confounders, the post-fracture period was associated with persistent vulnerability. These findings underscore the need for aggressive prevention, early bone health management, and close post-fracture surveillance in SLE populations.

NEURO-IMMUNE AXIS IN DIABETIC BONE LOSS: EVIDENCE FOR SUBSTANCE P-MEDIATED INFLAMMATION FROM HPLC-BASED ANALYSIS

S. Mohsin[1], P. Yuvaraju[2], M. Alketbi[1], H. Chafqa[1], M. Hussain[1], S. Kaimala[1]

[1]United Arab Emirates University/Department of Anatomy/College of Medicine and Health Sciences, Al Ain, United Arab Emirates; [2]United Arab Emirates University/Department of Pharmacology/College of Medicine and Health Sciences, Al Ain, United Arab Emirates

Objective(s)

To investigate the role of the neuro-immune axis—specifically Substance P (SP), mast cell activation, and pro-inflammatory cytokines—in mediating bone loss associated with Type 1 Diabetes Mellitus (T1DM).

Material and Methods

A streptozotocin-induced T1DM rat model was used to examine neuro-immune interactions in bone. SP concentrations in serum and bone were quantified by high-performance liquid chromatography (HPLC). Serum tryptase, cytokines (IL-1β, IL-6, TNF-α), mast cell counts, and bone resorption markers were measured using ELISA and histological analysis. Data were analyzed by one-way ANOVA ($p < 0.05$). All animal procedures were approved by the 'Animal Research Ethics Committee' of the College of Medicine and Health Sciences, UAE University (ERA_2017_5592).

Results

The T1DM group exhibited markedly higher SP levels in serum ($p < 0.05$) and bone ($p < 0.01$) compared to controls. Key pro-inflammatory cytokines were elevated, including IL-1β ($p = 0.0028$) and IL-6 ($p = 0.03$), while TNF-α and serum tryptase showed non-significant upward trends. Quantitative analysis confirmed that the increase in mast cell numbers in the diabetic group was statistically significant ($p = 0.03$). These findings indicate a diabetes-associated pro-inflammatory state in bone tissue, with IL-1β, IL-6, and mast cell activation playing prominent roles. Elevated SP levels parallel this inflammatory response, suggesting activation of a neuro-immune mechanism that amplifies local bone turnover.

Conclusion

Enhanced SP signaling, mast cell activation, and pro-inflammatory cytokine release contribute to diabetic bone loss through neuro-immune mechanisms. Targeting SP-mediated pathways may represent a novel therapeutic approach to reduce bone fragility in T1DM.

INCIDENCE OF BONE FRACTURE IN TYPE 2 DIABETES: A POPULATION-BASED COHORT STUDY

S. Naderpour[1], C. Gillies[1], Z. Karimi[1], G. Kacha[1,2]

[1]University of Leicester, Leicester, United Kingdom; [2]National Institute for Health and Care Research Applied Research Collaboration East Midlands, Leicester, United Kingdom

Background
Musculoskeletal complications of diabetes mellitus (DM), including impaired bone quality and increased fracture risk, are increasingly recognized as important contributors to morbidity, even in individuals with preserved or elevated bone mineral density. This study aimed to estimate the incidence of first bone fracture in individuals with Type 2 Diabetes (T2D) compared with those without diabetes at baseline. Additionally, we examined the relationship between T2D and fracture incidence while controlling for demographic and sociodemographic factors.
Methods
We conducted a population-based cohort study using a 2,000,000 random sample of individuals aged ≥18 years from the UK Clinical Practice Research Datalink (CPRD) Aurum, with linkage to Hospital Episode Statistics (HES). Study start was defined as 1 January 2007, at which time T2D status was ascertained based on a recorded diagnosis on or before that date. The comparison group comprised individuals without T2D, T1D, and gestational diabetes(GDM) at baseline. Individuals with a documented history of bone fracture prior to baseline were excluded. Fracture incidence rates were calculated per 1,000 Person-Years (PY) with corresponding Poisson confidence intervals. Incidence rate ratios were estimated using Poisson regression models with the logarithm of person-years as an offset; multivariable models were adjusted for age, sex, socioeconomic deprivation (Index of Multiple Deprivation decile), and ethnicity.
Results
The cohort included 770,641 individuals (28,149 with T2D; 742,492 without diabetes). Participants with T2D were older than the comparison group (mean age 66.0±14.2 vs 47.2±18.2 years) and had shorter mean follow-up (8.7±6.3 vs 10.6±7.0 years). Over 245,449 PY in the T2D group and 7,867,206 PY in the control group, 5,362 and 90,587 fractures occurred, respectively. Incidence Rate(IRs) were 21.8 per 1,000 PY (95% CI 21.3–22.4) in T2D and 11.5 per 1,000 PY (95% CI 11.4–11.6) in those without diabetes. The crude IRR was 1.90 (95% CI 1.85–1.95); after adjustment, baseline T2D remained associated with higher fracture incidence (adjusted IRR 1.25, 95% CI 1.21–1.28).
Conclusions
In this large population-based cohort with long follow-up (18 years), baseline T2D was associated with a substantially higher incidence of first bone fracture than in individuals without diabetes. Although the crude association was markedly attenuated after adjustment for age and sociodemographic factors, T2D remained independently associated with increased fracture incidence. These findings support targeted fracture risk assessment and prevention strategies for people with T2D.
Keywords
Type 2 diabetes, bone fracture, incidence rate, CPRD.

P1535

CASE SERIES: THE EFFECT OF IV ZOLENDRONIC ACID INFUSION IN TREATMENT OF TUMOR INDUCED HYPERCALCEMIA FOR FEMORAL FRACTURE PATIENTS

J. O'Hare[1], A. Bartlett[1], S. Naraen[1]

[1]Liverpool University hospital care group, Liverpool, United Kingdom

Aims and objective: To look Into the cause of Hypocalcemia after treatment of hypercalcemia according to national guidelines.
Case1
82year old female was admitted with distal femur fracture and had open reduction & internalfixation
She was known to have IgA Keppa Myeloma, CKDsatge 4 secondary to obstructive uropathy and tumor. She had have bilateral nephropathy.
Investigation revealed that her preoperative adjusted calcium was 2.96mmol/l,phosphate normal and alkaline Phosphatese 932U/L. Parathyroid hormone were not done.
Her adjusted calcium on 3rd postoperative day was 3.18 along withlow phosphate, EGFR 55ml/mim
And IV Zolendronic acid 4 mg infusion was given
Vitamin D level was done on 4th day after Zolendronic acid infusion,which was 20 nmol/l(VitaminD Deficiency).
Adjusted calcium started decreasing next day of infusion and went into hypocalcemia range on day 4 of Zolendronic acid infusion along with low phosphate. By 7th day it was as low as1.86mmol/l, Vitamin D Level was 30, Parathyroid hormone level was 44.9pmol/l
Patient received double oral dose & IV supplement of calcium and oral & IM supplement of Vitamin D, when it was first identified on 4 of hypocalcemia.
It then started improving on day 8 when vitaminD level were 58nmol/l (sufficient)and adjustedcalcium was in normal range on day 9.
Case2
80year old male was admitted with pathological fracture neck of femur and had intrmedullary nail done
He was known to have metastatic prostate cancer , type2 diabetes, and hypothyroid.
Investigation revealed that his 5th post -operative day was 2.81 mmol/l(normal2.2-2.6mmol/l)and phosphate was normal, alkaline phosphate 204U/L,EGFR 66ml/min. By post operative day 6 adjusted calcium increased to 3.05 mmol/l,phosphate remained normal VitaminD was 29mmol/l(vitamin D Deficiency), parathyroid level was 1pmol/l
IV Zolendronic acid 4 mg infusion was given
Adjusted calcium started decreasing and went into Hypocalcemia range on day 4 of zolendronic acid infusion along with low phosphate. By 6th day it was as low as 1.86mmol/l, vitamind was not checked. Parathyroid hormone levelwas 35.8pmol/l.
It then started improving on day7 and Vitamin D level 65mmol/l(sufficient)and was in normal range on day 8.
Conclusion: Treatment of hypercalcemia without replacing vitamin D deficiency resulted into Hypocalcemia and Calcium came in normal range once VitaminD was in normal range inspite of doubling calcium dose in patients with femoral fracture patients

PROTEOMIC PROFILING OF SYNOVIAL FLUID IN ACL INJURIES, HEALTHY CONTROLS, AND OSTEOARTHRITIS PATIENTS

A. Bumberger[1], A. Kleiner[1], K. Kratochwill[2], S. Nürnberger[1]

[1]Medical University of Vienna, Department of Orthopedics and Trauma Surgery, Vienna , Austria; [2]Medical University of Vienna, Core Facility of Proteomics, Vienna , Austria

Objective:
Anterior cruciate ligament (ACL) injuries are a significant risk factor for post-traumatic osteoarthritis (PTOA), with early biochemical changes in the joint playing a pivotal role in disease progression. This study performed for the first time an intradonor comparison of the proteomic profiles of synovial fluid (SF) from ACL-injured verus contralateral (healthy) knees and osteoarthritis (OA) controls. We aim to identify injury-specific alterations in the proteome that are characteristic of early signs of degeneration and inflammation.
Material and Methods:
Synovial fluid was collected during surgery of ACL-injured (6) and contralateral healthy (5) knees of patients enrolled 1-6 months post-injury and of OA patients (7). Proteomic analysis was performed using liquid chromatography-tandem mass spectrometry (LC-MS/MS) and differential protein expression analyzed. Furthermore pathway-enrichment analysis was performed.
Results:
A total of 3 037 proteins with abundant expression were identified across all groups. Periostin was one of the most significantly up-regulated proteins in injured knees compared to healthy knees (log2fc = 3.3, $p < 0.001$) and in OA versus healthy knees (log2fc = 1.1, $p < 0.001$). However, periostin was down-regulated in OA versus injured knee SF (log2fc = -1.6, $p < 0.001$). Additional proteins also showed significant alterations between groups. Pathway-enrichment analysis revealed that extracellular matrix (ECM) organization pathways were up-regulated in injured compared to healthy controls (log2fc = 0.078, $p < 0.001$). Conversely, immune system pathways were significantly down-regulated in ACL-injured knees (log2fc = -0.5, $p < 0.001$), with the highest entity ratio (0.17), indicating a high number of associated proteins.
Conclusion:
Our findings confirm that periostin is one of the key proteins associated with ACL injuries and may contribute to early osteoarthritis progression. Additionally, the down-regulation of immune system pathways in ACL-injured knees suggests a disrupted inflammatory response, potentially impairing tissue repair and exacerbating PTOA.

LACTOBACILLUS ACIDOPHILUS (LA) SUPPLEMENTATION MITIGATES INFLAMMATORY BONE LOSS BY MODULATING THE ILC3-ILCREG CELL AXIS

S. P. Kaur[1], A. Singh[1], R. K. Srivastava[1]

[1]All India Insitute of Medical Sciences, New Delhi, India

Introduction: Immunoporotic potential of the "Treg-Th17" cell-axis has been extensively studied in post-menopausal osteoporosis (PMO). However, the role of Innate Lymphoid Cells (ILCs), which represent the innate counterpart of helper-T cell subsets, is yet to be explored in PMO. Additionally, while our laboratory has demonstrated immunomodulatory potential of probiotics in regulating the "Treg-Th17" cell-axis, their effects on the ILCs remain unexplored. Therefore, this study aims to examine the potential of the probiotic Lactobacillus acidophilus (LA) to modulate the "ILC3-ILCreg" cell axis in a murine model of Osteoporosis.
Materials & Methods: Building on the novel concept of "Immunoporosis", we investigated the role of the "ILC3-ILCreg" cell axis in PMO and evaluated the Immunoporotic potential of LA supplementation in restoring the same. Female (C57BL/6J) mice were ovariectomized (OVX) and divided into Sham, OVX and OVX+LA groups (n=6/group). 45 days post-surgery, mice were sacrificed, allowing us to evaluate a range of osteoimmune parameters (ILC3-ILCreg, Treg-Th17) in the bone-marrow and mucosal tissues, along with serum cytokines (IL-17, IL-10, IL-22, etc.), and micro-CT analysis.
Results: Interestingly, our findings reveal that PMO conditions significantly disrupted gut integrity and enhanced RORγt+CCR6+ ILC3s, which was accompanied by a concomitant reduction in the anti-inflammatory ILC populations, i.e. RORγt+CCR6- ILC3s and GATA3+IL10+ ILCregs. Concomitantly, serum cytokine balance was tipped towards the inflammatory phenotype, suggesting a crucial role of the ILC3-ILCreg cell axis in inflammatory bone loss in OVX mice. Notably, the administration of LA ameliorates these effects by restoring the osteoimmune profiles (*in vivo* and *in vitro*),
Conclusions: Our findings for the first time provide compelling evidence for the osteoprotective potential of LA by modulating the ILC3-ILCreg cell-axis in the murine model of PMO, thus paving the way for clinical applications.

SYNOVIAL FLUID CELL TRANSCRIPTOMICS IDENTIFIES NEUTROPHIL ASSOCIATED MOLECULAR SIGNATURE LINKED TO OSTEOARTHRITIS SEVERITY

S. Pawar[1], A. Harsulkar[1], A. Electricwala[2]

[1]School of Bioengineering Sciences and Research, MIT ADT University, Loni Kalbhor, Pune, 412201, India, Pune, India; [2]Electricwala Hospital, A 4/1, Pleasant Park, Fatima Nagar, Wanowrie, Pune 411013, India, Pune, India

Background/Objective
We have established that synovial fluid (SF) is a key modulator in osteoarthritis (OA) pathophysiology, functioning as a pro-inflammatory niche that drives immune cell activation and differentiation. Although other immune cells have been studied in OA, the role of neutrophils, the key effectors of innate immunity, remains underexplored. Evidence indicates that neutrophils influence chronic inflammation through chemokine-driven recruitment, degranulation, reactive oxygen species generation, and neutrophil extracellular trap (NET) formation. This study aims to define neutrophil associated transcriptomic signatures within SF-cell transcriptome and elucidate its contribution to OA progression.
Materials and Methods
SF samples were collected from clinically and radiographically confirmed knee OA patients (40–75 years, Indian Asian) classified by Kellgren Lawrence (KL) grading system. A subset of these samples (n=20; five per grade) selected for transcriptomic profiling. Total RNA was isolated from SF cells, purified, quality checked and sequenced (NovaSeq X Plus, 150 bp paired-end, ~40M reads/sample). Demultiplexed FASTQ files were processed and aligned using Strand NGS v4.1. Differential gene

expression analysis was performed with KL grade-I samples as the reference control.

Results

Transcriptomic profiling of SF cells across KL grades showed major alterations in neutrophil associated pathways including activation, degranulation, and NET formation. Differential expression of neutrophil effector genes (ELANE, MPO, PRTN3, CTSG, AZU1, LTF, DEFA4) indicated enhanced degranulation, while upregulation of the neutrophil activation marker CD177 highlighted the presence of primed and migratory neutrophil subset. Grade dependent increases in neutrophil attracting chemokines (CXCL1, 2, 3, 5, and 8), DAMP associated S100 alarmins, oxidative burst and adhesion molecules further sustained neutrophil recruitment and activation. These findings highlight neutrophils as major contributers of synovitis and reinforce the concept of OA as a disease with significant innate immune activation.

Conclusion

Our findings demonstrate that OA progression involves a distinct shift in SF transcriptome, with neutrophil associated genes driving grade dependent inflammation. Higher KL grades showed strong upregulation of ELANE, MPO, CTSG, PRTN3, S100A8/A9/A12, CXCL chemokines, and CD177, indicating enhanced neutrophil activation, degranulation, and NET-related activity. This neutrophil associated signature suggests innate immune dysregulation, triggered by cartilage degradation products. These results highlight significance of neutrophils as a major inflammatory component in progressive OA and underscore their potential as biomarkers of disease severity and as therapeutic targets.

IMPACT OF ANKLE CENTER DEVIATION ON PROXIMAL TIBIAL CUT ANGLE IN TOTAL KNEE ARTHROPLASTY: A RADIOGRAPHIC SIMULATION STUDY

S. Pongthippanus[1], V. Yuenyongviwat[1]

[1]Department of Orthopedics, Faculty of Medicine, Prince of Songkla University, Songkhla 90110, Thailand., Hat Yai, Songkhla, Thailand

Objectives

Accurate identification of the ankle center is essential for restoring neutral mechanical alignment in total knee arthroplasty (TKA). In clinical practice, ankle center estimation may be inaccurate due to soft tissue coverage and challenges in intraoperative landmark identification, potentially altering the tibial mechanical axis and resulting in proximal tibial cut malalignment. Patient anatomy, particularly tibial length, may influence the magnitude of this alignment error. This study aimed to quantify the effect of ankle center deviation on proximal tibial cut angle deviation using radiographic simulation and to evaluate whether tibial length modifies this relationship.

Design and Methods

This radiographic simulation study included 100 preoperative long-leg standing radiographs from patients with osteoarthritis undergoing TKA. The tibial mechanical axis was defined from the knee center to the ankle center. The ankle center was systematically shifted by 5, 10, 15, and 20 mm to simulate ankle center misidentification, and the resulting proximal tibial cut angle deviation was measured. Participants were stratified into three tibial length groups, and differences across groups were evaluated.

Results

Varus alignment was present in 90% of cases, with a mean hip–knee–ankle angle of 11.9 ± 5.6°. Proximal tibial cut deviation increased stepwise with greater ankle center shift. Based on averaged measurements, the mean deviation was 1.02 ± 0.13° at 5 mm, 1.65 ± 0.44° at 10 mm, 2.51 ± 0.46° at 15 mm, and 3.41 ± 0.46° at 20 mm. The deviation range also increased accordingly (5 mm: 1–2°; 10 mm: 1–2.25°; 15 mm: 2–3°; 20 mm: 3–4°). Significant differences between tibial length groups were observed across all deviation levels ($p \leq 0.045$).

Conclusion

Ankle center misidentification leads to progressively increased proximal tibial cut malalignment and may reach clinically relevant errors at larger deviations. Shorter tibial length appears to increase susceptibility to alignment error, emphasizing the importance of precise ankle center determination during TKA.

P1540

IMPACT OF ADALIMUMAB AND UPADACITINIB ON THE RISK OF FRAGILITY FRACTURES IN PATIENTS WITH RHEUMATOID ARTHRITIS AND DIABETES MELLITUS

S. Popovic Pejicic[1], I. Ovcina[2], D. Trninic[2], D. Popovic[2], L. Bozic Majstorovic[2]

[1]Faculty of Medicine, University of Banjaluka, Banja Luka, Bosnia & Herzegovina; [2]University Clinical Centre of the Republic of Srpska, Banjaluka, Bosnia & Herzegovina

Introduction: The aim of this study was to evaluate differences in bone mineral density (BMD) and the incidence of fragility fractures between patients with rheumatoid arthritis (RA) treated with adalimumab (ADA) and upadacitinib (UPA), as well as to examine the association of diabetes mellitus (DM) with fracture risk in these therapeutic groups. **Materials and Methods:** A total of 28 patients with rheumatoid arthritis were included, 14 treated with ADA and 14 with UPA. Demographic and osteodensitometric data were collected, and parameters were compared between the two groups. **Results:** The overall mean age was 59.64±8.86 years, with 19 female patients (67.9%). Patients were divided into ADA and UPA treatment groups. The mean BMD at L1–L4 was 0.991, with a mean T-score of −1.668. The mean BMD at the left hip was 0.994, with a T-score of −1.63, while the mean BMD at the right hip was 0.988, with a T-score of −1.68. Normal bone density was observed in 5 patients (17.9%), osteoporosis in 8 (28.6%), and osteopenia in 15 (53.6%). A higher number of osteoporosis cases was recorded in the ADA group (6 patients). Fragility fractures occurred in 6 patients (21.4%), of which 4 were in the UPA group. Diabetes mellitus was present in 8 patients (28.6%), equally distributed between groups. In the UPA group, a significant association was found between DM and fragility fractures ($p<0.05$), whereas no such correlation was observed in the ADA group. **Conclusion:** A greater number of osteoporosis cases were registered in the ADA group, indicating a less favorable profile compared to UPA. Fragility fractures occurred in 21.4% of patients, more frequently in the UPA group. DM was present in 28.6% of patients, evenly distributed across both groups. A statistically significant association between diabetes and fragility fractures was confirmed in the UPA group, while no correlation was found in the ADA group. These findings highlight the considerable burden of reduced bone mass in patients with RA and suggest potential differences in the effects of ADA and UPA therapy, with particular emphasis on the association between DM and fracture risk in the UPA group.

istered in the ADA group, indicating a less favorable profile compared to UPA. Fragility fractures occurred in 21.4% of patients, more frequently in the UPA group. DM was present in 28.6% of patients, evenly distributed

across both groups. A statistically significant association between diabetes and fragility fractures was confirmed in the UPA group, while no correlation was found in the ADA group. These findings highlight the considerable burden of reduced bone mass in patients with RA and suggest potential differences in the effects of ADA and UPA therapy, with particular emphasis on the association between DM and fracture risk in the UPA group.

MORE THAN JUST A FALL:THE SILENT BURDEN OF CALCIUM AND VITAMIN D3 DEFICIENCIES IN INDIAN ADULT FRACTURE PATIENTS:EVIDENCE FROM A TERTIARY CARE CENTER

S. Pruthvi[1], S. Jeevannavar[1], K. Shenoy[1], P. Baindoor[1], S. Fernandes[1], R. Saundatti[1]

[1]SDM COLLEGE OF MEDICAL SCIENCES AND HOSPITAL, DHARWAD, India

OBJECTIVES

To evaluate serum calcium and vitamin D3 levels in adult patients admitted with fractures and to asses their association with fracture mechanisms, with the aim of identifying potentially modifiable metabolic risk factors.

MATERIAL AND METHODS

This prospective observational study was conducted over 1 year period at a tertiary care teaching hospital in South India. Patients aged 18 years and above admitted with radiologically confirmed fractures were included. Serum calcium and vitamin D3 levels were assessed at admission as part of standardized biochemical evaluation. Patients with known endocrine,metabolic,or hematological disorders affecting calcium or vitaminD metabolism were excluded. Demographic details, fracture patterns and mechanisms of injury were recorded using a predefined proforma. Data were analyzed descriptively.

RESULTS

A total of 96 patients satisfied the inclusion criteria. Low serum calcium levels were observed in 78 patients ,while an additional 10 patients demonstrated low-normal calcium values,vitamin D3 deficiency was identified in 66 patients, and 24 patients had insuffient vitamin D3 levels. Low velocity trauma,including simple falls accounted for fractures in 54 patients ,suggesting a substantial burden of underlying metabolic bone compromise rather than high energy injury alone

CONCLUSION

This study demonstrates a high prevalance of vitamin D3 defiency and suboptimal calcium levels among adult fracture patients,particularly those sustaining low energy injuries. These finding highlights the silent burden of metabolic bone diseases in fracture populations. Routine screening and early correction of calcium and vitamin D3 deficiencies may represent a simple and cost effective strategy to reduce fracture risk and improve long term musculoskeletal outcomes. Incorporation of metabolic bone health assessment into standard fracture management protocols should be considered ,especially in aging population.

INTER-JOINT COORDINATION STRATEGIES AND VARIABILITY DURING GAIT IN KNEE OSTEOARTHRITIS: A PILOT BIOMECHANICAL STUDY

S. Qiu[1], S. L. Goh[1], R. Razman[1], K. M. Tse[2]

[1]Universiti Malaya, Kuala Lumpur, Malaysia; [2]Swinburne University of Technology, Melbourne, Australia

Objective:

To investigate inter-joint coordination strategies during gait in patients with knee osteoarthritis (KOA), with a particular focus on coordination variability as an indicator of movement adaptability.

Material and Methods:

Eight patients with KOA underwent three-dimensional gait analysis during level walking. Following a standardized approach for continuous relative phase (CRP) calculation(1), sagittal-plane hip–knee and knee–ankle coordination were quantified. Coordination variability was assessed using the coefficient of variation (CV) across repeated trials as a measure of movement flexibility. Comparisons were performed between the affected and contralateral limbs.

Results:

Mean CRP values demonstrated comparable inter-joint coordination between limbs (hip–knee: $p = 0.441$, $d = 0.289$; knee–ankle: $p = 0.920$, $d = 0.037$), consistent with previous observations in osteoarthritis-related gait (3, 4). In contrast, coordination variability revealed a notable shift in movement strategy. Specifically, hip–knee coordination variability was reduced on the affected side, approaching statistical significance ($p = 0.061$) and exhibiting a large effect size (Cohen's $d = 0.788$). Knee–ankle coordination variability showed negligible differences between limbs ($p = 0.803$, $d = 0.092$).

Conclusion:

While average inter-joint coordination patterns appear resilient to unilateral KOA, movement adaptability (variability) is compromised on the affected limb. The large effect size ($d = 0.788$) for proximal coordination variability supports a highly stereotypical, "co-rigid" movement strategy, likely adopted to enhance joint stability at the expense of flexibility. These pilot findings suggest that coordination variability is a more sensitive biomechanical marker than mean kinematics for detecting motor control alterations in KOA, justifying its inclusion in larger longitudinal investigations.

Objective
Osteoporosis in men remains underdiagnosed and undertreated, partly due to later recommended ages for screening compared with women. Current international guidelines recommend bone mineral density assessment using dual-energy X-ray absorptiometry in men aged 65 years and older, or earlier in the presence of major risk factors. However, growing evidence suggests that clinically relevant osteoporotic manifestations may occur at younger ages. This study evaluated age-related changes in bone mineral density, fracture risk, and clinical indicators of osteoporosis among men aged 50 years and older, and assessed whether osteoporotic manifestations occur before the guideline-recommended screening age.

Materials and Methods
This cross-sectional analysis used data from the Iranian Multicenter Osteoporosis Study (IMOS). Male participants aged 50 years and older were categorized into six age groups: 50–54, 55–59, 60–64, 65–69, 70–74, and 75–79 years. Bone mineral density at the femoral neck was measured using dual-energy X-ray absorptiometry. Outcomes included major osteoporotic fracture risk and hip fracture risk, assessed with and without bone mineral density, as well as history of minor trauma fractures and height loss, collected through standardized IMOS questionnaires. Statistical analyses were performed using appropriate methods. One-way analysis of variance with Bonferroni post-hoc tests was used for continuous variables, and chi-square tests for categorical variables.

Results
Approximately 650 men were analyzed. Mean femoral neck bone mineral density showed a significant age-related decline, with a reduction observed before 65 years ($p < 0.001$). Significant differences across age groups were observed for major osteoporotic fracture risk and hip fracture risk, with and without bone mineral density (all $p < 0.001$). Men aged 50–64 years demonstrated measurable reductions in bone mineral density and clinically relevant fracture risk. Clinical indicators, including self-reported minor fractures and height loss, were present among men younger than 65 years.

Conclusion
Osteoporotic changes and clinically relevant fracture risk are present in men before 65 years. These findings suggest that the current age threshold for osteoporosis screening in men may warrant reconsideration. Earlier screening strategies, beginning in the sixth decade of life, may improve early detection and prevention of osteoporotic fractures in men.

P1544

THE IMPACT OF TOBACCO USE ON FALL-RELATED INJURIES IN THE NORTH AFRICA AND MIDDLE EAST REGION FROM 1990 TO 2023

M. Dehghani[1], M. Arab Yazdi[1], S. Moradpour[2], S. Akbarpour[3], S. Salehi[3]

[1]Non-Communicable Diseases Research Center, Endocrinology and Metabolism Population Sciences Institute , Tehran University of Medical Sciences, Tehran, Iran; [2]Endocrinology and Metabolism Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran; [3]Non-Communicable Diseases Research Center, Endocrinology and Metabolism Population Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran

Objective: To examine the contribution of tobacco use to the burden of fall-related injuries in the North Africa and Middle East region over the period 1990–2023.

Material and Methods: Age-standardized DALY and mortality rates for falls attributable to tobacco use were analyzed using Global Burden of

Disease 2023 data from 1990 to 2023, stratified by sex.
Results: Tobacco-attributable fall injury burden showed a gradual downward trend. The age-standardized DALY rate decreased from 3.43 per 100,000 in 1990 to 2.98 in 2023. Men consistently bore a much higher burden than women: male DALY rates declined from 5.80 to 4.97 (with deaths dropping from 0.13 to 0.095 per 100,000), whereas female rates were very low and nearly unchanged (around 1.00 to 0.98; deaths 0.019 to 0.013).
Conclusions: Although the overall burden of falls attributable to tobacco use has modestly declined, the pronounced male predominance persists. This pattern underlines the importance of continued tobacco control efforts and integrated fall-prevention programs, particularly targeting men. Public health authorities should address the synergistic risks of smoking and injury by prioritizing interventions (e.g., smoking cessation support, bone health improvement, and safety education) that can further reduce fall-related morbidity and mortality.

P1545

NATIONAL EXPOSURE TREND TO A DIET LOW IN MILK IN IRAN FROM 1990–2023

M. Dehghani[1], S. Karimi[2], A. Sheikhpour[1], S. Salehi[3], S. Akbarpour[3]

[1]Non-Communicable Diseases Research Center, Endocrinology and Metabolism Population Sciences Institute , Tehran University of Medical Sciences, Tehran, Iran; [2]Endocrinology and Metabolism Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran; [3]Non-Communicable Diseases Research Center, Endocrinology and Metabolism Population Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran

Material and Methods: This analysis used age-standardized Summary Exposure Values (SEVs) for insufficient milk intake derived from the Global Burden of Disease 2023 data for Iran. Data spanned the years 1990 to 2023 and were stratified by sex. Temporal trends were analyzed to identify patterns and disparities in exposure risk over time.

Results: In Iran, the age-standardized Summary Exposure Value (SEV) for low milk consumption remained extremely high with minimal change over 1990–2023. The SEV was 69.23 per 100 in 1990 and only slightly lower at 67.53 in 2023, indicating persistently widespread inadequate milk intake. A pronounced gender gap was observed: women consistently had near-saturation risk levels (SEV ~94.1, dropping slightly to 91.8), reflecting severe nutritional insufficiency, whereas men maintained much lower risk exposures (SEV 45.7 to 43.6) throughout the period.

Conclusions: The persistently high risk exposure to low milk intake — especially among Iranian women — highlights a critical public health challenge for bone health and nutrition. Stagnant progress in improving dairy consumption suggests that current dietary interventions have been insufficient. Health policymakers should prioritize targeted nutritional programs and education to increase calcium-rich food intake (or fortified alternatives), addressing the wide gender disparity and mitigating future osteoporosis and fracture risks associated with poor nutrition.

P1546

EPIDEMIOLOGICAL TREND OF LOW BACK PAIN PREVALENCE IN IRAN, 1990–2023

M. Dehghani[1], A. Hatami[2], S. Ramezani[1], S. Salehi[3], S. Akbarpour[3]

[1]Non-Communicable Diseases Research Center, Endocrinology and Metabolism Population Sciences Institute , Tehran University of Medical Sciences, Tehran, Iran; [2]Endocrinology and Metabolism Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran; [3]Non-Communicable Diseases Research Center, Endocrinology and Metabolism Population Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran

Objective: To examine long-term trends in the prevalence of low back pain (LBP) in Iran from 1990 to 2023.
Material and Methods: This study utilized Global Burden of Disease 2023 estimates to assess the prevalence of low back pain in Iran over a 33-year period. Age-standardized prevalence rates were extracted for the years 1990 to 2023, disaggregated by sex. Temporal trends and gender differences were examined to identify epidemiological patterns in low back pain burden.
Results: In Iran, the age-standardized prevalence of LBP declined slightly from 10,148.89 per 100,000 in 1990 to 9,147.41 in 2023. The trend was characterized by periods of modest decreases (notably around 1995–2000 and again after 2020) separated by long intervals of stagnation. A distinct gender disparity persisted: men experienced a more pronounced reduction in LBP prevalence (from 8,310.36 to 7,064.97) than women, whose prevalence remained higher and decreased only marginally (from 12,092.23 to 11,270.74).
Conclusions: Iran has seen only a minor reduction in LBP prevalence over three decades, and the burden remains substantial — particularly among women. The plateauing of rates for many years and the persistent female disadvantage indicate that past interventions may have been insufficient or unevenly effective. These findings call for renewed, gender-sensitive public health efforts to prevent and manage LBP, such as workplace ergonomic programs, chronic pain management services, and targeted outreach to support women's musculoskeletal health.

P1547

PREVALENCE AND DETERMINANTS OF SARCOPENIA IN THE BIRJAND LONGITUDINAL AGING COHORT IN IRAN

M. Dehghani[1], M. H. Falahat[1], P. Mohammadinejhad[2], S. Akbarpour[3], S. Salehi[3]

[1]Non-Communicable Diseases Research Center, Endocrinology and Metabolism Population Sciences Institute , Tehran University of Medical Sciences, Tehran, Iran; [2]Endocrinology and Metabolism Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran; [3]Non-Communicable Diseases Research Center, Endocrinology and Metabolism Population Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran

Objective: To determine the prevalence of sarcopenia and identify its key determinants among older adults in the Birjand Longitudinal Aging Cohort, Iran.

Material and Methods: This cross-sectional study utilized baseline data from the Birjand Longitudinal Aging Study (BLAS), a prospective cohort of community-dwelling older adults aged ≥60 years in Birjand, Iran. A total of 1,348 participants were included. Probable sarcopenia was defined according to the EWGSOP2 guidelines, based on low muscle strength (measured via handgrip strength). Participants were stratified by sex and age (<75 vs. ≥75 years). Data were analyzed using Stata software, utilizing chi- square tests to assess the statistical significance of differences in prevalence rates across demographic subgroups.

Results: In a sample of 1,348 seniors from the Birjand Aging Cohort, the overall prevalence of probable sarcopenia was 41.3%. Age was the dominant determinant: sarcopenia prevalence nearly doubled from 33.4% in adults under 75 years to 65.4% in those aged 75 and above (P<0.001). Females had a slightly higher prevalence (43.3%) than males (39.2%), but this sex difference was not statistically significant (P=0.121).

Conclusions: Sarcopenia affects roughly two out of every five older adults in this cohort, identifying it as a major public health concern in the aging population. The steep increase in sarcopenia with advanced age clearly demonstrates the need for early preventive interventions (such as resistance exercise, protein supplementation, and routine muscle function screening) well before age 75. The absence of a significant gender difference suggests that such interventions should be broadly applied to all older adults. Healthcare planners should prioritize sarcopenia detection and management as part of healthy aging strategies to reduce disability and improve quality of life for Iran's elderly.

P1548

THE ROLE OF TOTAL HIP BONE MINERAL DENSITY IN THE DIAGNOSIS OF OSTEOPOROSIS

S. Abdollahi[1], S. Salehi Nezamabadi[1], R. Kalantar Mehrjerdi[1], E. Hesari[1], K. Khalagi[2], M. Sanjari[1], N. Panahi[3], N. Malekraeisi[1], N. Fahimfar[1], A. Ostovar[1]

[1]Osteoporosis Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran; [2]Obesity and Eating Habits Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran; [3]Metabolic Disorders Research Center, Endocrinology and Metabolism Cellular and Molecular Institute, Tehran University of Medical Sciences, Tehran, Iran

Objective

Bone mineral density differs across skeletal sites due to variations in bone composition and structure. To standardize diagnosis, the World Health Organization (WHO) defines osteoporosis as a T-score ≤ −2.5 at any of three key sites: lumbar spine (L1–L4), femoral neck, and total hip. This study aimed to describe and compare T-score patterns at these three sites in Iranian men and women aged 50–89 years.

Material and Methods

This study used data from the Iranian Multicenter Osteoporosis Study (IMOS), a cross-sectional, population-based survey of adults aged ≥50 years from urban and rural regions of Iran. Bone mineral density was measured at the L1–L4 spine, femoral neck, and total hip using standardized protocols. Participants were grouped into 5-year age categories from 50 to 89 years, and median T-scores were evaluated separately in men and women.

Results

In both sexes and across all age groups, median T-scores at the total hip were consistently higher than those at the lumbar spine and femoral neck. The spine and femoral neck showed similar age-related declining patterns and generally lower T-scores compared with the total hip. Osteoporosis was identified in 22.10%, 14.92%, and 2.64% of participants at the lumbar spine, femoral neck, and total hip, respectively. No age group demonstrated osteoporosis at the total hip in the absence of osteoporosis at the spine or femoral neck. Based on these findings, inclusion of the total hip T-score did not alter the diagnosis of osteoporosis in this population.

Conclusions

Among Iranian adults aged 50–89 years, lumbar spine and femoral neck measurements show lower T-scores and greater sensitivity to bone loss compared with the total hip. These findings underscore the importance of spine and femoral neck assessment for osteoporosis detection.

P1549

METABOLOMIC MARKERS WERE ASSOCIATED WITH MUSCLE MASS OVER TIME IN PATIENTS WITH TYPE 2 DIABETES

S. Serena[1], K. Kiat Sern[2], H. Huili[1], K. Keven[1], S. Su Chi[1]

[1]Khoo Teck Puat Hospital/Clinical Research Unit, Singapore, Singapore; [2]Changi General Hospital/ Geriatric Medicine, Singapore, Singapore

Objectives
Patients with Type 2 Diabetes (T2D) are at high risk of sarcopenia or muscle mass decline. However, the underlying biological mechanism of muscle mass decline in T2D is unclear. Plasma metabolomics is gaining increasing recognition for use in understanding metabolic processes and monitoring diseases. We investigated how plasma metabolomics were associated with muscle mass longitudinally in T2D.
Materials and Methods
This was a prospective study on 897 patients with T2D recruited from Singapore Macroangiopathy and Microvascular Reactivity in Type 2 Diabetes (SMART2D) cohort. We used bioimpedance analysis to quantify appendicular skeletal muscle (ASM) mass which was divided by body mass index (BMI) to yield ASM/BMI at baseline and follow-up. Plasma metabolites were quantified by nuclear magnetic resonance (NMR). Linear regression was used to examine the association between plasma metabolites and ASM/BMI at follow-up, adjusting for age, gender, ethnicity, baseline ASM/BMI and follow-up period with Benjamini-Hochberg (BH) correction.
Results
The mean age was 58.9 ± 10.0. The median duration of follow-up was 5.0 years (IQR 4.4-6.2). 54 metabolites were associated with follow-up ASM/BMI with adjusted coefficients ranging -0.036 to 0.023 (BH-adjusted p <0.05). Creatinine, relative lipoprotein lipid concentration (e.g. triglycerides (TG) to total lipids ratio in intermediate-density lipoprotein (IDL), phospholipids to total lipids ratio in medium high-density lipoprotein (HDL)), fatty acids (e.g. ratio of monounsaturated fatty acids (MUFA) to total fatty acids, and MUFA), lipoprotein classes (e.g. TG in medium low-density lipoprotein, TG in small HDL), glycoprotein acetyls related to inflammation, and pyruvate related to glycolysis were associated with reduced muscle mass at follow-up.
Conclusions
Plasma metabolites were associated with muscle mass at follow-up. The findings were suggestive of glucolipotoxicity and inflammation as drivers of muscle mass decline. These metabolites are potentially useful to track the muscle mass changes for sarcopenia prevention in T2D.

USING RESEARCH TO TRANSFORM HEALTH POLICY FOR PATIENTS WITH FRAGILITY FRACTURE IN BRITISH COLUMBIA, CANADA

S. Singh[1], L. Funnell[2], J. Solarzano[3], L. Battersby[4], L. Li[1], T. Bubela[4], D. Whitehurst[4], S. Hejazi[5], S. Bayat[3], T. O'Callaghan[5], A. Godfreyson[3], I. Matthes[6], B. Ballantyne[5], L. Matheson-Jennings[5], J. Robinson[3], R. Kherani[1], A. Tecson[5], O. Slavutskiy[5], A. Virk[4]

[1]University of British Columbia, Vancouver, Canada; [2]Osteoporosis Canada, Surrey, Canada; [3]British Columbia Ministry of Health, Victoria, Canada; [4]Simon Fraser University, Burnaby, Canada; [5]Fraser Health Authority, Surrey, Canada; [6]Osteoporosis Canada, Vancouver, Canada

Objective: Fracture Liaison Service (FLS) is an effective post-fracture care model to reduce repeat fragility fractures and improve quality of life for older adults. An implementation science research team successfully implemented the first FLS in British Columbia (BC), Canada and spread FLS to three additional hospitals. The team is now using research methods to integrate FLS into routine orthopedic care in BC.
Material and Methods: The team – health providers, people with lived experience, academics, health sector decision makers and policy makers – brought together expertise in fracture prevention, research methods, patient experience, knowledge translation and health policy. Research methods included: a series of rapid literature reviews relevant to FLS scale-up and spread, a costing analysis of the impact of FLS spread in BC, a comparative policy review case study of FLS in other Canadian jurisdictions and a deliberative dialogue workshop with diverse stakeholders across Canada to provide input to shape the final BC FLS policy options.
Results: Literature reviews and costing analysis confirm that FLS is effective in preventing repeat fractures and associated health care costs. Patient-related factors important for FLS effectiveness include knowledge of osteoporosis, perceived treatment benefits, and trust with health providers. Successful FLS implementation strategies include primary care provider engagement, patient-centred approaches, adapting to local context, adopting team-based approaches, use of virtual technology and a stepwise approach to FLS spread. Barriers to implementation include lack of dedicated funding, shortage of primary care providers and limited experience reaching rural communities and specific populations (e.g., Indigenous peoples). Outputs from our research include 1) a policy brief (Canadian Institutes of Health Research website), 2) a detailed FLS spread business case and implementation plan for BC and 3) integration of FLS spread into the BC Ministry of Health's *Age Forward Strategy* (2024), a prevention-focused health strategy and action plan supporting older adults' needs.
Conclusion: A multi-disciplinary team, that included policy makers, successfully used research methods to transform the health system to benefit patients with fragility fractures.

P1551

AGREEMENTS OF DIAGNOSTIC BONE MINERAL DENSITY RESULTS BETWEEN SUPINE AND STANDARD POSITIONS

S. Sisai[1], T. Taerakul[1]

[1]Nuclear Medicine Department, Rajavithi Hospital, Bangkok, Thailand

Background: Osteoporosis is a common health problem among older adults and is associated with an increased risk of fractures. Bone mineral density (BMD) measurement using dual-energy X-ray absorptiometry (DXA) with standard positioning is the primary diagnostic method. However, some patients have physical limitations that prevent them from being positioned in a standard manner. Supine-position DXA scanning has recently been introduced to improve accessibility; however, its diagnostic agreement with standard positioning remains unclear. **Objective:** To evaluate the agreement and compare BMD and T-score values obtained from anteroposterior (AP) spine measurements between supine and standard positions. **Methods:** This prospective study included postmenopausal women aged ≥50 years and men aged ≥60 years who underwent BMD measurement at Rajavithi Hospital, Thailand, between December 2024 and June 2025. A total of 60 participants were enrolled. **Results:** The mean age of the participants was 69.8 ± 8.8 years; 5 participants (8.3%) were men and 55 (91.7%) were women. BMD and T-score measurements obtained from supine and standard positions demonstrated almost perfect agreement, with ICCs of 0.995 ($p < 0.001$) for both parameters. No statistically significant differences were observed between positions for BMD ($Z = -1.280$, $p = 0.201$) or T-score ($Z = -1.777$, $p = 0.076$). Agreement in T-score–based diagnostic classification was high, with a 95.0% agreement rate and a Cohen's kappa value of 0.919 ($p < 0.001$). All discrepancies occurred between adjacent diagnostic categories. **Conclusion:** Supine-position AP spine DXA provides BMD and T-score results comparable to those obtained with standard positioning, supporting its clinical use in patients with positioning limitations.

P1552

CASE SERIES: CHRONIC LOW-GRADE INFLAMMATION AS A SHARED ETIOPATHOGENIC FACTOR IN OSTEOPOROSIS AND CHRONIC CORONARY SYNDROME

S. Sokolovic[1], I. Sokolovic-Tahtovic[1]

[1]Society for Osteoporosis in Federation of Bosnia and Herzegovina, Sarajevo, Bosnia & Herzegovina

Background:
Chronic low-grade inflammation ("inflammaging") contributes to endothelial dysfunction, atherosclerotic progression, and disruption of bone remodeling. This case series evaluates patients presenting with both chronic coronary syndrome (CCS) and osteoporosis, focusing on inflammatory markers as a potential shared mechanism.
Material and Method:
A case series study with 3 postmenopausal women presenting with osteoporosis and chronic coronary syndrome. Laboratory inflammatory markers including hsCRP, Lipoprotein (a), Interleukin 6 (IL-6), Vitamin D and diagnostic imaging with Multi Slice Coronary Angiography (MSCT) and DEXA.
Results:
Case 1: Female, 72 years, Hypertension, dyslipidemia, postmenopausal status, Exertional chest discomfort, chronic back pain DXA: T-score −2.7 (lumbar spine), MSCT : Non-obstructive but diffusely atherosclerotic arteries, hs-CRP: 4.8 mg/L (↑), IL-6: mildly elevated, Vitamin D 16,7
Case 2: Female, 65 years, with a type 2 diabetes, obesity (BMI 31), sedentary lifestyle, Fatigue, reduced exercise tolerance, height loss over 5 years, DXA: T-score −2.2 (femoral neck), MSCT: calcified plaques and obstructive LAD (Agatston score 380), hs-CRP: 6.2 mg/L (↑) IL-6: elevated, HbA1c 7.8%, Vit D 21
Case 3: Female, 79 years, with a rheumatoid arthritis moderate disease activity, long-term low-dose glucocorticoids, Vertebral compression fractures, stable angina, DXA: T-score −3.3 (lumbar spine), MSCT: Obstructive coronary LAD and Cx, ESR: 48 mm/h (↑), hs-CRP: 7.9 mg/L (↑) Vit D 7,9
Conclusion:
Evidence of chronic coronary syndrome and osteoporosis with elevated inflammatory markers suggests inflammation as a shared pathophysiologic driver. Metabolic low grade chronic inflammation contributes to both skeletal fragility and accelerated coronary plaque formation.

P1553

IDENTIFYING SERUM BIOMARKERS FOR EARLY DIAGNOSIS AND PROGNOSIS OF LUNG INVOLVEMENT IN SYSTEMIC CONNECTIVE TISSUE DISEASES: FROM PATHOGENESIS TO CLINICAL PRACTICE

S. Spitsina[1], A. Trofimenko[2], E. Mozgovaya[2], S. Bedina[1], O. Emelyanova[2], O. Rusanova[2]

[1]Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky, Volgograd State Medical University, Volgograd, Russia; [2]Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky, Volgograd, Russia

Introduction. The need for serum biomarkers for early detection of lung involvement in diffuse connective tissue diseases (DCTDs) like systemic lupus erythematosus (SLE) and systemic sclerosis (SSc) persists. The detection of antibodies to elastin and elastase appears to be a promising direction in the search for new immunological markers of pulmonary involvement in DCTDs.
Objective. To conduct a comparative analysis of serum levels of antibodies to elastin and elastase in patients with SLE and SSc, assess their association with the presence of lung involvement.
Materials and Methods. A single-center prospective study included 65 patients with SLE (60 women, 5 men; mean age 42.5 ± 12.1 years; mean disease duration 8.4 ± 6.7 years) and 50 patients with SSc (38 women, 12 men; mean age 43.2 ± 14.6 years; mean disease duration 10.6 ± 8.2 years). The control group consisted of 30 apparently healthy donors matched for sex and age. Lung involvement was detected in 34 (52.3%) SLE patients: pleuritis – 21 (62%), alveolitis – 8 (23%), pneumosclerosis – 5 (15%). In the SSc group, lung involvement was diagnosed in 45 patients (90%): pneumofibrosis – 26 (58%), signs of pulmonary hypertension – 12 (27%), pleuritis – 7 (15%).

Results. Baseline levels of antibodies to elastin and elastase in patients with SLE and SSc were significantly higher than in the control group ($p<0.05$). In SLE, no statistically significant differences were found in the levels of antibodies to elastin and elastase between subgroups of patients with or without clinically and instrumentally confirmed lung involvement ($p=0.074$; $p=0.057$, respectively). In the SSc group, a significant correlation was found between antibodies to elastin and lung involvement ($p=0.003$). However, in the SSc group, differences in antibodies to elastase between subgroups with and without lung involvement did not reach statistical significance ($p=0.056$). Correlation analysis in the SSc group also revealed an association between antibodies to elastin and fibrotic changes ($p<0.05$).
Conclusion. The level of antibodies to elastin demonstrates an association with lung involvement in DCTDs, especially in SSc, which allows them to be considered as a promising laboratory marker for early detection and monitoring of the progression of pulmonary pathology in patients with SSc.

P1554

CANAKINUMAB AS A BIOLOGICAL THERAPY OPTION FOR RESISTANT ADULT STILL'S DISEASE

S. Spitsina[1], L. Shilova[2], E. Mozgovaya[3], A. Trofimenko[3], S. Bedina[1]

[1]Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky, Volgograd State Medical University, Volgograd, Russia; [2]Volgograd State Medical University, Volgograd, Russia; [3]Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky, Volgograd, Russia

Introduction. Adult-onset Still's disease (AOSD) is a rare systemic inflammatory disorder of autoimmune origin characterized by multiorgan damage. Standard treatment regimens, including glucocorticosteroids and synthetic disease-modifying antirheumatic drugs, do not always control disease activity, necessitating the use of targeted biologic agents.
Objective: To demonstrate the specific management strategy for adult Still's disease patients with insufficient efficacy of standard therapy.
Materials and Methods. Patient M., 23, diagnosed with AOSD a year ago, presented to the rheumatology department with complaints of low-grade fever (up to 38.0°C), severe pain and swelling of the knee and wrist joints with limited function, and an erythematous maculopapular rash on the skin of the trunk, worsening with hyperthermia. Laboratory examination data on admission revealed high inflammatory activity: neutrophilia, ESR of 52 mm/h, C-reactive protein of 45 mg/L, and hyperferritinemia (800 µg/L).
Results. The patient received methotrexate 20 mg/week and prednisolone 20 mg/day without significant clinical and laboratory response. Due to resistance to the therapy, the interleukin-1β (IL-1β) inhibitor canakinumab 300 mg subcutaneously every 4 weeks was prescribed against the background of a gradual reduction in the dose of prednisolone. Positive changes were noted after the first canakinumab injection: normalization of body temperature, regression of joint syndrome, and disappearance of skin rashes. After 4 months of therapy, complete clinical and laboratory remission was achieved: normalization of inflammatory markers (CRP ≤ 5 mg/L, ferritin 180 ng/mL) and neutrophils. Due to this improvement, the prednisolone dose was reduced to 10 mg/day without recurrence of symptoms. Canakinumab therapy was well tolerated, with no adverse effects reported.
Conclusions. Canakinumab therapy can be considered as the treatment of choice in patients with hormone-resistant forms of AOSD, providing a rapid and sustained clinical response combined with a favorable safety profile. These data confirm the key role of IL-1β in the pathogenesis of AOSD and support its targeted blockade as part of a treatment strategy.

P1555

RESISTIN AS A PROMISING BIOMARKER OF METABOLIC SYNDROME IN PATIENTS WITH DIFFUSE CONNECTIVE TISSUE DISEASES

S. Spitsina[1], L. Shilova[2], A. Trofimenko[3], E. Mozgovaya[3], S. Bedina[1]

[1]Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky, Volgograd State Medical University, Volgograd, Russia; [2]Volgograd State Medical University, Volgograd, Russia; [3]Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky, Volgograd, Russia

Introduction. The pathogenesis of metabolic syndrome (MS) in systemic lupus erythematosus (SLE) and systemic sclerosis (SSc) includes both traditional and specific factors: chronic systemic inflammation, immune dysregulation, and the impact of therapy. Adipokines, particularly resistin, are considered key mediators linking metabolic disturbances with the immune-inflammatory activity of the disease. However, data on resistin in SLE and SSc remain contradictory and require systematization.
Objective. To systematically analyze current data on the role of resistin as a potential biomarker of metabolic disturbances in patients with SLE and SSc.
Materials and Methods. A search and analysis of publications in PubMed, Google Scholar, and eLibrary databases for the period 2020-2025 was conducted using the keywords "resistin," "adipokines," "metabolic syndrome," "insulin resistance," "SLE," and "SSc," taking into account the level of evidence of the data presented.
Results. Most studies describe a significant increase in serum resistin levels in patients with SLE compared to healthy controls (Kuo C.Y. et al., 2020). An association between resistin and metabolic syndrome in SLE was established: its levels were significantly higher in patients with SLE and metabolic syndrome compared to SLE patients without metabolic syndrome ($p < 0.001$). Meta-regression analysis revealed a direct correlation between resistin levels and the degree of insulin resistance (HOMA-IR) in SLE (Kuo C.Y. et al., 2020). However, in another study, high resistin concentrations were negatively associated with MS, highlighting the inconsistency of the data (Apostolopoulos D. et al., 2020). Unlike SLE, no differences in resistin concentrations were found between the MS and non-MS groups in SSc. Furthermore, a positive correlation was found between resistin and SLE disease activity (Kuo C.Y. et al., 2020) and the presence of lupus nephritis (Chougule D. et al., 2025).
Conclusions. Resistin is a promising biomarker in SLE. Its serum level not only reflects the presence of concomitant metabolic disorders but also correlates with disease activity and specific organ damage (nephritis). Large, prospective, multicenter studies with a consistent design are needed to clarify the diagnostic and prognostic value of resistin.

P1556

DIAGNOSTIC FEATURES OF INFECTIOUS ENDOCARDITIS IN PATIENTS WITH ANKYLOSING SPONDYLOARTHRITIS

S. Spitsina[1]

[1]Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky, Volgograd State Medical University, Volgograd, Russia

Introduction. Diagnosis of infective endocarditis (IE) in patients with autoimmune pathology can be challenging, as its clinical and laboratory manifestations can mimic an exacerbation of the underlying disease. The greatest difficulties arise in patients receiving therapy with biologic agents.

Objective. To describe a clinical case of IE in a patient with ankylosing spondylitis (AS) and analyze factors complicating its diagnosis during immunosuppressive therapy.

Materials and Methods. A 38-year-old man diagnosed with AS received etanercept. The patient complained of a three-week low-grade fever, arthralgia and swelling of the knee and ankle joints, myalgia, unexplained weight loss of 6 kg over the past month, and the development of a hemorrhagic rash on the skin of the lower extremities. Objectively: the skin is pale; multiple petechiae 1-2 mm in diameter are present on the shins and thighs. Cardiac auscultation revealed a systolic murmur in the second intercostal space on the right and at Botkin's point. Joint syndrome manifested as swelling of the knee joints without signs of hyperemia or hyperthermia, with limited range of motion and moderate tenderness.

Results. Laboratory signs of systemic inflammation: leukocytosis with a neutrophilic shift, an increase in the erythrocyte sedimentation rate and the level of C-reactive protein. The hemogram revealed normochromic anemia and thrombocytopenia. Biochemical profile: hypoalbuminemia and signs of impaired renal function: eGRF=42 ml/min/1.73 m². General urine analysis revealed proteinuria, erythrocyturia and leukocyturia. Bacteriological blood culture verified the causative agent - Streptococcus oralis. Echocardiography revealed signs of vegetation on the aortic valve leaflets and aortic regurgitation of I-II degrees. Renal ultrasound revealed increased parenchymal echogenicity and thickened renal pelvis, consistent with nephritis.

Conclusions. This clinical case highlights the need for caution regarding IE in patients receiving biologic agents and the importance of conducting diagnostic workup when fever and new systemic symptoms develop. It is important to adhere to the recommended antibiotic prophylaxis for IE before invasive procedures in rheumatology patients receiving immunosuppressive therapy.

P1557

THE ROLE OF THE APELINERGIC SYSTEM IN THE PATHOGENESIS AND SEVERITY ASSESSMENT OF OSTEOARTHRITIS: DIAGNOSTIC AND THERAPEUTIC POTENTIAL

S. Spitsina[1], L. Shilova[2]

[1]Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky, Volgograd State Medical University, Volgograd, Russia; [2]Volgograd State Medical University, Volgograd, Russia

Introduction. Most studies indicate the involvement of the apelinergic system (apelin/APJ) in the pathogenesis of osteoarthritis (OA). However, data on its relationship with the clinical and radiological severity of the disease and its diagnostic value remain fragmented and require systematization.

Objective. To analyze current scientific data on the diagnostic and prognostic value of apelin/APJ as a biomarker for assessing the severity of osteoarthritis.

Materials and Methods. A search of publications in the international databases PubMed and Google Scholar was conducted without restrictions on the year of publication, with an emphasis on articles published between 2020 and 2025. The apelinergic system, represented by apelin and its receptor (apelin/APJ), is widely expressed in numerous tissues, particularly bone, joint, and muscle (Luo J., 2021). This review focuses on the effects of apelin/APJ on the course of OA. Fifteen studies were included in this systematic review.

Results. Apelin is involved in the pathogenesis of OA by regulating synovial angiogenesis and cartilage catabolism (Wang YH, 2020). Apelin/APJ stimulates chondrocyte proliferation and increases the expression of catabolic factors that break down proteoglycans (Luo, 2021; Jia S, 2023). Hu PF et al. described an increase in apelin in serum and synovial fluid in OA compared to controls ($p < 0.05$). A direct correlation was established between apelin and OA severity ($r=0.5498$; $p=0.0003$). Higher apelin levels in women ($p<0.05$) may explain gender differences in the prevalence and incidence of OA.

Conclusions. These data suggest that apelin is involved in the pathophysiology of OA. The established correlation between apelin concentration and clinical severity of OA supports its potential as a diagnostic marker. Inhibition of the apelin/APJ system represents a potential target for targeted OA therapy. Further research is needed to fully elucidate the role of apelin in cartilage metabolism.

PREVALENCE AND PREDICTORS OF OSTEOPOROSIS IN POSTMENOPAUSAL WOMEN

S. Tomasevic-Todorovic[1,2], D. Savic[1], S. Kecojevic[1], S. Jelcic[1]

[1]Clinic for Physical Medicine and Rehabilitation, University Clinical Center of Vojvodina, Novi Sad, Serbia; [2]Faculty of Medicine, University of Novi Sad, Novi Sad, Serbia

Objective(s): The objective is to determine the prevalence of osteoporosis and to analyze clinical and densitometric parameters associated with osteoporosis in postmenopausal women treated at a tertiary rehabilitation clinic.

Material and Methods: This cross-sectional study included 107 postmenopausal patients examined at the Clinic for Physical Medicine and Rehabilitation, University Clinical Center of Vojvodina. Bone mineral density (BMD) was measured by dual-energy X-ray absorptiometry. Demographic data, duration of menopause, body mass index (BMI), presence of clinical risk factors, FRAX scores (hip fracture and major osteoporotic fracture probability), and SARC-F questionnaire scores were collected. Statistical analysis included Student's t-test and logistic regression, with $p < 0.05$ considered statistically significant.

Results: The median age of participants was 64 years (range 40–89), and the mean duration of menopause was 15.5 years (range 1–42). Osteoporosis was diagnosed in 30 patients (28%), while osteopenia was diagnosed in 51 patients (47.7%). The mean BMI was 25.8 (range 17.4–44.6). The SARC-F questionnaire was ≥4 in 60 patients (56.1%). A statistically significant difference in right hip BMD was observed between patients with a duration of menopause >15 years and those with <15 years ($p < 0.01$). Mean right hip BMD was lower in patients with menopause duration >15 years (0.8059 ± 0.130) compared to those with <15 years (0.8803 ± 0.1289). Higher FRAX hip fracture probability (OR 6.2; 95% CI 2.46–15.60; $p = 0.0001$) and FRAX major osteoporotic fracture probability ($p = 0.0031$) were significantly associated with the presence of osteoporosis. Other analyzed factors, including duration of menopause, BMI, presence of clinical risk factors, and SARC-F score, were not independently associated with osteoporosis.

Conclusion(s): Osteoporosis was identified in more than one-quarter of the examined postmenopausal patients. Longer duration of menopause was associated with lower hip bone mineral density. Women diagnosed with osteoporosis exhibited significantly higher FRAX hip and major osteoporotic fracture probabilities. These findings highlight the coexistence of low bone mass and increased estimated fracture risk in postmenopausal women.

P1559

RISK OF FRAGILITY FRACTURES IN INDIVIDUALS WITH AND WITHOUT HIV INFECTION: A POPULATION-BASED MATCHED CASE–CONTROL STUDY

S. Tsai[1]

[1]Taipei Medical University Hospital, Taipei, Taiwan

Purpose

Patients with human immunodeficiency virus (HIV) infection are at increased risk of comorbidities, including osteoporosis, which predisposes them to fragility fractures (FFs). Evidence from Asian populations is limited. This study investigated the risk of FFs in an Asian population with and without HIV infection.

Methods

We conducted a nationwide retrospective matched cohort study using Taiwan's National Health Insurance Research Database. A total of 3,994 individuals with HIV infection and 15,976 matched controls were identified (1:4 ratio). Matching variables included age, sex, income, urbanization, liver cirrhosis, diabetes mellitus, renal failure, and hepatitis B and C infection. Fragility fractures were identified using ICD-9-CM codes, and Cox proportional hazards models estimated hazard ratios (HRs) with 95% confidence intervals (CIs).

Results

The incidence of overall fragility fractures (AFF) was similar between HIV-infected and uninfected individuals (12.9% vs. 11.9%, P = 0.097). However, HIV infection was associated with a significantly higher risk of hip fragility fracture (HFF) (HR 2.22, 95% CI 1.62–3.06, P < 0.001). Risk factors for FFs included age >50 years, modified Charlson Comorbidity Index ≥2, hypertension, and diabetes mellitus. Antiretroviral therapy (ART) mitigated overall fracture risk and was associated with substantially lower postoperative mortality after fracture surgery (9.4% vs. 36.1%).

Conclusion

HIV infection was associated with increased hip fracture risk in this Asian population. ART conferred protective effects on overall fracture risk and survival after fracture, underscoring its net clinical benefit despite skeletal concerns. These findings support targeted bone health monitoring and preventive strategies in individuals with HIV infection.

P1560

HOUNSFIELD UNIT VALUES OF CERVICAL VERTEBRAE PREDICT TITANIUM MESH CAGE SUBSIDENCE AFTER ANTERIOR CERVICAL CORPECTOMY AND FUSION

S. Wang[1]

[1]Department of Spine Surgery, Xi'an Honghui Hospital, Xi'an Jiaotong University, Xi'an, China

Objective(s)

Titanium mesh cage (TMC) subsidence after anterior cervical corpectomy and fusion (ACCF) may cause segmental kyphosis, recurrent neurological symptoms and mechanical failure. Bone mineral density is a major determinant of subsidence risk, but dual-energy X-ray absorptiometry does not accurately reflect local cervical vertebral bone quality. This study evaluated the predictive value of preoperative Hounsfield unit (HU) measurements from computed tomography for TMC subsidence after ACCF and sought to define a clinically useful HU threshold.

Material and Methods

We retrospectively analysed 64 patients who underwent one- or two-level ACCF with TMCs for cervical degenerative or compressive pathology between March 2011 and December 2019. Preoperative cervical computed tomography was used to measure HU values in vertebral bodies adjacent to the TMC using standardised elliptical regions of interest that avoided cortical bone and vascular channels. Subsidence was defined as segmental height loss greater than 3 mm on lateral radiographs compared with immediate postoperative measurements. Radiographic assessments were performed at baseline, postoperatively and at a mean follow-up of 19.3 ± 7.9 months. Patients were divided into subsidence and non-subsidence groups. Receiver operating characteristic (ROC) curve analysis was used to determine the optimal HU cut-off for predicting subsidence.

Results

TMC subsidence occurred in 22 of 64 patients (34.4 per cent). Mean HU values of adjacent vertebrae were significantly lower in the subsidence group than in the non-subsidence group (317.3 ± 32.3 vs 363.1 ± 25.2, $p < 0.001$). ROC analysis yielded an area under the curve of 0.859. An HU cut-off of 330.5 provided 100 per cent sensitivity and 72.7 per cent specificity for predicting subsidence. Patients with HU values below 330.5 had a markedly higher subsidence rate than those with HU values at or above this threshold.

Conclusion(s)

Preoperative cervical HU measurements are strongly associated with TMC subsidence after ACCF and offer a practical surrogate for local vertebral bone quality. An HU threshold of 330.5 may be used to identify high-risk patients, guide reconstruction strategies and tailor perioperative management in individuals with compromised cervical bone strength.

Disclosures

The authors declare no conflicts of interest related to this work.

P1561

MRI-BASED ENDPLATE BONE QUALITY SCORE PREDICTS CAGE SUBSIDENCE AFTER SINGLE-LEVEL ANTERIOR CERVICAL DISCECTOMY AND FUSION

S. Wang[1]

[1]Department of Spine Surgery, Xi'an Honghui Hospital, Xi'an Jiaotong University, Xi'an, China

Objective(s)

Cage subsidence after anterior cervical discectomy and fusion (ACDF) may result in segmental kyphosis, recurrent radiculopathy and mechanical failure. Bone quality is central to subsidence risk, yet dual-energy X-ray absorptiometry (DEXA) does not adequately capture local cervical endplate strength. This study evaluated an MRI-based endplate bone quality (EBQ) scoring method for predicting cage subsidence after single-level ACDF and compared its predictive performance with that of DEXA-derived bone mineral density.

Material and Methods

We retrospectively analyzed 160 patients who underwent single-level ACDF from C3 to C7 between 2008 and 2016. All procedures used either a zero-profile anchored cage (n = 90) or a plate–cage construct (n = 70). Preoperative cervical MRI was used to assign an EBQ score to the operative segment based on endplate signal intensity and morphology. Systemic bone mineral density was assessed using DEXA. Clinical outcomes included visual analogue scale scores for neck and arm pain and Neck Disability Index, recorded preoperatively and at follow-up. Radiographic parameters included disc height, cage subsidence, fusion status and time to motion stabilisation on dynamic radiographs. Cage subsidence was defined as radiographic loss of disc height with visible cage sinking into the endplate. Associations between implant type, EBQ, DEXA and subsidence were evaluated using appropriate statistical tests, with $p < 0.05$ considered significant.

Results

Both constructs provided significant improvement in pain and disability, with similar fusion rates at final follow-up. The zero-profile group showed greater disc height loss (2.26 ± 1.00 mm versus 1.76 ± 1.13 mm, $p = 0.004$) and a higher subsidence rate (24.44 per cent versus 11.43 per cent, $p = 0.036$) compared with the plate–cage group. Higher EBQ scores, indicating poorer endplate quality, were associated with an increased risk of cage subsidence. The EBQ method showed superior predictive accuracy for subsidence risk compared with DEXA, which was less discriminative for local endplate failure. Delayed motion stabilisation was also linked to greater disc height loss and higher subsidence rates.

Conclusion(s)

An MRI-based EBQ scoring method provides a targeted assessment of cervical endplate bone quality and improves prediction of cage subsidence after single-level ACDF compared with DEXA alone. Incorporating EBQ into preoperative planning may help identify high-risk patients, guide construct selection and optimise strategies to reduce implant-related complications.

Disclosures

The authors declare no conflicts of interest related to this work.

P1562

SHORT-SEGMENT BONE CEMENT–AUGMENTED PEDICLE SCREW FIXATION COMBINED WITH BONE GRAFTING FOR KÜMMELL DISEASE WITH SEGMENTAL INSTABILITY

S. Wang[1]

[1]Department of Spine Surgery, Xi'an Honghui Hospital, Xi'an Jiaotong University, Xi'an, China

Objective(s)
Percutaneous kyphoplasty and vertebroplasty are widely used for Kümmell disease, but they may be insufficient in cases with segmental instability. The objective of this study was to evaluate the clinical and radiological efficacy of short-segment bone cement–augmented pedicle screw fixation combined with bone grafting for the treatment of Kümmell disease with segmental instability.

Material and Methods
This retrospective study included 23 patients with Kümmell disease and segmental instability treated with short-segment bone cement–augmented pedicle screw fixation combined with bone grafting between January 2021 and January 2024. Clinical outcomes were assessed using the visual analog scale (VAS) for back pain and the Oswestry Disability Index (ODI) preoperatively, one week postoperatively and at final follow-up. Radiological parameters included vertebral anterior height and kyphotic Cobb angle. Operative time, intraoperative blood loss, length of hospital stay and complications were recorded. Fusion status was evaluated on follow-up imaging.

Results
VAS scores, ODI scores, vertebral anterior height and kyphotic Cobb angles improved significantly from preoperative assessment to one week after surgery and to final follow-up ($p < 0.05$). VAS and ODI at final follow-up were significantly lower than at one week postoperatively ($p < 0.05$), whereas vertebral anterior height and kyphotic Cobb angle were maintained without significant loss between one week and final follow-up ($p > 0.05$). Solid fusion was achieved in 21 of 23 patients (91.3 per cent). No serious complications, such as neurological deterioration or symptomatic cement leakage, were observed.

Conclusion(s)
Short-segment bone cement–augmented pedicle screw fixation combined with bone grafting is a safe and effective option for Kümmell disease with segmental instability. This technique provides substantial pain relief and functional improvement, restores and maintains vertebral height and kyphosis correction and is associated with a low complication rate.

Disclosures
The authors declare no conflicts of interest related to this work.

P1563

IMPROVING SURGICAL OUTCOMES IN OSTEOPOROTIC SPINE PATIENTS THROUGH PERIOPERATIVE BONE HEALTH OPTIMIZATION

S. Williams[1], N. Koumontzis[1], P. Cummings[2]

[1]West Virginia University School of Medicine, Charleston, United States; [2]Aegis Bone Health, Phoenix, United States

Materials and Methods: This review synthesizes contemporary guidelines, systematic analyses, randomized trials, and biomechanical studies addressing perioperative optimization in osteoporotic patients undergoing orthopedic surgery of the spine. Topics include screening strategies, pharmacologic management, vitamin D supplementation, and surgical techniques.
Results: Dual-energy X-ray Absorptiometry (DEXA) remains foundational for the diagnosis of osteoporosis, but CT-based Hounsfield unit (HU) quantification demonstrates stronger correlation with trabecular bone strength, vertebral microarchitecture, pedicle screw fixation strength, and fusion success. HU thresholds of <110 for osteoporosis and <135 for osteopenia offer >90% specificity, and preoperative HUs < 97.9 predict postoperative instrumentation failure. Vitamin D deficiency is an independent predictor of nonunion, increasing the risk of failed fusion and prolonging time to union. Supplementation shortens time to fusion and reduces postoperative pain.
Recent evidence suggests that teriparatide improves long-term fusion rates, decreases screw loosening, enhances pedicle fixation strength, and outperforms biphosphonates in meta-analyses. Biphosphonates remain beneficial for reducing postoperative vertebral fractures and improving pain and disability scores. Romosozumab and abaloparatide show promise but require additional data.
Surgical strategies include cement augmentation, which provides the greatest improvement in pullout strength regardless of screw design. Expandable screws and hydroxyapatite-granule augmentation offer alternative fixation strategies with reduced leakage and thermal risk. Fenestrated, cement-augmented screws reduce revision rates in osteoporotic patients.
Conclusions: Spine surgery in osteoporotic patients requires a multidisciplinary approach to bone health optimization incorporating bone quality assessment, correction of vitamin D deficiency, initiation of osteoanabolic therapy when indicated, and enhanced fixation strategies. Adoption of these evidence-based protocols may improve outcomes in this growing patient population.

P1564

THE RELATIONSHIP BETWEEN CORONARY ARTERY CALCIFICATION AND VASCULAR WALL STIFFNESS PARAMETERS IN PATIENTS WITH CORONARY ARTERY DISEASE AND TYPE 2 DIABETES MELLITUS

S. Y. U. Tsarenok[1], B. B. Tymkiv[1], V. V. Gorbunov[1], N. A. Ilyamakova[2], T. A. Aksenova[1], M. A. Malysheva[1]

[1]Chita State Medical Academy, Chita, Russia; [2]Clinical Hospital of Russian Railways Medicine of the city of Chita, Chita, Russia

Background: Bone mineral metabolism disorders and cardiovascular diseases, as age-associated pathologies, share not only similar risk factors but also common pathogenic mechanisms, explaining their close relationship.

Objectives : The aim of the study was to identify the relationship between vascular wall stiffness and bone mineral density in patients with coronary heart disease and type 2 diabetes.
Materials and methods: A total of 40 patients with coronary artery disease (CAD) were included in the study, 21 of whom were women aged 55 to 75 years (mean age 65.8 ± 4.7 years) and 19 were men aged 55 to 73 years (mean age 63.1 ± 4.2 years). The study included patients who signed voluntary informed consent, had at least one coronary artery (CA) stenosis of 50% or more (according to coronary angiography), or had a history of myocardial infarction, hospitalized for which more than 60 days before inclusion in the study. Among the patients, 8 people had type 2 diabetes. Patients underwent serum levels of phosphorus, calcium, alkaline phosphatase (ALP), 25(OH) vitamin D3, and lipid profile. Instrumental examinations included 24-hour monitoring of blood pressure and arterial stiffness parameters using the BPLab monitor and multispiral computed tomography (MSCT) of the coronary arteries with Agatston coronary calcium index calculation (SIEMENS SomatomPerspective 64/128 ECO CT). Statistical analysis was performed using StatTech v. 4.8.5. Quantitative parameters were assessed for compliance with normal distribution using the Shapiro-Wilk test. Quantitative parameters with a normal sample distribution were described using arithmetic means (M) and standard deviations (SD). Differences were considered statistically significant at $p < 0.05$.
Results: Among the 40 patients included in the study, 25 patients showed a moderate correlation with mean aortic pressure (0.428, P=0.006), pulse pressure amplification index (r=0.425, P=0.006), and mean pulse pressure (r=0.433, P=0.005).
Results: Among 40 patients included in the study, 25 had multivessel coronary artery disease, including 6 patients with type 2 diabetes. All examined individuals had signs of coronary artery calcification. In patients with multifocal atherosclerosis, a pronounced direct relationship with the degree of coronary artery calcification was noted; in individuals with multivessel disease, the Agatston index, which determines the degree of coronary artery calcification, was significantly higher (1519 CI versus 840 CI). When analyzing markers of phosphorus-calcium metabolism, a negative relationship was observed between the serum phosphorus level in the blood and the calcium index value according to MSCT of the coronary arteries ($r = 0.556$, $p < 0.001$), as well as with the parameters of vascular wall rigidity. Serum phosphorus level showed a direct moderate relationship with mean aortic pressure (0.428, P=0.006), pulse pressure amplification index (r=0.425, p=0.006) and mean pulse pressure (r=0.433, p=0.005).
Conclusions: Thus, the degree of coronary artery calcification is directly related to the prevalence of atherosclerotic lesions in the coronary artery system. Multivessel disease was observed in almost all patients with diabetes. Some parameters of arterial stiffness were correlated with phosphorus levels, the latter being negatively correlated with the calcium index.

P1565

LEGG-CALVE-PERTHES DISEASE IN A FEMALE WITH THREE GENERATIONS OF FAMILY MEMBERS: A CASE REPORT

S. Zanned[1], H. Ferjani[1], F. Majdoub[1], L. Kharrat[1], D. Ben Nessib[1], D. Kaffel[1], K. Maatallah[1], W. Hamdi[1]

[1]Kassab Institute of Orthopedics, Rheumatology department, Mannouba, Tunisia

Introduction:
Legg-Calve-Perthes disease (LCPD) is an avascular necrosis affecting the femoral head. It is characterized as a developmental anomaly of the hip, manifested by delayed and irregular ossification of the femoral epiphyseal nucleus. LCPD is predominantly observed in young males and is uncommon in girls. The presentation of LCPD in female patients has been reported as later in onset and associated with certain high-impact activities.
We present a case report of a 10-year-old female diagnosed with LCPD, with a family history of osteonecrosis of the femoral head in three generations with a focus on the potential genetic predisposition.
Case:
We present the case of a 10-year-old female patient who presented with limping and mechanical pain in the hip joint that had begun 3 years earlier. The pain increased with physical activity. There was no history of trauma and nothing of note in her medical history. On interrogation, we found a family history of head femoral osteonecrosis the brother, the father, the paternal uncle, and three aunts as well as the paternal grandfather. On examination, the child had bilateral hip pain and a limited range of motion. She was also noted to have an antalgic gait with a limp. Radiographs of the pelvis showed flattened and sclerotic femoral epiphysis. Blood tests showed a normal erythrocyte sedimentation rate (ESR) of 6 mm/h. All other blood tests including full blood count, C reactive protein, and bone profile tests were normal. Rheumatoid factor, anti-nuclear antibodies, liver function tests, proteins C and S, anti-phospholipid antibodies, and Hemoglobin electrophoresis came normal, ruling out other causes of aseptic necrosis of the femoral epiphysis. An MRI provided additional confirmation of the diagnosis of Perthes disease, revealing a bilateral avascular necrosis and collapse of the femoral capital epiphysis with transphyseal revascularization. The female sex, bilateral involvement, and family history of affected relatives in three generations were suggestive of a potential genetic component. Genetic analysis was indicated to identify the mutation of the COL2A1 gene of the 12q13 chromosome described in familial cases of LCPD.
Therapeutic management included antalgics as well as physiotherapy and rehabilitation. The case was also discussed with a pediatric orthopedic and concluded with a non-surgical indication.
The patient regained her normal activity and was advised to avoid impact activity and is seen regularly in the outpatient clinic with radiological follow-up. The younger sibling was convoked for screening through a clinical examination and a pelvis x-ray.
Discussion: While the reviewed literature provided evidence of cases of LCPD running in families, and epidemiological studies suggested a genetic role, twin studies reported no significant concordance (1,2).

Genetic factors have been suggested in the development of the disorder. Thus, COL2A1 alterations should be further studied to clarify their role in the pathogenesis and etiology of the LCPD.

Conclusion:

Understanding the genetic basis of LCPD will have significant implications for prognosis, treatment, and genetic counseling. In fact, genetic analysis and screening should be considered in LCPD with familial and/or bilateral cases.

Ethics: We have no conflicts of interest to disclose.

CHRONIC PAIN FOLLOWING TOTAL HIP ARTHROPLASTY: PREVALENCE, MECHANISMS, AND IMPACT ON QUALITY OF LIFE

S. Zanned[1], L. Rouached[1], Y. El Mabrouk[1], S. Ben Dhia[1], S. B. Bouden[1], I. Mahmoud[1], R. Tekaya[1], A. Ben Tekaya[1], M. Ben Salah[2], L. Abdelmoula[1]

[1]Charles Nicolle Hospital, Rheumatology department, Tunis, Tunisia; [2]Charles Nicolle Hospital, Orthopaedics department, Tunis, Tunisia

Background:

Total hip arthroplasty (THA) is an effective intervention for advanced hip osteoarthritis. Although most patients experience substantial postoperative pain relief, a significant proportion develop chronic postsurgical pain (CPSP), which may negatively affect physical function, mental health, and overall quality of life.

Objectives:

To determine the prevalence of CPSP after THA, characterize its underlying pain mechanisms, and assess its impact on quality of life. Methods Methods We conducted a cross-sectional study of patients evaluated after THA. Chronic postsurgical pain was identified and classified into nociceptive, neuropathic, and nociplastic components using validated tools: Visual Analogue Scale (VAS), DN4 questionnaire, PainDETECT questionnaire, and the Central Sensitization Inventory (CSI). Quality of life was assessed using the Short Form-36 (SF-36), including Physical (PCS) and Mental (MCS) Component Summary scores. Comparative analyses were performed between patients with and without CPSP.

Results:

Among the 51 included patients (mean age 51.6 ± 17.6 years; 38 men, 15 women): Chronic nociceptive pain was observed in 27.4% of patients (mean VAS: 45.5 ± 19.4). Neuropathic pain features were identified in 19.6% of patients using DN4 and in 21.6% using PainDETECT. Nociplastic pain was present in 19.6% of cases (mean CSI: 22.5 ± 16.7), and 21.5% of patients exhibited moderate to severe central sensitization (CSI > 40). Nociceptive pain was associated with significantly higher anxiety and depression scores (HAD-A 7.3 ± 3.3 vs 4.6 ± 1.2; HAD-D 8.2 ± 3.1 vs 4.7 ± 1.4; $p < 0.001$) and with marked impairment in quality of life, both physical ($r = -0.65$; $p < 0.001$) and mental ($r = -0.56$; $p < 0.001$). Neuropathic pain was more frequent among sedentary patients (OR = 4.7; $p = 0.002$) and those with chronic inflammatory rheumatism (OR = 2.9; $p = 0.028$) and was associated with significant reductions in both physical ($r = 0.39$; $p = 0.002$) and mental ($r = 0.38$; $p = 0.003$) SF-36 scores. Finally, nociplastic pain correlated with pain intensity and psychological scores ($p < 0.01$), was associated with chronic inflammatory rheumatism ($p = 0.04$), and led to moderate but significant decreases in both physical ($r = 0.28$; $p = 0.045$) and mental ($r = 0.29$; $p = 0.036$) quality of life.

Conclusions:

Chronic postsurgical pain after THA is frequent and multifactorial, with nociceptive, neuropathic, and nociplastic components. All pain phenotypes are associated with impaired physical and mental quality of life. Psychological factors and underlying chronic inflammatory disease appear to contribute to CPSP development, whereas early rehabilitation may help prevent persistent nociceptive pain.

P1567

TINGLING AND BURNING AFTER HIP REPLACEMENT: CHRONIC NEUROPATHIC PAIN, RISK FACTORS, AND QUALITY OF LIFE

S. Zanned[1], L. Rouached[1], Y. El Mabrouk[1], S. Ben Dhia[1], S. B. Bouden[1], I. Mahmoud[1], R. Tekaya[1], A. Ben Tekaya[1], M. Ben Salah[2], L. Abdelmoula[1]

[1]Charles Nicolle Hospital, Rheumatology department, Tunis, Tunisia; [2]Charles Nicolle Hospital, Orthopaedics department, Tunis, Tunisia

Background:

Neuropathic chronic postsurgical pain (CPSP) is increasingly recognized after THA. It is frequently multifactorial, often involving central sensitization, and can severely impair physical function and quality of life.

Objectives:

To identify factors associated with chronic neuropathic CPSP after THA and evaluate its impact on quality of life.

Methods : Neuropathic pain was assessed using DN4 and PainDETECT questionnaires. Anxiety and depression were evaluated using HADS, and quality of life using the SF-36. Associations with demographic, clinical and rehabilitation-related variables were analyzed.

Results:

Neuropathic CPSP was present in 11 patients (21.6%). No significant associations were found with age, sex, diabetes, or type of osteoarthritis. Neuropathic pain was more frequent in patients with chronic inflammatory rheumatic diseases (OR = 2.9; 95% CI [1.1–7.9]; $p = 0.028$) and in those with a sedentary lifestyle (OR = 4.7; 95% CI [1.6–13.4]; $p = 0.002$). Patients with neuropathic CPSP exhibited higher anxiety (8.8 ± 3.5 vs 5.3 ± 2.1; $p < 0.001$) and depression scores (8.9 ± 3.5 vs 6.1 ± 2.6; $p = 0.005$). Neuropathic pain was significantly associated with reduced SF-36 physical (PCS: $r = -0.39$; $p = 0.002$) and mental (MCS: $r = -0.38$; $p = 0.003$) component scores. Postoperative rehabilitation and analgesic use were not significantly associated.

Conclusions:

Approximately one-fifth of patients developed chronic neuropathic CPSP after THA. This condition was associated with chronic inflammatory rheumatic diseases, physical inactivity and psychological distress, and was responsible for significant impairment in both physical and mental quality of life.

P1568

NOCIPLASTIC PAIN AFTER HIP REPLACEMENT SURGERY: THE COMPONENT WE OFTEN MISS

S. Zanned[1], L. Rouached[1], Y. El Mabrouk[1], S. Ben Dhia[1], S. Bouden[1], I. Mahmoud[1], R. Tekaya[1], A. Ben Tekaya[1], M. Ben Salah[2], L. Abdelmoula[1]

[1]Charles Nicolle Hospital, Rheumatology department, Tunis, Tunisia; [2]Charles Nicolle Hospital, Orthopaedics department, Tunis, Tunisia

Background:
Nociplastic pain, driven by central sensitization rather than ongoing tissue or nerve damage, represents an under-recognized mechanism of chronic postsurgical pain (CPSP) and is rarely assessed in routine clinical practice. Although total hip arthroplasty (THA) generally provides substantial pain relief and functional improvement, a subset of patients develops persistent nociplastic pain, compromising postoperative outcomes.
Objectives:
To identify factors associated with chronic nociplastic CPSP after THA and to evaluate its impact on quality of life.
Methods : Patients who had undergone THA were included. Demographic and clinical data were collected, including age, sex, body mass index (BMI), comorbidities (diabetes, hypertension), presence of inflammatory rheumatic diseases (rheumatoid arthritis, spondyloarthritis), and postoperative rehabilitation. Nociplastic pain was assessed using the Central Sensitization Inventory (CSI). Anxiety and depression were evaluated using the Hospital Anxiety and Depression Scale (HADS). Health-related quality of life was measured with the SF-36 questionnaire.
Results :
Fifty-one patients were included (mean age 51.6 ± 17.6 years; 38 men, 15 women). Most patients lived in urban areas (68.2%) and were sedentary (68.6%). Hypertension (45.1%) and diabetes mellitus (37.3%) were the most frequent comorbidities. Secondary hip osteoarthritis related to chronic inflammatory rheumatic diseases accounted for 58% of surgical indications. Chronic nociplastic CPSP was identified in 9 patients (19.6%). Their mean age was 54.2 ± 16.8 years, and mean BMI was 24.8 ± 3.2 kg/m²; six were men and three women. Four patients (44.4%) had underlying inflammatory rheumatic disease, two (22.2%) had diabetes, and three (33.3%) had hypertension. The mean CSI score was 22.5 ± 16.7, and 11 patients (21.5%) demonstrated moderate to high central sensitization (CSI > 40). Nociplastic CPSP was significantly associated with chronic inflammatory rheumatism ($p = 0.04$) and higher anxiety ($p < 0.001$) and depression scores ($p < 0.01$). No significant associations were observed with age, sex, BMI, physical activity, osteoarthritis type, or postoperative analgesic or rehabilitation strategies. Nociplastic pain was negatively correlated with SF-36 physical (PCS: $r = -0.28$; $p = 0.045$) and mental (MCS: $r = -0.29$; $p = 0.036$) component scores.
Conclusions:
Approximately one-fifth of patients developed chronic nociplastic CPSP following THA. This painphenotype was strongly associated with chronic inflammatory rheumatic disease and psychological distress, and was responsible for significant impairment in quality of life. Early identification of high-risk patients and implementation of multidisciplinary management strategies, including psychological support and individualized rehabilitation, are essential to optimize postoperative recovery.

P1569

ASSOCIATION BETWEEN TNF -308 G>A (RS1800629) GENE POLYMORPHISM AND RESPONSIVENESS TO TNF BLOCKERS IN RHEUMATOID ARTHRITIS TUNISIAN PATIENTS

S. Zanned[1], I. Mahmoud[1], L. Rouached[1], S. Ben Dhia[1], S. Bouden[1], R. Tekaya[1], A. Ben Tekaya[1], L. Abdelmoula[1], I. Sfar[2]

[1]Charles Nicolle Hospital, Rheumatology department, Tunis, Tunisia; [2]Charles Nicolle Hospital, Immunology department, Tunis, Tunisia

Background:
The advent of biotherapies, including anti-TNFα agents, marked a turning point in the management of patients with chronic inflammatory rheumatic diseases by achieving disease control. However, a substantial proportion of patients do not respond to these agents. Among the sources of variability in this response, several polymorphisms have been proven to influence the response to anti-TNFα agents. Among them, an association between single nucleotide polymorphisms (SNPs) -308 G/A and response to antiTNF agents has been studied with conflicting results.
Objectives:
The aim of our study was to study the impact of this polymorphism on the therapeutic response to anti TNFα, bioavailability and immunogenicity in patients with Rheumatoid arthritis (RA).
Methods:
This is a cross-sectional, multicentric study from 2016 to 2019, patients with RA treated with TNF blockers for 6 months. Blood samples were collected for each patient immediately prior to drug administration. Quantitative measurements of the residual drug concentration (DC) and anti-drug antibodies (ADAb) were carried out by a commercial enzyme-linked immunosorbent assay (ELISA) kit (Promonitor®). Genotyping for SNP -308 was done by PCR-RFLP technique: 3 genotypes were found: G/G, A/A and G/A. EULAR criteria were considered to determine treatment response
Results:
Thirty-two RA patients were included. They were treated with TNF blockers for 6 months: 14 received Infliximab, 13 Adalimumab and 5 Adalimumab. Regardless of biologic type, 18 patients (58,1%) responded to treatment and 7 patients (21,8%) developed ADAb. The molecular study revealed that the heterozygous G/A genotype of SNP-308(G/A) was significantly associated with a decrease in median DAS28 after 6 months of treatment, compared to the heterozygous G/G genotype ($p=0.039$). Moreover, the G/A genotype was more prevalent in patients with a good EULAR response compared to non-responders. In addition, the heterozygous genotype G/A was associated with a significantly higher median DC rate than that found in G/G genotype patients ($p=0.0032$). However, this SNP did not correlate with the variation of the immunogenicity (production of ADAb) of these molecules.
Conclusion:
The -308G/A polymorphism might be a predictive factor of anti-TNFα therapeutic efficacy in rheumatoid arthritis. Additional larger-scale prospective studies accounting for other factors of variability in TNFblockers response are needed to confirm or refute the results of our cohort.

P1570

IMPACT OF THE TNF-A −308 G/A POLYMORPHISM ON ANTI-TNF RESPONSE, BIOAVAILABILITY, AND IMMUNOGENICITY IN SPONDYLOARTHRITIS

S. Zanned[1], I. Mahmoud[1], L. Rouached[1], S. Ben Dhia[1], S. Bouden[1], R. Tekaya[1], A. Ben Tekaya[1], I. Sfar[2], L. Abdelmoula[1]

[1]Charles Nicolle Hospital, Rheumatology department, Tunis, Tunisia; [2]Charles Nicolle Hospital, Immunology department, Tunis, Tunisia

Background:
The introduction of biotherapies, particularly tumor necrosis factor alpha (TNF-α) inhibitors, has substantially improved disease control in patients with chronic inflammatory rheumatic diseases, including spondyloarthritis (SpA). Nevertheless, a significant interindividual variability in therapeutic response persists. Genetic factors, notably single nucleotide polymorphisms (SNPs) affecting inflammatory pathways, have been suggested as potential contributors to this variability. Among them, the TNF-α −308 G/A polymorphism has been investigated, with inconsistent results regarding its influence on response to anti-TNF agents.
Objectives:
The aim of this study was to evaluate the impact of the TNF-α −308 G/A polymorphism on therapeutic response, bioavailability, and immunogenicity of anti-TNFα agents in patients with spondyloarthritis.
Methods:
This was a cross-sectional, multicentric study conducted between 2016 and 2019, including patients with SpA treated with TNF blockers for at least 6 months. Blood samples were collected immediately prior to drug administration. Residual drug concentrations (DC) and anti-drug antibodies (ADAb) were measured using a commercial enzyme-linked immunosorbent assay (ELISA) kit (Promonitor®). Genotyping of the TNF-α −308 G/A polymorphism was performed using the PCR-RFLP technique, identifying three genotypes: G/G, G/A, and A/A. Therapeutic response was assessed using changes in BASDAI and BASFI scores, as well as BASDAI20 and BASDAI50 responses at 6 months.
Results:
Forty-one patients with SpA were included. The reduction in BASDAI and BASFI at 6 months was greater among patients carrying the heterozygous G/A genotype compared with those with the G/G genotype; however, these differences did not reach statistical significance. Similarly, BASDAI20 and BASDAI50 responses were more frequent in G/A carriers, without significant association. No significant relationship was observed between the TNF-α −308 G/A polymorphism and residual drug concentrations or the development of ADAb in SpA patients. Nevertheless, ADAb-negative patients exhibited a significantly greater percentage of BASDAI improvement compared with ADAb-positive patients (p=0.037).
Conclusion:
In spondyloarthritis, the TNF-α −308 G/A polymorphism was not significantly associated with therapeutic response, bioavailability, or immunogenicity of anti-TNFα agents. These findings suggest a limited predictive value of this SNP in SpA, highlighting the need for larger prospective studies to better clarify the genetic determinants of anti-TNF response in this population.

P1571

DIFFERENTIAL IMPACT OF THE TNF-A -308 G/A POLYMORPHISM ON ANTI-TNF AGENTS RESPONSE IN RHEUMATOID ARTHRITIS AND SPONDYLOARTHRITIS

S. Zanned[1], I. Mahmoud[1], L. Rouached[1], S. Ben Dhia[1], S. Bouden[1], R. Tekaya[1], A. Ben Tekaya[1], I. Sfar[2], L. Abdelmoula[1]

[1]Charles Nicolle Hospital, Rheumatology department, Tunis, Tunisia; [2]Charles Nicolle Hospital, Immunology department, Tunis, Tunisia

Background:
Despite shared inflammatory pathways, rheumatoid arthritis (RA) and spondyloarthritis (SpA) show heterogeneous responses to tumor necrosis factor-α (TNF-α) inhibitors. Genetic variability, particularly single nucleotide polymorphisms (SNPs) within the TNF-α gene promoter, may contribute to this inter-disease variability. However, comparative data evaluating the influence of the TNF-α −308 G/A polymorphism on treatment response across different inflammatory rheumatic diseases remain scarce.
Objectives:
To comparatively assess the impact of the TNF-α −308 G/A polymorphism on therapeutic response, drug bioavailability, and immunogenicity of anti-TNF agents in patients with RA and SpA.
Methods:
A multicentric cross-sectional study included 73 patients treated with anti-TNF therapy for 6 months (32 RA, 41 SpA). Genotyping of the TNF-α −308 G/A polymorphism was performed using PCR-RFLP. Residual drug concentrations and anti-drug antibodies were quantified by ELISA (Promonitor®). Treatment response was evaluated using ΔDAS28 and EULAR criteria in RA, and ΔBASDAI, ΔBASFI, BASDAI20, and BASDAI50 responses in SpA.
Results:
In RA patients, the heterozygous G/A genotype was significantly associated with a greater reduction in disease activity (ΔDAS28) and higher residual drug concentrations compared with the G/G genotype. In contrast, although SpA patients carrying the G/A genotype showed a trend toward improved clinical outcomes, no statistically significant association was observed. No correlation between the TNF-α −308 G/A polymorphism and anti-drug antibody formation was found in either disease group.
Conclusion
The TNF-α −308 G/A polymorphism exhibits a disease-specific predictive value, significantly influencing therapeutic response and drug bioavailability in RA but not in SpA. These findings underscore fundamental differences in the pharmacogenetic determinants of anti-TNF efficacy across inflammatory rheumatic diseases and support a more individualized, disease-oriented approach to biologic therapy.

TOWARDS A CORE OUTCOME SET FOR SARCOPENIA INTERVENTION STUDIES: RESULTS FROM A DELPHI STUDY

S. van Heden[1], D. Sanchez-Rodriguez[2,3], O. Bruyère[4], J.-Y. Reginster[5], M. Surquin[6], C. Beaudart[1]

[1]Public Health Aging Research & Epidemiology (PHARE) Group, Research Unit in Clinical Pharmacology and Toxicology (URPC), Department of Biomedical Sciences, Namur Research Institute for Life Sciences (NARILIS), Faculty of Medicine, University of Namur, 500, Namur, Belgium; [2]Geriatrics Department, Brugmann University Hospital, Université Libre de Bruxelles, Bruxelles, Belgium; [3]Rehabilitation Research Group, Hospital del Mar Research Institute, 08003 Barcelona, Spain, Barcelona, Spain; [4]Research Unit in Public Health, Epidemiology and Health Economics, Department Physical Activity and Rehabilitation Sciences, University of Liège, Liège, Belgium, Liège, Belgium; [5]Protein Research Chair, Biochemistry Department, College of Science, King Saud University, Riyadh, Kingdom of Saudi Arabia, Riyadh, Saudi Arabia; [6]Geriatrics Department, Brugmann University Hospital, Université Libre de Bruxelles, 1020 Brussels, Belgium, Bruxelles, Belgium

Objective: A Core Outcome Set (COS) specific to sarcopenia is currently being developed to address the significant heterogeneity observed in outcome assessment in clinical trials. A COS is defined as "*an agreed standardized set of outcomes that should be measured and reported, as a minimum, in all clinical trials in a specific disease*". The development process involves several steps: a scoping review identifying 253 outcomes, patient interviews leading to 3 additional outcomes, the present Delphi study, and a final consensus process conducted by a multidisciplinary working group. Therefore, this study aims to establish expert consensus on the most relevant outcomes to inform the development of a COS for sarcopenia clinical trials.

Material and methods: A two-round Delphi study including international experts in sarcopenia evaluated 34 outcomes derived from the scoping review and patient interviews. Experts rated the importance of each outcome for inclusion in a common COS applicable to all intervention types and in intervention-specific sub-COSs (exercise, nutrition, and pharmacological) using a 9-point Likert scale (1 = not important; 9 = critically important). Consensus was defined as ≥75% of ratings between 7–9 ("consensus in") or ≥15% between 1–3 ("consensus out"). Expert voting was supported by Welphi software, and descriptive analyses were performed using RStudio.

Results: A total of 133 (round I) and 80 experts (round II) completed the survey. After completion of both rounds, 16 outcomes reached consensus for inclusion in the common COS. These outcomes, listed in descending order of consensus (≥75%), included muscle strength, falls, sarcopenia status, physical performance, mortality, physical status, activities of daily living, quality of life, frailty status, nutritional status, muscle mass, need for assistance, institutionalization, hospitalization, adverse events, and muscle power. Additional outcomes reached consensus only within intervention-specific sub-COSs. For example, appetite reached consensus for nutrition-based interventions, while cardiopulmonary function reached consensus for exercise-based interventions.

Conclusion: The selected outcomes will inform the final stage of the COS development process to establish consensus on outcomes for sarcopenia trials.

P1573

TARGETING FRACTURE RISK IN RHEUMATOID ARTHRITIS AND OSTEOPOROSIS: THE ROLE OF BONE MINERAL DENSITY (BMD), FRAX, AND SEROLOGICAL STATUS

S. Šarić[1], J. Mrđa[1], I. Ovčina[1], L. J. Božić Majstorović[1,2]

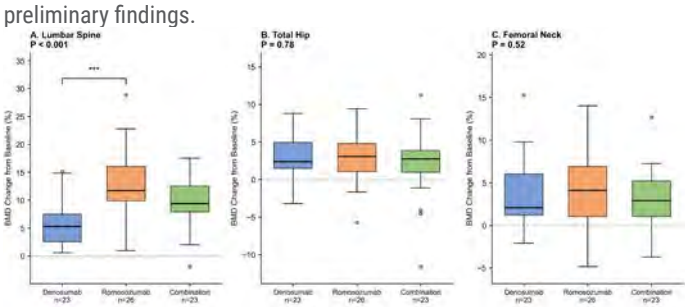
[1]University Clinical Center of the Republic of Srpska, Department of Rheumatology with General Internal Medicine, Clinic for Internal Medicine, Banja Luka, Bosnia & Herzegovina; [2]Faculty of Medicine, University of Banja Luka, Banja Luka, Bosnia & Herzegovina

Objectives. To assess the ten-year risk of osteoporotic fractures in patients with rheumatoid arthritis (RA) and osteoporosis, and to examine the association between FRAX scores and bone mineral density (BMD) parameters, clinical and laboratory markers of disease activity, and serological status.

Materials and Methods. This cross-sectional study included 30 patients with RA and osteoporosis. Anthropometric parameters, including body mass index (BMI), were recorded. BMD was assessed by dual-energy X-ray absorptiometry and expressed as T-scores of the lumbar spine (L1–L4) and femoral neck. Ten-year fracture probability was calculated using FRAX for major osteoporotic and hip fractures. Laboratory evaluation included RF, anti-CCP antibodies, erythrocyte sedimentation rate, and C-reactive protein. Data on glucocorticoid use, DMARD therapy, and osteoporosis treatment were analyzed.

Results. The study population included 28 women (93%) and 2 men (7%), with a mean age of 63.9 ± 6.2 years and mean BMI of 27.1 ± 2.3 kg/m². Mean RA duration was 19.4 ± 7.1 years. The mean lumbar spine T-score was −2.56 ± 1.11, and the mean femoral neck T-score was −1.94 ± 1.11. RF positivity was observed in 93% of patients and anti-CCP positivity in 87%. Glucocorticoids and DMARDs were given, 87% of patients receiving them. A history of prior osteoporotic fracture was present in 23% of patients. The mean ten-year FRAX probability was 16.19% for major osteoporotic fracture and 8.06% for hip fracture. A statistically significant negative correlation was found between FRAX score for major osteoporotic fracture and femoral neck T-score ($r = -0.43$; $p = 0.018$), confirming that lower BMD is associated with higher fracture risk. Seropositive patients showed higher inflammatory activity and a trend toward higher FRAX-estimated fracture risk. Long-term glucocorticoid exposure was associated with lower T-scores and increased FRAX risk, whereas stable DMARD therapy was associated with lower inflammatory markers and reduced fracture risk.

Conclusion. Patients with RA and osteoporosis are at markedly increased risk for osteoporotic fractures. Seropositivity amplifies inflammatory burden and fracture risk, highlighting the importance of integrated fracture risk assessment using FRAX and BMD-derived T-scores. Early identification of high-risk patients is essential for targeted osteoporosis management and fracture prevention in RA.



P1574

ROMOSOZUMAB AND DENOSUMAB, ALONE OR COMBINED, IN POSTMENOPAUSAL OSTEOPOROSIS: PRELIMINARY RESULTS FROM A THREE-ARM RANDOMIZED PILOT TRIAL

S.-H. Fu[1], J.-Y. Hsu[2], C.-C. Hung[1], H.-K. Yen[2], C.-Y. Wang[3]

[1]Department of Orthopedics, National Taiwan University Hospital Yun-Lin Branch, Douliu, Taiwan; [2]Department of Orthopedic Surgery, National Taiwan University Hospital, Taipei, Taiwan; [3]National Center for Geriatrics and Welfare Research, National Health Research Institutes, Huwei, Taiwan

Background
Romosozumab and denosumab are effective therapies for postmenopausal osteoporosis, yet their comparative and combined effects remain incompletely defined. This pilot randomized trial evaluated the short-term efficacy of romosozumab and denosumab, alone or in combination, on bone mineral density (BMD).
Methods
In this single-center, three-arm randomized pilot trial, postmenopausal women with osteoporosis were allocated to denosumab alone, romosozumab alone, or combined therapy. BMD at the lumbar spine, total hip, and femoral neck was assessed at baseline, 3 months, and 6 months. The primary outcome was percentage change in lumbar spine BMD at 6 months. Between-group differences were analyzed using nonparametric methods.
Results
Eighty-six participants were randomized, and 73 (84.9%) completed 6-month follow-up. Median lumbar spine BMD increased by 5.29% with denosumab, 11.73% with romosozumab, and 9.40% with combination therapy ($P < 0.001$). Both romosozumab and combination therapy achieved significantly greater lumbar spine BMD gains than denosumab alone, whereas no significant difference was observed between romosozumab and combination therapy. No significant between-group differences were detected for total hip or femoral neck BMD. At the lumbar spine, responder rates for BMD increase >6% were higher with romosozumab (85%) and combination therapy (87%) than with denosumab alone (44%).
Conclusions
In this three-arm randomized pilot trial, romosozumab, alone or combined with denosumab, was associated with greater short-term lumbar spine BMD gains compared with denosumab alone, while combination therapy did not demonstrate additional benefit over romosozumab monotherapy. Larger trials with longer follow-up are warranted to confirm these preliminary findings.

P1575

DETERMINANTS OF MORTALITY AFTER HIP-FRACTURE SURGERY IN THE ELDERLY: FACTORS BEYOND AGE

S.-P. Wang[1], W. Hsu[2]

[1]National Chung Hsing University, Taichung, Taiwan; [2]Taichung Veterans General Hospital, Taichung, Taiwan

Mortality following hip-fracture surgery in older adults remains substantial, while the associated risk factors remain incompletely defined and controversial. This study included 270 patients aged ≥60 years who underwent unilateral proximal femur fracture surgery at a tertiary center between 2018 and 2020, all managed under a fast-track orthogeriatric pathway. Survival status was determined from hospital records and follow-up. The median patient age was 83 years (IQR 75–88), 57% were female, and 67% were ASA class III. During a median follow-up of 14 months, 51 deaths (18.9%) occurred, with cumulative survival rates of 92.5%, 85.7%, 69.4%, and 67.1% at 6, 12, 24, and 30 months, respectively. Anthropometric indices such as calf and arm circumference, handgrip strength, and BMI were not significant predictors. Cox regression revealed that advanced age (HR 1.05 per year, CI 1.02 - 1.09, p=0.002), male sex (HR 2.07, 1.18 -3.61, p=0.011), and ASA III versus II (HR 5.52, 1.98 -15.39, p=0.001) were associated with higher mortality. Each 1 g/dL increase in day-1 postoperative hemoglobin correlated with increased mortality risk (HR 1.33, 1.17 - 1.51, p<0.001), whereas each 1 mg/dL rise in serum creatinine was protective (HR 0.79, 0.69 - 0.90, p<0.001). In conclusion, advanced age, male sex, higher ASA grade, elevated postoperative hemoglobin, and lower serum creatinine independently predict mid-term mortality after hip-fracture surgery in elderly patients, suggesting that these readily available parameters may facilitate early risk stratification and guide postoperative management.

SECONDARY OSTEOPOROSIS IN A PATIENT WITH NEUROSARCOIDOSIS ASSOCIATED WITH HYPOPITUITARISM

T. Bajraktarova Prosheva[1], N. Kjoseva[1], B. Todorova[1], M. Petrushevska[1], H. Vlavceska[1], I. Bitoska[1]

[1]University Clinic for Endocrinology, Diabetes and Metabolic Diseases, Skopje, North Macedonia

Introduction: Neurosarcoidosis may involve the hypothalamic–pituitary axis, leading to hypopituitarism and subsequent endocrine dysfunctions. Among these, hypogonadotropic hypogonadism and long-term exposure to glucocorticoid therapy are major contributors to secondary osteoporosis.
Case Presentation: A 48-year-old woman with biopsy-confirmed systemic sarcoidosis developed progressive neurological symptoms, including seizures, headaches, cognitive impairment, and somnolence. MRI revealed pituitary infundibulum thickening and leptomeningeal enhancement, suggesting neurosarcoidosis. Hormonal evaluation demonstrated hypothyroidism, low gonadotropins (FSH and LH) and clinical evidence of diabetes insipidus, confirming hypothalamo-pituitary dysfunction. The resulting hypoestrogenism due to hypogonadotropic hypogonadism, combined with prior glucocorticoid therapy, placed the patient at high risk for secondary osteoporosis, a well-recognized

complication of both estrogen deficiency and long-term steroid exposure. DEXA scan showed reduced bone mineral density consistent with osteoporosis (T-score: L1-3.0, L2 -4.2, L3 -3.3, L4-3.9, L1-L4 -3.6; Neck left -3.2, Total left -3.2, Neck right -3.0, Total right -2.8). Laboratory findings showed low levels of osteocalcin (3.74 ng/ml) and normal levels of beta-cross laps (0.249 ng/ml), serum ionized calcium Ca^{2+} (1.23 mmol/L), PTH (37.7 pg/ml) and vitamin D3 (47.25 ng/ml). Treatment included immunomodulatory therapy, hormone replacement therapy with Levothyroxine, dopamine D2 receptor agonist (Cabergoline), analogue of vasopressin (Desmopressin) and anticonvulsants, which led to clinical improvement. Once osteoporosis was confirmed, oral bisphosphonate therapy was added to her treatment plan. This, alongside the broader therapeutic strategy, contributed to the patient's overall clinical improvement.

Conclusion: This case underscores the importance of recognizing endocrine contributors to bone loss in neurosarcoidosis. Hypoestrogenism due to hypopituitarism and chronic glucocorticoid exposure are major etiologic factors contributing to secondary osteoporosis in affected patients. However, these patients also have abnormal calcium metabolism and underlying inflammation which increases their risk of osteoporosis. Early identification and proactive bone health management are essential to prevent long-term skeletal complications.

Keywords: Neurosarcoidosis, Hypopituitarism, Hypoestrogenism, Glucocorticoids, Secondary Osteoporosis.

TOWARDS CLINICALLY ROBUST AI: INVESTIGATING THE TRADE-OFF BETWEEN ANATOMICAL CONTEXT AND NOISE SUPPRESSION IN HIP X-RAYS FOR OSTEOPOROSIS CLASSIFICATION

T. Chobpenthai[1], P. Nonthasaen[1], R. Suwanaratana[1], P. Achararit[1]

[1]Princess Srisavangavadhana College of Medicine, Chulabhorn Royal Academy, Bangkok, Thailand

Background: Osteoporosis is a systemic skeletal disorder marked by reduced bone mass and microarchitectural deterioration, which substantially increases the risk of fragility fractures and their associated morbidity and costs. DualEnergy Xray Absorptiometry (DEXA) remains the clinical gold standard for assessing bone mineral density and diagnosing osteoporosis [1], but its use is constrained by equipment availability and workflow limitations, particularly in resourcelimited or highthroughput settings. In contrast, hip radiographs are inexpensive, widely available, and routinely acquired for trauma and degenerative conditions, creating an opportunity for opportunistic osteoporosis screening without additional radiation exposure or appointments. Recent advances in deep learning have shown that Convolutional Neural Networks (CNNs) can extract subtle radiographic signatures of low bone mineral density from plain films, achieving performance comparable to or complementing DEXA in several cohorts. However, these models are vulnerable to domain shifts caused by differences in acquisition protocols, presence of radiographic tags, implants, and other background artifacts that may distract the network from clinically relevant anatomy. Furthermore, CNNs are known to rely heavily on local texture cues, which raises concern that overly cropped inputs could strip away essential anatomical context needed for robust predictions. This study focuses on how data preprocessing, specifically masking versus cropping—modulates the stability and generalizability of CNNbased osteoporosis classifiers built from hip radiographs.

Objective: A retrospective cohort of 784 anteroposterior hip radiographs paired with groundtruth DEXA diagnoses was collected from Chulabhorn Hospital, representing a realworld spectrum of positioning, body habitus, and hardware. Osteoporosis status was defined according to standard Tscore thresholds at the femoral neck or total hip, and images were split into training, validation, and test sets at the patient level to prevent leakage [2]. Five Deep Convolutional Neural Network architectures were evaluated: VGG16, DenseNet121, Inception V3, Xception, and ConvNeXtBase, each initialized with generic pretraining and adapted for binary osteoporosis classification. To interrogate the role of preprocessing, five data curation strategies were implemented. The baseline used original radiographs with minimal resizing and normalization. ROI Masking preserved the pelvis and proximal femur while suppressing surrounding pixels, thereby removing tags and extraneous soft tissue but retaining global geometry. In parallel, three ROICropping variations produced focused patches centered on the femoral neck, unilateral crops (left or right hip), and more aggressive crops with reduced pelvic context. All strategies shared the same augmentation pipeline, including modest rotations and flips, to ensure that differences in performance could be attributed primarily to masking versus cropping decisions. Models were trained using standard optimization with early stopping guided by validation loss. Performance on the independent test set was summarized using area under the receiver operating characteristic curve, accuracy, sensitivity, specificity, and F1score. Stability was assessed by running each configuration across multiple random seeds, examining the smoothness of learning curves and quantifying variability in performance metrics across runs. Lower variance and less oscillatory training dynamics were interpreted as evidence of greater robustness.

Methods: A retrospective cohort of 784 anteroposterior hip radiographs paired with groundtruth DEXA diagnoses was collected from Chulabhorn Hospital, representing a realworld spectrum of positioning, body habitus, and hardware. Osteoporosis status was defined according to standard Tscore thresholds at the femoral neck or total hip, and images were split into training, validation, and test sets at the patient level to prevent leakage. Five Deep Convolutional Neural Network architectures were evaluated: VGG16, DenseNet121, Inception V3, Xception, and ConvNeXtBase, each initialized with generic pretraining and adapted for binary osteoporosis classification [3]. To interrogate the role of preprocessing, five data curation strategies were implemented. The baseline used original radiographs with minimal resizing and normalization. ROI Masking preserved the pelvis and proximal femur while suppressing surrounding pixels, thereby removing tags and extraneous soft tissue but retaining global geometry. In parallel, three ROICropping variations produced focused patches centered on the femoral neck, unilateral crops (left or right hip), and more aggressive crops with reduced pelvic context. All strategies shared the same augmentation pipeline, including modest rotations and flips, to ensure that differences in performance could be attributed primarily to masking versus cropping decisions. Models were trained using standard optimization with early stopping guided by validation loss. Performance on the independent test set was summarized using area under the receiver operating characteristic curve, accuracy, sensitivity, specificity, and F1score. Stability was assessed by running each configuration across multiple random seeds, examining the smoothness of learning curves and quantifying variability in performance metrics across runs. Lower variance and less oscillatory training dynamics were interpreted as evidence of greater robustness.

Results: Across all architectures, ROI Masking consistently matched or exceeded the performance of both raw and cropped inputs while demonstrating markedly improved training stability (Figure 1). VGG16 trained on masked images provided the most striking example: it

achieved the highest and most reproducible performance metrics, with narrow confidence intervals and smooth, convergent learning curves across repeated runs. This pattern suggests that when background noise is removed but anatomical context is preserved, texturebiased networks such as VGG16 can better focus on the trabecular and cortical signatures of osteoporosis rather than overfitting to spurious background patterns. In contrast, aggressively cropped inputs produced volatile learning curves characterized by oscillations and occasional divergence, particularly in deeper or more complex architectures. These models exhibited greater variability in test performance and appeared more vulnerable to cases with atypical projection angles, degenerative changes, or metallic implants, all of which may require broader anatomical context for correct interpretation. Although some cropped configurations achieved seemingly high training accuracy, they frequently failed to maintain this advantage on the test set, indicating overfitting to limited local textures. Using unprocessed raw radiographs yielded intermediate performance. While these models retained full anatomical context, their attention maps often highlighted cassette labels, collimation edges, or unrelated soft tissue, suggesting that the networks were partially distracted by artifacts. Compared with masked inputs, raw images led to slightly lower mean performance and greater runtorun variability, underscoring the detrimental influence of uncontrolled background features. Qualitative visualization of model attention supported the quantitative results: masked models focused primarily on the femoral head, neck, and intertrochanteric region, while cropped and raw models more frequently attended to nondiagnostic areas.

Conclusion: This study shows that datacentric preprocessing is a decisive factor in the robustness of deep learning models for opportunistic osteoporosis screening from hip radiographs. ROI Masking, which attenuates background noise while preserving the full geometric configuration of the pelvis and proximal femur, consistently enhances both performance and training stability across multiple CNN architectures. The particularly strong performance of masked VGG16 indicates that even architectures with pronounced texture bias can be steered toward clinically meaningful cues when preprocessing aligns the visual input with anatomical priors. Conversely, aggressive cropping that narrows the field of view around the femoral neck undermines stability and generalization, likely by removing spatial references needed to interpret projection quality, rotation, and bilateral differences in bone density. These findings caution against overreliance on tightly cropped patches and instead advocate for preprocessing pipelines that maintain global anatomical context while actively suppressing irrelevant background information. From a translational perspective, implementing maskingbased curation could make CNN models more resilient to variation across radiography systems and clinical environments, thereby supporting scalable, opportunistic screening programs that leverage routine hip radiographs to triage patients for confirmatory DEXA and early osteoporosis intervention.

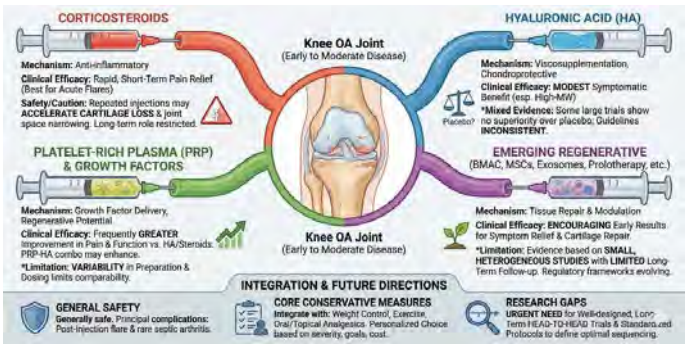
INTRA-ARTICULAR INJECTIONS FOR KNEE OSTEOARTHRITIS: A REVIEW OF NON-SURGICAL STRATEGIES

T. Chobpenthai[1], N. Rangchaikul[2], S. Sakdejayont[2], T. Poosiripinyo[3]

[1]Princess Srisavangavadhana College of Medicine, Chulabhorn Royal Academy, Bangkok, Thailand; [2]Princess Srisavangavadhana Faculty of Medicine, Chulabhorn Royal Academy, Bangkok, Thailand; [3]Department of Orthopaedics, Khon Kaen Hospital, Khon Kaen, Thailand



Objectives: Knee osteoarthritis (OA) remains the most prevalent and disabling joint condition, often leading to total knee replacement. However, many patients present with early or moderate disease or prefer to delay surgery, highlighting the importance of effective non-surgical interventions. Intra-articular (IA) injections have become central to conservative OA management. This review aims to succinctly present current evidence on IA injectables, focusing on their mechanisms, clinical effectiveness, safety profiles, and guideline recommendations, to support individualized, non-surgical care for knee OA.

Materials and Methods: This narrative review synthesizes findings from

randomized controlled trials, prospective studies, systematic reviews, network meta-analyses, and authoritative clinical guidelines (AAOS, OARSI, EULAR). The injectables considered include IA corticosteroids, hyaluronic acid (HA), platelet-rich plasma (PRP), bone marrow aspirate concentrate (BMAC), mesenchymal stem cells (MSCs), exosomes, growth factor concentrates, glucose prolotherapy, saline, and atelocollagen-based therapies. Outcomes assessed were pain relief, joint stiffness, functional improvement, cartilage effects, safety, and regulatory or translational challenges.

Results: IA corticosteroids offer prompt pain relief, making them suitable for acute exacerbations, but repeated use is linked with cartilage loss, limiting their long-term application. HA delivers modest benefits in symptoms, especially with high-molecular-weight formulas, due to its lubricating and anti-inflammatory properties; however, its superiority over placebo is debated, and clinical guidelines vary in their support. PRP, plasma rich in growth factors, often yields greater improvements in pain and function than HA or corticosteroids, and combining PRP with HA may further enhance results. Nonetheless, disparities in PRP preparation and dosing complicate comparisons. Emerging regenerative treatments—such as BMAC, MSCs, exosomes, targeted growth factors, glucose prolotherapy, and atelocollagen—appear promising for easing symptoms and repairing cartilage. However, existing research is limited, relying mainly on small, diverse studies with brief follow-up periods. Overall, IA injections are generally safe, with post-injection flare and rare septic arthritis as the main risks. Regulatory standards for advanced biologics are still evolving.

Conclusions: IA injection therapies are a vital component of non-surgical management for knee OA, providing meaningful pain relief and improved function, and potentially delaying the need for surgery when combined with core conservative measures such as weight management, exercise, and analgesics. Corticosteroids should be reserved for occasional flares, while HA, PRP, and regenerative injectables should be tailored to disease stage, patient preferences, costs, and local regulations. There is an urgent need for robust, long-term, comparative studies and standardized treatment protocols to establish the best use and combinations of IA therapies in personalized OA care.

P1579

PREFER STUDY: PATIENT-REPORTED PREFERENCES, SATISFACTION AND INTENTION TO PERSIST WITH OSTEOPOROSIS PHARMACOTHERAPY

T. Forfa[1]

[1]Independent Researcher, Caloundra, Australia

Objectives

Poor long-term persistence with osteoporosis pharmacotherapy remains a major barrier to fracture prevention. This study aimed to quantify patient-reported treatment experiences and preferences, examine their relationship with satisfaction and intention to persist with therapy, and generate structured data to inform preference-sensitive clinical decision support.

Material and Methods

A cross-sectional, anonymous online survey was conducted among adults with a diagnosis of osteoporosis (n=403). Data collected included demographics, treatment history, satisfaction, perceived benefits, side-effects, beliefs about medication, and intention to continue therapy. Patient preferences for key treatment attributes were quantified using Maximum Difference (MaxDiff) scaling. Multivariable regression and structural equation modelling (SEM) were used to assess relationships between treatment experience, satisfaction, and persistence intention.

Results

Among 403 respondents (90% women; 43% aged 65–74 years), 191 (47%) were currently receiving osteoporosis medication. Mean treatment satisfaction was 5.0/10, and perceived side-effect burden was 3.3/10. Intention to continue treatment was high (mean 2.55/3), while side-effects were the most commonly reported reason for discontinuation (31%).

MaxDiff analysis identified fracture risk reduction as the most valued treatment attribute, followed by fewer common side-effects, low likelihood of serious adverse effects, low cost, infrequent dosing (annual), and fixed-duration treatment. SEM demonstrated that perceived treatment benefit positively influenced satisfaction ($p<0.01$), while side-effects negatively influenced satisfaction ($p<0.001$). Satisfaction strongly predicted intention to persist with therapy ($B=0.11$, $p<0.001$), mediating the relationship between treatment experience and continuation. Exploratory analyses suggested higher satisfaction among users of anabolic therapies and romosozumab, although only romosozumab reached statistical significance. Route of administration was not independently associated with satisfaction. Among non-treated participants (n=212), concerns about side-effects (52%) and preference for non-pharmacological management (18%) were the most common reasons for non-use.

Conclusions

Patient satisfaction, driven primarily by perceived efficacy, tolerability, and convenience, is a key determinant of intention to persist with osteoporosis pharmacotherapy. Quantifying patient preferences alongside treatment experience provides clinically relevant insights that may support more individualised, preference-aligned treatment selection. These data offer a foundation for decision-support approaches that integrate patient values with evidence-based recommendations to improve long-term adherence in osteoporosis care.

P1580

EARLY EXPERIENCE OF ROMOSOZUMAB USE IN POSTMENOPAUSAL WOMEN

T. Gill[1], M. Dudley[1], J. Bubbear[1], R. Keen[1]

[1]Royal National Orthopaedic Hospital NHS Trust, Stanmore, United Kingdom

Objectives
To examine the initial use of Romosozumab within a specialist UK hospital, describing the effectiveness, safety, and treatment persistence in a real-world cohort of postmenopausal women.
Methods
A retrospective observational analysis of postmenopausal women who initiated Romosozumab between Aug 2022 and Dec 2023. All patients met UK/NICE prescribing criteria, which included being at high fracture risk and having sustained a major osteoporotic fracture (spine, hip, foream, proximal humerus) within the previous 24 months. Baseline demographic data, fracture history, prior osteoporosis therapies, and cardiovascular risk factors were collected. Changes in bone mineral density (BMD) at the lumbar spine and total hip were assessed using dual-energy X-ray absorptiometry (DXA). Adverse events and treatment discontinuation were recorded.
Results
In total, initial full data was available on 58 patients, median age 66.5 years (range 53-88). A majority of women had previously received bisphosphonates (n=30, 55%), although 15 (26%) were treatment naive. Vertebral fractures were the most common index fracture (n=30, 52%). The patients were osteoporotic at spine (mean T-score -2.7) and femoral neck (mean T-score -2.7), and were deemed to be high risk (mean 10-year risks for major osteoporotic fracture of 24.1% and for hip fracture of 10.3%)
At 12 months, Romosozumab treatment was associated with substantial increases in BMD at lumbar spine (10.1%) and total hip (3.3%). Treatment persistence was high, with 93% completing the planned course. Follow-on antiresorptive treatment was prescribed, with Zoledornate (n=28, 48%) and Denosumab (21, 36%) being the most widely used. Follow-up duration was too short inorder to determine the relative effectiveness of either treatment 12 months after cessation of osteoanabolic. Romosozumab was generally well tolerated, with minor injection-site reactions and musculoskeletal symptoms being the common reported adverse events. There were no cardiovascular events or fractures during the observation period.
Conclusions
In this real-world UK cohort of 58 women with severe osteoporosis, Romosozumab was associated with significant improvements in BMD at spine and hip. It also appeared safe and well tolerated. Longer term follow-up will help determine the optimal treatment strategy and sequencing for postmenopausal women at high fracture risk.

TECHNOLOGY-DRIVEN INNOVATIONS IN OSTEOPOROSIS: ARTIFICIAL INTELLIGENCE SCREENING AND MECHANOTRANSDUCTION DEVICES

T. Griadil[1]

[1]Uzhhorod National University/Institute of Postgraduate and Pre-university Education/Department of Internal and Family Medicine with courses in instrumental diagnostics, Uzhhorod, Ukraine

Objective(s): To evaluate the diagnostic accuracy of deep learning (DL) models for opportunistic screening and the clinical efficacy of wearable mechanobiological devices for fracture prevention.
Material and Methods: A systematic review (PubMed, Scopus, 2021–2026) analyzing artificial intelligence (AI) algorithms for bone density assessment via routine imaging and the effectiveness of vibration therapy was conducted. Key endpoints included Area Under the Curve (AUC) for diagnosis and vertebral strength preservation for therapy.
Results: DL models utilizing incidental imaging (X-ray, CT) demonstrated high accuracy. Specifically, a facial 2D-image analysis algorithm achieved 92–93% accuracy (AUC ~0.98) in classifying bone status [1]. In prevention, a wearable belt utilizing targeted mechanotransduction showed an 85% reduction in vertebral density loss and an 83% reduction in strength loss compared to placebo when used >3 times/week [2]. Additionally, smart airbag belts reduced hip fracture incidence to 2.2% vs 11.4% in the control group (p=0.003) [3].
Conclusion(s): AI facilitates scalable non-invasive screening, while mechanobiological wearables provide effective prophylaxis for osteopenic patients, significantly reducing fracture risk without systemic pharmacological intervention.

EMERGING THERAPEUTIC TARGETS IN OSTEOPOROSIS: SENOLYTICS AND MICROENVIRONMENT MODULATION

T. Griadil[1]

[1]Uzhhorod National University/Institute of Postgraduate and Pre-university Education/Department of Internal and Family Medicine with courses in instrumental diagnostics, Uzhhorod, Ukraine

Objective(s): To analyze the therapeutic potential of targeting cellular senescence and novel molecular regulators of bone turnover in osteoporosis management.
Material and Methods: Analysis of preclinical and clinical data (PubMed, Scopus, 2021–2026) regarding the impact of senolytic agents and specific regulatory proteins (Sfrp4, BAMBI) on bone tissue regeneration.
Results: Accumulation of senescent cells was found to drive a pro-inflammatory phenotype (SASP) that inhibits osteogenesis [1]. Senolytic

therapy (combination of dasatinib and quercetin) demonstrates the ability to selectively eliminate these cells, attenuating age-related bone degradation [1]. Furthermore, the Sfrp4 protein was identified as critical for maintaining skeletal stem cell functionality required for fracture repair [2], while modulation of the "gut-bone" axis via nutraceuticals improved mineralization [3].

Conclusion(s): The shift from traditional antiresorptive drugs to regenerative strategies targeting microenvironment rejuvenation and stem cell modulation offers a fundamentally novel approach to restoring bone architecture in elderly patients.

MULTIDIMENSIONAL BARRIERS TO OSTEOPOROSIS SCREENING AND THE EMERGING ROLE OF ARTIFICIAL INTELLIGENCE: A SYSTEMATIC REVIEW

T. Griadil[1]

[1]Uzhhorod National University/Institute of Postgraduate and Pre-university Education/Department of Internal and Family Medicine with courses in instrumental diagnostics, Uzhhorod, Ukraine

Objective The study aimed to analyze patient, physician, and systemic barriers to osteoporosis screening and evaluate the efficacy of artificial intelligence (AI) and opportunistic screening in bridging the global diagnostic gap.

Material and Methods A comprehensive review of literature published between 2020 and 2025 was conducted using PubMed and global health reports. Was analyzed data regarding screening adherence rates, physician surveys on diagnostic ordering, reimbursement policies, and performance metrics of AI algorithms applied to non-contrast computed tomography (CT) and dental panoramic radiographs (DPRs).

Results Analysis indicates a persistent global treatment gap where approximately 71-80% of high-risk individuals remain undiagnosed. Physician-level barriers are dominated by patient nonadherence (63%), cost concerns (56%), and time constraints (51%). Patient barriers stem primarily from low disease awareness ("silent nature"), fear of medication side effects, and socioeconomic disparities. Systemically, declining reimbursement for dual-energy X-ray absorptiometry (DXA) has reduced infrastructure availability. However, emerging solutions show promise: AI models analyzing routine CT scans demonstrated 99% agreement with manual radiologist assessment for trabecular attenuation. Similarly, AI-assisted analysis of DPRs achieved a pooled sensitivity of 87.9% and specificity of 81.9% for detecting low bone mass.

Conclusion Current screening strategies based solely on dedicated DXA are insufficient due to systemic and behavioral barriers. Transitioning to absolute fracture risk assessment and integrating AI-driven opportunistic screening into routine clinical workflows offers a scalable, cost-effective strategy to identify untreated high-risk populations and prevent fragility fractures.

IMPACT OF PATIENT EDUCATION ON TREATMENT ADHERENCE AND CLINICAL OUTCOMES: A SYSTEMATIC REVIEW

T. Griadil[1]

[1]Uzhhorod National University/Institute of Postgraduate and Pre-university Education/Department of Internal and Family Medicine with courses in instrumental diagnostics, Uzhhorod, Ukraine

Objective(s) To analyze the extent of treatment non-adherence in chronic and acute conditions, evaluate the biological and economic consequences, and determine the efficacy of educational interventions (pharmacist-led, digital, and multidisciplinary) in improving patient outcomes.

Material and Methods A structured literature review was conducted using PubMed, Scopus, and Web of Science databases (2019–2025). The analysis focused on the "Information-Motivation-Behavioral Skills" (IMB) model, comparing standard care with educational strategies. Key endpoints included adherence rates (measured by pharmacy claims and biomarkers like HbA1c or drug levels), clinical stability, and economic burden.

Results Non-adherence affects approximately 50% of patients with chronic diseases, contributing to €125 billion in annual healthcare costs in Europe. Low adherence drives pathogenesis, such as increased organ damage and tacrolimus variability (IPV) in transplant recipients. Education significantly improves health literacy ($r \approx 0.22$), which correlates with adherence ($r \approx 0.16$). Interventions utilizing mHealth and remote monitoring showed the highest efficacy (OR=5.65), while general health education doubled adherence odds (OR=2.42). In acute care, pharmacist counseling improved antibiotic course completion (OR=1.45). Digital tools and simplified content (via AI) effectively addressed cognitive barriers and misconceptions.

Conclusion(s) Patient education is a fundamental therapeutic mechanism, not merely an adjunct. By transforming patient beliefs and enhancing self-management skills, tailored educational programs significantly reduce morbidity and healthcare waste. Multidisciplinary approaches combining human interaction and digital health are critical for closing the gap between prescribed therapy and real-world effectiveness.

P1585

DIAGNOSTIC ERRORS AND EMERGING PARADIGMS IN OSTEOPOROSIS MANAGEMENT

T. Griadil[1]

[1]Uzhhorod National University/Institute of Postgraduate and Pre-university Education/Department of Internal and Family Medicine with courses in instrumental diagnostics, Uzhhorod, Ukraine

Objective(s). To analyze the prevalence of clinical diagnostic errors in osteoporosis, specifically technical pitfalls in Dual-energy X-ray Absorptiometry (DXA), and to evaluate the utility of advanced modalities including Quantitative Computed Tomography (QCT) and Artificial Intelligence (AI) in improving detection accuracy.
Material and Methods. A comprehensive review of recent literature (2021-2026) was conducted, integrating data on diagnostic discrepancies, secondary osteoporosis etiologies (e.g., celiac disease, CKD), and novel screening tools. The analysis compared standard BMD-centric protocols against volumetric imaging and AI-assisted algorithms.
Results. Current data indicate that up to 90% of DXA reports may contain technical or interpretation errors, such as misclassification of artifacts (osteophytes) or incorrect positioning, which often mask bone loss [1]. Routine radiographs fail to detect vertebral fractures in approximately 34% of cases. QCT identifies significantly more patients with osteoporosis than DXA in discordant populations. Furthermore, deep learning models applied to routine CT scans have demonstrated high diagnostic performance with an Area Under the Curve (AUC) of up to 0.96 [2]. The omission of bone turnover markers (P1NP, CTX-1) and neglect of secondary causes further exacerbate diagnostic gaps.
Conclusion(s). Effective fracture prevention requires transcending the limitations of standard DXA through rigorous quality control and the integration of precision tools. Adopting QCT, biochemical monitoring, and AI-driven opportunistic screening is essential to minimize diagnostic errors and address the global burden of osteoporosis.

P1586

OBESITY AS A DETERMINANT OF ACCELERATED STRUCTURAL DECLINE IN GONARTHROSIS: A COMPREHENSIVE ANALYSIS OF BIOMECHANICAL, METABOLIC, AND PHARMACOLOGICAL FRAMEWORKS

T. Griadil[1]

[1]Uzhhorod National University/Institute of Postgraduate and Pre-university Education/Department of Internal and Family Medicine with courses in instrumental diagnostics, Uzhhorod, Ukraine

OBJECTIVE To investigate obesity as a key determinant of rapid knee osteoarthritis (KOA) progression and evaluate the therapeutic efficacy of metabolic interventions, specifically glucagon-like peptide-1 (GLP-1) receptor agonists.
MATERIAL AND METHODS A systematic review of current literature was conducted to analyze the biomechanical and inflammatory mechanisms linking obesity to accelerated KOA. Data on predictive biomarkers (urinary CTX-II, MRI-detected bone marrow lesions) and clinical outcomes from recent pharmacological trials were synthesized to assess disease-modifying strategies.
RESULTS Obesity drives rapid KOA progression through a "whole joint" toxicity model that combines mechanical overload with meta-inflammation mediated by adipokines such as leptin and resistin [1]. This degenerative trajectory is significantly accelerated by comorbid depression and sarcopenia. Clinical evidence indicates that weight loss exceeding 10% is required to mitigate these risks. The STEP-9 trial demonstrated that the GLP-1 receptor agonist semaglutide reduced body weight by 13.7% and achieved a mean reduction in the WOMAC pain score of 41.7 points, significantly outperforming placebo [2]. These findings highlight the dual benefit of targeting metabolic pathways to alleviate symptoms and potentially slow structural decline.
CONCLUSION Obesity is a major modifiable predictor of rapid KOA progression. Integrating metabolic management via GLP-1 receptor agonists with weight loss strategies represents a paradigm shift in preventing joint failure and improving patient quality of life.

INSULIN RESISTANCE AS A MECHANISTIC DRIVER OF METABOLIC OSTEOARTHRITIS: FROM MOLECULAR PATHWAYS TO THERAPEUTIC TARGETS

T. Griadil[1]

[1]Uzhhorod National University/Institute of Postgraduate and Pre-university Education/Department of Internal and Family Medicine with courses in instrumental diagnostics, Uzhhorod, Ukraine

Objective(s) To synthesize evidence linking insulin resistance (IR) to osteoarthritis (OA) pathogenesis, defining the "metabolic OA" phenotype, and to evaluate the efficacy of insulin-sensitizing agents as disease-modifying strategies.
Material and Methods A narrative review of literature (PubMed, Scopus, Web of Science; 2019–2025) was conducted. Selection criteria focused on studies analyzing molecular crosstalk between type 2 diabetes and OA, biomarkers of metabolic dysregulation (e.g., TyG index, METS-IR), and clinical outcomes of repurposing metabolic drugs (metformin, GLP-1 agonists) for joint preservation.
Results Current data confirms that IR contributes to OA beyond mechanical loading, establishing a distinct metabolic phenotype. Systemically, IR correlates with chronic low-grade inflammation mediated by adipokines (leptin, resistin) and cytokines (TNF-alpha, IL-6), which degrade cartilage matrix. At the cellular level, osteoarthritic chondrocytes and synovial fibroblasts exhibit impaired insulin signaling (defective Akt phosphorylation) and GLUT-1 dysregulation, exacerbating oxidative stress and matrix metalloproteinase production. Epidemiologically, elevated metabolic scores for insulin resistance (METS-IR) are linear

predictors of OA prevalence and severity. therapeutically, metformin demonstrates potential to retard cartilage degeneration via AMPK activation, while GLP-1 receptor agonists reduce synovial inflammation and improve clinical outcomes in knee OA patients.
Conclusion(s) Insulin resistance is a fundamental driver of joint degeneration in metabolic OA. Integrating metabolic phenotyping into OA management and repurposing anti-diabetic therapies offer promising avenues for halting disease progression.
Disclosures The author declares no conflicts of interest.

OSTEOPOROSIS AND COGNITIVE IMPAIRMENT: CLINICAL PARALLELS AND SHARED MECHANISMS

T. Griadil[1]

[1]Uzhhorod National University/Institute of Postgraduate and Pre-university Education/Department of Internal and Family Medicine with courses in instrumental diagnostics, Uzhhorod, Ukraine

OBJECTIVE(S) To explore the bidirectional relationship between osteoporosis (OP) and cognitive impairment (CI), identifying shared risk factors and underlying molecular mechanisms to improve clinical management of aging populations.
MATERIAL AND METHODS A comprehensive review of recent epidemiological studies and meta-analyses was conducted to evaluate the association between bone mineral density (BMD) and cognitive function. The analysis focused on shared pathophysiology, including the "bone-brain axis," hormonal pathways, and biomarkers such as osteocalcin, RANKL/OPG, and Wnt/β-catenin signaling.
RESULTS Epidemiological data indicate a robust bidirectional link; patients with CI have a 1.56-fold increased risk of developing OP (RR=1.56; 95% CI 1.30–1.87) [1]. Conversely, patients with diagnosed OP show a significantly higher risk of developing dementia (HR=1.80), with the risk nearly doubling in those with osteoporotic fractures [2]. Shared mechanisms include estrogen deficiency, chronic inflammation, and disruption of the Wnt/β-catenin pathway, which regulates both bone formation and synaptogenesis. Osteokines like osteocalcin cross the blood-brain barrier, directly linking bone remodeling to neuronal function.
CONCLUSION(S) OP and CI are interconnected conditions of aging, sharing common etiological pathways beyond simple co-morbidity. Recognizing the "bone-brain axis" allows for better risk stratification. Integrated screening strategies targeting both bone health and cognitive function are essential for early intervention and improved patient outcomes.

OSTEOARTHRITIS AND QUALITY OF LIFE: A JOINT-SPECIFIC REVIEW

T. Griadil[1]

[1]Uzhhorod National University/Institute of Postgraduate and Pre-university Education/Department of Internal and Family Medicine with courses in instrumental diagnostics, Uzhhorod, Ukraine

Objective To evaluate the differential impact of osteoarthritis (OA) phenotypes on health-related quality of life (HRQoL), analyzing clinical and epidemiological data across knee, hip, hand, and spine localizations.
Material and Methods A comprehensive review of Global Burden of Disease (GBD) 2019 data and recent clinical studies was conducted. We analyzed HRQoL metrics (SF-36, EQ-5D), prevalence trends, and biopsychosocial factors affecting patients with site-specific OA.
Results OA is a complex "whole-joint" pathology whose global prevalence increased by 113% between 1990 and 2019, affecting approximately 528 million individuals [1]. Knee OA remains the most prevalent form, significantly impairing mobility and increasing cardiovascular mortality risk due to forced sedentary behavior. Hip OA is associated with profound utility loss and social isolation, with patients reporting substantial decrements in vitality. Hand OA affects manual dexterity and aesthetic self-perception, often leading to stigmatization, while spine OA is a primary driver of chronic pain and disability-adjusted life years (DALYs) [1]. Psychological comorbidities, including depression and anxiety, are prevalent and exacerbate pain perception through central sensitization mechanisms, further degrading HRQoL [2].
Conclusion OA imposes a substantial, site-dependent burden on HRQoL. Effective management requires a shift from a purely structural focus to a multimodal, biopsychosocial approach targeting the specific functional and psychological impairments associated with each joint phenotype.

P1590
INSULIN RESISTANCE AND OSTEOPOROSIS: PATHOGENESIS, CLINICAL ASSOCIATIONS, AND THERAPEUTIC STRATEGIES

T. Griadil[1]

[1]Uzhhorod National University/Institute of Postgraduate and Pre-university Education/Department of Internal and Family Medicine with courses in instrumental diagnostics, Uzhhorod, Ukraine

Objective: To elucidate the mechanisms linking insulin resistance (IR) to skeletal fragility and evaluate clinical implications for osteoporosis management.
Material and Methods: A comprehensive review of recent literature (2020–2025) and clinical data, including findings from the NHANES and MIDUS II studies, was conducted. The analysis focused on molecular pathways (PI3K/Akt/mTOR), bone turnover markers, and the impact of anti-diabetic therapies on bone health.

Results: Despite the anabolic potential of insulin via the PI3K/Akt pathway, systemic IR is associated with a "diabetic bone paradox"—preserved or increased bone mineral density (BMD) alongside elevated fracture risk [1]. Mechanisms driving this fragility include chronic inflammation, oxidative stress, and the accumulation of advanced glycation end-products (AGEs), which compromise collagen quality and suppress osteoblast function [2]. Clinical data indicate that while metformin exerts osteoprotective effects, thiazolidinediones are associated with bone loss. Furthermore, standard BMD assessment often underestimates fracture risk in IR patients due to cortical porosity not captured by DXA.
Conclusion(s): IR acts as a silent pathogen for skeletal health, degrading bone quality independent of bone mass. Metabolic management is crucial for fracture prevention, and therapeutic strategies should prioritize agents that preserve bone integrity.
Disclosures: The author declares no conflicts of interest.

ASSOCIATION OF KNEE AND HIP OSTEOARTHRITIS WITH INCIDENT DISABILITY: THE ROAD STUDY

T. Iidaka[1], C. Horii[2], G. Tanegashima[2], S. Muraki[3], H. Oka[4], S. Tanaka[2], N. Yoshimura[1]

[1]Department of Preventive Medicine for Locomotive Organ Disorders, 22nd Century Medical and Research Center, The University of Tokyo, Tokyo, Japan, Tokyo, Japan; [2]Department of Orthopaedic Surgery, Faculty of Medicine, The University of Tokyo, Tokyo, Japan, Tokyo, Japan; [3]Muraki Orthopaedics Clinic, Tokyo, Japan, Tokyo, Japan; [4]Division of Musculoskeletal AI System Development, Faculty of Medicine, The University of Tokyo, Tokyo, Japan, Tokyo, Japan

[Objective] We investigated the association between knee and hip osteoarthritis (OA) and the incidence of disability among Japanese men and women using data from a large-scale population-based cohort study, the ROAD (Research on Osteoarthritis/Osteoporosis Against Disability).
[Methods] Among participants aged 65 years or older who had not received disability certification at baseline in the ROAD study, 2,130 individuals (785 men and 1,345 women; mean age, 75.4 years) were included. Baseline radiographs of both knees and hips were evaluated using the Kellgren–Lawrence (KL) grading system. Radiographic knee and hip OA were defined as a KL grade ≥2, and severe knee and hip OA as a KL grade ≥3. Information on new disability certification was obtained during follow-up surveys conducted at 3, 7, and 10 years after baseline. Incident cases of disability were identified, and incidence rates were calculated using the person-year method. Cox proportional hazards models adjusted for age, sex, body mass index, and residential area at baseline were used to examine the associations between OA and incident disability.
[Results] The incidence rate of disability was 28.0 per 1,000 person-years (21.5 in men and 31.7 in women) and was significantly higher in women. The incidence rate increased significantly with age in both sexes. Adjusted Cox regression analyses showed that the hazard ratios (HRs) for incident disability were 1.03 (95% confidence interval [CI]: 0.83–1.30) for knee OA, 1.31 (95% CI: 1.03–1.66) for severe knee OA, 1.81 (95% CI: 1.03–2.94) for hip OA, and 1.06 (95% CI: 0.81–1.37) for severe hip OA. Significant associations were observed for severe knee OA and hip OA.
[Conclusion] In this large-scale population-based cohort with up to 10 years of follow-up, severe knee osteoarthritis and hip osteoarthritis were significantly associated with an increased risk of incident disability among individuals aged 65 years and older.

P1592

RADIOFREQUENCY ECHOGRAPHIC MULTISPECTROMETRY (REMS) IN OBESE TYPE 2 DIABETIC PATIENTS

A. Nikulina[1], A. Murasheva[1], K. Golovatyuk[1], K. Pogosian[1], A. Fedotova[1], T. Karonova[1]

[1]Almazov National Medical Research Centre, St. Petersburg, Russia

Objective: To evaluate the effectiveness of Radiofrequency Echographic MultiSpectrometry (REMS) comparing with Dual-energy X-ray Absorptiometry (DEX) in type 2 diabetic patients with overweight or obesity.
Material and Methods: 13 men and 22 women with type 2 diabetes mellitus (DM2) with body mass index (BMI) ≥25 kg/m2 were included in the study. Patients having osteoporosis, low-density fractures or those receiving specific therapy for osteoporosis were not included. All the patients underwent both DEX and REMS. Bone mineral density in vertebrae and femur neck, diabetic history, glucose-lowering therapy were analyzed. Thereafter 20 patients were administered GLP-1RA for body weight reduction. Baseline all patients both underwent REMS and DEXA. Subsequently, REMS in them after 6 months was conducted to compare the REMS bone density parameters, effectiveness of vertebrae visualization and the scanning depth required.
Results: Among 35 diabetic patients aged 60 [55; 67] years 7 patients (20%) were overweight (BMI 26.5 [25.7; 28.5], 17 (48.5%) had obesity 1 class (BMI 32.0 [31.4; 33.5]), 9 (25.7%) had obesity 2 class (BMI 36.4 [36.0; 38.5]) and 2 patients (5.7%) had obesity 3 class (BMI 42.9 [41.5; 43.3] kg/m2). All the patients received metformin, while 57% were also treated with GLP-1RA, 31% with SGLT2i, 6% with DPP4i and 20% with insulin. According to DEX, 30 patients had normal T-score in L1-L4, 3 had osteopenia, 2 had osteoporosis. According to REMS, 23 patients had normal T-score, 10 had osteopenia, 2 had osteoporosis, discordant values of DEX and REMS were observed in 13 cases (37%). DEX revealed normal values in femur neck among 22 patients, osteopenia in 12 patients and one case of osteoporosis. At the same time, REMS showed normal values in 27 patients, osteopenia in 8 cases and no cases of osteoporosis, discordant data were obtained in 11 cases (31%). We did not notice any correlation of discordant data with obesity class or glucose-lowering therapy. The loss of 7.0 [5.0; 11.0] kg (6.5 [5.5; 7.5] % from baseline) during 6 months of GLP-1RA therapy was associated with improved vertebral visualization (4 vs 3 vertebrae at baseline), though scanning depth or T-score did not significantly change.
Conclusion(s): REMS can be used as an adjunct to DXA in obese patients with T2DM, but its potential as a standalone diagnostic method requires further investigation. Moderate weight loss does not significantly affect REMS results.

P1593

PREOPERATIVE ABALOPARATIDE FOLLOWED BY POSTOPERATIVE ZOLEDRONIC ACID SYNERGISTICALLY ENHANCES FRACTURE HEALING IN RAT FEMORAL OSTEOTOMY MODEL

T. Kataoka[1], Y. Tsubouchi[2], R. Takase[1], T. Otsu[3], M. Kataoka[4], N. Kaku[5]

[1]Oita University Hospital Rehabilitation Center, Yufu, Japan; [2]Division of Human Biology, Department of Health Science, Oita University of Nursing and Health Sciences, Oita, Japan; [3]Division of Mechatronics, Department of Innovative Engineering, Faculty of Science and Technology, Oita University, Oita, Japan; [4]Physical Therapy Course of Study, Faculty of Welfare and Health Sciences, Oita University, Oita, Japan; [5]Department of Orthopaedic Surgery, Faculty of Medicine, Oita University, Yufu, Japan

Background: Delayed fracture healing can markedly delay a patient's return to daily activities. Abaloparatide (Abalo), an osteoporosis medication, may exert strong anabolic effects on bone, with several reports suggesting its potential to improve fracture healing. However, few studies have examined its combined use with bisphosphonates, which possess antiresorptive properties. We investigated whether preoperative Abalo administration followed by postoperative zoledronic acid (ZA) could synergistically promote fracture healing.

Methods: Fifty-six male Sprague–Dawley rats (9 weeks old) were randomly assigned to four groups: control (n=14), Abalo (preoperative Abalo for 6 weeks; 30 μg/kg, subcutaneously, 5 days/week, n=14), ZA (single ZA administration immediately after surgery; 0.1 mg/kg, subcutaneously, n=14), and Abalo + ZA (n=14). After 6 weeks of Abalo treatment, a right femoral midshaft osteotomy model was created. At 2 and 4 weeks post-osteotomy, bilateral femurs were harvested from seven rats per group. Radiographic evaluation, micro-CT for bone morphometry, and three-point bending tests for mechanical strength were performed. Serum and periosteal samples were collected to assess bone turnover markers (P1NP and CTX-1) and the expression of bone formation/resorption–related genes (*Runx2*, *BMP2*, and *RANKL*) by RT-PCR. Histological evaluation was conducted by toluidine blue staining of undecalcified specimens.

Results: Radiographs demonstrated enhanced callus formation and accelerated fracture healing in Abalo and Abalo+ZA groups compared with ZA and control groups, consistent with histological observations. Micro-CT at 4 weeks revealed a significantly higher trabecular bone volume fraction in the right femur of the Abalo+ZA group than in the control group. In the left femur, cortical and trabecular bone mineral density was significantly higher in Abalo and Abalo+ZA groups. On mechanical testing, the Abalo+ZA group had the highest maximum yield load and bending stiffness but the lowest Young's modulus.

Conclusion: Preoperative Abalo plus postoperative ZA treatment improved bone microarchitecture and fracture healing, which contributes to an earlier return to activity in planned fracture cases, such as osteotomy procedures in clinical settings.

P1595

DIGITAL FOUR-DOMAIN SCREENING IDENTIFIES MUSCULOSKELETAL DYSFUNCTION BEFORE PAIN ONSET: ACTIVITY LEVEL AS PRIMARY MODIFIABLE RISK FACTOR

T. L. N. Tik[1]

[1]Vitrue Health, London, United Kingdom

Objective(s)

Musculoskeletal disorders affect 1.71 billion people globally, yet functional decline precedes pain by years. We validated a digital screening tool to identify at-risk workers before symptoms develop, examining whether activity or pain better predicts functional capacity.

Material and Methods

We analyzed 243 working adults (mean age 42.4 years, 58% female) completing digital MSK assessments. The tool evaluated strength, balance, flexibility, and dynamic posture via self-administered interface. Using known-groups validation, we compared high-activity (≥3 sessions weekly, n=61) versus low-activity (≤1 weekly, n=37), and pain-free (n=35) versus moderate-severe pain (≥4/10, n=66). Analyses included Mann-Whitney U tests, Cohen's d, and Youden's Index.

Results

Among 143 completers, activity showed superior discrimination. High-activity individuals scored 12.35 points higher (76.5 vs 64.1, $p<0.001$, $d=0.889$), substantially exceeding pain effects (74.7 vs 67.5, $p=0.034$, $d=0.447$). Benefits persisted across ages 20-39 ($d=0.824$) and 40-59 ($d=0.926$). Low-activity workers with minimal pain showed marked impairment, representing high-risk individuals missed by symptom screening. Optimal threshold (score <67) showed specificity 93.8%, sensitivity 73.7%, OR=42.0 ($p<0.0001$). Novel gender interaction: pain impaired male function (11.42-point reduction, $p=0.035$, $d=0.700$) but not females (1.21 points, $p=0.664$, $d=0.085$).

Conclusion(s)

Digital screening identifies MSK risk before pain develops. Activity proves the strongest modifiable predictor, supporting proactive screening over symptom-based approaches. Low-activity asymptomatic workers represent critical intervention targets. The validated threshold enables evidence-based stratification with minimal false positives. Digital format addresses scalability barriers for population implementation. Gender-specific pain-function relationships warrant further investigation.

P1596

FIVE-DOMAIN FUNCTIONAL IMPACT OF PAIN INTENSITY IN 18,371 ADULTS WITH MUSCULOSKELETAL PAIN

T. L. N. Tik[1]

[1]Vitrue Health, London, United Kingdom

Background While pain intensity assessment using Visual Analogue Scale (VAS) is routine in musculoskeletal practice, the precise relationship between subjective pain ratings and objective functional outcomes across multiple life domains remains inadequately quantified. This study establishes comprehensive dose-response relationships between pain severity and five key outcome domains in a large-scale analysis.

Methods Cross-sectional analysis of 18,371 working adults with musculoskeletal pain who completed standardized assessments through a digital workplace health platform. Pain intensity (VAS 1-10) was correlated with work absenteeism, healthcare-seeking behavior, productivity impact, mental health impact, and social wellbeing. Logistic regression calculated odds ratios with 95% confidence intervals for each VAS level versus baseline (VAS 1), controlling for demographics and pain characteristics.

Results All five domains demonstrated statistically significant dose-response relationships (all p<0.0001). Absenteeism rates increased from 9.9% at VAS 1 to 41.2% at VAS 10 (OR=6.4, 95% CI 4.2-9.8). Healthcare-seeking rose from 27.9% to 76.3% (OR=8.3, 95% CI 5.3-13.1). Productivity impact escalated from 28.4% to 81.6% (OR=11.2, 95% CI 7.3-17.1). Mental health impact increased from 12.3% to 61.4% (OR=11.4, 95% CI 7.2-17.9). Social wellbeing impact rose from 13.0% to 65.8% (OR=12.8, 95% CI 8.1-20.4). A critical inflection point emerged at VAS 4, where productivity impact doubled (28.4% to 60.0%), mental health impact doubled (12.3% to 24.5%), and social impact more than doubled (13.0% to 29.9%).

Conclusions This study provides the most comprehensive quantification to date of pain intensity's functional significance across multiple life domains in musculoskeletal pain. The consistency of dose-response relationships, with effect sizes ranging from 6-fold to 13-fold increases, validates VAS as a meaningful predictor of real-world outcomes beyond subjective experience. VAS 4 emerges as a robust, evidence-based intervention threshold with profound implications for productivity, mental health, and social functioning. These findings support early intervention strategies in musculoskeletal pain management and provide empirical benchmarks for outcome measurement and treatment target setting.

P1598

EARLY POSTOPERATIVE VITAMIN D INSUFFICIENCY DESPITE MUSCULOSKELETAL IMPROVEMENT AFTER BARIATRIC SURGERY: IMPLICATIONS FOR METABOLIC BONE HEALTH

T. P. Peshkova[1], N. T. Tsintsadze[2], L. J. Jashi[3], I. N. Nakashidze[2], K. K. Kamashidze[4], K. S. Sakhechidze[1]

[1]Batumi Shota Rustaveli State University; Khozrevanidze Clinic, Batumi, Georgia; [2]Batumi Shota Rustaveli State University, Batumi, Georgia; [3]Avicenna Batumi Medical University, Batumi, Georgia; [4]University of Georgia; Khozrevanidze Clinic, Batumi, Georgia

Objective

To evaluate early changes in serum 25-hydroxyvitamin D (25(OH)D) and bone-related biochemical markers during the first four months after bariatric surgery and to assess concurrent changes in obesity-related joint symptoms.

Material and Methods

This retrospective observational study included 27 adults (17 women, 10 men) who underwent bariatric surgery at a general medical clinic in Batumi, Adjara, Georgia. Assessments were performed preoperatively (T0), at 1 month (T1), and at 4 months (T3) postoperatively. Body mass index (BMI), serum 25(OH)D, alkaline phosphatase (ALP), and ionized calcium were recorded at each timepoint. All patients received routine postoperative supplementation with a multivitamin preparation and additional vitamin D. Vitamin D status was defined as deficiency (<20 ng/mL), insufficiency (20–29 ng/mL), or sufficiency (≥30 ng/mL). A subset of patients had radiographically confirmed gonarthrosis and/or coxarthrosis with chronic joint pain prior to surgery. Longitudinal changes were analyzed using paired statistical tests.

Results

Vitamin D deficiency or insufficiency was common at baseline. Significant BMI reduction was observed at T1 and T3, reflecting rapid postoperative weight loss. Patients with preoperative knee or hip osteoarthritis frequently reported reduced joint pain, improved mobility, and enhanced functional capacity, including the regained ability to cross their legs, with overall improvement in quality of life. Mean 25(OH)D levels increased during follow-up; however, a substantial proportion of patients remained vitamin D insufficient at 4 months despite routine multivitamin and vitamin D supplementation. ALP demonstrated a rising trend over time, whereas ionized calcium remained within the reference range.

Conclusion

Early after bariatric surgery, marked improvement in weight-related joint symptoms occurs alongside persistent vitamin D insufficiency and biochemical changes suggestive of altered bone metabolism. This divergence between symptomatic musculoskeletal benefit and potential skeletal vulnerability underscores the need for early metabolic bone monitoring and individualized vitamin D replacement in the post-bariatric population.

Disclosures None.

P1599

PARICALCITOL INCREASES THE EXPRESSION OF VITAMIN D RECEPTORS IN MURINE LIVER BUT SHOWS HEPATOXICITY IN HIGH DOSES

V. Y. Malygina[1], T. P. Sataieva[1]

[1]V.I. Vernadsky Crimean Federal University, Simferopol, Russia

Background. Paricalcitol (PC) (19-nor-1,25-dihydroxyvitamin D2) is a synthetic analogue of D2 that binds to the vitamin D receptor and prevents the secretion of parathyroid hormone. The drug is widely used to treat and prevent secondary hyperparathyroidism in chronic renal failure. In addition, there is evidence of the anti-inflammatory and antioxidant properties of PC. Studies have shown that vitamin D receptors (VDRs) can be a promising target in osteoporosis. However, the effect of PC on the state of liver cells, which are the most important site of its metabolism, is devoted to single publications.

Aim. To study the effect of intraperitoneal administration of different doses of paricalcitol on the degree of activation of vitamin D receptors and to conduct a morphological assessment of the state of liver tissue in mice.

Materials and methods. The experiment involved male BALB/c mice without external pathological signs, weighing 16–18 g and aged 4–6 weeks. The animals were given paricalcitol intraperitoneally at a dose of 25 ng/mouse, 50 ng/mouse and 100 ng/mouse on days 1, 2, 4 and 7. Histological assessment of liver tissues of animals removed from the experiment on day 10 was performed according to generally accepted histological methods. Immunohistochemical examination was performed automatically in a Bond-Max immunohistostainer (Leica, Germany). Primary rabbit polyclonal antibodies to the vitamin D receptor were used.

Results and its discussion. The introduction of PC in different doses consistently increased the total number of liver cells expressing VDR, mainly due to immune cells. An increase in the percentage of intensely stained non-parenchymatous cells (++++ and +++) was observed by the 21st day of the experiment and amounted to 56.0% in subgroup 2.2, 46.6% and 4.2 – 48.0%, in the control group this value was 39.5%. The liver tissue structure closest to the control was observed in animals that received PC at a dose of 25 ng/mouse. In the groups of mice where the animals received PC at doses of 50 ng/mouse and 100 ng/mouse, certain microscopic changes were noted, mainly of a dystrophic and discirculatory nature, which reflected the toxic effect of these doses of PC on the metabolism of hepatocytes.

Conclusion. The introduction of different doses of paricalcitol leads to an increase in VDR expression mainly in non-parenchymatous liver cells that perform immune functions. VDR expression in hepatocytes of all subgroups increased by the 10th day of observation and decreased by the 21st day, which was probably due to the death of these cells. Microscopic examination showed that the use of PC in healthy mice leads to certain dose-dependent changes in the liver, the least toxic dose of PC is 25 ng/mouse.

ANTIDEPRESSANT USE AND RECURRENT FALLS AND FRACTURES IN COMMUNITY-DWELLING OLDER ADULTS WITH DEPRESSION: FINDINGS FROM THE ASPREE COHORT

T. Raru[1], J. Pasco[1], M. Lotfaliany[1], S. Ganjali[1], R. Woods[2], J. Ryan[2], A. Owen[2], M. Berk[1], M. Mohebbi[1]

[1]1Deakin University, the Institute for Mental and Physical Health and Clinical Translation (IMPACT), School of Medicine, Barwon Health, Geelong, Australia; [2]School of Public Health and Preventive Medicine, Monash University, Melbourne, Australia

Background: Antidepressant use among older adults in Australia is notably high, representing the most commonly used mental health-related medication, but only a few studies have compared the risk of recurrent falls and fractures across antidepressant classes. This study aimed to investigate the potential link between antidepressant treatment classes and recurrent falls and fractures among older adults with depressive symptoms.

Methods: This study draws upon data from the ASPirin in Reducing Events in the Elderly (ASPREE) clinical trial and ASPREE-Fracture sub-study. The study population for this study is older adults with depressive symptoms and a total of 3,224 participants with either depressive symptoms (CES-D-10 ≥ 8) or using antidepressants at the baseline were included. The outcomes for this study were the occurrence of falls and fractures as recurrent events. The Anderson-Gill model was used to estimate hazard ratios (HRs) associated with antidepressant exposure, adjusting for potential confounding variables.

Results: During the follow-up period, 508 participants experienced one or more serious falls (incidence rate of 116.1 per 10,000 person-years (PYs)), and 510 participants experienced one or more fractures (incidence rate of 117.3 per 10,000 PYs). We observed a 27% increase in the risk of recurrent falls among participants using any antidepressant medication (aHR = 1.27; 95% CI: 1.06-1.54) and a 44% increase among those using first-line antidepressant medication (aHR = 1.44; 95% CI: 1.15-1.79). In the analysis by antidepressant class, similar results were found for participants taking selective serotonin reuptake inhibitors (SSRIs), whereas associations for tricyclic antidepressants (TCAs) were not statistically significant. For recurrent fractures, the estimated rate was not significantly higher among participants using any antidepressant (aHR = 1.17; 95% CI: 0.98-1.41) and significantly higher among those using first-line antidepressants (aHR = 1.29; 95% CI: 1.03-1.61) and SSRIs (aHR = 1.26; 95% CI: 1.02-1.56).

Conclusions: The overall antidepressant use, first-line antidepressants, and SSRIs were significantly associated with the higher risk of recurrent serious falls, and first-line antidepressants and SSRIs were significantly associated with the higher risk of recurrent fractures. These risks were higher among male participants than female.

Keywords: antidepressants; depression; recurrent falls; recurrent fractures; geriatrics; bone health

SIGNIFICANT BONE MINERAL DENSITY RECOVERY FOLLOWING TERIPARATIDE THERAPY IN A 30-YEAR-OLD PRIMIPAROUS WOMAN WITH MULTIPLE VERTEBRAL FRACTURES

M. T. Tsagareli[1], E. G. Giorgadze[1], T. S. Sulikashvili[1], T. Z. Zerekidze[1], T. B. Bakhtadze[1]

[1]National Institute of Endocrinology, Tbilisi, Georgia

Background: Pregnancy- and Lactation-Associated Osteoporosis (PLO) is a rare but debilitating condition characterized by low bone mineral density (BMD) and fragility fractures, typically occurring in the third trimester or the early postpartum period.
Case Presentation: A 30-year-old woman (Height: 162.0 cm, Weight: 56.0 kg) presented with severe back pain and stiffness two months after delivering her first child. Four months following the onset of symptoms (six months postpartum), clinical evaluation confirmed multiple vertebral fractures. Initial diagnostic imaging via Dual-energy X-ray Absorptiometry (DXA) on October 24, 2022, revealed:

• AP Spine (L1-L4): BMD of 0.656 g/cm², Z-score (-4.4), indicating very low bone mass for her age.

• Total Left Femur: BMD of 0.662 g/cm² with a Z-score of -2.7.

• Trabecular Bone Score (TBS): 1.248 (Z-score -2.1), reflecting partially degraded bone microarchitecture.

Results: The patient immediately discontinued breastfeeding and was initiated on a therapeutic regimen consisting of Calcium Carbonate, Vitamin D and Forsteo (Teriparatide). After 1.5 years of treatment, the patient demonstrated a robust clinical response with significant bone mass accrual:

• Spine BMD increase: 12%.

• Total Femur BMD increase: 6%.

• TBS: was impruved: 1.330 (Z-score -1,2).

Conclusion: Following the 18-month course of anabolic therapy, the patient's skeletal status improved from osteoporosis to osteopenia. The patient remains stable and is currently planning a subsequent pregnancy. This case highlights the efficacy of Teriparatide in restoring bone density and microarchitecture in severe cases of PLO.

P1603

RELATIONSHIP BETWEEN THE CROSS-SECTIONAL AREA OF THE GLUTEUS MAXIMUS MUSCLE AND BONE MINERAL DENSITY OF THE FEMUR IN PATIENTS WITH PROXIMAL FEMUR FRACTURE: CROSS-SECTIONAL ANALYSIS OF MUSCLE BONE UNITS ACROSS DIFFERENT AGE GROUPS

T. Saito[1,2], I. Sugimoto[2], I. Kondo[2], A. Itagaki[3], S. Ogawa[2], S. Lee[2,4]

[1]Department of Rehabilitation, Matsuda Hospital, Sendai, Japan; [2]Aomori University of Health and Welfare Graduate School of Health Sciences, Aomori, Japan; [3]Department of Physical Therapy, Tokyo Metropolitan University, Arakawa, Japan; [4]Department of Physical Therapy, Aomori University of Health and Welfare, Aomori, Japan

Objectives
This study examined the relationship between the cross-sectional area (CSA) of the gluteus maximus muscle and bone mineral density (BMD) of the femur in patients with proximal femur fractures, and clarified the characteristics of age-related muscle and bone interactions.
Methods
Fifty-seven patients with proximal femur fractures were divided into three groups: 65–79 years (Group I), 80–89 years (Group II), and ≥90 years (Group III). BMD of the unfractured femur was measured using dual X-ray absorptiometry. The contralateral gluteus maximus muscle CSA was analyzed at the level of the greater trochanter using measurement equipment in the electronic patient chart. Statistical analysis was performed using R Commander software. Pearson's correlation coefficient was calculated to determine the relationship between CSA and BMD. Statistical significance was set at $p < 0.05$.
Results
A significant positive correlation was observed between the gluteus maximus CSA and total femur BMD in groups I ($r = 0.489$) and II ($r = 0.592$) (all $p < 0.05$).
Conclusion
The characteristics of muscle and bone interactions tend to increase with age, suggesting that strengthening exercises among the gluteus maximus muscles are essential for sustaining BMD.

P1604

CLINICAL EXPERIENCE WITH ROMOSOZUMAB IN PATIENTS WITH OSTEOPOROSIS: A MULTICENTRE DESCRIPTIVE STUDY

I. Martin Martin[1], T. Selfin Cintas[1], I. C. Peinado Ruiz[2]

[1]Hospital Universitario Torrecardenas, Almeria, Spain; [2]Hospital Universitario Virgen de las Nieves, Granada, Spain

Introduction/Objective

Romosozumab is a monoclonal antibody directed against sclerostin, with dual anabolic and antiresorptive effects, approved for the treatment of severe osteoporosis in postmenopausal women and men at high risk of fracture. Evidence from real-world clinical practice is limited. The objective of this study is to describe the baseline characteristics, treatment efficacy, and adverse events in patients treated with romosozumab at two referral hospitals.

Methods

A descriptive, observational study was conducted in patients with osteoporosis who started romosozumab between 2023 and 2025. Demographic variables, history of fractures, previous treatments, adverse effects, discontinuation, and availability of densitometry (DEXA) were collected at the end of 12 months of treatment.

Results

Thirty-one patients were included, with a mean age of 69.3 years, most of whom were women (96.8%). Eighty-three point nine per cent had previous fractures, mainly vertebral. Previous treatments: bisphosphonates in 18 patients (58.1 per cent), denosumab in 21 (67.7 per cent), and teriparatide in 9 (29.0 per cent).

To date, 19 patients (61.3%) have completed one year of treatment; post-treatment DEXA scans are available for comparative analysis in 15 of them. An improvement in bone mineral density (BMD) was observed, with a mean increase in T-score of +0.71 in the spine.

To date, 19 patients (61.3%) have completed one year of treatment; post-treatment DEXA scans are available for comparative analysis in 15 of these patients. An improvement in bone mineral density (BMD) was observed, with a mean increase in T-score of +0.71 in the lumbar spine and +0.21 in the femoral neck. These findings reflect the anabolic efficacy of the drug, with a more marked effect in the lumbar spine and a more modest but relevant response in the femoral neck, consistent with what has been described in pivotal trials. In no case were new fractures, adverse effects, or discontinuation of the drug reported.

Conclusions

In this multicentre cohort, romosozumab showed a favourable safety profile, good persistence and a consistent densitometric response, supporting its usefulness in real-world clinical practice.

P1605

A COMPARISON OF FRACTURE PATTERNS BETWEEN CEMENTED AND UNCEMENTED FEMORAL STEM FOR PERIPROSTHETIC FRACTURE AFTER BIPOLAR HEMIARTHROPLASTY

T. Sima[1], O. P. Phruetthiphat[1]

[1]Phramongkutkalo Hospital, Bangkok, Thailand

Objective

Previous studies established that the "reverse clamshell" fracture pattern did not show a significant association with either cemented or uncemented stem fixation. Furthermore, it has been proposed that identifying fracture patterns aids surgeons in recognizing stem instability, a critical factor in deciding between internal fixation and revision arthroplasty. Acknowledging a gap in validating these findings across different populations, this study aims to compare periprosthetic femoral fracture (PPF) patterns between cemented and uncemented stems following bipolar hemiarthroplasty, identify associated risk factors, and evaluate whether specific fracture patterns should influence the choice between fixation and arthroplasty to optimize outcomes.

Material and Methods

This retrospective cohort study analyzed patients undergoing bipolar hemiarthroplasty for femoral neck fractures. Patients were stratified into two groups based on stem type: cemented and uncemented. PPF cases were identified and classified using the Vancouver system; B2 fractures were further sub-classified into burst, clamshell, reverse clamshell, or spiral patterns. Risk factors were assessed through multivariate analysis. Clinical outcomes were compared between fixation and revision arthroplasty groups specific to each fracture morphology.

Results

A total of 607 hemiarthroplasties were analyzed (430 uncemented and 177 cemented). The overall PPF rate was 5.77% (35/607). Significant risk factors for PPF included heart failure (p = 0.016), Parkinson's disease (p = 0.024), and dementia (p = 0.037). Cemented stems were associated with a significantly higher rate of early pulmonary embolism compared to uncemented stems (5.08% vs. 1.40%, p = 0.017). Regarding B2 fractures, the distribution of fracture patterns did not significantly differ between stem types (p = 0.248), consistent with previous reports, although a trend toward reverse clamshell patterns was observed in cemented stems (50%) and spiral patterns in uncemented stems (62.5%). In terms of decision-making, revision arthroplasty exhibited trends toward higher functional scores compared to fixation in both reverse clamshell and spiral patterns.

Conclusion

Cemented stems were associated with higher rates of early pulmonary embolism and a numerical trend toward increased PPF incidence. While fracture patterns did not significantly differ by stem type, morphological trends were evident. Importantly, for decision-making in B2 fractures, our data suggest that revision arthroplasty may offer superior functional outcomes over fixation for specific patterns such as reverse clamshell and spiral. This indicates that fracture pattern recognition remains a vital, though not exclusive, guide for surgical strategy.

MANAGEMENT OF FRACTURE-RELATED OSTEOPOROSIS IN A PREMENOPAUSAL WOMAN WITH ACHONDROPLASIA TREATED WITH TERIPARATIDE

A. L. Chaliasou[1], D. Baikousi[1], M. Tzanela[1], T. Stratigou[1]

[1]Department of Endocrinology "D. Ikkos"- Diabetes Center–EndoERN, Evangelismos General Hospital, Athens, Greece, Athens, Greece

Objective: Achondroplasia is the most common skeletal dysplasia due to FGFR3 gene mutation, with a reported prevalence of approximately 1 in 20 000 individuals. We report a case of severe osteoporosis with multiple vertebral fractures in a premenopausal woman with achondroplasia and document the effects of anabolic therapy with teriparatide.
Materials and Methods: A 37-year-old female with a lifelong diagnosis of achondroplasia was referred to our osteoporosis clinic for musculoskeletal pain. She reported regular menses, had a body mass index (BMI) of 55.8 kg/m² and no prior osteoporosis treatment. Dual-energy X-ray absorptiometry (DXA) revealed osteoporosis (spine Z-score: −3.1; BMD: 0.828 g/cm²; femoral neck Z-score: −2.5; BMD: 0.693 g/cm²) and radiographs showed multiple vertebral fractures. Laboratory evaluation demonstrated severe 25-OH vitamin D deficiency (13 ng/mL), corrected with supplementation; other bone turnover indices (β-crosslaps, P1NP, BGP, PTH, calcium) were within normal limits. Secondary causes of osteoporosis were excluded. Treatment with teriparatide was initiated along with calcium and vitamin D supplementation.
Results: After 10 months of therapy, DXA showed marked improvement in bone density at the spine (Z-score: −1.2; BMD: 1.068 g/cm²) and femoral neck (Z-score: −1.9; BMD: 0.757 g/cm²). No new fractures were documented during follow-up.
Conclusion: Although achondroplasia is not classically associated with osteoporosis, case reports indicate osteopenia/osteoporosis in affected adults. This is, to our knowledge, the first report of teriparatide use in a patient with achondroplasia and fracture-related osteoporosis, with significant increases in bone mineral density and absence of new fractures after 10 months. These preliminary data suggest potential effectiveness of anabolic therapy in this rare clinical scenario, warranting further research.

P1607

HETEROGENEOUS QUALITY-OF-LIFE TRAJECTORIES AFTER GERIATRIC HIP FRACTURE SURGERY: A ONE-YEAR GROWTH MIXTURE MODELING STUDY

T. T. B. Nguyen[1], Y.-P. Chen[2]

[1]Can Tho University of Medicine and Pharmacy, Can Tho, Vietnam; [2]Wan Fang Hospital, Taipei Medical University, Taipei, Taiwan, Taipei, Taiwan

Background
Hip fractures represent a major cause of morbidity among older adults. Recovery following hip fracture surgery is highly heterogeneous, and longitudinal changes in quality of life (QoL) are not adequately captured by cross-sectional assessments. Identifying distinct QoL trajectories and their associated factors may facilitate risk stratification and individualized rehabilitation strategies. This study aimed to characterize one-year QoL trajectories after hip fracture surgery and to determine baseline predictors of trajectory membership.
Methods
We conducted a longitudinal cohort study using data from a hip fracture registry at a tertiary medical center. QoL was assessed using the EuroQol five-dimension three-level questionnaire (EQ-5D-3L) at admission, 6 months, and 12 months postoperatively. Growth mixture modeling was applied to identify latent subgroups with distinct QoL trajectories. Baseline demographic, clinical, and functional variables were compared across trajectory classes. Multinomial logistic regression was used to identify factors independently associated with trajectory membership.
Results
A total of 382 patients (mean age 80.2 years; 71.3% women) were included. Four distinct QoL trajectories were identified: (1) consistently high QoL (60.47%), characterized by stable, near-optimal QoL; (2) partially declined then stable (21.99%), showing a moderate decline at 6 months followed by stabilization; (3) notably decreased QoL (12.83%), demonstrating a steep and persistent decline and representing the poorest recovery profile; and (4) recovered QoL (4.71%), characterized by low baseline QoL with gradual improvement over one year. Multivariate analysis revealed that osteosarcopenia, lower pre-fracture EQ-5D-3L utility scores, and poorer activities of daily living were independently associated with the notably decreased QoL trajectory, while older age and cognitive impairment predicted membership in the partially declined then stable group. No baseline variables significantly predicted the recovered trajectory.
Conclusion
Older adults undergoing hip fracture surgery follow distinct and clinically meaningful QoL trajectories during the first postoperative year. Age, musculoskeletal health, cognitive status, baseline QoL, and functional independence are key determinants of unfavorable trajectories. Early identification of high-risk patients may enable personalized interventions aimed at preserving quality of life and preventing long-term decline.

P1608

THE RELATIONSHIP OF OSTEOPOROSIS WITH A NOVEL MEASURE OF SOCIOECONOMIC STATUS

T. Thacher[1], S. Hussain[1], K. Fischer[1], D. Jegen[1], J. Maxson[1]

[1]Mayo Clinic, Rochester, United States

Objective: Osteoporosis may be associated with a lower socioeconomic status (SES). Our objective was to test the hypothesis that women with lower SES are at greater risk of osteoporosis, using a novel measure of individual SES.
Material and Methods: We analyzed retrospective data from a large primary care practice in the Midwestern U.S. states of Minnesota, Wisconsin, and Iowa. All empaneled women, aged 66 years and older in 2022, were eligible for inclusion. We identified the first bone density test completed in the 16 years between 2007 and 2022. Using a large language model, bone density data were extracted from varying bone density report formats. Individual level housing-based socioeconomic status was determined with the Housing-Based Socioeconomic Status (HOUSES) index, linking patient to publicly available property data. Four property items (square footage of housing unit, estimated building value, number of bedrooms, and number of bathrooms) were used to calculate a composite standardized z-score. The HOUSES index was stratified

into quartiles, with Q1 representing the lowest SES. An advantage of the HOUSES index is that it does not depend on patient-reported data, which is more often incomplete or missing for those of lower SES.
Results: Of the 11,196 women included, 8538 (76.3%) had completed at least one bone density measurement in the prior 16 years. Hip and lumbar spine T-scores were extracted for 6507 and 6772 women, respectively. The lowest T-score at any hip site was used for analysis. Overall, the prevalence of hip and lumbar spine T-scores of -2.5 or less was 6.9% and 4.8%, respectively. The mean hip and lumbar spine T-scores were -0.7±1.3 and 0.0±1.6, respectively, and hip and lumbar spine osteopororsis were not related with HOUSES quartiles (P=0.16 and 0.12, respectively). In a mixed model analysis adjusting for age, race, medical comorbidities, and rural residence, the lowest HOUSES quartile did not have a greater risk of osteoporosis at any site compared with the highest quartile (OR 1.26, 95%CI 0.98 to 1.63).
Conclusion: Women with lower SES in a U.S. Midwest primary care setting were not at greater risk of osteoporosis than those of higher SES.

P1609

SAGITTAL BALANCE, A SPINOPELVIC PARAMETER PREDICTOR OF QUALITY OF LIFE ONE YEAR AFTER AN OSTEOPOROTIC VERTEBRAL FRACTURE

M. Jerum[1], L. Delente[1], M.-C. Tetard[2], M. Normand[3], A. Amouzougan[1], T. Thomas[4]

[1]Rheumatology Department, University Hospital of Saint-Etienne, Saint-Etienne, France; [2]Department of Neurosurgery, University Hospital of Saint-Etienne, Saint-Etienne, France; [3]Université Jean Monnet, Institut d'Administration des Entreprises de Saint-Etienne, Institut Camille Jordan, Saint-Etienne, France; [4]Université Jean Monnet, Rheumatology Department, University Hospital of Saint-Etienne, Saint-Etienne, France

Objective: Preserving quality of life (QoL) is an important therapeutic goal after an osteoporotic fracture event. Therefore, it is mandatory to better identify factors that may adversely affect QoL following an osteoporotic fracture.
Assessing the predictive value of anthropometric parameters, including spinopelvic parameters, in the evolution of QoL after the occurrence of an osteoporotic vertebral fracture (VF).
Material and Methods: Patients aged over 60 with a recent VF less than 8 weeks prior to inclusion were followed prospectively. Quality of life was assessed at inclusion (M0), at month 6 (M6) and 12 (M12) after inclusion, using the EQ-5D-3L questionnaire. Front and lateral plain X-rays of the entire spine were performed at M0 and M12 allowing measurements of spinopelvic parameters. Associations between QoL at M12 and factors at inclusion, likely to influence its evolution, were evaluated.
Results: Fifty-one patients, including 40 women, aged 75±9 years with a mean BMI of 26.4±5kg/m^2, were included. Thirteen patients were not reviewed due to death, significant cognitive impairment or loss to follow-up. At M0, mean values of sagittal vertical axis (SVA) and pelvic tilt (PT) were 67.6 ± 41.5 mm and 22.5 ± 8.5 degrees, respectively, values higher than normal range. Lumbar lordosis (LL) 46.1 ± 16.7 degrees, lower than normal range.Management of VF varied, dependent on pain course and VF severity, including brace wearing (21) percutaneous surgical osteosynthesis (10) and vertebroplasty (5).
Among baseline characteristics including all spinopelvic parameters, QoL at M12 was negatively associated with age (p<0.001), history of osteoporotic fracture (p<0.5) and SVA at M0 (p<0.01). Whereas QoL progressively increased on average between M0 and M12 (p<0.006), we determined two different SVA threshold values that were predictive of QoL: a VSA < 40 mm and a VSA > 70 mm were associated with the highest QoL and the lowest QoL values, respectively.
Conclusion: Among factors identified as predictors of a poor QoL following VF at 1 year, SVA was the only factor that could be corrected. Therefore, implementing treatment aiming to maintain a low SVA could improve QoL.

P1610

THE EVALUATION OF DXA PARAMETERS IN PATIENTS WITH NON-ALCOHOLIC FATTY LIVER DISEASE

T. Tsoriev[1], I. Skripnikova[1], E. Mamutova[1], A. Sheptulina[1], A. Yafarova[1]

[1]Federal State Budgetary Institution "National Medical Research Center for Therapy and Preventive Medicine" of the Ministry of Healthcare of the Russian Federation, Moscow, Russia

Objective:
To assess bone mineral density (BMD) and trabecular bone score (TBS) in patients with non-alcoholic fatty liver disease (NAFLD) depending on gender and age.
Materials and methods:
In a cross-sectional study involving 54 women (mean age 56.29±10.13 years) and 30 men (mean age 50.96±11.22 years), anthropometric, instrumental (BMD L1-L4 and in femoral neck (FN), T- and Z-scores, TBS) and laboratory (AlAT, AsAT, total calcium, phosphate, parathyroid hormone (PTH), 25(OH)-vitamin D3) indices were determined. AsAT/AlAT ratio and the Fibrosis 4 Index (FIB-4) were also calculated. TBS was classified according to the meta-analysis of McCloskey et al. (2016).
Results:
Decreased bone mass (osteopenia) was found in 57.2% of postmenopausal women and in 14.8% of men. The FIB-4 was significantly higher in women than in men : 1.022 (0.743; 1.488) versus 0.963 (0.780; 1.608), respectively (p = 0.033); its value was higher than 1.30 (F ≥3 on the METAVIR scale – significant liver fibrosis) in 3 men and 7 women.
BMD FN correlated positively with AsAT/AlAT (r = 0.311; p = 0.007) and FIB-4 (r = 0.343; p = 0.018), while BMD L1-L4 showed no relationship with liver disease indices. Decreased TBS values (<1.310) were detected in 5 men (16.67% of their number) and 9 women (also 16.67%).
A significant negative correlation between TBS and the AsAT/AlAT ratio was found in men (r = -0.360; p = 0.021), but not in women. A negative correlation was also established between TBS and FIB-4 in both men (r = -0.330; p = 0.019) and women (r = -0.127; p = 0.044).
Conclusion:
More than half of examined postmenopausal women or men over 50 years old with NAFLD had osteopenia. A positive correlation was observed between BMD FN and indices reflecting liver disease progression (AsAT/AlAT ratio and FIB-4), but not for BMD L1-L4. Significant negative correlation between TBS and the AsAT/AlAT, as well as between TBS and FIB-4, was revealed, which may indicate that the state of bone microstructure is linked with the severity of hepatocyte destruction. Such discordant results may be caused by insufficient sensitivity of BMD as a marker of bone tissue condition in NAFLD.

P1611

CALCIUM ISOTOPE RATIO MEASUREMENT (CIM) FOR MONITORING RESPONSE TO OSTEOPOROSIS TREATMENT

T. Vilaca[1], F. Gossiel[1], M. Paggiosi[1], R. Eastell[1]

[1]University of Sheffield, Sheffield, United Kingdom

Objectives

Calcium isotopes are calcium atoms that share the same number of protons but differ in neutron number. Lighter calcium isotopes are preferentially incorporated into bone, leading to natural variations in the relative abundances of isotopes in serum. The calcium isotope measurement (CIM) expresses this variation and has emerged as a tool for investigating calcium metabolism in health and disease; CIM reflects shifts in net bone calcium balance and typically moves toward more positive values following antiresorptive therapy.

We assessed CIM for monitoring bisphosphonate treatment using the least significant change (LSC) and premenopausal female median values, and compared it with procollagen I N-propeptide (PINP) and C-telopeptide of type I collagen (CTX).

Material and methods

We measured the fasting Ca-44 to Ca-42 isotope ratio ($d^{44/42}Ca$ ‰) using multicollector inductively coupled plasma mass spectrometry (MC-ICP-MS) and PINP and CTX using an automated immunoassay analyser (IDS-iSYS).

We used samples from 41 postmenopausal women measured weekly for 8 weeks to estimate means and precision error and calculated the LSC (LSC = 2.77 × precision error). We establish the premenopausal median in 118 healthy women aged 30 to 45 years. We used serum samples from 46 postmenopausal women with osteoporosis who were randomised to oral bisphosphonates (TRIO Study) for 96 weeks. We measured CIM and BTM at baseline and after 13 weeks of therapy. We compared the proportions of treatment responders.

Results

After 13 weeks of bisphosphonate treatment, we observed an increase in CIM greater than the LSC in 35 out of 46 women (76%), a decrease in 44 out of 53 (83%) for PINP (p=0.18), and 23 out of 54 for CTX (p=0.004). Applying the median for premenopausal women, CIM exceeded the median in 42 out of 46 (91%), similarly to PINP (52 out of 53, 98%, p=0.125) and CTX (46 out of 53, 87%, p=0.72) (figure).

Conclusion

CIM performed comparably to PINP and better than CTX for assessing response to bisphosphonates in postmenopausal women.

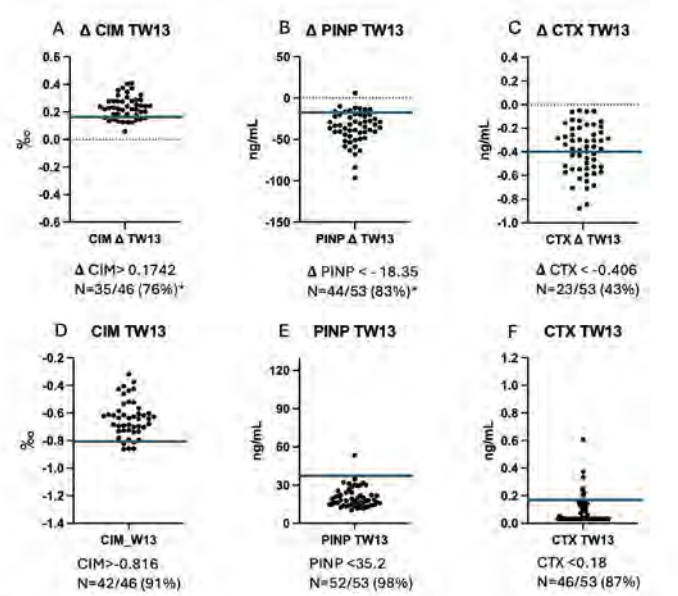

Figure - Scatter plots showing number and proportion of participants exceeding the least significant change (LSC) for CIM (A), PINP (B) , CTX (C) and the median for premenopausal women CIM (D), PINP (E) , CTX (F) . Cochrane test for comparison of proportions LSC p<0.001 *p<0.001 compared to CTX; Median premenopausal women (p=0.05)

DHPR INHIBITION ATTENUATES FORCE DECREASE BUT DOES NOT PREVENT ATROPHY IN THE THREE-DAY UNLOADED RAT SOLEUS MUSCLE

T. Y. Kostrominova[1], K. A. Sharlo[2], S. A. Tyganov[2], D. A. Sidorenko[2], R. O. Bokov[2], K. A. Zaripova[2], B. S. Shenkman[2], T. L. Nemirovskaya[2]

[1]Department of Anatomy, Cell Biology and Physiology, Indiana University School of Medicine, Gary, United States; [2]Myology Laboratory, Institute of Biomedical Problems, RAS, Moscow, Russia

OBJECTIVE: The depolarization of the sarcolemma is one of the first effects of unloading on skeletal muscle[1]. We hypothesized that unloading-induced activation of the dihydropyridine receptor (DHPR), a voltage-sensitive L-type Ca^{2+} channel, and depolarization of the sarcolemma trigger intracellular Ca^{2+} release from the sarcoplasmic reticulum and activation of Ca^{2+}-dependent signaling pathways resulting in muscle atrophy. Nifedipine, a DHPR calcium channel blocker, was used to study the role of DHPR in the regulation of signaling pathways during three days of rat soleus muscle unloading.

MATERIAL AND METHODS: Male Wistar rats were assigned at random to one of the three experimental groups: control with placebo (8 rats), unloading for 3 days, injected with placebo (8 rats), unloading for 3 days, injected with DHPR inhibitor nifedipine (8 rats; 5 mg/kg of body weight per day intraperitoneally).

RESULTS: Inhibition of DHPR during unloading attenuates the decrease of soleus muscle contractile properties, prevents the accumulation of ATP, ROS, and Ca^{2+} content in the sarcoplasm and the mitochondria, blocks the decrease of the PGC1alpha mRNA expression, and Junctophilin-1

proteolysis.
CONCLUSIONS: Inhibition of DHPR with nifedipine during three days of soleus muscle unloading attenuates the decrease of muscle contractile properties, blocks unloading-induced increase in the accumulation of ATP, ROS, Ca^{2+} content in the sarcoplasm and the mitochondria, and prevents the decrease in the PGC1alpha mRNA expression and Junctophilin-1 proteolysis. The improved contractile properties of the unloaded soleus muscle in nifedipine-treated rats could be mediated by the prevention of calpain-mediated degradation of the cytoskeletal proteins. Preventing a decline in muscle contractile properties during unloading by lowering Ca^{2+} levels with nifedipine might help to develop an effective preventive measure for the early stages of hypokinesia in humans.
The current study was supported by the Russian Science Foundation (RSF; project No. 24-15-00088, TLN).

CYSTICERCOSIS OF THE BRAIN (CLINICAL CASE)

A. Filipovich[1], T. Zagorskaya[2]

[1]Republican Scientific and Practical Center for Medical Expertise and Rehabilitation, Yukhnovka, Belarus; [2]Minsk Regional Children's Clinical Hospital, Minsk, Belarus

Introduction. Cerebral cysticercosis is a rare disease caused by the larval stage of the pork tapeworm (Taenia solium). Humans become infected by consuming undercooked pork. In some cases, humans can become infected with oncospheres through oral ingestion from an infected person or through self-infection (autoinfection) when oncospheres are ingested from the intestines during vomiting, or by consuming unwashed vegetables grown in soil fertilized with contaminated waste. As a result of infection with oncospheres, the cysts (cysticerci) can develop in the subcutaneous tissue, muscles, eyes, and often the brain, causing a serious human disease called cysticercosis.
Cysticerci appear as transparent vesicles 0.5-1.5 cm in diameter, filled with a colorless fluid. The head, which has the same structure as that of an adult tapeworm, is visible as a white dot inside. Cysticerci form within 2-4 months. They survive in the human body for 3-6 years, after which they die and calcify. The parasite's lifespan in the brain ranges from 5 to 30 years.
The pork tapeworm, or armed tapeworm (Taenia solium), is no more than 3 meters long. The pork tapeworm inhabits the small intestine of humans. The segments are excreted in the feces. If pigs ingest oncospheres (by eating contaminated feed or the feces of an infected person), the oncospheres develop in the muscles of these animals, which are structurally similar to those of the beef tapeworm. Prevention includes mandatory identification and treatment of patients, the construction of well-equipped indoor toilets on farms, the indoor housing of pigs, and the requirement for meat to undergo veterinary and sanitary inspection.
Material and methods of study. Patient L. serves as an example. A 6-year-old child presented to the Minsk Regional Children's Clinical Hospital with decreased vision in the right eye and convergent strabismus. The vision loss had been noticed for half a year.
Neurological status: active, answers questions correctly. Cranial nerve symptoms include convergent strabismus in the right eye, amblyopia on the right, and dyslalia. Peristaltic tendon reflexes are D=S. Babinski's sign is bilateral. The patient is stable in the Romberg position and performs the finger-to-nose test accurately. Gait is stable. There are no changes in the general blood and urine tests or the blood biochemistry. Ophthalmologist examination revealed the right eye was pale pink, with clear borders and normal vascularity. The left eye was normal. Diagnosis: optic nerve atrophy in the right eye, convergent strabismus with a paretic component (OD), vis OD – light perception, OS – 1.0.
X-ray computed tomography of the brain: Multiple calcifications up to 0.5 cm in diameter were detected in both cerebral hemispheres. There was asymmetrical (D>S) dilation of the ventricular system (lateral ventricles), with a change in the configuration of the anterior horn of the right lateral ventricle (to a spherical shape), measuring 1.8 x 1.9 cm in transverse dimension. The septum pellucidum was shifted to the left by 0.5 cm. The remaining sections of the ventricular system were moderately dilated.
Conclusion: CT scan revealed signs of cerebral cysticercosis in the calcification stage. Internal hydrocephalus. Severe deformation of the right lateral ventricle, likely due to the presence of a cysticercus bubble.
Abdominal ultrasound revealed no abnormalities. Stool analysis revealed no helminth eggs.
A neurosurgeon examined the patient. Diagnosis: Sequelae of a previous neuroinfection. A CT scan of the brain revealed isolated dilation of the body of the right lateral ventricle without disruption of cerebrospinal fluid circulation. Neurosurgical treatment is not required.
An infectious disease specialist examined the patient and recommended antiparasitic therapy, including albendazole for 10-14 days at 15 mg/kg per day in two divided doses. An ELISA test for antibodies to Taenia solium was recommended, and antibodies were detected.
Results and discussion. The most common clinical manifestation of cerebral cysticercosis is seizures. Seizures can be generalized (with loss of consciousness) or partial (twitching of the limbs without loss of consciousness). Seizures are often persistent, difficult to stop, and drug-resistant. Patients are required to take anticonvulsants for a long time, either alone or in combination, such as carbamazepine, depakine, lamictal, or topamax.
Depending on the underlying cerebral disorders, there are five main syndromes of this disease: hypertensive, occlusive, epileptic (convulsive), meningoencephalitic, and psychopathological. Depending on the location of the parasite, cysticercosis is classified as supratentorial (of the cerebral cortex and meninges, intraventricular, and mixed forms), infratentorial (of the fourth ventricle, posterior fossa cisterns, and mixed forms), and generalized. A special variant, racematous or branched (usually localized in the pia mater at the base of the brain and can extend to the spinal cord), is also distinguished.

P1615

DEMYELINISATION PROCESS RATE IN TEENAGERS

A. Filipovich[1], T. Zagorskaya[2]

[1]Republican Scientific and Practical Center for Medical Expertise and Rehabilitation, Yukhnovka, Belarus; [2]Minsk Regional Children's Clinical Hospital, Minsk, Belarus

Background and Aims
127 multiple sclerosis patients 15 to 19 years old were examined
Methods
CT and MRI of cerebrum and spinal cord, conventional clinical methods, immunoassays and a patented radioimmunobiological assay for measuring the myelinotoxic activity (MTA) of blood serum and spinal fluid were used.
Results
The MRI findings (decreasing T-1W signal and increasing T-2W signal) were diagnostically important in 91.4% of cases and the CT findings were important in 42.6% cases. Four groups of patients were distinguished: (1) latent phase (16.6%), (2) slow progradient phase (33.1%), (3) acute phase (35.4%) and (4) fast progradient phase (14.9%). Characteristic of group 1 were slight increase in MTA of blood serum (average of 7.6 units compared to 3.9 in control group), decreased CD4+ (33.9% compared to 40.1% in control) and increased CIC levels (94.65 optical units compared to 69.32 in control). In group 2 with MTA level as high as 22.1, clear decrease of T-lymphocyte, CD22+, CD4+ and CIC levels was noted, along increase in CD8+ level and weak induction of TNF-α. In group 3 MTA level was 40.2 units coupled with increased CD8+, IL-2P+, Ig G, A, M, TNF-α, IL-8 and CIC and decreased T-lymphocyte and CD22+ levels. In group 4 MTA level was as high as 79.3; high level of CD4+, CD8+, IL-2P+, IgG, IgM, IgA and CIC and low level of T-lymphocytes and CD22+ were noted.
Conclusions
Measurement of blood serum MTA in combination with immunoassay and MRI findings helps to correctly estimate the rate of dymelinization

P1616

TAY-SACHS DISEASE. CLINICAL OBSERVATION

A. Filipovich[1], T. Zagorskaya[2]

[1]Republican Scientific and Practical Center for Medical Expertise and Rehabilitation, Yukhnovka, Belarus; [2]Minsk Regional Children's Clinical Hospital, Minsk, Belarus

Tay-Sachs disease is a genetically determined disorder of ganglioside metabolism, characterized by increased levels of gangliosides in the gray matter of the brain, liver, and spleen.
K.D., a girl aged 1 year 5 months, complains of developmental delays: she cannot hold her head up, roll over, sit, walk, or speak. At 1 year 4 months, she began experiencing seizures involving brief jerking of her limbs. She was treated twice in the neurology department before 1 year 5 months due to delayed psychomotor development and underwent genetic evaluation to confirm the diagnosis. Objectively: the head is macrocephalic, she cannot hold her head up, the anterior fontanelle is closed, she cannot roll over, cannot sit, or walk. She has divergent strabismus. Muscle tone in the limbs is sharply reduced, and there is no support. Periosteal tendon reflexes are decreased.
Conclusion: CT scan shows signs of mixed hydrocephalus. Ophthalmologist. Diagnosis: Tay-Sachs disease. Partial atrophy of the optic nerves in both eyes.
Genetic testing results:
1. Mitochondrial DNA was analyzed at the Institute of Genetics and Cytology of the National Academy of Sciences of Belarus (Non-chromosomal Pathology Laboratory) for the T8993 G mutation (maternally inherited Leigh syndrome) and A3343 G (MELAS syndrome), as well as for large MT DNA deletions. PCR analysis of DNA samples isolated from leukocytes was performed. DNA analysis revealed no such mitochondrial genomic abnormalities.
2. Lysosomal enzyme activity in leukocytes: decreased β-hexosaminidase A activity: 10.7; 7.2 mmol/g. Diagnosis: GM2 gangliosidosis. Tay-Sachs disease. The risk of having a child with such diseases in a family is 25%—high. DNA samples from the affected girl and her parents were sent to the Medical Genetic Research Center of the Russian Academy of Medical Sciences in Moscow for partial analysis of the HEXA gene (Tay-Sachs disease, H1H 272800).
Treatment is symptomatic; specific enzyme replacement therapy has not been developed. The girl received anticonvulsants: depakine, carbamazepine, topamax, as well as diacarb, asparkam, and emoxipin.

P1617

GROWTH AND FORMATION OF L3 VERTEBRA IN WHITE RATS AFTER IMPLANTATION OF BIOGENIC HYDROXYAPATITE CONTAINING SELENIUM

N. Tischenko[1], V. Luzin[2], I. Soloviova[3], U. Bogusheva[2]

[1]FSBEI HI ST. LUKA LSMU of MOH of Russia; Department of hygiene and ecology, Lugansk, Russia; [2]FSBEI HI ST. LUKA LSMU of MOH of Russia; Human anatomy department, Lugansk, Russia; [3]FSBEI HI ST. LUKA LSMU of MOH of Russia, Department of medical chemistry, Lugansk, Russia

Objective of the study was to investigate growth dynamics of the L3 vertebra after implantation of hydroxyapatite material OK-015 containing 0.15%, 0.30%, and 0.50% of selenium.
Material and methods. 175 male rats weighing 135-145 g were divided: A-group comprised intact rats, B-group comprised animals with a defect in tibia, C-group comprised animals with the defects filled with pure hydroxyapatite (OC-015). In animals of the Sel-1-3-groups the same defects were filled with OC-015 containing 0.15%, 0.30%, and 0.50% of selenium. Upon 7, 15, 30, 60, and 90 days after surgery L3 vertebrae were collected and measured using standard methods.
Results. In animals of the B-group width of L3 body on the 7th and the 30th days after surgery was lower than that of the A-group by 5.14% and 4.48%, antero-posterior size in the same area decreased by 4.73%, 6.63%, 5.79%, and 5.88% in the period from the 15th to the 90th day. Body height decreased by 5.74% and 6.07% on the 30th and the 60th days. In animals of the C-group in comparison with the B-group width and antero-posterior size decreased by 5.24% and 4.35% on the 15th day. Body width on the 30th and 60th days increased by 5.33% and 4.47%, body height increased by 5.26% and 3.85% on the 60th and 90th days. In the Sel-1-2-groups in comparison with the C-group body width increased by 4.55% and 5.84% on the 15th day. In the Sel-3-group, body width on the 7th and the 15th days increased by 5.96% and 5.19%.
Conclusion. Selenium-containing hydroxyapatite implants have an optimizing effect on growth of undamaged bones. The most effective selenium concentration for optimization is 0.50%.

P1618

AI-DRIVEN DIAGNOSTIC RECOGNITION AND RISK ASSESSMENT FOR OSTEOPOROSIS, OSTEOARTHRITIS, AND MUSCULOSKELETAL PATHOLOGIES: A MULTI-TASK DEEP LEARNING FRAMEWORK

U. Gangadhar[1], V. Sharma[2], J. Singh[3], R. Rajput[4]

[1]Centre for Biomedical Research and Multiomics Foundation, Roorkee, India; [2]IDC Research Centre, Delhi, India; [3]MMIMSR, Ambala, India; [4]OPDSure Biomedical Research Foundation, Roorkee, India

Background: The co-occurrence of Osteoporosis and Osteoarthritis presents a formidable challenge to global public health, requiring sophisticated diagnostic tools to navigate the complexities of bone density attrition and articular degeneration. Traditional computational approaches often analyze these conditions in isolation, failing to capture the synergistic risks necessary for holistic patient safety and early preventive intervention.
Purpose: This investigation introduces a multi-task AI framework designed to bridge this gap by concurrently identifying disease progression phases, monitoring metabolic biomarkers, and ensuring rigorous adherence to evidence-based clinical protocols to optimize orthopedic recovery.
Methods: Utilizing a transformer-based deep learning architecture, the study synthesized longitudinal data from a cohort of 870 participants (ages 15–75), integrating high-resolution 3D reconstructions with multiomics profiles. The system comprises three core technological pillars: First **Disease Recognition:** A Temporal Transformer Network classifies stages of musculoskeletal degradation. Second, **Biomarker Tracking:** A predictive algorithm monitors 15 specific biological indicators of skeletal dysfunction. Third, **Safety Assessment:** A Visual-Semantic Embedding Network evaluates diagnostic compliance relative to critical anatomical and metabolic landmarks.
Results: The framework achieved a diagnostic accuracy of **89.4%** and demonstrated **95.2%** sensitivity in identifying high-risk thresholds for bone and joint failure. Implementation led to a **19%** acceleration in diagnostic timelines and a **22%** reduction in secondary complications compared to conventional standards.
Conclusion: By synthesizing molecular data with real-time imaging, this AI-driven framework offers a robust roadmap for precision-based orthopedic medicine, facilitating proactive and individualized therapeutic care.

INTRA-RATER RELIABILITY OF QUANTITATIVE SENSORY TESTING IN INDIVIDUALS WITH KNEE OSTEOARTHRITIS

U. Mcconville[1], C. Hanratty[1], C. Hughes[1], J. Mcveigh[2], M. Mansfield[3]

[1]Ulster University, Belfast, United Kingdom; [2]University College Cork, Cork, Ireland; [3]University of Birmingham, Birmingham, United Kingdom

Objectives: Reliability of QST in knee osteoarthritis (OA) remains under-examined. This study aimed to determine the intra-rater reliability of thermal and pressure QST parameters, following the DFNS protocol, in individuals with knee OA.

Material and methods: A test–retest reliability study was conducted with 22 adults with clinically diagnosed knee OA. Two identical QST sessions, 24 hours to 14 days apart, were completed by the same trained examiner. Testing was performed at the area of maximal pain on the affected knee and at a contralateral foot control site. Measures included cold detection threshold (CDT), warm detection threshold (WDT), cold pain threshold (CPT), heat pain threshold (WPT), and pressure pain threshold (PPT). Intraclass correlation coefficients [ICC(3,1), 95% CI] were calculated. Ethical approval was obtained from Ulster University.

Results: Participants had a mean age of 64.7 years (SD 12.6); 72.7% were female. Preliminary analyses showed ICCs at the knee ranging from moderate to excellent: CDT 0.78 (0.55–0.91), WDT 0.36 (−0.48–0.41), CPT 0.78 (0.52–0.90), WPT 0.64 (0.28–0.84), and PPT 0.88 (0.73–0.95). At the control site, ICCs were generally higher: CDT 0.97 (0.92–0.99), WDT 0.74 (0.46–0.89), CPT 0.92 (0.82–0.97), WPT 0.78 (0.53–0.91), and PPT 0.85 (0.65–0.94). Variability was greater in temperature detection thresholds than in pain thresholds.

Conclusions: Preliminary findings indicate that the DFNS protocol can be applied consistently in people with knee OA. Pressure pain thresholds demonstrated the highest intra-rater reliability, while thermal pain thresholds showed moderate to good reliability. These results support the feasibility of QST for future mechanistic and sensory profiling research in OA.

Disclosures: No conflicts of interest.

P1620

THE COMBINED PREDICTIVE VALUE OF QUANTITATIVE SENSORY TESTING AND PSYCHOLOGICAL FACTORS ON TOTAL KNEE ARTHROPLASTY OUTCOMES: A SYSTEMATIC REVIEW

U. Mcconville[1], C. Hanratty[1], C. Hughes[1], J. Mcveigh[2], M. Mansfield[3]

[1]Ulster University, Belfast, United Kingdom; [2]University College Cork, Cork, Ireland; [3]University of Birmingham, Birmingham, United Kingdom

Objectives: To synthesise evidence on whether combining pre-operative Quantitative Sensory Testing (QST) with psychological measures improves prediction of post-operative pain, function, or quality of life following total knee arthroplasty (TKA).

Material and Methods: Systematic searches of Medline, Embase, CINAHL, Scopus, PsycINFO and OpenGrey identified studies assessing adults undergoing primary TKA with pre-operative QST and psychological assessments and outcomes ≥6 months post-surgery. Two reviewers performed screening, extraction, and risk-of-bias assessment using QUIPS. Certainty of evidence was rated with GRADE. Due to heterogeneity in QST protocols, psychological measures, and outcome definitions, findings were synthesised narratively.

Results: Eight studies (n=1,405) met inclusion criteria; five evaluated combined predictive models. Combinations such as conditioned pain modulation with catastrophising, or temporal summation with anxiety, produced modest improvements in prediction compared with individual factors, typically explaining 9–20% of variance in post-operative pain or function. Predictive accuracy remained limited (AUC ≤0.70). Evidence was inconsistent, with very low certainty due to methodological variability, small samples, and risks of confounding.

Conclusions: Current evidence provides limited support for the combined use of QST and psychological measures to predict post-TKA outcomes. Although certain combinations show potential, existing models remain weak and inconsistent. Standardised QST procedures, consistent psychological instruments, and robust prognostic modelling are needed to clarify their joint value and determine whether integrated assessments can meaningfully support pre-operative risk stratification.

Disclosures: The authors report no conflicts of interest.

ADVANCING BONE HEALTH IN PREGNANCY: EVIDENCE FROM THE POI PROJECT USING REMS TECHNOLOGY

V. A. Degennaro[1], T. Bignardi[2], A. Bulfoni[2], I. Cetin[3], A. Cromi[4], G. Franzoni[2], F. Ghezzi[5], M. Ossola[3], H. Valensise[6], T. Ghi[7], M. L. Brandi[8]

[1]Department of Medicine and Surgery, Unit of Obstetrics and Gynecology, University of Parma, Parma, Italy; [2]Humanitas San Pio X Hospital, Unit of Obstetrics and Gynecology, Milano, Italy; [3]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico and University of Milan, Milano, Italy; [4]Ospedale del Ponte, University of Insubria, Varese, Italy; [5]4.Ospedale del Ponte, University of Insubria, Varese, Italy; [6]Department of Medicine and Surgery, Unit of Obstetrics and Gynecology, University of Rome Tor Vergata, Roma, Italy; [7]Policlinico Gemelli, Catholic University of the Sacred Heart, Roma, Italy; [8]Italian Fragility Fracture Observatory (OFF Italia), Firenze, Italy

TB, AB, IC, AC, GF, FG, MO, HV equal contributors in alphabetic order.

Objective(s): Pregnancy-related osteoporosis is characterised by increased bone loss and higher risk of fragility fractures, especially during the third trimester and the early stages of breastfeeding. However, the use of ionizing diagnostic methods has limited early diagnosis. This study aimed to monitor changes in bone mineral density and skeletal fragility during pregnancy and breastfeeding using the Radiofrequency Echographic Multi Spectrometry (REMS) technology integrated with clinical and nutritional data.

Materials and Methods: This study was conducted within the framework of the "Progetto Osteoporosi in Gravidanza (POI)" project from different centres in Italy. The inclusion criteria were: healthy Caucasian women in their first trimester of pregnancy. At the time of recruitment (T1), all participants underwent REMS densitometric scans of the proximal femur and completed the Predimed and AFEF questionnaires developed by the Fragility Fracture Observatory (FFO, Italy), to collect information on dietary habits and skeletal risk factors. Participants were re-evaluated in the third trimester of pregnancy (T2) through REMS ultrasound scanning of the femoral neck and the Predimed and AFEF questionnaires. Densitometric changes were analysed using paired *t*-tests.

Results: A total of 156 healthy women in their first trimester was recruited for the study (mean age = 32.7 ± 5.3 years and mean BMI = 23.4 ± 4.2 kg/m²). Among these, 36% received a diagnosis of osteopenia (-1 < T-score < -2.5). To date, 28 patients have completed the follow-up at the third trimester. In this subgroup, a ~1.3% significant reduction in BMD was observed (BMD T1 = 0.767 ± 0.06 g/cm$^{2;}$ BMD T2 = 0.757 ± 0.07 g/cm^2; p = 0.01).

Conclusion(s): Although the study is ongoing, the results show that 36% of women received a diagnosis of osteopenia in the first trimester, with a tendency to worsen over time. The study highlights the importance of constant and early bone monitoring for preventive purposes in pregnant women. Thanks to its non-ionizing and accessible nature, REMS enables broad access to this patient group. Integrating nutritional assessment with REMS-based monitoring may support the development of a risk chart to prevent bone fragility during pregnancy and breastfeeding.

HYALURONIC ACID IN OSTEOARTHRITIS, MOLECULAR WEIGHT MATTERS

V. A. Nestereko[1], A. E. Karateev[1], M. A. Makarov[1], E. I. Bialik[2], S. A. Makarov[2], V. E. Bialik[2], A. A. Roskidailo[2]

[1]V.A. Nasonova Research Institute of Rheumatology 115522, Russian Federation, Moscow, Kashirskoye Highway, 34A, Moscow, Russia; [2]V.A. Nasonova Research Institute of Rheumatology 115522, Russian Federation, Moscow, Kashirskoye Highway, 34A, Moscow, Russia

Introduction: Osteoarthritis (OA) is a serious social and economic burden for the world's population. At the same time, knee joint OA (KJ) occupies one of the leading positions. Intra-articular injections of high-molecular hyaluronic acid are one of the well-known means of helping patients with OA KJ. However, there is little data in the literature on the effectiveness of such drugs, depending on the frequency of administration.

The purpose of the study: to evaluate the effectiveness of a single or double injection of a high molecular weight hyaluronic acid preparation with chondroitin sulfate in post-traumatic OA KJ

Materials and methods: We evaluated the treatment results of 61 patients with post-traumatic OA KJ. High molecular weight hyaluronic acid with chondroitin sulfate was injected into the knee joint cavity of all patients, 36 patients received a single injection and 25 received a double injection with an interval of 7 days. To evaluate the results, the pain intensity was determined on a visual analog scale (VAS) and the total score on a numerical rating scale (NRS) before the start of treatment, 1, 3, 6 and 12 months after the course of intraarticular injections of hyaluronic acid by telephone interview.

Results: The overall results were distributed and showed the following figures: pain during movement at baseline, after 2 weeks, 1, 3, 6, 12 months was 6,7±3,1, 4,0±3,2, 4,3±3,1, 4,6±2,8, 4,5±2,5, 5,3±1,4 see VAS. The pain at rest was 2,7±3,1, 1,5±2,6, 1,8±2,6, 2,1±2,6, 2,2±1,8, 2,6±1,3 see VAS. The function indicators at baseline, after 2 weeks, 1, 3, 6, 12 months were 4,9±3,6, 3,5±2,9, 4,2±2,9, 4,0±3,2, 3,5±2,7, 4,3±1,9 according to the NRS. In the first group, there are similar indicators: pain when moving 6,7±3,1, 4,0±3,2, 4,3±3,1, 4,6±2,8, 4,5±2,5, 5,3±1,4 See VAS, in peace 2,7±3,1, 1,5±2,6, 1,8±2,6, 2,1±2,6, 2,2±1,8, 2,6±1,3 see VAS, function 4,9±3,6, 3,5±2,9, 4,0±2,9, 4,0±3,2, 3,5±2,7, 4,3±1,9 according to the NRS. In the second group, pain during movement initially, after 2 weeks, 1, 3, 6, 12 months 5,6±2,1, 3,3±1,7, 3,6±1,8, 3,4±1,6, 3,7±2,4,3,0±1,2 See VAS, the pain is at rest 2,6±2,4, 1,9±1,7, 1,8±1,6, 1,8±1,7, 1,5±2,1, 0,6±1,0 see VAS, function 4,0±3,1, 3,3±2,6, 3,6±2,7, 3,4±2,6, 3,3±3,1, 2,6±1,7 according to the NRS.

Conclusions: A two-time injection of high molecular weight hyaluronic acid with chondroitin sulfate with an interval of 7 days has a higher effectiveness in reducing pain and increasing function.

P1624

THE USE OF VALGATING ORTHOSES IN DEFORMING OSTEOARTHRITIS OF THE KNEE JOINT

V. A. Nestereko[1], A. E. Karateev[1], E. I. Bialik[2], M. A. Makarov[1], S. A. Makarov[2], V. E. Bialik[2], A. E. Khramov[2]

[1]V.A. Nasonova Research Institute of Rheumatology 115522, Russian Federation, Moscow, Kashirskoye Highway, 34A, Moscow, Russia; [2]V.A. Nasonova Research Institute of Rheumatology 115522, Russian Federation, Moscow, Kashirskoye Highway, 34A, Moscow, Russia

Deforming osteoarthritis of the knee joint (OA KJ) with a predominantly hallux valgus angle has high rates of disability worldwide. The extensive possibilities of conservative therapy make it possible to delay surgical treatment. In recent years, orthotics have been actively complementing an integrated approach to the prevention and treatment of OA KJ. With deforming OA KJ with a predominance of varus deviation, unloading valgating orthoses are increasingly used. However, there is relatively little data in the literature on the use of functional, unloading (varus-valgus) orthoses.

The purpose of the study: To evaluate the effectiveness and safety of the use of an unloading, valgating orthosis in patients with OA 3st and varus deformity of the knee joint.

Material and methods: The study involved 20 patients with OA 3 st. and varus deformity of the KJ, 30.0% of them were men and 70.0% of women, average age 64.5±8.9 years, BMI 30±3.4. To confirm the stage and deformity of the KJ, all patients performed an X-ray under stress. The inclusion criteria were: Osteoarthritis of the knee joint stage III according to Kellgren-Lawrence, established according to clinical and X-ray examination, age from 45 to 85 years, visually analog scale (VAS) of pain ≥40mm. All patients used a functional, unloading (varus-valgus) orthosis for 3 months. The orthosis was adjusted four times every 7 days for 4 weeks. The result was evaluated 1 hour after using the orthosis in the clinic, as well as after 1-3 months, according to outpatient examination and card filling. The assessment was carried out by filling out the VAS and Knee Injury and Osteoarthritis Outcome Score (KOOS) questionnaires.

Result: According to the results of the assessment, 14 patients noted a significant decrease in pain intensity, but the dynamics of functional indicators was insignificant. The average pain and function indicators among all patients were: VAS initially 49.0±11.3, in the first hour of use 27.0±13.9, after 1 month. 18.0±9.7, after 3 months. 15.0±8.5. KOOS initially, after 1 and 3 months 48±10,3, 56,7±10,6, 60,0±10,6. No adverse reactions were observed with the use of a functional, unloading (varus-valgus) orthosis.

Conclusions: The relief (varus-valgus) orthosis significantly reduces the intensity of pain starting from the first hours of its use and maintains positive dynamics throughout the wearing of the orthosis, however, it does not affect the function of the joint.

P1625

PERIARTICULAR ADMINISTRATION OF LOW MOLECULAR WEIGHT HYALURONIC ACID IN RHEUMATIC DISEASES

V. A. Nestereko[1], A. E. Karateev[1], M. A. Makarov[1], E. I. Bialik[2], S. A. Makarov[2], V. E. Bialik[2], S. V. Maglevanyi[2]

[1]V.A. Nasonova Research Institute of Rheumatology 115522, Russian Federation, Moscow, Kashirskoye Highway, 34A, Moscow, Russia; [2]V.A. Nasonova Research Institute of Rheumatology 115522, Russian Federation, Moscow, Kashirskoye Highway, 34A, Moscow, Russia

Rheumatic pathology of the periarticular soft tissues (RPPT), which includes tendinitis, enthesitis, fasciitis, is the cause of acute and chronic pain. Treatment of breast cancer is based on the combined use of nonsteroidal anti-inflammatory drugs, physiotherapy, rehabilitation, as well as local injection therapy (LIT), including the administration of hyaluronic acid (HA). However, there is relatively little data on the evaluation of the effectiveness of the use of LIT with HA in these pathologies.

The purpose of the study: to evaluate the efficacy and safety of LIT HA 500-730 kDa in patients with various RPPT.

Material and methods: The study included 30 patients with various types of RPPT (subacromial impingement syndrome (SIS), lateral/medial epicondylitis, plantar fasciitis), 10 people with each pathology. (40.0% of men and 60.0% of women, age 56.1±14.9 years). All patients underwent LIT with the use of low-molecular-weight HA in the subcutaneous region for 3 injections with an interval of 7 ± 2 days. The inclusion criteria were: Age ≥ 18 years, diagnosed by clinical and instrumental parameters (MRI) of RPPT: SIS, lateral/medial epicondylitis, plantar fasciitis, moderate or severe pain (≥40 mm on a visually analog pain scale, VAS 0-100) for more than 3 months, insufficient effect from previous therapy with glucocorticoids, the need for regular administration of nonsteroidal anti-inflammatory drugs. The result of the treatment was assessed after 1 and 3 months according to a telephone survey. The study was approved by the local ethics committee.

Result: On the background of treatment, we received the following results: with SIS, your baseline, after 1 and 3 months, was 57,5 ±15,8, 37,5±13,8, 33,7± 14,0, ASES is initial, after 1 and 3 months. 54,2±13,7, 64,5±10,3, 65,5±9,8. With lateral epicondylitis, VAS initial, after 1 and 3 months. made up 54,0 ±13,4, 35,0±9,7, 34,0± 11,0, The Mayo Elbow questionnaire was initial, after 1 and 3 months. It was compiled 72,0 ±11,5, 79,2±9,0, 82,7± 7,7. In plantar fasciitis, the initial VAS after 1 and 3 months was 60.0 ±16.5, 36.6±19.3, 34.4± 15.8. Functional index of the foot at baseline, after 1 and 3 months. Compiled 47,2%±22,8, 39,6%±29,7, 39,0%±29,9. During the study, no adverse reactions were observed during the LIT.

Conclusions: Low molecular weight LIT GLCs are an effective and safe method of treating breast cancer of various localization.

P1626

MODERN APPROACHES TO REHABILITATION AFTER LIGAMENTOUS INJURIES OF THE KNEE JOINT

I. H. Gasanova[1], Z. H. Gasanli[2], D. V. Chigilov[2], V. A. Riabko[1]

[1]V.I. Vernadsky Crimean Federal University, Simferopol, Russia; [2]"Crimean Smile" Clinic, Simferopol, Russia

Objective: Ligamentous injuries of the knee joint (ACL, PCL, MCL, LCL) represent a significant proportion of sports-related trauma and are a leading cause of long-term instability and dysfunction. Despite extensive surgical and conservative methods, meta-analyses indicate a persistent rate of unsatisfactory outcomes (10-25%), including re-injuries, development of post-traumatic osteoarthritis, and incomplete functional recovery. This review aims to analyze contemporary evidence-based rehabilitation protocols, their efficacy, and selection criteria to optimize patient outcomes.

Material and Methods: A systematic literature search was conducted in PubMed, Cochrane Library, and Google Scholar databases for the period 2015-2025. Keywords included: "knee ligament rehabilitation," "ACL rehabilitation protocol," "neuromuscular training," "cryotherapy," "electrostimulation." Inclusion criteria were randomized controlled trials (RCTs), systematic reviews, and clinical guidelines. A total of 47 relevant publications were selected for analysis.

Results: Modern rehabilitation is based on principles of early protected mobilization and criterion-based progression, tailored to the type of injury, treatment (conservative/arthroscopic reconstruction), and individual patient goals (return to sport/activities of daily living). Early Postoperative/Post-Traumatic Phase (0-6 weeks): The focus has shifted from passive Continuous Passive Motion (CPM) therapy, whose efficacy remains debated, towards edema and pain control (RICE protocol, cryotherapy), restoration of full extension, and quadriceps activation using neuromuscular electrical stimulation (NMES). NMES has demonstrated superiority over voluntary exercise alone in overcoming arthrogenic muscle inhibition. Strength and Proprioception Restoration Phase (6-12 weeks and beyond): Therapeutic exercise progresses from closed to open kinetic chain exercises, advancing from isometric to concentric and eccentric loading. Hydrokinesiotherapy is utilized not only in later stages but also early on to facilitate movement in a reduced-gravity environment. A critical component is proprioceptive and neuromuscular training (balance exercises, unstable surfaces), which significantly reduces the risk of re-injury. Return-to-Activity Preparation Phase (4-9 months): Biofeedback (BFB) training devices are used to correct movement patterns, while mechanotherapy (isokinetic dynamometers) provides objective assessment of strength deficits. Massage is primarily employed as an adjunct for soft tissue management.

Conclusions: Effective rehabilitation requires a strict criterion-based progression and an individualized approach, focused on current functional capacity rather than fixed calendar timelines. Protocols incorporating early neuromuscular electrical stimulation (NMES), eccentric training, and mandatory proprioceptive-neuromuscular components have the strongest evidence base for efficacy. The success of rehabilitation should be measured by objective benchmarks—not merely a "return to prior function"—including a limb symmetry index >90% (isokinetic testing), successful functional performance tests (e.g., hop tests), and psychological readiness (e.g., ACL-RSI scale). Promising future directions include the use of telemedicine and wearable sensor technology for monitoring adherence and load management in outpatient settings.

P1627

CHRONIC PURULENT SACROILIITIS MIMICKING ANKYLOSING SPONDYLITIS: A CASE REPORT HIGHLIGHTING DIAGNOSTIC PITFALLS

I. H. Gasanova[1], V. A. Riabko[1], Z. H. Gasanli[2], D. V. Chigilov[2]

[1]V.I. Vernadsky Crimean Federal University, Simferopol, Russia; [2]"Crimean Smile" Clinic, Simferopol, Russia

Objective: Ankylosing spondylitis (AS) is a common cause of inflammatory back pain and sacroiliitis. However, infectious processes, such as purulent sacroiliitis, can present with similar clinical and radiographic features, leading to misdiagnosis and delayed treatment.

Objective: To present a challenging clinical case of chronic purulent sacroiliitis initially misdiagnosed as AS and to discuss key differential diagnostic features.

Case Presentation: A 24-year-old male presented with chronic inflammatory low back pain, morning stiffness, and evening fever (up to 38°C). History included significant back trauma in 2025. Initial workup revealed elevated acute-phase reactants (ESR 55 mm/h, positive CRP). Radiographs and CT scan demonstrated bilateral sacroiliitis (asymmetric, right > left) and syndesmophyte formation in the lumbar spine, resembling a "bamboo spine" pattern. Based on imaging findings, a provisional diagnosis of AS was made.

Diagnostic Reevaluation: Despite meeting the modified New York criteria (1984) for AS radiographically, several atypical features prompted further investigation: 1) Marked asymmetry of sacroiliac involvement; 2) Unusual cystic and destructive bone changes on CT adjacent to the right sacroiliac joint; 3) Negative HLA-B27 antigen. Subsequent pelvic MRI revealed a right-sided chronic purulent sacroiliitis with a fistulous tract and a soft-tissue abscess in the gluteal region. The final diagnosis was corrected to chronic pyogenic sacroiliitis.

Conclusion: This case underscores the critical importance of differential diagnosis in patients with suspected AS. Atypical features such as highly asymmetric or unilateral sacroiliitis, prominent cystic/destructive changes on advanced imaging (CT/MRI), absence of HLA-B27, and presence of systemic symptoms like fever should serve as "red flags" prompting a search for alternative diagnoses, including infectious spondylodiscitis or sacroiliitis. MRI is the imaging modality of choice for identifying soft-tissue involvement and abscess formation. A multidisciplinary approach involving rheumatologists, radiologists, and surgeons is essential for accurate diagnosis and management.

THE ROLE OF NAILFOLD VIDEOCAPILLAROSCOPY IN ASSESSING THE RISK OF PULMONARY ARTERIAL HYPERTENSION AND DIGITAL ISCHEMIC COMPLICATIONS IN SYSTEMIC SCLEROSIS: A COMPARATIVE STUDY

I. H. Gasanova[1], V. A. Riabko[1], Z. H. Gasanli[2], D. V. Chigilov[2]

[1]V.I. Vernadsky Crimean Federal University, Simferopol, Russia; [2]"Crimean Smile" Clinic, Simferopol, Russia

Objective: Pulmonary arterial hypertension (PAH) remains a leading cause of mortality in systemic sclerosis (SSc). Despite the shared pathogenesis of microvascular damage in SSc-associated PAH and Raynaud's phenomenon (RP), the predictive value of nailfold videocapillaroscopy (NVC) for PAH risk stratification remains debatable. The aim of our study was a comparative analysis of capillaroscopic patterns and the frequency of digital ischemic complications in SSc patients with and without PAH.

Methods: A single-center cross-sectional study included 116 patients meeting the 2013 ACR/EULAR criteria, divided into two groups: SSc-PAH (n=51) and SSc without PAH (n=65). PAH diagnosis was confirmed by right heart catheterization (mean pulmonary arterial pressure ≥25 mm Hg, pulmonary artery wedge pressure ≤15 mm Hg). All participants underwent standardized NVC of the 2nd–5th fingers of both hands. Capillaroscopic findings were classified qualitatively (normal, early, active, late scleroderma patterns according to Cutolo et al.) and semi-quantitatively (capillary density, presence of giant capillaries, microhemorrhages, avascular areas). History of RP, presence and time to onset of digital ulcers (DU), and severe ischemic complications (gangrene, amputation) were also analyzed.

Results: RP was present in 100% of patients in both groups. The distribution of scleroderma NVC patterns showed no statistically significant intergroup differences ($p>0.05$, χ^2 test): the late pattern was predominant in the SSc-PAH group (58.8% vs. 41.5% in the non-PAH group), early pattern – 33.3% vs. 24.6%, active pattern – 27.5% vs. 12.3%. The frequency of DUs was also comparable (49.0% in SSc-PAH vs. 49.2% in SSc without PAH; $p>0.05$). The median time from first SSc symptoms to DU development was 56 and 44 months, respectively ($p>0.05$). The frequency of severe ischemic complications (ischemia, gangrene, amputation) was low and did not differ between groups (9.8% vs. 12.3%; $p>0.05$).

Conclusions: Our study revealed no significant differences in capillaroscopic patterns or the nature of digital vascular complications between SSc patients with and without PAH. These findings suggest that standard NVC likely lacks independent prognostic value for the early detection of PAH in SSc patients. For PAH risk stratification, integrating NVC with other biomarkers (e.g., NT-proBNP levels, echocardiographic data, and lung diffusion function) is probably required. The search for specific capillaroscopic markers associated precisely with pulmonary vasculopathy in SSc represents a promising direction for future research.

P1629

THE INFLUENCE OF ANTHROPOMETRIC DATA ON THE RISK OF OSTEOPOROTIC HIP FRACTURES IN THE ELDERLY PATIENTS

I. H. Gasanova[1], V. A. Riabko[1], Z. H. Gasanli[2], D. V. Chigilov[2]

[1]V.I. Vernadsky Crimean Federal University, Simferopol, Russia; [2]"Crimean Smile" Clinic, Simferopol, Russia

Objective: Osteoporosis is one of the most significant medical and social problems in gerontology, with low-energy fractures being its most severe complication. Among these, proximal hip fractures are distinguished by particularly high mortality, disability rates, and economic costs. Therefore, identifying modifiable risk factors for such fractures is a crucial task for prevention. Among the numerous risk factors for osteoporotic fractures, anthropometric indicators such as height, body weight, and body mass index (BMI) are considered key and easily assessable parameters. Low body weight and low BMI are believed to be associated with decreased bone mineral density and an increased risk of falls. However, the relationship between these indicators and the risk of hip fractures per se in the elderly, especially considering gender differences, requires clarification. Most research focuses on the female population, while data on men remain less studied.

Material and Methods: The study observed 96 women and men with osteoporotic hip fractures: of these, 56 (58.3%) were women and 40 (41.7%) were men. The control group consisted of 100 individuals: 53 (53.0%) women and 47 (47.0%) men. The patients' height and weight were measured. Body mass index (BMI) was assessed, calculated as weight divided by height squared (kg/m²). A BMI <20 kg/m² was considered low, and low body weight was defined as less than 57 kg. Weight loss of more than 10% from weight at age over 25 was considered. A questionnaire was completed by a physician during a personal or telephone interview.

Results: The average weight of women was 66.7 [62.4; 75.8] kg in the fracture group and 72.13 [67.2; 75.7] kg in the control group. It was shown that women in the hip fracture group had a statistically significantly lower body weight than women in the group without fractures (67.8 and 72.03 kg, respectively, p=0.001). BMI in the fracture group was statistically significantly lower than in the control group (25.49 [22.6; 28.33] and 27.27 [26.1; 28.2], respectively, p=0.0001).

The average weight of men was 78.9 [73.0; 87.3] kg in the fracture group and 78.6 [75.0; 85.1] kg in the control group, with no significant differences between the groups (p=0.9). It was found that men in the hip fracture group had a statistically significantly greater height than those in the group without fractures (176.2 cm and 171.4 cm, respectively, p=0.003). BMI differed statistically significantly between men with fractures and men in the control group (25.41 [23.5; 27.2] and 27.48 [26.1; 28.8], respectively, p=0.0001).

Conclusions: Thus, in the group of individuals with osteoporotic hip fractures, anthropometric data (BMI) were statistically significantly lower than in the control group for both male and female patients.

P1630

CARDIAC RHYTHM AND CONDUCTION DISORDERS IN PATIENTS WITH SERONEGATIVE SPONDYLOARTHRITIS: PREVALENCE AND RISK FACTORS

E. M. Dolya[1], N. A. Revenko[1], V. A. Riabko[1], S. A. Khamidova[2], K. K. Khallaev[3]

[1]V.I. Vernadsky Crimean Federal University, Simferopol, Russia; [2]Tashkent State Pedagogic University named after Nizami, Tashkent, Uzbekistan; [3]Tashkent State Medical University, Tashkent, Uzbekistan

Objectives: Cardiovascular involvement is a well-known extra-articular manifestation of seronegative spondyloarthritis (SpA), including ankylosing spondylitis (AS) and psoriatic arthritis (PsA). The relationship between electrocardiographic (ECG) changes, disease activity, HLA-B27 status, and the potential impact of drug therapy remains a subject of research.

Material and Methods: A cross-sectional study included 120 patients with SpA (78 with AS, 42 with PsA; 83 men, 37 women) and 129 control subjects without rheumatologic, inflammatory bowel, or psoriatic diseases (60 men, 69 women). The control group was older on average. All participants underwent clinical examination, laboratory tests (ESR, CRP), ECG, and echocardiography. Statistical analysis was performed using Statistica 11.0 with Mann-Whitney U, Kruskal-Wallis, Fisher's exact tests, and Spearman's correlation. P-values <0.05 were considered significant.

Results: Rhythm and conduction disorders were detected in 48 SpA patients (40.0%; 95% CI 31.5-49.0%) and in 39 controls (30.2%; 95% CI 22.7-38.8%), but the difference was not statistically significant (p=0.113). Notably, ventricular extrasystoles were significantly more frequent in the SpA group (4.2% vs 0%, p=0.025). First- and second-degree atrioventricular (AV) block was found in 10 SpA patients (8.3%; 95% CI 4.5-14.7%), with three cases of 2nd-degree block requiring pacemaker implantation. No significant association was found between ECG abnormalities and gender (p=1.000), HLA-B27 status (p=0.184), disease activity (high activity: 76.5% vs 71.2%, p=0.698), ESR (p=1.000), or CRP (p=0.791). The prevalence did not differ significantly between AS (41%) and PsA (35.7%) subgroups (p=0.856). Arterial hypertension (AH) was significantly more common in SpA patients with arrhythmias compared to those without (p=0.048). A weak positive correlation was found between PQ interval duration and both patient age (r=0.3, p=0.0005) and body weight (r=0.3, p=0.001) in the SpA group only. No significant influence of the type of therapy (NSAIDs only: 17%, conventional synthetic DMARDs: 44%, biologic DMARDs: 44%) on the development of conduction disorders was established, though these groups were not comparable at baseline.

Conclusions: Cardiac conduction disorders, particularly AV blocks, are common in patients with SpA, affecting approximately 40% in this cohort. The presence of arterial hypertension may be an additional risk factor for arrhythmias in this population. No association was found with HLA-B27, disease activity, or inflammatory markers. The observed correlation of PQ interval with age and weight in SpA patients requires further investigation. Study limitations include the age and sex mismatch between groups and the non-randomized nature of treatment allocation.

P1631

FEATURES OF SUBCLINICAL MYOCARDIAL INVOLVEMENT IN PATIENTS WITH PSORIATIC ARTHRITIS: A COMPARATIVE ECHOCARDIOGRAPHIC STUDY

N. A. Revenko[1], E. M. Dolya[1], V. A. Riabko[1], K. K. Khallaev[2], S. A. Khamidova[3]

[1]V.I. Vernadsky Crimean Federal University, Simferopol, Russia; [2]Tashkent State Medical University, Tashkent, Uzbekistan; [3]Tashkent State Pedagogic University named after Nizami, Tashkent, Uzbekistan

Objective: Psoriatic arthritis (PsA) is a chronic immune-mediated inflammatory disease associated with systemic inflammation, which confers an independent risk of cardiovascular disease (CVD). Current evidence indicates an increased prevalence of diastolic dysfunction and altered left ventricular (LV) geometry in PsA patients. However, the pattern of myocardial involvement, particularly of the right heart, in PsA remains understudied.

Material and Methods: This single-center comparative study included 55 patients: Group 1 – 37 patients with PsA (mean age 56.8±10.9 years); Group 2 – 18 patients with plaque psoriasis without arthritis (61.2±12.8 years). Exclusion criteria: coronary artery disease, atrial fibrillation, chronic heart failure (NYHA class II-IV), severe arterial hypertension (>180/110 mm Hg), diabetes mellitus. All participants underwent transthoracic echocardiography (Vivid E95, GE) with assessment of LV and RV systolic and diastolic function, including pulsed-wave and tissue Doppler imaging. Statistical analysis was performed using StatTech v. 4.8.11. The Mann-Whitney U test and χ^2 test were used for group comparisons. A p-value <0.05 was considered statistically significant.

Results: The groups were comparable in terms of sex, body mass index, and traditional CVD risk factors (p>0.05). Patients with PsA showed significant impairment of RV diastolic function: the tricuspid E peak was lower (47 [41.5-56] vs. 57.5 [54.3-61.3] cm/s; p<0.001), and the A peak was higher (47 [42-53] vs. 36.5 [34.5-43.8] cm/s; p=0.032), resulting in a decreased E/A ratio (1.04 [0.79-1.28] vs. 1.52 [1.37-1.54]; p<0.001). In the PsO-only group, signs of concentric LV remodeling were more common: increased interventricular septum thickness, LV posterior wall thickness, and LV mass index (p<0.05). The frequency of concentric LV hypertrophy was 92.3% in the PsO group vs. 45.9% in the PsA group, where the eccentric form predominated (54.1%; p<0.001). LV diastolic dysfunction was less frequent in the PsA group (13.5% vs. 38.9%; p=0.043).

Conclusions: Patients with PsA exhibit a distinct pattern of myocardial involvement characterized by predominant RV diastolic dysfunction and eccentric LV hypertrophy geometry. In contrast, patients with psoriasis alone more frequently demonstrate concentric LV remodeling and a higher prevalence of LV diastolic dysfunction. These differences may reflect the diverse impact of chronic inflammation in these conditions on myocardial remodeling processes and warrant further investigation considering cardiovascular risk factors and anti-inflammatory therapy.

Disclosures: All authors declare no conflict of interests.

SERUM FIBROBLAST GROWTH FACTOR 21 (FGF21) LEVEL IN RELATION TO CONSTITUTIONAL FACTORS AND COMORBIDITY IN PATIENTS WITH RHEUMATOID ARTHRITIS

V. A. Riabko[1], N. N. Riabko[2], V. B. Kaliberdenko[1], S. A. Khamidova[3]

[1]V.I. Vernadsky Crimean Federal University, Simferopol, Russia; [2]Multidisciplinary Clinical Hospital of St. Luke of the Crimean Federal University named after V.I. Vernadsky, Simferopol, Russia; [3]Tashkent State Pedagogic University named after Nizami, Tashkent, Uzbekistan

Objective: Fibroblast Growth Factor 21 (FGF21) is a hepatokine/myokine acting as an endocrine metabolic regulator. It plays a crucial role in glucose and lipid metabolism, particularly under conditions of metabolic stress. In chronic inflammatory and metabolic diseases, including type 2 diabetes mellitus (T2DM) and obesity, circulating FGF21 levels are often elevated, which is interpreted as a compensatory response or the development of tissue resistance to its action. In rheumatoid arthritis (RA), a disease associated with systemic inflammation and high cardiometabolic risk, the role of FGF21 remains insufficiently studied, and available data are contradictory. The relationship between FGF21 levels and constitutional factors (age, BMI) and comorbidity in RA patients has not been systematically investigated.

Material and Methods: A cross-sectional study included 95 female patients with RA diagnosed according to the 2010 ACR/EULAR criteria. Exclusion criteria were: trauma or surgery within the last 3 months, acute infectious diseases, oncological pathology, and decompensated somatic conditions. Men were excluded to eliminate gender as a confounding factor. The median (interquartile range, IQR) age was 49.2 (36.7-71.7) years, disease duration was 8.9 (3.9-18.6) years, and BMI was 27.1 (25.0-31.8) kg/m². Rheumatoid factor and anti-CCP antibodies were present in 70.5% and 64.2% of patients, respectively. Statistical analysis was performed using non-parametric methods: data are presented as Me [Q1-Q3]; Spearman's rank correlation coefficient (ρ) was used to assess relationships between variables; the Mann-Whitney U test was used for intergroup comparisons. A p-value <0.05 was considered statistically significant.

Results: A significant positive correlation was found between serum FGF21 levels and body weight (ρ=0.56; p<0.0001) and BMI (ρ=0.59; p<0.0001). The correlation with age showed a trend towards significance (ρ=0.20; p=0.057). A weak but significant negative correlation was observed between FGF21 levels and RA duration (ρ=-0.22; p=0.041). Patients with comorbid T2DM (n=12) had significantly higher median FGF21 levels compared to non-diabetic patients: 1651.0 pg/mL vs. 724.0 pg/mL, respectively (p=0.026). Furthermore, FGF21 levels in the T2DM subgroup exceeded the upper limit of the reference range.

Conclusions:

The strong positive correlation of serum FGF21 with BMI in RA patients confirms the role of adipose tissue as a key target and potential source of this hormone in chronic inflammation.

The identified negative correlation with RA duration requires further investigation in longitudinal studies. It may reflect a specific dynamic of FGF21 production during the progression of RA, potentially indicating an exhaustion of adaptive metabolic responses.

The significant increase in FGF21 in RA patients with T2DM aligns with

the concept of FGF21 resistance in metabolic disorders. Elevated FGF21 in this comorbidity may serve as a biomarker of pronounced metabolic dysfunction.
This study highlights FGF21 as a potential link between RA, metabolic syndrome, and comorbidity, underscoring the importance of assessing metabolic status in the management of RA patients.

P1633

METHODS OF IMAGING DIAGNOSIS IN ANKYLOSING SPONDYLITIS: THE ROLE OF MAGNETIC RESONANCE IMAGING

N. N. Riabko[1], V. A. Riabko[2], V. B. Kaliberdenko[2], S. A. Khamidova[3]

[1]Multidisciplinary Clinical Hospital of St. Luke of the Crimean Federal University named after V.I. Vernadsky, Simferopol, Russia; [2]V.I. Vernadsky Crimean Federal University, Simferopol, Russia; [3]Tashkent State Pedagogic University named after Nizami, Tashkent, Uzbekistan

Objective: Ankylosing spondylitis (AS) is characterized by the slow progression of structural changes in the sacroiliac joints (SIJ) and spine, leading to delayed radiographic diagnosis. Magnetic resonance imaging (MRI) allows for the visualization of active inflammatory changes (bone marrow edema) at early stages, preceding the formation of erosions, sclerosis, and ankylosis.
Material and Methods: The study included 84 patients with AS (median age 27 years [IQR: 22-35], median symptom duration 3 years [IQR: 1-6]). All patients underwent pelvic radiography. MRI of the SIJ was performed in 80 (95.2%) patients, and spinal MRI in 68 (81.0%). The control group consisted of 10 patients with other joint pathologies. MRI was performed on a Philips Multiva 1.5 T scanner. The stage of sacroiliitis on radiographs was assessed according to the modified New York criteria. Active sacroiliitis on MRI was diagnosed according to ASAS criteria based on the presence of bone marrow edema in typical subchondral areas of the SIJ, detected on STIR/T2-FatSat sequences or post-contrast T1-weighted images. Structural changes (erosions, sclerosis, ankylosis, fat metaplasia) were also evaluated.
Results: Bilateral sacroiliitis (stage II-III) was detected in 62 (73.8%) patients, unilateral (stage III) in 6 (7.1%). Active sacroiliitis on MRI was diagnosed in 65% of patients in the main group. Structural changes of the SIJ (erosions, sclerosis, ankylosis, fat metaplasia) were found in 65% of patients. In the control group, active inflammatory changes in the SIJ were absent. No statistically significant correlation was found between the severity of clinical symptoms and the presence of active inflammation on MRI of the SIJ ($p>0.05$). The specificity of MRI signs of active inflammation in our sample was 100%, although they were predominantly identified in patients with already established radiographic sacroiliitis.
Conclusions: MRI is a highly specific method for detecting both active inflammation and structural damage in AS. Its high diagnostic value is confirmed by its inclusion in the modern ASAS classification criteria. The lack of a direct correlation between MRI activity and clinical symptoms emphasizes the role of imaging as an objective assessment tool. To verify early (pre-radiographic) axial spondyloarthritis, a prospective selection of patients with a shorter disease duration is required.

P1634

ASSOCIATION OF TNFAIP3, TNFA, CTLA-4, BAFF, KCNS1, AND STAT4 GENE POLYMORPHISMS WITH TREATMENT RESPONSE IN RHEUMATOID ARTHRITIS PATIENTS SWITCHING BETWEEN BIOLOGICAL AND TARGETED SYNTHETIC DMARDS

V. B. Kaliberdenko[1], M. G. Nikolashin[2], S. A. Khamidova[3], K. K. Khallaev[4]

[1]I. Vernadsky Crimean Federal University, Simferopol, Russia; [2]V.I. Vernadsky Crimean Federal University, Simferopol, Russia; [3]Tashkent State Pedagogic University named after Nizami, Tashkent, Uzbekistan; [4]Tashkent State Medical University, Tashkent, Uzbekistan

Objective: Personalizing therapy for rheumatoid arthritis (RA) remains a pressing challenge. A promising approach is identifying genetic predictors of response to biological (bDMARDs) and targeted synthetic (tsDMARDs) disease-modifying antirheumatic drugs, particularly in patients who failed prior targeted therapy.
Material and Methods: 94 RA patients (85.1% female, mean age 47.2±13.8 years) with moderate/high disease activity (DAS28-CRP 5.38±0.90) who switched from an ineffective b/tsDMARD to an agent with a different mechanism of action. Therapy distribution: TNF-α inhibitors – 12 (12.8%), IL-6R inhibitor – 27 (28.7%), rituximab – 46 (48.9%), JAK inhibitors – 9 (9.6%). Outcome assessment: At 24 weeks, treatment response was evaluated using DAS28-CRP and EULAR criteria. Patients were categorized as responders (EULAR good/moderate response and/or DAS28-CRP ≤3.2) or non-responders (no EULAR response, DAS28-CRP >3.2). Genetic analysis: Genotyping was performed by real-time PCR. Statistical analysis: Associations were assessed using multivariate logistic regression adjusted for age, sex, baseline DAS28-CRP, and RF/ACPA seropositivity. Results are presented as odds ratios (OR) with 95% confidence intervals (CI).
Results: Responder and non-responder groups (n=47 each) were comparable in key clinical and demographic parameters. After adjustment for confounders, independent associations were found:
Risk of non-response: Carriage of the T allele of TNFAIP3 rs10499194 (CT+TT genotypes) (OR=2.84; 95% CI: 1.23–6.56; p=0.013) and the T allele of STAT4 rs7574865 (GT+TT genotypes) (OR=3.18; 95% CI: 1.36–7.46; p=0.007).
Factors for better response: Carriage of the minor T allele of BAFF rs9514828 (CT+TT genotypes) (OR=0.25; 95% CI: 0.10–0.66; p=0.004) and the minor G allele of KCNS1 rs734784 (AG+GG genotypes) (OR=0.29; 95% CI: 0.12–0.74; p=0.008).
For TNFA rs1800629, a multiplicative model was significant (G vs A allele: OR=3.12; 95% CI: 1.10–9.03; p=0.037). For *CTLA-4* rs231775, a superdominant model was significant (AA+GG vs AG genotypes: OR=2.60; 95% CI: 1.14–6.25; p=0.022).
Conclusions: In this study, polymorphisms in TNFAIP3 (rs10499194), BAFF (rs9514828), KCNS1 (rs734784), and STAT4 (rs7574865) genes were identified as potential independent genetic markers of treatment response after switching b/tsDMARD classes in RA. These findings require validation in independent, larger cohorts and may contribute to developing personalized treatment selection algorithms in the future.

P1635

COMPARATIVE ANALYSIS OF SPONTANEOUS AND INDUCED MONOCYTIC EXTRACELLULAR TRAP FORMATION IN RHEUMATOID ARTHRITIS AND OSTEOARTHRITIS: PATHOGENETIC AND DIAGNOSTIC ASPECTS

V. B. Kaliberdenko[1], M. G. Nikolashin[2], S. A. Khamidova[3], K. K. Khallaev[4]

[1]I. Vernadsky Crimean Federal University, Simferopol, Russia; [2]V.I. Vernadsky Crimean Federal University, Simferopol, Russia; [3]Tashkent State Pedagogic University named after Nizami, Tashkent, Uzbekistan; [4]Tashkent State Medical University, Tashkent, Uzbekistan

Objective: Dysregulation of innate immunity plays a key role in the pathogenesis of rheumatoid arthritis (RA) and osteoarthritis (OA). Recently, particular attention has been paid to the formation of monocytic extracellular traps (METs). In contrast to the relatively well-studied neutrophil extracellular traps (NETs), the mechanisms of MET formation (METosis) and their contribution to inflammation chronicity in RA and OA remain insufficiently studied. A comparative analysis of spontaneous and induced METosis depending on disease activity may contribute to understanding the pathogenetic differences between autoimmune (RA) and degenerative-inflammatory (OA) processes, as well as to the search for new differential diagnostic markers.

Material and Methods: The study included 37 RA patients (ACR/EULAR 2010 criteria), 35 OA patients, and 33 conditionally healthy donors (control). RA patients were in remission at inclusion (DAS28 ≤ 2.6), OA patients were not in an exacerbation phase. During follow-up, 17 (45.9%) RA patients developed active disease (DAS28 >3.2), and 25 (71.4%) OA patients developed synovitis flare-up. Peripheral blood monocytes were isolated by density gradient centrifugation using iodixanol (1.068 g/mL) according to an originally modified protocol. Cell viability and population purity were assessed using trypan blue staining and Romanowsky-Giemsa staining. METosis was induced by phorbol 12-myristate 13-acetate (PMA, 100 nM). MET formation was quantified by fluorescence microscopy using Sytox Green. Statistical analysis was performed using STATISTICA 11. Results are presented as median and 95% confidence interval (CI). Differences between groups were assessed based on the absence of 95% CI overlap.

Results: The rates of spontaneous and PMA-induced METosis were significantly higher in RA and OA patients compared to the control group (5.5% [4.3-6.7] and 18.1% [15.4-20.8], respectively). In RA remission, values were 8.7% [8.3-9.1] and 26.2% [24.5-27.9], while in active RA they reached 18.1% [17.8-18.4] and 38.2% [38.0-38.4]. In OA patients without flare-up, the rates were 7.9% [7.1-8.7] and 21.7% [19.2-24.2], and during synovitis – 15.0% [14.5-15.5] and 30.2% [28.1-32.3]. Upon disease activation, the relative increase in spontaneous METosis was more pronounced than that of induced METosis: +108.1% vs. +45.8% in RA and +89.9% vs. +39.2% in OA. The ratio of spontaneous to induced METosis levels was higher in active RA (2.8) than in exacerbated OA (2.3).

Conclusions: The obtained data indicate a significant increase in MET formation, especially spontaneous, in active RA and OA, confirming the involvement of METosis in the pathogenesis of chronic inflammation. The more pronounced dynamics of spontaneous METosis in RA likely reflect fundamental differences in innate immune activation in autoimmune versus degenerative joint diseases. MET parameters, particularly the ratio of spontaneous to induced forms, may be considered as promising auxiliary markers for differential diagnosis and disease activity assessment. Further studies accounting for anti-inflammatory therapy are required to evaluate METs as a potential therapeutic target.

P1636

THYROID NODULES AND SUBCLINICAL HYPOTHYROIDISM ARE COMMON IN ARMENIA

N. Hutchings[1], V. Babalyan[2], M. Qefoyan[2], S. Baghdasaryan[2], A. Afrikyan[2], A. Aghasaryan[2], S. Kara-Poghosyan[2], J. P. Bilezikian[1]

[1]Columbia University, College of Physicians & Surgeons, New York, United States; [2]Osteoporosis Center of Armenia, Yerevan, Armenia

Objectives: Bone health is heavily influenced by thyroid condition, and Armenia historically faced endemic goiter due to iodine insufficiency. This is now alleviated by widespread fortification of salt, however it is remains unknown if this has influenced the prevalence of thyroid hormone, antibody, or ultrasound abnormalities.

Material and Methods: Between Dec 2022 and Apr 2025, we randomly selected participants in a population-weighted geographical distribution representing all provinces of the Armenia. All underwent thyroid ultrasound on site, and blood was obtained for TSH (with reflex to free T4) and TPO or TRAb as indicated. A subset underwent TPO screening regardless of TSH level. The study was approved by the IRB of Columbia University and the Ethics Committee of Yerevan State Medical University.

Results: A total of 2170 participants from 64 sites were enrolled (71% female, average age 47), of which 102 were excluded from analysis for missing data. Mean TSH of the middle 90% of female participants was 2.52. Of all female participants, 23 (1.57%) had low TSH; overall prevalence of Graves' autoimmune hyperthyroidism was 0.27%. Of all female participants, 215 (14.68%) had elevated TSH, of whom 44 (3.00%) had low FT4 and the overall prevalence of Hashimoto's autoimmune hypothyroidism was 2.39%. Mean TSH of the middle 90% of the male participants was 1.93. Of the male participants, 6 (1.00%) had low TSH and 47 (7.79%) had high TSH; overall prevalence of Graves' was 0.17% and of Hashimoto's was 1.49%. Nodules were noted in nearly 40% of all participants, with enlarged thyroid in 6.00%. There was no significant relationship between age and TSH, age and thyroid size, or TSH and size among the men or women. Of the 1557 randomly screened, 20.17% had elevated TPO, and of those, only 10.51% (2.12% of the total) had clinically significant Hashimoto's.

Conclusion: Subclinical hypothyroidism is common among women in Armenia as is the presence of thyroid nodules, however the prevalence of clinically relevant thyroid dysfunction and autoimmune thyroid disease is reassuringly low, approximately on par with prior large epidemiologic studies in other countries.

P1637

RELATIONSHIP OF LIPOPOLYSACCHARIDE BINDING PROTEIN LEVEL WITH DISEASE ACTIVITY ON THE DAS28 SCALE IN PATIENTS WITH GOUT

V. Beloglazov[1], K. Bubley[1], I. Yatskov[1], O. Lifanova[1]

[1]V.I. Vernadsky Crimean Federal University, Simferopol, Russia

Objective: To analyze the relationship of lipopolysaccharide binding systems (LBPs) in the development and maintenance of inflammation in gout.
Materials and methods: Blood sampling was performed in patients with gout and the level of LBP in the blood plasma of 42 patients with gout was studied. The LBP concentration in plasma was measured by solid-phase enzyme immunoassay (ELISA) using Cloud Clone Corp. kits. (Hubei, China). Statistical data analysis was performed using IBM SPSS Statistics 26 software.
Results:A statistical analysis of the data of patients with gout revealed a significant positive correlation between the level of lipopolysaccharide-binding protein (LBP) and the degree of disease activity on the DAS28 scale (Spearmen correlation coefficient r = 0.61, p < 0.001; n = 38). The average LBP level was 14.18 ng/ml [10.87; 17.4], and the average DAS28 index was 4.1 [3.3; 5.1]. These data may indicate an association of systemic inflammatory activity with impaired barrier function and increased exposure to lipopolysaccharides in patients with gout, which confirms the pathogenetic significance of LBP as a potential biomarker of disease activity. The identification of a significant correlation between LBP and DAS28 highlights the prospects for further research on the role of endotoxinemia in the formation of severe forms of gout and may contribute to the search for new therapeutic targets.
Conclusion: The study showed that the level of lipopolysaccharide-binding protein (LBP) in patients with gout significantly correlates with the activity of the disease on the DAS28 scale. The revealed dependence confirms the involvement of endotoxin-limiting systems in maintaining chronic inflammation in gout and highlights the pathogenetic relationship between LBP and gout activity. The results obtained allow LBP to be considered not only as a potential biomarker of disease activity, but also shows that a disease such as gout has a multifactorial etiology.

P1638

THE EFFECTS OF TIBIAL FRACTURE MODELING AFTER 60-DAY ADMINISTRATION OF SODIUM BENZOATE OR TARTRAZINE ON THE MICROELEMENTAL COMPOSITION OF THE MANDIBULAR RAMUS IN WHITE RATS

V. Bibik[1], V. Luzin[1], O. Churilin[1], N. Muzychuk[1], A. Blinkov[1]

[1]FSBEI HI ST. LUKA LSMU of MOH of Russia; Human anatomy department, Lugansk, Russia

Objective of the study was to establish changes in the micro elemental content of the mandible of white rats with tibial defect (TB) after 60-day administration of sodium benzoate (SB) or tartrazine (TTZ).
Material and methods. 210 white rats weighing 200–210 g, were divided into 6 groups: group 1 — control; groups 2 and 3 — rats that received SB intragastrically in dosage of 1000 mg/kg/day or TTZ in dosage of 1500 mg/kg/day; group 4 — rats with a defect in the tibia. Groups 5 and 6 — rats with defect in the tibia after the end of the challenge. The content of copper and manganese in the ramus of mandible was determined using atomic two-photon absorptiometry.
Results. In group 2, the copper content from day 3 to day 24 decreased by 6.87-16.99%, and the manganese content from day 10 to day 45 decreased by 6.30-12.72%. In group 3, from day 3 to day 45, the copper content was lower than that of group 1 by 5.04-17.61%, and the manganese content decreased by 6.51-10.69%. In group 5, the manganese content by days 10 and 15 decreased by 7.54% and 8.51%, and the copper content by days 15 and 45 decreased by 8.02% and 4.78%. In group 6, the copper and manganese content from day 10 to day 45 was lower than the values of group 3 by 5.12%, 7.42%, 5.70% and 5.66%, and by 6.93%, 8.50%, 9.82% and 7.78%.
Conclusion. Exposure of experimental animals to SB or TTZ is accompanied by depletion of the microelement composition of the mandible. Damage to the TB against this background is accompanied by an aggravation of the identified changes.

P1639

THE OSTEOPOROSIS CARE SITUATION – A QUALITATIVE STUDY ON CLINICAL ERRORS OF PHYSICIANS IN SOUTHERN GERMANY

V. C. Jung[1], L. T. Braun[2], R. Schmidmaier[2]

[1]Department of Operative Dentistry and Periodontology, University of Ulm, University Hospital Ulm, Medical Faculty Ulm, Germany, Ulm, Germany; [2]LMU Munich, Munich, Germany

Objectives: The persistent osteoporosis care gap poses a significant healthcare challenge. In this qualitative interview study, physicians' clinical errors in the diagnosis and treatment of osteoporosis, as well as the possible reasons and causes, were categorized and analyzed.

Material and Methods: From June 2020 to November 2021 interviews with 30 physicians involved in osteoporosis care were conducted. Using a semi-standardized guideline, the physicians were surveyed on the diagnosis and treatment of osteoporosis. The primary source for the questionnaire was the DVO guideline 2017 (current at data collection). Transcription was done according to Dresing and Pehl. The qualitative content analysis was performed using the approach by Kuckartz and was computer-aided by the qualitative analysis software MAXQDA.

Results: The final category system formed the thematic structure of the analysis steps. In total, the system comprised approximately 92 individual categories, distributed across up to six hierarchical levels. Clinical errors were categorized as diagnostic errors, therapeutic errors, and faulty base for decision-making and corresponding subcategories. The analysis revealed pronounced heterogeneity in the care processes and the associated expert knowledge.
47% of the 30 respondents had not read the current osteoporosis guideline at the time of the survey. Of the 16 respondents who had read the guideline, 31% stated that the guideline was incomprehensible and too complex for application. This was also reflected in the coding frequency. The most frequently coded diagnostic errors were insufficient knowledge of: (1) risk profile (93%) and (2) basic diagnostic recommendations (87%).
Regarding therapeutic errors, these were inaccurate knowledge of: (1) side effects and consequences (90%), (2) specific treatment indications (77%), (3) follow-up (73%), and (4) incorrect context generation and interpretation (63%).

Systemic causes of the care gap were found, among others, insufficient DXA cost coverage and budgeting for specific medications. Systemic diagnostic errors included unclear responsibilities and inefficient processes.

Conclusions: Inadequate knowledge base and the subsequent misapplication or omission of guideline recommendations contribute to the deficient provision of osteoporosis care.

Overly complex guidelines complicate practical implementation and serve as a deterrent. The results of this study can inform research on clinical errors in osteoporosis and develop new approaches for revising guidelines and training concepts.

P1640

A TAXONOMY OF CLINICAL ERRORS IN OSTEOPOROSIS CARE – RESULTS OF A PROSPECTIVE QUALITATIVE STUDY IN SOUTHERN GERMANY

V. C. Jung[1], L. T. Braun[2], R. Schmidmaier[2]

[1]Department of Operative Dentistry and Periodontology, University of Ulm, University Hospital Ulm, Medical Faculty Ulm, Germany, Ulm, Germany; [2]LMU Munich, Munich, Germany

Objectives: The osteoporosis care gap is a worldwide phenomenon with inadequate treatment decisions leading to underdiagnosis and suboptimal therapy. The aim of this study was to categorize and analyze clinical errors (diagnostic and therapeutic errors) made by physicians in the context of osteoporosis care and develop a taxonomy that incorporates clinical and therapeutic reasoning, while synthesizing on pre-existing models and delve deeper into aspects of therapeutic reasoning.

Material and Methods: From June 2020 to November 2021 interviews with 30 physicians from 12 medical fields involved in osteoporosis care were conducted. Using a semi-standardized guideline, the physicians were surveyed on the diagnosis and treatment of osteoporosis. Transcription was done according to Dresing and Pehl. Qualitative content analysis was performed using the approach by Kuckartz and was computer-aided by the qualitative analysis software MAXQDA.

Results: The developed category system was an adaptation on pre-existing studies and medical malpractice definitions in Germany. It was further modified to the gathered qualitative data. Among the new categories developed in this study: (1) faulty base for decision making with subcategories (1.1) relying on external opinions and (1.2) gut feeling/personal experience, (2) organizational diagnostic error: unclear responsibilities, (3) systemic therapeutic errors with (3.1) budgeting influences drug selection, (4) therapeutic faulty context generation and interpretation: meshing of osteoporosis and oncological therapy (therapeutic misidentification), (4.1) issues with implementing the guideline in treatment, (5) error of omission with (5.1) no regular dental checkups. Code-Relations Models revealed, inter alia, an interference between faulty data gathering in diagnostics and faulty therapeutic knowledge regarding the risks, side effects, and consequences of specific osteoporosis medications.

Conclusions: Clinical errors in osteoporosis care are multifactorial, encompassing both diagnostic and therapeutic errors. A comprehensive understanding of the underlying causes and reciprocal relationships requires an integrated consideration of the two. The identified dominant problems involved cognitive (faulty knowledge and implementation) and systemic factors in diagnostic and therapeutic processes.

This study is one of the first to build on pre-existing models and its categorical framework is foundational for the refinement of therapeutic reasoning and its applicability across other medical fields.

P1641

TREATMENT OF OSTEOPOROSIS IN THE FIELD OF RHEUMATOID ARTHRITIS

V. D. Valbona[1], S. H. E. Shkodrani[2], A. K. Artur[1], A. Z. Artur[1], J. I. Isaku[3]

[1]Padilion of Reumatology, Mother Teresa Hospital Centre, Tirana, Albania; [2]Padilion of Dermatology, Mother Teresa Hospital Centre, Tirana, Albania; [3]Faculty of Medical Sciences, University of Medicine, Tirana, Albania

Background. Individuals with RA are at increased risk of developing osteoporosis. Chronic inflammation associated with RA, medications used to treat the disease, particularly prednisone and other corticosteroid ("steroids") drugs, all contribute to this risk. Inadequate intake or absorption of bone-building calcium, and less exercise due to fatigue and pain, may contribute to reduction in bone formation, bone mineral fractures due to osteoporosis than the average population, as well as a 40% increase in hip fractures, as well as loss of height and periodontal bone loss (loss of bone around the teeth in the jaw and skull).
Objectives. This study aims to identify the risk of fractures of osteoporosis in patients with RA with a prolonged treatement with corticosteroids. On the other hand we will evaluate how Osteoporosis has changed under treatment with Alendromat.
Methods. The study included 68 cases presented at the Rheumatology ward, QSUT and Trauma Hospital Tirana, Albania who had been under systematic treatment with AIJS for some time and have developed fractures due to Osteoporosis. Cases has been taken from patient with AR witch have developed fractures due to Osteoporosis.
Results. In the sample taken in the study, it was found 82 % (56) of the patients with AR developed Osteoporosis. It is known that the usage for a prolonged time of AIJS increase the risk of these condition. From this, 89% (61) patients have developed fractures due to Osteoporosis.52% (30) patients have fracture of bachin, 32% (18) patients developed fracture of toracal colon, 28% (16) patients fracture of femur. After the treatment with bisphosphonate (Alendronat) for more than 3 years it was seen that there was a significant improvement in the reduction of fractures. We have a reduction in the number of cases with fractures over 68% (38) patients of the cases that had developed at least one such before. At the same time in these patientis DEXA showed noticeable improvements.
Conclusions Loss of bone mineral density occurs naturally with the normal aging process. Rheumatoid arthritis and its treatment with corticosteroids can increase an individual's chance of developing a low bone mineral state such as osteopenia or osteoporosis.
Screening tests to identify poor bone mineralization are important along with treatment with Alendronat. Conservative measures such as diet, supplements, exercises and fall prevention are all important to include in a bone-healthy lifestyle. We have a reduction in the number of cases with fractures over 68% (38) patients of the cases that had developed at least one before.
Key words: *Reumatoid Arthritis, Osteoprosis, AIJS, Fracture, bisphosphonate (Alendromat)*

P1642

RELATIONSHIP BETWEEN EPIGENETIC AGE ACCELERATION AND PHYSICAL FUNCTION IN OLDER ADULTS WITH SARCOPENIA

V. Ginevičienė[1], K. Merkelytė[1], E. Pranckevičienė[1], A. Urnikytė[1], G. Anikevičiūtė[1], J. Kilaitė[1], R. Dadelienė[1], A. Mastavičiūtė[1], I. E. Jamontaitė[1], V. Alekna[1], I. Ahmetov[2]

[1]Vilnius University, Faculty of Medicine, Vilnius, Lithuania;
[2]Liverpool John Moores University, Liverpool, United Kingdom

Objective: to evaluate biological age acceleration (BAA) using two DNA methylation (DNAm)–based epigenetic clocks (GrimAge and PhenoAge) and to examine the associations between DNAmderived epigenetic clocks measures and physical functioning in older adults with and without sarcopenia.
Materials and Methods: A total of 238 participants were included: 64 communitydwelling older adults aged 65–96 years with sarcopenia (men n=20; women n=44) and 174 controls aged 65–75 years (men n=80; women n=94). Sarcopenia was defined according to EWGSOP2 criteria. Body composition and physical function (handgrip strength, gait speed) were assessed. DNA was extracted from blood leukocytes using the PureLink Genomic DNA Mini Kit. DNA was bisulfiteconverted using the Zymo EZ DNAm kit and analyzed with the Illumina Infinium MethylationEPIC v2.0 array, generating methylation data across ~850,000 CpG sites. DNAm-based epigenetic age was calculated in RStudio using the dnaMethyAge package and two validated clocks: PhenoAge and GrimAge. BAA was defined as the residual from regressing epigenetic age on chronological age, representing individual deviation from expected biological aging.
Results: No significant differences in BAA were found between sarcopenia and control groups using PhenoAge (p=0.225) or GrimAge (p=1.000). In the sarcopenia group, gait speed ranged 0.368–0.872 m/s, handgrip strength 4.00–28.67 kg, and muscle mass index 4.50–8.72 kg/m². BAA was not associated with gait speed or muscle mass index in either model. However, in the GrimAge model, BAA showed a significant positive association with handgrip strength (r=0.277, p=0.04). These differences may reflect the distinct orientations of the models: PhenoAge captures physiological aging processes, whereas GrimAge is more strongly linked to systemic biological aging and mortality risk.
Conclusion: Biological age acceleration estimated by PhenoAge and GrimAge did not differ significantly between older adults with and without sarcopenia, suggesting that accelerated epigenetic aging was not directly associated with sarcopenia in this sample. Although GrimAgebased biological age acceleration was positively associated with handgrip strength, this relationship likely reflects the broader systemic and mortalityrelated components captured by GrimAge rather than direct links to muscle function.
This project has received funding from the Research Council of Lithuania (LMTLT), agreement No S-MIP-22-36.

P1643

THE INFLUENCE OF THE C-159T POLYMORPHISM OF THE CD14 GENE ON THE CLINICAL MANIFESTATION OF ANKYLOSING SPONDYLITIS AND THE FORMATION OF CARDIOVASCULAR RISK

V. Beloglazov[1], A. Gaffarova[1], E. Ageeva[1], I. Yatskov[1], V. Kirichenko[1]

[1]V.I. Vernadsky Crimean Federal University, Simferopol, Russia

Objective: To evaluate the role of the C-159T polymorphism of the CD14 gene on the disease course and cardiovascular risk (CVR) in ankylosing spondylitis (AS).

Materials and Methods: The study included 176 patients diagnosed with AS. Genotyping of the C-159T polymorphism of the CD14 gene was performed using polymerase chain reaction.

Results. Patients with the TT genotype had the lowest BASMI index at a statistically significant level (CC 5.0 [3.0; 6.0] vs. CT 5.0 [4.0; 8.0] vs. TT 4.0 [3.0; 5.0], p=0.014, p2.3=0.016. CC homozygotes had the lowest HDL level (CC 1.4 [1.1; 1.6] vs. CT 1.8 [1.3; 2.3] vs. TT 1.6 [1.5; 1.9], p=0.026).

Carriage of the C allele in both hetero- and homozygotes was associated with a higher incidence of spondylitis at a statistically significant level (CC 32 (42.1%) vs. CT 8 (36.4%) vs. TT 14 (18.9%), p1,3=0,003, p=0,008). TT homozygotes had the highest frequency of detection of radiographic stage 2 of sacroiliitis (CC 40 (52.6%) vs. CT 10 (45.5%) vs. TT 58 (78.4%), p2,3=0.036), while carriage of the C allele determined more pronounced radiographic changes in the form of 3 (CC 16 (21.1%) vs. CT 6 (27.3%) vs. CC8 (10.8%)) and 4 radiographic stages (CC 20 (26.3%) vs. CT 6 (27.3%) vs. TT 8 (10.8%), p2,3=0.049). TT homozygotes had the highest frequency of radiographic stage 0 coxitis (CC 14 (17.9%) vs. CT 0 (0.0%) vs. TT 16 (21.1%), p1.2=0.033, p2.3=0.019). While CT heterozygotes had radiographic stage 3 coxitis most often (CC 8 (10.3%) vs. CT 8 (36.4%) vs. TT 10 (13.2%), p1.2=0.004, p2.3=0.014). A significantly higher frequency of extraskeletal manifestations was recorded in CC homozygotes (CC 24 (30.8%) vs. CT 2 (9.1%) vs. TT 14 (8.4%), p1.2=0.041, p=0.05).

The frequency of detection of hypertension was lowest in patients with genotype CT (CC 26 (41.9%) vs. CT 2 (10.0%) vs. TT 32 (45.7%), p1.2=0.026, p2.3=0.005, p=0.014). Carriers of the CT genotype significantly more often had hyperuricemia (CC 6 (8.3%) vs. CT 6 (33.3%) vs. TT 8 (11.1%), p1.2=0.013, p2.3=0.049, p=0.014).

Conclusion. Identification of the C-159T SNP of the CD14 gene is useful in predicting the progressive course of AS, as well as the development of comorbid pathology associated with CVR.

P1644

THE IMPACT OF PHYSIOTHERAPY ON BONE MINERAL DENSITY IN WOMEN WITH POSTMENOPAUSAL OSTEOPOROSIS AFTER ONE YEAR OF TREATMENT

V. Koevska[1], B. Mitrevska[1], C. Gjeracaroska-Saveska[1], M. Gocevska[1], B. Klacovska[1], M. Manoleva[1], D. Gecevska[1], A. Krsteska[1]

[1]Clinic for Physical Medicine and Rehabilitation, Faculty of Medicine, Ss Cyril and Methodius University of Skopje, Skopje, North Macedonia

Introduction: Osteoporosis is most common in post-menopausal women, due to loss of trophic support for bone tissue from sex hormones. Drug therapy decreases the risk of fracture, thus influencing on the mechanism of bone remodeling. Non-pharmacological interventions include specific exercises for osteoporosis that improve muscle strength and balance, decrease pain, maintains bone mineral density and improve quality of life.
Objective: To demonstrate the impact of physical therapy on bone mineral density (BMD) after one year of treatment.
Material and method: In the Clinic for Physical Medicine and Rehabilitation, Skopje we did a research on 90 patients with postmenopausal osteoporosis who were divided into three groups.The first group of 30 patients with exercise and physical modalities, the second group of 30 patients with exercise and the control group of 30 patients. BMD was determined by dual-energy x-ray absorptiometry BMI at admission and last control.
Results: Patients were with a mean age of 60.64±6.7 years. According to the level of education, patients with completed high school predominated (48.91%). Patients of the three groups did not differ significantly in terms of menopausal status (p=0,299), and for the number of risk factors present (p=0,444). Patients of the three groups did not differ significantly in BMI at admission and last control. The three groups of subjects didn't have significantly different BMD at the lumbar spine (p = 0.68, p = 0.72) and at the hip (p = 0.16, p = 0.06).
Conclusion: The time period for practicing the exercises is short for improving bone mineral density. However, research shows that it is important for maintaining it, which does not increase the risk of the consequences of osteoporosis.
Key words: physiotherapy, BMD, postmenopausal osteoporosis

P1645

THE INFLUENCE OF TIME FROM INJURY TO SURGERY OF ANTERIOR CRUCIATE LIGAMENT ON QUALITY OF LIFE

V. Krstic[1], R. Matijevic[2], M. Milankov[3]

[1]Sport Medica Polyclinic, Novi Sad, Serbia; [2]University of Novi Sad, Faculty of Medicine University Clinical Center of Vojvodina, Clinic for Orthopedic Surgery and Traumatology, Novi Sad, Serbia; [3]Milankov Med Polyclinic, Novi Sad, Serbia

The injury of anterior cruciate ligament (ACL) is one of the most common injuries in sport. Surgical treatment for these injuries is the most commonly used, because conservative treatment does not give adequate results. The aim of this study is to determine whether the time between the occurrence of ACL injury and the operation has an impact on quality of life.
This retrospective study included 791 participants who underwent the reconstruction of the ACL at the Clinic for Orthopedic Surgery and Traumatology of the Clinical Centre of Vojvodina. Based on the time from which injury occurred, participants were divided into 7 groups (0 – 3 months, 3 – 6 months, 6 – 9 months, 9 – 12 months, 12 – 24 months, 24 – 60 months, ⩾60 months). A questionnaire on the quality of life after the reconstruction of the anterior cruciate ligament was used to collect data. A statistically significant difference ($p = 0.000$; $p \leqslant 0.05$) was found between the impact of the injury on the quality of life and the time between injury and reconstruction. Significant increase in Tegner score was observed in relation to time from injury to surgery, while in Lysholm score there was no statistically significant difference between groups. A statistically significant difference between the groups exists in the associated injury ($p = 0.000$; $p \leqslant 0.05$). The most common joint injury is medial meniscus injury, except in the group where the subjects have been operated after more than 60 months after the injury, where the most common is the injury of both meniscuses.
A statistically significant difference exists in the return time to running, training, and competitive activity, where patients who have previously been operated have returned to these activities faster. BMI score increases with time between injuries and surgery.

P1646

SINGLE-STAGE MINCED CARTILAGE REPAIR: CLINICAL IMPROVEMENT DESPITE INCOMPLETE EARLY MRI MATURATION

V. Lykhodii[1], T. Pshenychnyi[2], Y. E. Rybchenko[1], O. Burianov[1]

[1]Bogomolets National Medical University, Department of Traumatology and orthopedics, Kyiv, Ukraine; [2]SI "The Institute of Traumatology and Orthopedics" by NAMS of Ukraine, Kyiv, Ukraine

Objective
To prospectively evaluate the short- and mid-term clinical outcomes of single-stage repair of knee articular cartilage defects using minced cartilage combined with fibrin glue.
One of the major challenges in the treatment of medium and large chondral defects is the selection of an optimal treatment strategy, which should be based not only on defect size but also on the presence of additional risk factors and associated lesions.
Materials and Methods
The outcomes of 27 patients (n = 27) with grade III–IV chondral lesions of the medial femoral condyle according to the ICRS classification were evaluated. Cartilage defects were assessed using MRI (1.5 T) and arthroscopic examination. Defect repair was performed using autologous minced cartilage fixed with fibrin glue.
MRI assessment of repair tissue maturation was conducted at 6 months postoperatively using the MOCART score. Clinical outcomes were evaluated using the KOOS and Lysholm scoring systems preoperatively and at 3, 6 and 12 months after surgery.
Results. A total of 27 patients were included, with a mean age of 37.96 ± 6.29 years; 15 patients (56%) were female and 12 (44%) male. The mean body mass index (BMI) was 27.92 ± 3.08 kg/m².
All patients presented with ICRS grade III–IV cartilage defects of the medial femoral condyle: grade III in 15 patients (55.6%) and grade IV in 12 patients (44.4%). The mean defect size was 2.44 cm² (range 1.3–3.5

cm²). Smoking was reported in 8 patients (29.6%).
The mean KOOS score improved from 65.3 ± 2.62 preoperatively to 70.04 ± 2.39 at 3 months, 73.2 ± 2.5 at 6 months, and 77.26 ± 2.63 at 12 months postoperatively (p = 0.006).
The Lysholm score increased from 67.6 ± 5.21 preoperatively to 75.14 ± 4.9 at 3 months, 81.07 ± 5.24 at 6 months, and 85.92 ± 3.59 at 12 months (p = 0.011).
Significant clinical improvement was observed between preoperative and 3-month postoperative assessments for both the Lysholm (p = 0.001) and KOOS (p = 0.001) scores.
The mean MOCART score at 6 months was 55.56 ± 4.46, indicating incomplete maturation of the repair tissue at this time point.
Correlation analysis revealed a significant moderate positive correlation between defect size and BMI (r = 0.58, p = 0.002), suggesting a negative impact of increased body weight on cartilage defect size. A significant moderate negative correlation was found between defect size and the 6-month MOCART score (r = −0.52, p = 0.005).
Conclusion. Single-stage minced cartilage repair with fibrin glue demonstrates favorable clinical and MRI outcomes in small to medium-sized knee cartilage defects. Further studies are required to evaluate long-term results and the applicability of this technique in large chondral defects.

P1647

LIMITATIONS OF BONE MINERAL DENSITY AND FRAX FOR FRACTURE RISK ASSESSMENT IN A DIABETIC PATIENT ON ANDROGEN DEPRIVATION THERAPY

J. Jaksic[1], L. Libric[1], T. Perko[1], V. Pandzic Jaksic[2]

[1]University of Zagreb School of Medicine, Zagreb, Croatia;
[2]Dubrava University Hospital, Zagreb, Croatia

Introduction: Androgen deprivation therapy (ADT) is a well-recognized cause of rapid bone loss and increased fracture risk. Although FRAX is often recommended for fracture risk assessment, it does not account for ADT and therefore underestimates risk. No validated FRAX adjustments for ADT exist.
Case report: A 74-year-old man with type 2 diabetes mellitus, treated with basal insulin, vildagliptin, and pioglitazone, had been receiving ADT for metastatic prostate cancer over the previous 14 months, with a favorable oncologic response. Dual-energy X-ray absorptiometry was performed. His height was 187 cm, weight 85 kg, and lumbar spine, total hip, and femoral neck T-scores were 0.2, −0.4, and -0.3, respectively, with a femoral neck bone mineral density (BMD) of 0.828 g/cm². FRAX using only BMD (secondary osteoporosis is already accounted for in the FRAX model when BMD is included) showed low fracture probabilities: 10-year major osteoporotic fracture (MOF) risk of 2.7% and hip fracture risk of 0.7%. When rheumatoid arthritis as a surrogate risk factor was added to BMD, FRAX estimates increased modestly (MOF: 3.6%; hip fracture: 1.0%). When the FRAXplus adjustment for diabetes duration of more than 10 years was applied, the MOF risk increased to 4.6% and the hip fracture risk to 1.9%. Only when FRAX was calculated without BMD but including secondary osteoporosis (hypogonadism), slightly higher risks were observed (MOF: 6.2%; hip fracture: 3.1%). Taking into account high-risk comorbidities, the patient was administered a single dose of zoledronate. Nevertheless, he sustained a hip fracture 8 months later, never recovered, and died two months thereafter.
Conclusion: This case aligns with findings from large series showing that BMD-derived FRAX indicated lower fracture risk in men with prostate cancer compared to FRAX without BMD. Osteoporosis assessment in ADT is a significant clinical challenge. Although BMD measurements and FRAX estimates are included in some oncology guidelines, they should be used only for basic bone assessment. Treatment decisions should not rely on them, as men receiving ADT may be at high fracture risk even with normal BMD. Emerging evidence underscores the importance of clinical judgment and suggests that timely, likely preventive, and more aggressive therapeutic strategies may be warranted.

P1648

SURGICAL MANAGEMENT OF SEVERE CRANIOFACIAL HYPEROSTOSIS IN A WOMAN WITH A HIGH BONE MASS DISORDER

L. Libric[1], T. Perko[1], J. Jaksic[1], V. Pandzic Jaksic[2], N. Aljinovic Ratkovic[2]

[1]University of Zagreb School of Medicine, Zagreb, Croatia;
[2]Dubrava University Hospital, Zagreb, Croatia

Background
High-bone-mass phenotypes associated with impaired sclerostin signaling provided the basis for the development of romosozumab, yet these disorders lack disease-modifying therapy. Management of severe generalized hyperostosis remains symptom-driven and may require complex surgical intervention.
Case presentation
A female patient presented at age 30 after an incidental finding of generalized skeletal hyperostosis. Imaging revealed cortical thickening of long bones, sclerotic vertebrae, hypertrophic metatarsal, metacarpal, and phalangeal bones, homogeneous cranial hyperostosis, and enlarged facial bones. Lumbar and hip bone mineral density was markedly elevated (Z-scores +10 to +13). Digital deformities suggested a sclerosteosis-like phenotype, although genetic testing did not identify a causative mutation. Intracranial volume was reduced without cranial nerve impairment. After an 8-year gap, progressive complications developed, including exophthalmos, torus palatinus, severe nasal obstruction, and obstructive sleep apnea. Occipital bone thickness reached 35 mm without evident intracranial compression. The first surgical procedure included bilateral remodeling of the orbital rims, floors, and roofs; extensive mandibular body osteotomy with tangential cortical reduction and reshaping; and widening of the nasal airway from the piriform aperture to the choanae. Two years later, a second procedure was performed to correct residual deformities, which involved additional bilateral mandibular cortical remodeling and contouring of the orbital roofs. During further follow-up, the patient reported hearing deterioration, intermittent facial paresthesia, persistent headaches responsive to nonsteroidal anti-inflammatory drugs, residual sleep apnea, and uncontrolled arterial hypertension. Brain MRI showed parenchymal impression without cerebellar tonsillar herniation.
Conclusion
Craniofacial surgery can provide functional benefit by alleviating airway obstruction and orbital compression. However, persistent symptoms and radiological findings of limited intracranial reserve underscore the constraints of surgical intervention, warranting long-term multidisciplinary surveillance.

P1649

EVALUATION OF BONE HEALTH AFTER CANCER DIAGNOSIS: GAPS IN BONE MINERAL DENSITY ASSESSMENT AND IMPLICATIONS FOR CLINICAL CARE

V. Rouach[1], Z. Versano[2], M. Sasson[2], Y. Greenman[3], A. Makori[2]

[1]Tel Aviv Sourasky Medical Center, Institute of Endocrinology, Metabolism and Hypertension, Tel Aviv, Israel; [2]Assuta Medical Centers, Tel Aviv, Israel; [3]Institute of Endocrinology, Metabolism and Hypertension, Tel Aviv Sourasky Medical Center, Israel, Tel Aviv, Israel

Background: Cancer-induced bone loss (CIBL) is a frequent complication of malignancy and its treatments, yet skeletal risk assessment remains inconsistently implemented in routine care. Real-world data describing bone mineral density (BMD) evaluation across unselected cancer populations are limited.

Objectives: To evaluate utilization, timing, and results of dual-energy X-ray absorptiometry (DXA) following a new cancer diagnosis in a large real-world cohort.

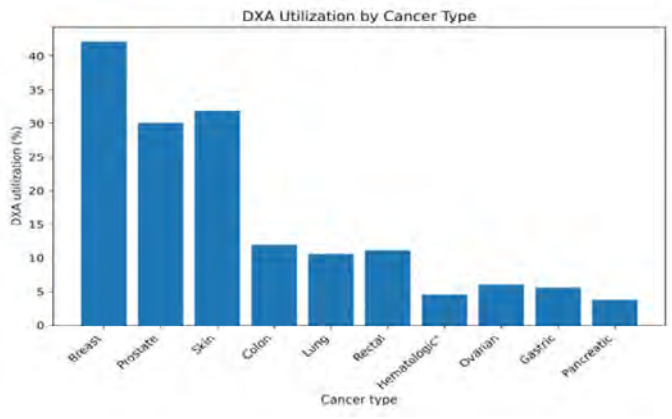
Methods: We conducted a retrospective cohort study including adults with a first cancer diagnosis between 2015 and 2024 treated within a large private healthcare network in Israel. DXA performance, timing relative to diagnosis, cancer type, sex, and BMD outcomes were analyzed. Osteopenia and osteoporosis were defined using WHO criteria based on the lowest T-score across measured sites.

Results: Among 21,112 patients (mean age 60.2 ± 13.1 years; 77% women), only 7,496 (35.5%) underwent DXA at any time following cancer diagnosis, and early assessment within 6 months was uncommon (7.3%). DXA utilization was markedly lower in men than in women (15.0% vs. 41.7%) and varied substantially by cancer type, being highest in breast (42.2%) and prostate cancer (30.0%), while remaining below 15% in most other malignancies. Median time from cancer diagnosis to DXA was 14.8 months. Among patients undergoing DXA, 59.7% already had abnormal BMD: 45.2% osteopenia and 14.5% osteoporosis.

Conclusions: In real-world oncology practice, BMD assessment after cancer diagnosis is infrequent, delayed, and strongly influenced by sex and cancer type rather than overall skeletal risk. The high prevalence of low bone mass at first DXA suggests missed opportunities for early identification and prevention of CIBL. These findings support more systematic integration of bone health evaluation into oncology and survivorship care pathways.

Figure 1. DXA Utilization by Cancer Type

Legend: Proportion of patients undergoing DXA assessment following cancer diagnosis, stratified by cancer type. **Hematologic malignancies were identified using an organ-based classification and may be under-ascertained.*



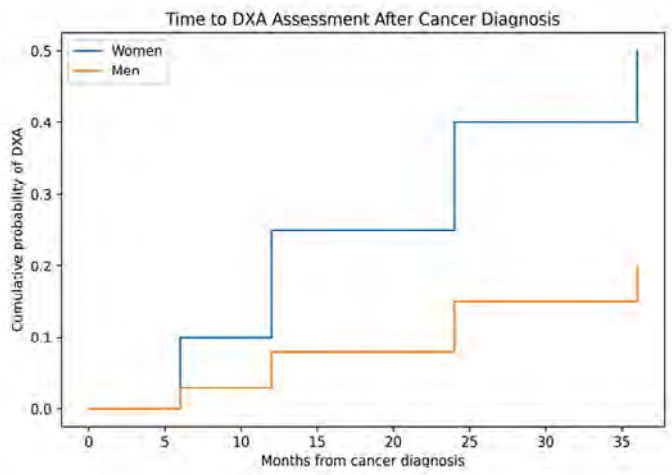


Figure 2. Time to DXA Assessment after Cancer Diagnosis

Legend: Kaplan–Meier curve showing cumulative incidence of DXA assessment following cancer diagnosis, stratified by sex.

UNRECOGNIZED SKELETAL FRAGILITY IN MEN AGED ≥70 YEARS: REAL-WORLD EVIDENCE FROM SYSTEMATIC DXA SCREENING

V. Rouach[1], Z. Versano[2], M. Sasson[2], A. Makori[2], G. Chodick[3], I. Goldshtein[4]

[1]Tel Aviv Sourasky Medical Center, Institute of Endocrinology, Metabolism and Hypertension, Tel Aviv, Israel; [2]Assuta Medical Centers, Tel Aviv, Israel; [3]School of Public Health, Gray Faculty of Medical and Health Sciences, Tel Aviv University, Tel Aviv-Yafo, Israel; [4]Dina Recanati School of Medicine, Reichman University, Herzeliya, Israel

Background: Osteoporosis screening guidelines for men remain inconsistent internationally, with the 2025 U.S. Preventive Services Task Force concluding that evidence is insufficient to recommend for or against screening, specifically citing lack of real-world prevalence data from systematic screening programs. Most existing prevalence estimates derive from small epidemiologic studies or clinic-based samples subject to selection bias. We evaluated the real-world prevalence of low bone mineral density (BMD) in men aged ≥70 years using data from the largest systematic screening initiative ever reported.

Methods: We analyzed DXA examinations performed between 2014-2024 at Assuta Medical Centers using GE Lunar densitometers, within a large Israeli integrated healthcare organization (Maccabi Health Services, 2.5 million members). An alert-based systematic screening initiative was implemented whereby primary care physicians received computerized prompts for all male patients aged ≥70 years without prior osteoporosis diagnosis or recent DXA testing. This approach approximates systematic screening implementation while preserving clinical decision-making. BMD was measured at lumbar spine and hip using standardized GE Lunar protocols and classified by T-score per World Health Organization criteria: osteoporosis (≤-2.5), osteopenia (-1.0 to -2.5), or normal (≥-1.0). Demographic and clinical characteristics including age, body mass index (BMI), smoking status, and diabetes prevalence were analyzed by BMD category. Analyses were performed per DXA examination and stratified by age (70–75, 75–80, ≥80 years). The cohort represents a screening-dominant, age-eligible population, although individual referral indications could not be fully ascertained.

Results: Among 57,433 DXA examinations in men aged ≥70 years, 39,779 had complete data allowing classification by the lowest T-score across all sites. Using this conservative definition, 48.8% met criteria for osteopenia and 18.3% for osteoporosis, such that 67.1% demonstrated low BMD. Men aged 70–75 years comprised the majority of examinations (n = 26,378). In this key screening-eligible group, 49.3% were osteopenic and 15.5% met criteria for osteoporosis using the lowest-site definition. Osteoporosis prevalence increased progressively with age, reaching 20.6% at ages 75–80 and 29.4% among men aged ≥80 years. Using the hip-based femoral neck definition, osteoporosis prevalence was more moderate but remained clinically meaningful: 13.8% at ages 70–75, 19.2% at 75–80, and 27.8% at ≥80 years, confirming a substantial burden of clinically relevant skeletal disease already present at the lower boundary of screening age. After excluding DXA examinations with indications suggestive of prior fracture, malignancy, or chronic glucocorticoid use, hip-based osteoporosis prevalence was approximately 11% among men aged 70–75 years, increasing to ~15–16% at ages 75–80 and ~22–24% among men aged ≥80 years.

Table: Prevalence of Osteoporosis by Age Group and Diagnostic Definition (Screening-Enriched Estimates After Excluding Likely Clinical Referrals)

Age group (years)	DXA exams included*	Hip-based osteoporosis (femoral neck)	Osteoporosis by lowest T-score (all sites)
70–75	~21,000	~10.5–11.0%	~13–14%
75–80	~6,600	~15–16%	~19–20%
≥80	~3,900	~22–24%	~27–29%
Overall ≥70	~31,500	~12–13%	~16–18%

*DXA examinations remaining after conservative exclusion of records with indications suggestive of **prior fracture, malignancy, or chronic glucocorticoid use**, based on referral text, diagnoses, and medication fields.

Conclusion: In this large real-world cohort of DXA examinations in men aged ≥70 years, low bone mass was highly prevalent regardless of definition. Importantly, a substantial burden of osteopenia and osteoporosis was already evident among men aged **70–75 years**, the population most relevant for screening decisions. By providing large-scale, age-stratified data from a systematic, age-based screening context, these findings directly address the evidence gap identified by the USPSTF and support reconsideration of osteoporosis screening strategies in older men.

P1651

HIP AXIS LENGTH ADDS INDEPENDENT INFORMATION BEYOND BMD FOR PREVALENT FRAGILITY FRACTURE IN POST-MENOPAUSAL WOMEN REFERRED FOR DXA

V. S. Sahu[1], M. B. Marwan[2]

[1]Lancaster University, Lancaster, United Kingdom; [2]Royal Lancaster Infirmary, Lancaster, United Kingdom

Objective(s):
To determine whether hip axis length (HAL) from hip structural analysis is independently associated with prevalent fragility fracture beyond bone mineral density (BMD) and clinical predictors in post-menopausal women referred for DXA.
Material and Methods:
Retrospective observational cohort of post-menopausal women undergoing DXA (June 2014-October 2024). Data were anonymised routinely collected NHS DXA service records from a DXA scanner in the North West of England; research ethics approval was obtained. Outcome was prevalent fragility fracture (yes/no). Multivariable logistic regression included age, BMI, rheumatoid arthritis, current smoking, excess alcohol (>14 units/week), years since menopause, DXA abdominal fat percentage, IMD quintiles and BMD. Parallel models compared L1-L4, femoral neck and total hip BMD because fracture-risk estimates vary by skeletal site. HAL (mean of left/right) was added to each model. Effects were per SD (BMD per SD decrease, HAL per SD increase). Discrimination was assessed using AUROC.
Results:
Among 4,078 women, prevalent fragility fracture was 46.7%. In complete cases with HAL (n=2,692), longer HAL was independently associated with fracture in the spine model (aOR 1.16, 95% CI 1.07-1.25, p=0.000295),

with consistent associations in femoral neck (aOR 1.14, 95% CI 1.05-1.23, p=0.00121) and total hip models (aOR 1.11, 95% CI 1.03-1.20; p=0.00802). Lower BMD remained strongly associated across sites (aOR per SD decrease: spine 1.41, 95% CI 1.29-1.53, femoral neck 1.39, 95% CI 1.27-1.52, total hip 1.43, 95% CI 1.30-1.58, all p≤1.5×10⁻¹²). Adding HAL modestly improved discrimination (AUROC spine 0.608 to 0.614, femoral neck 0.605 to 0.611, total hip 0.610 to 0.614).

Conclusion(s):

HAL provided independent and incremental information beyond BMD and traditional predictors in a real world DXA cohort, supporting consideration of selected hip geometry measures to complement BMD based fracture risk assessment. Prospective validation using incident fracture outcomes is required to confirm clinical utility.

Disclosures: None.

Table 1. Adjusted associations and discrimination with and without HAL. ORs are adjusted per SD (BMD per SD decrease, HAL per SD increase).

Model	n	BMD OR (95% CI)	HAL OR (95% CI)	AUROC base	AUROC +HAL
Spine	2692	1.41 (1.29-1.53)	1.16 (1.07-1.25)	0.608	0.614
Femoral neck	2692	1.39 (1.27-1.52)	1.14 (1.05-1.23)	0.605	0.611
Total hip	2692	1.43 (1.30-1.58)	1.11 (1.03-1.20)	0.610	0.614

P1652

EFFECTIVENESS AND SAFETY PROFILE OF DENOSUMAB VS ALENDRONATE. A COMPARATIVE STUDY

V. Salko[1], A. Zoto[2], E. Rapushi[3], V. Duraj[1], T. Backa[1], E. Xherahu[1]

[1]UHC"Mother Teresa",Department of Rheumatology, Tirana, Albania; [2]UHC"Mother teresa",Deparment of Rheumatology, Tirana, Albania; [3]UHC"Mother Theresa", Tirana, Albania

Objective: We aimed to explore the comparative effectiveness and safety of denosumab and alendronate in the same group of patients with primary or secondary osteoporosis.

Material and Method: This is a retrospective cohort study, which included 120 patients diagnosed with osteoporosis through DEXA scan. The mean age of participants was 55.3(SD 2.4), ranging from 42 to 74 years old. Out of 120 patients,17 were male(14%) and 103 were female (86%). Out of 103 women included in the study,92 were postmenopausal women. All the patients were treated for the first two years with oral bisphosphonates, once a week(alendronate 70 mg). A DEXA scan was demanded every 12 months. Then another DEXA scan was performed after 1 year for all patients who were included later to receive denosumab.

Results: Out of 120,3 patients died during the first two years(old age, cardiovascular disease, autoimmune disease). Of the rest of 117 patients,35 patients(30%) after two years of treatment were then classified as osteopenia. To the other 82 patients, the therapy with alendronate didn't succeed in treating osteoporosis or was interrupted due to adverse events, mainly gastrointestinal (10 patients). Switching to denosumab 60 mg once every six months was proposed to all 82 remaining patients, and 75 accepted the medication. After two pre-filled syringes with Denosumab, a DEXA scan showed a better improvement of T-score compared to two years of alendronate. Also, no therapy interruption was observed.

Conclusion: The therapy with Denosumab 60 mg/ml, sc, showed better efficacy and safety than alendronate to the same group of patients regardless of the cause of osteoporosis or gender of the patients.

P1653

DYNAMIC ASSESSMENT OF VERTEBRAL FRACTURES IN CHILDREN WITH OSTEOGENESIS IMPERFECTA

V. Vadzianava[1]

[1]Belarusian State Medical University, Minsk, Belarus

Objective: Osteogenesis imperfecta (OI) is one of the most common diseases associated with the primary osteoporosis in children. They often experience multiple vertebral fractures (VF). During childhood and adolescence, bone modeling prevails over remodeling, which allows the deformed vertebra to return to its original anatomical shape, the so-called reshaping. The aim of study was to evaluate the capabilities of the densitometric method in assessing VF in children with OI.

Methods. The study group of 67 children aged 11 (7; 13) years old, with established OI was examined. Anthropometry, general clinical examination, DXA with analysis of the spine using a program for vertebral fractures assessment (VFA) were performed. We used the Genant's classification. Statistical processing was performed using the program Statistica 10.0.

Results A total of 201 DXA-scanogram were evaluated with an interval of 12, 24 months between studies. A total of 37% (n=25) patients with OI had the VF. The most common localization of VF was the thoracic spine, specifically of the Th12 vertebra (n=12). In the subgroup of children with VF 17 (69%) patients had two or more at the same time. Over a two-year follow-up period, new VF were detected in 10% (n=7) of patients with no VF at baseline. Among children with existing deformities 12% (n=3) experienced progression of VF or the development of new VF in other spinal segments. However, some patients (n=4) (primarily those with grade 1 fractures) experienced an increase in vertebral height with restoration of their shape (reshaping), during bisphosphonate therapy.

Conclusion. The VFA densitometric assessment of the spine in patients with OI has high diagnostic potential in clinical practice. Furthermore, this method involves minimal radiation exposure (0.083 mSv), which is particularly important for children, and allows for a comprehensive assessment of bone mineral density and morphological changes in the vertebrae. VF are quite common (in 37% of patients with OI in our study) and are asymptomatic. Early diagnosis allows restoration of vertebral body structure during treatment. This phenomenon, unique to the pediatric skeleton, necessitates the inclusion of densitometric assessment of the VFA in the routine examination of such patients.

PATIENT PREFERENCES FOR TRACKER PIN–RELATED INCISION CONFIGURATIONS IN ROBOTIC-ASSISTED TOTAL KNEE ARTHROPLASTY

V. Yuenyongviwat[1], C. Anusitviwat[1], K. Iamthanaporn[1]

[1]Department of Orthopedics, Faculty of Medicine, Prince of Songkla University, Hatyai, Thailand

Objective: Robotic-assisted total knee arthroplasty (TKA) requires tracker pin placement, which may result in different incision configurations, ranging from a single longer midline incision to a midline incision with additional stab incisions. Although clinical outcomes across pin placement strategies appear comparable, patient preferences regarding incision design remain unclear.
Methods: This cross-sectional observational study was conducted at a tertiary university hospital. A total of 101 patients with knee osteoarthritis were recruited consecutively. Three incision configurations related to tracker pin placement were presented using standardized lower-limb models: (A) all-inside (longest single midline incision), (B) femoral pin in–tibial pin out (medium-length midline incision plus two tibial stab incisions), and (C) pin outside (shortest midline incision plus four stab incisions). Participants rated their preference for each design using a 5-point Likert scale and selected a single preferred option. Cosmetic and recovery concerns were assessed using five Likert-scale items.
Results: The mean age was 63.8 ± 5.8 years, and 86.1% of participants were female. Among incision-related concerns, postoperative scarring received the highest ratings, followed by the importance of recovery time, whereas concern about incision length and the number of incisions were lower; perceived impact of incision size on postoperative confidence was intermediate. Preference scores showed a numerical ranking (all-inside 3.41 ± 1.27; femoral pin in–tibial pin out 3.05 ± 1.13; pin outside 2.81 ± 1.45) without a statistically significant difference ($\chi^2 = 5.52$, $p = 0.063$). When selecting a single preferred option, 46.5% chose the all-inside configuration, 25.7% selected femoral pin in–tibial pin out, and 27.7% selected the pin-outside configuration.
Conclusions: No clear differences in overall preference were observed among incision configurations. Patients may prioritize concerns related to postoperative scarring and recovery expectations over incision length or the number of incisions. Therefore, when multiple technically acceptable pin placement strategies are available, incision planning may reasonably be guided by surgeon preference and technical considerations.

PREVENTION AND TREATMENT OF OSTEOPOROSIS IN BREAST CANCER PATIENTS UNDERGOING ENDOCRINE THERAPY: A RECOMMENDED APPROACH AND OUR EXPERIENCE

D. Michalska[1], M. Zimovjanova[2], J. Přibylova[2], D. Svobodova[2], R. Vlasakova[1], V. Zikan[1]

[1]3rd Department of Internal Medicine, First Faculty of Medicine, Charles University and General University Hospital in Prague, Prague, Czechia; [2]Department of Oncology, First Faculty of Medicine, Charles University and General University Hospital in Prague, Prague, Czechia

BACKGROUND: A significant adverse effect of long-term aromatase inhibitor (AI) therapy in patients with hormone receptor–positive (HR+) early non-metastatic breast cancer is bone loss leading to osteoporosis and fractures. Treatment initiation is traditionally based on a T-score ≤ −2.5 or manifest osteoporosis; however, most fractures occur in patients with osteopenia who are not treated until a fracture develops.
PURPOSE: To propose a management approach based on current European recommendations and our 10-year follow-up data.
METHODS: A total of 90 postmenopausal women with osteopenia treated with AI were prospectively followed over a 5-10-year period.
RESULTS: AI therapy causes significant and continuous bone mineral density (BMD) loss in the lumbar spine and hip, regardless of baseline BMD. A marked BMD decline during the first 1–2 years predicts further bone loss over the next 5 years. Baseline osteopenia (T-score < −1.5) combined with rapid BMD loss is associated with a higher incidence of osteoporosis during 5 years of AI therapy (21% vs. 3%). During treatment, 14 new low-trauma fractures occurred in 11 women (12%) without baseline osteoporosis or prevalent fractures. After 5 years of AI therapy, BMD loss is only partially reversible in the lumbar spine, while hip BMD remains unchanged. Prolonged AI therapy (>5 years) results in further hip BMD loss. Vitamin D deficiency is common, and supplementation is recommended. Early antiresorptive therapy prevented increased bone resorption and improved BMD compared with delayed treatment.
CONCLUSION: In non-osteoporotic patients treated with AIs, routine assessment of fracture risk and close monitoring throughout the duration of treatment are necessary. Timely initiation of antiresorptive therapy, even in patients with osteopenia or documented accelerated BMD loss, is essential to ensure effective prevention of bone loss.

DESCRIPTION OF THE FIRST FRACTURE LIAISON SERVICE IN MOROCCO: EXPERIENCE FROM THE MILITARY HOSPITAL OF RABAT – PRELIMINARY RESULTS -

W. Belhadj[1], A. Majjad[1], H. Taoufik[1], A. Bezza[1]

[1]Hopital militaire d instruction Mohammed V, Rabat, Morocco

Background:
Fragility fractures represent a major public health issue due to the high risk of secondary fractures, associated morbidity, and economic burden. In Morocco, osteoporosis and its prevention remain largely neglected. Structured post-fracture care programs, internationally known as Fracture Liaison Services (FLS), exist in several countries, but no organized service had been implemented in Morocco until now. This study aims to describe the implementation of the first FLS in the country, at the Military Teaching Hospital of Rabat.
Methods:
This prospective observational study was conducted at the Military Teaching Hospital Mohammed V of Rabat from October 2025 to October 2026 and included patients aged ≥50 years with suspected fragility fractures. High-energy traumatic fractures and non-osteoporotic pathological fractures were excluded.
Patients were identified in the emergency, traumatology, and rheumatology departments through a nurse-led standardized questionnaire and referred to a dedicated one-day Fracture Liaison Service (FLS) clinic for rheumatological evaluation (Figure 1). All patients underwent bone mineral density (BMD) assessment and a phosphocalcic laboratory workup performed in the same laboratory. Osteoporosis was defined as a T-score ≤ −2.5, and vitamin D deficiency as serum 25-hydroxyvitamin D levels <21 ng/mL.

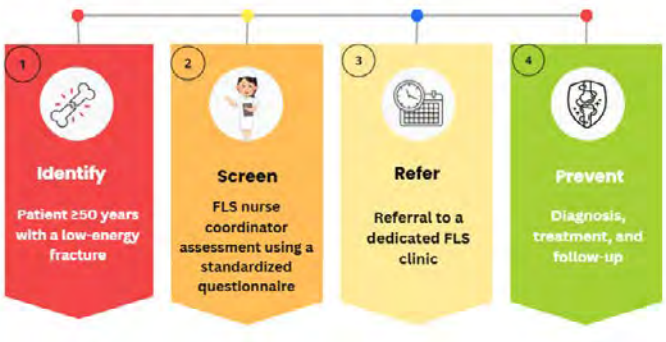

Figure 1. FLS identification pathway
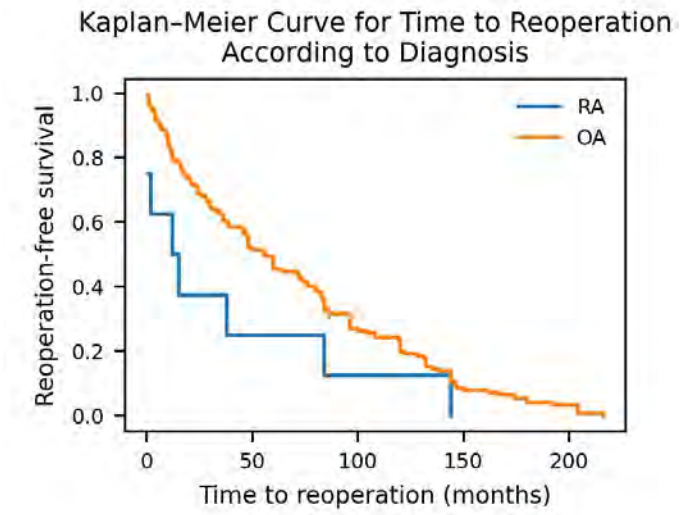
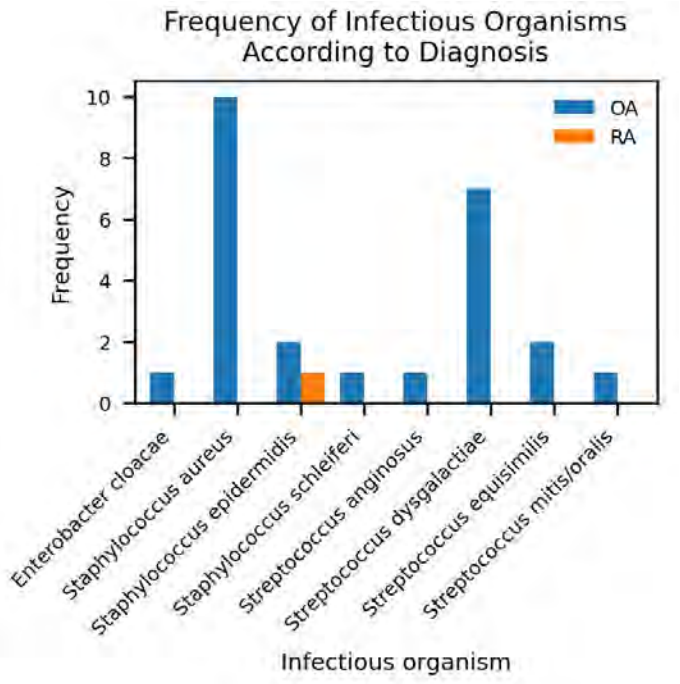
Results:
To date, 80 patients have been reported to the FLS, of whom 50 had a confirmed fragility fracture. The median age was 67.5 years [61–76], with a female predominance (59.2%). Fractures mainly involved the hip, followed by the wrist, humerus, and vertebral column. Vertebral fractures were identified by lateral vertebral assessment (LVA) in 15 patients, with L3 being the most frequently affected vertebra. Eight patients had a history of prior fragility fractures.
Bone densitometry revealed osteoporosis in the majority of patients, while 10 had osteopenia. A vitamin D deficiency was observed in 20 patients, and vitamin D and calcium supplementation was initiated in 35 patients.
The median delay between index fracture occurrence and initiation of anti-osteoporotic treatment was 97.5 days [28–145]. Two patients refused therapy, one received teriparatide, and the remainder were treated with zoledronic acid.
Conclusion:
This study demonstrates the feasibility of implementing a Fracture Liaison Service in Morocco, enabling early identification of fragility fractures and providing a structured framework for secondary fracture prevention.



P1658



DIFFERENCES IN REOPERATION PATTERNS BETWEEN RHEUMATOID ARTHRITIS AND OSTEOARTHRITIS FOLLOWING TOTAL KNEE ARTHROPLASTY

W. Jeong[1], J. Jinseok[1]

[1]University of Jeju, Jeju, South Korea

Objective
Total knee arthroplasty (TKA) is an established treatment for end-stage knee osteoarthritis (OA), while rheumatoid arthritis (RA), a systemic inflammatory disease, may also lead to progressive joint destruction requiring TKA. However, differences in reoperation patterns between patients with OA and RA remain unclear. The objective of this study was to investigate differences related to reoperation after TKA between patients with OA and those with RA.
Materials and Methods
This retrospective study included patients who underwent primary or revision TKA at a single tertiary university hospital between March 2003 and December 2022. Only patients with a confirmed diagnosis of RA or OA were included. Reoperation rates, causes of reoperation, microbiologically identified organisms, and time to reoperation were compared between the two groups using multivariable logistic regression, Kaplan–Meier survival analysis, and Cox proportional hazards models.
Results
A total of 5,245 patients were analyzed, including 157 patients with RA (3.0%) and 5,088 patients with OA (97.0%). Patients with RA were significantly younger than those with OA (69.8 ± 6.8 vs. 72.5 ± 6.4 years, $p < 0.001$) and had higher inflammatory markers, including ESR (43.5 ± 31.9 vs. 26.6 ± 22.6 mm/hr, $p < 0.001$) and CRP (1.8 ± 2.3 vs. 0.8 ± 2.1 mg/dL, $p < 0.001$). Overall reoperation rates were similar between groups. Infection accounted for the largest proportion of reoperations in the RA group (50.0%), whereas loosening was the most common cause of reoperation in the OA group (45.9%) ($p = 0.099$). Due to the limited number of microbiologically identified cases, no significant difference in pathogen distribution was observed, and Staphylococcus aureus was the most frequently isolated organism in both groups. RA was not an independent predictor of reoperation in multivariable logistic regression. Kaplan–Meier analysis showed a trend toward shorter reoperation-free survival in RA patients, and Cox regression demonstrated an increased but non-significant risk of earlier reoperation in RA patients (hazard ratio 1.90, 95% CI 0.92–3.90).
Conclusion
Although overall reoperation rates after TKA were comparable between RA and OA patients, the leading cause of reoperation differed, with infection predominating in RA patients and loosening in OA patients. These findings suggest that postoperative outcomes in RA patients may be more closely related to inflammatory burden than to RA diagnosis itself.

P1659

PATIENT PROFILE AND FUNCTIONAL IMPACT OF KNEE OSTEOARTHRITIS: A COMPARISON ACCORDING TO RADIOGRAPHIC SEVERITY

W. Khelif[1], L. Rouached[1], S. Ben Dhia[2], S. Bouden[3], I. Mahmoud[3], R. Tekaya[3], A. Ben Takaya[3], L. Abdelmoula[3]

[1]Rheumatology department of Charles Nicolle Hospital, Tunis, Tunisia; [2]Charles Nicoles Hospital, Tunis, Tunisia; [3]Rheumatology department of Charles Nicolle Hospital., Tunis, Tunisia

Introduction
Knee osteoarthritis (KOA) is a heterogeneous disease in which patient profile and functional impairment varies according to radiographic severity.

Objective
To evaluate patient profile and functional impact of early-stage versus advanced-stage of KOA

Methods
This analytical study included patients followed for KOA in the rheumatology department.. Patients were classified into two groups based on Radiographic severity: early KOA ((Kellgren–Lawrence [KL] (1–2) and advanced KOA (KL 3–4). Comparisons were performed for demographic characteristics and clinical indicators of functional impairment.

Results
We included 143 patients with KOA. Cases with advanced KOA were significantly older and had a longer disease duration than those with early KOA ($p<0.001$). Sex distribution was comparable between groups ($p = 0.5$). From a functional perspective, advanced KOA was associated with higher pain intensity (VAS scores, $p = 0.002$) and more handicap and severe functional impairment, reflected by higher Lequesne index score ($p<0.001$) and significantly lower KOOS scores across all domains (pain, symptoms, activities of daily living, sport/recreation, and knee-related quality of life ($p\leq0.003$).Regarding treatment patterns, patients with KL grades 3–4 used analgesics more frequently than those with early-stage disease ($p = 0.02$). No significant differences were observed in NSAID use ($p= 0.47$). Lifestyle factors were not significantly associated with radiographic severity, with no significant difference in physical activity ($p = 0.43$) and functional rehabilitation ($p = 0.19$). groups. Clinically, advanced KOA was associated with more frequent joint limitation ($p = 0.006$) and increased use of walking aids ($p = 0.003$). Advanced forms were also significantly associated with combined femorotibial and femoropatellar involvement ($p<0.001$).

Conclusion
Advanced knee osteoarthritis is associated with substantially higher functional impairment, and handicap. Increased analgesic use, joint limitation, and reliance on walking aids appear to be strong clinical markers of advanced disease.

P1660

EFFECT OF DOUBLE PLATELET-RICH PLASMA INJECTIONS ON PAIN, FUNCTION, AND DISABILITY IN EARLY- STAGE KNEE OSTEOARTHRITIS:

L. Rouached[1], W. Khelif[1], S. Ben Dhia[2], I. Mahmoud[3], R. Tekaya[3], A. Ben Takaya[3], L. Abdelmoula[3], S. Bouden[3]

[1]Rheumatology department of Charles Nicolle Hospital, Tunis, Tunisia; [2]Charles Nicoles Hospital, Tunis, Tunisia; [3]Rheumatology department of Charles Nicolle Hospital., Tunis, Tunisia

Introduction
Early-stage knee osteoarthritis (KOA) represents a key therapeutic window during which biological treatments may favorably influence pain symptoms and functional outcomes. Platelet-rich plasma (PRP) has emerged as a promising option.

Objective
To evaluate the effect of two intra-articular PRP injections on pain, function, and handicap in patients with early-stage knee osteoarthritis after three months of follow-up.

Methods
This prospective study included patients with early-stage KOA (Kellgren–Lawrence grades (KL) 1–2) followed in the rheumatology department of Charles Nicolle Hospital, who received two intra-articular PRP injections,

at a three-week interval. Pain intensity was assessed using the visual analog scale (VAS, 0–10), neuropathic pain using the DN4 questionnaire, function using the Knee injury and Osteoarthritis Outcome Score (KOOS), and disability using the Lequesne algofunctional index. Baseline-to–Month 3 comparisons were conducted. Statistical significance was set at p<0.05.

Results

Analyses included 32 patients. Pain intensity significantly decreased at three months, with mean VAS scores declining from 6.1 ± 1.5 at baseline to 2.3 ± 1.9 at Month 3, corresponding to a mean reduction of 3.8 points (p<0.001).

The neuropathic component of pain also showed significant improvement, with DN4 scores decreasing from 1.42 ± 1.75 to 0.45 ± 1.06 (p=0.001).

Function improved significantly, as reflected by an increase in the KOOS score from 68.3 ± 16.5 at baseline to 81.9 ± 19.4 at three months (p<0.001).

Finally, algofunctional disability significantly decreased, with the Lequesne index decreasing from 6.6 ± 2.7 to 3.3 ± 2.5 at Month 3 (p<0.001).

Conclusion

In patients with early-stage knee osteoarthritis, double intra-articular PRP injections were associated with significant improvements in pain, including its nociceptive and neuropathic components, as well as in function and disability at three months. These findings suggest that PRP may represent a relevant therapeutic option when introduced early in the course of knee osteoarthritis.

P1661

EFFECT OF DOUBLE PLATELET-RICH PLASMA INJECTIONS ON PAIN, FUNCTION, AND HANDICAP IN ADVANCED KNEE OSTEOARTHRITIS: A THREE-MONTH PROSPECTIVE STUDY

W. Khelif[1], L. Rouached[1], S. Ben Dhia[2], I. Mahmoud[3], R. Tekaya[3], A. Ben Takaya[3], L. Abdelmoula[3]

[1]Rheumatology department of Charles Nicolle Hospital, Tunis, Tunisia; [2]Charles Nicoles Hospital, Tunis, Tunisia; [3]Rheumatology department of Charles Nicolle Hospital., Tunis, Tunisia

Introduction

Advanced knee osteoarthritis (KOA) is associated with chronic pain and substantial functional disability, which are often inadequately controlled by conservative treatments. Platelet-rich plasma (PRP) has emerged as a biological therapeutic option with the potential to improve both pain and functional outcomes.

Objective

To evaluate the effect of two intra-articular PRP injections on pain, function, and disability in patients with advanced KOA at three months of follow-up.

Methods

This prospective study included patients with advanced KOA (Kellgren–Lawrence grades 3–4) followed in a rheumatology department, who received two intra-articular PRP injections at a three-week interval. Pain intensity was assessed using the visual analog scale (VAS, 0–10), functional disability and handicap using the Lequesne algofunctional index, and knee function using the Knee injury and Osteoarthritis Outcome Score (KOOS; symptoms, pain, activities of daily living, sport/recreation, and knee-related quality of life). Baseline-to–Month 3 comparisons were conducted, with statistical significance set at p <0.05.

Results

Among the 79 patients analyzed, mean baseline pain was (VAS score) of 6.8 ± 1.7. At three months following double PRP injection, pain intensity significantly decreased to 3.2 ± 2.4, corresponding to a mean reduction of 3.6 points (p <0.001).

A significant functional improvement was also observed. KOOS scores improved significantly across all domains: pain (54.9 ± 15.5 to 66.3 ± 20.8), symptoms (54.3 ± 18.5 to 67.4 ± 21.5), activities of daily living (57.5 ± 15.9 to 68.8 ± 21.1), sport and recreation (42.2 ± 18.8 to 50.6 ± 19.8), and knee-related quality of life (45.8 ± 15.8 to 60.6 ± 22.1) (all p< 0.001). The Lequesne index decreased from 10.6 ± 3.3 at baseline to 7.6 ± 3.1 at three months (p <0.001), indicating a reduction in algofunctional disability.

Conclusion

In patients with advanced KOA, double intra-articular PRP injections were associated with significant improvements in pain, function, and disability at three months. These findings support the potential role of PRP as a relevant symptomatic treatment option in advanced KOA.

P1662

PATIENT SATISFACTION AFTER PLATELET-RICH PLASMA INJECTIONS IN KNEE OSTEOARTHRITIS: INFLUENCE OF RADIOGRAPHIC STAGE

W. Khelif[1], L. Rouached[1], S. Ben Dhia[2], S. Bouden[3], I. Mahmoud[3], R. Tekaya[3], A. Ben Takaya[3], L. Abdelmoula[3]

[1]Rheumatology department of Charles Nicolle Hospital, Tunis, Tunisia; [2]Charles Nicoles Hospital, Tunis, Tunisia; [3]Rheumatology department of Charles Nicolle Hospital., Tunis, Tunisia

Background

Patient satisfaction is an important patient-reported outcome reflecting perceived benefit beyond clinical measures in knee osteoarthritis. Understanding whether satisfaction varies according to radiographic severity may help optimize patient selection for platelet-rich plasma (PRP) therapy.

Objectives

To assess patient satisfaction three months after double intra-articular PRP injections in knee osteoarthritis and to evaluate its association with radiographic stage.

Methods

An observational study was conducted in patients with knee osteoarthritis treated with two intra-articular PRP injections at the Rheumatology Department of Charles Nicolle Hospital, Tunis. Patient satisfaction was assessed at three months using the Patient Global Clinical Impression of improvement (PGCII). Radiographic severity was classified as early stage (Kellgren–Lawrence grades 1–2) or advanced stage (grades 3–4). Satisfaction distributions were compared using the chi-square test, and an ordered trend analysis (linear-by-linear association) was performed. Results are expressed as frequencies and percentages.

Results
A total of 65 patients completed the PGCII assessment in three months. Overall, 42 patients (64.6%) reported being much improved or very much improved, indicating a high level of satisfaction with PRP treatment. An additional 12 patients (18.5%) reported minimal improvement, while 8 patients (12.3%) reported no change. Only 3 patients (4.6%) reported worsening. The overall distribution of satisfaction did not differ significantly between early and advanced radiographic stages ($p = 0.264$). However, trend analysis revealed a significant linear association, with higher levels of perceived improvement more frequently reported in patients with advanced-stage knee osteoarthritis (linear-by-linear association, $p = 0.014$).

Conclusion
Most patients reported a high level of satisfaction three months after PRP treatment for knee osteoarthritis. While overall satisfaction did not significantly differ according to radiographic stage.

P1663

IMPACT OF PREOPERATIVE NUTRITIONAL STATUS ON PROGNOSIS AFTER VERTEBROPLASTY: A RETROSPECTIVE STUDY

Y. L. Teng[1], W. L. Chen[2]

[1]Nurse of Taichung Veterans General Nursing Department, TAICHUNG, Taiwan; [2]Taichung Veterans General Hospital, TAICHUNG, Taiwan

Objective(s) Osteoporotic vertebral compression fractures (OVCF) are frequently associated with malnutrition in the elderly. This study aims to retrospectively analyze the impact of preoperative bone mineral density and nutritional status on 2-year functional recovery and survival rates following vertebroplasty.
Material and Methods We retrospectively reviewed data from 395 patients aged ≥50 who underwent vertebroplasty or kyphoplasty between January 2017 and December 2023. Patients were stratified into groups based on T-scores and nutritional indicators (Albumin and Geriatric Nutritional Risk Index, GNRI). We compared the clinical outcomes of the "Robust Group" (G1: non-osteoporotic with normal nutrition) against the "Double-Hit Group" (G4: osteoporosis combined with malnutrition). The primary outcomes included the Oswestry Disability Index (ODI) and all-cause mortality over a 2-year follow-up period.
Results The Double-Hit Group (G4) was significantly older (median age 80.5 vs. 76.9 years) and presented with lower Body Mass Index (median 20.8 vs. 24.5 kg/m²) compared to the Robust Group (G1). Multivariate Cox regression analysis revealed that the G4 group had a significantly higher risk of mortality (Hazard Ratio = 2.01, p=0.022). Regarding functional recovery, while both groups exhibited improvement in ODI scores post-operatively, the G4 group sustained a persistent disability gap, ending with significantly higher disability scores at 24 months compared to G1 (median ODI: 50 vs. 40, p<0.001).
Conclusion(s) Preoperative malnutrition combined with osteoporosis is a significant predictor of higher mortality and poorer functional status in patients undergoing vertebroplasty. Although surgery provides pain relief, the physiological deficits in these high-risk patients result in long-term residual disability. We suggest that postoperative care should extend beyond fracture management to include aggressive nutritional support to improve long-term prognosis.

P1664

THE EFFECTS OF EXERCISE ON INTRINSIC CAPACITY AFTER HIP FRACTURE: A SYSTEMATIC REVIEW AND META-ANALYSIS OF THE LOCOMOTION AND COGNITION DOMAINS

W. Lok Ok Choo[1,2,3], P. Hewston[1,2], A. Azizudin[1,2], G. Duque[3], M. Sidhu[1,2], S. Thrall[1,2], A. Papaioannou[1,2]

[1]Geras Centre for Aging Research, Hamilton Health Sciences, Hamilton, Canada; [2]McMaster University, Hamilton, Canada; [3]McGill University, Montreal, Canada

Objective: To summarize the effect of exercise interventions in older adults following a hip fracture across intrinsic capacity locomotion and cognitive domains.
Methods: We searched EMBASE, MEDLINE, CINAHL, and CENTRAL. Eligible studies included: (i) randomized controlled trial design, (ii) older adults aged 60 years or older who experienced a hip fracture, (iii) an exercise intervention, and (iv) outcomes related to locomotor capacity. Risk of bias was assessed using the Cochrane Risk of Bias 2 (RoB-2) tool, and the certainty of evidence was evaluated using the Grading of Recommendations, Assessment, Development and Evaluation (GRADE) approach.
Results: Of 5053 records screened, 12 randomized controlled trials (N=1397 participants) met inclusion criteria. Exercise interventions after hip fracture varied in frequency (1-7 sessions per week), type (resistance, balance, endurance, or multicomponent programs), and duration (1 month –12 months). Exercise may improve physical function after hip fracture, although the certainty of evidence is low. Across six studies (n=219), exercise may reduce Timed Up and Go (TUG) time (MD −3.40 seconds, 95% confidence interval [CI] −3.78 to −3.02), exceeding the minimal clinically important difference (MCID). Across three studies (n=99), exercise may improve gait speed (MD 0.03 m/s, 95% CI 0.02 to 0.04). Across four studies (n = 184), exercise may improve endurance on the 6-minute walk test (MD 85.26 m, 95% CI 67.18 to 103.04), exceeding the MCID. Across two studies (n=56), exercise may improve performance on the 5x sit-to-stand (MD −3.36 seconds, 95% CI −5.85 to −1.06), exceeding the MCID. Only one study assessed cognition (Mini-Mental State Examination) pre- and post-intervention, precluding meta-analysis.
Conclusions: Structured exercise programs after hip fracture may have a positive effect on locomotor capacity recovery. Although cognition is central to hip fracture recovery, it is infrequently assessed in exercise trials, highlighting a gap between research outcomes and geriatric care priorities. More trials are needed to establish optimal exercise types, frequency, and duration. The ICOPE framework could be integrated as part of post-fracture rehabilitation.

P1665

AGE- AND SEX-SPECIFIC VERTEBRAL HEIGHT LOSS IN HEALTHY ASIAN OLDER ADULTS USING AUTOMATED CT MORPHOMETRY

W. P. Chan[1], C.-H. Chan[1], V. P. T. Vy[2], Y.-C. Lu[3], Y. C. Lin[4], J. F. Griffith[5]

[1]Department of Radiology, Wan Fang Hospital, Taipei Medical University, Taipei, Taiwan; [2]International Ph.D. Program in Medicine, College of Medicine, Taipei Medical University, Taipei, Taiwan; [3]National Center for Geriatrics and Welfare Research, National Health Research Institutes, Yunlin, Taiwan; [4]Department of Family Medicine, School of Medicine, College of Medicine, Taipei Medical University, Taipei, Taiwan; [5]Department of Imaging and Interventional Radiology, Prince of Wales Hospital, The Chinese University of Hong Kong, Hong Kong, Hong Kong SAR China

Objective: To define age- and sex-specific normative ranges of vertebral height loss in a healthy Asian population and assess their implications for refining vertebral compression fracture (VCF) diagnostic thresholds.
Materials and Methods: This retrospective study included 856 asymptomatic Asian adults aged 50–95 years (300 women) who underwent multidetector CT between January 2021 and March 2022. Automated morphometry measured anterior, middle, and posterior heights of T4–T12 vertebrae on mid-sagittal reformats. Maximum height loss was graded using Genant's semiquantitative method, and the vertebral level with the highest-grade VCF was identified by sex and 5-year age groups. Age-related height loss at each level was analyzed using linear regression, with sex differences tested by t-test. Normative ranges across vertebral levels were derived using normal distribution and interquartile range, and group differences were assessed using ANOVA with Scheffé post hoc testing.
Results: Among 856 subjects with complete T5–T12 vertebrae, the most severe VCFs reached ≥ grade 2 at all ages and progressed to grades 3–4 in individuals aged >70–95 years. In women, severe VCFs were mainly grades 2–3 between 50–80 years, became predominantly grade 3 after 80 years, and were concentrated at T5–T8. In men, the most severe VCFs most frequently involved T7, T11, and T12, with T9 notable; in men aged 80–95 years, T9 accounted for ~20% of the most severe VCFs. Vertebral height loss increased significantly with age ($p < 0.05$ per 10-year increment). Men showed the steepest losses at T8–T12 (slopes 0.17–0.21), whereas women showed the steepest at T8, T9, and T12 (0.16–0.18). Mean age-related slopes were identical (0.16), but baseline mean loss was higher in men (8.96%) than women (8.11%, $p < 0.05$). Mean vertebral height loss exceeded 20% at advanced ages and reached ~40% by 70–80 years, with men generally experiencing greater loss ($p < 0.05$).
Conclusion: Automated CT morphometry reveals distinct age- and sex-specific patterns of vertebral height loss and VCF distribution, supporting refinement of diagnostic thresholds to better distinguish normal aging from pathological fractures in Asian populations.

P1666

PHYSICAL ACTIVITY PATTERNS IN KNEE OSTEOARTHRITIS: INFLUENCE OF BMI AND KELLGREN–LAWRENCE GRADE

W. Ridah[1], S. Zaher[1], W. El Khattabi[1], L. Bukasa[1], M. Azekriti[1], Z. Moudakir[1], A. Nache[1], D. Lemkhannate[1], S. Benlalah[1], M. Erraji[1], L. Setta[1], I. Rabii[1], M. Maghfour[1], H. Bakadir[1], S. Alami[1], B. Kuyukunu[1], M. Ettaouil[1], A. Ajerouassi[1], W. Rachidi[1], K. Nassar[1], S. Janani[1]

[1]Department of Rheumatology, Ibn Rochd University Hospital, Casablanca, Morocco

Background
Beyond pharmacological and surgical options, physical activity (PA) is one of the most effective interventions to slow functional deterioration in knee osteoarthritis (KOA). Determinants of PA in KOA are multifactorial, and clarifying the influence of body mass index (BMI) and radiographic severity is essential to strengthen non-pharmacological strategies.

Objective
To assess the influence of BMI and radiographic severity (Kellgren–Lawrence stage) on physical activity practice in patients with KOA.

Methods
We conducted a cross-sectional study with radiographically confirmed KOA. BMI was categorized as normal (18.5–24.9 kg/m²), overweight (25–29.9), and obese (≥30). Radiographic severity was graded using the Kellgren–Lawrence (KL) system (1–4). PA practice was classified according to WHO thresholds: none (0 min/week), insufficient (1–149 min/week), or recommended (≥150 min/week).

Results
Among the 143 patients, 35 (24.4%) were normal weight, 52 (36.4%) overweight, and 56 (39.2%) obese. Mean KL stage was higher in obese patients (2.8) compared with normal-weight (2.4) and overweight (2.3). PA distribution varied across BMI groups: recommended PA was achieved by 14.3% of normal-weight, 26.9% of overweight, and only 5.4% of obese patients, while inactivity predominated in obesity (53.6%). According to radiographic severity, recommended PA was reported by 38.5% at KL1, 14.6% at KL2, 23.8% at KL3, and 7.7% at KL4, with inactivity reaching 53.8% at KL4.

Conclusion
Excess body weight was associated with more advanced radiographic severity and substantially lower adherence to recommended PA. Increasing KL stage also correlated with declining PA engagement. These findings highlight the compounded burden of obesity and structural progression in KOA, emphasizing the need for integrated strategies combining weight management and structured exercise programs to optimize outcomes.

P1667

FALL RISK AND NUTRITIONAL STATUS IN OLDER ALDULT

L. Rouached[1], W. Trabelsi[1], T. Bjeoui[1], S. Ben Dhia[1], S. Bouden[1], I. Mahmoud[1], R. Tekaya[1], A. Ben Tekaya[1], L. Abdelmoula[1]

[1]Rheumatology Department, Charles Nicolle Hospital, Tunis, Tunisia

Background:
Population aging is associated with an increasing burden of complex health conditions, particularly falls and nutritional disorders. Nutritional status is a key determinant of muscle strength, balance, and mobility and may therefore influence fall risk. This study aimed to evaluate the association between nutritional status and fall risk among older adults attending primary care.

Methods:
We conducted a cross-sectional study over a three-month period at the Ghedir El Golla primary care clinic. Individuals aged ≥65 years who were able to complete standardized assessments were included. Fall risk was evaluated using several indicators: number of falls (NF) in the preceding year, time spent on the ground after a fall (TSG), ability to rise independently, the Timed Up and Go test (TUG; abnormal if ≥12 s), and single-leg stance (SLS; abnormal if <5 s). Nutritional status was assessed using the full Mini Nutritional Assessment (MNA) and classified as normal (≥24 points) or at risk of malnutrition (≤23.5 points).

Results:
Thirty-eight older adults were included (mean age 76.5 ± 1.4 years; sex ratio 0.52). Most participants were illiterate (81.6%), not professionally active (63.2%), and had social health coverage (73.7%). Multimorbidity was present in 86.8% and polypharmacy in 50%.
The mean NF was 3.6 ± 0.5, the mean TSG was 7.8 ± 2.5 minutes, and 26.1% required assistance to stand after a fall. TUG was abnormal in 24% of participants, and SLS was impaired in 79%. According to the MNA, 84% of the cohort had nutritional impairment.
No significant association was observed between nutritional status and any fall risk indicator: NF (p = 0.67), TSG (p = 0.818), TUG (p = 1.00), or SLS (p = 0.587).

Conclusion:
Although nutritional impairment was highly prevalent in this population, it was not independently associated with fall risk indicators. These findings highlight the multifactorial nature of falls in older adults.

P1668

ASSOCIATION BETWEEN DEPRESSIVE SYMPTOMS AND FALL RISK INDICATORS IN OLDER ADULTS

L. Rouached[1], W. Trabelsi[1], T. Bjeoui[1], S. Ben Dhia[1], S. Bouden[1], I. Mahmoud[1], R. Tekaya[1], A. Ben Tekaya[1], L. Abdelmoula[1]

[1]Rheumatology Department, Charles Nicolle Hospital, Tunis, Tunisia

Background:
Falls represent a major cause of morbidity and functional decline in older adults. Depressive symptoms are also common in this population yet frequently underdiagnosed, and both conditions adversely affect autonomy and quality of life. This study aimed to examine the association between depressive symptoms and established clinical indicators of fall risk in older adults.

Methods:
We conducted a cross-sectional study among outpatients aged ≥65 years who were able to complete standardized assessments. Fall risk was evaluated using several indicators: number of falls (NF) in the preceding year, time spent on the ground after a fall (TSG), ability to rise independently, the Timed Up and Go test (TUG; abnormal if ≥12 s), and single-leg stance (SLS; abnormal if <5 s). Depressive symptoms were assessed using the 30-item Geriatric Depression Scale (GDS-30), with a score ≥10 indicating depression.

Results:
Thirty-eight participants were included (mean age 76.5 ± 1.4 years; sex ratio 0.52). Most were illiterate (81.6%), no longer professionally active (63.2%), and had social health coverage (73.7%). Multimorbidity was present in 86.8% of participants and polypharmacy in 50%.
The mean number of falls was 3.6 ± 0.5, the mean TSG was 7.8 ± 2.5 minutes, and 26.1% of patients required assistance to stand after a fall. TUG was abnormal in 24% of cases, while SLS was impaired in 79%. Depressive symptoms were highly prevalent, affecting 91.3% of the cohort.
No statistically significant associations were observed between depressive symptom severity and fall risk indicators: NF (p = 0.433), TSG (p = 0.163), TUG (p = 0.554), or SLS (p = 0.189).

Conclusion:
Although both depressive symptoms and fall risk were highly prevalent in this cohort of older adults, depressive symptoms were not associated with objective or clinical indicators of fall risk. These findings highlight the multifactorial nature of falls in older populations and suggest that determinants other than depression may play a more prominent role in fall vulnerability.

P1669

IMPACT OF VISUAL AND AUDITORY IMPAIRMENTS ON FALL RISK IN OLDER ADULTS

L. Rouached[1], W. Trabelsi[1], T. Bjeoui[1], S. Ben Dhia[1], S. Bouden[1], I. Mahmoud[1], R. Tekaya[1], A. Ben Tekaya[1], L. Abdelmoula[1]

[1]Rheumatology Department, Charles Nicolle Hospital, Tunis, Tunisia

Background:
Sensory impairments, particularly visual and auditory deficits, become increasingly prevalent with advancing age and may adversely affect environmental perception, postural control, and functional mobility. Falls remain a leading cause of morbidity and loss of independence among older adults. This study aimed to examine the association between visual and auditory impairments and fall risk in older adults attending primary care.

Methods:
We conducted a cross-sectional study among older adults consulting at a primary care clinic who were able to complete standardized assessments. Fall risk was evaluated using multiple indicators: number of falls (NF) during the preceding year, time spent on the ground after a fall (TSG), ability to rise independently, the Timed Up and Go test (TUG; abnormal if ≥12 s), and single-leg stance (SLS; abnormal if <5 s). Visual function was assessed using the Snellen chart, and hearing function using the whispered voice test.

Results:
Thirty-eight participants were included (mean age 76.5 ± 1.4 years; sex ratio 0.52). Most were illiterate (81.6%), not professionally active (63.2%), and had social health coverage (73.7%). Multimorbidity was present in 86.8% and polypharmacy in 50%.

The mean NF was 3.6 ± 0.5, the mean TSG was 7.8 ± 2.5 minutes, and 26.1% of participants required assistance to stand after a fall. TUG was abnormal in 24% of cases, while SLS was impaired in 79%. Sensory impairments were frequent, with reduced visual acuity and hearing impairment each affecting 71% of participants.

No statistically significant associations were found between visual impairment and functional fall risk indicators (TUG: $p = 0.179$; SLS: $p = 0.245$). Similarly, hearing impairment was not significantly associated with TUG ($p = 0.179$) or SLS ($p = 0.422$).

Conclusion:
Visual and auditory impairments were highly prevalent in this cohort of older adults. However, no significant association with functional indicators of fall risk was identified. Despite this, early detection and appropriate management of sensory deficits remain essential to enhance safety, preserve autonomy, and maintain quality of life in older populations.

P1670

IMPACT OF COGNITIVE IMPAIRMENT ON FALL RISK IN OLDER ADULTS

L. Rouached[1], W. Trabelsi[1], T. Bjeoui[1], S. Ben Dhia[1], S. Bouden[1], I. Mahmoud[1], R. Tekaya[1], A. Ben Tekaya[1], L. Abdelmoula[1]

[1]Rheumatology Department, Charles Nicolle Hospital, Tunis, Tunisia

Background:
Population aging is associated with a growing burden of complex health conditions, among which falls and cognitive decline play a central role. Cognitive impairment may alter attention, executive function, and motor planning, thereby compromising balance and mobility in older adults. This study aimed to evaluate the association between cognitive status and fall risk among older adults attending primary care.

Methods:
We conducted a cross-sectional study in individuals aged ≥65 years who were able to complete standardized assessments. Fall risk was evaluated using several indicators: number of falls (NF) in the preceding year, time spent on the ground after a fall (TSG), ability to rise independently, the Timed Up and Go test (TUG; abnormal if ≥12 s), and single-leg stance (SLS; abnormal if <5 s). Cognitive function was assessed using the Mini-Mental State Examination (MMSE; normal ≥24, impaired ≤23) and the Five-Word Test (FWT) by Dubois (pathological <10).

Results:
Thirty-eight older adults were included (mean age 76.5 ± 1.4 years; sex ratio 0.52). Most participants were illiterate (81.6%), not professionally active (63.2%), and had social health coverage (73.7%). Multimorbidity was present in 86.8% and polypharmacy in 50%.

The mean NF was 3.6 ± 0.5, the mean TSG was 7.8 ± 2.5 minutes, and 26.1% required assistance to stand after a fall. TUG was abnormal in 24% of participants, and SLS was impaired in 79%. According to the FWT, 52.6% had pathological scores, while 81.5% had cognitive impairment based on the MMSE.

A significant association was observed between MMSE score and TSG ($p < 0.05$). However, no significant associations were found between MMSE score and NF ($p = 0.249$), TUG ($p = 1.00$), or SLS ($p = 0.146$).

Conclusion:
Cognitive impairment was highly prevalent in this cohort and was associated with prolonged time spent on the ground after a fall. These findings suggest that cognitive decline may influence the severity and consequences of falls rather than their occurrence, supporting the integration of cognitive assessment into multidimensional fall prevention strategies in older adults.

P1671

PHYSICAL PERFORMANCE AND FUNCTIONAL AUTONOMY: IMPACT ON FALL RISK IN OLDER ADULTS

L. Rouached[1], W. Trabelsi[1], T. Bjeoui[1], S. Ben Dhia[1], S. Bouden[1], I. Mahmoud[1], R. Tekaya[1], A. Ben Tekaya[1], L. Abdelmoula[1]

[1]Rheumatology Department, Charles Nicolle Hospital, Tunis, Tunisia

Background
Falls are among the most serious and feared events in older adults due to their association with morbidity, loss of independence, and increased mortality. Functional autonomy is a key determinant of quality of life in aging populations, and its relationship with fall risk represents a major challenge in primary care. This study aimed to evaluate the association between fall risk indicators and functional autonomy in older adults.

Methods
A cross-sectional study was conducted among older adults attending a primary care clinic who were able to complete standardized assessments. Fall risk was evaluated using the number of falls in the previous year (NF), time spent on the ground after a fall (TSG), ability to rise independently, the Timed Up and Go test (TUG; abnormal ≥12 s), and the single-leg stance test (SLS; impaired <5 s). Functional autonomy was assessed using the Activities of Daily Living scale (ADL; 0–6) and the Instrumental Activities of Daily Living scale (IADL; 0–4). Group comparisons were performed using the Mann–Whitney test.

Results
Thirty-eight participants were included (mean age 76.5 ± 1.39 years; sex ratio 0.52). Most were illiterate (81.6%), not professionally active (63.2%), and had social health coverage (73.7%). Multimorbidity was present in 86.8% and polypharmacy in 50%.

The mean number of falls was 3.6 ± 0.5 per year, and the mean TSG was 7.83 ± 2.52 minutes; 26.1% required assistance to stand after a fall. TUG was abnormal in 24% of participants, and SLS was impaired in 79%. Functional dependency was frequent: 68.4% for ADL and 60.5% for IADL.

Participants with abnormal TUG scores had significantly lower ADL scores ($p = 0.012$) and a trend toward lower IADL scores ($p = 0.082$). Impaired SLS was strongly associated with both lower ADL and IADL scores ($p = 0.008$ and $p = 0.001$, respectively).

Conclusion
Reduced physical performance, particularly impaired balance and mobility, is strongly associated with decreased functional autonomy in older adults. These findings highlight the importance of systematic assessment of physical performance in primary care to identify individuals at high risk of functional decline and falls and to implement early, targeted preventive interventions.

P1672

IMPACT OF METHOTREXATE EXPOSURE ON BONE MINERAL DENSITY IN BIOLOGIC-TREATED RHEUMATOID ARTHRITIS

W. Trabelsi[1], F. Majdoub[1], D. Kaffel[1], L. Kharrat[1], I. Cherif[1], D. Ben Nessib[1], W. Hamdi[1]

[1]Rheumatology Department, Mohamed Kassab Institute of Orthopaedic Surgery, La Manouba, Tunisia

Background:
Patients with rheumatoid arthritis (RA) are at increased risk of osteoporosis due to chronic inflammation and therapeutic exposures. Bone disorders associated with Methotrexate -which is the cornerstone in RA treatment- have been described, however, its long-term effects on bone mineral density (BMD) remain debated, particularly in patients requiring biologic DMARDs (bDMARDs).
Objectives:
To assess the effect of Methotrexate exposure on bone mineral density and osteoporosis in biologic-treated rheumatoid arthritis.
Methods:
A retrospective monocentric study included patients, aged 18 years or older, fulfilling the 1987 ACR and/or 2010 ACR–EULAR classification criteria for RA. All patients were receiving first-line bDMARD therapy for at least six months. BMD was measured by dual-energy X-ray absorptiometry (DXA) at the anteroposterior lumbar spine (LS) and femoral necks (FN). Bone mass (BM) was expressed in g/cm², and T-scores were expressed as standard deviations (SD).
Results:
Forty-six patients with RA were included. The sex ratio was 0.095. The mean age was 54.4 ± 11.7 years [31-73] and the mean age at disease onset was 44.0 ± 11.5 years [19-60]. At least one comorbidity was present in 36 patients. Methotrexate had been used prior to bDMARD initiation in 98% of patients. The mean duration of MTX exposure was 50.3 ± 47.9 months, and the mean maximum weekly dose was 17.61 ± 3.18 mg.
The mean LS BMD was 0.952 ± 0.2 g/cm², with a mean T-score of −1.75 ± 1.3 SD. At the FN, mean BMD was 0.850 ± 0.1 g/cm², with a mean T-score of −1.41 ± 1.2 SD.
No correlation was found between MTX duration and BMD at the LS ($r = −0.149$, $p = 0.408$) or FN ($r = −0.105$, $p = 0.555$). Similarly, maximum MTX dose was not correlated with LS BMD ($r = −0.042$, $p = 0.793$) or FN BMD ($r = 0.147$, $p = 0.354$).
Conclusion:
Our study showed that MTX exposure, in terms of both duration and maximum dose, was not associated with reduced bone mineral density at the lumbar spine or femoral neck. Although a high prevalence of low bone mass was observed, no suggesting detrimental effect of Methotrexate on bone was identified in our population.

P1673

DOES BODY COMPOSITION IMPACT BONE MINERAL DENSITY IN PATIENTS WITH RHEUMATOID ARTHRITIS?

F. Majdoub[1], W. Trabelsi[1], D. Kaffel[1], L. Kharrat[1], I. Cherif[1], D. Ben Nessib[1], W. Hamdi[1]

[1]Rheumatology Department, Mohamed Kassab Institute of Orthopaedic Surgery, La Manouba, Tunisia

Background and objective:
Rheumatoid arthritis (RA) can be associated with altered body composition (BC), which can affect bone mineral density (BMD) and musculoskeletal health. We aimed to evaluate the impact of total, android and gynoid body composition on bone mineral density (BMD) in patients receiving biologic disease-modifying antirheumatic drugs (bDMARDs).
Methods:
A retrospective monocentric study included patients, aged 18 years or older, fulfilling the 1987 ACR and/or 2010 ACR–EULAR classification criteria for RA. All patients were receiving first-line bDMARD therapy for at least six months, initiated after failure, intolerance, or contraindication to one or more conventional synthetic DMARDs. Bone mineral density (at the anteroposterior lumbar spine (LS) and femoral necks (FN)) and BC were measured by dual-energy X-ray absorptiometry (DXA). Bone mass (BM) was expressed in g/cm², and Z-scores were expressed as standard deviations (SD). Body composition (BC) measures included android and gynoid lean and fat mass. Correlations between BC parameters and BMD or T-scores at the lumbar spine and femoral neck were analyzed.
Results :
Our study included 46 patients. The sex ratio was 0.095. The mean age was 54.4 ± 11.7 years [31-73] and the mean age at disease onset was 44.0 ± 11.5 years [19-60]. The mean LS BMD was 0.952 ± 0.2 g/cm², with a mean T-score of −1.75 ± 1.3 SD. At the FN, the mean BMD was 0.850 ± 0.1 g/cm², with a mean T-score of −1.41 ± 1.2 SD. On whole-body DXA analysis, the mean total fat mass was 45.5%, while the mean total lean mass accounted for 54.5% of BC. Regional analysis showed a higher proportion of fat mass in the gynoid region compared with the android region (50.5% vs. 49%), whereas lean mass distribution predominated in the android compartment compared with the gynoid compartment (51% vs. 49.5%).
No significant associations were observed between BC and BMD. LS BMD was not correlated with total, android, or gynoid lean mass (r = −0.14, 0 and −0.089; p = 0.931, 0.999 and 0.576, respectively) nor with total, android, or gynoid fat mass (r = 0.14, 0 and 0.089; p = 0.93, 0.999 and 0.576), while FN BMD similarly showed no associations with lean or fat mass across compartments, with near-null correlation coefficients (r = −0.019 to 0.019; all p ≥ 0.902). Consistently, T-scores at both the LS and FN were not significantly correlated with total, android, or gynoid lean mass (r = −0.187 to 0.009; p ≥ 0.22) or fat mass (r = −0.009 to 0.187; p ≥ 0.22).
Conclusion:
In biologic-treated RA patients, total and regional lean and fat mass were not associated with BMD or T-scores, indicating that body composition may have limited impact on skeletal health in this population. These findings support the need for systematic BMD assessment and targeted osteoporosis prevention, regardless of body composition.

P1674

WHICH IMPACT OF THE EULAR RESPONSE IN BIOLOGIC-TREATED RHEUMATOID ARTHRITIS ON BONE MINERAL DENSITY?

W. Trabelsi[1], F. Majdoub[1], D. Kaffel[1], L. Kharrat[1], I. Cherif[1], D. Ben Nessib[1], W. Hamdi[1]

[1]Rheumatology Department, Mohamed Kassab Institute of Orthopaedic Surgery, La Manouba, Tunisia

Background:
Rheumatoid arthritis (RA) is associated with an increased risk of low bone mineral density (BMD) and osteoporosis. Biologic disease-modifying antirheumatic drugs (bDMARDs) improve disease activity, but it remains unclear whether clinical response, as defined by EULAR criteria, is associated with skeletal health.
Objectives:
To evaluate the impact of clinical response to bDMARD therapy, measured by EULAR criteria, on bone mineral density, in patients with RA.
Methods:
A retrospective monocentric study included patients, aged 18 years or older, fulfilling the 1987 ACR and/or 2010 ACR–EULAR classification criteria for RA. All patients were receiving first-line bDMARD therapy for at least six months, initiated after failure, intolerance, or contraindication to one or more conventional synthetic DMARDs. Bone mineral density was measured by dual-energy X-ray absorptiometry (DXA), EULAR response at six months was determined using DAS28 scores and categorized into three groups: non-responders, moderate responders and good responders. For analysis, patients were grouped into good/moderate responders versus non-responders. Associations between EULAR response and BMD or T-scores at the lumbar spine and proximal femur were analyzed.
Results:
Forty-six patients with RA were included. The sex ratio was 0.095. The mean age was 54.4 ± 11.7 years [31-73] and the mean age at disease onset was 44.0 ± 11.5 years [19-60]. Biologic therapies included Etanercept (43%), Adalimumab (13%), Infliximab (9%), Certolizumab (9%), Tocilizumab (9%) and Rituximab (17%). At six months, 80.4% of patients were classified as good or moderate responders according to EULAR criteria. The mean lumbar spine BMD was 0.952 ± 0.2 g/cm², with a mean T-score of −1.75 ± 1.3 standard deviations (SD). At the proximal femur, mean BMD was 0.850 ± 0.1 g/cm², with a mean T-score of −1.41 ± 1.2 SD.
EULAR response values are presented as good/moderate responders vs. non-responders. No significant differences were observed between responders and non-responders in lumbar spine BMD (0.97 ± 0.23 vs. 0.86 ± 0.1 g/cm²; p = 0.224) or proximal femur BMD (0.85 ± 0.15 vs. 0.82 ± 0.13 g/cm²; p = 0.629). Similarly, EULAR response was not associated with T-scores at the lumbar spine (−1.64 ± 1.34 vs. −2.16 ± 1.06 SD; p = 0.29) or proximal femur (−1.41 ± 1.22 vs. −1.37 ± 0.99 SD; p = 0.926).
Conclusion:
In this cohort of biologic-treated RA patients, bone mineral density and T-scores at the lumbar spine and proximal femur were not associated with EULAR-defined clinical response. These results suggest that short-term improvements in systemic inflammation and disease activity may not directly translate into measurable changes in skeletal mass.

P1675

HOW DOES BODY MASS INDEX AFFECT THE RESPONSE TO BIOLOGICS IN RHEUMATOID ARTHRITIS?

F. Majdoub[1], W. Trabelsi[1], D. Kaffel[1], L. Kharrat[1], I. Cherif[1], D. Ben Nessib[1], W. Hamdi[1]

[1]Rheumatology Department, Mohamed Kassab Institute of Orthopaedic Surgery, La Manouba, Tunisia

Background:
Body mass index (BMI) reflects body composition and may influence inflammatory activity and the pharmacokinetics of biologic therapies. However, the impact of BMI on the clinical response to biologic disease-modifying antirheumatic drugs (bDMARDs), as defined by EULAR criteria, is still widely debated, which could represent a gap in the personalized management of rheumatoid arthritis (RA).
Objectives:
To evaluate the effect of anthropometric measures and clinical response to bDMARDs, as defined by EULAR criteria, in patients with RA.
Methods:
A retrospective monocentric study included patients, aged 18 years or older, fulfilling the 1987 ACR and/or 2010 ACR–EULAR classification criteria for RA. All patients were receiving first-line bDMARD therapy for at least six months, initiated after failure, intolerance, or contraindication to one or more conventional synthetic DMARDs. Anthropometric measures including weight, height and BMI were recorded. EULAR response at six months was determined using DAS28 scores and categorized into three groups: non-responders, moderate responders, and good responders. For analysis, patients were grouped into good/moderate responders versus non-responders. Associations between anthropometric measures and EULAR response were assessed.
Results:
Forty-six patients with RA were included. The sex ratio was 0.095. The mean age was 54.4 ± 11.7 years [31-73] and the mean age at disease onset was 44.0 ± 11.5 years [19-60]. The mean weight was 75.6 kg [43-98], with a mean height of 158 cm [106-178]. The mean BMI was 30.2 kg/m² [17.9–40.1]. Biologic therapies included Etanercept (43%), Adalimumab (13%), Infliximab (9%), Certolizumab (9%), Tocilizumab (9%) and Rituximab (17%). At six months, 80.4% of patients were classified as good or moderate responders according to EULAR criteria. EULAR response values are presented as good/moderate responders versus non-responders. No significant differences were observed in body weight (75.08 ± 11.52 vs. 77.67 ± 9.83 kg; p = 0.539), height (156.89 ± 10.85 vs. 162.89 ± 7.35 cm; p = 0.125), or BMI (30.31 ± 4.86 vs. 29.62 ± 5.56 kg/m²; p = 0.714) between responders and non-responders.
Conclusion:
In this cohort of biologic-treated RA patients, anthropometric measures including weight, heigh, and BMI were not associated with EULAR response at six months. These findings suggest that short-term clinical response to bDMARD therapy is independent of baseline anthropometric characteristics, highlighting the need to consider other factors when predicting treatment outcomes.

P1676

EROSIVE RHEUMATOID ARTHRITIS: WHAT IMPACT ON BONE MASS AND BONE MINERAL DENSITY?

W. Trabelsi[1], F. Majdoub[1], D. Kaffel[1], L. Kharrat[1], I. Cherif[1], D. Ben Nessib[1], W. Hamdi[1]

[1]Rheumatology Department, Mohamed Kassab Institute of Orthopaedic Surgery, La Manouba, Tunisia

Background and Objectives:
Rheumatoid arthritis (RA) is characterized by chronic inflammation that can lead to joint erosion and systemic bone loss. While erosive disease reflects localized structural damage, its association with systemic bone mineral density (BMD) remains no clearly defined. We aimed to evaluate the erosive status in biologic-treated rheumatoid arthritis and its effect on bone mineral density.
Methods:
A retrospective monocentric study included patients, aged 18 years or older, fulfilling the 1987 ACR and/or 2010 ACR–EULAR classification criteria for RA. All patients were receiving first-line bDMARD therapy for at least six months, initiated after failure, intolerance, or contraindication to one or more conventional synthetic DMARDs. Bone mineral density was measured by dual-energy X-ray absorptiometry (DXA). Erosive status was determined based on radiographic evidence. Associations between erosive status and BMD or T-scores at the lumbar spine and proximal femur were analyzed.
Results:
A total of 46 patients with RA were included. The sex ratio was 0.095. The mean age was 54.4 ± 11.7 years [31-73]. An erosive disease profile was present in 87% of patients. Biologic therapies included Etanercept (43%), Adalimumab (13%), Infliximab (9%), Certolizumab (9%), Tocilizumab (9%) and Rituximab (17%). The mean lumbar spine BMD was 0.952 ± 0.2 g/cm², with a mean T-score of −1.75 ± 1.3 standard deviations (SD). At the proximal femur, mean BMD was 0.850 ± 0.1 g/cm², with a mean T-score of −1.41 ± 1.2 SD.
Erosive RA status is presented as erosive vs. non-erosive RA. No significant differences were observed between erosive and non-erosive RA in lumbar spine bone mineral density (0.94 ± 0.22 vs. 1.02 ± 0.16 g/cm2; p = 0.383), femoral neck bone mineral density (0.84 ± 0.14 vs. 0.91 ± 0.15 g/cm2; p = 0.293), the T-scores at both the lumbar spine (-1.82 ± 1.3 vs. -1.26 ± 1.28 SD; p = 0.336) and the femoral neck (-1.45 ± 1.15 vs. -0.9 ± 1.27 SD; p = 0.258).
Conclusion:
In this cohort of biologic-treated RA patients, erosive disease was not associated with reduced BMD at the lumbar spine or proximal femur. These findings suggest that localized joint damage does not necessarily reflect systemic bone loss. A larger-scale study is needed to better understand the extent to which erosive status impacts bone mineral density.

P1677

GENSCIP133: A NOVEL DUAL FUNCTIONAL MOLECULE WITH PTH AND ANTI-RANKL ACTIVITIES FOR THE TREATMENT OF OSTEOPOROSIS

W. Xiaoxing[1], W. Shanshan[1], W. Peipei[1], L. Na[1], M. Qingjuan[1], S. Gao[1], K. Lishan[1], X. Guliang[1]

[1]Changchun GeneScience Pharmaceutical Co., Ltd, Shanghai, China

Objective: GenSciP133 is a chimeric protein comprised of anti-RANKL antibody and parathyroid hormone (PTH). This study aimed to evaluate the therapeutic potential of GenSciP133 for osteoporosis through *in vitro* and *in vivo* models.

Materials and Methods:*In vitro* PTH1R activation was measured in PTH1R-expressing Saos2 cells with/without expression of RANKL. Human osteoclast differentiation as an indicator for RANKL inhibition was assessed in Raw264.7 cells. *In vivo* efficacy studies were conducted in hu-RANKL transgenic ovariectomized (OVX) mice and a closed femoral fracture mouse model. A pharmacokinetic study was performed in hu-RANKL transgenic mice.

Results: GenSciP133 exhibited comparable PTH1R activities in PTH1R and RANKL co-expressing Saos2 cells (EC_{50} = 9.5 nM), while activities in PTH1R-expressing only Saos2 cells were largely attenuated (EC_{50} = 890 nM). Additionally, GenSciP133 demonstrated comparable inhibition of osteoclast differentiation in Raw264.7 cells to denosumab. These results suggested that GenSciP133 might be able to exert synergistic effects towards increases in bone mass while minimizing undesired effects in PTH1R-expressing only tissues such as kidney to avoid renal toxicity. In the OVX mouse model, GenSciP133 dose-dependently improved bone density and femoral biomechanics at 0.3, 1, and 3 mpk. The effects at the 1 and 3 mpk groups were superior to denosumab at 10 mpk and the animals were well tolerated. In the fracture model, GenSciP133 significantly enhanced bone mineral density (BMD), biomechanics, and structural integrity of injured bones after 4 weeks of treatment. The PK study showed a half-life of GenSciP133 similar to that of denosumab, indicating potential for less frequent dosing in humans.

Conclusion: We have developed a dual anti-RANKL and PTH molecule that demonstrate robust efficacy in promoting bone formation and improving bone quality with a favorable safety profile and a low dosing frequency. The results suggested that GenSciP133 has the potential to be further developed as a promising therapeutic candidate for osteoporosis.

MULTI-CENTER VALIDATION OF A FEDERATED LEARNING-BASED ARTIFICIAL INTELLIGENCE SYSTEM FOR SCREENING LOW BONE MINERAL DENSITY USING CHEST X-RAYS

W.-C. Hung[1], B.-R. Lin[2], W.-C. Sun[2], P.-W. Wu[2], W.-D. Liu[2]

[1]E-Da Hospital/I-Shou University, Kaohsiung, Taiwan; [2]Taiwan AI Labs, Taipei, Taiwan

Objective

To evaluate the diagnostic performance and generalizability of a novel artificial intelligence (AI) system trained via federated learning for opportunistic screening of low bone mineral density (T-score ≤ -2.5) using routine chest X-rays (CXRs) across two independent medical centers.

Material and Methods

We developed a deep learning model (OsteoPredict) utilizing a federated learning architecture to preserve patient data privacy, trained on 5,943 images. The system was validated retrospectively using an independent external cohort of 3,007 adult patients from two distinct tertiary medical centers who underwent same-day CXR and dual-energy X-ray absorptiometry (DXA). The ground truth was operationally defined as a lumbar spine DXA T-score of ≤ -2.5 for the entire cohort to ensure label consistency for model training. The primary endpoint was the Area Under the Receiver Operating Characteristic curve (AUROC), with sensitivity and specificity as secondary endpoints.

Results

Among 3,007 validation cases, 200 (6.7%) were identified with a T-score ≤ -2.5. The AI system demonstrated excellent discrimination with an overall AUROC of 0.942 (95% CI, 0.923-0.962), a sensitivity of 91.0%, and a specificity of 82.7%. Subgroup analyses revealed robust performance across the two different study sites (AUROC 0.947 and 0.936, respectively) and genders. Crucially, the system maintained high sensitivity in the high-risk elderly population (≥60 years), effectively minimizing false negatives in the group with the higher disease prevalence.

Conclusion

This federated learning-based AI system achieves high accuracy for detecting low bone mineral density (T-score ≤ -2.5) from standard CXRs and demonstrates robust generalization across multiple institutions. By leveraging widely available imaging data, it offers a scalable solution for opportunistic screening, effectively identifying at-risk individuals who may require further definitive DXA assessment.

AUTOMATED VERTEBRAL COMPRESSION FRACTURE ASSESSMENT SYSTEM USING DEEP LEARNING SEGMENTATION AND GEOMETRIC MORPHOMETRY ON LATERAL SPINE X-RAYS

W.-C. Hung[1], Y.-L. Lin[2], S.-Y. Sin-Yu[2]

[1]E-Da Hospital/I-Shou University, Kaohsiung, Taiwan; [2]National Yunlin University of Science & Technology, Yunlin, Taiwan

Objectives: Vertebral Compression Fractures (VCFs) are often underdiagnosed due to time-consuming manual measurements. This study aims to develop a fully automated Computer-Aided Diagnosis system integrating deep learning segmentation with geometric algorithms to locate Genant's semi-quantitative (SQ) diagnostic points for rapid VCF screening.

Material and Methods: A dataset of 192 lateral spine X-ray images was collected from a medical center, containing 1,576 individual vertebrae. The dataset distribution included 1,223 normal vertebrae and 353 fractured vertebrae (comprising 198 mild, 107 moderate, and 48 severe cases). We employed Mask R-CNN with a ResNet backbone for vertebral instance segmentation, which handles overlapping vertebral shadows better than traditional semantic segmentation (e.g., U-Net). A novel post-processing algorithm corrected rotation and identified six key landmarks (corners and endplate midpoints) to calculate height loss ratios based on standard SQ criteria. Performance was evaluated using the Dice coefficient for segmentation and Area Under the Curve (AUC) for fracture classification.

Results: The proposed Mask R-CNN model achieved a Dice coefficient of 0.871, significantly outperforming the U-Net (0.842) baseline in separating adjacent vertebrae. The automated six-point localization achieved an average Mean Absolute Error (MAE) of 23.46 pixels compared to expert ground truth. In the VCF classification task, the system demonstrated a high specificity of 94.61% and an accuracy of 88.01%. Although the sensitivity was 64.65% due to the high proportion of challenging mild fractures in the dataset, the AUC reached 0.796, indicating the system's robustness in distinguishing fractures from normal anatomy.

Conclusions: This study demonstrates the feasibility of an automated "segmentation-to-measurement" pipeline. By replicating the clinical standard Genant's method and providing interpretable morphometric data, this tool holds promise for integration into clinical workflows. Its high specificity makes it particularly suitable for large-scale screening to filter out normal cases and prioritize high-risk patients for radiologist review.

P1680

ANNUALIZED BONE MINERAL DENSITY CHANGES IN BREAST CANCER PATIENTS: A REAL-WORLD EXPLORATORY COMPARISON BETWEEN TRADITIONAL CHINESE MEDICINE AND ANTI-OSTEOPOROTIC THERAPY

W.-L. Chen[1], Y.-L. Deng[1], C.-Y. Hsu[1]

[1]Taichung Veterans General Hospital, Taiching, Taiwan

• Objective

Breast cancer patients are at increased risk of accelerated bone loss due to cancer-related treatments, including anti-hormonal therapy and ovarian suppression. While anti-osteoporotic medications are commonly prescribed to mitigate bone loss, traditional Chinese medicine (TCM) is also frequently used in Taiwan. However, data comparing bone mineral density (BMD) trajectories between these treatment approaches remain limited.

• Material and Method

To compare annualized BMD changes between breast cancer patients receiving TCM and those receiving anti-osteoporotic therapy in a real-world clinical setting, we retrospectively analyzed breast cancer patients aged ≥40 years with at least two BMD measurements. The index date was defined as the first DXA examination. Patients with prior TCM or anti-osteoporotic medication use before the index date were excluded. Each patient contributed one interval between the first and second DXA examinations. Annualized BMD change was calculated. Patients were categorized according to treatment exposure during the DXA interval. Baseline characteristics were compared, and multivariable-adjusted analyses are ongoing.

• Result

A total of 737 patients were included (TCM: 58; anti-osteoporotic therapy: 679). TCM users were younger than patients receiving anti-osteoporotic therapy, while baseline BMD values were comparable between groups. No statistically significant difference in annualized BMD change was observed between groups.

• Conclusion

In this preliminary real-world analysis, TCM use in breast cancer patients was not associated with an apparent worsening of BMD trajectories compared with anti-osteoporotic therapy. Given baseline differences and the exploratory nature of this study, further multivariable-adjusted and matched analyses are warranted.

• Limitation

This study is limited by the small sample size of the TCM group, baseline imbalance in age, and the lack of propensity matching in this preliminary analysis.

P1681

OPTIMISING OSTEOPOROSIS CARE FOR INPATIENTS IN GERIATRIC MEDICINE: A QUALITY IMPROVEMENT INITIATIVE AT A TERTIARY HOSPITAL IN SINGAPORE

X. F. Huang[1], X. T. Huang[1], A. F. Yap[1], A. Roy Chowdhury[1], X. M. Liu[1], W. C. Foo[1], H. M. J. Lee[1], K. L. Loy[1]

[1]Singapore General Hospital, Singapore, Singapore

Objective

To increase comprehensive osteoporosis management (case identification, investigations, calcium/vitamin D supplementation, education, appropriate follow-up plans and dental clearance plans) rates for eligible patients at Singapore General Hospital (SGH) Geriatric Medicine (GRM) from a baseline of 8% to 70% within 3 months post-intervention.

Material and Methods

In ward 63 of Singapore General Hospital, under the department of GRM, crtitical gaps in osteoporosis management were identified: low identification rates, lack of patient education, lack of clear follow-up plans and dental clearance plans.

Baseline data were collected for 158 eligible patients (≥ 65 years, with fragility fractures or osteoporosis diagnosed via a Bone Mineral Density test, excluding those bedbound, chairbound, with prognosis ≤1year or creatinine clearance ≤20 ml/min). Cause-and-effect diagram identified contributing factors to low management rates. Pareto chart prioritised four key root causes: Poor awareness and knowledge among junior doctors, lack of standardized workflows, inadequate patient/family education, and inpatient dental clearance challenges. Interventions included structured doctor training, establishment of a standardized workflow, nurse-led education, and outpatient dental clearance pathway in collaboration with the National Dental Centre.

Results

Post-intervention data were collected for 76 eligible patients. Comprehensive osteoporosis management rates improved from 8% to 80%, while 9% declined treatment and 11% received partial management. Specifically, case identification improved from 51% to 93%, calcium/vitamin D supplementation from 78% to 96%, patient education from 16% to 88%, follow-up plans from 42% to 86%, and dental clearance plans from 36% to 80%. The initiative enhanced junior doctors' confidence, empowered patients, and helped address systemic barriers to continuity of osteoporosis care.

Conclusions

This initiative demonstrated that a structured, multidisciplinary approach can significantly enhance inpatient osteoporosis management, highlighting the need to proactively address osteoporosis, a condition that is often underrecognized and undertreated during inpatient care.

[1]Beijing Hospital, Beijing, China

New Indicators Related to the Osteosarcopenia in the Elderly: Assessment of Intrinsic Capacity

Xiuqi Qiao[1,2], Qi Pan[1,2]

[1]Department of Endocrinology, Beijing Hospital, National Center of Gerontology, Institute of Geriatric Medicine, Chinese Academy of Medical Sciences, Beijing 100730, P.R. China; [2]Peking Union Medical College, Chinese Academy of Medical Sciences, Beijing 100730, P.R. China.

Corresponding author: Qi Pan. Email: panqi621@126.com

Abstract

Background

While intrinsic capacity (IC) has been associated with reduced sarcopenia risk, its relationship with osteosarcopenia remains unexplored. This study aimed to elucidate the association between IC and osteosarcopenia in older adults.

Methods

This cross-sectional study enrolled outpatient patients ≥ 60 years to investigate IC-osteosarcopenia associations. IC was quantified through a multidimensional score integrating cognition, mobility, vitality, psychological, and sensory domains. Osteosarcopenia was defined as concurrent osteoporosis and sarcopenia. Participants underwent stratification based on osteoporosis/sarcopenia comorbidity status. Multivariable-adjusted logistic models assessed IC-osteosarcopenia risk gradients, with subgroup analyses exploring age/sex-specific effects and comorbidity interactions.

Results

In this cohort of 461 older adults (median age 80 years), osteosarcopenia prevalence reached 26%. Logistic regression analysis identified: cognitive [odds ratio (OR): 0.871, 95% confidence interval (CI): 0.808–0.933] and sensory (OR: 0.633, 95% CI: 0.417–0.950) impairments specifically predicted osteosarcopenia, while vitality deficits demonstrated dual risks for both sarcopenia (OR: 0.820, 95% CI: 0.725–0.920) and osteosarcopenia (OR: 0.736, 95% CI: 0.648–0.826). Locomotor impairment and psychological distress emerged as pan-risk factors across sarcopenia, osteoporosis, and osteosarcopenia. Total IC scores exhibited dose-dependent associations with all three musculoskeletal outcomes ($P < 0.05$), maintaining significance across age/sex subgroups and after confounding variables adjustment.

Conclusion

Total IC score serves as a significant predictor of osteosarcopenia in elderly patients. Cognition, mobility, vitality, psychological, and sensory domains were associated with osteosarcopenia.

P1683

SYNERGISTIC EFFECTS OF BONE-FORMING THERAPY AND INTEGRATED LIFESTYLE INTERVENTION ON BMD AND FUNCTIONAL INDEPENDENCE IN PATIENTS AT VERY HIGH RISK OF FRACTURE: A CASE SERIES

X. R. Li[1], C. H. Liang[2], H. C. Hsieh[1]

[1]Department of Nursing, Tungs' Taichung MetroHarbor Hospital, Taiwan, Taichung, Taiwan; [2]Department of Orthopedics, Tungs' Taichung MetroHarbor Hospital, Taiwan, Taichung, Taiwan

Introduction:
Management of very high-risk osteoporotic patients requires more than just pharmacological intervention. While bone-forming agents significantly increase bone mineral density (BMD), the recovery of functional mobility is paramount in preventing falls and subsequent fractures. This study evaluates a multidisciplinary approach combining anabolic therapy with structured lifestyle interventions.

Methods:
Two postmenopausal women with severe osteoporosis (baseline T-score < -3.0) were followed over 24 months. The integrated intervention protocol included:

1. **Pharmacological Therapy:** Standard course of bone-forming agents.

2. **Nutritional Optimization:** Educator-led intake of Calcium, Vitamin D3, and high-quality protein.

3. **Exercise Physiology:** Supervised individualized resistance training targeting core stability and lower-limb power. Outcome measures included DXA-derived BMD (T-score), gait stability, and independence in Activities of Daily Living (ADLs).

Results:
Significant clinical improvements were observed across all parameters:

• **BMD Gain:** Patient 1 improved from a baseline T-score of -5.3 to -2.9; Patient 2 improved from -3.5 to -2.4.

• **Functional Mobility:** Both patients demonstrated marked progress in gait velocity and balance. Notably, Patient 1 transitioned from requiring walking aids to independent outdoor ambulation.

• **Safety & Falls:** Zero fall incidents or new fragility fractures were recorded during the 24-month follow-up, indicating enhanced dynamic postural control.

Conclusion:
This case series demonstrates that bridging bone-forming therapy with professional nutritional and exercise interventions creates a potent synergistic effect. Improving muscular stability and walking independence is as critical as BMD restoration in high-risk populations. This multidisciplinary model provides a robust clinical pathway for reducing fracture risk and improving quality of life.

Background: Vitamin D is essential for skeletal health and has been increasingly recognized for potential extraskeletal benefits. Despite this, vitamin D deficiency remains highly prevalent, with corrective efforts largely focused on skeletal outcomes while neglecting extra-skeletal effects and region-specific challenges.
Aim: This modified Delphi consensus aimed to address these gaps in the Kingdom of Saudi Arabia (KSA).
Methods: Eleven multidisciplinary key opinion leaders from KSA participated in a structured process involving a premeeting survey, two in-person meetings, and three iterative survey rounds. Consensus, predefined as ≥75% agreement, was achieved across all 38 statements, which covered the current landscape of vitamin D deficiency in KSA, strategies for correction and maintenance, monitoring practices, and safety considerations.
Results: Key recommenda&ons included: (i) vitamin D deficiency contributes to disease development, while correction improves outcomes; (ii) oral supplementation is the primary correc&ve strategy in the Saudi context; (iii) screening should be limited to patients in whom deficiency impacts disease or treatment, with empiric supplementation preferred otherwise; (iv) dosing regimens of 50,000 IU weekly for deficient or empirically treated patients and 1,000–2,000 IU daily or 50,000 IU monthly for sufficient patients; (v) indefinite maintenance with monitoring every 3–6 months for screened patients; (vi) target serum 25-hydroxyvitamin D (25(OH)D) levels of ≥30 ng/mL for the general popula&on, ≥50–<60 ng/mL for the elderly, and ≥70 ng/mL for pa&ents with comorbidities; and (vii) a strong safety profile even at high doses. This consensus provides the first Saudi-specific clinical framework for managing vitamin

D deficiency, addressing both skeletal and extra-skeletal outcomes, and offering recommendations tailored to cultural and regional contexts.

Conclusion: This modified Delphi consensus provides a region-specific, evidence-based framework for the diagnosis and management of vitamin D deficiency in Saudi Arabia. Based on both clinical reali&es and feasibility, oral vitamin D supplementa&on was iden&fied as the primary correction strategy, with recommenda&ons for empiric supplementation in symptomatic and high-risk populations and selective screening where clinically justified. The consensus further emphasized consenuous supplementation, tailored dosing goals, and monitoring strategies that account for age, comorbidities, and safety considerations. Collectively, these recommendations address critical gaps in existing guidelines by integrating cultural and regional factors, providing a practical and clinically actionable framework for improving vitamin D outcomes in Saudi Arabia. Future research should evaluate the implementation and long-term impact of these recommendations on both skeletal and extra-skeletal health outcomes.

Keywords: Vitamin D, deficiency, Saudi Arabia, Delphi consensus, supplementa&on, guidelines, endocrinology.

Table 1 summarizes the consensus statements on the current landscape of vitamin D deficiency in KSA.

Table 1. Consensus statements on the current landscape of vitamin D deficiency in KSA

Consensus Statement	%Agreement
Vitamin D deficiency is prevalent across all age groups and therapy areas.	100%
Vitamin D deficiency is especially prevalent among females of childbearing age.	91%
Vitamin D deficiency is a cofactor in the development of many skeletal and extra-skeletal conditions.	100%
The correction of vitamin D deficiency is associated with observed improvements in patients' co-existing conditions.	100%

Table 2 summarizes the consensus statements on KSA-specific Strategies for Vitamin D Correction.

Table 2: Consensus statements on KSA-specific Strategies for Vitamin D Correction

Consensus Statement	%Agreement
Fortified foods should not be the only source of vitamin D for vitamin D-deficient patients.	100%
Sun exposure should not be considered the main source of vitamin D due to the darker skin tone of the Saudi population and the risks of skin cancer.	91%
The lack of demonstrated cost-effectiveness is the main barrier against universal screening for vitamin D deficiency.	91%
Patients who are recommended for vitamin D deficiency screening are: • *Age >65 years old* • *Metabolic bone disease (especially, rickets, osteoporosis, osteopenia, chronic myalgia, hyperparathyroidism, osteomalacia)* • *Malabsorptive conditions or procedures (especially, celiac disease, bariatric surgery)* • *Chronic Kidney disease* • *Liver impairment* • *Cancers (especially, lymphoma, myeloma)*	91%
A unified and accurate serum 25(OH)D assay should be implemented across KSA to prevent the over- or underestimation of vitamin D deficiency.	91%
Patients with deficient serum 25(OH)D levels (<30 ng/mL) should be prescribed a loading vitamin D dose.	91%
Patients with deficient serum 25(OH)D levels (<30 ng/mL) are advised to receive 50,000 IU weekly supplementation.	91%
Patients with sufficient serum 25(OH)D levels should be prescribed a maintenance dose of vitamin D.	100%
Screened general population with sufficient serum 25(OH)D levels (>30ng/mL) should be prescribed a maintenance dose of vitamin D.	100%
Individuals with sufficient serum 25(OH)D level (>30ng/mL) are advised to receive 1,000–2,000 IU daily or 50,000 IU monthly.	91%
Tailoring vitamin D dose and frequency according to patients' preferences has a positive impact on adherence.	91%
Weekly dosing rather than daily improves patient adherence.	100%
Empiric vitamin D treatment is the preferred alternative strategy to vitamin D screening.	91%
Patients who are advised for empiric treatment without screening are: • *All women (especially, infertile, pregnant, and menopausal women; women with gynecological and obstetrics conditions, especially, miscarriage, pre-eclampsia, gestational diabetes, breast and cervical cancer, polycystic ovary syndrome, uterine fibroids, endometriosis, Stress incontinence)* • *Autoimmune disorders (especially, fibromyalgia, inflammatory myopathy, systemic lupus erythematosus, rheumatoid arthritis)* • *Obesity* • *Diabetes mellitus* • *Dyslipidemia* • *Thyroid disorders (hypo- and hyperthyroidism, autoimmune thyroiditis)* • *Recurrent infections* • *Patients receiving certain medications (especially, steroids, proton-pump inhibitors, anti-lipids, anti-epileptics)*	91%
Patients eligible for empiric treatment are advised to receive 50,000 IU weekly.	82%
Certain patient profiles are advised to receive a loading dose >50,000 IU/week, such as those with malabsorptive conditions.	100%

Table 3 summarizes the consensus statements on the maintenance of sufficient vitamin D levels.

Table 3: Consensus statements on the maintenance of sufficient vitamin D levels

Consensus Statement	%Agreement
Patients receiving empiric treatment are recommended to maintain their treatment indefinitely.	100%
Vitamin D treatment is maintained rather than stopped once patients achieve sufficient 25(OH)D levels.	91%
Serum 25(OH)D should be monitored in: • *Patients eligible for screening* • *Patients remaining symptomatic despite receiving supplementation* • *Patients suspected of vitamin D toxicity*	100%
Patients eligible for monitoring should be tested every 3–6 months.	100%
Patients already receiving vitamin D treatment, yet still symptomatic, should be tested for potential need for dose adjustment.	91%
Patients who were eligible for a loading dose of >50,000 IU/week should be monitored every 3-6 months for their serum 25(OH)D level, bone profile, and renal function.	91%
The goal serum 25(OH)D level should be tailored according to patients' age, gender, and co-existing conditions.	100%
The treatment goal for the general population is a serum 25(OH)D level >30 ng/mL	100%
The treatment goal for the elderly (>65 years old) population is a serum 25(OH)D level >50 ng/mL. However, it should not exceed 60 ng/mL	100%
The treatment goal for patients with comorbid conditions is a serum 25(OH)D level >70 ng/mL	100%
Vitamin D dose should be increased if the patient does not achieve the goal 25(OH)D serum level.	91%
Vitamin D dose is administered on a more frequent dosing schedule if dose escalation is required.	82%

Figure 1. Vitamin D Management Framework*‡‡

*These lists are not exhaustive, but represent the most commonly encountered conditions in KSA. Non-mentioned conditions are screened or empirically treated upon the recommendations of the treating physician.
† Treatment goal differs according to patients' age, gender, and comorbid conditions. See Table 3.
‡ Higher dosage could be recommended according to the discretion of the treating physician. See tables 2 and 3 for recommendations regarding high-dose vitamin D supplementations.

P1685

MICRONUTRIENTS LEVELS AND THEIR ASSOCIATION WITH OSTEOPOROSIS AND DEPRESSION IN ELDERLY HYPERTENSIVE PATIENTS: A CASE–CONTROL STUDY

Y. A. Abdelmotaleb[1], M. G. Ghit[2], Y. E. Elgazar[3]

[1]Rheumatology and rehabilitation department, faculty Of Medicine, Al-Azhar University, Cairo, Egypt, Cairo, Egypt; [2]Reumatology and rehabilitation department, Faculty Of Medicine, Al-Azhar university, Cairo, Egypt; [3]Geriatric Medicine Department, Faculty of Medicine, Helwan University, Cairo, Egypt

Background: Older hypertensive patients frequently presented with osteoporosis and depressive symptoms. Micronutrient imbalance may contribute to this overlap, yet the combined biochemical profile of this population remains underexplored.

Objective: To determine whether serum vitamin D, calcium, and zinc levels differ between elderly hypertensive patients with osteoporosis and depressive symptoms and matched hypertensive controls.

Methods: A case control study was conducted among one hundred hypertensive adults aged sixty years or older. Clinical assessments and fasting laboratory tests were performed. Independent t tests, correlation coefficients, and regression models were applied.

Results: Cases showed significantly lower calcium (9.24 ± 0.50 vs 9.61 ± 0.36 mg/dL), vitamin D (33.82 ± 16.63 vs 46.24 ± 16.00 ng/mL), and zinc levels (0.0108 ± 0.0015 vs 0.0144 ± 0.0043 mg/L) than controls, with all comparisons reaching $p < 0.001$. Strong negative correlations were

observed between micronutrients and lipid markers, including calcium with cholesterol ($r = -0.312$) and zinc with triglycerides ($r = -0.301$). In reduced regression models, lower calcium and zinc independently predicted case status.

Conclusion: Elderly hypertensive patients with osteoporosis and depressive symptoms exhibit marked and clinically relevant reductions in calcium, vitamin D, and zinc. These findings identify key biochemical vulnerabilities that may warrant targeted nutritional assessment and intervention.

Keywords: calcium, vitamin D, zinc, hypertension, hypertensive elderly, osteoporosis, depression, elderly patients, micronutrient status, biochemical profile, case control study

- Table(1) Lipid Profile Comparison

Variable	Cases mean ± SD	Controls mean ± SD	t value	p value	Cohen's d
Total cholesterol	199.82 ± 40.84	156.36 ± 28.25	6.189	<0.0001	1.32
Triglycerides	164.84 ± 63.80	120.28 ± 28.88	4.499	<0.0001	1.01
HDL	39.20 ± 6.15	43.52 ± 5.32	−3.755	0.0003	0.78
LDL	127.65 ± 41.50	88.78 ± 30.07	5.363	<0.0001	1.12

Cohen's d values above 0.8 indicate large effect sizes.

- Table (2) Micronutrient Comparison

Variable	Cases mean ± SD	Controls mean ± SD	t value	p value	Cohen's d
Serum calcium	9.2400 ± 0.4973	9.6120 ± 0.3635	−4.270	<0.0001	0.89
Vitamin D	33.8200 ± 16.6251	46.2400 ± 16.0058	−3.806	0.0002	0.76
Zinc	0.0108 ± 0.0015	0.0144 ± 0.0043	−5.697	<0.0001	1.16

- Table (3) Smoking-Stratified Analysis

Non-smokers only (n=82)

Variable	Cases mean ± SD	Controls mean ± SD	p value
Calcium	9.310 ± 0.465	9.612 ± 0.363	0.0009
Vitamin D	36.06 ± 16.44	46.24 ± 16.00	0.0020
Zinc	0.0112 ± 0.0019	0.0144 ± 0.0043	0.0004

BONE PROTECTIVE INTERVENTIONS TO MINIMISE FRACTURE RISK IN ADULTS LIVING WITH HIV: A SYSTEMATIC REVIEW AND ANALYSIS

Y. A. Nyemitei-Addo[1,2], M. A. Chimonides[3], P. E. Leventis[2,4]

[1]Maidstone and Tunbridge Wells NHS Trust, Tunbridge Wells, United Kingdom; [2]Kent and Medway Medical School, Canterbury, United Kingdom; [3]Faculty of Biology, University of Cambridge, Cambridge, United Kingdom; [4]Maidstone and Tunbridge Wells NHS Trust, Rheumatology Department, Tunbridge Wells, United Kingdom

Objectives:
This systematic review and analysis evaluated evidence for bone protective interventions to minimise fracture risk in people living with HIV (PLWH).
Materials and methods
Following PRISMA guidelines, Ovid MEDLINE, EMBASE and the Cochrane library were searched on 13th August 2025 using MeSH and free-text terms related to HIV, vitamin D and bone health. Eligible studies included PLWH aged >16 years, published in English within 30 years. Study quality was assessed using CASP, RoB 2 and ROBINS-I tools. Quantitative data were standardised and analysed in Microsoft Excel, with visualisation in R (ggplot2). Significant heterogeneity precluded meta-analysis. Findings were narratively synthesised with reference to graphical outputs.
Results
Database searches identified 1632 studies, 17 met inclusion criteria, 11 contributed to statistical analysis and 6 to narrative synthesis. Studies (9 RCTs and 8 observational) included 1402 PLWH (aged 20.9-56.5 years). 11 statistically analysed studies described mean vitamin D3 800-5000 IU/day for 12 - 156 weeks. Doses above 1785 IU/day consistently raised serum 25(OH)D concentrations beyond 75 nmol/L, whereas ≤1000 IU/day did not. Higher doses (≥2000-4000 IU/day) produced the largest improvements in serum 25(OH)D, with modest or inconsistent effects on PTH, BALP and CTX. PTH suppression was greatest at lower vitamin D3 doses of 800 IU/day for 52 and 156 weeks (range 1.9-3.2 pmol/L, p=0.002). BMD changes were small (<2%) although two trials reported smaller lumbar spine and hip BMD decline with 4000 IU/day. Minimal changes in bone turnover markers were reported.
Narrative synthesis studies indicated dose, formulation and duration effects. Multimodal exercise regimens significantly improved lumbosacral BMD in PLWH with low baseline BMD.
Conclusion
Vitamin D3 supplementation in PLWH reliably increases serum 25(OH)D and suppresses PTH, although BMD effects are modest and appear dependent on dose, duration and baseline vitamin D status. Exercise improves lumbar spine BMD and is a useful adjunct. Evidence is limited by heterogeneity, small sample sizes and lack of fracture-related outcomes. Well powered trials are required to define optimal vitamin D3 dosing and long-term fracture outcomes in PLWH.

P1687

IMPACT OF THERAPEUTIC ADHERENCE ON WORK-RELATED IMPAIRMENT IN CHRONIC INFLAMMATORY RHEUMATIC DISEASES

Y. Ben Slama[1], R. Grassa[1], N. Ben Chekaya[1], M. Ghali[1], S. Zrour[1], M. Jguirim[1], I. Bejia[1]

[1]Fattouma Bourguiba University Hospital, Department of Rheumatology, Monastir, Tunisia

Introduction
Poor therapeutic adherence is a major contributor to treatment failure in chronic inflammatory rheumatic diseases (CIRDs). This study aimed to evaluate patients' adherence levels and to identify factors influencing treatment compliance .
Patients and Methods
This was a cross-sectional study including consecutive patients followed for rheumatoid arthritis (RA), spondyloarthritis (SpA), and psoriatic arthritis at our Rheumatology Department. Therapeutic adherence was evaluated using the Compliance Questionnaire for Rheumatology (CQR). Work-related outcomes were assessed using the Work Productivity and Activity Impairment questionnaire (WPAI) and the Workplace Activity Limitations Scale (WALS). Scores were compared between RA, SpA, and psoriatic arthritis to identify which disease was associated with greater work and activity impairment.
Results
We included 55 patient in the study. The mean age was 48.4 ± 13.6 years. The sex ratio (M/F) was 0.08, with a marked female predominance (48 women and 7 men). Patients were followed for rheumatoid arthritis in 63.3% of cases, spondyloarthritis in 26.7%, and psoriatic arthritis in 10%.. The mean DAS28-CRP score was 3.7 ± 1.07, and the mean ASDAS-CRP score was 2.1 ± 0.89. The mean pain visual analogue scale (VAS) score was 40.5 ± 20.3. The mean CQR score was 11.7 ± 2.7 (range: 8–18), indicating suboptimal adherence to disease-modifying therapy.
Patients with rheumatoid arthritis showed significantly higher WPAI scores compared with SpA and psoriatic arthritis , with respectively an overall impairment of health-related activities of 54 % for RA , 43% for SpA and 38 % for psoriatic arthritis . Similarly, WALS scores were higher in RA patients, indicating more severe workplace limitations. The average WALS score in RA was 17 ± 2.7,compared to 14±1.9 in psoriatic arthritis and 13 ±2.1 in SpA .
In multivariate analysis,worse WPAI and WALS scores were associated with RA(p=0.03), higher disease activity(p =0.02), pain intensity (0.03) ,and poor therapeutic adherence (p=0.04).
Conclusion
These findings highlight the substantial occupational burden of RA and underscore the importance of optimizing disease control and improving therapeutic adherence to preserve work participation in patients with inflammatory arthritis.

P1688

FACTORS ASSOCIATED WITH DIFFICULT-TO-TREAT RHEUMATOID ARTHRITIS IN THE ERA OF TREAT-TO-TARGET

Y. Ben Slama[1], R. Grassa[1], M. Ghali[1], N. Ben Chekaya[1], M. Jguirim[1], S. Zrour[1], I. Bejia[1]

[1]Fattouma Bourguiba University Hospital, Department of Rheumatology, Monastir, Tunisia

Introduction Difficult-to-treat rheumatoid arthritis (D2T-RA) is defined as RA with failure of at least two biologic and/or targeted synthetic disease-modifying antirheumatic drugs (bDMARDs and/or tsDMARDs) with different mechanisms of action, following inadequate response to conventional synthetic DMARDs.
The objective of this study was to describe the clinical profile of patients with D2T-RA and to identify factors associated with this condition.
Patients and Methods This was a cross-sectional study including patients with RA fulfilling the 2010 ACR/EULAR classification criteria. Sociodemographic, clinical, biological, radiological, and therapeutic data were collected using a carefully designed questionnaire. Patients meeting the EULAR definition of difficult-to-treat RA were identified. Statistical analysis was performed using SPSS software.
Results A total of 118 patients with RA receiving biologic therapy were included, comprising 99 women (83.9%) and 19 men (16.1%), with a male-to-female ratio of 0.19. The mean age was 56.86 ± 11.61 years (range: 28–81). Among these patients, 26 met the EULAR definition of difficult-to-treat RA. In this subgroup, the male-to-female ratio was 0.13 (23 women and 3 men), with a mean age of 53.42 ± 11.49 years (range: 31–71). Twelve patients (46.15%) had comorbidities, mainly arterial hypertension (34.61%) and dyslipidemia (11.53%). The mean body mass index (BMI) was 27.8 ± 4.04 kg/m² (range: 19.13–34.7). The mean disease duration was 14.5 ± 5.1 years (range: 5–23). Anti-citrullinated protein antibodies (ACPA) and rheumatoid factor (RF) were positive in 61.5% and 65.4% of cases, respectively. The mean current DAS28-ESR score was 4.23, and the mean baseline Health Assessment Questionnaire (HAQ) score was 1.7 ± 0.72. Destructive and erosive disease was observed in 96.2% of patients. Five patients (19.23%) had hip involvement (coxitis). Extra-articular manifestations were present in 13 patients (50%), including osteoporosis in 12 cases. None of the patients were weaned off corticosteroids. The mean current corticosteroid dose was 8.95 ± 5.37 mg/day (prednisone equivalent). The mean number of conventional synthetic DMARDs used was 2.75 ± 0.9. All patients had received at least two biologic agents. Anti-TNF therapies were the most frequently prescribed (65.4%), including monoclonal antibodies in 12 patients and etanercept in 5 patients. Rituximab and tocilizumab were used in 19.2% and 15.4% of cases, respectively.
The presence of cardiovascular comorbidities, particularly arterial hypertension, was significantly associated with difficult-to-treat RA ($p = 0.05$). Significant associations were also found between difficult-to-treat RA and high baseline inflammatory burden, ACPA positivity, and the presence of structural damage assessed by the Sharp score, with p-values of 0.02, 0.03, and 0.05, respectively.
Conclusion These findings highlight the need for a better understanding of the mechanisms underlying therapeutic resistance in rheumatoid arthritis, in order to identify treatment barriers and guide the implementation of new and personalized therapeutic strategies.

P1689

FACTORS ASSOCIATED WITH STRUCTURAL DAMAGE PROGRESSION IN RHEUMATOID ARTHRITIS

I. Brahem[1], Y. Ben Slama[1], S. Zrour[1,2], M. Ghali[1], R. Grassa[1], N. Ben Chekaya[1], I. Bejia[1]

[1]Fattouma Bourguiba University Hospital, Department of Rheumatology, Monastir, Tunisia; [2]Research Laboratory "Nutrition, Functional Foods and Health" (LR12ES05), LabNAFS FMM-UM, Faculty of Medicine of Monastir, University of Monastir,, Monastir, Tunisia

Background: Despite advances in imaging, conventional radiography remains the reference standard for assessing structural damage progression in rheumatoid arthritis (RA).
Objectives: To describe radiographic joint damage in RA using validated scoring systems and to evaluate its progression over time and associated factors.
Methods: We conducted a retrospective longitudinal study including 103 consecutive RA patients fulfilling the 2010 ACR/EULAR criteria, followed at a tertiary rheumatology center between January 2022 and December 2024. Radiographic damage was assessed using Larsen, Sharp, modified Sharp, SENS, and Steinbrocker scores. Clinical, biological, and therapeutic data were collected. Factors associated with radiographic progression were analyzed.
Results: Women represented 76% of patients, with a mean age of 53 ± 12.5 years and a mean disease duration of 9 years. Disease activity was moderate to severe in over 80% of cases. Extra-articular manifestations were present in 92.2%, mainly sicca syndrome and osteoporosis. Rheumatoid factor and anti-CCP antibodies were positive in 75% and 66% of patients, respectively. Almost all patients received methotrexate (99%), with a mean initiation delay of 34 months, and 28.2% were treated with biologic therapy. Thirty-five percent of patients had at least two radiographs. The mean interval between the first and second radiographs was 3.0 ± 2.4 years. Significant radiographic progression was observed, with the global Larsen score increasing from 33.9 to 45.9 and the Sharp score from 24.2 to 105.4. Moderate to rapid progression was observed in 53.1% of patients.
Factors associated with radiographic progression included the number of tender joints at diagnosis, disease duration, platelet count, and inflammatory activity assessed by DAS28-ESR and DAS28-CRP.
Conclusion:
Structural damage in RA remains severe and progresses significantly, particularly in the absence of early optimal treatment. Early diagnosis and rigorous radiographic monitoring are essential to optimize therapeutic strategies and improve long-term outcomes.

P1690

THE OCCUPATIONAL BURDEN OF CERVICOBRACHIAL NEURALGIA AMONG MEDICAL SECRETARIES

S. Ben Hamza[1], N. Ben Chekaya[2], Y. Ben Slama[2], R. Grassa[2], M. Ghali[2], S. Zrour[2], I. Bejia[2]

[1]Fattouma Bourguiba University Hospital, Department of Physical medicine and Rehabilitation, Monastir, Tunisia; [2]Fattouma Bourguiba University Hospital, Department of Rheumatology, Monastir, Tunisia

Introduction Cervicobrachial neuralgia (CBN) is a frequent cause of functional impairment in the working population. Medical secretaries are particularly exposed to this musculoskeletal disorder due to prolonged static postures and intensive computer use. Identifying associated factors and assessing the functional impact in this population are essential to guide preventive and therapeutic strategies.
Objective The aim of this study was to assess the prevalence and clinical characteristics of cervicobrachial neuralgia among medical secretaries, as well as its impact on quality of life.
Materials and Methods A descriptive cross-sectional study was conducted in September 2025 among medical secretaries working at our hospital. A carefully designed anonymous self-administered questionnaire was used to collect sociodemographic data and ergonomic work habits. Functional disability and neuropathic pain were assessed using the Neck Disability Index (NDI) and the DN4 questionnaire (Douleur Neuropathique en 4 questions), respectively.
Results Twenty-three medical secretaries were included, all of whom were female. The mean age was 45.7 ± 7.1 years (range: 37–60). The most common comorbidities were diabetes mellitus and arterial hypertension, each present in 13% of cases. Most participants reported no prior medical history (73.9%). The mean body mass index (BMI) was 29.45 ± 3.25 kg/m². The mean professional seniority was 18.3 ± 9.1 years, and the average daily computer working time was 5.3 ± 1.1 hours. Eighty-seven percent of participants reported no regular physical activity. Ergonomic workstation adaptation was reported by 91% of participants. Clinically, 87% of participants presented with cervicobrachial neuralgia. Pain was bilateral in 56.5% of cases. The mean duration of symptoms was 7.5 ± 4.8 years. The most frequently involved nerve roots were C5 (56.5%), C6 (34.8%), C7 (8.7%), and C8 (4.3%). The mean pain intensity on the visual analogue scale (VAS) was 5.2 ± 1.7. Paresthesia was reported by 60.9% of participants, and motor deficit was observed in 26.1%. The main aggravating factors were prolonged work duration (43.5%) and constrained postures (34.7%). Regarding management, analgesics and nonsteroidal anti-inflammatory drugs (NSAIDs) were used by 82.6% and 52.1% of participants, respectively. More than half (60.9%) had consulted a healthcare professional at least once, whereas 39.1% had not sought medical advice. Functional rehabilitation was undertaken by 26.1% of participants. The mean DN4 score was 3.2 ± 2, suggesting a frequent neuropathic component. The mean Neck Disability Index score was 17 ± 9.2, indicating an overall moderate level of disability. Moderate disability was observed in 47% of participants, while 43% presented with mild disability.
Conclusion Cervicobrachial neuralgia appears to be a significant occupational health issue among medical secretaries, largely related to prolonged static postures and extended screen time. These findings emphasize the importance of ergonomic workplace adjustments, regular breaks, adapted physical activity, and improved access to rehabilitation in order to reduce the functional impact of this condition.

P1691

ADDRESSING CHRONIC PAIN IN RHEUMATOID ARTHRITIS: WHERE DO WE STAND?

I. Brahem[1], Y. Ben Slama[1], S. Zrour[1,2], R. Grassa[1], M. Ghali[1], N. Ben Chekaya[1], I. Bejia[1]

[1]Fattouma Bourguiba University Hospital, Department of Rheumatology, Monastir, Tunisia; [2]Research Laboratory "Nutrition, Functional Foods and Health" (LR12ES05), LabNAFS FMM-UM, Faculty of Medicine of Monastir, University of Monastir,, Monastir, Tunisia

Introduction: Chronic pain is a common and disabling manifestation of rheumatoid arthritis (RA). It arises from a multifactorial interplay between inflammatory activity, neurophysiological alterations, and psychosocial factors, and may persist even when inflammatory disease activity is adequately controlled.
Objective: To evaluate chronic pain in patients with RA and to identify factors associated with pain severity.
Methods: This retrospective longitudinal study was conducted in the Department of Rheumatology at Fattouma Bourguiba University Hospital, Monastir, over a 3-year period (2022–2024). Patients fulfilling the 1987 ACR and/or 2010 ACR/EULAR classification criteria for RA were included. Pain intensity was assessed using the visual analogue scale (VAS). Clinical, biological, and therapeutic data were collected, and factors associated with pain severity were analyzed.
Results: A total of 103 patients were included, with a mean age of 53 ± 12.5 years and a marked female predominance. The mean disease duration was 9 years. Chronic pain was almost constant, with a mean VAS score of 5.35 ± 1.08, indicating moderate pain. Severe pain was reported in 34% of patients and was associated with higher DAS28-ESR scores, a greater number of tender joints, more frequent joint deformities, and more pronounced functional symptoms, including morning stiffness and nocturnal awakenings. Despite treatment with methotrexate in 99% of patients and biologic therapy in 28.2%, pain frequently persisted. Patients receiving biologic therapy showed a modest reduction in mean pain intensity compared with those on conventional therapy (VAS 4.9 vs. 5.5), without complete pain relief.
Conclusion: Chronic pain remains highly prevalent among patients with RA, including those treated with advanced therapies. These results underscore the importance of a comprehensive, multidimensional pain assessment that integrates inflammatory, mechanical, neuropathic, and psychosocial components in order to guide personalized pain management strategies.

P1692

IS ANTI–CITRULLINATED PROTEIN ANTIBODY POSITIVITY PREDICTIVE OF DIFFICULT-TO-TREAT RHEUMATOID ARTHRITIS?

Y. Ben Slama[1], R. Grassa[1], M. Ghali[1], N. Ben Chekaya[1], S. Zrour[1], M. Jguirim[1], I. Bejia[1]

[1]Fattouma Bourguiba University Hospital, Department of Rheumatology, Monastir, Tunisia

Introduction :
Difficult-to-treat rheumatoid arthritis (D2T-RA) remains a significant challenge in routine clinical practice. Early identification of patients at risk of developing D2T-RA may allow more timely and personalized therapeutic interventions. Anti–citrullinated protein antibodies (ACPA) are well established as markers of disease severity and structural damage in rheumatoid arthritis (RA); however, their potential role in predicting the development of D2T-RA is not well defined.
Objective :
We aim to assess the association between ACPA positivity and the occurrence of difficult-to-treat rheumatoid arthritis.
Methods :
We conducted a cross-sectional study including patients with RA fulfilling the 2010 ACR/EULAR classification criteria. D2T-RA was defined according to the 2021 EULAR definition. Sociodemographic, clinical, biological, radiological, and therapeutic data were collected using a carefully designed questionnaire. ACPA status was recorded at baseline. Statistical analysis was performed using SPSS software.
Results :
A total of 118 patients with rheumatoid arthritis treated with biologic agents were included. The cohort comprised 99 women (83.9%) and 19 men (16.1%), yielding a male-to-female ratio of 0.19. The mean age was 56.9 ± 11.6 years (range 28–81). Twenty-six patients fulfilled the EULAR definition of difficult-to-treat rheumatoid arthritis. In this subgroup, the male-to-female ratio was 0.13 (23 women and 3 men), with a mean age of 53.4 ± 11.5 years (range 31–71). IN patients with D2T-RA , Anti–citrullinated protein antibodies and rheumatoid factor were positive in 61.5% and 65.4% of patients, respectively.
In both univariate and multivariate analysis, ACPA positivity remained independently associated with D2T-RA (p=0.02).
Conclusion :
ACPA positivity is independently associated with difficult-to-treat rheumatoid arthritis. ACPA status may represent a useful biomarker to identify patients at higher risk of developing D2T-RA and could support early personalized therapeutic strategies.

P1693

EVALUATING PRIMARY CARE PHYSICIANS' AWARENESS OF PREGABALIN: PROPER USE AND MISUSE

Z. Mezrissi[1], Y. Ben Slama[2], R. Grassa[2], N. Ben Chekaya[2], M. Ghali[2], S. Zrour[2], M. Jguirim[2], I. Bejia[2]

[1]2Fattouma Bourguiba University Hospital, Department of Physical medicine and Rehabilitation, Monastir, Tunisia;
[2]Fattouma Bourguiba University Hospital, Department of Rheumatology, Monastir, Tunisia

Introduction
Primary care physicians are often the first point of contact in the healthcare system and play a crucial role in guiding patients and coordinating their care. In recent years, medication misuse has increased, particularly for certain drug classes such as gabapentinoids, where new patterns of abuse have emerged.
Objective
The primary objective of this study was to evaluate the level of knowledge of primary care physicians about pregabalin, with a focus on its appropriate use and the risk of misuse.
Methods
This was a cross-sectional analytical study conducted over a two-month period, from February 1 to April 1, 2025, among primary care physicians practicing in different regions.
Results
A total of 40 participants were included in the study, of whom 28 (70%) were women. The mean age was 31 years (range: 26–41). Participants were distributed as follows: 24 family medicine residents (60%), 8 private practitioners (20%), and 8 public health physicians (20%). Thirty-three participants (82.5%) practiced in urban areas, while 7 (17.5%) practiced in rural settings. Regarding additional training, 4 participants (10%) had completed a university certificate (CEC) in pain management, 4 (10%) in addiction medicine, 1 (5%) in pharmacology, and 29 participants had completed other certificates. The mean global knowledge score of primary care physicians regarding pregabalin was 13.1 (range: 7.69–18.51), with a maximum possible score of 34. Among the participants, 67.5% had a total score below 17 (the mean score), while 32.5% achieved a score above 17.
In univariate analysis, female physicians were significantly more likely to have a score below 17 (77.8%, p = 0.045). Professional status (resident versus practicing physician), workplace setting (urban versus rural), and completion of a CEC in addiction medicine, psychiatry, pain management, or pharmacology were not significantly associated with the knowledge score.
Conclusion
The assessment of primary care physicians' knowledge of pregabalin revealed significant gaps and insufficient information. These findings highlight the need for targeted interventions. Continuous medical education on pregabalin is therefore essential to improve physicians' expertise and ensure safe, optimal, and individualized patient care.

ASSESSMENT OF MEDICATION ADHERENCE AND ASSOCIATED FACTORS IN PATIENTS WITH CHRONIC INFLAMMATORY RHEUMATIC DISEASES

Y. Ben Slama[1], M. Ghali[1], N. Ben Chekaya[1], R. Grassa[1], S. Zrour[1], M. Jguirim[1], I. Bejia[1]

[1]Fattouma Bourguiba University Hospital, Department of Rheumatology, Monastir, Tunisia

Introduction

Poor therapeutic adherence is a major contributor to treatment failure in chronic inflammatory rheumatic diseases (CIRDs). This study aimed to evaluate patients' adherence levels and to identify factors influencing treatment compliance .

Patients and Methods

This was a cross-sectional study including consecutive patients followed for rheumatoid arthritis (RA), spondyloarthritis (SpA), and psoriatic arthritis at the Rheumatology Department of Monastir. Therapeutic adherence was evaluated using the Compliance Questionnaire for Rheumatology (CQR).

Results

We included 55 patient in the study. The mean age was 48.4 ± 13.6 years. The sex ratio (M/F) was 0.08, with a marked female predominance (86 women and 7 men). Patients were followed for rheumatoid arthritis in 63.3% of cases, spondyloarthritis in 26.7%, and psoriatic arthritis in 10%. The most frequent comorbidities were diabetes mellitus and arterial hypertension, observed in 35.2% and 20.6% of patients, respectively. The mean disease duration was 13.53 ± 5.3 years (range: 1 month to 40 years). The mean DAS28-CRP score was 3.7 ± 1.07, and the mean ASDAS-CRP score was 2.1 ± 0.89. The mean pain visual analogue scale (VAS) score was 40.5 ± 20.3. The mean CQR score was 11.7 ± 2.7 (range: 8–18), indicating suboptimal adherence to disease-modifying therapy. The mean Pain Catastrophizing Scale (PCS) score was 24.25 (range: 12–44). A clinically significant level of catastrophizing (PCS > 30) was observed in 14 patients (25.4%).

Poor therapeutic adherence was significantly associated with higher disease activity and the presence of osteoporosis, with p-values of 0.03 and 0.04, respectively.

Conclusion

These results emphasize the need for a multidisciplinary and holistic approach to improve treatment efficacy and long-term outcomes in chronic inflammatory rheumatic diseases.

P1695

DOES SOCIAL SUPPORT PREDICT BETTER THERAPEUTIC ADHERENCE IN CHRONIC INFLAMMATORY RHEUMATIC DISEASES?

Y. Ben Slama[1], M. Ghali[1], N. Ben Chekaya[1], R. Grassa[1], S. Zrour[1], M. Jguirim[1], I. Bejia[1]

[1]Fattouma Bourguiba University Hospital, Department of Rheumatology, Monastir, Tunisia

Introduction:

Chronic inflammatory rheumatic diseases (CIRDs) are common conditions with a considerable impact on patients' quality of life. Optimal disease control relies on strict adherence to treatment. Identifying factors influencing therapeutic adherence, particularly psychosocial factors, represents a major challenge in rheumatology. This study aimed to evaluate the potential role of perceived social support on therapeutic adherence in patients with CIRDs.

Patients and Methods:

This was a cross-sectional study consecutively including patients followed for rheumatoid arthritis (RA), spondyloarthritis (SpA), and psoriatic arthritis at our Rheumatology Department. Perceived social support was assessed using the Multidimensional Scale of Perceived Social Support (MSPSS), and therapeutic adherence was evaluated using the Compliance Questionnaire for Rheumatology (CQR).

Results:

A total of 55 patients were included. The mean age was 48.4 ± 13.6 years. The sex ratio (M/F) was 0.08, with a marked female predominance (86 women and 7 men). Patients were followed for RA in 63.3% of cases, SpA in 26.7%, and psoriatic arthritis in 10%. The most common comorbidities were diabetes mellitus and arterial hypertension, present in 35.2% and 20.6% of patients, respectively.

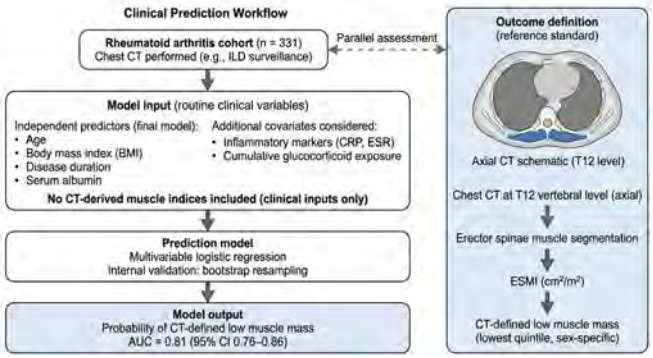
The mean disease duration was 13.53 ± 5.3 years (range: 1 month to 40 years). The mean DAS28-CRP was 3.7 ± 1.07, and the mean ASDAS-CRP was 2.1 ± 0.89. The mean pain visual analogue scale (VAS) score was 40.5 ± 20.3.

The mean total MSPSS score was 50.25 [21–83], reflecting a moderate level of perceived overall social support. Social support was perceived as "low" in 9 patients (16.3%), "moderate" in 27 patients (49%), and "high" in 19 patients (34%). The mean scores for the MSPSS subscales were 19.14 ± 5.5 for perceived family support, 14.83 ± 7.5 for support from a significant other, and 16 ± 6.5 for support from friends. The mean CQR score was 11.7 ± 2.7 [8–18], indicating suboptimal adherence to disease-modifying therapy.

A significant association was observed between good therapeutic adherence and a high level of perceived family support ($p = 0.03$) as well as overall perceived social support ($p = 0.02$).

Conclusion:

Our study showed that perceived social support significantly impacts therapeutic adherence in patients with chronic inflammatory rheumatic diseases, highlighting the importance of integrating the psychosocial dimension into their comprehensive management



P1696

PREDICTION OF CHEST CT-DEFINED LOW MUSCLE MASS IN RHEUMATOID ARTHRITIS USING ROUTINE CLINICAL DATA

Y. Choi[1], E. H. Park[2]

[1]Division of Rheumatology, Department of Internal Medicine, Jeonbuk National University Medical School, Jeonju, South Korea; [2]Department of Radiology, Jeonbuk National University Hospital, Jeonju, South Korea

Objective
Low muscle mass is a key component of sarcopenia and increasingly recognized as clinically important in rheumatoid arthritis (RA), contributing to functional impairment and poor outcomes. However, routine muscle mass assessment is seldom performed due to limited availability of body composition tools. We aimed to develop and internally validate a clinical prediction model for identifying RA patients at high risk of chest CT-defined low muscle mass using readily accessible clinical variables.
Methods
We conducted a retrospective study of RA patients who underwent chest CT at a tertiary referral center. The erector spinae muscle was manually segmented at the T12 vertebral level on axial CT images, and the cross-sectional area of the erector spinae muscle was normalized for height squared to derive the erector spinae muscle index (ESMI, cm^2/m^2). Low muscle mass was defined using sex-specific cut-offs corresponding to the lowest ESMI quintile. Clinical variables-age, body mass index (BMI), disease duration, inflammatory markers, serum albumin, and cumulative glucocorticoid exposure-were extracted from medical records. A multivariable logistic regression model was constructed to identify independent predictors of low muscle mass, and model performance was evaluated using the area under the receiver operating characteristic curve (AUC) with bootstrap resampling for internal validation.
Results
Of 331 RA patients included, 67 (20.2%) met criteria for CT-defined low muscle mass. Compared with those without low muscle mass, affected patients were older, had lower BMI and serum albumin levels, longer disease duration, and higher inflammatory burden. On multivariable analysis, older age, lower BMI, longer disease duration, and lower albumin levels emerged as independent predictors of low muscle mass. The model demonstrated excellent discrimination, with an AUC of 0.81 (95% CI, 0.76–0.86).
Conclusion
A straightforward clinical prediction model based exclusively on routinely collected clinical data can effectively identify RA patients at elevated risk of chest CT-defined low muscle mass. This approach may facilitate risk stratification in settings where CT imaging is not readily accessible and enable opportunistic sarcopenia screening without additional radiation exposure or cost in patients undergoing routine chest CT surveillance.

P1697

THE ROLE OF PHOSPHOLIPASE C-Γ1 IN SARCOPENIA VIA REGULATION OF MITOCHONDRIAL CALCIUM UPTAKE

Y. D. Ya[1], Y. X. Y. Yixin[1], Z. J. X. Zhongjian[1]

[1]Second Xiangya Hospital of Central South University, Changsha, China

Objective:
Sarcopenia is an age-related systemic muscular disorder characterized by loss of muscle mass and function. Its pathogenesis remains incompletely understood, and there is currently no targeted treatment. Ca^{2+} signaling plays a crucial role in maintaining muscle function. This study aims to investigate the role and potential mechanism of phospholipase C-γ1 (PLC-γ1), a key enzyme regulating intracellular Ca^{2+} release, in sarcopenia.
Methods:
PLC-γ1 expression was examined in skeletal muscle tissues from elderly (>80 years) and young (<30 years) individuals to determine whether it declines with age. Skeletal muscle-specific PLC-γ1 knockout mice were generated to assess the impact of PLC-γ1 on muscle function. Both control and knockout mice were intraperitoneally injected with dexamethasone to establish a sarcopenia model. Muscle strength was evaluated using treadmill and grip strength tests. Muscle fiber number, cross-sectional area, fat accumulation, and fibrosis were observed via H&E staining, immunofluorescence, Sirius Red staining, and Oil Red O staining. Proteomic sequencing of skeletal muscle tissue was performed, revealing involvement of mitochondrial calcium uptake signaling. Mitochondrial calcium uptake was visualized by confocal microscopy. Mitochondrial morphology was examined using electron microscopy and MitoTracker staining. Reactive oxygen species (ROS) levels were detected with the DCFH-DA fluorescent probe, and mitochondrial membrane potential was measured using the JC-1 fluorescent probe.
Results:
PLC-γ1 expression was reduced in skeletal muscle of elderly individuals. Skeletal muscle-specific PLC-γ1 knockout mice exhibited decreased endurance and reduced muscle fiber cross-sectional area. In the sarcopenia model, knockout mice showed more severe muscle atrophy and altered mitochondrial morphology. In vitro knockdown of PLC-γ1 led to decreased mitochondrial calcium uptake, mitochondrial shrinkage and fragmentation, significantly increased intracellular ROS, and reduced mitochondrial membrane potential.
Conclusion:
PLC-γ1 maintains mitochondrial function by promoting mitochondrial calcium uptake, thereby mitigating muscle atrophy in sarcopenia.

DIAGNOSTIC AND TREATMENT PATTERNS IN OSTEOPOROSIS: A RETROSPECTIVE REAL-WORLD ANALYSIS FROM A TERTIARY PM&R CENTER

Y. Yumusakhuylu[1], B. Erhan[1], A. Sunan[1], E. Ozkan[1], M. Koyuncal[1], Y. Demir[1]

[1]Department of Physical Medicine and Rehabilitation, Istanbul Medeniyet University Faculty of Medicine, Göztepe City Hospital, Istanbul, Türkiye

Objectives
Osteoporosis is a major public health problem that reduces quality of life and imposes a significant economic burden, particularly in aging societies. This study aimed to retrospectively evaluate the demographic, biochemical, and clinical characteristics of patients diagnosed with osteoporosis who presented to the Physical Medicine and Rehabilitation outpatient clinics of our hospital, and to provide an overview of diagnostic and treatment patterns in clinical practice.
Methods
This retrospective study included patients diagnosed with osteoporosis who attended the Physical Medicine and Rehabilitation outpatient clinics at Göztepe Prof. Dr. Süleyman Yalçın City Hospital between December 1, 2024, and December 1, 2025. Evaluated variables included age, sex, presence of pathological fractures, serum 25-hydroxyvitamin D levels, lumbar spine and femoral neck BMD T-scores, and osteoporosis treatments.
Results
Among 2,823 screened patients, 1,556 patients with osteoporosis were included (91.6% female, mean age 68.9 years). Pathological fractures were present in 592 patients (38.0%). Based on BMD T-scores, 35.6% had T-scores between −2.5 and −3.0, and 24.0% ≤ −3.0. Notably, 40.4% of patients had T-scores > −2.5 (i.e., not osteoporotic by DXA criteria) but presented with pathological/fragility fractures. The most frequently prescribed treatments were denosumab (30.1%), alendronate (25.9%), zoledronic acid (19.9%), romosozumab (0.2%), and vitamin D (± calcium) supplementation alone (11.8%). Treatment distribution differed significantly according to fracture status ($p < 0.003$) and T-score severity ($p < 0.002$), with an increased use of denosumab and zoledronic acid—agents with proven efficacy in preventing new fractures—among patients with lower T-scores and higher fracture risk.
Conclusion
Osteoporosis treatment choices in clinical practice are closely associated with fracture presence and BMD severity. The low proportion of male patients highlights the need for improved awareness and screening. This study provides a comprehensive overview of osteoporosis management and emphasizes the importance of a holistic approach beyond bone health alone.

P1699

A REAL-WORLD STUDY ON THE EFFICACY AND ADVERSE EVENTS OF ROMOSOZUMAB IN CHINESE PATIENTS WITH OSTEOPOROSIS

H. Wu[1], Z. Ouyang[2], C. Li[2], Y. Ding[2]

[1]Department of Orthopaedics, Sun Yat-sen Memorial Hospital, Sun Yat-sen University, Guangzhou, China; [2]Department of Orthopaedics, Sun Yat-sen Memorial Hospital, Sun Yat-sen University, Guangzhou, China

Purpose: To analyze the therapeutic and adverse effects of romosozumab among female osteoporosis patients at very high fracture risk in China.
Methods:A retrospective study initiated in October 2024 until December 2025, involving postmenopausal women with severe osteoporosis who are treated with romosozumab. Bone mineral density (BMD) at the lumbar spine (L1-L4), femoral neck, and total hip were measured by dual-energy X-ray absorptiometry at baseline, 6 months and 12 months. Serum bone turnover markers and calcium-phosphate metabolism parameters were also monitored.
Results: Among the 55 female patients, 56.3% were treatment-naive. The mean age ± standard deviation for treatment-naive patients and previously treated patients was 70.2 ± 9.3 years and 73.0 ± 8.6 years, respectively.The previous osteoporosis treatments were denosumab (36.8%), zoledronic acid (31.6%), and teriparatide (15.8%), with 15.8% of patients having received two or more types of medication. At 6 and 12 months of romosozumab treatment, the mean percentage increases in BMD from baseline were 7.4% and 16.6% at the lumbar spine, 2.8% and 5.9% at the total hip, and 3.0% and 7.5% at the femoral neck, respectively. All changes were statistically significant compared with baseline.When analyzed by prior treatment history, treatment-naive patients showed a 11.2% increase in lumbar spine BMD at 6 months, whereas previously treated patients showed a 2.8% increase. For the femoral neck, the increases were 3.1% and 3.3%, and for the total hip, 2.3% and 2.8%, respectively.No significant complications related to cardiac or other organ diseases were observed during treatment.
Conclusion: Significant improvements in lumbar spine, total hip, and femoral neck BMD were observed following 6 and 12 months of romosozumab treatment, according to real-world evidence.

THE INTERNATIONAL CLASSIFICATION OF FUNCTIONING, DISABILITY AND HEALTH AS A FRAMEWORK FOR A COMPREHENSIVE REHABILITATION PROGRAM IN GERIATRIC OSTEOPOROSIS - A CASE REPORT

I. Papaioannou[1], P. - A. Syrinoglou[1], P. Kappi[1], I. Papoutsi[1], A. Paisiou[1], I. - E. Panagiotopoulou[1], S. Ferfeli[1], D. Tsiamasfirou[1], G. Lygizos[1], Y. Dionyssiotis[1]

[1]2nd Physical Medicine & Rehabilitation Department, National Rehabilitation Center EKA, Athens, Greece

Objective(s): To integrate a comprehensive rehabilitation program in a geriatric patient with osteoporosis using the International Classification of Functioning, Disability and Health (ICF).
Material and Methods: This case report refers to a 90-year-old female patient with osteoporosis and a left intertrochanteric fracture due to a fall. Assessment was performed using the icf-core-sets.org platform, incorporating categories from the Rehabilitation Set, the Comprehensive Osteoporosis Core Set, and the Comprehensive Geriatrics Core Set.
The patient was hospitalized for approximately two months. Upon admission, she was able to maintain a sitting position with minimal assistance. Clinical assessment revealed mild pain in the right shoulder and right knee. Muscle strength was preserved in assessed muscle groups except those which could not be examined due to surgery.
Regarding the domain of Body Functions, mental functions were largely preserved. Where impairments were present (e.g. Energy and drive functions – b130), they were mild and considered age-related. Moderate impairment was observed in Sensation of pain (b280), Blood pressure functions (b420), Defecation functions (b525) and Mobility of joint functions (b710). Notably, severe impairment was identified in Gait pattern functions (b770) and within the Body Structures domain in the Structure of lower extremity (s750), respectively.
Regarding Activities and Participation domain, the greatest limitation was in the category Moving around (d455). Environmental Factors were predominantly identified as facilitators, based on the patient's report.
Results: Based on the assessment findings, the patient was enrolled in an individualized inpatient rehabilitation program including medical treatment, physiotherapy, occupational therapy and psychological support.
Functional improvements were observed at discharge. She achieved independent sitting and standing with minimal assistance and was able to ambulate short distances with good balance using a walker, while a wheelchair was required for longer distances. The aforementioned outcomes were achieved while considering the patient's psychological status and her expectations from the rehabilitation program.
Conclusion(s): The use of icf-core-sets.org platform enabled a comprehensive rehabilitation program beyond a disease-centered approach, allowing consideration of the multidimensional impact of osteoporosis on the older individual's functional ability and independence in everyday life.

P1701

OSTEOPOROSIS DOCUMENTATION FOLLOWING HIP FRACTURE: A RETROSPECTIVE COHORT STUDY FROM A TERTIARY HOSPITAL

Y. Eden-Friedman[1], A. Lizeachin[2], S. Gezunterman[2], A. Friedlander[2], B. Oberman[3], L. Toderis[3], I. Vered[1], L. Tripto-Shkolnik[1]

[1]Division of Endocrinology, Diabetes and Metabolism, Sheba Medical Center, Ramat Gan, Israel; [2]Department of Orthopedic Surgery, Sheba Medical Center, Ramat Gan, Israel; [3]ADAMS Center, Sheba Medical Center, Ramat Gan, Israel

Objective: Hip fractures are among the most common consequences of osteoporosis, yet adequate documentation of the diagnosis in medical records remains suboptimal. Evidence suggests that formal documentation increases the likelihood of treatment initiation. This study aimed to assess the rate of osteoporosis diagnosis following hip fractures in a tertiary hospital and to examine the association between diagnosis documentation and several outcomes.
Material and Methods: Population data extraction and exploration were done with the MDClone big data platform (ADAMS), and included patients aged ≥60 hospitalized with ICD-coded hip fractures between 2007-2024.
Results: The cohort comprised 6,933 patients, of whom 4,405 (63.5%) were women, with a mean age of 81.3 years. A total of 4,150 patients (59.8%) were discharged with a diagnosis of osteoporosis or osteoporotic fractures. A marked increase in documentation rates was observed after 2015, coinciding with nurse practitioner involvement. In a sub-analysis of patients who sustained fractures between 2016 and 2024, a lethal outcome was less likely among those with accurate documentation of osteoporosis, (adjusted HR 0.71; 95% CI, 0.64–0.78). No statistically significant differences were observed in subsequent osteoporotic fractures, rehospitalization, major infections and cerebrovascular ischemic events.
Conclusions: The rate of osteoporosis documentation following hip fractures was substantially higher than reported in the literature from centers without fracture liaison services. The inclusion of a dedicated nurse practitioner was associated with a significant increase in documentation of osteoporosis diagnosis. The observed association between accurate documentation and the lower mortality requires further exploration.

P1702

HOW COMMON IS IT? HIGH AND VERY HIGH-RISK FRACTURE RATES AMONG PATIENTS WITH A NON-OSTEOPOROTIC-RANGE BONE MINERAL DENSITY IN A DXA DATABASE FROM A TERTIARY MEDICAL CENTER

Y. Eden-Friedman[1,2], I. Vered[1], N. Tripto[3], N. Minsky[1,2], Y. Levy-Shraga[2,4], P. Rotman-Pikielny[2,5], L. Tripto-Shkolnik[1,2]

[1]Division of Endocrinology, Diabetes and Metabolism, Sheba Medical Center, Ramat Gan, Israel; [2]Gray Faculty of Medical and Health Sciences, Tel Aviv University, Tel Aviv, Israel; [3]Recah Institute of physics, Hebrew University of Jerusalem, Jerusalem, Israel; [4]Pediatric Endocrinology Unit, The Edmond and Lily Safra Children's Hospital, Sheba Medical Center, Ramat Gan, Israel; [5]Department of Endocrinology, Meir Medical Center, Kfar Saba, Israel

Objective: Fracture risk assessment has become a mainstay of osteoporosis management. Treatment paradigms for patients with a high or, especially, very high fracture risk based on FRAX assessment prioritize first-line anabolic treatment, even when bone mineral density (BMD) is in the non-osteoporotic (NOP) range. However, data regarding the prevalence of high or very high fracture risk among patients with NOP-range BMD are scarce.

Material and Methods: We utilized computerized BMD data from a tertiary medical center between 2024 and 2025. BMD was measured by the Lunar Prodigy Advance densitometer, and country-specific FRAX calculation ± Trabecular Bone Score (TBS) adjustment was performed by the Encore v18 software. Risk factors were reported by a self-administered questionnaire. Patients were classified as osteoporotic according to T-score ≤-2.5 at either the femoral neck, total hip, or at least two lumbar spine vertebrae. High/very high fracture risk was defined as ≥3/4.5% for hip, or ≥20/30% for major osteoporotic fractures (MOF), respectively. Statistical analysis was performed using Python.

Results: Five thousand and fifteen patients aged 40 years or older (40.3% males, age 66.8 ± 8.9 years) performed BMD test during the study period and were included. Overall, 1523 (30.4%) were classified as osteoporotic and 3492 (69.6%) with a NOP BMD. Among those with a NOP BMD, 1054 (30.2%) had high hip fracture risk, while 639 (18.3%) had very high risk. In contrast, regarding MOF, only 199 (5.7%) had high risk, and 52 (1.5%) had very high risk. TBS adjustment did not significantly change these proportions (high/very high hip fracture risk: 28.9%, p=0.248/17.2% p=0.247, high/very high MOF risk 4.7%, p=0.067;/1.0%, p=0.051).

Patients with BMD-defined osteoporosis, compared to patients in the NOP high-risk group, were younger (67.9 vs. 73.8 years, p<0.001), more likely to be female (82.6% vs. 55.6%, p<0.001), and to have lower BMI (25.5 vs. 27.1 kg/m², p<0.001). Among those with NOP-range BMD, the mean lumbar spine1-4/femoral neck/total hip T-score was 0.10±1.58/-1.24±0.86/-0.56±1.07, respectively.

Conclusions: The proportion of patients with high or very high fracture risk categories despite NOP BMD is substantial and driven primarily by hip fracture risk. These data can inform reimbursement policy decisions regarding first-line anabolic treatment.

P1703

TRABECULAR BONE SCORE (TBS): A CRITICAL COMPLEMENTARY TOOL TO DXA FOR ENHANCED FRACTURE RISK STRATIFICATION IN CLINICAL PRACTICE

Y. El Miedany[1], M. El Gaafary[2], M. Toth[3], W. Hassan[4], S. Mahran[5], M. H. Abu Zaid[6], S. Tabra[6], A. El Miedany[7], W. Elwakil[8]

[1]Canterbury Christ Church University, Canterbury, United Kingdom; [2]Community and Public Health Ain Shams University, Cairo, Egypt; [3]King's college London, London, United Kingdom; [4]Faculty of Medicine Benha University, Benha, Egypt; [5]Rheumatology and Rehabilitation Assiut University, Assiut, Egypt; [6]Rheumatology and Rehabilitation Tanta University, Tanta, Egypt; [7]Norwich medical school University of east Anglia, Norwich, United Kingdom; [8]Rheumatology and Rehabilitation Alexandria University, Alexandria, Egypt

Background

Osteoporosis diagnosis and fracture risk assessment traditionally rely heavily on Bone Mineral Density (BMD) measured by Dual-energy X-ray Absorptiometry (DXA). While BMD is a strong predictor of fracture risk, it accounts for only approximately 60% of fracture incidence, often classifying patients who still suffer fragility fractures as "non-osteoporotic. The Trabecular Bone Score (TBS) is a non-invasive texture parameter extracted from standard lumbar spine DXA images. TBS provides skeletal information regarding bone microarchitecture—specifically the quality and integrity of the trabecular network—that is *not* captured by the standard two-dimensional BMD measurement. TBS has been established as an independent risk factor for fracture, offering a crucial complementary assessment to enhance the precision of clinical fracture risk prediction.

Objective(s)

This study aims to evaluate the clinical utility of integrating the Trabecular Bone Score (TBS) with standard Bone Mineral Density (BMD) assessment via DXA to refine fracture risk prediction in a clinical cohort. Specifically, the study seeks to: 1) determine the prevalence of poor bone microarchitecture (low TBS) in patients classified as osteopenic or non-osteoporotic by BMD criteria; and 2) quantify the improvement in fracture risk stratification when TBS is incorporated into the assessment (e.g., used to adjust Fracture Risk Assessment Tool (FRAX) scores).

Methods

This was a retrospective/prospective (choose one) cohort study involving 167 postmenopausal men and women (age range 60-90 years old) undergoing routine osteoporosis screening. All participants underwent a standard DXA scan of the lumbar spine, hip, and femoral neck, providing T-scores and BMD values. TBS was subsequently calculated from the existing lumbar spine DXA files using ……..software. Patients were initially categorized based on WHO BMD criteria. The primary analysis involved reassessing fracture risk by incorporating the TBS value to adjust the 10-year probability of major osteoporotic fracture and hip fracture, typically using the TBS-adjusted FRAX score. Statistical analyses included logistic regression to compare the ability of BMD alone versus the combined BMD + TBS approach to correctly reclassify patients into high- and low-risk categories based on their clinical fracture history.

Results:

Analysis demonstrated that a low Trabecular Bone Score (TBS) was significantly and independently associated with both a history of fracture

and the incidence of new clinical fractures within the study cohort. Specifically, for every decrease of one standard deviation in TBS, the risk of a major osteoporotic fracture increased by [1.3 times (Odds Ratio: 1.3, P < 0.001], an effect that was shown to be largely independent of the standard Bone Mineral Density (BMD) measurement (Adjusted R^2 for the model increased by 8% after adding TBS).
The magnitude of the TBS effect was sufficient to significantly enhance fracture risk stratification when combined with BMD. The predictive ability of TBS was also independent of the Fracture Risk Assessment Tool (FRAX), as demonstrated by the consistent improvement in the Area Under the Curve (AUC) for fracture prediction (AUC improved from [0.76 for FRAX alone to 0.82 for FRAX adjusted by TBS].
The greatest clinical utility of incorporating TBS was observed in the osteopenic group (T-score between -1.0 and -2.5), where TBS values below the microarchitectural deterioration threshold (<1.2) led to the reclassification of 15% of patients into a higher-risk category warranting treatment, thereby refining clinical decision-making close to the intervention threshold.
Conclusion:
The robust, independent association between low Trabecular Bone Score (TBS) and fracture incidence, even after accounting for BMD and FRAX, confirms its significant clinical value. Integrating TBS into standard DXA reporting substantially enhances fracture risk stratification, particularly for patients classified as osteopenic, where treatment decisions are often ambiguous. Therefore, TBS is an essential, complementary diagnostic tool that refines personalized fracture risk assessment, leading to more accurate intervention targeting and improving the prevention of fragility fractures in clinical practice.

P1704

ASSESSING BONE MICROARCHITECTURE: ROMOSOZUMAB INDUCES FAVORABLE CHANGES IN TRABECULAR BONE SCORE COMPARED TO ANTI-RESORPTIVE THERAPY

Y. El Miedany[1], M. Toth[2], W. Elwakil[3], M. El Gaafary[4], A. El Miedany[5]

[1]Canterbury Christ Church University, Canterbury, United Kingdom; [2]King's college London, London, United Kingdom; [3]Rheumatology and Rehabilitation Alexandria University, Alexandria, Egypt; [4]Community and Public Health Ain Shams University, Cairo, Egypt; [5]Norwich medical school University of east Anglia, Norwich, United Kingdom

Background:
Osteoporosis is a systemic skeletal disease characterized by low bone mass and microarchitectural deterioration of bone tissue, leading to increased bone fragility and fracture risk. Current therapeutic strategies focus on reducing bone turnover through anti-resorptive agents (e.g., bisphosphonates) or stimulating bone formation through anabolic agents. The Trabecular Bone Score (TBS) is a readily available, non-invasive texture parameter that assesses bone microarchitecture independent of bone mineral density (BMD), providing crucial information on bone quality and fracture risk. Romosozumab, a novel bone-forming agent with a dual effect (increasing bone formation and decreasing resorption), has shown superiority in rapidly improving BMD compared to anti-resorptive treatments. However, data specifically demonstrating its impact on the critical measure of bone quality assessed by TBS, particularly when compared directly to standard anti-resorptive agents, remains limited.

Objective(s)
This study aimed to determine the comparative impact of Romosozumab versus anti-resorptive agents on the Trabecular Bone Score (TBS) in postmenopausal women with established osteoporosis. Specifically, the study sought to quantify the magnitude of change in TBS after treatment with Romosozumab compared to a control group receiving standard anti-resorptive therapy over a defined treatment period.
Methods:
This study was a retrospective, observational case-control analysis conducted to evaluate the comparative effect of Romosozumab on bone microarchitecture. The study included postmenopausal women with osteoporosis who were followed up for a 12-month period. Patients were categorized into two treatment groups: the Romosozumab group (N=21), who received 210mg subcutaneously monthly, and the Anti-resorptive group (N=28), who received oral bisphosphonates (Alendronate 70mg once weekly). Crucially, all participants in both groups received daily supplementation with calcium and vitamin D. The primary outcome measured was the percentage change in the Trabecular Bone Score (TBS) from baseline to the 12-month post-treatment assessment.
Results:
The primary outcome, the percentage change in the Trabecular Bone Score (TBS) from baseline to the 12-month post-treatment assessment, demonstrated a distinct difference between the two cohorts. The Romosozumab group experienced a mean increase in TBS of +2.88 + 3.05%, whereas the Anti-resorptive (bisphosphonate) group showed a minor mean decrease of -0.41 +3.02%. While the observed increase in TBS with Romosozumab was noticeable and favorable compared to the bisphosphonate group. However, the increase observed in the Romosozumab group did not meet the established Least Significant Change (LSC) threshold of 5% for TBS measurement.
Conclusion:
This study demonstrates that Romosozumab treatment is associated with a favorable increase in Trabecular Bone Score (TBS) in postmenopausal women with osteoporosis, contrasting with the minor decline observed in the anti-resorptive cohort. The numerical trend strongly suggests that the bone-forming action of Romosozumab positively impacts bone microarchitecture. These findings highlight that TBS may be a potentially useful, non-invasive tool for monitoring the anabolic effects of Romosozumab treatment, providing clinicians with a measure of bone quality improvement that complements traditional Bone Mineral Density (BMD) assessments.

P1705

THE ART OF STABILITY: INTEGRATING CREATIVE HEALTH INTERVENTIONS FOR BONE AND MUSCLE HEALTH OPTIMIZATION IN THE ELDERLY

Y. El Miedany[1], D. Stokes[2], M. El Gaafary[3], S. Plummer[1]

[1]Canterbury Christ Church University, Canterbury, United Kingdom; [2]The Halpern Charitable Foundation, Kent, United Kingdom; [3]Community and Public Health Ain Shams University, Cairo, Egypt

Objective

The objective of this protocol is to establish and implement a structured Creative Health Service tailored for older adults (aged 65 years and over) who are at increased risk of osteoporotic fractures and/or sarcopenia, and who face a high probability of falling. The service aims to improve dynamic balance, increase muscle and functional strength, and mitigate the psychological and social risk factors contributing to bone and muscle health deterioration. This will be achieved through the utilization of arts-based and creative activities as therapeutic interventions complementary to standard medical care.

Methods

The service will be delivered through intensive therapeutic cycles lasting a minimum of 12 weeks, with a frequency of twice weekly sessions. The program is built upon four core creative pillars: Specialized Dance/Movement (e.g., Tai Chi or ballet-based movements) to enhance balance and endurance; Rhythmic Movement and Group Drumming to improve upper body and grip strength; Music Therapy to enhance gait speed and consistency; and Expressive Arts for pain and stress management. Participants will be enrolled after obtaining medical clearance and undergoing a baseline assessment using standard tools including: the Timed Up and Go (TUG) test, Hand Grip Strength (Dynamometry), and pain/mood scales (GDS). Participants will be stratified into small groups based on their risk level and mobility status to ensure safety and personalization. Each intervention session (60-90 minutes) will focus on integrating weight-bearing and light resistance activities with relaxation techniques and social connection. Outcomes will be systematically evaluated pre- and post-intervention to measure changes in balance, strength, functional performance, and quality of life.

Outcomes: The service will employ a multi-faceted assessment and monitoring strategy, which will be stratified into 5 stages: Planning and Governance (Foundation), Program Structure and Modality Selection, Patient Intake and Risk Stratification, Implementation and Session Flow, and Monitoring and Evaluation (Outcomes)

Assessment (Intake and Stratification)

Before starting the 12-week program, every participant will undergo a comprehensive baseline assessment to ensure safety and personalize the intervention:

Medical Clearance: Essential confirmation will be obtained from a physician that the patient is safe to participate in low-impact, weight-bearing activities.

Functional Assessment: Standardized tools will be used to quantify baseline risk and function. This includes the Timed Up and Go (TUG) and the Berg Balance Scale/Tinetti Assessment to objectively measure fall risk and mobility. Muscle function and sarcopenia risk are quantified using SARC-F, Hand Grip Strength (Dynamometry) and the Chair Stand Test.

Psychosocial Baseline: Self-reported scales such as the Visual Analog Scale (VAS) will be used to gauge chronic pain levels, while tools such as the Geriatric Depression Scale (GDS) will be assess mood and quality of life.

Risk Stratification: Data from these assessments will be used immediately in the planning phase to assign participants to small, homogenous groups, ensuring the intensity of the creative activities is appropriate for their specific mobility level and fall risk.

Monitoring and Evaluation (Outcomes)

Monitoring will be formally conducted through a pre- and post-intervention evaluation design (Phase 5) to measure the service's efficacy:

Primary Clinical Outcomes: The core metrics for fall risk and strength (TUG Test, Hand Grip Strength, and Chair Stand Test) will be repeated after the 12-week cycle to quantify changes in balance, gait, and functional muscle endurance.

Secondary Outcomes: Measures of well-being will be repeated (VAS for pain, GDS for mood) to assess the psycho-social benefits of the intervention.

Adherence Monitoring: Session Attendance Rate will be continuously monitored (Phase 4 and 5) as a key indicator of patient engagement, adherence to the health behavior, and the overall enjoyment of the creative approach.

Conclusion:

The establishment of this Creative Health Service protocol marks a crucial step in modernizing preventative care for older adults facing high risks of falls and fragility fractures. Moving beyond traditional pharmacological and exercise-only models, our integrated approach leverages the intrinsic therapeutic mechanisms of creative arts—simultaneously improving physical balance through movement, increasing muscle recruitment through rhythm, and managing pain/stress through expression. The structured five-phase protocol, from rigorous baseline functional assessment (TUG, Dynamometry) to detailed outcome evaluation, ensures both patient safety and the generation of high-quality evidence. Successful implementation of this program is projected not only to yield statistically significant improvements in functional measures (e.g., increased grip strength and reduced TUG time) but also to validate Creative Health as a cost-effective, enjoyable, and essential complement to orthopedic and geriatric rehabilitation. This service offers a compelling pathway to empower older adults to actively participate in optimizing their musculoskeletal health and maintaining independence.

P1706

NUTRITIONAL RISK AS A PREDICTOR OF FUNCTIONAL IMPAIRMENT IN OLDER ADULTS CARE HOMES: IMPLICATIONS FOR INTEGRATED CARE

Y. El Miedany[1], N. Gadallah[2], M. Sarhan[3], M. Elgaafary[4], W. Hassan[5], N. El Gharbawy[2], S. Moussa[2], D. El Mikkawy[2], O. Saboony[2], A. Safar[2], S. Mahran[6], A. Samir[3], N. Ahmed[3], M. Mahgoub[7], W. Elwakil[8]

[1]Canterbury Christ Church University, Canterbury, United Kingdom; [2]Rheumatology and Rehabilitation, Ain shams University, Cairo, Egypt; [3]Egyptian Food Bank, Cairo, Egypt; [4]Community and Public Health Ain Shams University, Cairo, Egypt; [5]Faculty of Medicine Benha University, Benha, Egypt; [6]Rheumatology and Rehabilitation Assiut University, Assiut, Egypt; [7]Rheumatology and Rehabilitation, Benha University, Benha, Egypt; [8]Rheumatology and Rehabilitation Alexandria University, Alexandria, Egypt

Background: Older adults residing in long-term care homes represent a population highly vulnerable to both declining physical function (leading to falls, disability, and dependence) and malnutrition. Malnutrition in this setting is often multifactorial, stemming from factors like polypharmacy, poor dentition, and chronic disease, while poor physical function is exacerbated by sedentary behaviour and sarcopenia. The relationship between these two critical health domains is often synergistic: poor nutritional status accelerates the loss of muscle mass and physical capacity, and, conversely, reduced physical function can impair the ability to shop for or prepare food, contributing to inadequate intake. Despite this known interaction, the precise, independent association between specific measures of nutritional status and objective measures of physical function in the care home environment requires clear quantification to guide targeted, integrated interventions.

Objective(s)

This study aims to determine the strength and nature of the association between standardized measures of nutritional status and objective measures of physical function in a population of older adults residing in care homes. Specific objectives include: 1) to establish the prevalence of malnutrition and functional impairment within the cohort; and 2) to quantify the cross-sectional relationship between nutritional status scores and validated physical performance metrics, controlling for confounding factors such as age, sex, and comorbidity burden.

Methods:

This cross-sectional study included 209 older adults (mean age women 72.04±9.58 years, age range 50-106 years) residents in 10 care homes. The Nutritional status was assessed using Mini Nutritional Assessment (MNA) questionnaire, whereas physical functional was assessed using the Health Assessment questionnaire – Disability Index (HAQ-DI), with a score of ≤0.5 defined as functional remission. HAQ-DI score 0.5-1 was scored as mild disability, HAQ-DI score 2-3 was rated as moderate disability, whereas score >2 was rated as severe disability. Multivariable logistic regression analysis was conducted to examine the association between nutritional risk and functional remission, adjusting for relevant background factors including age, sex and comorbidities.

Results:

Among the 299 patients (65.2% female). Mean MNA score of 22.22 ± 3.84, and a mean HAQ score of 1.33 ± 0.84. Females were older than males (73.18 ± 10.02 vs 69.90 ± 8.35 years), had similar nutritional status (MNA 22.26 ± 3.82 vs 22.14 ± 3.89), but showed higher functional impairment (HAQ 1.44 ± 0.82 vs 1.12 ± 0.85). The cohort included 101 (48.3%) participants "at risk of malnutrition," 19 (9.09%) malnourished, and 89 (42.5%) with normal nutrition status, while HAQ categories revealed that 71 (33.97 %) mild–moderate difficulty, 68 (32.53%) moderate–severe disability, 31 (14.8%) normal/near-normal function, and 39 (18.7%) severe–very severe disability. MNA was significantly inversely associated with HAQ (Spearman's ρ = −0.213, p = 0.002; n = 209), indicating that better nutritional status was associated with lower functional impairment. Nutritional risk independently increases the odds of functional disability (OR: 1.86, 95% CI: 1.19–2.91).

Conclusion

This cross-sectional study in older adults residing in care homes establishes a significant, independent association between nutritional risk (assessed by MNA) and physical function disability (assessed by HAQ-DI). The finding that the prevalence of functional disability increases dramatically with the severity of nutritional risk, and that nutritional risk independently increases the odds of functional non-remission, underscores the crucial, synergistic relationship between these two domains. These results mandate that nutritional status assessment via tools like the MNA should be a standard and integrated component of functional assessment protocols in care home settings. Early identification and targeted nutritional interventions are essential, high-priority strategies for maintaining physical independence and preventing disability in this vulnerable population.

DYNAMIC ASSESSMENT OF INTRINSIC CAPACITY: A NOVEL APPROACH TO MONITORING MULTI-DOMAIN INTERVENTIONS THROUGH INTEGRATED INTERVENTION PROGRAM IN AGING POPULATIONS

Y. El Miedany[1], N. Gadallah[2], M. Sarhan[3], M. El Gaafary[4], W. Hassan[5], N. El Gharbawy[2], S. Moussa[2], D. El Mikkawy[2], O. Saboony[2], A. Safar[2], S. Mahran[6], A. Samir[3], N. Ahmed[3], M. Mahgoub[7], W. Elwakil[8]

[1]Canterbury Christ Church University, Canterbury, United Kingdom; [2]Rheumatology and Rehabilitation, Ain shams University, Cairo, Egypt; [3]Egyptian Food Bank, Cairo, Egypt; [4]Community and Public Health Ain Shams University, Cairo, Egypt; [5]Faculty of Medicine Benha University, Benha, Egypt; [6]Rheumatology and Rehabilitation Assiut University, Assiut, Egypt; [7]Rheumatology and Rehabilitation, Benha University, Benha, Egypt; [8]Rheumatology and Rehabilitation Alexandria University, Alexandria, Egypt

Background

The global aging population necessitates a transition from traditional disease-oriented models to proactive, functional assessments. The World Health Organization (WHO) defines **Intrinsic Capacity (IC)** as the composite of all physical and mental attributes an individual can draw upon. IC comprises five core domains: **locomotor, cognitive, psychological, sensory, and vitality**.

While multimodal interventions—incorporating physical activity, nutritional support, and psychological counselling—are recognized as the "gold standard" for preventing frailty, there is limited evidence on

how these domains respond dynamically to integrated programming. This study aims to evaluate the effectiveness of a targeted multimodal program in enhancing IC and to determine the feasibility of longitudinal IC monitoring as a clinical endpoint for older adults.

Methods

• **Study Design and Participants:** A prospective, longitudinal study was conducted involving community-dwelling older adults (>50-years) exhibiting signs of declining capacity or pre-frailty.

• **Multimodal Intervention:** Participants underwent a 24-week integrated program consisting of:

• **Physical:** Structured multicomponent exercise (aerobic, resistance, and balance training).

• **Nutritional:** Personalized counselling and protein-enriched dietary supplementation where indicated. Vitamin D supplementation when required following a blood check.

• **Psychological:** Psychotherapy, medical management when required.

Assessment of Intrinsic Capacity: IC was measured at baseline, and 24 weeks using the following validated tools:

• **Locomotor:** SARC-F, Chair stand test, time up and go, and gait speed.

• **Cognitive:** Mini Mental State Examination (MMSE).

• **Psychological:** General Health Questionnaire (GHQ-30).

• **Sensory:** Visual acuity (Snellen chart) and whispered voice test for hearing.

• **Vitality:** handgrip strength (dynamometry) and functional ability.

• **Nutrition:** Mini Nutritional Assessment (MNA)

Monitoring and Data Analysis: Changes in domain scores were analysed using linear mixed-effects models to account for individual variability over time. Feasibility was assessed through program adherence rates and participant-reported ease of monitoring. **Results**

A total of 209 participants (mean age women 72.04+9.58 years, age range 50-106, 65.2% female) completed the 24-week program. Significant improvements were observed across three primary IC domains:

• **Locomotor Capacity:** significant increase in the SARC-F score (p< 0.03) with a notable improvement in gait speed.

• **Vitality:** Handgrip strength improved by an average of 13.24 to15.76 **kg (p< 0.05)**, and functional ability improved from 1.33+0.6 to 1.18+0.08 (p< 0.01)

• Knowledge, Attitude, and Practice: significant improvement from 6.20+0.16 to 7.24+0.19 (p<0.01)

• MNA scores indicated a significant reduction in malnutrition risk.

• **Psychological:** There has been non-significant improvement of both GHQ-3- as well as Mini Mental State examination with reduction in depressive symptoms and improvement of the cognitive functions.

The integrated monitoring approach allowed for early detection of "micro-declines" in individual participants, prompting immediate clinical adjustments. Adherence to the multimodal program was high (87**%**), suggesting that the combined intervention is well-tolerated by community-dwelling older adults. **Conclusion** This study demonstrates that a structured physical, nutritional, and psychological program can effectively enhance or stabilize **Intrinsic Capacity** in older adults. The results emphasize that IC is not a static state but a dynamic one that responds to targeted, multi-domain interventions. Furthermore, the transition from traditional frailty screening to longitudinal IC monitoring provides a more holistic and person-cantered view of aging. These findings support the integration of IC assessment into routine geriatric care to prevent functional decline and promote "Healthy Aging" as envisioned by the WHO. Future research should focus on the long-term sustainability of these gains beyond the 24-week intervention period.

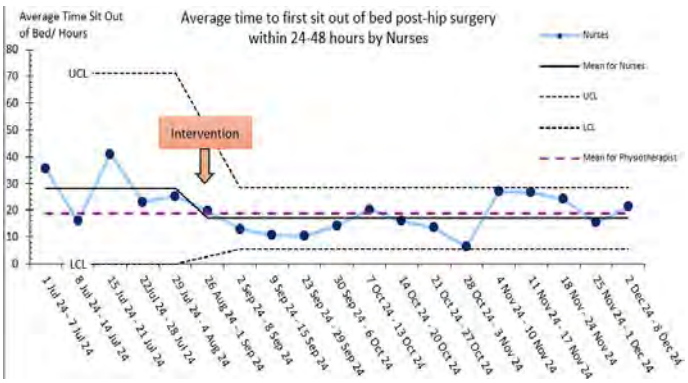
P1708

QUANTITATIVE BONE SPECT/CT PARAMETERS COULD PREDICT THE SUCCESS OF THE CONSERVATIVE TREATMENT FOR SYMPTOMATIC BASAL JOINT ARTHRITIS OF THE THUMB

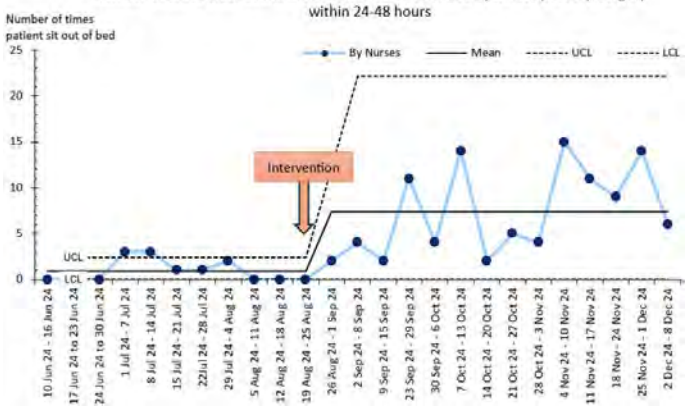
J. H. Ahn[1], Y. H. Shin[1]

[1]Department of Orthopedic Surgery, Asan Medical Center, University of Ulsan College of Medicine, Seoul, South Korea

Purpose: The aim of this study was to evaluate the role of quantitatively assessed bone SPECT/CT parameters for predicting the success of conservative treatment for symptomatic basal joint arthritis of the thumb.
Materials and methods: Seventy-eight patients (128 hands) with symptomatic basal joint arthritis of the thumb who underwent bone SPECT/CT scans within 4 weeks after their initial visit and completed conservative treatment for more than 6 months between April 2019 and April 2023 were retrospectively enrolled. Patient-Rated Wrist/Hand Evaluation (PRWHE) were evaluated in all patients before and after the treatment. The maximum standardized uptake value (SUVmax) from bone SPECT/CT was measured in the four peritrapezial joints, and the highest uptake was used for analysis.
Results: On the basis of the minimal clinically important difference in PRWHE scores, 64 hands (50.0% of 128 hands) were classified as the treatment success group and 64 hands (50.0% of 128 hands) were failure group. In multivariate logistic regression analysis, only high SUVmax (OR 1.097; 95% CI, 1.027–1.172, p = 0.006) was a factor significantly associated with the success of conservative treatment. In receiver operating characteristics curve analysis, the area under the curve of SUVmax was 0.649 (95% CI 0.554–0.744, p = 0.002). As a prognostic parameter for the success of conservative treatment, SUVmax showed a sensitivity of 56.3% and specificity of 70.3% with a cut-off of 9.52.
Conclusions: High initial SUVmax on bone SPECT/CT was significantly associated with the success of conservative treatment for symptomatic basal joint arthritis of the thumb.



P1709



IMPLEMENTING NURSE-LED MOBILITY PROTOCOL FOR OLDER ADULTS POST-HIP SURGERY: A PILOT CLINICAL IMPLEMENTATION STUDY

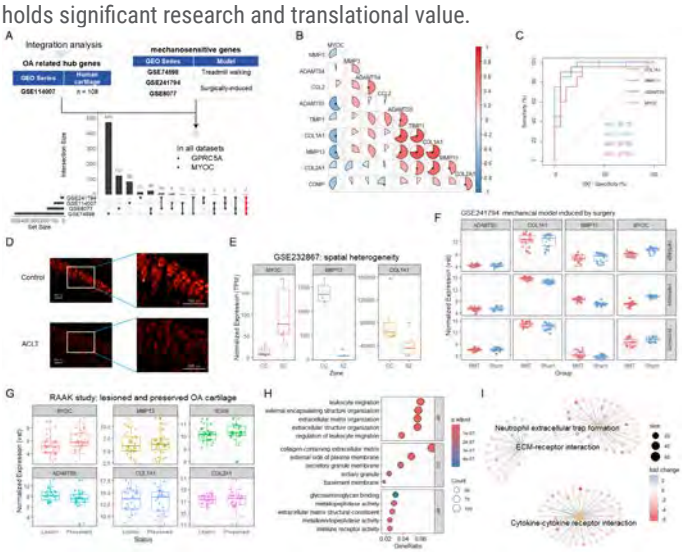
Y. H. Wong[1], P. Y. C. Tan[1], X. Z. Chen[1], W. Y. S. Tan[1], J. L. J. Foo[1], Z. H. M. Wong[1], S. Maniya[1], K. H. R. Goh[1], W. M. Siow[1]

[1]Sengkang General Hospital, Singapore, Singapore

• Objective(s)
1.To conduct mandatory education sessions to increase nursing staff knowledge and confidence on the benefits and methods of post-hip surgery mobility.
2.To introduce a nurse-led mobility protocol and achieve a compliance rate of ≥ 70%.
3.To increase the rate of early postoperative mobilization (sitting out of bed within 48 hours) by 50% within three months for older adults who have undergone hip fracture surgery through nurse-led mobility measures.
Secondary outcome measures included the average length of stay (ALOS), and the incidence of postoperative complications from the postoperative day to the day of discharge.
• Material and Methods
Participants and sample size:
1. 40 nursing staff
2. Pre & Post intervention groups of patiets aged ≥60 post hip surgery admitted in GFU:
i) The pre-intervention group included 43 patients admitted between June - August'24
ii) The post-intervention group included 48 patients admitted between September – December'24.
A nurse-led early mobility protocol was developed based on evidence and expert consensus to guide safe mobilization. Staff completed an Investigator-designed survey via a secure platform before and after attending mandatory structured education sessions delivered by the orthopaedics Advanced Practice Nurse(APN), pain specialty nurse, and physiotherapist.
This study was submitted to the Centralized Insitutional Review Board (CRIB) and classified as exempt.
• Results
Nursing confidence in assisting patients to sit out of bed improved by 40% with statistically significant increases in total confidence scores (p = 0.011). Early mobilisation frequency increased from 0.9 to 7.4 times within 24-48 hours post-surgery. Protocol compliance was ranging from 86-100%. Secondary outcomes showed reductions in pressure injury and urinary tract infections (both 2.1%, p = 1.000), delirium (7.2%, p = 0.185), and mean length of stay (1.08 days, p = 0.283).

• Conclusion(s)
The nurse-led early mobility protocol empowered nurses to initiate timely, safe mobilisation and demonstrated improved patient outcomes. Non-significant results likely reflect small sample size and short follow-up period.

P1710



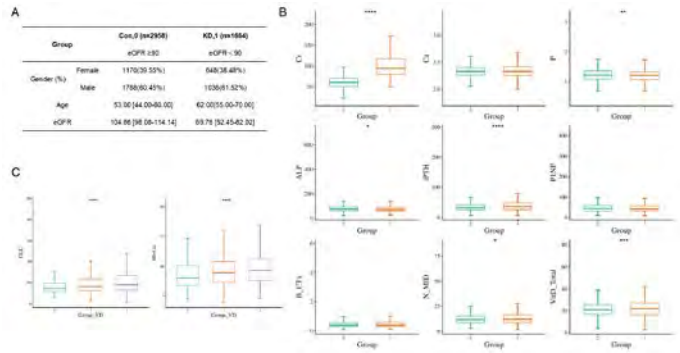
PROTECTIVE ROLE OF MYOC IN OSTEOARTHRITIS: A MECHANOSENSITIVE BIOMARKER FOR CARTILAGE EXTRACELLULAR MATRIX HOMEOSTASIS

Y. J. Song[1], F. Liu[1], X. Li[1]

[1]Department of Laboratory Medicine, Nanfang Hospital, Southern Medical University, Guangzhou, China

Multiple studies confirm that the secreted protein Myocilin, encoded by the gene MYOC, plays a key role in regulating processes such as cell adhesion and cytoskeleton functions. MYOC has been implicated in multiple diseases, including primary open-angle glaucoma, where it elevates pathological intraocular pressure by impairing trabecular meshwork cell function and disrupting aqueous humor outflow. To explore the role of MYOC in mechanically driven diseases like osteoarthritis (OA), we systematically analyzed its expression and function. Integrated omics data identified MYOC as the hub gene significantly associated with OA cartilage degeneration in a mechanical loading model. MYOC expression was significantly down-regulated in surgically induced mechanical instability animal models and human OA cartilage tissue, while the matrix marker MMP13 showed up-regulation. Physiological exercise promoted MYOC expression and inhibited MMP13, suggesting MYOC is mechanosensitive and may protect extracellular matrix (ECM)

homeostasis. ROC analysis revealed MYOC has high discriminatory efficacy for OA (AUC > 0.8), supporting its potential as a biomarker. MYOC expression correlated with cartilage damage severity and exhibited spatial heterogeneity, reinforcing its link to the mechanical microenvironment. Functional enrichment showed MYOC associated genes were enriched in ECM organization and immune regulation pathways. Human Protein Atlas data indicated MYOC is primarily expressed by fibroblasts and positively correlated with ECM remodeling markers. These results suggest MYOC regulates ECM homeostasis. In summary, MYOC may modulate ECM homeostasis across diseases, offering new insights into multi-scale mechanical mechanisms in disease pathogenesis. Identifying mechanically responsive biomarkers holds significant research and translational value.



P1711

RENAL FUNCTION MODIFIES BONE TURNOVER MARKERS IN DIABETIC OSTEOPATHY: A RETROSPECTIVE STUDY IN CHINESE POPULATION

Y. J. Song[1], X. C. Fang[1], F. Liu[1], X. Li[1]

[1]Department of Laboratory Medicine, Nanfang Hospital, Southern Medical University, Guangzhou, China

To explore the effect of different renal function status on bone turnover markers in patients with type 2 diabetes mellitus (T2DM), and provide evidence for clinical management of diabetic osteopathy. A single-center retrospective study was conducted to analyze data of 4642 hospitalized T2DM patients in a Chinese general hospital from January 2019 to December 2024. Patients were divided into control group (Con, n=2958) and renal function decline group (KD, n=1684) based on estimated glomerular filtration rate (eGFR) ≥90 or not, excluding cases with severe renal insufficiency (eGFR<30). Mann-Whitney U test was used to compare 110 laboratory indicators between the two groups, focusing on differences in bone metabolism and related markers. Significant differences were observed in creatinine (Cr), phosphorus (P), alkaline phosphatase (ALP), intact parathyroid hormone (iPTH), osteocalcin (N-MID), and total vitamin D (VitD) between the two groups ($p<0.05$). The medians of Cr, iPTH, and VitD in KD group were higher than those in Con group, while P, ALP, and N-MID were lower. No differences were found in total calcium (Ca), procollagen type I N propeptide (PINP), and β isomerized C-terminal telopeptide of type I collagen (B-CTX). In addition, 87.12% of patients had VitD deficiency/insufficiency, and elevated blood glucose was positively correlated with the severity of VitD deficiency. Early renal function decline can alter bone turnover marker levels in Chinese T2DM patients. The high prevalence of VitD deficiency in Chinese population is associated with lifestyle factors such as insufficient sunlight exposure and dietary structure, suggesting that comprehensive management strategies for T2DM patients in China and other East Asia should be optimized based on renal function status and VitD nutritional status.

P1712

THE ANABOLIC PARADOX: INCREASED INCIDENCE OF THORACIC SPINE SURGERY IN OSTEOPOROTIC PATIENTS ESCALATED TO TERIPARATIDE THERAPY – A PROPENSITY-MATCHED GLOBAL DATABASE ANALYSIS

Y. J. Yu Jui[1], C. M. Chih Ming[1]

[1]Taichung Veterans General Hospital, Taichung, Taiwan

Background: Teriparatide (Forteo) is a potent anabolic agent indicated for patients at high risk of fracture. In real-world clinical practice, it is often reserved for those with severe bone loss or those failing first-line anti-resorptives. This study utilizes a global federated database to evaluate the incidence of thoracic spine surgery (TSS) in patients escalated to teriparatide compared to those remaining on standard therapy, while strictly controlling for secondary bone pathologies and pre-operative prescription bias.

Methods: Using the TriNetX Global Health Research Network, we identified 1,376,971 patients with a diagnosis of osteoporosis. Two cohorts were established: **Cohort 1 (Meds + Forteo)** and **Cohort 2 (Meds, No Forteo)**.

- **Exclusion Criteria:** Patients with bone tumors, Paget's disease, and rickets or osteomalacia were excluded to isolate primary osteoporosis.
- **Matching:** Propensity score matching (1:1) was performed for age, sex, and race, resulting in **34,849 matched patients per group** (Mean Age: 74.9± m 11.5years; 85.2% Female).
- **Temporal Control:** To eliminate "pre-operative prescription bias," patients with surgical outcomes within the first 6 months of initiating teriparatide were excluded (N=1,741 in Cohort 1; N=447 in Cohort 2).

Results: Following the 6-month washout period, **33,108** patients in Cohort 1 and **34,402** in Cohort 2 were analyzed.

• **Surgical Incidence:** Cohort 1 demonstrated a significantly higher cumulative incidence of thoracic spine surgery (0.837%) compared to Cohort 2 (0.270%).

• **Risk Metrics:** The **Hazard Ratio (HR) was 3.006** (95% CI: 2.377, 3.802), and the **Odds Ratio was 3.113** (95% CI: 2.46, 3.939).

• **Risk Difference:** A significant risk difference of **0.566%** was observed (95% CI: 0.454%, 0.679%; z=9.964, p < 0.0001).

• **Survival Analysis:** Kaplan-Meier analysis confirmed a significantly lower survival probability (freedom from surgery) in the teriparatide group (97.6% vs 98.9%; Log-Rank X^2 = 93.225, p < 0.0001).

Conclusion: Despite accounting for pre-operative bias and secondary bone diseases, teriparatide escalation remains a strong statistical predictor for thoracic spine surgery. These results suggest a "Fragile Phenotype" paradox: in real-world settings, teriparatide is selectively prescribed to patients with the highest disease burden and impending spinal instability, necessitating surgical intervention regardless of potent anabolic medical management.This suggests that in real-world clinical practice, teriparatide serves as a marker for a "fragile phenotype"—patients with imminent structural failure that medical management alone may not prevent the outcomes of surgical interventions.

Table 1: Primary Outcome Analysis

Metric	Result	95% Confidence Interval
Hazard Ratio (HR)	**3.01**	(2.38, 3.80)
Risk Ratio (RR)	**3.10**	(2.45, 3.91)
Odds Ratio (OR)	**3.11**	(2.46, 3.94)

Table 2: Comparative Clinical Outcomes

Statistic	Value	95% Confidence Interval	p-value
Hazard Ratio	**3.006**	(2.377, 3.802)	< 0.0001
Risk Ratio	**3.095**	(2.448, 3.912)	< 0.0001
Odds Ratio	**3.113**	(2.460, 3.939)	< 0.0001
Risk Difference	**0.566%**	(0.454%, 0.679%)	< 0.0001

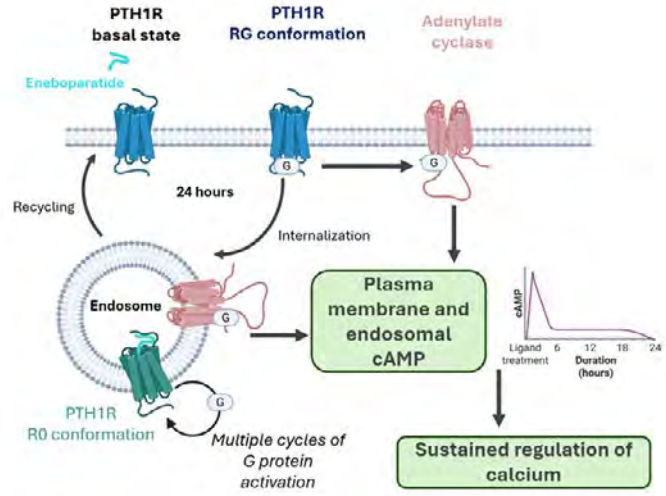
ENEBOPARATIDE: MECHANISM OF ACTION UNDERLYING THE SUSTAINED REGULATION OF CALCIUM IN HYPOPARATHYROIDISM

X. Gaume[1], Y. Kong[2], G. Ravel[3], C. Berardet[4], S. Allas[5], M. Aouadi[1]

[1]Discovery Biology, Alexion, AstraZeneca Rare Disease, Ecully, France; [2]Global Medical Affairs, Alexion, AstraZeneca Rare Disease, Boston, United States; [3]Clinical Pharmacology and Safety Sciences, Alexion, AstraZeneca Rare Disease, Ecully, France; [4]Process Development and Clinical Supply, Alexion, AstraZeneca Rare Disease, Ecully, France; [5]Clinical Development, Alexion, AstraZeneca Rare Disease, Ecully, France

Objectives: Here, we investigated the mechanism whereby eneboparatide provides prolonged calcium regulation *in vivo,* since in animal models and patients with chronic hypoparathyroidism (HypoPT), treatment with eneboparatide led to sustained regulation of urinary and serum calcium (sCa) despite its short circulating half-life.



Materials and Methods: PTH 1 and 2 receptor (PTH1R and PTH2R) activation was evaluated using a cell-based cyclic adenosine monophosphate (cAMP) assay. Receptor binding affinity was assessed by radioligand competition assay. PTH1R activation kinetics were investigated by measuring cAMP production for 24 h after ligand washout in cells expressing PTH1R. Tissue distribution was examined by quantitative whole-body autoradiography in rats. Structure-function studies evaluated the effect of amino acid substitutions, additions, and truncations of eneboparatide on PTH1R activation kinetics.

Results: Eneboparatide activated PTH1R and PTH2R, establishing it as a broad-spectrum PTH receptor agonist. Eneboparatide had high affinity for PTH1R R0 conformation, leading to extended cAMP signaling up to 24 h, contrary to the transient effect of PTH(1-34). (**Figure**). Eneboparatide showed prolonged and enhanced receptor occupancy in PTH1R-expressing tissues vs PTH(1-34), particularly in the kidney, with structure-function studies identifying molecular features underlying sustained PTH1R activation.

Conclusions: These data revealed the unique properties of eneboparatide needed for sustained activation of PTH1R, resulting in extended regulation of sCa via retention, particularly in the kidney, despite rapid circulatory clearance.

Acknowledgments: This work was funded by Alexion, AstraZeneca Rare Disease (Boston, MA, USA). Medical writing/editorial support was provided by Kayt Scott, PhD, and Lauren Hummel, BA, both of Arbor Scientia (Carlsbad, CA, USA), and funded by Alexion, AstraZeneca Rare Disease.

Disclosures: XG, YK, GR, CB, SA, and MA are employees of Alexion, AstraZeneca Rare Disease and hold stock/stock options. XG holds Adocia stock/stock options. Eneboparatide variants are included in European Patent Application No. 25306782.1.

REGENERATIVE APPROACHES TO THE TREATMENT OF OSTEOCHONDRAL DEFECTS: RESULTS BASED ON AN EXPERIMENTAL MODEL IN RABBIT

O. Burianov[1], T. Omelchenko[1], Y. Levytskyi[2]

[1]Bogomolets National Medical University, Department of Traumatology and Orthopedics, Kyiv, Ukraine; [2]Bogomolets National Medical University, Department of Traumatology and Orthopedics, Kyiv, Ukraine

Keywords: Osteochondral Defect, Cartilage, Bone Marrow-Derived Cell Transplantation, Platelet Rich Plasma, Experimental Study.

Objective

This experimental study aimed to assess the regenerative potential of Bone Marrow-Derived Cell Transplantation (BMDCT) and Platelet-Rich Plasma (PRP) for osteochondral defects treatment using morphological evaluation in a rabbit model.

Materials and Methods

The study involved 32 rabbits divided into four groups. Critical-size osteochondral defects (3 mm diameter, 5 mm depth) were created in the medial femoral condyle. Defects were left untreated, not filled (group 1), filled with a collagen-fibrin matrix (group 2), collagen-fibrin matrix combined with PRP (group 3), or BMDCT (group 4). Regenerative tissue was assessed for integration, structural organization, cellular composition, and extracellular matrix using a modified scoring system from the International Cartilage Regeneration & Joint Preservation Society (ICRS).

Results

Histological evaluation revealed hyaline cartilage formation only in groups 3 and 4, with minimal surface stratification. In group 3, the defect was filled with hyaline tissue containing chondroblasts, chondrocytes, and fibrochondrocytes densely occupying the lesion. In group 4, the regenerated tissue was well-developed hyaline cartilage with strong integration to surrounding tissue. Morphometric analysis demonstrated significant differences in all parameters between the PRP and BMDCT groups compared with controls. Between the experimental groups, BMDCT showed better tissue quality and cellular composition, with values approximately 1.4 times higher than PRP.

Conclusion

BMDCT demonstrated better regenerative efficacy compared to PRP in the treatment of osteochondral defects in this rabbit model, indicating its potential as an advanced therapeutic approach for cartilage repair.

P1715

IMPACT OF CYP2C19 GENOTYPES ON BONE MINERAL DENSITY CHANGES IN PROTON PUMP INHIBITOR USERS

Y. Liao[1], C. Hsu[2]

[1]Department of Pharmacy, Taichung Veterans General Hospital, Taichung, Taiwan; [2]Department of Physical Medicine and Rehabilitation, Taichung Veterans General Hospital, Taichung, Taiwan

Objective

Proton pump inhibitors (PPIs) are associated with increased fracture risk, while CYP2C19 polymorphisms affect PPI pharmacokinetics. This study evaluated the impact of CYP2C19 genotypes on bone mineral density (BMD) in PPI users to clarify interindividual variability in bone health.

Material and Methods

Participants using PPIs with a medication possession ratio above >= 70% and previous BMD data were recalled for repeat dual-energy X-ray absorptiometry measurements and lifestyle questionnaires. Genotyping was performed using the TWBv2 array to define normal metabolizer (NM), intermediate metabolizer (IM), and poor metabolizer (PM) phenotypes based on loss-of-function variants rs4244285, rs4986893, and rs72552267. Due to non-normal distribution, non-parametric methods and robust regression were employed for analysis.

Results

Among 91 PPI users (NM: 41, IM: 38, PM: 12), median BMD fractional change showed no significant group difference (spine p=0.437, left femoral neck p=0.068, right femoral neck p=0.779), though the PM phenotype exhibited a numerical trend toward greater loss. In the robust regression analysis, associations between CYP2C19 phenotypes and BMD changes varied by site. For the lumbar spine, neither IM (beta=-0.01, p=0.387) nor PM (beta=-0.03, p=0.174) was significantly associated with BMD outcomes. For the left femoral neck, the IM phenotype was significantly associated with greater BMD loss (beta=-0.03, p=0.005), and the PM phenotype showed a potential negative trend (beta=-0.04, p=0.084). In the right femoral neck, no significant associations were found for IM (beta=0.00, p=0.989) or PM (beta=-0.02, p=0.434). Male gender (beta=0.04, p=0.006) and concurrent osteoporosis therapy (beta=0.04, p=0.002) were significant protective factors. Positive trends were observed for exercise and daily vitamin D >800 IU, whereas BMI showed no significant influence.

Conclusion

The CYP2C19 IM phenotype was independently associated with accelerated hip bone loss among PPI users, with a similar numerical potential in PM users. Concurrent osteoporosis therapy and healthy lifestyle factors like exercise appear to mitigate bone loss. These findings suggest a need for personalized bone health management in long-term PPI users based on genetic and lifestyle profiles.

DIFFICULT TO TREAT AXIAL SPONDYLOARTHRITIS: CLINICAL CHARACTERISTICS AND ASSOCIATED FACTORS

Y. Makhlouf[1], O. El Haj Ahmed[1], H. Boussaa[1], S. Miladi[1], A. Fazaa[1], K. Ben Abdelghani[1], M. A. Laatar[1]

[1]The Rheumatology Department of Mongi Slim Hospital, Marsa, Tunisia

Objectives:
Our study aimed to describe the clinical characteristics of patients with difficult to treat axial spondyloarthritis (D2T ax-SpA), to determine its frequency and to identify the associated factors.
Methods:
A retrospective study was conducted including patients with ax-SpA fulfilling the ASAS 2009 classification criteria and diagnosed between January 1, 2013, and December 31, 2018. Patients were divided into D2T ax-SpA and non D2T ax-SpA, according to the ASAS definition published in 2024.
Results:
A total of 129 patients were included. The frequency of D2T ax-SpA was 8.5%. Among them, five patients (45.5%) experienced failure of two anti-TNFα agents and six (54.5%) had contraindications. Sociodemographic characteristics and SpA phenotypes were comparable between groups. D2T patients more frequently presented with fibromyalgia (p=0.03), peripheral neuropathy (p=0.01), migraine (p=0.034), IgA glomerulonephritis (p<0.001), chronic kidney disease (p=0.01) and neoplasms (p<0.001). They also exhibited a longer diagnostic delay (p=0.05) and a longer disease duration (p=0.015). Initial CRP and ASDAS-CRP values were higher (p=0.04 and 0.003, respectively). Methotrexate doses were higher in D2T patients (p=0.043). Switching from the first biologic therapy in this group was mainly due to primary treatment failure (p=0.018).
In multivariate analysis, factors associated with D2T ax-SpA were IgA glomerulonephritis (OR=5.02 [1.6–17.3], p=0.016), fibromyalgia (OR=1.65 [1–13.4], p=0.049), migraine (OR=7.34 [2.7–19.4], p=0.001), neoplasms (OR=6.99 [2.3–16.1], p=0.013), elevated baseline CRP (OR=2.98 [1.1–8], p=0.01), elevated baseline ASDAS-CRP (OR=2.38 [1.1–9.3], p=0.013) and longer diagnostic delay (OR=5.02 [1.97–7.2], p=0.036).
Conclusion:
In our study, the frequency of D2T ax-SpA was 8.5%. This form was associated with IgA glomerulonephritis, fibromyalgia, migraine, neoplasms, elevated initial CRP and ASDAS-CRP levels, and a longer diagnostic delay.

P1718

FRAILTY AND OSTEOSARCOPENIA IN OLDER MEN: A HIDDEN VULNERABILITY

Y. Polat[1], A. Okyar Baş[1], M. Levent[1], Z. Şahiner[1], E. Çeşmeci[1], C. Balcı[1], B. B. Doğu[1], M. Cankurtaran[1], M. G. Halil[1]

[1]1 Hacettepe University Faculty of Medicine, Department of Internal Medicine, Division of Geriatrics, Ankara, Türkiye

Objective: This study aimed to investigate the association between frailty and osteosarcopenia (OSP), defined as the coexistence of osteoporosis (OP) and sarcopenia, in male patients aged 65–70 years.
Material and Methods: This cross-sectional study included 234 community-dwelling men aged 65–70 years who presented to a geriatrics outpatient clinic. OSP was defined by the presence of both low muscle strength and OP. Comprehensive geriatric assessments (CGA) and physical performance tests were performed. Clinical Frailty Scale (CFS) was used to assess frailty status. The Fracture Risk Assessment Tool (FRAX) and modified FRAX (mFrax) scores were used to measure the risk of 10-year probabilities (%) of major osteoporotic fracture (MOF) and hip fracture (HF).
Results: Our study included 234 male geriatric patients with a median age of 68 [66–69] years. Among them, 52 patients (22.3%) were diagnosed with OSP, while 182 (77.7%) were classified as non-OSP. OSP was independently associated with living with frailty (CFS ≥4) after adjusting for age, BMI, chronic renal disease (CRD), number of medications, malnutrition, arrhythmia, Katz Activities of Daily Living (ADL) scores, Lawton Instrumental ADL scores, and depression(OR = 3.34; 95% CI: 1.54–7.23; p = 0.002). Higher CFS scores were significantly associated with an increased likelihood of OSP in older men(OR: 1.66; 95% CI: 1.07–2.55; p=0.021). Patients with OSP had higher CFS and lower MNA scores (p<0.05). CRD and medication use were associated with increased OSP risk, while BMI >25 was associated with lower risk (p<0.05).
Conclusions: Frailty is significantly associated with OSP in older men and may contribute to its development. Screening men aged 65–70 for both conditions may support early detection and prevention. Further studies are needed to clarify causality and guide interventions.

Table 1: Sociodemographic features and clinical variables of study groups

	Normal n = 182 (77.7%)	Osteosarcopenic n = 52 (22.3%)	P-value
Age (median, IQR)	68 (66 - 69)	68 (66 - 69)	0.982
BMI, median (IQR)	27.8 (26.1 -29.7)	27.6 (23.9– 30.0)	0.566
BMI(>25), n (%)	148 (81.8)	35 (67.3)	**0.025**

OSTEOBLASTIC 11B-HSD1-MEDIATED LOCAL GLUCOCORTICOID ACTIVATION DRIVES SUBCHONDRAL BONE SCLEROSIS TO PROMOTE CARTILAGE DEGENERATION IN OSTEOARTHRITIS

Y. Q. Yonghua[1], C. Z. Chuanxin[1], H. L. Hongrui[1], Y. Q. Yewen[2], X. L. Xinyi[1], N. L. Nanxi[1], Z. L. Zhanghao[1], X. W. Xiaoxin[1], S. H. Shu[2], A. L. Aiping[1], G. H. Guangxin[2], J. L. Jin[1]

[1]HongKong Baptist University, HongKong, China; [2]The Third Affiliated Hospital of Southern Medical University, GuangZhou, China

Objective: In osteoarthritis (OA), subchondral bone sclerosis is a hallmark pathology that often accompanies with cartilage degeneration, yet its molecular regulation remains poorly understood. Although physiological glucocorticoid (GC) signaling is required for bone homeostasis, whether local GC activation contributes to pathological remodeling of subchondral bone in OA is unclear. While previous studies showed that blocking GC signaling via transgenic overexpression of 11β-hydroxysteroid dehydrogenase type (11β-HSD2, GC-inactivated enzyme) attenuates OA, 11β-HSD2 is not normally expressed in bone. 11β-HSD1the enzyme responsible for local GCs activation, is substantially expressed in bone, yet its role in the pathological OA microenvironment is unclear. Therefore, this study aimed to investigate whether osteoblastic 11β-HSD1-mediated local GC activation contributes to subchondral sclerosis and cartilage degeneration in OA.

Methods: We first analyzed GC pathway gene expression in load-bearing versus non-load-bearing subchondral bone regions using a public OA patients' subchondral bone dataset (GSE284357). To validate findings, we utilized the destabilization of the medial meniscus (DMM) mouse model, analyzing 11β-HSD1 expression patterns via immunofluorescence. To define cell-specific functions, osteoblast-specific 11β-HSD1 knockout mice (Bglap-cre; Hsd11b1$^{fl/fl}$, CKO) and WT mice underwent DMM surgery. Knee joints were harvested at 4 weeks to assess subchondral bone microarchitecture (micro-CT) and cartilage integrity.

Results: Bioinformatic analysis of OA patients' subchondral bone samples revealed a stress-dependent GC pathway activation: GC-responsive genes were specifically upregulated, while GC-downregulated genes were repressed in load-bearing subchondral bone regions compared to non-load-bearing sites (**Figure. 1A**). Consistent with this, 11β-HSD1 expression progressively increased in the subchondral bone of DMM mice (**Figure. 1B-D**). Co-staining identified osteocalcin-positive osteoblasts as the primary source of this pathological 11β-HSD1 upregulation (**Figure. 1E**). Importantly, osteoblast-specific deletion of 11β-HSD1 significantly reduced subchondral bone sclerosis (**Figure. 2A**) and attenuated OA progression (**Figure. 2B**) at 4 weeks post-surgery.

Conclusion: Our findings identify osteoblastic 11β-HSD1–mediated local GC activation as a key regulator of subchondral bone sclerosis in OA. Targeting osteoblastic 11β-HSD1 may represent a novel strategy to limit subchondral sclerosis and slow OA progression.

P1720

RELATIONSHIP BETWEEN NAMPT AND CLASSICAL INFLAMMATORY MARKERS IN PATIENTS WITH OSTEOPOROSIS ASSOCIATED WITH RHEUMATOID ARTHRITIS

Y. R. Akhverdyan[1,2], E. V. Papichev[1,2], Y. V. Polyakova[1,2], L. E. Sivordova[1], B. V. Zavodovsky[1,2]

[1]Research institute of clinical and experimental rheumatology n.a. A.B. Zborovsky, Volgograd, Russia; [2]Volgograd State Medical University, Volgograd, Russia

Objective: To study the relationship between serum nicotinamide phosphoribosyltransferase (Nampt) levels and laboratory markers of inflammation in patients with osteoporosis (OP) associated with rheumatoid arthritis (RA).
Methods: We determined serum Nampt levels in 140 RA patients (96 women and 44 men) using an indirect enzyme-linked immunosorbent assay (RaiBiotech, cat. no. EIA-VIS-1). All patients had RA diagnosed according to generally accepted clinical guidelines; dual-energy X-ray absorptiometry was used to measure bone mineral density. The control group consisted of 20 women and 10 men aged 22 to 55 years who had no complaints of joint pain throughout their life. The average disease duration was 5.94 ± 0.37 years.
Results. All RA patients were divided into two groups: one group (118 patients) with elevated serum Nampt levels (more than 3.9 ng/mL) and the second group (22 patients) with normal levels.
CRP and ESR levels were determined in each of the two groups.
Patients with elevated Nampt levels had the following laboratory parameters (M±m): ESR - 37.83 ± 1.57, CRP - 56.09 ± 3.73 (normal - less than 5.0 mg/L). In the second group, the following results were obtained: ESR 22.46 ± 0.56, CRP 21.65 ± 1.38. Thus, patients with elevated Nampt levels had significantly higher ESR and CRP concentrations ($p < 0.001$).
Conclusions. A relationship was found between serum Nampt levels in patients with RA-associated AP and laboratory markers of inflammation, such as CRP and ESR. These data indirectly support the hypothesis that elevated Nampt levels in RA patients are associated with disease activity.

P1721

THE RELATIONSHIP BETWEEN THE LEVEL OF ANTI-RA-33 IN PATIENTS WITH OSTEOPOROSIS ASSOCIATED WITH RHEUMATOID ARTHRITIS AND LABORATORY PARAMETERS REFLECTING THE SEVERITY OF THE DISEASE

Y. R. Akhverdyan[1], E. V. Papichev[1], Y. V. Polyakova[1], L. E. Sivordova[1], B. V. Zavodovsky[1]

[1]Research institute of clinical and experimental rheumatology n.a. A.B. Zborovsky, Volgograd, Russia

Objective: To study the relationship between serum levels of antibodies to the RA-33 antigen and the characteristics of the course of rheumatoid arthritis.
Materials and methods. We observed 88 patients diagnosed with rheumatoid arthritis (RA) meeting the ACR/EULAR 2010 criteria; all patients had osteoporosis (OP) (according to dual-energy X-ray absorptiometry). The patients' age ranged from 22 to 81 years (M ± σ, 54.3 ± 12.1 years), with a predominance of older individuals (over 50 years). The duration of RA ranged from 0.5 to 30 years (M ± σ, 11.2 ± 8.6 years). Rheumatoid factor (RF) was detected in 64 patients (72.7%), and 59 (67%) study participants were anti-CCP positive. An indirect solid-phase ELISA was used to quantify anti-RA-33 in human serum. The study was conducted using the commercial IMTEC-RA33-Antibodies test system.
Statistical processing of the obtained results was performed using the STATISTICA 12.5 software package. To identify relationships between quantitative indicators, Spearman's rank correlation analysis was performed, calculating the correlation coefficient (r) and significance (p). Results were considered statistically significant at $p < 0.05$.
Results. The average level of anti-RA-33 in RA patients, calculated as M±σ, was 12.66±31.60 U/ml (from 0 U/ml to 44.26 U/ml). To identify the relationship between the level of anti-RA-33 and laboratory parameters reflecting the severity of the disease in RA patients, a correlation analysis was performed between the level of anti-RA-33 and the level of anti-CCP (correlation coefficient r=0.11, p=0.31), RF (correlation coefficient r=-0.20, p=0.22), ESR (correlation coefficient r=0.14, p=0.24), CRP (correlation coefficient r=0.33, p=0.002) and hemoglobin (correlation coefficient r=-0.07, p=0.55). The obtained data indicate the presence of a direct correlation of moderate strength between the levels of anti-RA-33 and CRP.
Conclusions. In the course of the study, a positive correlation was found between anti-RA-33 and CRP levels in patients with RA-associated OP.

P1722

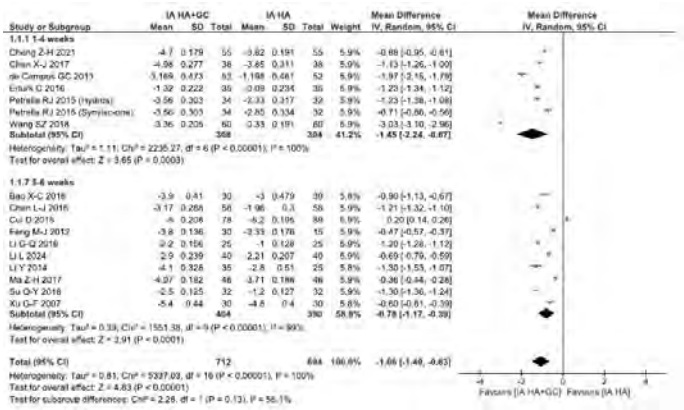
THE RELATIONSHIP BETWEEN SERUM NESFATIN-1 LEVELS AND THE PRESENCE OF OSTEOPOROSIS, OSTEOPOROTIC FRACTURES AND BMD IN PATIENTS WITH RA

Y. R. Akhverdyan[1,2], T. Z. Kvlividze[2], E. V. Papichev[1,2], B. V. Zavodovsky[1,2], Y. V. Polyakova[1,2], L. E. Sivordova[1]

[1]Research institute of clinical and experimental rheumatology n.a. A.B. Zborovsky, Volgograd, Russia; [2]Volgograd State Medical University, Volgograd, Russia

Objective: To study the relationship between serum nesfatin-1 levels and the characteristics of the course of osteoporosis in patients with rheumatoid arthritis.
Materials and methods. We observed 170 people: 110 patients with RA and 60 conditionally healthy individuals, who formed the control group. Among the patients with RA, there were 105 (95.5%) women and 5 (4.5%) men, whose average age was 54.07±11.3 (51.9-56.2) years, BMI - 28.8±6.09 (27.6-29.9) kg/m2. All patients with RA were examined by DEXA. Osteoporosis (OP) was diagnosed in 52 patients with RA.
The control group consisted of 60 conditionally healthy individuals: 33 (55%) women and 27 (45%) men, whose average age was 49.3±11.1 (46.4-52.2) years, median BMI – 27.90 [23.56-31.84], with no history of joint pain. RA patients were comparable in age and BMI ($p>0.05$) with the group of conditionally healthy individuals.
Results. The mean serum nesfatin-1 (NF-1) level in healthy individuals was 31.6±3.17 (30.8-32.4) ng/ml. The reference values for NF-1, calculated using the M±2σ formula, were 25.27–37.95 ng/ml. We then examined the relationship between serum NF-1 levels and a history of OP and osteoporotic fractures. Patients with OP and osteoporotic fractures had statistically significantly higher NF-1 levels than patients without

them (Z=-2.06; p=0.040 and Z=-2.37; p=0.017, respectively).
To clarify the mechanism of this relationship, a correlation analysis was conducted between serum NF-1 levels and bone mineral density (BMD) in patients with RA. There was no association between serum NF-1 levels and lumbar spine BMD (r=0.01299, p=0.893), femoral neck BMD (ρ=-0.03, p=0.785) and proximal femur BMD (ρ=-0.02, p=0.825).
Conclusions. It can be concluded that the relationship between NF-1 levels and the presence of osteoporosis is not due to its dependence on BMD. While BMD is an important factor, it is not the only one considered when diagnosing osteoporosis. For example, with age, the number of artifacts associated with degenerative changes in the spine and joints also increases, which can lead to an overestimation of BMD levels in densitometric studies. Therefore, it can be concluded that the association of NF-1 with osteoporosis may be due to its association with osteoporotic fractures.



P1723

INTRA-ARTICULAR HYALURONIC ACID WITH OR WITHOUT GLUCOCORTICOIDS FOR KNEE OSTEOARTHRITIS: A META-ANALYSIS

Y. S. Feng[1], Y. Yuan[2], Q. Liu[3], J. Wang[1], Y. Huang[3]

[1]Medical Affairs and Outcomes Research, Organon Research and Development, Shanghai, China; [2]Department of Orthopedics, Peking University People's Hospital, Beijing, China; [3]Department of Orthopedics, Beijing Jishuitan Hospital, Beijing, China

Objective(s): Adding intra-articular (IA) glucocorticoid (GC) to hyaluronic acid (HA) offered immediate pain relief and may enhance viscosupplementation in knee osteoarthritis (KOA). This study compared the effectiveness of IA HA with GC versus HA alone in patients with KOA for 12 weeks post-injection.
Material and Methods: We performed a meta-analysis (CRD420251031163), searching English and Chinese databases for literature published before April 2025. Randomized controlled trials (RCTs) and observational studies were included if they compared the effectiveness of IA HA with GC versus HA alone among patients with KOA. The primary outcomes were pain relief, measured by visual analog scale (VAS), and physical function, measured by Western Ontario and McMaster Universities Arthritis Index (WOMAC) at 1-4, 5-6, and 7-12 weeks post-injection. Treatment differences were estimated by the standard mean difference (SMD) and assessed against minimal clinically important differences (VAS: 0.9 cm).
Results: This meta-analysis included 20 studies (17 RCTs) on 1,847 patients. Compared with HA alone, HA with GC had significantly greater reductions in VAS (cm) at 1-4 (SMD: -1.43; 95%CI: -2.42, -0.44), 5-6 (SMD: -0.7; 95%CI: -1.02. -0.37), and 7-12 weeks (SMD: -0.41; 95%CI: -0.67, -0.15) post-injection. At 1-6 weeks, more VAS reductions were observed in patients receiving HA with GC (pooled SMD: -0.92; 95%CI: -1.34, -0.50), specifically, betamethasone (SMD: -1.08) or triamcinolone (SMD: -0.95). Results of function improvement measured by WOMAC total scores favored HA with GC at 1-6 (SMD: -7.45; 95%CI: -12.00, -2.90) and 7-12 weeks (SMD: -2.57; 95%CI: -4.72, -0.41). Adverse events were less frequent in patients receiving HA with GC across 12 weeks (OR: 0.61; 95% CI: 0.43, 0.87).
Conclusion(s): Intra-articular HA with GC was more effective than HA alone in pain relief and function improvement over 12 weeks post-injection. Treatment differences were more clinically relevant within 4 weeks. HA with GC experienced fewer adverse events.

P1724

RISK STRATIFICATION FOR FRAGILITY FRACTURES AND OSTEOPOROSIS UNDERDIAGNOSIS IN COMMUNITY-DWELLING WOMEN WITH MENOPAUSE: A POST-HOC ANALYSIS FROM A POPULATION-BASED, RANDOMIZED-SAMPLING, EPIDEMIOLOGICAL STUDY ON VERTEBRAL FRACTURES IN CHINA

X. Q. Lin[1], Y. S. Feng[2], C. H. Tang[1], J. Wang[2]

[1]Medical Affairs and Outcomes Research, Organon Research and Development, Shanghai, China, Shanghai, China; [2]Medical Affairs and Outcomes Research, Organon Research and Development, Shanghai, China

Objective(s): Treatment guidelines recommend risk stratification for fragility fractures (FFs) in postmenopausal women to optimize anti-osteoporosis (OP) therapy. We aimed to categorize FF risk and explore OP underdiagnosis in community-dwelling Chinese women with menopause.
Material and Methods: This study was a planned *post-hoc* analysis of a population-based, randomized, cross-sectional study on prevalent vertebral fractures (VFs) in 2,664 postmenopausal women from the community in China between 2017 and 2019 (ChiVOS). We stratified women into high- or very-high-risk groups for FFs, according to the guidelines of the Chinese Society of Bone and Mineral Research (CSOBMR 2022) and the American Association of Clinical Endocrinology (AACE 2020). We presented the risk category per CSOBMR (AACE) as percentages (prevalence) with 95% confidence intervals (CIs). Risk factors for underdiagnosis of OP were explored using multivariate logistic regression.
Results: In 2,655 subjects with eligible data, the prevalence of women with high risk and very high risk of FFs increased with age. In the age groups < 65 and ≥65 years, the prevalence of women with high risk of FFs was 17.7% (208/1173, 95%CI: 15.6%, 20.0%) and 29.8% (442/1482, 95%CI: 27.5%, 32.2%) (AACE: 18.2%, 30.3%); the prevalence of women with very high risk of FFs was 10.3% (121/1173, 95%CI: 8.6%, 12.2%) and 32.3% (478/1482, 95%CI: 29.9%, 34.7%) (AACE: 9.9%, 31.4%). In women of 55 – 59 and 60 – 64 years, 15.6% (64/410) and 23.2% (123/531) were with high risk (AACE: 15.6%, 24.3%); 7.6% (31/410) and 14.9% (79/531) were with very high risk (AACE: 7.6%, 14.1%). Rates of anti-OP therapy were low (<10.0%) across all age groups. Monotherapy with bone resorption inhibitors accounted for 2.2% (<65 years: 2.4%) and 1.7% (<65

years: 2.5%) in high- and very-high-risk groups for FFs. Undiagnosed OP was 72.6%. Household income <3000 RMB (OR: 1.99, 95%CI: 1.45, 2.74), age <65 years (OR: 1.67, 95%CI: 1.22, 2.29), and labour work (OR: 1.58, 95%CI: 1.15, 2.17) were factors associated with undiagnosed OP.
Conclusion(s): Community-dwelling Chinese women with menopause were at high and very high risks of FFs, even at a younger age. OP underdiagnosis was significant, with insufficient treatment. Study findings support the need for early screening in community-based postmenopausal women to prevent fragility fractures.

P1725

THE MAIN RISK-FACTORS OF LOW MUSCLE MASS IN POSTMENOPAUSAL WOMEN WITH SLE: A COMPARATIVE STUDY

Y. Seheda[1], S. Shevchuk[2], O. Shevchuk[3]

[1]University clinic of National Pirogov Memorial University, Vinnytsia, Ukraine; [2]Department of Internal Medicine of National Pirogov Memorial University, Vinnytsia, Ukraine; [3]Department of pharmacology of National Pirogov Memorial University, Vinnytsia, Ukraine

Background: It is a well-known that patients with SLE have an increased risk of early disability caused by complications associated with musculoskeletal system, especially with early development of muscle weakness. If the the muscle mass in general population is associated with age, nutrition, physical activity, hormonal status, etc., then in patients with SLE other factors may play a key role and are still need to be clarified.
Aim: To assess the freuquency of muscle mass loss in postmenopausal women with SLE compared with controls and to investigate its association with disease course.
Methods: 43 postmenopausal women with SLE (mean age 54.9±6.72 years, mean disease duration 18.4±6.05 years) and 37 age-matched healthy postmenopausal women (mean age 52.7±5.88 years) were included in this cross-sectional study. Muscular status was measured using dual-energy X-ray absorptiometry (DXA). The cut-off points for low muscle mass were appendicular skeletal muscle mass (ASMM) <15.0 kg and appendicular skeletal muscle index (ASMI) <5.5 kg/m2 according to the EWGSOP2 criteria (2019). The disease course was assessed by disease duration, laboratory activity indicators (CRP, ESR), SLEDAI-2K and SLICC scores. Statistical analysis was conducted with a t-test for mean difference and linear regression was used to adjust confounders.
Results: Patients with SLE showed significant lower measurements of muscle mass compared to the control group. Thus, the mean ASMM and ASMI were significantly lower in the SLE group than in controls (19605±1199.3g and 7.07±0.57 vs 25235±3568.3g and 9.23±0.73, p<0.001). The cut-off ASMM and ASMI points were recorded in 20.9% and 16.3% of SLE patients compared to 8.1% and 4.54% in controls. ASMM in SLE patients was associated with SLEDAI-2K, SLICC and CRP levels (p<0.005), while ASMI showed a close correlation with SLICC (p<0.001) and were not associated with ESR, age and disease duration.
Conclusions: SLE women in menopausal period have a significant disproportion in muscle mass compared to general population, which depends on the disease course, including activity and prevalence of the disease and does not depend on age, hormonal status and disease duration.

P1726

THE EFFECT OF SCHROTH METHOD EXERCISE ON PREOPERATIVE FLEXIBILITY IN AIS SURGICAL CANDIDATES, A RANDOMIZED CONTROLLED TRIAL

Y. Tangjaroenpaisan[1], W. Chaiyamongkol[2], K. Kittarakul[2]

[1]Prince of Songkla University, Hatyai, Songkhla, Thailand; [2]Prince of Songkla university, Hatyai, Songkhla, Thailand

Objectives: To compare the curve flexibility after Schroth method exercise and traditional exercise in AIS surgical candidates.
Study design: Randomized controlled trial
Background: Adolescent Idiopathic Scoliosis (AIS) surgical candidate is characterized by a spinal curvature of 30-40 degrees or more. Patients typically face wait times of 6 months to 2 years for surgery, during which maintaining spinal flexibility is crucial for better surgical outcomes. Physiotherapeutic Scoliosis Specific Exercise (PSSE), with the Schroth method being a well-researched technique, has shown effectiveness in improving spinal flexibility but limited research on the effects of these exercises for more severe curvatures.
Methods: A randomized controlled trial was conducted involving 21 AIS patients with Cobb angle of 40 degrees and greater. Patients were randomly allocated into two groups: Schroth method exercise group and control group. The Schroth method exercise group received supervised training and individualized home programs, with 2-3 in-hospital sessions per month and home exercises 3-5 days a week. The control group engaged in traditional exercise training, including stretching and core muscle training, with at least one in-hospital session in the first month and subsequent home exercises 3-5 days a week. Main curve flexibility index was assessed along with Cobb angle, ATR, and quality of life using Thai SRS-22 questionnaire at 3 and 6 months.
Results: 21 patients were included in the study (11 in Schroth method exercise group and 10 in control group). The Schroth method exercise group maintained a stable main curve flexibility index from the beginning of the study (51.60 ± 14.13) to 6 months post intervention (53.54 ± 18.46). On the contrary, the control group demonstrated a significant decline in main curve flexibility index from 43.87 ± 20.34 to 36.09 ±16.88 (p-value 0.032). The Schroth method exercise group also showed an improvement in quality of life based on the SRS-22 scores (from 3.757 ± 0.395 to 3.843 ± 0.393, p-value 0.023), while no significant change was observed for the control group (p-value 0.529). No significant change in Cobb angle and trunk rotation was observed throughout the study for both groups.
Conclusion: In this randomized controlled trial, the Schroth method exercise is superior to traditional exercise regimens in its ability to preserve spinal mobility in AIS surgical candidates and leads to statistically significant improvements in SRS-22 scores.
Keywords: Adolescent Idiopathic Scoliosis, AIS, Physiotherapeutic Scoliosis Specific Exercise, Schroth method exercise

P1727

THE EFFECT OF SYSADOA THERAPY ON GLYCEMIC LEVEL IN PRIMARY KNEE OSTEOARTHRITIS WITH TYPE 2 DIABETES MELLITUS

Y. Tawansareewattana[1], P. Amornwacharapong[1], I. Khongjaew[1], K. Jirawatthanasakda[1], P. Chompoonutprapa[2], T. Chattrapiban[3], A. Laoruengthana[2]

[1]Faculty of Medicine, Naresuan University, Phitsanulok, Thailand; [2]Department of Orthopaedics, Faculty of Medicine, Naresuan University, Phitsanulok, Thailand; [3]Clinical Epidemiology and Clinical Statistics Unit, Faculty of Medicine, Naresuan University, Phitsanulok, Thailand

Objective: Symptomatic slowing drug for Osteoarthritis (SYSADOA) is commonly prescribed for patients with knee osteoarthritis (KOA). Nevertheless, the effect of long-term use of SYSADOA, either Glucosamine or Diacerein on glycemic control in patients who coincide with Type 2 diabetes mellitus (T2DM) is still unclear. The aim of this study is to compare the mean difference in glycemic levels between patients with primary KOA and T2DM who received long-term SYSADOA and those with no SYSADOA (Reference group).

Methods: A retrospective cohort observational study included patients aged ≥40 years with KOA and T2DM. Exclusion criteria included patients who discontinued SYSADOA before 2 years, and had glycemic uncontrol requiring intensive stabilization. The primary outcome was fasting blood sugar (FBS) level and HbA1C which were sequentially assessed at least every 6 months over 2 years, following the initial administration of SYSADOA. Confounders, set a priori, including sex, age, and body mass index (BMI), alcohol, smoking, as well as the usage of NSAIDs, opioids, antidiabetic, lipid-lowering and antihypertensive drugs were adjusted in multilevel Gaussian regression to determine the mean differences of FBS (mg/dL) and HbA1C (%). The interaction terms between time and study groups were incorporated in the statistical models. The predictive margin was plotted to illustrate glycemic changes for each group.

Results: The study sample comprised of 64, 36, and 309 patients in the Glucosamine, Diacerein, and reference group, respectively. Predictive margins indicated an upward trend in FBS over two years in the Glucosamine group. Following confounder adjustment, the mean difference in FBS compared to the reference group was -6.8 (95%CI: -15.7, 2.1) mg/dL for the Glucosamine group and -3.7 (95%CI: -15.4, 7.9) mg/dL for the Diacerein group. Additionally, the mean difference for HbA1C relative to the reference group was 0.1 (95%CI: -0.3, 0.4) % for the Glucosamine group and 0.1 (95%CI: -0.3, 0.5) % for the Diacerein group, after confounder adjustment. The difference of FBS and HbA1C among groups were not statistically significant.

Conclusion: Glucosamine and Diacerein do not significantly affect glycemic levels, and thus additional glycemic monitoring is not required for T2DM patients receiving long-term SYSADOA.

P1728

FOOT PAIN AND FUNCTIONAL IMPAIRMENT IN RHEUMATOID ARTHRITIS: INSIGHTS FROM THE FOOT FUNCTION INDEX

Y. Tekaya[1], L. Rouached[1], S. Ben Dhia[1], S. Bouden[1], I. Mahmoud[1], R. Tekaya[1], A. Ben Tekaya[1], L. Abdelmoula[1]

[1]Charles Nicolle Hospital, Rheumatology department, Tunis, Tunisia

Introduction:
Rheumatoid arthritis (RA) is a chronic inflammatory disease that frequently affects the feet, leading to pain, deformities, and functional disability. Despite its high prevalence, foot involvement remains under-recognized in routine clinical practice.

Objective:
To evaluate the functional impact of foot involvement in patients with RA using the validated Foot Function Index (FFI).

Patients and methods:
We conducted a cross-sectional study including patients with RA fulfilling the 2010 ACR/EULAR classification criteria. Epidemiological data, clinical and podoscopic foot examinations, laboratory parameters, and radiological findings were collected. Foot pain was assessed using a visual analogue scale (VAS, 0–10). Functional impairment was evaluated using the validated French version of the FFI.

Results:
Thirty-five patients were included (29 women and 6 men; sex ratio 4.8), with a mean age of 54.0 ± 13.3 years and a mean disease duration of 13.8 ± 13.8 years. Foot involvement was observed in 82.9% of patients. The mean foot pain score was 4.65 ± 2.27. Forefoot, midfoot, and hindfoot involvement were present in 51.4%, 48.6%, and 51.4% of patients, respectively. Foot deformities were observed in 57%, podoscopic abnormalities in 60%, and radiological involvement in 74%.

The mean total FFI score was 38.5 ± 25.4, with subscale scores of 41.4 ± 27.9 for pain, 26.7 ± 27.7 for difficulty, and 44.4 ± 26.4 for activity limitation. Higher FFI scores were significantly associated with foot pain, pain on mobilization, positive squeeze test, abnormal podoscopic findings, hallux valgus, flat foot, and calcaneal valgus (all $p < 0.05$). The FFI correlated positively with disease activity (DAS28: $r = 0.677$), CRP levels ($r = 0.545$), and pain intensity (VAS: $r = 0.850$) (all $p \leq 0.001$). In multivariate analysis, pain intensity was the only independent predictor of functional impairment ($\beta = 0.65$, $p < 0.001$).

Conclusion:
Foot involvement is highly prevalent in RA and is associated with significant functional impairment, mainly driven by pain intensity. Systematic foot assessment should be integrated into routine RA management to optimize patient outcomes.

P1729

THERAPEUTIC PATIENT EDUCATION ENHANCES RESISTANCE TO STIGMA IN RHEUMATOID ARTHRITIS

Y. Tekaya[1], L. Rouached[1], M. Ben Hriz[1], S. Ben Dhia[1], S. Bouden[1], I. Mahmoud[1], A. Ben Tekaya[1], L. Abdelmoula[1]

[1]Charles Nicolle Hospital, Rheumatology department, Tunis, Tunisia

Introduction:
The Resistance to Stigma subscale of the Internalized Stigma of Mental Illness (ISMI) reflects patients' ability to oppose and cope with stigma, capturing elements of resilience and empowerment rather than internalized stigma itself. Interventions that strengthen resistance to stigma may therefore represent a meaningful therapeutic target in chronic diseases such as rheumatoid arthritis (RA).
Objective:
To evaluate the impact of therapeutic patient education (TPE) on the "Resistance to Stigma" subscale in patients with RA
Methods :
This prospective 11-month study included patients with RA followed in a rheumatology department. The Resistance to Stigma subscale was assessed at baseline and two months after completion of a structured TPE program. TPE sessions were delivered by two trained healthcare professionals in small groups of 6–7 patients, each lasting 90 minutes and combining interactive workshops, group reflection, discussion, and theoretical input. Associations between changes in Resistance to Stigma scores and sociodemographic, clinical, and biological variables were analyzed.
Results:
Eighty patients with RA were included (72 women, 8 men; female-to-male ratio 9:1), with a mean age of 61.1 ± 8.6 years. Most patients had a low educational level (78.8%), and nearly half had a medium socioeconomic status (49%). Obesity was present in 26.3% of patients. Regarding marital status, 68.8% were married, 18.8% single, 10% widowed, and 2.5% divorced. The number of children ranged from 0 to 7 (median 3 [2–5]).
The mean "Resistance to Stigma" score increased from 2.16 ± 0.63 at baseline to 3.22 ± 0.42 after TPE, with a mean change of 1.06 ± 0.56 ($p < 0.001$). The proportion of patients with high resistance to stigma increased markedly from 7.5% at baseline to 66.3% after TPE.
Among sociodemographic factors, marital status was significantly associated with score improvement ($p = 0.027$), and a positive correlation was observed between the number of children and change in resistance to stigma ($r = 0.280$, $p = 0.024$). No significant associations were found with age, sex, educational level, occupation, geographic origin, socioeconomic status, smoking, alcohol consumption, or body mass index.
Conclusion:
TPE substantially enhances resistance to stigma in patients with RA, supporting its role in fostering resilience and empowerment beyond symptom control.

P1730

DO RHEUMATOLOGISTS APPLY GLUCOCORTICOID-INDUCED OSTEOPOROSIS GUIDELINES ? KNOWLEDGE AND REAL-LIFE PRACTICES

Y. Tekaya[1], M. Ghali[1], N. Ben Chekaya[1], R. Grassa[1], R. Ben Tekaya[1], S. Zrour[1], I. Bejia[1]

[1]Fattouma Bourguiba Hospital, Rheumatology department, Monastir, Tunisia

Introduction
Glucocorticoid-induced osteoporosis (GIOP) is a common complication of long-term glucocorticoid therapy that increases fracture risk. Awareness and implementation of clinical guidelines in rheumatology practice remain unclear.
Objective
To assess rheumatologists' knowledge of GIOP management and its application in real-life practice.
Materials and Methods
An anonymous online survey was conducted among rheumatologists to collect demographics, clinical experience, and knowledge and application of GIOP management, including risk assessment, preventive measures, and treatment strategies. Descriptive analyses summarized guideline awareness and adherence.
Results
Among 43 respondents (mean age 41 years, 86 % women), most were early-career (<5 years, 86 %) and practiced in university hospitals (79 %). Half managed 10–20 patients on chronic glucocorticoids per month. Most (86 %) were aware of GIOP guidelines, using SFR/GRIO 2014 (53 %), ACR 2022 (26 %), both (16 %), or ECTS 2023/2024 (5 %).
For risk assessment, 76 % considered bone loss clinically significant after ≥3 months of therapy, 60 % evaluated fracture risk at ≥7.5 mg/day prednisone, and only one-third assessed risk systematically. DXA was most used (48 %), while FRAX adjustment was applied by 26 % (40 % unsure).
Preventive measures were partially applied: DXA in patients with prior fractures (50 %) or all on prolonged glucocorticoids (29 %), calcium and vitamin D routinely prescribed (83 %), fall prevention addressed (64 %). Anti-osteoporotic treatment was mostly initiated after DXA (78 %), with oral bisphosphonates universally preferred. High-risk patients were managed with anti-resorptives alone by 44 %, and younger patients (<40 years) assessed case-by-case (74 %). Re-evaluation after glucocorticoid tapering occurred always/often in 73 %, DXA follow-up every 2–3 years in 71 %. Main barriers were lack of time (24 %), economic constraints (14 %), and low patient adherence (14 %). Only 19 % fully applied guidelines, while 77 % applied them partially.
Conclusion
Rheumatologists are aware of GIOP guidelines, but application remains partial, especially for risk assessment, DXA, and treatment initiation. Simplified recommendations, decision-support tools, and targeted training may improve adherence.

P1731

KNOWLEDGE OF PREGABALIN USE AND MISUSE AMONG PRIMARY CARE PHYSICIANS: A CROSS-SECTIONAL STUDY

Y. Tekaya[1], R. Grassa[1], Z. Mezrissi[1], N. Ben Chekaya[1], M. Ghali[1], R. Ben Tekaya[1], S. Zrour[1], I. Bejia[1]

[1]Fattouma Bourguiba Hospital, Rheumatology department, Monastir, Tunisia

Background
The increasing prescription of pregabalin has raised growing concerns regarding misuse and dependence. In primary care, where most prescriptions are initiated, physicians' knowledge is crucial to ensure appropriate use and prevent medication-related harm.
Objective
To assess primary care physicians' knowledge regarding pregabalin use and misuse.
Methods
A cross-sectional analytical study was conducted among primary care physicians practicing in different regions. Data were collected using a structured questionnaire assessing demographic and professional characteristics, as well as knowledge related to pregabalin use and misuse. A global knowledge score was calculated (maximum score : 34).
Results
A total of 40 physicians were included; 28 (70%) were women. The mean age was 31 years (range: 26–41). Participants comprised 24 family medicine residents (60%), 8 private practitioners (20%), and 8 public health physicians (20%). Most participants practiced in urban settings (82.5%). Postgraduate certifications included pain management (10%), addictology (10%), and pharmacology (5%).
The mean global knowledge score was 13.1 (95% CI: 7.69–18.51). Overall, 67.5% of participants scored below the mean threshold of 17. Female physicians were more likely to have a score below 17 (77.8%, p = 0.045). Professional status, practice setting, and completion of postgraduate training in addictology, psychiatry, pain management, or pharmacology were not significantly associated with knowledge scores.
Conclusion
Significant gaps and inaccuracies were identified in primary care physicians' knowledge regarding pregabalin use and misuse. These findings highlight the need for targeted continuing medical education to improve prescribing practices and promote safe, effective, and individualized patient care.

P1732

WORK-RELATED IMPACT OF SPONDYLOARTHRITIS IN PATIENTS TREATED WITH BIOLOGIC THERAPY: A CROSS-SECTIONAL STUDY

Y. Tekaya[1], R. Grassa[1], N. Ben Chekaya[1], M. Ghali[1], R. Ben Tekaya[1], S. Zrour[1], I. Bejia[1]

[1]Fattouma Bourguiba Hospital, Rheumatology department, Monastir, Tunisia

Background
Spondyloarthritis (SpA) is a chronic inflammatory disease affecting young adults during their most productive working years. Despite advances in biologic therapy, SpA continues to substantially impair work participation and productivity.
Objectives
To assess work-related impairment in patients with SpA treated with biologic therapy, distinguishing between job loss and work limitations among employed patients, and to identify associated factors.
Methods
We conducted a descriptive and analytical cross-sectional study at the Rheumatology Department of Fattouma Bourguiba University Hospital (Monastir) between January and July 2025. Patients fulfilling the ASAS 2010 criteria and receiving biologic therapy were included. Retired individuals and students were excluded. Work impairment was evaluated using the Work Productivity and Activity Impairment (WPAI) questionnaire. Disease activity (ASDAS-CRP, ASDAS-ESR, BASDAI), functional status (BASFI, BASMI, BAS-G), pain intensity (VAS), and quality of life (ASQoL) were assessed.
Results
Forty-eight patients were included (27 men, 21 women), with a mean age of 44 ± 11.5 years and a mean disease duration of 13.7 ± 6.7 years. Job loss attributable to SpA was reported in 14.6% of patients (n=7), while 85.4% (n=41) remained professionally active. Job loss was significantly associated with longer disease duration (p=0.036), lower socioeconomic status (p=0.035), higher NSAID use (p=0.004), elevated inflammatory markers (ESR p=0.020; CRP p=0.006), higher disease activity (ASDAS-CRP, ASDAS-ESR, BASDAI; all p<0.001), poorer functional status (BASFI p<0.001; BASMI p=0.001; BAS-G p<0.001), worse patient global assessment (p=0.006), and impaired quality of life (ASQoL p=0.001).
Mean WPAI scores were 15.7 ± 23.4% for absenteeism, 39.9 ± 27.1% for presenteeism, 43.8 ± 30.2% for overall work productivity loss, and 37.5 ± 25.8% for activity impairment. Among employed patients, higher work impairment across all WPAI domains was moderately to strongly associated with greater pain intensity, higher disease activity, worse functional status, and poorer quality of life (all p≤0.001).
Conclusions
Despite biologic therapy, spondyloarthritis remains associated with significant work impairment, highlighting the need for early targeted interventions.

P1733

EFFECT OF BELT ELECTRODE-SKELETAL MUSCLE ELECTRICAL STIMULATION ON FRACTURE HEALING AND BONE MICROARCHITECTURE IN A RAT FEMORAL FRACTURE MODEL

Y. Tsubouchi[1,2], T. Kataoka[3], R. Takase[3], T. Otsu[4], R. Hamanaka[1], M. Kataoka[5], N. Kaku[2]

[1]Division of Human Biology, Department of Health Science, Oita University of Nursing and Health Sciences, Oita, Japan; [2]Department of Orthopaedic Surgery, Faculty of Medicine, Oita University, Yufu, Japan; [3]Oita University Hospital Rehabilitation Center, Yufu, Japan; [4]Division of Mechatronics, Department of Innovative Engineering, Faculty of Science and Technology, Oita University, Oita, Japan; [5]Physical Therapy Course of Study, Faculty of Welfare and Health Sciences, Oita University, Oita, Japan

Objective: Belt electrode–skeletal muscle electrical stimulation (B-SES) enhances bone remodeling, but its role in fracture healing remains unclear. This study evaluated the effects of B-SES in a rat femoral fracture model.

Methods: Twenty-one male Sprague–Dawley rats were used. Twelve with surgically induced femoral fractures were randomly assigned to a B-SES group or control group (n=6 each). Three additional rats were euthanized before fracture induction to obtain baseline periosteum and vastus medialis samples for reverse transcription polymerase chain reaction (RT-PCR). B-SES was initiated immediately after fracture induction. At 4 weeks, animals were sacrificed and the femur, tibia, periosteum, and vastus medialis were collected for radiography, micro-computed tomography (micro-CT), histology, biomechanical testing, and RT-PCR analysis.

Results: Radiography demonstrated improved cortical continuity and greater callus formation around fracture in the B-SES group. Micro-CT revealed significantly increased callus bone volume, trabecular thickness, and trabecular number in the fractured femur of B-SES group. Similar trends were observed in the intact tibia, with increased yield load and toughness. Histology confirmed a larger callus area in the B-SES group. RT-PCR showed that the expression of runt-related transcription factor 2 (Runx2), osteonectin, and receptor activator of nuclear factor κB ligand (RANKL) was upregulated in the periosteum around fracture, although these increases were not statistically significant, whereas sclerostin expression was significantly elevated. In the vastus medialis, myostatin expression was significantly reduced, whereas insulin-like growth factor-I (IGF-I) showed a non-significant upward trend.

Conclusion: B-SES significantly improved bone microarchitecture and mechanical strength, and further enhanced fracture healing by downregulating myostatin expression in a rat model. These findings highlight B-SES as a promising non-invasive therapeutic modality for promoting fracture repair and preserving musculoskeletal function.

P1734

SAFETY OF SEQUENTIAL ROMOSOZUMAB THERAPY AFTER DENOSUMAB DISCONTINUATION.

Y. Usón[1], J. Ulier[1], P. Martínez[1], T. Samudio[1], M. Robustillo[1], M. S. Moreno[1]

[1]Miguel Servet University Hospital, Zaragoza, Spain

Background

Denosumab discontinuation is associated with rapid loss of its antiresorptive effect, leading to increased bone turnover and a higher risk of vertebral fractures. Romosozumab, with combined anabolic and antiresorptive properties, may mitigate this rebound phenomenon; however, real-world evidence remains limited.

Objective

To assess the safety and effectiveness of romosozumab following denosumab discontinuation in routine clinical practice.

Methods

Prospective descriptive observational study including 11 patients with osteoporosis previously treated with denosumab and subsequently receiving romosozumab.

Collected variables included demographics, anthropometric data, fragility fracture risk factors, bone metabolism laboratory parameters, previous osteoporosis treatments, and bone mineral density (BMD).

Results

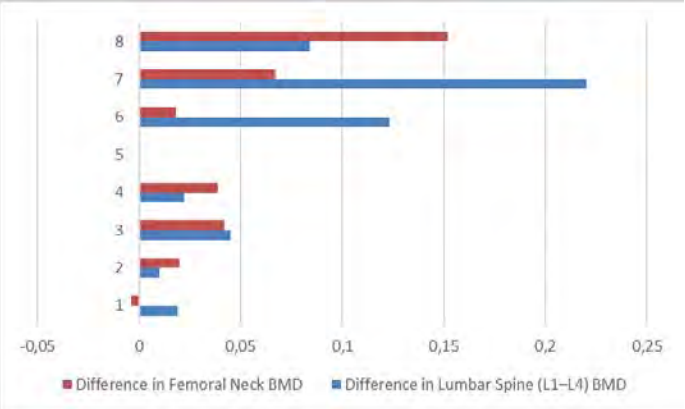
Baseline clinical, densitometric characteristics, and comorbidities are summarized in ***Table 1***.

In patients with available paired DXA data (N = 9), romosozumab treatment was associated with a trend toward increased BMD. The increase was statistically significant at the lumbar spine (p = 0.045). At the femoral neck, BMD also increased, although statistical significance was not reached (p = 0.0528).

Age showed a borderline association with lumbar spine BMD gain (p = 0.05), with greater increases observed in older patients; however, no significant associations were confirmed in multivariate analysis. Duration of prior denosumab treatment and history of fragility fractures were not associated with BMD changes.

No fractures occurred during the transition period.

Conclusion



Sequential treatment with romosozumab after denosumab discontinuation was safe and showed a favorable effect on bone density, particularly at the lumbar spine. These real-world findings support romosozumab as a potential therapeutic option after denosumab withdrawal. Larger studies are warranted to confirm these results.

BONE HEALTH IN LUNG TRANSPLANT CANDIDATES: CLINICAL PROFILE, RISK FACTORS, AND MANAGEMENT

Y. Usón[1], P. Martínez[1], J. Ulier[1], T. Samudio[1], M. S. Moreno[1]

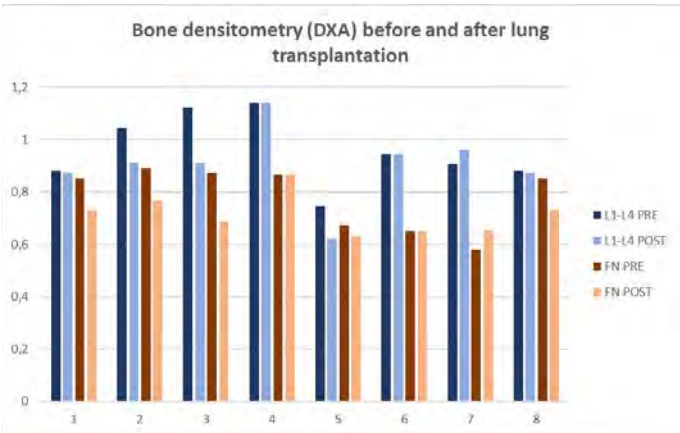
[1]Miguel Servet University Hospital, Zaragoza, Spain

Background/Objectives: Patients evaluated for lung transplantation are at high risk of osteoporosis and fragility fractures due to advanced age, chronic lung disease, long-term glucocorticoid use, reduced physical activity, systemic inflammation, and low BMI. Despite this, bone health remains underestimated during the pre-transplant evaluation. This study aimed to describe clinical characteristics, fracture risk factors, and anti-osteoporotic treatment patterns in lung transplant candidates

Methods: A descriptive study was conducted in 61 lung transplant candidates. Data collected included demographics, BMI, primary pulmonary diagnosis, fragility fracture risk factors, smoking status, glucocorticoid use, FRAX scores, prior bone mineral density (BMD) assessment, and anti-osteoporotic treatments before and after transplantation.

Results: The cohort comprised 21 women (34.4%) and 40 men (65.6%), with a mean age of 62.3 ± 7.33 years and mean BMI of 25.8 ± 3.86 kg/m². Interstitial lung disease was the most frequent diagnosis (55.7%), followed by COPD (42.6%) and other conditions (1.6%). Fragility fracture risk factors included prior fracture in 11 patients (18%), parental hip fracture in 3 (4.9%), premature menopause in 2 of 21 women (9.5%), and chronic glucocorticoid therapy in all patients (100%). Smoking history was present in 44 patients (72.2%), with 42 former smokers and 2 current smokers.

The mean FRAX-estimated risk was 7.37 ± 6.16% for major osteoporotic fracture and 3.06 ± 3.54% for hip fracture. BMD had been assessed in 34 patients (55.7%). Before transplantation, 36 patients (59%) were untreated for osteoporosis, 16 (26.2%) received oral bisphosphonates, 8 (13.1%) intravenous bisphosphonates, and 1 (1.6%) denosumab. After transplantation, untreated patients decreased to 27 (44.3%), with 15 (24.6%) on oral bisphosphonates, 12 (19.7%) on intravenous bisphosphonates, and 7 (11.5%) on denosumab.



Eight patients had BMD measured before and after transplantation. Treatment was initiated post-transplant in five (62.5%): three with oral bisphosphonates and two with intravenous bisphosphonates; two switched from bisphosphonates to denosumab, and three continued prior therapy. No significant changes were observed in lumbar spine BMD (L1–L4; p = 0.071), whereas femoral neck BMD significantly decreased (p = 0.046), independent of previous treatment.

Conclusion: Lung transplant candidates exhibit a high burden of osteoporosis risk factors and fragility fracture risk. Despite this, many do not receive adequate bone health assessment or treatment, particularly pre-transplant. These findings highlight the need for systematic evaluation and early preventive and therapeutic strategies in this high-risk population.

Tabla 1. Clinical Characteristics and Osteoporosis Risk Factors in Lung Transplant Candidates

VARIABLE			N=61
Sex, n (%)	Female		21 (34,4)
	Male		40 (65,6)
Age, mean (SD)			62,3 (7,33)
BMI, mean (SD)			25,8 (3,86)
Diagnosis, n (%)	COPD		26 (42,6)
	ILD		34 (55,7)
	Other		1 (1,6)
Risk factors associated with fragility fractures, n (%)	Previous fragility fracture		11 (18)
	Parental history of hip fracture		3 (4,9)
	Smoking status, n (%)	Current smoker	2 (3,3)

SCREENING STUDY FOR HIGH-RISK GROUPS OF OSTEOPOROSIS IN WOMEN OF SOUTHERN CHINA: A CROSS-SECTIONAL SURVEY OF 19,853 RESIDENTS

Y. W. Cai[1], D. Z. H. Xu[1], J. P. Fei[2]

[1]Osteoporotic Prevention and Treatment Clinical Guidance Center of Ningbo,Ningbo No.2 Hospital, Ningbo, China; [2]Osteoporotic Prevention and Treatment Clinical Guidance Center of Ningbo, Ningbo No.2 Hospital, Ningbo, China

Research Backgroun: Osteoporotic Prevention and Treatment Clinical Guidance Center of Ningbo, Ningbo,d: Osteoporosis has become a major public health issue threatening the health of middle-aged and elderly women. The prevalence of osteoporosis among women over 50 years old in China exceeds 30%, but large-scale screening data for women in the Ningbo area is lacking.In 2025, the Ningbo Women and Children Foundation launched the "Bone Mover" public welfare project, aiming to assess the distribution characteristics of osteoporosis risk in women over 40 years old through large-scale screening.

Methods:

Design: Cross-sectional survey (May 2025 - November 2025)

Sample: 19,853 women residents over 40 years old from 7 districts and counties (cities) in Ningbo

Screening: Positive IOF Osteoporosis Risk One-Minute Test; High-risk OSTA Score Scale; Ultrasound bone densitometer detecting T-value ≤ −1.0 at distal forearm or heel; High fall risk determination conditions: more than 2 falls in the past year / walking difficulties or balance problems / 6m walking speed < 1.0m/s

Sarcopenia determination condition: Calf circumference less than 33cm in women is considered positive.

Result: The overall high-risk rate reached 98.98%, with the positive rate of ultrasonic bone mineral density at 90.6% and that of IOF at 89.4%. The high-risk rate rose significantly with age.The risk of falls gradually increased among people aged over 60 (±23.5%), while the risk of sarcopenia went up among those aged over 40 (±24.4%).Elderly women are the key population for osteoporosis screening.

Figure 1. Distribution of Risk Factors by Age Group

Age Group	Cases	IOF Positive Cases	Percentage	OSTA Positive Cases	Percentage	Quantitative Ultrasound Bone Density Positive Cases	Percentage	High Fall Risk Cases	Percentage	Sarcopenia Risk Cases	Percentage
40-49Y	712	111	15.6%	0	0.0%	593	83.3%	31	4.4%	202	28.4%
50-59Y	1654	412	24.9%	1	0.1%	1428	86.3%	149	9.0%	476	28.8%
60-69Y	7891	7625	96.6%	169	2.1%	7124	90.3%	1373	17.4%	1851	23.5%
70-79Y	6985	6985	100.0%	1740	24.9%	6379	91.3%	1953	28.0%	1582	22.6%
80-89Y	2172	2172	100.0%	1762	81.1%	2038	93.8%	920	42.4%	585	26.9%
90+Y	439	439	100.0%	435	99.1%	415	94.5%	236	53.8%	141	32.1%

Conclusions: Screening reveals a negative correlation between aging and decreased bone mineral density. Meanwhile, it is found that the risk of sarcopenia emerges as early as the age of 40, indicating that muscle mass loss precedes bone mass loss. Sarcopenia and fall risk constitute key amplifiers in the "osteoporosis-fall-fracture" event chain. Comorbid chronic diseases further accelerate bone loss, becoming a major hidden danger for the elderly population. The bone health of women over 60 years old in Ningbo deserves close attention.

ABDOMINAL AORTIC CALCIFICATION SEVERITY IS INDEPENDENTLY ASSOCIATED WITH REDUCED FEMORAL BONE MINERAL DENSITY AND INCREASED RISK OF OSTEOPOROSIS KOREAN POSTMENOPAUSAL WOMEN

Y. Won[1], Y. Kim[2], S. Yoo[2]

[1]Department of Endocrinology and Metabolism/International St. Mary's Hospital/Catholic Kwandong University College of Medicine, Incheon, South Korea; [2]Department of Endocrinology and Metabolism/International St. Mary's Hospital/Catholic Kwandong University College of Medicine,, Incheon, South Korea

Background
Vascular calcification has been implicated in skeletal fragility; however, the clinical impact of abdominal aortic calcification (ACC) severity on site-specific bone mineral density (BMD) and osteoporosis risk remains insufficiently characterized.
Methods
This cross-sectional study included Korean postmenopausal women(n=312) who were classified into three groups according to AC severity. Baseline characteristics were compared using ANOVA and chi-square tests. BMD T-scores at the lumbar spine and bilateral femoral sites

were analyzed across ACC groups using ANOVA with Tukey post-hoc tests. Multivariable linear and logistic regression models adjusted for age and diabetes mellitus assessed independent associations between AC and BMD as well as osteoporosis risk. Predictive performance was evaluated using receiver operating characteristic analysis with five-fold cross-validation.
Results
Age and diabetes prevalence increased with higher ACC severity ($p < 0.001$ and $p = 0.004$, respectively), while other baseline characteristics were comparable. BMD significantly decreased across increasing ACC severity at all skeletal sites, with the strongest differences observed at femoral neck and total femur (all $p < 0.001$). Post-hoc analyses demonstrated that major BMD reductions occurred between mild ACC and moderate-to-severe ACC groups. Continuous ACC measures were inversely associated with femoral BMD independent of age and diabetes ($p < 0.01$). Higher AC severity was associated with a markedly increased risk of osteoporosis (unadjusted OR up to 12.0), which remained significant after adjustment for confounders. Models incorporating AC parameters significantly improved osteoporosis prediction compared with clinical variables alone (cross-validated AUC up to 0.81).
Conclusions
Abdominal aortic calcification severity is independently associated with reduced bone mineral density, particularly at femoral sites, and substantially increases osteoporosis risk. Incorporation of AC measures enhances the predictive accuracy for osteoporosis beyond traditional clinical factors, highlighting vascular calcification as a clinically relevant marker of skeletal fragility.

P1738

EVALUATION OF OSTEOPOROSIS IN PATIENTS WITH DEMENTIA ATTENDING A GERIATRICS OUTPATIENT CLINIC: REAL-WORLD DATA

Y. Yildiz[1], A. Tufan[1]

[1]marmara university, İstanbul, Türkiye

Objectives
Osteoporosis and dementia frequently coexist in older adults and are associated with an increased risk of fractures, functional decline, and mortality. The aim of this study was to evaluate the clinical, geriatric, and bone mineral density–related factors associated with incident fractures and mortality in older adults with dementia receiving anti-osteoporotic treatment.
Material methods
This retrospective observational study was conducted in patients aged ≥65 years. Among 2,000 screened patients, among these, 988 patients were identified with osteoporosis and 577 with dementia, with 280 had concomitant osteoporosis and dementia. After excluding individuals who received fewer than two doses of anti-osteoporotic therapy or had a follow-up duration of ≤6 months, 89 patients who received denosumab or zoledronic acid as anti-osteoporotic treatment were included in the final analysis. Osteoporosis was diagnosed based on dual-energy X-ray absorptiometry (DXA), FRAX scores, or the presence of fragility fractures. Comprehensive geriatric assessment, laboratory parameters, bone mineral density measurements, fracture occurrence during treatment, and mortality were evaluated. Statistical analyses were performed using appropriate parametric and non-parametric tests.
Results
Eighty-nine patients with dementia and osteoporosis (mean age 84.3 ± 5.6 years; 77.5% female) were followed for a median of 35 months. Most were frail (68.5%) and classified as very high fracture risk (92.1%). Injectable therapies were used in all patients (denosumab 84.3%, zoledronic acid 15.7%). Adverse events were infrequent (6.7%;6.7%; five cases of hypocalcemia and one of myalgia), and fractures under treatment occurred in 7.9%.
Patients treated with denosumab and zoledronic acid showed comparable baseline demographic, clinical, functional, nutritional, and dementia-related characteristics (all $p > 0.05$). Rates of treatment-related adverse events, new fractures during therapy (8.0% vs 7.1%), and mortality were similarly low between groups.
Both denosumab and zoledronic acid were associated with significant within-group improvements in lumbar spine bone mineral density and T-scores. Denosumab additionally showed significant gains in total femur BMD, whereas zoledronic acid mainly improved lumbar spine parameters. However, percentage changes in BMD (ΔBMD%) did not differ significantly between treatment groups at any skeletal site, with only a non-significant trend toward greater femoral neck BMD increase in the zoledronic acid group.
Conclusion
Both denosumab and zoledronic acid resulted in significant improvements in lumbar spine bone mineral density in older patients with dementia. No significant differences in percentage BMD change were observed between treatments, supporting the use of either agent based on clinical considerations.

IMMATURE GRANULOCYTE PERCENTAGE IN POSTMENOPAUSAL SARCOPENIC INDIVIDUALS: A POTENTIAL NOVEL BIOMARKER?

Y. Yildiz[1], N. Şentürk Durmuş[2], A. Yilmaz[3], E. Üner[4], E. D. Kaya[1], Z. R. Beşişik Yilmaz[1], ?. Alkaç[3], B. Can[1], A. Tufan[1]

[1]MD, Division of Geriatrics, Department of Internal Medicine, Marmara University Medical School, İstanbul, Türkiye; [2]MD, Geriatrician, Independent Investigator, Pendik, 34890, Istanbul, Türkiye, İstanbul, Türkiye; [3]MD, Division of Geriatrics, Department of Internal Medicine, Marmara University Medical School, Istanbul, Türkiye; [4]MD, Department of Biochemistry, Marmara School of Medicine, Marmara University, İstanbul, Türkiye

Background:
Sarcopenia is an age-related muscle disorder marked by loss of mass, strength, and function. Postmenopausal women face a greater risk because of alterations in hormones and metabolism. In addition, systemic inflammation has been proposed as a key contributor to this population. Although standard inflammatory markers, such as interleukin (IL)-6 and tumor necrosis factor (TNF)-α, are not readily available, the percentage of immature granulocyte (IGr%), easily obtained from routine blood tests, could be helpful as an indicator of inflammation.

Aim:
To investigate the association between IGr% and sarcopenia in postmenopausal women and identify related clinical and laboratory factors.

Methods:
This study was designed as a retrospective observational analysis. The study included postmenopausal women who attended the Geriatrics

and General Internal Medicine outpatient clinics between May and August 2024. The evaluation of sarcopenia involved SARC-F (Strength, Assistance with walking, Rising from a chair, Climbing stairs, and Falls) questionnaire, handgrip strength, bioelectrical impedance analysis, and a 4-meter gait speed test. Basic activities of daily living(ADL) were measured with the Katz ADL scale (22), while instrumental activities were assessed using the Lawton IADL scale (23) and Nutritional Risk Screening (NRS-2002). Laboratory parameters included IGr%, C-reactive protein (CRP), albumin, and white blood cell count (WBC).

Results:
Among 198 participants (mean age: 59 years), 43.9% had probable or confirmed sarcopenia. Sarcopenic women were older ($p < 0.001$), lower lumbar bone density ($p = 0.024$), had more comorbidities ($p = 0.001$), and greater functional dependency ($p = 0.001$). Sarcopenic individuals showed significantly higher IGr% in univariate analysis ($p = 0.046$), while no significant differences were observed in other inflammatory markers such as CRP, WBC, neutrophils, lymphocytes, the ratio of neutrophils to lymphocytes (NLR), and the ratio of platelets to lymphocytes (PLR) (all $p > 0.05$). Multivariate analysis revealed that older age (Odds Ratio (OR): 1.058, 95% Confidence Interval(CI): 1.022–1.096; $p = 0.002$) and albumin (OR: 0.891; 95% CI: 0.773–0.981; $p = 0.023$) were independent predictors of sarcopenia.

Conclusion:
Although IGr% was higher in sarcopenic individuals in univariate analysis, it did not remain an independent predictor after adjustment; however, as a readily available, cost-effective parameter from routine complete blood count, IGr% may serve as a potential early biomarker reflecting low-grade systemic inflammation in sarcopenia, warranting confirmation in larger, prospective, multicenter studies.

PLC-Γ1 PROMOTES SKELETAL MUSCLE REGENERATION THROUGH AUTOPHAGY ENHANCEMENT BY SUPPRESSING ROCK2

Y. Yu[1], Y. Ding[1], F. Xu[1], D. Dai[1], R. Sun[1], P. Hu[2], D. Bikle[3], Z. Xie[1]

[1]National Clinical Research Center for Metabolic Diseases, Hunan Provincial Key Laboratory of Metabolic Bone Disease, and Department of Metabolism and Endocrinology, The Second Xiangya Hospital of Central South University, Changsha, 410011, Hunan, China., Changsha, China; [2]State Key Laboratory of Cell Biology, CAS Center for Excellence in Molecular Cell Science, Shanghai Institute of Biochemistry and Cell Biology, Chinese Academy of Sciences, University of Chinese Academy of Sciences, Shanghai, 200031., Shanghai, China; [3]Departments of Medicine and Dermatology, University of California San Francisco and San Francisco Veterans Affairs Medical Center, San Francisco, CA, USA., San Francisco, United States

Objectives
Skeletal muscle possesses a remarkable regenerative capacity, enabling rapid restoration of muscle mass and function following injury. However, the precise cellular and molecular mechanisms governing this regenerative process are not fully understood. Phospholipase Cγ1 (PLCγ1) is a key intracellular signaling enzyme known to elevate cytosolic calcium levels upon activation. While calcium signaling critically involved in various aspects of muscle biology, including contraction and repair, the specific contribution of PLCγ1 to the skeletal muscle regeneration program remains unclear.
Materials and Methods
Skeletal muscle myoblast-specific PLC-γ1 knockout mice were generated using the Cre-Lox system. Acute muscle injury was induced by injecting cardiotoxin or $BaCl_2$ into the tibialis anterior muscle. Regeneration markers were analyzed using RTqPCR and Western blot; ultrastructural changes and autophagy were assessed by transmission electron microscopy (TEM).
In vitro, PLCγ1 was knocked down in primary myocytes via adenoviral infection. Autophagy was evaluated following bafilomycin A1 treatment through Western blot, immunofluorescence, and TEM.
Proteomic sequencing of muscle tissue at day3 postinjury identified Rho-associated protein kinase 2 (ROCK2) as a key downstream candidate. For in vivo validation, adeno-associated virus (AAV) carrying ROCK2shRNA was administered to suppress ROCK2 expression in the skeletal muscle of both knockout and control mice. An acute injury model was then established to examine whether downregulation of ROCK2 could rescue autophagy levels and regeneration capacity in PLC-γ1 knockout mice.
Results
Compared with control mice, PLCγ1 knockout mice exhibited significantly impaired skeletal muscle regeneration, evidenced by a decreased number of regenerated myofibers and reduced proliferative capacity. Autophagyrelated markers were also markedly downregulated. Knockdown of ROCK2 in primary myoblasts enhanced autophagic activity. In vivo, suppression of ROCK2 in PLCγ1 knockout mice restored autophagy levels and rescued skeletal muscle regenerative capacity.
Conclusions
PLCγ1 is essential for skeletal muscle regeneration, where it functions by promoting autophagy through the suppression of ROCK2 expression.

PREGNANCY AND LACTATION-ASSOCIATED OSTEOPOROSIS WITH MULTIPLE VERTEBRAL FRACTURES: A CASE REPORT

B. Erhan[1], Y. Yumusakhuylu[1], M. Zengin[1]

[1]Istanbul Medeniyet University, Istanbul, Türkiye

Background: Pregnancy and lactation-associated osteoporosis (PLO) is a rare but potentially debilitating condition that typically presents in the third trimester or early postpartum period with severe back pain due to vertebral compression fractures. It is often underdiagnosed or misdiagnosed as more common causes of back pain, such as lumbar disc herniation.
Case Presentation: We report the case of a 28-year-old primiparous woman who presented with severe back pain one month postpartum. She was initially misdiagnosed with lumbar disc herniation at an external center. Physical examination revealed severe paravertebral muscle spasms and tenderness at T11-T12 spinous processes with a Visual Analog Scale (VAS) score of 10/10. Radiographic imaging demonstrated height loss at T10, T11, T12, and L1 vertebrae. Dual-energy X-ray absorptiometry (DXA) revealed osteoporosis with a lumbar spine T-score of -2.6 (BMD 0.873 g/cm²) and femoral T-score of -1.7 (BMD 0.814 g/cm²). The patient was treated with lactation cessation, calcium and vitamin D supplementation, analgesics, rigid thoracolumbar brace, and intravenous zoledronic acid 5 mg. At two-week follow-up, her VAS score improved to 2/10, and she subsequently returned to work with continued brace use.
Conclusion: This case emphasizes the importance of maintaining high

clinical suspicion for PLO in young postpartum women presenting with severe back pain. Early recognition and comprehensive management are crucial to prevent diagnostic delays and optimize patient outcomes.

CLOSING THE DIAGNOSTIC GAP: A SUPERIOR PARADIGM FOR OSTEOPOROSIS SCREENING VIA AI-BASED OPPORTUNISTIC ANALYSIS OF CHEST RADIOGRAPHS

Y.-H. Fu[1], K.-C. Tu[1], C.-E. Lien[2], D.-J. Yang[3], A.-C. Huang[3], H.-H. Chiang[2], A. Y. Hsiao[2], S. Teng[2], K.-H. Chen[1]

[1]Department of Orthopedics, Taichung Veterans General Hospital, Taichung, Taiwan; [2]Acer Medical Inc., New Taipei City, Taiwan, New Taipei City, Taiwan; [3]Acer Inc., Taipei City, Taiwan, Taipei City, Taiwan

Background and Objectives

Osteoporosis remains a major public health challenge in aging societies, yet diagnostic rates remain critically low. While Dual-energy X-ray Absorptiometry (DXA) is the gold standard for diagnosis, its clinical accessibility is often limited. This study aimed to evaluate the performance of a deep learning-based chest radiograph (CXR) analysis tool (VeriOsteo™ OP) in predicting bone mineral density (BMD) abnormalities and to conduct a comprehensive comparison with conventional quantitative ultrasound (QUS) and multiple clinical risk assessment tools, including **OSTAi (TW,** Taiwan/Asian versions**)**, **OSTAi & MOSTAi (TW)**, **FRAX**, and **OSTA (Asian)**.

Methods

In this single-center, prospective study, 305 participants aged 50 years or older were enrolled. All participants completed DXA, CXR, and QUS examinations within a one-year window. Osteoporosis was defined as a DXA T-score ≤ -2.5 at any measured site (lumbar spine or femoral neck). The diagnostic efficacy, including the Area Under the Curve (AUC), sensitivity, and specificity, was compared between the VeriOsteo™ OP, QUS, **OSTAi (TW,** Taiwan/Asian versions**)**, **OSTAi & MOSTAi (TW)**, **FRAX**, and **OSTA (Asian)**. Pearson correlation coefficients were also calculated to assess the relationship between AI-predicted values and DXA-measured BMD.

Results

The study cohort had a mean age of **73.13 ± 8.43** years and an osteoporosis prevalence of 58.36%. VeriOsteo™ OP demonstrated superior diagnostic performance compared to all other screening modalities, achieving a high AUC of 0.866, which significantly outperformed QUS (AUC: 0.694), OSTAi (AUC: 0.722), FRAX (AUC: 0.695), and OSTA (AUC: 0.722). Furthermore, AI-predicted BMD values showed a strong positive correlation with DXA-measured values (r = 0.757). Subgroup analyses further revealed that the AI tool maintained exceptional robustness across female and high-BMI populations, effectively overcoming the physical interferences and anatomical inconsistencies that limited the efficacy of conventional QUS.

Conclusions

Deep learning-based analysis of standard chest radiographs provides superior accuracy and robustness in osteoporosis screening compared to currently used non-invasive tools. By enabling opportunistic screening through existing imaging data without additional radiation exposure or medical costs, this technology offers a transformative solution to improve identification and early intervention for high-risk individuals.

ASSOCIATION BETWEEN POSTOPERATIVE DENOSUMAB USE AND THE RISK OF REVISION SURGERY AFTER TOTAL KNEE REPLACEMENT: A NATIONWIDE POPULATION-BASED COHORT STUDY

Y. M. Chen[1], T.-H. Tseng[2], H.-K. Yen[2], C.-C. Hung[3], J.-Y. Hsu[4], Y.-H. Wang[5], S.-H. Fu[6], C.-Y. Wang[7]

[1]Department of Medical Education, Taipei Medical University Hospital, Taipei, Taiwan; [2]Department of Orthopaedic Surgery, National Taiwan University Hospital, Taipei, Taiwan; [3]Department of Orthopedics, National Taiwan University Hospital Yun-Lin Branch, Yunlin, Taiwan; [4]Department of Orthopedic Surgery, National Taiwan University Hospital, Taipei, Taiwan; [5]Department of Medical Education, National Taiwan University Hospital, Taipei, Taiwan; [6]Department of Orthopedic Surgery, National Taiwan University Hospital Yun Lin Branch, Yunlin, Taiwan; [7]National Center for Geriatrics and Welfare Research, National Health Research Institutes, Yunlin, Taiwan

Objective(s)

To investigate the association between denosumab use after total knee replacement (TKR) and the risk of all-cause revision and revision surgery due to aseptic loosening.

Material and Methods

This nationwide, population-based, retrospective cohort study used the Taiwan National Health Insurance Research Database (2012–2020). From an initial population of 186,472 primary TKR patients, we identified 20,506 who subsequently sustained hip or vertebral fractures with a diagnosis of osteoporosis. Exclusion criteria included death within one year post-fracture, tumor-related TKR, any anti-osteoporosis medication use prior to TKR, and duplicate TKR records. The final cohort comprised 15,615 patients (194 denosumab users; 15,421 non-users). A 1:4 propensity score matching was performed to balance baseline characteristics. Event-free survival was estimated using the Kaplan-Meier method. Associations between denosumab use and study outcomes were primarily estimated using Cox proportional hazards models, reporting hazard ratios (HRs) with 95% confidence intervals.

Results

Adjusted multivariable analysis revealed that denosumab use was associated with a significantly lower risk of all-cause revision (Adjusted HR 0.83; 95% CI, 0.69–1.00; p = 0.048). Furthermore, a reduction in revision risk secondary to aseptic loosening was observed, showing a protective trend (Adjusted HR 0.65; 95% CI, 0.42–1.00; p = 0.052).

Conclusion(s)

Postoperative denosumab use is associated with a lower risk of revision surgery in high-risk osteoporotic patients following TKR. Although the sample size of denosumab users was limited, the observed reduction in revision rates suggests that pharmacological bone preservation may help extend implant longevity.

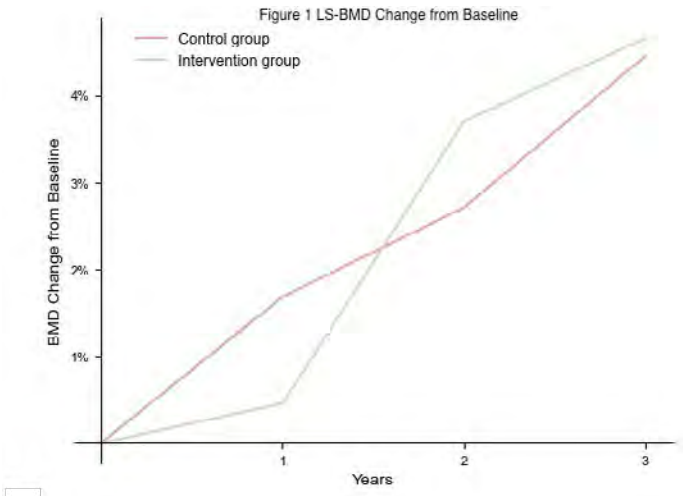
THE THIRD-YEAR RESULTS OF DENOSUMAB SEQUENTIAL THERAPY TRIAL: AN EXTENSION OF A RANDOMIZED CLINICAL TRIAL

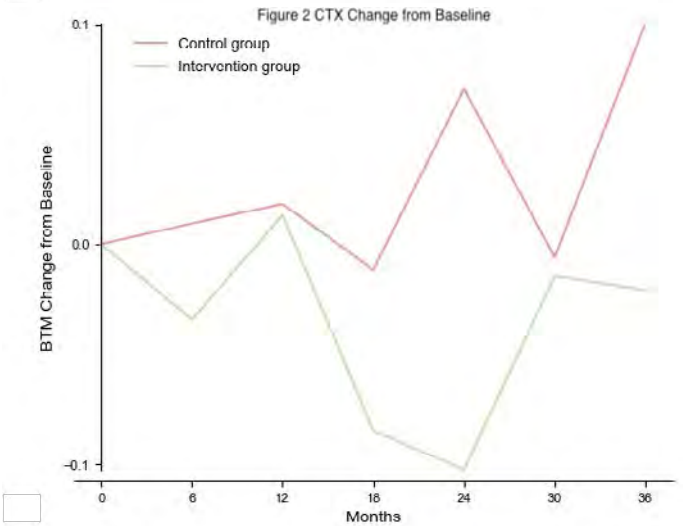
H.-K. Yen[1], M.-H. Chiang[1], S.-L. Tsao[2], J.-H. Liu[1], T.-H. Tseng[1], T.-C. Lin[3], C.-C. Lee[1], C.-C. Hung[4], Y.-H. Wang[2], C.-Y. Wang[5], S.-H. Fu[6]

[1]Department of Orthopedic Surgery, National Taiwan University Hospital, Taipei, Taiwan; [2]Department of Medical Education, National Taiwan University Hospital, Taipei, Taiwan; [3]Department of Molecular Oncology, Kyoto University Graduate School of Medicine, Kyoto, Japan; [4]Department of Orthopedics, National Taiwan University Hospital Yun-Lin Branch, Yunlin, Taiwan; [5]National Center for Geriatrics and Welfare Research, National Health Research Institutes, Yunlin, Taiwan; [6]Department of Orthopedic Surgery, National Taiwan University Hospital Yun Lin Branch, Yunlin, Taiwan

Objective(s)



To investigate the long-term efficacy and sustainability of an alternating regimen of denosumab and zoledronate on bone mineral density (BMD) and bone turnover markers (BTMs) over a three-year period.



Material and Methods

This prospective observational study is a one-year extension of the Denosumab Sequential Therapy 1 (DST1) trial, a multicenter, open-label, two-year randomized controlled trial (NCT03868033) (Lee et al., 2024). We included 26 participants (intervention vs. control; n=12, 14). Participants were postmenopausal women and men aged ≥ 50 who had received biannual Denosumab for at least 2 years prior to enrollment. The control group continued receiving denosumab. The intervention group received zoledronate in the first year, followed by a switch back to denosumab in the second and third years. The primary outcome was the percent change in lumbar spine BMD (LS-BMD) from baseline at 36 months. Secondary outcomes included BMD changes in the total hip (TH-BMD), femoral neck (FN-BMD), and BTMs: C-terminal telopeptide (CTX).

Results

At 36 months, BMD gains were similar in both groups across all regions. LS-BMD increased by 4.66% vs. 4.46% in the intervention vs. control group (95% CI, 1.45-7.87 vs. 2.05-6.86; p=0.91) (Figure 1). TH-BMD (2.19% vs. 2.35%) and FN-BMD (3.14% vs. 2.01%) also showed no significant differences. However, the intervention group exhibited significantly lower BTMs. CTX levels decreased by -0.02 vs. 0.10 µg/L (95% CI, -0.08 to 0.04 vs. 0.02-0.18; p=0.02) in the intervention vs. control group (Figure 2).

Conclusion(s)

An alternating regimen of denosumab and zoledronate is a viable strategy for managing osteoporosis, maintaining BMD gains while significantly reducing bone resorption activity compared to continuous denosumab. This approach may mitigate the rebound effect associated with denosumab discontinuation, highlighting the need for further prospective trials to evaluate its long-term safety and efficacy.

CARTILAGE REGENERATION AND FUNCTIONAL RECOVERY IN KNEE OSTEOARTHRITIS VIA ADIPOSE-DERIVED STEM CELL THERAPY: A SINGLE-CENTER EXPERIENCE IN TAIWAN

Y.-T. Guo[1], Y.-C. Chieh[1], C. Cheng[1]

[1]Tungs' Taichung MetroHarbor Hospital, Taichung, Taiwan

Objective:
Knee osteoarthritis affects 15% of Taiwan's population (3.5 million people). Since 2018, Regulation Governing the Application of Specific Medical Examination Technique and Medical Device start to performed autologous adipose-derived stem cells (ADSCs), which was used for grade 1–3 osteoarthritis and cartilage defects. This study analyzed nine cases, showing significant improvement in joint range of motion, quality of life, and a positive trend in cartilage regeneration.

Material and Methods:
Nine cases of knee osteoarthritis treated with knee joint injection with autologous ADSCs. Clinical assessment was done, in pre-injection and post-injection 1th, 3rd, 6th, and 12th month. The evaluation instruments including Knee injury and Osteoarthritis Outcome Score (KOOS), Pain Visual Analogue Scale (VAS), and Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC). Additionally, imaging study were performed at time of pre-treatment and one-year follow-up.

Results:
In nine cases, KOOS score improved from 53 to 74 after one year treatment. WOMAC score 16 decreased to 4 after treatment. Pain VAS score from 8 to 0 after treatment.(Figure1) Magnetic resonance imaging (MRI) demonstrated cartilage regeneration, cartilage thickness with an average increase of 0.66 mm in the right knee and 0.88 mm in the left knee.(Figure2.3)

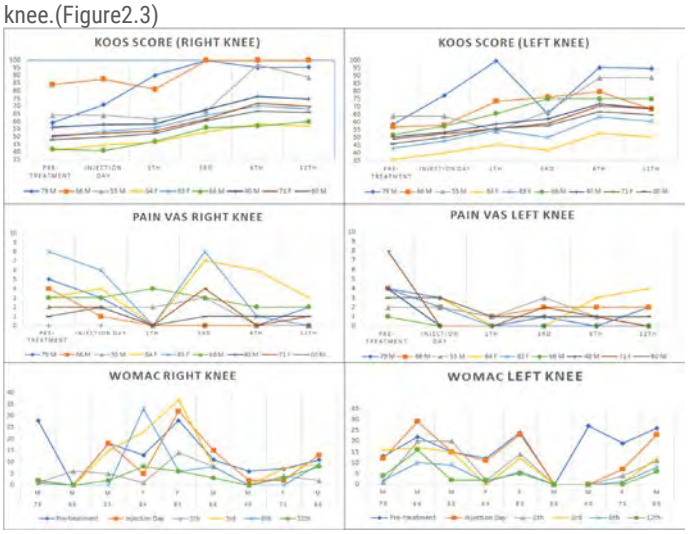

Fig.1. shows pre-and post-treatment improvements in KOOS, Pain VAS, and WOMAC scores.

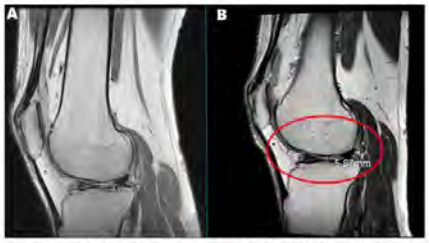

Fig.2. MRI right knee image before(A) and after(B) 12 th stem cells injection treatment.

Fig.3. MRI left knee image before(A) and after(B) 12 th stem cells injection treatment.

Conclusion:
ADSC treatment significantly improved in KOOS, Pain VAS, and WOMAC scores, reflecting reduced pain, less stiffness, and enhanced daily function. These clinical gains were accompanied by higher quality of life. One year MRI confirmed cartilage regeneration, proving that ADSCs effectively promote tissue repair and long-term functional recover.

P1746

BENEFICIAL INTERVENTION OF ARTIFICIAL TIGER BONE POWDER ON AGE-RELATED SARCOPENIA BY REGULATING MITOCHONDRIAL QUALITY AND INHIBITING THE CGAS-STING SIGNALING PATHWAY

Y. Xu[1], Y.-X. Guo[1], Y. Zhang[1]

[1]Spine Disease Research Institute, Longhua Hospital, affiliated to Shanghai University of Traditional Chinese Medicine, Shanghai, China

Objective: This study aims to investigate the therapeutic effects and the underlying mechanisms of artificial tiger bone powder (ATBP) on age-related sarcopenia.
Material and Methods: The grip strength, weight-loaded swimming time, muscle mass (quadriceps femoris, gastrocnemius, tibialis anterior and soleus muscles), and muscle fiber cross-sectional area (CSA) were measured in mice with age-related sarcopenia. The transcriptomic sequencing, RT-PCR, Western blot, immunofluorescence, and immunohistochemistry were employed to explore and validate the potential molecular mechanisms of ATBP. Additionally, the mice were administered with ATBP via oral gavage for 3 months, followed by a 3-month withdrawal period to observe the long-term effects of ATBP.
Results: The treatment with ATBP significantly improved muscle grip strength, muscle endurance, muscle mass, and elevated CSA of myofibers and expressions of muscular regulatory factors, as well as down-regulated expressions of MuRF-1 and Atrogin-1 in the ubiquitin-proteasome system. The ATBP administration of 12-month-old mice for 3 months significantly reduced the expression levels of senescence-associated secretory phenotypes and of age-related

markers (β-gal, P53, and P16). ATBP enhanced mitochondrial quality by promoting mitochondrial biogenesis through increased expression of peroxisome proliferator-activated receptor-γ coactivator-1α (PGC-1α) and mitochondrial transcription factor A (TFAM), restored mitochondrial dynamics via regulation of mitofusin-1 (MFN-1) and fission 1 (FIS-1), and activated PINK1/Parkin-mediated mitochondrial autophagy. The ATBP-induced maintenance in mitochondrial homeostasis led to the reduction in the leakage of mitochondrial DNA (mtDNA) into the cytosolic, thereby attenuating the activation of cGAS-STING signaling pathway and lowering NF-κB-evoked chronic low-grade inflammation in skeletal muscle, ultimately ameliorating age-related sarcopenia. After drug withdrawal for 3 months, the mice in ATBP-treated groups still displayed better muscle function and improvement in muscle aging.

Conclusion: ATBP benefits for alleviating aging conditions of skeletal muscle by maintaining mitochondrial homeostasis *via* regulating mitochondrial biogenesis, mitochondrial dynamics, and mitophagy. ATBP could effectively ameliorate age-related sarcopenia by inhibiting the cGAS-STING signaling pathway.

P1747

SMART LIAISON CARE PROGRAM FOR OSTEOPOROSIS AND SARCOPENIA: EVIDENCE FROM CHIAYI COUNTY, TAIWAN

W.-H. Chao[1], M.-H. Hsieh[2], P.-Y. Hsu[3], L.-C. Chang[1], Y.-Y. Hsiao[1]

[1]Chiayi County Public Health Bureau, Chiayi County, Taiwan; [2]Dalin Tzu Chi Hospital, Buddhist Tzu Chi Medical Foundation, Chiayi County, Taiwan; [3]Nanhua University, Chiayi County, Taiwan

Objectives

In April 2023, the Chiayi County Public Health Bureau launched the "Smart Liaison Care Program for Osteoporosis and Sarcopenia." The program aims to implement community-based screening to enable early identification of high-risk individuals, followed by risk stratification with referral to medical care or linkage to community-based exercise and nutrition interventions. This integrated approach seeks to operationalize preventive medicine and advance the vision of a "Healthy Chiayi."

Methods

Mobile healthcare units equipped with dual-energy X-ray absorptiometry (DXA) and other screening devices were deployed to deliver services directly to community settings. Individuals identified as being at risk were managed through the establishment of an "Osteoporosis and Sarcopenia Integrated Care Platform," which enables standardized data management, streamlined referral pathways, and consistent follow-up.

Beginning in 2024, a "High-Risk Osteoporosis and Sarcopenia Exercise and Nutrition Program" was introduced, consisting of 36 sessions (72 hours) integrating structured exercise training and nutrition education. The exercise components included high-load resistance training, combined walking programs, Baduanjin (Eight-Section Brocade), and supervised self-practice. Post-exercise high-protein supplementation was provided, forming a comprehensive "screening–diagnosis–intervention" continuum of care.

Results

By the end of December 2025, a total of 37,227 screening examinations had been completed, identifying 14,992 individuals at high risk. Among them, 585 participants were referred to hospitals for further medical treatment, while more than 14,000 individuals were continuously managed by local health centers through follow-up, exercise guidance, and nutritional counseling. In addition, 749 participants enrolled in the exercise and nutrition program organized by the Public Health Bureau.

Among participants who completed the exercise and nutrition program, the mean DXA T-score improved from −2.76 before the intervention to −2.74 after the intervention. Paired t-test analysis demonstrated a statistically significant improvement ($p < 0.01$), indicating the effectiveness of integrated exercise and nutrition interventions in improving osteoporosis- and sarcopenia-related outcomes.

Conclusions

The Smart Liaison Care Program for Osteoporosis and Sarcopenia demonstrates that an integrated care model combining mobile healthcare services with a digital management platform can effectively enhance community screening accessibility, optimize referral pathways, and establish a continuum of care. By enabling systematic risk management and linkage to community-based exercise and nutrition interventions, this program provides an evidence-based public health strategy for local governments to address population aging and the prevention and management of osteoporosis and sarcopenia.

P1748

EFFECTIVENESS OF A COMMUNITY-BASED INTEGRATED EXERCISE AND NUTRITION INTERVENTION FOR INDIVIDUALS AT HIGH RISK OF OSTEOPOROSIS AND SARCOPENIA

W.-H. Chao[1], M.-H. Hsieh[2], P.-Y. Hsu[3], L.-C. Chang[1], Y.-Y. Hsiao[1]

[1]Chiayi County Public Health Bureau, Chiayi County, Taiwan; [2]Dalin Tzu Chi Hospital, Buddhist Tzu Chi Medical Foundation, Chiayi County, Taiwan; [3]Nanhua University, Chiayi County, Taiwan

Objectives

The Chiayi County Public Health Bureau pioneered Taiwan's first community-based "Exercise and Nutrition Program for Individuals at High Risk of Osteoporosis and Sarcopenia." Following identification through mobile healthcare screening, high-risk individuals were referred for hospital-based treatment when indicated. In addition, a subgroup of relatively younger high-risk adults aged 50–65 years was specifically targeted to receive an integrated exercise and nutrition intervention aimed at enhancing muscle strength and bone health, thereby implementing preventive medicine strategies and delaying functional decline.

Methods

Since 2024, the "High-Risk Osteoporosis and Sarcopenia Exercise and Nutrition Program" has been implemented as a structured community intervention consisting of 36 sessions (72 hours in total). The exercise component included high-intensity resistance training, combined walking programs, Baduanjin (Eight-Section Brocade), and supervised home-based practice.

The nutrition intervention comprised post-exercise high-protein supplementation, along with on-site dietary counseling delivered by registered dietitians, focusing on high-calcium diets and nutrition education to enhance participants' self-management and health literacy.

Results

Based on pre- and post-intervention analyses of the 2025 program, a total of 345 participants with complete data were included. After the intervention, total skeletal muscle mass (SMM) increased by 73.2 kg, total fat mass decreased by 92.7 kg, and the skeletal muscle index (SMI)

increased by 10.47, all reaching statistically significant improvements ($p < 0.05$).

In 2025, 413 individuals participated in the program; 96 participants attended all 36 sessions, and 242 attended more than 30 sessions, representing an attendance rate of 58%, indicating high engagement, increased awareness of personal health issues, and improved health literacy.

Compared with one-on-one personal training programs, which would require approximately €1,560 per participant (total €644,280), the total program cost was €102,870 (NTD 3,800,000), achieving a 6.26-fold reduction in expenditure. Overall participant satisfaction reached 96%.

Conclusions

For individuals at high risk of osteoporosis and sarcopenia, an integrated intervention combining high-load resistance training, combined walking, Baduanjin exercise, and structured self-practice, together with high-protein and high-calcium nutritional support, effectively improves key indicators related to bone and muscle health. This community-based model also fosters proactive health management behaviors and strengthens awareness of preventive medicine, demonstrating a cost-effective and scalable approach for population-level prevention of age-related musculoskeletal decline.

P1749

EFFECTIVENESS OF OSTEOPOROSIS AND SARCOPENIA SCREENING USING MOBILE HEALTHCARE INTEGRATED WITH ARTIFICIAL INTELLIGENCE: A CASE STUDY OF CHIAYI COUNTY, TAIWAN

W.-H. Chao[1], M.-H. Hsieh[2], P.-Y. Hsu[3], L.-C. Chang[1], Y.-Y. Hsiao[1]

[1]Chiayi County Public Health Bureau, Chiayi County, Taiwan; [2]Dalin Tzu Chi Hospital, Buddhist Tzu Chi Medical Foundation, Chiayi County, Taiwan; [3]Nanhua University, Chiayi County, Taiwan

Objectives

As of December 2025, Chiayi County had a total population of 473,181, of whom 114,069 (24.1%) were aged 65 years or older, classifying the county as a super-aged society. This demographic shift poses substantial public health challenges, particularly in the prevention and management of age-related conditions such as osteoporosis and sarcopenia.

This study aimed to evaluate the effectiveness of integrating mobile healthcare services with artificial intelligence (AI) technologies to deliver osteoporosis and sarcopenia screening to remote and community-based settings, enabling rapid identification of high-risk individuals and improving healthcare accessibility and preventive outcomes.

Methods

To expand population-based screening for osteoporosis and sarcopenia, Chiayi County launched a mobile healthcare screening program in 2023. The mobile units were equipped with dual-energy X-ray absorptiometry (DXA), an AI-assisted bone mineral density (BMD) image interpretation system, a multifunctional body composition analyzer (Q-check), and the FRAX fracture risk assessment tool, enabling a one-stop screening workflow.

The AI-based BMD interpretation system provides lumbar spine T-score assessments within 10 seconds. Individuals identified as high risk for osteoporosis or sarcopenia (T-score ≤ −2.5) were selectively referred for confirmatory DXA examinations, allowing for precise risk stratification and resource allocation.

To further enhance accuracy and efficiency while reducing radiation exposure, hip X-ray AI-based BMD interpretation was introduced in 2023, followed by an upgrade to chest X-ray AI-based BMD interpretation in 2025.

Results

By the end of December 2025, a total of 37,227 screening examinations had been completed, identifying 14,992 individuals at high risk. Through county government funding, approximately €1,007,770 (NTD 37,227,000) in screening costs were subsidized, substantially reducing the financial burden on residents.

For individuals meeting the criteria for early pharmacological intervention following screening, the average monthly medication cost ranged from €27.07 to €40.61 (NTD 1,000–1,500), which is markedly lower than the costs associated with hip fracture surgery (€4,061–5,414; NTD 150,000–200,000) and subsequent long-term care.

Based on evidence indicating that DXA-based screening can reduce hip fracture incidence by approximately 20%, it is estimated that nearly 3,000 individuals may avoid hip fracture risk, resulting in significant reductions in healthcare and long-term care expenditures.

Conclusions

The integration of AI-assisted BMD interpretation into mobile healthcare screening effectively serves as a frontline risk stratification tool, improving screening efficiency and optimizing the use of medical resources. This model enables advanced screening services to reach rural and community settings, facilitating early detection and preventive intervention at the population level. Ultimately, this approach contributes to narrowing urban–rural health disparities and enhancing equity and effectiveness in public health prevention and healthcare delivery.

P1750

OBESITY AND ITS RELATIONSHIP WITH METABOLIC RISK IN SYSTEMIC LUPUS ERYTHEMATOSUS

Y. Afifi[1], Z. Banikhaled[1], S. Spitsina[2]

[1]Volgograd State Medical University, Volgograd, Russia; [2]Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovsky, Volgograd State Medical University, Volgograd, Russia

Introduction. Cardiometabolic complications are the leading cause of late mortality in systemic lupus erythematosus (SLE). Along with chronic inflammation and glucocorticoid therapy, obesity is considered a potentially significant modifiable risk factor. However, data on the predominant obesity phenotype (abdominal or gynoid) and its direct relationship with SLE activity markers are contradictory.

Objective. To study the characteristics of obesity, cardiometabolic risk, and their relationship with clinical and laboratory indicators of SLE activity.

Materials and Methods. Data from 10 patients with SLE without comorbidities (9 women, 1 man, mean age 39.7 ± 12.7 years) were analyzed. Anthropometric parameters (body mass index (BMI), waist circumference (WC), hip circumference (HC), and WC/HC), the FINDRISK score, SLE activity markers (ESR, CRP, complement levels, anti-dsDNA), complete blood count parameters, and renal function (creatinine, eGFR, proteinuria) were assessed.

Results. Obesity (BMI≥30 kg/m²) was detected in 40% of patients, and abdominal obesity according to the WC criterion was detected in 70%. Android-type fat distribution according to the WC/HC criteria (≥0.85) was

observed in 80% of patients. A statistically significant strong positive correlation was established between cardiometabolic risk according to the FINDRISK score and anthropometric parameters: with BMI (r=+0.93; p<0.01) and with WC (r=+0.92; p<0.01). However, no significant direct relationship was found between BMI and laboratory markers of inflammatory activity (ESR, CRP), which may indicate an independent comorbidity of obesity, requiring special attention when treating patients with SLE and reducing metabolic risk.
Conclusions. Patients with SLE are characterized by a high prevalence of android obesity, which is a key factor in increased cardiometabolic risk. These findings highlight the need to assess not only BMI but also WC and WC/HC in patients with SLE for cardiometabolic risk stratification.

P1751

MYOKINES FOR THE ASSESSMENT OF SARCOPENIA-RELATED PARAMETERS IN PATIENTS WITH TYPE 1 DIABETES MELLITUS

A. Zhdanova[1], Z. Belaya[1], M. Shamkhalova[1], L. Ibragimova[1], V. Ioutsi[1], L. Nikankina[1], V. Gunkina[1], L. Rozhinskaya[1]

[1]Endocrinology Research Centre, Moscow, Russia

Patients with type 1 diabetes mellitus (T1DM) are prone to earlier and progressive development of sarcopenia due to combination of pathogenetic factors including insulin deficiency, hyperglycemia, oxidative stress and mitochondrial dysfunction.
Objective.
To study the myokines levels along with other laboratory parameters in sarcopenia assessment in in patients with type 1 diabetes mellitus (DM) compared with a healthy control group (CG).
Materials and Methods.
A single-center, cross-sectional comparative study of a cohort of postmenopausal women with type 1 DM (n=40) and a CG (n=40) aged 50 to 75 years. The study included a SARC questionnaire, myokines (myostatin ELISA Kit (Immundiagnostik AG), follistatin immunoassay (R&D Systems)), cystatin C ELISA Kit (AssayPro), lipocalin 2 NGAL Immunoassay/Quantikine ELISA (R&D Systems), along with Insulin-like growth factor (IGF-1), assessment of muscle mass (MM) using Total Body (GE, iDXA), muscle strength (MS) assessed by dynamometry (grip strength), and muscle function assessed by Brief Exercise Battery tests.
Results.
The median age of the included patients was 62 y.o. [57;65]. The median HbA1c level in patients with T1DM was 8% [7,6; 9,3], with an average diabetes duration of 26 years [13;42]. The frequency of falls, the number of fractures and the level of physical activity didn't differ significantly between the groups. No differences in MM were found between the groups. MS according to hand dynamometry and 4-meter walking speed were higher in the CG. Myostatin levels was higher in patients with T1DM 52,73 [46,45; 58,26] mg/ml (p < 0,0001) and directly correlated with the level of HbA1c (p < 0,0001, r = 0,54), but no correlations were found between the parameters of MS and MM. HbA1c negatively correlates with the results of the five times chair rising test. IGF-1 levels were lower among patients with DM (92,7 ng/mL vs. 114,1 ng/mL, p = 0,014) and positively correlated with MS. Severe sarcopenia according to EWGSOP 2 criteria was diagnosed in only one patient with DM, whose myostatin level did not differ from the interquartile range for patients without sarcopenia.
Conclusion.
Patients with T1DM have reduced functional capacity, which is directly associated with HbA1c levels. Myostatin, among other biomarkers, is the most specific for patients with T1DM as it is influenced by glycemic control. However myostatin levels do not seem to directly affect physical performance or muscle mass in T1DM.

P1752

ROLE OF VITAMIN D METABOLITE MEASUREMENTS IN MONITORING DISEASE CONTROL IN HYPOPHOSPHATEMIC RICKETS WITH HYPERCALCIURIA

Z. Belaya[1], K. Arzumanyan[1], A. Bondarenko[1], E. Mamedova[1], E. Seniushkina[1], A. Bandovkina[1], F. Kaibova[1], V. Ioutsi[1], G. Melnichenko[1], L. Rozhinskaya[1]

[1]Endocrinology Research Centre, Moscow, Russia

Purpose: To assess vitamin D metabolites in patients with hereditary hypophosphatemic rickets with hypercalciuria (HHRH) and estimate whether phosphate treatment leads to vitamin D metabolite normalization and disease control.
Methods: a detailed biochemical, genetic, and clinical analysis was performed on three adult patients (aged two cases 19 and 25 years) with genetically confirmed HHRH. Genetic testing identified different *SLC34A3* gene variants: a compound heterozygous state (c.1394C>T and c.-40G>A; c.1304del and c.-846G>A) in two patients and a homozygous mutation (c.1058G>T) in one case. Simultaneous quantification of $25(OH)D_3$, $1,25(OH)_2D_3$, $24,25(OH)_2D_3$ was done using LC-MS/MS. We also calculated the $25(OH)D_3/24,25(OH)_2D_3$ ratio, which indicates the activity of relevant metabolic pathways. Biochemistry and clinical assessments were performed using routine tests.
Results: In Patient 1, who received long-term phosphate replacement therapy (Reducto Special 6-8 tablets per day), normal $1,25(OH)_2D_3$ (28.00 pg/mL) was accompanied by an elevated $25(OH)D_3/24,25(OH)_2D_3$ ratio (23.4) along with normal PTH (16.6 pg/mL), phosphate, serum and urine calcium. This profile was associated with persistent high bone turnover (osteocalcin 50.0 ng/mL, CTX 1.28 ng/mL), the absence of Looser's zones, or kidney stones. In contrast, Patients 2 and 3 who were not receiving phosphate at the time of admission exhibited a different pattern: elevation of $1,25(OH)_2D_3$ (85.00 and 176 pg/mL) with profound PTH suppression (6.5 and 8.6 pg/mL) and similarly elevated $25(OH)D_3/24,25(OH)_2D_3$ ratios (24.8 and 251.4), which was associated with hypercalciuria and hypophosphatemia.
Conclusion: Vitamin D metabolite measurements in serum are useful for assessment of metabolic disease control in adult patients with HHRH as well as for diagnostic evaluation in untreated individuals or those potentially misclassified as having other hypophosphatemic disorders. Further research is needed to determine the sensitivity of vitamin D metabolite measurements in relation to phosphate replacement dosing.

P1753

AN EXPLORATORY APPLICATION OF THE OSTEOGENIC INDEX ON LOW-INTENSITY, UPPER-BODY SUPPORTED EXERCISE IN ADULTS: A PILOT STUDY

Z. Boos[1], A. Winn[2], A. Miklosy[1], K. Spencer[1], D. Pinto[1]

[1]Marquette University, Milwaukee, United States; [2]University of Illinois Chicago, Chicago, United States

Objective: To quantify peak and cumulative loading of functional exercises and low-intensity plyometric exercises with upper body support.
Materials and Methods: All research was approved by the Marquette University (MU) Institutional Review Board (#5103). Participants were a convenience sample from the MU community. Women over 18 years of age were eligible to participate in the study. A total of 5 exercises chosen for the potential to increase bone loading were assessed including several from the Build Better Bones website. All exercises were performed on dual AMTI force plates (1000Hz) and participants used a ballet bar for balance support (at kitchen counter height). The Osteogenic Index (OI) was computed according to the Turner & Robling calculation using STATA software. During exercise, a peak threshold of 3.6xBW, reported to be osteogenic in humans, was used as a reference for peak loading. An OI value of 7 was used as a reference threshold suggesting osteogenic potential for cumulative loading.
Results: 15 women participated in this pilot study. Participants were 39 ± 17 years old (range: 23-68), 1.7m ± 0.8m tall, and 70 ± 12kg. Only the Step Down and the Pogo jump had average peaks over the 3.6xBW threshold. Only the Pogo and Bunny Hop met the OI threshold of 7. However, when all exercises were standardized to 20 reps (2 sets x 10 reps) every exercise surpassed the OI threshold of 7.
Conclusion: Current osteoporosis exercise guidelines lack quantitative thresholds for safe, home-based mechanical loading that can be scaled across large populations. Evidence from animal models suggests that cumulative exposure to low-intensity impacts may result in an osteogenic potential comparable to higher-magnitude loading. When cumulative loading is considered, each low-intensity exercise that was assessed appeared capable of achieving loading values that are theoretically consistent with osteogenic signaling, despite some having peak forces below osteogenic thresholds. These preliminary findings support further investigation of low-impact, accessible strategies for populations unable to participate in high-impact exercise. Longitudinal studies on bone-specific outcomes are needed to determine whether these loading profiles translate to meaningful adaptations.

P1754

ASYMMETRICAL STRENGTH AND LANDING IMPACT FORCES IN INDIVIDUALS AT RISK FOR KNEE OSTEOARTHRITIS

Z. Boos[1], L. N. Muhammad[2], M. Mcilheran[1], A. Miklosy[1], K. Spencer[1], D. Pinto[1]

[1]Marquette University, Milwaukee, United States; [2]Northwestern University, Chicago, United States

Objective: To quantify side-to-side differences in isometric knee flexor and extensor strength, and peak vertical ground reaction forces (pGRFs) during unilateral step-downs for individuals at elevated risk for knee osteoarthritis (KOA).
Materials and Methods: All research was approved by the Marquette University Institutional Review Board (#5103). Individuals with current knee pain (>3 months) and/or prior traumatic knee injury (i.e. ACL, MCL), established as risk factors for KOA, were recruited through convenience sampling. The "involved" side was defined as the injured, painful, or more painful limb (for those with bilateral symptoms); the opposite side was classified as "non-involved." Participants completed two warm-up trials followed by three maximal voluntary isometric contractions of the knee extensors and flexors using a Tindeq strain gauge. Torque (Nm) was calculated as force (N) × tibial length (m) and normalized to body mass (kg) to allow comparison across participants. Participants performed five trials, per side, of a unilateral step-down task from an 8-inch box onto a force plate (AMTI, 1000 Hz) to capture pGRFs, which were normalized to units of bodyweight. Paired t-tests compared the side-to-side differences in measures.
Results: 42 individuals participated in the study (23 females, age: 37 ± 16 y/o, height: 1.71 ± 0.08m tall, weight: 81.0 ± 15.2kg). Participants had significantly weaker ($p < 0.01$) knee extensor strength on the involved limb (2.06 ± 0.75 Nm/kg) compared with the non-involved limb (2.23 ± 0.72 Nm/kg). Knee flexor strength was not statistically significantly different ($p = 0.08$). Participants had significantly higher pGRFs ($p < 0.05$) when landing on the non-involved side (1.50 ± 0.26 xBW) than the involved side (1.44 ± 0.23 xBW).
Conclusion: The observed asymmetries in this population highlight the need for early screening of KOA-related risk patterns. Elevated pGRFs on the non-involved side are consistent with compensatory unloading strategies that may limit pain on the involved side. This supports consideration of unilateral symptoms as a bilateral condition given the increased exposure to higher impact forces on the uninvolved side. Repetitive asymmetric loading has implications for cartilage health, subchondral bone adaptation, and long-term joint degeneration.

P1756

PATHOGENETIC RATIONALE FOR THE APPLICATION OF COMBINED THERAPY FOR PERIODONTAL TISSUE DISEASES IN CHILDREN WITH DIABETES MELLITUS

Z. Dovbnya[1]

[1]V.I. Vernadsky Crimean Federal University, Simferopol, Russia, Simferopol, Russia

Introduction. Issues of prevention and treatment of inflammatory periodontal diseases in children remain relevant challenges in dentistry. Children with type 1 diabetes mellitus (DM) constitute a particular risk group, as periodontal pathology develops at an earlier age and is characterized by rapid progression. In patients with DM, pathological changes in the periodontium develop against the background of metabolic disorders, angiopathies, and decreased tissue resistance to infectious agents. This contributes to reduced local immunity, microcirculatory disturbances, and altered bone tissue metabolism. With this concomitant pathology, traditional treatment methods do not always provide therapeutic efficacy.

Aim of the study. To evaluate the efficacy of a complex containing herbal preparations in the prevention and treatment of periodontal tissue diseases in children with diabetes mellitus.

Materials and methods. A clinical and laboratory examination was conducted on 25 children aged 8-12 years with chronic catarrhal gingivitis (CCG) with underlying type 1 DM. The control group consisted of 20 children with clinically healthy periodontal tissues without background pathology. Children with DM underwent oral cavity sanitation and professional hygiene. Treatment measures consisted of gingival applications of a combination of phytopreparations containing eucalyptus, pine, mint, and fennel oils (1:1:1:1) based on bentonite clay (10:1). The proposed composition possesses regenerative, antioxidant, anti-inflammatory, and capillarystrengthening properties, and improves cellular metabolism of periodontal tissues. Gingival applications were performed for 20 minutes daily, №10. The oral hygiene status was determined using the Stallard index. The Papillary Marginal Alveolar (PMA) index (modified by C. Parma), and the Papillary Bleeding Index (PBI) by Saxer and Muhlemann were used to assess periodontal tissue status. Local immunity status was evaluated based on sIgA and lysozyme content in oral fluid. Control examinations were performed before and after treatment.

Results. The treatment of CCG in children with DM contributed to the elimination of the main signs of inflammation in gingival tissues, as well as pronounced positive dynamics of clinical indices. Following treatment of CCG according to the proposed protocol, the Stallard index decreased 3,8-fold ($p<0.01$), and the PMA index decreased 3,5-fold ($p<0.01$). The bleeding index decreased 2,8-fold. The sIgA level increased significantly (2,2-fold, $p<0.01$), as did lysozyme activity (1,6-fold, $p<0.01$). Their values approached those of the control group.

Conclusion. A comprehensive approach to the treatment of periodontal diseases in children with DM, targeting all pathogenetic mechanisms, contributes to the elimination of clinical signs of gingivitis, improvement of local immunity parameters, and prevention of the development of more severe forms of periodontal diseases.

UNUSUAL CORNEAL INVOLVEMENT ASSOCIATED WITH CERTOLIZUMAB PEGOL: A CASE REPORT

Z. Gassara[1], A. Jerbi[1], A. Feki[1], S. Ben Jmeaa[1], M. H. Kallel[1], S. Baklouti[1], H. Fourati[1]

[1]service de Rhumatologie CHU Hedi Chaker, Sfax, Tunisia

Introduction:
Anti-TNFα agents, such as certolizumab pegol, are widely used in the treatment of chronic inflammatory diseases. Although generally well tolerated, these therapies can occasionally cause rare adverse effects, including ocular complications. We report here a case of keratitis occurring under certolizumab pegol in a patient with rheumatoid arthritis (RA)—a complication that is scarcely documented in the literature.

Case Report:
Mrs. S., a 73-year-old woman with a history of hypertension, had been followed since 2012 for rheumatoid arthritis associated with secondary Sjögren's syndrome. She was initially treated with oral methotrexate (20 mg/week), achieving a good clinical and biological response.

In 2022, she developed methotrexate toxicity, manifested by erosive gingivostomatitis and pancytopenia. The treatment was then modified to sulfasalazine (2 g/day), hydroxychloroquine (400 mg/day), and oral prednisone (10 mg/day), allowing partial disease control (DAS28-ESR between 4.22 and 4.84).

In 2024, certolizumab pegol therapy was initiated, resulting in excellent joint improvement. However, three days after the first injection, the patient developed recurrent corneal ulcerations after each administration, eventually leading to corneal perforation. The biologic therapy was discontinued, and treatment with cyclosporine eye drops, local and systemic corticosteroids (10 mg/day), and an amniotic membrane graft was initiated. The clinical course was marked by progressive healing of the corneal ulcers.

Pharmacovigilance assessment concluded a probable causal relationship between certolizumab pegol and the corneal involvement. A switch in biologic therapy was recommended, with rituximab (Mabthera®) selected as an alternative.

Discussion:
The occurrence of corneal ulcers in this patient could have been favored by the presence of ocular dryness due to secondary Sjögren's syndrome, although this alone cannot fully explain the presentation. However, the temporal relationship between certolizumab pegol administration and the onset of symptoms, as well as their recurrence after each injection, strongly suggests a drug-induced adverse reaction.

While biologic therapies are commonly used to treat ocular inflammatory disorders, they may paradoxically induce corneal involvement, although this remains extremely rare. A few cases have been reported with adalimumab or tocilizumab, but none have been published to date with certolizumab pegol. This agent may, albeit infrequently, alter tear secretion, leading to dry eye syndrome and corneal ulceration. It is plausible that the ulceration observed in this case resulted from a paradoxical autoimmune reaction triggered by the immunogenicity of certolizumab.

Conclusion:
Ocular adverse effects associated with anti-TNFα agents are uncommon; however, our observation highlights that certolizumab pegol may, in rare instances, cause corneal ulcers. This underscores the importance of regular ophthalmologic monitoring and systematic pharmacovigilance reporting to enhance the understanding of the safety profile of these biologic therapies.

P1759
IVORY VERTEBRA : A RARE IDIOPATHIC CASE

Z. Gassara[1], H. Smaoui[1], M. Kallel[1], H. Fourati[1]

[1]Rheumatology Department, Hedi Chaker University Hospital, Sfax, Tunisia

Introduction : The ivory vertebra (IV) is defined as a homogeneous and diffuse sclerosis of the vertebral body. Although uncommon, its etiologies are diverse, mainly osteoblastic metastases, bone lymphoma and Paget's disease. Idiopathic forms are exceptional. We report a rare case of idiopathic IV after an extensive and negative etiological workup.
Case Report : A 40-year-old woman, with no medical history, presented with severe mechanical low back pain evolving for 3 months and resistant to analgesics. She reported repeated domestic and occupational microtrauma. Physical examination was normal except for localized L4 tenderness. Laboratory tests including inflammatory markers, Complete blood count, renal function, calcium, alkaline phosphatase, and serum protein electrophoresis were normal. Standard radiographs showed no abnormalities. CT revealed homogeneous sclerosis of the L4 vertebral body, consistent with IV **(Fig. 1)**. Spine MRI confirmed hypoT1 and isoT2–STIR signal without gadolinium enhancement **(Fig. 2)**. Bone scintigraphy showed increased uptake at L. Tumoral, infectious, metabolic, hematologic, and inflammatory causes were ruled out through normal imaging, negative tumor markers, and absence of biological abnormalities. A CT-guided vertebral biopsy excluded malignancy, granulomatous disease, and mast cell or lympho-plasmacytic infiltration. Two-month MRI follow-up showed stability of the lesion without progression. Clinically, the patient reported improvement of pain under conservative management.
Discussion : In the literature, very rare cases of idiopathic IV have been reported. Most described lesions occur in the lumbar spine, as in our patient. Suggested pathogenic mechanisms include total or segmental vertebral body sclerosis, reactive to disco-vertebral disruption caused by trauma or degenerative changes [1,2].
Conclusion : The causes of IV are varied and require an exhaustive etiological evaluation, often including bone biopsy, to identify the underlying pathology. The idiopathic form remains extremely rare. Repeated microtrauma appears to have played a triggering role, leading to localized reactive bone sclerosis without any identifiable systemic disease.

UNUSUAL CORNEAL INVOLVEMENT RELATED TO CERTOLIZUMAB PEGOL : A CASE REPORT

Z. Gassara[1], A. Jerbi[1], M. Kallel[1], S. Baklouti[1], H. Fourati[1]

[1]Rheumatology Department, Hedi Chaker University Hospital, Sfax, Tunisia

Introduction : Anti-TNFα agents, such as certolizumab pegol, are widely used in the treatment of chronic inflammatory diseases, but can rarely cause ocular adverse effects. We report here a case of keratitis under certolizumab pegol in a patient with rheumatoid arthritis (RA), a rarely documented complication.
Case presentation : Mrs. S., 73 years old, with a history of hypertension, has been followed since 2012 for RA and secondary Sjögren's syndrome. She was initially treated with oral methotrexate (20 mg/week) with good clinical and biological response. In 2022, she developed methotrexate toxicity characterized by erosive gingivostomatitis and pancytopenia. The treatment was then changed to sulfasalazine (2g/day), hydroxychloroquine (Plaquenil®: 400 mg/day), and systemic corticosteroids (prednisone 10 mg/day), which allowed partial disease control with a DAS28-ESR score ranging from 4.22 to 4.84. In 2024, certolizumab pegol therapy was initiated, resulting in excellent articular response. However, 3 days after the first injection, recurrent corneal ulcerations appeared with each injection, leading to corneal perforation.

Biotherapy was stopped, and the patient was treated with cyclosporine eye drops, local corticosteroids, and an amniotic membrane graft. The evolution was favorable with progressive healing of the corneal ulcers. Pharmacovigilance suggested probable imputability of certolizumab pegol. The biological treatment was switched to Rituximab.

Discussion : Dry eye syndrome may have contributed to corneal ulcers in this patient but the timing and the recurrence after each certolizumab pegol injection strongly suggest a drug adverse effect. While biotherapies are usually used to treat corneal inflammation [1], they can, paradoxically and rarely, cause corneal lesions. Few cases have been reported with Adalimumab or Tocilizumab [2], but no previous cases exist with certolizumab pegol. Impaired tear secretion and possible paradoxical autoimmune reactions may explain the corneal ulcers [2].

Conclusion : Ocular adverse effects related to anti-TNFα agents are rare, but our observation illustrates that certolizumab pegol can exceptionally cause corneal ulcers. Regular ophthalmological monitoring and systematic pharmacovigilance reporting are recommended.

PREDICTIVE FACTORS OF A GOOD RESPONSE TO ANTI-TNFA THERAPY IN SPONDYLOARTHRITIS

Z. Gassara[1], A. Jerbi[1], A. Feki[1], M. Kallel[1], S. Baklouti[1], H. Fourati[1]

[1]Rheumatology Department, Hedi Chaker University Hospital, Sfax, Tunisia

Introduction : Spondyloarthritis (SpA) comprises a group of chronic inflammatory rheumatic diseases primarily affecting the axial skeleton, as well as entheses and peripheral joints. The aims of this study were to identify sociodemographic, clinical, and paraclinical factors associated with a good response to anti-TNFα therapy in patients with SpA.

Patients and Methods : We conducted a retrospective, descriptive, and analytical study including SpA patients, regardless of clinico-radiological phenotype, who has been treated with anti-TNFα agents for more than six months. Sociodemographic, clinical, biological, and radiological data were collected. Therapeutic response was assessed using ASDAS-ESR at baseline, 6 months, and 12 months. A *p*-value < 0.05 was considered statistically significant.

Results : Fifty-five patients were included (mean age 48.3 ± 10.8 years; M/F = 1.39). The mean age at symptom onset, diagnosis, and biologic initiation was 32 ± 10, 36 ± 10, and 44 ± 10 years, respectively, with a median disease duration of 17 years [2–49]. Four patients (7.2%) reported a family history of SpA. Axial radiographic ankylosing spondylitis was observed in 74.5% (n=41), psoriatic arthritis 12.7% (n=7), and Inflammatory Bowel Disease associated SpA in 12.7% (n=7). Hip involvement occurred in 38.2% and uveitis in 14.5%. HLA-B27 was positive in 65.5%. Biologics used included infliximab (47.3%), adalimumab (20%), certolizumab (18.2%), etanercept (10.9%), and golimumab (3.6%). Mean ASDAS-ESR scores at baseline, 6, and 12 months were 3.2 ± 0.7, 2.4 ± 0.6, and 2.3 ± 0.8, respectively. No significant association was found between ASDAS improvement and age, sex, smoking, disease duration, SpA phenotype, HLA-B27, or Antinuclear antibodies status. Higher body mass index (BMI) was significantly correlated with persistently higher ASDAS-ESR at 6 and 12 months (*p = 0.015; p = 0.02*), while elevated baseline CRP and ESR predicted a better response at 6 and 12 months (*p = 0.003; p = 0.004*).

Conclusion : Our study demonstrated that, among patients with spondyloarthritis, elevated baseline CRP and ESR levels may predict a better therapeutic response to anti-TNFα agents, whereas higher BMI appears to negatively affect treatment efficacy and disease activity over time.

HEPATIC INVOLVEMENT IN CHRONIC INFLAMMATORY RHEUMATIC DISEASES : FREQUENCY AND CLINICAL IMPLICATIONS

Z. Gassara[1], A. Jerbi[1], M. Kallel[1], S. Baklouti[1], H. Fourati[1]

[1]Rheumatology Department, Hedi Chaker University Hospital, Sfax, Tunisia

Introduction : Chronic inflammatory rheuamtic diseases such as rheumatoid arthritis (RA) and spondyloarthritis (SpA), are associated with various extra-articular manifestations, among which hepatic involvement has gained increasing interest. This study aimed to evaluate the frequency, clinical features, and etiological profile of hepatic involvement in this population.

Patients and Methods : We conducted a retrospective study including 150 patients followed for RA or SpA over a 5-year period (2020–2024). Sociodemographic, clinical, biological, ultrasonographic, and histopathological data of patients presenting hepatic abnormalities were analyzed.

Results : The mean age was 47±12 years and the female-to-male ratio was 3. 100 patients were followed for RA and 50 for SpA (40 ankylosing spondylitis and 10 psoriatic arthritis). The mean disease duration was 10±3.8 years. In RA, 90% of cases were erosive and seropositive, with a mean DAS-28 score of 3± 1.1. In SpA, the mean ASDAS score was 3.2± 1.5. Almost all patients received paracetamol (98%), 90% received NSAIDs (90%) 60% systemic corticosteroids (mean dose: 9.8±1.2 mg/day), 72% methotrexate, and 18% biologic therapy (anti-TNF agents). Hepatic involvement occured in 24.6% (n=37). Among them, abdominal pain was reported in 13.5% and hepatomegaly was noted in 16.2%. Regarding biological abnormalities, hepatic cytolysis was noted in 54% and cholestasis in 29.7% (n=11). Abdominal ultrasound performed in these patients (n=37) revealed hepatomegaly in 24.3% (n=9) and a hepatic tumor in 5.4% (n=2). Liver biopsy was performed in 2 patients (5.4%), showing non-suppurative destructive cholangitis with peri-biliary infiltrate in one case and granulomatous hepatitis in the other. Etiologies were mainly drug-induced (64.8%) most frequent paracetamol (33%), NSAIDs (13.5%) and methotrexate (10.8%). The case of granulomatous hepatitis was linked to prolonged high-dose indomethacin. Two cases were related to anti-TNF agents (rituximab and etanercept). Other etiologies included viral hepatitis (16.2%), autoimmune hepatitis (5.4%), primary biliary cirrhosis (5.4%), benign hepatic tumors (5.4%), and hyperthyroidism (2.7%).

Conclusion : Hepatic involvement in chronic rheumatic diseases is frequent in our series. Often asymptomatic, it requires regular and systematic monitoring. The etiologies are diverse, predominantly drug-induced.

P1764

DO OBESE INDIVIDUALS HAVE MORE SEVERE DEGENERATIVE DISC DISEASE ? A COMPARATIVE MRI STUDY

Z. Gassara[1], R. Drira[2], Y. Hentati[2], H. Fourati[1]

[1]Rheumatology Department, Hedi Chaker University Hospital, Sfax, Tunisia; [2]Radiology Department, Hedi Chaker University Hospital, Sfax, Tunisia

Introduction : Common low back pain due to degenerative disc disease (DDD) is a frequent condition and currently represents a public health issue. It involves mechanical, biochemical, genetic, and environmental factors. Among the identified risk factors, overweight and obesity play a determining role in the onset and progression of disc degeneration (DD). The objective was to assess the severity of DD on MRI in obese individuals, as well as pain levels and functional disability in this population compared with non-obese subjects.

Patients and Methods : We conducted a cross-sectional, case–control, analytical study including patients suffering from chronic common low back pain (>3 months) related to MRI-confirmed DD. Subjects were divided into two groups : G1: Overweight or obese subjects (BMI ≥25 kg/m²) / G2: Normal-weight subjects (BMI <25 kg/m²). Pain intensity was assessed using the Visual Analog Scale (VAS), functional disability using the Oswestry Disability Index, and the severity of DD on MRI using the Pfirrmann classification. According to this classification, three levels are distinguished: mild (grades 1 and 2), moderate (grade 3), and severe (grades 4 and 5).

Results : A total of 150 patients were included and distributed as follows : G1 : n=87 (58%) and G2 : n=63 (42%). Mean age was similar in both groups : 48.2 ± 11.3 years vs. 47.9 ± 10.85 years (p=0.77), as was the sex ratio : 0.38 vs. 0.39 (p=0.87). Pain level was significantly higher in G1 : a VAS ≥7 was found in 45.3% of G1 compared with 29% of G2 (p<0.01). Functional disability was also greater in overweight/obese subjects: an Oswestry score ≥40 (severe disability) was observed in 40.7% of G1 versus 27.3% of G2 (p<0.05).

Finally, overweight and obesity were significantly associated with severe DD according to the Pfirrmann classification (grades 4 and 5): 65.3% in G1 vs. 34.7% in G2 (p=0.01).

Discussion : Excess body weight is an important risk factor in the occurrence of low back pain and DD. Indeed, overweight exerts increased mechanical pressure on spinal structures, particularly the paravertebral muscles, thereby disrupting lumbar balance [1,2]. In addition, metabolic factors associated with obesity (such as diabetes and hyperlipidemia) promote local inflammatory mechanisms through pro-inflammatory adipokines, which contribute to and worsen disc degradation [3].

Conclusion : Our study highlights higher levels of pain and functional disability, as well as more severe DD, in overweight/obese subjects compared with those of normal weight. These findings reinforce the idea that excess body weight plays a key role in the progression and worsening of lumbar degenerative disc disease.

MANAGING FRAIL MULTIPLE MYELOMA PATIENTS WITH MELPHALAN : OUTCOMES FROM A 15-YEAR RHEUMATOLOGY EXPERIENCE

Z. Gassara[1], C. Zayeni[1], A. Ferah[1], M. Kallel[1], S. Baklouti[1], H. Fourati[1]

[1]Rheumatology Department, Hedi Chaker University Hospital, Sfax, Tunisia

Introduction

Multiple myeloma (MM) primarly affects older adults, a population frequently characterized by increased frailty. Melphalan-based protocols, such as MPT (melphalan, prednisone, thalidomide) and MP (melphalan, prednisone), remain an important therapeutic option for patients ineligible for intensive treatment.

This study aims to evaluate the efficacy and safety of these regimens in frail MM patients managed in a rheumatology department.

Patients and Methods

We conducted a retrospective and descriptive study including symptomatic MM patients treated with MPT or MP over a 15-year period (January 2014–December 2024). Diagnosis was based on the 2014 International Myeloma Working Group (IMWG) criteria. MPT and MP were prescribed to patients considered ineligible for intensive therapy, with intermediate to high frailty assessed by the Revised Myeloma Comorbidity Index (R-MCI). Hematological response was evaluated at the end of treatment according to the 2016 IMWG response criteria.

Results

Among 40 MM patients, 27 (67.5%) received MPT (n=22, 55%) or MP (n=5, 12.5%). MP was used in 5 patients due to thalidomide contraindications, including pre-existing neuropathy, (n=3) or a thromboembolic history (n=2). The mean age at diagnosis was 69.3 years [65,92], with a male-to-female ratio of 1.7. All patients had at least one CRAB criterion : hypercalcemia (37.1%, n=10), renal insufficiency (26%, n=7), anemia (51.8%, n=14), and bone lesions (93%, n=25). Immunological subtypes were dominated by IgG kappa (37%, n=10), IgG lambda (29.6%, n=8), and light chain myeloma (22.2%, n=6). For MPT patients, frailty risk was intermediate in 63.6% (n= 14) and high in 36.4% (n= 8), while all MP patients (n=5) were highly frail.

Regarding the MPT protocol, melphalan was administered at a dose of 0.2 mg/kg in 19 patients and 0.25 mg/kg in 3 patients. Prednisone was administered at 2 mg/kg in all 22 patients. Thalidomide was given at 100 mg/day in 19 patients and 50 mg/day in 3 patients. The mean number of cycles was 10.89 ± 3.43 [5–12]. Twelve cycles every six weeks were received by 63.4% (n=14), while earlier treatment discontinuation occurred in 36.4% (n=8).

The MP protocol (n=5) was administered with a melphalan dose of 0.2 mg/kg and prednisone dose of 2 mg/kg in 2 patients, and with a melphalan dose of 0.15 mg/kg and prednisone dose of 15 mg/kg in 3 patients. The mean number of cycles was 6.8 ± 1.92 [4–9].

Among patients on MPT, the therapeutic response at the end of treatment was : good (≥ partial response) in 14 patients (63.6%), stable disease in 3 patients (13.6%), and progression in 5 patients (22.7%). The mean overall survival was 76 ± 15.2 months. Three patients died (13.6%), all due to disease relapse.

For patients on MP, the therapeutic response was insufficient for all, with stable disease in 2 patients and disease progression in 3 patients. All 5 patients died, with a mean overall survival of 14 ± 7.5 months.

Good hematologic treatment tolerance was observed in 22.7% of cases (n=5), while adverse effects occurred in 77.3% (n=17), including infections (n=13, 60%), hematologic toxicity (n=7, 25.9%), thromboembolic events (n=2, 10%), and neurologic complications (n=2, 10%).

Conclusion

Melphalan-based protocols, particularly MPT, can achieve meaningful responses and acceptable survival in frail MM patients, though toxicity remains significant. These findings reinforce the importance of individualized therapy for frail patients in a rheumatology context.

P1766

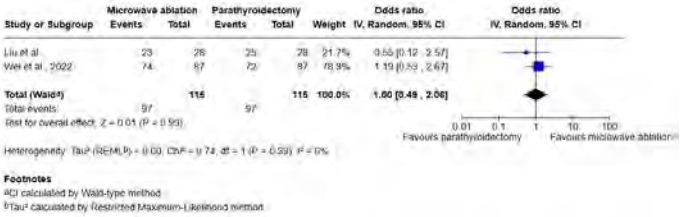
THERMAL ABLATION VERSUS PARATHYROIDECTOMY FOR PRIMARY HYPERPARATHYROIDISM: A SYSTEMATIC REVIEW AND META-ANALYSIS

Z. Issa[1], L. Youness[1], G. El Hajj Fuleihan[2], M. Chakhtoura[2]

[1]American University of Beirut Medical Center, Department of Internal Medicine, Beirut , Lebanon; [2]Calcium Metabolism and Osteoporosis Program, WHO Collaborating Center for Metabolic Bone Disorders, Faculty of Medicine, American University of Beirut—Medical Center, Beirut, Lebanon, Beirut , Lebanon

Background: Parathyroidectomy (PTX) is the standard treatment for primary hyperparathyroidism (pHPT). Thermal ablation has emerged as a less invasive alternative.

Objective: To compare the effectiveness and safety of thermal ablation versus PTX in adults with pHPT, assessing parathyroid hormone (PTH), calcium and phosphorus levels, cure rates, and adverse effects.



Methods: We conducted a comprehensive literature search of MEDLINE, EMBASE, and Web of Science from inception to March 2025, following a PROSPERO-registered protocol CRD420251009401. We included comparative studies reporting outcomes for adults with pHPT treated with thermal ablation and PTX. Two reviewers screened, extracted data, and assessed risk of bias using ROBINS-I, independently and in duplicate. We performed random-effects meta-analysis when ≥2 studies with comparable interventions and outcome definitions were available; otherwise, results were synthesized narratively.

Results: We screened 3,765 records at title/abstract level, assessed 11 full texts, and included 3 comparative retrospective cohort studies conducted in China. Mean age ranged from 53.5 to 57.7 years, and the proportion of females ranged from 65% to 79%. Preoperative serum calcium ranged from 2.69 to 2.80 mmol/L and reported adenoma size ranged from 1.4 to 2.13 cm. Meta-analysis was performed for microwave ablation (MWA) vs PTX (2 studies; MWA n=115, PTX n=115). Cure rate defined as normalization of serum calcium and PTH at 6 months follow-up was similar between MWA and PTX (odds ratio [OR] 1.00, 95% CI 0.49–2.06, I^2=0%) Figure 1. Post-treatment calcium (mean difference [MD] −0.00 mmol/L, 95% CI −0.20 to 0.19, I^2=93%) and phosphorus (MD 0.00 mmol/L, 95% CI −0.05 to 0.05, I^2=0%) were similar. Hypocalcemia was less frequent after MWA (OR 0.33, 95% CI 0.12–0.92, I^2=24%). Hoarseness showed a non-significant trend toward being more common with MWA (OR 3.54, 95% CI 0.84–14.94, I^2=0%). PTH could not be pooled because one study did not report SD. The two studies were judged at serious risk of bias.

Conclusion: In adults with pHPT, limited comparative evidence suggests

MWA achieves similar cure rates to PTX and may reduce hypocalcemia, but conclusions are constrained by small study numbers and serious risk of bias. Larger prospective comparative studies are needed, including direct comparisons across ablation modalities.

Figure 1. Cure rate MWA vs PTX

DON´T BREAK – BE THE BONE ALL YOUR LIFE

Z. Lörinczová[1], N. Vaňová[1], T. Ševčík[2], M. Mydlárová Blaščáková[3], L. Mikulová[4]

[1]Internal Clinic Faculty of Medicine, P. J. Šafarik University, University Hospital AGEL Košice-Šaca Inc., Košice-Šaca, Slovakia; [2]Department of Musculosceletal and Sports Medicine, Faculty of Medicine, P. J.Šafarik University, University Hospital AGEL Košice-Šaca Inc., Košice-Šaca, Slovakia; [3]Department of Biology, Faculty of Humanities and Natural Sciences, University of Prešov in Prešov, Prešov, Slovakia; [4]Department of Technical Disciplines in Health Care, Faculty of Health Care, University of Prešov in Prešov, Prešov, Slovakia

Objectives: Osteoporosis is a metabolic bone disease with increasing prevalence worldwide. Puberty represents a critical period for bone mass development, and insufficient intake of calcium, vitamin D, other essential nutrients, and inadequate physical activity during this time may negatively affect bone health. The aim of the pilot project Healthy Bones in Secondary Schools was to raise awareness of osteoporosis among secondary school students, with an emphasis on prevention, healthy lifestyle promotion, and proper nutrition.

Material and methods: The pilot project was implemented in two secondary schools in the Košice district (Slovakia) and involved 364 first- and second-year students. A questionnaire with 26-item was developed, containing open and closed questions to assess students' personal medical history, their knowledge of osteoporosis, and selected risk factors such as smoking, physical activity, calcium and vitamin D intake, sun exposure, corticosteroid use, and fracture history. After an initial assessment of their knowledge, the students participated in an educational activity consisting of a lecture and discussion on osteoporosis, its causes, symptoms, and prevention. In addition, specific exercises aimed at promoting bone health were recommended during six weeks of physical education. A follow-up questionnaire assessed changes in students' knowledge, attitudes, and perceptions of the project.

Results: Only 35.71% of students were informed about osteoporosis. Smoking was reported by 6.90% of girls and 4.85% of boys. Frequent consumption of Coca-Cola or energy drinks (four or more times a week) was reported by 13.41% of girls and 22.32% of boys. Daily consumption of dairy products was reported by 49.81% of girls and 60.19% of boys. Approximately half of the respondents reported taking vitamin D supplements (49.81% of girls, 55.34% of boys). Insufficient physical activity (<30 minutes/day) was reported by 14.56% of girls and 7.7% of boys. Students spent an average of 4.64 hours per day using electronic devices. The effectiveness of the educational activities was confirmed by a control questionnaire.

Conclusion: After the educational activity, knowledge about osteoporosis increased by 24.29%. More than two-thirds of students felt informed about maintaining bone health throughout their lives, and approximately 38% reported that this information would have a positive impact on their eating habits and lifestyle.

COMPUTABLE QUALITY INDICATORS FOR OUTPATIENT KNEE OSTEOARTHRITIS CARE USING STRUCTURED AND FREE-TEXT ELECTRONIC MEDICAL RECORDS

Z. R. Wang[1], J. Jiang[1], G. X. Ni[1]

[1]The First Affiliated Hospital of Xiamen University, Xiamen, China

Objective

To develop and evaluate computable, guideline-aligned quality indicators (QIs) for outpatient knee osteoarthritis (OA) care using real-world electronic medical record (EMR) data, and to assess their feasibility for large-scale quality measurement.

Methods

We conducted a retrospective observational study using seven years (2018–2024) of outpatient EMR data from a tertiary hospital in China. Knee OA encounters were identified through a computable phenotype integrating structured diagnostic codes and free-text documentation. Five process-based QIs reflecting international guideline recommendations for conservative OA management were operationalized using transparent, rule-based logic applied to structured fields and curated text lexicons. Indicator extractability, score distributions, temporal trends, and correlations were examined at the encounter level.

Results

A total of 11,833 outpatient knee OA encounters were included. All five QIs were computable across all encounters. The mean total quality score was 51.3 (SD 17.2) on a 0–100 scale. Indicators derived primarily from structured data showed higher and more stable performance, whereas text-dependent indicators, particularly documentation of exercise or rehabilitation advice, demonstrated extremely low extractability (mean 0.27/10), with over 95% of encounters scoring zero. Correlations between indicators were low, suggesting that each captured a distinct domain of care. Quality scores showed modest variation over time with stable algorithm performance.

Conclusion

Computable, guideline-aligned quality indicators can be derived from routine EMR data to enable scalable assessment of outpatient knee OA care. The findings reveal substantial and persistent gaps in the documentation and visibility of recommended non-pharmacologic management, particularly exercise-based care. These results highlight structural limitations in current EMR systems and underscore the need for improved documentation and system-level support to facilitate high-quality, guideline-concordant OA management.

P1769

OSTEOPOROSIS IN OLDER ADULTS IS MORE THAN BONE LOSS: THE ROLE OF GERIATRIC SYNDROME BURDEN

Z. Şahin Tırnova[1], D. Gül Çetin[1], D. Sezer[1], S. Güven[1], T. Erdoğan[1], S. Özkök[1], M. A. Karan[1], G. Bahat[1]

[1]Istanbul University Faculty of Medicine, Geriatrics, Istanbul, Türkiye

Background/Aim:

Osteoporosis is a major health problem in older adults, not only due to increased fracture risk but also because it frequently coexists with multiple geriatric syndromes. This study aimed to examine the prevalence and co-occurrence of geriatric syndromes among older adults diagnosed with osteoporosis and to examine whether geriatric syndrome burden is associated with osteoporosis.

Participants and Methods:

We retrospectively evaluated patients aged ≥65 years attending a tertiary geriatric outpatient clinic. Demographic characteristics, clinical parameters—including age, sex, body mass index (BMI), handgrip strength (HGS), body composition parameters, comprehensive geriatric assessment (CGA) parameters like history of falls, fear of falling, urinary incontinence, frailty, nutritional status, sarcopenia (defined according to EWGSOP2 criteria, based on low HGS and low skeletal muscle mass measured by bioelectrical impedance analysis and adjusted for BMI), and comorbidities (depression and dementia)—were recorded. Patients were categorized by osteoporosis diagnosis. A geriatric syndrome burden score (GSBS, 0–6) was calculated by summing impaired IADL (IADL<8), fear of falling, chronic pain, malnutrition/risk (MNA-SF≤11), depression (physician diagnosis/antidepressant use and/or GDS-15≥5 or GDS-30≥10), and slow gait speed (<0.8 m/s). Multivariable logistic regression models were adjusted for age, sex, and BMI.

Results:

Among 1,254 patients (median age 76 years; 68.7% female), osteoporosis was present in 24.6% (n=308).

In multivariable logistic regression analysis, female sex (OR 5.02, 95% CI 3.41–7.37; p<0.001), older age (OR 1.05 per year, 95% CI 1.02–1.07; p<0.001), chronic pain (OR 1.47, 95% CI 1.09–1.98; p=0.011), and sarcopenia (OR 1.50, 95% CI 1.09–2.07; p=0.012) were associated with higher odds of osteoporosis, whereas higher BMI was protective (OR 0.94 per kg/m², 95% CI 0.92–0.97; p<0.001). Frailty was not associated with osteoporosis after adjustment (OR 1.17, 95% CI 0.84–1.64; p=0.354). Also, GSBS was independently associated with osteoporosis after adjustment (OR 1.10 per 1-point increase, 95% CI 1.01–1.21; p=0.038).

Conclusion:

Our findings suggest that older adults with osteoporosis commonly present with multiple coexisting geriatric syndromes, including sarcopenia and chronic pain. Furthermore, increasing geriatric syndrome burden was independently associated with higher odds of osteoporosis. These findings underscore the importance of comprehensive geriatric assessment, with particular emphasis on muscle strength evaluation, in the holistic management of older adults with osteoporosis.

Table 1: Multivariable logistic regression analysis of factors associated with osteoporosis (n = 1254)

Variable	Model 1 OR (95% CI)	P value	Model 2 OR (95% CI)	P value
Sex (female)	5.02 (3.41 – 7.37)	<0.001	5.00 (3.37 – 7.40)	<0.001
Age	1.05 (1.02 – 1.07)	<0.001	1.05 (1.03 – 1.07)	<0.001
BMI	0.94 (0.91 – 0.97)	<0.001	0.94 (0.91 – 0.97)	<0.001
Chronic Pain	1.47 (1.09 – 1.98)	0.011	-	
Sarcopenia	1.50 (1.09 – 2.07)	0.012	-	
Frailty	1.17 (0.84 – 1.64)	0.354	-	
GSBS			1.101 (1.005 – 1.206)	0.038

OR: odds ratio; CI: confidence interval; BMI: body mass index; GSBS: geriatric syndrome burden score.

Model 1 included age, sex, BMI, chronic pain, sarcopenia, and frailty.

Model 2 included age, sex, BMI, and GSBS instead of individual geriatric syndromes to avoid multicollinearity.

P1770

REAL-WORLD TREATMENT STRATEGIES FOR OSTEOPOROSIS IN OLDER ADULTS WITH CKD-MBD: IMPACT OF GERIATRIC SYNDROMES AND TREATMENT COMPLIANCE

Z. Şahin Tırnova[1], E. Pınar[1], Z. Fetullahoğlu[1], D. Seyithanoğlu[1], H. Arıcı[1], T. Erdoğan[1], S. Öztürk[2], O. Soyluk Selçukbiricik[3], G. Yenidünya Yalın[3], N. Gül[3], A. S. Artan[2], M. A. Karan[1], G. Bahat[1]

[1]Istanbul University Faculty of Medicine, Geriatrics, Istanbul, Türkiye; [2]Istanbul University Faculty of Medicine, Nephrology, Istanbul, Türkiye; [3]Istanbul University Faculty of Medicine, Endocrinology, Istanbul , Türkiye

Aim: Osteoporosis (OP) management in chronic kidney disease (CKD) is complicated by altered bone turnover, mineral metabolism, renal drug clearance, and coexisting geriatric syndromes. Frailty and high fall risk may justify treatment even without low T-scores. This study presents a real-world, multidisciplinary, and individualized approach to managing older adults with OP and CKD–mineral bone disease (MBD), focusing on geriatric syndromes and treatment compliance (access, duration, adverse effects).

Participants and Methods: Twenty older adults with OP and stage 3a–5 CKD were evaluated by a multidisciplinary team. Baseline data (December 2023) included clinical, DXA, biochemical, and comprehensive geriatric assessment(CGA) findings; fracture and treatment history; inappropriate medication use(IMU); and fall-risk-increasing drugs (FRIDs). Patients were categorized as OP-only, OP + adynamic bone disease(ABD), or OP + osteomalacia(OM). Treatment was individualized based on bone turnover, renal function, prior therapy, and CGA. Compliance was reassessed at two years (December 2025).

Results: Median age was 78 years; 45% were male. Frailty was present in 50%, orthostatic hypotension in 50%, falls in 35%, and polypharmacy in 95% (median 9 drugs). IMU was identified in 12(60%) of patients, with 1–3 inappropriate drugs deprescribed per patient, and FRIDs were used by 75%. Malnutrition was present in 25%. Prior fragility fractures were common (65%), yet only two patients were on OP treatment at baseline.

Diagnosis, treatment decisions, and compliance are summarized in Table 1. At two years, 50% patients were fully compliant, 30% required treatment modification (reimbursement issues, comorbidities, or switching/interruptions), 10% were lost to follow-up, and 10% were managed conservatively. No severe hypocalcemia, new fragility fractures, or adverse-effect–related discontinuations occurred.

Conclusions: Managing osteoporosis in older adults with CKD requires a nuanced, patient-specific strategy supported by multidisciplinary collaboration, considering bone turnover, renal impairment, and complex geriatric syndromes. Treatment compliance remains crucial; in our cohort, reimbursement delays and comorbidities were the main barriers. Overall, denosumab—combined with structured calcium supplementation and monitoring—appeared to be the most feasible therapeutic option.

Table-4: Diagnosis, Treatment Decisions, Duration and Compliance Outcomes of the Study Patient

Patient Number	Diagnosis	Decision	Treatment Compliance	Treatment Duration (months)
1	CKD-MBD (ABD) + OP	Teriparatide	Lost to follow-up	-
2	CKD-MBD (ABD) + OP	Teriparatide after discontinuation of vit D and calcium	Could not start teriparatide (reimbursement issues); switched to denosumab	18
3	OP-only	Oral bisphosphonate therapy continued	Compliant, no complications	28
4	OP-only	Zoledronate	Compliant, no complications	21
5	CKD-MBD (ABD) + OP	Teriparatide after discontinuation of active vitamin D and phosphate binders	Compliant, no complications	18
6	CKD-MBD (ABD) + OP	Follow-up without treatment (Due to no indication) Cessation of active vitamin D and calcium	Follow-up without treatment	-
7	OP-only	Romosozumab	Compliant, no complications	12 mo romosozumab, followed by denosumab
8	OP-only	Romosozumab	Irregular romosozumab use, later switched to denosumab	10 months irregular romosozumab, then switched to denosumab
9	OP-only	Denosumab + Testosterone replacement	Compliant, no complications	17
10	OP-only	Teriparatide	Could not initiate teriparatide due to recurrent hospitalizations (GI bleeding, ileus); later switched to denosumab	7
11	OP-only	Denosumab	Compliant, no complications	18
12	OP-only	Denosumab	Lost to follow-up	-
13	CKD-MBD (ABD) + OP	Teriparatide	Compliant, no complications	24 months teriparatide, followed by denosumab
14	CKD-MBD (ABD) + OP	Teriparatide	Compliant, no complications	10
15	CKD-MBD (ABD) + OP	Denosumab, after discontinuation of calcium and no evidence of ABD	Compliant, no complications	10
16	CKD-MBD (OM) + OP	Denosumab after calcium and vitamin D supplementation	Interrupted after 2nd denosumab dose (1-year gap), later resumed therapy	19 months (with interruption)
17	OP-only	Follow-up without treatment (Due to low life expectancy and being bedridden)	Follow-up without treatment	-
18	CKD-MBD (OM) + OP	Teriparatide after vitamin D supplementation	Could not start teriparatide (recurrent UTIs/ urosepsis) then refused further treatment	-
19	CKD-MBD (OM) + OP	Denosumab after vitamin D supplementation	Delayed denosumab initiation due to cardiac problems; sustained fracture during delay, denosumab later started	3
20	OP-only	Denosumab	Compliant, no complications	3

ABD: Adynamic Bone Disease, CKD-MBD: Chronic Kidney Disease – Mineral and Bone Disorder, OM: Osteomalacia, OP: Osteoporosis, UTI: Urinary Tract Infection, GI: Gastrointestinal

THE IMPORTANCE OF CONE BEAM COMPUTED TOMOGRAPHY FOR THE DIAGNOSIS OF BONE MINERAL DISORDERS IN DENTAL PRACTICE

Г. Парфенюк[1], В. Коннов[1]

[1]Саратовский государственный медицинский университет, Саратов, Russia

Georgy Vladimirovich Parfenyuk, Candidate of Medical Sciences, Saratov State Medical University named after V.I. Razumovsky, Russia
Konnov Valery Vladimirovich, MD, Professor, Saratov State Medical University named after V.I. Razumovsky, Russia

The importance of cone beam computed tomography for the diagnosis of bone mineral disorders in dental practice

The widespread occurrence and significant socio-economic consequences of mineral and bone disorders in dental patients necessitate the introduction of high-tech diagnostic techniques into clinical practice. One of the promising innovations is cone beam computed tomography (CBCT). The similarity of the symptoms of the pathology and the lack of clear diagnostic criteria for various forms of bone lesions

force us to look for certain clinical, laboratory or instrumental signs that allow us to assume its further development in the early stages of the disease, which allows for a more favorable treatment outcome and social prognosis in patients. At the first stage of diagnosis of bone mineral disorders, dentists use an orthopantomogram. Unfortunately, it does not always allow for a detailed assessment of changes in bone structure. However, until now, radiation diagnostics, especially assessment of the severity of damage to the maxillary system, is often carried out only by this method in everyday clinical practice. According to some authors, multisection computed tomography (MSCT) is considered the most informative method for detecting characteristic radiological changes, but its use in clinical practice is limited by many factors, including relatively high radiation exposure. Currently, it has become possible to use high-tech cone beam computed tomography (CBCT) techniques for such studies. The aim of the study was to evaluate the possibilities of using CBCT in the dental practice of patients with mineral and bone disorders in somatic pathology that led to chronic kidney disease. Materials and methods As part of the work, 420 middle-aged patients (postmenopausal women, men over 50 years old) were examined at the University Dental Clinic, who underwent dental implantation and preimplantation correction using reconstructive and reconstructive surgery to ensure satisfactory conditions for implantation. The examined patients had somatic pathology: kidney diseases (urolithiasis, pyelonephritis, glomerulonephritis, polycystic fibrosis) in 151 cases, of which 70 were men, diseases of the cardiovascular system (hypertensive nephropathy, ischemic kidney disease) in 76 cases, of which 35 were men, rheumatological diseases (gout, undifferentiated collagenosis, Sharpe syndrome, systemic lupus erythematosus, rheumatoid arthritis): 42 cases, 18 of them men. A combination of cardiovascular and kidney diseases occurred in 105 cases, including 47 males, and a combination of cardiovascular and rheumatological diseases in 46 cases, including 24 males).

Renal osteodystrophy was determined by the level of the hormonal regulator of calcium and phosphorus metabolism, intact parathyroid hormone (i-PTH). Prior to the dental implantation operation, the examined patients underwent cone beam computed tomography (CBCT) on a KaBo 3D eXam dental tomograph (KaBo Dental GmbH, Germany) with the i CATVision CT data visualization program (i CAT, Gendex CB-500). During postprocessing of the CT scans of the jaws, the shape, contours of the bone, and signs of bone damage were reliably visualized: areas of osteolysis; cyst-like cavities; bone structure restructuring and erosion; enthesophytes; narrowing of articular crevices, subluxations and dislocations, bone ankylosis of the temporomandibular joints; bone deformities. In addition, CBCT allowed us to evaluate not only the bone structure, but also dense soft-tissue anatomical formations in cases where diffuse periarticular thickening and compaction of soft tissues occurred. In terms of optical density (in Hounsfield units - units). HU) in the area of missing teeth, at the site of the proposed implant surgery, osteoporosis can be confirmed or rejected. Conclusions: Taking into account the low radiation load on the patient, compared with MSCT, the possibility of detecting foci of structural changes, as well as relatively low direct research costs, CBCT can be recommended as a first-stage technique for diagnosing bone forms of pathology in somatic pathology that led to chronic kidney disease in dental patients. In addition, this technique can be used to monitor the effectiveness of the treatment, gradually replacing radiography.

ON THE INTERPRETATION OF DENSITOMETRY DATA IN THE EXAMINATION OF DENTAL PATIENTS IN THE LATE STAGES OF CHRONIC KIDNEY DISEASE

Г. Парфенюк[1], В. Коннов[1]

[1]Саратовский государственный медицинский университет, Саратов, Russia

Georgy Vladimirovich Parfenyuk, Candidate of Medical Sciences, Saratov State Medical University named after V.I. Razumovsky, Russia
Konnov Valery Vladimirovich, MD, Professor, Saratov State Medical University named after V.I. Razumovsky, Russia

On the interpretation of densitometry data in the examination of dental patients in the late stages of chronic kidney disease.

Dentistry is a field of medicine that allows for the earliest diagnosis of bone mineral disorders in chronic kidney disease (CKD). Osteoporosis (OP) is common in such patients. Dentists, having enlisted the support of endocrinologists, increasingly use the results of densitometry in their work to diagnose OP. The interpretation of the obtained results causes certain difficulties. Thus, in the study of middle-aged patients who applied for dental implantation surgery, they often have a history of OP. After referral to an endocrinologist, medical records confirm this diagnosis. Some of them even had instructions about antiresorption therapy. From the moment of treatment to the present treatment, more than 5 years of remission have passed. When performing densitometry at the time of treatment, the T-criterion is <1.0. Other examples are patients at the G4–G5g stage of CKD, who have no data on osteoporosis, and according to densitometry, the T-criterion is < -2.5. And the same patients who have a history of OP diagnosis confirmed by low-traumatic compression fractures of the spine, while at the time of treatment, the T-test score is >-2.5. How to assess such conditions? Obviously, in the first case, OP should not be present in the main diagnosis. It should be mentioned in concomitant diseases. As for the second case, we are talking about mineral and bone disorders of chronic kidney disease (MCD-CKD) and OP in these patients. We regarded the third cases as MNK-CKD-OP. Obviously, in the first case, consultation with an endocrinologist is not required, while the rest require a multidisciplinary approach to diagnosis and treatment. The limited diagnostic methods of OP in outpatient dental practice make the method of densitometry the most preferable, although imperfect.

FROM RISK STRATIFICATION TO INNOVATION: ADVANCING CARE FOR VERY HIGH FRACTURE RISK PATIENTS

N. C. Harvey[1], P. Ebeling[2], B. Langdahl[3]

[1]Professor of Rheumatology and Clinical Epidemiology, MRC Lifecourse Epidemiology Centre, University of Southampton, Southampton, United Kingdom; [2]Head of the Department of Medicine and Head of School of Clinical Sciences, Monash University, Melbourne, Australia; [3]Clinical Professor at Department of Endocrinology and Internal Medicine, Aarhus University Hospital and Aarhus University, Aarhus, Denmark

Objective:

Experts faculty to discuss how advances in risk stratification can be translated into timely, system-based interventions that improve outcomes for patients at Very High Fracture Risk. By bridging clinical risk identification with structured care models - particularly Fracture Liaison Services (FLS) - and exploring the role of innovation and technology, the session aims to demonstrate how healthcare systems can move from reactive fracture management to proactive, coordinated prevention.

Chair's introduction[1]

Osteoporosis management has evolved from a simple reliance on BMD T-score to use of absolute fracture probability to direct treatment decisions. In recent years, the greater and faster impact of bone building anabolic than antiresorptive therapies has led to the development of novel treatment stratification approaches to target specific medications according to baseline fracture risk. Those at sufficiently high fracture risk should be targeted with bone anabolic medications to rapidly reduce their risk before maintenance with antiresorptive therapies. A recent fracture has an immediate marked impact on future fracture risk and is an indication for urgent risk assessment and treatment. This symposium will address new approaches to risk stratification in osteoporosis management, and place these within the specific context of barriers and facilitators to optimal fracture liaison service provision.

Very High-Risk Fracture: Why Stratification Must Drive Action[2]

Selecting patients optimally treated by anabolic drugs requires their assessment as having a very high fracture risk. The recency, severity and number of fragility fractures together with the degree of bone loss all drive this increase in fracture risk. The presence of a fragility fracture within the past 2 years and a bone mineral density T-score of <-2.5, or the presence of a severe vertebral fracture or multiple fractures indicate very high fracture risk. International guidelines have also proposed absolute fracture risk thresholds, measured by FRAX®, of ≥30% for major osteoporotic fracture or ≥4.5% for hip fracture as being indicative of very high fracture risk[4]. Fractures or bone loss on antiresorptive therapy also indicate a very high fracture risk, but this group may have reduced gains in BMD with anabolic therapy, particularly following denosumab therapy. A goal-directed approach helps ensure that the most appropriate treatment is selected for each patient at each stage of life. Although the goal of treatment is freedom from fragility fractures, a validated surrogate endpoint is achieving a total hip BMD T-score >-2.5, or >-2.0 in the presence of a fragility fracture. The choice of initial therapy will depend on the baseline bone mineral density and the probability of achieving the treatment target after three years of treatment. In patients with the lowest bone density, anabolic therapy is preferred. It is critical to note that anabolic drugs work best if used as first-line, rather than as second-line drugs when increases in BMD on anabolic therapy will be attenuated. On completion of a course of anabolic therapy, timely initiation of antiresorptive drug therapy is required to maintain bone mineral density. The choice of antiresorptive drug will depend on the proximity of the bone mineral density to the treatment target and whether another course of anabolic therapy is planned. Denosumab would be preferred if the bone mineral density is still well below the treatment target, however, an oral or intravenous bisphosphonate would be preferred if a further future course of anabolic therapy is being contemplated. In conclusion, stratification by the identification of patients at very high fracture risk and the highest probability of achieving a target with treatment must drive action.

From First Fracture to Re-fracture: Why Systems Fail and the importance of FLS[3]

Fractures are the consequence of osteoporosis. Fractures are associated with increased morbidity and mortality. The risk of a subsequent fracture remains elevated compared to the risk of a first fracture for years after a fracture, but is especially high during the first 2 years, leaving the patients at imminent and sometimes high imminent risk of a subsequent fracture.

Therefore, patients with a recent fragility fracture should have the attention of the healthcare systems and be offered diagnosis, initiation or change of osteoporosis treatment if indicated. It has been demonstrated that Fracture Liaison Service (FLS), which is a systematic approach to identification, characterization and management of patients with fragility fractures, is the most effective service to accomplish this goal. In addition, it has been demonstrated to be cost-effective. Despite these advantages, it has proven challenging to implement FLS in many hospitals. Examples of FLS implementation and the challenges associated with implementation and running of FLS's will be presented and discussed.

OPPORTUNITIES AND CONTROVERSIES IN OSTEOPOROSIS MANAGEMENT USING SEQUENTIAL THERAPIES

S. Ferrari[1], D. Kendler[2], E. Casado[3]

[1]Division of Bone Diseases, Geneva University Hospital, Geneva, Switzerland; [2]Department of Medicine, University of British Columbia, Vancouver, Canada; [3]Department of Rheumatology, University Hospital Parc Taulí, I3PT Research Institute (UAB), Sabadell, Spain

Advances in osteoporosis therapeutics have underscored the importance of treatment sequencing, particularly in patients at high and very high fracture risk. Chaired by Serge Ferrari and Enrique Casado, the symposium will address current opportunities and controversies in the use of sequential osteoporosis therapies.

Serge Ferrari will review international and European guideline recommendations supporting an anabolic-first approach in patients at very high fracture risk. He will highlight the substantial variability in how "very high risk" is defined across guidelines and discuss how real-world implementation is constrained by reimbursement criteria and specific contraindications, which may limit the use of osteoanabolic agents as first-line therapy.

David Kendler will focus on the clinical challenge of fractures during treatment, often perceived by patients and clinicians as treatment failure. As osteoporosis therapies reduce fracture risk by 20–80%, fractures may still occur in successfully treated patients. The presentation will review the International Osteoporosis Foundation position on treatment failure, which requires either at least two fractures after a minimum of one year of therapy, or one fracture in the presence of declining bone mineral density or an insufficient bone turnover marker response exceeding the least significant change.

The importance of excluding secondary causes of bone loss will be emphasised, as nonadherence or noncompliance represents the most common reason for apparent treatment failure. In this context, long-interval parenteral antiresorptive regimens may offer advantages for selected patients. Therapeutic options following fracture on treatment will be discussed and tailored to individual patient needs, including switching from oral to parenteral antiresorptive therapy or to bone anabolic agents. Considerations regarding treatment sequencing, including the potential blunting of bone mineral density response when switching from bisphosphonates to anabolic therapies, will also be addressed.

The symposium will integrate guideline perspectives with practical clinical considerations to support clinicians in determining treatment failure appropriately and selecting optimal therapeutic sequences for patients at high and very high fracture risk.

This satellite symposium is funded and organised by Gedeon Richter Plc. and is intended for Healthcare Professionals only.

PROTECTING HER FUTURE WITH ROMOSOZUMAB FIRST

K. Javaid[1], R. Schmidmaier[2], N. Napoli[3], B. Langdahl[4]

[1]University of Oxford, Oxford, United Kingdom; [2]Ludwig-Maximilians-Universität, Munich, Germany; [3]Fondazione Policlinico Universitario Campus Bio-Medico, Rome, Italy; [4]Aarhus University Hospital, Aarhus, Denmark

Following a fracture, immediate and rapid intervention to reduce fracture risk is vital, as approximately half of subsequent fractures occur within the first 2 years.[1-3]

In this interactive, case-based symposium, leading experts will share insights into the management of patients with postmenopausal osteoporosis (PMO) at very high fracture risk (VHFR). They will explore how romosozumab, through its rapid bone-building ability, stands out as an optimal approach to rapidly reduce fracture risk and, when followed with an antiresorptive, provides long-term protection from future fractures.[1,4,5]

Case 1: The Urgent Imperative

Professor Ralf Schmidmaier will discuss guideline-recommended strategies to address elevated fracture risk in patients who have recently suffered a fragility fracture. Through exploration of both clinical and real-world efficacy data, he will share insights into romosozumab's rapid bone-forming action and anti-fracture efficacy in PMO patients at VHFR.[1,4,5]

Case 2: Breaking the Cycle

Despite being a recommended first-line therapy for PMO patients at VHFR, [3,6] many patients receive alternative therapy prior to romosozumab.[7] Professor Nicola Napoli will illustrate how romosozumab remains an optimal strategy to prevent fractures in the VHFR population, irrespective of prior antiresorptive exposure, showcasing its superior bone mineral density gains compared with a parathyroid hormone (PTH) analogue in pre-treated patients.[8,9]

Case 3: Rebuilding Foundations in VHFR

Professor Bente Langdahl will share valuable insights into optimised treatment sequences, [9] showcasing both short- and long-term outcomes seen with romosozumab when used first-line followed by antiresorptive therapy.[5] Furthermore, Professor Langdahl will explore the latest evidence regarding romosozumab's benefit-risk profile and how this is incorporated into her clinical decision-making.

The Time Is Now

Closing the symposium, symposium chair Professor Javaid will share critical insights into how robust post-fracture management pathways can prioritise early identification of patients at VHFR, supporting timely intervention and first-line initiation of romosozumab to maximise potential benefits for eligible patients.[1,4,5]

THE OA TREATMENT JOURNEY: FROM EARLY INTERVENTION TO LONG-TERM MANAGEMENT

N. Fuggle[1]

[1]Associate Professor of Rheumatology at the MRC Lifecourse Epidemiology Centre, University of Southampton, Southampton, United Kingdom

Osteoarthritis is a progressive condition characterized by structural joint changes, pain, functional limitation, and increasing disability over time. Early stages of OA represent a critical window of opportunity in which timely intervention may modify symptom burden and potentially alter the disease trajectory.

In this presentation, Dr. Nicholas Fuggle will explore the osteoarthritis treatment journey from early diagnosis through long-term disease management. The session will review key clinical features of early OA, the importance of accurate assessment, and the role of guideline-supported therapeutic strategies across different stages of disease severity.

Particular attention will be given to evidence-based early interventions, including lifestyle measures and pharmacological options, and how these strategies can be adapted over time as OA progresses. The presentation will also discuss the long-term management of OA, highlighting the need for sustained symptom control, functional preservation, and individualized treatment planning in routine clinical practice.

SY5

HOLISTIC OA MANAGEMENT: HOW DISEASE SEVERITY CAN GUIDE NSAID CHOICES

O. Bruyère[1,2]

[1]Professor of Clinical Epidemiology in the Department of Public Health Sciences and of Geriatric Rehabilitation in the Department of Rehabilitation and Sport Sciences of the University of Liège, Liège, Belgium; [2]Head of the Research Unit in Public Health, Epidemiology and Health Economics, University of Liège, Liège, Belgium

The management of osteoarthritis-related pain often requires a tailored approach that considers disease severity, patient characteristics, and the balance between efficacy and safety. Non-steroidal anti-inflammatory drugs (NSAIDs) remain a cornerstone of pharmacological treatment for OA, particularly in patients with moderate to severe symptoms.

In this lecture, Prof. Olivier Bruyère will discuss a holistic framework for OA management, focusing on how disease severity, symptom profile, and patient risk factors can inform NSAID selection. The presentation will review current international guidelines and clinical evidence supporting the rational use of NSAIDs within a comprehensive OA treatment strategy.

The session will emphasize the importance of individualized decision-making, integrating clinical evidence with patient-specific considerations, to optimize pain control while minimizing potential risks. This approach supports a broader, patient-centered model of OA care, aligned with contemporary recommendations for long-term disease management.

SY6

REMS TECHNOLOGY IN CLINICAL PRACTICE: APPLICATIONS THAT ENHANCE OSTEOPOROSIS DIAGNOSIS

R. Matijevic[1]

[1]University of Novi Sad, Faculty of Medicine, Clinic for Orthopedic Surgery and Traumatology, Clinical Center of Vojvodina, Vojvodina, Serbia

Objective: Osteoporosis often remains clinically silent until a fragility fracture occurs, particularly in patients with secondary osteoporosis or multiple comorbidities, where fracture risk is frequently underestimated. Radiofrequency Echographic Multi Spectrometry (REMS) is a non-ionizing technology that improves early diagnosis and fracture risk assessment, overcoming limitations of conventional densitometry. This review summarizes clinical evidence of REMS across different patient populations.

Materials and Methods: A review of REMS applications in several clinical settings was conducted. REMS measurements were compared with DXA for agreement, diagnostic performance, reproducibility, and ease of use.

Results: Clinical evidence confirms REMS applicability across multiple medical specialties. In endocrinology, REMS improves detection of bone fragility in conditions such as type 2 diabetes, obesity, eating disorders, and during hormone-based therapies, where DXA may underestimate fracture risk. In nephrology, REMS enables accurate bone evaluation in chronic kidney disease, peritoneal dialysis, and kidney transplantation by

overcoming artefacts related to vascular calcifications. In rheumatology, REMS overcomes BMD overestimation often observed with DXA in the presence of osteoarthritis, spondyloarthritis and other inflammatory conditions. In geriatric and orthopedic settings, REMS supports fracture prevention and secondary fracture management through bedside assessments and accurate evaluation in the presence of vertebral deformities or prosthetic implants. In gynecology, REMS allows safe bone health monitoring across pregnancy, lactation, and menopause. In oncology, REMS facilitates early identification of therapy-induced bone loss and fracture risk stratification. Across specialties, REMS demonstrates high reproducibility, portability and diagnostic accuracy.

Conclusions: REMS expands access to osteoporosis diagnosis and fracture risk assessment, offering a safe, accurate, and portable alternative to conventional densitometry, including for previously underserved populations. Its broad applicability supports early diagnosis, personalized management, and continuity of care.

SY7

FROM INNOVATION TO CLINIC: REMS AS A BREAKTHROUGH TOOL IN OSTEOPOROSIS MANAGEMENT

F. Conversano[1]

[1]Institute of Clinical Physiology, National Research Council, Lecce, Italy

Objective: To illustrate the clinical value of REMS as an innovative tool in osteoporosis management, with practical insights into interpreting REMS-derived BMD.

Materials and Methods: Targeted literature review on REMS as an innovation transitioning into routine osteoporosis management. Evidence was synthesised from key methodological descriptions and clinical studies, with practical examples addressing the role of age/BMI in the REMS pathway and the ability to monitor BMD over time.

Results: REMS yields a BMD result derived from patient-specific ultrasound information. Anthropometric and demographic parameters are taken into account to place the measurement within an appropriate reference framework. Importantly, the measurement retains strong individual specificity, such that patients with the same age and BMI can display a broad spread of BMD values. In addition, REMS processing can identify and automatically exclude signals consistent with common artefacts (e.g., osteophytes, calcifications, prosthetic material), keeping the provided BMD representative of bone-related information. Across follow-up studies, REMS has demonstrated the ability to detect significant BMD changes over time, including decline during pregnancy (around −2% in reported series), early postpartum recovery (about +0.02 g/cm² at 1 month in one cohort), and measurable variations over 12-month monitoring in metabolic/therapeutic settings (e.g., adults with type 2 diabetes starting GLP-1 receptor agonist therapy; breast cancer patients undergoing aromatase inhibitor based therapy, with and without denosumab administration).

Conclusions: REMS represents a breakthrough tool for osteoporosis care, translating patient-specific bone information into BMD values that can support diagnosis and monitoring in several different clinical settings. REMS leverages spectral-model matching of raw backscatter signals against reference profiles (stratified by patient characteristics and skeletal site), which is a key technical enabler of its patient-specific BMD output in real-world pathways. Age and BMI are embedded in the workflow, but they are not the determinants of the final value, enabling substantial BMD variability to be captured among individuals with similar anthropometrics and supporting longitudinal assessment.

SY8

IDENTIFYING FRAGILITY BEFORE FRACTURES OCCUR: THE ADDED VALUE OF REMS IN OSTEOPOROSIS CARE

N. Fuggle[1]

[1]MRC Lifecourse Epidemiology Centre, University of Southampton, Southampton, United Kingdom

Fragility fractures frequently represent the first clinical manifestation of osteoporosis, underscoring persistent challenges in the early identification of skeletal fragility. Radiofrequency Echographic Multi Spectrometry (REMS) has emerged as a non-ionising, ultrasound-based technique proposed as a complementary approach to bone assessment.

An expanding body of evidence suggests that REMS-derived BMD correlates well with that derived from Dual-Energy X-ray Absorptiometry (DXA). The REMS Fragility Score, may provide additional information on skeletal microarchitecture that is independent of BMD. By automatically integrating T-Score and Fragility Score values, REMS identifies short-term fracture risk, enabling stratification into seven risk categories aligned with five-year fracture probability. Observational and comparative studies have reported associations between REMS parameters and fracture risk in selected clinical settings, including conditions known to affect bone quality such as diabetes mellitus and chronic kidney disease. REMS has also been evaluated in populations for whom conventional imaging may be less suitable or practical, including pregnant women, frail inpatients, paediatric cases and individuals with severe disability, reflecting its portability and important absence of ionising radiation.

Overall, REMS represents a potentially useful adjunct or alternative for osteoporosis assessment by integrating quantitative evaluation of bone density and bone quality with short-term fracture risk assessment. Its especial clinical value also lies in scenarios where conventional tools provide incomplete risk characterisation.

SY9

LOW PHOSPHATE AND THE BONE DOCTOR

M. L. Brandi[1]

[1]FIRMO Foundation, Italy and McMaster University, McMaster, Canada

Chronic hypophosphatemia is an under-recognized yet clinically significant contributor to metabolic bone disease, leading to impaired mineralization, bone fragility, pain, and functional limitation. Despite its clinical relevance, low phosphate often remains overlooked in routine bone assessments, resulting in delayed or missed diagnoses with prolonged patient morbidity. Hypophosphatemic disorders may be congenital (such as X-linked hypophosphatemia) or acquired (such as tumor-induced osteomalacia), exhibiting different primary causes and onset patterns, but overlapping pathophysiology and clinical manifestations.

Advances in the understanding of phosphate dysregulation have

highlighted the central roles of fibroblast growth factor 23 (FGF23), renal phosphate transport, measured through tubular maximum reabsorption of phosphate (TmP/GFR), and vitamin D in the development of chronic hypophosphatemia. However variability in clinical manifestations, gaps in the routine use of specific biomarkers, and complexities in the interpretation of laboratory findings, including the need for age- and sex-specific reference ranges, continue to pose diagnostic challenges.

Recognizing the signs of hypophosphatemic disorders, including bone abnormalities, skeletal deformities, occurrence of fractures/pseudofractures and pain, can help raise earlier suspicion, and aid timely and accurate diagnosis. Diagnostic confirmation from clinical, biochemical, and imaging assessments, along with genetic testing in congenital forms, is mandatory for the optimal management of rare metabolic bone disorders.

This lecture will synthesize current knowledge on hypophosphatemic disorders in clinical practice, highlight gaps in recognition and assessment, and illustrate practical, guideline-informed approaches to suspicion and diagnosis using real-world cases, with the aim of supporting earlier identification and improved patient outcomes.

SY10

BIOSIMILARS IN BONE HEALTH: TRANSLATING CLINICAL EVIDENCE INTO SUSTAINABLE OUTCOMES

R. Eastell[1], A. Khan[2], B. Langdahl[3]

[1]University of Sheffield, Sheffield, United Kingdom; [2]McMaster University, Hamilton, Ontario, Canada; [3]Aarhus University Hospital and Aarhus University, Aarhus, Denmark

Biosimilars have emerged as an important advancement in bone health management, offering the potential to expand patient access to biologic therapies while supporting healthcare systems' sustainability. However, their successful integration into clinical practice and acceptance among clinicians and patients depend on a clear understanding of the scientific principles underpinning biosimilar development. This symposium will provide an integrated overview of biosimilar fundamentals, with a particular focus on Canadian real-world experience with biosimilar denosumab, and strategies to support sustained patient outcomes.

The session will open with an overview of biosimilars' development, regulatory approval, and evidence requirements. Key focus will be on addressing knowledge gaps related to biosimilars, including concerns about switching and perceived differences in effectiveness, safety, and immunogenicity compared with their reference medicines. The potential impact of these concerns on the nocebo effect in patients will also be evaluated.

The panel discussion will then explore Canadian real-world experience with treatment adherence and clinical outcomes following initiation and transition to biosimilar denosumab. The faculty will discuss emerging system- and practice-level considerations, including evolving clinical guidance, provincial formulary access, patient switching approaches, and healthcare professional engagement. In addition, they will highlight findings from a Sandoz-sponsored Canadian patient-reported satisfaction survey (N=435) following transition from reference to biosimilar denosumab, to provide insights into patient experience, communication around treatment transitions, innovative approaches to long-term antiresorptive therapy, and factors influencing confidence in biosimilar therapy.

Finally, denosumab in the long-term management of osteoporosis will be explored, recognising its strength as a potent antiresorptive treatment option. The evidence underlying treatment sequencing, strategies to minimise rebound bone loss, safety considerations, including osteonecrosis of the jaw and atypical femoral fractures, will be discussed, taking into consideration the balance between clinical value, access and cost in real-world practice.

Disclosures:

Richard Eastell receives consultancy funding from Immunodiagnostic Systems, Sandoz, CL Bio, CureTeQ, Biocon, Grunenthal, Takeda, Theramex, meeting presentations for Alexion, Radius, UCB, and Amgen, travel funding from Samsung, Sandoz and CL Bio, and grant funding from Alexion, CL Bio, and Osteolabs. He is the chairman of the DSMB for CureTeQ and STOPFOP.

Aliya A. Khan receives research funding from Ascendis Pharma, Amolyt Pharma, BridgeBio, and Alexion.

Bente Langdahl receives funding for advisory boards and lectures from UCB, Amgen, Gedeon-Richter, Samsung-Bioepis, Mereo, Angitia, and for lectures from Sandoz and Entera-Bio.

SY11

ADVANCES IN THE DIAGNOSIS AND MANAGEMENT OF PATIENTS WITH HYPOPHOSPHATASIA (HPP) ACROSS THE DISEASE CONTINUUM

Alexion[1]

[1]AstraZeneca Rare Disease

HPP is a rare disease caused by deficient activity of alkaline phosphatase (ALP).[1,2] In this session, leading experts will explore how to recognize and diagnose HPP across the lifespan of a patient, discuss how to effectively manage HPP, and provide a practical overview of assessments that can be performed in the clinical setting.

HPP Presentation and Diagnosis Across the Disease Continuum
Prof. Maria Luisa Brandi (FIRMO Foundation, Italy)

Prof. Maria Luisa Brandi will review HPP diagnosis in children and adults, including practical considerations for differential diagnosis. She will explore key patient archetypes and review new mechanistic data on muscular symptoms of HPP.

HPP Disease Impact and Management Throughout the Patient Lifespan

Prof. Florian Barvencik (University Medical Center Hamburg-Eppendorf, Germany)

Prof. Florian Barvenick will review the disease impact of HPP, covering structural (skeletal) and functional manifestations. He will review effective management strategies in appropriate patients.

Future Directions in HPP

Dr Eric T. Rush (Children's Mercy Hospital, Kansas City, MO, United States; University of Missouri–Kansas City, Kansas City, MO, United States)

Dr Eric T. Rush will provide an overview of the key clinical assessments

to evaluate disease burden and management in patients with HPP. He will review practical considerations across both structural and functional assessments, including mobility, physical function, pain, fatigue, and quality of life.

geriatrics

an Open Access Journal
by MDPI

Impact Factor 2.1
CiteScore 3.4
Indexed in PubMed

Aims and Scope of *Geriatrics*

Editor-in-Chief
Prof. Dr. Ralf Lobmann

Geriatrics (ISSN 2308-3417) is a peer-reviewed scientific journal that publishes original articles, critical reviews, research notes and short communications in the areas of the health and healthcare of elderly people including issues regarding the healthcare systems and policies. Our aim is to encourage scientists to publish their experimental and theoretical results in as much detail as possible. There is no restriction on the maximum length of the papers. The full experimental details must be provided so that the results can be reproduced. Electronic files or software regarding the full details of the calculation and experimental procedure, if unable to be published in a normal way, can be deposited as supplementary material.

Main research areas include (but are not limited to):

- Geriatric biology
- Geriatric health services research
- Geriatric medicine research
- Geriatric neurology, stroke, cognition and oncology
- Geriatric surgery
- Geriatric physical functioning, physical health and activity
- Geriatric psychiatry and psychology
- Geriatric nutrition
- Geriatric epidemiology
- Geriatric rehabilitation

muscles

an Open Access Journal
by MDPI

Tracked for Impact Factor
Indexed in PubMed
Indexed in Scopus

Aims and Scope of *Muscles*

Muscles (ISSN 2813-0413) is an international and interdisciplinary peerreviewed open access journal, published quarterly online by MDPI. *Muscles* publishes articles investigating the molecular and biochemical mechanisms underlying a wide range of muscle pathophysiologies such as development, the regulation of mass and function, aging, metabolism, exerciseinduced stress, nutrition, degeneration, dystrophy, and regeneration.

Muscles welcomes the submission of manuscripts, either original research or reviews with an emphasis on describing muscle health, its maintenance, and its interactions with non-muscle cell types and regulatory modulators. Our main focus is on human studies but work in animal models will also be considered.

Main research areas include (but are not limited to):

Muscles covers all aspects of muscle science, including, but not limited to, nerve and neuromuscular junction pathology, physiology, anatomy, myopathies, muscular dystrophy, other acquired muscle endocrine or immunological disorders, pharmacology, epidemiology, nutrition, sarcopenia, muscle imaging, and other sport-related injuries or muscle metabolic adaptations.
